Hypotheses:

1. There will be significant difference between male and female on practice code of ethics among the physicians
2. There will be significant difference between age groups of the physicians on practice code of ethics
3. There will be significant differences between work experiences of physicians on practice code of ethics.
4. There will be significant differences between general practitioner and specialist on practice code of ethics.

Methodology: For the present study, the targeted respondents were the general practitioners and the specialist in the medical ground from the selected district of Assam. 114 samples comprising of male (56) and female (58) respondents were selected. Ages of the participants were grouped accordingly 25-29 years, 30-34 years and above 34 years. To accomplish the objectives stratified random sampling technique was used.

Tools Used:

1. Socio-demographic data sheet (self, 2019): Socio-demographic data sheet consist of the personal records of the respondents like age, gender, education level and work experience
2. Practice related code of ethics: Practice related code of ethics is a questionnaire developed, based on the Ethiopia's health professional code of ethics[17]. Practice related code of ethics is assessed using 16 practice based questions related to medical practice. Scoring is done on a 5-point likert scale.

Result and Discussion

Demographic Profile of Respondents: To portray the sample, demographic profile of the respondents such as sex, age, education, work experience and level of satisfaction were assessed. Sex (M=1.51, S.D. = .50) was coded as male and female. Age (M= 35.07, S.D. = 10.89) of the participants was coded with the following levels: 25-29 years, 30-34 years and above 35 years. Education (M= 1.46, S.D. = .50) was coded as general practitioner and specialist. Work experience (M= 8.1, S.D. = 8.6) was coded as less than 4 years, 4-8 years and more than 8 years.

Table 1: Demographic characteristics of the sample

Characteristics	Categories	Frequency	Percentage %
Sex	Male	56	49.1 %
	Female	58	50.9 %
Age	25-29 yrs	44	38.6 %
	30-34 yrs	30	26.3 %
	>34 yrs	40	35.1 %
Work experience	<4 yrs	67	58.8 %
	4-8 yrs	4	3.5 %
	>8 yrs	43	37.7 %
Education	General practitioner	61	53.5 %
	Specialist	53	46.5%

Source: Self

Gender wise, 49.1% respondents working in the hospitals were male, followed by 50.9% female. As far the age of the physicians is concerned, majority (38.6%) of respondents were from the age group 25-29 years, followed by 34 years and above (35.1%). Only 26.3% respondents were from 30-34 years. Work experience of the respondents is concerned; majority (58. 8%) of the respondents with work experience was less than 4 years, followed by 37.7 % more than 8 years. Only 3.5 % of the respondents were found to have work experience between 4 – 8 years. Education wise, 53.5% respondents working in the hospitals were general practitioners, followed by 46.5% specialist.

Testing of Hypothesis:

Table II: Mean, SD and t- test of male and female physicians on practice code of ethics

Gender	N	Mean	SD	t-value	Non- Sig
Male	56	47.40	10.45	.23	0.16
Female	58	50.47	7.9		

* Correlation is significant at the 0.05 level (2-tailed), **Correlation is significant at the 0.01 level (2-tailed)

Table II shows the mean score of male and female physicians, which are 47.40 and 50.47 respectively. The t value of both male and female is .23 (not significant). The first hypothesis of the study "There will be significant difference between male and female on practice code of ethics among the physicians" is rejected. The result goes in parallel to the previous studies where no difference between male and female on ethical behaviour was found[18]. However, in the present era females are getting more dynamic and outgoing rather than keeping themselves intact to their emotions and family duties. Moreover females might have higher expectation about jobs, and place more significance on promotion, leading to greater satisfaction in the job. This might facilitate both men and women to move in a parallel platform, equally fighting for their rights on competitiveness, success and status. Another study reveals that males are more prone to conformity pressure than female [19]. This means that peer pressure impacts males due to their vulnerability to conformity pressure. This finding can be supported by a strong argument, if there would have been a difference, which might show males to have a stronger career orientation than females, due to which men are at risk for ethical decision making.

Table III: Mean, SD and F value of three age groups among physicians on practice code of ethics

Age	N	Mean	SD	F	Non-Sig
25-29	44	50.75	5.49	2.16	0.12
30-34	29	48.27	9.57		
>34	41	47.47	10.71		

* Correlation is significant at the 0.05 level (2-tailed), **Correlation is significant at the 0.01 level (2-tailed)

Table III shows the mean score of ages 25-29, 30-34 and >34 among the physicians, which are 50.75, 48.27 and 47.47 respectively. The F value of the three age groups is 2.16 (not significant). The second hypothesis of the study "There will be significant difference between age groups of the physicians on practice code of ethics" is rejected. This means that there is no significant difference between the age groups of the physicians on practice code of ethics. The result shows that the mean of the physicians of age group 25-29 years are greater than the others age group. This might indicate that ethical practice might be greater in age group 25-29 years in compared to the other groups. This might be due to the fact that younger physicians are new in the healthcare field and are eager to practice appropriately what they have been trained and educated in the medical school. Moreover, the older practitioners, due to heavily involved in various medical organizations with increases burnout might lead to involve in breakdown of ethical behaviour. As the physicians spent enough time with the co-workers or supervisors, witnessing them might make them experience confusions about ethical principle[20] .However, a study conducted in Rajasthan found no age difference to be associated with ethical behaviour[21]. Another study showed no differences on age group regarding issues such as whether patients should be informed if the doctors were wrong, whether consent should be taken from the children or if it was acceptable for the doctors to conduct illegal actions without prior permissions[22].

Table IV: Mean, SD and F value of three groups of work experience among physicians on practice code of ethics

Work experience	N	Mean	SD	F	Sig
<4 yrs	64	48.93	9.27	9.43	.000
4-8 yrs	5	31.75	11.50		
>8 yrs	45	50.22	5.83		

*Correlation is significant at the 0.05 level (2-tailed), **Correlation is significant at the 0.01 level (2-tailed)

Table IV shows the mean score of work experiences <4 years, 4-8 years and >8 years among the physicians, which are 48.93, 31.75 and 50.22 respectively. The F value of the three age groups is 9.43 (significant at .000 level). The third hypothesis of the study "There will be significant difference between work experiences of the physicians on practice code of ethics" is accepted. This means that there is a significant difference between the work experiences of the physicians on practice code of ethics. Medical doctors with work experience above 8 years are likely to have favorable attitude towards ethical code of conduct than doctors with 4-8 years of experience. Possible explanation supporting the differences of work experience might be the commitment and interest of physicians for their work with work experience greater than 8 years. Doctors with more experience in work might be able to identify the importance of the ethical code of behaviour. Moreover physicians can gather more knowledge with the increase of work experience, which might facilitate to understand what is right and what is wrong to practice code of ethics [23].

Table V: Mean, SD and F value of level of education among physicians on practice code of ethics

Level of education	N	Mean	SD	t value	Sig
General practitioner	56	48.51	10.30	1.75	0.01
Specialist	58	50.1	6.72		

*Correlation is significant at the 0.05 level (2-tailed), **Correlation is significant at the 0.01 level (2-tailed)

Table V shows the mean score of level of education i.e. general practitioner and specialist which are 48.51 and 50.1 respectively. The t value is 1.75 (significant at .01 level). The fourth hypothesis of the study "There will be significant difference between levels of education on practice code of ethics" is accepted. This means that there is a significant difference between the levels of education of the physicians on practice code of ethics. However, since the mean value of specialist is higher than the general practitioner, the specialist practices ethical codes of conduct. As the specialist physicians are expected to be more careful and cautious while dealing with a specific illness they need to communicate properly with the clients. This might make obligatory for the specialist to behave ethically than the general physicians.

Conclusion

Education level, and work experience, was found to be significantly different on practice of code of ethics. Whereas, age and gender were found to have no significant difference regarding practice code of ethics. Therefore it is vital to change the attitude of physicians and have adequate knowledge and awareness about the ethical codes among all the stage of the medical process. This can be done through training programs, increasing public awareness about the health care deliverance, client/patient rights, establishing ethical committee in the institution, strengthening practical based education, proper medical ethics course and reporting of unethical conducts.

Ethical Clearance: No Ethical Considerations Apply.

Issues in India's Healthcare System

Chandrakanta Sahoo[1], Himanshu Bhusan Mishra[1], Tanvi Chawda[2]

[1]Assistant Professors, Department of MBA, Institute of Management and Information Technology, Cuttack, A Constituent Institute of Biju Patnaik University of Technology, Odisha, [2]Tanvi Chawda, Assistant Professor, Department of Commerce, Department of Commerce, Sailabala Womens' Autonomous College, Cuttack

Abstract

India as the second most populous country of the world where more than 60% of its population rely on Agriculture and allied occupations, healthcare has remained the matter of concern. With a weak primary health sector, lack of skilled medical professionals, inadequacy of regulation for private hospitals, low public spending on health, fragmented health information system, rising cost of medical treatment in India, medical research in India having very little application and weak governance and accountability of the sector are the matters of great concern from the perspective of service delivery. The Supreme Court of India held healthcare as the fundamental right under article 21 of the constitution, but in practice, it has not been fundamentally right in India. Though Ayusman Bharat, is a well thought out project, intending healthcare for the masses, its delivery and sustainability is questionable. The paper is an attempt to discuss the problems inherent in the India's healthcare system.

Keywords: *Health, Hospital, Medical Treatment, Ayusman Bharat.*

Introduction

India, as one of the World's fasted growing economies and second most populous nation, faces a lot of challenges and unprecedented opportunities as far as access to quality health services is concerned. India has witnessed record-breaking economic growth over a decade which has brought down poverty significantly.[1] According to a report published by the World Bank, infant mortality rate has come down from 66 to 38 per 1000 in India from 2000 to 2015. Life expectancy rate has gone up from 63 to 68 years. Maternal mortality rate has been decreased from 374 to 172 per lakh live births during the said period.[2] Over the period,India has developed the world-class scientists in health sector, leading hospitals and the dynamic pharmaceutical and biotechnology industries which has attracted foreign patients for treatment. India, nevertheless, faces persistent and daunting challenges, particularly for the poor as far as access to health services are concerned. In Odisha, a tribal man was forced to shoulder the dead body of his wife due to denial of mortuary van by the medical authority.[3] Another Odisha man was also forced to carry daughter's dead body for 6 km after ambulance dropped them midway.[4] Many such incidents are being reported and published in newspapers over the years.

Some of the other challenges that health sector in India is facing are low birth weights and child undernutrition which often result in premature death of the child, neonatal mortality, life long health problems; growth in noncommunicable diseases such as diabetes, obesity and tobacco use, resulting in cancer and other diseases; injuries and deaths due to high rates of road traffic accidents. Though the Government of India is providing comprehensive health coverage for all through the schemes like *Ayushman Bharat*, nevertheless, the nation's rapidly developing healthcare system remains an area of concern. Health sector is often seen to be underfunded, in many cases, funded amounts are underutilized. In many cases, it is also found to be underregulated. Odisha Sum Hospital Tragedy that killed around 20 patients in fire due to non-compliance

Asst. Professor, Department of MBA, Institute of Management and Information Technology, Cuttack

of safety issues is a case in point.[5]As a result of which many hospitals are having reported to have safety issues of the patients. There are disparities in health and health care systems between rich and poor states. The present government is increasing coverage, but insurance remains limited.

Structural Problems in Indian Health Care System: Despite several recorded improvements in Indian health care system, the country is reported to have lagged behind many health indicators. The country comprises of around 18% of the World land areas, but accounts for 20% of the world burden of diseases, 21% of all child deaths (less than 5 years) and 27% of the all neonatal deaths.[6] Indian healthcare system is facing many structural problems today which are summarized below:

(a) A Weak Primary Health Sector: In 2015, one government hospital bed was available for every 1833 persons as compared with 2336 persons a decade earlier. However, the study found that the availability of the beds in government hospitals across the states of India is inequitably distributed. For example, one government hospital bed was available for 614 persons as compared with 8789 persons in Bihar[7]. The care facilities ware also quite inadequate. Figure 1 represent the sorry state.

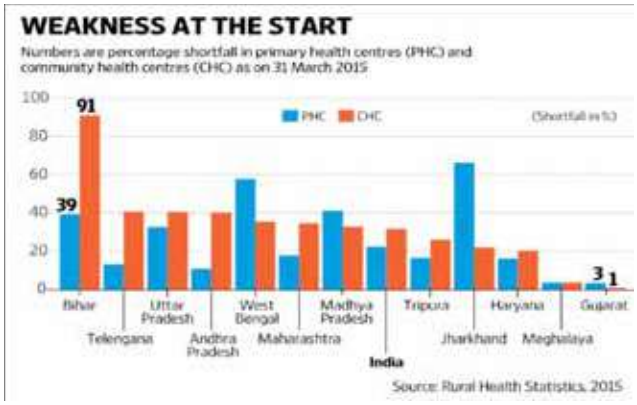

Figure 1:

(b) Unequally Distributed Skilled Manpower: Despite increase of seats in MBBS and nursing programs, India still suffers from paucity of skilled health professionals. In many states such as Gujarat and West Bengal, the shortfalls of skilled health professionals exceed 80%. The Lancet study said:

"India does not have an overarching national policy for human resources for health. The dominance of medical lobbies such as the Medical Council of India has hindered adequate task sharing and, consequently, development of nurses and other health cadres, even in a state like Kerala that has historically encouraged nurse education and has been providing trained nurses to other parts of India and other countries." [7]

(c) Large Unregulated Private Sector

The National Sample Survey Office (NSSO) number found that there has been decrease in the use of public hospitals over the period of past 2 decades- only 32% of urban Indians use them compared to 43% in 1956-96. The study also found that many of the private practitioners don't have requisite qualification or are underqualified. Lancet stated: "the many new institutions set up in the past decade... encouraged by commercial incentives, have often fuelled corrupt practices and failed to offer quality education."[7]

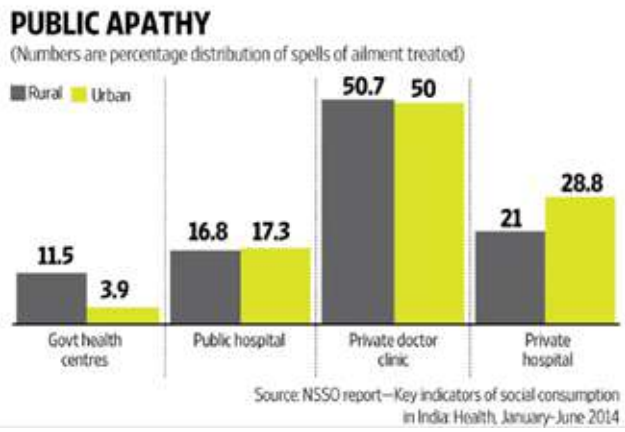

Figure 2

(d) Low Public Spending on Health: Expenditure on public health remains meagre in India. Even though, there has been 7% annual increase of expenditure in recent years, central government expenditure has plateaued. Many state governments fail to use the allotted funds which reflects the structural weaknesses in the system which need to be addressed.

Table 1: Year-wise Projected Demand, Actual Allocation and Expenditure of Department of Health Research (Including ICMR)

Financial Year	Projected Demand (Rs in crore)	Actual Allocation (Rs in crore)	Actual Expenditure (Rs in crore)	% Increase of expenditure over previous year
2013-14	2283	726	461.84	
2014-15	2581.5	726	569.61	23.33%
2015-16	2817.91	713.17	590.65	3.70%
2016-17	1689.43	750	647.82	9.67%
2017-18	2933	1500	911.07	40.66%

*Expenditure upto February, 2017

Source: https://health.economictimes.indiatimes.com/news/industry/the-sorry-state-of-medical-research-in-india/58241623

(e) Fragmented Health Information System: Clean and up-to-date health data is not available. Though many agencies such as NSSO to the Registrar General of India to disease specific programme-based systems are working for maintenance of health data, yet still, data is missing in many cases as they exclude private sector. In many cases, data is also duplicated. And agencies don't talk to the parties concerned.

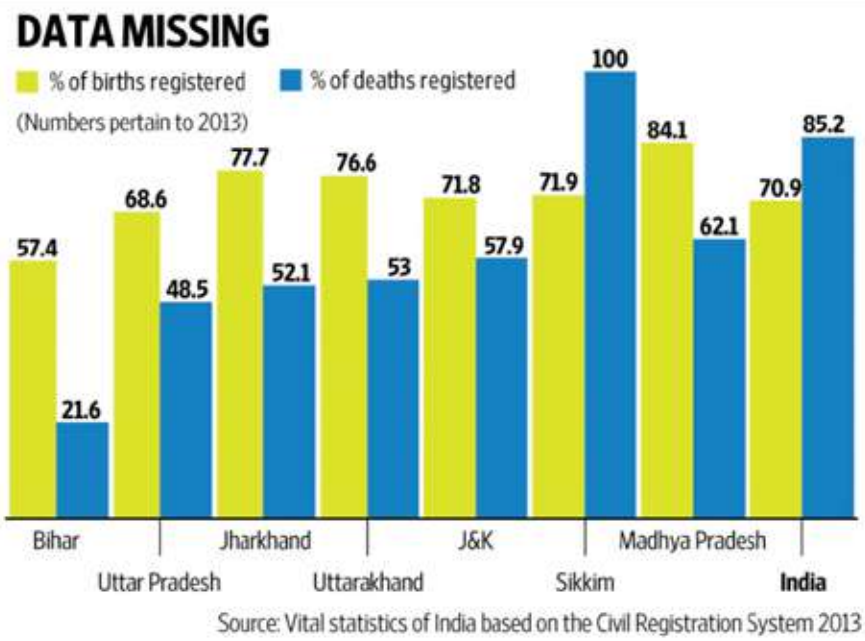

Figure 3

Figure 3 exhibits the % of births and deaths registered. As in states, health data is missing, its is difficult to forecast the health facilities requirement.

(f) Rising cost of Medical Treatment: Rising cost of medical treatment is one of the reasons attributed to poverty. Though, government of India has introduced *Jan Aushadhi* campaign to provide 361 generic medicines at affordable prices and different price regulation policies, but in reality, these have not been fully effective. Corruption in healthcare system has increased irrational use of drugs and technology. The nexus between the doctors, medicine stores, pharmaceutical and device companies compel the patients to follow unnecessary procedures such as CT scans, caesarean sections and stent insertions.

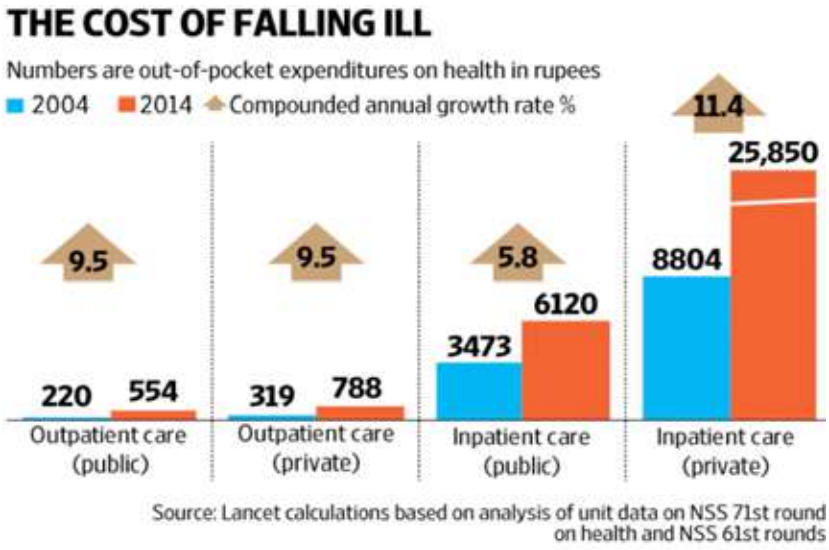

Figure 5

(g) Sorry State of Medical Research in India: The Indian Council of Medical Research (ICMR) has 800 scientists working across 32 institutes in India,but failed to list even a new intervention in terms of vaccine, new drugs, diagnostic test or treatment procedure developed by hundreds of scientists over a period of last two years.[8]

Table 2: Research Output of ICMR

Years	Published Papers	Patent filed	Patent granted	Research Project funded
2015	965	33	2	1745
2016	720	12	1	

Source: https://health.economictimes.indiatimes.com/news/industry/the-sorry-state-of-medical-research-in-india/58241623

7. Weak governance and accountability: "In the past 5 years, the government has introduced several new laws to strengthen governance of the health system, but many of these laws have not been widely implemented," said Lancet. In some cases, the "scope of (some) regulations is still unclear, and there are fears that these laws have hindered public health trials led by non-commercial entities."[7] Inadequate public investment in health, lack of trust and engagement between various healthcare sectors and poor coordination between central and state governments are some of the impediments to assure universal health care in India.

Table 3: Health Law and their status of implementation

Law	Status
Clinical Establishments Act 2010 (provides for registration and regulation of clinical establishments and prescribes minimum standard of facilities and services)	Enacted only in 9 states
National Mental Health Care Bill (mandates right to care)	Cleared by cabinet, awaiting passage in Parliament
Medical Devices Regulation Bill, 2006 (provides for quality standards of biomedical equipment manufacturing and marketing)	Yet to be passed

Source: Lancet, **Note:** These are just examples and not an exhaustive list

Critique of *Ayusman Bharat* Scheme: There are two types of health schemes of government of India. Majority of them are well thought out schemes, but these are poorly implemented. As a result of which these don't reach out to the intended beneficiaries fully. But there are some schemes which are drafted at policy stage. These have very little possibility of working and if these worked, would b e very difficult to sustain. *Ayusman Bharat* falls in the second category.

Free universal healthcare is already available in India. In India, Most of the government hospitals charge no fees or a very nominal fee. But accessibility and quality of service delivery remain a matter of concern. Secondary and tertiary care are in scarce supply in many states. But on paper, free healthcare exists. Therefore, *Ayusman Bharat* does the more or less the same things. As the government hospitals lack adequate healthcare facilities, the government use private hospitals which would reinforce the impression that private hospitals are better than government hospitals.

There are issues when private hospitals provide healthcare services free of fees. Their infrastructure will benefit the poor patients. But there is no regulatory mechanism to monitor the quality of their services. As the fee under the scheme is low, hospital may not be able to sustain the services without the revision of fee rates. Poor patients' lives may be put at risk at the mercy of private hospitals due to unavailability of appropriate regulations.

Budget allocation for the year Rs. 3200 crore under the scheme in 2018 which is quite meagre to cover a small subset of the 10 crore families enrolled. If we assume that 5 per cent of those enrolled claims 20 per cent of those eligible Rs. 5 lakh, the scheme would need Rs 50000 crore. It's doubtful whether Government will be able to cover 10 crore families. An if this happens if it will be able to sustain it will be a matter of concern because of the high operating costs. The IT infrastructure needed for this scheme is also enormous and it is dubious if government will be able to maintain the data privacy and security when the patients use their Aadhar information to access this scheme.

Conclusion:

The Supreme Court of India held healthcare as the fundamental right under article 21 of the constitution, but in practice, it has not been fundamentally right in India. For every 51000 people, there is only one healthcare centre often managed by one doctor. But this is where 90% health needs can be met. The health sector has attracted good investments, but delivery remains contentious. Though private players have entered the health sector and increased competition, nevertheless, improved quality and efficiency in the healthcare delivery has remained a question mark. Lack of penetration, opaqueness in diagnosis, exorbitant billing and poor quality of service indicates that Indians get treated below the standards prescribed by World Health Organization. Although Indian healthcare system services are among cheapest in the world, yet, it has become unaffordable for many locally. It's high time to introspect the feasibility of the schemes like *Ayusman Bharat*. But it's roll-out is very much like GST. Public and private health systems are placing huge demands on the capacity of the nation's health leaders and professionals. Rising to meet these challenges, the citizens of India have an opportunity to have a major influence on their own health on the future of public health and medical research globally.

A Pre-experimental Study to Assess the Effect of Planned Teaching Programme on Knowledge of Staff Nurses Regarding Hemodialysis in Selected Hospitals at Jaipur

Christa Mathew

Assistant Professor, School of Nursing Science and Research, Sharda University, Greater Noida, NCR Delhi India

Abstract

The word dialysis derived from Greek word "dialusis", meaning dissolution, "dia" meaning through, and "lysis" meaning loosening. Dialysis is a process for removing waste and excess water from the blood, and is primarily used to provide an artificial replacement for lost kidney function in people with renal failure. Dialysis may be used for those with an acute disturbance in kidney function or for those with progressive but chronically worsening kidney function[1].

Purpose: Sometimes nurses fail to adopt modern or recent nursing care for the hemodialysis due to the lack of knowledge and ignorance for learning therefore, the investigators is challenged to explore the knowledge level of staff nurses is relation to hemodialysis with a view to develop a planned structured teaching. The investigator during his training period and clinical experience observed. Lack of desirable knowledge and any standardized protocols in the dialysis and related units. So, the need to develop a planned teaching programme on hemodialysis was felt for nursing staffs in selected hospital. Objectives: 1. To determine the level of knowledge of the staff nurses regarding haemodialysis measured by structured knowledge questionnaire. 2. To evaluate the effectiveness of structured teaching programme by comparing the pre and post knowledge score. 3. To determine the association between the pre-test knowledge score with selected demographic variable on hemodialysis among staff nurses.

Methodology: The research design was Pre-experimental one group pre-test and post-test design, the setting chosen to conduct study was SMS Hospital, Jaipur, Rajasthan 203012. Sample size was 60;the sampling technique used was purposive sample technique. The staff nurses who fulfilled the inclusion criteria were selected as samples. The tool was submitted to seven experts of department of Medical Surgical Nursing and statistician and doctors. Experts were asked to give their opinions and suggestions about the content of tools. The interpretation of the score cut-off; Poor 0-40,Average 41-60, Good- 61-74 and very good 75 and above. The data gathered and analyzed by using descriptive and inferential statistics method and interpretation is made on the basis of objectives of the study.

Major Findings: The analysis of the study findings revealed that the pre-test mean was 16.02 with a standard deviation of 2.86 and the post-test mean was 23.88 with a standard deviation of 3.06. The tabulated value of score at 5% level of significance and 59 degrees of freedom is 2 and the table value was less than the calculated value (7.86).

Conclusion: This study represents the significant gain in knowledge through the planned teaching Program. Thus it suggests that the STP has been effective in increasing the knowledge of staff nurses about hemodialysis.

Introduction

The word dialysis derived from Greek word "dialusis", meaning dissolution, "dia" meaning through, and "lysis" meaning loosening. Dialysis is a process for removing waste and excess water from the blood, and is primarily used to provide an artificial replacement for lost kidney function in people with renal failure. Dialysis may be used for those with an acute disturbance in kidney function or for those with progressive but chronically worsening kidney function[1].

Absolute indications for dialysis include: severe volume overload refractory to diuretic agents, severe hyperkalemia and/or acidosis, encephalopathy not otherwise explained, and pericarditis or other serositis. Additional indications for dialysis include symptomatic uremia (e.g., intractable fatigue, anorexia, nausea, vomiting, pruritus, difficulty maintaining attention and concentration) and protein-energy malnutrition/ failure to thrive without other overt cause. No absolute serum creatinine, BUN, creatinine or urea clearance, or glomerular filtration rate (GFR) is used as an absolute cut-off for requiring dialysis, although most individuals experience, or will soon develop, symptoms and complications when the GFR is below _10 mL/min[1].

Nurses must take on important contribution towards maintenance of health in all aspects due to scientific changes in medical science and technology. Those expanding responsibilities of nursing based on growing demands of more knowledge and raise the need for critical evaluation of the educational programs that prepares the nurses to entire in to the skilful nursing profession.

The majority of nurses 53.9% had very high level of educational needs 33.8% had high level and 12.3% had moderate level of educational needs[3].

Nurses have been identified as being more enthusiastic in constantly working in a hospitals nephrology nursing and renal dialysis is a highly specialized field because the health team member are giving special care to fulfil the basic needs such as elimination of waste from the blood products and to maintain the electrolyte balance. The renal patients care being treated with Hi-Tech equipments[4].

The nurses' responsibilities for the haemodialysis patients are to maintain the patency of the vascular access site and keep it free from infection, to monitor the patient before, during, after treatment, to teach the patient and family about dialysis treatment and often home treatment and to assist the patient and family to cope with necessary life style changes and problems[9].

Materials and Method

Research approach: Quantitative Research approach

Research design: Pre experimental research design

Setting of the study: SMS Hospital, Jaipur, Rajasthan, 302012

Population: Staff Nurses

Sample: Staff nurses

Sample size: 60

Sampling techniques: Purposive sampling techniques[7]

Criteria for sample selection

Inclusion criteria

Staff Nurses who

- Staff nurses who are present during data collection.
- Staff nurses who are willing to participate.
- Staff nurses who are working in nephrology units.

Exclusion criteria

1. **Student Nurses.**

Development and Description of the Tool:

Section A: Assessment of Demographic Variables: Personal data sheet on the demographic characteristics of elderly includes such as age in years, gender, professional qualification, years of experience, areas of working and previous information.

Section B: It Includes Structured Knowledge Questionnaire: The related literature was reviewed for the construction of the structured knowledge questionnaire. It consisted of 30 items divided into 3 areas. They are:

- Dialysis : 5 items
- Haemodialysis : 10 items
- Management before, during and post haemodialysis: 15 items

All the items were multiple choice questions, which had 3 alternative responses. A score value of 1 was allotted to each correct response and for wrong response zero was awarded. Thus there were 30 maximum obtainable scores. The level of knowledge was categorized based on the scores obtained.

Findings: The data analysis was done using descriptive and inferential statistics.

Descriptive Statistics:

1. Frequency and percentage distribution was used to analyse the demographic variables of staff nurses.
2. Mean and standard deviation to assess the level of knowledge among staff nurses.

Inferential Statistics

1. The calculated paired t-test to compare pre-test and post-test level of knowledge among staff nurses after planned teaching programme.
2. Chi square test was used to associate the post- test level of knowledge among staff nurses with their selected demographic variables[7]

Organisation of the Data

Section I:	• Description of socio-demographic characteristics of samples.
Section II:	• Percentage distribution of overall knowledge levels and knowledge in Specific areas related to haemodialysis among staff nurses in pre Test and post-test. • Mean, mean% and standard deviation of pre-test and post- test knowledge scores
Section III:	• Effectiveness of planned teaching programme among staff nurses on haemodialysis knowledge by comparing the pre-test and post-test assessment. • Significance difference between pre-test and post-test knowledge scores
Section D:	• Association between the knowledge of staff nurses on haemodialysis with selected demographic variables.

Effectiveness of planned teaching programme on level of knowledge among staff nurses. N=60

Depression	Mean	S.D.	Paired 't' value
Pre-test	16.02	2.86	t = 14.3
Post test	23.88	3.06	P<0.05

P<0.05 S-Significant

The table shows that the pre-test mean score of depression among geriatrics was 16.02 with S.D 2.86 and the post-test mean score of depression was 23.88 with S.D 3.06. The calculated paired' value of t=14.3 was found to be highly statically significant at p<0.05 level. This clearly indicates that after providing planned teaching on haemodialysis to the staff nurses, their post-test level of knowledge hasincreased and this clearly indicates that planned teaching programme on haemodialysis was found to be highly effective in increasing the level of knowledge regarding haemodialysis among staff nurses.

Section D: Association of post test level of knowledge among staff nurses with their selected demographic variables: The post-test level of knowledge among staff nurses at p<0.05 level all the demographic variables had not shown statistically significant association with the post- test level of knowledge among staff nurses.

Discussion

The analysis shows that in the pre-test, majority 54(90%) of staff nurses had average level of knowledge, 4(6.67%) had good level of knowledge and only 2(3.33%) were poor, whereas in the post test after providing the planned teaching on haemodialysis, majority 58(96.67%) were very good and 2(3.33%) had good level of knowledge and no one had average and poorknowledge. The calculated paired' value of t=14.3 was found to be highly statically significant at p<0.05 level. Hence H_1 hypothesis stated earlier that "there will be a highly statistically significant association between the pre-test level of depression score and post-test level of depression score. The post-test level of depression among geriatrics at p<0.02 level all the demographic variables had not shown statistically significant association with the post- test level of depression among geriatrics. Hence H_2 hypothesis stated earlier that "there will not be a statistically significant association between

the post-test levels of depression score with selected demographic variables**.**

Conclusion

Majority of staff nurses have average and good knowledge level before administration of PTP. The hypothesis H_1 was accepted suggesting that there will be significant difference between pre and post-test knowledge score of staff nurses regarding haemodialysis and H_2 was rejected suggesting that there will be no significant association between the knowledge of haemodialysis and selected demographic variables.

Source of Funding: Self

Ethical Considerations:

- Formal permission was obtained from dean of Jaipur Hospital College of Nursing, Jaipur
- Written consent was obtained from the Medical Superintendent of SMS Hospital.
- Consents from the participants were obtained

A Study on Consumers' Satisfaction Level towards Select Organic Food Products in Salem District of Tamil Nadu

M. Suguna[1], D. Kamatchi[2]

[1]Assistant Professor, [2]Research Scholar, Department of Commerce, Periyar University, Salem

Abstract

The Organic Farming is carried out in 178 countries across the world at present. More than 90% of sales took place in North America and Europe. USA, Germany and France hold the highest share and Switzerland, Denmark and Luxembourg are the top three countries where the consumption per capita is the highest pertaining to organic foods as per the report given by the IFOAM. On the other hand, Asia Pacific market is growing rapidly at 29% and Projected as the fastest growing market. According to IFBL report, India has the largest number of organic food producers in the world. Increased health consciousness among people, food safety, environmental protection, and increase in the usage of organic and natural products are some of the key reasons for the expansion of this organic food markets. Organic food products are focused in developed countries because, the purchasing power of consumers are very high. Consumer satisfaction is a key indicator used to measure the customer loyalty and retention. So the researcher focused on the Consumers' Satisfaction towards Select Organic Food Products in Salem District of Tamil Nadu. The population size of the study was 100 respondents from Salem district by using convenience sampling technique. The percentage analysis and chi-square analysis were applied for testing the data. Finally the researcher providing suitable suggestions and conclusion based on their results and findings from study.

Keywords: *Organic Food Products, Farming, Health and Environmental Friendly.*

Introduction

Agriculture is the primary sector and backbone of the Indian economy. The people are getting food and food products from the agriculture sector. The drastic growth of population is creates more demand for food and food products. Due to increasing population in the world the exploitation of natural resources was started. To meet the more demand for foods, the farmers are applying the chemicals based fertilizers and pesticides at the time of cultivation and to getting more yields and profitable. This resulted not only in undesirable side effects in the agro-ecosystems and also affects the human health. After the long period of time the people are turned to think about the healthy food and back to organic farming. The consumption of organic food products provides the high nutritional value for human health. The organic food products are grown naturally without use of chemicals, pesticides and fertilizers. The organic farming works at gross root level preserving the reproductive and regenerative capacity of the soil, good plant nutrition, sound soil management and produces nutritious food in rich vitality which has resistance to disease[1]. India have lot of potential to produce all varieties of products due to the agro climatic region. The organic producers to tap the market which growing steadily in domestic and export market. The government of India has implemented many schemes to promote organic farming like Paramparagat Krishi Vikas Yojana (PKVY), National Project for Organic Farming (NPOF), National Mission for Sustainable Agriculture (NMSA), etc., all the schemes are running successfully in many states especially PKVY is more successful one. The farmers are more benefited from these schemes[2]. The organic food market is large distance spread and the consumers are becoming more intended to buy organic food products. The adoption of organic products and processing is highly depends by market demand. Now a days the food consumption pattern are changing rapidly for the reason of health and environmental issues. The reason for purchasing organic food products is the consumers are feel these products is healthier and environmental friendly. The previous studies are found

that the consumers are got more awareness on organic food products and started buying and utilizing for their regular consumption[3]. Hence, the organic food becomes a most important food in the emerging life of every human beings.

Importance of the Study: India has the largest number of organic producers in the world, according to the World of Organic Agriculture report 2018 has published more than 835000 certified organic producers in India. Organic food industry has nascent stage and steadfast growth in the fast few years. India has ranked 9th place in terms of world organic agricultural land and in terms of total number of producers at 1st place as per the data given by FiBL report 2018[4]. Sikkim has become first fully organic state in India. The consumption of organic food products is significantly increasing in the world. The consumers are prefer organic food products, because these are the promoted as superior and better option for the development of our human health. Looking demand side of organic food market there are several factors are influencing the consumer to prefer organic food products like certification, health benefits, environmental friendly and price etc. The consumer satisfaction plays a vital role in every business[5]. The satisfaction level of the consumers are most important for repurchasing the organic food products. Hence, the researcher to study the satisfaction level of the consumer towards select organic food products in Salem District of Tamil Nadu. The organic food markets is spread to move on from Tier I cities to Tier II cities and Metro cities. The Salem District is one of the Tier II and also Metro cities one. So, the research select the Salem District and to conduct the study from the Salem District organic food consumers[6].

Statement of the Problem: Organic farming is not new one. It is started 1000 years of ago, the people have been growing food by natural and organic method. The quality of food and food products have greater demand in the market, but increasing population in the world to meet the high demand of food the agriculture industries are adding numerous chemicals, fertilizers and pesticides at the time of cultivation and getting more yields. These type of conventional food products are neatly packaged and reached to the consumers in the marketplace. The consumer are consuming these products and its affects the various illness like nausea, diarrhea, anxiety, cramps, chronic diseases etc[7].In this situation the negative impact of contemporary food industries turned the people to think about the chemical free food products. The organic food products are not processes using irradiation, industrial solvents or chemical food additives. The prevention from many illness, thus increasing our quality of life by the way of using organic food products. The population of organic food consuming is increasing trend and consuming varieties of organic food products. When the consumer are attract and satisfied after using the organic food products, he or she buy again and again, so the marketers to know the satisfaction level of the consumers. The consumer satisfaction plays a very important role in any business. At this juncture the researcher intended to study the Consumer's Satisfaction Level towards Select Organic Food Products in Salem District of Tamil Nadu.

Objectives of the Study:

1. To study the demographic profile of the respondents in the study area.
2. To examine the consumer's attitude towards organic food products.
3. To measure the satisfaction level towards select organic food products in Salem District.
4. To offer suitable suggestions and conclusion.

Material and Method

The descriptive research design was adopted. The study was covered both primary and secondary data. The primary data was collected through well-structured interview schedule from 100 respondents in the study area by using convenient sampling technique has been used. The secondary data were collected from various websites, magazines & journals and government reports. In order to analyze the data percentage analysis and chi-square analysis was used to testing the data.

Findings of the Study:

Age: 10% of the respondents are age group of up to 25 years, 39% of the respondents are 26-35 years, 30% of the respondents are 36-45 years, and 11% of the respondents are 46-55 years and remaining 10% are 56 and above.

Gender: 56% of the respondents are Male and remaining 44% of the respondents are Female.

Educational Qualification: 6% of respondents are illiterate, 20% & 46% of the respondents are Up to H.Sc. & Graduates, 23 of the respondents are Post Graduates and rest of 5% under others category.

Employment Status: 15%, 34%, 19%, 09% of the respondents are belongs to Govt & Private employee, Business, Professional and remaining 23% of the respondents are belongs to Others category.

Monthly Income: 15% of the respondents are belongs to the income level of Upto Rs.10000, 45%, 21%, 09% and 10% of the respondents are belongs to the income level of Rs.10001-20000, Rs.20001-30000, Rs. 30001- 40000 and above Rs.40000.

Marital Status: 76% of the respondents are married, 24% of the respondents are unmarried.

Family Pattern: 53% of the respondents are Nuclear Family and remaining 47% of the respondents are Joint Family.

No. of Family Members: 37%, 54%, 09% of the respondents are upto 3 members, 4-6 members, and above 7 members.

Residence: 28% of the respondents are belongs to Rural Area, 17% of the respondents are Semi-urban, and remaining 55% of the respondents are belongs to Urban area.

Findings Related Consumer's Attitude towards Organic Food Products: The above table shows that, the consumers are mostly to know the organic food products through self, friends and relatives, and Magazines. The purchase decision of consumers made by self and friends. The more number of the consumers to purchase OFP for the past 1-2 years. The consumer's spending amount to purchase OFP is Rs. 1001-2000 per month. The majority of the consumers to preferred millet, jiggery & sugar, and oil items, because these product are most essential commodities in daily usage foods.

Satisfaction Level towards Organic Food Products:

Variables	Chi-square	df	Significance
Nutrition value of the product	84.200[a]	4	.000
Hygienic value of the product	57.600[b]	3	.000
Freshness of the products	1.014E2[a]	4	.000
Taste of the organic food products	82.800[a]	4	.000
Packaging of the OFP	67.900[a]	4	.000
Quality of the product	65.200[b]	3	.000
Price of the organic food products	1.052E2[a]	4	.000
Availability of product and Shops	84.300[a]	4	.000
Originality of the organic food products	51.440[b]	3	.000
Health improvement by using Organic food products	1.094E2[a]	4	.000
More number of varieties	1.040[c]	2	.595
Atmosphere on organic shops	33.840[b]	3	.000
Customer service on the shops	26.000[b]	3	.000
Product Advertisement	67.500[a]	4	.089
Brands of the organic food products	62.500[a]	4	.000
Satisfaction on label	65.200[a]	4	.000
Pleasant texture	49.040[b]	3	.000

Source: Primary Data, **Note: a.** 0 cells (.0%) have expected frequencies less than 5. The minimum expected cell frequency is 20.0., **b.** 0 cells (.0%) have expected frequencies less than 5. The minimum expected cell frequency is 25.0c. 0 cells (.0%) have expected frequencies less than 5. The minimum expected cell frequency is 33.3.

The above variables were used to measure the satisfaction level of the consumers. Out of seventeen variables only two variables are not significant at 5% level. The result indicates that consumers are not satisfied with more number of varieties of the products and product advertisement in the market.

Discussion

- The availability organic food products are very low and more number of varieties are lacking in the market. The consumer tastes are differing from person to person. The consumers are expected more number of varieties, because when the conventional foods are lot of varieties in the market. They are also expecting more varieties in organic food products. So, the marketers and farmers focus to satisfy the consumers' expectation.
- The most of the consumers are know about the organic food products only through the family members, friends and relatives. The advertisement strategy is adopted by the marketers are very low in market. So, the retailers are focused the advertisement campaign to improve the strategy in marketing of the products. The government also arrange the publicity and to create awareness about the organic food advantages among the peoples in the society.

Conclusion

The health and environmental benefits are emerged as the most important determinants to prefer organic food products. Organic foods are having more benefits like better quality, good for health, free from chemical residues which resulting no side effects and do not cause the harmful to the consumers' health etc. The consumers are aware about the benefits of organic food products. The nutritional value, hygienic, quality of products and many terms are to measure the satisfaction level of the consumers towards organic food products. So, the marketers to measure the consumer expectation and satisfaction level is important to increase the market shares. The competitive market place where the business are constantly competing for customers. The study of consumer satisfaction has made a number of benefits to the marketers for inviting customers to express their opinion and also opportunities to invite the customers to learn new information about the products and services. Once the consumers are satisfied in purchasing, he or she buys again and again. Satisfaction is only determined the future markets. The government to create awareness and encouraging sustainable purchase with organic products.

Ethical Clearance: My research entitled "A Study on Consumers' Satisfaction Level towards Select Organic Food Products in Salem District of Tamil Nadu". My research aims and methodologies to make sure that the research will be conducted in a way that protects the dignity, rights and safety of the research participants, and that the research design is ethically sound.

An Empirical Relationship between Stress and Time Management of School Students

D.S. Premalatha

Research Scholar, Vistas, Pallavaram, Chennai

Abstract

Time management is the main factor to reduce stress among the students. The main aim of this study is to find the factors causing stress among the students and impact of time management on stress. The researcher used regression analysis to find the result. Time management and stress are negatively correlated. Poor time management increase stress level to the students. The results shows that pressure of parents and pressure of teachers increase stress level than the other factors.

Keywords: *Stress, Time Management, Academic Performance.*

Introduction

Time Management has been defined as a "combination of time assessment, goal setting, planning, and monitoring activities" (Hafner & ¨ Stock, 2010, p. 430)[9] or a "self-controlled attempt to use time in a subjectively efficient way to achieve outcomes" (Koch & Kleinmann, 2002, p. 201)[10], while others do away with the need to define time management altogether (e.g., Barling, Cheung, & Kelloway, 1996; Trueman & Hartley, 1996)[4].

Good time management such as setting goals and priorities as well as monitoring the use of time can facilitate productivity and minimize stress, contributing to work effectiveness, maintaining balance and academic success. From this broadened perspective, people can see that the real value of time management is that it enhances their lives in all dimensions. What people gain from time management, in essence, is not more time, but a better life (Britton & Tesser, 1991; Misra & McKean, 2000)[6].

Time management is essentially to the students and this will be trained by the teachers how they managed the time to provide high performance and to reduce stress. Most of the time students face problems like task aversion and uncertainty, so they start to procrastinate because they lack organizational skills. As a result, students will not be able to organize duties according to their priorities, so they get distracted easily, ending up procrastinating. Effective time management is associated with greater academic performance and lower levels of anxiety in students; however many students find it hard to find a balance between their studies and their day-to-day lives.

Time management skill is one of the criteria that are used by students which results in an academically successful performance; the attempt for success is called academic motivation. Academic motivation means internal tendency of the learner that leads them to learning, skill acquirement and academic achievement. Academic motivation is very important for nursing students. Reduction of motivation has adverse effects on nurses, health of patients and society, and it diminishes many assets.

The students know to manage the time wisely make them calmly to do the work and complete the portions on time without any stress. This will useful to the students to achieve high in their academic performance.

Review of Literature: Alexander Hafner et al (2014) Decreasing students' stress through time management training: an intervention study. The purpose of this study

Corresponding Author:
Dr. S. Subramanian
HOD & Research Supervisor, Department of Commerce(Ca), Vistas, Pallavaram, Chennai

was to observe the effects of a time management training program on perceived control of time and perceived stress in the context of higher education. As expected, perceived stress decreased and perceived control of time increased after training, whereas demands did not change. Therefore, time management training might be beneficial for undergraduate students' well-being[1].

Ahmad Saleh Al Khatib (2014) Time Management and Its Relation to Students' Stress, Gender and Academic Achievement among Sample of Students at Al Ain University of Science and Technology, UAE. The objective of the present study was to investigate the relationship between time management, perceived stress, gender and academic achievement among United Arab Emirates college students. Time management was measured by Time Management Questionnaire" developed by Britton and Tesser (1991), while perceived stress was measured by The Perceived Stress Scale developed by Cohen (1985). The findings of the study showed that there was statistically significant negative relationship between time management and perceived stress[2].

Faisal Z. Miqdadi, Abdulla et al(2014) The Relationship between Time Management and the Academic Performance of Students from the Petroleum Institute in Abu Dhabi, the UAE. ASEE 2014 Zone I Conference, April 3-5, 2014, University of Bridgeport, Bridgpeort, CT, USA. This research study is about time management and how it is related to academic performance the Petroleum institute (PI) in Abu Dhabi, the UAE. The study was made by surveying male freshmen and sophomore students regarding problems of procrastination, disorganization, interruptions and work load stress. The results obtained showed that time management is highly related to academic performance. Finally, by discussing the results, we came up with recommendations that can lead the PI students to a better level of time management[7].

Dr. Ghada Abd Elasalm Eldeeb, Dr. Entisar Kamel Eldosoky (2016). Relationship between Effectiveness of Time Management and Stress levels among Nursing Students. The aim of the study is to compare time management and stress among 3rd and 8th levels nursing students. No students in both groups have high levels of time management. Regarding stress 3rd level students have higher mean scores of stress than 8th level students. There is non statistical significant positive correlation between time management and stress. The objective of the present study was to investigate the relationship between time management, perceived stress, gender and academic achievement among United Arab Emirates college students. The respondents were 352 college students from Al Ain University of Science and Technology. The findings of the study showed that there was statistically significant negative relationship between time management and perceived stress. Females reported higher time management compared to their males counter mates. Higher time management and lower perceived stress were associated with high levels of academic achievement[8].

Brad Aeon, Herman Aguinis (2017) It's About Time: New Perspectives And Insights On Time Management. Time management has helped people organize their professional lives for centuries. This study illustrate how time structures and time norms operate at the team, organizational, and national levels of analysis in influencing time management outcomes. It rely on the behavioral economics literature to describe how cognitive biases influence individual time management decisions. Integrating insights from a diverse set of fields results in a better understanding of past research and allows us to reinterpret conflicting results prevalent in the time management literature[5].

Arezoo Mohamadkhani Ghiasv and et al(2017) Relationship between time management skills and anxiety and academic motivation of nursing students in Tehran. Time management skills are essential for nursing students' success, and development of clinical competence. The purpose of this study was to determine the relationship between time management skills and anxiety and academic motivation of nursing students in Tehran medical sciences universities in 2015. Most participants had a moderate level of time Management skills (49%), State Anxiety (58%), Trait Anxiety (60%) and Academic Motivation (58%). The results also showed a statistically significant negative correlation between the students[3]

Richelle V. Athoms (2019) Impact of Time Management Behaviors on Undergraduate Engineering Students' Performance. This article examines the self-reported time management behaviors of undergraduate engineering students using the Correlation analysis, regression analysis, and model reduction are used to attempt to determine which aspects of time management the students practiced, which time management behaviors were more strongly associated with higher grades within

the program, and whether or not those students who self-identified with specific time management behaviors achieved better grades in the program. It was found that students' perceived control of time was the factor that correlated significantly with cumulative grade point average. On average, it was found that time management behaviors were not significantly different across gender, age, entry qualification, and time already spent in the program[11].

Objectives of the Study:

1. To find the factors causing stress on school students
2. To Evaluate impact on time management on stress
3. To study the relationship between stress and time management

Hypotheses of the Study:

1. There is significant difference among the factors causing stress on school students
2. There is significant influence of time management on stress
3. There is significant relationship between stress and time management

Analysis and Discussion: There are lot of factors causing stress among school students whereas heavy portions, deadlines to complete the portions, examinations, competition, pressure of parents, pressure of teachers and to attain the desired goal. These are all the factors causing stress among the school students. The regression analysis shows the relationship between these factors and how this factors affects their academic performance. The results are presented below:

Table 1: Model Summary

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.996[a]	.993	.992	.63350

a. Predictors: (Constant), S1,S2,S3,S4,S5,S6,S7

Source: Computed data

From the above table it is found that R=.996 R square = .993 and adjusted R square .992. This implies the stress create 99% variance over the students' performance. The cumulative influence of eight variables of stress over students' performance is ascertained through the following one way analysis of variance.

Table 2: ANOVA[a]

Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	26277.140	7	3753.877	9353.721	.000[b]
	Residual	197.452	492	.401		
	Total	26474.592	499			

a. Dependent Variable: Academic Performance

Table 3: Coefficients[a]

Model B		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		Std. Error	Beta			
1	(Constant)	-.129	.113		-1.148	.252
	Examination	1.269	.099	.202	12.875	.000
	Pressure of teachers	1.063	.101	.165	10.484	.000
	Pressure of Parents	1.162	.082	.207	14.174	.000
	Attain the desired goal	.356	.091	.070	3.913	.000
	Heavy Portion	1.089	.107	.181	10.206	.000
	Competition	.614	.103	.109	5.981	.000
	Health issues	.498	.117	.090	4.271	.000

Dependent Variable: Academic Performance, **Source:** Computed data, It illustrates that Examination (Beta = .202, t = 12.875, p = .000), Pressure of teachers (Beta = .165, t = 10.484, p = .000), Pressure of parents (Beta = .207, t = 14.174, p = .000), Attain the desired goal (Beta = .070, t = 3.913, p = .000) Heavy portions (Beta = .181, t = 10.2016, p = .000), Competition (Beta = .109, t = 5.981, p = .000), Health Issues (Beta = .090, t = 4.271, p = .000) are statistically significant at 5% level. This specifies that pressure of parents and pressure of teachers creates stress among the students and they measure them during the realization of academic performance.

Findings and Conclusions

The factors affecting stress among the school students are Examination, Pressure of teachers, Pressure of parents, attain the desired goal, heavy portions, competition, and health issues of the students. Pressure of teachers and pressure of parents are create more stress among the students than other factors.

Time Management is the main factor to reduce stress among the students. This will reflects in their academic performance. The teachers should have to provide the time management chart to the students to attain the desired goals in their academic performance effectively. Effective time management produce good academic performance to the students. Time management and stress are negatively correlated. Poor time management increase the stress level.

Finally the study concludes that management should teach time management to the students and this will lead to produce good results to the students as well as the management.

Prevalence of Anemia among Higher Primary School Girls in Selected Urban and Rural Schools

Dayanand V. Belagavi[1], Manju John[2]

[1]Assistant Professor, Sumandeep Nursing College, Sumandeep Vidyapeeth, Piparia, Waghodia, Vadodara, Gujarat,
[2]Prof. Manju John Principal, Nishad College of Nursing and Science, Satna, Madhya Pradesh, India

Abstract

Introduction: Anemia is one of the world's most wide spread health problem having major consequences for human health as well as social and economic development and affecting both developing and developed countries[1]. The body required increased amount of iron when growing rapidly and when frequent blood loss occurs through menstruation, hence adolescent girls are significantly high risk of developing iron deficiency. This is especially true for some adolescent girls who experience heavy blood loss during menstruation[2].

Objective: To determine and compare the prevalence of anemia among higher primary school girls between urban and rural schools.

Methodology: A descriptive comparative study was conducted among 450 (urban) and 450 (rural) school girls at higher primary schools, Belgaum, Karnataka. Stratified random sampling technique was used to select the school girl children. Haemoglobin estimation was done by using Sahli's method to determine anemia.

Results: Higher prevalence of anemia was observed to be (90%) among rural higher primary school girl children compared to the urban (79.8%) counterpart. The occurrence of anemia reported through the study, was associated with age, class, religion of the child, parents' occupation (p value<0.05) in urban and rural higher primary school. In addition, there was also significant association was found between prevalence of anemia and type of diet, previous source of information, parents' education, family income of participants (p value <0.05) in rural school.

Conclusion: Present study showed higher anemia prevalence in rural school girl children compared to urban. Early intervention is utmost required by considering these factors along with the existing programs will help directly to overcome this issue.

Keywords: *Anemia; higher primary school girls; knowledge; prevalence; rural; urban.*

Introduction

Anemia is one of the world's most widespread health problem having major consequences for human health as well as social and economic development and affecting both developing and developed countries[1].

In developing and developed countries the prevalence of anemia among adolescent is estimated to be 27% and 6% respectively[3].

India is one of the country tagged with highest anemia prevalence according to estimates from WHO, which estimates that, in developing countries 27% of adolescents were anemic[4] the high incidence of low birth weight babies, high prenatal mortality and the consequent high fertility rates. Objective was to determine the prevalence of anaemia among school going adolescent girls. The present study included 320 adolescent girls from selected Government Secondary Schools of district Rohtak (Haryana).

Today, the country is suffering from most wide spread disorder of nutritional deficiency mainly due to anemia occurring primarily due to iron deficiency. More than 39% girls of age 15–19 years which fall under adolescent group were mildly anemic, while 15% were

moderately anemic and 2% severely anemic[5]. A cross-sectional study carried out in four villages of Wardha among 630 adolescent girls, the prevalence of anemia was found to be 59.8% and the prevalence of severe, moderate and mild anemia was 0.6%, 20.8% & 38.4% respectively[6]. Thus, this anemiastill remained as a serious public health problem.

Objectives:

1. Compare the prevalence of anemia among higher primary school girls between urban and rural schools.
2. Find out the association between prevalence of anemia and socio demographic variables of higher primary school girls in urban and rural schools.

Null Hypothesis:

H_{01}: There will be no difference between the prevalence of anemia among higher primary school girls in selected urban and rural schools.

H_{02}: There will be no association between the prevalence of anemia and socio demographic variables among higher primary school girls in selected urban and rural schools.

Materials and Method

Research approach: Quantitative research approach.

Research design: A descriptive comparative research design

Setting: The present study was conducted in 7 Urban and 6 Rural higher primary schools in Belgaum district.

Population:

- Target population: girls studying in selected urban and rural higher primary schools of Belgaum district.
- **Accessible population:** girls who are studying in 6th, 7th and 8th standard, who are fulfilling the selection criteria in selected 7 urban and 6 rural higher primary schools of Belgaum district.

Sampling Procedure: In the present study, Out of 129 urban higher primary schools, 7 were selected and out of 659 rural higher primary schools, 6 were selected randomly. Among 7 Urban schools 226 students (girls) were studying in 6th standard, 370 in 7th and 401 in 8th standard. Using the stratified random sampling method according to different classes, picked 102 school girl children (samples) in the 6th standard, 167 samples in 7th standard and 181 samples in 8th standard proportionately. Further, using the method of simple random sampling, girls from each class were selected who were fulfilling the sampling criteria.

The same sampling procedure was used for selecting samples from the rural area.

Sample and sample size: 450 urban and 450 rural girls studying in higher primary schools.

Inclusion Criteria:

- School girls studying in VI, VII and VIII standards.
- Girls who are present in the school at the time of data collections.
- Girls willing and their parents' consent to withdraw blood sample for haemoglobin estimation.

Exclusion criteria:

- School girls who were seriously ill & Psychiatric problems as reported by their teacher.

Demographic Variables: Child's data: The items included were hemoglobin level, age, class, type of diet and residence.

Parent's Data: The items included were educational status of father and mother, occupational status of father and mother, religion, type of family, monthly income of family and number of siblings.

Data Collection Procedure: Before collecting the data prior permission was obtained from the Health and family Welfare Officer, Belgaum, Block education officer and the Principals of selected schools. The concerned authority of institution had given dates and timings to conduct the research study. Keeping in mind the ethical aspect of research, consent form was sent along with the child to home to get the parents signature (consent). The researcher collected the data after the respondents were assured the anonymity and confidentiality of the information provided by them. The Hemoglobin estimation of selected girls was done by using Sahli's method under the supervision of principal investigator, the laboratory technicians checked the haemoglobin level.

The process adopted for haemoglobin estimation was as follows:

Blood was mixed with N/10 HCl resulting in the conversion of Hb to acid hematin which is in color brown. The solution was diluted till it's color matches with the brown colored glass of the comparator box. The concentration of Hb was read directly.

Data Analysis:

1. **Descriptive Statistics:** Frequency distribution, percentage, mean, was used to assess the demographic variables.
2. **Inferential Statistics:** Chi-square test and Fisher's Exact test was used to determine the association of prevalence of anemia with the selected demographic variables.

Findings:

Part I: Description of demographic characteristics of urban and rural school girl children.

- In Urban schools, out of 450, 180 (40.00%) participants were age of 13 years, 132 (29.3%) were 14 years, 126 (28.0%) were 12 years, 7 (1.6%) were 11 years and remaining only 5(1.1%) were 15 years. Almost similar was observed in rural area.
- In urban schools, out of 450, 181 (40.2%) participants were belongs class VIII, 167 (37.1%) were class VII and remaining 102(22.7%) participants were class VI. The same was observed in rural area.
- In urban area, out of 450, more than 85% participants belongs to urban residence and in rural area almost all the participants belongs to rural residence.
- In urban schools, more than 50% participants had mixed dietary habit, 186 (41.30%) had vegetarian. In rural area around 70.00% participants had vegetarian, 143 (34%) had mixed food habit.
- Majority 91.1% fathers of participants qualified with secondary, under graduate and pre-university education in urban, whereas in rural area about 91.3% were studied primary, secondary and pre-university but no one has done post graduation.
- In urban area, around 50% fathers were self employed, 148(32.9%) were working in private sector and 84(18.7%) fathers were government employee and none them were unemployed. In rural area around 85% of fathers were self employed, 51(11.3%) were working private sector, 15(3.3%) were in government sector and only 3 fathers were unemployed.
- In urban area, more than 80% mothers were housewives, 53 (11.8%) were working in private sector and 22 (4.9%) mothers were government employee. In rural area almost all the mothers were housewives.
- Out of 450 participants in urban area majority them belongs to Hindu religion, followed by 82 (18.2%) belongs to Muslim and 42 (9.3%) belongs to Chirstian and in rural area more than 80% participants belongs to Hindu religion 51 (11.3%) belongs to Muslim and only 6 belongs to Chirstian.
- In urban area majority of participants belongs to nuclear family whereas in rural area majority participants belongs to joint family.
- Regarding family income, in urban area 182 (40.4%) participants has more than 1500 rupees, 140 (31.1%) participants was 10001 to 15000 rupees, 125 (27.8%) participants was 5001-10000 rupees and only 3 (0.7%) participants was less than 5000 rupees. Where as in rural area almost three-fourth participants family income was 5001-10000, followed by 57 (12.7%) participants was 10001-15000, followed by 30 (6.7%) participants was less than 5000 rupees and 27 (6.0%) participants was more than 15000 rupees.
- In urban area, out of 450, around 50% participants had only one sibling, 120 (26.7%) had two siblings, 71 (15.8%) had no siblings and 51 (11.3%) participants had three and more siblings. In case of rural area, 159 (35.3%) participants had two siblings, 148 (32.9%) had three and more siblings, 136 (30.2%) had only one sibling and only 7 (1.6%) participants had no siblings.

Part II: Anemia Prevalence and its comparison between urban and rural higher primary school girls.

Table 1: Prevalence of anemia and its comparison

Type of Anemia	Group		Total	χ^2 Calculated value
	Urban	Rural		
No anemia (>12g/dl)	91	45	136	35.56 S
	20.2%	10.0%	15.1%	
Mild anemia (10-11.9g/dl)	268	245	513	
	59.6%	54.4%	57.0%	
Moderate anemia (07-09.9g/dl)	91	160	251	
	20.2%	35.6%	27.9%	
Total	**450**	**450**	**900**	
	100.0%	**100.0%**	**100.0%**	

S: Significant, χ^2 Table value = 5.99, $p<0.05$

The data shows that out of 900 participants, majority of 513 (57.0%) in urban and rural area had mild anemia. In urban, 91 (20.2%) and rural area 160 (35.5%) had moderate anemia. Remaining 20.2% and 10.0% participants had no anemia in urban and rural area respectively. The prevalence of anemia among higher primary school girls in urban and rural area was 79.8% and 90% respectively.

The above table shows that the calculated chi-square (χ^2) value (35.56) is more than the table value (5.99) hence the null hypothesis is rejected. Therefore, concluded that there was significant difference between the prevalence of anemia among higher primary school girls in urban and rural schools ($p<0.05$).

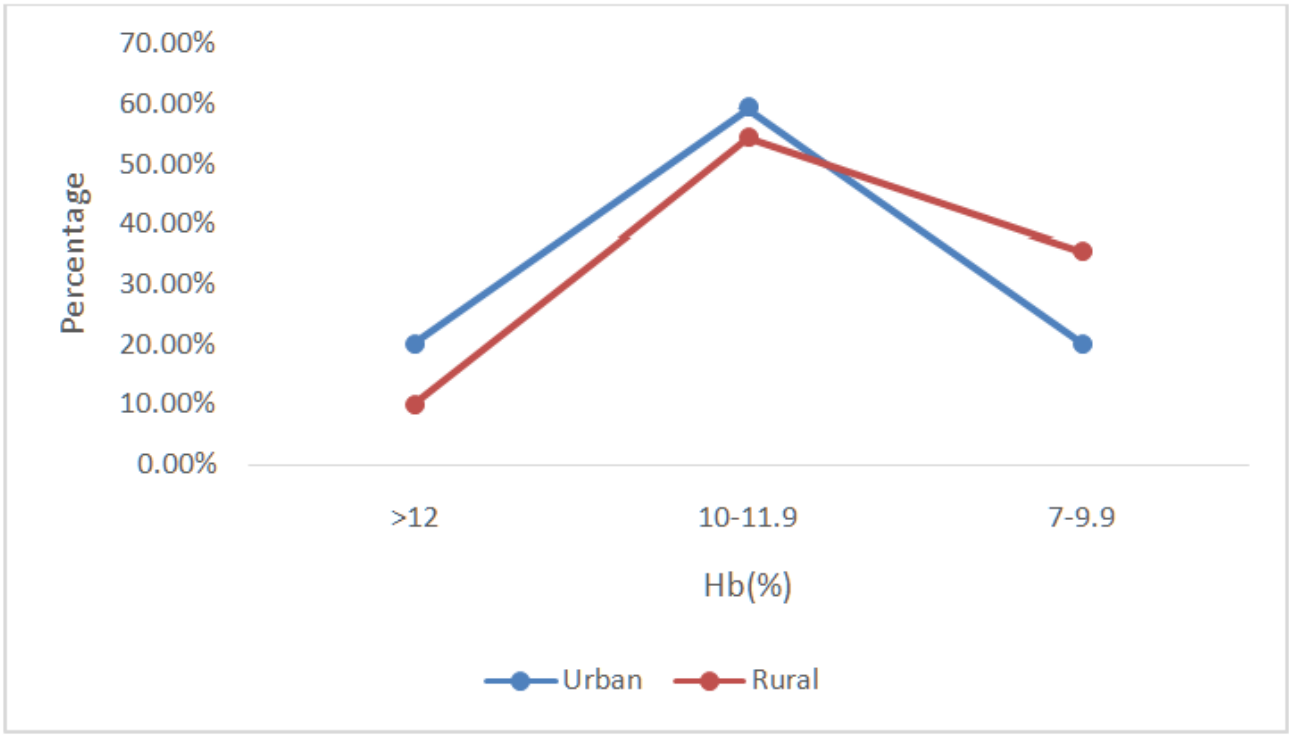

Fig. 1 Prevalence of anemia and comparison between urban and rural schools.

Part II: Association between the anemia prevalence & socio-demographic variables in urban higher primary schools.

The demographic variables of age, class, father occupation, mother occupation and religion, the calculated value of Fisher-Exact test and chi-square is greater compared to table value. Hence the null hypothesis is rejected at 5% significance level. Therefore, concludes a significant association between age of the participants and anemia (p value<0.05).

Regarding residence, type of diet, father education, Type of Family, family income and No. of siblings, the calculated value of Fisher-Exact test and chi-square is less compared to table value. Hence the null hypothesis is not excluded at 5% significance level. Therefore, there was no significant association between type of residence of the participants and anemia (p value<0.05).

Part III: Association between anemia prevalence & socio demographics variables in Rural higher primary schools

The calculated chi-square value is greater than table value in class, previous source of information, religion except type of family. Hence the null hypothesis is rejected at 5% level of significance. Therefore, the results of Chi-Square test for rural school girl children show that there is significant association between class, previous source of information, religion and prevalence of anemia (p value <0.05).

The calculated Fisher-Exact test value is greater than table value in age, type of diet, father & mothers' education and occupation, family income, number of siblings. Hence the null hypothesis is rejected at 5% level of significance. Therefore, the results of Fisher-Exact test for rural school girl children shows that there is significant association between age, type of diet, father & mothers' education & occupation, family income, number of siblings and prevalence of anemia (p value <0.05).

Discussion

In India, anemia prevalence among adolescent girls was comprehensively demonstrated in rural and urban differentials in the present study. While there are different causes that are connected with the anemia prevalence, our study highlighted socioeconomic factors which are responsible for anemia. Factors like age, education, family size, religion, economic status and region of residence were the significant determinants of anemia.

Almost two fold of anemia prevalence was observed among children residing in rural areas when compared to that of children of urban area. Statistical analysis of the present study revealed that majority of the participants in urban and rural area had mild anemia. But in rural area moderate mild was observed as high when compared with the urban area. No anemia was observed in very few participants of urban area when compared to rural area.

The difference seen was mainly due to poor accessibility to health care facility, lacking awareness, defecation in open air, poverty & illiteracy which is commonly more observed in rural parts of India. Addition to this, most of the children in rural area was deprived of nutrition which is also one of the factor the increased anemia prevalence. A study conducted in Belagavi, Karnataka showed that the prevalence of anaemia among school children was found to be 47.9%. A high prevalence of 57% was seen among girls. Prevalence was more in rural area i.e. 52.7% compared to that of urban i.e. 43%. Mild anaemia was found to be more prevalent in both urban and rural children i.e. 28.7% and 29.7% respectively[7]. In rural Hassan, a study reported of moderate (40.1%) and severe (4.9%) anemia in girls[8].

Pattnaik et al., 2012, in their study described about the anemia prevalence in girls at their adolescence age residing in parts of rural area of Khordha District, Odisha. Around 78.8% anemia prevalence rate in girls at their adolescence age. Of the total 119 girls who were anaemic, 75.6% were suffering from mild degree of anemia and 24.4% girls were having moderate degree of anemia and also reported that anemia was significantly higher with H/O excessive menstrual bleeding (P=0.001), no H/O intake of IFA in last 6 months (P=0.001)[9].

Chant. et. al., study reported that the. Prevalence of anaemia was significantly high (80%) in the adolescent girls who already attained menarche. A statistically significant relation exists between family size and anaemia. Percentage of anaemia was high among labour class (85%) than business class (61.7%). Prevalence of anaemia was to be found high in vegetarian (78.13%) than non-vegetarian (75.29%)[10] poor dietary intake of iron, prolonged menstrual period, and worm infestation.

A study was conducted with the objective to determine the associated risk factors of anaemia among adolescent girls.\nMETHOD A cross-section study was conducted among 202 adolescent girls in rural area of Katihar. Information was collected on a predesigned and pretested proforma about contributory factors in relation to anaemia, by oral questionnaire method. Sahli's haemoglobinometer was used for the haemoglobin estimation.\nRESULTS Prevalence of anaemia and severity of anaemia was found to be high in the age group 17 to 19. Prevalence of anaemia was significantly high (80%.

In the present study, school children of adolescence age with family size of more than five & five are more prone to anemia prevalence in comparison to school going adolescents with small size family having less than five members. The reason behind this could be because large family size results in less care for each individual of the family also constrain of income in intake of a sufficient diet that includes food varieties that is micro-nutrient rich as that of iron.

Conclusion

This study concludes that anemia prevalence among girls during adolescence were very high in India which requires concerted efforts by all the stakeholders, policy maker, planners involved in National Health Policy. Results clearly indicated that the prevalence of anemia is higher in rural place than the urban schools of Belgaum district. The present study also showed the parents' education, parents' occupation, socio-economic status, family size; dietary intake will directly influence the anemia among the community.

Hence, improvement of society's economic status and poverty mitigation is one of a critical tactic to minimize the anemia prevalence.

Relative Effect of Conventional and Specific Hockey Skill Training on Selected Motor Fitness, Physiological Variables and Playing Ability of Hockey Players in Tamil Nadu

K. Govarthanan[1], K. Vaithianathan[2]

[1]Ph.D. Scholar, [2]Director of Sports, Dept. of Physical Education and Sports Science, SRMIST, Kattankulathur, Chennai, Tamil Nadu, India

Abstract

The purpose of the study was to study conventional and specific hockey skill training on Motor fitness, physiological and playing ability of Hockey players. There were selective three motor fitness and three physiological components which were used as a criterion measures for this study. For analysis the data and to find out the relationship between selective motor fitness, physiological and playing ability Pearson product moment correlationship was applied. Level of confidence was set at .05 levels. Firstly, selective motor fitness, Second, physiological components were evaluated. The result of the study clearly disclosed that specific hockey skill training has considerable relationship with the playing ability of Hockey players in SRM University, Tamil Nadu. On the basis of results and associated discussion it may be concluded that conventional training and playing ability had low correlation. There might be some reasons of the low correlation in the perspective of good scientific coaching. There was the possibility of the lack of coaching aspects, which shows clearly in the findings that the specific hockey skill training was less correlated with playing ability.

Keywords: *Conventional training, specific hockey skill training, playing ability.*

Introduction

Hockey is one of the favourite of all. Hockey is the game of skill; it is a well-known concept of ancient Indian hockey which elaborates the importance of conventional and specific of skills training. Hockey is a dynamic field game, played by male and female, requiring high level skills, excellent conditioning and well coordinated team efforts[1]. Hockey is one of the most popular and attractive sports in the world. Hockey is a sport with many complex techniques and tactics that can be seen speed, power, endurance and movement frequently in it[5].

Research in the field of Physical Education and Sports is highly demand of the today. Researches in this field brought so many fitness in and various skill training. We can say that the progress of the field directly linked with research. It is fact that at present situation research in Physical Education, and Sports is an important area of study to improve the sports performance. The past decades have seen the rise of an area of study called futurism or futuristic, which attempts to scientifically examine the future[2].

A physiological benefit available, through motor activity is positively associated with aspects of psychological well-being. In particular, significant relationships have been identified between self-perceived health and motor activity. The argument exists, therefore, that the promotion of sports participation and achieve leisure pursuits may at least be rewarded by better health perceptions. The poor performance of Indian sportsman and sports women in the international competitions is the result of lack of motor fitness. Therefore, it is felt that

there is a dire need to improve the motor fitness level of Indian youth for raising the performance and standard in games and sport[4].

Motor fitness, physiological variables have been considered as important prerequisite for sportsmen to secure the top level performance in the game. A good hockey player must have the following physical activity. He must have the motor fitness to perform the specific skills training that the game of hockey requires. These include speed endurance, muscular endurance, and aerobic endurance with precision accuracy and confidence. Perfection in vital capacity, respiratory rate, and respiratory volume is most important for all good players irrespective.

Coaching in the sports would be based on scientific and systematic information derived from research[3]. With regard to physical fitness there are several factors that a number of overlapping activities. The term physical fitness has been divided into two distinct categories: skill-related and physiological-related motor fitness.

Methodology of the study

Selection of Subjects: For the purpose of present study forty five field hockey players from SRM University, Department of Physical Education and Sports Science, Kattankulathur, Chennai, Tamil Nadu State, India were selected as subjects at random and their ages ranged from 18 to 25 years. These subjects were divided in three groups. Each group would be consists of 15 players.

Selection of Variable: Twelve weeks conventional training and specific hockey skill training acts as an independent variable and motor fitness, physiological acts as dependent variable for the present study.

Research Design: The selected subjects (N=45) were divided into three groups equally and randomly. Of which one group was undergoing conventional method of training to develop selected dependent variables whereas the other group underwent specific hockey skill training to develop the selected motor fitness, physiological variables and playing ability and the third group acted as control group.

Collection of Data: Before the administration of conventional and specific hockey skill training, the motor fitness, physiological test were administered on both the experimental and control groups to collect pretest data. After the completion of 12 weeks of specific hockey skill training again the same tests were conducted to collect the post training data. Necessary instructions were given to the subjects before administration of the tests.

Experimental Design: For the study pretest & posttest randomized group design, which consists of no training group (n=15) and two experimental group (n=30) was used. Equal numbers of subjects were assigned randomly to the group. Two groups served as experimental group (conventional training and specific hockey skill training group) on treatment.

- Experimental Group I: subjects were considered as Conventional training on regular male field hockey players.
- Experimental Group II: Subjects were allowed to perform Specific hockey Skill training on regular male field hockey player.
- Control Group III: Subjects were not given special training other than the training on regular male field hockey players respectively.

For experimental group I & II the present study training given for three days per week (alternate days) for twelve weeks. Every training session lasted for 60 to 90 minutes. The training program was scheduled for the morning between 6.00 am to 8.00 am.

However, they were participating in their regular physical activities and game practice. The subject underwent their respective programme under strict supervision prior to and during every session. Subject underwent training for & 90 minutes including warm up and cool-down exercises which included jogging, stretching, striding and warm-ups. Measurement of motor fitness, physiological variables, and playing ability was taken for the three groups.

Hence the results concluded that specific hockey skill training influences the speed endurance, muscular endurance, aerobic endurance, vital capacity, respiratory rate, and respiratory volume, of the players. It was also proved that the better effect was seen in regular male field hockey players in group II.

Statistical Procedure: To find out the effect of static and conventional training and specific hockey skill Training on motor fitness, physiological and playing ability of the subjects the pretest and post test scores were analyzed by using descriptive statistical

and Analysis of Co-Variance (ANCOVA). To test significance of difference among means test was applied. The data analyzed with the help of (IBM) SPSS (20.0 version) software and the level of significance was set at 0.05 level of confidence.

Findings of the Study:

Table I: Analysis of covariance of means of conventional training and specific hockey skill training and no training groups on speed endurance

	Conventional Training	Specific Hockey Skill Training	No Training	Source of Variance	Sum of Squares	df	Means Squares	F-ratio
Pre-Test Means	6.08	6.23	6.05	BG	0.27	2	0.14	1.31
				WG	4.47	42	0.10	
Post-Test Means	5.76	5.85	5.32	BG	2.37	2	1.18	8.55*
				WG	5.83	42	0.13	
Adjusted Post-Test Means	5.76	5.85	5.32	BG	2.304	2	1.15	8.10*
				WG	5.830	41	0.14	

*Significant at 0.05 level of confidence.

The table-I indicated that the pretest means conventional training and specific hockey skill training and no training groups group were 6.08, 6.23 and 6.05 respectively. The obtained F-ratio for the pre-test was 1.31 and the table F-ratio was 3.22. Hence the pre-test mean speed endurance F-ratio was insignificant at 0.05 level of confidence for the degree of freedom 2 and 42. The post-test means of the conventional training and specific hockey skill training and no training groups group were 5.76, 5.85 and 5.32 respectively. The obtained F-ratio for the post-test was 8.55 and the table F-ratio was 3.22. Hence the post- test mean speed endurance F-ratio was significant at 0.05 level of confidence for the degree of freedom 2 and 42. The adjusted post-test means of the conventional training and specific hockey skill training and no training groups were 5.76, 5.85 and 5.32 respectively. The obtained F-ratio for the adjusted post-test means was 8.10 and the table F-ratio was 3.23. Hence the adjusted post-test mean speed endurance F-ratio was significant at 0.05 level of confidence for the degree of freedom 2 and 41.

Table II: Analysis of covariance of means of conventional training and specific hockey skill training and no training groups on muscular endurance

	Conventional Training	Specific Hockey Skill Training	No Training	Source of Variance	Sum of Squares	df	Means Squares	F-ratio
Pre-Test Means	11.45	11.59	11.19	BG	1.23	2	0.62	1.35
				WG	19.28	42	0.45	
Post-Test Means	10.61	11.12	9.52	BG	20.20	2	10.10	18.73*
				WG	22.65	42	0.53	
Adjusted Post-Test Means	10.64	11.10	9.51	BG	19.99	2	9.99	18.33*
				WG	22.36	41	0.54	

*Significant at 0.05 level of confidence.

The table-II indicated that the pretest means conventional training and specific hockey skill training and no training groups were 11.45, 11.59 and 11.19 respectively. The obtained F-ratio for the pre-test was 1.35 and the table F-ratio was 3.22. Hence the pre-test mean muscular endurance F-ratio was insignificant at 0.05 level of confidence for the degree of freedom 2 and 42. The post-test means of the conventional training and specific hockey skill training and no training groups were 10.61, 11.12 and 9.52 respectively. The obtained F-ratio for the post-test was 18.73 and the table F-ratio was 3.22. Hence the post- test mean muscular endurance F-ratio was significant at 0.05 level of confidence for the degree of freedom 2 and 42. The adjusted post-test means of the conventional training and specific hockey skill training and no training groups were 10.64, 11.10 and 9.51 respectively. The obtained F-ratio for the adjusted post-test means was 18.33 and the table F-ratio was 3.23. Hence the adjusted post-test mean muscular endurance F-ratio was significant at 0.05 level of confidence for the degree of freedom 2 and 41.

Table III: Analysis of covariance of means of conventional training and specific hockey skill training and no training groups on aerobic endurance

	Conventional Training	Specific Hockey Skill Training	No Training	Source of Variance	Sum of Squares	df	Means Squares	F-ratio
Pre-Test Means	42.40	44.33	42.40	BG	2	18.68	2	1.01
				WG	42	18.44	42	
Post-Test Means	51.53	52.46	47.93	BG	2	85.95	2	3.77*
				WG	42	22.77	42	
Adjusted Post-Test Means	50.35	53.05	48.52	BG	2	77.99	2	10.52*
				WG	41	7.41	41	

*Significant at 0.05 level of confidence.

The table-X indicated that the pretest means conventional training and specific hockey skill training and no training groups were 42.40, 44.33 and 42.40 respectively. The obtained F-ratio for the pre-test was 1.01 and the table F-ratio was 3.22. Hence the pre-test mean aerobic endurance F-ratio was insignificant at 0.05 level of confidence for the degree of freedom 2 and 42. The post-test means of the conventional training and specific hockey skill training and no training groups were 51.53, 52.46 and 47.93 respectively. The obtained F-ratio for the post-test was 3.77 and the table F-ratio was 3.22. Hence the post- test mean aerobic endurance F-ratio was significant at 0.05 level of confidence for the degree of freedom 2 and 42. The adjusted post-test means of the conventional training and specific hockey skill training and no training groups were 50.35, 53.05 and 48.52 respectively. The obtained F-ratio for the adjusted post-test means was 10.52 and the table F-ratio was 3.23. Hence the adjusted post-test mean aerobic endurance F-ratio was significant at 0.05 level of confidence for the degree of freedom 2 and 41.

Discussion on Findings

The prime intention of the researcher was to analyse the relative effect of conventional training and specific hockey skill training on selected motor fitness, physiological and playing ability of field hockey players. The theme behind this study was to observe the influences of conventional training, specific hockey skill training and no training as a alternate means to develop the selected physical, physiological and playing ability of field hockey players. To achieve this, two different training were designed as conventional training group, specific hockey skill training group and no training group. The results of the effect of two training packages on variables used in this study are analysed so as to reach the theme of the present study, and sources behind such similarities and variations observed on variables between the training groups, have been discussed here using scientific studies and logical in nature.

Conventional training is using another sport, activity or training techniques to help improve playing ability in

the primary sport activity. Specific hockey skill training is specifically designed to develop the playing ability related field hockey players.

Hence, compared the effects of three different training improvements in vertical jump performance and leg strength[6]. Speed endurance training facilitates aerobic endurance processes, whereas resistance training increases muscular endurance and vital capacity[7]. The speed endurance, muscular endurance and aerobic endurance and agility increased significantly after training[8]. Compared the changes in running economy, foot impact shock, run performance, and resting respiratory rate and respiratory volume elicited by increases in training volume via run training and conventional and specific hockey skill training[9].

In a field hockey game players need a high level of energy and analytical skill to fulfill the requirements. Sports-specific physical training is paramount in field hockey [10].There was no significant improvement in the shooting, passing and dribbling ability of the control group. The developed an effective testing battery for male field hockey by using anthropometric, physiological, and skill-related tests to distinguish between regional representative male field hockey players.These sprinting speed, agility, dribbling control, aerobic and muscular power, and shooting accuracy can distinguish between male field hockey players [11].

Conventional training effects never exceed those induced by the specific hockey skill training mode. For the general population, conventional training may be highly beneficial in terms of overall fitness. Similarly, conventional training may be an appropriate supplement during rehabilitation periods from physical injury and during periods of overtraining or psychological fatigue. Since, conventional training was one of the most advanced forms of sports training the combination with specific hockey skill training produces significant changes. Anyhow these two different training when in conjunctional nature, the effect might have been strengthened as a value added one.

Conclusion

The result of the present study reported that participation in the specific hockey skill training program; improve playing ability in experimental group. Hence significant difference was found between the regular male filed hockey players of SRM University, Chennai in relation to motor fitness, physiological and playing ability.

- The specific hockey skill training group had shown significant improvement in all the performance variables than the conventional training group.
- The specific hockey skill training with conventional training group had shown significant improvement in all the selected motor fitness, physiological and playing ability.
- The control group has shown significant no improvement in all the selected motor fitness physiological and playing ability variables.

Effect of Yoga on Body Composition in Person with Visual Disabilities

Mohd Arshad Bari[1], Mohammed Aiyad Mahmood Alobaidi[2], Hussein Ali Hasan Alghazal[2], Haq Nawaz Mir[2], Ali Azeez Aneed Al-Mijbilee[2]

[1]Assistant Professor, [2]Research Scholars, Department of Physical Education, Aligarh Muslim University, Aligarh,India

Abstract

Aim: The aims of this study were to determine the effect of selected yoga asanas on body composition of visually challenged School Going Children.

Materials and Method: Total of 24 visually disabled male school going children (12 to 18 years) were participated as subjects in this study. It was divided into two equal groups as experimental group (n=12) and control group (n=12). The experimental group was regularly practiced 15 minutes warming up and selected yogic asana for 45 minutes per day, 05 days per week, for 6 weeks with proper technical assistance. The pre-test and post-test were taken of all the body composition parameters before and after six (6) weeks of yogic exercise training program. The body composition variables were Age, Height, Weight, Blood Pressure (B.P.), Pulse Rate, BMI, BMR, Body Fat and Visceral Fat%, which were measured by standard body composition analyzer. To test the significance of changes made from the pre and post-test on two groups (Experimental and Control) groups' paired sample -test was used.

Results: Significant reduction ($P < 0.005$) in the percentage of Body Fat, Basal Metabolic Rate (B.M.R), Pulse Rate and Blood Pressure (s) were noted in the experimental group after 06 weeks of yoga training. However, there were no significant differences in Visceral Fate, Body Mass Index (B.M.I), Blood Pressure (d) in the yoga and control group. These changes might be due to yoga training but for more significant results, yoga training required for visually disabled person longer duration time with proper assistance.

Keywords: *Yogic asana, Body Mass Index (BMI), Basal Metabolic Rate, Visceral Fat, Visual Disability.*

Introduction

The word of yoga is derived from the Sanskrit word "yuj", which means summation or union. Pantanjali described the word of yoga as an eight-limbed path consisting of Yamas, Niyamas, Asana, Pranayama, Pratyahara, Dharana, Dhyana, and Samadhi [20]. The yoga is a scientific discipline of psycho-somatic-spirituality for achieving the union of Body, Mind, and Soul[17]. Yoga is also known as the way of life in ancient India, which includes meditation, social, behavioral changes, and the practice of asana for enhancing the different levels of fitness and wellness[20]. The major objective of this study was to find out the effect of some selected yogic asana on the body composition of visually challenged school-going children. Categorizations of visual disabilities based on its degree of severity which is notified in Gazette of India, 2001.

The proper function of the body of an individual depends upon the optimum function of the major muscle groups, level of physical fitness and flexibility, without the proper function of it the individual health may be under risk. It is necessary for a healthier lifestyle for

Mohd Arshad Bari, Ph.D.
Assistant Professor, Department of Physical Education, Aligarh Muslim University, Aligarh, India-202002

children to promote proper growth, development and an active lifestyle in their aptitude. It is most important for an individual to continue being active throughout their lives. In the case of the visually disabled persons, they required extra energy due to disability for various day to day activities such as finding direction, locating the position and daily normal activity[2].

Visually disabled children were physically inactive [19,12] less physically fit [19], lower quality of life [4] and poor in locomotors activity [10] than there peer group without disability[05]. Optimum levels of motor skills are essential for successful acquiring motor fitness and healthy lifestyle[19]. Previous studies reported that yoga plays an important role to maintain physical fitness, balance[12], normal function of GAIT[19] and posture also prevent falls[04]. Yoga asanas were seen as good benefits on fitness related to health in muscle strength[03], endurance[05, 04], flexibility and cardiovascular tolerance for school children. Its positive effects in children with visual impairment are also well documented, including autonomic stimulation[24], balance[13], and proprioception[18].

Despite all these benefits, children with visual disabilities are more restricted in their participation in physical activity, have a lower level of fitness and have a higher level of obesity than their peers without disabilities[11]. The fear of injury is one of the reasons for visually challenged person's lack of participation in physical activity[11]. Lack of physical activity leads to a different kind of bodily changes/differences as compared with the peer without disabilities[15.] . To Till date, no studies were found to found out the effect of yoga on body composition on visually challenged persons in the Indian scenario. The main aim of this study is to find out the effect of selected Yoga asana on Body Composition of Visually Disabled School going Children.

Materials and Method

Twenty Four (n-24) Visually Disabled school going children 12 to 18 years of age male students of Ahmadi School for the Visually Challenged, Aligarh Muslim University., Aligarh, India were selected as subjects for this study. Twenty four (n-24) visually disabled persons were equally divided into two equal groups. The first group was treated as a control group (n-12) and the second group treated as the experimental group (n-12). Quasi Experimental design was used for this study.

In the Experimental group, selected assistive yogic exercises were performed five (n-05) times per week for six (n-06) weeks under the direction of trained yoga experts. This experimental session, Yoga exercises (60-minute duration) include stretching, pranayama, asana, and meditation. Some of Asana's exercises were as follows: Tadasana (standing on the right), Trikonasana (normal triangle), Vrikshasana (tree pose), uttanasana (standing and forward bend), Dundasana (sitting on the right) and Sidhasana (Guru Vidha). Meditation (relaxation) was carried out in the last ten minutes of each workout.

In Control group (n-12) subjects did not participate any training program during the course of study. Subjects were also advised not to change their lifestyle during the study. The pre-test and post-test were taken of all the body composition parameters before and after six (6) weeks of yoga training. The body composition variables were Age, Height, Weight, Blood Pressure (B.P.), Pulse Rate, BMI, Body Fat %, Subcutaneous Fat %, Visceral Fat%, which were measured by standard body composition analyzer.

The results are expressed as the mean ± standard deviation. Within-group comparisons were made using paired sample t-tests. Statistical examinations were carried out by using SPSS version 20.0 for Windows.

Results

The results of the study on effect of 06 weeks of yoga as programmed with selected variables of body composition of experimental group and control group .The experimental group was received the daily yoga training of one hour duration which consists of 15 minutes warming and stretching exercises and remaining 45 minutes yoga and relaxation.

Table 1. Descriptive statistics of the subjects.

	Measures	**Mean ±SD**	
Experimental Group		**Pre**	**Post**
	Weight (kg)	57.12±13.03	55.48±11.65
	Height (cm)	165.41±8.62	
	Age (year)	15.33±2.15	
Control Group		Pre	Post
	Weight (kg)	47.3±6.94	46.22±6.34
	Height (cm)	16.41±5.56	
	Age (year)	13.58±1.31

		Post	115±7.89					
Control		Pre	125±11.98	3.83	7.88	2.75	1.68	0.20
		Post	121±10.40					
Experimental	Blood Pressure (d)	Pre	76.42±12.23	1.67	5.91	1.71	0.98	0.35
		Post	74.75±9.79					
Control		Pre	80.83±18.30	1.58	6.82	1.97	0.80	0.44
		Post	79.25±14.21					

Significant reduction ($P < 0.05$) in the percentage Pulse Rate and Blood Pressure (s) were noted in the experimental group after 06 weeks of yoga training. However, there were no significant differences in Blood Pressure (d) in the experimental and control group.

Discussion

Results of the study deal with the analysis of data collected from visually disabled school-going children. Results of the study revealed that insignificant differences existed between pre- and post-testing of children with disabilities in the experimental group's of Body Fat%. Body fat% was insignificantly decreased in the yoga group compared with the control group ($p > 0.05$). This result contra indicts with previous studies [1,7,8,9] indicate that the significantly increase body density and weight it's maybe due to yogic training program reduce body fat [1, 7, 9]. The results of the study show that there were insignificant differences exist between pre and post-test of disabled children in their, visceral fat and BMR of the experimental group and control group ($p>0.05$). The results of the study found that reducing BMI as compared to that of the previous studies [24, 25]. Our findings clearly suggested that obesity in visually disabled persons can be reduced by assistive yoga therapy for a longer period of time. Results show that there were significant differences exist between pre and post-test of disabled children in their B.M.I (kg/m^2) of the experimental group and control group ($p<0.05$). This proved that there was significant differences exist between the groups of pre and post-test of both experimental and control groups. The mean difference between pre and post shows that the effects of yogic exercises on BMI are positive and significant. The result of this study on Body Mass Index (BMI) has in line with the previous studies [26, 01], who has conducted the study on yoga: managing overweight and found that the BMI decreased significantly. Exercise training significantly improved, body mass index, lean muscle mass, resting HR, fitness, and systolic blood pressure[27, 28]. The analysis of data shows that there were insignificant differences exist between pre and post-test of disabled children in their Blood Pressure (Systolic and Diastolic) of the experimental group and control group[27]. Mean differences between pre and post-test shows that yoga exercises were positively affecting on body composition of visually disabled persons. But better and significant results of yoga exercises on the body composition of the visually disabled persons, it is suggested that yoga exercises should be a long duration and exercise with proper assistance. The result of this study on systolic blood pressure has in line with the study conducted by Shantakumari et al in 2012, has conducted a study on the effect of a yoga intervention on hypertensive diabetic patients and found that systolic and diastolic blood pressure decreased significantly[21]. The yoga asanas help the regularize and balance the nervous system and maintain optimum health. Further, the function of the sympathetic and parasympathetic nervous system optimized through the regular practice of yogic asanas resulting in regulation of (B.P.) blood Pressure[21]. The asana belongs to the different body posture i.e. supine positions, forward bends, sitting, and inversions group regulate the Blood Pressure (B. P.). However, fundamental asanas of forward bends which can be helpful for regulate high Blood Pressure (B. P.)[1, 8] .The horizontal position of the body in these asanas regulates the heart function to slow down the stress to the heart to pump the blood against gravity[20, 21]. Our results support the findings which stated that the yoga practice reduces systolic and diastolic Blood Pressure (B. P.) [24]. In addition, all participants were found to achieve good health after performing yoga. Our results support the findings which stated that the yoga practice reduces systolic and diastolic Blood Pressure (B. P.). [24] The analysis of data shows that there is significant differences exist between pre and post-test of disabled children in their Pulse Rate of the experimental group ($p<0.05$). Whereas there is insignificant difference exists in their pulse rate of the control group ($p>0.05$). Our result supported that pulse rate was significantly reduced in the pulse rate occurs in subjects practicing yoga ($P < 0.001$) [22, 06, 15] and contraindicate with the results of the study [14] reveal that there was no significant difference among the yogasana practices and physical training on systolic blood pressure, diastolic blood pressure and pulse rate.

Uncorrected Refractive Error as a Cause of Headache: A Cross Sectional Study

Nandita Chaturvedi[1], Nidhi[2], Payal Jain[3], Malobika Bhattacharya[4]

[1]Assistant Professor, Department of Ophthalmology, [2]Senior Resident, Department of Ophthalmology, [3]Associate Professor, Department of Internal Medicine, [4]Associate Professor, Department of Paediatrics, Government Institute of Medical Sciences, Greater Noida, India

Abstract

Purpose: Many patients suffering from unexplained headache go through a battery of investigations without much resolution. In a large number of these patients, searching for and correcting an underlying refractive error often provides permanent relief. We aimed to search for an association in the population visiting Ophthalmology OPD in our hospital.

Method: Four hundred patients with headache were investigated for refractive error under cycloplegia and any refractive error detected was classified into myopia, hypermetropia, astigmatism or compound refractive error. The prevalence of refractive error and the various sub types was calculated.

Conclusions: Refractive errors coexist with headache frequently. Patients with persistent headache need to be investigated thoroughly for refractive error as correction of the same can provide permanent and cost effective resolution of the headache.

Keywords: *Headache, ocular, refractive error.*

Introduction

Headache is defined as pain above the orbitomeatal line[1]. Ocular headache is defined as headache having evidence of causation demonstrated by at least two of the following:

Headache has developed and/or significantly worsened in temporal relation to the onset or worsening of the refractive error(s); headache has significantly improved after correction of the refractive error(s); headache is aggravated by prolonged visual tasks at an angle or distance at which vision is impaired; headache significantly improves when the visual task is discontinued[2]. Various studies on ocular causes of headache have reported the role of refractive error and accommodative deficiency as a having a possible role[4]. Many cases having refractive error and associated headache consult the Neurologist first thus subjecting themselves to expensive and time consuming investigations that could be avoided if an Ophthalmologist had been consulted in the primary instance.[5] Thomas et al observed that the proportion of headache patients visiting an Ophthalmologist were nearly similar to the proportion of patients visiting a general practitioner, being 21% and 27% respectively.[6]

In 1966, Gordon et al forwarded the claim that minor refractive contributed more towards headache and eye strain symptoms than major refractive errors.[7]

The aim of the present study was to analyze the prevalence of uncorrected refractive error in patients with headache complaints, presenting to a general ophthalmology Out Patient Department, in a community based hospital.

Method

The study was approved by the Government Institute of Medical Sciences Greater Noida institutional review board and was fully compliant with the principles of the Helsinki Declaration.

The study had a descriptive cross sectional design. We enrolled 400 consecutive patients between 5 – 30 years of age, visiting the ophthalmology department and complaining of headache. Patients with pre existing conditions predisposing to headache like migraine, hypertension, pregnancy, presbyopia were excluded. All the patients had not been investigated for refractive error previously and none of them were currently on any medication for headache.All the patients underwent complete ophthalmological examination including assessment of visual acuity, ocular alignment, ocular motility, pupillary assessment, slit lamp biomicroscopy and dilated fundus examination. All patients under the age of 18 years underwent cycloplegic refraction with 2% Homatropine. Subjective refraction was carried out after 3 days in these patients. Refractive status was divided into emmetropia (-0.25D - +0.25D), hypermetropia (≥+0.50D), myopia(≥-0.50D), astigmatism (≥0.50D cyl), compound error(spherical+ cylindrical error). All refractive examinations were performed by a single optometrist who did not know the headache history of the patient. All patients were reviewed after two weeks from the start of wearing refractive correction to evaluate the amelioration of headache symptoms.

Results

During the course of our study we studied 400 patients whovisited our OPD with the main complaint of headache. 278 (69.50%) of all patients were female and 122 (30.50%) were males.(Figure 1)This female preponderance was maintained through all the age groups except in the 6 – 10 year age group where there was a slight male predominance (55.6% male and 44.4% female). Figure 2. The mean age of the patients was 21.3 years (SD= 5.4)226 (56.5%)patients reported the site of headache as frontal, whereas 95(23.75%) and 79(19.75%) had temporal and global headache respectively. The temporo-frontal localisation of the headache was statistically significant by Chi Square Test(p=0.04).In a large majority of patients, visual acuity in the worse eye at presentation was between 6/6 – 6/9 in 249(62.25%). Of the remaining, 71 patients (17.75%) had visual acuity 6/12 – 6/18, 62(15.5%) had 6/24 – 6/36 and 18(4.5%) had visual acuity in the worse eye </= 6/60.Of these a total of 159 patients(39.5%) had uncorrected visual acuity of 6/6 in both eyes at presentation. A total of 231 patients complained of nausea and vomiting associated with the headache. There was positive correlation between astigmatism and complaints of Nausea/vomiting (chi square: p=0.03).

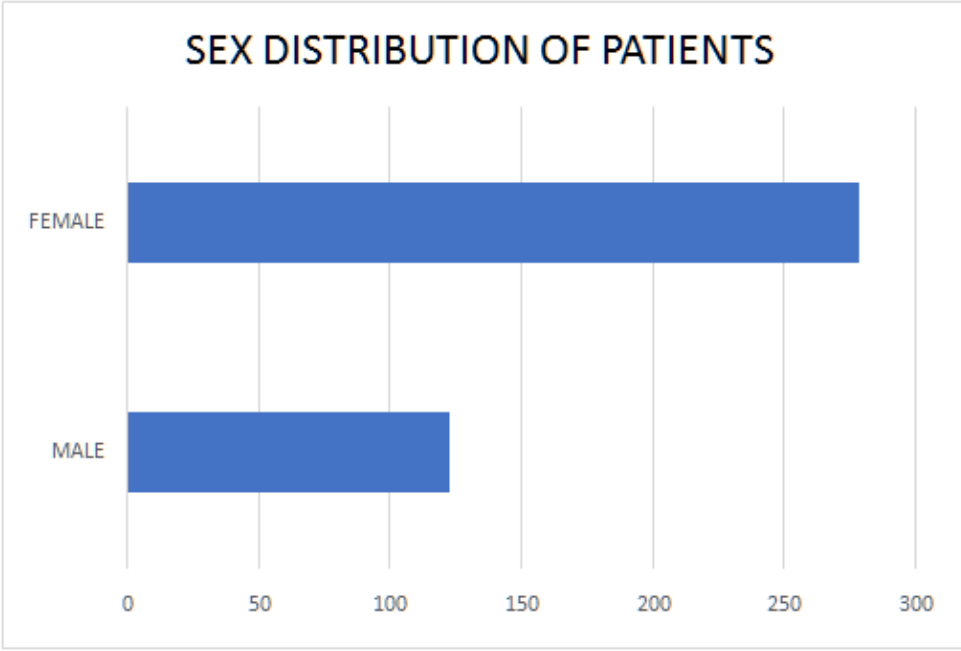

Figure 1

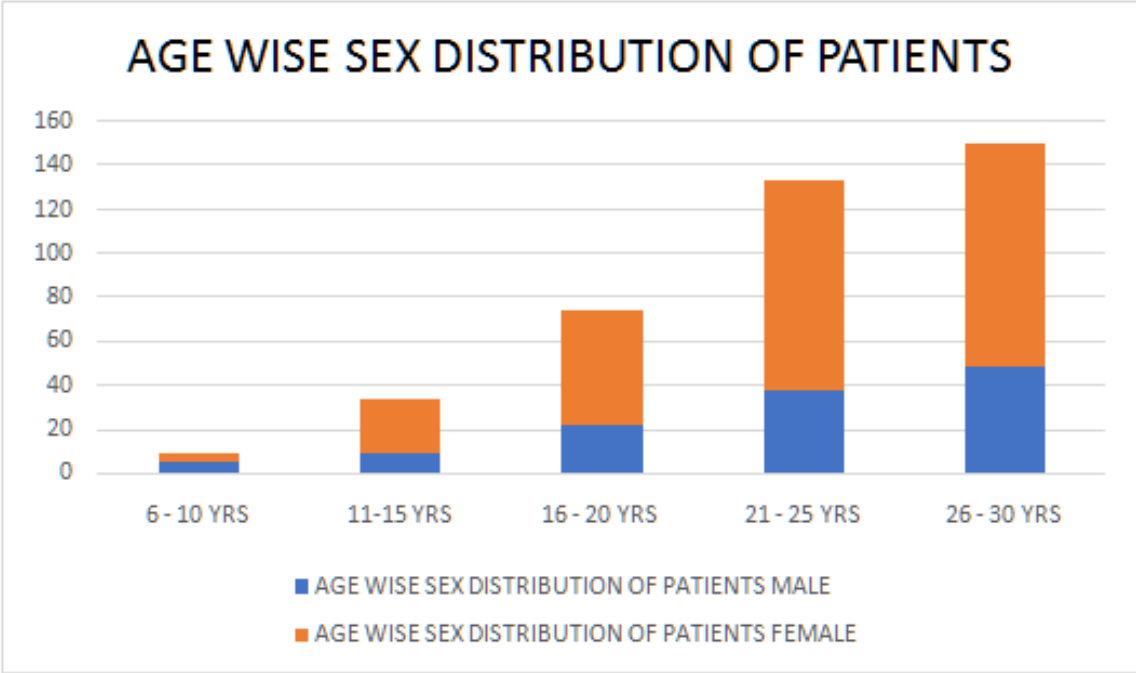

Figure 2

Of the 400 patients 380 (95%) were diagnosed as having an uncorrected refractive error. The remaining 20 (5%) patients did not have any refractive error. They were found to have convergence deficit on further examination and were advised convergence exercises.

The refractive error diagnosed of 89(23.42%) patients was myopia, of 117 (30.79%) patients was hypermetropia, of 149 (39.21%) patients was astigmatism and of 25 (6.58%) patients was compound ametropia. Figure 3.

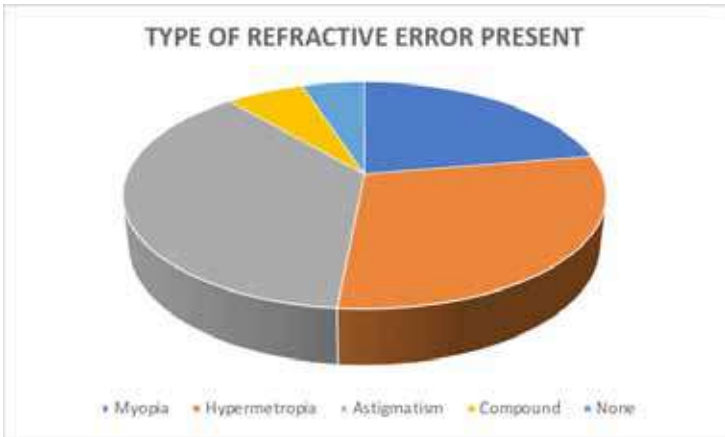

Figure 3

Of the 159 patients with B/L 6/6 presenting acuity and headache, 79.2% (126) were eventually diagnosed with astigmatism or hypermetropia (chi squarep=0.008; Odds Ratio=1.862). The rest were accounted by myopia and convergence deficit (13 and 20 patients respectively). Figure 4

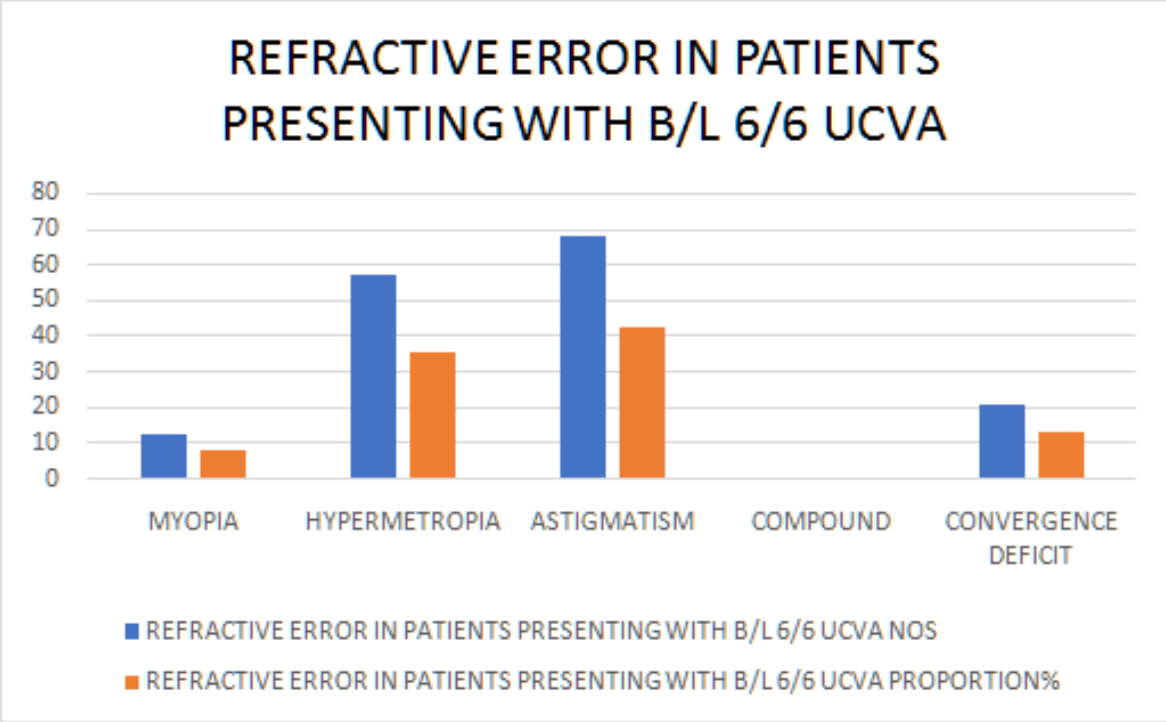

Figure 4

In all the various subgroups of ametropia, the most common localization of headache was frontal, followed by temporal headache. Figure 5.

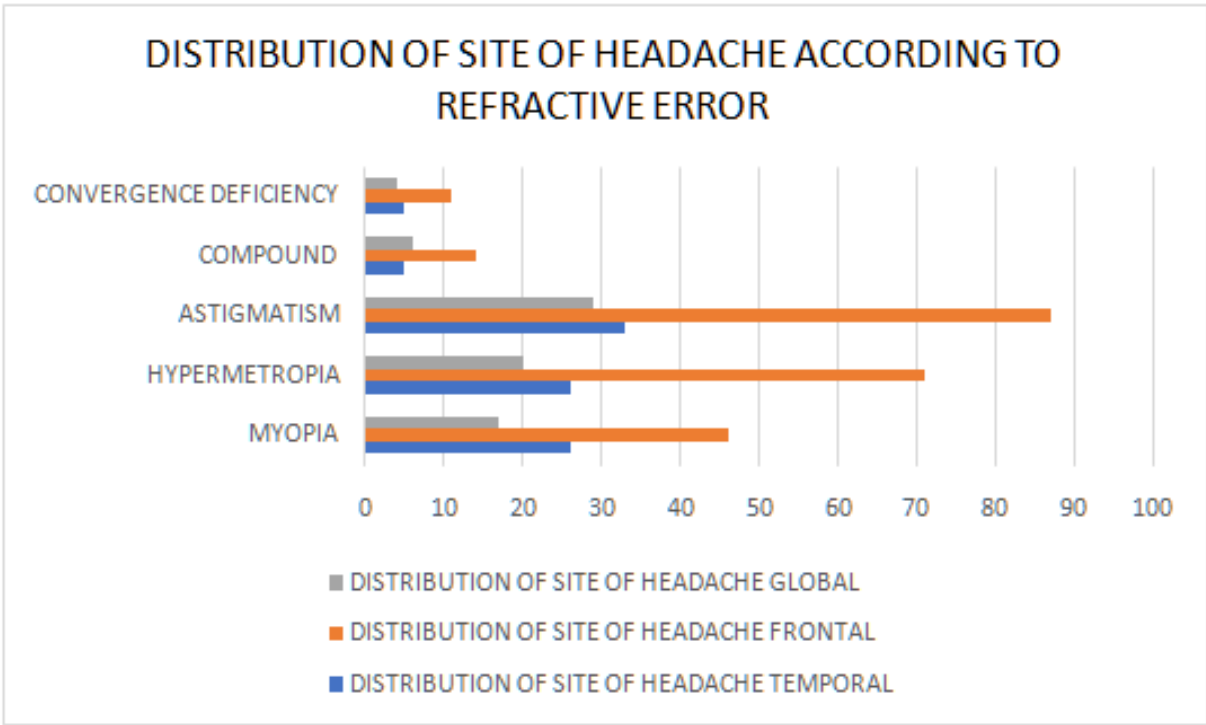

Figure 5

A total of 226 patients(59.5%) reported experiencing frontal headache whereas only 90(23.7%) and 79(20.8%) patients reported temporal and global headache respectively.

Two weeks following refractive correction 337(88.68%) of the 380 patients reported a complete resolution of headache. 43(11.32%) patients had incomplete resolution of headache and required additional convergence exercises. Only the 20 patients who were diagnosed with convergence deficit alone and no refractive error, responded only to convergence exercises. Figure 6.

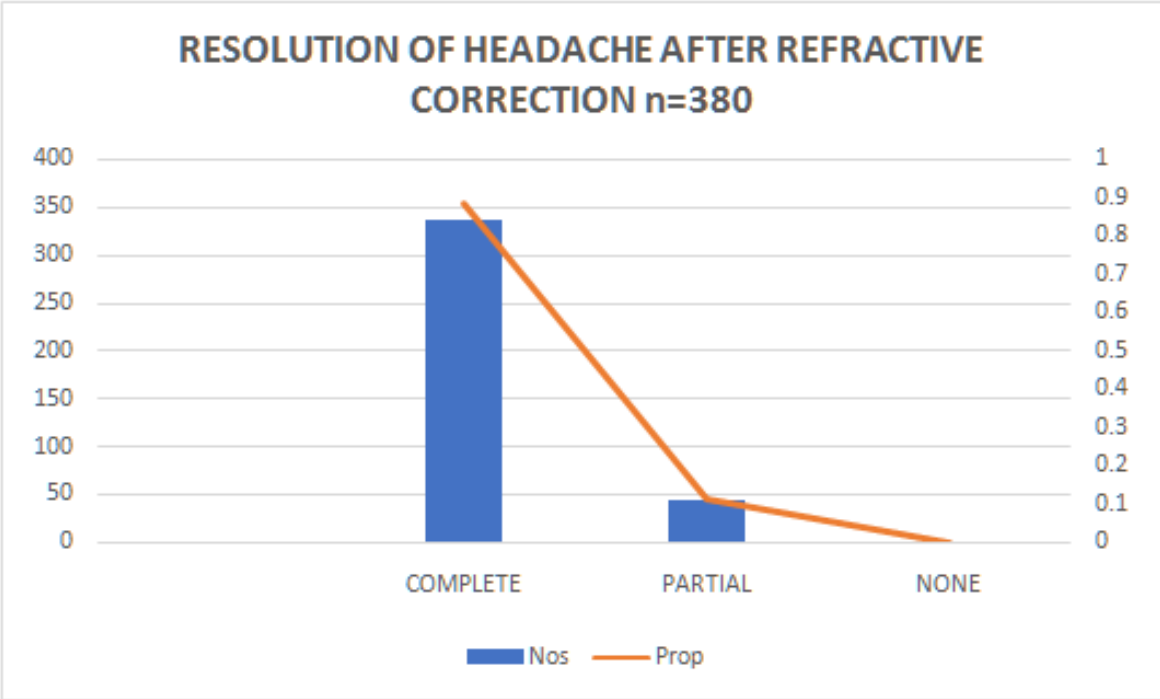

Figure 6

Discussion

In our study we describe 400 patients who had presented with the main complaints of headache. Other systemic examination was normal in all the patients. In a large majority uncorrected refractive error was diagnosed and two weeks after using refractive correction there was complete resolution of headache in most of them.

Headache is a complaint frequently encountered in the Ophthalmological practice. It is important to be able to recognise headache complaints caused due to refractive error from other causes.

Various studies on headache have reported the role of visual anomalies like refractive error and vergence deficiencies[3]. The uncorrected refractive errors are often believed to be associated with frontal or occipital headache[8].

Cameron[9] estimated a low prevalence of refractive error in 50 patients suffering from headache. Jain et al[10] reported only 1.48% prevalence of refractive error in headache patients. Noticeable in these studies is the inclusion of all patients of headache without excluding patients with other known pathologies predisposing to headache.

In our study we observed a prevalence as high as 95%of uncorrected refractive error in patients of headache. This exceeds the prevalence observed in the study by Marasini et al[11], of 45%; and by Fasih et al[12] who reported a prevalence of 16.36%.

Our study observed a preponderance of female patients presenting with headache. 278(69.5%) of our patients were females. Compared to male patients the proportion of female patients was 2.28 times more. This finding was in concurrence with a studyby Hendricks et al[13] who reported headache more frequently in girls than boys; as did Fasih et al[12] who observed a female prevalence of 59.4%. We observed that the largest number of patients lay in the 26–30 year age bracket,

showing a prevalence of 37.5%, closely followed by 21 – 25 years age group at 33.25%. These observations were corroborated by Marasini et al[11]who also reported a higher prevalence in the pre presbyopia age group.

There are some researchers who claim that there is no difference in occurrence of headache in persons with and without refractive error[14]. Others like Korczyn et al[15] and Hedges[16] hold the view that refractive errors are not an important contributory cause of headache. These authors attribute the relief of headache following refractive correction to a placebo like effect.

Contrary to these, in our study we observed that 380(95%) patients who presented with headache were diagnosed with an uncorrected refractive error and of these 337(88.6%) reported complete relief of headache symptoms within two weeks of using refractive correction. These findings are similar to observations made by Marasini et al[11]. Gil Gouveia et al[14]also observed that 73% of subjects had improvement in symptoms after optical correction which included 38% who reported complete relief from headache.

Additionally, our results suggest that low degrees of refractive error have more predilection towards causing headache, as demonstrated by the observation that 249(62.25%) patients had presenting visual acuity between 6/6 – 6/9 in the worse eye. In fact, 159 patients had presenting visual acuity of 6/6 in both eyes. These findings are comparable to a study in Nepal[11]in which 88% of patients had a presenting visual acuity ranging from 6/6 – 6/9. This may be explainable by the hypothesis that lower degrees of ametropia induce greater effort from the eye in an attempt to reduce the blur. Hypermetropia can cause sustained effort of accommodation and thereby induce headache due to painful ciliary muscle contracture[13,17].Myopia may cause headache by increasing the squinting of eyelid and foreheadin an effort to achieve pin hole effect[13]. The mechanism causing headache in astigmatism is not fully understood, but in all likelihood, is related to visual blur[18]. One hypothesis claims that even minor degrees of astigmatism cause changes to visual perception that alter the hyperexcitability in visual cortex of headache sufferers[19]. Astigmatic blur may exacerbate the perception of striped patterns that are hypothesised to be important visual triggers in various kinds of headaches[20].

We have observed in our study that prevalence of astigmatism is the highest (43.68%) in headache sufferers, followed by hypermetropia, myopia and compound refractive error in that order (32.11%, 20.53%, 3.68% respectively). These findings are in agreement with those of Marasini et al[11] and of Patwardhan and Sharma[21] who found similar trends in their studies.

Our study has some limitations which should be considered while interpreting its results. Firstly, our patients were recruited from the population visiting a hospital outpatient department and thus may not be truly representative of the general population as a whole. Secondly, we did not have a control group so we cannot determine whether the prevalence of uncorrected refractive error in patients with headache is different from that in patients without headache. Prospective, case control studies may be required to establish the correlation more strongly. The strength of our study was in its very selective patient enrolment. We have excluded all the other common causes of headache prior to enrolling our patients.

Conclusion

In conclusion, uncorrected refractive error is a possible cause of headache. Therefore, all patients presenting with headache should undergo complete ophthalmological examination to rule out that pathology. Patients with no visual complaints should also be evaluated as many patients having headache correlated to refractive error apparently had no visual anomalies at presentation. Accurate identification and correction of refractive error provide a definitive cure to these patients, while at the same time sparing them the expense and anguish of undergoing a lengthy battery of investigations.

Tuberculosis Knowledge: A Survey among Students of a Medical College from Coastal Karnataka, India

Natasha Aquinas[1], Vaman Kulkarni[2], Ashwini Hegde[3], Radhakrishna M.[4]

[1]Ph.D. Scholar, Department of Biotechnology, Manipal Institute of Technology, Manipal, [2]Associate Professor, Department of Community Medicine, [3]Associate Professor, Department of Microbiology, [4]Associate Professor, Department of Microbiology, Kasturba Medical College, Mangalore (A Constituent Unit of Manipal Academy of Higher Education, Manipal, Karnataka)

Abstract

Background: Tuberculosis (TB) is one of the most common diseases, and globally, it ranks second, first being AIDS. It has been said that one-third of the global population is already infected with *M. tuberculosis*. By 2020, an estimated 200 million of these people would contract TB. A very crucial step for containment of TB is to make sure that there is understanding of its risk factors, mode of transmission, and diagnosis.

Aims and Objectives: This study aimed to assess the knowledge and understanding of MBBS students at coastal Karnataka, India Medical College, about Tuberculosis.

Methodology: An online survey was conducted addressing areas of general factors, risk and transmission factors, diagnosis factors, treatment, and prevention factors. A total of 31 statements were given in the online survey.

Results: The respondents showed overall good knowledge about Tuberculosis. The females had a better understanding than males, and the interns scored better on the study than the other MBBS students.

Conclusion: This study has shown that the students have high essential awareness about TB. However, section by section analysis shows that knowledge about a few topics needs to be strengthened.

Keywords: *Tuberculosis, Survey, Medical students, Knowledge.*

Introduction

Tuberculosis (TB) is one of the most immemorial diseases in humankind's history. Globally, it is amongst the top 10 diseases, only second to AIDS. In 1882, Robert Koch discovered the bacilli that causes Tuberculosis, *Mycobacterium tuberculosis.*[1] The causative agent of Tuberculosis is known as the *Mycobacterium tuberculosis* complex.[1] The *M. tuberculosis* complex consists of *M. tuberculosis, M. bovis, M. microti, M. africanum.* Of these, the leading causative agent of tuberculosis is *M. tuberculosis.* In other animal species, *M. bovis* is a significant cause of Tuberculosis.[1] Humans are infected by *M. bovis* by consuming milk, milk products, or meat of such animals.[2] Tuberculosis, a contagious disease, is transmitted from one person to another through air. Persons who are infected with active lung tuberculosis have a higher chance of spreading the disease when they speak, cough, sneeze, and spit.[3] Hence, those in close contact with these infected people are at a greater risk of acquiring the infection. Symptoms of pulmonary tuberculosis include a chronic cough with/ without bloody sputum, fever, sweats at night, weight loss.[4] It is said that one-third of the global population is already infected with *M. tuberculosis.* By 2020, an

Corresponding Author:
Dr. Radhakrishna M.
Department of Microbiology, Kasturba Medical College, Mangalore-575001
Ph. No. +919448163835

estimated 200 million of these people would contract TB, and around 35 million deaths would be caused among them unless the infection is curtailed.[5] Around 10.4 million new TB cases were present worldwide, in 2016, as per the world health organization report. Of these cases, 6.2 million were men, 3.2 million were women, and 1 million were children. 64% of the new cases were from seven countries, viz. India, Indonesia, China, Philippines, Pakistan, Nigeria, and South Africa.[6] Out of these, the highest number of TB cases in the world are accounted for by India.[7] Many newer method of diagnosis and treatment of TB have been established over the years, but unfortunately, people still suffer from this disease. Most anti-tuberculosis drugs have been used for years, and due to this, the resistance to these drugs is widespread. Multidrug-resistant tuberculosis (MDR-TB) is caused by bacteria that do not respond to at least one of the two most potent and effective anti-tuberculosis drugs, Isoniazid, and Rifampicin.[8] Apart from MDR-TB, another form is Extensively drug-resistant tuberculosis (XDR-TB), which is also resistant to two groups of second-line anti-tuberculosis drugs. XDR-TB makes it even more challenging to treat patients with tuberculosis.[8] Directly observed treatment short course (DOTS) is a strategy that ensures not only a clinical approach to patients but also patient adherence to treatment, adequate drug supply, management of public health systems.[1] Since the dawn of DOTS, awareness, diagnosis, and treatment of TB have greatly improved.[9]

A very crucial step for containment of TB is to make sure that the understanding of its risk factors, mode of transmission, and diagnosis.[10] Various studies have been undertaken in the form of surveys in different demographic regions, different colleges, and universities. The objective of the present study was to assess the knowledge and understanding of MBBS students at Kasturba Medical College, Mangalore, Karnataka about Tuberculosis.

Materials and Method

A cross-sectional study was done in the form of an online survey. The online survey consisted of an informed consent form, and only those participants that voluntarily agreed to participate in the study were included. The survey was conducted among MBBS students of second last year, last year and interns. The questionnaire had four parts viz. General factors, Risk and Transmission factors, Diagnosis factors, Treatment, and prevention factors.

Results

312 students participated voluntarily in this study. Females accounted for 54.5%, and males were 45.2%. The ages ranged from 21 years to 25 years. The questions and the percentage of responses are given in Table 1 and 2.

Table 1: General factors, risk and transmission factors

Statement	Agree	Disagree	I Don't Know
Mycobacterium tuberculosis causes tuberculosis (TB)	98.7%		
Mycobacterium could be dormant for many years and get reactivated	98.1%		
TB is confined only to the respiratory tract		98.7%	
Multidrug-resistant TB (MDR-TB) is caused by organisms that do not respond to Isoniazid & Rifampicin	94.6%		
Extensively drug-resistant TB (XDR-TB) is another form of MDR-TB that does not respond to any two groups of second-line anti-tubercular drugs	75.6%	11.2%	13.1%
TB is caused by a virus		98.7%	
Close contact with a person having pulmonary TB is harmless		98.4%	
Crowded places are excellent environments for the transmission of TB	98.7%		
You can acquire TB by drinking raw milk from an infected animal	88.8%		
Keeping a pulmonary TB patient at home carries the risk of infecting others	95.5%		
There is a close relationship between HIV and TB	50.6%		47.4%
The most common mode of transmission of pulmonary TB is through inhalation of aerosols	98.7%		

Table 2: Diagnosis, Treatment and Prevention factors.

Statement	Agree	Disagree	Idon't Know
Every patient with pulmonary TB coughs out bloody sputum		95.8%	
Fever, cough, weight loss, chills are some of the symptoms of TB	98.7%		
Albert's staining is the best staining method for *Mycobacterium*	20.5%	68.3%	11.2%
Mantoux test is a tuberculin test used to check for active infection	74.4%	24.7%	
The prevalence of TB infection can be detected by the Mantoux test	36.5%	11.2%	52.2%
Lowenstein-Jenson medium is most commonly used to culture *Mycobacterium*	85.9%		11.2%
MGIT stands for *Mycobacterium* growth indicator tube. It is a system used to cultivate *Mycobacterium*	33%		63.8%
The GeneXpert MTB/RIF is a rapid test to identify the DNA and resistance to Rifampicin	84%		14.7%
The Mantoux test is used to detect the exposure to TB	41%		52.2%
TB is a treatable disease	99.7%		
Anti-tubercular drugs can be classified into the first line and second line drugs	99%		
Precautions like wearing a mask, washing hands & proper ventilation are helpful while taking care of a pulmonary TB patient	100%		
First line drugs consist of Isoniazid, Rifampicin, Pyrazinamide, Ethambutol, Streptomycin	94.9%		
Directly Observed Treatment Short Course (DOTS) is a TB control strategy recommended by the WHO	94.6%		
Short course chemotherapy is divided into an intensive phase (spreads throughout 2-3 months) & a continuation phase (extends up to 4-5 months following the intensive phase).	98.1%		
BCG vaccine is used to prevent childhood tuberculous meningitis and miliary disease	88.1%		7.4%
MDR-TB treatment program was implemented in India to provide diagnosis facilities & standardized treatment.	56.1%	19.6%	24.4%
One of the main aims of the DOTS programme is to improve the patient's compliance	98.7%		
For prevention, in India, the WHO recommends Danish 1331 strain of BCG	41.3%		57.7%

The responses were scored as correct and incorrect. This was done for easy comparison between the gender wise responses and responses amongst different batches of MBBS students. SPSS version 20 was used for statistical analysis, and the tests applied were the Chi-Square test and students T-test. Total number of questions was 31. The mean score scored by females was 25.786, and males were 25.172. Females had a slightly higher rating than males (51% and 49% respectively). This is depicted in figure 1. Comparison of the scores was also made between the MBBS interns and the second last and final year MBBS students' responses. As expected, the interns scored better than the other students. The mean score of the interns was 26.9394, and that of the other MBBS students was 25.3441. This is depicted in figure 2. These scores were statistically significant (P<0.05).

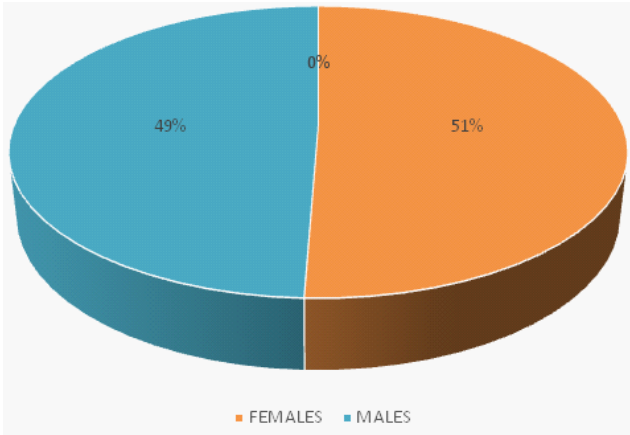

Figure 1: Comparison of knowledge between Females and Males

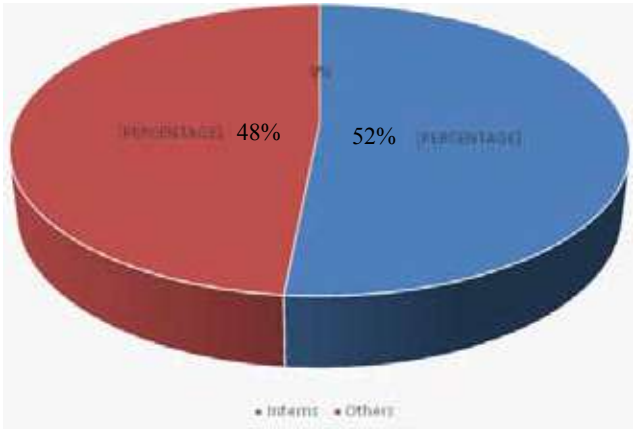

Figure 2: Comparison of knowledge between Interns and Other MBBS students

Discussion

Tuberculosis is one of the most well-known infectious diseases worldwide. India accounts for about one-fifth of the global TB incidence.[11] It becomes very crucial when a doctor has to apply his theoretical knowledge practically and treat patients that presumably have tuberculosis. Undergraduate medical students and interns are also at this threshold, and hence, it is necessary to assess their understanding of this disease and its related aspects. This study revealed an overall good knowledge and understanding of Tuberculosis amongst the students. However, for specific questions, ambiguities were seen. In the first section, that was, General factors, uncertainty was seen in the question which addressed Extensively drug-resistant tuberculosis. In the next section, Risk and Transmission factors, about 47.4% of the respondents lacked knowledge about the close association between TB and HIV. In the diagnosis section, there were mixed responses about the staining method, and about 20.5% said Albert's staining method was the best staining method for *Mycobacterium* whereas 11.2% did not know about the staining method. A lot of ambiguity was seen in questions related to the Mantoux test. Only 33% of the respondents knew about the MGIT (*Mycobacterium* growth indicator tube). Overall, a lot of mixed responses came from the Diagnosis section. This similar pattern was also seen in another study conducted in a medical college in Chennai wherein 80% of the students had correct general knowledge about the disease, but gap about knowledge in the diagnosis section was huge.[12] Another study done in China showed that older medical students had more knowledge about the diagnosis of tuberculosis than the newer students.[13] In the Treatment and Prevention section, 56.1% of the respondents agreed that the programme implemented in India to provide diagnosis facilities, and standardized treatment was known as the MDR-TB programme. However, the answer to this question was the DOTS programme.

Conclusion

This study has shown an overall good knowledge, necessary awareness, and understanding of Tuberculosis amongst the MBBS students. However, section by section analysis showed that knowledge in a few areas need to be strengthened. These areas involve knowledge about the Mantoux test, Extensively drug-resistant tuberculosis and the BCG vaccine. Females showed a slightly better response than the males, and as expected, the interns had a better understanding than the other students. More emphasis has to be given on the Diagnosis part of the existing curriculum since health education is one of the essential defenses in the era of the ever-increasing drug-resistant infection.

Acknowledgments: Our special thanks to all the participants who participated wholeheartedly in this study. This study was approved by the institutional ethics committee of Kasturba Medical College, Mangalore, Manipal Academy of Higher Education (MAHE). We want to thank them for the same. We would also like to thank the experts for validating the questionnaire.

Abstract

The hand in the human body plays a major role in daily life, communication, social contact and basic functions such as grasping. Finger and partial finger amputations are the most frequently found forms of hand loss and trauma which lead to an impact on the psychological health, functional abilities and aesthetics of an individual. A prosthesis with good fitting, comfort and aesthetics can make the patient feel capable and whole again. This article describes a technique for fabrication of a custom made glove type finger prosthesis using silicone elastomers along with a ring for providing more retention to the prosthesis. Shade matching has been achieved by using intrinsic acrylic paints. This case report paper describes a technique to prosthetic rehabilitation of an amputated finger by fabrication of custom finger prosthesis by using silicone elastomer, which is aesthetically acceptable, comfortable to use and is cost effective with a simple approach.

Keywords: *Silicone elastomer, finger prosthesis, color matching, retention.*

Introduction

It is rightly said "Grief is in two parts, the first is loss, and the second is the remaking of life." The loss of a limb or a digit has an immense impact on one's mind, it can manifest as anxiety, depression or post-traumatic stress disorder on an individual.[1]Replacement of the missing finger by fabrication of an artificial finger is a very challenging process and technique sensitive procedure in the terms of artistic abilities and skill expertise. Prosthesis made for patients should be comfortable to wear, durable, light weight, aesthetically pleasing and easy to put on and remove.

Case Report: A 60 year old male patient reported to the Department of Prosthodontics Crown and Bridge, Maharishi Markendeshwar College of Dental Sciences and Research, Mullana, Ambala, for the fabrication of Complete Denture. On general examination, it was noticed that the patient had lost part of his left index finger (distal phalange) about 5 years back, due a traumatic injury. On physical examination a solitary healed scar was seen on palmar surface of the amputated finger. The surrounding surface and area of the finger appeared to be normal with no signs of pain, infection or any inflammation. Informed consent was made with a detailed explanation of the procedure. [Figure 1].

Figure 1:Amputated left index finger

Technique:

1. Patient was requested to keep his hand in normal resting position and not stretched. Lubrication with a

uniform thin layer of petroleum jelly is done, which prevents the adhering of the hydrocolloid to the skin on the site of the impression surface. A cardboard box was selected larger in size than the patient's hand. One side of the cardboard box was cut open to place and remove the hand.[2] A thin uniform mix of hydrocolloid (*Zhermack*) was poured inside the box creating the base of the impression on which the patient was instructed to place the palmar aspect of the hand over of the impression material, simultaneously the dorsal surface of the whole hand was covered.[3] In the end, a layer of dental plaster (*Kalabhai Kaldent)* was poured over the impression material for imparting strength to the impression made as well as to prevent its tearing on removal of the patients hand. [Figure 2].

Figure 2: Alginate Impression andImpression surface

2. The impression made was poured with dental stone (*Kalabhai Kalstone)* with vigorous tapping ensuring the complete flow of the dental stone. A positive replica of the site was obtained and finished.[2] [Figure 3].

Figure 3: Dental stone model

3. In this case, the wax pattern was fabricated by Donor Finger which involved making a hydrocolloid impression of the donor index finger. The donor finger should be of the same side of the patient's amputated finger and same sex. The donor was selected by matching the appearance and size of the fingers using the model obtained. The impression made was poured with heated liquid modelling wax (MAARC).[4] The wax pattern is carefully sculpted hollow from the inside followed by finishing and carving to give it a natural appearance. [Figure 4]
4. The custom made glove type wax pattern prosthesis is tried on the patient's amputated index finger. Proper fit and length is established with verification of the correct orientation.[Figure 4].

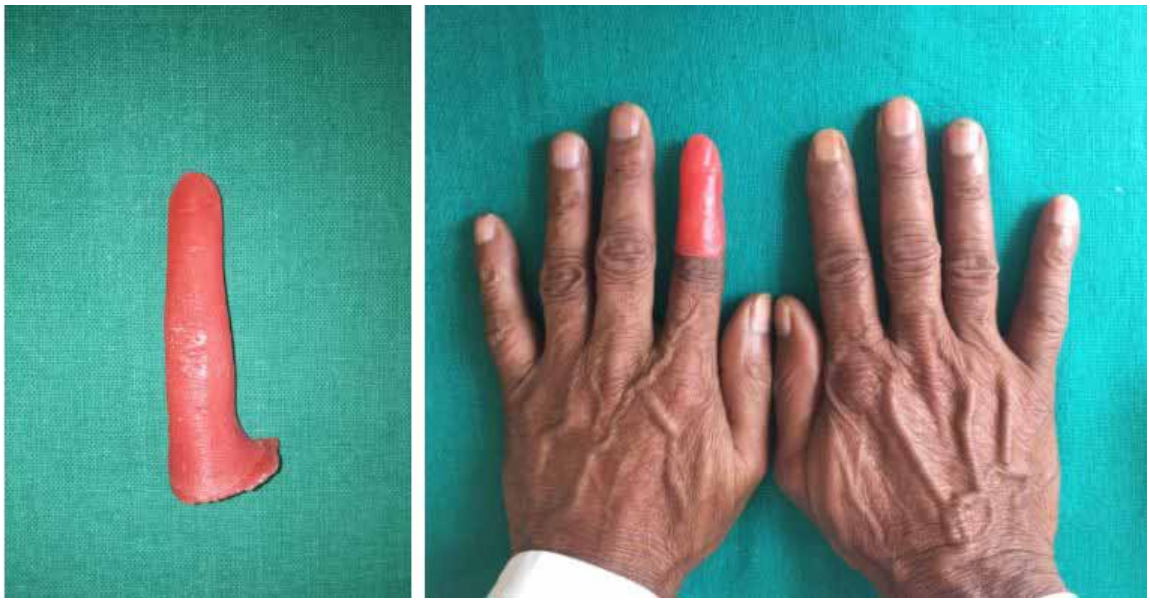

Figure 4: Trial of wax pattern on amputated finger

5. The wax pattern was invested. After complete set, de-waxing is carried out. A mould is obtained.[5]
6. Silicone (RTV Silicone, MP Sai Enterprises, Mumbai) was used along with acrylic paints (KURTZY Acrylic color paintv12 shades) as intrinsic shades. The colors Red, Blue, Yellow, Black, were used to create the natural skin tone of the patients hand, mixing was carried out on a glass slab. Color matching was done in natural light.[6] After desired shade was achieved and the silicone material was packed into the mould, bench pressed and was left overnight for processing.[Figure 5]

Figure 5: Shade Matching

7. A prefabricated artificial nail was used (Electromania Acrylonitrile Butadone Styrene Style Plane Nail Tips Pack of 24).
8. The final prosthesis was retrieved, excess was trimmed and finished. The artificial nail was trimmed and glued according to esthetics, followed by insertion of the final prosthesis on the patient's amputated left index finger. A ring was placed over the silicone finger prosthesis, which provided more retention to it. The prosthesis was delivered to the patient, was completely satisfied and contented with the outcome.[4]
9. To maintain its hygiene, the prosthesis should be washed with antibacterial soap from inside and outside air dried and then worn.[7] Exposure to high temperatures should be avoided. Smoking may discolour and stain the prosthesis. The prosthesis is not to be worn overnight as it will lead to irritation of the underlying skin.[Figure 6]

Figure 6: Silicone Finger Prosthesis

Discussion

It has been reported that the most common found amputations are partial hand amputations, presenting with loss of one more fingers. They are commonly resulted from occupational hazard, automobile accidents. [3]Other causes of amputations can be congenital, diabetes, gangrene and infections resulting from lack of basic public health. Partial finger amputations lead to functional deficiencies, aesthetic problems resulting in poor self-esteem, and psychological instability and economic damage to the individual. Many materials such as Acrylic, Polyurethane, polyvinylchloride have been used to produce finger prosthesis.[7] The restoration of the lost limb, finger depends upon the amount of the tissue involved and bone involvement, the level and the angle of amputation along with the number of fingers involved and the choice and acceptance of the person for the restoration of the finger. There are numerous replacement techniques accessible to restore the finger. [8] A well fitted and color matched prosthesis gets rid of the constant reminder of disability to a person.[9][10]

Conclusion

Rehabilitating the finger or its partial finger segment with an artificial prosthesis can be rewarding and satisfying with a pleasant outcome for a maxillofacial prosthodontist. The artificial prosthesis given can greatly enhance the psychological health, self-esteem of the patient. The process requires great skill, technique sensitivity and artistic skills along with the understanding of the patients need.

Abstract

In today's modern world, diseases are increasing day by day. Amid the different types of diseases, cancer has turned out to be a deadliest disease in human beings. According to the latest medical statistics, Cancer is accountable for high mortality rate. Skin cancer is usually identified beginning with preliminary screening by clinicians and followed possibly by dermoscopic investigation, a biopsy and histopathological inspection. Differentiating and predicting different types of skin lesions on inspection of images is one of the most challenging and difficult task because of the minute variations in the appearance of skin lesions. The images of different lesions seem to be identical and it is very difficult to manually differentiate them. Hence, deep convolutional neural networks are now emerging as a solution to address this problem. The main objective of this work is to review the indexed papers that addresses the issues of automatic classification of skin lesions. This paper summarizes about the different types of datasets available, the type of deep learning models used for training and the parameters used for performance measurements.

Keywords: *Skin lesion classification, Deep Learning, Data Augmentation, Artifacts, Transfer Learning.*

Introduction

Cancer is one of the common disease accountable for 0.3 million deaths per year. Almost every instance of cancers have been found in Indian population. Out of all cancers in India, skin cancer constitutes about 1 to 2 percent of all diagnosed cancers.

Tropical countries like India receive higher levels of UV radiation and this raises the risk of skin cancer. Different types of skin cancer are found in India. The three most common types are Basal Cell Carcinoma, Squamous Cell Carcinoma and Melanoma. These three types of skin cancers are classified on the basis of three different types of skin cells found in the epidermis - Squamous Cells, Basal Cells and Melanocytes. Various categories in pigmented lesions include Actinic Keratoses (AK) and intraepithelial carcinoma/Bowen's disease (akiec), basal cell carcinoma (bcc), benign keratosis-like lesions (solar lentigines/seborrheickeratoses and lichen-planus like keratoses, bkl), dermatofibroma (df), melanoma (mel), melanocytic nevi (nv) and vascular lesions (angiomas, angiokeratomas, pyogenic granulomas and hemorrhage, vasc).

Differentiating and predicting different types of skin lesions on inspection of images is one of the most challenging and difficult task because of the minute variations in the appearance of skin lesions. The images of different lesions seem to be identical and it is very difficult to manually differentiate them. Hence, deep convolutional neural networks are now emerging as a solution to address this problem. It has been found that some literatures are evolving to solve this issue from 2015 onwards.

This paper is mainly focused on organizing a systematic review of the literatures of skin cancer classification using deep learning.

Skin Cancer Lesion Characteristics: Bkl includes lichenoid keratosis and seborrheic keratosis. Lichenoid keratosis will usually be a little swollen macule or slim pigmented plaque. Seborrheic keratosis will be in the forms of fissures, comedo-like openings, and milia-like cysts ant it is almost similar to nevi. The figure 1(a) is the histopathology bkl picture of a 80 year old male on scalp, figure 1(b) is the histopathology bkl image of a 40 year old male on upper extremity and figure 1(c) is

the histopathology bkl image of a 70 year old female on back.

Df are benign skin growths and the color varies from pink, gray, red or brown and may change color over the years. It will be firm and hard and can be found anywhere on the body. The figure 1(d) is the histopathology df image of a 75 year old male on back, figure 1(e) is the histopathology df image of a 55 year old female on upper extremity and figure 1(f) is the consensus image of a 50 year old male on lower extremity.

Melanomas are malignant and its presence shows various shades of black, brown or tan. The figure 1(g) is the histopathology mel image of a 40 year old female on chest, figure 1(h) is the histopathology mel image of a 70 year old male on face and figure 1(i) is thehistopathology mel image of a 85 year old female on lower extremity.

Vascular lesions include lesions of angiokeratomasand angiomas. Angiokeratomas are the type of vascular lesions that are shiny, soft, dark red nature of size 2–10 mm papules that may end up in blue to black color and a surface scale. Cherry angioma will seem like firm red, blue or purple papule of size varying from 0.1–1 cm in diameter. The figure 1(j) is the consensus vasc image of a 85 year old female on back, figure 1(k) is the consensus vasc image of a 5 year old male on back and figure 1(l) is the histopathology vasc image of a 70 year old female on abdomen.

A melanocytic nevus can either be malignant or benign containing nevus cells.It appear as small brown, tan, or pink spots. The figure 1(k) is the follow-up nv image of a 45 year old male on abdomen, figure 1(l) is the follow-up nv image of a 60 year old male on lower extremity and figure 1(m) is the histopathology nv image of a 40 year old male on back.

BCCs looks like sores that are open, patches that are red with pink growths, bumps that will be glittery, growths that are slightly elevated with a central indentation. AK are usually small in size (0.5-2.0 cm) and look like patches of rough, scaly skin which vary in colors of pink, red, brown, or the same colour as normal skin. Bowen's disease patches appear as more red and scaly when compared to AK and size varies from 0.5-2.0 cm in size. The figure 1(n) is the histopathology image of a 70 year old male on upper extremity, figure 1(o) is the histopathology image of a 40 year old male on abdomen and figure 1(p) is the histopathology image of a 65 year old male on neck.

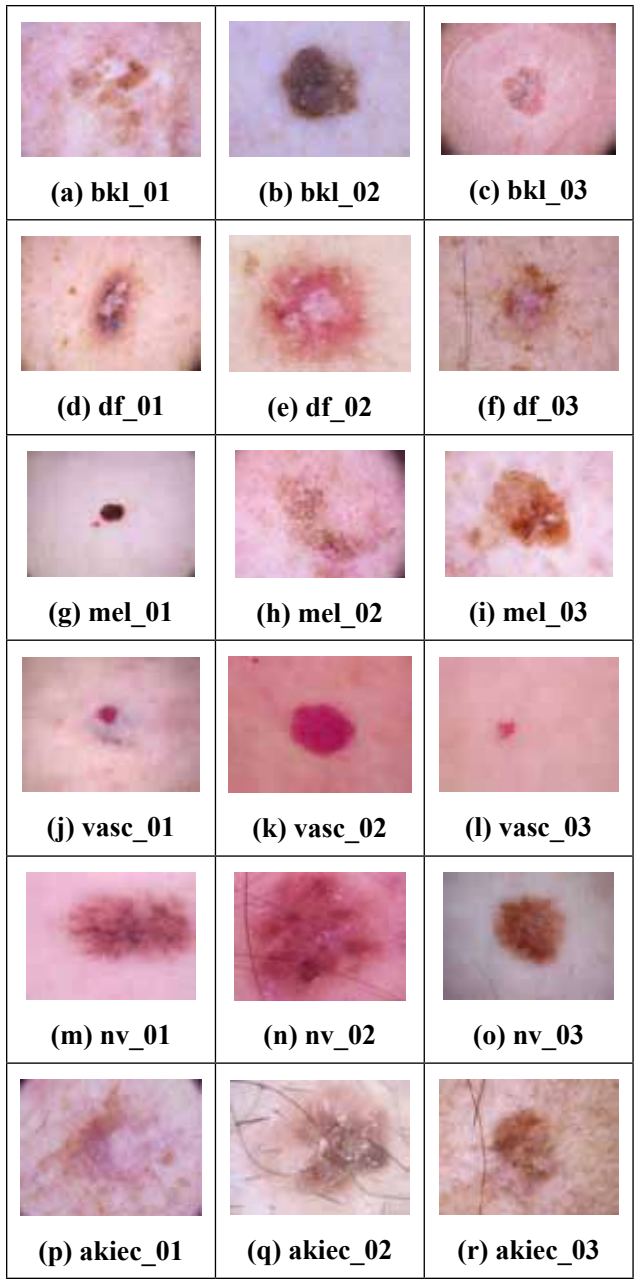

Figure 1 Sample Skin Cancer Lesions

The characteristics are analyzed from the medicinal information available from dermoscopedia. In order to find the lesion as benign or malignant, the lesion class has to be identified. From the figure 1, it can be seen that most of lesion colors are similar and it is difficult to classify on visual investigation. Thus only a well-experienced clinician can correctly classify the lesions. To err is the human and hence the problem of classification of skin lesions is becoming a research trend in deep learning.

Some of the sample images taken from MNIST dataset are shown in figure 1. Three images from each seven classes of lesions are shown in the figure.

Materials and Method

Datasets: Training of deep convolutional neural network for accurate classification of lesions needs large datasets. Many datasets are publicly available. The datasets that has been used in the standard publications are discussed here.

The PH database consists dermatoscopic images of 200 melanocytic lesions that includes lesions of common nevi, atypical nevi, and melanomas. The information includes medical annotation of manual segmentation, the clinical diagnosis, and the identification of several dermoscopic structures, performed by expert dermatologists, in a set of 200 dermoscopic images.[1]

The Atlas Dermofit Image Library is a collection of 1,300 skin lesion images and their segmentation masks divided among 10 classes. The diagnoses were provided by knowledgeable dermatologists and dermatopathologists, generating a gold standard ground truth. Although this dataset isn't publicly offered, it can be purchased.

HAM10000 ("Human Against Machine with 10000 training images") dataset consists of 10015 dermatoscopic images of 7 classes which includes lesions of bcc, bkl, df, mel, nv and vasc. The images are acquired from different population through examination by clinicians, pathology, while the ground truth for the rest of the cases was either follow-up, expert consensus, or confirmation by in-vivo confocal microscopy. HAM10000 dataset has been deposited at the Harvard database. It is publicly available. Most of the recent researches are found to use this dataset.[2]

The International Skin Imaging Collaboration (ISIC) archive contains the largest publicly available collection of quality controlled dermoscopic images of skin lesions. Presently ISIC 2019 challenge contains 25,331 images available for training across 8 different categories. Future researches may use ISIC 2019 dataset.[3]

Data Preparation: Training a machine learning model needs tuning its parameters such that it can map a particular input (say, an image) to some output (a label). The optimization goal is to chase that sweet spot where the model's loss is low, which happens when the parameters are tuned in the right way.. Naturally, if there are a lot of parameters, the model should be shown a proportional amount of examples, to get good performance. The main problem with the skin cancer datasets is the class imbalance and availability of only few thousands of images. In order to have a good training accuracy, the dataset should be large and classes should be balanced. So the solution to this problem is data augmentation. The different types of augmentation techniques are flipping, rotating, scaling, color changing, illumination etc.

Most of the literatures used augmentation techniques such as rotation, flipping and shifting. Augmentation techniques such as color changing and illumination are not preferred for skin cancer classification because the lesions are characterized by its color. Changing color or illumination may results in loss of information. The data augmentation performed on MNIST image is shown in figure 2.

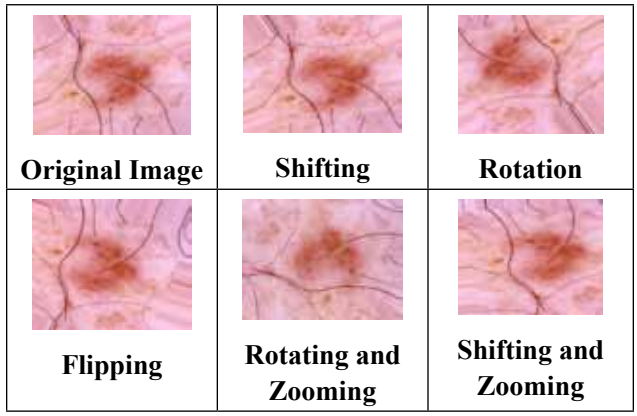

Figure 2 Data Augmentation

Some of the literature preprocessed the dataset by removing unwanted artifacts in the image such as the hairs and performed lesion segmentation[11] while some literature did not do preprocessing and lesion segmentation.

Deep learning in classification of lesions: Estevaet al[4] trained the convolutional neural network with a dataset of size 1,29,450 images consisting of 2032 different diseases. They employed transfer learning and trained using Google's Inception v3 model. They analyzed using three way classification and nine way classification of lesions. Three way classification involves classifying of lesions as benign, malignant and neoplastic lesions and obtained an accuracy of 72.1%. Nine way classification obtained a accuracy of 55.4%. The lower accuracy may be due to the fact that their dataset consists of images acquired under varying lighting and capturing conditions (more like practical case) whereas most of the other dataset consists of

images obtained under standard lighting and capturing conditions. The larger dataset is the combination of ISIC Dermoscopic Archive, the Edinburgh Dermofit Library and data from the Stanford Hospital. The main advantage of this work is that they created disease taxonomy of inference classes and training classes.

Chaturvedi et al[5] trained the convolutional neural network with HAM10000 dataset of size 10,015 images consisting of 7 different classes. They employed transfer learning and trained using MobileNet model. The classification obtained an accuracy of 83.1%. This model has been employed as a web application for public use. The main merit of this model is lighter architecture and faster performance.

Fisher et al[6] investigated the classification of 10 different types of skin lesions from Edinburgh Dermofit Library. Two families of architectures such as semi-learned hierarchical classifiers and deep net classifier were explored. The limitation of this work is that images in the dataset were acquired under standard lighting and capturing conditions.

Hosny KM et al[7] in their work investigated the classification of skin lesions using AlexNet model. They analyzed the results with three data sets ISIC dataset, MED-NODE dataset and The DermQuest dataset. They performed training with each dataset separately and done two kinds of experiments, one with augmentation and the other without augmentation. The average accuracy with the DermIS- DermQuest, MED-NODE dataset and ISIC dataset are 96.86%, 97.70% and 95.91% respectively.

Haenssle et al[8] used GoogLeNet Inception v3 model for skin lesion classification with transfer learning for classification of dermatoscopic images of melanoma versus benign nevi. The AUC ROC achieved for this task was .86. The limitation of this work is data is not clearly provided about the training data and the important merit is that it included comparison result with 52 dermatologist and it has been proved that additional clinical information improves the accuracy of the model.

Han et al [9] used Resnet 152 model for skin lesion classification of 12 different skin diseases. They trained for 19398 images obtained from Asan dataset, MED-NODE dataset, and atlas site images. The important merit is that it included comparison result with 16 dermatologist and it has been proved that additional clinical information improves the accuracy of the model.

Sourav Kumar Patnaik et al used three pre trained models such as Inception V3, Inception Resnet V2, Mobile Net. The results from the three models were combined and the disease was predicted with the maximum voting from the three models.[10]

Halil Murat Ünver et al employed Yolov3, a deep learning for object dectection. This work combined Yolo model and grabcut algorithm and performed lesion segmentation after the removal of the artifacts.[11]

Performance Metrics: The different types of performance metrics found in the literature are accuracy, precision, recall and F1-Score. The equations of the evaluation metrics are shown in the equations 1,2,3 and 4 respectively.

$$\text{Accuracy} = \frac{TP+TN}{TP+TN+FP+FN} \quad (1)$$

$$Precision = \frac{TP}{TP+FP} \quad (2)$$

$$Recall = \frac{TP}{TP+FN} \quad (3)$$

$$F1-Score = \frac{2*(Precision*Recall)}{Precision+Recall} \quad (4)$$

Where TP, TN, FP and FN denotes true positive, true negative, false positive and false negative respectively.

Table 1: Comparison of different existing models for skin cancer classification

Literature	Dataset	No of classes	Total images	Data augmentation	Model	Type of learning	Results Accuracy
4	ISIC Dermoscopic Archive, the Edinburgh DermofitLibraryand data from the Stanford Hospital	3	1,29,450	Rotation and flipping	Google's Inception v3	Transfer learning	72.1%
		9					55.4%
5	HAM10000	7	10015	Rotation, flipping, shifting and zooming	MobileNet	Transfer learning	83.1%
6	Edinburgh Dermofit Library	10	1300	-	Resnet50	Transfer learning	78.7%

Literature	Dataset	No of classes	Total images	Data augmentation	Model	Type of learning	Results Accuracy
7	DermIS-DermQuest	2	206	Rotation	AlexNet	Transfer learning	96.86

	ISIC	3	2000				95.91
10	Not mentioned	6	-	-	InceptionV3	Transfer learning	68.15%
					Inception Resnet V2		79.07%
					MobileNet		46.72%
11	PH and the ISBI 2017	4	2950	-	YoloV3	-	94.40% 96% (detection)

Conclusion and Future Work

With increase in diseases due to change in the environmental factors and food habits, it is need of the day to diagnose the disease as early as possible. Earlier diagnosis of the diseases will help in curation of the diseases. Early, accurate and automatic diagnoses need a highly advanced deep learning model to be developed. From the literature review of the various works related to skin cancer classification, many works are evolving to accurately predict the type of skin lesions. Most of the works preferred transfer learning rather than scratch learning. Already pretrained networks were used to fit in for the medical data. Comparison of the different works is not possible as the datasets and number of lesions classified varies between the literatures. Thus it can be concluded that developing a highly accurate deep learning model to classify the different types of skin lesions is still a challenging task. More research works need to emerge to address this issue and to make a standard model for preliminary skin disease diagnosis.

Epidemiology of Osteoporosis: A Case-Control Study among the Pre and Post Menopausal women of Allahabad District

Pallavi Singh[1], Virginia Paul[2], Aditya Kumar Singh Pundir[3]

[1]Assistant Professor, School of Allied Health Sciences, Jaipur National University, Jaipur, Rajasthan, [2]Professor, Department of Food, Nutrition and Public Health, Ethelind School of Home Science, SHUATS, Allahabad, Uttar Pradesh, [3]Professor, Department of ECE, Arya Collage of Engineering and Information Technology, Jaipur, Rajasthan India

Abstract

Osteoporosis is a bone disorder which is a prevalent global public health problem associated with compelling morbidity, mortality and socioeconomic burden. This disorder can be prevented and treated if diagnosed early and accurately. This study was conducted among the pre and post-menopausal women of Allahabad District aged between 35-65 years to observe the strength of association between the risk factors and the prevalence of osteoporosis. A total number of 316 respondents were screened through P-DEXA scan in a hospital based free BMD check-up camps and a WHO guideline for the diagnosis of osteoporosis was used to assess the prevalence of osteoporosis in the selected respondents. Diagnosed patients of osteoporosis were identified as cases **(N=84)** while controls **(N=84)** of the study were free from less bone mineral density. A pre-tested questionnaire was used to collect information regarding behavioral, Anthropometric, Clinical and genetic risk factors of the osteoporosis.The finding shows that 27.22 percent women were normal while 46.2 percent had osteopenia and 26.58 percent had osteoporosis. The study shows the strong association of different risk factors like lack of physical activity (**OR= 3.003**), high consumption of tea/coffee (**OR=1.437**), less exposure to sun light (**OR**=2.608), obesity (**OR=1.3125**), large body frame (**OR=1.313**), poor hand grip strength (**OR=1.819**), prior history of fracture (**OR**=2.426) and maternal history of fracture (**OR**=7.604) with the prevalence of osteoporosis. This study recommended a healthy life style pattern in the daily life as osteoporosis is highly preventable disease and most of the associated risk factors are modifiable.

Keywords: *Osteoporosis, Osteopenia, Prevalence, Epidemiology, Bone mineral density.*

Introduction

Osteoporosis is a bone disorder which is a prevalent global public health problem associated with compelling morbidity, mortality and socioeconomic burden. The prevalence of osteoporosis intensifies with age for all sites and according to World Health Organization (WHO) definition of osteoporosis up to 70% of women above the age 80 years have osteoporosis. Worldwide, women over 45 years of age, more than 200 million have osteoporosis and this is responsible for over 1.5 million fractures annually.[1] Osteoporosis is a bone disorder that can be prevented and treated if diagnosed early and accurately. Unfortunately, it is mostly undiagnosed until a fracture occurs. So the number of people encouraged to be screened for this disease should be increased. Measurement of Bone Mineral Density is a major tool for the diagnosis of Osteoporosis. Osteoporosis is also prevented by obtaining peak bone mass during skeletal growth, preserving bone mass during adulthood, and reducing loss of bone density with advancing age. Thus, people should be encouraged to adopt healthy life style behaviors for ideal skeletal health by increasing the level

of weight bearing exercise, optimal intake of dietary calcium and vitamin D, proper nutrition and maintaining ideal body mass index, cessation of smoking, regular sun exposure for vitamin D and moderate intake of alcohol, caffeine and sodium.[2]

Objectives: To observe the strength of association between the risk factors and the prevalence of osteoporosis among the pre and post-menopausal women of Allahabad District

Materials and Method

This study was a community based cross-sectional study conducted among the pre and post-menopausal women of Allahabad District aged between 35-65 years. This study was carried out in one specialized hospital named ***Yashlok Hospital***, which provides advanced health services to the community and organized free BMD check-up camps regularly through P-DEXA machine for the general population of Allahabad district. All relatively healthy women aged between 30-60 years who came to the referral hospital outpatient department during the free BMD check-up camps were randomly and purposively approached to participate in the study. A total number of 316 respondents were screened through P-DEXA scan and a WHO guideline for the diagnosis of osteoporosis was used to assess the prevalence of osteoporosis and osteopenia in the selected respondents**.** [3] Diagnosed patients of osteoporosis were identified as cases **(N=84)** while controls **(N=84)** of the study were all participants that were identified as free from less bone mineral density after undergoing the P-DEXA scan. A pre-tested questionnaire was used to collect information from the selected respondents regarding behavioral risk factors of the osteoporosis like duration of sun exposure, intake of number of tea cups, type of physical activity, Anthropometric risk factors like BMI and Body Frame and Clinical and genetic risk factors like Hand grip strength, prior history of fracture and maternal history of fracture. The statistical representation of the data was done with the help of statistical techniques like chi-square test, level of significance at 5%, odds ratio and relative risk for analysis of the possible association and strength of association of behavioral factors with the prevalence of osteoporosis.

Results

Table 1: Estimation of Prevalence of Osteoporosis among the Pre and Post-Menopausal Women of Allahabad District

S. No.	Bone Mineral Density	No. of Respondents	Percentage
1.	T-Score (>-1) Normal	86	27.22
2.	T-Score (-1to-2.5) Osteopenia	146	46.20
3.	T-Score (=-2.5) Osteoporosis	84	26.58
Total		316	100

The finding after the screening of bone mineral density of selected women by using P-DEXA scan machine shows that among the women who were selected as respondents in this study, 27.22 percent women were normal while 46.2 percent had osteopenia and 26.58 percent had osteoporosis.

Table 2: Estimation of Risk: According to the Behavioral Risk Factors of the Osteoporosis

S. No.	Physical Activity	Case		Control		Estimation of Risk			
		n	%	n	%	Odds Ratio	95% CI	Relative Risk	95% CI
1.	Walking	28	33.3	25	29.8	0.333	0.141 to 0.789	0.685	0.509 to 0.923
2.	Yoga	19	22.6	48	57.1	0.118	0.05 to 0.277	0.368	0.244 to 0.555
3.	No Exercise	37	44.1	11	13.1	3.003*	1.268 to 7.115	1.459*	1.084 to 1.965
*Significant									
S. No.	Number of Tea Cups	Case		Control		Estimation of Risk			
		n	%	n	%	Odds Ratio	95% CI	Relative Risk	95% CI
1.	2-4 Cup	28	33.3	30	35.7	1.111*	0.512 to 2.414	1.058*	0.7 to 1.598
2.	More Than 6 Cup	35	41.7	29	34.5	1.437*	0.671 to 3.075	1.198*	0.814 to 1.763
3.	No Intake	21	25	25	29.8	0.9	0.414 to 1.955	0.946	0.626 to 1.429
*Significant									
S. No.	Duration of Sun Exposure	Case		Control		Estimation of Risk			
		n	%	n	%	Odds Ratio	95% CI	Relative Risk	95% CI
1.	15 Minute	56	66.7	34	40.5	2.608*	1.127 to 6.035	1.607*	1.003 to 2.575
2.	Half an Hour	16	19	31	36.9	0.817	0.319 to 2.095	0.879	0.485 to 1.595

*Significant									

Table 2 shows the results regarding estimation of odds and relative risk in concern with the physical activity of the selected women shows that the respondents with no physical exercise had a strong association with the occurrence of osteoporosis (**OR= 3.003**) and they had **1.459** times more risk to develop this disease in comparison with other group of respondents who performed some physical exercise like walking (**OR=0.333**) and yoga (**OR=0.118**) regularly while the data regarding caffeine intake in the form of number of tea cups among the respondents revealed that women with more than 6 cups daily consumption of tea had a strong association with the occurrence of osteoporosis (**OR=1.437**) and they had **1.198** times more risk to develop this disease in comparison with other group of respondents who had 2-4 cups consumption (**OR=1.111**) and no consumption (**OR=0.9**) of tea in their daily life. Less sun exposure with sun light for the absorption of Vitamin D in the skin also shows the strong association with the occurrence of osteoporosis (**OR=**2.608) and these women had **1.607** times more risk to develop this disease in comparison with women with half an hour daily sun exposure (**OR=0.817**) and one hour exposure to sunlight daily (**OR=0.384**).

Table 3: Estimation of Risk: According to Anthropometric Measurements among Case and Control

S. No.	BMI	Case		Control		Odds Ratio	95% CI	Relative Risk	95% CI
		n	%	n	%				
1.	Overweight	15	17.9	18	21.4	1.313*	0.69 to 2. 497	1.333*	0.988 to 1.8
2.	Obese	23	27.4	24	28.6	0.807	0.385 to 1.692	0.902	0.627 to 1.296
3.	Underweight	8	9.5	10	11.9	0.674	0.238 to 1.91	0.819	0.468 to 1.433
4.	Healthy	38	45.2	32	38.1	0.702	0.306 to 1.611	0.837	0.544 to 1.289
*Significant									

S. No.	Body Frame (r- Value)	Case		Control		Estimation of Risk			
		n	%	n	%	Odds Ratio	95% CI	Relative Risk	95% CI
1.	Large (<10.1)	38	45.2	42	50	1.313*	0.69 to 2 .497	1.143*	0.834 to 1.566

The results regarding Hand Grip Strength of the respondents revealed that with poor hand grip strength had a strong association with the occurrence of osteoporosis (**OR=1.819**) and they had 1.335 times more risk to develop this disease in comparison with other group of respondents who had average hand grip strength (**OR=0.986**) and good strength of hand grip (**OR=0.549**). While presence of history of previous fracture among the respondents had a strong association with the occurrence of osteoporosis (**OR**=2.426) and they had 1.623 times more risk to develop this disease in comparison with women with no history of previous factures (**OR=0.412**).Presence of maternal history of fracture among the respondents had a strong association with the occurrence of osteoporosis (**OR**=7.604) and these women had **2.071** times more risk to develop this disease in comparison with women with no history of maternal fractures (**OR=0.132**).

Discussion

The results of the study show that among the selected respondents, 46.2 percent had osteopenia and 26.58 percent had osteoporosis. In comparison, a study reported that the prevalence of osteopenia and osteoporosis in the lumbar spine of the urban Indian pre and post-menopausal women aged between 40-75 years was 48.4 percent and 25.8 percent respectively.[4]Our estimations of prevalence of osteoporosis (26.58 percent) were similar when compared with other studies like in Hyderabad (29 percent) among the low income group women aged between 30-60 years[5],followed by in Jammu (20.25 percent) among the urban women aged between 25-65 years[6]. However, among the women from low income group aged between 30-60 years, bone mineral density at all skeletal sites was much lower than value reported from developing countries, with a high prevalence of osteopenia (52 percent) and osteoporosis (29 percent).[7]

In the estimation of the risk of developing osteoporosis in relation with the behavioral factors among the respondents shows that lack of physical activity, less exposure to the sun light and extra consumption of caffeine in the form of number of tea cups show the strong association with the occurrence of disease. This strong association between no physical exercise and prevalence of osteoporosis has shown in some studies [8]in which it was observed that physical activity and fitness reduced the risk of osteoporosis, related fractures and fall related injuries. The epidemiological studies revealed that sports activity, therapeutic and weight bearing exercise, household chores and fewer hours of daily sitting are significantly associated with the reduced risk of osteoporosis.[9] In some other studiesit was observed that high caffeine intake from the tea or coffee is significantly associated with osteoporotic fracture and according to some studies it is a known risk factor for osteoporosis.[10]

Osteoporosis is a severe bone condition which is heavily influenced by the vitamin D level in the body. Studies documented that sunlight exposure can increase the bone mineral density of vitamin D deficient bone and lead to the prevention of non-vertebral fractures.[11] It was suggested that 10-15 minutes sun exposure of hand, arm and face, 2-3 times per week is sufficient for the synthesis of required amount of vitamin D in the body.[12]

Among the anthropometric risk factors of the osteoporosis, body mass Index and Body Frame shows the positive association with the prevalence of osteoporosis in which obese and women with large body frame had more chances for developing this disease. The co-relation between the body mass index and prevalence of osteoporosis and related fractures are well documented in the various epidemiological studies. Recent studies show that overweight, obesity and larger body frames were also significantly linked with the future osteoporotic fractures but independent of bone mineral density.[13]

Assessment of clinical and genetic risk factors of the osteoporosis, it was observed that poor hand grip strength, prior history of fracture and maternal history of fracture had a strong association with occurrence of the disease. Hand Grip Strength is generally is an indicator of normal muscle strength but it is a potentially useful objective parameter to predict fracture as it is associated with the fragility and propensity to fall. A cross sectional study[14] confirms the association of poor hand grip strength is a predictor of future fracture risk and that its effect is independent of BMD and other clinical risk factors. History of previous fracture is a well-documented risk factor for future fracture risk but its relation with BMD and prevalence of osteoporosis is still not well established.[15] But some studies reported that non-traumatic fractures in women are significantly associated with the osteoporosis at the femoral neck and the site of previous fractures impacts on future osteoporotic fractures independent of BMD.[16]

Maternal history of fracture especially hip fracture is a well-documented genetic risk factor for the osteoporotic fractures that is independent of BMD among the women.[17]Furthermore, the effect of family history is not a general but site specific predisposition to fractures. But the data on effect of family history on the prevalence of low bone mineral density is still not a well-documented risk factor for osteoporosis

Conclusion

The study concluded that most of the women after 40 years of age were suffering from low bone mineral density while advanced age women after the age of 50 were osteoporotic and may experienced osteoporotic fractures and associated mortality and morbidity. The data regarding associated risk factors of the osteoporosis revealed that behavioral risk factors like lack of physical activity, extra consumption tea and coffee and less exposure with the sun light, anthropometric risk factors

like High Body Mass Index and Large Body Frame, Clinical risk factors like poor hand grip strength and prior history of fracture and genetic risk factor like maternal history of fracture had a strong association with the occurrence and prevalence of osteoporosis.

Recommendations: This study recommended a healthy life style pattern in the daily life as osteoporosis is highly preventable disease and most of the associated risk factors are modifiable. So regular exercise and healthy diet pattern is the major tool to maintain a healthy body weight and hand grip strength which will contribute in the maintenance of healthy bone mineral density and reduced risk of fractures and related consequences. Regular exposure with the sun for getting recommended amount of vitamin D will help in the absorption of more calcium in the body and improvement of bone mineral density.

Work Life Balance of Hotel Employees: An Empirical Study

Paresh Bali[1], Piyush Sharma[2], R.K. Gupta[3]

[1]Research Scholar, Amity School of Hospitality, [2]Associate Professor, Amity School of Travel & Tourism, Amity University Uttar Pradesh, Sector 125 Noida (U.P.), [3]Professor, Department of Management, Delhi University, Delhi

Abstract

Introduction: Work life balance (WLB) is a very critical issue for people wellbeing and satisfaction, due to the work environment and nature of work hotel employees experience a lower level of WLB that result in to various issues like stress, lack of satisfaction etc, the main objective of the paper is to measure the levels of WLB.

Methodology: The study is based on the information collected from 521 hotel employees through a questionnaire. The information was analyzed with the help of statistical tests like factor analysis, ANOVA, Tukey HSD and student's T test to interpret.

Results: It was found that hotel employee do not experience satisfactory WLB. Significant differences were found in WLB of employees of different departments. Gender, marital status and age were found to have significant association with levels of WLB.

Research limitations/implications: Study provide a quantitative measure of WLB of hotel employees and assess empirically levels of association of factors like department, age, marital status & gender.

Originality/value: Study provides an empirical approach to measure levels of WLB of hotel employees in context of department and demographic factors.

Keywords: *WLB, luxury hotel, employee, and department.*

Introduction

Hotel industry is a people oriented industry, dependent on skills and performance of employees to deliver quality services to guests and achieve its objectives. Work in hotel is known for its characteristics like irregular and stretched working hours, heavy workloads, rigid work schedules, handling difficult customers and job insecurity. [1,2,3,4,5]

Such work characteristics have direct impact on WLB of an individual leading to variable issues. WLB is equal engagement and satisfaction in work and family roles[6] and there is a direct relation between WLB and satisfaction and between employee satisfaction and performance at work[7,8]. WLB helps in better employee retention and recruitment of better staff[9,10] a positive WLB is considered as a successful business strategy[11].

In Indian context as weanalyze feedback of employees on various job portals and job review sites, we observe that major issues reported by employees is lack of WLB or too long work duration, a well established and accepted fact by hoteliers. The primary objective of this paper is to measure the WLB experienced by employees and assess results to ascertain that employee from different department have same levels of WLBand to analyze the levels of WLB in context of factors like gender, age and marital status.

Theoretical background: WLBis a state of equilibrium where employee is able to meet

Paresh Bali
Research Scholar, Amity University Uttar Pradesh, Sector 125 Noida (U.P.)

requirements arising from his workplace and family domains[12,13]achieving WLB require equal distribution of personal resources like energy, time and commitment[14] but trend of individuals spending more time on work and lesser time on other aspects of lives[15]lead to issues of WLB. It can be stated that WLB prevails if there is proper functioning at work and at home with a minimum of role conflict[16]In context of Indian hotel industry, as per Federation of Hotel & Restaurant Association of India one of the main reason and concern about the high attrition rate in hotel industry of competent staff and seeking offshore assignments is the lack of WLB, as per estimates the attrition rate in hotel industry is around 45%, indicate WLB as a critical factor in controlling the attrition rate in Indian hotels.

Work in hotels requires to achieve hard deadlines, unexpected interactions with guests, shift working & issues of coordination resulting in to difficulties in achieving a suitable WLB, employee has to work on festivals and unable to celebrate with family, they need to put more efforts and devote more time during festivals and busiest shift times in hotels are weekends and public holidays when majority of people enjoy their leisure time with family and friends[17] this affects their personal lives as they cannot provide enough quality time to their family and personal life leading to further degradation of WLB and decrease in moral[18]complicating the matter further[19]hotels also lack family supportive work environments necessary for the benefit of employees and organization[20,21,22]and is more prominent in Indian context.

WLB issue is not a minor issue but affects performance of employee[23]considering the fact that hotels are 24 hour industry & employeesare pushed to work round the clock[24]requires innumerable hours at work & sacrifice their family & personal life[25].Gender of employee has been investigated as a predictor of WLB[26,27] studies found that men & woman face almost similar issues related to WLB & gender of employee is not a significant factor[26,28,29-34,35]as it was stated levels of women's involvement at work did not differ from men, both experience negative consequences only relationship is found to be stronger in case of women. In case of India, women may experience more issues of WLB as they are assumed to be more responsible because of childbearing engagements, cooking & managing home whereasmales are considered as bread winners this lead to different challenges for women & men in managing work life matters.

Need of WLB increases with changes in marital status & family structures as individual desire to achieve a balance between career progression & focus towards family & get attracted towards organizations that offer flexibility to manage both. Studies have found that individual's with different marital status & family structure has differential levels of WLB. Single have lesser issues ofWLB in comparison to married counterparts.At same time married individual may experience a better WLB if spouse is supportive increasing the ability of individual to decrease impact of work life imbalance[43] & balancing work life is also related to happier marriages[31].Studies have shown that WLB practices help to improve financial results of company as it improve productivity, enhance retention & decrease the levels of absenteeism[44]. Primary aim of study is to ascertain the levels of WLB of employees in hotels & to find any definitive association of demographic factors of the employee & the department of work with the WLB experienced by them.

Hypotheses for the study:

H1: Hotel employees have WLB.

H2: Employee from different departments experience different levels of WLB.

H3: The levels of WLB is different for both male & female employees.

H4: The WLB of employees from different age group is different.

H5: The WLB of married & single employees is not different.

Material and Method

The study was based on the information collected from 521 employees of the luxury hotels of Delhi, the capital of India. The data was collected with the help of a questionnaire developed after an explorative research where in the available literature on the issue was reviewed, review of employee feedback on job portals was conducted, interviews of Indian hoteliers in articles were analyzed, followed by in depth interviews with academician, HR managers & employees. The explorative research helped to identify four dimension of WLB namely quality time, involvement, satisfaction & health & to formulate statements. A research instrument was developed in the form of a self-administered questionnaire that has statements pertaining to WLB &

after a pilot study the information was collected from the sample. A combination of random & convenience sampling were used. Only criteria followed to identify the participant for study was employee should be employed in hotel for minimum of one year in any of the operational department of the hotel to an extent of supervisory level. The managers were excluded. Participants were requested to record agreement or disagreement on a five point Likert scale.The participants were required to provide their responses on the basis of their own experience & opinions. Each dimension was assigned equal weight & total score was level of WLB. Total score for WLB was 400 & score of 300 was considered to be threshold value to consider the levels as satisfactory, as it signify respondent's agreement to majority of statements. In the instrument some of the statements were negatively quoted, for analysis the scores for such statements were reversed.

More than 700 questionnaires were delivered & 578 were received, only 521 were found to be complete & fit for further analysis for the study. Data was fed in to SPSS software & analyzed through statistical tests like KMO, factor analysis, student t test, ANNOVA & Tukey HSD to draw any inferences.

Findings and Discussions

Values for KMO were found to be 0.845 & Bartlett's test of sphericity was significant (p value less than 0.05), ensuring sample adequacy for factor analysis & statistically significant correlations among the variables.

A total of 29 statements were analyzed through factor analysis, principle component analysis was employed & the data was rotated through varimax rotation to extract only 4 factors for the study. As per the result of principal component analysis, it was noted that four factors accounted for 71.27 percent variation in overall sample. The result of one sample t test, Table-1 test value of 300 as a threshold was considered for acceptance, with p value less than 0.05 & t value -12.684, the hypothesis H1: Hotel employees has WLB, was rejected. Results of ANOVA test, indicate ($p< 0.05$) there exist significant differences in the levels of WLB among employees of different departments of hotels, accepting hypothesis H2 employee from different departments experience different levels of WLB. Result of Tukey HSD ($p<0.05$)indicated that WLB of employee from front office is highest followed by employees from f & b service & housekeeping, lowest levels of WLB found for employee of food production department. ANOVA result ($p<0.05$), reflect WLB levels for women employee were significantly different from men, accepting hypothesis H3 levels of WLB is different for both male & female employees. Results of ANOVA, ($p<0.05$), proves WLB levels are different for the employees from different age groups, accepting the hypothesis H4 WLB of employees from different age group is different.As per the result of Tukey HSD, the highest levels of WLB was recorded for employee between 25-30 years & then there is a gradual decline in the levels of WLB till the age group of 35-40, & then WLB levels again increase from the age group of 40-45 & 45-50 years. As per results of ANOVA, ($p<0.05$), WLB was found significantly different for employee with different marital status, accepting hypothesis H5: The WLB of married & single employee is not similar.

Conclusion

The study found that there is a lack of satisfactory WLB for hotel employee, employees working in different departments of hotels have significantly different levels of WLB, the highest level of work life was recorded for employees working in front office, followed by employees from housekeeping & food & beverage service, the lowest level of WLB was found for employee working in food production. Levels of WLB were found to be significantly different for male & female, female employees have higher levels of WLB as compared to males, this was in contrast to assumptions & other studies. WLB levels for employees in age group 25-30 years & 45-50 years were found to be highest, whereas employees in the age group of 30-45 years were found to have lower levels of WLB. Study also concludes that WLB for married employees were found to be less than single.

Implications of the Study: The study provides an empirical approach towards measurement of WLB of hotel employees; the study has assessed the levels of WLB & analyzed it with factors like department of work, gender, age & marital status. Further study can be done to find the reasons behind the differences noted in the levels of WLB among different employee classifications. The study can help individual aspiring a career in the hotel industry & to hotels to introspect & devise interventions that can improve the levels of WLB of employees.

Table 1: One-Sample Student T Test to assess the levels of WLB

	Test Value = 300					
	T	df	Sig. (2-tailed)	Mean Difference	95% Confidence Interval of the Difference	
					Lower	Upper
WLB (WLB) Score	-12.954	520	.000	-27.84366	-29.9678	-21.8902

Perceptions of Nurses Regarding Barriers to Implement Maternal and Newborn Care at Rural Community Health Centers of Madhya Pradesh, India: A Phenomenology Study

Mamta Verma[1], Kanchan Mukherjee[2]

[1]Ph.D. Scholar, Tata Institute of Social Sciences, Mumbai, Maharashtra, [2]Professor, School of Health Systems Studies, Tata Institute of Social Sciences, Mumbai, India

Abstract

Introduction: Nurses are vital to providing high-quality rural maternity care throughout the continuum of adolescence, pregnancy, birth and postpartum period. Objectives: The objective of this study is to examine the barriers perceived by nurses in maternal and newborn care at community health centers in rural areas of India. Material and Method: A qualitative study was conducted to identify barriers at two selected community health centers of Madhya Pradesh. Participants were interviewed and data were analyzed using Atlas.ti software. Results: Major themes that surfaced during data analysis were related to manpower, facilities, nurses, culture and rural area. Conclusion: It is very crucial to address these reported barriers in order to provide better & evidence based maternal and newborn care in rural areas.

Keywords: *Nurses perception, Rural health care, Barrier, Maternal care, Neonatal care.*

Introduction

WHO fact sheet on maternal mortality (2017) projected that approximately 810 women die every day across the world due to pregnancy related complications[1]. A wide gap in maternal mortality ratio (MMR) has continued to persist between developed, developing and least-developed countries. About 94% of maternal deaths have been reported in the low and middle-income countries[1]. In 2017, Nigeria and India had the highest estimated numbers of maternal deaths, accounting for approximately one third (35%) of estimated global maternal deaths[2]. MMR in India has declined in the last ten years from 254 (2004–2006) to 130 (2014–2016)[3]. As per NITI Ayog Data (2014-16) MMR in India is 130 per 100000 live births and needs to be improved to 100 by 2020[4,5]. Current maternal mortality ratio in Madhya Pradesh is 173 which is significantly high in comparison to the national database and thus is a matter of grave concern[6].

The global health observatory data about infant mortality rate (IMR) in India is alarming. In 2017, 4.1 million infant deaths occurred within the first year of life[5,7]. Inequality in IMR persists among the States/ Union Territories of India. It ranges from 9 in Manipur to 50 in Madhya Pradesh for 2015[8].

Majority of the maternal deaths occur due to severe bleeding, infections in post-natal period, high blood pressure during pregnancy and complications during delivery and unsafe abortion[1]. A skilled pair of hands to help mothers and newborns around the time of birth, along with clean water, adequate nutrition, basic medicines and vaccines, can make the difference between life and death[9].

Women who reside in rural and remote communities should receive high-quality care near to her home. It should be collaborative & women and family centered[8,10]. Given the non-availability of doctors in remote areas of India nurse's role and contribution is imperative. Nurses are essential for the provision of high-quality rural maternity care throughout pregnancy, birth and the post-

partum period[8,10]. Under the national health mission (NHM) initiative of the government of India, there is a strong felt need for providing newer roles to nurses in far-flung areas where doctors are not available[11].

Nursing care providers in remote areas of the country face many barriers while providing maternal & neonatal care. Therefore, the objective of this study is to assess the perceptions of nurses regarding the barriers to maternal and newborn health-care –in rural community health centers (CHC) of Madhya Pradesh.

Material and Method

Study area: The study was conducted in the state of Madhya Pradesh. A rural district with 77 % of rural population was selected from Bhopal division. Out of total CHCs of the study district two CHCs one maximum and one minimum performing CHC were selected. Maximum and minimum performing CHC selection was based on Health Management Information System (HMIS) indicators such as the percentage of institutional deliveries to total ANC registration in the year 2018-2019.

Participant's Selection Criteria: Three categories of nurses based on their experience in maternal and newborn care were selected. Category 1- Experience more than 10 years, category 2- Experience between 5 to 10 years, category 3- Experience less than 5 years. Two pilot interviews were conducted.

Research Study Method: In-depth interviews of nurses were conducted between May and August 2019. The duration of each interview ranged from twenty to sixty minutes. All interviews were conducted at the CHCs and in Hindi language. Each interview was audio recorded by the researchers.

Ethical Considerations: Administrative approvals from government authorities were obtained. Investigator obtained written informed consent from each participant prior to start of each interview. The data collected from participants was kept confidential.

Trustworthiness: It was ensured by following the Guba's (1985) four criteria credibility, Transferability, dependability and conformability[11,12]. Robust triangulation method were applied to enhance the confirmability of data and constructs emerged from current study.

Analysis: Total of six interviews (3 nurses from minimum performing and 3 from maximum performing) were analyzed by Atlas.ti qualitative data analysis software.

Results

Table 1: Demographic distribution of participant's profile (N=6)

Age (Years)	Qualification	Year of Experience
37	G.N.M.	13
25	G.N.M.	03
26	P.C B.SC Nursing	05
47	G.N.M.	20
30	G.N.M.	05
28	G.N.M.	04

Participant's age varied between 25 to 47 years. Their experience also varied between 3 to 13 years.

Barriers observed by Nurses:

1. Manpower Linked:

Shortage of Nurses: The majority of the participants have voiced their concern that there is an extreme shortage of nurses as per workload.

"Number of nurse's post must be enhanced"

If one nurse goes on leave another nurse has to do double shift or when patient load increases nurses are asked to return from home after their scheduled duty hours to assist.

"*There are lots of vacant posts of nurses. Many nurses retired but vacant post is not filled*."

Shortage of specialist doctor: Doctors who are working at community health center are MBBS qualified and they are not expert in labour cases and newborn care.

"We don't have Obstetrics and Gynecology specialist, if we would have, we could do LSCS (Lower Section Caesarean Section) here only"

Shortage of supporting staff:

"we have problem of laundry, Dai (Birth Attendants), security guards"

2. Facility Linked:

Infrastructure: Lack of diagnostic facilities creates difficulty in the decision-making process in obstetric emergency cases.

"There is *lack of investigation services on twenty-four hours basis".*

Participants expressed the opinion that management of postpartum hemorrhage (PPH) cases in absence of any arrangement for blood transfusion is risky.

"*There is lack of blood transfusion facilities. We provide basic care. As we do not have blood bank, that's why no major surgeries are performed here".*

Lack of medicine inventory management: A participant informed that medicine supply and consumption are not balanced.

"*We get sufficient medicine. Some medicine like dopamine & hydrocortisone are not prescribed to patients, hence these medicines expire. There should be rational use of medicine."*

Inadequate basic facilities: Nursing is a noble profession however these professionals are struggling for basic amenities like toilet etc.

"We do not have exclusive duty rooms while on night duty, we take rest in a meeting room. Earlier we use to sleep on floor while night duty"

Security and safety threats: Almost all participants expressed their concern regarding safety and security threats while on the job.

"I don't feel safe, when I am on duty as there is no security guard, no other gents. We fight for our self as compare to security guards".

3. Nurses Linked:

Unclear task shift to nurses: One of the key themes which emerged from narration was that task assignment to individual nurses is frequently ambiguous making for difficulty in effective discharge of duty.

"*Many times, doctors do not support us if we commit any mistake. We feel fear when we work alone like dealing with PPH ceases and eclampsia cases*".

Nurses are targeted by everyone related to the health system.

"*I bear because he is a patient if he lodges a complaint to government, ultimately government will blame me*."

Direct patient care is the prime responsibility of nurses however due to administrative reasons nurses are engaged in clerical work like data entry and maintenance of register.

*"Sometimes I feel bad as we have to maintain many register*s"

"*We do pending work at our home finish my register and other pending documentation at home. In hospital clinical work is our top most priority*."

No promotion opportunity: Senior participants reported the lack of any scope for career progress.

"*I will be working as staff nurse only from joining to retirement. We should have opportunity to get promotion. I wish to upgrade from class three to class two rank."*

Contractual Job: Another challenge faced by some nurses is the absence of job and hence financial security as they are hired on contractual basis.

"I am on contractual basis. Salary is not sufficient. Many times, I wish I should also get a permanent job"

No provision of financial incentive for higher education: Nurses did not get any financial incentive after acquiring higher education.

"After completion of course our skills improve but financial raise should be there it will sustain our motivation."

Ineffective patient-provider communication: Effective communication is the key to fruitful maternity health care. However the participants highlighted the difficulties they face while trying to interact with patients which ranged from simple lack of understanding to even outright verbal arguments.

"*I explain multiple time same thing to patients and they expect again same repetition.*

"Sometime family member approach us and tell there is patient in labour go and see her, when we ask bring patient here, they start fighting with us".

4. Culture Linked: Male gender preference: The participants revealed that the rural community is still heavily biased towards the male gender of the child and thus while conducting deliveries nurses have to act accordingly.

"*If women deliver a son family feels okay if women deliver second son than it superb and satisfactory for them. If a daughter born then everyone seems to be sad. Then we support and encourage mother".*

The participants in this study also reported that many myths regarding breastfeeding are prevalent in the rural society and they try hard to dispel them while at the same time motivating the new mothers to opt for early feeding.

"*Relatives say that yellow color milk is bad and it should be discarded but we encourage that it should be fed to baby."*

Post-natal care practices: Similarly, the participants also shed light on the myths regarding post-natal maternal and neonatal care that they have to fight against. One common practice followed in Bhopal is the burning of cow dung to generate smoke which is then aired to the genitalia of women who recently delivered. New mothers are not allowed to consume ordinary food while neonates are fed honey and pre-lacteal feed.

"There are many factors such as myths of patients like eating harira just after delivery

"They often give honey to new born, apply oil on umbilical cord, prelactal feedings etc. (participant number three)

Rural area linked: Many participants voiced their issues that arise as a result of serving in rural areas for which they either have to commute daily or as an alternative have to reside away from their spouse/family.

"I am sacrificing a lot here; I live alone with my younger daughter in campus & manage it with many difficulties. My nights are sleepless."

On the other hand nurses who are young and unmarried experienced a different kind of problem while adapting to rural lifestyle. They spoke of loss of freedom of attire and the sarcastic comments from male family members that they have to bear while working in hospital. Often their youth was equated with inexperience by their patients and thus adding to their issues in patient interaction.

"*My dressing style is different; mostly I wear western dresses so people take it in other way that why I pretend as a strong woman. When I insert intravenous cannula, male patients pass sarcastic comments such as sister be gentle, I feel bad as I could sense what actually they mean*."

"*I am unmarried that's why many women hesitate to tell me their history. I am short heighted and young so many patient and family members are doubtful in my abilities to handle labour cases*."

Limited internet connectivity: Limited network connectivity was a major barrier perceived by the participants.

"*This is a small place & I cannot do many online works. I can't apply online for other job even I could not process renewal of my Registration certificate as there is no cybercafé here."*

Discussion

Analysis of participant's interviews verified that spectrum of barriers ranges from shortage of nurses coupled with high patient volume and low supporting staff. Similar constraints have been previously reported by other studies[13-15]. It has thus been suggested that sufficient staffing of nurses in rural health centers should be enacted to compensate for nursing shortage and to enhance the efficiency of public health care services in rural areas[15].

Results of the current study demonstrates that extensive documentation work required for keeping detailed records of the maternal and newborn health care dispensed by the CHCs was a burden on already overworked nurses. Factors that compound this problem such as time, the attitude of the midwives and the relatively few numbers of midwives working in each shift have also been reported by Dike et al. in 2015 from their study conducted in Nigeria[16]. Fear of blame was evident from the respondent interviews. Nurses are not only blamed by doctors but also by patient and family members in adverse situations. These findings were supported by published literature.[13,15]. An article published in 2014 lists other prominent fears reported by nurses such as the death of a baby at the time of delivery, missing something that causes harm, obstetric emergencies, maternal death, being watched, being the cause of a negative birth experience, dealing with the unknown and losing passion and confidence around normal birth[17]. Research findings of this study illustrates that nurses are deprived of basic facilities such as a decent duty room, toilet, and even seating space. Similar results have been found in other studies as well[18].

Unavailability of basic facilities is not conducive to delivery of effective health care.

In the current study nurses were not provided any accommodation facility within the campus of the community health centers to which they were attached which was a major cause of disquiet among the respondents. Working in rural areas away from their native place seems to adversely affect the family life of nurses and this finding is supported by an article published by Sumankuuro et al. in 2018[15]. Priscilla Poga (2019) also highlighted in her study that accommodation plays a vital role in staff retention[16,18]. Security and safety threats were widely reported by nurses in our study. The study by Poga also showed that nurses are generally more concerned with the 'internal factor' of safety than with other external factors. It reveals that safety at the workplace is highly prized by rural nurses because without it, they cannot achieve their aims[18].

Manpower linked barrier such as shortage of specialist doctors and supporting staff also emerged as a major theme in this study. Similar constraints have been reported in different studies[14,15]. Further, this study has identified several cultural linked barriers such as male gender preference, myths about breast feeding and intra-natal and post -natal maternal care rituals. Results of a similar nature have been published by other studies as well[14,15]. Rural area linked barriers such as Illiterate community, limited telephone network and internet connectivity has been revealed by this study. Young nurses in our study, especially those hailing from different ethnic and language backgrounds faced diverse challenges in integration and acceptance as has documented previously[19].

Limitation of study: This study has been conducted focusing on the nursing staff of the selected community health centers of rural Madhya Pradesh and the challenges faced by nurses working in the limited geographic area might not accurately represent the scenario faced by nurses elsewhere. Such individual expression bias and lack of generalizability is inherent to the qualitative research methodology and thus persists in our study as well. However, the contextually rich data obtained through in-depth interview compensates for any loss in reproducibility.

Conclusion

To improve maternal and neonatal health care in the rural sector it is of utmost importance to resolve the barriers identified by this study. Manpower shortage should be addressed on a priority basis & measures to improve the diagnostic resources available in rural health care setting need to be considered. Task delegation of nurses should be unambiguously defined. Career progress schemes are vital to motivate and retain nurses working in rural areas. Basic amenities for nurses such as provision of duty room and nurses work stations must be provided. Effective communication is vital for both patient and nurse's satisfaction and thus nursing staff should be educated regarding the same. Finally, the felt need to generate awareness among the rural community about the significance of following evidence-based maternal and newborn healthcare should be acknowledged by policymakers and appropriate efforts should be initiated.

Conflict of Interest: None initiated.

Morphological Study of Neurons in the Trigeminal Ganglion

T. Jeevapriya[1], R. Archana[2], Gunapriya Raghunath[3], P.K. Sankaran[4]

[1]Research Scholar cum Assistant professor, Department of Anatomy, Madha Medical College, Bharath Institute of Higher Education and Research, Chennai, Tamilnadu, India, [2]Associate professor, Department of Anatomy, Shri Balaji Medical College, Chennai, [3]Professor & Head, Department of Anatomy, Saveetha Medical College, Chennai, [4]Associate professor, Department of Anatomy, AIIMS, Mangalagiri.

Abstract

The pseudounipolarneurons in the trigeminal ganglia carry sensation from the face to the brainstem. These neurons vary in its sizes that carry specific sensations. In this study trigeminal ganglion neurons are classified based on its diameters in to three types namely large, medium, small sized with the help of histomorphometry. The small sized neurons of trigeminal ganglion modulate pain sensation in migraine. To classify the trigeminal ganglion neurons in to large, medium and small sized and to study the diameter of the neurons in the trigeminal ganglion. Neurons in the trigeminal ganglion which is also sensory ganglion homologues to dorsal root ganglion were classified based on its diameter in to small (approx. > 22). Most nociceptors are responding to touch and pressure, thermal and chemical stimuli. Large neurons thatis mainly nociceptive.

Keywords: *Pseudounipolar neurons, trigeminal ganglion, histomorphometry.*

Introduction

Trigeminal ganglion is a ganglion on the sensory root of the fifth cranial nerve situated in a cleft within the dura matter on the surface of the pars petrosa of the temporal bone, and giving off the ophthalmic and maxillary and part of the mandibular nerve called also Gasserian or semilunar ganglion.[1] It comprises pseudounipolar neurons from three divisions of the trigeminal nerve. The pseudounipolar neurons can be classified in to different types based on its diameter in to type 1 cells that are large and contain scattered clumps of nissil substance connected to myelinated nerve fibres.[2] The remaining cells are classified as type II cells which are small sized and contain coarser clumps of nissil substance connected mainly to unmyelinated nerve fibres. The small sized neurons of trigeminal ganglion modulate pain sensation in migraine.[3] The aim of the present study to classify the trigeminal ganglion neurons in to large, medium and small sized and to study the diameter of the neurons in the trigeminal ganglion.

Materials and Method

Male albino wistar rats (n=6) of weight ranging from 200g was the histomorphometry in the present study. The rats were obtained from experimental animal; facility of saveetha medical college. The animal was kept in cages with not more than the three animals in one cage.[4] They were maintained at 12hrs:12hrs light/ dark cycles with water and food available ad libitum.

Tissue Collection: Fixation was done using 500ml of 4% formaldehyde in 0.1M phosphate buffered saline, through transcardiac perfusion then dissect the rat brain trigeminal ganglion was identified and removed. Tissues were sectioned (20µm) using cryostat and stained with Cresyl violet.[5]

Morphometric Analysis of Trigeminal Neurons: The Cresyl violet stained sections were visualized using progRes image capture from senoptik progRes capture pro 2.7 (Germany) in 20x objective in an e-600 nikon compound light microscope.[7] The diameters of the neurons from energy fifth section were measured using progRes image analysis software. The measured diameters were then divided into three types small sized, medium sized and large sized using spss software.[8]

Results

Table 1. Frequency distribution of maximum diameter of right side
Total Number of Neurons Measured – 1462

S.No.	Range	Frequency	Percent (%)
1.	10-20 µm	302	21.9
2.	21-30 µm	721	47.2
3.	31-40 µm	384	25.3
4.	41-50 µm	52	3.4
5.	51-60 µm	3	0.2

Table 2. Frequency distribution of maximum diameter of left side
Total Number of Neurons Measured – 1548

S.No.	Range	Frequency	Percent (%)
1.	10-20 µm	328	21.2
2.	21-30 µm	772	49.3
3.	31-40 µm	373	24.1
4.	41-50 µm	67	4.2
5.	51-60 µm	7	0.5
6.	61-76.58µm	1	0.1

Table 3. Results of statistical analysis using SPSS

Statistical Measures		Right Trigeminal Ganglia Neurons (µm)	Left Trigeminal Ganglia Neurons (µm)
Mean		26.19	26.30
Median		25.4	25.38
Standard deviation		7.45	7.50
Std error of mean		0.17	0.17
Range		48.75	66.32
Minimum		10.55	10.26
Maximum		59.31	76.59
Percentiles	33.33	22.18	22.28
	66.66	29.1	28.88

Statistical Analysis: The means of diameter of right and left side trigeminal ganglion were compared using student test which was found to be significant P>0.05. The statistical data were explained in the tables below;

The diameters of the neurons measured were analysed statistically using SPSS software and the values were divided into three groups.

Table 4. Classification of neurons

Types of Neurons	Right Trigeminal Ganglia Neurons (µm)	Left Trigeminal Ganglia Neurons (µm)
Small Neurons	<22.10	<22.20
Medium Sized Neurons	22.11-29.0	22.21-28.80
Large Neurons	>29.01	>28.81

Discussion

Dorsal root ganglia neurons had been classified in three main types (A, B, C) on the basis of their size.[9,10] Type A neurons are large neurons (40 – 75 in diameter) Type B neurons correspond to medium neurons (20 – 40 in diameter) whereas Type C neurons are the smallest cells with a diameter of less than 20.[11,12] In the present study, Neurons in the trigeminal ganglion which is also sensory ganglion homologues to dorsal root ganglion were classified based on its diameter in to small (approx. >22) Each type of neurons is concerned with different sensation, for e.g. small and medium sized neurons are mainly concerned with pain and temperature which are called nociceptors.[13,14] Most nociceptors are respond to touch and pressure, thermal and chemical stimuli.[15] Large neurons thatare mainly nociceptive.[16]

Determinants Influencing Towards the Consumption of Green Products among the Consumers: A Structural Equation Approach

Vijaya Kumar[1], Shanthini[2], Nishad Nawaz[3]

[1]Assistant Professor, Department of Commerce, Sir Theagaraya College, Chennai, [2]Assistant Professor, Department of Commerce, Govt. Arts and Science College, Chennai, [3]Assistant Professor, Department of Business Management, College of Business Administration, Kingdom University, Bahrain

Abstract

Rationale of the Study: The extensive writing on consumer of green newly focus by the marketers and markets. Even though consciousness environmental in Indian consumers is examined through the literature, their buying behavior towards products green is not so far implicit. Therefore, the present study is contemplate on make out the determinants influencing the consumption of green products in Chennai city.

Research Design: The research makes use of survey method technique to test a hypothetically grounded position of hypotheses. A simple convenience sampling method used and collected the data from 709 users of organic food products. To test the hypothesis of the study, the Structural Equation Modelling utilized.

Findings: The determinants, namely environmental protection, environmental responsibility, Experience of personal, Social Appeal aspect, and Environmental kindliness, significantly influence the buying decision of green products in the study area.

Implications of the Study: The study results are useful to the marketing professionals of green products. It also helps the organizations to frame the strategies of marketing aspect and also helpful to the organizations to identify the consumer's perception and satisfaction of using green products.

Keywords: *Consumer, Consumer Behaviour, Green Products, Research on Marketing.*

Introduction

The attentiveness of annihilation of natural supplys out come from the behavior of human has lifted the subject of ecological fortification and the perception environment in behavior of consumer. It has enhanced the stipulate for green category merchandises in the market universal. A green category items defined the product manufactured using at no cost toxic components and environmentally-gracious process, and which specialized as distinguishd organization[1]. Greening manufactured goods takes consign over its complete life-cycle from product intend and procurement of raw material to the process of production, storeroom, carrying, practice, and post-practice activities. While familiarity of users marketplace and capriciouss inspiring buying behavior of green enlarge to have momentous implications. The cross-countries, studies connected to behavior of green, have observe the developing ecological consciousness in the mind of consumers. The study reveal prioritize of Indian consumers in different category products and services from environmentally gracious organizations and are becoming hard to please in their behavior of purchase in expressions of predilection for products of green, quality of product, their spirited values and their responsibility in the stores of product[2].

Decisions of Green product buying: The consumers of green are portrayed the environmental significances of their utilization prototypes and propose to change their buying intensions and the behavior of consumption for decreasing the environmental aspect.

The green consumers purchase decision originate to be the middle subject in the current condition of study on behavior of consumers related to green.

The decision of buying supporting the organizations of the green, preferences of eating green commodities and probable to expend additional for green products. Mostly two important factors pressure the buying decisions of green consumers. The genuine behavior outcome of consumers' habitual habits, product information, and the environmental factors namely the campaign of promotional.

Supporting Environmental Protection: Shore up environmental fortification is important causes for users to perform environmentally gracious in buying decision[3]. The users distinguish the responsibility of merchandises of green in increasing the excellence level of the atmosphere, and consumers demonstrate prop up for ecological safety by buying and owning products of green. The consumers capable to transmit the correctness of superior level prices of products category of green benefits suggested by them and build up a positive perception in the intelligences of consumers.

H1: Consumers are significantly influencing towards the buying behavior of green products for the prime reason for support of environmental protection

Environmental Responsibility: The environmental liability drive related to users commitment level towards the protection challenges and individual focuses to enhance the quality of atmosphere. Realizing the unhelpful impact of atmosphere on human and consumers know responsibilities for environmental protection. The users inspired by natural think about the excellence of the world and inhabitants create to be above all engaged in environmental protection . Consumers ecological apprehension, compassion, and conviction in the subsistence of environmental predicaments at the personality level to execute environmentally gracious.

H2: The consumers preferring towards the buying behavior of green products for the reason of environmental responsibility

Experience of Green Product: Consumers' understanding of green products an extra powerful variable to persuade green products buying decisions. The users inquisitiveness to increase knowledge about the environmental characteristics of green products. The users struggle to study about green products on individual and increase comprehension related to ingredients of green products[4]. Additionally, the users shre the information and knowledge of green products with companions[5]. The product assessment facilitates them to recognize the environmental advantages of green products and outcomes in successfully mounting predisposition towards green products[6].

H3: Consumers prefer the usage of green category products because of their personal experience of green products consumption

Social Appeal: Consumers increase and understand the meaning of products when the users interrelate with others and collect related in sequence[7]. Consumers fraction of a society or social group, obtain and contribute to information, and identify what others believe for a meticulous product[8] and assess the products pedestald on the observations and opinion of others[9]. Besides, consumers usually attracted with the product that enhances a intelligence of self and the approach want to be distinguished by others. Thus, the widespread application create influential in developing the preference of prodcuts. Never the less, users be set to to buy products that go behind the perceptions of culture as well as build their social-identitie[10].

H4: The consumers Buying decision of green products because of excellent Social Appeal

The society of environmental gracious, users extensively distinguish the reputational and contemporary technique of lifestyle to perform environmentally friendly[11]. It has emblematic meaning of principles, thinking, nature-orientation, and eco-objectives. It guides to decisive functional outcomes for users, i.e., pro-social standing of being reliable, expensive companion, and status (prestige).

H5: The Consumers Buying Decision of Green Products because of Environmental friendliness

Methodology

The study is concentrate on make out the determinants influencing the consumption of green products among the consumers in Chennai city. The study used both primary and secondary level data. The study used both primary level and secondary level data. The secondary level data collected through articles, magazines, and research papers. The primary information collected from the consumers of green products in Chennai city. Overall,

709 responses are finalized and used for the analysis. The study used a convenience sampling method. The data is collected from the users of organic product consumers in Chennai city. To evaluate the association between the determinants of green products and purchase decisions, the construct was developed[12]. The constructs of the study, such as environmental protection, environmental responsibility, personal understanding, Social type Appeal, and Environmental easiness buying decisions of green products. The study used Structural Equation Model to measure the relationship connecting the determinants of green products and buying decision.

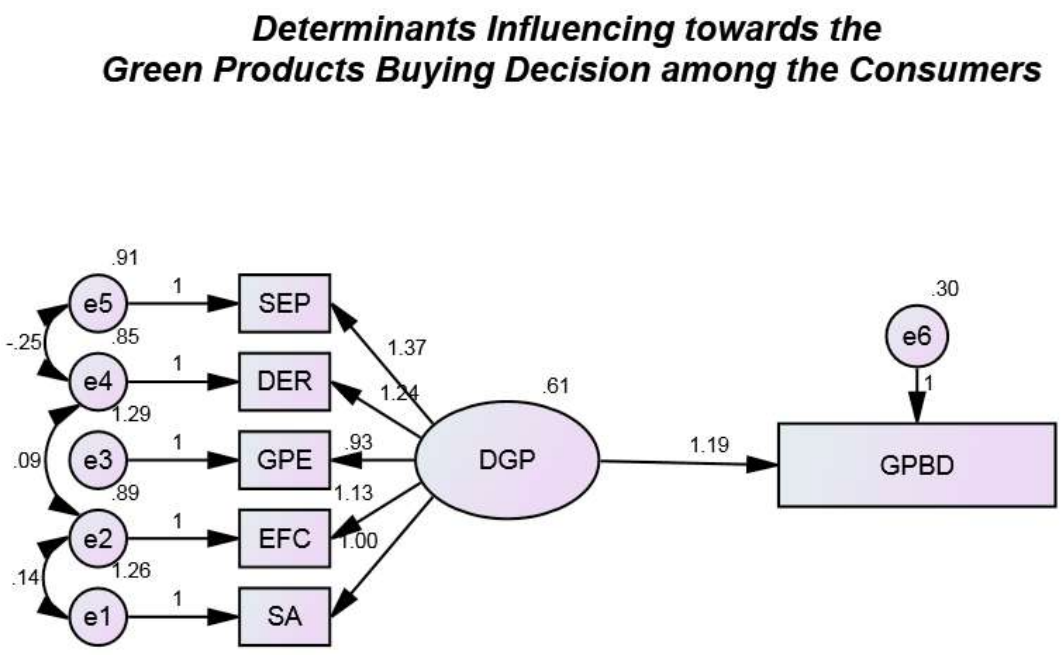
Results and Discussion

Demographic Profile of green products consumers in the study region and the results reveal that the majority of 52.6 of the consumers are male category. Age group-wise, 26.9% of the consumers are in the age group of 31-35 yeas. The study demonstrates that the majority of the consumers married. Regarding the educational qualification of consumers, the majority 35.3% of the consumers under-graduates, and the monthly earnings concern majority 41.5% of the consumer's monthly income between Rs.50,001 – Rs.1,00,000. The study also exhibited that around 52.3% of the consumers are salaried class.

Structural Equation Modelling: SEM is a advanced statistical method that is utilized to scrutinize structural relationships. It the mixture of factor study and multiple model regression analysis, and it is utilized to scrutinize the structural relationship between measured segment of variables and latent type constructs. The hypothesized model of the study is whether the determinants of green products, namely support of environmental protection, environmental responsibility, personal experience, Social Appeal, and Environmental friendliness significantly influence towards the buying decision of green products in the study area. The SEM Model results are given below:

Parameter	CMIN/DF	P	GFI	AGFI	CFI	RMSEA
Results	1.628	0.135	0.995	0.984	0.998	0.030

The analysis indicates the CMIN/DF value is <3, GFI, AGFI, CFI values are >0.9, and the RMSEA value <0.05. Based on the results is that the proposed model is fit. The study inferred that the determinants of green products, namely support of environmental protection, environmental responsibility, personal experience, Social Appeal, and Environmental friendliness, significantly influence towards the buying decision of green products among the consumers in the study area.



To test the proposed hypotheses of the study, i.e., Consumers are significantly influencing the buying behavior of green products for the prime reason for support of environmental protection. The output of the AMOS results indicates that the p-value for the buying behavior of green products for the prime reason for support of environmental protection is <0.01. The results of the study maintain the hypothesis and confirm that environment protection significantly influencing consumers to use green products in the study area.

To examine the hypothesis, i.e., consumers preferring towards the buying behavior of green products for the reason of drive for environmental responsibility. The results mentioned that the p-value of these factors is <0.01. The results of the study supported the hypothesis and inferred that environmental responsibility is also the prime reason for using green products in the study region.

As for the third hypothesis of the study is, Consumers prefer the usage of green category products because of their personal experience of green product consumption. The results indicate that the p-value is <0.01. Therefore the could be inferred that the consumers are using the green products of their personal experiences. The study also supports that the consumers prefer to utilizing green products because of the environmental friendliness of the organization(p value=<0.05). The consumers inspired that the aspect of the environmental friendliness of the promoters. Supplementary, the connection linking socialappeal of green product buying assessments is create statistically considerable of hypothesis (p=<0.05). it point outs individuals be part of environmentally welcoming culture and to put up up and prolong environmentally gracious customarys of income are additional credible to buy green products.

Conclusion

The enhancing environmental mindfulness of consumers inspired managers postion of green products to solicit details apprehensioning the environmentally welcoming buying behavior of consumers. The continuous advancement in the domain of green category research, current studies have concentrated on eating pattern, therefore the buying behavior of products green can be scrutinized. In the wake of these directions, the present study has endeavored to build up an considerate of consumers' observation of green products decreasing the effect of their eating patterns. The study results specify that consumers in India have a high level of environmental consciousness, it is displayed in their green category product buying decisions. The consumers apprehensioned with environmental guard issues understand their responsibilities towards the protection, consider in the existence of environmental difficultys and their clarification at individual levels, comprehensively search for product-connected ecological information, and create environmentally gracious purchase decisions. The study inferred that the receipt of green products depends upon the commodities' environmental uniqueness needed by users. The research also registers that there is a meaningful association of supporting environmental shield and push for accountability of environmental with green category product buying conclusion substantiate that the choice to acquire a green product necessitates a free mindful assessment of environmental, personal, and social importance associated with products of green. It more indicates that consumers see for the accomplishment of their functional, emotional, and experiential requirements, which impact their buying decisions. It emulates an friendly existence in their using blueprints and the significance of green products to users. Subsequently, marketing experts for products green need speak how users attention about protection environmental and abilities environment are discussed by buy, using, and disposing of green products. Overall, the determinants, namely support of environmental protection, environmental responsibility, personal experience factor, Social Appeal aspect, and Environmental friendliness, significantly influence the buying decision of green group creations in the study area.

Effect of Methanolic Leaf Extract of Ficus Religiosa on Neuronal Degeneration: A Pilot Study in Male Albino Wistar Rats

Amit Massand[1], Rajalakshmi Rai[2], Ashwin R. Rai[3], Teresa Joy[3], B.V. Murlimanju[2], Aradhana Marathe[4]

[1]Tutor, [2]Associate Professor, [3]Assistant Professor, Department of Anatomy, [4]Tutor, Department of Biochemistry, Kasturba Medical College, Mangalore, Manipal Academy of Higher Education, Manipal, Karnataka, India

Abstract

The present study aims to evaluate the effect of *Ficus religiosa* (FR) leaf extract on aluminium chloride (AlCl3) induced neurotoxicity in rats. Adult male albino Wistar rats were randomly arranged into 4 groups with 6 rats in each group. Group 1 was the control group, group 2 rats orally received 100mg/kg body weight of AlCl3for 25 days, group 3 and 4 comprise treated animals (*Ficus religiosa* leaf extract of 200mg/kg body weight and 300mg/kg body weight (per oral), respectively for 15 days) after the initial AlCl3 administration for 25 days. On the last experimental day after FR treatment, behavioural changes were studied in all animals by passive avoidance test. Later the animals were sacrificed and the brain was removed & processed for histological study. Neuronal assay in the hippocampus of the brain tissue was conducted by staining with cresyl violet. In both behavioural test and neuronal assay, significant difference ($p<0.001$) was seen when control and induced group AlCl3 were compared. Similarly, when AlCl3 administered rats were compared with FR extract treated rats,significant improvement ($p<0.001$) was observed directing towards neuroprotective potential of FR leaf extract in aluminium-induced neurotoxicity.

Keywords: *Hippocampus, Ficus religiosa, neurodegeneration, behaviour.*

Introduction

There are many factors for neurodegeneration and aluminium (Al) is one among them,which enters our body knowingly or unknowingly[1].Aluminium accumulates inthe hippocampus as well as frontal cortex of cerebrum. It can cause neurotoxicity, which increases the risk of neurological diseases likedementia and Alzheimer's disease (AD)[2,3].Al generates free radicals and is considered an attributing factor for the neurodegenerative disorders with alteration in behaviour and cognitive dysfunction[4,5]. It is also reported that Al causes loss of memory by producing inflammation in the brain[6]. AlCl3, when administered in male Wistar rats for 30 days, increased the rate of lipid and protein damage in the brain[7]. Al has been found in the neurofibrillary tangle and senile plaques in brain of ADpatients[8]. It is also believed that Al causes apoptotic loss of neurons, which is an indicator of neuronal degeneration in AD[9].

Though there are several drugs available, which can control the neurodegenerative diseases, on many occasions these diseases are not properly treated. Adverse effects from the long term use of recognized drugs is also a concern. *Ficus religiosa* is a large tree, which consists of heart shaped, long tipped leaves. It is commonly known as 'peepal tree'in India[10] and this has shown religious, mythological and medicinal importance[11]. FR has phytoflavonoidsand was used along with the antiepileptic drugs relieving the psychiatric and cognitive symptoms[12]. Aim of our pilot study is to elucidate the effect of FR leaf extract on AlCl3 induced neurodegenerative changes in the albino

Wistar rats through behavioural and histomorphological parameters.

Materials and Method

Extract Preparation: The FR leaves were washed with water, dried over the shadow for one month, and made into a coarse powder form by using the grinder. About 70 grams of dried FR leaves coarse powder with methanol was placed in a Soxhlet apparatus, which was then heated to reflux. Methanol was used as a solvent in ratio of 1:1 along with distilled water. The heater of Soxhlet apparatus was set at 50°C and extraction procedure was performed for three days[13], approximately 50 cycles. The silicon metallic balls were added on daily basis to identify the increased temperature. The extract was heated with Bunsen burner to evaporate methanol from the extract. The total dry extract was amounting to a yield of approximately 7%. This extract was kept in refrigerator (about 4°C) until further use.

Animals: The present study was carried on in-house bred male albino Wistar rats (12-16 weeks), weighing 200-250gms (at the commencement of the study) and they were given *ad libitum* food and water. The animals were accommodated in paddy husk bedded polypropylene cages, under controlled temperature, light and dark cycle (12:12 hours). Institutional animal ethics committee has given clearance for this investigation. The animals were maintained and used in accordance with the guidelines of government of India for the usage of laboratory animals[14].

Animal Grouping: The rats were randomly distributed in 4 groups, with 6 rats in each group. The grouping details are as below:

Group 1: Control group

Group 2: Rats orally received 100mg/kg body weight of AlCl3 for 25 days

Group 3: Rats orally received 100mg/kg body weight of AlCl3 for 25 days. This was followed by 200mg/kg body weight of FR leaf extract orally for 15 days

Group 4: Rats orally received 100mg/kg body weight of AlCl3 for 25 days, which was followed by 300mg/kg FR leaf extract orally for 15 days

Induction of neuronal degeneration: The group 2, group 3 and group 4 rats were given AlCl3 solution orally (100 mg/kg body weight) for 25 days to induce neuronal degeneration. The AlCl3 powder was mixed with distilled water and administered orally using oral gavage tube.

FR leaf extract treatment: The group 3 and 4 rats were treated orally with the FR leaf extract of 200mg and 300mg/kg body weight dosage respectively for 15 days. These group animals initially received oral AlCl3 for induction of neuronal degeneration.

Behavioural Study: *Passive avoidance test:* This behavioural test evaluates memory retention capability[15]. The apparatus had a large bright and a small dark area with floor having grid, which was attached to a shock source. On the 1st day of test, the rats were allowed to explore both the chambers for 5 minutes, which was followed by 3 test trials of 5 minutes each. The time spent in each compartment in each trial was noted. In the 4th trial, as soon as the rat moved into dark area, a foot shock was given and rats were replaced backin home cage. After 24 hours, rats were placed again in the test apparatus and their latency to enter the dark chamber was noted. Control group rats avoided moving into the dark chamber, as they remembered the shock stimulus given on previous day. Decreased latency of the rats to enter the dark chamber suggested reduced memory power in AlCl3 administered rats. The time spent in light chamber for each rat was noted in seconds and finally the mean value was calculated. This was done for all the groups individually and the data were expressed as mean ±SE. The analysis was done by using SPSS software (version 25). One-way ANOVA test was used to perform the comparison statistically. The 'p' value less than 0.001 was considered as statistically significant.

Histological Study: *Perfusion and brain removal:* Next day after the treatment with FR leaf extract, the animals were deeply anesthetized with sodium pentobarbital (40mg/kg body weight, given intraperitoneally). The heart was exposed by opening the chest cavity, followed by perfusion with 100-150ml of 0.9% normal saline through the left ventricle at a rate of 1ml per minute. This was followed by perfusion with 10% formalin at the same rate of flow. The brain was removed by dissecting cranial cavity in all the animals and kept in 10% formalin for 48 hours for further histological study.

Each brain was sectioned in coronal plane into two pieces and was kept in separate 10% formalin containers.

The posterior section was used in this study for the hippocampal neuronal assay. Standard histological tissue processing procedures were followed using different grades of alcohol and xylol. Paraffin blocks of the brain tissue were prepared and sections of 6-7µm thickness were taken using rotary microtome.

Staining: Cresyl violet is a reliable stain to study the morphological changes in the neurons as it highlights the structural features of it. This stain helps to count the number of neurons. In 100ml of distilled water, 100mg of Cresyl violet was dissolved and then 10% acetic acid is added to the same solution to reach a pH of 3.5 to 3.8.

Scoring: Six sections from each animal's brain was mounted serially on air-dried gelatinized slides. The slides were scrutinized with Nikon trinocular microscope (H600L) at 20X magnification. The imaging software NIS Elements Br version 4.30 was used to quantify the neurons. The number of viable neurons were counted in the CA3 region of both sides of hippocampus[16]. The cell count was expressed as the number of cells per unit length of the cell field (cells/250µm length) in hippocampus. The data is expressed as mean ±SE. The analysis was done using SPSS software (version 25). One-way ANOVA test was used to forstatistical comparison. The 'p' value less than 0.001 was considered statistically significant.

Results

Among all cornuaamonis (CA) regions of hippocampus, CA3 region showed maximum neuronal degeneration in group 2 rats which were induced with AlCl3($p<0.001$). Fig. 1A shows the normal neurons at the CA3 region of the hippocampus in control (group 1) rats. The degenerated neurons were identified in 50X50µ area by the disrupted cell membrane, pyknotic and peripheral nuclei or absent nuclei within the neuron (Fig. 1B). However, rats treated with FR leaf extract (group 3 & 4) showed significantly improved ($p<0.001$) number (Fig. 3) as well as quality of neurons (Figs. 2A and 2B). The quality of neurons was better than that of the AlCl3 induced group and they were with centrally placed nucleus and intact cell membrane. However, the difference was non-significant($p>0.05$) between group 3 and 4 with respect to the morphology of neurons in CA3 region of hippocampus (Fig. 3).

Similarly, the AlCl3 administered rats showed significantly decreased latency to enter the dark compartment (Figure 4, $p<0.001$) in AlCl3 administered rats (group 2) when they were compared with that of control group rats (group 1). The latency again was enhanced significantly (Figure 4, $p<0.001$) in FR extracted treated group of rats (group 3 and 4).However, there was no statistically significance difference in latency was observed between the animals of group 3 and 4 ($p>0.05$).

Discussion

Aluminium enters the body through drinking water, food, utensils, body deodorants and medicines[1]. Roskams and Connor opine that Al crosses blood brain barrier through certain receptors[17]. Al accumulation leads to deteriorated antioxidant defence mechanism and increased amyloid deposition in the brain[18]. Al toxicity also causes necrosis and apoptosis, both types of neuronal cell death[19]. Al neurotoxicity causes memory loss, both short term as well as long term, and reduces locomotor activity[20]. The present study displayed significantly decreased number of normal neurons in CA3 region of hippo campus in AlCl3 induced rats. The group 2 animals demonstrated chromatolysis of the neurons at the CA3 region. There was swelling of the perikaryon and eccentricity of the nucleus. These morphological features were suggestive of degeneration of neurons due to AlCl3. In the hippocampus CA3 region plays key role for memory consolidation, as suggested by Morris Maze study on mice[21]. The group 2 rats exhibited decreased latency period to enter the dark chamber, which was indicative of rats having dementia. Both these observations from the behaviour and microscopic study of the neurons indicated that Al has induced neuronal degeneration.

Aiyegoro and Okoh[22] warranted a thorough research for the competency of FR against neuro-inflammatory and neuropsychiatric disorders, as well as oxidative stress related disorders. AD can also be managed to some extent by the traditional usage of FR as suggested by Vinutha et al.[23]. The present study hypothesizes that FR leaf extract may exert neuro-modulatory effect, leading to alleviation of AlCl3 induced inflammation-driven neurodegeneration. Bhangale et al.[24] have shown the promising effect of FR leaves on Huntington's rat model. Petroleum ether extract of FR leaves disclosed beneficial effect in Parkinson's induced rats[25].

Conclusion

The present study has witnessed increased latency of the Al administered rats to enter the dark compartment after FR treatment (groups 3 and 4), demonstrating their improved memory. This improvement in behavioural change was co-relating with the significantly improved normal neurons in the CA3 region of hippocampus in

FR leaf extract treated rats. Both these physiological and micro-anatomical observations were indicative of neuroprotective property of FR leaf extract. Therefore, this study believes that FR leaf extract is effective in oral doses and it may alleviate the symptoms of AD. This can be further endorsed with a larger sample size and more study parameters. This inference adds to the existing therapeutic benefits of FR and offers a substantial evidence for its future medicinal application.

Abdominal Muscular Strength Endurance: Normative Reference Values for Children 11 to 15 Years of Age

Nayana Nimkar[1], T.K. Bera[2], Amritashish Bagchi[3], Ravi Narnolia[4]

[1]Director, Symbiosis School of Sports Sciences, Symbiosis International University, [2]Professor, College of Physical Education, Bharati Vidyapeeth, [3]Assistant Professor, [4]Student, Symbiosis School of Sports Sciences, Symbiosis International University, Pune, Maharashtra, India

Abstract

Introduction: One minutesitups is one of the most popular standardized test which is used to measure the muscular strength endurance of the abdominal muscles.

Objective: To develop the norms for 1 minute Situptest for Indian youth aged 11-15 years.

Methodology: For the purpose of the study a sample of 5000 male (13.14 ± 1.316 years) and 4000 female (13.31 ± 1.163 years) school going students were selected for the study. One minutesitups was used for measuring abdominal muscular endurance. Various statistical method were opted for analysing the relationship between the variables, normalization and visualization of data and the development of norms.

Results and Discussions: The results of the study indicated significant differences (p value < 0.05)in male category across all the age groups. Whereas, in female category there were only 3 significant differences (out of 10) found between age 14 – 15, 14 – 13 and 14 – 11. It shows that the muscular strength endurance for male students changed significantly across these 5 years as compared to female students, which were found to be more consistent. Urban students (Male and Female) were also found to be significantly higher in muscular strength endurance than rural students.

Applications: Norms are necessary to test, compare, analyze and evaluate one's strengths and weaknesses. The norms will guide and direct the Indian youth about their muscular endurance status. It will also help coaches and trainers to design a training plan accordingly.

Conclusion: Urban students are better than rural students in one minutesitups. Due to the physiological differences, the muscular strength endurance for male students was greater in all terms than the female students. Norms were developed for the Indian youth aged 11 – 15 years.

Keywords: *Norms, 1 minute Situp, Gender, Rural and Urban.*

Introduction

Over the past 20 years, the invigoration of research regarding physical activity and physical education has generated a greater understanding of its importance, and how they should be promoted[1]. "Physical literacy" has subsequently emerged as a concept that captures both the desire to participate in physical activity, as well as learning from it. The concept was initially proposed by Whitehead (2001), in response to concerns as to the direction of physical education and the alarming levels of physical inactivity across the life course (Hallal et al., 2012)[2,3,4]. Physical fitness is a good summative measure of the body's ability to perform physical activity and exercise, and it also provides an important summative indicator of health[5,6,7].

In addition to the health implications, physical fitness is an important determinant of success for many popular youth sports and athletic events[8]. Positive trajectories of HRPF in children and adolescents require an understanding of behavioral attributes and causative mechanisms that promote these outcomes[9].

One minutesitups is one of the most popular standardized test which is used to measure the muscular strength endurance of the abdominal muscles. In this study we aimed to examine and develop sit ups norms for children aged 11 to 15 years. During the sit-ups test, subjects repeatedly bend and extend the torso at the hip for a specific period of time hence, endurance of abdominal and hip muscles is largely related[10]. The simplicity of the sit-ups test that is not requiring special devices for it makes this test extremely practical. Since many modifications are made to sit-up exercises in an attempt to maximize the activation of abdominal muscles considered to contribute to trunkstability and minimize the compressive forces on the lumbar spine[11,12].

The normative standards for measuring muscular endurance will increase the utility of the test and improve the efficiency in the interpretation of the test score in several ways. It may also help in prescribing curriculum for maintenance and improvement of Muscular strength endurance. It will help the coaches and trainers to design a training schedule and to select students for higher performance. Norms will help in classification of the students according to their performance level and remedial training could be undertaken to bring students to a predetermined level.

There are two objectives of the study, first to develop the norms for 1 minute Situp test for Indian youth aged 11 – 15 years and second to compare the muscular strength endurance of Rural and Urban children.

Methodology

Selection of the participants: A total of 9000 (male 5000 and 4000 female) healthy school going students from different schools of Pune district were enrolled for the study. The age of all the participants ranged from 11 to 15 years(Male 13.14 ± 1.316 years; Female 13.31 ± 1.163 years). The participants had no history of any major disease and also had no injury prior to the test. Stratified random sampling technique was used to select the participants from 20 different schools (10 Urban schools and 10 Rural schools).Informed consent was obtained from the parents and permissions were taken by the schools for conducting the test.

Selection of the variables: For the purpose of the study,the performance in 1 minutesitups was selected as a dependent variable along with age, gender, BMI, and Waist Hip Ratio as independent variables.

Data Collection: The test was conducted on different days in twenty different schools. The directions about the process of test administration were explicitly determined and conveyed to each student prior to the test. On the day of data collection for each school, all the participants were assembled for a briefing of the testing procedure and an unique identification number were marked on their uniforms to simplify and facilitate procedures. All the participants were instructed to do 5 minutes of jogging before the test. Participants were also instructed to take light meal 2-3 hours before the test and refrain themselves from any energetic physical activity for that period. The 1 minute situptest is a standardized test to measure muscular endurance with high test retest reliability (0.98), moderately high inter apparatus reliability (0.71), high inter tester reliability (0.76) and validity (0.67) [13].

Statistical Technique: Descriptive statistics such as mean, Standard deviation, skewness, kurtosis, CV etc were used to summarize the nature of data. Histogram with mean and standard Deviation as a part of descriptive statistics were used for data visualization. Kruskal Wallis H test was used for comparing the situps performance of five different age group and Mann Whitney U test was used for comparing the situps performance of rural and urban students. It was also used to compare the situps performance of male and female students. Percentile and Stanine scale was used to develop norms. All the statistical analysis were done in SPSS version 24. The level of significance was set at 0.05.

Results and Discussion

After collecting 5000 male and 4000 female participants data for 1 minutesitups performance, data cleaning was done. A total of 661 data entries were found to be bad data, typing errors, wrong entries, outliers and extreme scores, which were removed from the final data set. This final data set used for the development of the norms consisted of 4848 male and 3491 female participants. Before removing the outliers and extreme scores a two-step approach for transforming continuous variables to normal method has been used. In step one, all the data for the selected variables were transformed into fractional rank for getting the uniformly distributed probabilities. The second step consisted of applying the

inverse-normal transformation to the results of the first step to form a variable consisting of normally distributed z-scores[14,15]. The descriptive statistics such as mean, standard deviation, skewness and kurtosis with their standard error are shown in the below table.It can be seen from the standard deviation value in table 1 that, the 1 minutesitups test data points are spread out over a wider range of values. Even it can be seen from the table that female participants have higher variability (CV) in the 1 minutesitupsas compared to male participants. After the transformation of data and removing the outliers and extreme scores, the data set for the beep test became normal as the skewness and kurtosis values were less than twice their standard error.

Table 1:Gender wise descriptive statistics for 1 minutesitups performance

Descriptive Statistics	Gender	
	Male (n = 4848)	Female (n = 3491)
Mean	22.2096	15.6009
Std. Deviation	10.35956	8.50159
Coefficient of Variation (CV)	.46644	.54494
Skewness	.014	.034
Std. Error of Skewness	.037	.041
Kurtosis	-.079	-.132
Std. Error of Kurtosis	.073	.083

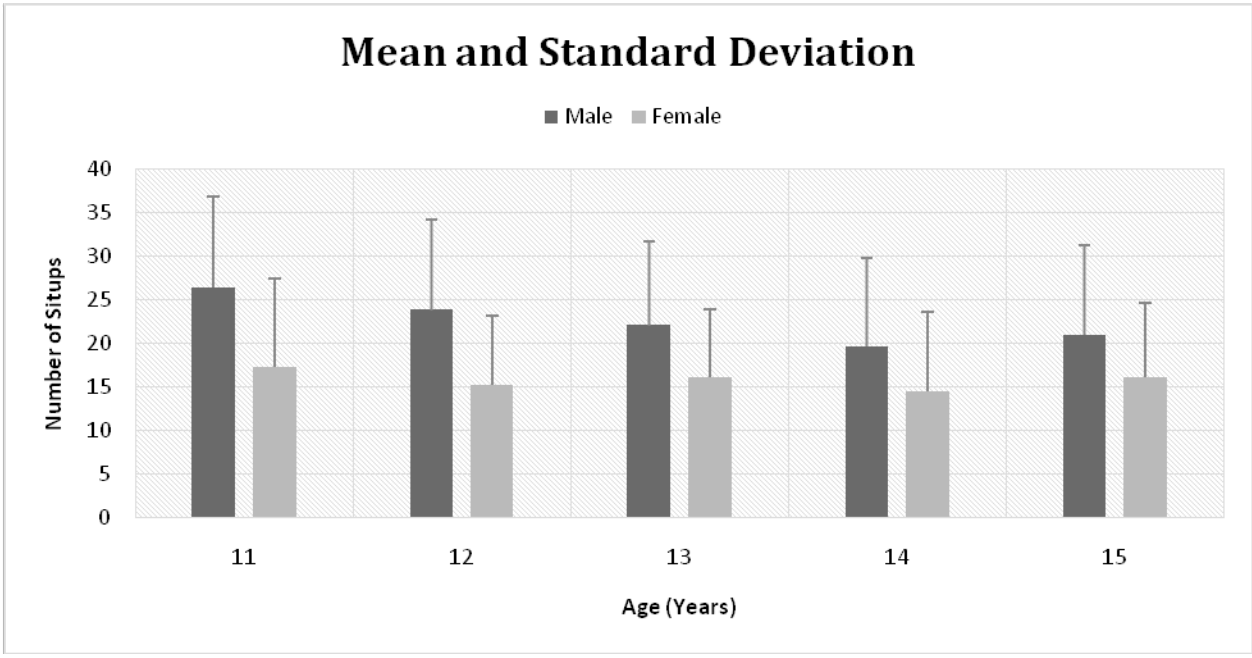

Figure 1:Mean and Standard deviation for visualizing the gender wise comparison of 1 minute sit ups performance across all the age groups

The results of Kruskal Wallis H test shows a significant (p value = .000) difference while comparing the situps performance of five different age group (Genderwise). As Kruskal Wallis H test won't show which groups were different, Mann Whitney U test was performed. Bonferoni corrections (level of significance divided by number of comparison) was used to reduce the type 1 error. It was found that in male category there were significant differences among all the age groups. Whereas, in female category there were only 3 significant differences (out of 10) found between age 14 –15, 14 – 13 and 14 – 11. It shows that the muscular strength endurance for male students changed significantly across these 5 years as compared to female students, which were found to be more consistent.

Also, significant differences (p value = .000) were found between male and female students in across all age categories. The result shows that even from 11 to 15 years male abdominal muscular strength is more than of female, this is due to the sex-specific and age-specific differences[16]. Gantiraga et al. (2006) has determined

that strength in boys before puberty is more than girls, although the difference is less and it keeps on increasing after puberty[17]. Kriemleret al. (2008) has found that in children aged 6-13 years, boys had greater muscle strength and were more physically active than girls[18]. In this study the age range of all the participants were from 11 to 15 years. Although, the onset of puberty varies from person to person. Puberty usually occurs in boys between the ages of 12 and 16, while in girls it generally occurs early, between the ages of 10 and 14[19].

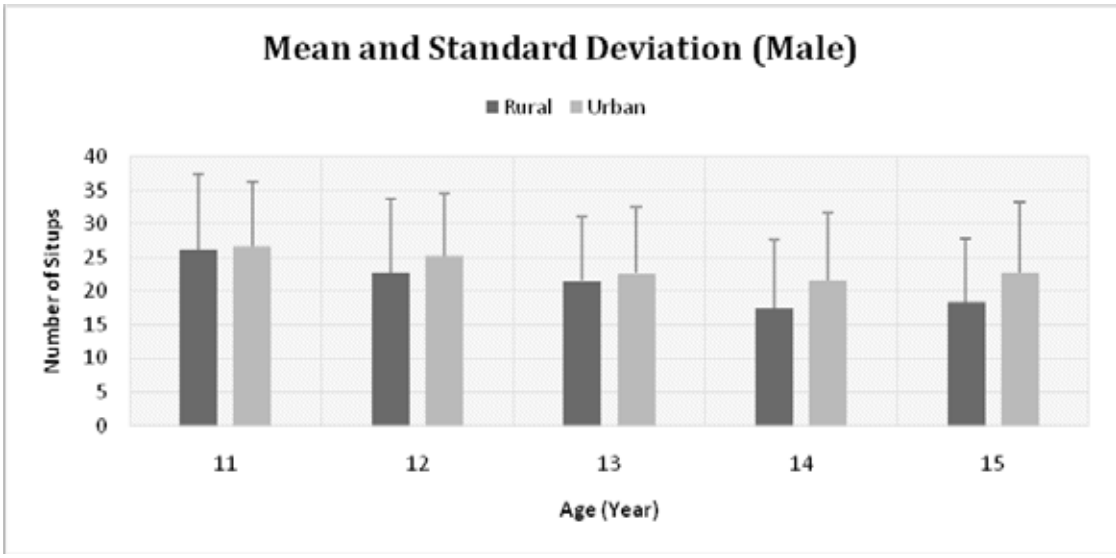

Figure 2: Mean and Standard deviation for visualizing the 1 minute sit ups performance of rural and urban male students across all the age groups

A comparative analysis has been carried out to investigate the differences in the abdominal muscular endurance of rural and urban students. It can be clearly seen from figure 1 and 2 that urban children have more abdominal strength endurance than rural children. Mann Whitney U Test was performed to check whether these differences are real. It was found that except 2 male age categories (11 & 13 years), in all other categories abdominal muscular strength endurance of urban students were found to be significantly higher than rural students. In female, significant differences were found in all the age categories, where urban students score higher than rural students.

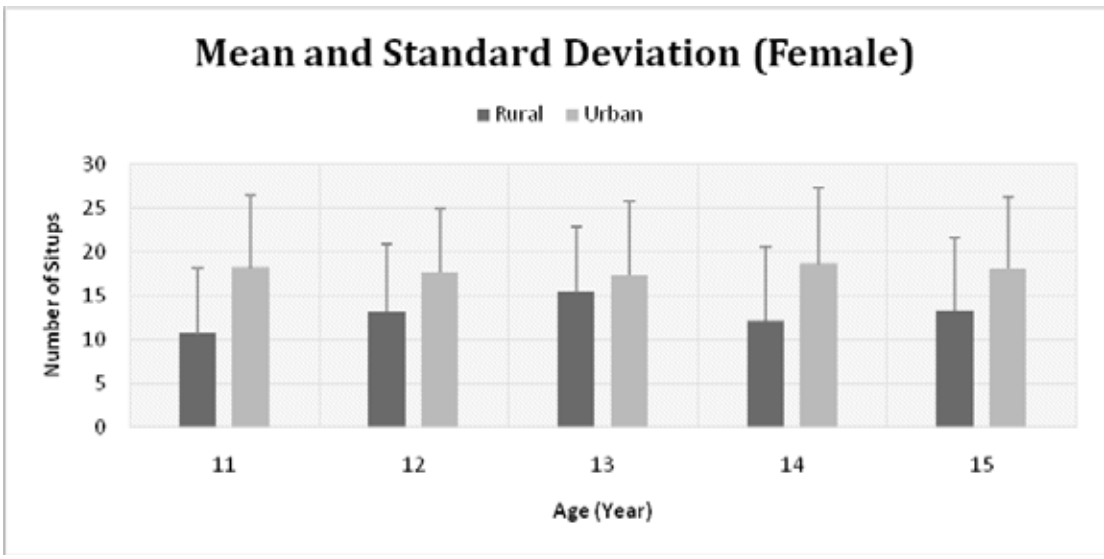

Figure 3: Mean and Standard deviation for visualizing the 1 minute sit ups performance of rural and urban male students across all the age groups

Studies have shown that in some physical parameters urban children are found to be better as compared to the rural children, especially in developed countries. These differences are due to the technological advancements, emerging trend of fit and healthy lifestyle and also awareness about importance of fitness, nutrition and health in schools. Most of the Schools in urban areas have better transportation, sports facilities, advance equipments and playgrounds[20,21,22,23].

Table 2: Percentile values for Male and Female participants

Percentiles	Male		Female	
	Transformed Score	Raw Score	Transformed Score	Raw Score
4th	3.93	5	2.3850	3
22nd	14.4351	13	8.9491	8
76th	29.5260	30	22.0521	22
96th	40.4175	40	30.2119	30

For normalization, we have transformed the entrie data set by using two-step approach as mentioned above. Standard nine (Stanine) scale was used to develop the norms. Only four Percentile values were taken such as 4th Percentile, 22nd Percentile, 76th Percentile and 96th Percentile.

Table 3: Sit-up norms for youth aged 11-15 years

Gender	Age	Very Poor	Poor	Average	Good	Very Good
Male	11-15	< 5	5 – 13	14 – 30	31 – 40	> 40
Female	11-15	< 3	3 – 8	9 – 22	23 – 30	> 30

The developed norms shown in table 3 can be used for analyzing and evaluating abdominal muscular strength endurance (one minutesitup performance) of male and female students aged 11-15 years. It can be used to design training programmes by coaches or trainers for improving performance. These norms can also be used to compare the situps performance with other countries.

Conclusion

The purpose of the study was to develop the one minutesitupsnorms for youth aged 11 – 15 years and to compare the muscular strength endurance of urban and rural students. Urban students were better than rural students in one minutesitups. Due to the physiological differences, the muscular strength endurance for male students was greater in all terms than the female students. Standardized norms are necessary to test, compare, analyze and evaluate one's strengths and weaknesses. The developed norms will guide and direct the Indian youth about their muscular strength endurance status. It will also help coaches and trainers to design a training plan accordingly. More research needs to be carried out in the development of norms, as the population in India is very diverse in nature. In this study, we have only focused on the age range of 11-15 years. There is a scope to develop norms for other age range with similar characteristics of the population.

Functional and Aesthetic Rehabilitation of Missing Tooth by Using Immediate Implant Placement: A Case Series

Nayana Prabhu

Associate Professor, Department of Prosthodontics and Crown & Bridge, Manipal College of Dental Sciences, Manipal, Manipal Academv of Higher Education, Manipal, India

Abstract

Replacing a single or multiple tooth pose various clinical challenges to the clinician during prosthetic rehabilitation. This clinical challenge is more complicated with fixed dental prosthesis when there is an insufficient space for the pontic. Replacing the tooth in these quantifiable situation is best suited by implant supported prosthesis. In the presented case series, we present three such cases where missing teeth were restored with implant supported prosthesis immediately post extraction to satisfy patients aesthetic as well as functional needs.

Keywords: *Immediate Implant, Post extraction, Tooth replacement, Esthetic zone.*

Introduction

In this current era of advancement with newer techniques to restore single or multiple teeth gives ease of restoring missing teeth with optimum to ideal results. However, occasionally clinicians face clinical challenges depending on the kind of treatment cater to the patient. Fixed denture prosthesis provide adequate function but compromise esthetics due to small pontics. In some cases, maintenance of hygiene is also difficult due to ridge lap design of pontics and there is need to prepare adjacent abutment teeth. Similarly in a removable denture prosthesis esthetics and hygiene is acceptable but functionally it is inferior to a fixed prosthesis. [1] Due to these existing shortcomings related to fixed and removable prosthesis, the dental rehabilitation is growing with implant supported fixed prosthesis since last few decades. Longitudinal studies have shown dental implants to have a success rate of above 90%. Some prospective studies stated that implant survival rate varied from 84.9% to 100%. [2] Conventional implant placement guidelines advocate a period of 3 months post extraction for soft and hard tissue healing followed by another 3 months and 6 months for loading the implant in mandible and maxilla respectively. [3] This accounts to almost a year for single tooth replacement which is unacceptable functionally, esthetically and psychologically from the patients perspective view. Thus, a new protocol of immediate implant placement post extraction was introduced; wherein the time period of treatment was reduced to 3-4 months required for osseointegration. In some cases, depending on the pre-load or the torque achieved immediate provisionalization has produced good results. Plethora of research analysis have documented excellent results in terms of esthetics and optimal preservation of hard and soft tissues by immediate implant placement.[4,5,6]

Case Report: In this case article, we narrate a series of three cases of tooth replacement by immediate implant placement post extraction.

Case 1: Single tooth replacement with immediate implant in the anterior esthetic zone.

A 53yr old female presented with a history of trauma with respect to maxillary left central incisor about 5yrs back. Post failure of an attempt for an endodontic

treatment patient was advised to undergo extraction due to poor prognosis pertaining to that tooth. On examination there was Grade II mobility, spontaneous bleeding, deep periodontal pocket and suppuration. Radiographically, the tooth showed a periapical lesion with a radiopaque restoration in the pulp chamber. Some amount of external root resorption had also occurred (Fig 1).

After an atraumatic extraction of the tooth, the socket was thoroughly debrided, granulation tissue was removed and rinsed with sterile saline. A 4.3 × 15-mm Nobel Replace Select implant (Nobel Biocare, Sweden) was placed andtemporization with Bisacryle composite material was done. Bio-Oss collagen graft (Bio-Oss® Collagen) was deposited between the surfaceof the implant and the wall of the socket.[7,8] Shade selection was done. Stage 2 surgery was performed 7 months later and at re-entry, the graft was found to be properly integrated with the host bone. The implant was immobile, one of the criteria for success according to the parameters established by Albrektsson et al.[9] For the final esthetic result cement retained porcelain fused metal crown was cemented over an esthetic abutment. Post cementation radiograph revealed properly seated crown over the integrated implant. (Fig. 2)

Case 2: Single tooth replacement with immediate implant in the posterior region.

A 25yr old male patient presented with fractured tooth resulting in insufficient remaining root length with respect to maxillary right second premolar. Clinical examination revealed non-vital tooth fractured at the gingival margin (Fig 3). Radiographic examination revealed endodontically treated tooth where obturation was short of root apex. Endodontic retreatment had a questionable prognosis and hence the tooth was indicated for extraction.

After atraumatic extraction of the tooth, the socket was examined. All the walls of socket was found to be intact. The socket was thoroughly curetted and debrided for any granulation tissue and rinsed with normal saline. A 4.3 x 11.5mm Nobel Replace Select implant (Nobel Biocare, Sweden) was placed taking anchorage on the palatal wall, about 3mm beyond apex and at the crest of the ridge. Cover screw was placed and the jumping distance on the buccal side was covered with synthetic hydroxyapatite bone graft (SyboGraf™ Plus). The flaps were completely approximated by interrupted sutures.

The second phase surgery was done 6 months later the earlier surgical procedure. The second-phase healing abutment was placed then the flaps were sutured. After 2 weeks on removal of healing abutmenta well formed gingival cuff surrounding implant could be seen. The implant was restored with a cement retained porcelain fused crown(Fig 4). Clinical examination with radiographs demonstrated successful restoration of the prosthesis.

Case 3: Teeth replacement with single immediate implant in esthetic zone.

A 26yr old female patient presented with endodontic failure and root fracture with respect to maxillary right canine (Fig 5). Patient gave history of loosening of endodontic post with the crown followed by fracture of crown. Radiographic examination showed fractured tooth, obturated canal at the apex with prepared post space and congenitally absent adjacent lateral incisor. As the prognosis of endodontic retreatment was poor it was decided to extract the tooth.

Replacement of maxillary canine with implants immediately post extraction is a challenging proposition due to its long roots and thin facial bone. Careful atraumatic extraction was carried out with the help of periotome. The extracted tooth socket was examined for any facial bone fracture, debrided and measured to determine the length of implant. A 4.3 x 13mm Nobel Replace Select implant (Nobel Biocare, Sweden) was placed taking anchorage on the palatal wall and at the crest of the ridge (Fig 6).

Second phase surgery was done 6 months later implant placement. Esthetic abutment was placed. A porcelain fused metal crown with respect to canine and a splinted cantilevered crown with respect to lateral incisor was cemented. 7 month post-operative radiograph presented a successful osseointegrated implant prosthesis.

Discussion

The placement of immediate implants has become a routine clinical procedure. The idea of immediate implantation and provisionalization for replacing a tooth in the premaxilla are associated with some clear benefits: As it combines tooth extraction, implant surgery, and restorative treatment, the time gain can be optimized.[10] The success rate is comparable to data published for single-tooth implants placed according to the standard

protocol in healed sites.[11] The main benefits of placing immediate implants are the decrease in time of therapy, decrease in surgical periods and conservation of the bone and gingival tissues. Larger amount of bone resorption happens during the first 6 months subsequent to tooth extraction, if an implant is placed or a socket augmentation procedure performed. The timely maintenance of the gingival form significantly facilitates the peri-implant gingival tissue esthetics by preserving support for the interdental papillae. [12] With respect to the distance between the socket wall and the implant, it was stated that if the jumping distance is above 2mm, grafting is suggested. Minorspaces could heal naturally. From the reviewed studies, it looks that ISQ values are slightly lesser in immediately placed implants compared to implants placed in pristine bone. However, these changestend to vanish overtime. ISQ values seem to risegradually during healing over the first few months in immediate implants.[13] Immediate implants placed with a submerged or a non□submerged method display comparable success and survival rates with comparable behaviour of peri□implant hard and soft tissues, with a mean of 1mm of vertical recession of the papillae and the midfacial gingival margin when matched with the soft tissue levels before tooth extraction. Substantial decrease of keratinized tissue was witnessed when using the submerged method [14]. It should be emphasized that the cause of the infection must be the diseased tooth, be it periodontally or endodontically involved, or the result of fractureand that during surgical treatment the cause of the infection, ie, the tooth, is removed. Another important part of the surgical treatment is the complete, thorough debridement and rinsing of the alveolus. If proper preoperative and postoperative care is provided, immediate implants can be placed successfully into chronically infected sites.[15]

Fig 1: Periapical lesion with a radiopaque restoration

Fig 2: Cement retained porcelain fused metal crown

Fig 3: Non-vital tooth fractured at the gingival margin

Fig 4: Cement retained porcelain fused crownwith respect to maxillary right second Premolar

Fig 5: Endodontic failure and root fracture with respect to maxillary right Canine

Fig 6: 4.3 x 13mm Nobel Replace Select implant (Nobel Biocare, Sweden) was placed

Conclusion

Early implantation helps in preservation of the alveolar anatomy and maintain the bony crest. The immediate restoration of dental implants engaged into the fresh extraction sockets has proved to be safe and probable procedure. The success rate, radiographic and clinical outcomes are similar to those found following the regular procedure. Short time survival rates and clinical results of immediate and delayed loaded implants are equivalent and similar to those of implants engaged in healed alveolar ridges. Thus, immediate implant placement has become a significant part of implant therapy which provides timely esthetic implant restorations.

Assessment of Physical Activity and Sedentary behaviour among Overweight Adolescents in Selected Urban Schools of Puducherry

P. Sumathy

Professor cum Vice-Principal, Kasturba Gandhi Nursing College, Sri Balaji Vidyapeeth (Deemed-to-be-University), SBV Campus, Pillaiyarkuppam, Puducherry 607 402 & Ph.D. Scholar of Sri Ramachandra Institute of Higher Education & Research, Chennai

Abstract

Introduction: Physical inactivity is increasing among children and adolescents and may be contributing to the increasing prevalence of overweight and obesity. Only 30% of adolescents perform sufficient physical activity . Sedentary behaviours, especially watching TV, sitting at the computer and playing video games/ mobile phones, are increasing among children. Aim: To assess the level of physical activity and sedentary behaviour among overweight adolescents and to examine the association between physical activity, sedentary behaviour and screen time with BMI.

Materials and Method: Participants were 140 overweight adolescents aged 11-14 years from 2 Urban schools of Puducherry. They were assessed for their physical activity and sedentary behaviour by using Modified Physical Activity Questionnaire -Older children and Adolescent Sedentary Activity questionnaire. The analysis was carried out using SPSS Statistics Version 25. Linear Regression coefficient was used to examine the association between physical activity, sedentary behaviour and screen time with BMI.

Results: More than half of the overweight adolescents (58%) engaged in low levels of physical activity with females being more physically inactive than males. Likewise the mean time spent in sedentary behaviour was more than 12 hours/day with a SD of 3.83. The mean time spent in screen time was 8 hours/day with a SD of 2.56. Use of smart phones contributed largely to the screen time that was significant at $p<0.001$. Linear Regression analysis implies that screen time was positively associated with BMI at $P<0.05$.

Conclusion: Overall, the current study has indicated a low prevalence of physical activity and high sedentary behaviour among overweight adolescents.

Keywords: *Physical activity, sedentary behaviour, adolescent, overweight, obesity.*

Introduction

World Health Organization defines physical activity as any bodily movement produced by skeletal muscles that requires energy expenditure including activities undertaken while working, playing, carrying out household chores, travelling, and engaging in recreational pursuits.[1] Physical inactivity is increasing among children and adolescents and may be contributing to the increasing prevalence of overweight and obesity. Modern environments and technological advancements have changed the way we live. Globally, 81% of adolescents aged 11-17 years had insufficient physical

Corresponding Author:

activity in 2010[2]. In India, prevalence of insufficient physical activity among adolescents aged 11- 17 years was 71.6% and 69.6% among girls and boys respectively[3]. Overweight children and adolescents are more likely to become obese and to develop noncommunicable diseases (NCDs) during adulthood [4]. Physical activity in young people has become a major issue in public health as evidence emerges on the important role of physical activity in many health conditions, including overweight and obesity, type 2 diabetes, cardiovascular disease risk, skeletal health, and mental health. In particular, the issue of obesity in youth, and the link between this condition and type 2 diabetes, as well as the increases in diabetes [5] is topical and currently demanding much attention in physical activity research.[6]

Reduction in physical inactivity would reduce between 6% to 10% of the major NCD's and increase life expectancy[4] . Adequate levels of physical activity throughout an individual's life ensure an optimal state of health. Only 30% of adolescents and 10% of adults perform sufficient physical activity to facilitate proper physical, psychological/mental and emotional development. International data published in the recent Lancet Physical Activity Series reports that 80% of 13–15 year olds do not meet the current physical activity recommendations of 60 minutes of moderate to vigorous physical activity per day, and also highlights the need for more physical activity.[7] Sedentary behaviours, especially watching TV, sitting at the computer and playing video games/mobile phones are increasing among children in developed and developing countries .This trend is a major public health problem because sedentary lifestyle in childhood has been found to increase the risk of chronic diseases in adulthood.[8]

The aim of this study was to assess the level of physical activity and sedentary behaviour among overweight adolescents and to examine the associations between physical activity, sedentary behaviour and screen time with BMI.

Materials and Method

Descriptive Research design was used for the study. Participants were 140 overweight adolescents aged 11-14 years from 2 Urban schools of Puducherry. They were assessed for their physical activity and sedentary behaviour using the following tools.

Part I: Consisted of the socio-demographic data of children which included age, type of family, standard of education, educational status of parents, mode of transport to school, BMI etc.,

Part II: Modified Physical Activity Questionnaire-Older Children (PAQ-C) was used for the study. The PAQ-C is a self-administered, 7-day recall instrument. It was developed to assess general levels of physical activity throughout the week for students from 11 to 14 years of age. The tool consisted of 10 items. The activity score is between 1 and 5 for each item excluding item number 10. The mean of the 9 items, results in the final PAQ-C activity summary score.[9] A score of 1 to 2 indicates low physical activity, 3 moderate physical activity and a score of 5 indicates high physical activity.

Part III: Adolescent Sedentary Activity Questionnaire (ASAQ) was used for the study which assessed the time spent in a comprehensive range of sedentary activity outside of school hours. Students were asked to think about a normal week, during school term, and to report how long they usually spent in 11 different sedentary behaviours before and after school on each day of the week and on each day of the weekend. The time spent in sedentary behaviours were summed across weekdays and weekends to obtain the total time spent in doing sedentary behaviours per day.[10] A score of >4 hours/day indicated high sedentary behaviour.

The overweight children who fulfilled the inclusion criteria were selected and informed consent was obtained from the mothers and assent from the adolescents. The adolescents were administered the physical activity questionnaire and were asked to find out the level of physical activity for the last 7 days .Similarly the adolescents were administered the ASAQ and were asked to write down how much time they spent in sedentary behaviour outside school hours both during the weekdays and weekends. The analysis was carried out using SPSS Statistics Version 25.

Results

Socio-Demographic Variables: Out of 140 overweight children 30% were in the age group of 11 years, 35% were in the age group of 13 years. 56.6% were females and 40.6% were males. 26.4% were in 8th standard and majority 34.3% were in 9th standard. 77.1% were from nuclear families and majority 37.9% were from upper middle class. Almost 80.7% were non vegetarians. Most of the students 40.7% came to school by two wheeler and 57.9% slept for 8 hours. The mean BMI of overweight children was 23.271 with a SD of 1.399.

Table 1: Distribution of level of Physical activity among overweight adolescents N=140

Level of Physical Activity	Frequency	Percentage	Male N(%)	Female N(%)	Mean	Standard Deviation
Low (1-2)	82	58.6	32(55%)	50(61%)		
Moderate (3)	48	34.3	21(36%)	27(32%)	2	0.76
High (4-5)	10	7.1	5(9%)	5(6%)		

Concerning physical activity most of the children 82 (58.6%) engaged in low levels of physical activity with more females being physically inactive than males. (61%versus 55% respectively). 34.3% engaged in moderate level of physical activity. Only 10(7.1%) engaged in high levels of physical activity. The mean physical activity was 2 with a standard deviation of 0.76 (Table 1).

Moreover nearly 50% of the children did not engage in physical activity either during recess or lunch break. Only 30% engaged in physical activity right after school 5 times a week, however most of the children 92% were active during Physical Education Classes.

Table 2: Distribution of time spent in sedentary behaviour and screen time among overweight adolescents N=140

Variable	Frequency	Percentage	Mean (SD) hours/day
Sedentary behaviour			
Low<4hours/day	3	2.1	12(3.83)
High>4hours/day	137	97.9	
Screen time			
< 2 hours/day	5	3.5	8(2.56)
>2hours/day	135	94.4	

Table 2 implies that 137(97.9%) of the overweight children had a sedentary behaviour of >4 hours/day and only 2% had less sedentary behaviour. The mean time spent in sedentary behaviour was 12 hours/day with a SD of 3.83.

94% of the overweight children spent more than 2 hours/day in screen time which included watching television, using smart phones for games, playing video games and the most common was using smart phones for games at $p<0.001$ level.

Table 3: Regression coefficients for Physical activity, sedentary behaviour, screen time and BMI

Variable	BMI
Physical activity	0.992
Sedentary behaviour(Non TV leisure time)	0.079
Screen time (watching TV, playing video games, using mobile phone for games)	0.041*

*$p<0.05$

The association between physical activity and sedentary behaviour examined by linear regression with BMI implies that physical activity and non TV leisure time were not associated with BMI while screen time that included watching TV, using mobile phones were positively associated with BMI. ($p<0.05$).

Discussion

The study findings revealed that out of 140 children nearly 60% of the children engaged in low physical activity with females being more physically inactive than males. This implies that children are becoming more sedentary in nature mainly due to media and smart

phones. The findings corroborate with a similar study findings where nearly 44.3% of the adolescents had low physical activity levels, with more females 55% being physically inactive than males.[11] These findings were also in accordance with studies conducted in Mangaluru, Puducherry and Punjab.[12-15] The reasons probably might be that females are not allowed to play outside their homes.

50% children did not engage in physical activity either during recess or after lunch. This possibly could be that they wanted to finish their homework or were lazy or not motivated by their teachers. The findings are consistent with a similar study where only 38% of the children played hard at the time of recess and 43% out of 100 sat down normally at lunch.[16]

The study findings also revealed that only 30% of the children engaged in some form of physical activity right after school. The reason might be that nowadays right after school children are engaged with some other classes or watch television and while away their time in sedentary behaviours. The findings are supported by a similar study where the findings indicates that the late evening segment was significantly less active and showed the highest proportion of sedentary time.[17]

The present study also demonstrates that 98% of the children were highly sedentary > 4hours/day out of the 8 hours free time that they had out of school hours. The findings are similar to a study where 54.1% were highly sedentary.[18] The mean time spent in screen time which included watching television, using computers/laptops for fun and playing with smart phones was 8 hours/day, with the most common being the use of smart phones $p<0.001$, followed by watching television and use of computers. This probably might be that nowadays smart phones are seen in the hands of every child which has led to its addiction[19].

Conclusion

Overall, the current study has indicated a low prevalence of physical activity and high sedentary behaviour among overweight adolescents. This implies that children should be motivated to engage in physical activity for at least 60 minutes a day and prime focus should be on reduction of screen time as it is primarily associated with obesity. Daily device-free social interactions and outdoor play should be encouraged. In addition, parents/teachers should be supported to devise and enforce appropriate screen time regulations and to model healthy screen-based behaviours.

Effect of Activation of Deep Neck Muscles as an Adjunct to Vestibular Rehabilitation in Vertigo

Anagha A. Deshmukh[1], Suraj B. Kanase[2]

[1]Intern, [2]Associate Professor, Department of Neurosciences, Faculty of Physiotherapy, Krishna Institute of Medical Sciences Deemed to be University, Karad, Satara, Maharashtra, India

Abstract

Aim: The study was conducted to find effect of activation of deep neck muscles as an adjunct to vestibular rehabilitation in vertigo.

Materials and Method: A total 20 subjects (9 males and 11 females) between 18-30 years diagnosed with Vertigo were selected for study considering inclusion criteria. Subjects were grouped into Experimental group (Group A), Control Group (Group B). Group A received exercises for deep neck muscle activation along with vestibular rehabilitation and group B received Vestibular rehabilitation. Each session was conducted for 30 minutes duration, 3 days per week for 4 weeks. Outcome assessment used was Dizziness Handicap Inventory (DHI), Motion Sensitivity Quotient (MSQ) which was assessed pre, post exercise session. Statistical analysis was done using unpaired t test.

Result: Within group comparison-Pre-intervention,Post-intervention Mean ±SD of Dizziness Handicap Inventory (DHI) of group A was 37±6.48 and 23.6±8.09 respectively. In DHI there was statistically extremely significant difference with p-0.0003 and t-5.57. Group B pre and post intervention mean±SD of DHI was 38.6±3.27 and 23.6±5 respectively which was statistically not significant with p- 0.0786 and t-1.98. Pre and Post Mean ± SD of MSQ of Group A was 30.82±5.75 and 9.72±4.83 respectively. Post treatment extremely significant improvement was noted according to the p value-<0.0001, t value 16.95 and Group B was 30.62±7.36 and 25.28±7.19 respectively which was statistically not significant with p-0.075 and t- 2.013.

Between group comparison-Post intervention mean ±SD DHI was 23.6±8.09 and 35.2±5 respectively which was statistically extremely significant with p-0.0012 and t- 3.85 with decrease in disequilibrium, dizziness and limitations in daily activities. MSQ post intervention mean±SD was 9.72±4.83 and 25.28±7 which was statistically extremely significant with p<0.0001 and t-5.67 with decrease in balance, functional mobility impairments.

Conclusion: Activation of deep neck muscles as an adjunct to vestibular rehabilitation in vertigo had significant effect in improving postural stability with balance, functional mobility, reduced impact of symptoms on daily activities. So, this study accepts alternate Hypothesis.

Introduction

Vestibular dysfunction is characterized by vertigo, imbalances causing disturbances and postural instability.[1] Dizziness is one of the common terminology describing several symptoms like Vertigo, light headedness, disorientation, etc., Commonly occurring in older individuals approximately 30%,

women are affected by 36% more than men 22%.[2] Rotatory movement either of the self or surroundings is called Vertigo.[2]

Dizziness may occur due to various diseases or disorders, causes of which can be Otological- middle ear disease, unilateral peripheral vestibular dysfunction, benign paroxysmal positional vertigo (BPPV), bilateral vestibular failure, Meniere's syndrome;Neurological-cerebellum, cranio-cervical junction,cortex issues, 7th cranial nerve damage.

Active neuronal changes in brainstem, cerebellum in response to sensory conflicts due to vestibular system pathology alters vestibular functions.[3]Vertigo refers to illusion of self-motion on standing/sitting i.e. sense of spinning/falling due to alteration in the signals ascending vestibular nerves to vestibular nuclei.[4] Integration of signals from vestibular system, visual system, neckproprioceptors, trunk aid in maintaining balance, equilibrium.[5] Dysfunction of cervical spine, neck injuries, whiplash, cervical degeneration is main cause of dizziness.[5]

In upper cervical region, neck pain, reduced proprioception of cervical region leads to dizziness which can be initiated due to end range movements of cervical spine. Pain, reduced cervical joint ROM, uncontrolled movements leads to deep cervical muscle insufficiency which indeed results in altered structure of deep neck muscles.[6]

Cervical spine disorders not being highlighted in locomotor system dysfunction, deep neck flexors play an important role. Disequilibrium, vertigo, dizziness occurs due to alteration in locomotor system dysfunction. [7]

Altered performance of cervical spine muscles results in impaired balance between posterior neck aspect and deep cervical flexors (DCF) with improper posture, alignment of the cervical spine leading to dysfunction and neck pain.[8]To reduce dizziness and improve proprioception specifically for reducing neck pain, DCF activation regimes- gaze stability exercises, head and trunk control exercises and co-ordination of hand and eye exercises are being focused. Studies suggest that exercises for activation of deep cervical muscles improve altered neuromuscular control of the cervical flexors, reduces provocation of dizzinesssymptoms.[8]

The main aspect of vestibular rehabilitation is graded exercise program including body, head/eye movements reducing vestibular dysfunction thereby, eliminating fear, gaining confidence.[9] The goals of vestibular rehabilitation mainly include education of patient about symptoms,balance training, Limiting motion provoking symptoms,Improve general conditioning, reduce disability etc.[10] In cervical spondylosis, cervical zygapophyseal joints are under mechanical stress causing poor balance, dizziness linked with spinal degeneration.[11]

Chronic dizziness is accompanied by anxiety, hyperventilation, neck pain caused by attaining a steady posture to avoid provocation of symptoms.[12]

BPPV is described as episodes of vertigo on altered head position. Posterior canal BPPV occurs in 90% of cases whereas lateral BPPV 8% of the cases.[13] Diagnosis of posterior canal BPPV is done with history of vertigo on changing head positions, nystagmus on performing Dix Hallpike test which determines semi-circular canal dysfunction and considered a gold standard test. Diagnosis of lateral BPPV is done with history of vertigo with changes in head position, presence of horizontal nystagmus on performing supine roll test.[11,13]

Poor balance, postural issues due to provoked head movements are disabling for Vertigopatients having adverse effect onquality of life and health. It is necessary to improve stability of surrounding neck structures to improve strength of the muscles which would aid in attaining reduction of symptoms triggered on performing head movements, postural stability and achieve balance.

Materials and Methodology

Study type-Experimental study, Study Design-Comparative study (pre-treatment and post-treatment), study duration-3 months,Place of study- Physiotherapy OPD, KIMS Hospital, Karad, Sample size-20,Sampling Method-Simple random sampling.

Inclusion Criteria: Subjects diagnosed with dizziness or vertigo secondary cervical pathologies like stenosis, facet osteoarthritis, disc herniation, spondylosis, BPPV,Gender- Male, Female.

Age group 18 -30 years.

Exclusion Criteria: Subjects with a non-vestibular cause of dizziness,progressive central disorders,Diabetes Mellitus, Hypertension.

Outcome Measures: Ethical Clearance was obtained from Institutional Ethical Committee KIMSDU (0368/2018-2019). Demographic data was collected. Procedure was explained to included subjects, written consent was taken from patients willing to participate and were enrolled into control and experimental group (10 subjects each) by simple random sampling. Pre-assessment was done using DHI (test retest reliability r = 0.97, good internal consistency reliability r = 0.89)[14] and MSQ[14] [ICC]=0.99 and test sessions (ICC=0.98 and 0.99) following which the control group received Vestibular rehabilitation and Experimental group received exercises for activation of deep neck muscles with Vestibular rehabilitation. Post test subjects from both the groups were assessed for DHI and MSQ. Results were analyzed on the basis of differences between pre-assessment and post assessment.

Subjects in the Experimental group (group A) received Vestibular Rehabilitation along with exercises for activation of deep neck muscles for 4 weeks (3 days per week 30 minutes per session).

1. Gaze Stability Exercises.[14]
2. BPPV treatment Techniques[14]
   (a) Canalith maneuver
   (b) Liberatory Maneuver
   (c) Brandt Daroff Exercises[14]
3. Balance exercises and progressions [14,15]
   (a) Begin with standing, feet shoulder width apart and arms across the chest. Progression-Bring feet together, close eyes and stand on cushion/ foam.
   (b) Begin with ankle sways: Medial, lateral, anterior, posterior. Progress to Circle sways with eyes closed.
   (c) Walk with heel touching toe on firm surface. Repeat the exercise on carpet
   (d) Walk 5 steps and turn 180 degrees left and right. Progress with closed eyes making smaller turns.
   (e) Walk and move the head side to side, up-down. Count backward from 100 by threes.

Exercises for activation of deep neck muscles[16]:

Isometric Exercises:

(a) Flexion-Patient places both hands on forehead while pressing forehead on palms without moving head.

(b) Side bending-Patient places one hand over the side of head attempting side bend, without any motion.

(c) Axial Extension-Patient presses back of head against the hands placed at back on top of head.

(d) Rotation-Patient presses one hand against superior region, lateral to the eye looking over shoulder without attempting movement.

Isometric resistance activities-a)Patient stands with inflatable ball between forehead and wall. Having chin tucked in, forward head posture is avoided. Position was maintained by superimposing arm positions. Progressed by adding weights to arm motions.

DCF-In supineposition having patient rest on wedge shaped bolster underthorax and head reducing effects of gravity. The patient was asked to practice chin tucking, head curl up. Progressed by decreasing angle of board/ wedge and adding manual resistance.

Manual resistance-cervical muscle-Patient position was supine. Placing one hand on the patients head to oppose motion.

Functional exercises-Patient specific functional activities-pushing, lifting,reaching activities. Contracting DCF patient was asked to gently nod head so flexion occurs between head/neck. Progression of movement up to middle of neck.

Slowly return to neutral position. Patient was asked to move one vertebra at a time. Patient was asked to activate deep cervical core muscles indifferent positions for dynamic activities. Standing, back lying, Sitting, Stomach lying, Side lying, Quadruped, Squatting, Walking.

Subjects in Control Group (Group B) received Vestibular Rehabilitation for 4 weeks (3 days per week 30 minutes per session).

Results

1. Within Group Comparison

Dizziness Handicap Inventory

Group A:

Table No. 1

Dizziness Handicap Inventory			
PreTest		Post Test	
Mean	SD	Mean	SD
37	6.48	23.6	8.09

Interpretation-Pre and Post Mean and SD values which was 37±6.48 and 23.6±8.09 respectively. Post treatment extremely significant improvement was noted according to the P value-0.0003.

Group B:

Table No. 2

Dizziness Handicap Inventory			
Pre Test		Post Test	
Mean	SD	Mean	SD
38.6	3.27	35.2	5

Interpretation-Pre and Post Mean values which was 38.6±3.27 and 35.2±5 respectively. Post treatment improvement was not quite significant according to the p value -0.0786.

Motion Sensitivity Quotient:

Group A:

Table No. 3

Motion sensitivity Quotient			
Pre- Test		Post Test	
Mean	SD	Mean	SD
30.82	5.75	9.72	4.83

Interpretation-Pre and Post Mean and SD values which was 30.82±5.75 and 9.72±4.83 respectively. Post treatment extremely significant improvement was noted according to the p value-<0.0001.

Group B:

Table No. 4

Motion Sensitivity Quotient			
Pre Test		Post Test	
Mean	SD	Mean	SD
30.62	7.36	25.28	7.19

Interpretation-Pre and Post Mean values which was 30.62±7.36 and 25.28±7.19 respectively. Post treatment improvement was not considered significant according to the p values - 0.075.

2. Between Group Comparison

Dizziness Handicap Inventory

Table No. 5

Dizziness Handicap Inventory				
Group A	Group B	p value	t value	Inference
23.6±8.09	35.2±5	0.0012	3.852	ES

Interpretation-Post Mean and SD values which was 23.6±8.09 and 35.2±5 respectively in the study. Post treatment improvement was considered extremely significant according to the p values- 0.0012.

Motion Sensitivity Quotient

Table No. 6

Motion Sensitivity Quotient				
Group A	Group B	p Value	t Value	Inference
9.72±4.83	25.28±7.19	<0.0001	5.67	ES

Interpretation-Post Mean and SD values which was 9.72±4.83 and 25.28±7.19 respectively. Post treatment improvement was considered extremely significant according top value<0.0001.

Conclusion

Activation of deep neck muscles as an adjunct to vestibular rehabilitation in vertigo had significant effect improving postural stability, balance, functional mobility and reduced impact of symptoms on daily activities. So, this study accepts alternate Hypothesis.

Discussion

Among subjects,altered vestibular function, balance issues, postural instability; subjects in experimental group showed significant improvement with mean± SD

DHI for 1) Group A-23.6±8.09,2) Group B-35.2±5 and MSQ were 1) Group A9.72±4.83, 2) Group B25.28±7.19.

A study conducted on Dizziness in older adults [17] suggests that more often women are affected by vestibular symptoms than men, accordingly our study includes 11 females, 9 males. Our study includes subjects within age group of 18-30 years with Mean± SD of 25.5±3.50, as in, a study conducted on presentation of dizziness in general practice community sample of working age group[12] suggested that dizziness occurring in younger population is more often linked to BPPV, labyrinthitis, anxiety disorders,etc.

Group B subjects received exercises for Vestibular Rehabilitation which included Gaze stability exercises, BPPV treatment techniques, Balance,progression exercises. Group A subjects received- Isometrics of neck, Isometric resistance activities, DCF, functional exercises,further progression exercises along with Vestibular Rehabilitation.

A study conducted on "Vestibular rehabilitation therapy: Review of indications, mechanisms and key exercises" [3]suggests that gaze stability exercises, exercises of eye, head movements, exercises done while standing on a narrow base or cushion with eyes closed improve postural stability, reduce vertigo symptoms, improve activities of daily living and aid in alleviating provocation of vertigo. In our study, subjects in control group who received Vestibular rehabilitation showed improvement in gaze stability, postural control, balance activities according to pre and post mean values of DHI - 38.6±3.27 and 35.2±5.0 and MSQ- 30.62±7.36 and 25.28±7.19 respectively.

Another study on "Clinical effects of DCF muscle activation in patients with chronic neck pain"[18] suggested that neck pain, functional status, neck-shoulder postures in chronic neck pain patients were improved by (DCF) exercises than simple general strengthening exercises. Similarly, in our study activation of deep neck muscles with vestibular rehabilitation proved effective as strengthening of deep neck muscles improved stability which aided for proper alignment of cervical spine along with improved proprioception thus reducing pain, dysfunction and dizziness levels.

A study on trigger points and head/neck posture in migraine individuals suggests, Correct alignment of the vertebra of the cervical spine is related to muscle contraction.[19] Accordingly, in the current study activating the deep neck muscles along with vestibular rehabilitation aided the individuals to attain stability of deep neck muscles thereby maintaining correct head/ neck posture alignment.

Attaining good cervical spine posture reduces tension, overloading on posterior cervical structures.[20] The endolymphmoves effectively in each of semicircular canals with response to head movement. Therefore, gaining good stability for deep seated cervical spine muscles with activation reduces intensity of dizziness, imbalance, postural instability.

Thus, the results show that Experimental group had significant improvement in outcome variables reducing symptoms of Vertigo, improved postural stability, reduced dizziness, improved balance and activities of daily living. And confirmed using statistical analysis by 'Paired t- test' for within group comparison and 'Unpaired t-test' for between group comparisons.

This suggests that activation of deep neck muscles along with Vestibular Rehabilitation is effective in improving the postural control, balance, reducing cervical spine dysfunction, pain and limiting provocation of symptoms in vertigo. It can be due to specificity of exercise program that helped in achieving stability of neck muscles which aided the individuals attaining proper head/neck posture delaying spinal degeneration thereby nullifying symptoms.

Conclusion

The current study suggests that exercises for activation of deep neck muscles along with Vestibular rehabilitation were effective in reducing provocation of symptoms of vertigo, its impact on daily activities, disequilibrium, and balance issues.

Life Beyond the Diagnosis of Breast Cancer: A Qualitative Study on the Lived Experiences of Breast Cancer Survivors

Binsha Pappachan C.[1], Fatima D'Silva[2], Safeekh A.T.[3]

[1]Ph.D. Scholar, Nitte University, Mangalore, [2]Principal, Nitte institute of Nursing Sciences, Mangalore, [3]HOD, Dept of Psychiatry, Father Muller Medical College, Mangalore

Abstract

Background: The advances in biomedical technology that lead to an increase in early diagnosis and treatment have helped to increase the number of health breast cancer survivors in Indian as well as worldwide. Researches carried out on survivorship have focused mainly on the psychological impact and health outcome of the disease. The goal of this study was to focus on exploring the lived experiences of breast cancer survivors from diagnosis of the disease till the survivor life.

Objective: To explore the lived experiences of women who are breast cancer survivors.

Design, Setting and Participants: A purposive sampling strategy was used to recruit participants from amedical college hospital. A total of 18 women breast cancer survivors were interviewed.

Findings: The study concluded with four major themes that described lived experiences of women. These were factors from the diagnosis and treatment of breast cancer impacting survivorship, support system and relationships, and issues in survivor life. All the participants noted that it was so stressful journey that they went through after diagnosis till the completion of various treatment modalities. Each one found their own way to cope with the stress. Support from family was shared as the key which gave them strength and courage through the different stages of treatment. However, they found it difficult to explain what survivorship meant.

Conclusion: This study using in-depth interview techniques, shed light on the lived experiences of breast cancer survivors who have completed the treatment. All of them had fear and frustration during their diagnosis and treatment. They felt depressed due to body changes still the support they received from their partners and family helped them to come out of that feelings. However, they noted that they still live with the fear of recurrence of cancer.

Keywords: *Lived experiences, breast cancer, survivor, qualitative.*

Introduction

Breast cancer is now the most common cancer in most cities in India, and 2nd most common in the rural areas. In India, we are witnessing more and more numbers of patients being diagnosed with breast cancer to be in the younger age groups[1]. Breast cancer has ranked number one cancer among Indian females with age adjusted rate as high as 25.8 per 100,000 women and mortality 12.7 per 100,000 women. The age adjusted incidence rate of carcinoma of the breast was found as high as 41 per 100,000 women for Delhi, followed by Chennai (37.9), Bangalore (34.4) and Thiruvananthapuram District (33.7).[2]

At the same time, the number of breast cancer survivors is increasing due primarily to advances in

Mob.: 9964340783

biomedical technology leading to an increase in early diagnosis and treatment. Mortality rates also have been decreasing since 1990, and there are over 2.9 million women in the United States who have survived breast cancer.[3] The cancer registry data at the urban city level show that India will face a rapidly increasing number of breast cancer survivors in future. However, this survivor population has until now received very little attention.[4] Health professionals have low awareness of recognizing the long-term and late effects of cancer and its treatment and supportive care services specifically for cancer survivors are lacking in the country.[5] Under such circumstances, breast cancer survivors are often marginalized in the health-care system and have many unmet medical and psychosocial needs, requiring special attention.

There is not much research done on the various experiences Indian women are undergoing after the diagnosis and treatment of Breast Cancer. The term survivor is defined as life without cancer after treatment.[6] Thus, the purpose of this phenomenological study was to understand the lived experiences of breast cancer 'survivors'. The central research question was 'What is the experience to be a breast cancer survivor?'

Sub questions were as follows:

1. How did they cope with the diagnosis of cancer?
2. How did the cancer diagnosis affected their personal life?
3. How do breast cancer survivors perceive life after diagnosis and treatment?

Method

Ethics Approval: The central ethics committee of KSHEMA has approved the study. Each participant was informed about rights to withdraw from the study anytime they want and principles of protection of human subjects, and each approved their participation with a written informed consent.

Selection and recruitment of participants: All the women were recruited from K S Hegde Medical Academy. Women those who have come for follow up after two year were considered for sampling. A purposive sampling strategy was used by researcher to recruit the participants (N = 18). The desire was to have a sample that represented a variety of perspectives but shared some common experiences. The aim of the purposive strategy was to recruit participants that represented a range of perspectives within the follow up cases.

A diversity of experiences was based on age at diagnosis, stage at diagnosis and financial background. The goal was to get a broad cross section of perspectives within this framework. At eighteen participants, we had reached a level of saturation with the population of breast cancer survivors from our potential sample frame. There was no further new information that contributed to our analysis of the breast cancer survivor experience. The inclusion criteria were women: (i) 18-70 years of age (ii) English-speaking; (iii) a diagnosis of breast cancer; and (iv) completion of treatment, surgery, chemotherapy and/or radiation.

Data Collection: The data collection method was by a one-to-one semi-structured, in-depth interview with all participants in the counseling room of the Oncology OPD. Topic guides were developed based on the cancer literature and the researchers' experiences working with cancer patients. During the interview the participant's statements provoked further questions and clarifications.

Analysis: The research was focused to develop a set of logical and consistent understandings based on the perspectives of women with breast cancer. Data were analyzed following phenomenological coding guidelines. Analysis of data began after all tapes were reviewed by the researchers several times to get familiar with data and expressions of participants in regard to their breast cancer experience. Initiallya line-by-line analysis of the data was conducted and the identified statements were highlighted. Next the overlapping statements were eliminated. From the final list of statements, the researchers created meanings without disrupting the original meaning of the participants. Codes were assigned to all meaningful units, which were then organized into categories of similar codes. Finally the themes were developed by considering all categories of codes to include the commonalities that cover several categories which gave a clear understanding of the experiences of breast cancer survivors.

Reliability and validity of the study: The following measures were taken by the researchers to ensure the reliability and validity of the instrument and study: (i) the first author who interviewed all participants transcribed tapes verbatim and completed the first phase of analysis (ii) the second and third authors reviewed the codes and themes to ensure the validity of the themes and subthemes with the reality (iii) finally all the authors met to explore differences and final refinement of codes.

Rigor: To ensure rigor we initially established methodological coherence by ensuring the validity across the study that each part matches the research objective and also is consistent with its methodological assumptions. Secondly, we adopted the rule of purposive sampling by ensuring that 18 participants selected were able to provide a rich and in-depth understanding of survivorship experience. To enhance the reliability of the study, we used a single researcher and the same interview schedule to increase the consistency of data collection.

Findings: Eighteen breast cancer survivors participated in interviews that lasted from 60 to 90 min. The age of participants ranged from 32 to 69 years. Of the eighteen women, five were diagnosed at stage I, eight at stage II and five women had stage III cancer. Nine women had been cancer free between 6 and 12 months, while eight reported between 1 and 2 years cancer free. Analysis of the interviews identified three major themes that were important to the lived experiences of the women. These were (i) diagnosis and treatment of breast cancer impact on survivorship (ii) support system impact on survivorship (iii) and issues in survivor life.

Factors from the diagnosis and treatment management impacting survivorship: According to some of them though very little, the awareness they had about breast cancer helped them to identify early and they feel happy about it. However most of them agreed that they didn't have much knowledge about breast cancer and hence they ignored the appearance of lump as a common symptom of any infection and expected to disappear in due course. Only when it grown to severe extend where it was very much palpable they seek for medical checkup, by then it crossed first stage.

Survivor 3 explained that one day accidentally she felt 'a small lump on the left lateral side of her breast, which was of the size of a small peanut' and she could sense the danger that something is wrong with her breast. She was happy that she had enough awareness about breast cancer from the media and society and she rushed for the treatment. Although she was happy that she could diagnose her cancer in the initial stage she worries about the larger portion of society who is ignorant about the same and landing up in the late stages for the diagnosis and treatment.

Stage at diagnosis was another factor that impacted the survivorship. Survivors explained about the reaction at the point of diagnosis as 'shocked' or as 'end of life' feeling. Survivor 2 who was diagnosed stage 2 expressed as 'I thought it is going to be and of my life as the recurrence may be at any time and any form'. Though she was a health worker, she ignored the initial symptoms and postponed her screening test at the earlier stage which she is regretting very badly. Those survivors who had an early stage diagnosis were happy that their recurrence chances are less. Whereas those who had late diagnosis were more upset and fearful as they were having a fast recurrence.

The changes in their physical appearances were the major problem they had faced. None of them seemed to be bothered about the disfigurement by mastectomy; however all of them had a difficult time to cope with their emaciated body and the evident hair loss during chemotherapy. The financial burden was expressed by two of them who didn't have any insurance coverage. During treatment they had to literally sell of many things to fetch money for the treatment. Who had health insurance were thankful for that so that they could maintain a good quality of life during treatment which was difficult if they didn't have an insurance coverage.

According to them the journey after cancer diagnosis and treatment was a 'terrific one with full of anxieties and uncertainties' which was even complicated by other associated problems of family, work and financial issues.

Support system impact on survivorship: All of them had expressed that the support they had received during and after the treatment of cancer was the key factor for their successful completion of cancer journey. Survivor 12 said ' I was so surprised to see the overwhelming care and concern that was showered up on me by my relatives and was feeling so blessed to know my importance for all of them'.

Participants also expressed that even the friends and colleagues have turned up to be so caring and protecting in all the phases of the treatment. Emotionally, physically and financially all of them had offered themselves to these participants. Survivor 7 expressed her concern for her parents by saying 'I was feeling that I had gone back to my childhood, seeing the way my parents caring for me as if I was in my preschool period, and it was hurting me that instead of caring for them in their retirement life, they had to care for me'. All of them agreed that the support they had received from their closed ones have gave them strength and motivation to complete the journey successfully.

Issues in survivorship: Each participant had their own way of explaining their survivor life. They agree that it was a tough journey, though were not sure what lies in future. Most of them still had a fear of recurrence at any time but said that they are ready to face anything that comes in their life. Most of them were happy that they could come back to their normal life.

Survivor 9 said 'Now I feel I am more confident on myself and I know what I have to do in my future. I have a plan for each day and a list of things to complete before it (cancer) hits me back again..The days in my hand I feel are counted and will be grateful to God for every blessing he showered up on me'

Discussion

This study envisaged to explore the lived experiences of a cancer survivor and various factors that are affecting the survival life of breast cancer survivors. In the analysis various factors emerged to be having an influence on the survival life and the issues that they experience during their survivorship.

Individuals who had undergone their breast cancer treatment and living a cancer free life are often called as cancer survivors. However most of the survivors are not happy to be called as cancer survivor as it brings all the painful memories to their mind. Some of them expressed that they are still not sure that they are really cancer free. Though the active medical treatment is stopped and they need not go for regular check- ups to hospital, they feel they still have some ailments for which much attention is not given.

Some of them said that the care they were receiving from family and friends have suddenly dropped caring and they found it difficult to adjust as their recovery is not complete. From this study the major problem breast cancer survivors faces is the fear of recurrence. They live their day and night thinking when it will come back. One of them even expressed her wish to surrender to death if recurrence occurs. Along with the fear of recurrence they also had concerns about body disfigurement, resuming their family and work responsibilities, sexual life post mastectomy which was supported by other studies.[7]

Social support was one of the key factors which helped them to cope with the stress effectively.[8] Support from family members, friends and co-workers motivated them and gave them encouragement to fight with cancer. Similar studies also showed the effectiveness of social support in breast cancer women.[4] Most of the participants also had the same experiences. Other important factors which came out in the present study were the influencing factors such as stage at diagnosis, age of women during diagnosis etc which had a greater impact on the survivorship. Young women were more depressed and worried about their future and commitments and those who diagnosed cancer at the later stages were having more fear of recurrence and death. This also was supported by similar studies. Consistent with other study findings the hair loss decreased their self esteem and self confidence to a larger extent[9]; in fact the mastectomy did not affect much. Financial burden came from the treatment cost had affected the quality of life of women who were not insured, however others thankful for the services they had received from the insurance.

Conclusion

This study tried to shed some light in to the undiscovered experiences of women went through the traumatic life experiences after breast cancer diagnosis and treatment. It also tried to explore the experiences of survivorship and what it actually meant for them to live in a society with all fears of recurrence. These experiences what they have shared should be a guiding light for health care professionals to plan policies and protocols to support women to undergo the journey of breast cancer survivorship effectively. The three areas identified during the in-depth interviews can be explored further by researchers so that those areas can be focused in the management of women with breast cancer.

Acknowledgement: The authors are grateful to the participants who were very cooperative in willingly sharing their experiences.

Conflicts of Interest: None declared.

Ethics Approval: The central ethics committee of KSHEMA has approved the study.

Virtual Prominance of Prognosticator Variable in Discriminating Cost Gears. A Pragmatic Analysis in Select Pharma Companies

F.J. Peter Kumar[1], C. Samuel Joseph[2], S. Paul Jefferson Clarence[3]

[1]Associate Professor, Department of Management Studies, [2]Professor & Head, Department of Management Studies & Commerce, [3]Formerly Student of MBA (Finance), Department of Management Studies, Karunya Institute of Technology and Sciences, Coimbatore

Abstract

The purpose of this paper is to identify the cost variables that are relatively important in discriminating Pharmaceutical Companies. The manufacturing costs are a major part of company's total expenses in pharmaceutical industry(1). In this study, a thorough investigation on the cost components and income categories of pharmaceutical companies are analyzed and their relationships were found to understand,to know the difference among various types of pharmaceutical companies. The analysis on the data set between 2009 and 2018 reveals that, costs play a dominant role and they are different for all the five companies that are listed. The study also reveals that there is a considerable amount of discrimination in the cost of manufacturing and operating expenses which discriminate the pharmaceutical companies in their approach towards the market. The Structural Equation Modelling has explained that the variables chosen has a good impact as predicted and it implies that the performance of the company is growing among the years chosen for the study.

Keywords: *COGS, Pharmaceutical Manufacturing Companies, Discriminate, Structural Equation Modeling.*

Introduction

India is the largest provider of generic drugs globally. Indian Pharmaceutical sector, discovers, develops, produces, and supplies over 50 per cent of global demand for various vaccines, 40 per cent of generic demand in the US and 25 per cent of all medicine in UK to be administered to patients to cure them, vaccinate them and alleviate a symptom. Presently over 80 per cent of the anti-retroviral drugs used globally to combat AIDS are supplied by Indian Pharmaceutical firms. Every business eventually boils down to a rupee sign, and Pharma Companies are no exception to it. All the manufactured products must be sold for a profit to ensure the company survive and grow with an assurance of competitive advantage in the domestic and global market.

Statement of Problem: In Pharmaceutical sector, the cost of bringing a new drug to the market place has been steadily increasing (2). But at the same time the market grew 5.5 per cent in 2017 to 7.1 per cent. Medicine sales in India increased 8.1 per cent year-on-year in November 2017. Much expenses are incurred in the pre-clinical trials. Further it takes about 7 to 10 years of gestation period to bring in adequate revenue to cover up the developmental costs. This place, pharma companies on a mission mode in discovering a successful drug that clears the approval mechanism, and brings in sufficient revenue on commercialization, and helps firms achieve the desired profits. All this could be possible

only if the sector is conscious of its inherent cost. Hence this study has been undertaken.

Objectives of the Study:

The following are the main objectives of the study:

1. To Infer the Relative Importance of variables that discriminates pharma companies with lower operating profit and higher operating profit.
2. To Investigate the nature of relationship that exists between various cost components and its profitability

Research Design and Methodology

This study is descriptive in nature which quantifies the behavior of cost components and traces it to the firm performance measured in terms of profitability. The data used in this work were extracted from secondary sources like, the annual reports of the respective pharma companies, web resources from Bombay Stock Exchange, National Stock Exchange, besides, databases like PROWESS, ACE and HOOVERS were also rallied upon. Top Five Pharmaceutical companies, which are extremely performing well were selected based on the annual revenues for 2018. These companies engage themselves in manufacturing of branded generic and prescription drugs, development of wide range of formulation's and therapies. The data, pertains for a period of 2008-09 to 2017-18. Inferential statistics were used to investigate the different dimensions on the selected Pharma companies which include Discriminant Analysis, Multiple Regression, and Path coefficient analysis. The results are presented accordingly in the subsequent pages.

Literature Review: Basu, Et. al. (2008) International Society for Pharmaceutical Engineering, "In the pharmaceutical industry, costs attributed to manufacturing are a major part of a company's total expenses[1]. The analysis shows that, between 1994 and 2005, manufacturing costs (as a percentage of total sales) are different for the three groups of companies listed above. Okunbor (2013) "The issue of cost behaviour and cost estimation is vital and fundamental in tactical decision-making, planning and control[2]. Novák, et. al (2014) "Cost management is one of the most important issues of corporate performance and corporate financial management. This study compares four models that predict cost behavior. From the results of transformed model we believe that asymmetric cost behavior is affected by asymmetric behavior of the production in kg in proportion to the production time[3]. Novák et. al. (2014) "The paper is focused to the variability of costs, cost behaviour and discusses the issues of sticky costs. The main goal of this paper is to analyze the issue of the author´s project targeted at the topic of cost behaviour and its projection to the costing systems and confront it with the current state of knowledge in the field[4]."Oberholzer M (2004) "Cost behaviour classification and cost behaviour structures of manufacturing companies. The purpose of this paper is to determine the cost structures of companies that formed part of an empirical investigation[5]. Aleem, et. al. (2016) "After its induction in the 19th century, the pharmaceutical industry covered a long way and now it became one of the most successful and influential industries in the world, with both praise and controversy on its part. Like the other profit-driven organizations, the main aim of the pharmaceutical firms is to earn the maximum profit. The profitability also depends on the costing system. The current paper evaluates the costing systems, the level of satisfaction regarding the costing system, the major problems faced during the costing process and the best method of costing in the pharmaceutical sector[6]. Al-Hebry et. al. (2017) has aimed to show such theoretical cost approach in accounting thought. The article has divided the cost approach into two groups, the traditional approach that includes the volume based costing, French cost accounting approach and contemporary cost approaches which include four approaches activity-based costing (ABC), time-driven ABC, resources consumption accounting and lean accounting[7]. Oluwagbemiga et. al. (2014) "This study investigates the relationship that exists between cost management practices and firm's performance in the manufacturing organizations using data from 40 manufacturing companies listed on the Nigeria stock exchange during the period of 2003 to 2012[8]. Drury (2008) "whether a cost is fixed or variable with respect to a particular activity measure or costs driver is affected by the length of the time span under considerations, stressing that the longer the time span, the more likely the cost will be variable[9]. Lucey (2007) states that classification of cost into fixed and variable, according to their behaviour and characteristics is an essential preliminary to be able to make any form of cost prediction and classification[10].

Relative Importance of Cost Variables Discriminating Pharma Companies: The relative importance of Cost Variables Discriminating Pharma Companies has been studied with the help of discriminant

analysis, path analysis and inter correlation matrix. The results are presented below

Discriminant Analysis: Discriminant analysis is a statistical technique which allows to study the differences from two or more groups with respect to several variables simultaneously and provide a means of classifying any object/individual into the group with which it is most closely associated and to infer the relative importance of each variable used to discriminate from different groups. A linear combination of predictor variables, weighted in such a way that it will best discriminate among groups with the least error is called a linear discriminant function and is given by:

$D = L_1.X_1 + L_2.X_2 + \ldots\ldots\ldots\ldots\ldots + L_K.X_K$, where Xi 's are predictor variables, Li's represents the discriminant coefficients, and D is the value of the discriminant function of a particular individuals/element such that if this value is greater than a certain critical value D*=(D1 bar + D2 BAR)/2, the individual would be classified in group I (n1 = 5); otherwise the individual would be classified in Group II (n2 = 6).

In the present study there are two groups namely those Years with Lower Operating profit (Group I n1=5) and Years with Higher Operating profit (Group II n2=6).. Seven Predictor variables considered for the analysis includes the following: Raw material consumes-X1,,Power & fuel used-X2, Employees cost-X3, Other manufacturing expenses-X4, General & Administrative expenses-x5, Selling and Distribution expenses-X6 and Miscellaneous expenses-X7

Table 1: Tests of Equality of Group Means Univariate ANOVAs

Explanatory Variables	Wilk's Lambda	F (DF=1, 9)	Sig
Raw Material-X1	0.16	45.57*	0.00
Power & Fuel-X2	0.17	45.08*	0.00
Employee Cost-X3	0.24	27.74*	0.00
Other Manufacturing Exp-X4	0.39	14.24*	0.00
General Administrative Exp-X5	0.21	34.44*	0.00
Selling & Distribution Exp-X6	0.27	23.89*	0.00
Miscellaneous Exp-X7	0.42	12.24*	0.01

** Significant at 1 % level

The above table showed that the mean difference between two groups with respect to the variables namely X3, X4, X5 and X6 is significant.

Relative Importance of Predictor Variable: The relative importance of each predictor variables in discriminating from the two groups is obtained and the results are presented below.

Table 2: Relative Importance of Variables in Discriminating Between the Groups

Explanatory Variables	Importance value of the variable (Ij)*	Relative Importance (Rj) %	Rank
Raw Material-X1	27.0034	37.8	1
Power & Fuel-X2	5.4217	7.6	5
Employee Cost-X3	19.9275	27.9	2
Other Manufacturing Exp-X4	9.7009	13.6	4
General Administrative Exp-X5	2.9969	4.2	6
Selling & Distribution Exp-X6	11.8108	16.5	3
Miscellaneous Exp-X7	0.5509	0.8	7
Total	**77.4121**	**108.4**	

*(mean difference between lower & higher operating profit) *Disc. coefficient

It is seen from the above table that three variables namely *Raw Material (X_1), Employee Cost (X_3), and Selling & Distribution Expenses (X_6)* are substantially important variable in discriminating between the two groups namely years with lower operating profit and respondents with higher operating profit among Companies..

Path Coefficient Analysis: The Path coefficient analysis segregates the total correlation of each independent variable with the dependent variable Y into direct response and indirect response via other independent variables. The direct effect of each of the explanatory variables on the dependent variable and the indirect effect of each explanatory variable on the dependent variable through other explanatory variables are furnished in the Table No. 4

Table 3: Direct & Indirect Effect of Explanatory Variables on Y-Operating Profit

	RM	PF	EC	OME	GA	SD	MISC	OPPROF
RM-X1	0.57	0.01	-0.62	0.37	0.10	0.19	-0.13	0.49
PF-X2	0.43	0.01	-0.61	0.36	0.11	0.21	-0.09	0.41
EC-X3	0.39	0.01	-0.90	0.52	0.16	0.39	-0.19	0.37
OME-X4	0.35	0.01	-0.78	0.60	0.13	0.33	-0.15	0.49
GA-X5	0.30	0.00	-0.78	0.42	0.19	0.32	-0.26	0.19
SD-X6	0.23	0.00	-0.75	0.42	0.13	0.47	-0.10	0.41
MISC-X7	0.18	0.00	-0.45	0.24	0.12	0.12	-0.39	-0.17

Significant at 5 % level.

It is seen from the above table that among the explanatory variables, the variable Raw Materials (X1) showed higher positive direct effect on the dependent variable Operating Profit (Y). The variable X1 also had higher positive indirect effect on Y through Other Manufacturing Cost (X4) and Selling & Distribution Expenses (X6). The variable Other Manufacturing Expenses (X4) showed higher positive direct effect on Operating Profit (Y) this variable X4 also had higher positive indirect effect on Y through Raw Material (X1) and Selling & Distribution Expenses (X6) this variable X6 also had higher positive direct effect on Y. Selling & Distribution Expenses (X6) also had higher positive indirect effect on Y through X1 and X4. Hence the three variables Raw Material – X_1, Other Manufacturing Expenses –X_4 and Selling & Distribution Expenses – X_6 are substantially important contributing variable for the dependent variable Operating profit-Y.

Structural Equation Model Determining the Path on the Variables Identified of Select Pharma Companies

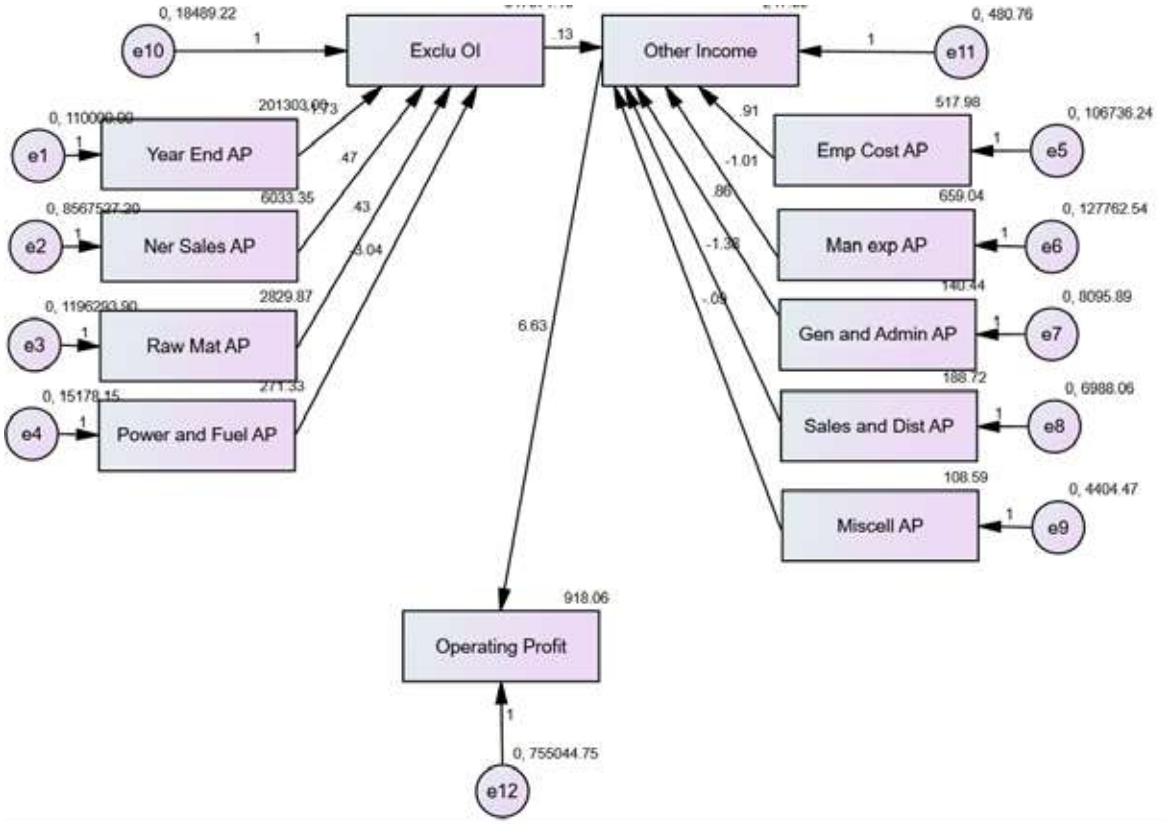

Fig 1. SEM Model for Aurobindo Pharma

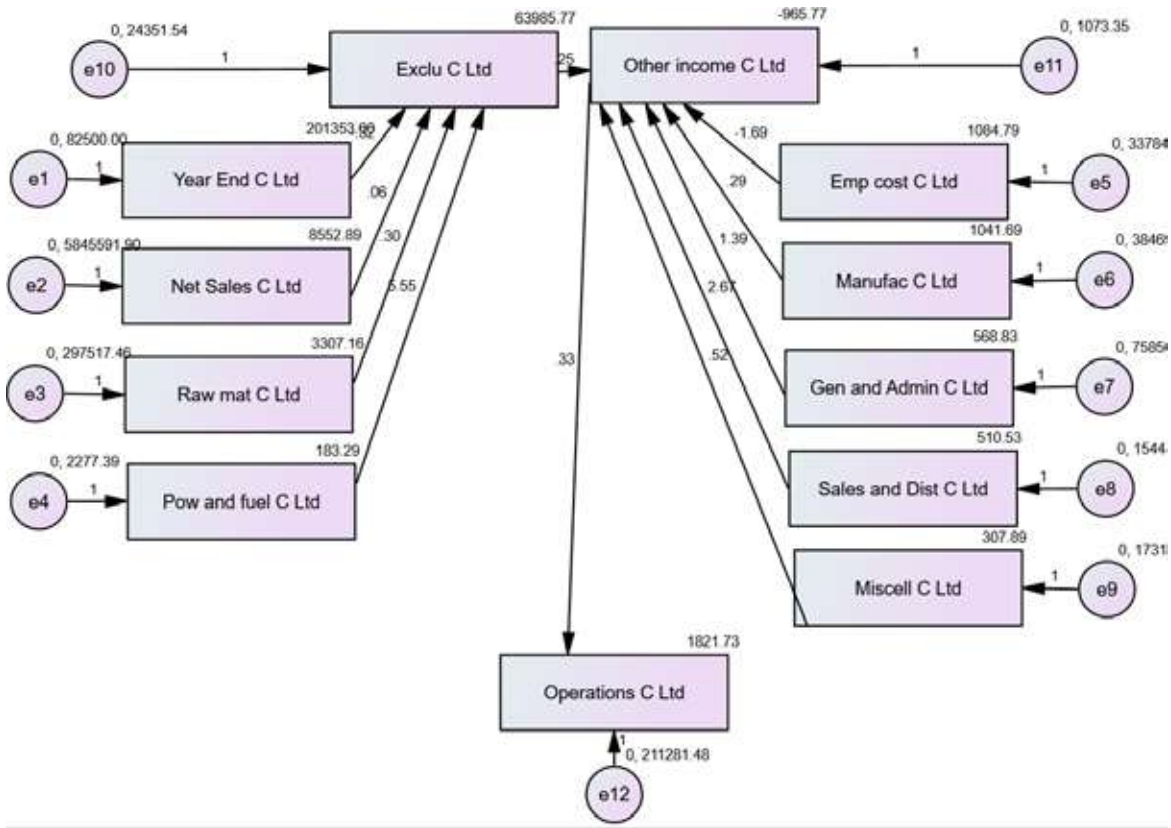

Fig 2. SEM Model for Cipla

The expenses of Aurobindo, Cipla, Dr. Reddy's, Lupin Pharma Companies has an impact on the Company's income generated and also has an interdependence among other expenses which reveals the cost behavior and the Firm's performance level. The values indicate that the variables chosen has a good impact as predicted and it implies that the performance of the company is growing among the years chosen for the study.

Regression Analysis: Multiple regression analysis with Operating profit-Y with a set of independent variables namely X1, X2, X3, X4, X5, X6 and X7,the following regression model is fitted for performance.

Y2 =bo + b1X1 + b2 X2 +b3 X3 + …….

Where b1, b2, …. and b7 are partial regression coefficients; bo-constant and the results are presented in the following equation.

Regression Fitted: Y = -414.83 + 0.60 X1 + 0.08 X2 – 1.65 X3 + 1.31 X4 + 0.59 X5 + 1.89 X6 -2.46 X7

Table 4: Analysis of Variance for Regression

Source	S S	D F	M S	F
Regression	30334049	7	4333436	7.66**
Residual	26598452	47	565924.5	
R^2	.533			

** Significant at 1 % level

The Multiple regression model indicated that out of the explanatory variables under study six variables namely Raw Materials (X1), Other Manufacturing Expenses (X4), Selling & Distribution Expenses (X6) and Miscellaneous Expenditure (X7)are significantly contributing to Operating Profit - Y. The analysis of variance of multiple regression model for Y indicates the overall significance of the model fitted. The coefficient of determination R^2 value showed that these variables put together explained the variations of Operating profit-Y to the extent of 53.3 %.

Findings of the Study:

1. *Raw Material (X_1), Employee Cost (X_3), and Selling & Distribution Expenses (X_6)*are substantially important variable in discriminating between the two groups.
2. Path Coefficient reveals that the three variables Raw Material – X_1, Other Manufacturing Expenses –X_4 and Selling & Distribution Expenses – X_6 are substantially important contributing variable for the dependent variable Operating profit-Y.
3. The Multiple regression model indicated that out of the explanatory variables under study six variables namely Raw Materials (X1), Other Manufacturing Expenses (X4), Selling & Distribution Expenses (X6) and Miscellaneous Expenditure (X7) are significantly contributing to Operating Profit - Y.
4. The expenses of the company have an impact on the income generated and also has an interdependence among other expenses. The values indicate that the variables chosen has a good impact as predicted and it implies that the performance of the company is growing among the years chosen for the study.

Therefore the present study confirms the earlier studies by Basu, Et. al. (2008)[(1)] Okunbor (2013)[(2)]. Novák, et. al (2014) in the theory that "Cost management is one of the most important issues of corporate performance, and the issue of cost behaviour and cost estimation is vital and fundamental in tactical decision-making, planning and control.

Recommendations for Management: It is recommended for the Management of these Pharma Companies to concentrate on Cost Components like Raw Materials, Selling & Distribution expenses, Other Manufacturing Expenses and Miscellaneous Expenditure, who are significantly contributing to Operating Profit. The Firms to organize adequate training programs on cost management and cost control by professional cost and management accountants.

Limitations of the Study: The author has assumed that the data reported by the companies in their financial statements are based on the same interpretation of various categories. The study is only a representation of companies under pharma sector, a significant number of companies have not been included in the study.

Conclusion

Given the proliferation of Indian Pharmaceutical sector, for various vaccines assumes greater significance in the Market place as they serve the health industry and contribute for the longevity of life of every human being. They are bound to supply the drugs at a price that is affordable to the downtrodden and at the same time balance their competitive advantage for the survival and growth of their enterprise.

Ethical Clearance: This study is an original study by the author's and all references were acknowledged in the references with due reverence.

Effect of Interdental Brushing as Modality of Plaque Reduction in Ongoing Fixed Orthodontic Patients: A Randomised Clinical Trial Study

Jeeva Rekha M. MDS

Associate Professor Department of Dental Surgery Government Medical College Omandurar Government Estate Walajah Road Chennai

Abstract

Fixed Orthodontic treatment is used to enhance the form, function and aesthetics of an individual. The biggest drawback of a fixed appliance is the increase in plaque and bacteria around the appliance due to the inherent nature of the appliance and inability to clean all the surfaces thoroughly leading to plaque accumulation. This study was designed to evaluate the effect of interdental brushes in reducing plaque accumulation. A randomised split mouth study was done and the results showed a significant reduction of plaque accumulation in the experimental side. The results were statistically significant at $p<0.001$.

Keywords: *Plaque reduction, Interdental brushes, Fixed orthodontic treatment.*

Introduction

Fixed Orthodontic treatment entails the use of fixed components on the tooth surfaces to enable the movement of teeth . Although Orthodontic treatment helps in improved facial appearance and confidence of the patients, it does bring with it, a significant risk of periodontal disease in patients who do not keep a meticulous oral hygiene . Several method of keeping good oral hygiene and reduce plague accumulation have been devised and the Orthodontist, General Dentist and Periodontist share a responsibly to keep it within acceptable limits. Along with meticulous brushing method the use of interdental brushes for removing plague around fixed attachments have been advocated. This study aims to quantify the effect of interdental brushing in fixed orthodontic patients. The study is designed to a randomised clinical trial study .

Method and Methodology: 55 fixed Orthodontic patients were selected for the study after excluding patients who had significant periodontal degradation. The patients were evaluated by two examiners and were divided into two groups, the selection of the group was done by picking of lots and the maxillary left set of teeth were selected as controls.

The Plaque index was used to measure the quantity of plaque at the start of treatment (T1) and the end of three months (T2).

Results: The results show a significant difference in accumulation of plaque on the control side after the completion of the study T2. 6 patients discontinued the study as they did not follow a stringent protocol. Overall the difference of plague formation was significant compared to the control side . The results were statiscally significant at $p<0.001$

Discussion

Maintenance of Oral hygiene is off paramount importance especially when a patient is undergoing fixed orthodontic treatment . Studies have proved that there is an increase in the bacterial count a few hours after fixing the orthodontic attachments[1]. Several efforts have been made to improve patient compliance to meticulous oral hygiene, but the peculiarity of the appliance makes it very difficult to rely primarily on tooth brushing with tooth brushes as an effective mean of reduction of plaque accumulation during orthodontic treatment . Several adjunct measures like incorporating oral mouth rinses, interdental brushes and water flossing have been advocated[1,2] . Studies showing the role of interdental brushes in the reduction of plaque index (PI) have been few and non conclusive[3]. The role of poor oral hygiene and development of periodontitis and later enamel decalcification in the form of "white spot lesions " have also been widely published . Hence all method to improve oral hygiene in fixed orthodontic appliances must be taken[4,5,6,7,8,9,10,11,12,13,14,15] .

The current study was focused on understanding the role of interdental brushing and reduction of PI in patients undergoing orthodontic treatment using interdental brushes . The study was designed as a ramdomised split mouth study . Both the patients and evaluators were blinded . The results were statistically significant $p<0.001$.

Conclusion

The study of effect of interdental brushing using interdental brushes was designed as a randomised split mouth study, the results show a significant reduction in plaque index between the control and experimental side . The use of interdental brushes help in significantly lowering the plaque in fixed orthodontic patients .

Epidemiological Profile of Trauma Victims Attending a Tertiary Care Hospital in Delhi and Application of Haddon Matrix to Identify Risk Factors of Road Traffic Accidents

Shubham Sharma[1], Madhu Kumari Upadhya[2]

1MBBS Student, University College of Medical Sciences & GTB Hospital, Dilshad Garden, Delhi, [2]MD Associate Professor, Department of Community Medicine, University College of Medical Sciences & GTB Hospital, Dilshad Garden, Delhi

Abstract

Background: Injury is one of the leading causes of morbidity and mortality in both developed and developing nations, accounting for 12% of total global burden of disease worldwide and the fourth leading cause of death for all ages. The aim of this study was to improve the understanding of the mode of trauma, severity of injuries, and analyzing the injury patterns to determine the factors associated with their outcomes.

Objectives: To study the epidemiological profile of trauma victims attending the emergency department, to identify the risk factors of road traffic accidents (RTA) using Haddon Matrix and the factors associated with the outcomes of injury in these patients.

Methodology: Cross-sectional hospital based study was conducted amongst 248 patients with injuries aged 15 years and above coming to the Emergency department (ED) using a predesigned semi-structured interview schedule. 9 cell Haddon Matrix was also used for recording the host, agent and environmental factors existing in the pre-event, event and post event phase of the injury.

Results: The mean age of the study participants was found to be 38.06 years with a SD of 16.26. Road traffic accident emerged as the single most important mode of injury (50.8%), followed by fall (23.6%) and assault (13.2%). The mean Glasgow Coma score of the study participants was 13.25 $\pm$ 3.14 (mean $\pm$ SD). Around 13% of the participants had sustained vascular injury during the accident. Important host factors identified in Haddon Matrix leading to RTA were over speeding, young age of participants, alcohol intake and fatigue of the driver.

Conclusion: Our study shows that RTA and falls are the predominant causes of trauma.

Keywords: *Epidemiological profile, trauma victims, Haddon Matrix.*

Introduction

Injury is one of the leading causes of morbidity and mortality in both developed and developing nations, accounting for 12% of total global burden of disease worldwide and the fourth leading cause of death for all ages. Of the various modes of injury, RTA alone contributes to nearly one fourth of the total injury related deaths. For adult men aged 15-44 years road traffic accidents are the biggest cause of ill health and premature death worldwide. (2) According to WHO report on road safety, road traffic accidents would be the fifth leading cause of death worldwide by the year 2030. (3) Incidence of injury is greatest in young adults less than 45 years is associated with a far greater rate of years of life lost (YLL) per death as revealed by the study

of Indian Council of Medical Research on 'causes of death by verbal autopsy'. [4] Each year, several thousand people sustain injuries serious enough to produce long term disability. [5]

A majority of trauma deaths also occur in the pre hospital periods due to insufficient pre-hospital care where the first 60 min after trauma has been considered as the "golden hour" of trauma. [6]

The aim of this study was to improve the understanding of the mode of trauma, severity of injuries, and analyzing the injury patterns to determine the factors associated with their outcomes.

Our study also endeavoured to use a 9-cell Haddon's Matrix[7,8] which is an extension of the well known epidemiological triangle to assess road traffic accidents during the three phases of its occurrence i.e. the pre event phase (i.e. before an injury occurs), the event phase (while an injury is occurring) and the post event phase (after an injury occurs) to identify personal, equipment-related, and environmental risk factors which served as a tool to analyze individual injury events and had a potential to suggest preventive interventions pertinent to each phase.

Objectives: To study the epidemiological profile of trauma victims attending the emergency department, to identify the risk factors of road traffic accidents (RTA) using Haddon Matrix and the factors associated with the outcomes of injury in these patients.

Material and Method

This Cross-sectional hospital based study was conducted at a tertiary care health facility in Delhi from May 2017 to June 2017.

Study Population/participants: Patients with injuries aged 15 years and above coming to the Emergency department (ED) of the Hospital.

Inclusion Criteria: Patients with injuries or their attendants (in case of unconscious patients) giving written consent to participate in the study

Exclusion Criteria:

- Patients with burn injuries, poisoning and with other medical or surgical emergencies
- Patients who have already succumbed to their injuries at the time of arrival

Sample size:1049 persons with injuries attended the emergency department during the months of May and June 2017; out of which 329 required admission in various departments of the hospital and 248 met the above mentioned inclusion criteria, so were included for the purpose of this study.

Data collection tool: A predesigned semi-structured interview schedule comprising of 4 sections was used for the study. First section comprised of socio-demographic details of the participants, second section had questions pertaining to the details of injury sustained in terms of date and time of occurrence of injury and the time of arrival to the ED, mode, type, site, intent and mechanism of injury and any other chronic illness suffered by the patient prior to the occurrence of the injury, the third section contained the details of care received by the patient at the hospital like recording of vital statistics, classification of severity of injury based on Glasgow Coma Score, Revised Trauma Score and presence of vascular injury, investigations done, and information about whether the patient was discharged from ED, required to be admitted or succumbed to his injuries. The fourth section of the schedule had the 9 cell Haddon Matrix in which the host, agent and environmental factors existing in pre-event, event and post event phase of the injury was recorded.

Method: Patients with injuries aged 15 years and above attending the emergency department and meeting the inclusion criteria were included as the study participants. After patient had been evaluated and stabilized (in case of patients with severe injuries) or attended to by the team in the ED, they werecontacted by the investigator. They were explained about nature and significance of the study and assured about the confidentiality of the information given by them. Those consenting to participate were interviewed personally by the investigator using a semi-structured schedule. Since it was not possible for the researcher to be physically present in the ED round the clock, the patients who had been admitted wereto be contacted in the various departments of the hospital. Those patients who were discharged from the ED before they could be contacted by the researcher, their injury related information was extracted from the record being maintained by the ED.

Data analysis: The data was analyzed using SPSS version 20.0. Simple descriptive tabulation was done for the socio-demographic variables and classification of injuries. Mean/median time delay between the

occurrence of injury and arrival to the hospital was computed. Qualitative analysis was done for Haddon matrix to identify the risk factors of RTA. T test and Chi square tests was used for continuous and categorical variables respectively to find out the factors associated with outcomes of injury. P-value <0.05 was considered as statistically significant result.

Results

A total of 248 participants were included in the study. The mean age of the study participants was found to be 38.06 years with a SD of 16.26. Majority of the participants were males (77%) and were married (60%). Nearly one third of the participants were unmarried. More than one- fourth of our participants were illiterate and a very small fraction had received professional education. The monthly family income of most participants ranged between Rs 5843 to Rs 36551.

Table 1: Details of injury sustained by the study participants (n=248)

S.No.	Variable	Number (%)
1.	Health Facility Visited prior to this hospital:	
	Yes	112 (53.2%)
	No	136 (44.8%)
2.	Able to reach this hospital in the Golden hour	
	Yes	77 (31.2%)

	Limbs	175 (70.6%)
	Chest	51 (20.3%)
	Spinal	43 (17.2%)
	Abdomen	31 (12.4%)
	Facial	64 (25.4%)
	Poly-trauma	65 (25.7%)

S.No.	Variable	Number (%)
8.	Injury Setting	
	Home	70 (28.2%)
	Workplace	35 (14.1%)
	School	8 (3.2%)
	Road	130 (52.4%)
	Others	5 (2.1%)
9.	Chronic Illness	
	No	207 (83.5%)
	Yes	41 (16.5%)

Table 1 shows the details of the injury sustained by the study participants. Nearly half of the study participants had visited some other health facility prior to visiting this hospital. Only around one – third of the study participants were able to reach the hospital within the crucial golden hour after the injury. In majority of the study participants (78%) injury was unintentional. Almost 55% of participants had suffered deep injuries. Road traffic accident emerged as the single most important mode of injury (50.8%), followed by fall (23.6%) and assault (13.2%). Most common mechanisms of injury identified were collision (28.2%) followed by fall from height and blunt trauma (19.4% each). Majority of the study participants suffered from limb injuries. Most of the injuries were sustained on the roads (52.4%) followed by home.

Table 2: Details of care received by the study participants at the hospital(n=248)

S.No.	Variable	Number (%)
1.	**Vital Statistics at the time of arrival**	
	Observed	140 (56.5%)
	Not observed	108 (43.5%)
2.	**Vascular Injury**	
	Yes	32 (12.9%)
	No	216 (87.1%)

	Blood Tests	221 (89.1%)
	USG	79 (31.9%)
	None	2 (0.8%)
	*numbers (%) do not add up-to 248 as some subjects underwent multiple investigations	
4.	**Referral to other department of the hospital***	
	General Surgery	118 (47.4%)
	Neurosurgery	88 (35.3%)
	Orthopedics	163 (65.5%)
	ENT	45 (18.1%)
	Ophthalmology	41 (16.5%)
	Plastic Surgery	32 (12.9%)
	*numbers (%) do not add up-to 248 as some subjects were referred to more than one department	
5.	**Operative procedure done within 48 hours of arrival**	
	Done	126 (50.8%)
	Not Done	122 (49.2%)

The mean Glasgow Coma score of the study participants was 13.25 ± 3.14(mean ± SD). Details of care received by study participants at our hospital(Table 2) showed that vital statistics were observed for more than 56% of the victims. Around 13% of the participants had sustained vascular injury. Investigations most frequently done on the study participants were X ray (83.5%), CT scan (49.6%) and blood tests. Departments to which the study participants were mostly referred were Orthopedics (65.5%) followed by General Surgery (47.4%) and Neurosurgery (35.5%). Nearly 50% of the study participants required some form of operative procedure within 48 hours of arrival at this hospital.

In order to identify the factors associated with the outcomes of injury we studied the association between various socio-demographic variables, severity of injury (GCS) and site of injury, pre-morbid condition of patient and the outcomes. Statistically significant association was seen between age and outcome of injury with participants in the age group of 18 – 30 years showing better outcome in terms of not requiring any surgical intervention as compared to those above 30 yrs. (p value = 0.03). Participants with head and neck injury and those with GCS >13 showed greater likelihood of surgical intervention in our study as compared to participants with injuries of other parts and GCS <13 and this difference was also statistically significant (P= 0.01 and 0.04 respectively).

Qualitative analysis of the Haddon's matrix was done to identify the agent, host and environmental factors operating before, at the time and after the accident took place. Important pre-event factors which were identified were over-speeding, fatigue of driver & alcohol intake (Host factors), faulty brakes (Agent Factor) and low illumination (Environmental Factors). The factors playing a role at the time the event took place were young age, pre-morbid condition of the subject (Host factors), riding on two wheelers, type of vehicle (Agent Factor), and tree too close to the road, ditches (Environmental Factors). Similarly important post event factors identified were severity of injury and bleeding from the wound (Host factors), entrapment (Agent Factor), and slow emergency response and improper handling of the victim (Environmental Factors).

Discussion

Only around one – third of the study participants were able to reach the hospital within the crucial golden hour after the injury. In majority of the study participants (78%) injury was unintentional. Almost 55% of participants had suffered deep injuries.

Road traffic accident emerged as the single most important mode of injury (50.8%), followed by fall (23.6%) and assault (13.2%). Most common mechanisms of injury identified were collision (28.2%) followed by fall from height and blunt trauma (19.4% each). Most of the injuries were sustained on the roads (52.4%) followed by home.

Similar findings were observed ina retrospective study done by Kundavaram et al at the department of Emergency Medicine at Christian Medical College, Vellore. [9] Road traffic accident (RTA) (65%) was the most common mode of injury, followed by fall on level ground (13.5%), fall from height (6.3%), work place injuries (6.3%), and others in their study.

In our study majority of the study participants suffered from limb injuries. Head and neck injury was also reported in a substantial proportion of subjects. Study done by Kundavaram et al also showed that traumatic brain injury was seen in 17% of patients while 13.3% had polytrauma with two-wheeler accidents contributing to the majority. [9]

The mean Glasgow Coma score of the study participants was 13.25 ± 3.14(mean ± SD). Departments to which the study participants were mostly referred were Orthopedics (65.5%) followed by General Surgery (47.4%) and Neurosurgery (35.5%). Nearly 50% of the study participants required some form of operative procedure within 48 hours of arrival at this hospital. Study of Kundavaram et al also showed that theED team alone managed 23.4% of patients while the remaining 76.6% required evaluation and treatment by the trauma, surgicalteams. [9]

Conclusion & Recommendations

Trauma is a major problem in India with severe and wide-ranging consequences for individuals and society as a whole. Our study shows that RTA and falls are the predominant causes of trauma. The study provides baseline information about the types of injuries which commonly affects the community, has helped identify groups which are particularly vulnerable and also helped elicit the factors which influence the outcome of injuries. This knowledge would go a long way in designing comprehensive intervention strategies like awareness

campaigns and capacity building at all levels of health care to tackle injuries and reduce its impact on those affected.

Pattern of Utilization in Primary Health-Care Facility: A Case Study in Nagaon District

Mahfuja Begum

Assistant Professor, Department of Economics, Jorhat College (Amalgamated), Dist: Jorhat, State-Assam

Abstract

A sound health care system is the prime requisite for the effective health conditions of the people of a nation. But unfortunately the performance of India in this respect is quite disappointing. Evidences showed that studies on public health care delivery system are limited both in Indian as well as in the context of the North Eastern Region. This paper is an attempt to assess the pattern of utilization of primary health care. The study is based on primary data. The study found that there are problems associated with health care delivery system like lack of accessibility to the public health care facilities, shortage of medical equipment, shortage of medicines in government hospitals, lack of infrastructural facilities, low seat capacity and over crowdedness etc.

Keywords: *Health, Primary Health Centers, Rural health, Manpower, Health infrastructure.*

Introduction

The most widely acceptable definition of health is that given by WHO (1984), "Health is a state of complete physical, mental and social well-being, not simply the absence of disease". Healthier workers are likely to be able to work longer, be generally more productive than their relatively less healthy counterparts, and consequently be able to secure higher earnings than the latter. Although India has made considerable progress in health infrastructure under NRHM, the improvement has been quite uneven across regions with large-scale inter-state variations (Kumar, 2013[1]; Hazarika, 2013[2]; Baru*et al*., 2010[3]). In India a large proportion of people live below poverty line. So, expanding utilization of primary health care is a critical priority for the government of India. Efforts to that have addressed numerous issues and much progress can be reported. The health care system in India, at present, has a three-tier structure to provide health care service to its people. The first tier knows as the primary tier has been developed to provide health care services to the vast majority of rural people. The primary tier comprises two types of health care institutions: Sub Centre (SC), Primary Health Centre (PHC). Various types of family welfare programme, immunization programme and family planning measures are executed by these entire primary health care service providers.

Utilization of health care is an important component of overall health system and has a direct impact on the burden of disease. Assam government took various steps to increase the accessibility of primary health service to improve health outcomes in the state. In Assam the crude birth rate, death rate and infant mortality rates shown a secular declaring trend since 1981, but it has been found to be higher for the state than that of national average as a whole which. In the state the key infrastructure for delivery of primary health care are PHC's, CHE's and SC's.

The main objective of the study is: To examine the pattern of utilization of primary health-care facility.

Significance of the study: A well-developed health infrastructure contributes positively to better health

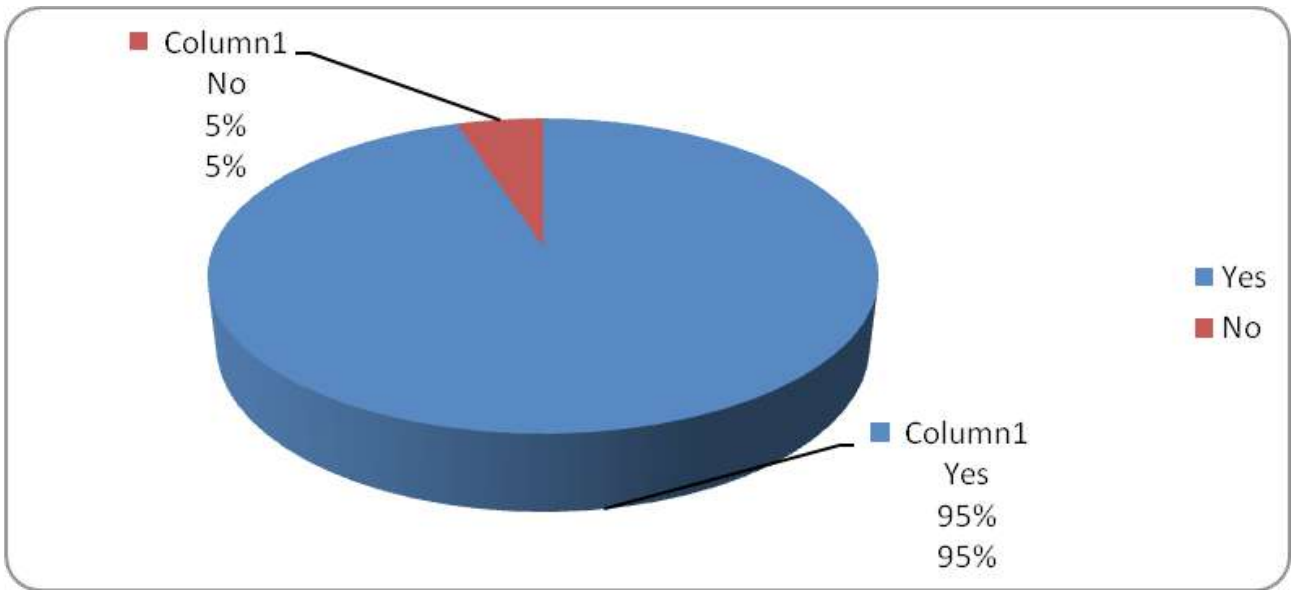
status among the people which in turn contributes positively to economic development. In Assam the Crude Birth Rate, Crude Death Rate and Infant Mortality Rates has shown a secular declining trend since 1981, yet it has been found to be higher for the state than that of national average. In the state the key infrastructure for delivery of primary health care are PHCs and SCs. These services are very important for health outcomes. So it is essential to examine the utilization of primary health care services. So far as no significant study has been done on utilization of primary health care service, therefore the study has been attempted.

Materials and Method

This research work is based on the primary data collected through a sample survey. The geographical location for the present study has been selected as Nagaon district under judgment sampling method. Nagaon district has two sub divisions viz. Nagaon and Kaliabar comprising 13 development blocks namely Khagorijan, Pakhimoria, Dolonghat, Raha, Batadrba, Juria, Ruphihat, Bajigaon, PachimKaliabor, Kaliabor, Lowkhowa, Barhampur and Kathiatoli. In the next step one block from each sub division i.e. Juria from Nagaon sub division and Kaliabor from Kaliabar sub division have been selected, as they have highest population in their respective sub division. From the two blocks Balikotia and Jakhalabandha revenue villages were randomly selected for the study. A total of 100 respondents are selected for this survey.

Findings and Discussion: This study tries to analyze utilization of primary health care. For access to government health service, they should be of good quality because of increasing competition from private sources. The reasons behind the low preference for government service are also analyzed in the study.

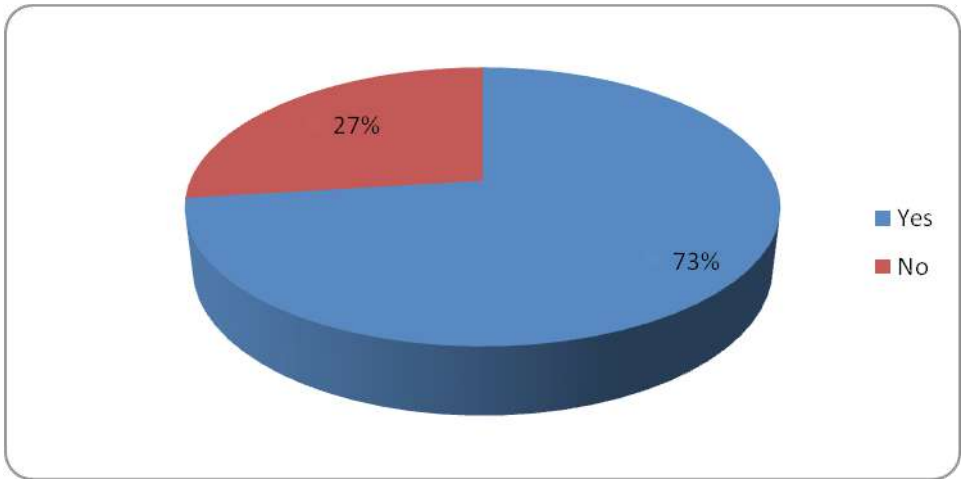
Knowledge about Primary Health Centre: The following figure (1) presents the level of knowledge of the people about the existence of primary health centres. It shows that major proportion of people knows about the primary care centres. On average, around 95 percent of the total sample population knows about the primary health centres in their area.



Source: Compiled from Field Survey

Fig. 1: Knowledge about PHC

Ever visit to Primary Health Centre to receive service: The following pie diagram (2) presents the proportion of people who have ever visited to primary health centres to receive services. It shows that around 73 percent of people have visited to primary health centres in their lifetime to receive services. The difference is very high in comparison to knowledge and use of service at primary health centre.



Source: Compiled from Field survey

Fig. 2: Sample Households who have visit to Health Centre

Selection of health institutions by morbid persons: Selection of institution depends on type of disease and distance to the facility. The sample households reported that the complex cases which cannot get cured in rural health institutions are referred to a higher facility as most of the PHC and CHC are not in a position to deliver the specialized health care service.

Table 1: Distribution of morbid persons seeking treats in different types of health institutions

Type of Institutions	No. of Morbid Persons	Percentage
PHC	16	16%
District hospital	38	38%
Private hospital	20	20%
Private clinic	26	26%
Total	**100**	**100**

Source: Compiled from Field survey

It appears from the table (1) that 38 percent of morbid persons seek treatment from district hospital. Likewise 16 percent seek treatment in PHC. However, treatment sought from private hospital is relatively lower (20). 26 percent of morbid persons visit to private clinic for treatment. It has been observed that a relatively higher proportion of morbid person visit to district hospital.

Place of Delivery: Most of the maternal deaths are attributed to the lack of proper care at delivery. In Nagaon district it seems to have been working good and almost all the mothers during 5 years in the survey area reported that their delivery took place in various health institutions.

Table 2: Place of delivery

Place of Delivery	Percentage of Child
Home	7
PHC	19
CHC	23
District Hospital	45
Private hospital	6
Total	**100**

Source: Compiled from Field survey

Place of Child Vaccine: In the surveyed area it has been reported that most of the children getting vaccine in government institutions like SC, PHC, CHC and government hospital.

Table 3: Place of vaccination

Place of vaccine	Percentage of child
S.C.	60
PHC	9
CHC	3
District hospital	18
Private hospital	10

Source: Compiled from Field survey

Reason behind low preference for government services:

The major issue emerged in the survey are as follows:

- There are lack of basic facilities at PHC's and Sub-Centre's like building, water and electricity, no proper in-patient facility. Moreover at many places, there is no laboratory facility and basic medicines

are also not available. So most of the tests are to be done outside.

- Most of the doctors are more interested in their private practice rather in providing the services through government health services. So, they are speedy and not ready to hear all the problems of patients.
- Lack of cleanness and rush also reported as two major reasons for low preference of government health service.
- Another problem in the government health institutions is the problem of low seat capacity and over crowdedness.

Table 4: Response of the households on reasons behind low preference towards government services

Reason	No. of Households	Percentage
No proper inpatient facility	67	67
Shortage of doctor	55	55
Rush	63	63
Lack of cleanness	74	74
Time consuming	68	68
Many a time lack of medicine	70	70
Most of the test are to be done outside	75	75
Rough behavior of nurses	20	20
Speedy-not ready to hear all problems	40	40

Total sample households: 100

Source: Compiled from Field survey

From the response of the respondents it has been observed that 75 percent of households mentioned most of the test done outside as a major reason behind low preference for government services. Apart from this lack of medicine, lack of cleanness and time consuming are also mentioned as major issues regarding low preference towards government health institutions.

Conclusion

The study indicates that there are problems of accessibility, infrastructure, and rude behavior of the health personnel, shortage of medical equipments, and shortage of medicines, low bed capacity and shortage of manpower in the sample villages. Complaints related to the supply of medicines, lack of testing laboratory were major factors hindering utilization of health care service in primary health centre. Very few medicines are available there and rest have to be brought from outside and most of the test are to be done in outside. Though the households at large are aware of the availability of service at primary health care centre's but the motivation for utilization is very poor. It needs the effective and continuous strategy to develop the demand and motivation towards the primary health services. The entire health system needs to be reformed to ensure efficient and effective delivery of good quality health services.

Measuring Adequacy and Optimization of Antenatal Quality of Care and Client Satisfaction During Pregnancy: A Cross Sectional Study of Two Aspirational Districts of Jammu & Kashmir

Naseer Uddin[1], Majid Hussain Qadri[2]

[1]Ph.D. Scholar (Public Health Management), [2]Assistant Professor, Department of Management Studies, University of Kashmir

Abstract

Ameliorating the mother-child health care has been a global and national priority as evidenced from persistent socio-economic and health policy interventions like National Health Mission. Despite the long standing public policy commitments and interventions to address lack of high-quality health care to scale down mother child mortality, the progress so far has been far from optimal especially during the pregnancy.This study elaborates how service quality structure-processes and the use of proficiencies typically associated with "service quality framework" can have direct application across the continuum of care architecture.

This Study by design is a cross-sectional, based on mixed methodology approach. Study showed that there are lacunae and evidences of inequity, inaccessibility and exclusion in MCH service quality and delivery, we need strategies and service infusion policy interventions aimed at delivering quality health services.

Keywords: *Antenatal care, Quality of care, client satisfaction, Aspirational districts.*

Introduction

Healthcare quality has tenaciously been neglected since early decades in India due to adoption of didactic model of care based on western philosophy, emphasizing less of the structural, social values and traditions of India which has ultimately led to an immense gap that needs to be covered in terms of service quality improvement standards. Despite the long standing public policy commitments and interventions to address lack of high-quality care to reduce maternal-child related deaths and complications, the progress so far has been far from optimal particularly, during the pregnancy and at the time of delivery.Regardless there has been substantial increase in coverage of service delivery, but without convergent improvement of quality of care[1]. The suboptimal achievement of MDG goals related to mother-child health in the last decade and now recent concern to achieve goals related to National Health policy 2017 and SDG health goals has elucidated the ignored health quality agenda.Ameliorating the mother-child health has been a global and national priority as evidenced from persistent socio-economic and health policy interventions like National Health Mission and recent Ayushman Bharat Mission.

Around an estimated 27 million women become pregnant and 17 million newborn babies are delivered each year in India and most of them do not receive appropriate care or care that is as per recommended standards. Access and availability to optimal quality care, during continuum of care is crucial for maternal outcomes and early-infant development. In India it is approximated that annually, the mortality of pregnant women is around 30000 during delivery and about seventy percent of newborn die (WHO 2017) due to poor in effective service delivery, quality processes and deficient health system[2].

In designing quality care interventions, service process optimization is a crucial element to the health outcomes and benefits related to service factors which matter most to maternal-child health[3]. During the early phase of pregnancy, the availability and accessibility of

care provided by the competent service providers have been found to be important factor for optimization of care[4]. Enhancing the efficiency and quality are decisive factors in service delivery optimization as it represents around 80% of the cost of healthcare, as compared to 20% for skilled services[3]. There are evidences of inequity, gaps in management practices and lack of access to high service care throughout continuum of care,especially during critical period of pregnancy[5]. The care during the pregnancy has seen lack of evidence-based intervention and best practices, which could otherwise strengthened the existing maternal-child healthcare system especially in fragile and intense regions like Kashmir valley[6].

Antenatal Period and Dimensions of Care: Antenatalcare is defined as "the care provided by skilled health-care personnel to women during pregnancy and at the time of labour in order to ensure the quality positive health outcomes". Care provided during the antenatal period establishes a grounding base across continuum of care, during and after pregnancy[7], studies have demonstrated that impelling service interventions and managing complications during antenatal period will significantly decrease the maternal and neonatal mortality by 50-60%[8]. Researchers have argued about formulating composite and combining indicators for ANC, but have not been able to deliver within a logic framework for evaluating continuity and adequacy of quality care. In this study, antenatal care quality model assessment based on three dimensions of ANC process—access to antenatal care services; timeliness of services provided and appropriateness of care are used.

Structure of Quality-Care and Models of Measurement: There is no ubiquitously defined structure and definition of "quality care", it is considered to be a "composite and multilayered" dimensional system existing between provider and client. As per Hulton (2000) maternal quality of care is defined as "the degree to which maternal health services for individuals and populations increases the likelihood of timely and appropriate treatment for the purpose of achieving desired outcomes that are both consistent with current professional knowledge and uphold basic reproductive rights"[9].

Measurement of quality is a core element of standards of care. Defining measures of quality is challenging task due to multidimensional nature of care, many models have been used to devise a conceptual quality framework, standards and measurement of quality care. These frameworks can channelize service providers and implementers to augment service quality and delivery. A number of quality care models have been accounted in the literature (Donabedian, 1980; Maxwell, 1992; Ovretveit, 1992; Institute of Medicine, 2001). Many method of assessment have been devised which review quality measurement initiatives and frameworks for monitoring progress in maternal-child healthcare[10]. This study applied the Donabedian's model of quality care coupled with WHO quality care framework as shown in Figure:1.

Donabedian Quality of Care Framework and Customer Satisfaction as Quality Parameter: This framework underlines client satisfaction as an outcome of care, an crucial parameter of farming quality health care system[11]. Assessment of quality can be done through its parameters by measuring input, process, and output indicators. Measures of quality includes standards that "assess, measure and monitor" the care as per statements of quality. Many studies explored the gaps in delivery of services and consumer perception of high-quality care and these have shown that health service quality should be measured as perceived quality instead of objective quality due to intangible and inhomogeneous nature of service quality[12].

Objectives of Study: This study tries to allay the continuum of care literature gap and examines deficiencies at different levels of service implementation in delivering MCH services to clients against the backdrop of NITI Ayog mapped SDG framework of "Transformation of Aspirational Districts". The objectives of study are:

1. To assess and measure structure-process outcome of service quality in J & K region,
2. To examine the implementation of National Health Mission Program in context to antenatal service architecture across continuum of care, and;
3. To suggest evidence-based data driven optimization of SDG aspirational health goals.

Materials and Method

Study design: The study is an ecological cross-sectional based on mixed methodology approach. The study consisted of three gauged data collection survey instruments as:

1. The facility-based checklist measuring the access,

availability and infrastructure related to service delivery.

2. The service provider schedule and observations capturing the structure-process, perceptions and application of standard service delivery.
3. Client interviews-schedules capturing and understanding the knowledge, attitude and perception of how the services were delivered to them.

Sampling Strategy: Study was done between January-October 2019 across two aspirational districts Baramulla and Kupwara of Jammu and Kashmir. The inclusion criteria of health facilities included were ANC services were provided and were at least one lady doctor and two auxiliary ANC staff were present. Table: 1 depicts the sampling strategy used in the study for two aspirational districts.

Measurement of Variables: Measurement of quality was assessed on three parameters of quality; structure, process and outcome. The structural parameters came from the facility assessment and provider interview; the process variables came from the observations and the exit interview of end users; the outcome parameter was client's measured satisfaction and service coverage-utilization indicators.

Structure and process indicators: These were framed through the WHO quality care framework for Service Availability and Readiness Assessment (SARA)[13], OCED indicator framework[14] and facility assessment SDG index framework given by NITI Ayog for aspirational districts. The structural variables were facility's inventory related to MCH service access and availability, physical infrastructure, quality assurance committees and were combined into a composite index score, using factor analysis. The process variables included socio-personal and competent aspects of the provider–client reciprocation with coverage utilization indicators (shown in figure 1). The Process variables were combined into a composite index, using factor analysis.

Outcome Variables: Client's satisfaction was assessed by a composite index using principal component analysis based on responses to 22 qualitative and quantitative statements-questions related to visit to facility.

Covariates-cofounding variables: Controlling of factors of service provider and clients such as years of experience, maternal age, order of ANC visit which could affect client's satisfaction was done.

Statistical Analysis: Categorial variables were tested for independence, mean differences and changes in continuous variables using ANOVA F test and T tests. Factor analysis was done for composite indexing of structural and process variables. GLM regression was used to assess the relationship between the outcome, structural and process attributes. Analyses was done using SPSS 25 and Atlas.

Findings: The services provided during the ANC period in both aspirational districts were below the recommended levels provided by the NITI Ayogs' aspirational performance framework and WHO standards[13], despite that access and availability of ANC services have increased across all levels of NRHM implementation in Jammu and Kashmir. Access and availability of different structural services provided at public facilities in two districts are summarized in Figure 2.

Status of Antenatal Services: In Baramulla district 32% pregnant women (PW) had four or more visits with appropriate ANC content as compared to 28.8% in Kupwara district, the level of services during ANC period varied widely; 91 % PW were checked for weight, only two-thirds had a urine sample checked and less than half were informed of signs of pregnancy complications in Baramulla, the situation was similar to worst in Kupwara. In both districts, most structural measures varied significantly between facility types. The higher-level facilities generally scored higher on structural measures than PHC facilities. The Figure:3 summarizes the status of service delivery to clients in two aspirational districts.

Client's Satisfaction: Waiting time for consultation was significant variable measure of client satisfaction given by all PW at all facility types and was significantly shorter at PHC's than higher facilities. In Baramulla district client satisfaction score did not significantly vary in facility types as compared to Kupwara were score was higher at DH and CHCs. In Baramulla, increased client's satisfaction was associated with a higher structure score. Among process attributes, receiving essential medicines and TT vaccination were crucial to satisfaction of clients.

Table 1: Showing sampling of Health facilities in two Aspirational Districts of Union Territory of Jammu and Kashmir

Aspirational Districts	Baramulla	Kupwara
	N (%) weighted	N (%) weighted
Public Health Facilities		
District Hospital	01 (2.5)	01 (2.6)
Sub District Hospital (SDH/CHC)	06 (15.3)	07 (18.5)
Primary Health Centre (PHC)	31 (79.7)	30 (78.9)
Specialized MCH hospital	01 (2.5)	-
Total Facilities	39 (100)	38 (100)
Service Provider		
Doctor	47	42
ANM/staff related to ANC	64	68
Total Service Providers	111	110
Client-Enduser Interview		
End-user Pregnant Women-Mother	158	138

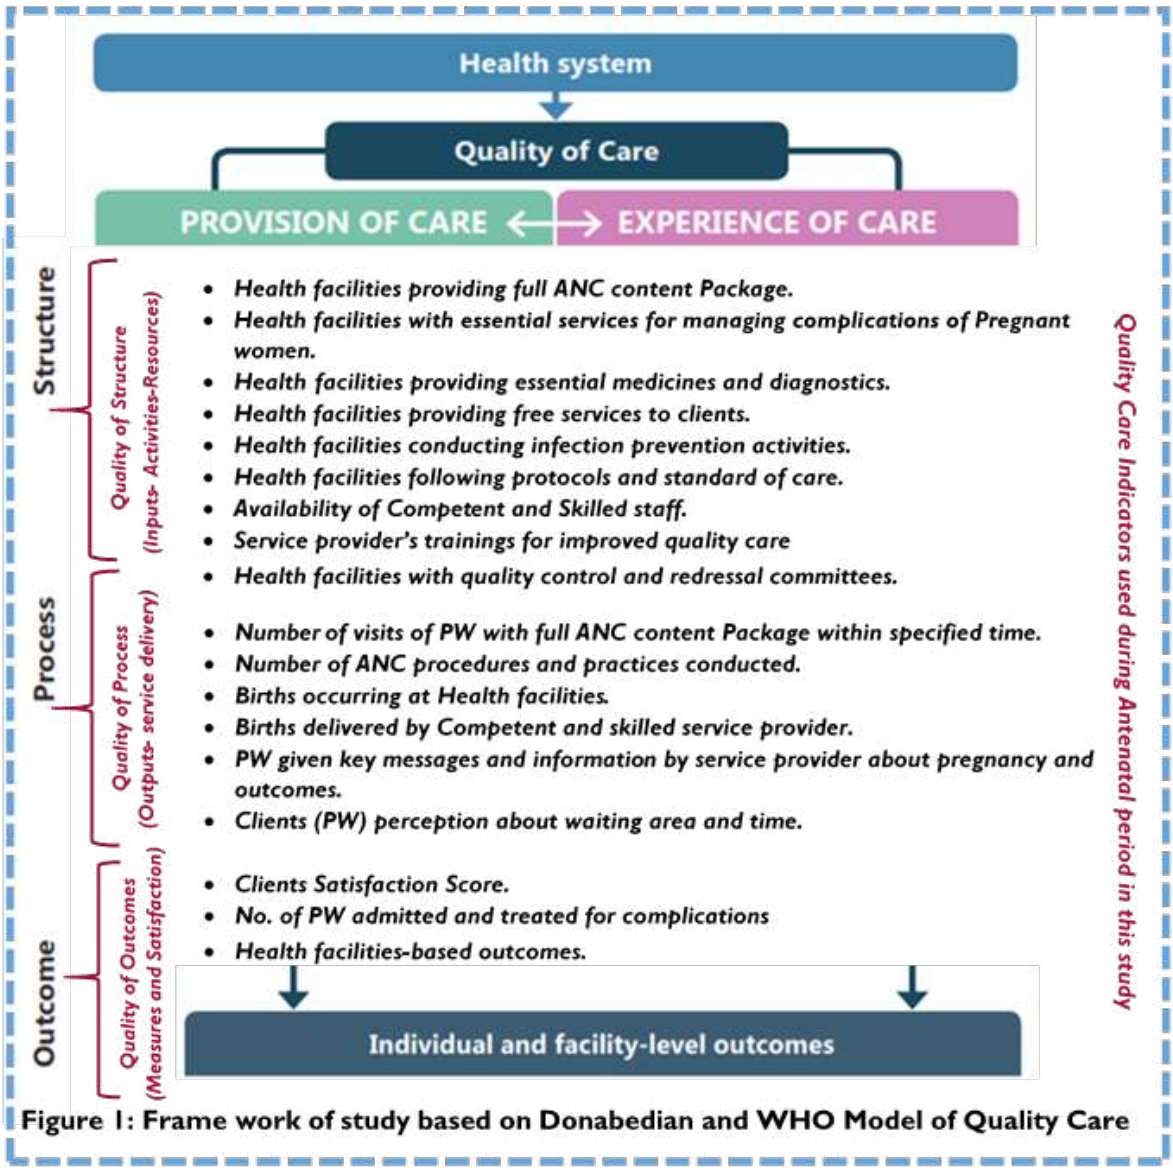

Figure 1: Frame work of study based on Donabedian and WHO Model of Quality Care

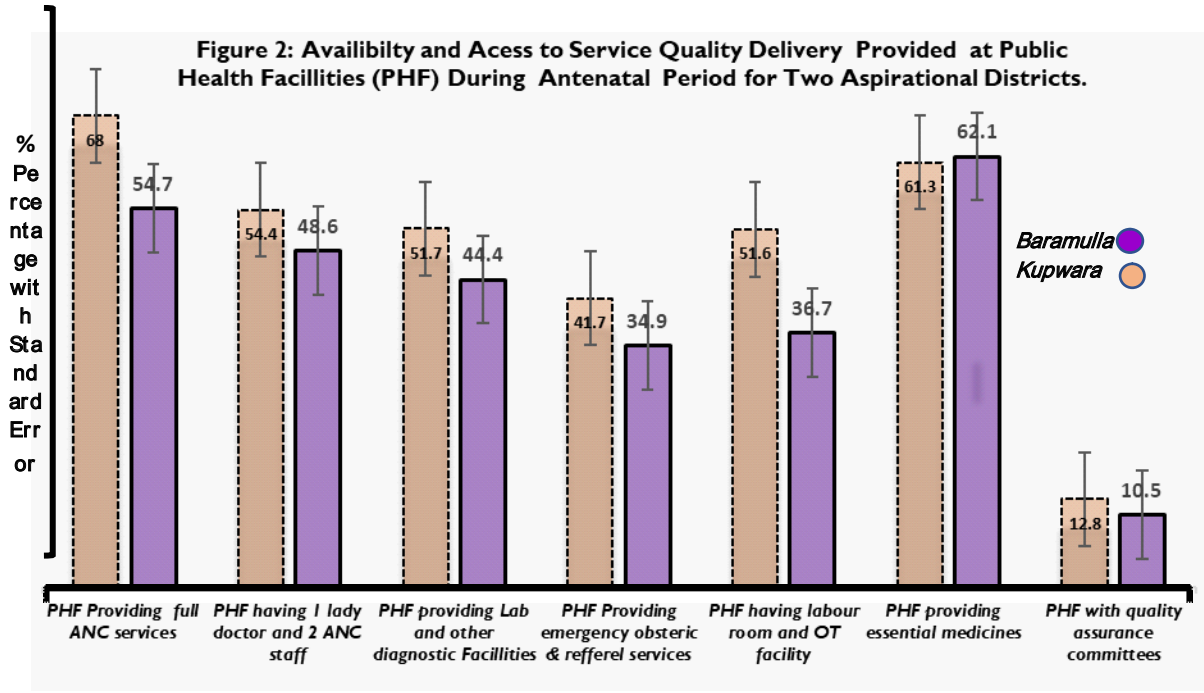

Figure 2: Availibilty and Acess to Service Quality Delivery Provided at Public Health Facillities (PHF) During Antenatal Period for Two Aspirational Districts.

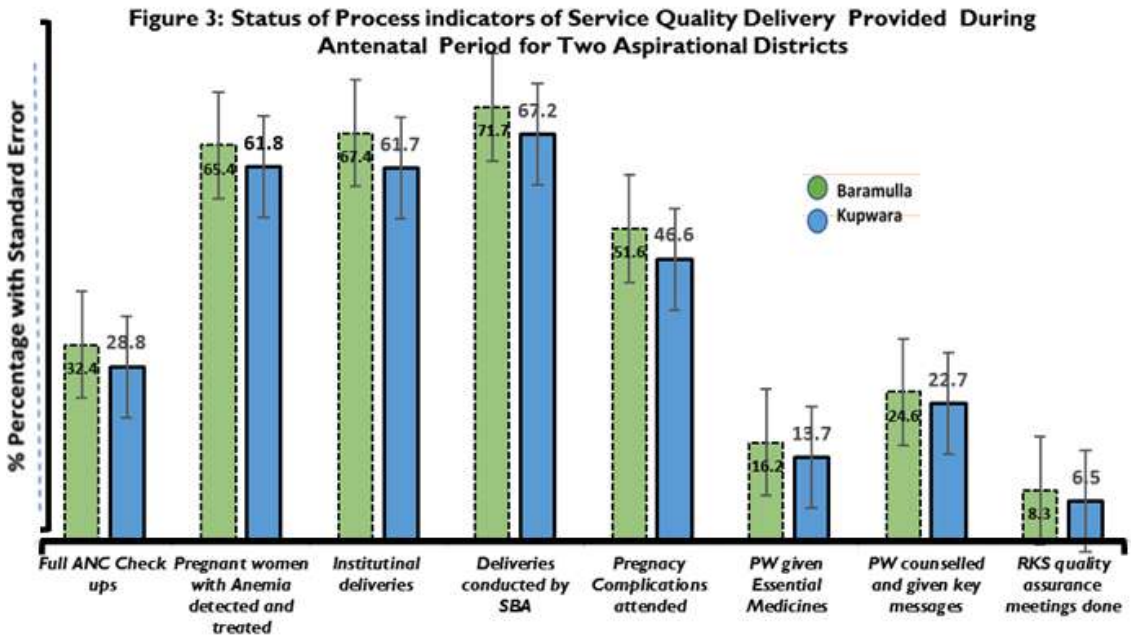

Figure 3: Status of Process indicators of Service Quality Delivery Provided During Antenatal Period for Two Aspirational Districts

Discussion

The study showed that gaps exists in access, availibity and delivery of quality healthcare which affect the client's satisfaction. The recent NITI Ayog report 2018 on performance of aspirational districts had put Baramulla on 33rd rank and Kupwara on 37th out of 101 aspirational districts. The report showed marginal decrease in ANC service care and institutional deliveries to the previous base year which was consistent with our findings. Availability of staff was the major variable which contributed to services being provide because of demand for services at district and specialized hospitals

is much higher, resulting in more allocated resources. In Kupwara, both interaction about pregnancy outcomes and preparing for delivery scored higher at lower-level facilities than higher-level facilities showing that better structural attributes may not necessarily improve the quality of service delivery[15]. Long waiting time which is important contributing service factor[16,17] showed negative association with client satisfactionand was consistent with literature findings[18]. Results showed that structure attributes were important for determining client satisfaction, which was inconclusive with other studies[19]. This study also showed positive relation though not always significant between client's satisfaction and process dimensions, and conclusions were consistent with other studies depicting that receiving essential medicines was an important factor for client's satisfaction[18,20]. Our study suggests that twining data from health facilities and providers about satisfaction of client can offer a comprehensive solution for the optimization of quality care.

Conclusion

There are evidences of inequity, inaccessibility and exclusion in MCH service quality and delivery across regions of Jammu & Kashmir. To address these deficiencies, we need strategies and service infusion policy interventions aimed at delivering quality healthcare. Providing optimal quality care should be essence of all strategies improving health outcomes especially in line with achieving SDGs. Implementing agencies, targeting improvement interventions in quality care should focus on decentralized structure, incorporating management service science, edification of institutional capacity and encouraging a culture of data-driven actions based on quality data sets. A paradigm shift is required in integrating newer innovations both technological and social to overcome the barriers in scalability and sustainability of chronically deficit mother-child ecosystem. A renewed course of action and resources stimulated by the 2030 SDG deadline are needed to augment this translational shift towards achieving sustainable universal access to quality care for maternal-child health.

Administration of Magnesium Sulphate Prior to Vecuronium: Effects on the Speed of Onset and Duration of Neuromuscular Block

Panchakshari Gouda Patil[1], K.R. Baliga[2], Sunil Baikadi Vasudevarao[3]

[1]Principal, Department of Anaesthesiology, KMC Mangalore, Karnataka, [2]Professor, Departmentt of Anaesthesialogy, KMC Mangalore, [3]Associate Professor, Department of Anaesthesiology, KMC Mangalore, Manipal Academy of higher education, Mangalore

Abstract

Background: We commonly encounter surgical patients who are on magnesium therapy in the operation theatre. It is important to know the interaction of magnesium on anaesthetic drugs including neuromuscular blocking agents. Our aim is to observe and compare the onset and duration of action of vecuronium following magnesium pre-treatment.

Material and Method: 50 patients were randomly divided into 2 groups. Group 1 (n = 25) received placebo (normal saline) and group 2 (n=25) received 40 mg/kg magnesium sulphate added to 100 ml of normal saline infused over a period of 15 minutes prior to induction. Following the induction of anaesthesia muscle relaxation was achieved by 0.1 mg/kg vecuronium and time for onset, duration of neuromuscularblock and vecuronium dose requirement during surgery was assessed by monitoring the tactile response to Train of four stimulation.

Results: Onset of time for intubation was significantly reduced to 120.19±6.53 seconds in the magnesium group compared to 259.150±26.131 seconds in thecontrol group($P< 0.001$). It was observed that the average duration of neuromuscular blockage of vecuronium was almost doubled and statistically significant ($P = 0.001$) in the magnesium group(26.89±2.91) as compared to the control group (42.28±1.41).The total dose of vecuronium used or required was significantly less in the magnesium group when compared to the control group ($p=0.008$). Duration from last dose of vecuronium to reversal of anaesthesia was prolonged in the magnesium group (40.2±3.96) compared to the control group(29.8±6.03) which is statistically significant($p<0.001$).

Conclusion: Magnesium sulphate administered before vecuronium significantly accelerates the onset of neuromuscular block necessary for intubation of trachea and significantly increase the time course of neuromuscular blockade. Intraoperative consumption of vecuronium was less in the magnesium group.

Keywords: *Vecuronium, magnesium sulphate, neuromuscular block, TOF.*

Introduction

Magnesium sulphate ($MgSO_4$) is a chemical salt, by nature andhas many uses in medical emergencies like eclampsia, acute asthmaand complex cardiac arrhythmias. It is abundant in intracellular space and we commonly under-diagnose the magnesium-related symptoms[1]. We frequently encounter patients on magnesium sulphate treatment for preeclampsia in obstetric anaesthesia. We usually recommend regional blocks for these obstetric conditions but because of associated coagulation irregularities we often end up

in general anaesthesia. $MgSO_4$ has a unique action at neuromuscular junction (NMJ) as it augments the action of skeletal muscle relaxants[1,2] .The presence of magnesium at neuromuscular junction naturally antagonises the calcium ion that binds to acetylcholine vesiclesthus reducing the amount of acetyl choline released. At postsynaptic area the presence of excessive extra cellular magnesium reduces the strength of acetylcholine evoked responses[3,4]. Magnesium sulphate as an adjuvant to general anaesthesia may modulate nociception through its interaction with NMDA receptors[2] .

Vecuronium is a commonly used relaxant in our hospital and we frequently encounter many patients who are on magnesium sulphate. At the NMJ magnesium concentration of 5 mmol/l and above produces significant neuromuscular blockade. Magnesium potentiates the action of vecuronium and prolongs the duration of all nondepolarising muscle relaxants[5] .

We investigated the interaction between magnesium sulphateand vecuronium froman anaesthesia perspective. We compared the effect of onset and duration of action of vecuronium with and without magnesium pre-treatment.

Materials and Method

Ethical committee approval from KMC medical college and informed consent from each of the patients participating in the study were obtained. Fifty patients undergoing various elective intra-abdominal and limb surgeries lasting for at least 2 hrs, belonging to ASA1 and 2 classes and in the age group 20-60 yrs were included in the study. Patients belonging to ASA class 3 and above, those with renal, liver, cardiacor neuromuscular dysfunction, possible difficult airway, atrioventricular block,asthma, chronic obstructive respiratory disease, and who were hypertensive and on calcium channel blocker, as well as pregnant female patients were not included in the study.

Patients were randomly divided in to 2 groups by block randomization. Group 1 (control group) received 100 ml normal saline overa period of 15 minprior to induction. Group 2 received 40 mg/kg magnesium sulphate added to 100 ml normal saline. This was infused over 15 minutes prior to induction. Parenteral solution was prepared by an independent anaesthetist who was not involved in the study. A peripheral nerve stimulator was used to evaluate the neuromuscular blockade and it was done by tactile assessment of twitch response of adductor pollicis muscle to supra maximal stimuli (2 Hz) for 2 seconds. Monitoring of neuromuscular blockade was performed from the time of induction till neuromuscular recovery was completed by applying supramaximal stimuli initially every 12 seconds during induction and thereafter every 5 minutes till appearance of T1 and then every 1 minute till the end of study. Monitors used were ECG, non invasive BP, pulse oximeter and ETCO2. The core body temperature was monitored and maintained between 36-37 degree centigrade using aforced air warmer.

All the patients received fentanyl 2 mcg/kg and midazolam 0.02mg/kg prior to induction of anaesthesia with thiopentone 5 mg/kg. A peripheral nervestimulator was used to stimulate ulnar nerve. Tactile response of adductor pollicismuscleto TOF stimulation was monitored every 12 seconds. Following induction, patients were paralysed with a loading dose of vecuronium (0.1mg/kg). All patients were intubated with endotracheal tubes of appropriate sizes when no twich response could be felt with TOF stimuli. Intubating conditions were graded as excellent,good or poor and noted in each case. All the patients were ventilated with oxygen and nitrous oxidein the ratio of 1:1 and appropriate concentrationof isoflurane to keep Minimum alveolar concentration value at 1. Intermittent bolus dose of vecuronium 0.02mg/kg was given when 2nd response to TOF was noticed. Residual neuromuscular blockade was antagonised with neostigmine (0.05mg/kg) and glycopyrollate (0.01 mg/kg) when 3rd response to TOF was present. Patients were extubated when all the 4 twiches were present without fade in response to TOF stimuli and also when patients met the subjective criteria for extubation (eye opening on calling,head lift for 5 sec,can protrude tongue, hand grip). Time duration from last dose of vecuronium to reversal, reversal to extubation, and last dose of vecuronium to extubation was noted and compared. Patellar jerk was elicited in the immediate postoperative period, and the response was noted in all patients.

The sample size was calculated using the formula:

$n= 2 (Z\alpha + Z\beta) 2X \sigma 2/ d2$

where $Z\alpha = 1.96$ (95% confidence interval)

$Z\beta = 0.84$ (80% power)

$\sigma = 0.39$

$d = 0.29$

The observations and results were analysed using Students unpaired 't' test and P value less than 0.05 was considered statistically significant.

Results

There was no significant difference between the two groups with respect to age, sex, weight, and duration of surgery (Table 1).

Table 1. Age and weight of the patients studied and the duration of surgery.

	Group	N	Mean	SD	Z/P
Age	1	25	40.850	11.235	0.109
	2	25	42.75	7.506	P = 0.914
Weight	1	25	61.200	8.675	0.1380
	2	25	60.75	7.30	P = 0.89
Duration	1	25	2.869	0.407	1.890
	2	25	3.161	0.558	P = 0.066

The two groups were comparable in terms of age, weight and duration of surgery.

Onset of time for intubation was significantly reduced (120.15±6.53 seconds) in the magnesium group compared to the control group(259.150±26.131 seconds) with the P value less than 0.001(Table 2). Intubating conditions were comparable between the 2 groups.

Table 2. Onset time (loading dose to intubation)

Onset time	Group	N	Mean	Std Deviation	Z/P
	1	25	259.15	26.131	5.413
	2	25	120.19	6.531	P < 0.001

Onset of time was significantly reduced to 120.19 ± 6.53 seconds in the magnesium group compared to 259.150 ± 26.131 seconds in the control group (P < 0.001).

Duration of neuromuscular blockage by vecuronium was almost doubled and statistically significant(P= 0.001) in the magnesium group(42.28±1.41)when compared to the control group (26.89±2.91)(Table 3). Total dose of vecuronium consumption was reduced significantly in the magnesium group (P=0.008). The rate of vecuronium consumption (mg/kg/hr) was significantly less(P=0.001) in the magnesium group (0.056±0.01) compared to the control group (0.08±0.01) (Table 3).

Average duration of neuromuscular blockage of vecuronium was higher and statistically significant (P < 0.001) in the magnesium group (26.89 ± 2.91) compared to the control group (42.28 ± 1.41). Total dose and rate of vecuronium (mg/kg/hr) consumption was reduced during the procedure in the magnesium group and it is statistically significant (p = 0.001).

Table 3: Duration of neuromuscular blockade and total dose and rate of vecuronium consumption.

	Group	N	Mean	Std dev	Z/P
Average duration for top up (min)	1	25	26.8925	2.912	5.415
	2	25	42.28	1.41	P < 0.001
Total dose vecuronium used (mg)	1	25	10.91	2.24	2.658
	2	25	9.04	1.508	P = 0.008
Vecuronium rate (mg/kg/hr)	1	25	0.0807	0.011	5.255
	2	25	0.0568	0.0066	P = 0.001

Duration from last dose of vecuronium to reversal of anaesthesia was prolonged in the magnesium group (40.2±3.96) compared to the control group(29.8±6.03) which is statistically significant(p<0.001). Recovery timing from reversal to extubation was significantly more (P=0.001) in the magnesium group(11.2±2.14) compared to the control group (7.55±1.468) (Table 4).

Table 4. Recovery characteristics.

	Groups	N	Mean	Std Deviation	Z/P
Last dose of vecuronium to reversal (min)	1	25	29.80	6.03	4.473
	2	25	40.20	3.968	P < 0.001
Reversal to extubation	1	25	7.55	1.468	4.622
	2	25	11.20	2.1425	P = 0.001
Last dose of vecuronium to extubation	1	25	36.30	5.563	5.311
	2	25	51.25	2.572	P < 0.001

Duration from last dose of vecuronium to reversal of anaesthesia was prolonged in the magnesium group (40.2 ± 3.96) compared to the control group (29.8 ± 6.03) which is statistically significant (p < 0.001).

Timing from reversal to extubation was significantly more (P = 0.001) in the magnesium group (11.20 ± 2.14) compared to the control group (7.55 ± 1.468).

Discussion

Magnesium sulphate is the drug of choice for various clinical conditions and an anaesthetist who

uses both vecuronium and magnesium sulphate together during surgery should have the knowledge of interaction between them. In our studyonset of complete neuromuscular block for intubation wasmarkedly less in the magnesium group. Wang *et al*. observed a synergic action between magnesium sulphate and vecuroniumon acetylcholine receptors at neuromuscular junction[1]. Fuchs Buder T*et al*. observed a shorter onset of time for vecuronium following magnesium sulphate pre-treatment. They also noted improvement in intubating conditions andpredictedthatit could serve as an alternativeto succinylcholine for rapid sequence intubation[2]. They found that ED 50 and ED 90 of vecuronium with magnesium sulphate pre-treatment were 25% lower than the control group. Mean onset of time was 147.3 sec in magnesium and vecuronium group compared to 297.3 sec for the control group[2]. Normal range of serum magnesium is 0.7-1.1 mmol/l. Fuchs Buder T*et al*. used the bolus dose of 40 mg/kg magnesium intravenously which raised baseline plasma concentration of magnesium from 0.9 mmol/l to 1.08 mmol/l which is significant statistically but still within the physiological range[2]. Ryu JH*et al*. used bolus dose of 50 mg/kg magnesium followed by 15 mg/kg/hr infusion without increasing serum magnesium level to toxic range[6] .In our study pre-treatment with $MgSO_4$ increased the duration of vecuronium block to 42.3 min compared to 26.8 min in the control group which is similar to that noted by Fuchs Buder T *et al*[2]. They noticed a prolonged duration of neuromuscular block in the magnesium and vecuronium groups(43.3 min) compared to the control group(25.2 min)[2].

The latter part of our study was about the consumption of vecuronium during the study period. Telci *et al*. observed that the use of magnesium decreases the anaesthetic drug requirement during total intravenous anaesthesia[7]. Gupta *et al*. found that magnesium has anaesthetic,analgesic, and skeletal muscle relaxation action and it significantly reduces the requirement of anaesthetic drugs[8]. We also noticed a reduced vecuronium requirement in the magnesium sulphate group (0.05mg/kg/hr) compared to the control group (0.08mg/kg/hr). Okuda T*et al*. compared the effect of 2 different doses of magnesium (20 and 40 mg/kg) on the potency of vecuronium and found that 40 mg/kg dose enhances vecuronium-induced neuromuscular block[9]. In our study excellent intubating conditions were obtained within 120.15 seconds in all patients ofthe magnesium group whereas it was 259.15 sec in the control group. Park SJ*et al*. also observed abetter intubating condition with rocuronium administration following magnesium sulphate pre-treatment[10]. Limitation of our study is that we did not measure serum magnesium and calcium levels during the study period. Previous studies have used varied doses of magnesium sulphate (20-50mg/kg) without any complications[2,6].In the present study, a bolus dose of 40 mg/kg of magnesium was used without any complications. Earliest warning sign of magnesium toxicity is the loss of patellar jerk which is seen when plasma magnesium level exceeds 3.5 mmol/l[11,12]. We did not encounter any patient with loss of patellar jerk in the immediate postoperative period.

Conclusion

We conclude that magnesium administration before vecuronium significantly accelerated the onset of neuromuscular block necessary for intubation of trachea. It also increased the duration of neuromuscular blockade and can be safely used for surgeries lasting for more than 1 hour. Monitoring of neuromuscular function and reduction in dose of vecuronium are required while using these two drugs in combination.

Assessment of Teaching Ability among University Level Health Science Teachers: Pilot Study

U. Ganapathy Sankar[1], Monisha R.[2], Naresh Bhaskar Raj[3], Sankara Kumaran Pandian[4], Deepthi Ganesan[4], Kaviarasu Mahalingam[5]

[1]Dean & Professor, [2]Ph.D. Scholar, SRM College of Occupational Therapy, SRMIST, Kattankulathur, Chennai, [3]Faculty of Health Sciences, Universiti Sultan Zainal Abiding, Gong Badak Campus, Kuala Nerus, Terengganu Darul Iman, Malaysia, [4]Lecturer, School of Physiotherapy, AIMST University, [5]Lecturer AIMST University

Abstract

Background: University level teachers were at stress and depression as because of their higher working hours with undergraduate, postgraduate and doctoral students. Which make the teachers to sit for hours and hours in class and stand with blackboard in-order to cover the syllabus hours and to encourage the students to be successful in career? Till now there are no studies done on assessing the cognition and teaching ability of a teacher in relation to the comorbidies they experience as a teaching staff.

Objective: To find out the cognition using ruff figural fluency test.

Procedure: The subjects according to inclusion and exclusion criteria and who were willing to participate in the study will be given a questionnaire of faculty workload survey 2001, Nordic questionnaire to evaluate the musculoskeletal pain and ruff figural fluency test kit to evaluate their cognition.

Results: The teachers inspite of the maximum engagement with curriculum, they have good academic performance, but the cognition is poor as the hours of the day passes by, it is due to the maximum stress they experience in dealing with their musculoskeletal pain.

Keywords: *Health science, students, university, Teaching ability.*

Introduction

Stress is the cause for work inefficiency and from decades the maximum stress has been experienced by the person who is the sole responsible for the children. Thus the university level teachers were considered to have maximum teaching hours; they were engagement with the curriculum developmental works and also engaged with student developmental programmes[1]. They have less time for self analysis and there is a need to look and examine the cognition and teaching performance and ability level of a university level health science teacher. Cognitive function can be greatly influenced by stress[2]. Importantly, although the majority of studies so far have focused on stress effects on memory function—which will be the main focus of this overview—most cognitive operations (from attention to decision making) are, in fact, susceptible to be affected by stress[3]. But not all the teachers in the university will be exposed to stress, few will be resistant and others were vulnerable[2,3]. No human study has done to examine the stress and its impact on cognition, only few animal studies exist.

It is believed that occupational pain over the muaculoskektal pain is caused by multiple factors, generally categorized into mechanical and psychosocial ones. Various mechanical factors have been found to be associated with pain in different body regions. Heavy

e-mail: dreamsfuture000@gmail.com

physical work, heavy or frequent manual operations, repeated rotation of the trunk, whole body vibration, and prolonged sitting were positively associated with low back pain[3,4]. Working with hands at or above shoulder level, flexion of the neck, static contractions, monotonous or repetitive work with arms, high working pace, and unsuitable work place were responsible for neck and shoulder pain. Psychosocial factors at work have also been shown to play important roles in the development of musculoskeletal pain. Important psychosocial factors included work demands and decision latitude, symptoms of stress, social support, type A behaviour, and psychological distress[4]. After reviewing 59 relevant studies, Bongers and colleagues concluded that monotonous work, high perceived workload, time pressure, low control on the job, lack of social support from colleagues, and stress symptoms were related to musculoskeletal problems. Carayon and colleagues reviewed work organisation, job stress, and work related musculoskeletal disorders, and concluded that work organisation and psychosocial factors at work could contribute to upper extremity disorders[5-8]. They further indicated that work organisation and ergonomic factors might interact to affect the musculoskeletal system.

Pain and cognition share an inherent overlap owing to the fact that pain itself has a cognitive-evaluative component, requiring learning, recall of past experiences and active decision making[5]. This should be borne in mind when assessing the effects of pain on cognitive function. Similar studies were majorly done on office workers, school teachers and manual workers. The study is needed as there is no study done on university level staffs

Methodology

We included the teaching staffs of age 50 years, gender both male and female and the information sheet which contained the need to conduct the study has been submitted to the teachers and a written consent form has been signed by the entire faculty. Non-teaching staff were excluded from the study. The staffs that were willing to participate in the pilot study were given with a manual that contains questionnaire that rate the musculoskeletal pain they experience and there is a black space which needs to be addressed by the faculty, which contains type of work, working hours, years of experience and workload. The RFFT is used to analyze the cognitive defects the faculty experience and it contains only line drawing which last 60s and needs maximum attention from the participants. Participants are presented test forms that contain rows of squares and within each is an array of five dots. Participants are then informed that, within each square, they must connect two or more dots by always using straight lines. The goal of the task is to generate as many unique designs as possible without replicating any drawings (Ruff, 1988). The participants were instructed to do so in between their working hours for 1 day.

Data Analysis:

Table 1: Shows the working hours, years of teaching experience, age and gender

	Working Hours	Experience	Ruff Figural Fluency Test	Age	Gender
N	**50**				
Mean	7.20	7.80	1.04	30.9	2.60
Standard Deviation	.216	1.64	0.64	4.78	.343

Table 2: Shows the musculoskeletal pain experienced by the teachers

	Pain in Neck for last12 weeks	Pain in neck for last 7 days	Pain in shoulder for past 12 months	Pain in shoulder for past 7 days	Pain in elbow for past 12 months	Pain in elbow for past 7 days	Pain in wrist for past 12 months	Pain in wrist for past 7 days	Pain in upper back for past 12 months	Pain in upper back for past 7 days
N	**50**									
Mean	5.40	5.60	6.30	4.80	3.50	7.80	3.50	3.70	4.20	5.70
SD	.567	.763	.654	.576	.765	.876	.234	.754	.876	.234

Discussion

When correlation analysis is performed, their exist no correlation between working hours and ruff figural fluency test. Negative correlation exists between age and ruff figural fluency test and there is no correlation between chronic musculoskeletal pain and ruff figural fluency test. The current study documents that musculoskeletal pain experienced by the teaching faculty at the university level will not influence the cognitive ability and it is not going to be a confounding factor in their teaching ability and it will not restrain the administrative role the faculties perform. The total sample selected and recruited from the university was 70, in which 10 were withdrawn from the study due to inadequate time as they were posted in the examination duty, 10 faculties revealed that the questionnaire were filled by the students as they experience inadequate time, thus the forms were rejected. The overall study showed a no or negative correlation between cognition and musculoskeletal pain. According to Richelle et al (2018), in his study concluded that prolonged sitting led to discomfort in lower back, hip and thigh but there was no attention deficit. In contrast to the study of Moriarty et al (2011), concluded that there appears to be sufficient evidence from preclinical and clinical investigations to support the theory that pain is associated with impaired cognitive function. Cognitive deficits in tests with high ethological validity, suggest that cognitive impairment in pain patients may be an obstacle to everyday tasks. As such, this impairment may have a marked impact on patients' quality of life. But the current study has documented that the faculties were not influenced negatively with the increased age, increased working hours and musculoskeletal pain.

Conclusion

This study concludes that there is no relation between Teaching ability and musculoskeletal pain.

A Critical Study of Women's Health in India from a Socio-Cultural and Gender Perspective

Parismita Bhagawati

Ph.D. Research Scholar, Political Science, Cotton University, Panbazar, Guwahati, Assam

Abstract

If we conceptualise health in a holistic sense, we would understand that it is not merely about the absence of diseases but essentially a socio-biological concept which hinges upon not just one's physiology but the socio-cultural and psychological variables as well. It is in this context, health issues among women in general and Indian women in particular, as a subset of the larger corpus of health concerns,needs to be inevitably understood and contextualised in the societal and cultural milieu within which women operate. Indian society, with its conservative culture and distinct ascribed social roles, engineers a woman's position in the social hierarchy and personal life experiences. Consequently, socio-cultural attitudes and gender constructs need to be understood as powerful decisive factors of one's health that colludes with other variables like age, family, educational attainment, occupational structure, income and social support etc. Against the backdrop of this social model of health, this paper tries to understand the role played by socio-cultural factors and gender constructs in determining health of women in India. The paper also conclusively, tries to provide various holistic strategies and suggestions for improvement of women's health.

Keywords: *Social model of health, gender, cultural norms, gender mainstreaming, reproductive health.*

Introduction

The World Health Organization's Ottawa Charter for Health Promotion (1986) sees health as multidimensional and espouses a social model of health. It defines health as 'a positive concept emphasising social and personal resources, as well as physical capacities.' In the social model of health, while human biology, physiology and health care are considered as important elements, besides these, it incorporates within its purview a variety of other variables and factors that have the potential to impact the health of an individual. These factors range from social and cultural attributes, political environment, economic and financial factors, psycho-social factors to various other inter-personal and environmental factors as well as their reciprocal communications that might lead to health or illness. Therefore, the concept of health is definitely not unidimensional, it is multifaceted. Such a positive conceptualisation of health necessitates and warrants a discussion and analysis of women's health status and scenario with respect to the role played by the social construct of gender and the various socio-cultural roles and attitudes that flow from it.

Objective and Method

The primary motive of the paper is to study the present scenario of women's health in India. This research paper whilst trying to enquire into the status of women's health, particularly, tries to understand and highlight the role of the contextual socio-cultural factors and gender constructs that operate in Indian society; in serving as determinants of women's health. To this effect, a predominantly qualitative research approach has been adopted to critically inquire into the topic at hand. Data at all stages are secondary in nature and garnered from a variety of published sources. A thorough study of journal articles, newspaper and government health reports, books relevant to the topic has been undertaken. The methodology of data analysis is descriptive, explorative and analytical .

Findings and Discussions

The findings of the study and consequent recommendations have been presented and discussed in various sections dealing with various related observations and ideas.

Indian societal realities and women: It has been evident that women in modern India face a paradoxical situation. While women are increasingly making inroads into erstwhile male-dominated professions and admirably hiking up the corporate hierarchy, there is still a sizeable section of Indian women languishing without any sense of their identity or any form of human rights. Although, the government is striving hard to bring in women-centric legislations and devise policies for women empowerment and uplift, what is happening in ground reality remains unaffected; women still in a very large number and in variegated ways receive systemic discrimination in society. Patriarchy as the basis of India's social functioning operates within a web of norms that possess an inherent tendency to disempower and control women's every aspect of life. The women in India having to survive and grow up in such an environment and simultaneously having to do their best and live up to their own best potential as well as society's expectations from her, proves to be a burdensome toil for all women throughout their life-cycle. The social construct of gender engineers a woman's position in the social hierarchy and also has a prominent bearing on her social and personal life experiences. Consequently, socio-cultural context and gender need to be understood as powerful decisive factors of women's health in India that colludes with other variables like age, family, educational attainment, occupational structure, income and social support etc.

Gender and Health: Crucial Revelations: The effect of the construct of gender is clearly visible in differential allocations of factors of risk and burden of diseases between the genders throughout their cycle of life. A difference between the genders is apparent in risk factors and disease burdens across the lifecycle, from childhood, through adolescence and adulthood, to old age[1,2]. Data provided by National Family Health Survey(2015-16) shows that boys recorded a higher neonatal mortality rate but post-neonatal mortality rates were higher for girls. This alludes to the fact that there exists gender discrimination leading to improper childcare which ultimately quashes the biological advantage girls enjoy in terms of a lower neo-natal mortality rate as compared to boys[1]. Gender gaps are also revealed in nutrition levels with higher rates of anaemia among women and girls. A similar situation prevails in the scenario of immunisation rates. Pregnancy and delivery-related complicacies in the Indian context also serve as significant reasons for death among 15-19 year old girls. Marriage and childbirth at an early age further compound the risks to the health of young women which may include mental stress and depression, pregnancy related complications, miscarriage etc[3]. Studies and statistics reveal that around 50-90% pregnant women in India suffer from iron deficiency which flares up risks of maternal deaths[4]. A typical sort of gender bias is also visible in the pattern of health policy sector where reproductive health services and policies come exclusively to be attached to women and sexual health especially, with reference to HIV/ AIDS is prioritised as a sector for males. This makes bare the lack of gender mainstreaming in Indian health policy sector. In the arena of mental health, typically, in the case of women, the construct of gender and other socio-cultural factors have a significant role to play. There appears to be deeper connexion between gender and suicidal behaviour. Factors like childhood abuse, marital rape, domestic atrocities play a significant role in goading suicidal behaviour among women. A socio-cultural variable responsible for female suicide typical to Indian society is the practice of dowry in marriages. "The precipitants for suicide, according to Indian government statistics, among women compared to men are as follows: Dowry disputes (2.9% versus 0.2%); love affairs (15.4% versus 10.9%); illegitimate pregnancies (10.3 versus 8.2); and quarrels with spouse or parents-in-law (10.3% versus 8.2%). The common causes for suicide in India are disturbed interpersonal relationships followed by psychiatric disorders and physical illnesses."[5]"According to an eye-opening United Nations report, around two-third of married women in India were victims of domestic violence and one incident of violence translated into women losing 7 working days in the country. Furthermore, as many as 70% of married women between the ages of 15 and 49 years are victims of beating, rape or coerced sex."[6] Female Indian psychiatric patients share a serious concern of sexual coercion. "Sexual coercion was reported by 30% of the 146 women in an Indian study. The most commonly reported experience was sexual intercourse involving threatened or actual physical force (reported by 14% of women), and the most commonly identified perpetrator was the woman's husband or intimate partner (15%), or a person in a position of authority in their community (10%)."[7]

Cultural Norms, Gender Roles and Women's Health: The socio-cultural and gender norms in a conservative society like India has a strong bearing upon women's health. The cultural attitude and social orientations towards the institution of marriage and the

culture ordained role of a woman entering into marriage, the cultural value attached to fertility and the religious importance attached to the sex of the child, the nature of familial organisation and the ideal role coveted of the women by cultural conventions determine a woman's position in a family, her access to healthcare, levels of nutrition, education and her reproductive and overall health.

Marriage in India other than carrying personal significance, also carries tremendous social, cultural and religious significance not only to the individuals tying the knot but the entire sphere of extended families. The cultural insistence on the marriage of women in the ripe phase of their childbearing period leads to a high fertility rate and each additional child is a burden on the mother affecting both her physical and mental health.

Women's reproductive health in India is strongly impinged upon by the culture of preference for sons. Caste-Hindu philosophy as contained in various religious manuscripts like Manusmriti, portrays an exorbitant amount of importance to males and constructs women as 'lesser' human beings. It is a clearly embedded religious worldview in the majoritarian Hindu society that it is only a son that can enable the parents to heaven after their deaths. Moreover, daughters are considered as a liability as they leave their parents' home after marriage and the father as his paternal duty needs to arrange for a dowry to be sent away with the daughter in marriage. Such religion induced practices strengthen a strong preference for sons. This promotes multiple attempts at conception and successive childbirths until a male-child is born creating unnecessary health and mental burden upon the mother. Such a culture of son-preference also leads to crimes like female infanticide, sex-selective abortions etc.

The construction of a woman's personhood and capacity in Indian society contributed by the religious prescriptions, caste and patriarchal dictates brings to fore the image of a subordinate and dependant social identity. From the very early years, a girl is taught to be docile and obedient and in a way systematically internalise her subordinate position in the household and she translates in the same capacity to her husband's house after marriage. The consequences of this subordination incorporates lack of any kind of control over her reproductive rights, lack of equal access to food and nutrition, even access to healthcare.

Patriarchy induced gendered division of labour forces women to absorb themselves in the domestic sphere of life. In rural areas, the girls from a very young age are made to do strenuous household chores and labour which takes a toll on their health and deprives them of their childhood freedom. Many rural Indian households follow the norm where the male heads of the house eat first while the woman eat last and have to make do with the leftovers. Especially, when it comes to poor families, such a patriarchal norm contributes towards the consistent inadequate nutrition levels in women. This vicious combination of strenuous household labour and inadequate nutrition contributes to poor health of women in India especially, in the rural scene. In the urban scene, situations are not better either. While women are breaking the glass ceiling and entering into the public sphere of workplace, they are not relieved of the gender roles society imposes upon them. As a result, they suffer from a situation called the "double burden" wherein the women have to overwork themselves to play the dual role of breadwinner as well as do strenuous household labour. During the period of pregnancy, childbirth and the consequent period of childrearing, these working women are the ones who go through extreme mental and physical frustration. These unreal societal expectations that women have to live up to naturally take a toll on their mental and physical health.

From their childhood, girls are taught not to complain and to maintain secrecy about their physical troubles. With menstruation, taboos are enforced and restrictions placed on their mobility. They are unable to discuss their health problems, if any, or to visit a doctor. In the later stages of life, as a mother who is more often than not, vested with the entire responsibility of childcare and nurturing, has a strong tendency to hush down any physical or health trouble until the trouble overtakes them.

The Way Ahead: For the improvement of women's health in India, mere policy interventions evidently, would not suffice. A holistic paradigm shift is required in the way women's health concerns are addressed and approached. The aim should be to implement a truly social model of health which emphasises on not just the mere absence of diseases but also improving or eliminating other environmental, social, cultural or personal factors or variables that positively or negatively impact upon one's health. To this end, a five-pronged strategy can be suggested as follows:

- The first step necessarily, would be to formulate such strategies, policies and codes that challenges existing

norms and attitudes that directly harm women's health and ensure stringent implementation.

- Recognise and address differential health needs and concerns of men and women not just basing the understanding on their biological differences but also how their biology interacts with various social norms and gender roles to produce different health vulnerabilities.
- Another potent strategy would be gender-mainstreaming in the entire corpus of health policy sector ensuring women's voices and needs are present in all levels of health policy process.
- Infusing a gendered perspective into the health policy research spectrum. The focus should be on broadening the scope of health research and link biomedical and social dimensions, including gender considerations.
- Transform the gendered politics of health systems by improving their awareness and handling of women's problems as both producers and consumers of health care, improving women's access to health care, and making health systems more accountable to women.[9]

Conclusion

Therefore, it has been made inarguably clear that women's health is not a lone impervious variable, it has to be considered in association with their socio-cultural context and gender roles . Any policy or mere discussion on women's health concern should involve her emotional and mental well-being along with her physical health at all stages of her life. It is a common occurrence where policies in India view women's health very narrowly in terms of reproductive and maternal health solely. Such a constricted policy worldview in India has greatly contributed towards reinforcing the idea that women only exist as mothers and procreators. Moreover, when an individual woman suffering from a certain health concern is focused in isolation as a singular independent biological entity divorcing her condition from her sociological realities, it runs a risk of placing the burden of reformation on the women alone. But as we would agree that change for women is well beyond their control and is possible only with a bigger positive social transformation. Given these realities, it becomes imperative to undertake stratagems and schemes that would target the social factors responsible for having a degrading impact on women's health. Such strategies may involves social policies to reduce gender gaps in all fields of social existence, enhance women's status in society by giving them their due or at least empower and educate them enough that they are able to voice out their demands and grasp their rights for themselves.

Actions of Riluzole on Glast and GLT_1 Transporters in Rat Migraine Model

T. Jeevapriya[1], R. Archana[2], Gunapriya Raghunath[3], P.K. Sankaran[4]

[1]Research Scholar cum Assistant professor, Department of Anatomy, Madha Medical College, Bharath Institute of Higher Education and Research, Chennai, Tamilnadu, [2]Associate Professor, [3]Professor & Head, Department of Anatomy, Saveetha Medical College, Chennai, [4]Associate Professor, Department of Anatomy, AIIMS, Mangalagiri, India

Abstract

Riluzole exerts a neuroprotective effect through different mechanisms including action on glutamatergic transmission. We investigated whether this drug affect glutamate transporter mediated uptake expressing the rat glutamate transporters GLAST, GLT. We found that riluzole significantly increased glutamate uptake in a dose-dependent manner. This may facilitate the buffering of excessive extra cellular glutamate under pathological conditions suggesting that riluzole's neuroprotective action might be mediated by its activating effect on glutamate uptake.

Keywords: *Riluzole, Glutamate transporters, neuroprotective.*

Introduction

Glutamate transporters are a family of neurotransmitter transporters proteins that move glutamate -the principal excitatory neurotransmitter – across the membrane. The family of glutamate transporters is composed of two primary subclasses the excitatory amino acid transporter (EAAT) family and vesicular glutamate transporters (VGLUT).[1] In the central nervous system, astrocytes regulate extracellular glutamate concentration via two types of glutamate transporters, glutamate transporters-1 (GLT-1) and glutamate aspartate transporters (GLAST). In physiological conditions, glutamate transporters uptake glutamate from the extracellular space.[2] However, in pathological conditions such as ischemia, astrocytes release large amounts of glutamate via reverse transport, and is increased extracellular glutamate participates in neurotoxicity.

Riluzole, a neuroprotective drug approved for ALS, riluzole enhances the activity of glutamate transporters GLAST and GLT_1 and reduces extracellular glutamate concentration in the CNS.[3] In the contrast to this glutamate reducing effect in the CNS. Some studies proved that a local injection of riluzole in the locus coeruleus resulted in activation of noradrenergic neurons to induce descending inhibition in rats. The facilitation of glutamate-induced glutamate release from astrocytes.[4] However, the mechanism by which riluzole might activate glutamate-induced glutamate release from astrocytes in unknown.[5]

Materials and Method

Male albino wistar rats (n=6) of weight ranging from 200g was the histomorphometry in the present study. The rats were obtained from experimental animal; facility of saveetha medical college. The animal were kept in cages with not more than the three animals in one cage. They were maintained at 12hrs:12hrs light/ dark cycles with water and food available ad libitum.[6]

Experimental Design: The rats were divided into three groups

- Group 1 control rats (n=6)- saline treated rats
- Group 2 migraine model rats (n=6)- nitroglycerin (10mg/mg subcutaneous bark of neck) induced rat migraine for 7 days
- Group 3 riluzole treated rats (n=6)- riluzole (6mg/kg i.p) treated nitroglycerin induced rat migraine model for 7 days. Riluzole was given 1h before the administration of nitroglycerin.

Tissue Collection: Fixation was done using 500ml of 4% formaldehyde in 0.1M phosphate buffered saline, through transcardiac perfusion then dissect the rat brain trigeminal ganglion was identified and removed. Tissues were sectioned (20µm) using cryostat and stained with Cresyl violet.

Immunohistochemistry: The antibodies for GLAST and GLT_1 subunits were obtained from sigma laboratories and the standard dilution ratio was determined after repeated histochemical localization at various dilution ratio. The free-floating sections of trigeminal ganglion were localized for GLAST and GLT_1 subunits focused by JENOPTIK ProgRes capture pro 2.7 (Germany) captured using ProgRes image capture software.

Measurement of Small Neurons: The neurons in the image of immunostained trigeminal ganglion will be measured for the maximum diameter using image j software. The neurons of diameter <22µ were small neurons and the staining pattern of those neurons were studies.

Result

The GLAST and GLT_1 subunits were localized in the cytoplasm of trigeminal ganglion neurons in the control rats and there was upregulation in migraine model rats, especially in the small neurons (Figure 1 and 2). The GLAST subunits expression in the small neurons was decreased after treatment of riluzole (Figure 1). The GLT_1 expression was also seen in satellite glial cells surrounding the neurons but there was no difference in the intensity of expression in all these groups.

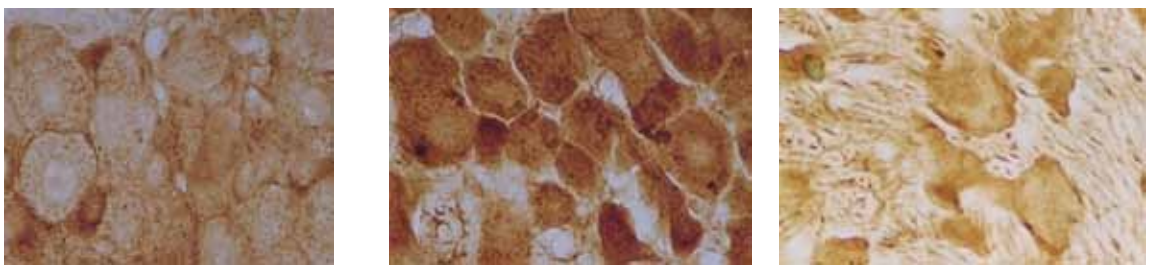
Figure 1: a, b and c: Localization of GLAST in the cytoplasm of the neurons (Figure 1 a), its upregulation in the small neurons (Figure 1 b black arrow). The upregulation has been decreased after riluzole treatment (Figure 1 c).



a **b** **c**

Figure 2: a,b and c: Localization of GLT in the cytoplasm of the neurons (Figure 2 a), its upregulation in the small neurons (Figure 2 b black arrow). The upregulation has been decreased after riluzole treatment (Figure 2 c).

Discussion and Conclusion

Riluzole is a neuroprotective drug acts by blocking glutamatergic cell transmission and controls the neuroexcito-toxic damage. It is though that the neuroprotective action is done by noncompetitive blockage of the NMDA receptors and G protein dependent signals transduction, thus controlling the excitotoxicity.[7]It was also proved that any neuropathic pain is due to an imbalance between the inhibitory and excitatory synaptic function followed by nerve injuries. riluzole, a novel neuroprotective has been used to prolong the survival of patients with amyotrophic lateral sclerosis.[8]

The neuroprotective effect of riluzole is also known to rely in part on inhibition of sodium channels the inhibition of sodium channels was correlated with post ischemic neuronal protection.[9]Riluzole had a higher affinity for the inactivity state than the resting state of sodium channels which resulted in a selective block of damaged or depolarised nerve thereby preventing excess stimulation of the glutamatergic receptors.[10]

NMDA receptors gate the ion channels present in the presynaptic and postsynaptic regions also in some extra-synaptic locations.[11] The amount of glutamate present in the synaptic cleft is very important in deciding stimulatory and excitatory transmission so the maintenance of glutamate concentration between the neurons is very important so that excessive activating of glutamate transporters can lead to various pathological conditions.[12]In this study, after treatment with there is a decrease in the expression of NR2B subunits compared to migraine induced rats. Riluzole a neuroprotectant and with antiglutaminergic activity modulate the neurons and protects from excitotoxicity.[13] Administration of riluzole increase the uptake of glutamate by increasing the glutamate transporters and reduce its antiglutaminergic action is exerted mainly by blocking the sodium channels by inhibiting the alpha activity and stabilizing the voltage gated calcium channels.[14]

So this study was done to prove the changes in the transporters and its counter-regulatory actions of riluzole on GLAST & GLT_1 transporters in a rat migraine model.[15] Also riluzole can be used in the treatment of migraine due to the neuroprotectant and neuromodulatory actions.[16]

Factors Affecting Child Development: Highlighting the Facts in the Perspective of Child Abuse in Indian Scenario

Arunangshu Giri[1], Satakshi Chatterjee[2], Pradip Paul[3], Manigrib Bag[4], Abanti Aich[5], Swatee Biswas[6]

1Associate Professor, School of Management & Social Science, Haldia Institute of Technology, [2]Assistant Professor, Department of Pharmaceutical Management, Haldia Institute Management, [3]Senior Manager (Retail Sales), Haldia Divisional Office, Indian Oil Corporation Ltd., [4]Assistant Professor, School of Management & Social Science, Haldia Institute of Technology, [5]Assistant Professor, Department of Science and Management, Haldia Institute of Health Sciences, [6]Officer in Charge, Administration Department, Haldia Institute Management, Haldia, West Bengal, India

Abstract

Child abuse occurs in all cultural, income and ethnic groups and it can be broadly classified under physical, verbal, sexual, emotional or through neglect. It is often assumed that child abuse is an underlying problem encased in bigger problems like human trafficking, etc. The main objective of the paper is to identify the root causal factors of this problem of Child Abuse. This study has identified seven factors which had some contribution to this problem and they are broadly classified as: health-related problems, physical-abuse-related factors, education-related factors, income-related factors, family-related factors,overall child development and socio-economic improvement. The data was collected with the help of a structured questionnaire using a Likert scale. The reliability as well as validity testing was done for this study. Furthermore, structural equation modeling (SEM) was used for the analysis of the data.

Keywords: *Child development, Child Abuse, Indian Scenario, Structural Equation Modeling (SEM).*

Introduction

Child Trafficking is also a major crime as it was seen that more than half of the children trafficked for sex and they had experienced sexual violence, along with domestic servitude and labour exploitation. Child Sexual Abuse is also a major segment under Child abuse and it is defined as using children in any kind of sexual activity, often without the consent and understanding of the children (Krishnan, et al., 2017)[6].It has been also seen that sexual assault to children is not generally reported to the authorities due to social stigmatization and many other reasons such as guilt, embarrassment, lack of awareness of the victim's rights, the need to keep the event hidden from certain people, unwillingness of the victim to confront the abuser in a legal setting and also fear of not being believed (AlMadani, et al., 2012)[2]. However, it has been seen that the children exhibits first signs of exhibiting sexual abuse by talking to their most trusted adults when they are carefully prompted and asked thoughtfully. Reporting of child abuse to the proper relevant authorities may help in the protection of the children from this evil. A comprehensive public health strategy may go a long way in the prevention of child maltreatment if implemented properly.

Literature Review: Some of the physical consequences have been defined as thermal injury, Shaking Trauma Syndrome, which is also called STS, blunt trauma, etc. Intentional burns are the most serious kind of child abuse injuries and it must be immediately diagnosed in order to prevent the perpetrator from further harming the child (Pawlik, et al., 2016)[8]. Child

Sexual Abuse, specifically, can be the cause of the child developing internal lacerations and bleeding as a part of most severe physical injuries and in the most severe cases, damage to the internal organs is also seen which can ultimately result in the death of the child (Aboul-Hagag & Hamed, 2012)[1]. Though physical maltreatment is very insufferable by the child, emotional maltreatment is also considered as a type of abuse which has many detrimental effects in the long run such as emotional abuse (4.8 per cent) and emotional neglect (6.2 per cent) (Taillieu, et al., 2016)[11]. Neglect can stream from an unstable family environment wherein the women who encounter Intimate Parental Violence have mental health needs that need to be fulfilled in order for them to show effective improvement (Bowen, 2015)[3]. Consequently, it has been seen that interventions made to prevent Intimate Parental Violence further explicitly impacts the children's subjection to violence and can effectively improve parent-children relationship in the long run (Kyegombe, et al., 2015)[7]. A study conducted in Canada revealed that the children or youth who are removed from their parental home due to instances of maltreatment fall under the increased risk group of showcasing Suicide Related Behaviour in the Emergency Departments (Rhodes, et al., 2012)[10]. Thus, it is very important to nip this bud right from the very start by identifying the perpetrators, however, the child abusers are people who are not strangers to the children but they are known to them, they may be family friends, neighbours or some relatives, who have some level of trust in the family (Feng, et al., 2015)[4]. However, certain models have been formulated to assess the risk of maltreatment of the children by looking at certain parameters and stopping the act from escalating further and they can also help the government in formulating certain preventive strategies to permanently stop the recurrence of these events (Prinz, 2017)[9].

Hypotheses Development:

H1: 'Physical Abuse Related Factor' negatively influences the 'Overall Child Development'.

H2: 'Education Related Factor' negatively influences the 'Overall Child Development'.

H3: 'Family Related Factor' negatively influences the 'Overall Child Development'.

H4: 'Income Related Factor' negatively influences the 'Overall Child Development'.

H5: 'Health Related Factor' negatively influences the 'Overall Child Development'.

H6: 'Overall Child Development' positively influences the 'Socio-Economic Improvement'.

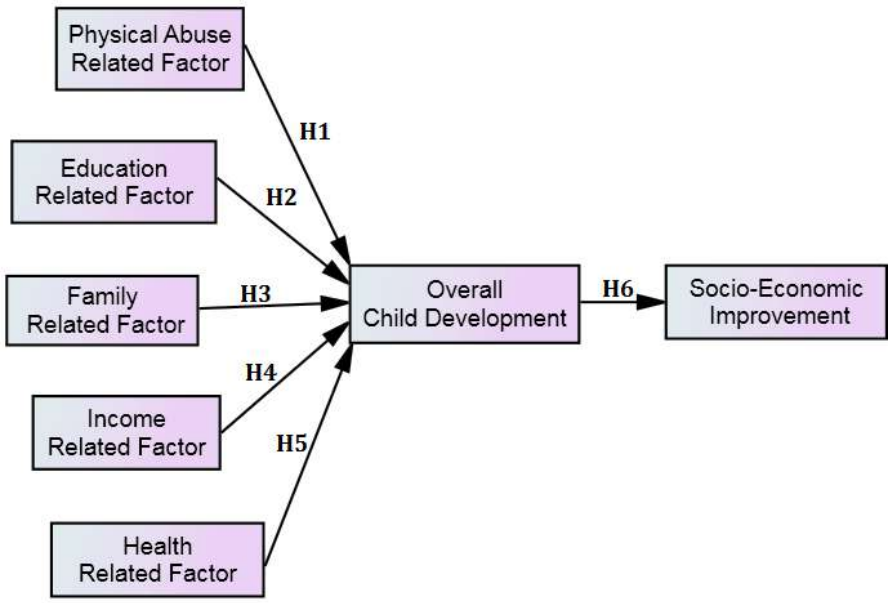

Figure 1: Hypothesized Research Model Establishment

Figure 1 showcases the hypothesized Research Model Establishment of the factors.

Research Methodology: The 'Hypothesized Research Model' (Figure 1) was developed by collected factors from literature review. A structure questionnaire was framed with related variables for survey. 5 point Likert scale is used for measuring the responses of people related with child abuse related issues. 250 responses were finally collected for this study. The data was collected in two stages using non-probabilistic sampling techniques. In the first stage, three states were decided from which the samples would be collected by Convenient Sampling. These states were Chhattisgarh, Bihar and Maharashtra. These states were selected for this research study as they contain the largest slums of India from where relevant data pertaining to this study could be collected. As a result,samples were collected in a relatively short amount of time, that is, 5th August, 2019 to 5th October, 2019. In the second stage of Sampling, simple random sampling was used in order to collect data from the caregivers or guardians or parents of the children who underwent abuse.

Analysis and Results

After collecting the primary data, Structure equation modeling (SEM) was used for developing the model and establishing the hypothesis by the help of AMOS 23 software. Model fitness was judged through structural model. Here, Cronbach alpha value (0.811) for all items which was greater than 0.70, shows the satisfactory range of reliability. The fitness indexes (Table 1) were verified as follows and hypotheses were tested.

Table 1: Fit indices of Confirmatory Factor Analysis for Structural Model

Fit Index	Acceptable Threshold Levels	Structural Model Values
χ^2/df (Chi-square / degree of freedom)	Values less than 3	0.525
RMSEA (Root mean-square error of approximation)	Values less than 0.06	0.001
GFI (Goodness of fit index)	Values greater than 0.90	0.998
AGFI (Adjusted goodness of fit index)	Values greater than 0.90	0.978
NFI (Normed fit index)	Values greater than 0.90	0.991
CFI (Comparative fit index)	Values greater than 0.90	0.999

Here the fit indices of Structural model (Figure 2) indicate the acceptable range and prove a good model fit.

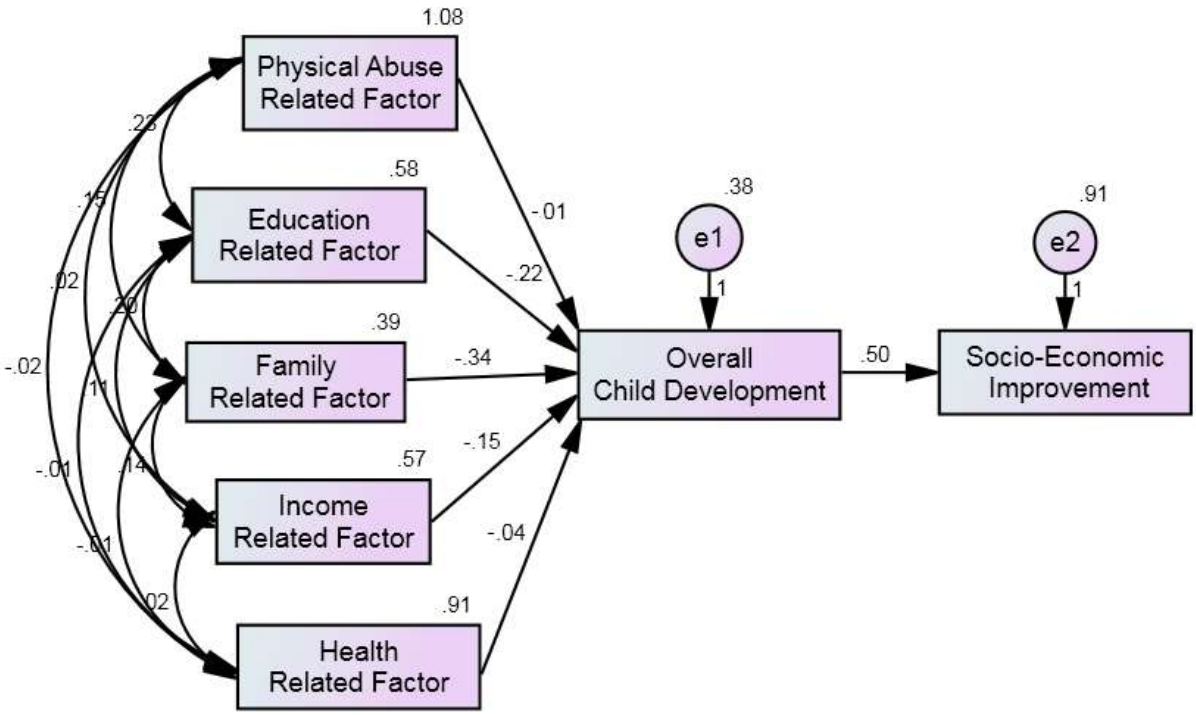

Figure 2: Path diagram of hypothesized structural model

Table 2: Path analysis of Structural Model

Measurement Path			Hypothesis	Estimate	S.E.	C.R.	P	Assessment
Overall Child Development	←	Physical Abuse Related Factor	H1	-.010	.045	-.014	.041	Supported

Socio-Economic Improvement	←	Overall Child Development	H6	.464	.094	4.934	***	Supported

*Significant Regression co-efficient (P<0.01 and 0.05)

Table 2 represents the Structural Model of the Path Analysis.

Research Findings: Health related factors include HIV and other epidemics, Illnesses, alcohol addiction and substance abuse. Victims of Child abuse often suffer from various health issues, be it psychological or physical. There has been some conclusive research in this area and it suggests that the victims of Child Sexual Abuse are very susceptible to a wide range of psychological problems in the long run such as depression, sexual disorders and dissociation symptoms. Adults who have a history of experiencing Child Sexual Abuse also suffer from poor health conditions such as not optimal physical health, psychosomatic physical complaints, DSM disorders, psychosomatic disorders, etc. and the variety of these conditions to be manifested in the victims depends on the kind of abuse that the victim has undergone amongst other factors (Gallo, et al., 2017)[5]. The women who have experienced abuse have more chances of being obese, poor mental health, alcohol dependent and drug dependent. Burns were also identified as one of the most common physical assault injuries in patients. Health factors are also interconnected that might cause the child abuse victims to succumb to the societal pressures and take up certain habits which will prove to be detrimental in the long run. It is evident that the adverse experiences are responsible for various mental conditions; however, it has been shown that they also instigate various physical health problems like risky sexual behaviours and substance abuse and it may also have certain health outcomes like cardiovascular diseases, obesity, diabetes, cancer, etc., furthermore, having certain economic repercussions and social outcomes which hamper the education and subsequently employment of the individual. Sexually Transmitted Infections were more common in girls who were raped which had further negative effects on the physical health of the victims.

Managerial Implications: The industry might help in a big way by identifying these vulnerable children and help them to equip themselves with sustainable tools such as education, so that they can contribute towards the Indian society. Different organizations can take up this activity as a part of CSR (Corporate Social Responsibility) and they can provide the means for these children to survive these adverse conditions. While interacting with these children, some bright talents could be found who would contribute nicely towards the society, and at large, the economy of the country. This will further have certain deep rooted implications on the productivity of the nation.

Conclusion

This study reveals that exploitation of a child, be it physical or emotional, can have detrimental effects to the child. Children who have been sexually exploited are more prone to substance abuse, cutting behaviours, suicide ideations and also of attempted suicides. Emotional abuse and neglect have a long term effect and negatively influences the overall Child Development. Often, PTSD is seen to be co-occurring with psychosis especially in the population experiencing situations which are likely to cause highly stressful and traumatized situations. This study establishes the fact that abused children share their experience with trusted caregivers when an opportunity is given to them to talk. This helps them to avail therapy for their trauma and it helps in their healing process. Once that is done, overall child development takes place which further helps the child in contributing positively to the society resulting

in affirmative socio-economic development. Mother's parenting and Father's parenting plays a very important role in the overall development of the child which enables them to contribute to the society in the long run.

Ethical Clearance: *Ethical approval for this study has been taken from selected* Municipal *Authorities from selected states in India for carrying out the data collection procedure smoothly. Also respondents have been assured for maintaining* full confidentiality of their feedbacks related to this research.

Use of Throat Swab as a Method of Sputum Induction in Suspected Cases of Tuberculosis

Abhishek Chauhan[1], Jai Kishan[2], Sameer Singhal[3], Achchhar Singh[4], Aditi Gupta[5], Pankaj Saini[1]

[1]Junior Resident, [2]Prof and Head, [3]Professor, [4]Associate Professor, [5]Assistant Professor, Department of Respiratory Medicine, MMIMSR, M.M. Deemed to be University, Mullana, Ambala, Haryana, India

Abstract

Tuberculosis is an infectious disease. It is caused by bacteria Mycobacterium Tuberculosis. It can be diagnosed by demonstrating AFB by either phenotypic method like sputum smear microscopy, culture or by genotypic method like NAAT or LPA. For better results there should be a good quality sputum sample. Induction of sputum is a method for improving the quality of sample. The most commonly used method is induction using 3% saline. It has been seen that during taking throat swab specimen patients usually produce cough. This induced cough can produce better quality of sputum. The following study was done to know about the role of throat swab as a method of sputum induction.

Keywords: *AFB, CBNAAT, LPA, Mycobacterium Tuberculosis.*

Introduction

Sputum smear microscopy is a very common method for diagnosis of TB but it has limited sensitivity. In RNTCP two method are currently used; one is by ZN staining based microscopy using a regular microscope and secondly is LED based fluorescent microscopy (LED FM).[1] Culture is highly sensitive and specific method for diagnosis of TB but it is very time consuming as it requires 2-8 weeks for results. Newer method of rapid molecular tests like CBNAAT (cartridge based nucleic acid amplification test) and LPA (Line probe assay) have been developed.

According to RNTCP two quality samples should be collected and subjected to microscopy. One of these should be collected early morning empty stomach. Sputum should be 3-5ml in quantity and should be mucoid or muco-purulent preferably. For the success of any diagnostic method like smear examination for AFB, fluorescent method, CBNAAT, LPA, or culture the quality of sputum specimen is of paramount importance. Even highly sensitive techniques may fail to give the desired results if the quality of sputum specimen is not adequate.

Induction of the sputum can be done for obtaining good quality sputum sample. It can be done by using various method. Most commonly used method is induction of sputum using 3% saline.[2] But these techniques may not be available at peripheral health institutions. Throat swab is used for obtaining specimen in conditions like H1N1, scarlet fever rheumatic fever, candida albicans, pertusis diphtheria and other respiratory diseases.[3] It has been observed that while taking throat swab, once the pharynx is touched, patient starts coughing and produces expectoration. From throat swab the smear can be prepared on slide and induction of cough on touching pharynx may produce sputum expectoration which may give the good quality sputum and thus the higher yield.

Material and Method

This study was conducted in the department of Respiratory Medicine of MMIMSR, MMDU, Mullana, Ambala. A total of 300 patients of presumptive TB were taken over a period of 12 months for the study. Children

Corresponding Author:
Dr. Jai Kishan
Professor and Head, Department of Respiratory Medicine, MMIMSR, Mullana, Ambala, Haryana, India
e-mail: jaikishantb@gmail.com

less than 14 years were excluded. Any patient having haemoptysis were excluded. Patients who had cardiac disorder like CHF were excluded. Patients who have undergone recent surgeries of heart, abdomen, eye, ENT were also excluded.

The patients were asked to give the 1st spot sample. The quality and result of the sputum sample was noted. The patient was asked to come the next day and bring early morning sputum sample. Patient who refused to come the next day were offered second spot sputum examination. In this group all the patients were also subjected to induction by throat swab method.

Induction of sputum using throat swab: The steps of the procedure were explained to the patient and consent was taken. After taking personal protective measures using N95 mask and gloves, we first asked the patient to wide open his mouth so that the buccal cavity is fully visualized along with pharyngeal wall and tonsillar pillars etc. Thus a throat swab was taken from the buccal cavity with a swab stick. When the patients who were subjected to throat swab examination, the touching of the buccal cavity pharynx induced cough which yielded the sputum from within the chest. Throat swab was repeated to make the patient cough multiple times and sputum expectorated was collected in container and analysed. A smear was prepared using the throat swab and analysed

The quality of sputum specimen of the 1st spot specimen, second spot specimen, early morning sputum specimen and throat swab expectoration were noted. Sputum smear positivity rates and their grades on 1st spot, 2nd spot examination, sputum smear on throat swab examination and sputum smear of the cough expectoration produced on throat examination and the next day early morning sample were noted and compared. The grading of all the samples was done according to the RNTCP guidelines. The first spot sample was taken of 272 patients, 28 patients could not spontaneously produce sputum. Second spot sample was obtained from 95 patients. Early morning sample was taken from 157 patients. All 300 patients were subjected to sputum induction by throat swab on the first day.

Results

Table 1: Among sample types in case group, most positive reports were obtained by the early morning sample (11.4%) followed by induction method (8%) and throat swab smear (7%). Positivity rate of spot and second spot sample were 3.3% and 1.1% respectively. Highly positive reports (3+) were seen only in samples taken by induction method and in early morning samples.

Table 2: More positive results were seen in mucoid samples. Highest yield (26 positive) was seen in mucoid samples that were more than 5ml (M3).

Table 3: There was no statistical significance observed between sputum positivity rates of early morning sample given on next day when compared with the induced specimen. Thus instead of calling next day, patients can be subjected to induced sputum specimen on same day this will save the patients of additional cost incurred for food, transport, loss of wages and will also lead to avoidance of failure to get 2nd early morning specimen at all.

Table 1. Results of samples according to sample type in case group

Sample Type / **Results**	**Spot Sample**	**2nd Spot**	**Throat Swab Slide**	**Induction by Swab Stick**	**Early Morning Sample**
SCANTY	5	1	18	7	7

Discussion

Sputum smear microscopy is the most important tool for the diagnosis of PTB. It is reliable inexpensive easily accessible and also a very rapid method to diagnose tuberculosis. All the method for TB diagnosis whether it is genotypic or phenotypic method require a good quality sample for the diagnosis of TB. For any method to give to give desired results the quality of sputum specimen is of paramount importance. It is seen that the yield of sputum is low in females and children. Females and children are in habit of swallowing of sputum. A study was done in which qualitative differences in sputum smear microscopy results for acid fast bacilli by age and sex in four countries Moldova, Mongolia, Uganda and Zimbabwe were studied.[4] They found striking differences in the low-grade positivity in these four countries. They found that females had lower bacillary counts. The low-grade positivity was more commonly seen in the extremes of the ages. This supports the role of high-quality sputumto improve the yields. Similarly, induction of sputum is helpful in TB diagnosis in children also.

Sputum induction is a method which can lead to increase in quality and quantity of the sputum sample. There are various method of sputum induction. Most commonly used method is by nebulisation with hypertonic saline. Various other method used are nebulisation with salbutamol, ambroxol, N-acetylcysteine. By using these method yield of sputum can be increased.[5]

Throat swab specimen is standard for obtaining samples in case of H1N1, diphtheria. It is seen that when we touch the pharynx with any object like when taking throat swab sample there is elicitation of cough. When cough is produced it brings out sputum. So it was postulated that sputum induction could be used as a method of sputum induction for diagnosis of tuberculosis.

Five different samples were included in the study from case group including spot sample, second spot sample, an early morning sample, samples after induction by pharyngeal stimulation with throat swab and throat swab slide. Spot sample was taken from all patients who could produce sputum (272 patients). Participants were then asked to come next morning for early morning sample. Second spot sample was taken from those (95 patients in total) who refused to come next day. Sputum induction was done of all 300 patients and sample was taken. A smear slide was also prepared from throat swab

in all 300 patients. Early morning sample was taken from 157 patients as 48 patients did not come despite agreeing. The samples were analysed by FM staining. The positivity rate was highest (11.4%) in early morning sample, followed by induction method (8%). Swab stick smear showed a positivity rate of 75 which was higher than spot sample and second spot sample being 3.3% and 1.1% respectively. Although, the yield was higher with early morning sample than induction sample but this was statistically not significant (p-value >.05) The positivity rate of induction method was significantly higher than spot and second spot samples and this was statistically significant with p-value <.05. So, we propose that in cases where patients refuse to come for early morning sample on next day or there is high likelihood that patient will not come, the induction method should be used as this method significantly improves the diagnostic yield of smear microscopy.

In order to improve the sputum positivity rate sputum induction using 3% saline, bronchoscopy and gastric lavage are being used. All these method have their limitations. Gastric lavage requires overnight stay so that the secretions from stomach can be collected in the morning and analysed. Sputum induction using 3% saline may cause bronchoconstriction in patients especially with bronchial hyper reactivity.[5] Bronchoscopy requires highly skilled medical professionals and specialised bronchoscopy suite. Induction using throat swab is a simple process which can be performed anywhere and requires minimal skills. It can also be performed in peripheral health institutes where many facilities are not available and electricity supply may be erratic.

Conclusion

In conclusion, our study shows that although early morning samples have a higher positivity rate for AFB than post-induction sample but induction sample can be useful in cases where early morning sample is not available. Induction technique can also be useful in cases where sputum production is sparse or in female who usually swallow and don't expectorate.

mLearning Using Whattsapp Application to Interconnect the Class

Sanjay Bedi[1], Anshu Gupta[2], Karun Bhatti[3], Poonam Bharti[4]

[1]Professor, Dept. of Pathology, Adesh Institute of Medical Sciences and Research Bathinda, [2]Professor, Dept. of Pharmacology, 3Associate Professor, Dept. of Medicine, [4]Associate Professor, Dept. of Psychiatry, MMIMSR, M.M. Deemed to be University, Mullana, Ambala, Haryana, India

Abstract

E-learning is one such platform used to help students learn with the use of electronic devices like computers and internet. M-learning is one another emerging methodology that follows all the principles of E-learning but with even smaller electronic tools like smartphones, table ts etc. The use of mobile applications in medical and dental education has been shown to increase student participation, enhance the feedback process and improve communication between student and tutor.

Keywords: *E-learning, smartphones, M-learning.*

Introduction

In Recent times, there has been increased research into mobile learning (mLearning) and specifically the use of instant messaging services.[1] This Application is very addictive and can create a great impact on regular users. Communication has become easier, faster and cheaper with Whatsappmessenger. Mobile phones are banned in selected educational institutions;however, the restriction is only in the campus and not in most of the hostels where the mobiles are used to the most by the students. With our Internet bandwidths growing and the expected freedom to use free internets in the public places and educational campuses, our expectations for the paradigm shift of learning from laptops to mobile devices is not so far. Studies have shown that there are two benefits of Whatsapp for distance learning: mobile learning and context free access to learning resources.[2] Many researchers have been done in technological profession. Very less data is available in the usage of WhatsApp as a teaching media in medical colleges. More work needs to be done to explore in detail the advantages and disadvantages of WhatsApp. Hence the study was planned to evaluate the experiences and thoughts of second year pathology students using WhatsApp Messenger discussion group to supplement their learning experience.

Material and Method

The study was conducted in MMIMSR on second year medical students after obtaining Institutional Ethics Committee approval and an informed verbal consent of the students. The study period was 50 days and a whatsapp group named “pathopharma 2014-2015 was created, all the students who had consented (150) were included. Rules & regulations were charted and strict adherence was advised. One girl and one boy who volunteered served as group admin other than the facilitator. Most of the students have the free wifi access in their hostels provided by the university so that the students had not to bear the extra costs. After the conventional lectures being taught in the class about lung pathology the students were sent certain important videos of the patients related to the condition. Since the application supported the internet youtube videos and educational material was also sent on the app. We were even been able to conduct MCQ based class test using a whatsapp based application linked to google drive.

Analysis: A questionnaire was designed in Google forms to document the perceptions and feedback on this teaching learning methodology. It comprised of both close ended and open ended questions. Quantitative analysis, Likert scale of 5 was used for close ended questions and a qualitative analysis was conducted on the items.

Results

Out of 150 students of second professional MBBS 123(82%) students filled the feedback proforma provided to them. Twenty-seven students did not fill the feedback form. Sixty-eight (55.3%) girls and 55(44.7%) boys responded to it. All the students (100%) have smart phones and internet access on their phones.

All the students are using WhatsApp out of which 97% for both social and academic purposes and 3% for social purposes only.

77% of the students watched the videos. Out of which all the three videos were seen by 17%, maximum students saw the two videos 48% and single video was seen by 12% of students.

Out of 123 students 23% of the students could not see the videos due to lack of interest, could not access easily due to slow internet, problem in buffering of video.

On analysis of 95 students who saw the video for the design and usability of WhatsApp in teaching and it was found that and 65% think that it took reasonable time for watching the video whereas 35% think that it was highly time consumable.

It was a new experience to study pathology this way and 78% of the students enjoyed it very much. Twenty two percent found it long and boring.

The overall presentation and design was rated more than 7 by 58% of the students, 7-5 by 34% and less than 5 by 8%.

Most of the students 89% had a view that both class room and videos suit them best for developing good understanding of the topic.

Qualitative analysis

Theme 1: WhatsApp as a learning medium and usability

They think that by this way topic is better understood, interesting, it's fun, more interactive session, some find didactic lecture boring, practical learning, creates interest in topic and subject, more retention of the topic. "It has made my understanding regarding chronic lung diseases better. I can be more confident with the patient now"The videos can be seen whenever required.

Theme 2: Content of the videos:

92% found it to be well balanced

84% told that it provided useful information regarding topic

78% feel that it has clear layout

85% found it to be detailed

92% found it to be interesting

It was helpful to the students in implying what is being read. Some students also felt that topic was much stretched.

Theme 3: Better learning

Most of the student like this method of teaching as it is different way of learning, innovative, interactive and helps in more retention. 87% students were of the view that it improves learning as AV aids make more impact. Improves practical learning, pictorial impressions of the topic, better retention, one student feels to self-read the topic from book after watching the videos which is not done by the student otherwise. Few students wanted the videos to be of short duration.

Theme 4: students who could not watch the video due to any of the reasons mentioned:

Classroom lectures more interesting

Could not comprehend and understand

Slow network but wanted to see the videos as they can be paused and be seen again.

Improves understanding and helps in retaining things.

Should be shown in class itself

Time consuming

Theme 5: Feelings about teaching learning methodology

Students feel that the teaching and learning should be informative, interactive as well as few exam oriented things should also be considered. They want all the teachers to incorporate interactive method of teaching in classes. According to a student "interaction makes the topic very familiar and easy to retain."

Discussion

On the examination and analysis of our research results we found very interesting findings. Hundred twenty-three students participated in this study. All the students have the smart phones which they use for both social and academic purpose. There was an immediate acceptance of our medical students to the new mode of learning. This gave us an understanding that changes in the teaching learning methodology are readily welcomed by our students. Our results were in concurrent with the findings of others who have reported the positive attitude of students over the implementation of M-learning methodology.[3] There is a successful integration of social media tool with academics or teaching learning process. It helps in improving the learning concepts among students.

In the journey from memory based schools to the vast medical curriculum, medical students face considerable challenges and hurdles. This scenario worsens further when all the content delivery is primarily based on didactic lectures.[4] To address this crisis, Medical Council of India (MCI) has revised the medical curriculum which recommends the shift from teacher centered to student centered learning by using various interactive strategies.

WhatsApp used as a social media tool can be successfully integrated with teaching learning methodology. No extra costs incurred so no financial burden on the students. Study by Renu et al had a view that using WhatsApp had a positive effect like making students work like team, improves quality of expression among students and students can learn any anytime anywhere.[5] The results of this study demonstrate how WhatsApp can be a useful tool for students in the problem based learning process through promoting media sharing, improving communication and generating learning opportunities. It provided a platform for the students to foster a collaborative approach to learning. At present, both the American and British Medical Associations have recommended guidelines for professional use of social media tools by medical students to promote medical information and education.[4,5] Inspite in Indian Scenario it is in infancy stage and is picking up slowly.

Limitations: Firstly, it was restricted for a single batch of students in Para clinical block. Secondly it only included one section of the subject the assessment could not be done.

Conclusion

Students welcomed and liked the use the Whatsapp in enhancing their learning experience in medicine. It was successful in providing an interactive environment, supplement knowledge and skills by watching videos; we propose that this methodology can be used to enhance student's learning.

Conflict of Interest: None

Source of Funding: Self

Ethical approval and Informed consent: The study protocol was reviewed by the Ethical Committee of Hospital and was granted ethical clearance. After explaining the purpose and details of the study, a written informed consent was obtained from the participants.

Mobile Phones of Nursing Staff: A Neglected Source of Cross Infection

Gulnar[1], Varsha A. Singh[2], Sachin Sharma[3], Sonia Mehta[4], Rosy Bala[5], Sameer Singla[6], Rahilla Tabassum[7]

[1]P.G. Tutor, Department of Microbiology, MMIMSR, Maharishi Markandeshwar (Deemed to be University), Mullana, Haryana, [2]Professor, Department of Microbiology, MMIMSR Maharishi Markandeshwar (Deemed to be University), Mullana, Haryana, [3]M.Sc. Microbiology, MMIMSR, Maharishi Markandeshwar (Deemed to be University), Mullana, Haryana, [4]Professor,Department of Microbiology, MMIMSR, Maharishi Markandeshwar (Deemed to be University), Mullana, Ambala, Haryana, [5]Assistant Professor, MMIMSR, Department of Microbiology, Maharishi Markandeshwar (Deemed to be University), Mullana, Ambala, Haryana, [6]Senior Resident, Department of Surgery, Gian Sagar Medical College, Jhansla, Punjab, [7]Demonstrator, MMIMSR Department of Microbiology, GMC Rajouri, India

Abstract

Introduction: Inevitable usage of mobile phones by the nursing staff makes them an open admittance for transmission of microorganisms to the patients and other health care-associates specially when used carelessly in intensive care units (ICU).

Methodology: The Study was conducted on 400 samples. Out of which 200 samples were from mobile phones of nursing staff posted in ICU without prior notice and other 200 were from various sites of patients like catheter tip (Urinary & central venous catheters), surgical drains, endotracheal tube and swab from wound of patients after 48hr of admission in ICUs.

Results: Predominant organisms in patient samples were *Escherichia coli (E. coli)* (39.2%) followed by Staphylococcus aureus (34.6%) and Methicillin Resistant Staphylococcus aureus (MRSA) (34.6%) and in mobile phones were Coagulase negative Staphylococcus (CONS) (64.1%) which were non-pathogenic and among pathogenic was E.coli (50.2%) followed by growth of different types of bacteria.

Conclusion: Mobile phones are cumbersome to clean and we rarely even make an effort to disinfect them. As a result, these devices have the potential for contamination with various bacterial agents. Besides, there are no guidelines for disinfection of mobile phones that meet the set hospital standards.

Keywords: *Klebsiella pneumoniae, Escherichia coli, catheter tip, surgical drains, ET secretions, wound swabs, nosocomial pathogens, nursing staff.*

Introduction

In modern era, mobile phones have become an indispensable part of communication.[1] Though the mobile phones are beneficial but they carry pathogens more than a handle of a public restroom. Since 2005 numerous studies has been published in PubMed, Medline, Google Scholar, Science Citation Index and Scopus on the Mobile Phones of health care workers which has strong circumstantial evidence that mobile phones can be a source of nosocomial infections but the fact has not been definitely proven.[2] Nursing staff always play a chief role in patient care. The careless use of mobile by them can cause cross infection especially in critically ill or Immuno-compromised patients admitted in ICU which can be diagnosed by

diverse phenotypic and genotypic method.[3]In the last few decades, the genotypic method are frequently being used for the identification of bacteria. However major drawback is the expensive nature & requirement of technical staff well-skilled for performing these method. In a developing country like India phenotypic method are still considered mainly for epidemiological typing. Antimicrobial susceptibility (Antibiogram) and bio typing are the mainstay of phenotypic typing method as they are easy to perform, interpret and are reproducible Hence this study was conducted with the aim to determine the cross-transmission of infection from cell phones of nursing staff to the patients.

Unfortunately, such studies have never ever been funded therefore antibiogram was used as a typing method in this study.

Material and Method

The Study was conducted in the department of Microbiology at MMIMSR, Mullana over a period of six months (September 2015-march 2017). A total of 400 samples were taken. Out of which 200 samples were from mobile phones of nursing staff posted in ICU without prior notice and other 200 were from various sites of patients like catheter tip (urinary & central venous catheters), surgical drains, endotracheal tube and swab from wound of patients after 48hr of admission in ICUs.

Sample Collection: A sterilized cotton swab dipped in sterile normal saline was taken. Samples from mobile phones were collected by rotating the wet cotton swabs & patient's samples were collected as per standard procedure. All the samples were cultured on Blood agar & MacConkey agar; incubated overnight at 37^0C. Organisms were identified as per standard protocol. The antibiotic sensitivity pattern of the organisms was tested by Kirby Bauer's disc diffusion method following CLSI guidelines 2016 using HiMedia discs.[15] The multidrug resistant strains were identified & further subjected for screening of MRSA and carbapenemase production.

Detection of MRSA strains by Cefoxitin Disc Diffusion Method: Methicillin resistant Staphylococcus aureus strains were confirmed by Kirby-Bauer disc diffusion method using cefoxitin (30 µg) disc. The strains of *Staphylococcus aureus* having zone of inhibition of ≤21mm to cefoxitin disc (30 µg) were considered as MRSA strains.

Screening of carbapenemase producing strains by Meropenem Disc Diffusion Method: 10 µg meropenem disc was used for screening of carbapenemase production. The strainshaving zone of inhibition of ≤21mm to meropenem disc (10 µg) were considered as positive for carbapenemase production.

Results

Among 200 samples from mobile phones 112 (56%) revealed more than one organism while 88 (44%) revealed only single isolate, which comprises a total of 424 organisms. Among which 209 (49.3%) were gram positive and 215 (50.7%) were gram negative organisms.

However, from 200 various samples of patient yielded 108 (54%) single pathogenic organisms while 92 (46%) were either sterile or showed growth of nonpathogenic organisms. Out of 108 organisms 52 (48.2%) were gram positive organisms and 56 (51.8%) were gram negative organisms. (Table 1)

The organisms isolated from catheter tip were CONS (3), MSSA (1), MRSA (1), Candida sp. (4), E. coli (12), carbapenemase producing E.coli (4), Klebsiella sp. (5), carbapenemase producing Klebsiella sp. (3) and Acinetobacter sp. (1). From ET secretions MSSA (1), MRSA (1), E. coli (3), carbapenemase producing E. coli (1), Klebsiella sp. (6), carbapenemase producing Klebsiella sp. (3), Pseudomonas sp. (1) and Acinetobacter sp. (1) were isolated. From surgical drains CONS (1), MSSA (6), MRSA (5), Candida sp. (2), E. coli (4), carbapenemase producing E. coli (2), Klebsiella sp. (1), carbapenemase producing Klebsiella sp. (1) and Acinetobacter sp. (1) were isolated. The organisms isolated from wound swabs were CONS (6), MSSA (10), MRSA (11), E. coli (3), carbapenemase producing E. coli (1), Klebsiella sp. (2), carbapenemase producing Klebsiella sp. (1).

Surprisingly carbapenamase producing *E. coli* (50%), carbapenamase producing *K. pneumonia* (25%), MRSA (33%)and CONS (33%) from various patient samples showed identical antibiogram with the isolates from the mobile phones of nursing staff. Isolates displaying identical sensitivity pattern (antibiogram) was from surgical drains (40%), endotracheal intubation (30%), wound swabs (20%) and catheter tip (20%).

Discussion

Worldwide increasing incidence of Hospital

acquired infections (HAI) is worrisome to all medical practitioners.[4] HAI are attributed to transmission of Micro-organisms which can be from person to person or from inanimate items like stethoscopes, aprons, mobile phones and fixed telephones to hand and vice versa. In this study, microbial association of one such inanimate object mobile phone with patient's sample was assessed.[5]

Now days, the mobile phones are multi-utility non-medical devices used in the healthcare facility and in the community with unlimited benefits. Unfortunately, these are used without check in specific, critical areas like the operation room and ICUs, irrespective of their unidentified microbial load.

In current study both gram positive as well gram negative bacterial pathogens were isolated from mobile phones of nursing staff. The findings of this study are in concordance with study by SE Amala et al.[6] (2015) which showed an overall percentage prevalence rate of 80.6% and 69% pathogen isolates from mobile phones of medical personnel.

Gram-positive and Gram-negative bacteria can persist on dry inanimate surfaces for months or more but humid and lower-temperature conditions prolong their survival. Moisture, optimum temperature of palms and heat generated by mobile phones provide the ideal condition for the bacteria to grow.[7] In current study from mobile phones of nursing staff among Gram positive organisms majority were CONS (64.1%) and 29.7% gram positive isolates were Staphylococcus aureus .While in gram negative organisms *E.coli* (50.2%) and *Klebsiella pneumonia* (17.2%) were isolated. Similar organisms were also reported by Shekhar pal et al.[3] (2015)and Raghavendra Rao Morubagal et al.[5] (2017). Furthermore the great concern was the isolation of Acinetobacter (5.6%), carbapenemases producing *Klebsiella pneumonia* (5.1%), carbapenemases producing *E. coli* (15.8%), *P. aeruginosa* (6%) and MRSA (6.2%).

The occurrence of antibiotic-resistant bacteria is a critical issue which hampers prevention and control of hospital acquired infection. The geographic distribution or dissemination patterns of these bacteria differ within and across the region.

In the present study from patients among Gram positive organisms majority were MRSA (34.6%) and (34.6)% gram positive isolates were Staphylococcus aureus were isolated. While in gram negative organisms *E.coli* (39.2%) and *Klebsiella pneumonia* (25%) were isolated. Furthermore the great concern was the isolation of Carbapenemases producing *Klebsiella pneumonia* (14.3%), Carbapenemases producing *E. coli* (14.3%), *P. aeruginosa* (3.6%), Acinetobacter (3.6%) (Table 1) which was similar to the study of Bastola R et al.[8](2017),Negi V et al.[9](2015)and Timothy OO et al.[10](2014).

This study is unique in its own way as there are many studies suggesting the role of inanimate objects causing cross contamination of pathogens leading to outbreaks specially in ICUs.[11,12] However in the present study, taking into consideration that mobile phones can be a chief source of microbial transmission identical pathogens with similar antibiotic sensitivity pattern from patients and mobile phones were isolated which could be a strong evidence suggestive of cross transmission of bacteria. In present study, Carbapenamase producing *E. coli* (50%), Carbapenamase producing *K. pneumonia* (25%), MRSA (33%)and CONS (33%) from various patient samples showed identical antibiogram with the isolates from the mobile phones of nursing staff. To the best of our knowledge none of the researchers till date have shown such relationship but analogous to this Chang HC et al.[13](2017) has extensively studied the correlation between nasal colonization & bacterial transmission of mobile phone.Although genotypical confirmation of bacterial cross transmission between mobile phones & patient is essential but unfortunately, none of such studies have been financially funded enough thus antibiogram were used as a typing method in this study.

Inanimate surfaces in vicinity of patients can rapidly get contaminated via shedding of microorganisms by patients which may lead to cross transmission because of high-frequency interactions between nurses hands and high-touch surfaces.[14] In current study Isolates displaying identical sensitivity pattern was from surgical drains (40%), endotracheal secretions (30%), swab from wound(20%) and catheter tip (20%).Which are the frequently handled sites of the patients. Calls and answers to call while working are obvious enabling transfer of microbes. In spite of repeated warning the nursing staff receives the phone calls while performing the procedures thus we hypothesized that may be this is the reason for cross transmission of pathogens from patient sites to mobile and vice versa. Although strenuously searched in the literature we still could not found such type of correlation.

Conclusion

This study concludes that nursing staff is disclosed to nosocomial pathogens including multidrug resistant (MDR) species which can be easily transferred to their mobile phones thus acting as a source of infection but further studies are needed to evaluate this correlation. Complete restriction on the use of cell phones in the hospital is not a solution to the concern. Though, there should be controlled use in high risk areas of the hospital like ICU's or the modest way out to implement a solution in developing countries (where resources are inadequate) is recurrent cleaning of cell phones with alcohol based disinfectants which should be followed by regular hand washing practices. There should be ultimate Guidelines for Environmental Infection Control in Health Care Facilities which proposes periodic disinfection of mobile phones.

Table I: Frequency of Bacterial Pathogens from Patient Sample and Mobile Phones of Nursing Staff

Nature of Pathogens / **Gram Positive Bacteria**	**Patient Sample (n=52)**	**Mobile Phones (n=209)**
CONS	10 (19.2%)	134 (64.1%)
S. aureus	18 (34.6%)	62 (29.7%)
MRSA	18 (34.6%)	13 (6.2%)
Candida spp	6 (11.5%)	-
Gram negative Bacteria	**(n=56)**	**(n=215)**
E.coli	22 (39.2%)	108 (50.2%)
Carbapenemase producing E.coli	8 (14.3%)	34 (15.8%)
K. pneumonia	14 (25%)	37 (17.2%)
Carbapenemaseproducing K.pneumoniae	8 (14.3%)	11 (5.1%)
Acinetobacter	2 (3.6%)	12 (5.6%)
P. aeruginosa	2 (3.6%)	13 (6%)

CONS: Coagulase Negative Staphylococci, S.aureus: Staphylococcus aureus, MRSA: Methicillin-resistant staphylococcus aureus, Candida spp: Candida species, E.coli: Escherichia coli, K.pneumoniae: Klebsiella pneumonia, P.aeruginosa: Pseudomonas aeruginosa.

Comparative Study to Evaluate the Outcome of Sutures Versus Sutureless in Attachment of Conjunctival Autograft for Pterygium Excision

Kunal Sharma[1], P.K. Manjhi[2], M.L. Pandey[3], Neha[4], Vineet Gupta[5], Roopam Chauhan[6], Kritika Singla[6]

[1]Post-graduate Resident, [2]Professor & Head, [3]Professor, [4]P.G. Resident, [5]Assistant Professor, [6]Senior Resident, Dept. of Ophthalmology, MMIMSR, Maharishi Markandeshwar (Deemed to be University)

Abstract

Background: Suturing of conjunctival graft is a traditional technique for pterygium excision surgery. Owing to its many disadvantages & complications many newer techniques like autologous fibrin glue have been introduced & accepted as an alternative method of graft adhesion.

Methodology: The present study was conducted at the Department of Ophthalmology, MMIMSR, Mullana (Maharishi Markandeshwar Deemed to be University) in the time period extending between December 2017 and January 2019. 100 eyes of patients of either sex with primary pterygium were selected and divided into 2 groups of 50 each in Group 1- patient underwent conjunctival auto graft with 10-0 ethilon sutures while in Group 2 suture less conjunctival auto graft was done with patient's own blood fibrin.

Results: Parameters such as mean operating time, presenting complaints like pain, watering, burning and foreign body sensation, complications & recurrence were compared between the two groups on postoperative Day 1, Day 7, 2 weeks, 1 month, 2 month, 3 month & 6^{th} month. Statistical significant difference ($p<0.01$) was found between the suture and sutureless surgery for pterygium in relation to post-operative discomfort grading. There was a significant difference ($t = 22.149$, $p = 0.001$) in the duration of surgery for GROUP I surgery.

Conclusion: Conjunctival auto graft with autologous serum is a safe and fast method. It is equally effective as conventional sutured autograft technique. Post operative discomfort is significantly less in this method. It also prevents suture related complications

Keywords: *Pterygium, sutures, sutureless, duration of surgery postoperative discomfort, complications, recurrence.*

Introduction

Pterygium defined as a degenerative disease characterized by triangle shaped fibrovascular growth of bulbar conjunctiva encroaching the cornea[1]. Etiology includes several environmental factors such as ultraviolet radiation, geographical location, heat, muddy dust and a arid weather[2–4]. Though surgical removal remains the treatment of choice[5] but various conservative treatments like artificial tear drops, vasoconstrictor drops and topical steroid drops have been tried in the early stages because recurrences after pterygium excision are common and aggressive. Conjunctival auto grafting (CAG) with autologus blood (blood fibrin) as it activates the coagulation cascade and eventually leading to fibrin polymerization. It has become the standard procedure of choice for both primary and recurrent pterygium as it offers excellent results with less complication rates & recurrences[6]. LCAT is also the most popular surgical

procedure which requires sutures for adhering the graft as it is assumed that addition of limbal stem cells act as a barrier to the migrating conjunctival cells onto the cornea[7] . This technique requires experience and is allied with certain disadvantages such as increased surgical time, postoperative discomfort, inflammation and granuloma formation etc[8,9]. India has a geographical location near to the equator suggesting the impact of UV light as well as high grade of the pterygium due to their occupation and lifestyle of people[10,11,12]. It is being recognized that higher grade act as a risk factor for recurrence[13]. Anbari AA conducted a comparative study to evaluate efficacy, safety and reliability of autologous cryoprecipitate in comparison with absorbable sutures in pterygium excision surgery & concluded that application of autologous cryoprecipitate glue instead of sutures for attaching the conjunctival auto graft in pterygium surgery resulted in less postoperative pain and shorter surgical time[14]. In a similar study conducted by Foroutan a et al observed that autologous fibrin was a safe and useful alternative method for graft attachment in pterygium surgery[15] .

Materials and Method

The present study titled "A Prospective Comparative Study To Evaluate Sutures versus Sutureless in Attachment of Conjunctival Autograft For Pterygium Excision" was carried out at the tertiary care hospital in Department of Ophthalmology of Maharishi Markandeshwar deemed to be University (M.M.I.M.S.R.) Mullana, Ambala in a time period between December 2017 to January 2019.

100 eyes of patients of either sex with primary pterygium were selected from those attending the OPD at The Department of Ophthalmology, MMDU (MMIMSR), Mullana.

Patients would be divided into 2 groups of 50 each:

Group 1: Conjunctival auto graft with sutures.

Group 2: Suture less conjunctival auto graft with (patient's own blood fibrin.

A written informed consent was obtained from each patient explaining them the procedure and the study in detail. Ethical approval for conducting this study was obtained from Institutional Ethics Committee vide letter number 1084.

Inclusion Criteria: Patients with pterygium consenting for surgery & with any of following indications for surgery- encroachment upon visual axis, inducing visually significant astigmatism, causing recurrent irritation or cosmetically bothersome to the patient, Gender i.e males & females, age equal to or more than 20 years

Exclusion Criteria: Recurrent pterygium, Bilateral pterygium, Pseudopterygium, Patients with scarred superior conjunctiva, Patients with cicatricial ocular surface disease, Patients with history of ocular trauma, Patients on anticoagulant therapy, Patients with deranged coagulation profile, Patients with dry eye syndrome, Patients having collagen vascular diseases

50 patients underwent primary pterygium excision and conjunctival auto grafting with autologous fibrin glue (glue group) and 50 with 10-0 ethilon suture.

In Suture Less Group:

- The graft was slided over the cornea without lifting the tissue off the cornea, towards the bare sclera and it was spread and positioned such that the limbal polarity was maintained. The edges of the graft were placed below the undermined edges of the surrounding conjunctiva of the host bed. The graft was allowd to adhere with the help of residual blood. The scleral bed is viewed through the transparent conjunctiva and to ensure residual bleeding does not re-lift the graft. Small central haemorrhages were tamponaded with direct compression using sponge-tipped applicator until haemostasis was achieved, usually within 8–10 minutes.

In Suture Group: The four corners of graft were anchored with episcleral bites to maintain the position of graft. The limbalside of graft were affixed to limbal area and the sides of graft were attached to surrounding conjunctiva at intervals of 1-1.5mm with simple interrupted 10-0 ethilon sutures. The eye was then patched and bandaged for 24 hours with 0.5% moxifloxacineyedrops.

In suture group, sutures were removed approx 2 weeks after surgery. Patients were followed up at day 1, day 7, 2nd week, at 1 month, 2 month, 3 month and then at 6 months. Additional visits were as and when required. Postoperative discomfort, complications related to graft on above described follow up & recurrences were observed & analysed.

Fig. 1: Conjunctivalautograft in place using Autologus blood fibrin

Fig. 2: Conjuctival cyst formation after attaching conjunctival auto graft using 10-0 ethilion sutures (slit lamp view)

Data was collected by using a structured proforma and was entered in MS excel sheet and analysed by using SPSS 19.0 version IBM USA. Quantitative data was expressed in terms of Mean and Standard deviation. Association between two variables was assessed by using Pearson's Chi-square test.. Operating time between the two groups was compared using unpaired t test. A p value of <0.05 was considered as statistically significant whereas a p value of <0.001 was considered as highly significant.

Results

Majority of patients in both the group were found to be in between 41-50 years. Overall mean age in group I was estimated to be 45.98 + 12.95 years while in group II it was estimated to be 48.82 + 11.13 years.

Maximum patients in both the groups were male.

Significant difference ($p<0.01$) was found between the suture and sutureless surgery for pterygium in relation to post-operative discomfort grading.

In Group I; 2% patients had conjunctival cyst, 6% patients had conjunctival granuloma, 2% patients had graft displacement, 8% patients had graft edema, 2% patients had graft rejection, 4% patients had recurrence of pterygium. No graft loss was seen in any patient. In Group II; 2% patientsc had conjunctivl cyst; 6% patients had graft displacement, 2% patients had graft edema, 2% patients had graft loss, 2% patient had graft rejection, while no patient had graft granuloma. No statistically significant difference ($p>0.05$) was found between the suture and sutureless surgery for pterygium in relation to post-operative complications due to less sample size.

Group 1 (SUTURE) had a mean duration of 36.46 + 2.67 minutes minutes while Group II (SUTURELESS) had a mean duration of 24.88 + 2.55 minutes. Overall mean duration of surgery was noted to be 30.67 + 6.37 minutes. There was a significant difference ($t = 22.149$, $p = 0.001$) in the duration of surgery for GROUP I surgery.

In Group I maximum rate of complication were observed at 3 months i.e. 6%. In Group II maximum complications were seen on day 1 ie 6% & day 7 ie 4%.

Both the groups had recurrence of pterygium . In Group I 3 patients had recurrence after pterygium surgery while in Group II only 1 patient had recurrence. No statistically significant difference ($p>0.05$) was found between the suture and sutureless surgery for pterygium in relation to recurrence of the disease.

Overall complication rate in Group I was 20% with 4% patients having recurrence while in Group II was 16% with 2% patients having recurrence.

Discussion

In the present study statistically significant difference was found between the suture and sutureless surgery for pterygium in relation to post-operative discomfort grading. Similar results were seen in a study conducted by G.D. Donepudi, et al.(2019) & Anita Minj et al (2018)[16-17] in early post- operative period there was remarkable pain and discomfort in group A (sutures) than in group B(sutureless). There was a significant difference in the duration of surgery for suture (M= 36.46, SD= 2.674) and sutureless (M= 24.88, SD= 2.553) surgery; t = 22.149, p = 0.001. In a study conducted by Sucharita das etal (2018)[18] there was statistically significant difference in the mean operating times between the two groups with results favouring the autologus blood group ($p<0.05$). Similar type of

study by donepudi et al (2019)[16] concluded that average duration of surgery was significantly less in Group I than in Group II. In our study maximum rate of complication in Group I was seen at 3 months i.e. 6% .In GP II maximum complications were seen on day 1 ie 6% & day 7 ie 4%. Similar study conducted by harpalsinghetal (2017) shows the complications following both groups of pterygium excision. In group A (sutureless), the graft displacement was found in 2 (7.1%) patients, whereas in group B, there was no graft displacement seen. While in group B(sutures), 2 (9.1%) patients had granuloma formation and also the recurrence of pterygium, which was high (22.7%) in group B as compared to group A (3.6%). Mohammed Moizuddin et al (2019)[19] conducted a similar study & found that 40% patients had graft oedema & 10% had graft displacement in autologus blood group while 10% patients had graft oedema & granuloma formation in sutures group. Recurrence was also noticed in both the groups in our study. In both the groups recurrence was seen after 3 & 6 months. No statistically significant difference was found between the suture and sutureless surgery for pterygium in relation to recurrence of the disease. In a study conducted by maiti et al(2017)[20] no significant difference was found in the recurrence rate between FG and ABC, but graft stability was found to be better with fibrin glue compared with autologus blood coagulum. 1.32% recurrence was noticed in a study conducted by Thatte et al(2019)[21] over 6 months of followup.

Conclusion

Efficacy wise both the techniques are comparable. However post operative discomfort and surgical time required are significantly less in autologous serum method. Graft loss is one of the major complication seen in this technique, which may be avoided by makin a thick film of blood over recipient bed and by taking thin and uniform graft without tenon's capsule.

Reported Adverse Drug Reactions in Off–Label Use of Azathioprine in Dermatology: A Review

Gunjeet Singh[1], Dr ShashankShekhar Gautam[2], Dr Anshu Gupta[3], Dr Pankaj Saini[4]

[1]Post Graduate Student, [2]Senior Resident, [3]Professor, Department of Pharmacology, [4]Post Graduate Student, Department of Microbiology, MMIMSR, MMDU, Mullana

Abstract

The skin is one of the largest organs in the human body. Majority of skin diseases requires lifelong treatments since they are chronic in nature. Thereby, appropriate diagnosis by the physicians and rational prescription of drugs becomes a vital component of drug therapy. ADR monitoring is considered to be mandatory as they become severe and potentially life-threatening. Primarily, in off-label setting, patients are treated with drugs which are not registered for that specific indication. Dermatologists have been at the forefront of the application of azathioprine and have thus been using the immunosuppressant for treating patients over several years.

Keywords: *Azathioprine, off-label, adverse drug reaction.*

Introduction

The skin is one of the largest organs in the human body. It is thus exposed to injury by various extrinsically based factors such as chemical, environmental, infectious agents as well as the intrinsic factors comprising of the metabolic, immunological and genetic. Majority of skin diseases requires lifelong treatments since they are chronic in nature. Thereby, appropriate diagnosis by the physicians and rational prescription of drugs becomes a vital component of drug therapy.[1] While a prescription is determined as a message conveyed by the physician to the patient.[2] Adverse drug reaction (ADR) is described as the unintended effects of drugs occurring during the use of drugs. ADR monitoring is considered to be mandatory as they become severe and potentially life-threatening. Azathioprine is widely used in medicine today as an immune-modulating drug. This drug in the United States is used in dermatology as an off label. Although in most European countries the use of azathioprine is licensed for the treatment of pemphigus vulgaris and dermatomyositis, it is extensively used off-label. Primarily, in off-label setting, patients are treated with drugs which are not registered for that specific indication.[3] Dermatologists have been at the forefront of the application of azathioprine and have thus been using the immunosuppressant for treating patients over several years. Moreover, azathioprine is discerned to be substantially more affordable.[4] For decades, physicians have utilized azathioprine and it is available in relatively inexpensive and generic formulation. Since azathioprine is no longer patented and not as lucrative as newer, more costly medications, the pharmaceutical industry appears to have lost interest in scrutinizing azathioprine. The effectiveness of azathioprine in dermatology is supported by numerous studies, reports and expert opinion. However, by the strictest evidence-based medicine standards, the level of evidence supporting the off-label use of azathioprine for many conditions is not as strong as for some newer medications. Thereby, there is a lack of strong evidence due to the time-honoured recognition of the efficacy of azathioprine and the relative newness of evidence-based medicine to the field of dermatology. For instance, dermatologists have been using azathioprine to treat immunobullous diseases for nearly 35 years successfully.

Overview of off-label drugs: Off-label is determined as the medication that is being used in a manner not prescribed by the Food and Drug Administration as an approved packaging label. Despite the prominence of off-label drug use, few patients as per the experts are aware that they are receiving a drug off-label and hence doctors are not required to tell that the drug is being used as an off-label. Therefore, when a prescription is formed by the doctor for an unapproved use, it is then determined as an "off-label" prescription.[5] For dermatologists, the use of "off-label" is a common practice for treating dermatologic conditions. According to a study r drugs that have both well acceptable therapeutic value in the medical community and also the proven efficacy on the basis of results of clinical trials, these off-label prescriptions are being used.[6] As per the reports conducted, in the United States, the largest review conducted of outpatient prescribing patterns discerned that 21% of the prescriptions were off-label based .[7] Due to the potential benefits associated with the off-label use and prescribing, it is commonly used worldwide. Off-label use may benefit the patients, in particular to those with a life-threatening illness, as off-label use might turn out effective where no standard treatments are available or existing treatments have failed; in some cases, off-label uses may also be perceived as the standard of care.[8] Despite the benefits, there are also concerns associated with the off-label use of a drug. Few of the potential concerns include adverse reactions, lack of public or private drug coverage for off-label uses[9, 10] liability for healthcare professionals and the illegal promotion of off-label uses by manufacturers.[11] There are numerous reasons for off-label use. Firstly, the FDA-approved therapies might not be discerned to exist for the treated population's specific disease. Secondly, physicians might replace within a class of medication if in case one medication is approved for a particular use while the others are not. Thirdly, the features of the two conditions might be perceived to be similar and physicians may accept one approved drug for both the conditions.[12] To quote an example, off-label psychiatric drug use is a common practice in children due to the reason that mental illnesses are challenging to diagnose. Moreover, the children are rarely included in clinical trials for drug approval.[13]

Indications for Azathioprine: For over 40 years, azathioprine has been available as an immunosuppressive agent. Moreover, the current routine use of azathioprine in dermatology is not restricted to the licensed indications. Azathioprine is an immuno-modulating drug for the control of graft rejection during the transplant surgery.[14] As per the licensed indication, dermatomyositis, pemphigus vulgaris and systemic lupus erythematosus are included. Either it is used for these conditions alone, or they are used in combination with corticosteroids. Moreover, the therapeutic effect is typically delayed for weeks or even 2-3 months and includes a steroid-sparing effect that reduces the long-term toxicity of corticosteroids. Azathioprine is also used more frequently as monotherapy in non-licensed indications including atopic eczema. Additionally, 15-28% of patients have adverse drug reactions with azathioprine and includes myelosuppression, rash, nausea and vomiting, hypersensitivity and pancreatitis. As per the study polymorphism in thiopurinemethyltransferase (TPMT) gene predicts haematological adverse drug reactions in 5–10% of patients treated with thiopurinedrugs.[15] While the remaining adverse drug reactions are unexplained and may be further perceived to be mediated by immune mechanisms or by other variables affecting the metabolic fate of the drug. Therefore, it is essential to continue monitoring blood counts throughout treatment with azathioprine.[16] Azathioprine is approved by the Food and Drug Administration (FDA) for the symptomatic treatment of active rheumatoid arthritis.[17]

Off-Label uses of Azathioprine: According to a study the off-label uses of azathioprine in dermatology was asserted in a systematic review paper.[18] Evidence pertaining to the effectiveness, efficacy and safety of off-label azathioprine utilized in dermatology was summarized in the paper. In a study conducted the researcher aimed to explore and highlight the off-label uses of Azathioprine (AZA).[17] The study manifested the uses of AZA in the treatment of inflammatory bowel disease,[20] autoimmune hepatitis (for maintenance treatment along with steroids),[21] Churg-Strauss syndrome, chronic ITP (second-line agent), connective tissue disease-associated ILD,[22] severe myasthenia gravis, multiple sclerosis, recurrent pericarditis,[23] non-infectious uve itis,[24]psoriasis,relapsingpolychondritis,[25]erythemam ultiforme,dermatomyositis/polymyositis, severe and refractory atopic dermatitis, pyoderma gangrenosum, chronic actinic dermatitis, pityriasisrubrapilaris, Behcet disease, lichen planus, cutaneous vasculitis, pemphigus vulgaris and bullous pemphigoid. It was asserted that AZA or 6-MP are used for the treatment options of Crohn disease in children in the form of maintenance treatment.[26] Strong clinical recommendation was

rendered for the use of azathioprine as an alternative treatment in atopic dermatitis.[3] The researcher presented high quality of evidence for a moderate therapeutic response. Azathioprine can be considered an alternative treatment option for severe atopic dermatitis although the efficacy is not as pronounced as for cyclosporine (SASSAD improvement of 39% to 57%).[20] The study also concluded in the major findings that azathioprine is discerned to be a corticosteroid-sparing agent which can reduce the corticosteroid-related adverse events. Comparative effectiveness research was elucidated of azathioprine on the clinical and serological response in Pemphigus vulgaris.[27] It was concluded from the study that azathioprine has a slower onset of action with a statistically significant improvement seen by 6 months (P = 0.016). In a study it was contemplated that azathioprine is an immunomodulator that is associated with several serious adverse effects. Susceptibility to its toxicity further varies with the age, medication dosage and the genetic differences.[17] In the patient's compliance, the adverse effects are a limiting factor. Therefore, the physicists and the pharmacists must be aware of the potential adverse effects with AZA, even in patients with asymptomatic. Pharmacists must thus verify that dosing is appropriate to a condition treated.

Monitoring and evaluating off-label use of Azathioprine in dermatology: According to a study the researcher reviewed the short-term nature, with the limited populations and often incomplete or missing reports of AEs, probably because of the emphasis on efficacy in the study design.[18] Thereby, conclusions pertaining to the (long-term) safety could not be drawn. The study concluded that a strong clinical recommendation was rendered for the azathioprine in atopic dermatitis. Thereby, pertaining to the safety in an off-label setting could not be reached because of scarce and incomplete data. As per the research, it was asserted that for several decades, dermatologists had utilized azathioprine for the numerous treatments with regards to the skin disease.[19] The most recognized uses deliberating to the azathioprine are for immunobullous diseases, photodermatoses and generalized eczematous disorders. It was manifested that physicians have successfully employed azathioprine to treat myriad conditions, including inflammatory bowel disease (IBD; ulcerative colitis and Crohn disease), myasthenia gravis, multiple sclerosis, autoimmune conditions and malignancies.[28] It was elucidated that off-label use is denoted for the use of the drugs outside of licence applied for and evaluated and approved by the national and European licensing agencies. The study conclusively asserted that there is an urgent need for a data bank to include off-label therapies in dermatology as well as a dermatologic diagnosis for which no other therapy option beyond off-label use exists. Off-label use occurs, especially when licensed therapy options are missing or when sufficient data for approval are not available.[29]This is especially true among children and pregnant women.

Findings and Discussion

Overall, the study asserted the off azathioprine is efficacious for the treatment of severe dermatitis problems; however, a robust data on adverse drug reactions in "off-label" use of azathioprine in dermatology needs to be explored and highlighted. Azathioprine is metabolized by the enzymes by the enzyme thiopurine-S-methyltransferase (TPMT) and causes immunosuppression via inhibition of the lymphocyte cell cycle.[19] Although azathioprine is generally a well-tolerated and as a favourable therapeutic index in comparison to many other traditional immunosuppressant. From the review of the literature, it is concluded that the most common symptomatic side effects of azathioprine comprised of gastrointestinal, ranging from diarrhoea to nausea. Within the first ten days of the treatment, it is not uncommon for patients to experience vomiting, mild nausea and gastrointestinal discomfort. Case reports of patients with the symptoms imitating viral gastroenteritis (nausea, vomiting, anorexia, diarrhoea and fever) hours after a single dose of 25 mg have been discerned. Thereby, azathioprine must be discontinued immediately in those patients'with severe gastrointestinal symptoms, as they may be developing an intolerant or hypersensitivity reaction. While some patients may also experience fatigue and malaise that may necessitate the reduction of dose or discontinuation within a few weeks of initiating therapy. Azathioprine hepatotoxicity may also be developing in some of the patients; however, this side effect is generally not common. Furthermore, bone marrow depression is also a well-known concern pertaining to azathioprine. Therefore, laboratory monitoring of complete blood count is vital to avert hematologic toxicities during the initial weeks of therapy. In addition to this, these known dermatologic problems are discerned to be more frequent in the process of transplantation than in the non-transplantation patients on azathioprine. Some of the significant risk factors in the development of skin lesions include excess sun exposure, pale skin types and

also the duration of the allograft. While a few common skin factors include verrucae, zoster increased skin colour, alopecia and malignant neoplasms.[19]

Conclusion

Conclusively, throughout the current review paper, the adverse drug reactions in 'off-label' use of azathioprine in dermatology is explored and highlighted. By reviewing the prior studies in azathioprine, off-label drugs, monitoring and evaluating off-label use of azathioprine in dermatology and indications for azathioprine are elucidated.

Evaluation of Technique Using Pressurized Metered dose Inhaler and its Determinants among COPD Patients: A Cross Sectional Study

Achchhar Singh[1], Jai Kishan[2], Sameer Singhal[3], Vishvdeep Saini[4], Abhishek Chauhan[4]

[1]Associate Professor, [2]Professor and Head, [3]Professor, [4]Junior Resident, Department of Respiratory Medicine, MMIMSR, M.M. Deemed to be University, Mullana, Ambala, Haryana, India

Abstract

The aim was to evaluate the inhalation technique among COPD patients using pressurized metered dose inhaler and determinants of incorrect inhalation technique. In this hospital based cross-sectional study, total 92 COPD patients were enrolled. Basic socio-demographic information was collected. The inhalation technique was visually observed and scored on checklist. Statistical Analysis Used: Chi-square test and Fisher exact test. Among the 92 patients observed, 69 (75.0%) were males. The mean age of the patients was 45.8 ± 1.4 years. Correct technique was observed in only 22 (23.9%) patients step at which maximum number of patients committed mistake was exhalation 65.2% followed by breath holding 45.7% and multiple actuations were seen in 44.5%. It was found that substantial errors were made in the inhalation technique hence proper training and follow-up of the patients is required to achieve the desired effects of the inhaled medications.

Keywords: *COPD, pMDI, Inhalation technique.*

Introduction

COPD is a disease state characterized by airflow limitation that is not fully reversible. The airflow limitation is usually both progressive and associated with an abnormal inflammatory response of the lungs to noxious particles or gases.[1]

Chronic respiratory diseases which include asthma and chronic obstructive pulmonary diseases, it is responsible for an estimated burden of more than 100 million people in India.[2] Chronic obstructive pulmonary disease progresses over many decades and tends to present in advanced stages, thus most treated patients are middle aged or elderly. Chronic obstructive pulmonary disease is the fourth leading cause of death worldwide resulting in more than 2.7 million deaths in 2000.[3]

Over the years, inhalation therapy has become the backbone in the treatment of these disorders, although new inhalers have been intended to improve ease of use, significant rates of incorrect use have been reported among COPD and bronchial asthma patients, even among regular adult users.[4]

Incorrect use not only undermines the patient acquiescence, but also hampers the effectiveness of these devices on a large scale which leads may leads to poorer control of symptoms due to insufficient drug delivery and inefficient lung deposition and higher rates of asthma instability and increased burden on emergency services. Our study evaluates the inhalation technique in COPD patients using pressurized metered dose inhalers (pMDI) attending a tertiary care hospital in Ambala, India.

Materials and Method

Study Design, Study Duration, Study Population and Study area: A cross-sectional study was carried out

Corresponding Author:
Dr. Jai Kishan
Professor and Head, Department of Respiratory Medicine, MMIMSR, Mullana, Ambala, Haryana, India
e-mail: jaikishantb@gmail.com

among indoor and outdoor patients of COPD in a tertiary care hospital in Ambala, India.

Inclusion Criteria:

Subjects fulfilling the eligibility criteria of

- Voluntary participation
- Those patients using pMDI
- Patients above 18 years of age who had been using pMDI for at least 6 months

Exclusion Criteria:

- Those not willing to participate in the study
- Those patients with recurrent exacerbations, chronic infections and
- Those using spacer devices or other inhalation devices

Sample Selection: The sample size was calculated based on the study by Sehajpal R et al.[5] using a prior type of power analysis by G* Power Software Version 3.0.1.0 (Franz Faul, Universitat Kiel, Germany). The minimum sample size was calculated, following these input conditions: power of 0.90 and $P \leq 0.05$ and sample size arrived were 92 participants.

Training and Calibration: Before the commencement of the study, the examiner was standardized and calibrated in the by the senior faculty member to ensure uniform interpretations and understanding of the steps of inhalation. The kappa value was 0.88, which denoted substantial level of agreement between the examiners.

Data Collection: The study involved collection of the basic socio-demographic information and visual observation of the inhalation technique of the patients and scoring of their technique on the inhaler specific checklist simultaneously by the examiner.

Inhalation Technique: The technique of inhalation was divided into 7 steps, namely shaking, positioning, exhalation, actuation, hand mouth coordination, slow deep inhalation, breath holding. With a view, that each of these steps is crucial for effective delivery of the drug to the lung and also for instant onset of action. Note was also made of the person who taught the patient the technique at first place and a correlation between efficiency of the technique and guide was looked for.

Statistical Analysis: The recorded data was compiled and entered in a spreadsheet computer program (Microsoft Excel 2010) and then exported to data editor page of SPSS version 19 (SPSS Inc., Chicago, Illinois, USA). Descriptive statistics included computation of percentages and mean. The statistical tests applied for the analysis were Pearson'schi-square test (χ^2) and fisher exact test. For both the tests, confidence interval and p-value were set at 95% and ≤ 0.05 respectively.

Results

Present study was conducted among 92 patients of COPD 57 (61.9) patients had age more than 35 years, 69 (75.0%) were males. The mean age of the patients was 45.8 ± 1.4 years. 57.6% of the patients were from the rural background and the number of illiterate patients was 51 (56.5%). 55 (59.8%) were using the device for more than 1 year.

Table 1: reveled that only 22 (23.9%) of the patients were able to perform inhalation technique correctly and a total of 70 (76.1%) patients performed at least one step incorrectly. In this study, the step at which maximum number of patients committed mistake was exhalation 65.2% followed by breath holding 45.7%, multiple actuations were seen in 44.5% of the patients, Hand-Mouth coordination 40.2%, Slow deep inhalation 39.1%, shaking 35.0% and positioning 24.0%.

Table 2: depicted that patients who had been using the device for longer duration performed the technique correctly (P = 0.04). No significant correlation found between age, sex, education level, area of residence and the correctness of the inhalation technique.

Table 1: Distribution patients according to incorrectly following the technique

Inhalation technique steps checklist	Incorrect (%)
Shaking	35
Positioning	24
Exhalation	65.2
Actuation	44.5
Hand-Mouth co-ordination	40.2
Slow deep inhalation	39.1
Breath holding	45.7

Table 2: Correlation of patient characteristics with correctness of the inhalation technique

Variables	p-value

Discussion

To the most effective of our information the current study is that the 1st of its kind performed in Ambala, India and highlights not solely the importance of demonstration of correct technique to the patients however calls attention to the essential steps that the patient may well be playing wrong, in order that these specific steps in inhalation technique will be corrected and stressed for higher relief of the symptoms. This might not solely assist in raising the patient compliance however also enhance the patient still as a physician's confidence within the medical care.

We found that solely 22 (23.9%) of the patients were able to perform inhalation technique properly as we evaluated the technique by visual observation and scored it on the listing. 70 (76.1%) patients performed a minimum of one essential step incorrectly. The controlled metered dose inhalator presents a transparent challenge for a patient with respiratory illness which needs to comprehend and execute the steps that involve synchronous coordination of metabolic process and motor movements.

The substantial variety of mistakes relating to inhalation technique as discovered in our study is in line with previous literature. Study done by Buckley[6] reportable that solely 18 out of 71 patients (25%) had excellent technique, twenty six (37%) had adequate technique and twenty seven (38%) had poor technique and therefore the patients presumably to own poor technique were those employing a nongovernmental organization. Molimard et al.[7] conjointly reported similar results that a minimum of 76 of the pMDI users created more than one mistake.

In this study, the step at which maximum number of patients committed mistake was exhalation: 65.2% followed by breath holding 45.7%, multiple actuations were seen in 44.5% of the patients, Hand-Mouth co-ordination 40.2%, slow deep inhalation 39.1%, shaking 35.0% and positioning 24.0%. A study conducted in Trivandrum, authors found that the key incorrect steps were, not breathing properly before inhalation (62%), not holding breath properly (57%), not properly shaking the inhalator (55%) and not inhaling properly (17%) for pMDI.[8] In another study by Rootmensen et al.,[9] for the pMDI the steps concerning hand-lung coordination; that is, "activate canister in beginning of a slow inhalation" and "continue to inhale slowly and deeply," were most frequently performed incorrectly (respectively, 72 and 31%).

In a study conducted in Turkey also it was found that the most common basic error associated with inhalation maneuvers was failure to exhale before inhaling through the device (18.9%).[10] Research studies show that it is very important for patient to exhale normally until functional residual capacity is reached and then take a slow, but deep breath and hold it for at least 10s for maximum drug penetration into the airways. Multiple actuations do not provide any benefit as the subsequent pumps do not carry medicine as the necessary pressure does not build up and also patient ends up exhaling medicine from first actuation before inhaling deeply.[11,12]

Limitation: There are varied factors which may influence the patient's adaptation to the inhalation technique like accomplishment level of the patient that affects the comprehension of the technique, variety of pedagogue who instructed the technique that affects the correctness of technique at the preliminary level. Another limitation was; analysis setting was dissimilar to the house surroundings, which can have affected task performance. However, this qualitative study style is common for exploring inhalation devices and allowed discussion with participants to explore the foundation causes of determined errors.

Conclusion

Our study shows that a considerable proportion of COPD patients in health care setting create mistakes once breathing medication using pMDI because the inhalation device. Although it's the first responsibility of the physician prescribing the dispenser to produce patient with correct directions for utilizing the device, however the responsibility may even be branched among the health care team like pharmacists who could play an important role in teaching and reinforcing the technique. Teaching correct technique won't solely improve patient's compliance however conjointly can result in higher un-wellness management and lesser price and stress on emergency medical services.

Glue Free and Suture Free Conjunctival Autograft in Pterygium Excision: A North Indian Perspective

Vineet Gupta[1], Kunal Sharma[2], Neha[2]

[1]Assistant Professor, [2]III[rd] Year Resident (Deptt. of Ophthalmology), M.M.I.M.S.R., (Maharishi Markandeshwar Deemed to be University)

Abstract

Aim: To study postoperative outcome & related complications of Glue free and suture free conjunctival autograft in pterygium excision in Haryana-A North Indian state.

Materials and Method: The present study was conducted at the Department of Ophthalmology, MMIMSR, Mullana (Maharishi Markandeshwar Deemed to be University) in the time period extending between December 2017 and January 2019. 50 eyes of patients of either sex with primary pterygium were selected and pterygium was excised & sutureless & glue free conjunctival autograft was done with patient's own blood fibrin. Parameters such as mean operating time, presenting complaints, grade, complications & recurrence were observed on postoperative Day 1, Day7, 2 weeks, 1 month, 2 month, 3 month & 6th month.

Results: The mean age of the study population was 48.82 + 11.13 years... Out of 50 eyes only 1 (2%) had conjunctival cyst, 2 (4%) graft edema and 3 (6%) had graft displacement, 1(2%) had graft lost, 1(2%) had graft rejection & 1(2%) had recurrence at 6 month follow up. The mean operation time was 24.88 minutes. Regarding type of the pterygium, out of 50 patients 9(18%) were grade 1, 26(52%) were grade 2, 11(22%) were grade 3 and 4(8%) were grade 4.

Conclusion: Conjunctival autograt using patients own blood technique is a safe, cheaper, effective, with less surgical time & has minimal postoperative discomfort.

Keywords: *Complications, pterygium, recurrence, suture free, glue free conjunctival autograft.*

Introduction

Historically, pterygium and its treatment was first described in 1000 BC by Susruta.[1-2] Thereafter, though many surgical options for pterygium have come out and develop through three centuaries, complications like recurrence after surgery have been troublesome. The bare sclera technique which was popular from 1960 to the early 1980s has been discarded due to the unacceptable recurrence rate, often as high as 60%–80%.[3] The logical approach is a safe method with low recurrence rate and less complications. Conjunctival autograft (CAG) fulfils the above criteria and gained popularity in the 1980s following the landmark article by Kenyon et al.[4] in 1985 who reported a low recurrence rate of 5.3%. Prabhasawat et al.[5] (1997)reported that autologous CAG is the best method, with a low recurrence rate and higher safety margin. Thereafter, several prospective randomised trials of CAG for pterygium surgery have reported higher recurrence rates of 16%–39% in high-risk population.[6-7] Nonetheless, CAG has now been in vogue for more than 3 decades and has stood the test of time as the standard of care in pterygium surgery.

The use of fibrin glue was first described by Cohen et al.[8] in 1993. This is faster and simpler. There is less post-operative pain and discomfort.[9-10] Disadvantage with fibrin glue is that it is expensive & difficult to

obtain than sutures. Fibrin gluealso has a potential risk of transmitting viral disease alongwith hypersensitivity reactions as it is a blood derivative.[11] The latest approach is fixation of the graft with autologous blood, a technique also known as suture and glue freeautologous graft.[12] Patients own blood is used as a bioadhesive or fixative.[13] Autologous blood is natural, has no extra cost, no associated risk and can overcome postoperative irritation, redness and foreign body sensation.

Our study intended to evaluate the technique of securing the CAG with fibrin, using the normal physiological clot from the patient's own blood at the surgical site acting as a bioadhesive.

Materials and Method

Type of study was prospective study. The present study was conducted in M.M.I.M.S.R. (Maharishi Markandeshwar Deemed to be University) Department of Ophthalmology,50 patients of nasal pterygium were included in the group. All the patients underwent pterygium excision with suture free and glue free autologous graft. Subjects included in the study were from 20 to 75 years of age having pterygium (primary) involving any eye. Necessary approval from Institute was obtained beforehand. Written informed consent was taken from each patient. Preoperative ocular examination included refraction and assessment of best-corrected visual acuity, slit lamp biomicroscopy, fundus examination and photographic documentation of the pterygium. Surgeries were done from December 2017 to January 2019. Grading of the pterygium was done as:

Grade I-pterygium head up to the limbus

Grade II-head between the limbus and a point midway between limbus and pupillary margin

Grade III-head between a point midway between limbus and pupillary margin and pupillary margin

Grade IV-crossing pupillary margin. Inclusion criteria were primary nasal pterygium and recurrent pterygium.

Exclusion criteria were temporal pterygium, patients taking oral nonsteroidal anti-inflammatory drug (NSAID) and anticoagulant, active infection or inflammation, symblepharon, past ocular surgery within last 6 months,trauma, systemic diseases such as diabetes mellitus, collagen vascular disease, pregnancy, bleeding disorders.

Indications of Surgery:

1. Pterygium causing foreign body sensation
2. Defective vision
3. 3 to 4 mm encroachment on the cornea
4. Cosmetic intolerance
5. Diplopia due to interference with ocular movements

Surgical Technique: All surgical procedures were done under peribulbar anesthesia. All the surgeries were done under amicroscope by the same single surgeon using the sametechnique. Taking all aseptic precautionary, eyelid wasthen separated by a speculum and sub-conjunctival andsubpterygial 0.5 ml lignocaine solution (xylocaine 2%)was injected. Gentle massage over the lesion was applied by cotton-tipped applicator for few seconds. The neck of the pterygium was then lifted up with the help of fine toothed forceps, while the head of the pterygium was gently avulsed from the cornea by placing closed tips of acurved corneal scissors or Iris repository underneath the neck of the pterygium mass, keeping the same constant tractional force throughout. Gentle dissection was then carried out in-between the conjunctiva and the sclera withthe help of crescent knife, to resect at least 4-5 mm thepterygium mass that included both the superior and inferior border. Neither cautery nor saline irrigation was used throughout the surgery, except active bleeding, with bi-polar cautery whenever required to check excess hemorrhage. The size of the bare sclera defect was then measured with Castroviejo calipers. Corneal care was taken by applying wet cotton throughout the procedure. Now, approximately 0.5 ml xylocaine 2% was used to balloon up a conjunctival flap. Corneal scissor was used to make a fine film of 0.5 mm oversized, free conjunctival graft, carefully avoiding inclusion of tenon, or making buttonhole within it. The graft was then laid over the bare sclera ensuring same limbus to limbus orientation. We waited for 5 to 10 min for hemostasis to occur. In cases, where the surgeon appreciated the lack of adequate amount of blood at the recipient site, episcleral blood vessel was intentionally punctured to create bleeding. The eye was then patched for 24hrs. The eye was assessed for symptom, graft adherence, or any complication (s) under slit lamp. Postoperatively, patient was put on topical antibiotic and steroid combination for first 2 weeks thereafter tapered over next 4weeks. Thereafter, an attempted follow-up of cumulative 6 months (at postoperative day 1, 1 week, 2week, 1 month, 2 month 3 month, 6 month) was done to

every patient. At each postoperative visit, thorough slit lamp examination and any recurrence, complication (s), or any complaints were recorded. The primary outcome measure was the recurrence and the secondary measures were complication (s) and surgical time.

Results

Discussion

Pterygium surgery should ideally have a low or no recurrence, minimum complications and should be cosmetically acceptable . Conjunctival autograft using sutures used to be a standard procedure. The grafts were stable with acceptable cosmetic results. Suture related complications like postoperative inflammation, granuloma formation, pain, foreign body sensation were observed. Suture's presence may lead to prolonged healing and fibrosis. Later, complications such as formation of symblepheron, forniceal contracture, restriction of ocular movements, diplopia, scleral necrosis and infection are much more difficult to manage and may be sight threatening.[14] Fibrin glue usage is quicker and easier with less postoperative complications. But fibrin glue is expensive and difficult to obtain. Foreign materials or Plasma derived products such as fibrin glue may produce possible hypersensitivity reactions or anaphylaxis in susceptible individuals and transmission of viral diseases.[11] Recent introduction of auto graft technique using patient's own blood as bioadhesive substance on the excised bed of the pterygium have become popular. It has minimized the surgical time, trauma to the conjunctiva, cost of surgery and recurrence rate. In our series, the operation time was only 24.88 minutes and there was only 1 case of pterygium recurrence after 6 months of surgery though we had 3 cases of graft displacement with one patient of conjunctival cyst, graft loss & graft rejection each. The technique is cost effective and easy to perform with less

discomfort to patient. The result was comparable to other studies with similar techniques.[15] Sutureless and glue free conjunctival auto graft using blood clot as a bioadhesive is a useful alternative method for graft fixation in pterygium surgery. We found the new procedure of auto grafting free of any untoward complications. Suture and glue free autologous graft has no extra cost or associated risks and can overcome the post-operative irritation, pain and foreign body sensation to a great extent. The procedure was cosmetically better. The opposition of the lids to the bulbar conjunctiva provides a natural biological dressing and confers a unique wound healing environment.[11] The main disadvantage of this method is the risk of graft getting lost in the immediate post-operative period. Graft loss is usually seen in first 24 to 48 hours. These complications were associated with larger grafts. This could be due to inadequate excision of the pterygium tissue or leaving too much tenon's tissue onthe graft.[9] Meticulous dissection of the sub-epithelial graft tissue is required.[11]

Conclusion

Pterygium excision and conjunctival auto graft with autologous blood is a viable and better surgical option formanagement of primary as well as recurrent pterygium. The probability of attachment of graft without glue and sutures is promising. The risks associated with the use of fibrin glue and suture related problems can be avoided in this technique. This technique has excellent outcome. It is cheaper, time saving, has less surgical time and safe for the patients with good cosmetic output.

Effect of Change in Position of Finger on SpO_2 Value by Pulse Oximetry: A Cross Sectional Study

Jai Kishan[1], Obul Reddy[2], Achchhar Singh[3], Sameer Singhal[4]

[1]Professor and Head, [2]Junior Resident, [3]Associate Professor, [4]Professor, Department of Respiratory Medicine, MMIMSR, M.M. Deemed to be University, Mullana, Ambala, Haryana, India

Abstract

Background: Pulse oximetry is widely used in patients of respiratory diseases for monitoring the oxygen saturation in blood. First commercial pulse oximetry was used in 1975. Although there have been many improvements in its design since then, still there are a few limitations. The limitations of pulse oximetry include mechanical artefacts accuracy, electromagnetic interference, calibration, delay, pulse dependence-volume and rhythm, abnormal haemoglobins, other absorbents, pulsatile veins, pigmentation.

Objective: Despite so many studies on the pulse oximetry, there still isn't any study on pulse oximetry which focused changes in the readings of pulse oximeter with respect to position of finger in relation to the sensor. So in this study we tried to analyse the effect of anatomical plane of finger on O_2 saturation as measured by pulse oximetry.

Material and Method: This study was done on 400 patients and included both healthy and unhealthy patients. Portable pulse oximeter was used in the study. Pulse oximetry was done on the subjects with finger in supine, prone and lateral position in respect to the probe, while the patient was in sitting position with a waiting period of 1 min between each reading.

Results: The study shows no significant difference (p value > 0.05) between Spo_2 value obtained from any position of finger in relation to the sensor while applying the pulse oximeter.

Conclusion: Pulse oximetry is a very safe, non-invasive and inexpensive way of continuous O_2 saturation monitoring in critical patients. Mal-positioning of sensors can be potentially dangerous as it may give erroneous high or low readings. The ways to prevent mal-positioning of the sensor are good design of pulse oximeter and ensuring that it is properly visible to the clinician.

Keywords: *Pulse oximetry, oxygen saturation variation, sensor mal-positioning.*

Introduction

Pulse oximetry is widely used for patients who require monitoring of oxygen saturation in variety of clinical settings. Its main purpose is the early detection of hypoxemia in diverse situations and the monitoring of perfusion and circulation. The prototype pulse oximeter[1] made use of a halogen incandescent lamp as a light source and the broad bandof energy is passed to a fingertip probe through a glass fibre bundle. There were many disadvantages to this prototype e.g. it had a heavy probe; the fibreoptic cable was unhandy; there were instances of finger burns by unwanted wavelengths passing through the finger; it was insensitive to even moderately low pulse pressure;and its analogue electronics were error prone.

The first commercial pulse oximeter was available in 1975. All currently available conventional pulse

Dr. Obul Reddy
Junior Resident, Department of Respiratory Medicine, MMIMSR, Mullana, Ambala, Haryana, India
e-mail: doctorobulreddy@gmail.com

oximeters use a combination of two wavelengths, normally 660 nm and 940 nm, generated in the probe by combining light-emitting diodes with a miniature semiconductor photodetector, thus providing a compact probe for attachment to the ear or fingertip. A small lightweight cable connects the probe to the main unit.

Conventional pulse oximeters function by comparing the absorption of energy at two wavelengths, usually 660 nm and 940 nm, passed through an extremity. A value, SpO_2, which is approximately equal to arterial haemoglobin saturation, SaO_2, is determined from the ratio of the absorption of the energy at the two wavelengths.

However, there are several limitations to the pulse oximetry which include mechanical artefacts, accuracy, electromagnetic interference, calibration, delay, pulse dependence- volume and rhythm, abnormal haemoglobins, other absorbents, pulsatile veins, pigmentation.Various studies have been done on pulse oximetry but to the best of our knowledge none has focused on the position of finger in relation to the sensor. In this study we tried to analyse the effect of anatomical plane of finger on O_2 saturation as measured by pulse oximetry.

Material and Method

This study was done on 400 patients and included both healthy and unhealthy patients. Portable pulse oximeter was used in the study. Pulse oximetry was done on the subjects with finger in supine, prone and lateral position in respect to the probe, while the patient was in sitting position with a waiting period of 1 min between each reading. The sensors were placed appropriately on index finger and reading was taken with stable plethysmograph. The statistics were calculated using repeated ANOVA test. Significance was calculated using p value and significance level was set at 0.05.

Results

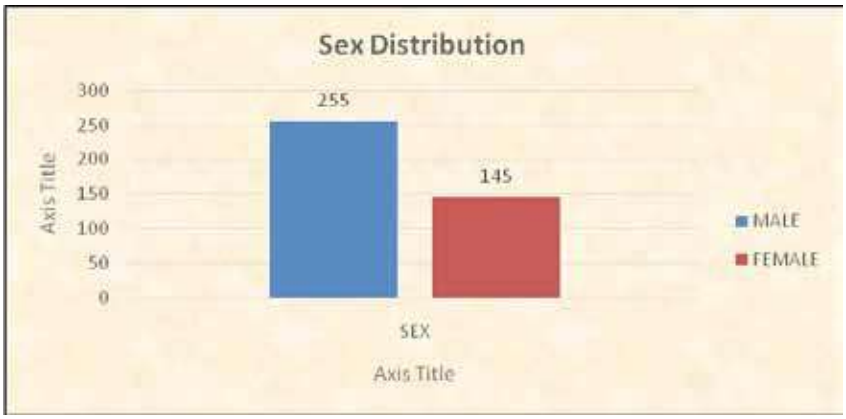

Chart 1. Sex Distribution

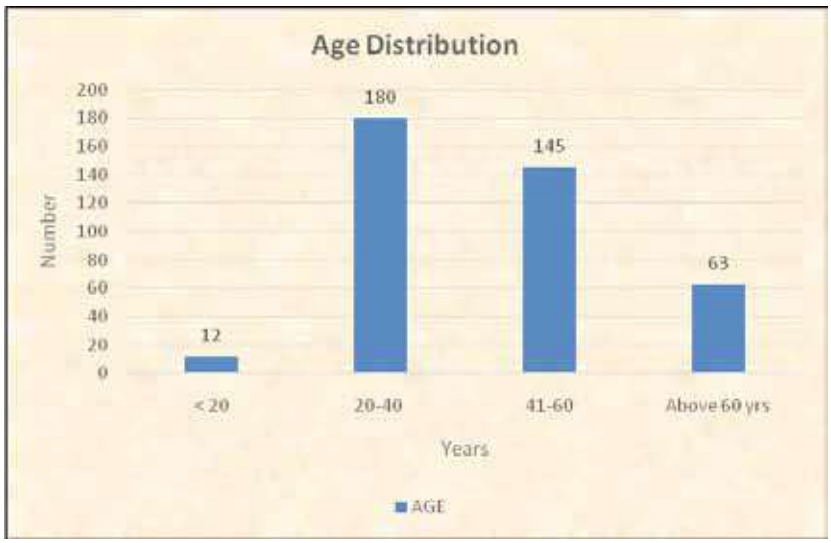

Chart 2. Age distribution

There were 255 males and 145 female subjects in the study. The age distribution of subjects is given in Chart 2. The mean and standard deviation value for various parameters are given in Table 1. The study shows no significant difference (p value > 0.05) between Spo_2 value obtained from any position of finger in relation to the sensor while applying the pulse oximeter.

Table 1. Different Parameters with mean values and standard deviation

Parameter	Mean±SD	p value
Hb	12.7±1.83 g/dl	
Pulse	84±1.83/min	
AP diameter (Distal Phalanx)	12.3±1.09 cm	
Transverse Diameter	14.95±1.49 cm	
SpO2 in Prone finger	96.91±4.06%	0.41
SpO2 in Supine finger	96.91±3.80%	
SpO2 in Lateral finger	96.87±3.93%	

Discussion

The mal-positioning in terms of improper application of sensor is significant as shown by various studies but the position of finger while the sensor is appropriately placed has not been studied. We did this study to see if position of sensor in relation to the anatomical position of finger affects the Spo_2 value but the results showed no significant difference. The penumbra effect refers to an erroneously low SpO_2 reading when the probe is mal-positioned.

The penumbra effect and the errors due to mal-positioning of the pulse oximeter probe are a combination of technical and physiological problems. This may be caused by there being a finite distance between the red and infrared light-emitting diodes and hence different path lengths for the two wavelengths, especially with babies and children. The penumbra effect has also been noted in adults, which may be due to different path lengths or to pulsatile venules at the tips of the extremities. In a study by Kim et al.,[2] the investigators suggested that the pulsatile venules are a result of the rich arteriovenous anastomoses in the cutaneous circulation at these sites. Cutaneous blood flow may vary from 1 ml/min/100 g of skin to as much as 150 ml/min/100 g in response to thermoregulatory and other vasodilatory stimuli. Cutaneous venules may be pulsatile owing to the arteriovenous anastomoses or the close proximity of pulsatile arterioles. Kelleher and Ruff[3] also speculated that these cutaneous venules might contain desaturated blood from the cutaneous capillaries and that as the arteriovenous anastomoses render these venules pulsatile, inaccurately low SpO_2 readings are therefore displayed. They also suggested that if the pulse oximeter probe is poorly applied then most of the pulsatile signal is generated by the cutaneous blood flow, with its pulsatile venous component. This would explain why the penumbra effect is less common in conditions causing vasoconstriction, such as hypothermia and peripheral shutdown, when the cutaneous arteriovenous anastomoses are closed, thus reducing the pulsatility of the venules.

Barker et al.[4] investigated about the effect of mal-positioning of the pulse oximeter probe and reported that improperly placed or displaced probes may cause pulse oximeters readings to become erroneous. Most pulse oximeters under-read, a failsafe condition because it prompts urgent medical attention, but some either overread or failed to follow trends in saturation. The possible explanations include the penumbra effect and that a weak plethysmograph signal.

Conclusion

The pulse oximetry is a very safe, non-invasive and inexpensive way of continuous O_2 saturation monitoring in critical patients. Mal-positioning of sensors can be potentially dangerous as an erroneous high reading may give false sense of security while an erroneous low reading may result in excessive financial burden on the patient in terms of unnecessary and more invasive investigations. The ways to prevent mal-positioning of the sensor are good design of pulse oximeter and ensuring that it is properly visible to the clinician. Finally it doesn't make any clinically significant change in spo2 level with relation to the position of finger be it supine,prone or lateral.

Abstract

Introduction: In cases of infected Nonunion of long bones Antibiotic coated nail provides mechanical support for the affected bone with delivery of high concentration of antibiotics for infection control and a conclusive environment for fracture healing. The aim of the study was to observe and study the treatment of infected non-union of long bones with antibiotic coated nailing in infection control and bony union.

Material and Method: The study was conducted on 30 patients (male and female between the age of 18-70 years). All patient on admission were subjected to detailed history, relevant investigations and thorough clinical examinations. Minimum follow-up period was 6 months. Radiological and blood investigations were done for infection control and bony union.

Result: In the current study of 30 patients with mean age of 43.67 years, Infection control and bony union was achieved in 27 patients without any need for subsequent procedures. Current study provides an alternative to external fixation alone as a means of stabilizing non-unions while providing a high concentration of antibiotic locally for combating this difficult problem.

Conclusion: The clinical results and final outcome after antibiotic coated I.M. nailing in infected nonunion of long bones are both satisfactory and reproducible as evident by the comparison of this present study with the previous literature available.

Keywords: *Infected nonunion, antibiotic coated nail.*

Introduction

Infected non-union of long bones is one of the most challenging clinical situations faced by orthopedic surgeons. It presents with dual problems of controlling infection and providing stability. Various local (Infection at or around the fracture site, Implant failure, Fracture fragments, Inadequate immobilization of the fracture) and systemic factors (Age, nutrition, Immunodeficient states, smoking) contribute to infected nonunion. The presence of poorly vascularized tissues, adherence of bacteria to bone and implant, along with slow bacterial replication rate contribute to persisting infection[1-2]. The method of treatment proposed here provides a combination of fracture stability and local antibiotic delivery for infection control in a single procedure.

Patients and Method

The study was conducted on 30 patients (male and female between the age of 18-70 years) in the Department of Orthopedics, Tertiary Care Centre, MMIMSR,

Mullana. Infected nonunion of the long bones of upper and lower limbs were included in this study after informed consent was obtained. Patients included in this study had compound diaphyseal fractures of long bones, Bone gap less than 3 cm, age more than 18 years and No radiological signs of union despite previous mode of treatment used. Patients excluded from study - Patient with large bone gaps (>3 cm), Infection involving the joint and patients with allergy to the antibiotic (to be used in cement) were excluded.

Surgical Steps: The surgical technique involved a series of steps. The first step was evaluation of pre-op culture and sensitivity results and radiographs. Samples were taken after 72 hours of stopping antibiotics. Pre-operative measurements of the length of the bone femur, tibia, humerus were taken. Surgery began with exploration and excision of sinus tracks followed by removal of any metal work present at the nonunion site.

Second step was Debridement of infected tissues such as skin, soft tissues and bone, was done until bleeding viable tissue was present at the margins (in case of bone- Paprika sign). The fracture site and surrounding soft tissues were irrigated with saline and samples were sent for gram staining and culture.

Third step was preparation of the Intramedullary canal for nail insertion as per standard procedure according to the bone involved i.e. femur/tibial/humerus. Length of the nail required was calculated using the scale under C-Arm. Appropriate size of nail was determined and then used accordingly. Fracture was reduced and a flexible guide wire inserted in medullary cavity. Then reaming was done with the flexible power reamer in graded sequential manner. This was done one or two sizes (1-2mm) more than that of the intramedullary nail removed. In cases where there was no intramedullary nail in-situ, reaming was done to 1.5-2mm more than size of antibiotic coated nail. On a separate table Required antibiotic cement-impregnated nail according to culture and sensitivity was prepared. If the culture was sterile then gentamicin impregnated cement (40 g) along with 4 g vancomycin was used. Custom made molds and nails were used. The size of the mold varied from 9-10 mm for tibia nails and 10-11 mm for femoral nails. For tibia, nails with diameter 7 to 8mm and for femur nails with diameter 8 to 9mm were used. Before putting the cement, molds were coated with a thin layer of sterile lubricant gel and sprinkled with powdered cement to facilitate easy removal of the cement-coated nail from the molds. The bone cement was mixed with culture specific antibiotics and was put on the mold with the help of cement gun in semiliquid state. The nail was put in mold. The locking sites of the nail were covered with cut pieces of chest tube which were subsequently removed. The nail with antibiotic cement coating was removed after the cement sets (usually in 8 to 10 minutes). The interlocking sites were left free without any bone cement when the cut ends of chest tube were removed. Figure-1. The nail was inserted into the intramedullary canal using standard entry point for the respective bones which were already prepared, the fracture was reduced and nail was inserted into the distal fragment. In cases where interlocking I.M nail couldn't be used because of narrow intermedullary canal, K-nail was used. It was prepared using measuring scale method. The k-nail was covered with antibiotic. Impregnated cement with hands and then the nail was passed through a nail measuring scale for uniformity. Wound closure was done in layers and appropriate postoperative splint were given accordingly. Patients were kept on follow up at 2, 6,12 weeks and 6 months. Routine investigations as required such as CBC, ESR, CRP and X-rays were done to assess rate of union,and control of infection. Non weight bearing walking was started first followed by partial weight bearing depending upon healing on X-rays and clinical assessment.

Results

30 patients of infected nonunion of long bones were treated using Antibiotic cement-coated IM nails. Minimum follow-up period was 6 months. 9 female and 21 male patients (age range, 18–70 years) with a mean age of 43.6 years were included in the study. In current study 9 femur, 20 tibia and one humerus were treated. When the fracture occurred primarily 20 were open and 10 were closed. The primary procedures performed in these patients were as follows

Table 1 Open fractures are more commonly associated with infected non-union. In 17 patients, the organism isolated was Staph. Aureus out of which 10 patients had MRSA. 2 patients had klebsiella, 3 patients had pseudomonas aeruginosa, in 4 patients signs of infection were present but no organism was isolated in rest of the patient's multiple organisms were isolated.

Table 2 depicts pre-operative organisms, their sensitivity and antibiotics used. In 21 cases interlocking I.M nail was used while K-nail was used in 9 cases. Infection Control was successfully achieved in 90%

(27 patients) of the cases. In 3 patients discharge was present for more than 8 weeks. In rest of the patient's average time for infection control was around 3.3 weeks. The clinical assessment of the union was mainly based on complete absence of pain and tenderness at the fracture site. Radiological criteria for union are evidence of bridging periosteal and endosteal callus formation in minimum 3 cortices. Bony union was achieved in 90% of the cases with average mean time of union at 27.27 weeks of time. The mean time of bony union of femur was more than tibia at 29.66 weeks. The mean time for union of tibia was 26.17 weeks in 17 patients. Figure 2 shows a tibia patient. In humerus bony union was achieved by 24 weeks. Deformity was present in 3 patients. In 3 patients were no signs of bony union were present secondary procedure, Ilizarov[3,4,5] was done after nail removal. In 2 out of these 3, infection control and bony union was successfully achieved

Table 1: Primary Procedure

Primary Procedure	No. of Cases	Percentage
Conservative	3	10.0%
External Fixator	11	36.7%

Image 2: Shows pre-op, post op 2 months and post op 8 months radiographs of a patient of infected Non-union of tibia.

Discussion

Infective non-union of long bones require treatment method that offer control of infection and provide stability to the bone to promote union.[6] There is no single universally accepted modality of treatment presently available for the management of infected non-union. Thorough debridement, rigid fixation and prolonged antibiotics are the mainstay in treatment of infected non-union of the long bone.[7,8] The infected foci within the bone are surrounded by a sclerotic, relatively avascular bone covered by a thickened periosteum, scarred muscle and subcutaneous tissue. This avascular envelope of scar tissue leaves systemic antibiotics essentially ineffective.[9] Osteomyelitis[7,10] is polymicrobial in majority of patients. The most common infecting organism in the literature and in our study is Staphylococcus aureus.[11,12] The choice of antibiotic is culture dependent heat stable broad-spectrum antibiotic such as gentamicin and vancomycin. Main advantage is Local concentration of antibiotics is far higher than what can be achieved with systemic antibiotics. Clinical and experimental studies show them to have good elution properties from bone cement and no deleterious effects on bone healing.[6,13] In order to cure biofilm-related infection, four principles formulated by Cierny and Mader must be observed: (1) Complete surgical debridement with dead space management (2) Fracture/ nonunion stabilization (3) Soft tissue coverage and (4) Adequate antibiotic levels.[2] Antibiotic cement has been shown to elute antibiotic at the local sites for up to 36 weeks thus having a therapeutic effect on refractory infection.[1,14] Various studies have reported success with the use of intramedullary antibiotic-impregnated bone cement rods for the management of infected non-unions of long bones.[6, 15-19]

Culture specific antibiotics gentamycin, vancomycin and tobramycin were used for their broad spectrum of activity, heat stability and low allergenicity. We used custom made molds for I.M nails and chest tube for K-nail. Patients were advised for implant removal once infection control and bony union was achieved. We removed implant in 3 patients. Paley and Herzenberg also retained their cement-coated rods for up to 753 days without any major complication except rod fracture in one patient.[20] It is advantageous over external fixators, as it eliminates the complications of external fixators and has good patient compliance.

Conclusion

Antibiotic cement impregnated nailing provides effective infection control and good stability to promote union, traditionally provided by two separate procedures. It is advantageous over external fixators, as it eliminates the complications of external fixators and has good patient compliance.

Antibiotic cement impregnated nailing is a simple, economical and very effective procedure than the traditional method in management of infected nonunion of long bones.

Role of Tranexamic Acid in Controlling Blood Loss in Major Orthopaedic Surgeries (TRAMOS): A Comparative Study

Manjeet Singh[1], Ashwani Ummat[2], Vishesh Verma[3], Praveen Thivari[3], Harsimarjit Kaur[4]

[1]HOD, [2]Professor, Deptt. Orthopedics, [3]PG Resident M/S Orthopaedics, Maharishi Markandeshwar (Deemed to be University), Mullana, Ambala, [4]Associate Professor, Deptt. Anatomy, Government Medical College and Hospital, Patiala

Abstract

Introduction: Tranexamic Acid has been used in major surgeries in various fields of medicine. It has shown to effective in reducing the blood loss during surgery. But it's use in orthopaedic surgeries was limited due to concern regarding efficacy and safety.

Material and Method: 54 patients were included in the study during the study period. Patients were randomly allotted to 2 groups of equal participants. The first group (Group A) received Tranexamic Acid. The second group (Group B) was given placebo. The Total Blood Loss and Fall in Haemoglobin levels were measured post-operatively at 24 and 72 hrs of post-operative period.

Result: The group A had showed significantly reduced total blood loss and fall in Haemoglobin, thus, requiring less blood transfusions. No complications were noted with tranexamic acid use.

Conclusion: We conclude that Tranexamic acid can be effective in reducing blood loss and subsequent fall in haemoglobin. Its judicious use may thus reduce allogenic blood transfusions in major orthopaedic surgeries.

Keywords: *TRAMOS, Tranexamic acid, Bleeding, Major Orthopaedic surgeries.*

Introduction

Major orthopaedic surgeries like Total Hip Arthroplasty, Total Knee Arthroplasty, Major Spine Surgery are associated with significant perioperative blood loss.[1-3] The amount of blood loss in such surgeries can be significant necessitating allogenic blood transfusion.[4,5] Allogenic blood transfusion is inherently associated with potential risks like infections, immunologic reactions, apart from increasing the cost of care. Reducing the blood loss and thus the need for blood transfusion remains a major concern.

Tranexamic Acid (TXA), a synthetic analogof Lysine, binds to lysine binding site on plasminogen thereby blocking its activation to plasmin. It thus prevents degradation of blood clot resulting in reduced blood loss. It has proved to be effective in reducing the perioperative bleeding in various surgeries like Liver Transplantation, Cardiac Surgeries, Maxillofacial Surgeries.[6,7] The efficacy of Tranexamic Acid in Major Orthopaedic Surgeries is being established. The ideal dose for maximum effect is still under evaluation.[8,9] It has recently been shown to control the perioperative blood loss.[10] But it's widespread use has been affected by concerns regarding its safety, especially the propensity to precipitate an VTE.[11] On the promising side, use of such pharmacological agents to control perioperative bleeding can significantly reduce healthcare costs and prevent potential risks of blood transfusion.

Material and Method

The study was conducted in Department of Orthopaedics at Maharishi Markandeshwar Institute

of Medical Sciences and Research, Mullana-Ambala, Haryana.

Period of study: 1st July 2018 – 30th June 2019.

Inclusion Criteria:

1. Age: 18-70 years
2. Gender: Both
3. Primary Total Hip Replacement
4. Primary Knee Replacement
5. Major Spine Surgeries–Decompression with Instrumentation.

Exclusion Criteria:

1. Revision arthroplasty
2. Revision Spine Surgery
3. Presence of comorbid medical conditions like coronary disease, bleeding disorders, chronic renal failure, previous thromboembolism.
4. Active Infection

Study Design:

Type: Double Blind Randomised Parallel Placebo Control Trial

Method of Randomisation: Simple Random Sampling–Random number generator in Microsoft Excel.

Intervention Agent: The first group (Group A) received Tranexamic Acid 500mg intravenous bolus just before skin incision and 500mg slow intravenous infusion which was started just before the surgery.

Comparator Agent: Normal Saline

Primary Outcome Measures: Total Blood Loss

Fall in Haemoglobin levels

Time points of Outcome Measure:

- Primary Endpoint: 72 hours after closure of skin incision.
- Secondary Endpoint: 24hours after closure of skin incision.

The study was approved by institutional review board. A total of 72 patients were screened for the study. of these, 18 patients were excluded due to comorbid conditions. Total of 54 patients who underwent major orthopaedic surgical interventions in the institute who satisfied the inclusion criteria during the study period were enrolled into the study. Informed Consent was taken for the same.

The intervention group (Group A) received Tranexamic Acid 500mg intravenous bolus and 500mg slow intravenous infusion which was started just before the surgery. The control group (Group B) did not receive any Tranexamic Acid during surgery, instead control agent i.e Normal Saline was administered in similar method as to intervention group. The drug was packed into an envelope by an OT nurse. The drug administered by the operating team anaesthetist by opening the envelope. Both the operating surgeon and the anaesthetists were blinded for the content of the envelope.

Surgical Technique: All the arthroplasties were performed by a single surgeon. Spine surgeries was performed by another surgeon.

Total Hip Arthroplasty: A standard posterior approach was used. Cemented and Uncemented THR was decided according to patient profile.

Total Knee Athroplasty: Performed with medial parapatellar incision.

Spine Decompression and Instrumentation was performed with standard midline posterior approach.

Standard Bipolar electro-cautery was used for haemostasis during surgery. Wound was closed in anatomical layers with vacuum suction drain placed in-situ. Wound dressing was done on post-op day 2.

Estimating the Total Blood Loss: Total Blood Loss was estimated intraoperatively and post-operatively. Total Blood Loss was estimated to be the sum of Intra-op and Post-op estimated blood losses.

Intra-Op blood loss estimated by weighing all the mops used during surgery (whose dry weight had been standardised and documented using an electronic weighing scale) and total blood lossin the suction drain.

Post-op Blood loss was calculated by the soakage of the incision site dressing at first post op dressing (done using pre-weighed cotton pads) and negative pressure suction drain collection wherever applicable. Suction drain was removed on 2nd post-operative day.

The formula for calculation of total blood loss was derived as follows:

a. Blood loss in suction drain = Total amount of suctioned fluid – amount of normal saline used during lavage.

b. Blood loss in mops = Total weight of mops used – n x (standardised dry weight of a single mop), where "n" is the total number of mops used.

c. Post Op Blood Loss = Amount of blood in negative pressure suction drain + [weight of dressing pads – dry weight of pads].

Total blood loss calculated by adding all three.

Total Blood Loss = a + b + c

Comparison Variables: The two study groups were compared based upon:

a. Total blood loss

b. Fall in Hb

Results

The results were compiled in Microsoft Excel and the Statistical relation between the two groups was analysed using SPSS software. Paired Student T-Test was applied for the compiled data. P-value of <0.05 was considered significant.

The average of patients in Group A was 59.1 years whereas 57.7 years in Group B. Male predominance was seen with 59% in Group A and 55% in group B. (Table 1).

The intraoperative blood loss in Group A was 160.1±23.3ml and 203.7±33.7ml for the Group B. The postoperative blood loss measured in suction drain was 371.3±464ml in group A and 455.5±66.8ml for group B. Mean reduction of the intraoperative blood loss was 43.5ml which was statistically significant (p value <0.05). Mean reduction in the postoperative blood loss was 84.2ml which was also significant (p value <0.04).

Mean Total Blood Loss in group A was 531.5±48.8 ml and 659.2±72.5ml in Group B. There was 19% reduction in the total blood loss. Total blood loss in patients receiving tranexamic acid, i.e. Group A was significantly lower compared to the Group B which did not receive tranexamic acid (p value < 0.008).

Mean Loss in Haemoglobin in group a was 2.38±0.26mg/dl and 3.72±0.29mg/dl in group B. There was 36% improvement in Haemoglobin values. Group A had significantly less drop of haemoglobin values compared to group B (p value <0.001). Requirement of blood transfusion was also lower in the group A.

None of the patients in both groups had any complications.

Table 1

Demographic Characteristics	Group A	Group B
Age (Years)	59.1	57.7
Sex – Male (Female)	16 (11)	15 (12)
Height (cm)	161.7	163.5
Weight (kg)	66.6	64.7
Mean Intraoperative Blood Loss (ml)	160.2	203.7
Mean Postoperative Blood Loss (ml)	371.3	455.6
Mean Total Blood Loss (ml)	531.5	659.3
Mean decrease of Haemoglobin (mg/dl)	2.4	3.7

Discussion

Tranexamic acid has been used to control the blood loss during major surgeries. However, the efficacy and safety of its usage in Orthopaedics Surgeries is being established. The concerns regarding prothrombotic effects lead to avoidance of its use in orthopaedic surgeries.

Recently various researchers have tried to study the efficacy and safety of tranexamic acid. In a recent meta-analysis, Huang F.et al[12] had reported significant reduction in blood loss in major orthopaedic surgeries. It was observed that there was significant reduction in intra-operative (125.65ml) and postoperative (214.58ml) blood loss in tranexamic acid group. The results of the present study show a mean reduction of 43.52ml in the intraoperative period and 84.26ml in the postoperative period.

It is noted that the effect of tranexamic was seen to be greater if the dose of the tranexamic acid was increased.[13] This explains the results obtained in our study, where the mean difference in total blood loss was 127.8ml between the two groups. Blood loss could further be reduced by increasing the dose of Tranexamic acid but evidence regarding the safety of the higher dose treatment is lacking. He had established the

effectiveness of tranexamic acid in reducing the need for blood transfusion.

Kagoma et al.[14] in a meta-analytical study had concluded that tranexamic acid, including other antifibrinolytics had reduced the blood loss and thus need for blood transfusion. However, they also reported inadequate evidence regarding the safety of these agents in the major surgeries. They reported no increased incidence of VTE in the perioperative period.

There are now reports of safety and efficacy of tranexamic acid in the major surgical procedures.[15,16] There is not much reported data in Indian subcontinent. Although the present study has smaller sample size, it is established that TXA can be effectively and safely reduce the blood loss in Orthopaedic Surgeries.

Conclusion

We thus conclude that tranexamic acid can be an effective tool to reduce blood loss in major orthopaedic surgeries and prevents gross fall in haemoglobin levels thus contributing to the early recovery in the postoperative period. This in-turn limits the adverse effects associated with blood transfusions and reduces cost of patient care.

Repair of Chronic Achilles Tendon Rupture by Modified Bosworth Technique

Manjeet Singh[1], Harish V.K. Ratna[2], Ashwani Ummat[3], Jasneet Chawla[4], Harsimarjit Kaur[5], Vishesh Verma[4]

[1]Professor and HOD, Department of Orthopedics, [2]Postgraduate Resident M.S. Orthopedics, [3]Professor, Department of Orthopedics, [4]Postgraduate Resident M.S. Orthopedics, Maharishi Markandeshwar (Deemed to be University), Mullana, Ambala, [5]Associate Professor, Deptt. Anatomy, Government Medical College and Hospital, Patiala

Abstract

Introduction: The Tendo-achilles, also known as the calcaneal tendon is a strong fibrous tissue structure that connects muscles of the calf to the heel (calcaneus). The calf muscles-gastrocnemius and the soleus muscle along with the plantaris muscle, unites into a strip of tissue and becomes the Tendo-achilles at the lower end of the calf and acts as a main flexor of the ankle joint. The Achilles tendon rupture is considered to be chronic if the injury is past 4-6weeks of duration.

Materials and Method: From May 2016 to May 2018, 15 Patients with long-standing rupture of the Achilles tendon were treated with the operative technique mentioned below, in MMDU, Mullana, Ambala. All the patients gave informed consent prior to being included in the study. Results All patients were evaluated according to The American Orthopedic Foot and Ankle Society (AOFAS) Ankle-Hindfoot Score. 8 patients had excellent results, 4 patients had good results, 2 had fair results and 1 patient had poor result. All patients resumed work at 6 months postoperatively.

Conclusion: Our technique is ideally suitable for chronic ruptures in zone I (where there is no distal stump available for repair) and ruptures that have a large gap of more than 5-6 cms. This is accomplished with a single long incision, with a good post-operative range of ankle motion and function and no major post op complications.

Keywords: *Chronic TA Rupture, Modified Bosworth Technique, Zone 1 Ruptures.*

Introduction

The Tendo-achilles/Calcaneal tendon is a strong fibrous tissue structure that connects muscles of the calf to the heel (calcaneus). The calf muscles-gastrocnemius and the soleus muscle, along with the plantaris muscle, unites into a strip of tissue and becomes the Tendo-achilles at the lower end of the calf. The gastrocnemius, the soleus and the plantaris muscles mainly functions as the ankle flexors, while the gastrocnemius also functions as a knee flexor.[1, 2]

The Tendo-achilles is considered as one among the strong structures, a large and a thick tendon in the human body.[1,3,4] The Achilles Tendon measures about 15 cms in length, ranges from 10 to 25 cms, is about 6.8 cms in width (ranges from 4.8–8.8 cms) at its origin and it gradually decreases in size at the mid-section (1.8 cms, ranges from 1.2–2.4 cms). The Achilles tendon then turns into rounded structure at an average of about 4 cms above its insertion into the calcaneus and has a width of about 3.4 cms (ranges from 2.0–4.8 cms) at its site of insertion over the posterior surface of the calcaneus.[1,5] Hence the aim of this study was to observe and study the

treatment of chronic tendo-achilles rupture by modified Bosworth technique.

Materials and Method

From May 2016 to May 2018, 15 Patients with long-standing rupture of the Achilles tendon were treated with the operative technique mentioned below, in MMIMSR, Mullana, Ambala. All the patients gave informed consent prior to being included in the study. The study was approved by the Ethics committee of our Institution.

The duration of the symptoms ranged from 3 to 12 months. None of the cases were compound ruptures. All the patients had difficulty in walking and pain around the ankle which was of moderate severity. 8 of 15 patients were manual laborers, 5 patients were students and the other 2 patients were homemakers. (Table-1)

Because of the chronicity of the symptoms, none of the patients had ecchymosis, swelling and point tenderness, which are most commonly associated with an acute tendon rupture. There was only moderate swelling and edema around the posterior aspect of the ankle, but all patients had complaints of inability to do active plantar flexion and Difficulty in walking (a limp), Difficulty in Climbing Stairs & Difficulty in getting up from Squatting position. In 12 patients, the defect in the Achilles tendon was visible or palpable. Usually there was some tenderness about the proximal and distal stumps of the ruptured tendon. The Thompson test was positive in all patients (that is, squeezing of the calf did not result in plantar flexion of the foot). Plain radiographs revealed Achilles tendon rupture by the gap between the tendon ends and presence of calcification in the distal portion of the proximal stump of the Achilles tendon.

All patients had undergone an ultrasound scan of the Achilles tendon to confirm the rupture. 9 patients had a rupture in zone I (rupture within 2 cm of the calcaneal insertion). 6 patients had a rupture in zone II (rupture 2 to 6 cm from the calcaneal insertion). The patients who received steroid injection had an avulsion of the tendon from the calcaneum. Intraoperatively, Calcification of the tendon along with necrosis was seen in a few patients.

Operative Technique: After Administering, Epidural/Spinal Anesthesia,the patient was made to lie down in prone position over the operating table . Next step was to inflate the lower limb tourniquet. The back of the leg over the affected side was prepared with aqueous iodine based solution from popliteal fossa till the heel and covered with sterile drapes. We used A straight long midline incision extending proximally about 10–12 cms below the knee joint and this incision was continued distally, distal to the site of insertion of the Achilles tendon up to the heel. The length of the incision was about 15–20 cms. After performing the skin incision, two important structures viz., the short saphenous vein and the sural nerve were secured and isolated. Then a wide strip of Achilles tendon measuring about 1-1.5 cms was cut and freed of from the central portion of the aponeurosis. The aponeurosis was then left attached (about 1.5-2 cms) proximal to the ruptured end. The hole was made in calcaneus from lateral to medial direction and strip was passed through it, taking care that there is free movement of the tendon raphe inside the bony tunnel (Figure-1). The strip was then sutured back to the main Achilles tendon in Zone-1 Ruptures (Figure-2). The strip was passed through the calcaneum and through distal stump for better anchorage and stability (in Zone-2 Ruptures).

While suturing, a proper amount of tension was maintained in the tendon by plantar flexing the ankle. The precautions that were taken during the surgery were (1) without any subcutaneous dissection, making the skin incision up to the Achilles tendon, (2) to prevent wound dehiscence, by doing a tight continuous subcutaneous suturing, (3) by suturing back the Para-tenon to provide stability.

In the post-op period, a long, non-weight-bearing above knee cast with the ankle in plantar flexion (Equinus) and the knee in 30° flexion was applied for 4 weeks. Wound dressing was done through a window created over the cast 2 days after surgery. The sutures were removed 14 days after surgery. After 4 weeks, the knee was freed from the cast and a short leg cast with the ankle in 20° plantar flexion was applied for 4 weeks. A walking short leg cast with the ankle Plantigrade was applied for 4 more weeks and completely freed from casting after 3 months. After 3 months, gradual calf strengthening and stretching exercises were started along with weight bearing.

Follow Up and Result Evaluation: Ankle pain was Assessed using, The American Orthopedic Foot and Ankle Society (AOFAS) Ankle-Hindfoot Score. Patient was followed up in the OPD after two weeks post operatively, then on monthly basis for 6 months. The scoring included subjective factors such as pain,

Activity Limitations, Maximum walking distance (in Blocks), walking surface, as well as objective factors such as Gait Abnormality, Sagittal Motion (Flexion plus Extension),Hind-Foot(Inversion plus Extension), Ankle-Hindfoot Stability (Antero-Posterior, Varus-Valgus), Alignment. The maximum number of points achievable was 100. The results were classified as Excellent (>/= 90 points), Good (75–89 points), Fair (60–74 points) or Poor (<60 points). The patients were asked to give answers to a Non-Validated subjective Symptoms Questionnaire.

Results

All patients were evaluated according to The American Orthopedic Foot and Ankle Society (AOFAS) Ankle-Hindfoot Score. Data collected was entered into Microsoft Excel worksheet and Analyzed Statistically by using SPSS (Statistical Package for Social Sciences). 8 patients had excellent results, 4 patients had good results, 2 had fair results and 1 patient had poor result.

All patients resumed work at 6 months postoperatively. 2 patients had mild pain at the end of 1 year at the ankle joint, but this did not hinder their daily or recreational activities. However, 1 patient had moderate pain that limited them from Sports activities but not from daily activities. Slight Gait Abnormality was noted in 1 patient at the end of 1 year, but this did not limit their daily or recreational activities. 2 Patients complained of Moderate Restriction In Sagittal motion. Almost all the patients had normal walking and stair climbing. There was significant improvement in the range of ankle motion postoperatively. There was an equal range of motion in both ankles in 13 out of 15 patients during follow-up of patients at the end of 1 year. 2 patients were unable to raise their heels from the floor equally when on tiptoe because of other unrelated causes such as old age and obesity.

Table 1: Study Design

Characteristics	Value
Total Number of patients	15
Sex ratio M:F	7:8
Duration of follow-up	1 Year
Zone I ruptures	9
Zone II ruptures	6
Mechanism of injury	
Steroid intake	8
Severe trauma	4
Trivial trauma	3

Complications in this study included Scar Hypertrophy (in 1 patient), superficial infection (in 1 patient) and delayed wound healing (in 1 patient, Due to Co-morbidities like Type-2 Diabetes Mellitus). Superficial infection was treated with oral antibiotics and regular dressings. In 1 patient, there was delayed healing and it took nearly 1 month to heal completely with regular dressings. Fortunately, none of the patients had an episode of re-rupture of the Achilles tendon Post Surgery.

Figure 1: Tendon RAPHE being passed through the hole made in the calcaneum

Figure 2: STUMP Then sutured back to the main achilles tendon with ankle in plantar flexion.

Discussion

The cause of Tendo-Achilles rupture is still unknown, whereas in certain studies it has been proven that the most common cause from samples sent for histological studies is chronic degenerative changes.[6,7] In various studies it has been mentioned that failure the diagnose Achilles tendon rupture in the first visit

of the patient is the most common reason of delayed intervention. Hence, patient is unable to get the required treatment in time and thus showing a wide range of presentation.[4] Patients with Achilles tendon ruptures face problems like not able to maintain posture on the toes on the ruptured side, but patients can perform active plantar flexion due to the following reasons viz., (A) partial ruptures, (B) an intact plantaris muscle and (C) recruitment of plantar flexors. No obvious loss of plantar flexion and the lack of pain can be misleading and this may be reason due to which in up to 20-25% of cases the diagnosis of Achilles tendon rupture is being missed during the initial presentation.[8,9]

In 1956, Bosworth devised the repair of the neglected tendoachilles tears with a long strip of proximal aponeurosis of the Achilles tendon passed through the proximal and distal tendon stumps. This repair is ideally not suitable for Zone 1 ruptures.[10]

Langergran and Lindholm (1958), based on vascularity, divided the tendoachilles into three zones(based on vascularity). Zone I is around <3 cms away from the insertion, zone II 3–6 cms away from the insertion and zone III >6 cms away from the insertion.[11]

In 1972, In A study conducted by Bala subramaniam et al. it is stated that the main reason for necrosis of Achilles tendon and a delayed healing is because of the injection of steroids into the insertion site of Achilles tendon.[12] The symptoms of tendon damage like pain may be masked due to the analgesic and anti-inflammatory properties of corticosteroids, provoking the patients to continur their routine day-to-day activities though the tendon is ruptured.[13]

In 1991, Mann et al. conducted a study in which FHL tendon was taken from Mid-foot and the distal portion of the ruptured tendon was sutured to FHL. The proximal end of the ruptured tendon being attached to the calcanei by pullout wire technique. But the above-mentioned method is not applicable, when the distance across the two ruptured parts is >5cms.[14,15]

In 2013, Pavan Kumar A et al. modified the Bosworth technique by passing a part of aponeurosis of gasctrocnemius muscle which was taken and then made into a tendon-like structure and inserted through the calcaneum by making a hole in it, which is then attached back to the proximal end of the tendon. This method is ideal for Zone 1 ruptures also.[15]

In 2016, Yangjing Lin et al. did a study on 29 subjects who had chronic tendoachilles rupture and had used flexor hallucis longus tendon transfer, gastrocnemius fascia turndown flap, orV-Y advancement based on the presence or absence of achilles tendon stump, gap that prevails between the ruptured ends and the length of the rupture and all the subjects of the study had the opportunity once again to participate in sports activities of preinjury level.[16]

In our Study, we have used the aponeurosis of the gastronemius itself, thereby not needing any tendon transfers, which would compromise the function of that tendon. As we were using the same tendon aponeurosis, the strength remained balanced. Our technique would be ideal for a gap of more than 5-6 cms that needs tendon transfer with additional synthetic grafts.

Conclusion

Our technique was ideally suitable for chronic ruptures in zone I (where there is no distal stump available for repair) and ruptures that have a large gap of more than 5-6 cms. This is accomplished with a single long incision, with a good post-operative range of ankle motion and function and no major post op complications.

Comparative Evaluation of Conventional Media with Bactec MGIT 960 for Detection of Mycobacterium Tuberculosis in Clinically Suspected Cases of Pulomonary and Extra-Pulmonary Tuberculosis

Harit Kumar[1], Varsha A. Singh[2], Sonia Mehta[2], Shavi Nagpal[3], Rosy Bala[3], Dipankar Biswas[4]

[1]Tutor, [2]Professor, [3]Assistant Professor, [4]Tutor, Department of Microbiology, MMIMSR, Maharishi Markandeshwar (Deemed to be University), Mullana

Abstract

Background: Tuberculosis (TB) is a leading cause of morbidity and mortality worldwide, despite being a treatable and preventable disease. The emergence of Multi Drug Resistant (MDR) TB had exacerbated the situation further. To prevent the spread of infection & to accelerate the administration of Anti-tubercular treatment, early detection of TB is required.

Methodology: This Cross-sectional study was carried out on 236 samples clinically suspected cases of Pulmonary & Extra-Pulmonary Tuberculosis processed for Direct Ziehl-Neelsen Staining, Decontamination by NALC-NaOH and Culture in MGIT tubes & Lowenstein-Jensen Medium.

Results: Out of 60 samples, 60(25.42%) were culture positive cases showed highest isolation rate by BACTEC MICRO MGIT as compared to LJ Medium 42(17.79%) with time of detection by BACTEC MICRO MGIT was 17 days and LJ Medium was 33.72 days. The Diagnostic accuracy of BACTEC MICRO MGIT when LJ Medium considered to be gold standard was also exhibited which showed sensitivity of 95.24%, Specificity of 89.69% while Negative Predictive value (NPV) & Positive Predictive value (PPV) was 98.86% and 66.67% respectively. The BACTEC MICRO MGIT detects mycobacteria early, with less contamination rates and has good sensitivity & specificity as compared to LJ Medium.

Conclusion: So it can be concluded that BACTEC MICRO MGIT can be used as method of isolation of Mycobacterium tuberculosis either alone or in combination with LJ Medium.

Keywords: *Tuberculosis, Pulmonary, Extra-Pulmonary, Lowenstein-Jensen Media, Mycobacterial.*

Introduction

Tuberculosis is a global public health problem with significant incidence and mortality rates predominantly in developing countries. According to a World health organization report, approximately 1.7 million cases of TB were notified and 0.42 million TB deathsoccured in 2018.[1] The early diagnosis of tuberculosis can play a major role in reducing the mortality rate and economic burden.[2] However the most common presentation is pulmonary tuberculosis but Extra Pulmonary Tuberculosis (EPTB) is also the emerging clinical problem.[3] The diagnosis of Extra pulmonary tuberculosis infections are difficult due topaucibacillary nature.[4]

The Lowenstein Jensen (LJ) culture and the AFB microscopy remains the basis of diagnosis of tuberculosis, but the traditional method has very low sensitivity, especially in samples containing few number of microorganisms.[5] Specifically, In order to reduce

Varsha A. Singh
Professor, Department of Microbiology, MMIMSR, Maharishi Markandeshwar (Deemed to be University), Mullana
e-mail: drvarshasinghmicro@gmail.com

the time to detect and identify Mycobacteria in clinical specimens, a variety of manual and automated systems have been developed.[6] MGIT 960 (mycobacterial growth indicator tube) is a non-radioactive detection system which uses fluorochrome based method for early detection (7-12 days) of Mycobacteria.[4]

This study was conducted to evaluate the capability, efficiency and reliability of MGIT in comparison to Lowenstein Jensen (LJ) Media for detection of Mycobacteria from Pulmonary and Extra-Pulmonary specimens.

Materials and Method

A Cross-sectional study for duration of 2 year (2016-2018) was carried out in the Department of Microbiology, MMIMSR, Mullanaon 236 samples from clinically suspected cases of Pulmonary & Extra-Pulmonary tuberculosis. The ethical clearance was taken from the institutional ethical committee.

All samples from clinically suspected cases of tuberculosis were includes while patients on Anti-tubercular treatment (ATT), diagnosed cases of lower respiratory tract infection were excluded from the study.

Sample Processing:

The Samples were subjected to:

i. Direct Ziehl-Neelsen Staining of Sample.

ii. Decontamination of sample by NALC-NaOHas recommended by the CDC's Public Health Mycobacteriology: A Guide for the Level III Laboratory.

iii. Culture

(a) Inoculation in MGIT tubes.

(b) Inoculation on Lowenstein-Jensen Medium

LJ Medium was incubated at 37°C for 8 weeks as per standard guidelines. The culture was first examined after 1 week followed by 15 days up to 8 weeks. Growth was confirmed by Ziehl-Neelsen staining and Gram staining.

MGIT tubes were incubated at 37ºC for 2-8 weeks. The reading was taken thrice in a week till up to 2 weeks then twice in a week up to 8 weeks. Reading of MGIT tubes was taken by BACTEC micro MGIT instrument and positive tubes were sub-cultured on LJ Medium and Acid fast smears were also prepared. Also to rule out contamination, positive tubes were also sub-cultured on Blood Agar and gram staining was also done.

Table I: Frequency of Mycobacterial isolates in clinically suspected cases of pulmonary and extra-pulmonary tuberculosis

Number of samples studied	Number of culture positive cases		
236	60 (25.42%)	Pulmonary	54
		Extra-Pulmonary	6

Table II: Sample wise distribution and positivity rate of ZN staining, BACTEC MICRO MGIT & Lowenstein Jensen Medium

Samples	Total no. of samples	ZN staining	Growth of Mycobacterium		p-value
			BACTEC MICRO MGIT	Lowenstein Jensen Medium	
Sputum	158	28	54	36	0.041

Endometrial Biopsy	12	1	1	2	
Total	236	33(13.98%)	60(25.42%)	42(17.79%)	

*The result is significant at $p < .05$. By Chi-Square Test.

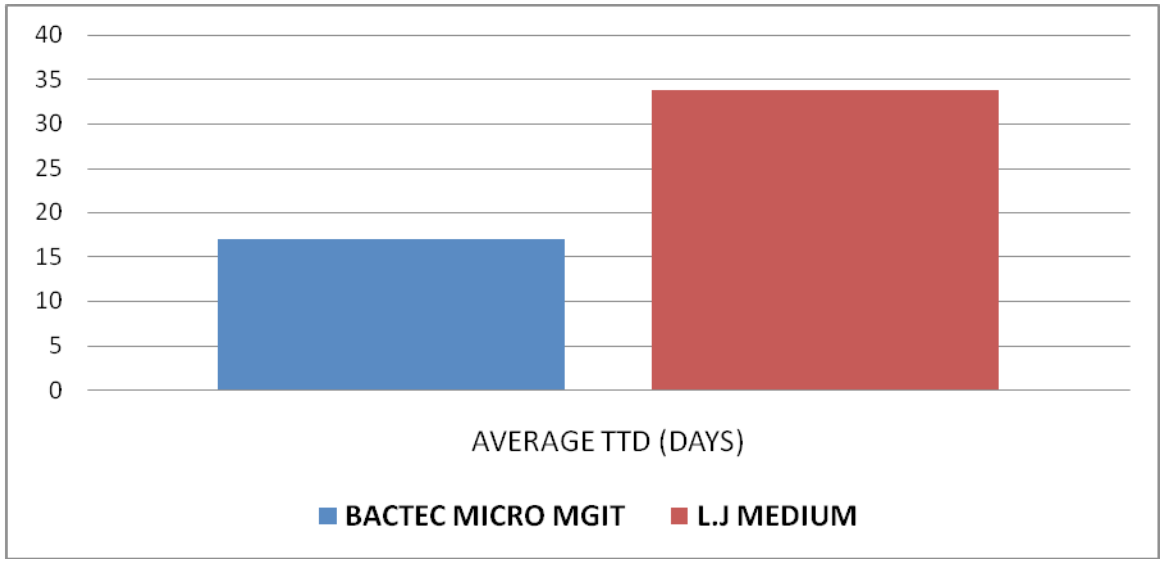

Fig. I: Average Time of Detection

		BACTEC MICRO MGIT (N=236)					
		+VE	**-VE**	**Sensitivity (%)**	**Specificity (%)**	**PPV (%)**	**NPV (%)**
L.J MEDIUM (N=236)	+VE	40	2	95.24	89.69	66.67	98.86
	-VE	20	174				

Table III: Diagnostic accuracy of BACTEC MICRO MGIT in comparison to L.J Medium (Gold standard) in detection of Mycobacteria in clinically suspected cases of pulmonary and extra-pulmonary tuberculosis

Result

Out of 236 clinically suspected cases of pulmonary and extra-pulmonary tuberculosis, 60 (25.42%) samples were positive by MGIT, 42(17.79%) samples showed growth on L.J Medium while Z.N Staining detected 33(13.98%) samples positive. [Table-I & II].

The average time of detection in MGIT was 17days while on L.J Medium was 33.72 days. [Figure I].

The Diagnostic accuracy of MGIT was also calculated considering L.J Medium as gold standard which showed 95.24% sensitivity, 89.69% specificity, 66.67% Positive predictive value and 98.86% Negative predictive value. [Table-III]

Discussion

Tuberculosis has been affecting humankind for thousands of years and still is one of the most deadly infectious diseases in the world. The emergence of Multidrug resistant (MDR) and extensively drug resistant tuberculosis (XDR) has agitated the situation further. Hence, the early diagnosis of tuberculosis is critical in appropriate management of Tuberculosis. Culture still is considered as Gold standard.[7]

In Present study total culture positive cases were 60 (25.42%) which is supported by the studies conducted by Sebastian G et al[8](2016) (22%) while lower percentage was reported by Bunger R et al[9] (2015) (11%). The High positivity rates were also reported by Rodrigues C et al[10] (2009) (42%). The rate of positivity varies from region to region and depends on many other factors.

Under the Revised National Tuberculosis Control Program (RNTCP), priority is given to the smear-positive cases. Every smear positive person, if left untreated, has potential to infect 10–15 persons per year. Ziehl-Neelsen staining technique for sputum microscopy is employed as the standard case-finding tool. Although advances in diagnostics are leading to the introduction of new tests, the backbone of TB diagnosis worldwide continues to be smear microscopy.

In Present study, 33 (13.98%) cases were found to be AFB positive with ZN Microscopy (Table II). The Present finding was found to be in concordance with studies conducted by Saini D et al[4] (2017) (15.15%).

The present finding was found to be higher than the studies conducted by Roy A et al[11] (2016) (6.67%) while the higher positivity rate was found in studies conducted by Tortoli E et al[12] (1999) (54%). The detection rate of Mycobacteria by Direct AFB smear examination in Extra-Pulmonary samples is significantly less as compared to the pulmonary samples.

Even though AFB microscopy and the LJ Medium are the cornerstones of diagnosis of tuberculosis but the sensitivity of these conventional method is quiet low, especially in samples with less number of organisms. There is a need of rapid, accurate and sensitive method for the early detection of these organisms in clinical specimen so as to prevent the cross-infection among community & accelerate the appropriate antimycobacterial therapy for the infected persons.

In Present study, 60 (25.42%) of Mycobacteria were isolated from BACTEC MICRO MGIT (Table IV). The Present finding was found to be in concordance with studies conducted by Roy A et al[11] (2016) (18%). The present finding was found to be higher than the studies conducted by Siddiqui MAM et al[13] (2013) (15%). The higher positivity rate was found in studies conducted by Rishi S et al[14] (2007) (50.6%). The average time of detection by MGIT was 17 days which is supported by studies conducted by A Oberoi et al[15] (2004) which showed mean time to be 16 days.

In Present study, 42 (17.79%) of mycobacteria were isolated on LJ Medium (Table IV). The Present finding was found to be in concordance with studies conducted Siddiqui MAM et al[13] (2013) (15%). The Present finding was found to be higher than the studies conducted by Roy A et al[11] (2016) (8%). The higher positivity rate was found in studies conducted by Rodrigues C et al[10] (2009) (24%). The Average time of detection by L.J Medium was 33.72 days which is supported by study of Nor MF et al[16] (2009) (33 days).

The less average time of detection by MGIT is due to growth supplements like Bovine Albumin, Dextrose, Polyoxyethylene stearate, Catalase & Oleic acid which are absent in LJ Medium. Thus BACTEC MICRO MGIT detects Mycobacteria more rapidly than LJ Medium.

Higher Contamination rates are the major drawback of fully automated system but in our present study, the contamination rate was found to be lower with BACTEC MICRO MGIT (7%) as compared to L.J Medium (9%). The results are in concordance with the study conducted by Bunger R et al[9] (2013) (6%). The BACTEC MICRO MGIT is a liquid media which is supplemented with antimicrobial agents like PANTA (Polymyxin B, Amphotericin B, Naldixic acid, Trimethoprim & Azlocillin) while LJ medium contains only Malachite green to reduce the contamination. Thus more the number of Antimicrobial agents lesser are the chances of contamination.

Conclusion:

The results of this study demonstrated that the MGIT system provided better recovery of Mycobacteria than the traditional LJ slant. The average time of detection, Contamination rate in MGIT was significantly less as compared to the conventional culture method i.e. L.J Medium. So it can be concluded that MGIT can be used as method of isolation of Mycobacterium tuberculosis either alone or in combination with LJ Medium.

Abstract

Non-tuberculous mycobacterium (NTM) has been identified in human pulmonary and extra pulmonary diseases and is of great concern for clinicians and microbiologists because of their increasing global incidence. They are now increasingly recognized as important pathogens in both immunocompromised and immunocompetent population. They should be identified rapidly and should be carefully differentiated as contamination, colonization ordisease. Cultures were made on conventional LJ and LJ with PNB media. Growth was confirmed as AFB (acid fast bacilli) by ZN staining. NTM were identified by growth on LJ with PNB media, colony morphology, rate of growth, pigmentation, catalase activity and confirmed by MPT 64 antigen rapid test (using SD Bioline TB Ag MPT 64 test kit) . Data was analysed statistically using SPSS software. Out of total 500 processed samples (250 pulmonary & 250 extrapulmonary), 12(21.05%) and 7(21.8%) NTM were isolated from pulmonary and extrapulmonary samples respectively. Maximum pulmonary NTM (41.7%) were isolated from > 60 years age of patients in contrast to extrapulmonary NTM isolates which were more in 20-40 years of age group. There was 16.7% previously treated patients in pulmonary while 100% were newly diagnosed patients in extrapulmonary TB cases. This study highlights the importance of early diagnosis and differentiation among *Mycobacterium tuberculosis*and NTM so that these NTM are not underestimated in routine diagnostic procedures merely as environmental or laboratory contaminants.

Keywords: *Non-tuberculous mycobacterium, p-nitrobenzoic acid, Pulmonary TB, extrapulmonary TB, MPT64 antigen.*

Introduction

Of all infectious diseases pulmonary tuberculosis is the leading killer and is endemic in India but extrapulmonary TB is also emerging rapidly. The primary causative agent of these infections is *Mycobacterium tuberculosis* (M.tb) however, rising prevalence of NTM draws attention as an important pathogens in both immunocompromised and immunocompetent persons gaining importance for clinicians,microbiologists & epidemiologists[1]. In immunocompetent persons especially in individuals with chronic obstructive pulmonary disease it causes pulmonary fibrosis or cavitary lung disease while in immunocompromised hosts it produces systemic infection which may or may not mimics MTBC but the treatment regimen of both are different. The NTMs are often resistant to drugs used for treating *Mycobacterium tuberculosis complex* (MTBC) which helps falsely conclude the patients as 'multidrug

resistant tuberculosis (MDRTB)' who correspondingly take the treatment of 'MDRTB'.Indicating clearly that early and accurate identification of NTM is essential for precise treatment and management of patient. However in India it is still the tip of iceburg, may be because of unavailability of comprehensive data depicting occurrence of NTM in pulmonary and extrapulmonary diseases. As very less number of studies are available from this region therefore, this study was conducted with aim (1) to determine the frequency of NTM in pulmonary and extrapulmonary TB cases (2) to assess the NTM from newly diagnosed and previously treated cases of pulmonary and extrapulmonary TB (3) to assess the age wise distribution of NTM in pulmonary and extrapulmonary TB.

Material and Method

Study Design & Period: The cross sectional study was conducted in the Department of Microbiology at MMIMSR, Mullana, Ambala during 2017-2019 after taking approval of Ethical Committee of the Institute.

Clinical specimens & Data collection - A Total 500 sampleswere analysed for laboratory diagnosis of nontubercular mycobacterial infection from pulmonary & extrapulmonary cases. The pulmonary patients were selected as per ATS (American Thoracic Society) criteria[2] i.e clinically and radiologically suspected tuberculosis cases. Two samples were collected from each patients (either two sputum samples or one sputum and one BAL sample). 2-10 ml. of nonrepeated samples were collected from suspected cases of extrapulonary TB.

The specimens were included as lymph node aspirate, pleural fluid, cerebrospinal fluid, ascetic fluid,pus,endometrial biopsy materials, menstrual blood and endotracheal secretions. All the patients signed due consent for sample collection.

RNTCP defined, Newly diagnosed and previously treated TB patients were also included in the study[3]. The clinical history regarding present and past history of antitubercular treatment (ATT) and family history of tuberculosis and any other associated disease were taken in prescribed performa.

Processing and Microbiological Analysis of Specimens: Samples were subjected for concentration and decontamination by standard NALC-NaOH technique[4] except sterile specimens which were centrifuged & processed directly. After concentration sediment was subjected to smear microscopy by Ziehl-Neelsen (ZN) staining method & inoculated simultaneously overthe slants of LJ media and LJ with PNB (p-nitrobenzoic acid) media as per Koneman EW and Mackie & Maccartini practical medical microbiology book[4]. The LJ medium slopes were incubated at 37^0 C. Growth was checked daily during first week for Rapid growers and then weekly for a maximum of six weeks. Growth was confirmed by smear microscopy for the presence of acid fast bacilli (AFB). No growth after 6 weeks of incubation was treated as negative for mycobacteria. NTM were identified on the basis of growth on LJ with PNB media, colony morphology, rate of growth, pigmentation,catalase activity[4] and confirmed by SD Bioline TB Ag MPT 64 kit which is a rapid immunochromatographic test to differentiate NTM from *Mycobacterium tuberculosis complex* (MTBC).

Result

The present study was conducted on 500 samples (which includes 250 pulmonary & 250 extrapulmonary). The pulmonary samples includes 244 sputum and 6 bronchoalveolar lavage (BAL) while extra pulmonary samples were pleural fluid (70/250), pus (56/250), CSF (45/250), endometrial biopsy (35/250), menstrual blood (15/250), lymph node aspirates (14/250), ascetic fluid (10/250) and endotracheal secrection (5/250).

Out of total 500 samples 57(22.8%) & 32(12.8%) mycobacteria were isolated from pulmonary and extrapulmonary samples respectively. The frequency of NTM among Mycobacterial isolates of pulmonary samples was 12(21.05%) while of extrapulmonary was 7(21.8%) which was statistically insignificant(p-value 0.701) (table 1).

In pulmonary isolates, 41.7% were from> 60yrs followed by 33.4% from 41-60 years and 16.5% from 20-40 years of age group with male predominance (75%). In contrast, extrapulmonary isolates which have female predominance (57.14%) with 71.4% of 20-40 years followed by 14.2% of 41-60 years and 14.2% of > 61 years of age group suffered from EPTB caused by NTM (table 2).

As per sample wise distribution was concern, pulmonary isolates, 12(100%) were from sputum samples whereas in extrapulmonary, 4(57.14%) isolates were from pus, 2(28.6%) isolates were from endometrial samples and 1(14.3%) isolate was from pleural fluid (fig 1).

Among pulmonary cases, (83.4%) NTM were from newly diagnosed & (16.7%) were previously treated patients in contrast to it, in extrapulmonary tuberculosis 100% isolates were from newly diagnosed cases (table 3).

Table I: Frequency of Non Tubercular Mycobacteria (NTM) in pulmonary and extra-pulmonary TB isolates

Mycobacterial isolates Total no. of Non Tubercular mycobacteria (NTM)	
Pulmonay (n=57)	12 (21.05%)
Extra-pulmonary (n=32)	7 (21.8%)
Total isolates (n=89)	19 (21.3%)

By Chi square test: Statistically not significant (p value 0.701)

Table II: Age wise distribution of NTM isolates in pulmonary and extrapulmonary TB patients.

Age Group	Pulmonary TB		Extrapulmonary TB	
	M	F	M	F
20-40 years	3(33.4%)	-	3(100%)	2(50%)
41-60 years	2(22.3%)	2(66.7%)	-	1(25%)
>61 years	4(44.5%)	1(33.3%)	-	1(25%)
Total	9	3	3	4

Table III: Frequency of NTM in previously treated & newly diagnosed patients of pulmonary & extrapulmonary tuberculosis.

Site Involved	Previously Treated Patients	New Patients
Pulmonary (n=12)	2(16.7%)	10(83.4%)
Extrapulmonary (n=7)	0	7(100%)

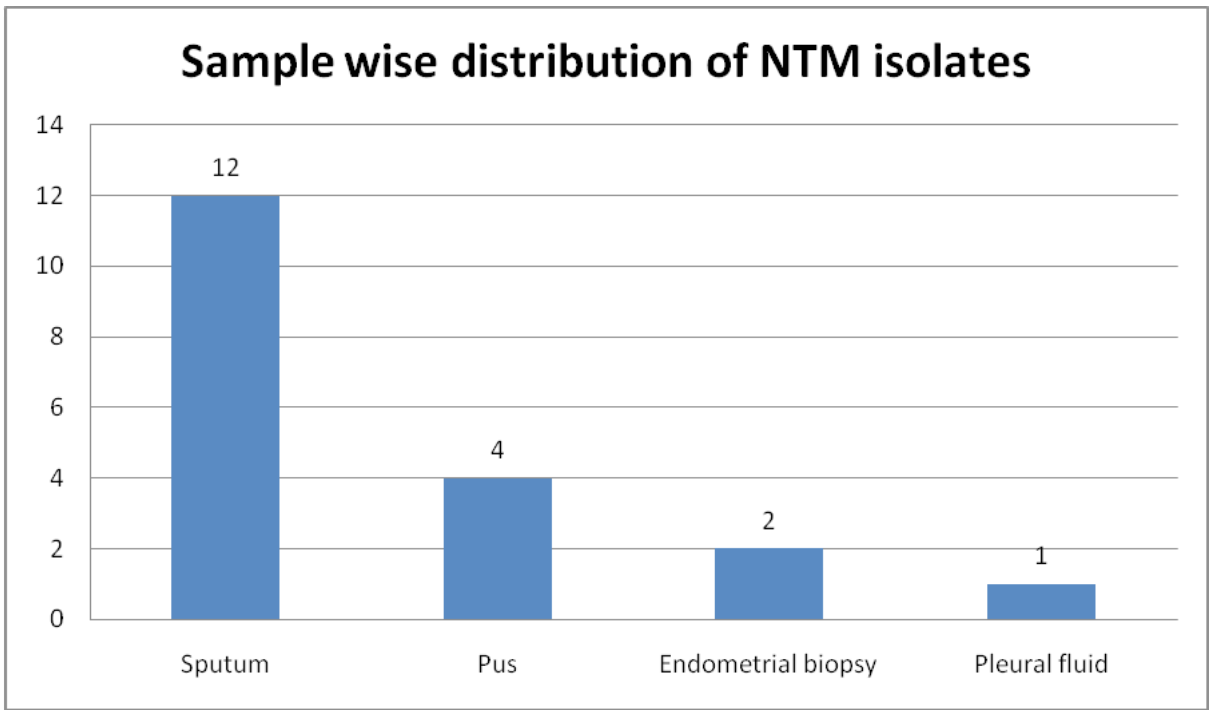

Fig. 1

Discussion

Prevalence of NTM is unknown in India as NTM disease is not reportable and there is lack of awareness among clinicians coupled with lack of laboratory capacity to diagnose these infections. Identification of NTM is of clinical relevance as most of the NTM are notably resistant or only partially susceptible to the standard anti-tubercular drugs and the treatment strategies and the duration of these infections differs from MTB. In the current study, from pulmonary samples out of 57 mycobacterial isolates, 21.05% NTM were detected (Table I) which is in concordance with Eliane Picoli et al[5] who detected 23% NTM and M.J.Nasiri et al[6] (15.1%) in their study whereas higher rate was detected by Sarika Jain et al[7] (69.2%) in 2014. Lesser isolation rate of NTM in pulmonary samples were observed by Yan Shao et al[8] (3.37%) in their study. Similarly,21.8% NTM were detected in extrapulmonary mycobacterial isolates, which is supported by Sarika Jain et al[7] (30.8%) and Archana. B. Wankhade et al[9] who observed 15.9% NTM in pus samples. Lesser isolates were detected by V.P.Myneedu et al[10] (0.38%) in their study. In India prevalence rate of NTM increases every year. According to study conducted by Sarika Jain et al[7], prevalence rate of NTM in India was 1.0% in 2005, 3.5% in 2008 and upto 88.6% of NTM isolation rate is clinically relevant.

In current study, as age wise prevalence of NTM is concern, maximum 41.7% patients were from >60 years of age group with male predominance were suffered from pulmonary tuberculosis caused by NTM whereas maximum 71.4% of 20-40 years of age group with more of females were revealed diseased from extrapulmonary TB by NTM. Similar results were observed by Maura J. Donohue[11] and Hywoon Lee et al[12] in their study. They also found that NTM effects more to older age group (>60 years) with female predominance. In contrast Pooja Sharma et al[13] reported 41-60 years of age group infected more with NTM in their study. Pulmonary NTM were more isolated from old patients, may be due to age related immunosuppression or underlying lung disease like COPD (common in rural people due to use of hukka habit). In contrast, NTM from Extrapulmonary TB were more isolated from reproductive age group with female predominance presented mainly as infertility and cervical lymphadenitis.

Relapse of tuberculosis (TB) is defined as re-emergence of clinical symptoms after stopping anti-TB treatment, while this treatment appeared effective initially. Relapse of TB can occur in patients that are therapy-compliant, but the risk of relapse is dramatically increased when patients are non-compliant. Also TB caused by NTM is falsly reported as relapse or MDR TB as drugs used to treat MTBC are not effective for the treatment of NTM. Some epidemiological factors like age, sex, smoking, immunosuppresion, history of contact, HIV co-infection etc. are also related with recurrence of pulmonary and extrapulmonary TB. In this study, 83.7% patients were newly diagnosed whereas 16.4% were previously treated patients for pulmonary tuberculosis caused by non tubercular mycobacteria (NTM). Results were in concordance with study conducted by Mu-Lu Wu et al[14] (12%) in 2018. Higher relapse rate of NTM was observed by Daniel. P. Boyle et al[15] (25%) and Bo Young Lee et al[16] (31.6%) in their study. In this study, no relapse was found in case of extrapulmonary TB caused by NTM. In India, NTM infections usually get undiagnosed due to overwhelmed cases of MTb and poor diagnostic resource settings. After exhaustive search no relevant reference was found to support the result.

Conclusion

Due to scarcity of literature and unawareness of clinicians, usually NTMremain unreported or misinterpreted as MDR TB. Therefore, there is need for awareness regarding appropriate NTM diagnosis among physicians. NTM should be differentiated between colonization and disease by following the ATS diagnostic criteria. Every sample in the laboratory coming from clinically suspected pulmonary and extrapulmonary tuberculosis cases should be inoculated on LJ and LJ with PNB media specially in low budget set ups where molecular method are not available for NTM detection. Therefore, Growth on LJ with PNB media should be confirmed by at least with biochemical tests and MPT 64 antigen test.

Clinical Evaluation of Pyuria, Bacteriuria and Culture for Diagnosis of Urinary Tract Infection

PankajSaini[1], Varsha A. Singh[2], Pottathil Shinu[3]

[1]Junior Resident, [2]Professor,Department of Microbiology, M.M.I.M.S.R., Maharishi Markandeshwar (Deemed to be University), Mullana, Ambala, Haryana, [3]Assistant Professor, Department of Biomedical Sciences, College of Clinical Pharmacy, King Faisal University, Al Ahsa, 31982, Saudi Arabia

Abstract

Background: Culture remains the gold standard for the diagnosis of urinary tract infections (UTIs). However, the diagnosis of UTIs can be potentially enhanced when clinical characteristics of UTI, pyuria and bacteriuria are considered.

Methodology: To evaluate the relationship between pyuria, bacteriuria and clinical characteristics with culture, un-centrifuged urine samples (N=817) were subjected to direct wet mount, direct Gram staining and semi-quantitative culture and the results were compared.

Results: The direct wet mount and direct gram staining showed an overall sensitivity, specificity, positive predictive value and negative predictive value of 11.08%, 88.88%, 87.96%, 29.28% and 34.21%, 96.55%, 91% and 38.89%, respectively, as compared to semi-quantitative culture. Alternatively, the overall sensitivity, specificity, positive predictive value and negative predictive value of clinical characteristics of both upper and lower UTIs (most sensitive and specific symptoms combined) were found to be 55.14%, 76.06%, 71.29%, 31.47%, respectively. Conclusion: Both the direct wet mount and direct Gram staining could be considered as screening tests for diagnosis of UTI due to its low sensitivity and high specificity. However, integrated approaches wherein clinical characteristics of UTI combined with culture results would be of high diagnostic value in the diagnosis of UTI.

Keywords: *Urinary tract infection, significant bacteriuria, pyuria, semi quantitative urine culture.*

Introduction

Urinary tract infections (UTI) are one of the most common bacterial infections that constitute major public health problem across the world. UTIs are the second most common infection in both hospitalized and community practices[1]. UTIs are most common among females of reproductive age[2]. UTI is a heterogeneous disease, which may be of various types such as acute and chronic, complicated and uncomplicated, asymptomatic bacteriuria and recurrent cystitis [3]. Patients having lower UTI generally have symptoms like burning micturition, dysuria, frequency urgency, suprapubic pain. Upper UTI (e.g. pyelonephritis) may be characterized by fever with or without chills, flank pain, nausea, vomiting, diarrhoea, haematuria, fatigue and change in mental status. It is difficult to differentiate indubitably between upper and lower UTI due to the low sensitivity of these symptoms in diagnosing UTI[4]

Literature indicates that both pyuria (the presence of polymorphonuclear leukocytes (PMNs) in urine) and bacteriuria (presence of bacteria) are good indicators of bacterial infection other than genitourinary symptoms. Alternatively, the dipstick leukocyte esterase test is a simple technique having the advantage of detecting

Corresponding Author:
Dr. Varsha A. Singh
Professor, Department of Microbiology, M.M.I.M.S.R., Maharishi Markandeshwar (Deemed to be University), Mullana, Ambala, Haryana

leukocyte esterase activity from both intact and lysed PMNs; however, when it is used alone, the sensitivity, specificity and positive predictive value are relatively low[5]. Significant bacteriuria increases the diagnostic value of UTI. The significant bacteriuria is defined as the presence of 10^5 or more colony forming units (CFU) per ml of urine[6]. This suggests that the presence of both pyuria and bacteriuria may markedly increase the probability of UTI[7]. However, currently, no published data are available to evaluate the significance of these parameters. Therefore, the current study was designed to evaluate the significance of pyuria, bacteriuria and clinical features of UTI with culture in the diagnosis of UTI.

Material and Method

The study was carried out (between October 2017 and March 2018) in the Department of Microbiology, M.M.I.M.S.R, Ambala). Mid-stream urine samples (5-10ml) were collected from patients having symptoms of UTI. Further, catheterized patients, post-chemotherapy and all other patients who were receiving or received antibiotics in the last one month were excluded from the current study. The clinical histories of all consecutive patients were collected. Immediately after the specimen collection, urine samples were transported to microbiology laboratory (most of the urine samples were processed within 2 hr. of the collection). This midstream urine sample was subjected to direct wet mount examination, direct gram staining and, semi-quantitative urine culture.

Laboratory Method: Direct wet mount; Direct wet mount was prepared by taking 50 µl of an uncentrifuged urine sample on a glass slide (25x75 mm) and covered with a coverslip (22x22mm)[8].

Gram stain; Each un-centrifuged urine sample was mixed and Gram-stained as per standard laboratory protocol[9].

Microscopic examination; All the smears were examined using 40x high power objective (Nikon E100 - magnification 400x) for a minimum of seven fields and the cells per field were noted.For gram staining, a minimum of 20 microscopic fields was examined using 100x oil immersion objective (Nikon E100 - magnification 1000x) and the average number of organisms per field was recorded. The Gram stain was considered positive if one or more organisms per microscopic field were seen[8].

Semi-quantitative urine culture: Uncentrifuged urine samples were cultured on cystine–lactose–electrolyte-deficient agar using calibrated loop technique as suggested by Clarridgeet al[10]. Growth was recorded as $<10^2$, 10^2-$<10^3$, 10^3-$<10^4$,10^4-$<10^5$, or $\geq 10^5$ CFU/ml. Samples were considered positive (significant growth) if it contained $\geq 10^2$-$\geq 10^5$ CFU/ml along with symptoms of UTI as mentioned in patient inclusion criteria of the current study.

Results

In the current study, urines samples were collected from all the patients recruited (N=841). The study profile, demographics and clinical characteristics of the study participants are presented in Table-1. The male-female ratio was 1:3.4(184/633).The most commonly affected age group was 34.5 (SD=15.5). Further, of the 69.76% (570/817) significant isolates obtained, 92.81% (529/570) isolates were having growth of a single type organism and the remaining 7.19% (41/570) showed multiple organisms (mainly two types organisms). However, for data analysis, each urine culture isolates (even multiple organisms) was considered as growth of single organism.

Table-2 demonstrates the comparison of the direct wet mount and Gram staining results with culture. of the 570 significant isolates obtained in culture, direct Gram staining could detect the presence of bacteria in 68.42% (390/570) cases. of these 68.42% isolates, 59.23% (231/390), 37.63% (147/390), 2.56% (10/390) and 0.5% (2/390) were having CFU of $\geq 10^5$, 10^4-$<10^5$, 10^3-$<10^4$ and 10^2-$<10^3$ respectively. Similarly, of the 570 significant isolates obtained in culture, the direct wet mount could demonstrate the presence of WBCs in 98.25% (560/570) cases. of the 98.25% cases, 42.32% (237/560), 29.82% (167/560) and 18.57% (104/560) and 9.28% (52/560) were having significant growth of $\geq 10^5$, 10^4-$<10^5$ and 10^3-$<10^4$, 10^2-$<10^3$, respectively. However, of these 98.25% (560/570) specimens, direct gram staining could detect the presence of bacteria in 68.04% (381/560) urine specimens.

Table-3 illustrates the diagnostic accuracy of the direct wet mount and direct Gram staining with culture. It is apparent from Table 3 that the difference between sensitivities of ≥5 bacilli/field and ≥1- <5 bacilli/20 fields were not statistically significant (Fishers Exact test, p=0.5623). The urine specimens having six to ten WBCs per high power field (HPF) in the direct wet

mount of urine (Table-3) demonstrated relatively higher sensitivity and specificity than culture in the diagnosis of UTI. The direct wet mount and direct gram staining showed an overall sensitivity, specificity, positive predictive value and negative predictive value of 11.08%, 88.88%, 87.96%, 29.28% and 34.21%, 96.55%, 91% and 38.89%, respectively, as compared tosemi-quantitative urine culture. It is evident from Table-3 that sensitivity of Gram staining was relatively higher than that of the direct wet mount.

Discussion

Accurate diagnosis of UTI is challenging because of the lack of both sensitive and specific laboratory tests. The current study was conducted to evaluate the relationship between direct wet mount (for WBCs in urine), direct Gram staining (for bacteria in urine) and genitourinary symptoms with semi-quantitative urine culture (the gold standard for diagnosis of UTI)[11]. The other vital features of the study design were the inclusion of patients with a minimum of at least two symptoms of either upper or lower UTI (or symptoms of both). Further catheterized patients, post chemotherapy and all other patients who were receiving antibiotics or received antibiotics in last ten days were excluded from the study as any kind of antibiotic intake may affect the growth of bacteria in culture. These criteria helped in excluding most of the patients receiving antibiotic particularly inpatients. In the current study, most predominant organism isolated was Escherichia coli (55.79%), Klebsiella pneumonia (9.12%) and Enterococcus species (8.42%), respectively. This distribution was comparable with previous workers wherein the incidence of Escherichia coli, Klebsiella species and Enterococcus species varied between 53-72%, 6-12%, 1.7-12%, respectively [12-13].

Pyuria is a condition wherein an increased number of polymorphonuclear leukocytes (PMNs) are excreted in the urine. This excretion of PMNs may be an indication of an inflammatory response in the genitourinary tract[14]. In the current study, it is evident from the Table-3 that urine specimens having six to ten WBCs per HPF in the direct wet mount demonstrated relatively higher sensitivity (34.21%) and specificity (100%) with culture for the diagnosis of UTI. This clearly explains that the presence of WBCs is more specific but relatively less sensitive for the diagnosis of UTI. It is also evident from Table-3 that urine samples containing 1-5 WBCs/ HPF were having low sensitivity and specificity when compared with urine samples containing 6-10 WBCs/ HPF. However, the sensitivity of direct wet mount (for diagnosis of UTI) was decreasing for urine specimens containing a comparatively higher number of WBCs per HPF (>11 or more). This low sensitivity of pus cells in direct wet mount reaffirms the high specificity of WBCs for diagnosis of UTI. Further, it is evident from Tables (2 and 3) that four urine specimens were positive for sterile pyuria. This may be substantiated due to the fact that sterile pyuria is usually seen in patients having renal tuberculosis, sexually transmitted diseases, or inflammatory diseases like interstitial nephritis, indicating pyuria itself is not a marker for diagnosis of UTI and is not effective in differentiating symptomatic and asymptomatic UTI.

It is estimated that the presence of one or more bacteria per oil immersion field reciprocates with most of the significant bacteriuria cases and thus suggest the presence of active UTI [9,11.15-16]. In the current study, it is evident from Table-2 that direct Gram staining could detect the presence of bacteria in 68.42% (390/570) cases of significant growth. However, this low detection rate may be attributed to the low sensitivity of Gram stain to detect the presence of bacteria, particularly in urine specimens having $<10^3$CFU/ml [17-21]. Further, it is apparent from Table-3 that there was no difference between sensitivities of ≥5 bacilli/field and ≥1- <5 bacilli/20 fields. This clearly substantiates the fact that one or more bacteria per field indicate significant bacteriuria. Further, it was also observed that the sensitivity of Gram staining was relatively higher than that of the direct wet mount. This may be attributed to high specificity and low sensitivity of direct wet mount in the diagnosis of UTI. The presence of any bacteria in midstream urine may indicate bacteriuria. The other advantages of Gram staining include; rendering instant information about the nature of the infecting organisms and thus assisting the physician for choosing appropriate empirical therapy[21]

Conclusion

Both direct wet mount and direct Gram staining (from uncentrifuged urine) were having comparatively low sensitivity but high specificity for the diagnosis of UTI as compared to culture. Therefore, direct wet mount or direct gram staining may be considered as screening tests for the diagnosis of UTI. However, an integrated approach wherein clinical characteristics of UTI (having both higher sensitivity and specificity) when combined with culture would be of high diagnostic value in the diagnosis of UTI.

Detection and Enumeration of Parasitic Infections in Stool Samples from Tertiary Care Hospital of Rural Setting

Nitasha Kumari[1], Ritu Garg[2], Varsha A. Singh[3], Ashma Khatun[4]

[1]M.Sc. Student, [2]Associate Professor, [3]Professor and Head, [4]M.Sc. Student, Department of Microbiology, Maharishi Markandeshwar Institute of Medical Sciences & Research, MMDU, Mullana, Ambala (Haryana)

Abstract

Background: Parasitic infections are the major public concern particularly in developing countries like India. Routinely used microscopy method for the detection of parasitic infections have compromised sensitivity.

Materials and Method: The study was carried out on 500 stool samples received in Department of Microbiology MMIMSR, Mullana (Haryana) for a period of 6 months (August 2017 to January 2018). Stool samples for detection of ova and cyst were included.

Result: Of these 500 samples examined, 235 (47%) stool samples showed positive results for ova/cyst after the use of simple salt floatation technique while it was merely 33% (n-165) without using the salt floatation method. of the 235 positive samples 29.8% were cyst of *Giardia lamblia* followed by eggs of *Ascarislumbricoides* (Fertilized and unfertilized) and cyst of *Entamoebahistolytica each of* 19.1%, *Ancylostomaduodenale* 14.9%, *Hymenolepis nana* 10.6%, *Entamoeba coli 4.2%* and *Trichuristrichiura* 2.1% were also identified.

Conclusion: There is a need for more tests that do not sacrifice sensitivity and that can be used in poor resource field settings.

Keywords: *Parasitic infection diagnosis, Ova/cyst, stool samples.*

Introduction

Parasitic infections remain the major global health problem particularly in developing countries.[1] Prevalence of parasitic infections varies in different geographical area. It depends upon a number of factors like level of sanitation, socioeconomic status, malnutrition, population density of the area, low health status, unavailability of potable drinking water and lack of personal hygiene.[2,3] Intestinal parasitic infections are recognized as neglected tropical diseases because of lack of adequate research, inability to prevent by immunization as no effective vaccine is available against them, compromised investigative modalities for the diagnosis of parasitic infections are among the major drawbacks to fight against this neglected public health problem.[4,5]

The infirmities caused by parasitic diseases vary from mild discomfort to severe manifestations. Some parasites may lead to anaemia and protein malnutrition which can be the cause of growth retardation in children.[3] Amoebiasis, ascariasis, hookworm infection are the most common infections responsible for iron-deficiency anaemia, chronic diarrhoea and impaired physical development in children along with other comorbidities.[5, 6]

The routinely used method for the detection of Ova/cysts in diagnostic laboratories are wet mounts like saline wet mount and iodine wet mount. But the sensitivity of this method is compromised i.e. false negative results

e-mail: dr_rittu07@yahoo.co.in

which affects the treatment adversely and leads to worsening of symptoms and spread of infection in the community.[7]

The burden of intestinal parasitic infections needs to be cautiously monitored in the developing countries. Several studies have been undertaken in different parts of India. In India, the overall prevalence rate ranges from 12.5% to 66%. The prevalence rate for individual parasite varying from region to region.[3,7,8,9] These infections still continue to predominate and similar studies would definitely add to the existing knowledge of parasitic infections in patients suffering from gastrointestinal problems.

According to literature detection rate of parasite can be improved by use of staining method like Lactophenol cotton blue and various concentration techniques.[10]

Lactophenol cotton blue stains internal structure of parasites and facilitates their detection and identification.[11,12] Lacto-phenol cotton blue preparation is made by using glycerol which is hygroscopic in nature, which help to absorbs the water molecules from the environment and prevents the drying the wet mount preparation.[10]

Addition use of concentration techniques can detect parasites which are present in small numbers which can be missed easily by using direct wet mounts.[3] Various concentration techniques are available and can be used for the detection of the parasitic infections depending upon availability of resources. So there is dire need of simple, economical, reliable and sensitive diagnostic method for the detection of these parasitic infections.

By keeping in mind the above facts, we have planned a study with following objectives:

- To detect parasitic infections by using wet mount preparations like saline, iodine and staining method like lacto phenol cotton blue wet mount before and after applying concentration technique.
- To see the effect of concentration technique for the detection of ova/cyst from stool samples over microscopy alone without concentration techniques.

Materials and Method

The prospective study was carried out on 500 stool samples received in Department of Microbiology MMIMSR, Mullana (Haryana) for a period of 6 months (August 2017 to January 2018). Ethical Clearance: Taken from Institutional ethical committee. Stool samples for detection of ova and cyst were included.

Methodology

The patients were provided wide mouthed clean, dry, properly labelled plastic container for collection of samples. The stool samples were examined within 1-2 hours of collection. The stool samples which were contaminated with the patient's urine were rejected. Both the formed and the unformed stools were examined freshly. After the macroscopic examination of the stool including colour, consistency, presence of blood and mucus were noted. The stool specimens were examined for the presence of worms like segments of *Taenia*, adult Hookworm, round worm either with the naked eye or with the aid of a hand lens.[4]

Each stool specimen was processed by the direct microscopy including Saline wet mount, Iodine wet mount, Lactophenol cotton blue and concentration technique using simple salt floatation method.[13,14]

Results

A total of 500 stool samples were examined. of these 500 samples examined, 235 (47%) stool samples showed positive results for ova/cyst after the use of simple salt floatation technique while it was merely 33% (n-165) without using the salt floatation method. (Table 1).

Of the total 235 positive samples 42.5% was from the age group 6-14 years, followed by 21.28% from the age group 0-5 years, followed by 17.1% in the age group above 60 years, followed by 10.6% and 6.4% in the age group 15-30 years and 46-60 years respectively and the least positivity rate was seen in the age group 31-45 years. (Figure I).

Of the 235 positive samples 29.8% were cyst of *Giardia lamblia* followed by eggs of *Ascarislumbricoides* (Fertilized and unfertilized) and cyst of *Entamoebahistolytica each of* 19.1%, *Ancylostoma duodenale*14.9%, *Hymenolepis nana* 10.6%, *Entamoeba coli 4.2%* and *Trichuris trichiura* 2.1% were also identified.(Table II).

Photographs showing *Hymenolepis nana*in saline (P1a), Iodine (P1b) and Lactophenol Cotton blue wet mount (P1c).

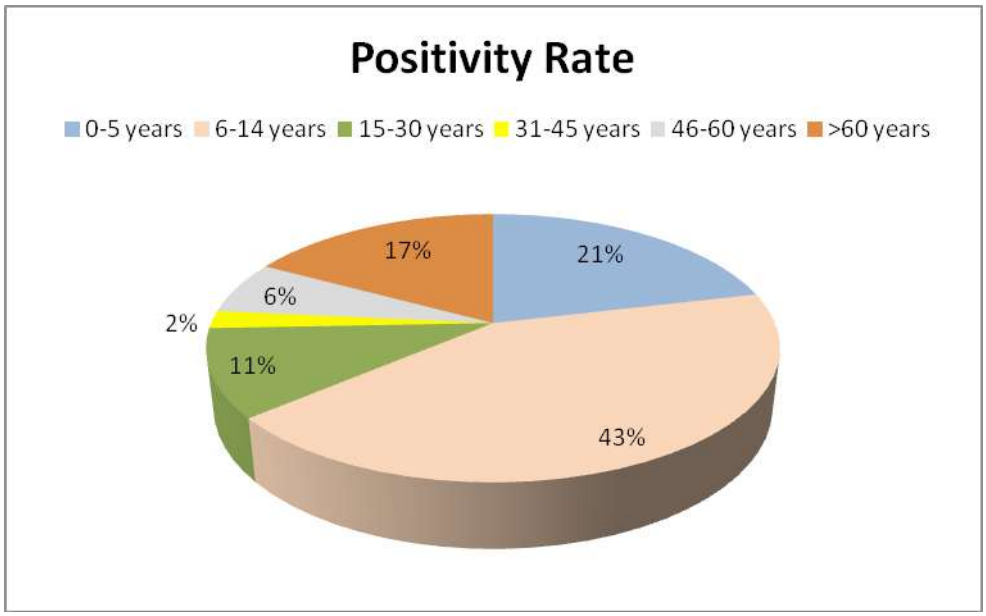

Figure I: Age wise prevalence of parasitic infection

Table I: Positivity rate before and after concentration technique

Total Sample	Positivity Before Salt Floatation Method	Positivity After Salt Floatation Method
500	165	235

Table II: Distribution of Parasites in total Positive Sample

Parasite	Number	Percentage
Giardia lambliacyst	70	29.8%
Ascarislumbricoideseggs (Fertilized and unfertilized)	45	19.1%
Entamoebahistolytica cyst	45	19.1%
Ancylostomaduodenale egg	35	14.9%
Hymenolepis nana egg	25	10.6%
Entamoeba coli cyst	10	4.2%
Trichuristrichiura egg	5	2.1%

Discussion

Parasitic infections are the significant cause of morbidity and mortality in developing countries like India. Method for the diagnosis of parasitic infections have stagnated in the past three decades. Labor-intensive method such as microscopy still remain the mainstay of several diagnostic laboratories.[15] There is a need for more tests that do not sacrifice sensitivity and that can be used in poor resource field settings. In our study we had used lacto-phenol cotton blue staining technique in addition to routine wet mounts which helped demonstration of better morphology so made identification easier and also used simple salt floatation technique; by this technique we were able to diagnose 70 more positive samples as compared to wet mount examination alone.

In the present study positivity rate was 47%. Previous study in our department showed slightly lower positivity rate.[3]

Of the total 500 samples maximum positivity rate was 43% from the age group 6-14 years and least was 2% in the age group 31-45 years. A study done by Parameshwarappa et al, showed highest prevalence of parasitic infection between age group 10-20 years. [7] The reason for higher rate of prevalence of intestinal parasitic infection in these age groups may be due to lack of awareness, lack of health care, education level.[16]

In the present study the maximum positivity i.e. 29.8% was shown by *Giardia lamblia*, followed by *Ascarislumbricoides*eggs (Fertilized and unfertilized) and *Entamoeba histolytic* cyst i.e. 19.1% each which was followed by *Ancylostomaduodenale* egg i.e. 14.8%, followed by *Hymenolepisnana* egg 10.7% and *Entamoeba coli* cyst 4.2%. And least positivity was shown by Trichuris*trichiura* (2.3%). A study done by Rajvir Singh et al. showed higher prevalence for *Giardia lamblia* 58.5%.[17] In another study done by Kang et al.; commonest parasitic infection was hookworm followed by Giardia and Cryptosporidium.[18] Soprevalence of different ova/cyst differs from area to area which can be due to different food habits in different regions, differences in geographical conditions and culture practices accounts for variations in parasitic prevalence

Of the 500 samples positivity rate before salt floatation was 33% (n-165) and 47% (n-235) with the addition of salt floatation method, showing higher prevalence of intestinal parasites by including simple salt floatation method, related to the study done by Parameshwarappa KD et al., 38%was positivity rate before salt floatation method and 42% with simple salt floatation method.[7]

This study also showed advantage of Lactophenol cotton blue wet mount above iodine wet mount and saline wet mount. This was in accordance with the study done S.C. Parija et al in their study they concluded that Lactophenol cotton blue helps to stain the internal organs of the ova and cyst and easy to identify the internal parasites.[8]

Conclusion

Intestinal parasitic infection is on the rise and remains the cause of concern. Improvements in sanitation, limiting open defecation by provisions of sanitary latrines forall and hygiene and health education are the required interventions that will be helpful in preventing these infections. Such types of hospital-based studies are always helpful in accessing the present burden of parasitic infections in patients suffering from gastrointestinal diseases. Our study would surely add to the existing knowledge of parasite prevalence in such type of patients and serve as a measure of their inclination toward the health indicators.

Evolution Proof-Antibiotics: A Hopeful Future to Combat Antibiotics Resistance

Nitin Gupta[1], Rosy Bala[2], Varsha A. Singh[3], Harit Kumar[4], Shavi Nagpal[2], Sonia Mehta[3]

[1]Assistant Professor, Department of General Medicine, [2]Assistant Professor, [3]Professor, [4]Tutor, Department of Microbiology, M.M. Institute of Medical Sciences and Research, Mullana, Maharishi Markandeshwar (Deemed to be University)

Abstract

Over the years we have seen many antibiotics have been developed, each one supposedly better than the previous, but still we have not been able to overcome the persistent problem of antibiotic resistance regardless of the potency of the drug. There is an urgent need to develop new antibiotic strategies to overcome this problem that is different from previous efforts. Hence a method should be focused on the area of inhibition of bacterial evolution for resistance-"evolution proof Antibiotics".

Keywords: *Antibiotics, miracle molecules, Anti microbial resistance (ARM), Evolution proof molecules, evolvability factor.*

Introduction

Evolution is cleverer than we are. Over the years hundreds of "miracle" molecules- (antibiotics) have been discovered that have brought many pernicious infections to heel. But every time researchers identify a new drug, resistance arises regardless of the nature or potency of the drug. Anti microbial resistance (ARM) is global problem; causes of which may be: over-population, enhanced global migration, wildlife spread, excessive use of antibiotics in humans as well in animals, over-the-counter sale of antibiotics, selection pressure, poor sanitation, poor sewerage disposal system, release of nonmetabolized antibiotics or their residues into the environment through feces etc.[1,2] There is increasing evidence that directly associates antibiotic use with the emergence of resistant bacteria such as methicillin-resistant staphylococcus aurous (MRSA), vancomycin resistant enterococcus, resistant gram negative bacilli and clostridium difficile. This often lead to development of superbugs and will limit the therapeutic options in the treatment of even minor infections making them life threatening ones.[3] We thrust; they (bacteria) parry. In vitro development of resistance to last resort drug colistin in *Pseudomonas aerogenosa* has shown the power of adaptive mutations in response to increasing dose of drug due to the network of genetic changes.[4] These bacteria evolve rapid resistance and also express an additional factor of cross-resistance. This shows the inherent capacity of the bacteria to overcome the huge spectrum of antibiotics and further flourishing the problem of antibiotic resistance.[5]

1930s to 1960s remained the "golden era" of antibiotics which gave rise to many antibiotics. Unfortunately, this era came to the end because scientists were unable to maintain the pace of antibiotic discovery with regards to emerging resistant pathogens.[6] Estimates suggest that antimicrobial resistance causes at least 700,000 deaths every year worldwide, a figure that could rise to 10 million by 2050 and surpass cancer as the primary global cause of death. Organizations like the Centers for Disease Control and Prevention (CDC)

and World Health Organization (WHO) have declared antibiotic resistance to be a "global public health concern."[7,8]

Analysis of bacterial genomes concluded that over 20,000 potential resistance genes (r genes) are present. However, the functional resistance determinants are far less in number.[6,9]

Discussion

Although many recommendations and resolutions have been proposed, several reports have also been written, the increase in antibiotic resistance is a persistent issue. Most of our strategies against pathogenic bacteria have focused on developing new antibiotic drugs, but the resistance has arisen to every antibiotic. There should be an alternate strategy to resolve this problem: inhibiting evolution. Lowering mutation rates in bacteria might be a way to hinder the emergence of antimicrobial pathogens. There can be two kinds of 'evolution-proof' antibiotics. The first category can literally be evolution-proof antibiotics to which bacteria cannot become resistant by mutation or horizontal gene transfer. The second category can be of molecules to which resistance may arise, but so rarely that it does not become epidemic.[10]

To overcome this hurdle we need to understand the molecular trajectories and the biochemical pathways associated with the development of resistance. A major success has been achieved with the identification of MfD; an evolvability factor. The term evolvability factor refers to the protein that has the ability to increase mutation rate and so accelerates the bacterial evolution. Mfd is a highly conserved ATP dependent DNA translocase that mediates the role of Transcription-Coupled-DNA-Repair (TCR) in bacteria. MfD enhance mutations at genetic level leading to hypermutator alleles which eventually result in development of resistance in bacteria and that this holds true for multiple classes of antibiotics. Mfd promotes mutagenesis in bacteria both during laboratory growth and during infection of eukaryotic cells. Researchers have found that disabling the protein MfD reduced mutation rate and the ability of pathogenic bacteria such as *Mycobacterium tuberculosis* (Mtb) and *Salmonella typhimurium* to develop resistance to antibiotics. Tests were done using wild-type and Mfd-deficient *M. tuberculosis which* showed marked differences in the ability of bacteria to develop resistance to rifampicin drug. The bacterial strains lacking Mfd protein had 1,000-fold lower resistance to the drug. In *S. typhimurium* Mfd was seen to promote hypermutation—a key mechanism that leads to rapid AMR development. About half of the strains studied developed hypermutator alleles during the course of developing resistance towards the drug trimethoprim. In contrast, strains lacking the protein Mfd didn't form hypermutator alleles.[11]

At present, while developing new drugs our target is mainly essential proteins but this approach has its own limitations. The alarming rate at which the micro-organisms are adapting to our present drugs, the need is to address the problem at its core level i.e. developing drugs which will function as "anti-evolution" drugs that specifically block evolvability factors like Mfd or other evolvability factors that promote mutagenesis could be a revolutionary strategy to alleviate the problem of chromosomally acquired mutations that promote AMR.[11,12]

Conclusion

To fight the growing number of antibiotic-resistant bacteria; researchers are focusing on the need for new approach to find novel antibiotics. Inactivate the evolvability factors is an unexplored route towards "battling the AMR crisis." This concept of an "evolution-proof" antibiotic seems more of a dream rather than a reality. In the present scenario, it may be a stepping stone to more rigorous and concrete models in the hopeful future.

Abstract

Violence against medical professionals at the workplace is not a new phenomenon. In recent times, the reports of doctors getting thrashed by patients or their relatives have made headlines around the world. Almost every doctor has experienced some kind of violence whether physical or verbal at certain stage of their profession. This article aims to discuss the risk factors associated with violence against doctors and the possible steps that are needed to prevent such incidents.

Keywords: *Violence, medical professionals, Health care setting.*

Introduction

Earlier Doctors were given respect and were treated as equivalent to God and now they are not even treated as human beings, so where is the humanity??

Violence against doctors is certainly not India specific. It is a global phenomenon. The US, Britain, China, Bangladesh, Pakistan have all had victims of violence.[1] A few years ago, a paediatrician in China's Fujian province was injured after leaping out of a fifth-floor window to escape angry relatives of a newborn baby who had died under his care.[2] This year, large numbers of cases have been reported related to violence on doctors. To protest against this, large number of doctors was on strike and candle march was done in various parts of our country. Even doctors wore helmet in order to protect themselves from the anger of mob and to save their life. Similarly in 2017, More than 2000 junior doctors from 17 government-run hospitals in India's largest city, Mumbai, went on strike for 4 days in March, to protest a recent spate of violence against doctors.[3] At least four separate incidents of assault on a junior doctor at a government hospital were reported in the week preceding the strike in the state of Maharashtra of which Mumbai is the capital.[4] The chief demand of the striking doctors was better security from the government to protect them at hospitals. So, every year violence against doctors is increasing.

Violence against doctors in India is not new and a 2015 survey by the Indian Medical Association suggests that as many as 75% of doctors in India have faced some form of violence at work.[5] How doctor can serve humanity if he will not survive?

Now even doctors are thinking not to make their children doctors, only to save their life and doctors are thinking to opt non-clinical branches for their postgraduation.

There arises a question...

There are many cases for medical negligence but how many cases have been registered on the patients and

Nitin Gupta
Assistant Professor, Department of General Medicine, MMIMSR, Maharishi Markandeshwar (Deemed to be University), Mullana, Ambala
e-mail: drnitintayal@gmail.com

their relatives under the prevention of violence against doctors act?

Looking towards the assessment of reasons behind violence against doctors?

Causes of Violence:

- **Psychology of Family:** Violence is an outburst of anger mixed with the frustration among the relatives of the people. Whenever we face the demise of any of our dear and near one, we go through phasic alterations in our mind and pass through five main stages of grief, denial, anger, bargaining, depression and finally acceptance. People exhibit the displacement of anger and denial to cope with the situation and it is the emotion transfer from a situation or person to another that is the main reason for violence against doctors and other health staff.
- **Advanced Medical Care Technology:** Has revolutionized medical care outcomes on the one hand; however, it has led to high expectations for 100% cure among patients and relatives. The difference between these high expectations and actual ground realities is the main root cause of this curse.
- **Doctor-Patient Relationship:** Doctor–patient mistrust, changing dynamics of the doctor–patient relationship although the other factors cannot be ignored.
- **Social Factors:** Giving more importance to medical negligence. As all the fingers of the hand are not alike, then how can all doctors are the same?? The mistakes of some of the doctors are made sensational by media people and that further leads to damaging the image of doctors in the society.
- **Less Budjet for Health and Poor Quality Healthcare:** Of the total GDP of India, only 1.5% is for healthcare. So, there is pathetic condition of health in government sector. There is overcrowding, long waiting time to meet doctors, absence of a congenial environment, multiple visits to get investigations done as well as consult doctors, sharing a bed by two and sometimes three patients and poor hygiene and sanitation.
- **Lack of Faith in the Judicial Process:** As judicial cases take a long time for their hearings as there are a lot of cases in queue and a person with a grievance does not trust the mechanisms of redressal provided by law.[6]
- **Mob Mentality:** Mob mentality frequently snowballs into a violent crisis in hospitals. In China mobs, called 'yinao', regularly protest at hospitals or harass hospital administrators in exchange for money.[7] In India, emotional turmoil due to death of a loved one is sometimes used by local politicians as an opportunity to demonstrate their political relevance by orchestrating violence at the clinical establishment.
- **Cost of Healthcare:** The rising cost of healthcare is the key reason for the breakdown of the bond between doctors and their patients. As, in private sector the patient is paying a lot of expenses then, they think they have just to pay rest doctors have to see. But doctors are not God, they can give treatment then, its patient who will respond or not, they can't say. So, only blaming doctor for everything is not wise.

Various studies on risk factors associated with violence against doctors found the following[8]

- Younger doctors face more physical violence, as they think that they are much experienced that's why they suffered loss.
- Female doctors are more likely to face violence.
- Department of obstetrics and gynaecology reported the highest rates of violence, followed by the paediatrics and medicine department with allied specialties and surgery with allied specialties.
- Verbal violence was the most common form of violence. In the emergency department, 100% of doctors reported some kind of verbal violence.

Due to the rising rates of violence, doctors are reluctant to take up serious cases, compromising health-care delivery. Thus, there is an urgent need to make health-care facilities safe for doctors as only then can they work with complete dedication. This needs to be done at various levels by the government, media and medical professionals alike.

- Higher authorities (government level)-As the saying goes, "health is wealth." Policymakers need to understand that the overall health of the people contributes to the efficiency of the workforce, in turn, contributing to the growth of the economy. More health budget spending would translate to better facilities and increased doctor–patient ratio,

leading to a decrease in violence related to these factors.

- Social levels (Media)-Doctors are almost always portrayed negatively by the media. There are sensational news reports of death and sting operations against doctors. Media needs to understand that the practice of medicine is not a black-and-white subject. Diagnosis of a patient is essentially a hypothetico-deductive process and with the appearance of new evidence through investigations and knowledge, the diagnosis of some of the cases continues to be questioned and refined.
- Doctor role- Modern medicine is reaching new frontiers, but at the same time, a negative public perception of doctors is leading to an increase in litigations. Thus, every doctor should follow the cardinal principle "do not overreach," i.e., do not treat beyond the scope of one's training and facilities to prevent both violence and litigations against themselves. Second, all doctors should ensure that a valid and informed consent is taken properly and not just considered a formality.
- Medical institutions- Hospitals can do much to reduce the violence. In government hospitals, this can be done as a part of general reform for the hospital services in the form of: (*i*) Improvement of services in a global fashion (*ii*) employment of adequate number of doctors and other steps to ease the rush of patients and long waiting hours (*iii*) use of computer and internet technology (*iv*) hospital security should be strengthened and it needs to be properly interlocked with nearby police station (*v*) no arms/ammunition by patient or their relatives should be allowed inside the hospital(*vi*) there should be transparency on rates of different investigations, rents and other expenses in the hospital and (vii) there should be a proper complaint redressal system in the hospital.

It is important to be vigilant and look for early warning signs of violence by using the STAMP approach as follows[9]:

- Staring is an important early indicator of potential violence. Nurses have felt that staring was used to intimidate them into prompter action–when they responded to this cue violence tended to be avoided.
- Tone and volume of voice has been associated with violent episodes. Most instances involve raised voices and yelling but also involved sarcastic and caustic replies.
- Many people who attend the emergency department are anxious and nurses are aware of how stressful such a visit can be. They should intervene before anxiety reaches dangerous levels, but sometimes patient's anxiety does escalate to violence.
- A majority of patients who become violent have been observed to be mumbling, using slurred or incoherent speech or repeatedly asking the same question or making the same statements. Mumbling has been perceived to be a sign of mounting frustration and a cue for violence.
- Pacing was seen as an indication of mounting agitation and has been observed in instances that resulted in violence. Other physical indicators include staggering, waving arms or pulling away from healthcare personnel attempting to treat them.
- Restrict entry- The most important step in preventing mob violence in a hospital is restricting entry of the public. Entry should be strictly by passes and this must be implemented through good security, preferably by deploying ex-army personnel. Security guards must be placed inside the hospital at sensitive areas such as intensive care units, operation theatres and casualty.
- Standard operating procedure (SOP)-All clinical establishments should develop an SOP for violence. Mock drills need to be conducted and each member of the staff should be clear about his role if the situation of impending or actual violence does arise.
- Insurance- Insure the establishment against mob violence, damage to property and injury to workers to at least mitigate the financial losses that are incurred in the aftermath of violence.

Conclusion

Although violence against doctors and other health workers is not uncommon, the incidence in India seems to be increasing. Doctors need to pressurize the government to equate assault on a doctor with assault on a public servant on duty. Necessary changes should be made urgently in the IPC and Criminal Procedure Code (CrPC) to have a deterrent effect and prevent future incidents of violence against doctors. However, for this to happen a coordinated effort is needed. We hope no more healthcare personnel lose their lives to violence

before action is initiated by their associations and the government.

Let the doctors live and work freely, only then they are able to serve the humanity and save life of others….

Swachh Bharat mission is going on- why not swachh mentality of citizens for doctors too??

Microbiological Profile of Diabetic Wound Infection

Shavi Nagpal[1], Varsha A. Singh[2], Harit Kumar[3], Aditi Pandey[4], Sonia Mehta[2], Rosy Bala[1]

[1]Assistant Professor, [2]Professor, [3]Tutor, [4]M.Sc. Medical Microbiology, Department of Microbiology, MMIMSR, Maharishi, Markandeshwar (Deemed to be) University (MMDU), Mullana (Ambala), Haryana, India

Abstract

Introduction: Diabetic wound infections is a dreaded complication of diabetes and often the leading cause of hospitalization for patients with diabetes worldwide. Infection if not treated timely and properly can even lead to amputation of the infected part. The present study was conducted as an attempt to evaluate the different microorganisms infecting diabetic wounds and to find out the antibiotic susceptibility patterns.

Material and Method: A total of 128 patients of diabetic wound infections were included in this study from September 2018 to August 2019. Samples were processed as per standard guidelines, the microorganisms (bacterial and fungal) were isolated and further antibiotic susceptibility pattern for bacterial isolates was studied.

Results: Out of 128, 106 (82.82%) yielded growth of microorganisms on culture. Predominance of bacterial growths (73.58%) as a causative etiology in diabetic wound infections were noticed over fungal (26.42%). Gram positive bacterial growths accounted to 39.74%, whereas 60.27% were gram negative growths. Staphylococcus aureus (29.49%) was the most predominant organism isolated, followed by Escherichia coli (25.64%) and Pseudomonas aeruginosa (24.36%). of the Staphylococcus aureus, 73.92% were methicillin resistant while 72.34% among gram negative isolates were ESBL producers with Escherichia coli accounting the highest degree of ESBL production. Linezolid, vancomycinandteicoplanin were the most sensitive drugs for Staphylococcus aureus and Gram-negative isolates were mostly sensitive to imipenem based on our susceptibility results. Candida species (89.28%) was noted to be the most dominant fungal pathogen in diabetic wound infections.

Conclusion: A good knowledge about the microbiological profile of diabetic wound infections and antimicrobial susceptibility patterns of the isolates can be helpful in guiding the clinicians to promptly and effectively treat diabetic wound infections.

Keywords: *Diabetic wound infections, Bacterial isolates, Fungal isolates, Antimicrobial Susceptibility, Extended spectrum beta-lactamase (ESBL), Methicillin resistant staphylococcus aureus (MRSA).*

Introduction

Diabetes mellitus, a chronic disease, affects a large segment of population and is now a worldwide epidemic. Among all the WHO member states, India has the highest number of people with diabetes.[1]

A variety of factors related to diabetes weaken wound healing, together with wound hypoxia, infection and nutrition deficiencies.[2] It is estimated that about 12%–25% of diabetics across the world will develop a foot ulcer at some time during their life, thus contributing to a major public health issue even to the endpoint amputation as 85% of major leg amputations begin with a foot ulcer.[3,4,5]

Diabetic neuropathy and micro- or macro-angiopathy

leading to ischemia are the two main risk factors that cause foot ulcers.[6] The most common cause of morbidity and mortality associated with foot ulcers is infections, which are seen in 40%–80% of the cases.[7] Exposed subcutaneous tissue supplies a favorable substratum to the broad variety of microorganisms to contaminate and colonize, causing devitalization of the involved tissue and the host immune response is compromised, the conditions become best for microbial growth[8] Impaired micro vascular circulation and elevated blood sugar levels further reduces the effectiveness of bacteria fighting cells to the infected areas hence necessitating limb amputation. [9]

These problems are largely preventable and successful treatment depends on the correct evaluation of the patient, diagnosis, proper and timely management of infection. Wound infections in diabetics are largely mixed infections in nature with a combination of both bacterial and fungal isolates.[10] Thus, the present study was an attempt to evaluate the different microorganisms infecting diabetic wounds and to know the antibiotic susceptibility patterns to the bacterial isolates.

Material and Method

One hundred and twenty-eight patients (OPD and IPD) of diabetic wound infections were included in this study. The prospective and observational hospital-based study was conducted from September 2018 to August 2019 in the Department of Microbiology of a tertiary care hospital. The Institutional Ethical Committee's clearance was obtained prior to conducting the study.

Inclusion Criteria: Diabetic patient who had wound infection or developed deep tissue wound infection leading to ulceration were included.

Exclusion Criteria: Non diabetic patient with wound infection were excluded.

After obtaining informed consent from the patients, the samples such as wound swab, pus or tissue debris were collected in a sterile container and transported to our microbiology lab within 10 to 15 minutes for further processing. The samples were first microscopically examined by Gram staining and Potassium hydroxide wet mount. Further, aerobic microbial culture and fungal culture were performed.

For aerobic cultures, the samples were inoculated on blood agar and MacConkey's agar and plates were then incubated at 37°C for 24-48 hours. Bacterial isolates were identified as per the standard operating procedures.[11] Antibiotic susceptibility testing was done by Kirby-bauer disc diffusion method and the susceptibility patterns of the bacterial isolates were detected following the antimicrobial agent's panel recommended by Clinical and Laboratory Standards Institute (CLSI) guidelines, 2018 and 2019.[11,12,13]

For fungal cultures, the scrapings were directly inoculated into two slants of Sabouraud's dextrose agar with chloramphenicol and cyclohexamide. The slants were incubated at 22-25°C and the other at 37°C with periodic observations for about 4 weeks. Identification was made based on the colony characteristics, rate of growth and microscopic examination by lactophenol cotton blue stain, KOH (10%) and gram staining.[14] Antifungal susceptibility testing was however not performed in our laboratory.

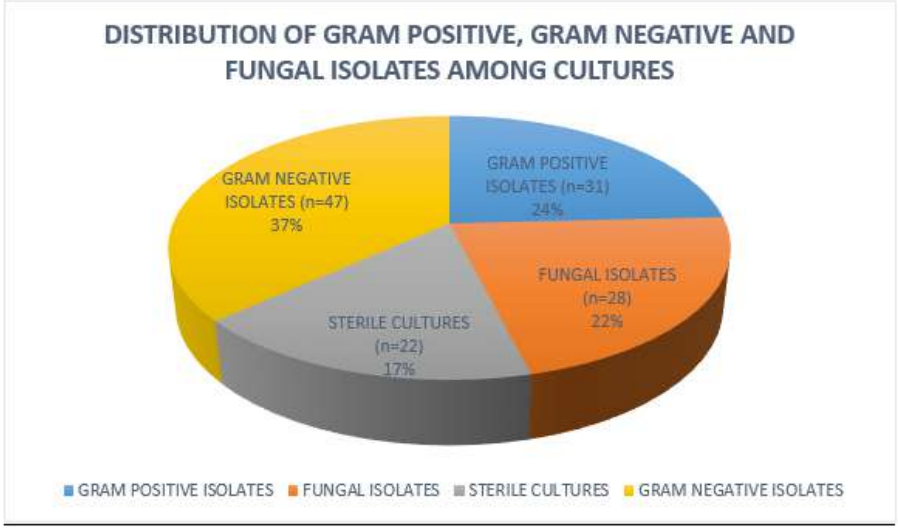
Results

A total of 128 diabetic patients presenting with diabetic wound infections attending our hospital in the period from September 2018 to August 2019 were included in this study.

Of 128 patients, 72 (56.25%) were males and 56 (43.75%) were females. Most patients (64.1%) in this study belonged to age group 51-70 years, while relatively less patients belonged to age groups 30-50 years (14.8%) and 71-90 years (21.1%) respectively.

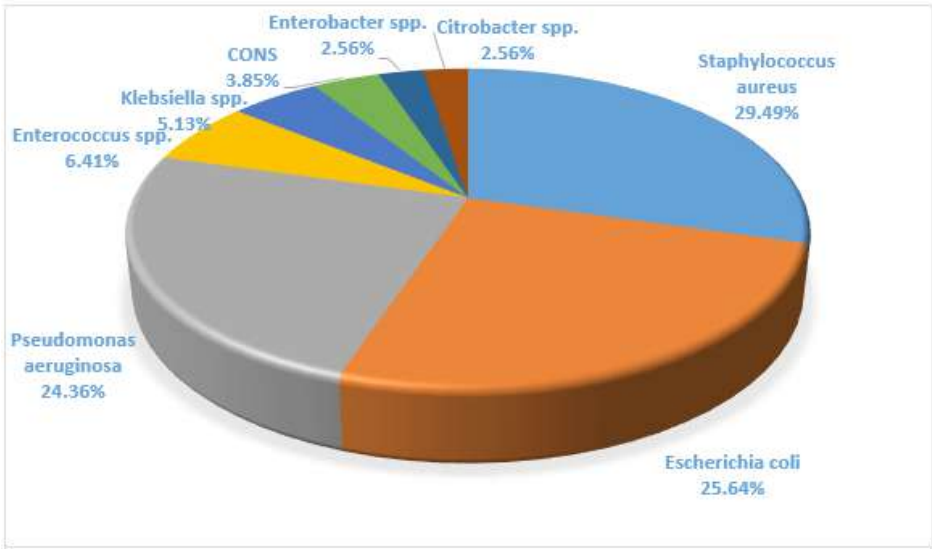
In this study, the total numbers of patients showing culture positivity were 106 (82.82%) [Figure-1], out of which there were 73 (68.87%) monomicrobial cases and 33 (31.13%) polymicrobial cases. Predominance of bacterial growths as a causative etiology in diabetic wound infections were noticed over fungal.

FIGURE 1: MICROBIOLOGICAL PROFILE OF CULTURE GROWTHS IN PATIENTS WITH DIABETIC WOUND INFECTION (n=128)



The positivity rate of bacterial isolates was 73.58% and 26.42% for fungal isolates. Among the bacterial isolates, gram positive bacterial growths were present in 31 (39.74%) cases, whereas gram negative growths were seen in 47 (60.26%) cases. [Figure-1]. The most predominant bacterial growth was that of Staphylococcus aureus (29.49%), followed by Escherichia coli (25.64%) and Pseudomonas aeruginosa (24.36%). [Figure-3].

FIGURE 3: DISTRIBUTION OF VARIOUS BACTERIAL ISOLATES



In the present study, most of the Staphylococcus aureus were sensitive to Linezolid (100%), Vancomycin (95.65%) and Teicoplanin (91.30%). [Table-1] Nearly 73.92% of Staphylococcus aureus were methicillin-resistant Staphylococcus aureus (MRSA). [Figure-4] Imipenem showed to be most sensitive antibiotic among the gram negative bacterial isolates, 72.34% of these were ESBL producers with Escherichia coli accounting the highest degree of production of ESBL. [Table-2, Figure-4].

Among the fungal isolates in our study, Candida species (89.28%) was noted to be the most dominant in diabetic wound infections. [Table-3].

TABLE 3: FUNGAL PATHOGENS ISOLATED FROM DIABETIC WOUND INFECTION

FUNGAL SPECIES	FREQUENCY (NO. OF ISOLATES)	PERCENTAGE (%)
Candida albicans	21	75%
Candida tropicalis	03	10.71%
Candida parapsilosis	01	3.57%
Aspergillus Niger	02	7.15%
Aspergillus flavus	01	3.57%
Total	28	100%

Discussion

Diabetic foot infections are a rising problem worldwide affecting millions of people. Patient care for Diabetic wound infections is complex and necessitates a multi professional collaborative approach to provide comprehensive wound care. The constant non healing wounds are more susceptible to infection further leading to decrease in the healing procedure and often may result in amputations.

Among the 128 patients in the present study, 72/128 (56.25%) were males and 56/128 (43.75%) were females. Similar figures indicating higher male prevalence have been reported by Jain and Barman.[15] This could be attributed to outdoor occupation in males as a consequence of which males are more vulnerable to trauma as compared to females.

In this study, most patients (64.1%) belonged to age group 51-70 years. This could be an indication of increased level of physical activity among this age group as well as the higher prevalence of comorbidities such

as peripheral neuropathy, peripheral vasculopathy, etc. in males. Similarly, studies by Nithyalakshmi et al and Gadepalli et al, mentioned that the majority of patients with diabetic wound infections were in 50-70 years'age range.[16,17]

The data of present study showed a culture positivity of 82.82% which was comparable to the report of Khare et al [18] (90.32%) who quoted this data from a Tertiary care centre in South India. However, around 17.18% were culture negative and showed no microbial growth which could be attributed to prior antibiotic therapy.

Diabetic wound infections are unique as it can be caused by single organism or in combination suggesting mixed etiology).[19,20] In current study, the prevalence of monomicrobial infection (68.87%) was seen over polymicrobial infection (31.13%). Our findings are comparable to various studies by Otta et al (62.2%)[21], Kavitha et al (58.73%) [22], Ali et al (55%)[23] where higher prevalence of monomicrobial infection has been documented over polymicrobial infection.

Predominance of bacterial isolates are observed over fungal in this study with positivity rates of 73.58% (bacterial) and 26.42% (fungal) similar to study reported by Chellan et al.[24]

Our study indicates gram negative isolates (60.26%) as the most predominant infection in patients with diabetic wound infections over gram positive isolates (39.74%), which is in accordance with earlier studies by Zubair et al,[25] Umadevi et al [26] and Shanmugam et al.[27] Few other studies, however reported that gram positive bacteria were more frequently isolated in comparision to gram negatives. [21,28]

Staphylococcus aureus (29.49%) was the predominant organism in the present study, followed by Escherichia coli (25.64%) and Pseudomonas aeruginosa (24.36%). Similar pattern has also been observed by other studies.[15,29,30]

In our study, like many others,[21,31,32] Linezolid (100%), Vancomycin (95.6%) and Teicoplanin (91.3%) were the most susceptible antibiotics for Staphylococcus aureus and other gram positive bacteria isolated. Susceptibility pattern for gram negative isolates demonstrated that Imipenem was the most effective antimicrobial agent which was in accordance to other studies.[33-35]

With the emergence of multidrug resistant bacteria, treatment of diabetic wound infection gets difficult resulting in poor outcome, longer hospital stays and further deteriorating the wound condition. In the present study, we demonstrated additional resistance pattern for staphylococcus aureus and noticed that nearly 73.92% of Staphylococcus aureus were methicillin-resistant Staphylococcus aureus (MRSA). Various other studies[21,29,31] also showed similar rates of MRSA(77.8%, 66.7% and 60%) respectively. Preliminary detection of Vancomycin resistant gram positive bacteria was also noted by Kirby-Bauer's method, however since Minimum Inhibitory Concentration (MIC) was not performed it could not be confirmed. Hence, our study lacks data on important resistance mechanisms like Vancomycin-resistant Staphylococcus aureus (VRSA) and Vancomycin-resistant Enterococcus species (VRE).

In our study, ESBL production was noted in 72.34% of gram negative isolates in our study with Escherichia coli as the highest ESBL producer (52.94%) followed by Pseudomonas aeruginosa (38.23%). Similarly, in a study by Jain and Barman,[15] ESBL producing gram negative bacteria were seen in 79.16% of patients and highest prevalence of ESBL was observed in Escherichia coli.

The present study depicts Candida species (89.28%) as the most frequently occurring fungi in diabetic wound infections. A similar study showed that among the fungal isolates, 76.6% were Candida species.[24] Furthermore, our study showed84% Candida albicans and 16% Candida non-albicans respectively. This observation was comparable to the study of J. Nithyalakshmi et al[16] and Saba Fata et al.[36] Our data also revealed the occurrence of Aspergillus species (10.72%) which was similar to a study by Chellan et al (5% Aspergillus species).[24]

Conclusion

The emerging menace associated with MDR pathogens and their associated complications worsen the problems of Diabetic wound as infections with these isolates are more difficult to manage and treat. It is to help guide the clinicians by postulating our study data about the microbiological profile of these infections, prevalence of isolates and their antimicrobial susceptibility patterns. These are important findings related to good patient management and for development of empirical antimicrobial guidelines.

Correlation between Bio-Film Formation and Carbapenem Resistant Enterobacteriaceae Isolates Obtained from Various Clinical Specimens

Sakshi Dalal[1], Sonia Mehta[2], Shinu Pottathil[3], Varsha A. Singh[2], Shavi Nagpal[4]

[1]B.Sc. M.Sc. Medical Microbiology, [2]Professor, Department of Microbiology, MMIMSR, Maharishi Markandeshwar (Deemed to be University), Mullana Ambala, Haryana, [3]Assistant Professor, Department of Biomedical Sciences, College of Clinical Pharmacy, King Faisal University, Al Ahsa, 31982, Saudi Arabia, [4]Assistant Professor, Department of Microbiology, Department of Microbiology, MMIMSR, Maharishi Markandeshwar (Deemed to be University), Mullana Ambala, Haryana, India

Abstract

Introduction: The ability to form bio-film is a universal trait of bacteria by attaching to the surfaces. Carbapenem resistance in Enterobacteriaceae might be endorsed by bio-film formation which augmented colonization of pathogens.

Aim: To correlate between bio-film formation and carbapenem resistant Enterobacteriaceae isolates obtained from various clinical specimens and to compare the qualitative and quantitative assay for bio-film production.

Method: Study was conducted on 150 strains of Enterobacteriaceae isolates. of these, carbapenem resistant Enterobacteriaceae isolates were subjected for bio-film formation by Modified Congo red agar method, tube adherence method and Tissue culture plate method.

Results: Carbapenem resistant Enterobacteriaceae strains were found to be 60.66% and the rate of bio-film producers was 75.53% by any of the phenotypic method. Tissue culture plate method was found to be (67.6%) better than Modified Congo Red agar method (54.9%) and Tube adherence method (39.4%). The highest number of bio-film producers was isolated from urinary tract infections (36.61%).

Conclusion: TCP method is most reliable, precise and sensitive method for detection of bio-film formation by Enterobacteriaceae isolates and is ideal to use as a general screening tool to detect bio-film production.

Keywords: *Carbapenem resistant Enterobacteriaceae; bio-film; qualitative; quantitative assays.*

Introduction

The ability to form bio-film is a universal trait of bacteria by attaching to the surfaces. Bio-films significantly increase the capability of the pathogen to evade host defenses as well as antibiotics. Such bio-film phenotype leads to emergence of multi-drug resistant organisms and consequently treatment failure.(1)

Development of bio-film is a survival strategy for fungi and bacteria to adjust to their living atmosphere. The microbial cells under bio-film protection turn out to be tolerant and resistant to immune responses and antibiotics, thereby increasing difficulties in treatment.(2)

The Enterobacteriaceae are the most frequent pathogen detected among gram negative bacteria

contributing to majority of infections. Enterobacteriaceae resistance to broad spectrum antibiotics is an increasing problem worldwide. Carbapenem resistant Enterobacteriaceae (CRE) are emerging as tremendously drug resistant bacterial pathogens. These organisms are typically resistant to almost all existing antibiotics and risk of mortality has increased due to infections caused by them. Overuse of antibiotic, hygienic practices and improper sanitation has led to huge extent rate of these multidrug resistant strains.(3)

In recent years, carbapenem-resistant Enterobacteriaceae (CRE) have been acknowledged more gradually as a cause of healthcare associated infections and outbreaks of disease also reported from several countries.(4,5,6,7,8)

Bio-films pose a serious trouble for public health because of the increased resistance of bio-film-associated organisms to antibiotics.(9) Carbapenem resistant Enterobacteriaceae further possess several resistance mechanisms which makes them extremely difficult to treat and almost impossible in a few cases. (10)

Carbapenem resistant in Enterobacteriaceae might be endorsed by bio-film formation which augmented colonization of pathogens. So, to develop more effective treatment for Enterobacteriaceae infections, perceptive of the development of bio-films and intercellular interactions within the bio-films is of great significance.(11)

Considering the above issues, the current study was designed to correlate bio-film formation and carbapenem resistant in Enterobacteriaceae isolates obtained from various clinical specimens.

Material and Method

Study Period: It was a cross-sectional study conducted at the Department of Microbiology, MMIMSR, Mullana, Ambala, over a period of one year i.e. from 2018 to 2019.

Bacterial Isolates: A total of 150 isolates of Enterobacteriaceae were obtained from a total of 1250 various clinical specimens such as Urine, Blood, Pus, Sputum, Wound, HVS, Drain, Stool, Foley's Tip and ET Secretion. All the isolates were identified to species level by Gram staining and a battery of biochemical tests. Antibiotic susceptibility testing was done by Modified Kirby Bauer disc diffusion method according to CLSI guidelines using antibiotics which were obtained from Hi-Media, such as - Ciprofloxacin (5 mcg), levofloxacin (5 mcg), Ampicillin-Sulbactam (10/10 mcg), Piperacillin/Tazobactum (100/10 mcg), Amoxyclav (30 mcg), Cefepime (30 mcg), Ceftriaxone (30 mcg), Imipenem (10 mcg), Meropenem (10 mcg), Co-Trimoxazole (25 mcg), Sulphafurazole (300 mcg), Gentamicin (10 mcg), Amikacin (30 mcg).

Detection of Bio-Film Formation: Carbapenem resistant Enterobacteriaceae isolates were screened for bio-film production by quantitative and qualitative assays, using *Escherichia coli* (ATCC 25922) as a positive control and *Klebsiella pneumonia* (ATCC 700603) as a negative control.

Modified Congo Red Agar Method: It is a qualitative method described by Freeman DJ *et al* (12) 1989 to detect bio-film production by using Modified Congo Red Agar (MCRA) medium which is composed of BAB-2, Glucose and Congo red dye. Enterobacteriaceae isolates were inoculated onto MCRA plates and the medium was incubated aerobically at 37°C for 24 to 48 hours. Positive and negative results were interpreted by observing black colored colonies with dry crystalline consistency and red colored colonies respectively.

Tube Adherence Method: A qualitative estimation of bio-film formation was described by Christensen *et al* (13) Enterobacteriaceae isolates were inoculated in a glass tube containing Brain heart infusion (BHI) broth with 2% sucrose and incubated at 37 °C for 24 hours. After 24 hours the supernatant was decanted and the sediment was washed with PBS (Phosphate Buffer Saline, Ph7.3) so as to remove non-adherent cells. Dried tubes were stained with 0.1% crystal violet and the excess stain was removed. Then, tubes were washed three times with distilled water and kept in inverted position to dry. Bio-film formation was observed by ring formation indicating positive result and the absence of ring was considered as negative result.

Tissue Culture Plate Method: It is most widely used quantitative assay described by Christensen *et al* (14) to detect bio-film formation. Enterobacteriaceae isolates were inoculated in BHI (Brain heart infusion) broth with 2% sucrose and incubated for 24 hours at 37 °C. The broth was diluted with fresh medium to 1:10 and then 20 µl pipetted to each well of 96 wells microtiter plate and incubated overnight at 37°C. After incubation, plate was washed thrice with PBS, pH 7.2 to remove free

floating bacteria. After washing, fixed with 2% sodium acetate for 15 minutes, decanted and stained with 0.1% crystal violet for 20 minutes. The wells were washed with distilled water to remove excess stain and dried. Optical density (OD) of stained adherent bacteria was established with a micro ELISA auto reader (model 680, Bio rad) at 570 nm wavelength (OD 570 nm). These OD values were taken as an indicator of bacterial adherence to the surface and bio-film formation.

Data analysis was performed using both descriptive and inferential statistical analysis.

Results

During the study period, 1250 samples (urine, pus, blood, sputum, wound, HVS, drain and others) were processed and a total of 150 Enterobacteriaceae isolates were obtained. of these 150, maximum numbers were *Escherichia coli* (79) followed by *Klebsiella* spp. (48), *Citrobacter* spp. (15), *Proteus* spp. (5) and *Enterobacter* spp. (3).

Antibiotic sensitivity pattern of Enterobacteriaceae isolates is shown in Table 1. All the 150 isolates were found to be multi drug resistant Enterobacteriaceae (resistant to ≥3 classes of antibiotic).

Table 1: Antibiotic sensitivity pattern of Enterobacteriaceae isolates screened for bio-film production

Antimicrobial Agents			Percentage of Sensitivity					
			Escherichia Coli (79)	Klebsiella spp. (48)	Citrobacter spp. (15)	Proteus spp. (5)	Enterobacter spp. (3)	P value

Out of 150 Enterobacteriaceae isolates, 91 (60.66%) showed resistance to carbapenems. These carbapenem resistant Enterobacteriaceae were then subjected for detection of bio-film production by three phenotypic method namely Tissue culture plate method, Tube adherence method and Modified Congo red agar method. The rate of bio-film producers among carbapenem resistant Enterobacteriaceae was found to be 75.53% by all phenotypic method (Table 2).

Table 2: Distribution of strains showing resistance to Carbapenems and the no. of bio-film producers

Carbapenem resistant Enterobacteriaceae (CRE)	Bio-film producers and percentage	p value
91	71 (75.53%)	<0.0001
One proportion z test used to calculate significant level, the result is significant (*p value < 0.001)		

Quantitative tissue culture plate method (TCP) showed 67.6% isolates positive for bio-film production, which were further categorized as strong, moderate and non/weak bio-film producers (figure 1). Strong and moderate bio-film producers were 10 and 14 respectively, while weak or non-bio-film producers were 24 (50%).

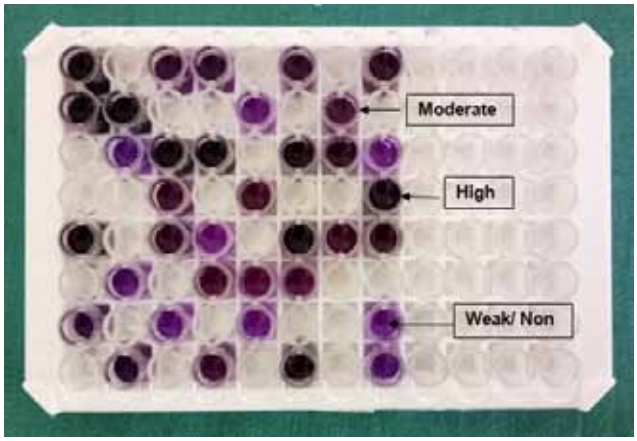

Figure 1: Quantitative assay for bio-film detection, showing high, moderate and weak/non bio-film producers.

Qualitative Tube adherence method (TAM) and Modified Congo red agar method (MCRA) of bio-film detection showed 39 (54.9%) and 28 (39.4%) bio-film producers respectively. The positive isolates in tube adherence method showed blue colored ring formation at the liquid-air interface (figure 2). While in MCRA method, positive isolates showed black colored colonies and negative isolates showed red colored colonies as shown in figure 3.

Figure 2: Qualitative Tube Adherence Method showing Biofilm producer (ring formation) and Non- biofilm producer (absence of ring formation)

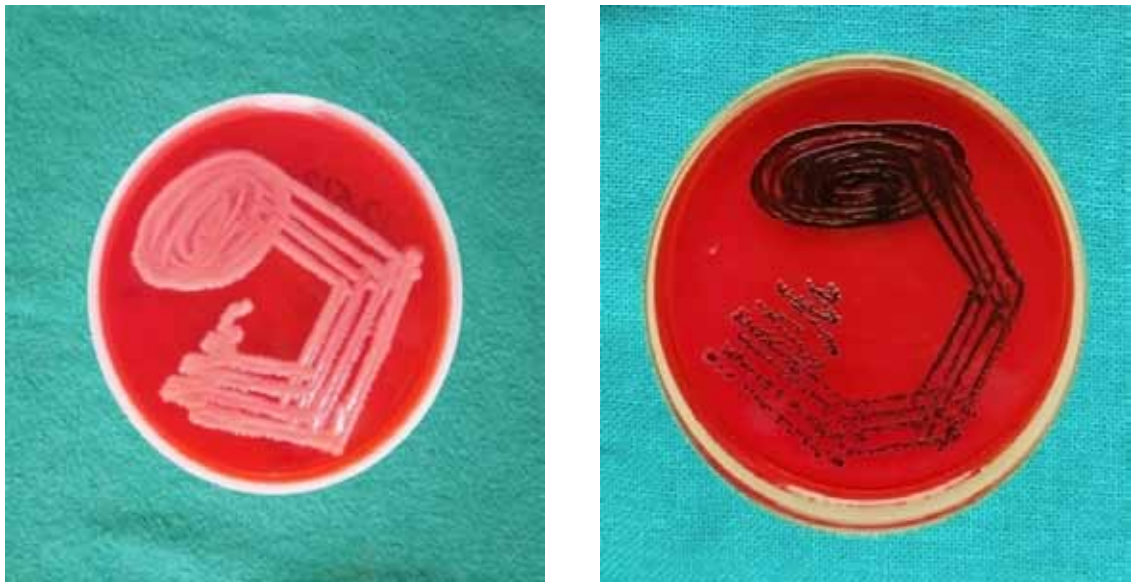

Figure 3: Qualitative Modified Congo Red Agar Method showing Biofilm producer (black colonies) and Non biofilm producer (pinkish-red colonies)

The maximum number of bio-film producers were isolated from urinary tract infection (36.6%) followed by wound infection (19.7%) as shown in Table 3.

Table 3: Distribution of bio-film producers according to clinical diagnosis

Clinical Diagnosis	Total CRE (n=91)	No. of Bio-film Producers (n=71)	Percentage of Bio-Film Producers
Urinary tract infection	30	26	36.61%
Wound infection	16	14	19.71%
Pneumonia	11	9	12.6%
Otitis media	9	6	8.45%
Abscess	8	7	9.8%
Endocarditis	6	4	5.63%
Bronchitis	4	2	2.8%
Vaginitis	3	2	2.8%
Biliary tract infection	2	0	0%
Intestinal infection	2	1	1.4%

Chi-square value (with Yates correction) is 0.529, p value is 0.9999. The result is not significant at $p<0.05$

In our study the rate of bio-film formation was highest by tissue culture plate method 48 (67.6%) followed by tube adherence method 39 (54.9%) and modified congo red agar method 29 (39.4%) (Table 4).

Table 4: Detection of bio-film production in Carbapenem resistant Enterobacteriaceae isolates (71) by three method

Method	No. of bio-film producers	Percentage of bio-film Producers
Tissue culture plate method	48	67.6%
Tube adherence method	39	54.9%
Modified Congo red agar method	28	39.4%

Interestingly, the rate of bio-film production in our study by combination of all three method was highest 24 (33.8%), also the results of tube adherence method correlate well with tissue culture plate method (Table 5).

Table 5 : Rate of bio-film production by three method in combination

Total no. of Positive Strains N= 71	No. of bio-film producers	Percentage
MCRA + TAM+TCP	24	33.8%
MCRA + TAM	3	4.22%
TAM+TCP	8	11.26%
MCRA+TCP	0	0%

TCP: Tissue culture plate method, MCRA: Modified congo red agar method, TAM: Tube adherence method

Discussion

Enterobacteriaceae are amongst the most common human pathogens causing wide ranging infections. *They* cause hospital and community-acquired infections as well as device-associated infections.

Carbapenem resistant Enterobacteriaceae (CRE) have been reported worldwide and has become a major health threat across the world due to their emerging resistance to nearly all existing antibiotics via acquisition of carbapenemase genes. This resistance is probably associated with the capability of these organisms to form bio-film.. In our study the rate of bio-film production in Carbapenem resistant Enterobacteriaceae isolates was 75.53%. The association has been found to be highly significant statistically with p value <0.0001. Our results

were in accordance to the study done by Swarna SR[15] who showed that 74.50% isolates were positive for carbapenem resistance as well as bio-film production.

There are many studies who also reported that bio-film formation was highest by tissue culture plate method.[16,17,18,19]

Since the best results were obtained by combination of all the method, we highly recommend that all the laboratories must include these tests for bio-film production to assess the better positivity rate.

In our study maximum no. of bio-film producers were isolated from Urinary tract infections (36.61%) followed by Wound infections. None of the clinical conditions has been found to be statistically significant (p value 0.9999) for bio-film production. This is contrary with the study done by R Srinivasa Rao *et al* [11] who reported that higher number of bio-film producing isolates were isolated from wound infection (44%) followed by 30% from nosocomial pneumonia patients. The contradiction was obvious as in our study the maximum number of isolates was that of hospitalized patients, so it directly increases the chances of Urinary tract infections rather than wound infections which were possibly associated with urinary catheters.

Conclusion

The present study highlights the need to detect bio-film production among Carbapenem resistant Enterobacteriaceae isolates. Also, there is a need to institute standard guidelines on the care of indwelling medical devices in the hospital to prevent bio-film formation as bio-film formation depends on the adherence of bacteria to various surfaces.

Role of DLCO in Differentiation or Subtyping of Obstructive Lung Disease Beyond Spirometry and CT Scan

Vishvdeep Saini[1], Sameer Singhal[2], Sukhjinder Pal Singh[3], Achchhar Singh[4], Aditi Gupta[5]

[1]Junior Resident, Department of Respiratory Medicine, [2]Professor, Department of Respiratory Medicine, MMIMSR, M.M. Deemed to be University, Mullana, Ambala, Haryana, [3]Senior Resident, Department of Respiratory Medicine, MMMC & H, Kumarhatti, Solan, Himachal Pradesh, [4]Associate Professor, Department of Respiratory Medicine, [5]Assistant Professor, Department of Respiratory Medicine, MMIMSR, M.M. Deemed to be University, Mullana, Ambala, Haryana, India

Abstract

Introduction: Spirometry helps us to differentiate between obstructive and restrictive disease, body plethysmography tells about lung volumes and DLCO about diffusion defect. Determining which tests to do depends on the clinical question to be answered i.e. whether test is being done to diagnose a disease or for evaluation for lung surgery or some other reason.

Material and Method: 46 patients coming to department of respiratory medicine, who were diagnosed with obstructive lung disease by PFT as per GOLD guidelines were considered for the study. Chest X-ray and CT chest were also done. Then DLCO was performed in every patient. Single breath hold method was used in the study. The report of the DLCO was interpreted according to the American Thoracic Society/European Respiratory Society statement on PFT interpretation.

Results: Male preponderance was seen in study cases with 65.2% males to 34.8% females. Mean age of the study group was 54.39 years with most cases (18) from 31-50 years of age group. Most common diagnosis was COPD emphysema (22) followed by chronic bronchitis (12), bronchial asthma (10) and bronchiectasis (2). Among obstructive lung diseases, B. asthma had the highest mean DLCO percentage predicted of 102.20 ± 14.36 followed by COPD-Bronchitis (76.33±5.57), COPD–Emphysema (37.80±13.41) and bronchiectasis (62±4.48).

Conclusion: DLCO can be helpful beyond spirometry in classification of obstructive lung diseases. DLCO values in COPD Emphysema variant are decreased, COPD bronchitis variant remains normal or slightly reduced and asthma either normal or increased. So, DLCO can help in differentiation or sub categorization of obstructive disease more than spirometry.

Keywords: *DLCO, Obstructive diseases, Lung function test, COPD, Emphysema, Bronchial Asthma.*

Introduction

Carbon monoxide diffusing capacity is the least understood pulmonary function test in clinical practice worldwide, even among experienced pulmonologists. There are lot of different tests used for evaluation of lung functions. These tests may be performed individually or in combination with other tests. Pulmonary function test report includes spirometry, diffusing capacity, lung volumes and airway resistance (R_{aw}) measurements in a commonly used format. Spirometry help us to differentiate between obstructive and restrictive disease, body plethysmography tells about lung volumes and DLCO about diffusion defect. Determining which tests to do depends on the clinical question to be answered

Corresponding Author:
Dr. Sameer Singhal
Professor, Department of Respiratory Medicine, MMIMSR, Mullana, Ambala, Haryana, India
e-mail: singhal.sameer@gmail.com

i.e. whether test is being done to diagnose a disease or for evaluation for lung surgery or some other reason. Measuring the diffusing capacity of lungs for carbon monoxide is 2nd most important pulmonary function test that is done after spirometry.

The single breath test of carbon monoxide (CO) uptake has a long history, from its birth (Kroghand Krogh, 1909)[1] to the first publication by Ogilvie et aldescribing a standardized technique for the diffusing capacity measurement (DLCO) in 1957.[2] The DLCO was devised originally as a physiological tool to test the notion that the lung, like the swim bladder of some deep-sea fish, could secrete oxygen against the normal tension gradient provided by inspired air by Bohr in 1900 although this notion is now long abandoned.

As a clinical test DLCO was introduced in 1915 by Marie Krogh, but the measurement never caught on because method of measuring carbon monoxide were so cumbersome.[3] But now a day's single breath technique is in common use. DLCO measures the transfer of a diffusion-limited gas (CO) across the alveolocapillary membranes.

DLCO is increased in the circumstances when pulmonary capillaries are recruited, as occurs during exercise, during a Mueller (reverse Valsalva) manoeuvre, pulmonary hemorrhage, polycythemia,obesity, asthma etc. DLCO is decreased in cases of lung resection, pulmonary emphysema affects capillary or alveolar bed, pulmonary vascular disease including PAH and chronic venous thromboembolism, interstitial lung diseases, anemia, drugs induced fibrosis e.g. bleomycin, amiodarone, pulmonary lymphangitic carcinomatosis.

Material and Method

23 patients coming to department of respiratory medicine of MMIMSR, who were diagnosed with obstructive lung disease by PFT, Chest X-ray or CT chest, were considered for the study. At baseline, patient's medical history was recorded and thorough physical examination was done. The medical history chiefly included history of symptoms related to respiratory system, namely shortness of breath, cough, weight loss, fatigue, expectoration and any other symptom related to other systems. Obstructive disease was categorized as post-bronchodilator FEV1/FVC <0.70 for COPD and post bronchodilator change in FEV1 by >12% and 200ml in case of Bronchial asthma. Chronic bronchitisis defined clinically as the presence of a chronic productive cough for 3 months during each of 2 consecutive years after excluding other causes of cough. Then DLCO was performed in every patient. Single breath hold method was used in the study. The report of the DLCO was interpreted according tothe American Thoracic Society/European Respiratory Society statement on PFT interpretation and is as follows – normal - >80% predicted DLCO, mild reduction - 79% to 60% of predicted DLCO, moderate reduction - 59% to 40% of predicted DLCO, severe reduction - < 40% of predicted DLCO.

In this present study we aimed to find out the importance of DLCO in differentiation of obstructive disease beyond spirometry and CT evidence as some of the COPD patients may also show post-bronchodilator reversibility.

Results

Male preponderance was seen in study cases with 65.2% males to 34.8% females. Mean age of the study group was 54.39 years with most cases (18) from 31-50 years of age group. Most common diagnosis was COPD emphysema (22) followed by chronic bronchitis (12), bronchial asthma (10) and bronchiectasis (2). 14 (30.4%) patients were smokers, 12 (26.1%) were non-smokers and 20 (43.5%) patients were ex-smokers. Among obstructive lung diseases, B. asthma had the highest mean DLCO percentage predicted of 102.20± 14.36 followed by COPD-Bronchitis (76.33±5.57), COPD–Emphysema (37.80±13.41) and bronchiectasis (62±4.48).

Table 1: Distribution of study cases as per Diagnosis

Diagnosis	N	%
Chronic Obstructive Pulmonary Disease – Emphysema	22	47.82%
Chronic Obstructive Pulmonary Disease – Bronchitis	12	26.08%
Bronchial Asthma	10	21.73%
Bronchiectasis	2	04.34%
Total	**46**	**100%**

Table 2: DLCO value in Obstructive lung disease

	N	Mean	SD
B. Asthma	10	102.2	14.32
COPD – E	22	37.80	13.41
COPD – B	12	76.33	5.57
Bronchiectasis	2	62	4.48
Total	**46**	**62.39**	**29.44**

Discussion

DL_{CO} measurement is very reliable and sensitive. DL_{CO} is determined by the amount of blood recruited in thealveolar capillary bed and the alveolo-capillary surfaceavailable for diffusion.

The decrease in DL_{CO} is probably more closely related to the loss of lung volume, alveolar surface area, or capillary bed than to the thickening of the alveolocapillarymembranes. DLCO also decreases when there is loss of lung tissue or replacement of normal parenchyma by space-occupying lesions such as tumours. DLCO may also be decreased in pulmonary oedema as in congestive heart failure. Surgical lung resection for cancer or other reasons also reduce DLCO except in LVRS and bullectomy because the resected areas generally have little to no blood flow.

In acute and chronic obstructive lung disease also DLCO may be decreased. But other obstructive diseases (e.g., chronic bronchitis, asthma) may not reduce DLCO unless they result in markedly abnormal patterns.Some asthmatic patients may have an increased DLCO, but the cause is not completely understood.

Obstructive lung diseases in our study included B. Asthma, Chronic obstructive pulmonary disease-emphysema and bronchitis variants and bronchiectasis. The mean value of DLCO in obstructive lung diseases was 62.39 ± 29.44. In specific diseases, B. asthma had the highest mean DLCO percentage predicted of 102.20 ± 14.36. Saydain G[4] et al did a study on clinical significance of elevated DLCO in 245 patients who had elevated DLCO values. He found that most patients with elevated DLCO had the diagnosis of obesity, asthma or both. Our study also showed COPD- bronchitis patients had the mean DLCO of 76.33 ± 5.57 while COPD-emphysema patients had a mean predicted DLCO value of 37.80 ± 13.41. There were only two bronchiectasis patients in the study and the mean DLCO value was 62±4.48.

To summarize, DLCO is a very good tool for early identification of lung diseases. It can be used to differentiate between COPD and asthma as percentage predicted DLCO is usually decreased in emphysematous patients while it may be normal or increased in asthmatic patients. Bronchitis patients may also show normal or slightly decreased DLCO values.

Conclusion

DLCO can be helpful beyond spirometry in classification of obstructive lung diseases. DLCO values in COPD Emphysema variant are decreased, COPD bronchitis variant remains normal or slightly reduced and asthma either normal or increased. So DLCO can help in differentiation or sub categorization of obstructive disease more than spirometry.

Time Lag in Reporting of CBNAAT Under RNTCP in Rural Tertiary Health Care Centre

Vishvdeep Saini[1], Jai Kishan[2], Sameer Singhal[3], Sukhjinder Pal Singh[4], Achchhar Singh[5]

[1]Junior Resident, [2]Professor and Head, [3]Professor, Department of Respiratory Medicine, MMIMSR, M.M. Deemed to be University, Mullana, Ambala, Haryana, [4]Senior Resident, Department of Respiratory Medicine, MMMC & H, Kumarhatti, Solan, Himachal Pradesh [5]Associate Professor, Department of Respiratory Medicine, MMIMSR, M.M. Deemed to be University, Mullana, Ambala, Haryana, India

Abstract

Introduction: CBNAAT is a very useful rapid diagnostic test for the early diagnosis of DS and DR TB. Report of sample can be available in just 2 hours. But the results of these tests are not available for many days to weeks which results in delay in diagnosis and treatment initiation.

Material and Method: This study was conducted for a period of 4 months from mid-April to mid-august 2018 in MMIMSR, Mullana. A total of 535 samples were sent for CBNAAT to TB Hospital, Ambala and the time taken from sending of samples to the receiving of report was analysed and time lag was calculated.

Results: Out of 535 samples, 429 samples were negative, 104 were positive for MTB and 2 samples resulted as invalid/error. Out of 104 positive samples, 95 were rifampicin sensitive and 9 were rifampicin resistant MTB. The average time lag in reporting of CBNAAT samples was 11.1 days with shortest time being 2 days and longest being 33 days.

Conclusion: CBNAAT is a very useful modality in TB diagnosis and should be made available to all eligible patients especially so in high DR-TB prevalence areas. But delay in reporting undermines the purpose of the test i.e. rapid diagnosis and treatment. There is an urgent need to establish more centres with CBNAAT facility throughout India so that there is no delay in reporting and early treatment can be started.

Keywords: *RNTCP, CBNAAT, Tuberculosis, NIKSHAY, TB prevalence.*

Introduction

TB has been an important challenge for India from last century. From diagnosis to treatment, challenges have been posed that have remained unresolved for many years. The implementation of National Strategic Plan (NSP) 2017-2025 envisions a TB-Free India with zero deaths, disease and poverty due to tuberculosis. The goal of the NSP 2017-2025 is to achieve a rapid decline in burden of TB, morbidity and mortality while working towards elimination of TB in India by 2025.[1] The requirements for moving towards TB elimination have been integrated into the four strategic pillars of "Detect – Treat – Prevent – Build" (DTPB).[1]

The NSP intends to detect Drug sensitive and drug resistant TB by universal implementation of high sensitivity rapid diagnostic tests for diagnosis of TB. These tests like CBNAAT (Cartridge Based Nucleic Acid Amplification Test) is a very useful in early diagnosis of drug resistance and sensitivity patterns of TB. These tests have been incorporated into the TB diagnostic algorithm and are being increasingly used under the RNTCP for diagnosis of TB and drug resistance. But the

Corresponding Author:
Dr. Jai Kishan
Professor and Head, Department of Respiratory Medicine, MMIMSR, Mullana, Ambala, Haryana, India
e-mail: jaikishantb@gmail.com

facilities where these tests are available are very few and the number of samples are increasing day by day. There is a considerable gap between the potential of CBNAAT for early diagnosis of TB within 2 hrs and that being achieved in the field.

CBNAAT takes about 2 hours for the reporting. But from the rural and remote centres the sample has to be sent to these centres which are usually available only in district headquarters. This process takes time and resources and it is usually seen that there is delay in reporting of these tests ranging from days to weeks. This results in delay in diagnosis as well as initiation of treatment. This leads to transmission of TB which in some cases may be drug resistant TB.

This study was undertaken in the department of respiratory medicine, MMIMSR, Mullana to find out the average number of days taken after giving sample by the patient till there porting of CBNAAT samples and to analyse the cause for this delay.

Material and Method

This study was conducted in the department of respiratory medicine in MMIMSR, Mullana, Ambala. Sputum samples of suspected TB patients attending OPD of respiratory medicine department and patients admitted in respiratory medicine ward were collected in the hospital DMC and sent by courier to Ambala District TB Hospital for CBNAAT test. Samples were collected over a period of 4 month from mid-April to mid-august 2018 and 535 patients were included in the study. The reports *were* received through e-mail in the month of April through mid-August 2018 and the average number of days lapsed between sending of samples from our hospital to receipt of the report through e-mail was calculated.

Results

Out of 535 samples, whose report was received during study period, MTB was detected in 104 (19.4%) samples. Out of these 104 samples, 95(91.2%) samples were rifampicin sensitive MTB (RS-TB) and 9 (8.8%) were detected as rifampicin resistant MTB(RR-TB). 1 sample was reported as invalid and 1 as having erroneous result. (Table 1). The rate of CBNAAT positivity was 19.4% in the study.

Out of 104 samples that were positive for MTB, 96were Pulmonary TB and 8 were EPTB. Out of total PTB cases, 88 (91.6%) were rifampicin sensitive TB (RS-TB) and 8 (8.4%) were rifampicin resistant TB (RR-TB). Out of 8 EPTB cases, 7cases (87.5%) were RS-TB and 1(12.5%) was RR-TB. From positive cases 4 (50%) were pleural TB, 1 (12.5%)TB meningitis and 3 (37.5%) cold abscess. In EPTB group 1 RR-TB case was pleural TB.(Table 2)

The average time lag between collecting the sample from the patient in our hospital DMC to receiving the report of that sample was calculated as 11.1 days. The longest duration for receiving a report was 33 days for 1 sample while the shortest duration was of 2 days that was for 8 samples out of 535 total samples sent. Maximum number of samples 58(10.8%) were in the 11 days lag bracket followed by 10 days lag for 57(10.6%) samples. (Table 3).

71.4% of samples had a delay of more than 1 week, 26.5% (142) of samples had a delay of more than 2 weeks, 10% of sample reports were received after a delay of more than 3 weeks. 1.32% reports were received after 4 weeks of delay. (Table 4).

Maximum number of samples consisted of sputum specimen [n = 435 (81.34%)] followed by pleural fluid samples [n= 34 (6.35%)]. Remaining samples included pus, ascitic fluid, Cerebrospinal fluid (CSF), Lymph node (LN), Endometrial tissue, Gastric aspirate, Broncho alveolar lavage (BAL) fluid and 3 other samples. Only a single sample per patient was sent owing to high work load at district CBNAAT lab. Repeat sample was sent only in case of positive result. (Table 5).

Table 1: Distribution of CBNAAT Reports and Sensitivity pattern

S.No.	Result	No. of Cases	Percentage

Conclusion

Molecular rapid diagnostic tests have become an integral part of Revised National TB control Program in India. It is recommended for diagnosis of TB in all previously treated patients, Childhood TB and extrapulmonary TB apart from detecting the drug resistant TB. Under National Strategic Plan RNTCP is of the vision that molecular method for diagnosis of TB are to be implemented in country wide manner in all suspected TB cases. But in remote and rural areas CBNAAT facility is not yet available in most centres so the time from sending of samples to receiving the report is too long. It may range from few days or weeks to a month or more in which time the patient is potentially transmitting the disease to household persons, at occupational place and at social and public places. These delays lead to lack of trust of patients in government TB control program as the same report can be obtained within few hours from private labs despite of it being free of cost in government hospitals.

Delay can occur in the process of sending of samples from the DMC, dispatching of samples by the courier service provider, processing of samples by the receiving district lab, short supply of cartridges or other

accessories, reporting of the test by the lab personnel or due to delay in sending the e-mail by the district hospital or delay in communication of the report to the patient or time taken by the patient to collect the report. All these factors may contribute to the delays in reporting which in turn delays the process of diagnosis and initiation of treatment. A number of patients never show up or show up days or weeks later to collect the report. Delays in diagnosis of drug resistant TB can be very hazardous as this not only results in delay in treatment initiation butalso in transmission of DR TB which is already taking up epidemic proportions in India.

In our study the causes of delay are due to several factors including high sample load leading to back log of samples at district lab, high TB incidence in the region, lack of CBNAAT machine at our centre, lack of human resources, delay in sending the samples as they are sent by courier and are sent after a certain number of samples are collected due to financial constraints and delay in opening the e-mail at the receiving end as reports are received by e-mail. But the major part of delay occurred at district lab because the average delay in our study is 11.1 days while samples are usually sent within 1 day of collection from our centre.

The result of our study shows that one of the purposes for which CBNAAT was introduced, i.e. rapid diagnosis of TB, is not being served in most of the remote and rural areas where CBNAAT facility is not available or available too far away. Just implementing a new diagnostic algorithm is not enough; there is an urgent need to set up new centres for molecular testing in remote and rural areas so that this time lag can be reduced if not eliminated.

Conclusion

The effectiveness of the CBNAAT as rapid diagnostic tool does not depend only on the machine but at each level from collecting the sample up-to receiving of the report. The delay can be reduced by increasing the number of machines at district level and by providing CBNAAT machines in more centres especially in areas of high TB burden, in medical colleges and by provision of adequate workforce and sufficient funding by the government. Apart from these the prompt action of personnel at each level can improve the current appalling state of affairs in rural areas where most of the population lives in India. This will not only result in early diagnosis and treatment initiation but will also prevent transmission of TB and will help in achieving the goal of TB elimination by 2025.

Abstract

Aim: To study the prevalence of obstructive airway disease in patient of OSA diagnosed by polysomnography.

Method: This study is a descriptive cross-sectional and was carried out in patients admitted in the department of Respiratory Medicine who were diagnosed with OSA after polysomnography. Total 41 patients who were diagnosed as cases of obstructive sleep apnea were clinically evaluated and investigated by history taking and final diagnosis were made as either COPD, Asthma on basis of GOLD and GINA guidelines respectively.

Results: Mean age of the study participants was 50.95 years. Prevalence of Asthma and COPD among cases with OSA was 58.5% and 14.6%.Mean AHI and ESS score was 42.45 and 16.80 respectively. The most common co-morbid condition was GERD (19.5%).

Conclusion: Present study concluded that asthma is more prevalent than COPD in patients of obstructive sleep apnea. The main factors associated with Obstructive lung diseases and its pathogenesis is the obesity, hypertension, smoking habits, adenoids, tonsillitis, musculoskeletal changes, weakness and atrophy of muscles of upper respiratory tract.

Keywords: *Asthma, COPD, Obstructive Sleep Apnea, Polysomnography.*

Introduction

Sleep is a natural periodic state of rest for the psyche and body, where the eyes generally close and cognizance is totally or incompletely lost so that there is a lessening in real development and responsiveness to external stimuli. It is said that "sleep is remunerated for somewhere in the range of, a discipline for others." Obstructive sleep apnea (OSA) is leading medical issue in developed and developing countries.[1]

Untreated OSA leads to excessive daytime sleepiness, diminished performance and overall poor quality of life. Sleep disorder breathing (SDB) includes a spectrum of conditions including snoring, upper airway resistance syndrome (UARS) and OSA. The most severe of which is obstructive sleep apnea syndrome (OSA). It is potentially disabling condition characterized by disruptive snoring, repeated episodes of complete or partial pharyngeal obstruction during sleep resulting in nocturnal hypoxemia, frequent arousals and excessive day time sleepiness.[2]

Prevalence of OSA varies in different population. In most of the studies it varies from 3-7%. In India prevalence of obstructive sleep apnea is 7.5% in males and that of 4.5% in females.[3] Several studies have investigated the association between OSA and obstructive airway disease (OAD), including both asthma and chronic obstructive air way disease (COPD). A high prevalence of OSA has been reported in asthma cases[4] and asthma may also be common in OSA.[5] Sleep related symptoms do also occur in patients of COPD.

Whenever both these condition present together is called "Overlap Syndrome."

It is not surprising that research attentions have focused on the overlap syndrome between these two highly prevalent conditions with the aim of determining their relationship. In patients with COPD, studies have shown that as the depth of sleep increases, there is a reduction in minute ventilation with an increase in upper airway resistance[6] with up to 20% patients of severe COPD exhibiting co-existent OSA.[7] In the previous literature there is some controversy as to whether the association between obstructive lung diseases and OSA is that expected merely on the basis of the conjunction of two relatively common clinical conditions or whether having OSA or obstructive lung diseases confers increased risk for having the other.[8] In the current study, we explored the prevalence of obstructive airway disease in patients of OSA diagnosed by polysomnography.

Material and Method

Study Design: The present descriptive cross-sectional study was carried out in patients admitted in the department of Respiratory Medicine of our hospital who were diagnosed with OSA after polysomnography. The patients fulfilled the inclusion criteria and exclusion criteria were finally taken up for the study. Total 41 patients who were diagnosed as cases of obstructive sleep apnea, these cases were further clinically evaluated and investigated by history taking and final diagnosis were made as either COPD, asthma on basis of GOLD and GINA guidelines respectively.

Sample Size Calculation: The sample size was calculated using following formulae:

$n = (Z_{\alpha/2})^2 * (PQ)/E^2$

n - Sample size

$Z_{\alpha/2}$ – Z value at 5% error (1.96)

E – Absolute error (taken as 20%)

Sample size was found to be 23 by using this formula. However, we decided to take more than 30 cases in the present study.

Inclusion Criteria: All OSA cases diagnosed by polysomnography in department of respiratory medicine will be taken up for the study.

Exclusion Criteria:

1. Patients who were critical ill.
2. Patients who were known cases of CVA.
3. Hemodynamically unstable patients.
4. Pregnant women

Methodology

Patient's evaluated using polysomnography after taking history clinical examination and investigations were done:

1. Vitals
   - Blood pressure
   - Pulse rate
   - SPO2
   - Respiratory rate
   - Temperature
2. Body mass index
3. Chest x-ray PA view
4. ECG 12 lead
5. Spirometry with reversibility test

Diagnosis of COPD, Asthma and overlap syndrome or any other comorbid condition was established

Statistical Analysis: The recorded data was compiled and entered in a spreadsheet computer program (Microsoft Excel 2010) and then exported to data editor page of SPSS version 20 (SPSS Inc., Chicago, Illinois, USA). Descriptive statistics included computation of percentages, means and standard deviations.

Table 1: Distribution of gender, clinical symptoms and personal history

Gender	**N**	**%**
Male	30	73.2
Female	11	26.8
Clinical Symptoms		
Snoring	40	97.6
Fatigue	29	70.7
Day time Sleepiness	25	61.0
Difficulty in Sleeping	13	31.7
Smoking and Alcohol Intake		
Ex-smoker	1	2.4
Smoker	8	19.5
Alcohol	6	14.6
Alcoholic + Smoker	1	2.4

Table 1: Mean age of the study participants was 50.95 years. Male predominance was seen among study cases with 73.2% males to 26.8% females. Most common presenting symptoms among study population were snoring (70%) followed by day time sleepiness (61.0%) fatigue (70.7%) and difficulty in sleeping (31.7%). Out of all, 19.5% are smokers and 14.6% were alcoholics.

Table 2: Distribution of mean Age, Anthropometry, Spirometry, AHI & ESS

Variables		Mean	Std. Deviation
Age		50.95	11.48
BMI		31.24	5.61
Neck circumference		40.71	1.68
Spirometry	FEV1 (%)	63.19	19.70
	FVC (%)	70.82	18.23
	FEV/FVC (%)	87.36	15.94
AHI		42.45	20.86
ESS		16.80	4.22

Table 2: Mean age of the study participants was 50.95 years. Mean BMI of study participants was 31.24 kg/m^2 while mean neck circumference was 40.71 cm. Mean FEV1, FVC and FEV1/FVC was 63.19, 70.82 and 87.36. Mean AHI and ESS score was 42.45 and 16.80 respectively

Table 3: Prevalence of COPD, Asthma and COPD/ Asthma Combined

Variables	N	%
Asthma	24	58.5
COPD	6	14.6
Combined	0	0.0
Total	**41**	**100.0**

Table 3: Prevalence of asthma and COPD among cases with OSA was 58.5% and 14.6%

Table 4: Distribution of Co-morbidities

Variables	N	%
GERD	8	19.5
HTN	5	12.2
Diabetes	4	9.8
CAD	3	7.3
DNS	2	4.8
Rhinitis	2	4.8
Hypothyroidism	0	0.0

Table 4: The most common co-morbid condition was GERD (19.5%) followed by hypertension (12.2%), Diabetes (9.8%), CAD (7.3%), DNS and Rhinitis (4.8%) each.

Discussion

Sleep medicine is an emerging field of medical science that has recently become popular due to developments in technology and medical science. Development in the field of sleep medicine has come in leaps and bounds in recent years and it has coincided with its emerging popularity in the developing world. Obstructive and central sleep apneas are two forms of sleep disordered breathing that has received most interest. Obstructive sleep apnea is the most commonly seen sleep abnormality and is the one in which most interest has been shown by the medical fraternity.

In present study we aimed to find out the prevalence of COPD and asthma in patients diagnosed with Obstructive Sleep Apnea. A total of 41 cases of OSA fulfilling the inclusion criteria and exclusion criteria were include in the study. Cases were subjected to physical examination included measurement of height, weight, Body Mass Index (kg/m2), neck circumference and spirometry. Epworth sleepiness scale was applied to the patients and total score was also calculated and severity of OSA was recorded using AHI Index. All patients were subjected to a full night hospital-based sleep study for diagnosis of OSA.

In present study, prevalence of Asthma and COPD (as defined by GOLD and GINIA guidelines) among cases with OSA was 58.5% and 14.6%. The mean AHI and Epworth sleepiness score was 42.45 and 16.80 respectively. Our study supports the notion that there is an association between OLD and OSA. Our findings were in agreement with study conducted by Greenberg-Dotan et al. (2014), COPD was found prevalent in 7.6% patients and asthma was found in 10.4% of the patients.[9]

In the present study the most common presenting symptoms among study population was snoring (70%) followed by day time sleepiness (61.0%) fatigue (70.7%) and difficulty in sleeping (31.7%). Similarly, Snoring is the most frequent symptom of OSAS, occurring in up to 95% of patients, but has poor predictive value because of the high prevalence in the general population.[10] However, the absence of snoring makes OSAS unlikely and only 6% of patients with OSAS did not report snoring in one report.[11] Between 30-50% of the general population report significant sleepiness.[12] Other than

EDS, such as fatigue, memory impairment, personality changes, morning nausea, morning headaches, automatic behavior and depression.[13,14] Although these features may be important in assessing the impact of sleep apnea on a patient and the effectiveness of therapy, there has been no systematic study of the capacity of these features to predict the presence or absence of OSA

The role of smoking and alcoholism has also been studied in OSA. In our study 19.5% were smokers and 14.6% were alcoholics. Scanlan et al. found that alcohol resulted in a small but statistically significant rise in the frequency of obstructive apnoeas and hypopneas, without prolonging the apnoea length or worsening hypoxaemia.[15]

Proposed mechanisms for the adverse effects of alcohol upon OSA include selective reduction in genioglossus and hypoglossal motor nerve activity, increased nasal mucosa oedema and thereby increased resistance,a reduction in arousal response and a reduced haemoglobin affinity for oxygen.[16,17]In addition, considerable evidence exists that alcohol fragments sleep, independent of apnoea status, which may further aggravate OSA.[18,19]

In the present study the most common co-morbid condition was GERD (19.5%) followed by hypertension (12.2%), Diabetes (9.8%), CAD (7.3%), DNS and Rhinitis (4.8%) each Link between sleep apnea and hypertension has been consistently demonstrated in many studies and the finding of hypertension in a patient with symptoms suggestive of OSAS increases the likelihood of the disorder.[20,21] OSAS also relates independently to diabetes and the metabolic syndrome.[22,23] Assad et al (2013) indicated that asthma is associated with three components of metabolic syndrome, the abdominal obesity, hypertension and elevated fasting glucose or diabetes in an un-adjusted models.[24] From the aforementioned studies, it is understandable that the abdominal obesity, insulin resistance (elevated glucose) and hypertension are the main risk factors that associate metabolic syndrome with asthma. Based on these risk factors, there are several suggestive mechanisms which explain the link between metabolic syndrome and asthma. It can be due to mechanical effect, genetic factors, epigenetic factors, inflammatory effect, mitochondrial dysfunction, hormonal effect and the effect of other co-morbidities.[25]

Conclusion

The present study concluded that asthma is more prevalent than COPD in patients of obstructive sleep apnea. The main factors associated with Obstructive lung diseases and its pathogenesis is the obesity, hypertension, smoking habits, adenoids tonsillitis, musculoskeletal changes, weakness and atrophy of muscles of upper respiratory tract.ESS can be an important predictor of presence of OSA as well as severity of OSA, when used in combination with patient history, symptoms and physical examination. Studies show that there is improvement in symptoms after CPAP therapy was reported by the patients on follow up visits but this aspect was not analyzed in the current study as our study mainly deals with prevalence of COPD and asthma not with treatment part. But we recommend future prospective studies to evaluate the role of CPAP in these patients.

Correlation of Chest Radiography with Microbiological Findings for the Diagnosis of Pulmonary Tuberculosis

Nikita Jaiswal[1], Varsha A. Singh[2], Ali Ilham K.[3], Pankaj Saini[4], Gulnar[5]

[1]Assistant Professor, [2]Professor, [3]M.Sc. Student, [4]Junior Resident, [5]P.G. Tutor, Department of Microbiology, MMIMSR, MMDU, Mullana, Ambala, Haryana

Abstract

Introduction: Tuberculosis is a major health problem faced by mankind since ancient times till date in spite of advances in our knowledge. Recently HIV hastened this & it became the single largest infectious disease-causing high mortality in humans leading to numerous deaths annually.

Early & prompt diagnosis is the only solution to control it. In developing country like India RNTCP depends on chest radiography & smear microscopy but culture is still GOLD standard method. Thus this study was designed to correlate the radiologically suspected tuberculosis cases with Zeihl-Neelsen staining & culture on LJ medium.

Method: A cross-sectional study conducted on 60 radiologically suspected cases of pulmonary tuberculosis to compare the efficacy with conventional LJ medium culture and ZN staining. The samples were chosen using simple random sampling method.

Results: Out of total 60 cases, 40(66.66%) cases showed positive results by any of the method. ZN staining (100%) rendered highest positivity than LJ media (80%) in far advanced with cavity while in minimal lesion LJ media (25%)was more effective than ZN staining (12.5%). Maximum number of Grading 3+ cases were with far advanced with cavity (100%) followed by moderate lesion with cavity (72.7%). Advanced with cavity showed highest and earliest growth i.e. 60% within 2 weeks while in moderate lesion with cavity it was 18.8%

Conclusion: Correlation between radiological and microbiological findings must be the mainstay for the diagnosis in clinical suspected case of pulmonary TB.

Keywords: *Tuberculosis, ZN staining, Cavity lesions, LJ media.*

Introduction

Tuberculosis (TB) is a global problem that seriously threatens public health causing several deaths annually. Nearly 95% of all tuberculosis cases and 98% of deaths due to tuberculosis are in developing countries and 75% of tuberculosis cases are in the economically productive age group.[1] In India there are about 500,000 deaths occurring annually due to TB with the incidence and approximately 1.8 million persons develop TB annually of which about 0.8 million are new smear positive highly infectious cases.[2,3] It affects both sexes and all ages due poverty, overcrowding, low socioeconomic status, multiple pregnancies, active & passive smoking, lack of health education, under-nutrition, poor housing etc.[4] RNTCP guidelines are based on recommendations of the World Health Organization (WHO) and focus on detection of cases using acid fast bacilli (AFB) smear microscopy.[5] The mainstay for its control is the rapid

Professor, Department of Microbiology, MMIMSR, MMDU, Mullana, Ambala, Haryana
e-mail: drvarshasinghmicro@gmail.com

and accurate identification of infected individuals. This will detect only those patients with the highest number of TB organisms in the sputum, presumed to be the most infectious cases. Although less infectious than smear positive patients, smear- negative patients are capable of transmitting disease and experience substantial morbidity and mortality.[6] The tools used for diagnosis of TB have remained largely unchanged since the 1880s when sputum microscopy, Mycobacterium tuberculosis culture on solid media tuberculin skin testing and chest radiology were initially developed.[6] Chest x-ray is one of the most popular and non-expensive imaging tools for the diagnosis of pulmonary TB.[7] There should be correlation of detection & isolation of Mycobacteria with abnormal x-ray finding in every clinically suspected tuberculosis patient. Therefore this study was designed to compare on the radiologically suspected tuberculosis cases, the culture on LJ medium which is a gold standard.

Materials and Method

Study Design: A prospective cross-sectional test validation study.

Sample Size: A total of 60 radiologically suspected TB patients attending OPD and IPD of M.M. Institute of Medical Sciences & Research Centre were recruited for the study.

Sampling: Systematic random sampling.

Specimen collection and transport: Sputum samples from the patients of suspected pulmonary tuberculosis were collected by standard aseptic precaution as per RNTCP guidelines.

Processing: The sputum samples were processed for

i. ZN-Staining

ii. Culture-After digestion/decontamination and concentration (standard NALC–NAOH procedure) sputum samples were inoculated on LJ media.[8]

Results

The rate of mycobacterial species amongst radiologically suspected tuberculosis patients 40 (66.66%) cases showed positive results by any of the method i.e. culture on LJ media and ZN staining (Table 1). Growth of LJ and ZN staining rendered highest positivity in far advanced with cavity, 80% and 100% respectively ensued by moderate lesions with cavity, where smear was positive for 81.8% and culture for 63.6% of patients (fig 1). It confirms the affirmative relation between extent of radiological lesions and the ZN smear grading (fig 2). The highest number of cases which were positive by radiological findings were seen with grading 3+ and the maximum number of cases (100%) had far advanced with cavity followed by moderate lesion with cavity (72.7%). The cavitatary nature of the lesion corroborates with rapidity in growth on LJ media (Table II). For advanced with cavity showed highest and earliest growth i.e. 60% within 2 weeks while in moderate lesion with cavity it was 18.8%

Discussion

India, holding the highest percentage of the Mycobacterium tuberculosis patients & its fatal nature along with the increasing resistance to anti tubercular drugs further worsens the situation. In the current scenario, the diagnostic aspect of the disease has improved manifolds and every day, scientists are out there to invent newer and better diagnostic method. An age old and efficient method to diagnose tuberculosis has been radiology. The images formed on radiograph give a fair idea about the intensity of the disease as well. But the radiological appearances of many other lung diseases also give similar images thereby making it difficult for the accurate detection as far as pulmonary tuberculosis is concerned.

Microbiology, a department dealing right away with the causative agent has been providing a variety of authentic method for the detection. Culture being the gold standard for the diagnosis of mycobacteria tuberculosis is one of the most effective ways. But due to the delay in giving growth, which further delays the initiation of treatment generates a need to involve a relatively rapid technique along with it. Speaking of rapid method, Ziehl – Neelson staining has been one of the most reliable method, which actually show the mycobacteria in microscopy and in addition give the approximate bacterial count as well. As an adjunct, various method like tuberculin testing, ELISA, BactT/3D Alert and PCR have come but some of them are not cost efficient whereas some of them lack specificity, thereby making them able to strengthen the diagnosis only. In view of that the present study is conducted on 60 radiologically suspected patients of pulmonary tuberculosis to traverse the distance of old age till new age by various microbiological detection method viz Growth on LJ media and AFB staining. The samples were received in

the department of Microbiology from different wards and OPD's of MMIMSR, Mullana.

Multiple test increases the overall percentage positivity and many researchers believe in the same. Jena J et al.[9] (1995) and Kamal Mostafa M A et al.[10] (2009). In their studies rendered the overall positivity rate 47.9% and 44% respectively while in the present study, the rate of mycobacterial species by one or more tests came out to be 66.66% (Table 1) which is on higher side, maybe because of the selection criteria (equal number of samples were positive for ZN staining). While the present study is in accordance with Rao SK et al.[2] (2010) which illustrated 71.1% positivity.

The radiological picture to diagnose pulmonary TB still considered holding a genuine significance. There is a very strong correlation between the extent of radiographic findings and the prevalence of bacillary disease. In the present study, far advanced lesion with cavity have highest rate of growth on LJ culture as well as smear positivity i.e 80% and 100% respectively, followed by moderate lesions with cavity where growth on LJ culture came out be 54.5% and smear positivity, 81.8% (Fig. I). These findings were quite high when compared to non cavitatry lesions (minimal, moderate/ far advanced without cavity and fibrotic and calcified). This is further supported by Tupasi ET et al.[11] (2000) who observed maximum smear positivity and growth on LJ media i.e. 90.9% and 90.9% in far advanced lesions with cavity.

The presentation of radiological lesions i.e. minimal, moderate/far advanced without cavity. Moderate with cavity, far advanced with cavity or fibrotic and calcified lesions can be mimicked by many other lung diseases making it unreliable for accurate diagnosis .This is even supported by the American thoracic society. Thus, one of the most rapid reliable microbiological method of diagnosis, ZN Staining can be relied upon for making the diagnosis of pulmonary tuberculosis. The presence of cavitary lesions in radiological findings had high number of mycobacteria because the cavity facilitates spreading of the bacteria and such lesions would show early growth on LJ media as well as the AFB staining of sputum would show higher grade in the present study, 3+ grade is shown by cases which had far advanced lesions with cavity (100%) followed by moderate lesions with cavity (12.5%) (Fig. II).

While in the present study, far advanced lesions with cavity presented highest growth, 80% and that to in 2 weeks followed by moderate lesions with cavity, 54.5%. Moderate lesions with cavity and minimal lesions showed late growth on LJ i.e. 31.25% and 25% and after 4-7 weeks (table II). As per our best of knowledge is concerned, such studies have not been conducted in the past.

Table 1: Detection of mycobacteria species in radiologically suspected patients of pulmonary tuberculosis

Total number of patients	60
Total positive cases by microbiological tests	40(66.6%)

Table 2: Interrelation of radiographic findings with weekly growth on L.J. media in detection of mycobacterium tuberculosis

Lesions	1 Week	2 Week	3 Week	4 Week	5 Week	6 Week	7 Week	Total
Minimal lesion (n=24)	Nil	nil	Nil	nil	3(12.5%)	2(8.3%)	1(4.7%)	6
Moderate without cavity (n=16)	Nil	nil	Nil	2(12.5%)	2(12.5%)	1(6.2%)	nil	5
Moderate with cavity (n=11)	Nil	4(18.2%)	1(27.3%)	1(9.01%)	nil	Nil	nil	6
Far advanced with cavity (n=5)	Nil	3(60%)	1(20%)	nil	nil	Nil	Nil	4
Fibrotic and calcified lesion (n=4)	Nil	nil	Nil	nil	nil	Nil	Nil	nil

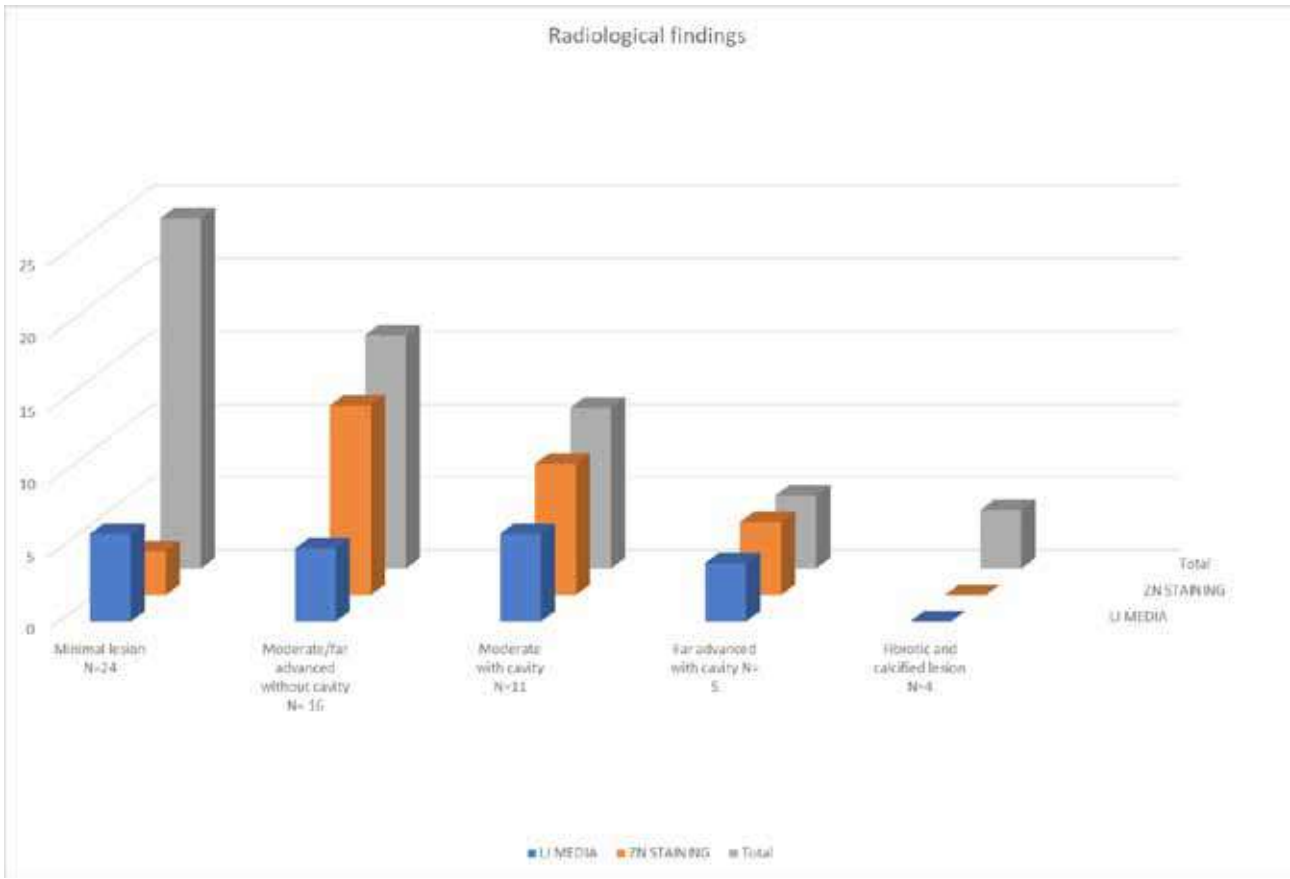

Figure 1: Correlation of radiological findings with LJ Media and ZN staining in detection of Mycobacterial tuberculosis

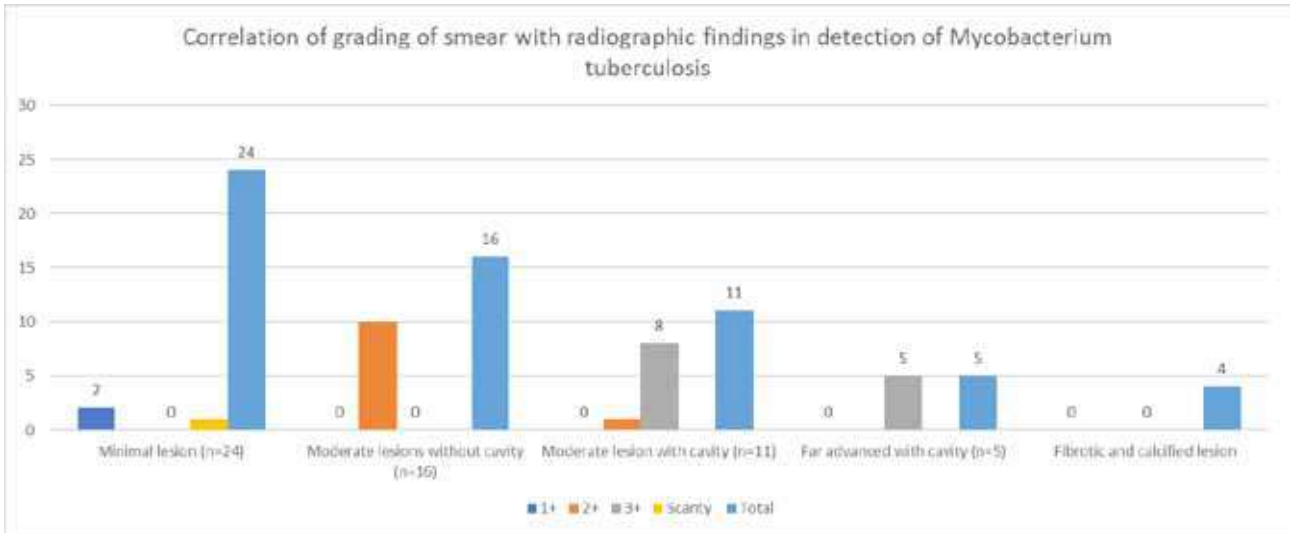

Figure 2: Correlation of grading of smear with radiographic findings in detection of Mycobacterium tuberculosis

Conclusion

To achieve the final diagnosis of Pulmonary TB clinical correlation between radiological and microbilogical findings are must. In India, RNTCP also recommends the sputumsmear positivity or cavitatry lesions in chest X ray to diagnose pulmonary TB before the commencement of ATT. In the current study, correlation between radiological (minimal lesions, moderate lesions

without cavity or with cavity, far advanced lesion with cavity and fibrotic calcified lesion) and microbiological findings were established to empower the diagnosis of pulmonary TB.

Perception of Students Regarding Small Group Teaching in Microbiology at Undergraduate Level

Ritu Garg[1], Rosy Bala[2], Varsha A. Singh[3]

[1]Associate Professor, [2]Assistant Professor, [3]Professor & Head, Department of Microbiology, Maharishi Markandeshwar Institute of Medical Sciences & Research, MMDU, Mullana, Ambala (Haryana)

Abstract

Background: Active learning strategies for understanding the subject like microbiology is need of the hour. Small group teaching is considered to nurture active learning by the students. It is a student centered method and promotes active learning. So by keeping in mind the usefulness of the active learning, the present study was planned to assess the perception of students after introducing small group teaching (SGT) in Microbiology.

Materials and Method: The study was conducted on 150 MBBS second year professional students in the department of microbiology of Maharishi Markandeshwar Institute of Medical Sciences & Research, Mullana. Small group teaching method were conducted for all selected topics. At the end of the sessions of SGT, perceptions of students were taken on feedback questionnaire and analysed on 3 point Likert scale.

Result: Total 150 MBBS second Professional Students taken part in Study. Out of 150 students, 142 (94%) students took part in the study. Above 90% stated that it is easy and fun filled method, concepts are clearer and stronger, interaction increased with teachers, retention of the subject increased. Above 80% stated that willingness to study increased, doubts cleared easily, attention in the class increased, increased application of knowledge, sharing of ideas. Above 70% stated that clinical correlation, learn team work, self-directed learning.

Conclusion: By Small group teaching, students will be apply their knowledge and will be able to provide effective diagnostic services in the community. Small group teaching can be easily adopted in curriculum by proper management of time and by cooperation of faculty and students.

Keywords: *Small group teaching, active learning, student centred teaching method.*

Introduction

Active learning occurs when students are given the opportunity to develop interactive relationship with the course content, encouraging them to apply rather than simply receive knowledge.[1] Small group teaching is considered to nurture active learning by the students.[2] In current medical education, learning relevant to the health requirements of the community is the need of the hour. Indian Medical Graduate (IMG) should be competent to function aptly and efficiently as a physician of first contact in the community.[3]

In microbiology, students are taught about infectious diseases, so correlations of infectious agents with the diseases are essential which cannot be achieved by traditional method. By adopting active learning strategies students will be able to apply correlation of infectious agent with the diseases.[4]

Small group discussions for general microbiology and introduction of case in small group teaching for

e-mail: dr_rittu07@yahoo.co.in

applied microbiology improves clinical applications of theoretical knowledge gained about the subject by the student . By keeping in mind the usefulness of the small group teaching method the present study was conducted with following objectives:

1. To evaluate the perception of medical students regarding small group teaching for general microbiology
2. To evaluate the perception of medical students regarding case based small group teaching for applied microbiology
3. To investigate faculty perceptions on small group teaching.

Materials and Method

The cross sectional study was conducted on 2nd Prof Students in microbiology department, MMIMSR, Mullana for period of 4 months. The study was conducted on 150 Second professional MBBS students. Informed consent was taken from students .The faculty of the department was sensitized regarding the method used in the study. Topics for the study were taken from the scheduled time table . Students were taught general microbiology and applied microbiology in small groups. For general microbiology,two topics, Culture media and Antimicrobial susceptibility was selected for the study and for applied microbiology two topics, Urinary Tract infection and Tuberculosis was taken. The questionnaire was designed to document the students' responses. Case based scenarios were prepared to teach applied microbiology and scenarios were validated by faculty of the department. A sample case scenario used for UTI is provided below.

A 31 year old female was admitted with dysuria and increased frequency of micturition for the past 5 days. A urine sample was collected for culture and sensitivity. *Escherichia coli* were isolated from the sample. Patient was treated as per the sensitivity report and responded well to the treatment.

- What was the clinical diagnosis?
- How to collect the urine sample?
- Enumerate etiological agents causing UTI.
- What is the importance of antimicrobial susceptibility testing?

Student's feedback questionnaire Containing 15 questions was prepared and was validated by peer review. Group dynamics was also explained to the students. Practical classes were used for the sessions of small group teaching. As MBBS batch is of 150 students. Whole class is divided into two practical batches of 75 students each. Here Group A is batch A and Group B is batch B. further sub grouping was done for the session of small group teaching. Each batch A & B was divided into further 9 groups (A1-A9) and (B1-B9) containing eight to nine students each for the session. All the groups in batch A and batch B were given a case scenario for applied microbiology one week prior and asked to read about the topic from different sources like books, internet etc. After one week they join together in their respective groups and again discussed the scenario with each other for 20 minutes. Then every group discussed the Case based scenario with their respective teachers. Same method was followed with rest of the topics. In this way all the students was exposed to all the sessions At the end of the sessions, perceptions of students were taken on a 3 point Likert scale regarding the small group teaching method adopted. [5]Feedback was taken from faculty also. The feedback from faculty was also taken by asking open ended questions.

a. Is there need of introduction of student centered teaching learning methodologies in microbiology?
b. What will the impact on students learning and performance?
c. How it will motivate self-directed learning?
d. What will be the impact on shy students?
e. How students will understand the clinical aspect of microbiology better?
f. What will be the impact on interest in microbiology?

Results

Total 150 MBBS second Professional Students taken part in Study. Out of 150 students, 142 (94%) students took part in the study. 91% students stated that with small group teaching concepts are more clearer and stronger and it is easy, quick and fun filled method of learning. 77% stated that method adopted different views for the same topic help to understand the concept easily,Clinical correlation is more as compared to traditional method, We learn to work together . 79% opined that it motivates for self -directed learning. 82% students felt that doubt are cleared easily, Willingness to study in class is increased, Improved application of

knowledge, 85% students stated that there is Sharing of ideas and knowledge, Shy students get a chance to interact in groups and gain confidence of speaking, 88% students stated good method for recall of prior knowledge and attention in class is improved. 92% stated that retention of topic is increased by discussions with others and 95 felt that more interaction with teachers and classmates [Table/Fig-1).

Faculty Feedback: All the faculty members opined that dire need of introduction of student centered teaching learning methodologies in microbiology, great impact on students learning and performance, Motivates self-directed learning, Shy students gets chance to interact with teachers, students will understand the clinical aspect of microbiology better, Small group teaching helps the students to increase their interest in microbiology. But they also felt that CBL is a tedious and time consuming process so more resources and proper management of time is required.

Table 1: Perceptions of the students regarding small group teaching (%)

Sr No.	Items	Agree	Neutral	Disagree
1.	Concept becomes more clear and stronger with small group teaching	91	7	2
2.	Easy, quick and efficient method of learning	91	8	1
3.	Different views for the same topic help to understand the concept easily	77	17	6
4.	Doubt are cleared easily	82	15	3
5.	Sharing of ideas and knowledge	85	13	2
6.	Good method for recall of prior knowledge	88	9	3
7.	Retention of topic is increased by discussions with others	92	8	0
8.	Motivates us for self -directed learning	79	16	5
9.	Clinical correlation is more as compared to traditional method	77	16	7
10.	Willingness to study in class is increased	82	16	2
11.	Attention in class is more	88	10	2
12.	Shy students get a chance to interact in groups and gain confidence of speaking	85	14	1
13.	More interaction with teachers and classmates	95	5	0
14.	Improved application of knowledge	82	13	5
15.	We learn to work together	77	13	10

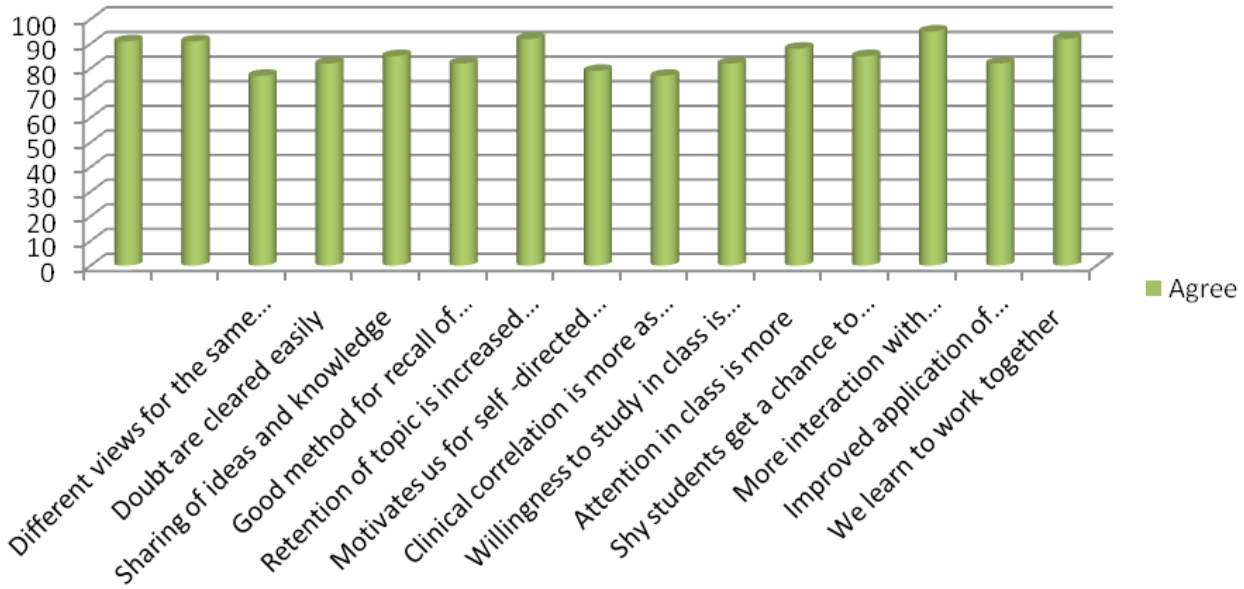

Figure 1: Bar Chart showing students perceptions on small group teaching (%)

Discussion

The present study was conducted on implementation of small group teaching in microbiology at undergraduate level. Feedback given by students on small group teaching clearly indicated that there is improvement of clinical correlation of the microbiology. Above 90% stated that it is easy and fun filled method, concepts are clearer and stronger, interaction increased with teachers, retention of the subject increased. Above 80% stated that willingness to study increased, doubts cleared easily, attention in the class increased, increased application of knowledge, sharing of ideas. Above 70% stated that clinical correlation, learn team work, self-directed learning. Study done by Kassebaum D et al showed that students are more engaged, interested and involved in the class.[6]

In another study above 77% students stated CBL contributed to better understanding of the microbiology learning objectives, helped them retain the relevant information.[1]

Kanchan Gupta in her study showed 94.4% students opined that subject effectively illustrated the medical concepts. 78% opined that motivated them to use addition resources. 87.29% feels that stimulated their interest in subject. 89.6% opined that intervention of the teacher was useful, 72% opined that session was better than theory classes.[7]

Neena Bhattacharya et al. in their study "Introducing problem based learning in physiology in the conventional Indian medical curriculum" found that almost all the students found PBL to be useful (96.6%). Most of the students (92.4%) strongly felt that PBL helped in self-directed learning and 87.8% wanted more PBL sessions preferably in combination with conventional learning. Interestingly, 69.3% of the students wanted a complete changeover to PBL.[8]

Kawai et al and Tiwari et al. stated that most students enjoyed case-based teaching and considered that their clinical reasoning, diagnostic interpretation and ability to think logically were improved. They observed that one advantage of this teaching strategy is that students have the opportunity to perform in-depth analyses and apply critical thinking to realistic, complex patient care situations in a safe environment. [9, 10]

Conclusion

Our study showed that small group teaching for the subject of microbiology used can promote active learning among students. Response from the students was very encouraging and that will motivate teachers to implement learner oriented strategies.

Proximal Fibular Osteotomy–A Novel Technique for Decompression of Isolated Medial Compartment Osteoarthritis Knee

Vishesh Verma[1], Manjeet Singh[2], Ashwani Ummat[3], Praveen Thivari[4], Harsimarjit Kaur[5], Jasneet Chawla[6], Vineet Pruthi[6]

[1]P.G. Resident M/S Orthopaedics, [2]HOD Department Orthopaedics, [3]Professor Department Orthopaedics, [4]P.G. Resident M/S Orthopaedics, Maharishi Markandeshwar (Deemed to be University), Mullana, Ambala, [5]Associate Professor, Deptt. Anatomy, Government Medical College and Hospital, Patiala, [6]P.G. Resident M/S Orthopaedics, Maharishi Markandeshwar (Deemed to be University), Mullana, Ambala

Abstract

Introduction: Proximal Fibular Osteotomy (PFO) is removing 1-1.5 cm of FIBULA, 7 to 10 cm below its head, which provides symptomatic relief from pain of medial compartment Osteoarthritis (OA) knee. It is a procedure wherein we remove Proximal part of fibula to stop mechanical axis of knee going into further varus and hence putting a stop to progression of disease. The aim of the study was to observe and study the resultsin patients of isolated medial compartment Osteoarthritis of Knee,treated by Proximal Fibular Osteotomy.

Material and Method: The study was conducted on 36 patients amounting to 50 knee joints (male and female between the age of 50-70 years) with medial compartment OA Knee. Patients were followed up till 6 months. Medial and lateral joint space along-with visual analogue score for pain were recorded pre-operative, immediate post-operative and at final follow up.

Result: Significant improvement in mean visual analogue pain score (VAS), from 7.32 + 0.98 preoperative to 2.72 + 1.20 at the final follow up was observed (p-value <0.001). Medial joint space opening from 1.17 + 0.29 to 4.07 + 0.69 at final follow up was observed. American knee society score was divided into 2 subsets, knee score and functional score. Both of them showed significant improvements from 39.72 + 3.47 and 44.20 + 8.47 (pre-operative) to 86.58 + 10.79 and 84.60 + 8.38 respectively, at final follow up (p-value < 0.001).

Conclusion: The objective as well as functional outcome after proximal fibular osteotomy were satisfactory. With correct patient selection and meticulous adherence to basics, Proximal fibular osteotomy offers an excellent alternative to tedious and extensive procedures like High tibial osteotomy (HTO) and Uni-compartmental Knee Arthroplasty (UKA). It is specially enthralling in country like ours where everyone cannot afford expensive surgeries and are forced to live a life of misery and morbidity.

Introduction

Knee joint is one of the largest synovial joint in human body.[1] It is a complex hinge joint which consists of 3 partially separated compartments, medial and lateral tibiofemoral compartments and a patellofemoral

compartment.[1] It is the major weight bearing joint and as a result of inherent complex anatomy, subcutaneous nature with large surface area, it is prone to get affected by various traumatic and nontraumatic disorders.[2] The joint is constantly exposed to loading and bending and/or rotation acting in coupled fashion.[3] Primary osteoarthritis of knee is more common than that of the other joints[4,5] The main triggering factors for development of osteoarthritis are biomechanical due to microfracture of subchondral bone or fatigue fracture of collagen fibres.

Although it is common knowledge and observation that medial compartment is the weight bearing component and it draws upon itself 60-80% of the load, none has accurately described the reason behind this non-uniformity of load sharing.[6] The current consensus is that the weight is distributed along the mechanical axis, which due to the anatomy of the joint lies medial to the knee centre. It is evidently clear that in an osteoporotic setup, fibula delivers a lateral support to the tibia which is responsible for uneven settlement of the plateau leading to its regression [6]. This causes an axial shift of load going medially away from the medial plateau and contributes in the development of knee varus, which in turn forms a vicious cycle further accelerating the rate of progression of OA of medial compartment of knee. Taking this into consideration, fibular osteotomy alleviates the escalating load from the medial compartment and mitigate the symptoms of medial compartment OA of the knee joint.

Most of the treatment available for the disease are either too radical like joint arthroplasty or unproven like various intra-articular injections. The current gold standard TKA can reinstate anatomical alignment, provide pain relief and greatly improve functionality. But, in case of young, active patients or patients with moderate OA, it might not be taken as modality of choice. In the present study, we focused on a surgery, PROXIMAL FIBULAR OSTEOTOMY which was safe, easy to perform, wasaffordable and could postpone TKA in the subset of population with early OA knee. Short term efficacy of the procedure in terms of radiographic and clinical improvement was meticulous evaluated with a follow up of 6 months.

Material and Method

Institutional review board approval was obtained for this study vide number IEC-1095. All patients were informed about the benefits and complications of the procedure. Written informed consent was obtained from all patients in study group.

The study was conducted on 36 patients amounting to 50 knee joints (male and female between the age of 50-70 years) with medial compartment OA Knee in the Department of Orthopaedics, MMIMSR from 17-Feb-2018 to 30-Aug-2019.

Patient Selection: Inclusion criteria included symptomatic isolated medial compartment OA knees, radiographically falling into Ahlback[7] grade1 or 2, aged between 50-70 years who consented for surgery. Exclusion criteria included Post Traumatic arthritis, patello-femoral OA, Bi or Tri Compartmental OA, Inflammatory Joint Disease, patients who had history of Previous Operations or fractures around the knee joint, patients with deformity associated with tumours around the knee and patients with comorbid conditions like deranged Hepatic or Renal Functions, uncontrolled Diabetes or Hypertension. 52 patients with medial compartment OA were identified as candidates for either unilateral or bilateral PFO. Out of these 8 were lost to follow up, 5 did not consent for surgery due to unproven nature of surgery and 3 refused for any operative intervention.

Primary and Secondary Outcomes: The primary measured outcome was difference in medial joint space, pre-operatively, immediate post-operative and at final follow up. Measurements were done on weight bearing radiograph using Indian one-rupee coin (diameter 20mm) as standardisation tool. Secondary measure outcome was pain measured by visual analogue score (VAS)[8–10]. Data pertaining to age, sex, height, affected side, lateral joint space and American knee society score[11] (2 subsets, knee and functional score) were recorded at baseline, immediate follow up and at final follow up. Intra-operative data such as use of tourniquet, requirement of blood transfusion and operative time were also recorded.

Surgical Technique: Under Spinal/Epidural anaesthesia, patient was made to lie in supine position. Tourniquet was applied in all cases but inflated according to need. The knee over the affected side was prepared with an aqueous iodine-based scrub, followed by painting the part with povidone iodine solution from middle of the thigh up to the ankle and covered with sterile drapes. Fibular head palpated and marked. Level for osteotomy was then localised 7.5-8.5 cm below the

fibular head using sterile metal scale. A hypodermic needle was placed at that point and position re-confirmed under C-arm.(Figure-1a) This over-jealous approach of correct level aided in prevention of injury to the common peroneal nerve and other post-op neurovascular complications. The level for fibular cut was decided based upon guidelines in literature [12]. In patients with height less than five and half foot (165cms), cut was taken at 7.5-8cms and for those more than 165cms was taken at 8-8.5 cms.A generous 5-7 cms lateral skin incision centred over the location of hypodermic needle was given and fibula is exposed between the Peroneus and Soleus muscle. Retractors were carefully placed and gently retraced so as to avoid injury to nearby neurovascular bundle. Bone levers were avoided as they present with higher chances of neuropraxia. Multiple drill holes were done in proximal and distal margin of the segment to be resected.(Figure-1b)Osteotome used to mobilise the segment and a 1-2 cm section was removed using Kocher forceps.(Figure-1c) After resecting, open ends of the fibula were sealed off with the application of Bone Wax. Gentle thorough lavage with normal saline was done and incision was closed in layers achieving complete haemostasis. Aseptic dressing was done, followed by application of compression bandage. Patient was allowed weight bearing according to tolerance, at 1st post-op day.

Follow-up: After discharge, patients were called for follow up on post op day 12-14 for sutural removal. Then they were followed up monthly for 6 months. Data recording was done during immediate post op period (POD 2-4) and at final follow up (6 months post-op).

Statistical Analysis: Data collected was entered into Microsoft Excel worksheet and analysed statistically by using Statistical Package for Social Sciences (SPSS Inc., Chicago, IL). Mean and standard deviation was calculated for all quantitative variables for description and measures of dispersion. For normally distributed data means of two groups was compared using paired student t-test. Qualitative or Categorical variables were described as frequencies and proportions. The nonparametric test (Wilcoxon's signed rank test) was applied to analyse the VAS and KSS data.p-value less than 0.05 was considered statistically significant.

Results

The mean age of study group was 56.40. Maximum number of patients were in the age group of 50 to 60 years (72%). The study population showed a male preponderance, with males being 72% of total and females being 28%. This is against the general trend and is attributed to the subset of patients that present to the OPD, which mainly consist of daily wage workers & manual labourers. 31 patients (62%) patients were shorter than 165cms of height and 19 (38%) were taller than that. Average male height in study group was 164.6 while average female height was 152.3 cms. 22 out of 50 knees were left side (44%) and 28 were right side (56%). Tourniquet was used in 30 out of 50 patients (60%). We found no significant difference in blood loss in patients operated with or without tourniquet. Blood transfusion was not required in any of the case operated. The mean operative time for the procedure was 28.30 + 2.80 minutes (recorded from incision to closure and aseptic dressing of operative wound).

Medial joint space reduction is one of the early signs of OA before the development of osteophytes and development of deformities. The current study showed statistically significant medial joint space opening at immediate post-op as well as at the final follow up. Joint space opening at immediate post-op period was minute (1.17 + 0.29 pre-op to 1.78 + 0.37 post-op), but significant (p-value <0.001), as there were no extreme variations in the standard deviation. There was considerable medial joint space opening at the final follow up (1.78 + 0.37 immediate post-op to 4.07 + 0.69 at final follow up), p-value being < 0.001 significant). Table-1 compares current study against other landmark studies, thus cementing reproducibility of results.[6,13] It was also observed that lateral joint space reduced from 7.20 + 0.46 pre-operatively to 5.11 + 0.64 at final follow up. Patients reported excellent pain relief, even in the immediate post-operative period. The 10-point VAS score improved from 7.32 + 0.98 pre- operative to 4.64 + 1.26 immediate post-operative and 2.72 + 1.20 at the final follow up (p-value < 0.001).Table-2 shows that comparable results were obtained in other studies conducted with similar aim.

Part-1 of American knee society score(table -3) focuses on objective scoring including pain on various activities of daily living, range of motion, stability of the joint and rest pain, if any. There was significant improvement of knee score from 39.72 + 3.47 pre-op to 69.12 + 10.85 immediate post-op (p-value < 0.001). Improvement continued up-to final follow up as knee score was 86.58 + 10.79 at 6 months follow up (p-value < 0.001).Part-2 of American knee society(table -3) score

focuses on functional capabilities of the joint of patient. It includes parameters like how much is the patient able to walk without pain, whether he can climb up and down the stairs normally and functional deductions like use of crutches or walker, if any. There was improvement of functional score from 44.20 + 8.47 pre-op to 73 + 11.95 immediate post-op (p-value < 0.001). Improvement from immediate post-op to final follow up was also significant, 84.60 + 8.38 (p-value < 0.001).

After the procedure, 2 patients reported increase in pain (one out of them developed a hematoma which was eventually evacuated). EHL weakness was observed in 4 out of 50 patients and all 4 of them also reported midfoot numbness. Total 6 patients reported tingling and midfoot numbness including previous 4. 1 patient developed foot drop that resolved after 3 months post-op. Neurological complications are depicted in table-4.

Discussion

Knee osteoarthritis is a joint disorder that is very commonly encountered with an incidence of 30% in population aged more than 60 years.[14] It is reported that even in a healthy knee, medial compartment bears around 60-80% of the total load. This is why early changes of OA are encountered most commonly in this compartment. Treating the disease at the stage of uni-compartmental pathology hence saves the patient from debilitating complications that follow later on. Conservative modalities employed at early stages include intra-articular injection of steroids, PRP or hyaluronic acid. Various studies have shown that these modalities lead to an acceleration of disease pathology due to excessive joint loading after temporary pain relief is achieved and thus the harms out-weight pain relief in long term.[15,16] Another modality this is commonly employed at this stage are consumption of NSAIDs. PFO is a relatively cheap procedure and the economic burden is little when compared to the burden of purchasing drugs for pain relief regularly. But there is no such analysis that has been carried out to support this claim. However, there are literature challenging cost-effectiveness of conservative non-surgical modalities that included NSAIDs, bracing and intra-articular injections.[17,18] Operative Procedures commonly employed at this stage are HTO and UKA. Patello-femoral disturbances are commonly found in cases of HTO as it interferes with functioning of patellar tendon.[19] UKA when performed in expert hands give excellent improvements, but is an extensive procedure and must not be advocated in initial stages of OA.

There have been cadaveric studies that demonstrate significant decrease in medial compartment pressure after performing proximal osteotomy of fibula.[20,21] Our study confirms the efficacy and safety of the procedure in early OA knee involving isolated medial compartment. Proximal osteotomy of the fibula weakens the lateral fibular support and leads to subsequent shift of loading forces from the medial compartment more laterally, leading to decreased pain,opening of medial joint space and a satisfactory objective as well as functional recovery (as evident by improvement in knee society scores).

Although it is an easy procedure care must be taken to avoid neuropraxic injury to Common peroneal nerve or superficial peroneal nerve. 6 patients that had developed neurological complications in the study were managed with vitamin B12 and pregabalin supplementation. All 6-patient showed complete recovery in between 6 weeks to 3 months. It was observed that bone levers were used in all 6 of these patients. In our study, bone levers were used intra-operatively in 10 out of 50 patients. No patient developed such complications wherein we used langenback retractors. Although there is no clear evidence to suggest these two findings are related, it is our recommendation to make use of simple langenback retractors during the procedure.

Conclusion

The current study advocates PFO as a tool to decelerate the progression of the disease and hence help delay or even prevent arthroplasty. It provides excellent pain relief to the patient and improves function. It is by no means a replacement for knee arthroplasty and high tibial osteotomy which remain gold standard procedures in advanced knee OA. The key to the success of the PFO lies in correct patient selection and avoiding neurological complications.

Abstract

Introduction: Plantar fasciitis or calcaneus pain syndrome is the inflammation of origin of plantar fascia and the nearby perifascial structures which is attached to the medial process of the calcaneal tuberosity Histology suggests mainly degeneration rather than inflammation but fasciitis still remains more prominent in the literature. The windlass mechanism describes the biomechanics associated with plantar fascia.

Material and Method: This study included 60 patients who were divided into 2 randomized selected groups on the basis of arrival. 30(even) patients were made to do calf stretching exercises and 30(odd) did plantar fascia stretching exercises. The stretches mainly included 8 repetitions, 20 seconds each, 2 times a day and 3 times a week for a duration of 4 weeks. Data was collected and described by using independent t-test and Repeated Analysis of variance was also used.

Results: Maximum number of patients who had plantar fasciitis were in the age group 41-50 (36.6%). Both the stretching exercises were assessed with VAS, FFI and AOFAS at day 0 and every follow up i.e 1st week, 2nd week and at the end of 4th week which showed more improvement and better satisfactory outcome in plantar fascia stretching exercises than the calf stretching exercises. Range of motion showed more improvement with calf stretching exercises.

Conclusion: This study promotes the use of the tissue-specific plantar fascia-stretching protocol as the key exercise. Long-term benefits of the stretching includes a marked decrease in pain and high rate of satisfaction. This approach provides the health-care practitioner with an effective, non-invasive, inexpensive and straightforward treatment protocol.

Keywords: *Plantar Fasciitis, Calf Stretching Exercises, Plantar Fascia Stretching Exercises.*

Introduction

Plantar fasciitis or calcaneus pain syndrome is defined as the inflammation of origin of plantar fascia and the nearby perifascial structures.[1] It is a condition that can be painful, debilitating and is a frequent cause of pain in the heel and in the foot.[2,3] Plantar fasciitis is much more likely seen in obese people, prolonged standing and people with restricted flexion of their ankle.[4]

The Clinical sign of this disease is localized pain in the heel or along the entire plantar fascia to its insertion, most noticeable with initial steps after a period of inactivity and usually lessens with increasing level of activity during the day, but will tend to worsen towards

e-mail singhsingh001@yahoo.com

the end of the day. Long walks or long periods on their feet can also be uncomfortable for these patients, thus disrupting the daily routine of many people.[5-7]

The etiology of PF is multi factorial, it can develop from inflammatory or degenerative factors. It is currently thought to be secondary to myxoid degeneration, microtears within the plantar fascia, collagen necrosis and angiofibroblastic hyperplasia of the plantar aponeurosis and not due to an inflammatory process.[8] PF can also be triggered by other factors such as overload of the plantar fascia linked to intrinsic weakness in the foot, anatomical and biomechanical alterations in the plantar arch, discrepancy between the lower limbs, inappropriate footwear and alterations in the static and dynamic positioning of the Feet.[9-12]

Foot surgeons continue to debate the source and etiology of plantar heel pain, as well as the most appropriate modality of treatment.[1] According to current literature, because of the chronicity and degeneration associated with this condition it should be known as a fasciosis rather than fasciitis due to inflammation.[13]

Material and Method

This study was commenced after obtaining approval from the Institutional Ethics Committee. This experimental randomized control study was done on 60 patients who presented to the Out-Patient Door (OPD) of Department of Orthopaedics at MMIMSR, Ambala with presenting symptoms of Plantar fasciitis. Patients were diagnosed on the basis of detailed history and physical examination which mainly included the tenderness at the posteromedial aspect of the foot and the heel pad. Detailed history and local examination, basic investigations were done. Written informed consent was taken after explaining the complete procedure to the patient. Patients were informed about the disorder and about various other treatment modalities out of which the stretching exercises were mainly chosen being non-invasive and easy to perform.

This study included 60 patients who were divided into 2 randomized selected groups on the basis of arrival. 30(even) patients were made to do calf stretching exercises and 30(odd) did plantar fascia stretching exercises. The stretching exercises were done 2 times a day which included 8 repetitions 20 seconds each, 3 times a week for the duration of 4 weeks.

Procedure:

Calf Stretching Exercises: It was done by leaning forward on the wall keeping one of the knee straight & heel was kept on ground. The other leg was placed in the front, keeping the knee bent. In order to stretch calf muscles & heel cord, hips were pushed towards the wall in a balanced manner as shown in figure 2. The stretch was held for a count of 20 seconds and repeated at least 8 times in each session 2 times a day, strong pull was felt in the calf while stretching.[14]

Another method ofcalf stretching exercise in sitting position was done by applying a downward pressure at the calcaneum along with the foot in dorsiflexion. This position was maintained for the same duration.

Plantar Fascia Stretching Exercises: The patient crossed the affected leg over the contralateral leg while placing the fingers across the base of the toes, the patient pulled the toes back towards the shin until he or she felt a stretch in the arch or plantar fascia[14]. The plantar fascia-specific stretch was performed by dorsiflexing the toes with one hand (taking advantage of the windlass mechanism)[15] and palpating the plantar fascia with the other hand to ensure the tautness as shown in figure 1. The stretch was held for a count of 20 seconds and repeated at least 8 times in each session 2 times a day. It was done especially before taking the first step in the morning and before standing following a period of prolonged sitting.

Another method involved rolling a frozen can under the foot with moderate pressure for five to ten minutes at the end of each day.

Statistical Analysis: Data were described in terms of range; mean ± SD), median, frequencies and relative frequencies as appropriate. Comparison of quantitative variables between the study groups was done using independent t-test and Mann Whitney U test for independent samples for parametric and non-parametric data respectively. Repeated ANOVA was also used. For comparing categorical data, Chi square (χ^2) test was performed and exact test was used when the expected frequency is less than 5. A probability value (p value)less than 0.05 was considered statistically significant. All statistical calculations were done using SPSS (Statistical Package for the Social Science) SPSS 21 version statistical program for Microsoft Windows.

Results

A thorough analysis and follow up of the patients was done and the following is the summary of the results obtained. Maximum number of patients who had plantar fasciitis were in the age group 41-50 (36.6%).More number of females were affected by plantar fasciitis i.e. 42(70%).In this study exercise was performed by 35 left feet and 25 right feet. Both the stretching exercises were assessed with VAS, FFI and AOFAS at appropriate follow up intervals at day 0, 1st week, 2nd week and at the end of 4th week which showed improvement.

In the study Visual Analogue Scale (VAS) was used in both the stretching exercises which showed a decreasing trend at every follow up.p value was statistically significant in both the stretching exercises in VAS(p value<0.000). Plantar fascia stretching exercises proved out to be clinically more satisfactory with higher mean difference in VAS than calf stretching exercises as shown in Table 1. Range of motion was also assessed at every follow up interval which showed an increasing trend more in calf stretching exercise as shown in Table 2. Range of motion had a higher mean difference in calf stretching (35.20⊥10.23) than plantar stretching (31.67⊥9.45) and showed a superior clinical outcome. p value (<0.000) was significant in both the exercises in Range of Motion.

Ankle Hind Foot Scale was calculated in both the stretching exercises which had a better clinical outcome in plantar stretching exercise whereas p value (<0.000) was significant in both. Plantar stretching exercises turned out to be clinically superior than calf stretching exercises with higher mean difference as calculated in FFI with highly significant p value (<0.000) in both the stretching exercises.

Table 1: VAS calculated in both stretching exercises at each visit

VAS (cm)	Calf Stretching	Plantar Stretching
Day 0	6.03±0.76	7.27±0.69
1 week	4.73±0.74	5.20±0.71
2weeks	3.63±0.55	3.80±0.55
4weeks	2.87±0.78	2.47±0.51

Discussion

Plantar fasciitis is a common problem in the adult population. It occurs over a wide age range and is seen in both sedentary and athletic individuals. Although its precise cause remains unclear, the most common theory is repetitive partial tearing and chronic inflammation of the plantar fascia at its insertion on the medial tubercle of the calcaneus. Non-operative treatments for plantar fasciitis vary widely and include shoe modifications, use of prefabricated and custom inserts, stretching exercises, physical therapy, non-steroidal anti-inflammatory medications, cortisone injections, night splints, application of a cast, or any combination of the foregoing modalities.

This study was designed to compare the efficacy of plantar fascia stretching versus calf stretching exercise in patients with plantar fasciitis. This experimental randomized control study was done on 60 patients who presented to the Out Patient Door (OPD) of department of orthopedics.

In our study range of motion was calculated in terms of total motion at the ankle joint. In calf stretching exercise the mean difference at the end of 4th week follow up came out to be 35.20 which showed better clinical outcome in comparison with plantar stretch exercise in which the mean difference came out to be 31.67. However at the end of the final follow up both the stretching exercises were proved to be statistically significant in which the p value was <0.000 in both the exercises. In the study conducted by David Porter et al[16] the mean difference in range of dorsiflexion only came out to be 13.7 at the end of 4 month follow up and p value was <0.033 which was significant whereas in study conducted by Joel A. Radford[17] the mean difference was 25.8 at the end of 2 weeks follow up and p value was 0.470 which is statistically non-significant. In study conducted by Vinod Babu K. et al[18] calculated mean difference as 19.0 at the end of 2 weeks and p value <0.000.

In our study the functional outcome of the subjects was studied on the basis of Foot Function Index, the questionnaire which involves the pain sub-scale, pain scale for disability and pain scale for recreational activities. We have compared the mean difference for both plantar and calf stretching exercises at the baseline and at the end of 4th week. The mean difference for plantar stretching was 7.08 and 19.86 at baseline and follow up respectively which was significant with p value< 0.000. The mean difference for calf stretching at the baseline and at the end of 4th week follow up was 6.63 and 15.10 respectively with a significant p value of <0.000, however the clinical outcome as measured by the foot function index was more favorable for the plantar fascia stretching exercises. In other studies, conducted by Benedict F DiGiovanniet al[19] had 2 groups-A (plantar fascia stretching), B (Achilles tendon stretching exercises). The mean difference for plantar stretching exercises at 8 weeks from baseline and 2 years from baseline were 19.6 and 36 respectively with significant p value of <0.0001. The mean difference for Achilles tendon stretching exercises at 8 weeks from baseline and 2 years from baseline were 8.3 and 28.6 with significant p value of <0.0106 and <0.0001 respectively. However,

the reduction in the pain and overall satisfaction was observed earlier in the group A, who followed the plantar fascia stretching exercises, but on continuing with both the exercises results were similar and equally satisfactory in both the groups after a follow up period of 2 years.R K Jha et al[20] conducted a study in which the mean difference at the baseline of plantar stretching exercise was 25.69, Achilles tendon stretching exercise was 26.12 with a p value of <0.599, the mean difference at 8 weeks follow up for plantar stretching exercises was 14.00, for Achilles tendon stretching exercise was 16.64 with a significant p value of <0.005 and the comparison has been showed in Table 3.

In this study, to determine the functional outcome of the patients performing plantar fascia and calf stretching exercises, Ankle Hindfoot Scale (AHS) was included. The Mean value of AHS at baseline for Calf Stretching Exercise was 65.87 and at 4week follow up were 84.67 with a significant p value of <0.000. The Mean value of AHS at baseline for Plantar Stretching Exercise was 69.40 and at 4week follow up was 89.90 with a significant p value of <0.000 and along with this the subjects also reported better and earlier relief clinically with the plantar fascia stretching exercises. In another Study conducted by Hesham A.[21] the mean value at the baseline was 48.79 and at 6 months of follow up was 91.33 with a significant p value of <0.05.NeenaK.et al[22] conducted a study in which the baseline AHS mean value was 64 and at 4 weeks follow up AHS was 78 with a p value of <0.005. Casper Grin et al[23] conducted a study in which the baseline AHS mean value was 54 and 3 month follow up was 87.9 with a significant p value of <0.01 and the comparison has been shown in Table 4.

Conclusion

This study promotes the use of the tissue-specific plantar fascia-stretching protocol as the key exercise. Long-term benefits of the stretching include a marked decrease in pain and high rate of satisfaction. This approach provides the health-care practitioner with an effective, non- invasive, inexpensive and straightforward treatment protocol.

Abstract

Introduction: Sciatica is one of the most excruciating type of pain resulting due to irritation of the sciatic nerve in the lower back. Pain radiates along the distribution of the sciatic nerve in the lower limb. Lumbar disc herniation is commonly implicated as a cause of sciatica. Treatment options include initial conservative approach with epidural injection and analgesics and in patients with no relief decompression surgery performed. The short-term efficacy of the epidural injections is well established but the long-term outcome remains controversial. Even, spinal decompression surgeries have shown significant relief of symptoms at short term but in long term remain doubtful. This study attempts to compare both these treatment options in people with disabling chronic sciatic pain.

Materials and Method: This prospective randomized controlled trial conducted on 25 patients for duration of 1 year with sciatica symptoms lasting for more than 6 weeks. Complete history and examination with imaging studies was carried out with pain assessment done by using a Roland Disability Questionnaire (RDQ) and Visual Analogue Scale (VAS). Follow up Assessment of the patient's were done at regular interval of 0, 2, 4, 12, 26, 52 weeks post intervention.

Results: Of the 25 patients 12 were assigned randomly to early surgery group and 13 to epidural injection group. Immediate post-op and follow up assessment showed significant improvement in pain and disability scores for patients randomized to early surgery group with a significant difference between areas under the curve. The short-term benefit of early surgery was no longer significant by 6 months and by the end of 1 year outcomes were similar between the two groups.

Conclusion: Early surgery achieved more rapid relief of sciatica than conservative care, but outcomes were similar by one year in patients of both groups.

Introduction

Sciatica is one of the most excruciating type of pain resulting due to irritation of the sciatic nerve in the lower back. Pain radiates along the distribution of the sciatic nerve in the lower limb. It is often associated with numbness and paresthesia.[1] Sciatica results in significant morbidity resulting in loss of work days. The financial burden of chronic sciatica can also have significant effect on the quality of life. Sciatica most commonly occurs as a result of lumbar disc displacement which directly impinges on the nerve, causing irritation or inflammation of the nerve roots producing the symptoms of sciatica.[2] The most used test in opd basis which is routinely done is straight leg raise test or Lasegue's sign.[3] Treatment options include initial conservative approach with epidural injection and analgesics and in patients with no relief decompression surgery performed. The short-term efficacy of the epidural injections is well established

but the long-term outcome remains controversial. Even, spinal decompression surgeries have shown significant relief of symptoms at short term but in long term remain doubtful. This study attempts to compare both these treatment options in people with disabling chronic sciatic pain.

Materials and Method

Study Design: Randomised Control Trial

Study Duration: 1 Year

Period of Study: June 2018 – June 2019

The study was conducted tertiary care hospital in north Indian state of Haryana.

Sciatic pain was defined by the presence of a radiating pain in the lower limbs beginning in the lumbar or gluteal region and extending below the knee, with positive straight leg raising test(3) and sciatic stress test.

Inclusion Criteria:

- Age: 18 – 70 years
- Sciatic pain for more than 6 weeks not relieved with usual care
- MRI evidence of lumbar disc herniation causing nerve root compression

Exclusion Criteria:

- Cauda equina syndrome.
- Power <3/5 in any lower limb muscle group.
- Associated with other spinal disorders like Infective Spondylodiscitis, Inflammatory Spondylodiscitis, Vertebral Fractures, tumours.
- Patients with scoliosis >15 degree
- Previous lumbar spine surgery.
- Co-morbid conditions like deranged liver or renal functions or uncontrolled diabetes or hypertension.

Patients were explained about the possible treatment options including continuing usual care or epidural injection trial and decompression surgery of the lumbar spine. Patient who had consented for further surgical intervention were included in the study.

Patients were randomly assigned for spinal decompression surgery or epidural injection with random number generating method. Even numbers underwent lumbar decompression surgery, odd numbers were assigned for epidural injection.

Pain was assessed using a Roland Disability Questionnaire (RDQ) and Visual Analogue Scale (VAS)

Follow-up: Assessment of the patients were done at regular interval of day 1, 2, 4, 12, 26, 52 weeks post intervention. Physical Examination was done and assessment was using VAS and RDQ at each visit.

Results

During the study period total of 25 patients were included in the study and randomly divided into surgical and epidural injection management groups. Both groups were matched for age and sex distribution. The average age in surgical group was 46.1 yrs and there were 5 no of males and 7 no of females, where as the epidural group had 7 males and 6 females with an average age of 44.5 yrs. Mean duration of symptoms was 43.5 weeks for surgical groups and whereas for epidural group it was 44.2 weeks. Sensory loss was present in 6 patients(table 1) out of 12 in the surgical group and in 8 patients out of 13 in the epidural (table 1). Out of 12 patients evaluated in surgical group pre-operatively 1 patient had muscle power 3/5, 7 patients had power 4/5 and 4 patients had mucle power 5/5 whereas in the epidural group 8 patients had muscle power 4/5 and 5 patients had power 5/5 in the pre-operative period. In the Post-operative evaluation muscle power in the surgical group was 4/5 in 2 patients and 5/5 in 10 patients whereas in the epidural group 2 patients had muscle power 4/5 and 11 patients had muscle power 5/5 (table 2).

Mean VAS score pre-op in surgical group was 7 whereas in epidural group was 6.5 as compared to post-op at 52 weeks in surgical group was 0.7 and epidural was 0.8(figure 2). RDQ Score of the patient showed a general decreasing trendline with mean RDQ score pre-op in surgical group was 15.8 and epidural group was 15.7 as compared to post-op at 52 weeks in surgical group was 0.5 and in epidural group was 0.8 (figure 1). There was a significant improvement in both surgical and epidural group in subsequent follow-up from pre-op period but results showed similar trends in both the groups at 52 weeks follow-up i.e. The effect of decompression surgery in symptomatic relief was much more pronounced compared to epidural group in short term at 4 weeks ($p = <0.05$). Over a long term (52 weeks) both groups had similar symptomatic relief when assesed by both RDQ and VAS($p = >0.05$).

Table 1: Sensory Loss

Sensory Loss	Surgical Group	Epidural Group
Yes	6	8
No	6	5

Table 2: Muscle Power

Muscle Power	Surgical		Epidural	
	PreOp	PostOp	PreOp	PostOp
3	1	0	0	0
4	7	2	8	2
5	4	10	5	11

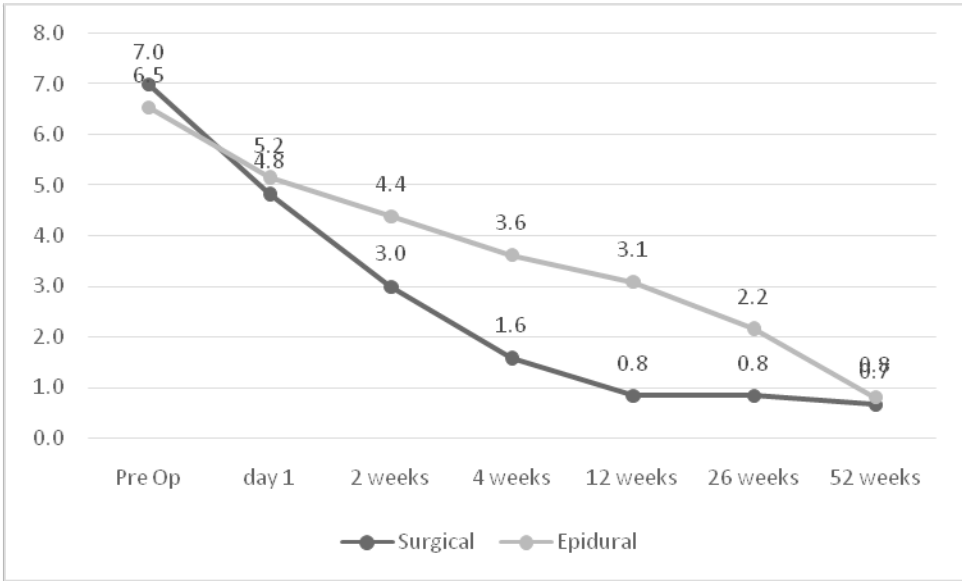

Figure 2: Mean VAS Score in Surgical and Epidural group

Discussion

Sciatic pain is said to be known to ancient Roman and Greek physicians. Hippocrates is said to be the earliest one to coin the term sciatica denoted by the greek word ischios meaning hip.[4]

20-40% of people have sciatica at some point their life commonly seen in age group of 40-60 yrs. Sciatica has high direct and indirect costs most of which are not generated by medical treatment but are attributed to loss of productivity. Range of motion, muscle power, reflexes, sensations are checked for in the patient which help to know the neurological status. Management of sciatica is divided into conservative and surgical intervention. Conservative management includes bed rest, physiotherapy, medications like NSAIDS, muscle relaxants, opioids and epidural steroid injections.[5] This was a randomized controlled trial conducted on 30 patients in a tertiary care setup. According to our study and the results obtained, The major advantage of surgical intervention for patients with sciatica is more rapid relief of leg pain, reassurance about recovery and earlier return to normal activities. There were significant benefits at 4 weeks in the surgery group as compared to the epidural injection group, however at 1 year follow up the statistically the difference between both the treatment option groups was not significant for it to be clinically meaningful. In the study conducted by Steven J Atlas and his associates in 2001, Out of the total 402 patients, 220 patients were managed with surgical intervention and 182 who were managed with non-operative interventions. The results showed that people treated surgically reported early relief of pain lasting longer in duration than those treated non surgically.[6] Although patients treated surgically had significantly greater improvement in symptoms, functional status and satisfaction than patients treated non-surgically, work disability outcomes and vas scores at end of follow up were almost similar for both the groups of patients.[6] In 2006 James Weinstein published a study on surgical versus non-operative management of low back ache and radiculopathy. A randomized trial i.e. SPORT (The Spine Patient Outcomes Research Trial) was conducted on 472 patients out of which 230 were treated surgically and 242 underwent non operative treatment. Outcome of the study was that although patients in both groups reported improvement in their symptoms, the surgically treated group had better results in their symptoms but results showed that there appear to be no substantial differences between any of these method in end of follow-up period i.e no significant statistical difference between the 2 groups of patient.[7] In 2007 a randomized study conducted on 283 patients by Wilco C Peul and his associates who had sciatica symptoms for a minimum 6weeks. They were managed by early surgery, epidural or prolonged conservative management. Out of 283 patients 141 underwent surgery and 142 treated conservatively. The outcome of this study showed that there was significant relief from pain and faster recovery in patients who underwent early operative intervention.[8]

Our study also showed results on similar trend with greater relief of pain for patients in the surgery group as compared to epidural patients. Our results however do not imply that surgery is the only preferred treatment for all patients with sciatica caused by a herniated lumbar disc. Patients with mild symptoms did well with epidural injection also. For those with moderate or severe symptoms, surgery may hasten early recovery and result in better outcomes compared with nonsurgical treatment. However, long term follow up is needed to obtain reliable data to detect a possible difference between treatment options available.

Conclusion

In general there is evidence that early surgery in patients with sciatica provides a better relief in pain as compared to epidural injection group. No significant differences were found between surgery and epidural injection group at the end of 1 year. The therapeutic role of surgery for sciatica is restricted to faster recovery and relief of leg pain. But comparing our results epidural injection might also be one of the treatment modalities to be used for patients with sciatica as it is cost-effective.

A Prospective Study to Compare the Perioperative Oral Duloxetine and Gabapentin for Postoperative Quality of Recovery in Female Patients Undergoing Lower Abdominal Gynecological Surgeries

Sapna Bansal[1], Laveena Dabla[2], K.S. Bhatia[3], Becki[4], Aiysha[4]

[1]Assosciate Professor, [2]Post Graduate Student, [3]Professor, [4]Post Graduate Student, Department of Anaesthesiology, Maharishi Markandeshwar Deemed to be University

Abstract

Background: Continuous efforts are being taken to provide better postoperative quality of recovery especially in female patients in terms of both physical and emotional parameters after surgery and anaesthesia.

Method: The present study was carried out in 70 female patients of ASA Grade I & II between the age group of 20-50 years scheduled to undergo lower abdominal surgery. They were randomly divided into two groups of 35 patients each to receive either table t duloxetine 60 mg or gabapentin 900 mg orally 3 hours prior to surgery and repeated 24 hours later with the same dose.

Results: Both the groups were comparable regarding mean age and weight of the patients (Table I). There was highly significant difference in both mean and median values of quality of recovery in both the groups with better scores in the gabapentin group. The mean opioid requirement in group A was 2.83±1.20 and in group B was 1.90±1.04 which was also highly significant, p value 0.0009. Regarding patient satisfaction 54.28% patients in gabapentin group showed excellent satisfaction as compared to 28.50% patients in duloxetine group, p value 0.057. Side effects were observed more in Group A

Conclusion: Gabpentin should be considered as an effective strategy for improving the postoperative quality of recovery and reducing the post-surgical narcotic consumption and related side effects.

Keywords: *Duloxetine, Gabpentin, Postoperative Pain, Quality of Recovery.*

Introduction

The recovery after surgery and response to general anaesthesia is different in either gender. Women's recovery after surgery is poor despite emerging faster from general anaesthesia.[1] It could be because of greater sensitivity for pain and multidrug associated side-effects.[2] Various pharmaceutical and regional strategies had been tested and tried to alleviate postoperative pain to improve quality of recovery.

Professor, Department of Anaesthesiology, Maharishi Markandeshwar Deemed to be University

Duloxetine is mostly used for the treatment of major depression and anxiety. It acts by inhibiting reuptake of serotinin-norepinephrine. It is also found to be useful in management of chronic pain.[3,4] It is also effective in treating perioperative as well as acute postoperative pain and also might prevent transient emotional problems associated with pain. The combination of reduced pain and better emotional status can result in better independent state thereby improving quality of recovery after surgery. All these benefits of duloxetine are attributed to its action to augment the norepinephrine and serotonin neurotransmission in descending inhibitory pain pathways of brain and spinal cord.[5]

Gabapentin, an antileptic structurally similar to g-aminobutyric-acid was earlier used an anticonvultant

in late 1980s with poor results.[6] Like duloxetine it has also showed promising results for treating chronic pain conditions and chronic neuropathic pain.[7,8] Several meta-analysis have confirmed the efficacy of gabapentin in decreasing post-operative opioid use and pain.[9,10] It exhibits its action by altering the peripheral and central response to painful stimulus by inhibiting the C fibre response to external painful stimulus.

Recently prevention and control of acute postoperative pain has become the primary aim of both anaesthesiologist and surgeons. Inadequate control of postsurgical pain can cause more physical and emotional trauma, longer stay at hospital, propensity to develop chronic pain leading to increased morbidity and poor quality of life. A number of pharmacological and non pharmacological method and techniques are being developed continuously in this field of utmost importance.[11] One such technique is use of preemptive analgesia. Here the selective drug is given to the patient hours before surgery either orally, intramuscular route or intravenously. Preemptive analgesia is thought to act by central desensitization to the painful stimulus. With this idea the present study was conducted with the objective of comparison of effect of Duloxteine with Gabapentin given orally preoperatively on quality of recovery in female patients undergoing lower abdominal gynecological surgeries.

Method

A prospective, randomized, comparative and single blinded study was carried out after ethical committee approval in 70 female patients, aged 20-50 years of ASA grade I and II undergoing elective gynecological surgery for benign diseases at a tertiary care center.

Patients were divided randomly by computer generated numbers to one of the following groups.

Group A (n=35) where patients were given table t Duloxetine 60mg orally 3 hours prior to surgery and repeated with same dose 24 hours later

Group B (n=35) where patients were given table t Gabapentin 900mg orally 3 hours prior to surgery and repeated with same dose 24 hours later

Subjects with consent refusal, ASA grade III and IV, any history of allergy to Duloxetine or Gabapentin, pregnant females, patients receiving opioids and/ or antidepressants were excluded from study. A post hoc power analysis was conducted using the software package, G Power (Faul and Erdfelder 1992). The alpha level used for this analysis was $p<0.05$ and beta was 0.20. If the post hoc analysis reveals the statistical power of 0.40, it detects a small effect size, whereas if the power exceeds 0.80 it detects moderate to large effect size. By using the parameter Quality of recovery at 24 hours, which was the primary outcome of our study, Power of the study has been calculated to be 0.96 and with an effect size of 0.90 with 10% chance of error for total sample size 70 i.e 35 each for 2 groups.

Preoperative assessment was done a day prior to surgery. Patients were informed about the study and written informed consent was taken. Patients were nil by mouth for 6 hours. On the day of surgery in the operation theatre, all standard non invasive monitors were applied and baseline values were recorded. A large bore 18G cannula was introduced and ringer lactate was started. Under all aseptic conditions an epidural catheter was put at L_3-L_4 intervertebral space with 18G Tuohy needle of combined spinal epidural set and spinal anaesthesia was provided with 15mg of 0.5%H bupivacaine by 27G spinal needle of the same combined spinal epidural set in lateral decubitus position. After confirming the appropriate level at T_6 dermatome surgery was started. All vital parameters were monitored and maintained within 30% of baseline values.

Perioperative data recorded was the subject's age, weight and ASA physical status. The Quality of Recovery-40 questions (QOR-40) were compiled by the subjects at 24 and 48 hours after the sugery. The QOR-40 scoring system was explained to all the patients and reviewed to provide accurate understanding of all questions. The questions evaluate 5 components of patient recovery which include physical comfort, physical independence, emotional state, patient support and pain. The sum of these generates an aggregate Global QOR-40 score ranging from 40-200. Pain scale by NRS {0-10} and side effects were noted at interval of 1, 2, 4, 8, 12, 24, 36 and 48 hours. They were given epidural tramodol 100 mg diluted to 10ml with normal saline when pain was >5 NRS and postoperative nausea and vomiting (PONV) was treated with ondasetrone 4mg IV stat. Number of times the analgesia by epidural route were noted. The results were collected, tabulated and statistically analysed. A p-value was used to reject type I error. A p value 0f <0.05 was considered statistically significant. The primary outcome of our study was the QOR-40 score at 24 hours and 48 hours. The secondary

outcomes were the postoperative opioid consumption, patient satisfaction and side effects.

Statistical Analysis: Data were described in terms of range; mean ±standard deviation (± SD), median, frequencies (number of cases) and relative frequencies (percentages) as appropriate. Comparison of quantitative variables between the study groups was done using Student t-test and Mann Whitney U test for independent samples for parametric and non-parametric data respectively. For comparing categorical data, Chi square ($\chi 2$) test was performed and exact test was used when the expected frequency is less than 5. A probability value (p value) less than 0.05 was considered statistically significant. All statistical calculations were done using SPSS (Statistical Package for the Social Science) SPSS 21 version statistical program for Microsoft Windows.

Observations: Both the groups were comparable regarding mean age and weight of the patients (Table I). There was highly significant difference in both mean and median values of quality of recovery in both the groups with better scores in the gabapentin group. Total median score in the duloxetine and gabapentin group was 169 (165-173) versus 175 (171-178) at 24 hours and 187 (185-189) vs 194 (192-196) at 48 hours respectively with p value of 0.000. Opioid top-ups were required in 18 patients in Group A and 11 patients in group B. The mean opioid requirement in group A was 2.83±1.20 and in group B was 1.90±1.04 which was also highly significant, p value 0.0009. Regarding patient satisfaction 54.28% patients in gabapentin group showed excellent satisfaction as compared to 28.50% patients in duloxetine group, p value 0.057. Side effects were observed more in Group A in terms of nausea, vomiting, dizzines, headache and pruritis. The most common side effect observed was postoperative nausea and vomiting which was seen in 45.7% in Group A and 25.7% in Group B patients and was relieved with 4 mg intravenous administration of ondansetrone. Excessive somnolence was the only side effect seen with gabapentin.

Discussion

QOR-40 is evolving as a multidimensional measurement tool for assessment of recovery in patients after surgery and anaesthesia. It measures every aspects related to patient recovery in terms of physical, emotional and pain. Previously anaesthesiologists were only concerned about the adequate reversal, pain and its management. Various factors like preoperative anxiety, preoperative and postoperative pain are linked to poor quality of recovery which can be addressed by preoperative counseling and pharmacotherapy.[12] Preemptive analgesia has found to be beneficial in dealing with preoperative as well postoperative pain. Both the drugs used in our study are effective in combating anxiety and pain. Both duloxetine and gabapentin provide better quality of recovery after hysterectomy with an edge towards gabapentin. There is statistically significant difference in the median score between duloxetine and gabapentin group. Castro-Alves LJ[13] in his study found significant effect on quality of recovery in female patients after hysterectomy with duloxetine. Similar results of perioperative duloxetine were also documented by Koh IJ et al[14] regarding better quality of recovery in centrally sensitized patients undergoing knee

arthroplasty. Effect of gabapentin on quality or recovery is not studied much. In his study Martins M et al[15] found no effect on quality of recovery with gabapentin in bariatric patients. It might be due to use of single lesser dose, 75mg than required. However it has significant effect on the opioid consumption. Studies of Doha NM et al[16], Arumugam S et al[17], Melemeni M et al[18], Khan MA[19] have demonstrated the significant reduction in opioid consumption both peri and postoperatively with gabapentin when given preoperatively as preemptive analgesia. Preoperative duloxetine has also been found to be effective in reducing opioid consumption and postoperative pain when given as a part of multimodal analgesia technique or for a long period both pre and postoperatively[20,21]. In our study gabapentin group had shown significant reduction in opioid consumption postoperatively than duloxetine group. Patients in both the groups were satisfied with their treatment with 58.28% patients in gabapentin group reported excellent satisfaction as compared to 28.50% in duloxetine group. Only two patients in gabapentin group had poor satisfaction in contrast to nine in gabapentin group. Duloxetine has been known for various side effects like nausea, vomiting, pruritis and headache etc. In our study we found significant side effects in duloxetine group where as previous studies showed no or minimal side effects [21,22,]. It could be attributed to prolonged consumption of duloxetine for 1-2 weeks preoperatively in these studies or more perception of side effects in female gender in our study. Excessive sedation was the only side effect of gabapentin as reported in previous studies. Grant MC et al[23], Achuthan S et al[24] studied the protective effect of gabapentin on postoperative nausea and vomiting and stressed that it should be considered for prevention of PONV.

Conclusion

To conclude preoperative gabapentin is effective in reducing postopetative pain and improves postoperative quality of recovery in female patients undergoing lower abdominal procedures without any significant side effects. Therefore gabpentin should be considered as an effective strategy for improving the postoperative quality of recovery and reducing the post-surgical narcotic consumption and related side effects.

A Comparative Study of the Proseal Laryngeal Mask Airway (PLMA) Insertion by Three Different Technique I.E. Introducer, Digital and Stylet

Divya Vijay[1], Sapna Bansal[1], Somika Aggarwal[1], Priyam[1]

Postgraduate Student III[rd] Year, Maharishi Markandeshwar Deemed to be University

Abstract

Background: Supraglottic airway devices have been widely used as an alternative to tracheal intubation during general anesthesia. Proseal Laryngeal Mask Airway (PLMA) is an effective alternative to ETT with inflatable cuff forming pressure seal around laryngeal inlet and permitting ventilation. In view of this, the present study was undertaken to compare the different insertion techniques to insert PLMA in adult patients undergoing elective surgeries.

Methodology: Ninety patients scheduled for elective surgical procedures under general anesthesia belonging to ASA grade I and II were included in the study and were randomly divided into three groups with 30 patients in each group. In Group I (n=30), PLMA was inserted using introducer, in Group II (n=30) PLMA was inserted using digit and in group III (n=30) PLMA was inserted using stylet. Groups were compared in relation to number of attempts, insertion time, ease of insertion, orogastric tube insertion and, hemodynamic changes.

Results: The success first attempt rate for placement of PLMA was highest with introducer as compared to digit or stylet and the results were statistically significant (p=0.029). The mean time of insertion for PLMA using introducer was 27.03±4.08 seconds which was shortest whereas with digit it was highest 35.27±4.97 (p=0.000) and by using stylet 31.33±3.12 seconds. There was no change in hemodynamic after the insertion of PLMA with either technique.

Conclusion: To conclude introducer technique of PLMA insertion was best as compared to digit and stylet technique.

Keywords: *Proseal Laryngeal Mask Airway; Supraglottic Airway Device.*

Introduction

Supraglottic airway devices (SAD) have become a popular fixture filling gap between intubation and face mask. These devices cover larynx, sit in hypopharynx and provide an effective airway without intubating the trachea. The classic laryngeal mask airway (cLMA) was the first SAD invented by Dr. Archie Brain in 1981. Brain's goal was to develop device that could rapidly overcome an obstructed airway and yet be simple and atraumatic to insert. It forms a seal around larynx and permits both spontaneous and controlled ventilation.[1]

PLMA, a reusable device, which has a specially designed cuff to provide a better and more effective seal than classic LMA along with the presence of gastric drainage port which can be considered as a potential protection against aspiration.[2,3]

The drainage tube of Proseal LMA enhances seal and serves to evacuate gastric contents and decompress the stomach; thus, reducing the chances of aspiration.[4]

Corresponding Author:

There are advantages of PLMA as compare to ETT such as reduce anesthetic requirement for airway tolerance,ease of insertion by inexperienced person, improved hemodyanamic stability at induction and during emergence, minimal increase in intraocular pressure following insertion.

So, the present study was undertaken in Department of Anaesthesia, Maharishi Markhandeshwar Institute of Medical Sciences and Research Deemed to be University to compare the method of P LMA insertion by three different techniques i.e. introducer, digital & stylet.

Material and Method

The present study was conducted in Department of Anesthesiology, Maharishi Markandeshwar Institute of Medical Sciences And Research, Mullana Deemed to be University. After approval of protocol from the Institutional Ethics Committee, 90 healthy adult patients were included in the study as per following inclusion criteria

Exclusion Criteria:

- Cardiac, Hepatic and Renal diseases
- Upper respiratory tract infection
- Anticipated difficult airway (MP III and IV)
- Known uncontrolled hypertension
- Known diabetic and epileptic
- Pregnant patients
- Emergency surgeries
- Mouth opening < 2.5 cm
- Patients with increased risk of aspiration
- Obese patient (BMI>25kg/m^2)
- Cervical spinal disease
- Head and neck surgical procedures

Study Design: Randomized, prospective comparative study.

In the study, patients were randomly divided into three groups with 30 patients in each group,for insertion of PLMA by different techniques (introducer, digit, stylet) using coded sealed envelope method.

Group I (n=30): Insertion of PLMA by introducer tool. Group II (n=30): Insertion of PLMA by index finger.

Group III (n=30): Insertion of PLMA by stylet tool.

A thorough pre-anesthetic evaluation was done prior to the surgery and all the necessary routine investigations were carried out. A written informed consent was taken from every patient.

All patients were asked to fast overnight. They were pre medicated with table t alprazolam 0.25mg and table t ranitidine 150mg orally at bed time the previous night before surgery and again 2 hours prior to surgery with 1-2 sips of water.

An IV line was secured with 18G cannula and 0.9% normal saline was started. Inj. glycopyrrolate 0.2mg, Inj. midazolam 0.03mg/kg and Inj.fentanyl 1-2 mcg/kg were administered intravenously. Baseline parameters-peripheral oxygen saturation, heart rate, systolic, diastolic and mean blood pressure were noted.

Anesthesia was induced with Propofol 2.5mg/kg i/v, titrated to loss of response to verbal commands .Oxygen and Nitrous oxide (1:1) were provided via face mask and adequacy of mask ventilation was confirmed. Thereafter neuromuscular blockade was achieved with Inj. vecuronium 0.1mg/kg i/v. The patient's lungs were ventilated with a face mask for 90 seconds to allow for full relaxation of the jaw before placing the device. Appropriate size of PLMA was chosen as per group allocation of the patient. The cuff of PLMA was fully deflated prior to insertion. A clear water based jelly (KY jelly) was used for lubricating the posterior aspect of the cuff. For PLMA insertion by introducer, stylet & index finger technique and in all three group standard recommended insertion technique was followed.

For males size 4 was used, in females size 3 was used

After placement, in case of PLMA, cuff was inflated. The PLMA was then connected to the circle system of anesthesia machine and manual ventilation was started. The position of the device was confirmed by square wave capnograph trace, bilateral chest movements on gentle manual ventilation and auscultation of epigastrium and larynx.

The time interval between removing of face mask and obtaining an effective airway by square capnograph was recorded as Insertion Time. The device was fixed by taping the tube over chin according to the manufacturer's instructions. Manual ventilation was started. In presence

of partial or complete airway obstruction or a significant air leak, the device was removed and reinsertion attempted. A maximum of three insertion attempts were allowed before the device was considered as failure. An alternative device such as endotracheal tube (ETT) was used in such a situation. Number of Attempts to secure the airway was noted. The Ease of Insertion was graded as easy and difficult. If the device was placed without resistance or if any one maneuver (head hyperextension, mask rotation, finger manipulation) was required, it was graded as 'easy'. When there was resistance to insertion or more than one maneuver was required, it was graded as 'difficult'. Orogastric tube insertion was performed to confirm correct position of the distal end of the drain tube at the proximal end of oesophagus. Correct placement was decided by suction of fluid or detection of injected air by epigastric auscultation. It was graded as easy= if placed in one attempt, difficult = if placed in two attempts .

The ventilation of lung was done with tidal volume of 8ml/kg, the respiratory rate was adjusted to maintain $EtCO_2$ of 35-40 mm of Hg with inspiratory: expiratory ratio of 1:2. Anesthesia was maintained by nitrous oxide: oxygen mixture (60:40), isoflurane (0.5-0.8%) and intermittent boluses of vecuronium (0.01mg/kg) administered i/v.

After the completion of procedure, anesthesia was discontinued and residual neuromuscular blockade was antagonized with neostigmine methyl sulphate (0.05mg/kg) and glycopyrrolate (0.01mg/kg). 100% oxygen was provided on emergence and device was removed once the patient was fully awake.

The following parameters were observed:

- Number of attempts at PLMA insertion by all three different techniques.
- Insertion time
- Ease of insertion of the supraglottic device (easy, difficult & failure).
- Heart rate,vnon invasive blood pressure, arterial oxygen saturation, end tidal CO_2 level, before insertion and after insertion of PLMA by three different technique.
- Orogastric ttube insertion (easy, difficult & failed).

Result

There was no statistical significant difference with respect to the demographic profile, ASA grading and mallampati class. (Table 1-3).The insertion of PLMA by introducer in first attempt was more successful as compare to stylet and digit (p< 000.029).

The time taken for placement of PLMA in introducer was least (27.3+/-4.08) as compared to the digit and stylet. (p 0.000).The ease of insertion of PLMA was highest with introducer technique (group I) and least with group digit (group II). There was no significant statistical difference between three groups (p 0.044). (Table 4,5). Regarding the number of attempt of gastric tube there was no significant statistical difference between three groups (p 0.585).The ease of gastric tube insertion there was no statistically significant difference between three groups. (Table 6.) Hemodynamic response in three groups were comparable in terms of heart rate, systolic blood pressure, diastolic blood pressure, mean arterial blood pressure, EtCO2 and arterial saturation before and after insertion of PLMA.

Discussion

PLMA is considered a type of 'double mask', separates respiratory and gastric tracts, physically 'plugging' inside the upper esophageal sphincter (UES) and being the first SAD to offer a dedicated channel access to the gastric content.

In our study, insertion of PLMA by introducer was successful in first attempt in 93.3% cases as compared to 66.7% cases by using digits and 83.3% by using stylet. Second attempt was required in 6.7% cases in group I, 33.3% cases in group II and in 16.7% cases in group III to insert PLMA. On comparing, introducer group with digit group there was statistically significant difference (p=0.08).There was no statistically significant difference when introducer group was compared with stylet group and when digit was compared with stylet. Similarly Chen M[5] et al, concluded that the stylet and introducer groups were comparable. In contrast to our study Myatra S et al[6] study concluded that PLMA insertion with a stylet tool has a higher first attempt insertion success and superior placement than conventional introducer tool. In their study in stylet group, the stylet was introduced up to the tip of drain tube so that PLMA cuff could not fold on itself. The stylet shapes and stiffens the cuff of the PLMA which may have prevented failed pharyngeal placement and positioning. In introducer group there were failed insertions due to failed pharyngeal placement of PLMA.

Das B et al [7] found that combined IT and stylet technique is better than the digital or IT technique and no significant difference between digital or IT technique in pediatric patients without cervical spine motion.

In our study the mean time required to insert the PLMA by using introducer, digits, stylet was 27.03 ± 4.08; 35.27 ± 4.97; 31.33 ± 3.12 seconds respectively. Statistically, this result was highly significant (p0.000). Chen M et al[5] concluded that introducer is best technique as it required less time as compared to stylet ($p<0.001$). Singh C et al [51]2017, showed significant difference in insertion time .The insertion of PLMA by introducer took less time as compare to digit ($p<0.02$). In contrast with our results Myatra S et al[6] the insertion of PLMA by using introducer required more time as compare to stylet

In our study, the ease of insertion of PLMA was highest with introducer technique (group I) and least with group digit (group II). There was no significant statistical difference between three groups (p 0.044).

In our study the ease of gastric tube insertion was statistically non significant (p value 0.585). In group I 93.3% had easy insertion of gastric tube while 6.7% had difficult insertion. In group II 96.7% had easy insertion of gastric tube while 3.3% had difficult insertion. In group III 90.0% had easy insertion of gastric tube while 10.0% had difficult insertion. Singh C[7] et al study was concurrent with our study showed that orogastric tube insertion success in introducer group was 100% in first attempt and in digit group the first attempt rate was 90%. Similarly study conducted by Saini S et al[8] was concurrent with our study and showed that orogastric tube insertion was 100% in introducer group while 88% success rate by using digital technique. Myatra S et al[6] in their study concluded that there were failure of insertion of gastric tube was more in introducer technique as compare to stylet group. In introducer group the PLMA tip was folded on itself where as in stylet group the stylet was inserted till the drain tube, so the PLMA cuff could not be folded.

In our study, the basal heart rate, systolic blood pressure, diastolic blood pressure, mean arterial pressure, was comparable in all three groups. There was no significant difference in change between group I, group II and group III after the insertion of PLMA by introducer, digits and stylet respectively.

The attempt rate of introducer technique was more successful and higher as compared to digital technique for insertion of PLMA because introducer use less area and provides adequate curvature and stiffness to PLMA. Moreover it directs the cuff over the oropharangeal inlet and facilitates good depth of insertion. The stylet technique can provide the curvature and stiffness to the PLMA. Thus makes it insertion easy. Hence there was no significant difference regarding number of attempt as compare to introducer technique.

The digital technique requires more skill. At many times, depth of insertion of finger in the patient's mouth may not be sufficient to place the device hence number of attempts required to insert PLMA by digits was high.

Conclusion

In conclusion insertion of PLMA by introducer technique is the best technique as compared to digit and stylet techniques in terms of least number of attempts, lesser insertion time, easy to insert, successful placement of orogastric tube and no hemodynamic changes.

Study of Drug Utilisation and Prescribing Pattern in the Department of Dermatology

Gunjeet Singh[1], Sanjeev Gupta[2], Rani Walia[3]

[1]Post Graduate Student, Dept. of Pharmacology, [2]Professor & Head, Dept. of Dermatology, [3]Professor & Head, Dept. of Pharmacology, MMIMSR, M.M. Deemed to be University, Mullana, Ambala, Haryana, India

Abstract

Skin diseases seriously impact the quality of life of an individual. It affects all age groups and its chronic nature disturbs the financial status of the sufferer and family. Periodic audit of prescription in the form of drug utilisation study is a way to improve the quality of prescription and reduces the irrational prescribing and use of drugs. The present study was done to assess the drug prescribing patterns in dermatology outpatient department.

Keywords: *Drug utilisation, Dermatology, Irrational.*

Introduction

Drug utilisation studies facilitate us to understand the pattern of prescribing drugs and their usage in a scientific manner.[1] Rational prescribing is the most desired component in the drug supply-use chain that is required to ensure the rational use of drugs and a cost-effective medical care. However, irrational prescribing and use of drugs has been reported as a global problem[2] in terms of depletion of available therapeutic resources, higher cost of treatment, worsening of existing disease condition, ineffective and unsafe treatment, iatrogenic illness and increasing resistance to antimicrobials.[3] Therefore, an effort was started in 1985 in the form of a global conference of experts at Nairobi to promote rational use of drugs.[4]

World Health Organization developed prescribing indicators and that are used globally for documentation of most important problems associated with prescribing such as poly-pharmacy, preference of prescribers for branded products, deviation from essential medicines list and overuse of costlier medicines i.e. antibiotics and injections.[5,6]

In India there is a practice of prescribing irrational combination of drugs, over use of antibiotics, multivitamins and irrational drugs. . This behavior of irrational prescribing drugs by the clinicians was due to lack of knowledge about drugs, unethical drug promotion, academic literatures, professional colleagues, commercial publicity and government regulations.[7,8]. Skin disorders have strong detrimental effect on quality life of the individuals in terms of physical, social, psychological as well as financially.[9] Dermatologists prescribed antibiotic range was almost 5% worldwide and most of the disease conditions require prolonged treatment.[10]

Method

This was a prescription based prospective cross sectional study under taken in department of pharmacology in collaboration with department of dermatology at MMIMSR, Ambala from 27th October 2017 to 30th April 2019. After getting approval from institutional ethics committee a total of twelve hundred prescriptions of patients attending department of dermatology were considered for the study. The inclusion criteria for the study included patients of all age group and both gender, first time visitors at the department of dermatology (outdoor and indoor) and

Corresponding Author:
Dr. Sanjeev Gupta
Dept. of Dermatology, MMIMSR, M.M. Deemed to be University, Mullana, Ambala, Haryana, India
e-mail: sanjeevguptadr@gmail.com

subjects who have given informed consent to access their prescription. Subjects who are not willing to give consent and patients coming on subsequent visits and for follow up were excluded from the study. The prescriptions were collected from outpatient department slip or prescription in case of outpatients, case sheets or record in case of indoor patients and from hospital medical record in case where prescriptions cannot be collected due to some unavoidable reason. The data was analyzed for demographic profile of the patient, disease pattern, average number of drugs prescribed, common class of drugs prescribed, drug dosage form and their route of administration.

Statistical Analysis: The collected data was entered in to SPSS version 24 for analysis. The descriptive analysis of categorical variables was calculated as absolute (n) and relative (%) frequencies.

Results

A total of 1200 patients attending the department of dermatology with their prescriptions were included in the study after meeting inclusion criteria. Table 1 presents the demographic data of the patients. All the study participants were in the range of age group 1 to 90 years. More than 71% of our patients were in the age group of 13-40 years. Majority of them belongs to 21-30 years. In this study, number of male patients was 697(58.1%) and number of female patients was 503 (41.9%). The male to female ratio was 1:0.39. Majority of them were married (63.8%). In the study, majority (29.4%) of the patients were housewives followed by students (29.9%), farmers (15.9%), labourers (7.3%), shopkeepers (6.8%) and least 0.1% were accountant and zamindar in each respectively.

Table 1: Demographic data of the patients.

Variable	Number (N)	Percentage (%)
Age Group in Years		
≤12	53	4.4
13-20	246	20.5
21-30	358	29.8
31-40	245	20.4
41-50	147	12.2
51-60	93	7.8
>61	58	4.8
Sex		
Male	697	58.1
Female	503	41.9
Marital Status		
Married	765	63.8
Unmarried	435	36.2
Occupation		
Accountant	1	0.1
Army	2	0.2
Businessman	14	1.2
Carpenter	5	0.4
Employee	25	2.1
Farmer	191	15.9
Housewife	353	29.4
Labourer	87	7.3
Not applicable	31	2.6
Retired	7	.6
Shopkeeper	81	6.8
Student	347	28.9
Teacher	26	2.2
Worker	29	2.4
Zamindar	1	0.1

As shown in Figure 1, dermatophytosis (52.3%) was the most common skin disease noticed in the patients followed by scabies (12.8%), eczema (5%), urticaria (4.7%) and acne (4.5%). Very small percentage of patients had psoriasis (1.4%), folliculitis (0.8%), dermatitis (0.5%), eczema (0.5%) and others but these were relatively uncommon.

Table 2 shows the analysis of number of drugs prescribed per prescription. A total of 3915 drugs were prescribed. The average number of drugs prescribed per prescription was 3.26. Analysis of polypharmacy showed maximum 6 and minimum 1 drug was prescribed. Majority of study participants 672 (56.0%) received 4 drugs followed by 3 drugs in 255 (21.3%) participants.

Table 2: Analysis of the number of drugs prescribed per prescription (n=3915).

Number of Drugs/ Prescription	Number (N)	Percentage (%)
One	13	1.1
Two	211	17.6
Three	255	21.3
Four	672	56.0
Five	45	3.8
Six	4	0.3

In our study, total of 3915 drugs were prescribed in 5 different dosage forms. The most common dosage

form, prescribed was a table t (63.7%) followed by cream (21.1%) and lotion (12.7%) and other dosage forms like capsule (2.3%) and syrup (0.1%) were very less in the prescribed drugs.

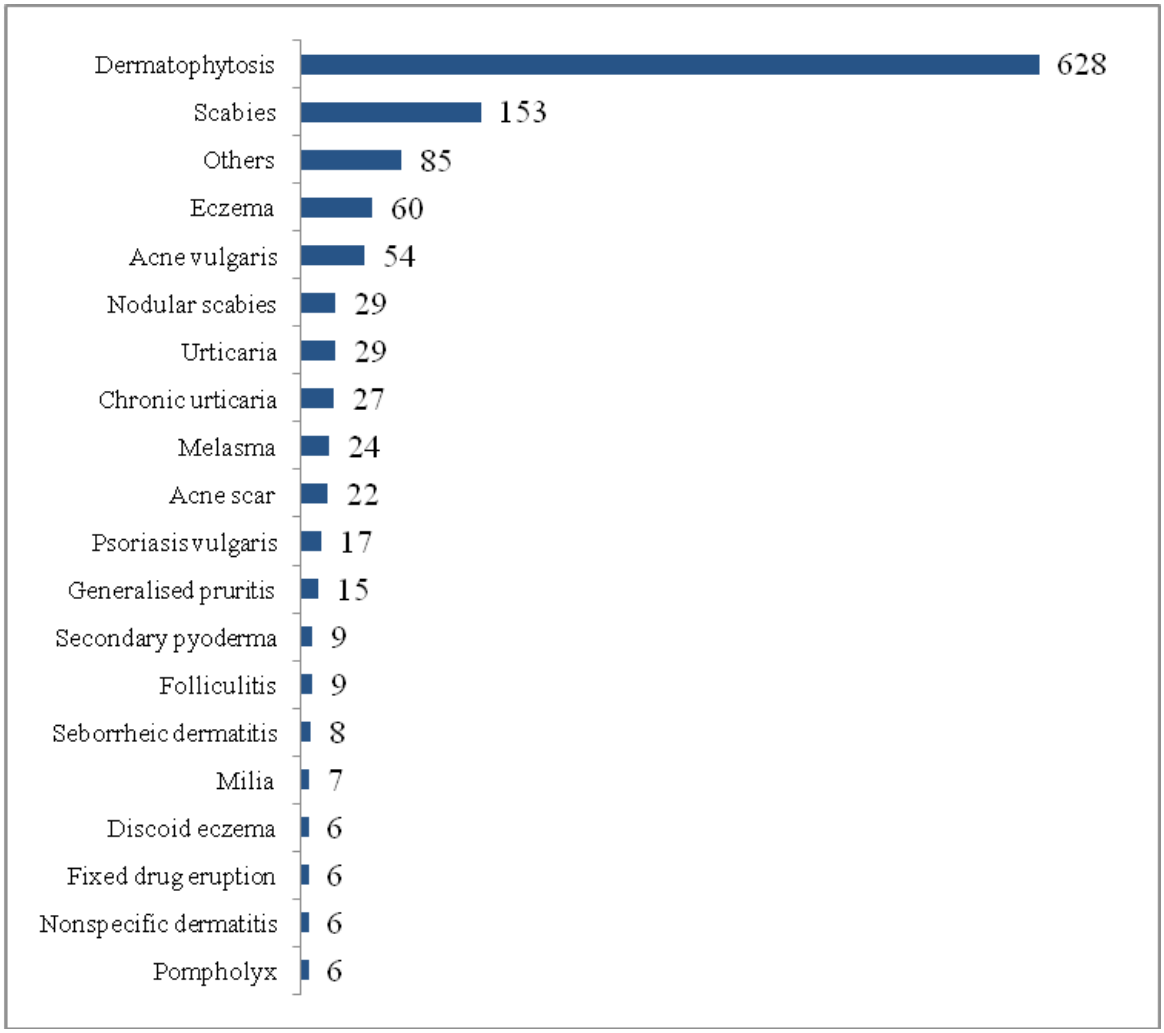

Figure 1: Distribution of patients as per the disease condition.

Table 3: Analysis of various dosage forms in the prescribed drugs (n=3915).

Dosage form	Number (N)	Percentage (%)
Tablets	2496	63.7
Capsule	90	2.3
Syrup	5	0.1
Creams	826	21.1
Lotions	498	12.7

As shown in Table 4, antihistaminics(39.8%)were the most common drugs prescribed (39.8%). Among antihistaminics, hydroxyzine (49.3%) was common followed by cetirizine (45.3%), Ebastine (4.5%), bepotastine (0.7%) and levocetrizine was less commonly used (0.2%).

Antifungals (31.2%) were the second most commonly used drug. Among oral antifungals terbinafine is the commonly prescribed drug (89.5%) followed by itraconazole (9.8%) and among topical agents luliconazole (75.5%), miconazole (12.2%) and cicloprix (4.5%) were used in the form of creams and ketoconazole (4.7%) in form of lotion.

Fixed drug combinations (9.1%) were used in both oral and topical route. Among oral route montelukast and levocetrizine was the most prescribed combination (96%) and through topical route clobetasol and gentamycin cream (48.9%) was the commonly prescribed medication.

Antibiotics (3.5%) were used in both oral and

topical route.Topical corticosteroids were prescribed more frequently compared to oral drugs. Among antihelmintics, oral Ivermectin was the drug prescribed in few cases (n=40). Antivirals and antifibrinolytics were given in each 0.2% cases. Immunosuppressants were prescribed in 0.3% cases. Other miscellaneous drugs in the form of topical agents were prescribed in 11.1% cases. Other drugs used are multivitamins (2.7%) and injectable antineoplastics were prescribed in one case.

Table 4: Distribution of various drug groups and their routes of administration.

Drug Groups	Oral N (%)	Topical N (%)	Injectable N (%)	Total
Antihistamines	1558 (99.9)	2 (0.1)	-	1560 (39.8)
Antifungals	585(47.7)	641(52.3)	-	1226 (31.2)
Miscellaneous	-	435 (100.0)	-	435 (11.1)
Fixed Drugs Combinations	226 (65.7)	131 (10.0)	-	357 (9.1)
Antibiotics	70 (50.4)	69 (49.6)	-	139 (3.5)
Multivitamins	102 (95.3)	-	5 (4.7)	107 (2.7)
Anthelmintics	40 (100.0)	-	-	40 (1.0)
Corticosteroids	9 (34.6)	14 (53.8)	3 (11.5)	26 (0.7)
Immunosupressants	6 (50.0)	6 (50.0)	-	12 (0.3)
NSAIDS	5 (62.5)	3 (37.5)	-	8 (0.2)
Antivirals	6 (100.0)	-	-	6 (0.2)
Antifibrinolytics	3 (42.9)	4 (57.1)	-	7 (0.2)
Antineoplastic	-	-	1 (100.0)	1 (0.0)
Total	**2610 (66.5)**	**1305 (33.3)**	**9 (0.2)**	**3924 (100.0)**

Discussion

A prescription is a valuable source of data to analyse the attitude and knowledge of the prescribers in treating a disease condition rationally using pharmaco-therapeutic approach bearing in mind the patient's physical and financial conditions.[11] In our study, the total number of patients attending OPD dermatology was 1200 including only new patients with one visit. In the present study, the percentage of male patients (58.1%) visiting the dermatology department was higher when compared to female patients (41.9%). This was comparable to previous studies by Gambre et al, Jena et al and Bhagawati et al, where the percentage of male (58.7%; 56.6%; and 52.27%) outnumbered the percentage of female patients (41.34%, 43.3% and 47.73%) of total 600, 719, 449 and 238 prescriptions respectively. One of the possible reasons could be that most of the female in our study (29.4%) and in India were housewives, who are financially dependent.[12-14].

Majority of the patients in our study belonged to the age group 13-40 years (>71%) and the maximum number of patients (29.8%) belonged to age group 21-30 years. This was in line with the study by Sajith et al.[15] According to his study, out of 320 prescriptions, a maximum number of patients (38.8%) belonged to the age group 20-30 years of age.

Majority of the patients in our study group were married (63.8%) and the findings were similar to Bandyopadhyay findings.[16] Also, the majority were housewives (29.4%) followed by students (28.9%) and farmers (15.9%). Since, the study was conducted in one of the best medical university, located in Mullana, a village in Ambala district, most of the participants were housewives, followed by students and farmers.

Out of 58 types of dermatologic disease noticed in our study, most of the patients visited the dermatology department for complaints of dermatophytosis, (52.3%) and scabies which is increasingly prevalent in India due to climatic condition, poor hygienic conditions, occupation type, family history, poor economic background over-crowdedness etc. Our findings were consistent with the study by Gambre et al, where the most common dermatological disorder encountered among 600 OPD prescriptions from a dermatology department of a tertiary care hospital in Mumbai, India was dermatophytosis (33.2%).[12] But study by Sajith et al

reported acne vulgaris, a common skin disorder among adolescents and young adults.[15]

For many years, transdermal route of medicinal administration has been preferred in dermatology due to sustained drug delivery, ease of administration, controlled dosage of antibiotics, low risk of side effects or drug interactions, better patient's compliance and to overcome the disadvantages of oral route such as rapid metabolism of medicines, poor bioavailability and chances of intolerance.[17] In our study, we concluded that the most preferred route of drug administration was oral (66.5%), in dosage forms such as table ts (63.7%), capsules (2.3%) or syrups (0.1%) when compared to topical (33.3%). Our findings were comparable to Pathak et albut different from Bhagawatiet al where the most preferred route was topical (49.22%).[11,14]

Prescription assessment according to WHO prescribing indices (world health organisation, 1993) reveal that the average number of drugs prescribed per prescription, was 3.26 (3915 drugs per 1200 prescriptions), with a maximum of 6 drugs and a minimum of 1 drug per prescription. This was much lesser than those reported by Kumar et al, where, the average number of drugs per prescription was 4.76.[2] However, current study findings were in line with studies by Patil et al which assessed drug utilisation pattern in OPD of dermatology wing at a tertiary hospitals in Mumbai, North-East India, Puducherry and Luthiana, where the average number of drugs per prescription was 3.27.[18]

The most commonly prescribed class of drug was antihistamine which was mostly prescribed orally followed by antifungals. Our findings were in consistent with previous studies by Patil et al which reported the most commonly prescribed class of drugs as Antihistamines followed by Antifungals with oral dosage form being the most commonly prescribed form.[18] Also our findings of the most commonly prescribed class of drug and its route of dosage were in line with studies by Bhagawatiet al, Tikoo et aland Krishna et al.[14,19,20] Out of different anti-histamines, most commonly prescribed oral H1 Anti-histamines were, Hydroxyzine and Cetirizine and similar findings were reported by Afzal Khan et al.[21]

Total percentage of oral antibiotics prescribed from the entire study group was 2.7%, which was much lesser than studies Pathak et al, assessing prescription pattern of antibiotics in Dermatology OPD in India.[11] When compared to the WHO standards of less than 40% by Suhaina et al, our study shows a lower percentage of antibiotics prescription.[22] While topical route of administration was preferred in our study, similar findings was reported by Pathak et al.[11]. Most common orally administered antibiotics was azithromycin which was consistent with the study by Kumar et al.[2]

Conclusion

The findings of the study conclude that the common skin diseases encountered in the study population was dermatophytosis and scabies which are increasingly widespread in India. These observations suggest the prescribers to consider age, economic status, occupation and family history before writing any prescription. The study also suggests the prescribers to consider factors of polypharmacy. It should be noted that comorbid condition like diabetes and hypertension should be taken into consideration while practicing polypharmacy as it not only increase financial burden, but can also cause adverse reactions, especially among elderly population

Conflict of Interest: The authors declare no conflict of interest.

Fibromyalgia: Latest Drugs for the Treatment

Shashank Shekhar Gautam[1], Gunjeet Singh[2]

[1]Senior Resident, [2]Post Graduate Junior Resident, Dept. of Pharmacology MMIMSR, MMDU, Mullana, Ambala

Abstract

Fibromyalgia is a chronic condition with unknown aetiology. Fibromyalgia is characterized by chronic widespread pain and several additional symptoms such as fatigue, cognitive dysfunction, depressive episodes and anxiety. The underlying pathophysiology of fibromyalgia is still poorly understood and treatment is often unsatisfactory. Current treatments include drugs that target serotonin and noradrenaline levels within the central nervous system, e.g., tricyclic antidepressants, serotonin noradrenaline reuptake inhibitors and voltage-gated calcium channel subunit ligands, e.g., gabapentin and pregabalin. Investigation of a range of novel targets, such as melatoninergic, cannabinoid, dopamine, NMDA, angiotensin, orexin and opioid receptors and ion channels, in addition revisiting bioamine modulation and subunits has provided efficacy outcomes that improve the health status of patients with FM. Nevertheless, modest and limited efficacy is often observed reflecting the heterogeneity of FM with existence of subpopulations of patients, the contribution of peripheral and central components to the pathophysiology and the extensive range of accompanying co-morbidities. The complexity and multidimensional nature of FM is emphasized by the diversity of pharmacological targets gaining interest. Clues to underlying mechanisms which offer themselves as novel and potential targets for new medications are being provided by advances in the understanding of the pathophysiology of FM.

Keywords: *Fibromyalgia, chronic pain,fatigue, NMDA receptors, melatonin receptors, gabapentanoids.*

Introduction

The biggest health burden at global level is chronic pain. As such chronic pain being a grave public health concern, which is affecting 14%-16% of the adult population in western countries.[1-3] The percentage of people suffering on account of chronic pain at global level is between 30%-40%.[4] According to a survey it was found that number of adults suffering from chronic pain in India are between 18%-20%.[5] Irrespective of huge advancements in the management of chronic pain conditions, there is a section of these individuals for which pain management still remains a gruesome problem. A large number of data suggests that dysfunctions arising from spinal cord and brain are the most common causes of the failure to the treatment of chronic pain.[6,7] One of the most commonly affecting chronic pain condition at global level being fibromyalgia.[8,9] Fibromyalgia (FM) is a chronic wide spread musculoskeletal pain and tenderness, along with neuropsychological symptoms like – anxiety, sleep disturbance, generalised fatigue, stiffness, impaired cognition and depression. FMis more common among female as compared to males with a ratio of 9:1.[10] In this paper we will review current and upcoming treatment strategies for the treatment of fibromyalgia.

Current Treatment Strategies: The treatment of FM can be divided into two therapeutic approaches– pharmacological and non-pharmacological but this article emphasises on the pharmacological bases for the treatment of fibromyalgia. As fibromyalgia has a strong association with various neuropsychological symptoms therefore suppression of excitatory neurotransmitters release makes it a noticeable pharmacological property for the treatment of fibromyalgia. Various classes of

Corresponding Author:
Dr. Shashank Shekhar Gautam
Senior Resident, Dept. of pharmacology, MMIMSR, MMDU, Mullana, Ambala
e-mail: shanky2386@gmail.com

drugs currently being used for the management of fibromyalgia are– anti-depressants like amitriptyline and cyclobenzaprine; serotonin noradrenaline reuptake inhibitors like milnacipran, duloxetine; selective serotonin reuptake inhibitors like fluoxetine, paroxetine; voltage-gated calcium channel subunit ligands like gabapentin and pregabalin and weak opioid and serotonin-noradrenaline reuptake inhibitor.[11-13] All these drugs focused on reducing pain, anxiety and fatigue and improving sleep in patients with fibromyalgia. The main limitation of the efficacy of current treatment is worsened by the increasing incidence of adverse effects leading many patients to discontinue the therapy.

Novel drugs undergoing clinical trials or completed trials for potential treatment of fibromyalgia:

Drugs	Mechanism of Action	Domains
ASP0819[14]	Calcium-activated potassium channel openers	Pain
NYX-2925[15]	NMDA receptor modulator	Pain
Dextromethorphan[16]	Uncompetitive NMDA Receptor Antagonist and Sigma-1 Receptor Agonist	Pain
Milnacipran[17]	SNRI	Pain, cognition
ASP8062[18]	$GABA_B$ receptor agonist	Pain, sleep disturbance and fatigue
EMA401[19]	Angiotensin 2 receptor antagonist	Pain
Suvorexant[20]	Orexin receptor antagonist	Sleep, insomnia, pain

Conclusion

The goal of this review was to provide an overview of the recent updates in the treatment of fibromyalgia. Fibromyalgia is a complex chronic pain condition where current and emerging pharmacological therapies suppress the central hyper-excitability associated with the pathophysiology. A diversity of pharmacological targets and mechanisms such as bioamine modulation, subunits, NMDA receptors, melatonin receptors and cannabinoid receptors, has been identified at which drugs act to demonstrate effectiveness in the management of the symptoms of FM. Although efficacy has been demonstrated by many of the drug treatments discussed leading to improved health status in patients with FM, outcomes related to individual mechanisms of action were not always consistent and not all symptoms were controlled by a single drug. The modest and limited efficacy often observed may reflect the heterogeneity of FM with existence of subpopulations of patients, the contribution of peripheral and central components to the pathophysiology and the extensive range of accompanying co-morbidities. Although the optimal treatment approach would be drug monotherapy, the complexity and multidimensional nature of FM emphasizes the need for a pharmacology targeting multiple molecular mechanisms. In addition to biological variables psychological and social factors have been identified to contribute to the complexity of FM supporting consideration of a biopsychosocial model. Nevertheless, clues to underlying mechanisms as novel and potential targets for new medications are being provided by advances in the understanding of the pathophysiology of FM.

A Study on Delay in Giving the Early Morning Sample and Barriers in Accessing Sputum Smear Microscopy Services at Tertiary Care Hospital

Abhishek Chauhan[1], Jai Kishan[2], Sameer Singhal[3], Achhar Singh[4], Aditi Gupta[5]

[1]Resident, [2]Prof. and Head, [3]Professor, [4]Associate Professor, [5]Assistant Professor, Department of Respiratory Medicine, M.M. (Deemed to be) University, Mullana, Ambala, India

Abstract

Sputum examination is the most widely used test for diagnosis of TB. Under RNTCP two samples of sputum are required for examinations which are preferably 1st spot and early morning sample or two spot samples collected on the same day. Patients usually come from far off places at the tertiary care centre and frequent visits are usually not possible. Giving an early morning sample is usually defaulted by the patient due to various reasons. The present study was aimed at studying the delay in giving the early morning sample and barriers in accessing the sputum smear microscopy services at a tertiary care hospital. In this study 300 presumptive TB patients were studied. Patients were asked to give a 1st spot sample for sputum smear examination and asked to bring early morning sputum sample. Patients who refused to give early morning sample were asked to give 2nd spot sample and the reason for not coming early morning were noted. The patients who did not come despite agreeing to come were noted. If they came after a delay of few days, then also the reason of delay were noted. It was found that nearly one third (31%) of the patients agreed and came on the next day to give early morning sample. A large number of patients (16%) did not come at all to give the early morning sample.

Keywords: *Pulmonary tuberculosis, presumptive TB patient, sputum microscopy, spot sample, early morning sample, RNTCP.*

Introduction

On world TB day on 24th March 2014, WHO has urged the countries to find, treat and cure the 'missing' million 1 million patients who are not getting the TB services, so that the progress towards 'Zero' TB mortality, infection, sufferings and stigma is accelerated[1,2].

A presumptive Pulmonary Tuberculosis patient may have any of the symptoms like fever of more than 2 weeks, cough of more than 2 weeks, loss of appetite, loss of weight, haemoptysis or any abnormality in the chest X-Ray or HIV patient and contact of sputum positive patients cases having cough of any duration. Sputum smear microscopy is the most commonly used method for diagnosis of TB[3,4] In RNTCP two method are currently used; one is by ZN staining based microscopy using a regular microscope and secondly is LED based fluorescent microscopy (LED FM)[5]. Under RNTCP the medical officers of the health care facilities should find out all the presumptive TB patients from those attending the health care facilities and refer them for examination to the designated microscopy centre. In medical colleges and other hospitals too the patients should be referred by the treating physician using the RNTCP laboratory request form[6].

Earlier there was a provision of testing three samples of sputum. Several studies have shown that screening of tuberculosis using two samples for testing

Corresponding Author:

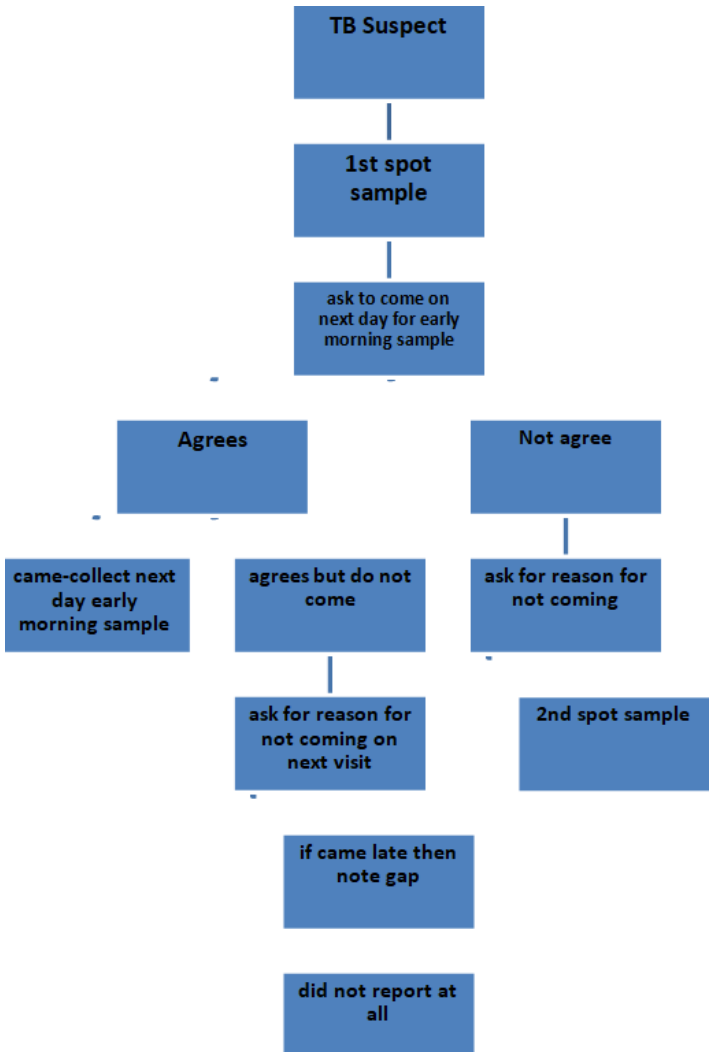
Prof. and Head, Department of Respiratory Medicine, M.M. Deemed to be University, Mullana, Ambala, India
e-mail: jaikishantb@gmail.com

is as effective as testing three samples[7,8,9,10,11]. Under RNTCP for sputum smear microscopy two samples are collected within a day or two consecutive days. One spot sample is collected on the spot under the supervision while other sample is collected early in the morning[12]. Patient is asked to come back with the early morning specimen on the next day. If patient refuses to come next day to give the early morning sample then there is the provision to give a second spot sample on the same day. Some patients do not report back for early morning sputum specimen examination due to various reasons. So in this present study we planned to study the delay in collection of the sputum smear various reasons given by the patients for the delay.

Material and Method

This study was conducted in the department of Respiratory Medicine. The presumptive TB patients coming to OPD of respiratory department of MMIMSR, MM(D)U Mullana during one year were taken up for study after taking informed consent. A total of 300 cases were studied. A detailed history was taken followed by clinical examination. Relevant blood and radiological investigations were also advised. Subsequently they were advised to collect two sputum samples for microbiological examination. Patients were asked to give the 1st spot sample and were asked to come the next day to give early morning sample. Patient who refused to come the next day were offered 2nd spot sputum examination and reasons for refusal to come next day were noted. A note was also made of patients who did not come on the next day to give the early morning sputum specimen despite agreeing to come and the reason for not coming were recorded. If the patient came late with early morning sample despite agreeing to come on the next day, then the number of days in gap were noted along with their reason for coming late. Note was also made of the patients who did not come at all after a duration of one month.



Findings:

Table 1. Distribution of cases as per Age group

Distribution of Cases as per Age group		
Age Group	**N**	**%**
< 20 years	21	7%
21-30 Years	68	22.7%
31-40 years	53	17.7%
41-50 years	59	19.7%
51-60 years	55	18.3%
61-70 years	37	12.3%
>70 years	7	2.3%
Total	**300**	**100%**
Mean ± SD	43.05 ± 15.96 Years	

Table 2. Distribution of cases according to schedule of early morning sample

Distribution of cases according to schedule of early morning sample		
	N	**%**
Refused to come	95	31.6%
Came Next Day	93	31%
Came after Gap of some days	64	21.3%
Did not Come despite agreeing at all	48	16%

Table 3. Distribution of cases according to reason for refusal to come for early morning sample

Reasons for refusal to come next day to give early morning sample		
	N	**%**
Lack of money	7	7.4%
Loss of wages	4	4.2%
Distance from hospital	19	20%
Lack of time	21	22.1%
Lack of transport	9	9.5%
No one to accompany	18	18.9%
No leave from employer	4	4.2%
Social function	4	4.2%
Other	9	9.5%
Total	**95**	**100%**

Table 4. Reasons for not coming next day or coming late to give early morning sample despite agreeing to come

Reasons for not coming on next day/coming late despite agreeing to come		
	N	**%**
Lack of money	2	3.1%
Loss of wages	12	18.7%
Distance from hospital	18	28.1%
Lack of time	7	10.9%
Lack of transport	5	7.8%
No one to accompany	9	14.0%
No leave from employer	2	3.1%
Social function	2	3.1%
Other	7	10.9%
Total	**64**	**100%**

Table 5. Distribution of cases according to number of days lapsed for follow up

Number of Days	No of Patients
Next Day	93
1	12
2	8

11	3
12	3
13	1
14	3
15	1
16	1
20	1
22	1
Total	**157**

Out of total 300 patients 184(61.3%) patients were males while 116 (38.7%) patients were females. Mean age of the study population was 43.05 years. The highest proportion of population was in 21-30 years (22.7%) age group. 95 (31.3%) patients refused to come next day to give early morning sample. 93 (31%) patients came next day while 64 (21.3%) came after a period of few days. 48 (16%) patients never came despite agreeing to come. Approximately 2/3rd amongst the patients did not report the next day. Only 31% of total patients came on the next day.

The top three reasons for refusal to come on next day for early morning sample was lack of time (22.1%). Second most common reason was distance from hospital (20%)and the third most common reason was that no one was available to accompany the patient (18.9%). The top three most common reasons given by patient for not coming on the next day and coming late despite previously agreeing to come was the distance from hospital(28.1%) followed by loss of wages (18.7%) and third common reason was no one to accompany (14.0%).

Although 93 patients came on the next day 64 patients came after a gap ranging from 1 day to 22 days (although patient was followed up till 30 days before labelling as did not not come at all). 27 out of 64 patients came back with the early morning sputum sample within 3 days, while 42 patients came within a week.

Discussion

Tertiary care hospitals and medical colleges are playing a very important role in diagnosis and management of tuberculosis. 23 percent of the new smear positive cases are being detected at the medical colleges[13]. Smear positive pulmonary tuberculosis is the most common and infectious form of tuberculosis. Each case of untreated pulmonary tuberculosis can spread infection to 5-15 persons per year[14]. Thus, it is of prime

importance to rapidly detect such patients to curb the menace of tuberculosis.

Out of the study population of 300, 95 patients refused to come next day so a second spot sample was taken. Those who agreed to come (205), were asked to get an early morning sample. 93 came next day with a sample while 64 of these did not come next day but came after a gap of few days. 48 patients did not come at all despite agreeing to come. Only 31% of cases came on the next day.

The reasons for not coming were several. Among these were lack of money, loss of wages, distance from hospital, lack of time, lack of transport, no one to accompany, no leave from employer, social function etc. Among all of these, the most common reason for refusal to come as well as for coming later than next day was distance from hospital in both case and control groups. In present study, this reason may be because the institute is located in a rural area and most of the population it caters to comes from surrounding district of Saharanpur, Yamunanagar and Kurukshetra. These areas constitute a vast geographical region. Frequent visits can be difficult, time consuming and heavy on the pocket of the patient. Other common reasons were lack of time, no one able to accompany the patient. Patient may also lose wages and employer doesn't allow leave for frequent visits to hospital. This in addition to the cost of investigation and treatment is usually difficult for the patient and their family to bear. Patients of extremes of age group and women usually require someone to accompany them for the hospital visit as the tertiary care centres are situated at far off places. Frequent visits to give sample or collect reports become difficult as they do not have someone to accompany them. Sometimes patient or family members have some prior commitments or any social function which prevents them from coming for follow up to the tertiary care hospitals. Because of these reasons patients despite agreeing are unable to give early morning sample on the next day and bring the sample after a gap of few days. Patient may not receive their reports on the same day too. This causes the delay in the diagnosis. These factors also lead to increase in the cost of the treatment of tuberculosis[15]. Few new studies are thus focussing on assessing the feasibility of diagnosing pulmonary TB by examining two spot samples in one day[16].

Conclusion

Although early diagnosis of pulmonary TB patients is important to prevent the transmission to others, there are various barriers while accessing the microscopy services at tertiary care centre. The distance from the hospital is a main reason for difficulty in giving early morning samples. Patients are asked to bring early morning sample as advised by RNTCP, but many patients refuse to give the early morning sample. For such patients there is a provision to give a second spot sample. But adequate counselling can prevent early default of the patients. Efforts should be made to reduce the number of the visits to the tertiary care hospital. Frequent visits by a TB patients may also lead to spread of the infection while they are using public transport to commute. Fast tracking of TB patients may be helpful. Alternate strategies for single day diagnosis of TB should be sought for.

An Unusual Presentation of Achalasia Cardia: Mediastinal Widening

Ajit Yadav[1], Jai Kishan[2], Sameer Singhal[3], Achchhar Singh[4], Aditi Gupta[4]

[1]Junior Resident, [2]Prof. and Head, [3]Professor, [4]Associate Professor, Department of Respiratory Medicine, MMIMSR, M.M. Deemed to be University, Mullana, Ambala, Haryana, India

Abstract

Cough as symptom to diagnose achalasia cardia. Achalasia typically presents with dysphagia and regurgitation of undigested food. Diagnosis is usually performed with esophageal manometry, barium swallow before macroscopic anatomical changes appear. But sometime cough as a symptom can diagnose. We present a 45-year old women whose diagnosis was suspected with chest-x-ray showing enlargement of right mediastinum. Diagnosis was then confirmed with upper endoscopy and barium swallow.

Keywords: *Cough, Dyspnoe Achalasia; Dysphagia; Barium swallow; Heller myotomy; Pneumatic dilatation.*

Introduction

Achalasia cardia is a rare primary neuromuscular motility disorder of the esophagus due to a reduction in ganglion cells of the myenteric plexus of the lower esophagus.[1] Achalasia cardia was first described by Sir Thomas Williams in 1672. In 1929, Hurt and Rake described the disease which is due to failure of relaxation of the lower esophageal sphincter (LES) and they coined the term achalasia, means failure to relax.[2] It has an incidence of 1.6 cases/lakh population and the prevalence of 10 cases/lakh individuals. However, the incidence of achalasia cardia in India is not known due to underreporting of the cases. It affects both genders equally and can affect any age group, more commonly seen between 25 and 60 years of age group individuals.[3] The autoimmune etiology is being proposed in majority of the cases that usually follows the viral infection.[4] Since achalasia cardia is a rare disease, therefore, we report a case of primary achalasia cardia in an adult.

Case Report: A 45 years old female presented to our department with complaints of cough and dyspnoe from last 1 month. Cough without any expectoration increase while lying down supine, no diuranal variation, dyspnoe mild grade (mmrc 2) no positional variation, no history fever or haemptysis.

Figure 1: Plain X-ray showing mediastinal widening with retrocardiac mass and absent gastric air bubble

Chest x-ray suggestive of mediastinal widening right side [Figure 1]. CT chest done which suggestive of grossly distended dilated oesophagus in entire course with thickenening of lower oesophagus and GE junction likely involving adjacent cardia of stomach

with narrowing of GE junction. Wich is suggestive of achalasia cardia and possibility of GE junction malignancy and lymphoma. [Figure 2].

After this we go for barium swallow and endoscopy and finally diagnosis of achalasia cardia and treated with balloon dilation. [Figure 3].

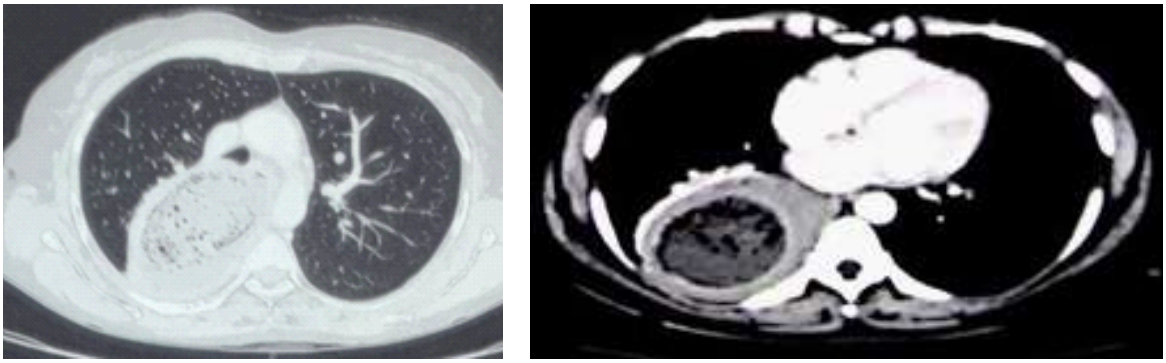

Figure 2: Computed Tomography showing dilated oesophagus without secondary involvement

Figure 3: Barium meal showing narrowing of lower end of oesophagus and dilation of the upper part, suggestive of achalsia cardia

Discussion

In a significant number of patients, the respiratory symptoms bring them to the doctor. Chronic pulmonary inflammatory conditions like aspiration pneumonitis, bronchiectasis and pulmonary fibrosis are common in these patients due to aspiration in the recumbent position.

Common causes of mediastinal widening mentioned are

Traumatic Aortic Injury

Vascular Anomalies:

- unfolded aorta
- double SVC
- aberrant right subclavian artery
- azygos continuation of the IVC
- pneumomediastinum

Lung:

- atelectasis

- pulmonary masses abutting the mediastinum
- mediastinal lymphadenopathy
- enlarged pulmonary arteries
- mediastinal lipomatosis

Masses:

- anterior mediastinal masses
- middle mediastinal masses
- posterior mediastinal masses

Thymus

Diaphragmatic hernia

Technical factors (on chest x-ray):

- rotation
- poor inspiration
- supine position
- lordotic position

As achalasia cardia not commonly presented among causes of mediatinal widening here we draw attention that symptoms of respiratory system can also leads to diagnosis of achalasia cardia and apart from thinking of malignancy as cause for cough while seeing chest xray one of rare differential should be kept in mind.

Achalasia is characterized by insufficient LES relaxation and loss of peristalsis. It is shown in less than 0.2% of all upper endoscopies. The mean age at diagnosis is usually over 50 years. Esophageal manometry is key to diagnosis.[5] Treatment options are multiple, but randomized controlled trials are few, so decisions are based on local expertise, patient performance status and patient and physician preferences.[5,6] In those patients who fit and willing to undergo surgery either a pneumatic dilation protocol or a laparoscopic surgical myotomy with a partial fun duplication as the first treatment are recommended. These techniques should be performed in high-volume centres of excellence. Laparoscopic Heller myotomy presents serious complications in There are two other alternative treatments. Botulinum toxin injection, which is recommended in patients who are not good candidates for pneumatic dilation or surgery, is a safe procedure, but over 50% relapse after 6 months, requiring multiple injections. Pharmacological treatments (calcium channel blockers, phosphodiestetase-5-inhibitor, anticholinergic agents) are the last alternative and is employed when dilation or surgery cannot be performed and when botulinum injection has failed.[6-9] Although an excess risk of carcinoma (standardized incidence ratio: 10.5, 95% CI 7.0-15.9) has been observed in operated and nonoperated patients, making upper endoscopy a first line investigation in symptomatic relapse, guidelines do not support surveillance.[6]

Conclusion

In a significant number of patients, the respiratory symptoms bring them to the doctor. Chronic pulmonary inflammatory conditions like aspiration pneumonitis, bronchiectasis and pulmonary fibrosis are common in these patients due to aspiration in the recumbent position.

A plain chest X-ray shows mediastinal widening, an air-fluid level at the arch of the aorta and a paramediastinal double stripe. The height of the air-fluid column above the cardia indicates the fluid column the LES can support. Pneumonitis or lung abscess may be seen. On barium swallow, there is absence of peristalsis, gross oesophageal dilation and failure of LES to relax. Achalasia cardia among one of rare differential diagnosis of mediastinal widening.

Abstract

Aim: study the prevalence of various risk factors and co-morbidities in patients with acute exacerbation of chronic obstructive pulmonary disease.

Material and Method: 73 patients admitted with AE-COPD data on body mass index (BMI), smoking, symptoms, co-morbidities course of the disease, spirometry management were obtained.

Results: Eighty-eight percent of the admitted patients had current or past smoking habit of 'Bidi' and 9% were cigarette smokers. of admitted patients, 46% had at least one co-morbid condition. Mean FEV1 was 42.5%.

Conclusion: Study concluded that the hospitalized patient with AE-COPD suggests spirometric impairments because majority of the patients had current or past smoking habits. Diabetes and cardiovascular diseases were found to be the major co-morbidities.

Keywords: *AE-COD, Co-morbidities, FEV1.*

Introduction

Chronic respiratory diseases which include asthma and chronic obstructive pulmonary diseases, it is responsible for an estimated burden of more than 100 million people in India.[1] Chronic obstructive pulmonary disease progresses over many decades and tends to present in advanced stages, thus most treated patients are middle aged or elderly. Chronic obstructive pulmonary disease is the fourth leading cause of death worldwide resulting in more than 2.7 million deaths in 2000.[2]

Hospitalisations due to exacerbations of COPD account for major economic costs in addition to causing disease progression.[3] The available studies[4,5] have mostly focused on risk factors for admission of stable COPD patients, external factors (e.g., air pollution) and admission[6], or prognostic factors for hospital mortality.[7-9] Spirometry is essential to make a clinical diagnosis of COPD. The presence ofFEV1/FVC less than 0.70 (post - bronchodilator) confirms the presence of persistent airflow limitation and help in making diagnosis as COPD.[10]

Observational studies with various designs have evaluated risk factors for hospitalization due to COPD. But due to paucity of the data in the present population this study was conceived to determine the various risk factors and co-morbidities in the patient's admitted with Acute Exacerbation of Chronic Obstructive Pulmonary Disease

A cross-sectional study was carried out among patients admitted over a period of one year with AE-COPD in a tertiary care hospital in Ambala, India.

Inclusion Criteria: Patients with COPD were diagnosed as per the criteria of World Health Organization-Government of India (WHO-GOI) guidelines-2003 for the management COPD.[11]

Methodology

Baseline data relating to demographics, respiratory disease history, frequency of admissions to hospital for COPD in the past one year, current respiratory medications and co morbidities was collected. Data on BMI, smoking, symptoms, disease course, other investigations, management and outcome during the hospitalization were obtained from the patient and in-patient records. Records of previous hospitalizations were also obtained. If a patient was admitted number of times during the study period, the parameters recorded during most recent admission were considered for analysis.

Statistical Analysis: The recorded data was compiled and entered in a spreadsheet computer program (Microsoft Excel 2010) and then exported to data editor page of SPSS version 19 (SPSS Inc., Chicago, Illinois, USA). Descriptive statistics included computation of percentages and mean.

Results

We collected data of 81 admitted patients over one year duration. 77 patients met the inclusion criteria for the study. Our sample comprised of 72.7% males. The demographic baseline characteristics of the patients are shown as;

Table 1: 63.8% of the admitted patients had smoking habit. of admitted patients, 46% had at least one co-morbid condition. Mean FEV1 was 41.2%. The medication histories during showed 34 (44.2%) patients were using inhaled and oral corticosteroids, respectively before admission. There were 59 (77.6%) patients on inhaled β2-agonists, out of which 18 (23.4%) were on short-acting and 41 (53.2%) were on long acting β2-agonist, respectively.

Table 2: Patients were admitted with different types of co-morbidities but 19 (24.7%) diabetes, 11 (14.3%) cardiovascular disease and 8 (10.4%) hypertension were found more common and often co-existed.

Table 1: Distribution of demographic and characteristics of the study population

Variables	
Age	59.34±4.1
Male/Female	56:21
FEV1%	41.21±6.71
Smoking habit (n=77)	49 (63.4%)
Inhaled short acting β2 -agonists	18 (23.4%)
Inhaled long acting inhaled β2 -agonists	41(53.2%)
Inhaled and oral corticosteroids	34 (44.2%)

Tables 2: Distribution of different co-morbidities in the study population

Co-morbidities	Number (N)	Percentage (%)
No co-morbidity	31	40.3
Diabetes	19	24.7
Coronary artery diseases	11	14.3
Hypertension	8	10.4
Diabetes and Hypertension	6	7.8
Tuberculosis	4	5.2
Others	2	2.6
Total	**77**	**100.0**

Discussion

This study was carried out to determine the factors associated with hospital admission among adults who were admitted with exacerbations of COPD. Our findings revealed that hospitalizations due to AECOPD were impairment of FEV1. The consistent and important association of decreased FEV1 during frequent exacerbations is well known. A low FEV1 is also a pre-eminent risk factor for mortality from COPD in most epidemiological studies.[12,13]

We believe this is the first study from northern India to gather information about associated risk factors for hospitalization due to AE-COPD. In addition, this study was done in reference to recommendation of current WHO-GOI guidelines.[11] We found various associated risk factors for exacerbations which may be useful clinically and may be considered in formulating further guidelines.

Nearly half of the patients in our study had one or more co-morbidities. Fifteen percent patients had cardiovascular related problems and 11% of patients had at least two co-morbidities. Our results also suggest that co-morbidity is a risk factor for frequent exacerbations. This was found in agreement with the study conducted

by Ball et al.[14] found that co-existent cardiopulmonary disease was a risk factor for hospitalization. Among these, diabetes may be an important risk factor for exacerbations requiring longer periods of hospitalization associated with aggressive bacterial infection.[15]

With the growing prevalence of COPD and exacerbations, there is a need for closer follow-up and precise therapeutic and preventive measures to avoid hospital admissions. The risks factors observed in the present study might find a role in decision making in the clinical management of AE-COPD and may reduce frequency of hospitalization.

Conclusion

Present study concluded that the hospitalized patient with AE-COPD suggests spirometric impairments because majority of the patients had current or past smoking habits. Diabetes and cardiovascular diseases were found to be the major co-morbidities.

Ethical approval and Informed consent: The study protocol was reviewed by the Ethical Committee of Hospital and was granted ethical clearance. After explaining the purpose and details of the study, a written informed consent was obtained from the patients who participated in the study. It was emphasized that strict confidentiality would be maintained at all times and the patients could withdraw at any time without being penalized.

Outcome of Trabeculectomy in Early Primary Open Angle Glaucoma in Respect of Retinal Nerve Fiber Layer Thickness and Optic Nerve Head Parameters

M.L. Pandey[1], Neha Sharma[2]

[1]Professor, [2]Resident Doctor, Department of Ophthalmology, M.M. Institute of Medical Science and Research, Maharshi Markandeshwar (Deemed to be University), Ambala, Haryana, India

Abstract

Introduction: Glaucoma is the group of acute and chronic multifactorial condition where lowering IOP is the mainstay of the treatment in the patients, but despite of all effort progression of disease is inevitable . The prevalence of primary open angle glaucoma (POAG) in India is 1.62% and increasing with age, where 98.5% were not even aware of the disease. In our study, we assessed the outcome of trabeculectomy using retinal nerve fiber layer (RNFL) thickness measurements and clinical parameters.

Material and Method: Twenty seven patients of primary open angle glaucoma undergoing trabeculectomy were included. Ophthalmological examinations including best corrected visual acuity, pupils and anterior segment evaluation, intraocular pressure, fundus and optic disc examination, perimetry and optic coherence tomography were performed preoperatively and 1 week, 1 month and 3 months postoperatively in each and every subject.

Results: With mean age of 57.9 years, total of 18 male and 9 female patients were recruited. IOP was decreased by 43.85% from baseline but best corrected visual acuity was increased marginally after 3 months postoperatively. Optic nerve head parameters were improved significantly. Visual Field analysis showed that mean sensitivity and mean deviation were improved from 8.73±4.5493 and 19.044±4.6111 preoperatively to 9.859±5.5606 and 17.926±5.4928 dB postoperatively, respectively.

Conclusion: Our data suggested that in early POAG, trabeculectomy provides good IOP control and clinical outcome with little complication rate under experienced hands.

Introduction

Glaucoma is the group of acute and chronic multifactorial optic neuropathies affecting retinal ganglion cell (RGC) axons leading to optic atrophy and demonstrable visual field defects. Being the second most common cause of blindness in the world, glaucoma affected 64.3 million adults (aged 40–80 years) in 2013.[1,2] The prevalence of primary open angle glaucoma (POAG) in India is 1.62% and increasing with age, where 98.5% were not even aware of the disease.[2]

Out of the multiple factors, increased intraocular pressure (IOP) is the most important and only preventable factor for decreasing vision in glaucoma[3]. Decreasing IOP is the aim in the treatment and associated with decrease rate of disease progression in POAG.[4] As a

surgical option in treatment, trabeculectomy is the well-known and preferred technique of filtering surgery for POAG to decrease IOP.[3]

Increased IOP decreases axonal outflow in RGC by mechanical pressure and cause ischemic injury to RGC. This RGC loss can be measured with retinal nerve fiber layer (RNFL) thickness and optic nerve head (ONH) parameter by optical coherence tomography (OCT). OCT can be used to measure same parameters to check treatment effectiveness and disease progression.[5]

Here, our project aimed to study RNFL and ONH parameter using OCT and automated visual field analysis before and after trabeculectomy in POAG and effectiveness of the surgery at our center.

Material and Method

Study Population: Patients diagnosed with POAG undergoing Trabeculectomy were included in the study. If both eyes require surgery then the eye with greater IOP and glaucoma progression was included in the study. Patients with optic neuropathy due to other causes than POAG, previous eye surgery, other ocular diseases, advanced stage of glaucoma, inconclusive OCT and unable to undergo surgery were excluded from the study. The study was ethically cleared by Institutional ethics committee of our institute.

Initial Assessment: Opthalmological examinations including best corrected visual acuity (BCVA), pupils and anterior segment evaluation, IOP, fundus and optic disc examination, perimetry and optic coherence tomography were performed in each and every subject.

Surgical procedure and postoperative care: Trabeculectomy was performed under local anaesthesia in accordance with standard procedures. Postoperative assessment included all preoperative parameters, slit lamp biomicroscopy and post-operative bleb examination. OCT scans, perimetry and disc photography were repeated at 1 week, 1 month and 3 months. The results were recorded and analysed.

Statistical Analysis: All statistical analyses were performed using GraphPad Prism version 7.03. Continuous variables were expressed as mean ± SD. The data collected from the study was analysed by using repeated measure ANNOVA with Bonferroni correction. P-value of <0.05 was considered significant.

Results

Age and gender distribution: A total of 27 patients were recruited in this study. The age distribution of patients in various groups. The mean age of patients was found to be 57.9 years. A total of 18 male and 9 female patients were recruited in this study. The distribution of patients on the basis of gender is depicted in Table 1.

Clinical parameter evaluation and their association: Various clinical parameters were recorded pre and post-operatively and the mean of the clinical parameters in different observational periods were used to check the association of the particular clinical parameter in different durations of observational period.

1. **Visual Acuity Test:** The visual acuity test values were found to be to slightly increase post-operatively in different observation periods but the difference was not found to be statistically significant as shown in Table 2.
2. **Intra-Occular Pressure (IOP):** The IOP values were found to be randomly decreased after 1 week of surgery and then there was a slight increase in the values after 1 month and 3 months post-operatively. The difference of IOP in the different observational periods was found to be statistically significant as shown in Table 3.
3. **Optic Nerve Head Parameters:** Various optic nerve parameters have been evaluated have been evaluated pre and post-operatively. The disc area was found to be increased upto 1 month post-operatively and then decreased and the difference was not statistically significant. The rim area showed to be marginally increased post-operatively and the difference was found to be statistically significant. The rim volume was found to be increased post-operatively upto 1 month and then showed to remain static and the difference was found to be statistically significant. The cup area showed fluctuating values. The cup volume was found to be decreased post-operatively after 1 month and the difference was statistically significant. The cup volume and cup/disc ratio values were found to be marginally decreasing post-operatively and the difference was found to be statistically significant as shown in Table 4.
4. **Peripapillary RNFL Thickness (µm):** The peripapillary RNFL thickness was measured and recorded. The peripapillary RNFL thickness was measured pre and post-operatively but there was no

statistically significant association with any of the measured parameters as shown in Table 5.

5. **Automated Visual Field Analysis:** The mean value of mean sensitivity was found to be increased from 1 month to 3 months post-operatively and this difference was found to be statistically significant. The mean values of mean deviation were found to be decreased post-operatively and this difference was statistically significant. The mean values of square root loss of variance were found to be decreased post-operatively but this difference was not statistically significant as shown in Table 6.

Discussion

Glaucoma is the heterogenous condition where lowering IOP is the mainstay of the treatment in the patients, but despite of all effort progression of disease is inevitable.[6] With increasing age, risk of POAG is increasing and in our study mean age is 57.9 years which is matching with other Indian and foreign studies.[7-9] Sex distribution M:F is 2:1 in our study which coinciding with other studies[7,8] but one south Indian cohort study reported 1:1.[9]

Different studies mentioned decrease in IOP by 38 to 56% from preoperative baseline IOP after 3

months postoperative.[5,10-12] In our study, IOP decreased by 43.85% from baseline after 3 months, which is comparative with other international studies.[5,10-12]

Hong et al suggested better visual acuity after triple procedure than trabeculectomy in POAG[10], while 3 months postoperative BCVA improvement was fair in our study but data was not statistically significant. Change in ONH parameters as depicted in Table 4 were matching with available literature.[5,10-12]

RNFL thickness was increased initially postoperative period but at 3 months postoperatively started decreasing. Increase in RNFL thickness was not significant and not correlating with clinical improvement or change in ONH parameters. Berkowska et al stated similar changes in RNKL thickness but it also mentioned that rate of change in RNFL thickness was correlating with rate of change in lamina cribrosa depth.[5]

No patients in our study was prescribed oral medications for IOP control. There was no endophthalmitis, hyphema, bleb leak or any other serious complications reported, except only one patient had hypotony postoperatively which was managed conservatively. Although our study had some limitations i.e short postoperative follow up, small number of subjects, review of literature suggested very few Indian studies providing such data.

In conclusion, our data suggested that in early POAG, trabeculectomy provides good IOP control and clinical outcome with little complication rate under experienced hands.

Axenfeld-Rieger Syndrome–A Rare Phenomenon

Kunal Sharma[1], Neha[1], M.L. Pandey[2], Vineet Gupta[3], Pankaj Saini[1]

[1]Resident, Department of Ophthalmology, [2]Professor, M.M. Institute of Medical Science and Research, [3]Assistant Professor, Department of Ophthalmology, M.M.I.M.S.R. (Maharishi Markandeshwar Deemed to be University), Ambala, Haryana, India

Abstract

Purpose: Axenfeld-Rieger syndrome is an ocular anterior segment dysgenesis, autosomal dominantly inherited, commonly associated with glaucoma and systemic anomalies. This study presents various clinical manifestations of Axenfeld-Rieger syndrome within one family.

Material and Method: Three members of the family: patient 1--father (54 years old), patient 2--son (12 years old) and patient 3--daughter (8 years old), underwent complete ophthalmic examination, including standard glaucoma diagnostics. It was impossible to perform complete eye examination in one case (patient 1) because of severity of ocular changes.

Results: All family members described had iris abnormalities (hypoplastic iris stroma) and advanced glaucoma, however severity of symptoms were different in each case. The most advanced disease was recognized in patient 1. Other findings included: posterior embryotoxon (patients 2 and 3), iridocorneal angle abnormalities (patients 2 and 3), stretch holes and extraocular features (patient 2): dental anomalies (microdontia and hypodontia), maxillary hypoplasia and periumbilical skin fold. All of these symptoms supported the diagnosis of Axenfeld-Rieger syndrome. In addition, we also diagnosed high myopia & strabismus (patient 2) and corneal scar in (patient 1).

Conclusion: Reported cases of Axenfeld-Rieger syndrome demonstrate phenotypic variability of the disease among family members, which is characteristic for this disorder and can cause diagnostic problem.

Keywords: *Axenfirldreiger syndrome, Glaucoma, Corectopia, Iris Stretch holes, Maxillary hypoplasia, dental abnormalitiies.*

Introduction

In 1920, Axenfeld characterized the anomaly which bears his name when he described posterior embryotoxon and iris strands adherent to the anteriorly displaced Schwalbe's line.[1] Rieger described patients with congenital iris abnormalities including iris hypoplasia, correctopia and polycoria, now referred to as Rieger anomaly, in 1935.[2]

Axenfled-Rieger syndrome is autosomal dominant in most cases, but it can also occur sporadically. It has complete penetrance with variable expressivity and is associated with a 50% risk of glaucoma. ARS is a genetically heterogeneous group of abnormalities as a result of mutations in at least 4 different gene loci. Mutations in PITX2 on ch 4q25, FOXC1 on 6p25, PAX6 on 11p13 and FOXO1A on 13q14 have been associated with formation of ARS.[3] Developmental anomalies of anteriorangle cause increase of outflow resistance and ocular hypertension in nearly 50%of the cases.[4] The characteristic craniofacial signslike maxillary hypoplasia, dental features including

hypodontia,oligodontia and microdontia and umbilical anomalies were also reported in ARS patients.[5]

Materials and Method

We present the clinical features & findings of a family with Axenfeld-Riegers syndrome.

Case 1-Father: A 35 year's old male was brought to us by a social activist for PKP in the month of August with corneal opacity Right eye (and phthisis left eye). The patient had a history of glaucoma since 16 years and had undergone a Trabeculectomy 2 times since then. IOP was still not controlled and patient eventually developed corneal opacity secondary to corneal decompensation. Left eye was lost in childhood due to infective keratitis. The visual acuity was PL,PR –ve. The patient underwent keratoplasty procedure. Graft clarity: Pristine clear graft I.O.P : Controlled with single Medication. VISION: F.C 2mtrs, Pt. is mobile & is now self dependent to a large extent.

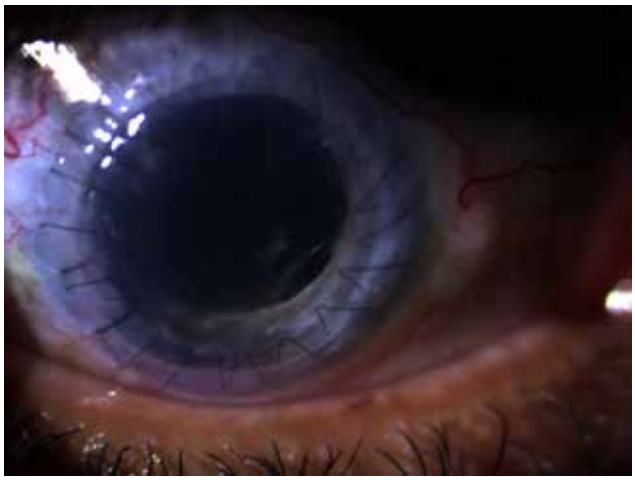

Fig 1: Keratoplasty with pristine clear graft

Case 2-Son: 12 year-old male Best visual acuity equal to 6/18 (R/E) and 6/18 (L/E).

Slit lamp evaluation revealed: Bilateral posterior embryotoxon, Iris atrophy, Corectopia, Stretch holes.

- The IOP

  R/E 51mm hg

  L/E 12 mmHg.

- On Fundus examination

  C:D ratio

  R/E 0.9

  L/E 0.3.

He was on medical management, we preferred surgical intrvention and performed trabeculectomy. And IOP is controlled without any medication now Pt is on regular follow up with us.

Fig 2: Corectopia with stretch hole in iris with posterior embryotoxn

Fig 3: Iris stretch holes

Fig 4: Maxillary hypoplasia with dental abnormalities

Case 3- Daughter: An 8 year-old female with visual acuity equal to 6/12 (R/E) and 6/9 (L/E). IOP was 17 mm Hg in both the eyes.Slit lamp examination revealed :Pseudopolycoria, iris atrophy, Embryotoxon.

General physical examination revealed:

- Maxillary hypoplasia
- Microdontia
- Diastema
- Fundus examination revealed the healthy disc with C:D ratio 0.3 in both the eyes.

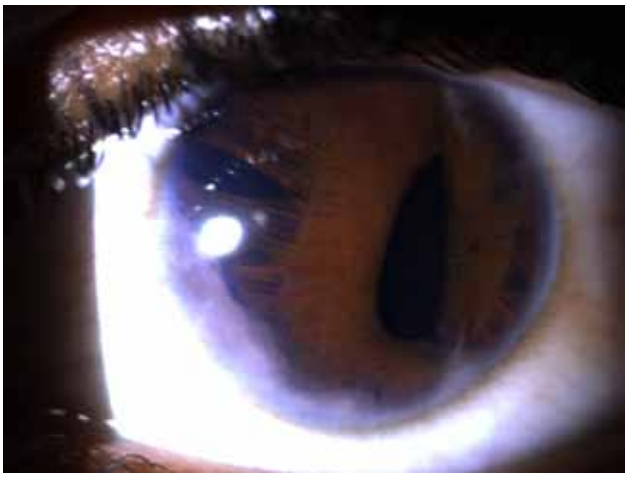

Fig 5: Pseudopolycoria, Iris Atrophy, Embryotoxon

Fig 6:

Discussion

This is a remarkable case series in which a family, including two generations presented with Axenfeld-Rieger anomaly. The trait appeared to be autosomal dominant with high penetrance (100% in this case), considering that both siblings inherited the abnormalities of the father. The mechanism of the ocular development has been widely studied and discussed. Often the factors that result in disturbance of neural crest may act at more than one phase of this process, producing anomalies that involve more than one tissue derived from neural crest. Espana et al.[6] and Parikh et al.[7] reported 2 cases with unusual presentation of detached Schwalbe line suspended in anterior chambers, respectively. Theanterior segment structure Schwalbe line has its genesis fromneural crest cells, the impaired development of which is related tothe pathogenesis of ARS may explain such clinical manifestation.[4] Hypoplasia of extraocular muscles derived from mesodermalcomplex also appeared in ARS. Bhate and Martin[8] reported a 6-year-old boy with hypoplasia of right inferior rectusmuscle presenting exotropia; while Park et al.[9] reported another4-year-old girl with more posteriorly insertion of superior obliquepresenting exotropia and dissociated vertical deviation (DVD). Since around 50% of ARS patients will develop glaucoma,conventional glaucoma surgeries like trabeculectomy andtrabeculotomy are still required. With a 20-year followup, Mandal and Pehere confirmed

the safety and effectiveness of the combination of trabeculotomy and trabeculectomy for ARS children with early-onset of glaucoma.[10] Mitomycin C(MMC) or the newly developed Ologen Collagen matrixreducing subconjunctival fibrosis may effectively lower IOP in long-term.[11-12] As to the maxillary hypoplasia and dentalanomalies of ARS, specialized oral and maxillofacial surgery,special dental care and application of orthodontic unit may be helpful.[13]

Conclusion

Two different inherited genes appearing together in an entire family may suggest a single molecular and genetic etiology, but additional studies are necessary to explain the relationship among these overlapping phenotypes and their inheritance All three family members described had iris abnormalities (hypoplastic iris stroma) and advanced glaucoma, however severity of symptoms were different in each case. The most advanced disease was recognized in Case 1.

Other findings included: Posterior embryotoxon (Case 2 and 3) Iridocorneal angle abnormalities (case 2 and 3). Stretch holes and extraocular features (Case 2): Dental anomalies (microdontia and hypodontia), maxillary hypoplasia and periumbilical skin fold. All of these symptoms supported the diagnosis of Axenfeld-Rieger syndrome. In addition, we also diagnosed high myopia & strabismus (Case 2) and corneal scar in Case 1.

Perhaps, in future, it would be possible to develop alternative therapeutic tools for the treatment of glaucoma, based on the knowledge of their etiology.

Study of Correlation of Hyperuricemia with Knee Osteoarthritis

Rajdeep Singh Bajwa[1], Rakesh Gautam[2], Subodh K. Pathak[3], Aryan Sharma[1], Vineet Pruthi[1], Vishesh Verma[1]

[1]PG Resident M/S Orthopaedics, [2]Associate Professor, [3]Assistant Professor, Department Orthopaedics, Maharishi Markandeshwar Deemed to be University, Mullana, Ambala

Abstract

The present study was conducted to identify the link between increased uric acid and osteoarthritis and to find out the prevalence of hyperuricemia in population suffering from osteoarthritis of knee.

Material and Method: The study was conducted on 100 patients (male and female between the age of 40-70 years) with knee pain for more than 6 weeks to establish a correlation between knee osteoarthritis and hyperuricemia.

Result: In the current study female preponderance was seen. Mean age of the patients was 50.10 years and maximum patients were in the age group of 40-50 years. KOA patients had higher values of uric acid as compared to patients without KOA however no stastically significant relation was found between increasing uric acid levels and severity of KOA with p-value .668 being insignificant. The mean BMI of patients with KOA was higher than the patients without KOA but no statistical significant relation was found between increased incidence of KOA in females as compared to males with increasing BMI p-value 0.777 being insignificant. There was no statistically significant correlation between hyperuricemia and either gender with p-value being >.0.05 (0.119). VAS and WOMAC scoring was done at 0 and 16 weeks however no significant improvement was seen except for the pain component which improved in KOA patients.

Conclusion: In this present study we observed increased prevalence of OA knee in females and in patients with hyperuricemia and also with patients with higher BMI. Serum levels of CRP and ESR also show positive prevalence in patients with KOA in this study. However, no s statistically significant correlation was observed between levels of hyperuricemia and severity of KOA. Hence in conclusion our study points towards positive correlation between hyperuricemia and KOA. Limitations of our study included inability to homogenise groups in terms of BMI, age, activity level, smoking, alcohol etc.

Introduction

Osteoarthtis is a disease of biomechanics. Although the increased mechanical forces initiate the cartilage damage its progression depends on cellular and biochemical factors, including chondrocyte activation and the secretion of inflammatory mediators.[1,2] A strong association has been found and well recognised for joint affected by gout, especially first metatarsophalangeal joint.[3] Uric acid (UA) is constitutively present in normal cells is found in increased concentration with cell injury or death3. The sole presence of hyperuricemia might eventually lead to increase pericellular urate levels leading local formation of crystals at the microscopic level. Thus, asymptomatic hyperuricemia might affect cartilage damage even in the absence of frank gout.[4] Unfortunately, few studies have addressed this potentially important issue and the results have been mixed. Increase

in uric acid beyond its limit of solubility can lead to MSU crystal formation, which can stimulate the NLRP3 inflammasome and promote IL-1β production which may lead to acute and sometimes chronic inflammation. MSU crystal aggregates can also directly damage the cartilage. Age and obesity can predispose to both osteoarthritis[5] and gout and hence confound the association between both conditions.[6,7] Whether serum UA may serve as a biomarker to convey or predict OA risk is not known. The present study was conducted to identify the possible link between increased uric acid and osteoarthritis and to find out the prevalence of hyperuricemia in population suffering from osteoarthritis of knee.

Materials and Method

This study was commenced after obtaining approval from the Institutional Ethics Committee vide IEC number - 1098. Study was done on 100 patients who presented to the Out-Patient Door (OPD) of tertiary care center with presenting symptoms of insidious onset of knee pain for more than 6 weeks. Patients with history of gout, rheumatoid conditions, history of previous trauma in same knee were excluded from the study. Upon presentation, patients were subjected to detailed history, relevant investigations including serum uric acid levels, ESR and CRP. Thorough general examination and knee examination with bilateral knee x-rays was done in weight bearing anteroposterior view and lateral view. The clinical severity was studied by Western Ontario Mac Master University (WOMAC) scores and the radiological severity by Kellgren & Lawrence (KL) grading of the disease. In the study serum uric acid levels were divided in to 3 groups <6, 6-8 and >8.

Statistical Analysis: Data collected was entered into Microsoft Excel worksheet and analyzed statistically by using Statistical Package for Social Sciences (SPSS Inc., Chicago, IL). Mean and standard deviation was calculated for all quantitative variables for description and measures of dispersion. For normally distributed data means of two groups was compared using paired student t-test. Qualitative or Categorical variables were described as frequencies and proportions. p value less than 0.05 was considered statistically significant.

Results

The mean age of the cohort was 50.10 years (range 40-70 years) and majority of the study population were between 40 to 55 years.Study had more preponderance of females with knee pain as compared to males (59% and 41%respectively). All the patients with Knee osteoarthritis (KOA) were graded according to severity based upon radiological finding according to Kellgren Lawrance (KL) grade, total patients in KLgrade 2 were 35%.of the total, in KL-3 were 39%.and KL-4 were 26%.

Out of 100 patients, 42 patients had hyperuricemia and 58 patients had no hyperuricemia. Out of 100 patients 31 patients had hyperuricemia with knee osteoarthritis (KOA),11 patients just had hyperuricemia with no KOA, 26 patients had KOA without hyperuricemia and 32 patients had no KOA or hyperuricemia. The study showed a significant relation between hyperuricemia and knee osteoarthritis with p-value <0.05 being significant as seen in Table 1. Increasing severity of KOA was compared to increasing uric acid levels however there was no statistically significant relationship found (p-value 0.668) as shown in Table 2.

Total number of patients with hyperuricemia in the study were 42 from which males and females were 21 each. Out of 21 female patients 18 had hyperuricemia with KOA and only 13 males had hyperuricemia with KOA implying there was increase incidence of hyperuricemia in females with KOA as observed in this study but the overall comparison was statistically insignificant($p<0.05$)(Table 3).

In the study at time of presentation BMI, ESR, CRP levels of patients were taken in to account and it was seen that mean BMI in knee osteoarthritis patient was comparatively higher being 26.54 and in patients with no radiological signs of KOA was 23.10 so signifying that patients with high BMI values were more prone to develop KOA (p-value= 0.043). However, there was no statistically significant gender predilection seen towards increasing BMI.

It was seen in the study that patients with Knee OA had mean CRP of 5.56 and mean ESR 20.84 respectively. While patients without Knee OA had mean CRP level 3.67 and mean ESR levels 15.10 respectively. The pvalue-0.001 for CRP and p-value 0.002 for ESR respectively showed that the results were statistically significant and the patients with KOA had raised levels of CRP and ESR as compared to patients with no KOA.

The overall mean WOMAC score in the study was 40.6 ± 12.5(range 21 to 69). On sub analysis patients with Knee osteoarthritis (n=57) had a mean WOMAC score of 58.2±8.4(range 42 to 68) while those without OA knee (n=43) had a mean WOMAC score of 29.7±6(range

21 to 44) (p value =0.0043). The mean WOMAC score for males with OA knee and hyperuricemia (n=13) was 53±11.8 (range 47 to 65) and that for females (n=18) was 61.2±9.6 (range 54.4 to 69) (p value =0.682). It was seen that WOMAC score was higher in patients with KOA and hyperuricemia as compared to patients with KOA without hyperuricemia and increased uric acid had positive correlation with grading of knee osteoarthritis (r=0.568) (Fig 1).

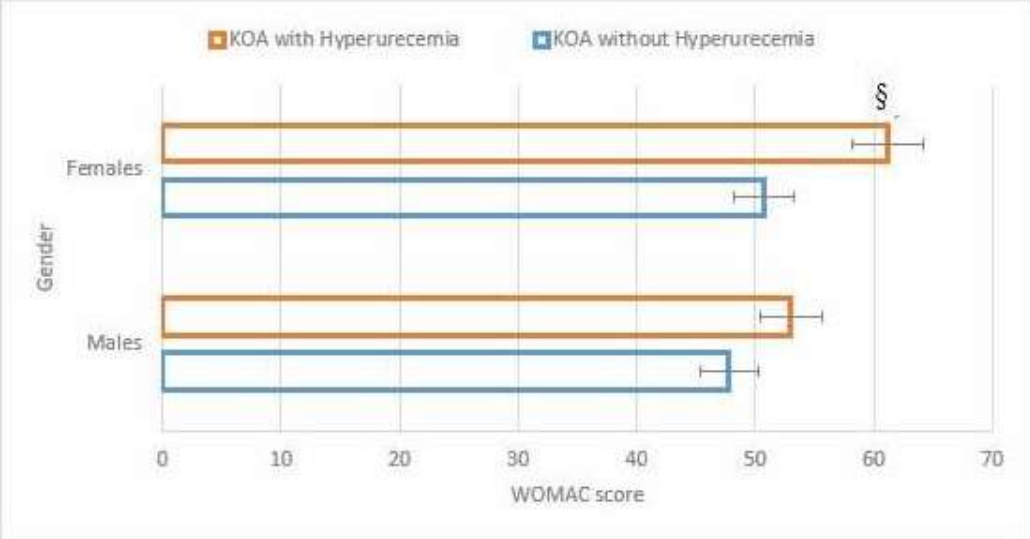

Fig. 1: WOMAC score with KOA (Knee Osteoarthritis) with and without hyperuricemia in males and females. Although differences in WOMAC score with and without hyperuricemia was seen in both males and females, Statistical significance is seen in females. • Mean statistical significance (p=0.029)

Discussion

The beginning and progression of knee osteoarthritis is determined by the surrounding environmental factors, mechanical forces, structural alteration and genetic factors.[8] Aetiology of OA still remain unclear but various factors contribute to risk and progression which include obesity, joint malalignment, trauma, age and female gender.[9] Shared pathophysiological features have been identified between crystal induced inflammation and OA recently, however the data from various studies regarding the relation between uric acid and OA still remains controversial.[10-15] One cross sectional study that used the New Haven 1960 Census identified an association between uric acid and whole body OA.[10] However, subsequent retrospective studies, including the Health and Nutrition Examination Survey, Framingham Heart Study Cohort and Chingford Study, demonstrated no association between knee OA and the serum uric acid level.[16-18] Results from different cohort studies that found that uric acid was associated with the severity or susceptibility of OA lost statistical significance after adjusting for covariates including age, BMI, or gender.[14,15] Recently, different groups have suggested that the highest tertile of uric acid level is associated with generalized OA or osteophytes in knee OA.[11,19]

The study population showed a female preponderance in the present study. Other studies had more of male preponderance. Jain et al.[20] had a study group comprising of 66.2% males and 33.8% females. Ding x et al19 had a study group which had 52.3% males and 33.8% females. Challa et al.[21] conducted a study which comprised of 67.6% males and 32.4% females, While the study by Kim et al.[22] showed a female preponderance similar to current study with 42.7% male and 57.3% females. The current study population had 59% females and males were 41%.

Study by Ding et al.[19] demonstrated out of 775 patients with hyperuricemia 72.4% were males and 27.6% were females. In the study by Sujit Jos et al.[23] out of 154 patients with hyperuricemia 78% were males while 28% were females, therefore both the studies showed male preponderance towards hyperuricemia however the current study had equal no of males (50%) and females (50%) with hyperuricemia implying insignificant correlation between hyperuricemia and either gender.

In this study there was female preponderance towards developing KOA. Study by Kim et al.[22] had total no of 669 patients with OA out of which 112(16.7%) were males and 557(83.3%) were females. Challa et al.[21] carried a study in which total number of KOA patients were 187 out of which 134 (71.6%) and 53 (28.3%) were females. In the study by Sujit jos et al.[23] out of 183 total KOA patients 131(71.6%) were males and 52 (28.4%) were females. All the studies showed male preponderance towards developing KOA but in the current study we found statistically significant distribution of gender in developing OA knee. Fifty-seven patients had OA knee out of which 39 (69.4%) were females and 18 (31.6%) were males, showing statistically significant correlation of female gender to develop KOA when compared to males (p-=0.016).

In our present study, we have observed positive correlation of presence of hyperuricemia with knee osteoarthritis. There was no statistically significant correlation between the level of hyperuricemia and the severity of osteoarthritis among the subjects. The positive correlation was also observed as high ESR and higher levels of CRP among subjects with OA knee in our study. Possible explanation of observation of positive incidence of hyperuricemia with KOA but statistical variations observed may be due to confounding factors like age distribution, BMI, menopause in female. In our study we found higher WOMAC scores in subjects with Osteoarthritisand Hyperuricemia as compared to patients without hyperuricemia. Women had higher WOMAC score for the same grade of OA as compared to male counterpart. The increase in both hyperuricemia and OA in women after menopause may point to hormonal mechanisms. Despite this limitation our study successfully points towards positive association of hyperuricemia with knee osteoarthritis warranting further evaluation.

Conclusion

We conclude that the presence of hyperuricemia, is associated with increased knee OA prevalence and severity especially in women. Measurement of serum uric acid levels is an inexpensive utility which can serve as a biomarker for osteoarthritis progression. The potential help of uric acid lowering drugs to limit OA progression requires further investigations.

How Efficacious is Esmolol in Suppressing the Stress Response to Laryngoscopy and Intubation in ENT Surgeries

Babita Ramdev[1], Dinesh Kumar Sharma[2], Sangita R. Sharma[3], Sapna Bansal[4], T. Venugopal[5], Ritu Singh[5]

[1]Associate Professor, Department of Anaesthesia, MMIMSR, Mullana, Ambala, [2]Assistant Professor, Department of E.N.T.GMC, Patiala, [3]ENT Consultant, [4]Associate Professor, Department of Anaesthesia, MMIMSR, Mullana, Ambala, [5]Post Graduate Student, MMIMSR, Mullana, Ambala

Abstract

Introduction: Attenuation of stress response during laryngoscopy and intubation has been one of the major concerns of the anaesthetist. Various techniques have been used to suppress this response like deepening the level of anaesthesia and various drugs like β blockers,local anaestheticsetc. In this study Esmolol was used to suppress the stress response.

Material and Method: 60 patients undergoing elective ENT surgery under general anaesthesia of ASA grade I and II were randomly divided into two groups of 30 each. Group I (n=30)-Control –no drug was given. Group II (n=30)-patients received pretreatment with Injection Esmolol 0.5mg/kg.

Results: The results were tabulated and statistically analyzed with student t-test and Chi square test using ANOVA (analysis of variance).

Conclusion: Esmolol attenuates the stress response to laryngoscopy and intubation in the form of increase in pulse rate and blood pressure and that esmolol given 3 minutes before induction provides stable cardiovascular conditions as compared to the control group and attenutates the pressor response but does not obliterate it completely.

Keywords: *Esmolol, Stress Response, Laryngoscopy, Intubation.*

Introduction

Induction of anaesthesia, laryngoscopy and intubation are associated with various stress responses. Increase in blood pressure and heart rate occursmost commonly from sympathetic discharge due to laryngotracheal stimulation, which leads to increased plasma nor epinephrine concentrations.[1] The circulatory pertubations consist of elevations in heart rate and systemic[2,3] and pulmonary artery pressures[4] which occasionally lead to myocardial ischaemia,heart failure and cerebrovascular catastrophies.[5,6] These changes start within seconds of laryngoscopy, peak within 1-2 minutes and return to control level within 5 minutes. Various techniques and drugs have been used to attenuate these cardiovascular responses like deepening the anaesthesia, pretreatment with ganglion blockers, β blockers, calcium channel blockers and vasoldilators. Also prior administration of local anaesthetics, topical anaesthesia of upper respiratory passages and use of narcotic analgesics. β blockers like esmolol minimize the increase in heart rate and myocardial contractility by attenuating the positive chronotropic and ionotropic effects of increased adrenergic activity. Esmolol is an ultra short acting β 1adrenoceptor antagonist with rapid onset and a plasma half life of approximately 9 minutes.[7] The primary objective of our study was tostudy the efficacy of esmololin blunting the haemodynamic response to laryngoscopy and intubation

Material and Methodology

The prospective randomized study was done on 60 patients of ASA I and II grade, aged 20-60 years, of either sex undergoing elective ENT surgery under general anesthesia at a tertiary care centre after approval by the institute ethical committee. The following patients were excluded from the study, those with coronary artery disease, heart failure, IInd and IIIrd degree heart block, ASA grade III/IV, Mallampati grade III and IV.A written informed consent was taken from all the patients. All the patients were kept nil per oral for at least 8 hours. Patients were randomly divided into two groups. In Group I (n=30)-Control Group -no drug was given and in Group II (n=30) patients received pretreatment with injection Esmolol0.5mg/kg. In the operation theatre, routine monitors like ECG, pulseoximetry and NIBP were attached. Premedication was done with injection Midazolam1mg and injection Fentanyl 2µg/kg in both the groups. After stabilization time of 5 minutes, pulse rate, blood pressure and ECG were recorded (baseline =T0) Patients were pre-oxygenated with 100% oxygen for 3 minutes. For control group, T1 measurement was taken just before anaesthetic induction. In group II, injection esmolol 0.5mg/kg was given and pulse rate and blood pressure recording was done 3 minutes after pretreatment(T1).Induction was done Injection Propofol 2mg/kg followed by Injection Suxamethonium 2mg/kg I/V. Following successful intubation, anaesthesia was maintained by nitrous oxide and oxygen mixture and isoflurane 1-1.5% and injection vecuronium bromide as musclerelaxant. After the surgery anaesthesia was reversed with injection neostigmine 0.05mg/kg and injection glycopyrrolate 0.01mg/kg. Blood pressure and pulse rate were recorded as follows.T0-Preinduction baseline, T1-3 minutes after giving the study drug,T2-after giving the induction agent propfol,T3-1 minute after intubation,T4-3 minute after intubation,T5-5 minute after intubation.

Statistical Analysis: Data was analyzed using Statistical Package for Social Sciences (SSPS) version17 for windows. Categorical data like gender was presented as numbers. Age, weight, heart rate and blood pressure were presented as Mean±SD. Intra group comparison of mean heart rate was done using ANOVA. The p value≤0.05 was considered significant.

Results

The mean age of group I was 35.87±11.97 and of group II was 38.17±11.70 and difference between both the groups was statistically non significant.(p>0.05).The mean weight of group I was 50.03±7.31 and of group II was 55.33±11.56 and the difference between them was statistically non significant(p>0.05).There were 36% males and 64%females in group I and 30%males and 70%females in group II.(Table 1)

The mean baseline heart rate(T0) of group I was 82±6.659 and of group II was 85.37±11.156. At 1 minute after intubation (T3) the mean pulse rate of group I was 122.07±7.799 and in group II was 100.47±12.011 beats per minute and the difference between both the groups was highly significant. At 3 minute after intubation (T4)the mean pulse rate of group I was 117.60±7.990 and of group II was 97.20±15.992 and the difference between both the groups was highly significant..At 5 minute after intubation (T5),the mean heart rate of group I was 114.67±8.470 and of group II was 90.50±10.382 and the difference between both the groups was highly significant.(Table 2)

The mean baseline systolic blood presure (SBP) (T0) of group I was 123.30±6.176 and of group II was 124.33±7.858 mm Hg. At 1 minute after intubation (T3) the mean SBP of group I was 169.03±8.471and in group II was 138.57±12.519 and the difference between both the groups was highly significant. At 3 minute after intubation (T4) the mean SBP of group I was 155.07±7.692 and in group II was 129.27±9.490 and the difference between both the groups was highly significant. At 5 minute after intubation (T5), the mean SBP in group I was 152.67±9.018 and in group II was 120.40±7.885 and the difference between both the groups was highly significant.(Table 3)

The mean baseline diastolic blood pressure (DBP) (T0) of group I was 79.53±3.627 and of group II was 81.20.±4.390 mm Hg. At 1 minute after intubation (T3) the mean DBP of group I was 107.27±6.443 and of group II was 89.27±11.537 and the difference between both the groups was highly significant. At 3 minute after intubation (T4)the mean DBP of group I was 100.20±5.44 and in group II was 86.27±7.894 and the difference between both the groups was highly significant. At 5 minute after intubation (T5),the mean DBP in group I was 99.00±6.057 and in group II was 80.10±7.625 and the difference between both the groups was significant.(Table 4).

The mean arterial pressure MAP (T0) in group I was 92±5.02 and in group II was 89.17±7.03mm Hg. At 1 minute after intubation (T3) the mean arterial pressure of

group I was 115.08±4.72 and in group II was 102.32±8.79 and the difference between both the groups was highly significant. At 3 minute after intubation (T4) the mean arterial pressure of group I was 112.10±4.92 and in group II was 93.71±7.32 and the difference between both the groups was highly significant. At 5 minute after intubation (T5), the mean arterial pressure in group I was 105.50±3.40 and in group II was 94.80±4.46 and the difference between both the groups was significant. (Table 5).

Discussion

The noxious stimuli of laryngoscopy and intubation produce marked sympathetic responses manifesting as tachycardia and hypertension. Anaesthetics use a wide variety of techniques and drugs to obtund these responses. Esmolol a cardioslective β adrenergic blocking agent is used to blunt the stress response due to its short duration of action as it is metabolized by plasma esterases.

Patients in both the groups did not differ significantly with respect to the demographic data ie age weight and sex.

In our study in group I there was a 32% increase in the pulse rate with an average increase of 40.07 beats/min as compared to the baseline value at 1 minute interval after intubation, whereas in group II after the administration of esmolol hydrochloride there was an increase of 12.1 beats/min (12%). Helfman et al. (1991) studied the effects of esmolol in a dose of 150mg post laryngoscopy and intubation and observed that there was a significant fall in heart rate from 98 beats per minute to 78 beats per minute with a mean change of 15%.[8]

In the present study the average increase in SBP was 27% in the control group at 1min interval after intubation. There was a 10.2% increase in SBP at 1minute interval after intubation in the esmolol group which came near to baseline value 5 minute after intubation. Kumar et al. (2003) observed that there was an average rise in SBP (19.6%) immediately after intubation in the control group. Esmolol group showed significantly less rise in SBP (6%) after intubation.[9]

In our study in group I there was no significant change in DBP at 3min interval and following induction. At 1 minute interval after intubation there was a rise in DBP by 27.74 mmHg (25.8%) and a rise in DBP by 19.47 mmHg at 5minute interval after intubation. Where as in group II at 1 minute interval after intubation there was rise in DBP by 11 mmHg (11.9%) which was statistically significant. At 3and 5 minute interval after intubation, the mean DBP returned to the baseline value. Taneja et al. (2003) in their study showed that a highly significant rise in DBP was observed in control as well as the esmolol group after following laryngoscopy and intubation which returned to baseline values at 4 minute after intubation in the control group and 2 minute after intubation in the esmolol group.[10]

In our study in group I there was no significant change in MAP at 3min interval and following induction. At 1 minute interval after intubation there was a rise in MAP by 22.61 mmHg (19.64%) and a rise in MAP by 13.03 mmHg at 5 minute interval after intubation. Where as in group II at 1 minute interval after intubation there was rise in DBP by 13.15mmHg (12.5%) which was statistically significant. At 5 minute interval after intubation, the mean MAP returned to the baseline value. Lui et al. (1986) in their study observed that the rise in MAP was 19mmHg (18.4%) after intubation in the esmolol group as compared to 30 mmHg (31.25%) in the control group which was statically highly($p<0.001$).[11] Also Ebert et al. (1989)compared the effects of placebo, fentanyl and esmolol in circulatory response to larygoscopy and found that the mean change in MAP in the esmolol group was 16.2mmHg(13.3%) after intubation as compared to 32.3mmHg (24%) in the control group. The rise in MAP was statistically highly significant in both the groups at 1minute after intubation and returned to the baseline value in the esmolol group at 5 minute after intubation which was statistically non significant ($p>0.05$).[12]

Conclusion

Laryngoscopy and endotracheal intubation does produce pressor response in form of increase in pulse rate and blood pressure and that esmolol given 3 minutes before induction provides stable cardiovascular conditions as compared to the control group and attenutates the pressor response but does not obliterate it completely.

Conflict of Interest: None

A Prospective Observational Study Comparing Three Different Techniques of Intubation Using C-Mac Video Laryngoscope

Shruti Gupta[1], J.R. Thakur[2], Anita Lega[1], Tapkirat Monga[1]

[1]PG Resident, Department of Anesthesiology, MMDU, Ambala,
[2]Prof & Head, Department of Anesthesiology, MMDU, Ambala

Abstract

Aim: To compare three different techniques of endotracheal intubation using C-MAC video laryngoscope.

Methodology: A prospective, randomized clinical study. A total 60 patients of ASA physical status I and II, aged 18 – 60 years were randomly divided into three groups of 20 each. In Group NS patients were intubated using ETT alone, Group S – stylet was used and Group B – bougie was used. Comparison was done in terms of time for intubation, procedure time and success rate.

Results: All the patients in B group were intubated in first attempt whereas maximum number of attempts was required in NS group followed by S group. Mean intubation time was least for S group followed by B group and maximum for NS group with significant p value between NS vs S and S vs B. Mean procedure time taken was least for S group followed by NS group and maximum for B with significant p-value between NS vs S group and S vs B.

Conclusion: Use of bougie as an aid to endotracheal intubation performed best as compared to stylet or no stylet when used with conventional C–MAC blade.

Keywords: *Conventional C-MAC, no-stylet, stylet, bougie.*

Introduction

Airway management is the prime goal in anaesthesia. Orotracheal intubation is the most common way to secure airway.[1]The best view for intubation can be achieved by flexion at the cervical spine and extension at the atlanto-occipital joint also known as sniffing position.[2]Despite continuous efforts of improvements in airway devices, the most common obstacles in anaesthesia, critical care and emergency is unexpected difficult airway.[3] Video laryngoscopy provides improved glottic view in comparison to classical Macintosh blade laryngoscopes and attenuated response to hemodynamic instability.[4] The C-MAC is a video laryngoscope similar to Macintosh blade, with a micro camera at the distal third of the blade, coloured images are transmitted from a distal camera to a display monitor. The video unit displays a magnified colour image from the distal camera.[5]

Studies have been done comparing C-MAC video laryngoscope blade to Macintosh laryngoscope blade in emergency, ICU, predicted difficult intubation, restricted neck movements and found to be superior in terms of higher success rate of first attempt, improved glottis view and decreased esophageal intubations. Therefore, in our studies we compared different techniques of endotracheal tube placement using stylet, bougie or endotracheal tube alone through C MAC laryngoscope.

Materials and Method

A prospective, randomized study was conducted after ethical committee clearance in 60 patients at Department of Anaesthesiology, Maharishi Markendeshwar Institute

of Medical Sciences and Research, Mullana, Ambala over a period of 2 years. Informed consent was taken from the patients.

Patients aged between 18 – 60 years, ASA I and II and undergoing elective surgery under general anesthesia were taken. Patients excluded from the study were ASA III, IV or V, patients with anticipated difficult intubations, pregnant patients, any contradiction to use muscle relaxant.

Study Design:

Patients was randomized in one of the three groups by a computer generated randomization:

Group NS – No stylet used. Endotracheal tube alone was used for intubation.

Group S – With stylet. Stylet was used along with tube.

Group B – With bougie. Bougie was placed first and then tube is passed over it.

Anaesthetic Technique: Standard NPO guidelines was followed and patients were kept fasted overnight. Tab. Alprazolam 0.25mg and Tab Ranitidine 150mg was given on previous night and on the coming morning of surgery as pre medication.

Inside the operation theatre (OT) availability of C-MAC videolaryngoscope was checked, charging status and proper functioning of equipment was ensured. The usual baseline heart rate (HR), non-invasive blood pressure (NIBP) and oxygen saturation (SpO_2) of the patient was recorded.

After securing intravenous access in the OT patient was pre oxygenated by manual ventilation for three minutes. In the meantime, appropriate sized endotracheal tube was selected. Induction was achieved with fentanyl 2mcg/kg, etomidate 0.3mg/kg followed by rocuronium 0.9mg/kg after confirming mask ventilation. Maintenance of anaesthesia was done with isoflurane, 40% oxygen, nitrous oxide and vecuronium 0.1mg/kg.

With the use of C-MAC videolaryngoscope Macintosh blade was inserted through midline up to the valleculum, tongue was shifted and depressed along with lifting of epiglottis with the tip of the blade. After visualization of the vocal cords endotracheal intubation was done according to the group in which the patient belonged (i.e. group NS, S, B). Once successful intubation was done, laryngoscope blade was removed and ETT was connected to a closed circuit, ventilated with 100% oxygen. ETT was secured in place after confirming equal bilateral air entry.

During procedure, if saturation falls below 90%, patient was taken on manual ventilation with 100% oxygen. If failure of intubation occurs, mask ventilation was resumed to achieve SpO_2 of 97%-100%. Next attempt was done using other technique. If intubation was not successful by all three method, then intubation was done with conventional laryngoscope using Macintosh blade.

In our study, the primary outcome was to evaluate time for intubation, time for procedure and number of attempts to intubate. Secondary outcomes were recorded as failed intubations and complications such as desaturation and bradycardia (heart rate less than 20% of baseline).

Parameters to be Recorded:

1. **Time for Intubation:** Time taken from insertion of the blade between the teeth until the tracheal tube was seen passing through the vocal cords.
2. **Time for Procedure:** Time for intubation plus $etCO_2$ trace seen on monitor.
3. **Success Rate:** No of attempts taken to successfully intubate.

Observation and Result

This prospective randomized study was carried out on 60 patients of age 18 – 60 years and ASA I or II scheduled for elective surgery under general anesthesia.

All the patients were comparable in terms of demographic data including age, sex, ASA grade, MP grade.

Table 1: Demographic characteristics

	NS	S	B	p-value
Age (Years) Mean ± SD	31.05 ± 8.68	32.65 ± 9.94	34.05 ± 9.89	0.611
Sex (M/F)	9/11	9/11	15/5	0.089
ASA (I/II)	7/13	10/10	7/13	0.535
MP (I/II)	8/12	8/12	8/12	1.000
Mouth Opening (cms) Mean ± SD	6.44 ± 0.55	6.40 ± 0.52	6.43 ± 0.51	0.971

Table 2: Comparing insertion parameters between three groups

	NS	S	B	p-value
Number of attempts (I/II)	8/12	16/4	20/0	0.000
Intubation time (seconds) Mean ± SD	47.60 ± 10.19	20.10 ± 10.47	47.15 ± 3.77	0.000
Procedure time (seconds) Mean ± SD	72.50 ± 11.59	40.45 ± 12.76	73.50 ± 7.25	0.000

Discussion

Intubation is a lifesaving procedure. Up until the development of video laryngoscopes, classic Macintosh and Miller blade remained unequaled. With development of video laryngoscopes, they are now considered as a vital part in managing airway today. Many studies have now proved that video laryngoscopes provide better view of glottis and improves the operator view during laryngoscopy. They are also used in managing difficult airway and emergency situations.[6-8]

In our study we evaluated three different techniques of intubation using C-MAC video laryngoscope. Thus after approval from Institutional Ethical committee we conducted a prospective randomized study for a period of two years in which patients were allocated into three groups of twenty each. Informed consent was taken from all patients.

All the study groups were comparable in relation to distribution of age, gender and ASA grading, Mallampati grading and mouth opening.

Number of Attempts for Intubation: Comparing the number of attempts in our study among NS group, 40% of intubations were successful in single attempt while other 60% took two attempts, among S group 80% of intubations were successful in single attempt while 20% took two attempts and among B group 100% of intubations were successful in single attempt. No patient required more than 2 attempts in any group. The p values for NS vs S was 0.022, S vs B was 0.035 and NS vs B was 0.000 which was significant.

Brian E Driver et al conducted a study in which first attempt intubation success rate using C-MAC in Stylet group was 321/366 (88%) as compared to 356/362 (98%) in Bougie group with significant p-value of 0.001 which is in accordance with our study where on comparison between S and B group significant p-value of 0.035 was obtained. So better intubation success in first attempt was seen with B group in our study as well as in Brain E Driver's study.[9]

Bisanth Batuwitage et al. conducted a study in which they were able to intubate all patients successfully in first attempt using bougie which coincides with our study.[10]

Dilek Omur et al. compared number of attempts in different groups i.e. no stylet, hockey sticks, d blade type and, copilot stylet, gum elastic bougie and found significantly higher number of attempts with no stylet in comparison to hockey stick stylet with significant p-value < 0.05 which is in accordance to our study.[3]

Time for Intubation: In our study the mean intubation time taken by NS, S and B group was 47.60±10.19, 20.10±10.47 and 47.15±3.77 seconds respectively. Hence least time was required by S group and longest duration was taken by NS group. The p-values on comparing NS with S group were 0.000, S group with B was 0.000 which were significant and NS vs B were 0.871 which was non-significant.

Our study is similar to Bisanth Batuwitage et al. study where significant p-value of <0.05 was observed among Stylet and Bougie groups for intubation time.[10]

Our study is also in accordance with Renu Sinha et al. who found that time for intubation in non - stylet group was 19.5 seconds and in stylet group was 13.0 seconds with significant p-value of 0.03.[11]

Study conducted by Dilek et al. stated that time to intubation in non - stylet group was 41.8±18.7 seconds, for stylet group was 17.3±9.8 seconds while for bougie it was 38.6±20.6 seconds with significant difference between non stylet and stylet group as well as stylet and gum elastic bougie group which is similar to our study.[3]

Pulak Tosh et al. found mean intubation time with Stylet group was 16.97±7.91 and in Bougie group was 77.43±35.55 seconds with statistical significantly (p-value <0.001) lower time required for intubation in stylet group which is in accordance to our study.[12]

Nidhi Gupta et al conducted a study in which mean time for intubation in NS group was 52 seconds whereas for S group it was 27 seconds with significant p value of 0.006 supporting the results of our study.[13]

Procedure Time: In our study the mean procedure time taken by NS, S and B group was 72.50±11.59,40.45±12.76 and 73.50±7.25 seconds respectively. Hence least time was required by S group and longest duration was taken by B group. The p values on comparing NS with S group was 0.000, S group with B was 0.000 which were significant and NS vs B was 0.771 which was non – significant.

Our study is consistent with studies conducted by D. Omur et al. [3] and Renu Sinha et al.[11]

D.Omur et al. concluded that procedure time for Non-Stylet, Stylet group and Bougie was 55.0±19.3, 30.8±7.9 and 3.9±18.3 seconds with statistically significant p-value of 0.009.[3]

Renu Sinha et al. noted that time for procedure in Non-Stylet group was 30.5 seconds while for Stylet group it was 24.5 seconds and the p value was 0.02 which was significant.[11]

Conclusion

The intubation attempts were seen least with bougie group but intubation and procedure time was prolonged. The use of bougie as an aid to intubation is best as compared to stylet or no stylet when used with conventional C – MAC blade.

Evaluation of Ambu Aura Gain and Plma in Short Surgical Procedures: A Prospective Randomised Study

Anita Lega[1], Madhavi Santpur[2], Shruti Gupta[1], J.R. Thakur[3], Hiba Siddiqui[1], Iram Waris[1]

[1]PG Resident, [2]Professor, [3]Professor & Head, Department of Anesthesiology MMDU, Ambala

Abstract

Background and Aim: The importance of supraglottic airway devices is soaring high as an aid to intubation and a means to ventilation. Proseal is a modification of classic LMA while Ambu auragain is a newer perilaryngeal sealer. The aim of the study was to evaluate the efficacy of the devices in view of insertion parameters.

Methodology: Study Design: A prospective, randomised study. A total 100 patients of ASA grade I or II, aged 18-65 years, were randomly allocated into two groups of 50 each. In group I (n=50) ambu aura gain was used and in group II (n= 50) PLMA was used. Both the devices were compared in relation to insertion parameters, haemodynamic changes and complications.

Observations and Results: Ambu aura gain was easier to insert (p-0.019), requiring less time for insertion (11.6 versus 13.4 seconds) with p-0.008. Ease of insertion of nasogastric tube was easier with group I (p-0.014). Other parameters and post op complications were comparable.

Conclusion: Ambu aura gain aids easy and rapid insertion along with easy insertion of nasogastric tube as compared with PLMA.

Keywords: *Ambu aura gain, PLMA, ease of insertion, efficacy.*

Introduction

The placement of second generation SAD is an asset to the difficult airway armamentarium owing to gastric access port and an increased seal pressure.[1] PLMA improves laryngeal seal without increasing mucosal pressureand provides high airway seal pressure with positive pressure ventilation.[2] Ambu aura gain (AAG) is a new second generation perilaryngeal sealer introduced in 2014.[3]

The present study, aims to evaluate the efficiency of AAG and PLMA with respect to ease of insertion of device, number of attempts, mean difference in insertion time between both groups, ease of insertion of nasogastric tube (NG), quality of initial airway and confirmation of correct placement by fibreoptic laryngoscopeas a primary outcome measure. Haemodynamic changes and complications that occurred were observed as a secondary outcome measure.

Material and Method

The present study was conducted in the department of Anaesthesiology, Maharishi Markandeshwar Institute of Medical Sciences and Research, (Deeemed to be University), Mullana during february 2017-july 2019. After approval of protocol from the Institutional Ethics Committee, 100 adult patients were included in the study as per following inclusion criteria.

Patients aged between 18- 65 years of either gender, ASA grade I and II with written informed consent were included in the study. Patients excluded from the study were obese patients (BMI >30), with anticipated difficult airway (Mallampati III and IV), patients with a history of difficult intubation, pregnant patients, patients with complaints of sore throat and an oral or laryngeal pathology, patients with cervical spine disease and neck pathology along with non-fasting patients.

Allocation of Groups:

Study Design: Prospective, randomised study.

The study population was randomly divided into two groups with 50 patients in each group. The patients were randomly allocated to either AAG or PLMA group using coded sealed envelope method.

Group 1 (n=50): Insertion of AAG

Group 2 (n=50): Insertion of PLMA

Methodology

A thorough preanaesthetic evaluation was done a day prior to the surgery and all the necessary routine investigations were carried out.

All patients were kept fasting overnight. They were given tab alprazolam 0.25 mg and tab ranitidine 150 mg by mouth on the night before operation and again on the day of surgery at 6.00 am with a sip of water.

In the operation theatre (OT), baseline parameters-oxygen saturation (SpO_2), heart rate (HR), systolic (SBP), diastolic (DBP) and mean blood pressure (MBP) were noted. An intravenous (IV) line was secured with 18G cannula and ringer lactate (RL) 500 ml was started. Patients were premedicated with IV glycopyrrolate (0.005mg/kg), IV midazolam (0.05mg/kg) andIV fentanyl (1µg/kg).

After three minutes of pre oxygenation, anaesthesia was induced with IV propofol (2.5mg/kg) and IV suxamethonium (1mg/kg). Appropriate size of PLMA or AAG was selected according to the weight of the patient and the group allocation.

Following parameters were noted while inserting SAD:

1. Number of attempts: maximum two attempts were allowed for insertion.
2. Insertion timewas recorded as the time gap between taking up of the supraglottic device and securing an efficient airway.Maximum of two insertion attempts were allowed considering device as a failure. Alternative device such as an ETT was used in such a situation. Numbers of attempts taken to secure the airway were noted.
3. Ease of insertion was graded as very easy/easy/ difficult.• Very easy - If the device had placed without resistance and no manoeuvre was required

- Easy - If the device was placed with aid of a single manoeuvre (head hyperextension, mask rotation, finger manipulation)
- Difficult - If resistance present on introduction

- If requirement of manoeuvre was more than one time

4. Ease of insertion of NG was graded as easy and difficult.
5. Assessment of the quality of the initial airway during manual ventilation was judged and graded as

- Excellent- if there was no audible leak;
- Good- if there was an audible leak with sufficient ventilation and $EtCO_2$ of 40mm Hg or less;
- Poor- if sufficient ventilation required again to position and to place the device.

6. Fiberoptic grading of the airway tube position was carried out for both the groups. The fibreoptic positions were graded as

- grade 1 if vocal cords were visible,
- grade 2 if vocal cords and posterior epiglottis were visible,
- grade 3 if vocal cords and anterior epiglottis were visible and
- grade 4 if vocal cords were not visible.

Fibreoptic grade 1 and 2 was considered as good anatomical placement of device.

Anaesthesia was maintained by N_2O:O_2 mixture (50:50), isoflurane (0.5-0.8%) on spontaneous ventilation. Adequacy of ventilation was observed by SpO_2 and $EtCO_2$.

The following perioperative complications were observed:

- Gastric insufflation,

- Regurgitation/Aspiration,
- Bronchospasm and Laryngospasm.
- Trauma, sore throat, hoarseness, post-operative nausea and vomiting.

The haemodynamic parameters were monitored at stipulated time intervals.

Statistical analysis: SPSS version20 p-value<0.05 was considered significant. For qualitative data Chi Square test, Fisher Exact Test and for quantitative data student t-test was used.

Observations and Results

The study was conducted on 100 healthy adult patients of ASA grade I and II of either sex, aged 18-65 years, scheduled for elective surgery under general anaesthesia.

The demographic profile including age, gender, BMI, ASA grade, MP grade were comparable in both the groups.

Table 1: Demographic characteristics expressed as mean ± SD

	AAG (n=50)	PLMA (n=50)	p-value
Age (Years) Mean ±SD	38.0±15.7	40.4±14.6	0.231
Gender (M/F)	28/22	19/31	0.071
BMI (kg/m^2) Mean ±SD	23.9±1.6	23.4±1.3	0.134
ASA (I/II)	28/22	26/24	0.688
MP (I/II)	27/23	28/22	0.841

Table 2: SAD insertion related parameters

	AAG (n=50)	PLMA (n=50)	p-value

T_4	86.0±5.1	87.6±5.1	0.126

Table4: Side effects among both the groups

Side Effect	AAG (n=50)	PLMA (n=50)	p-value
Sore Throat	4	4	1.00
Hoarseness	4	4	1.00
Cough	3	3	1.00
Any Other	0	0	-

Haemodynamic parameters (HR, SBP, DBP, MAP, SpO□, EtCO□) and side effects (intra and post-operative complications) were comparable in both the groups.

Discussion

The anaesthesiologist must ensure a patent airway and adequate ventilation. Till date the cuffed tracheal tube was considered as ideal for providing a safe glottis seal under general anaesthesia.[4]

The laryngeal mask airway (LMA) was introduced in 1982 to simplify airway management. It can often be used instead of tracheal intubation,[5] therefore avoiding complications specifically associated with it.[6] Positioning of the first generation LMAs was often found to be difficult.[7] Their use was also limited by the potential risks of aspiration and instability following insertion.[8] Several modifications were introduced to reduce these problems. The second generation of LMAs also allow passage of a tube for gastric decompression.[9]

The PLMA is one of such devices. It is a modification of classic LMA.[10] The cuff of the PLMA is specially designed with an aim to provide a more effective seal around the glottis than CLMA and the drain tube provides a bypass channel for regurgitated gastric contents.[11]

AAG is a new second generation perilaryngeal sealer introduced in 2014.[12] It is a single use, disposable, cuffed laryngeal mask airway.[13]

Group 1 comprised of 50 patients in whom AAG was used while group II consisted of 50 patients in whom PLMA was used.

In our study, patients in both the groups were comparable with respect to age, gender, BMI, ASA and MP grade and the results were similar with other studies.

Table 5: Comparison of insertion parameters between present study and other studies

Study Author & Year	Ease of Insertion of Device Very Easy/Easy/Difficult			Insertion Time (Seconds)			Ease of Insertion of NG Easy/ Difficult		
	AAG	PLMA	p-value	AAG	PLMA	p-value	AAG	PLMA	p-value
Present study	36/13/1	23/21/6	0.019*	11.6	13.4	0.008*	48/2	40/10	0.0143*
Singh K et al 2017[13]	0/18/12	0/22/8	0.273	13.57	11.60	0.001*	21/9	0/30	0.001*
Joshi R et al 2018[14]	34/11/2	38/8/1	0.3	12	20	<0.001*	46/1	39/8	0.01*

*Statistically significant

As shown in table no. 5: AAG is easier to insert than PLMA as in AAG group insertion of device was very easy in 72% patients, easy in 13% patients and was difficult in only 1% patients while in PLMA insertion of device was very easy in 46% patients, easy in 42% patients and difficult in 6% patients with p-value of 0.019 which was statistically significant.

While in the study done by Singh K et al[13] and Joshi R et al[14],showed the statistically non-significant results w1hich was non-consistent with our present study.

In our study the mean time required to insert the AAG and PLMA was 11.6 and 13.4 seconds respectively. Statistically the result was significant (p- value=0.008) and was consistent with Joshi R et al[14], study while in the study conducted by Singh K et al[13], showed more time was required for AAGinsertion as compared to PLMA. In his study insertion time for AAG and PLMA was 13.57 and 11.60 seconds respectively. The result was statistically significant (p- value=0.001).

Also the ease of insertion of NG was studied. It

was easy in 96% cases in AAG and 80% in PLMA while it was difficult in 4% cases in AAG and 20% in PLMA group. The result was statistically significant (p-value=0.014) and consistent with the other two studies.

Number of attempts taken to insert the device, quality of initial airway and fibreoptic grade were comparable in both the groups and consistent with other studies.

Haemodynamic parameters[HR (per minute), SBP (mmHg), DBP (mmHg), MAP (mmHg), SPO□ (%) and EtCO□ (mmHg)] were compared in both the groups at various time periods as, T0 before the insertion of device, T1 at the insertion of device, T2 at two minutes after the device insertion, T3 at five minutes after the device insertion and T4 after the removal of the device. All the parameters were compared among both the groups at T0, T1, T2, T3 and T4 time interval and the result was comparable among both the groups and was statistically non-significant at all-time intervals. In other studies also similar results were observed.

Side effects such as sore throat, hoarseness of voice, cough and any other side effect were compared in both the groups after the removal of the device and it was found that the results were comparable in both the groups and were statistically non-significant and consistent with other studies.

Limitations of the Study: Because of the smaller study group, the results cannot be extrapolated to a larger population and further studies are required to prove its efficacy as a conduit for endotracheal intubation.

Conclusion

The present study concluded that AAG and PLMA, can be used effectively as an alternative to endotracheal intubation in short surgical procedures. AAG aids easy and rapid insertion as a supraglottic airway device, requiring less time for insertion as compared with PLMA. Also insertion of nasogastric tube was easier with AAGthan PLMA. Patients exhibited stable haemodynamic parameters throughout the surgery without any complications hence can be used in clinical practice as a new emerging alternative to endotracheal intubation.

Association between CO in Blood and Lung Physique of Toll Road Officers

Winariani[1], Soetomo[2]

[1]Department of Cardiovascular, Medical Faculty of Universitas Airlangga,
[2]General Hospital, Surabaya 60131, Indonesia

Abstract

Introduction: Carbon monoxide (CO) is an odorless and colorless gas produced by incomplete combustion of carbons, its characteristic is easily bonded to hemoglobin rather than oxygen. Short-term immediate visible effect on respiratory tract after inhalation of toxic gas exposure is an inflammatory reaction, whereas restriction and obstruction abnormalities will appear as long-term effects of toxic gas exposure. Therefore, it is necessary to check lung physique to detect pulmonary abnormalities early before clinical complaints found.

Objective: To analyze the association between CO in blood and lung physique of toll road officers.

Method: The samples were male and female, aged 37 - 55 years and had a minimum of 20 years working hours. Samples were collected by random sampling and statistically analyzed using SPSS (SPSS, Inc., Chicago, IL).

Result: The level of CO in blood of toll road officers are higher than CO levels in the air. It was obtained restriction and obstruction abnormalities. There was no significant association between blood levels of CO and FEV1, FEV1/FVC, and PEFR but there was a significant relationship between blood CO concentration and FVC.

Conclusion The exposure of CO to toll road officers caused decreased ventricular lung function. There were obstructive and restrictive abnormalities of the lung. The level of CO in the blood did not correlate with most of pulmonary physiological parameters.

Keywords: *Blood levels of Carbon Monoxide, Lung Physiological Examination, Toll Road Officers, Carbon Monoxide Exposure.*

Introduction

Rapid economic progress drives an increasing transportation needs, on the other hand the natural environment that supports human needs is increasingly threatened by quality, thus the negative effects of air pollution on human life are increasingly growing [(1)]. Short-term immediate visible effect on respiratory tract after inhalation of toxic gas exposure is an inflammatory reaction, whereas restriction and obstruction abnormalities are long-term effects after toxic gas exposure, but few researchers have investigated the long-term effects of exposure inhalation of toxic gas [(2)]. One of these toxic gases is carbon monoxide (CO). CO is an odorless, colorless gas produced by incomplete combustion of carbon, its nature is easily bonded to hemoglobin rather than oxygen, thus oxygen supposedly bound to hemoglobin is replaced by CO resulting in tissue cyanosis [(3)].

Some previous studies suggested that CO has a negative effect on the body. Previous research examined

e-mail: burhanudinunair@gmail.com

the acute and chronic respiratory complaints of toll gate workers and administrative workers in Taiwan [4]. The results found significant differences for acute respiratory tract complaints on toll gate workers compared to administrative workers, while for chronic complaints there was no significant difference. Another study of the acute effects of cardiorespiratory system on smokers using pipes reported that after 2 hours, there was an increase in HbCO, blood pressure, and transient pulse, decrease FVC, PEFR and decrease percentage of eosinophil in the blood. Another study of in and out of town workers due to air pollution caused by various types of vehicles in Nigeria showed the highest impact for motorcycle users and smokers with FVC <80% and FEV1/FVC <70% [5].

Examination to measure respiratory function is pulmonary physiological examination. Lung physique is parameter used to assess any changes or anatomical abnormalities of the lung influencing lung function [6]. A pulmonary physiological examination can detect early pulmonary abnormalities before clinical complaints. The Central Bureau of Statistics states that the use motor vehicles since 1987-2012 increased significantly. In 2012, the growth of motor vehicles was 94,373,324 units. The decline of air quality occurred over the last few years indicates that it is important to promote emissions reduction efforts by socializing industrialists and communities or by conducting research for the application of emission reduction technologies [7].

PT Jasa Marga (Persero) Tbk is a State-Owned Enterprise engaged with toll road service providers. High vehicle sales growth and better regulatory authority policy will make Jasa Marga's position stronger in toll road industry in Indonesia. The officers have a high risk of CO exposure that can interfere health, especially respiratory function. In addition, studies about relationship between CO gas and lungs in Indonesia are still limited.

Method

The subjects of this research were employees of PT. Jasa Marga who worked on the gate and administration of Waru - Sidoarjo Toll road that met the criteria of inclusion and exclusion. Inclusion criteria were ≥10 year working time, having the same shift, aged 30-55 years, able and cooperatively underwent CO testing in the blood and lung physique (FVC, FEV1, FEV1/FVC and PEFR). Exclusion criteria were having lung disease history based on existing medical record data, which might affect the lung function [6].

This research was conducted at tool road of waru-sidoarjo owned by PT. Jasa Marga Tbk. The data collection was done based on: reading and recording medical record data, filling questionnaire and physical examination, subject demography factor (sex, age, education, place of work, duration of work), and result of CO examination in blood and lung physique [8]. The method of analyzing CO in the blood was releasing CO with H2SO4 dilute solution. This free CO was reacted with excess PdCl2 solution, CO would oxidize to CO2 while Pd2+ would be reduced to Pd metal. The residual Pd2+ was reacted with Kl dilute solution resulting I and Pd. The color of I2 solution (in KI, due to excessive KI) was measured its intensity with the spectrophotometer. By using standard solution, it could be known the concentration of I2 equivalent to PdCl2 which is equivalent to CO. The spectrophotometer worked in double beam spectrophotometer method based on Lamber-Beer (Beer-Lambert-Bouguer) law. While examination of lung physique performed at the time agreed using a portable spirometer device of Koko Legend model 314000.

It was analysed the impact of CO exposure on lung physique using observational analytic statistic of association between lung physiology change and the working hours and habit of using self-protection tool (mask) which functioned to describe the influence of CO exposure on lung abnormalities. The test used is Pearson correlation test with significant value of $p < 0.05$ using the SPSS program [9].

Result

Table 1: Subject Frequency Distribution

Characteristic		N (%)
Sex	Male	24 (63.2%)
	Female	14 (36.8%)
Age	<41 years	3 (7.9%)
	41 – 45 years	7 (18.4%)
	46 – 50 years	22 (57.9%)
	>50 years	6 (15.8%)
Education	Elementary	1 (2.6%)
	Junior High School	1 (2.6%)
	Senior High School	28 (73.7%)
	College	8 (21.1%)
Work place	Indoor (non-counter)	15 (39.5%)
	Outdoor (counter)	23 (60.5%)

Characteristic		N (%)
Working hours	11 – 20 years	10 (26.3%)
	21 – 30 years	26 (68,4%)
	>30 years	2 (5.3%)

	Normal	23 (60.5%)
Pulmonary obstruction	Moderate	7 (18.4%)
	Mild	11 (28.9%)
	Normal	20 (52.6%)

*pulmonary physycal abnormalities criteria based on Pneumobile Project Indonesia

Distribution of subject's characteristics can be seen in Table 1. Most of them were male as many as 24 (63.2%), aged 46-50 years as many as 22 (57.9%), high school educated as many as 28 (73.7%), work at counters as many as 23 (60.5%), having work period of 21-30 years as many as 26 (68.4%). Subjects who had restriction lung abnormalities in the normal category was 23 (60.5%) and obstruction in the normal category was 20 (52.6%).

Table 2: Subject's characteristics based on restriction and obstruction

Characteristic		Restruction		Obstruction		
		Mild	Normal	Moderate	Mild	Normal
Workplace	Outdoor	13 (56.5%)	10 (43.5%)	5 (21.7%)	8 (34.8%)	10 (43.5%)
	Indoor	2 (13.3%)	13 (86.7%)	2 (13.3%)	3 (20.0%)	10 (66.7%)
Smoking status	Smoker	9 (52.9%)	8 (47.1%)	3 (17.6%)	7 (41.2%)	7 (41.2%)
	former smoker	3 (75.0%)	1 (25.0%)	1 (25.0%)	2 (50.0%)	1 (25.0%)
	non-smoker	3 (17.6%)	14 (82.4%)	3 (17.6%)	2 (11.8%)	12 (70.6%)
Mask using	Never	6 (46.2%)	7 (53.8%)	4 (30.8%)	3 (23.1%)	6 (46.2%)
	Sometimes	6 (30.0%)	14 (70.0%)	1 (5.0%)	7 (75.0%)	12 (60.0%)
	Always	3 (60.0%)	2 (40.0%)	2 (40.0%)	1 (20.0%)	2 (40.0%)

It was found that the toll officers who worked at both counter and non-counter had a restriction disorder. Lifestyle of smokers, former smokers and non-smokers also provided different restriction abnormalities. Similarly, the use of masks also obtained different restriction abnormalities, in the case of different mask type used. It was found that toll officers who worked at both counter and non-counter had moderate and mild abnormalities obstruction although some were normal. Smokers, former smokers and non-smokers also provided both abnormal and normal. Similarly, the use of masks obtained different abnormalities of obstruction, where the type of mask used was not the same[10].

Table 3: Distribution of CO in blood based on smoking status and mask using

	Total	Average ±SD (µg/Nm^3)	p
Smoking Status			
Smoker	17	15.85±2.43	
Former Smoker	4	16.34±2.95	0.053
Non-Smoker	17	14.33±2.48	
Mask Using			
Never	13	16.50±2.24	
Sometimes	20	15.37±2.47	0.482
Always	5	14.18±3.39	

The comparative analysis of CO gas in smoking subject was p = 0.053 and using mask subject was p = 0.482. The highest abnormalities is found on subject with outdoor job.

Table 4: Level of CO in blood and lung physique

	Kadar gas CO (µg/Nm^3)	FVC (ltr)	FEV1 (ltr/dtk)	FEV1/FCV (%)	PEFR (ltr/sc)
Total (N)	38	38	38	38	38
Average±SD	15.21 ± 2.56	2.53 ± 0.29	1.66 ± 0.25	0.65 ± 0.07	6.85 ± 1.29

The results showed a minimum value of 10.19 μg/Nm^3 and maximum of 18.06 μg/Nm^3, with average of 15.2192 μg/Nm^3. While CO examination in air East Java Province Environmental Unit showed the value of 12,549.7 μg/Nm^3.

Table 5: Association of CO in blood and lung physique

Variable		FVC	FEV1	FEV1/FCV	PEFR
CO level	r	-0.598	-0.309	0.216	0.274
	p	0.000	0.059	0.193	0.096

There was a significant relationship between CO and FVC levels at the 0.598 with negative prognostic value. This meant that the higher the CO in the blood, the lower the FVC value. While the CO in the blood did not have a relationship with the value of FEV1, FEV1/FVC and PEFR.

Discussion

In this study, the data shows restriction abnormalities by a significant inverse relationship between CO and FVC indicated by negative values that had moderate strength at the level of 0.598 whereas for FEV1, the ratio of FEV1/FVC and the Peak Expiration Flow (PEFR) had no association with CO in the blood. Researchers suspected that abnormalities could be caused by smoking, masks and workplace location. In addition, the effect of nutritional status, location of residence and type of transportation used might also cause deterioration of lung function [(4)].

Previous research mentioned that non-smokers would experience an average decrease of FEV1 at a rate of 30 ml/year, whereas in smokers there would be an average decline of twice faster, which was about 60 ml/year. It also mentioned that the cessation of smoking would restore the rate of decrease in FEV1 to non-smokers rate. Nevertheless, the inflammatory process would remain in the former smokers, which would lead to narrowing of respiratory tract [(11)].

Increased HbCO levels could decrease lung volume including vital pulmonary capacity. The relatively stronger and more stable HbCO bond caused decreased oxygen in the lung. Therefore, the ability of Hb in binding oxygen would decrease, resulting in a decrease in diffusion capacity due to carbon monoxide (DLCO) [(12)]. If this happened for a long time it would cause abnormalities of the pulmonary parenchyma structure thus the pulmonary physiological measurement would obtain decrease value of vital capacity (VC) and total lung capacity (TLC). This finding was consistent with previous studies conducted on 944 tunnel and bridge workers over 3 years of decrease in FVC and FEV1 as well as an increase in HbCO [(13)]. The different results in FEV1 might be influenced by the length of research observation. The results obtained in this study were similar to a study of 510 Taiwan toll-road workers for 1 year that obtained no difference in the prevalence of chronic lung disease. Restriction abnormalities could be expected if a decrease of VC and FEV1/FVC ratio was normal or increased [(5)].

Overall, there was no significant relationship between blood CO concentration and lung function according to FEV1, FEV1/FVC, PEFR parameters, because only FVC parameter obtained significant relationship. This meant that the lung physique considered homogeneous and the results could be ignored [(14)]. This conclusion might be influenced by several factors such as the existence of a workplace exchange policy where every half hour was switching the counter, in addition to the use of personal protective equipment in the form of masks that were still used by the officers in different type and frequency [(15)]. Another factor was the number of vehicles to be handled by each officer that was not always the same.

Conclusion

It was found a significant relationship of CO in the blood and the decrease of FVC value ($p < 0.05$), which was shown by negative prognostic value with moderate strength at 0.598 level. This meant that the higher the CO gas in the blood, the lowere the FVC.

Ethical Clearance: This research involves participants in the process using a questionnaire that was accordant with the ethical research principle based on the regulation of research ethic regulation. The present study was carried out in accordance with the research

principles. This study implemented the basic principle ethics of respect, beneficence, non-maleficence, and justice.

Conflict of Interest: The authors have not found any conflict of interest related to this research so far.

Abstract

Type two diabetes mellitus (T2DM) is utmost shared form of diabetes described by the raised plasma glucose levels and instigated because of the both insulin action and secretion's impairment. This is actually turning prevalent while leading to numerous complications. Furthermore, its occurrence and prevalence are surging at a distressing degree in few countries such as Iraq while increasing a main concern of health. Mutually, the environmental and genetic features play an essential role to manifest such composite genetic ailment. The purpose of this research was the recognition of the genomic regions' relatedness.

The few current years showed an outbreak of molecular genetics inspection while comprising the whole genome scans. This was utilized to assess the genetic variant's linkage with T2DM in several pathways of pathophysiology.

Numerous candidate genes are recognized as related to the T2DM, although, merely few of them demonstrates the stability in relationship to various ethnic group and population. Comparatively, because of greater T2DM risk in Iraq as well as the constituent substructure residents and enormous genetic heterogeneity, the number of researches is smaller enough to distinguish the illnesses' genetic base in Iraq.

Keywords: *Genome-wide Association scan (GWAS), Insulin deficiency Candidate genes, Ethnic variability Indian scenario.*

Introduction

The current intense advancement in several affected individuals specifies the lifestyle features associated to the development and inactive professions might be mostly significant in initiating the genetic elements responsible for this diabetes type. Thus, being authoritative to specifically inaugurate the essential environmental & genetic factors after such intricate genetic syndrome in order to initiate the preventive measures[1].

Our attempt of reviewing the already directed research regarding molecular genetics universally, regarding T2DM and also the ethnic, environmental & epidemiological factors involved in the T2DM expression.

Obesity is the utmost prevailing non-infectious ailment of 21st century which is related to the dispositioning of the triglycerides in hepatocytes moving towards the non-alcoholic NAFLD (fatty liver disease).

Nowadays, NAFLD is about a 3rd of the world population. The epidemiological researches have determined that cultural background is significant factor in complexities and treatment of the disease [2].

Background: Adjusting for the population stratification's probable impacts which is a substantial concern for the intricate traits of genome wide association studies (GWAS) [3].

Genetic structure's principal component analysis

(PCA) of population in study having successive integration of initial numerous principal components (PCs) in GWAS regression [4].

In livestock, residual inconsistency has been considered as a background due to the concerns of improving the uniform production. Numerous researches have delivered the indications related to the residual alteration is partly under the control of genetics. Though, some of the examinations have illuminated the genes that control them.

Background and Objectives

Polycystic ovary syndrome (PCOS) is the women's utmost communal disorder of reproductive endocrine with perimenopause. About the specified phenotypic overlap amongst type 2 diabetes mellitus (T2DM) & PCOS, the investigation was done to acknowledge regarding the T2DM implicated genes' association to the vulnerability of PCOS amongst women of city Baghdad.

Introduction

Diabetes mellitus (DM) is a complex heterogeneous group of disorders characterized by persistent hyperglycemia and caused by an absolute or relative deficiency of insulin, which is an anabolic hormone, produced by the beta cells of the islets of Langerhans located in the pancreas. While the World Health Organization (W.H.O) [5, 6] describes DM as a metabolic disorder of multiple etiologies characterized by chronic hyperglycemia with disturbances of carbohydrate, fat and protein metabolism resulting from defects in insulin secretion, action or both, the American Diabetic Association (ADA) [7-8] defines DM as a group of metabolic diseases characterized by hyperglycemia resulting from defects in insulin secretion, insulin action or both. The different types of Diabetes mellitus include Type1 & 2 and rare forms of MODY and Gestational diabetes

Method

A total of 248 women with PCOS and 210 healthy women as controls were genotyped, in the teaching hospitals in Baghdad governorate. For a panel of 15 single nucleotide polymorphisms (SNPs) from the nine T2DM genes, such as IGF2BP2, TCF7L2, SLC30A8, CDKAL1, HHEX, CDKN2A, IRS1, CAPN10 and PPARG, on SequenomMassARRAY platform [9].

Numerous related researches have deliberated the significance of illuminating the association amongst the type 2 diabetes development and genetic polymorphism[10].

The pursuit of candidate genes primarily relied on the gene encoding proteins unswervingly incorporated in the T2DM pathophysiology, associated encoders such as development of pancreas, secretion, production and insulin's inactivity [11].

Progressively, several developing investigations recommended the involvement of different other factors in T2DM development, for instance, other molecules & pro-inflammatory cytokines' expressionperform in the process of inflammation which also play a crucial role in DM's chronic complications' development [12].

Numerous studies indicate that the impact of several polymorphisms on the cytokines pro-inflammatory genes are a risk for developing the metabolic syndrome, diabetes and obesity [13].

Results

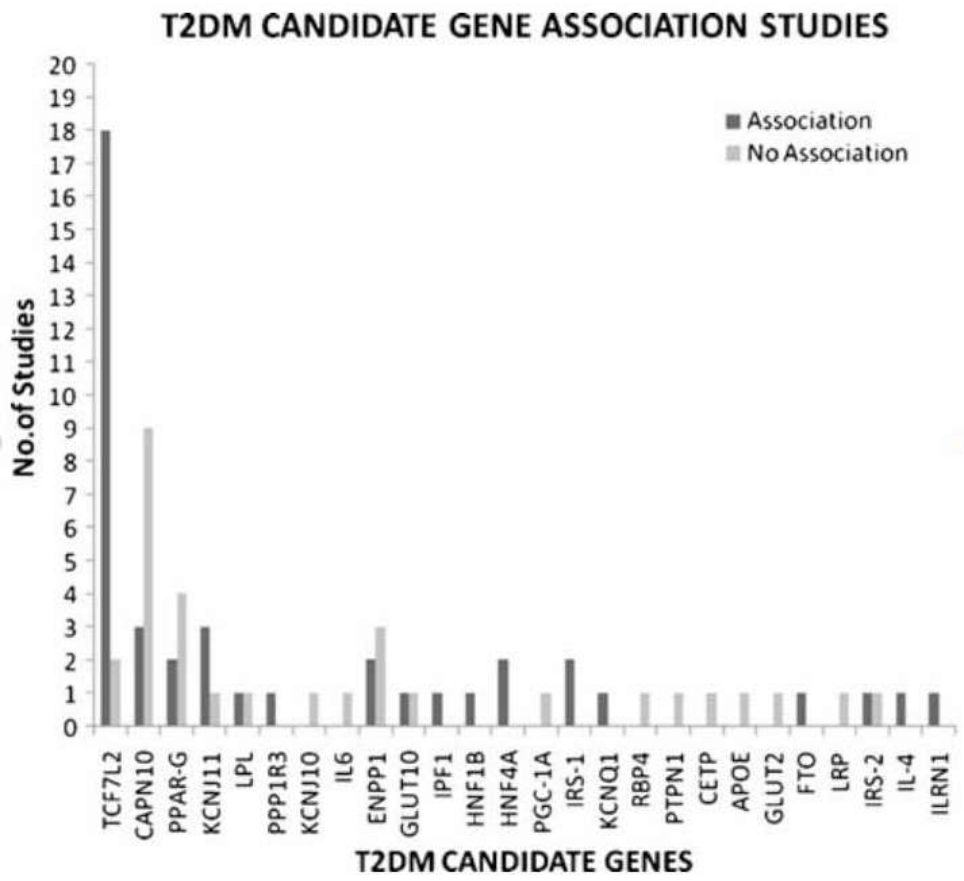
None of the 15 SNPs were observed to be substantially related to PCOS after Bonferroni correction for multiple testing, either in the univariate or multivariate context.

The cumulative effect of risk alleles observed with reference to T2DM was also not seen with reference to PCOS. Interpretation & The latest review of article (18) demonstrated the T2DM genetic base context. The candidate genes list incorporated in the T2DM etiology with particular location of chromosome & genomic regions having specifiedroles. While, various population's T2DM candidate gene research with their study design and variants are organized. Moreover, Fig.1. Signifies the bar diagram presenting numerous studies with or without several candidate gene & T2DM linkage [8].

Genetic foundations of T2DM is finely demonstrated in the latest article review [14]. Moreover, the candidate genes list incorporated in the T2DM etiology along with relevant locations of chromosomes & region of genome as well as their functions.

Furthermore, the candidate genes of T2DM in several populations with the alterations & study design.

The Fig. (1) Indicate a bar diagram presenting several researches with or without a relationship amongst various candidate genes & T2DM.



In Caucasians, the GWAS (Genome-wide association studies)have acknowledged the 14 index single nucleotide polymorphism (iSNPs) which stimulates the risk of colorectal cancer (CRC). An estimation about the function of 11 iSNPs or sSNPs (surrogate SNPs) in greater linkage disequilibrium (LD, r(2)≥0.8) was done inside the 100kb iSNPs' locality in 2000 age & gender matched Singapore Chinese cases (SCH) & controls.

Merely sSNPs, rs7226855, rs2059254, rs11986063, rs3087967, & rs6695584 at 18q21.1, 16q22.1, 8q23.3, 11q23.1, & 1q41, and iSNP rs6983267 at 8q24.21 corresponding lydisclosedindication of linkage with the risk of CRC having odd ratios (OR) in a range from 1.13 to 1.40. Further, the sSNP rs827401 at 10p14 was related to the risk of rectal cancer (OR = 0.74, 95% CI 0.63-0.88) nonetheless the prognosis of illness (OR = 0.91, 95% CI 0.69-1.20).

Amusingly, the sSNP rs3087967 at 11q23.1 was linked to the male CRC risk such as (OR = 1.34, 95% CI 1.14-1.58) in comparison to the women (OR = 1.07, 95% CI: 0.88-1.29), thus, proposing a specified gender function.

The half of the variants recognized for Caucasians, comprising finely mapped loci of BMP pathway i.e. BMP2, GREM1, LAMA 5 and BMP4 did not indicated any confirmation for the relation of CRC in SCH (OR ~1; p-value > 0.1).

Associating these outcomes of research with Hong Kong & Northern Chinese indicated the variants at 10p14, 18q21.1, 11q23.1 & 8q24.21 chromosomes.

Complementary outcomes amongst the Chinese and Caucasians can be because of various genetic heterogeneity, LD patterns and allelic frequencies.

The investigation of intricate genetics for autoimmune diseases has proceeded at an inconceivable speed over former four years. This is due to the thorough conclusions of massive advantages prepared by the GWAS (genome wide association studies). However, new genetic discoveries are unceasingly being testified with the speedy genetic technological growth, huge collection of samples and refined statistical analysis. This is pretty clear now that the multiple genes participate in various complicated genetic ailments while comprising RA (rheumatoid arthritis). There are also several

communal risk factors related to genetics that cause the spectrum autoimmune illnesses [15].

The particulars of recent genetic setting of RA explains about capability of GWAS regarding shared autoimmune risk loci, missing heritability, presence of genetic heterogeneity and subsets of disease.

Moreover, separation of mechanism related to the genes directly encouraging the RA cause will give us a clue about considerate acknowledgement of this sickness. Further it will provide a direct clinical impression and also notifying the improvements of novel therapies used for RA treatment.

The conclusions indicate that extra communal alternates causing the CRC predisposition are still needed to be recognized.

Genome-wide association studies (GWAS) for the colorectal cancer (CRC) acknowledged the 5 regions nearby the genes related to the transforming growth factor β-genes such as GREM1, RPHN2, CDH1, SMAD7 and BMP4.

Accurate risk alleles are still needed to be recognized in such regions as well as their function in non-European population for CRC risks are still required to be studied. Our former research described substantial genetic heterogeneity for GWAS acknowledged single nucleotide polymorphisms (SNPs) amongst the European Americans (EAs) & African American (AAs) [16].

It was hypothesized that associations might not be replicated in AAs because of its independent or differential genetic structure.

Examining this hypothesis, about 1352 controls such as 367 EAs and 985 AAs as well as about 195 tagging SNPs through five regions of genes in 1194 cases of CRC i.e. 795AAs & 399 EAs were genotyped. Further, imputation was done to test the relation among the imputed & genotyped SNPs comprised of covariates, e.g. sex, ancestry and age.

Two out of 5 genes were initially connected to the CRC and indication of such association was observed in AAs containing rs1862748 in CDH1 (ORAdd = 0.82, P = 0.02) as well as in GERM1 SNPs rs10318 (ORRec = 60.1, P = 0.01), rs12902616 (OR Rec = 1.28, P = 0.005) and rs11632715 (ORRec = 2.36; P = 0.004) and finally, linkage disequilibrium with SNP rs4779584 that had been formerly recognized [17].

Analyzing such associations more generally in the AAs gene regions, we analyzed 3 substantial statistical association peaks in RHPN2 and GERM1 and these were not acknowledge in EAs. It was concluded that several CRC risk alleles were common among the AAs, EAs and other certain populations [18].

DM (Diabetes mellitus) is deliberated as a universal epidemic illness and its form of type 2 includes > 95% of all incidences. Moreover, TNF- α (Tumor necrosis factor-alpha) is considered as a pro-inflammatory cytokine whose dysregulation has been connected to a diverse human illnesses such as T2DM (type 2 diabetes mellitus).

This cytokine's controlled expressions are related to the resistance of insulin that have a resilient genetic impact. This relationship can be considerate through the literature of entire case researches from 2000 to present date.

Further, the frequencies of genotype exhibited in 10 publications of diverse ethnicities were paralleled. The relationship among the T2DM developing risk and TNFA promotor genotypes remained scandalous because of several inconsistencies in various available researches.

The alterations in ethnicity might play a role in such contradictory outcomes from the dispersal of TNFA promotors' polymorphism which is distinct amongst the persons having unrelated racial basis.

Though, the association among the T2DM occurrence & existence of polymorphism at TNFA gene's position 308 is not completely known, therefore, the outcomes of these studies recommended the necessity for additional inquiry[19].

The characterization of diabetes as being a metabolic disorder of numerous etiologies which is categorized by chronic hyperglycemia due to the instabilities of protein, carbohydrates and fats' metabolisms causing from the insulin action or secretion flaws.

Being an anabolic hormone, insulin which is synthesized by pancreas β- cells which endorses the glucose conversion to glycogen in skeletal muscles Insulin through exciting the uptake of glucose and triggering glycogen synthase with the assistance of insulin signaling pathway.

Conclusion

The resistance of insulin plays a substantial function in PCOS & T2DM's intricate traits' pathophysiology.

The nine genes considered in our study were reported to play a prominent role in the manifestation of T2DM among populations of different ethnic backgrounds 17, including in the population of Hyderabad 20.

These genes are known to be implicated in different pathways such as insulin secretion and action, pancreatic beta-cell function & homeostasis of glucose, and the cross-talk between these pathways is, in turn, linked to insulin signaling cascade.

T2DM 9 genes deliberated in this investigative research might not be a PCOS' chief liability factor amongst the women of India. Our outcome complement the lack of indication of the relationship of the T2DM geneshaving PCOS amongst Caucasians & Chinese while mentioning the potential pattern's possibility. Preciselyintendedinclusive studies that include women with T2DM and PCOS are required to explore the precise role of the diabetes genes.

Lastly, this study states the primary challenges confronted during the translation of genetic discoveries into influential biological mechanisms which participate into the phenotype & genotype association.

Aerodigestive Tract of Foreign Body in 12 Indonesian Academic Hospital

Aditya Wira Buana[1], Prof. Sri Herawati Juniati[1], Rizka Fathoni Perdana[1]

[1]Departement of Otorhinolaryngology-Head and Neck Surgery, Faculty of Medicine Universitas Airlangga, Surabaya 60132, Indonesia

Abstract

Objective: To explore the profile of patients with aerodigestive tract of foreign bodies, who had performed bronchoscopy and esophagoscopy in 12 Otorhinolaryngology centers

Method: A descriptive research with a retrospective approach. Data samples were obtained from the recapitulation of medical services in the Broncho-Esophagology Division at 12 centers of Otorhinolaryngology education throughout Indonesia. All the extraction was carried out in the operating room of the emergency room at each education center.

Results: We obtained 487 cases of the laryngo-tracheo-bronchial foreign body, and 1499 of esophageal, then 1177 patients male and 809 female as subjects. The number of patients with aerodigestive foreign body was dominated by male n=1177 (59%) than female by n=809 (41%). The highest percentage of organic object was found in peanuts by n=84 (74%) and inorganic objects was needle n=180 (48%). The highest number of organic objects was meat n=271 (51%), and inorganic objects was coins n=481 (49%).

Conclusion: There was no significant difference in sex in male and female. The highest foreign body in the feeding process was a coin, while in the airway flow was a needle. The types of unknown objects can be related to educational background, cultural culture, and diettary in every country.

Keywords: *Aerodigestive, foreign body, bronchoscopy, esophagoscopy, academic hospital.*

Introduction

Foreign body of the aerodigestive tract are all objects either in the form of food boluses, or other hard objects that are ingested intentionally, or not so that they can cause blockages and injury in the aerodigestive tract. The foreign body aspiration process occurs when there is an object in the laryngotracheobronchial tract. The ingestion of foreign body occurs when the object enters through the esophagus.[1] Aspiration and ingestion of foreign body is still a cause of significant morbidity and mortality.[1-3]

The main symptoms that appear in an foreign body aspirations can mainly be shortness of breath and stridor.[2] In cases of ingestion, the symptoms that appear can be a permanent sensation that is persistent or arises when swallowing.[3] Mental retardation and disorders in children generally come with complaints of choking feeling, unwillingness to eat, vomiting, excessive salivation and saliva mixed with blood.[1] Along with the development of bronchoscopy and esophagoscopy technique has reduced morbidity and mortality due to complications from the act of expulsion of foreign bodies in the aerodigestive tract.[4]

Research in India shows at least 25.000 cases of aerodigestive foreign bodies have been handled by local government hospitals. 5 Cases of aerodigestive

foreign bodies can occur in adults and children. Types of foreign bodies that are ingested in children and adults are different. In adults, the most ingested species are cuts of meat, bones, and dentures.[1] In children, generally small toys and coins.[2,3] References from India suggest that most foreign bodies, especially those aged 1-10 years with percentages by 44.98% of the total cases.[6] Predisposing factors are include not growing molar teeth that able to chew and swallow well, coordinating the process of swallowing and imperfect laryngeal inlet in the age group 6 months to 1 year, mental retardation, growth disorders, and other neurological diseases.[6,7, 8]

Rigid bronchoscopy and esophagoscopy are the main choices for foreign body extraction in the aerodigestive tract, while they can be used to diagnose cases of suspicion.[1-3,9] A study in Tunisia reported that in less than 10 years at least 333 (53.2%) foreign bodies extraction with esophagoscopy and 215 (34.3%) extraction with bronchoscopy.[7, 8] Other studies taken at third-level health facilities in India stated, in the past 7 years 1.125 cases of aerodigestive foreign body. The most cases in esophagus were located at cricopharyngeal (78.92%). Most foreign airway objects were found in the right-sided main bronchus (61.94%).[5]

The aim of this study was to explore the profile of patients with aerodigestive tract of foreign bodies, who had performed bronchoscopy and esophagoscopy in 12 Otorhinolaryngology centers throughout Indonesia during the period 2011 to 2015.

Materials and Method

Types of Research: The type of research was descriptive with a retrospective approach.

Sample, Place and Time of Research: Data samples were obtained from the recapitulation of medical services in the Broncho-Esophagology Division at 12 centers of Otorhinolaryngology education throughout Indonesia. The 12 education centers are Universitas Brawijaya (UB), Universitas Gajah Mada (UGM), Universitas Indonesia (UI), Universitas Airlangga (UNAIR), Universitas Andalas (UNAND), Universitas Diponegoro (UNDIP), Universitas Hasanuddin (UNHAS), Universitas Padjajaran (UNPAD), Universitas Sebelas Maret (UNS), Universitas Udayana (UNUD), Universitas Sriwijaya (UNSRI) and Universitas Sumatera Utara (USU). All the extraction was carried out in the operating room of the emergency room at each education center. The data were taken from 2011 to 2015.

Research and Analyze Data: The data of foreign body of the aerodigestive tract consists of laryngo-trachea-bronchial, and esophageal foreign body. Each data was divided into organic and inorganic group. The sample in this study included patients who had carried out foreign body extraction procedures by using rigid bronchoscopy and esophagoscopy at the emergency department at each education center. The samples that were not successfully extracted theforeign body and had incomplete data were not included in the calculation. Furthermore, the sample was processed using the Microsoft Excel 2013 program.

Results

Demographic Characteristics: In the period from January 2011 to December 2015, there were 1986 cases of aerodigestive foreign body which were successfully extracted with complete data. There were 487 cases of the laryngo-tracheo-bronchial foreign body, and 1499 of esophageal, then 1177 patients male and 809 female as subjects.(Table 1)

The highest number of laringotracheobronchial foreign body was in the Universitas Padjajaranby n=164 (34%), while the lowest case was in the Universitas Sebelas Maretby n=15 (13%). The highest number of esophageal foregin body was in the Universitas Airlanggaby n=241 (16%), while the lowest case was found in the Universitas Sriwijayaby n=54 (4%).

Characteristics of Subject: The number of patients with aerodigestive foreign body was dominated by male n=1177 (59%) than female by n=809 (41%). The dominance of theesophageal in malewas n=944, while the dominance of laryngo-tracheo-bronchial in femalewas n = 254 andhas the highest in the 0-10 year age group by n=827 (42%). Then, the number of patients decreased in the next decade n=280 (14%). While the number of patients with the oldest aerodigestive in the age group>90 years was n=1 (0%). The highest number of patients of laryngo-tracheo-bronchial in the first decade age group was n=259, then decreased in the next decade by n=199. (Table 2).

The highest percentage of organic object was found in peanuts by n=84 (74%), while the lowest was cinnamon by n=1 (1%). The highest number of inorganic objects was needle n=180 (48%), followed by whistle n=92 (25%), and then corrosive battery by n=6 (2%). (Table 3).

The highest number of organic objects was meat n=271 (51%), followed by bone n=184 (35%), and meatballs by n=24 (5%). The highest number of inorganic objects was coins n=481 (49%). Followed by teeth n=295 (30%) and the last battery by n=14 (1%). (Table 4).

Discussion

The revolutionary management of patients with foreign body in the aerodigestive tract using rigid bronchoscopy and esophagoscopy was pioneered by Chevalier Jackson in 1904. This management reduced mortality from 20% to 2%.[10] Rigid bronchoscopy and esophagoscopy are options for the diagnosis and extraction of foreign body in the aerodigestive tract. The use of rigid esophagoscopy is more advantageous for extractionbecause the flow airway is more patent. The use of extractor instruments such as forceps and telescopes can be entered in large sizes object.[9] Selection of rigid bronchoscopy is also the main choice in cases of laryngo-tracho-bronchial foreign bodybecause it is easier to control the flow of oxygen, carry out secret extraction and ease of extraction.[11]

Based on the results study, there were 487 cases of laryno-tracheo-bronchialand 1499 esophageal foreign body. These results were consistent with studies at tertiary health facilities in India that there were 878 foreign body in the digestive tract and 247 cases in the respiratory tract.[6] Based on the results of the study, foreign body in the laryno-tracheo-bronchial were foundconsisting of 114 organics and 373 inorganic objects. This result different from the study in India which showed respiratory organic object(n=189, 527 cases) was higher than inorganic (n=58, 927 cases).[6] This result was opposite from the study in Nepal which stated that 72.22% of cases were organic and 27.77% inorganic.[12] Quoted from Rajashekhar T, the type of unknown object can be related to educational background, culture, and diettary in every country.[13] Sex distribution of patient obtained by male (n = 1177) was higher than female (n = 809). This was in consistent with other studies that showed a non-significant comparison between male (n = 137) and female (n = 110).[6] Other studies also showed that there were no significant differences in sexdistribution.[13,14] The results of the comparison were insignificance that caused by the number of sample cases that were still lacking.

The results was found that the highest cases were in the 0-10 year age group (n = 259). This was in accordance with several other studies which stated the highest average age in the group was 0-10 years.[5, 6] Predisposing factors in children are congenital anomalies, not yet growing molar teeth, coordination of swallowing processes, imperfect laryngeal sphincter in the 6 months to a year, mental retardation, growth disorders, and

underlying neurological diseases. Predisposing factors in adults are the use of dentures accompanied by loss of palpable sensation, neural disorders, and psychosis.[9]

Based on the results of the study, the highest number of organic object was obtained n=84 (74%), and the lowest was cinnamon by n=1 (1%). While the highest number of inorganic objects was needle n=180 (48%), followed by whistle n=92 (25%). This result is similar to that of Showkat et al., which stated that the highest unknown organic objects were peanuts (18.51%). The high incidence of needles can be caused by the habit of biting it by patients when wearing clothes.

The highest number of unknown organic esophageal object was meat n=271 (51%), followed by bones n=184 (35%). The highest number of inorganic objects was coined n=481 (49%),followed by teeth n=295 (30%). These results are in accordance with research by Shawat, where bone, coins, meat, and teeth are the highest 4 large unknown object in the digestive tract.[6] The results of the study also found corrosive objects, namely batteries by 2% on airway flow and 1% on the esophageal tract. Batteries are dangerous materials and must be immediately evacuated and treated as life-threatening unknown objects. The electrochemical composition has the potential to damage the surrounding mucosal area extensively.[15] Quoted by Thabet et al, the consequences of damage to the mucous area depend on the position of the battery, the duration, size, power and mechanism of absorption of heavy metals by the body.[15]

Conclusion

An foreign body in the highest aerodigestive tract occurs at less than 10 years. This case depends on predisposing factors, such as congenital anomalies, the absence of molar teeth that to be able to swallow properly, coordination of the process of swallowing and laryngeal sphincter that was not perfect, mental retardation, growth disorders, and underlying neurological diseases. Predisposing factors in adults were dentures who have lost sensation from the palate, neural disorders, and psychosis. There was no significant difference in sex in maleand female. The highest foreign body in the feeding process was a coin, while in the airway flow was a needle. The types of unknown objects can be related to educational background, cultural culture, and diettary in every country.

The Relationship between the Cochlear Roughness, the Stimulus Level 30dB and the Otoacoustic Emissions

Adnan Al Maamury

Assistant Professor in the Department of Medical Physics, College of Science, Karkh University of Science, Baghgad, Iraq

Abstract

The hearing mechanism is influenced by a number of factors, whether sound or physiology. These factors include the stimulus level of sound and cochlear roughness.

In this work, the otoacoustic emissions was studied with the stimulus level of sound 30 dB different cases. In each case the cochlear roughness was changed to study the otoacoustic emission. Cochlear roughness changes for each case and it is noted that the hearing mechanism is affected by cochlear roughness. The most important conclusion of this work is that cochlear roughness is very important to hearing efficiency. It is clear that the stimulus level gave good results regarding the hearing mechanism.

Keywords: *Hear process, frequency map, ear, stimulus level, distribution.*

Introduction

External acoustic emissions OAEs are a physiological byproduct Mammal Cochlear Activity Probst Et al, (1991)[1]. OAE generation and backward transfer. It is effectively prescribed by a cochlear transmission line models which including resonant cross-resonance, for example, Talmadge et al. (1998)[2]. These conditions must also model for the mechanism of mediated active reactions outer hair cells OHCs, which are responsible for excellent threshold sensitivity and frequency resolution of Mammals hearing system.

In 1895, Helmholtz introduced the roughness as the term for the first time to describe cruel, clatter Phonological sensation or noisy[3]. Hearing roughness is an aspect of the bell associated with frequent and rapid fluctuations. Amplitude or frequency, is often described by referring to qualities such as cruelty, Lightness, hoarseness. Used as a measure of sound quality assessment in industrial applications, such as the automotive industry, for example, Gonzales et al., (2003)[4], and clinical evaluation of sound quality, for example, Webb et al.,(2004)[5].

Different roughness models have been developed in the past,the detection of frequency components in the spectrum of the sound and map it onto a psychoacoustical curve of roughness is called curve mapping model. The type of the roughness model was designed by Vassilakis (2000)[6,7].

Roughness is important in musical contexts as well. Perceived tension provisions. The ropes show a great positive relationship with the roughness of the estimated ropes Values of Bigand et al., (1996)[8]. Roughness assumes amplitude modulation tones due to inability. The auditory system to solve the stimulation components, ie carrier and two lateral bands, either spectrally or temporarily Zwicker and Fastl, (1990)[9].

Based on earlier work before Terhardt et al., Zwicker and Fastl(1990)[10] suggested that the roughness be limited by frequency resolution at low carrier frequencies and time resolution at higher carrier frequencies.

For carriers less than 2000 Hz, the modulation rate at which the peak of roughness occurs is high the peak, the rate of formation at which the roughness disappears, all grow with the increase of the carrier repeat. This is due to the amplitude of the audio channels as the carrier frequency.

Increases, allowing the interaction between stimulation components more spaced. In the carrier frequencies above 2000 Hz, Zwicker and Fastl 1990(9)

reported that roughness up to peak at modulation rates of about 70-80 Hz and disappear at about 250 Hz,

Regardless of the carrier frequency, which indicates that time accuracy is the limiting factor.

Method

The calculations were done by the non-linear model, the stimulus level 30 dB was studied for six different cochlear roughness.

Results and Discussion

One of the auditory tests is otoacoustic emission. In this work the otoacoustic emission of low stimulus levels is studied and the stimulus level 30 dB is used. Cochlear roughness is an important factor for hearing. In this work, the relationship between rougheness and intensity level 30 dB is studied. The study is in the form of stages to study the relationship between the stimulus level 30 dB and roughness and the impact of this relationship on the hearing mechanism.

The results are in the form of different cases in each case roughnessvariesand the value of cochlear roughness for the first case is the lowest value for the rest of the cases and is considered the lowest, the cases are as follows:

The first case: In this case, the transient evoked otoacoustic emission is studied with the stimulus level 30 dB, which is considered to be one of the lowest stimulus levels so that the roughness of the cochlea is weaker in comparison with the following cases.

Figure 1 shows the energy distribution of the transient evoked otoacoustic emissions of the first case. It is very clear that the otoacoustic emission through energy distribution is weak and this reflects hearing loss and the reason that the coarseness of the cochlea is very weak.

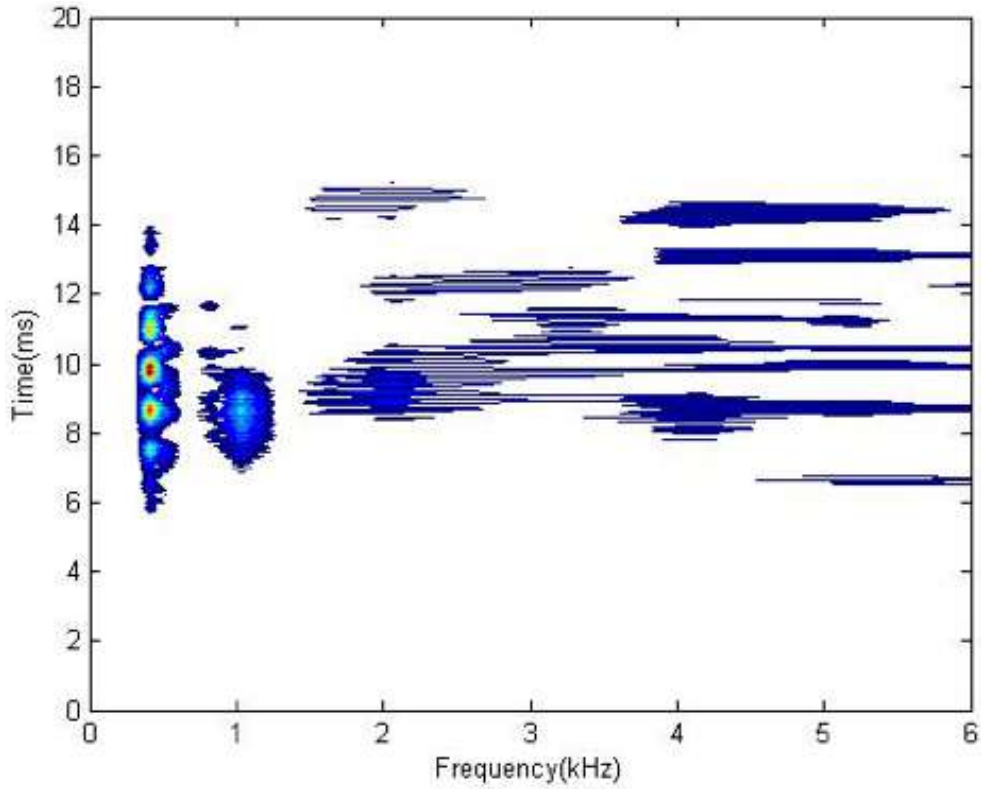

Figure 1: The otoacoustic emission (30 dB) for the first case.

The second case: In the second case, the study mechanism for otoacoustic emission is continued using the same stimulus level 30 dB, but with different cochlear roughness. In this case, roughness is greater than in the previous case.

Figure 2 shows the transient evoked otoacoustic emission of the second case, shows that otoacoustic emission status is better than the second case compared to Fig. 1, which represents the first case, and because the roughness in the second case is greater than the second case, the reason for the improvement of auditory emission is the change in cochlear roughness.

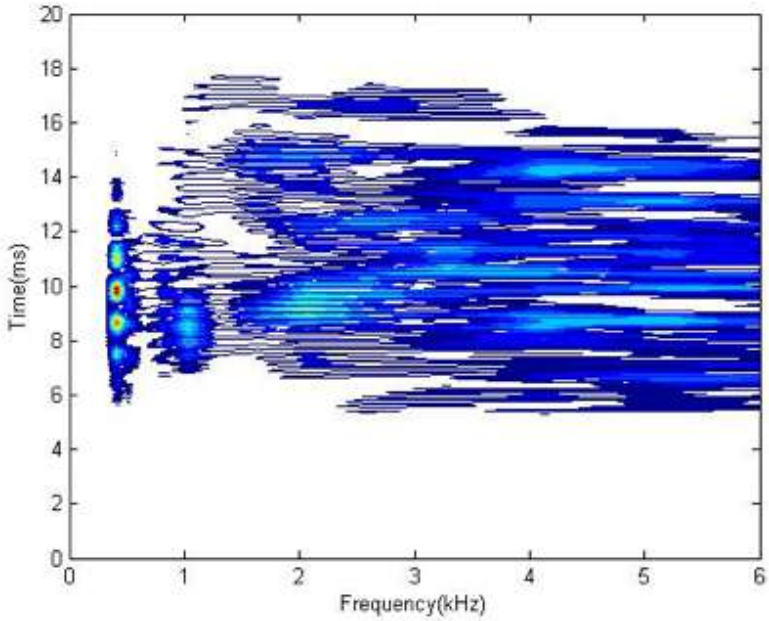

Figure 2: The otoacoustic emission (30 dB) for the second case

The third case: In the third case, the process of changing the roughness continues to be different from the previous cases. The otoacoustic emission of the stimulus level 30 dB is obtained using a different roughness condition than the previous ones.

Figure 3 shows the otoacoustic emission of the stimulus level 30 dB for another different cochlear roughness condition.

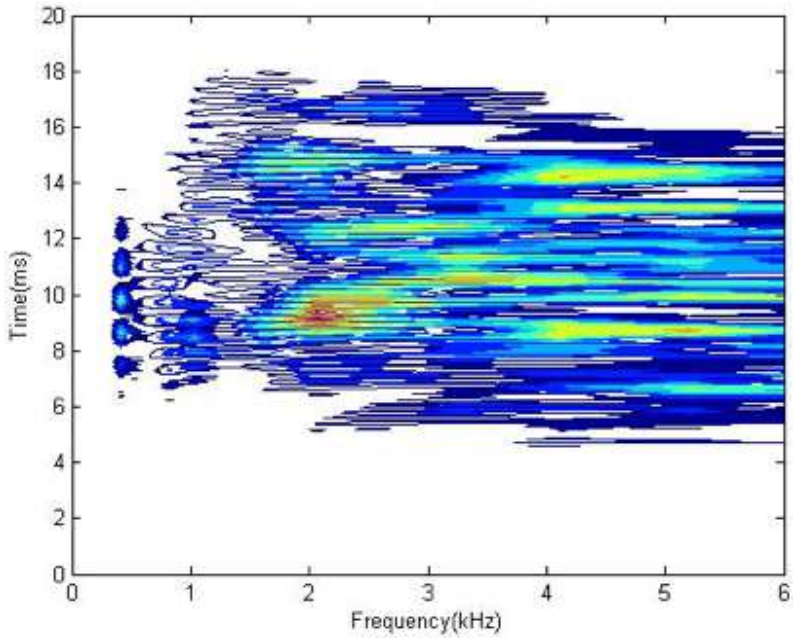

Figure 3: The otoacoustic emission (30 dB) for the third case

The fourth case: In the fourth case, the process of changing the roughness continues to be different from the previous cases. The otoacoustic emission of the stimulus level 30 dB is obtained using a different roughness condition than the previous cases.

Figure 4 shows the otoacoustic emission of the stimulus level 30 dB for another different cochlear roughness condition.

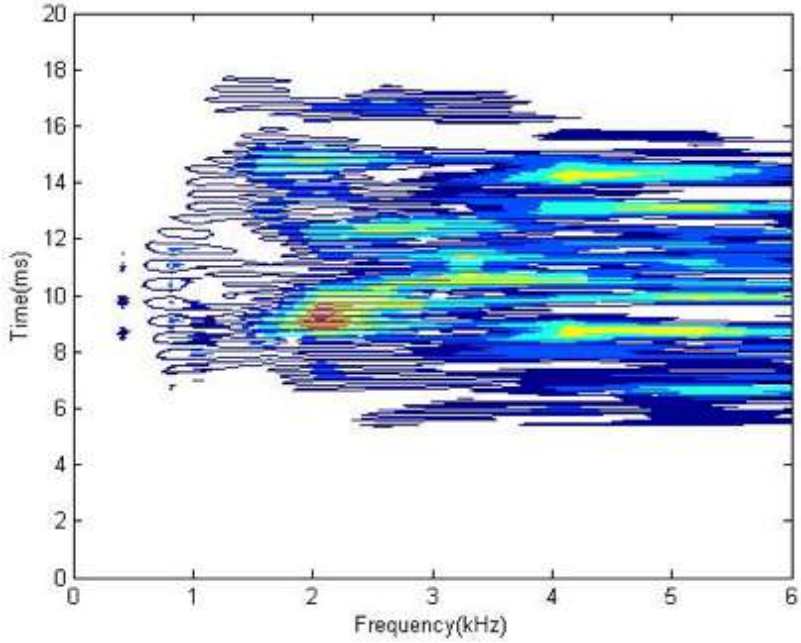

Figure 4: The otoacoustic emission (30 dB) for the fourth case.

The fifth case: In the fifth case, the otoacoustic emission of the stimulus level 30 dB is obtained using a new cochlear roughness condition different from all previous cases.

Figure 5 shows the otoacoustic emission of the stimulus level 30dB using different roughness from all previous cases.

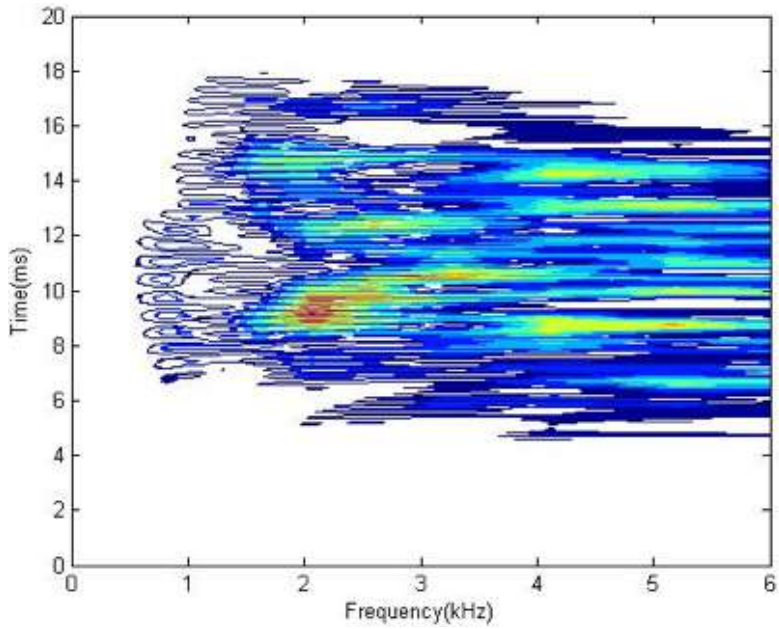

Figure 5: The otoacoustic emission (30 dB) for the fifth case.

The sixth case: The sixth and final case where a different cochlear roughness condition is used to obtain the otoacoustic emission of the stimulus level 30 dB.

Figure 6 shows the otoacoustic emission of the last case using roughness in a different case than all previous cases of the stimulus level 30dB.

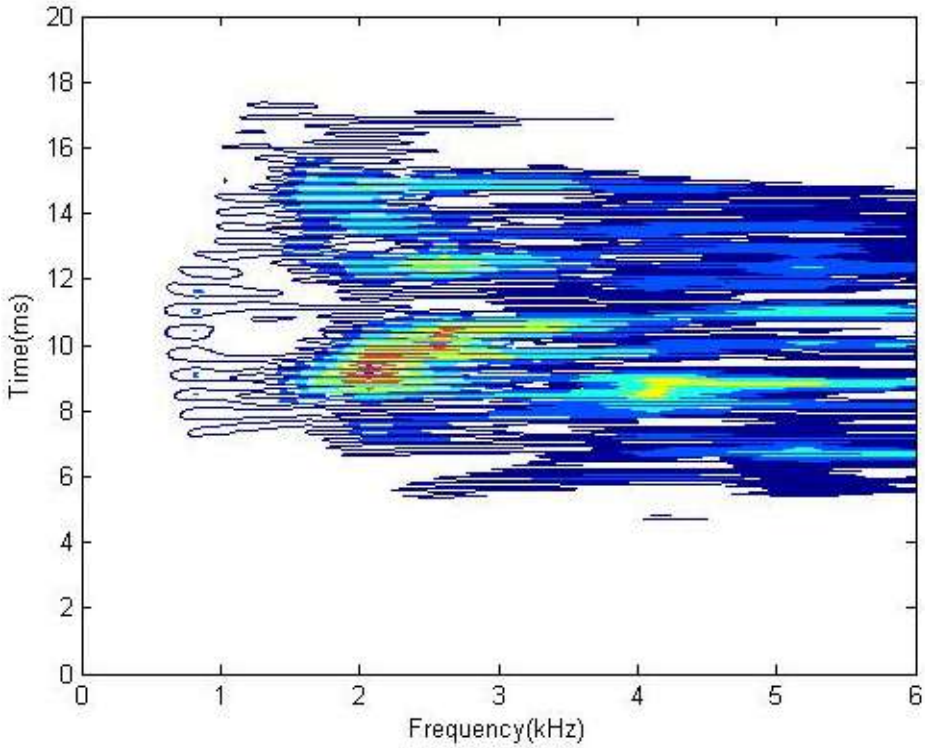

Figure 6: The otoacoustic emission (30 dB) for the sixth case.

The six cases in this work represent the study of hearing through the most important auditory tests, which is the otoacoustic emission for the purpose of studying the relationship between the stimulus level 30 dB,the roughness and hearing.

The calculations were made using a non - linear model, where six different roughness conditions were used with one stimulus level of 30 dB.

By studying Figures 1, 2, 3, 4, 5, and 6, it is noted that otoacoustic emission is different for all cases and the cause of variation is roughness.

Figure 1 shows a state of the otoacoustic emission in poor condition and Figure 2, although better than Fig. 1, but also in poor condition, cochlear roughness condition is the cause of the poor state of otoacoustic emission.

For the other four cases, the third, the fourth, the fifth, and the sixth, the resulting of the otoacoustic emission is better than the first and the second.

In general, the last four cases 3, 4, 5 and 6 give different but acceptable results. This is because the roughness of the four cases is better than cases 1 and 2.

At the same time, cases 3 and 4 almost gave similar results, and cases 5 and 6 also gave similar results, but cases 5 and 6 gave better results than cases 3 and 4.

The reason for the different otoacoustic emission status of the six cases is the different roughness condition used for each case.

According to the results of the work obtained, both in terms of the cochlear roughness or the stimuluclevel. The results of the work are in agreement with previous studies[11,12].

Conclusion

In analyzing the results of the work, the otoacoustic emission reflects the auditory state. The results of the six cases were different. In the first and second cases,

the otoacoustic emission was not good and reflected an unusual state of hearing.

We conclude from this that the cochlear roughness is the cause of the difference in the results, where the roughness condition is not good so the first and second case that gave a poor auditory emission.

Because the roughness of the other four cases was different but good, it gave good and acceptable auditory resurgence.

We conclude that roughness plays an important role in the auditory process and the role of roughness can be described as total and partial.

The stimulus level 30 dB, which is classified as low stimulus level, gave acceptable results for otoacoustic emission and according to the role of roughness and the stimulus level 30 dB reflected a consistent good condition as the stimulus level.It is concluded that the hearing mechanism depends directly and importantly on the relationship between coarseness and coarseness level. According to the results obtained in this work, the results were good, acceptable and compatible with previous studies.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the Department of Medical Physics, College of Science, Al-Karkh University of Science, Baghdad, Iraq and all experiments were carried out in accordance with approved guideline.

Abstract

In playing basketball, body fitness is important. It is closely related to biomotor abilities which consist of several components, one of which is endurance. An attack movement in a basketball game would require good cardiorespiratory endurance. Aerobic endurance is related to oxygen intake.This study aims to determine the improvement of cardiorespiratory endurance in male students who took basketball as a preferred extracurricular activity gained through circuit training. This is experimental research with one-group pretest-posttest design. The sample of this research consisted of 15 male students. Circuit training was carried out three times a week for four weeksat an exercise intensity of 65%–90% of maximum heart rate. From hypothesis testingwitha paired t-test,it was found out that P = 0.000 (0.000 < 0.05), suggesting that there was a meaningful difference. This result shows that circuit training improved cardiorespiratory endurance.

Keywords: *circuit training, cardiorespiratory endurance, male basketball players*

Introduction

Basketball games are considered to be one of the most dynamic and flexible sports which require high levels of physical fitness[1]. Physical relations are associated with biomotor abilities because biomotor abilities are the abilities to measure human performance[2]. One of these biomotor components greatly affects a person's endurance, namely resilience. Resilience is the ability of the heart, lung, and blood vessels to work optimally when carrying out activities for a long time without experiencing interference[3]. Resilience can be grouped into anaerobic resistance and aerobic resistance[4],[5]. The training session applied by the coach was directed more to technical training and games. This affected the physical strength of poorly trained players[1],[6].

Cardiorespiratory endurance can be increased by a variety of training techniques, one of which is circuit training[1],[7]. Circuit training is a combination of several types of exercises carried out in several training posts [2]. At each training post, an athlete will perform a predetermined type of exercise[8]. One circuit training set is said to be complete if an athlete has completed training in all training posts according to the prescribed dose. The movements included in this circuit training are as follows: push-ups, sit-ups, vertical jumps, abdominal curls, back extensions, astride jumping over benches, pull-ups, bench stepping, burpe, shuttle run, thrust squats, side bend, skipping, and running on the spot[9].

Material and Method

Participants: The population in this study was all male students who took extracurricular activities at a middle school in Denpasar, Bali. The sample in

this study was male students who took basketball as a preferred extracurricular activity. The sample used had to meet the following criteria: the participants were male middle school students who took basketball as an extracurricular activity, were aged 13–14 years, had low cardiorespiratory endurance of < 35 (poor), and did not take part in any cardiorespiratory resistance training program other than circuit training during the study. After each of these posts the students were given a break period of 15 to 20 seconds before proceeding to the next post. After completing one circuit, the students were also given a break period of 15 to 20 seconds.

Circuit training measures: In this study, some interviews and observations were carried out, and information related to age and some complaints experienced was generated. This would affect the daily physical activity and the training process and would let the researchers know whether the respondents observed were not too large. Several circuit training posts consisting of running on the spot, shuttle run, skipping, squats, push-ups, sit-ups for each set were established. This exercise was performed in 2 repetitions (sets) with a break time of 15–20 seconds between stages and between circuits.

a. Stage 1: Running on the spot. This training post lasted for 20 seconds.

b. Stage 2: Shuttle run. This training post lasted for 30 seconds (the students run back and forth and touched the predetermined boundary line).

c. Stage 3: Skipping or jumping rope. This training post lasted for 30 seconds (the students made a leap using the rope provided).

d. Stage 4: Squat. This training post lasted for 30 seconds (the students stood then bent both knees to a half squatting position and repeated continuously for a specified time period).

e. Stage 5: Push-up. This training post lasted for 30 seconds.

f. Stage 6: Sit-up. This training post lasted for 30 seconds.

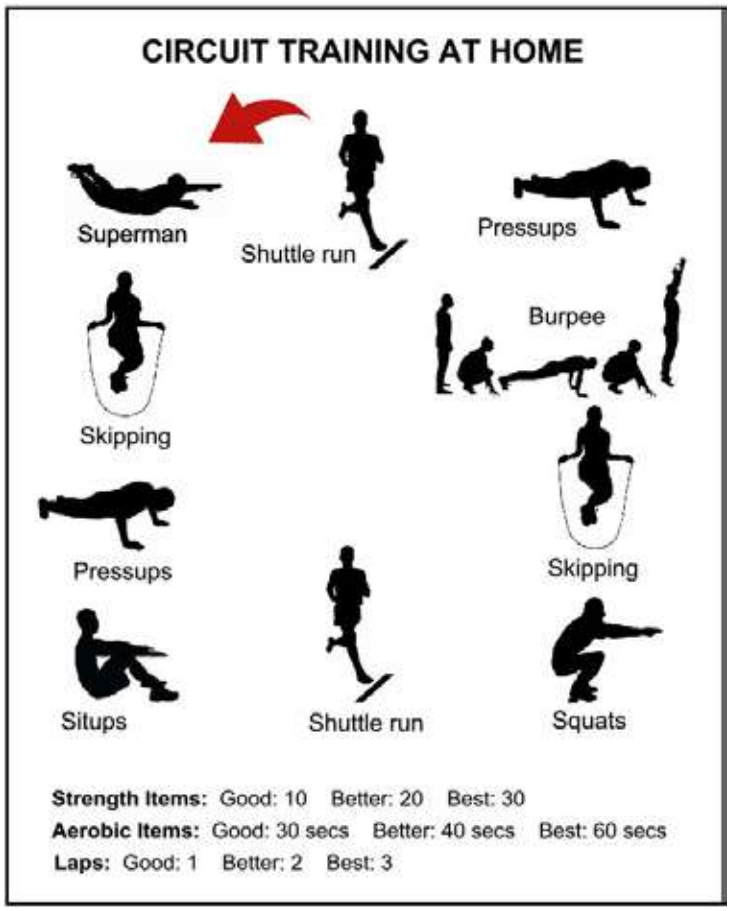

Fig. 1. Circuit trainning[9]

Statistical Analyses: This study used an experimental method with one-group pretest-post design. The data in the study were analyzed using SPSS. The analysis was conducted to describe the results of the research in the field without having to manipulate the facts. The data from the group weresubjected to a Shapiro-Wilk test at a significance level of 0.05. It was used to examine the average chest expansion before and after treatment in each group.

Finding and Results

Table 1 shows the number of respondents based on age:10 respondents (66.7%) were 13 years old, and the remaining 5 respondents (33.3%) were 14 years old.

Table 1: Age distribution of respondents

No	Age	Frequency	Percentage (%)
1	13	10	66,7
2	14	5	33,3
	Total	**15**	**100%**

Table 2 shows the number of respondents based on the VO_{2max} values obtained from the Balke test before the circuit training was performed: 5 respondents (33.3%) obtained values of < 35 and fell into the very poor category, 8 respondents (53.3%) obtained values of 35–37 and fell into the poor category, and 2 other respondents (13.3%) obtained values of 38–44 and fell into the fair category.

Table 2: Distribution of VO2 max values through Balke Test before being given Circuit Training

The VO2 max value in the balke test	Total		
	Category	F	Percentage (%)
< 35	Very poor	5	33,3
35 – 37	Poor	8	53,3
38 – 44	Fair	2	13,3
Total		**15**	**100%**

Table 3 shows the number of respondents based on the VO_{2max} values from the Balke test after the circuit training was performed: 1 respondent (6.7%) obtained a value of < 35 and fell into the very poor category, 6 respondents (40.0%) obtained values of 35–37 and fell into the poor category, and 8 respondents (53.3%) obtained values of 38–44 and fell into the fair category.

Table 3: Distribution of VO2 max values through Balke Test after being given Circuit Training

VO2 max value	Total		
	Category	F	(%)
< 35	Very poor	1	6,7
35 – 37	Poor	6	40,0
38 – 44	Fair	8	53,3
Total		**15**	**100%**

Table 4 shows that the average VO_{2max} value obtained by a sample of 15 from the Balke test before the circuit training was performed was 35.68, the median was 36.2, the lowest value was 31.60, and the highest value was 39.60. Meanwhile, from the Balke test after the circuit training was performed to the same sample, the average VO_{2max} value was 38, the median was 38.5, the lowest value was 33.30, and the highest value was 44.

Table 4: Results of Measurement The average VO2 max value through the balke pre-test and post-test.

Variable		Mean	Median	Min	Max	%
Balke test	Pre-test	35,68	36,20	31,60	39,60	6,5%
	Post-test	38,00	38,50	33,30	44,00	

Table 5 shows the results of the normality test using the Shapiro-Wilk test. The pre-test VO_{2max} was 0.980. Because 0.980 > 0.05, the pre-test data were normally distributed. Meanwhile, the post-test VO_{2max} was 0.848. Because 0.848 > 0.05, the post-test data were normally distributed.

Table 5: Data Normality Test Results Measurement of VO2 max values through the balke test

Variable		Statistics	Sig,	Interpretation
Balke test	Pre-Test	0,982	0,980	Normal
	Post-Test	0,969	0,848	Normal

Table 6 shows that the paired t-test comparing the pre-test and post-test VO_{2max} values obtained from the Balke tests conducted on the sample yielded a significant result of 0.000 (0.000 < 0.05), indicating that there was a change in cardiorespiratory endurance after circuit training was performed.

Table 6: Results of paired t-test analysis

Results		Df	Sig	Information
Balke test	Pre-Test	14	0,000	There are significant differences
	Post-Test			

Discussion

Cardiorespiratory endurance in males aged 13–14 (adolescents) can increase if training is applied in accordance with a stipulated dosage or training load[10], [11].Age affects all components of physical fitness, and VO_{2max} plays an important role in respiratory fitness. VO_{2max} of children aged 8–16 years shows a progressive and linear increase in peak aerobic ability. Thus, it can be increased by applying active sports such as circuit training[12], [13], [14]. However, circuit training produces different levels of VO_{2max}, causingnon-optimal VO_{2max}achievement[6], [15]. Circuit training is designed to develop cardiorespiratory fitness, cardiovascular endurance, flexibility, strength, and muscle endurance [16]. This exercise has a number of advantages: it can be performed in a short time period;it can be applied to one person or a group of persons; and it does not require any complicated equipment [2]. Circuit training is designed to stimulate the cardiorespiratory organs, and, as a result, the resistance aspect is emphasized [17].

Some research studies reveal that male basketball players aged 10–12 years saw an increase of VO_{2max} after carrying out circuit training exercises for 6 weeks as well as average initial score and average final score by 7.68 ml/kg BW/minute (20.68%) [18],[3]. According to the American College of Sports Medicine in 2006, the target heart rate rangeone should achieve when conducting a circuit training exercise to experience cardiorespiratory benefits is 65%–90% of the maximum heart rate [15],[21]. This is in accordance with the results of the research conducted—that is,the dose used should be based on the size of the maximum heart rate to achieve changes in the cardiorespiratory aspect [19]. Recent studies related to exercises that have an effect on cardiorespiratory function have shown that breathing exercises are able to increase the amount of O_2 intake, for instance, chest expansion, with a p value of <0.05[20], [22]. Thus, the exercise also has an impact on the aerobic capacity of both sick patients and healthy people.

The results of this study show an increase in the cardiorespiratory endurance of male students taking basketball as an extracurricular activity based on the VO_{2max}values obtained from a Balke test (p= 0.000). The students were given circuit training 3 times a week for 4 weeks of meetings with a training load of 65%–90% of the maximum heart rate. Each circuit training treatment consisted of 2 sets of exercises, each of which consisted of 6 types of exercises that had to be carried out in each training post provided. Based on the VO_{2max} values before the circuit training was given to the sample, 20% of the respondents fell into the very poor category, 66.7% to the poor category, and 13.3% to the fair category. The 6 types of exercises were running on the spot, shuttle run, skipping, squats, push-ups, and sit-ups. This study's results are supported by previous research that was conducted on middle school students, which reveals that 6-week circuit training exercises on leg muscle strength could increase VO_{2max}[18], [23], [8].

The main limitation of our study is that we have yet to find anyother types of training comparative to circuit training for increasing the cardiorespiratory fitness of middle-school basketball players, thus we are in need of literature related to other types of aeorbic training. Therefore, more precisely, we recommend exercise to overcome the decline in cardiorespiratory fitness, for example, a decrease in the functional aerobic capacity.

Conclusions

From the observations conducted three times a week for four weeks, it was found that the provision of circuit training could increase the cardiorespiratory endurance of male students who took basketball as an extracurricular activity. However, in order to gain further insights regarding the improvement of cardiorespiratory fitness of long-term male basketball players, the sample size should be greater because the fitness level of each man may vary.

Conflict of Interest: The authors declare that there is no conflict of interest related to this study.

Source of Funding: The authors declare that there is no source of funding from anyone.

Ethical Clearance: The experiment was approved taken from by the Research Ethics Committee of Medical Faculty of Udayana University/Sanglah Hospital.

Relationship between Self-Care for Fluid Limitation and Interdialytic Weight Gain among Patients with Hemodialysis at Ratu Zalecha Hospital, Martapura

Agus Rachmadi[1,2], Ita Ratnasari[2], Nursalam[3(CA)], Arief Wibowo[4]

[1]Doctoral Student, Public Health Faculty, Universitas Airlangga, Surabaya, Indonesia, [2]Health Polytechnic Banjarmasin, Ministry of Health, Indonesia, [3]Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia, [4]Public Health Faculty, Universitas Airlangga, Surabaya; Indonesia

Abstract

Chronic kidney failure is progressive and irreversible which caused metabolism disorder as well as electrolyte imbalance. This condition makes the patients to conduct hemodialysis. Patients with hemodialysis must have the ability to do self-care for fluid limitation management. Self-care deficit in managing fluids can cause interdialytic weight gain. The aim of this study was to measure the correlation between self-care for fluid limitation and interdialytic weight gain among chronic kidney disease patients with hemodialysis in Ratu Zalecha hospital Martapura. This study used cross-sectional study, total sampling and the final sample was 50 respondents. Data were collected in 2018. We used Spearman Rank Correlation to analyze the data. The result showed that there was a correlation of self-care for fluid limitation and interdialytic weight gain among patients with hemodialysis in Ratu Zalecha Hospital Martapura (p-value< 0,000; r= 0,589). The capability of self-care for fluid limitation and increase self-confidence among patient with hemodialysis to prevent interdialytic weight gain is needed.

Keywords: *Self-care, Fluid limitation, Interdialytic weight gain, hemodialysis.*

Introduction

Kidney has an important role in the human body to maintain fluid volume and distribution [(1).] Kidney failure requirements long treatment [(1)]. More than 500 million people had Chronic kidney failure [(2)]and only 0.1% of kidney failure was detected [(3)]. 2,622,000 people with kidney failure conducted end-stage renal disease (ESRD), and 77% undergo hemodialysis treatment [(3)]. *National Center For Chronic Disease Prevention and Health Promotion* (2014) noted that the prevalence of chronic kidney failure was increased [(4)].

Chronic kidney failure is progressive and irreversible. The urea creatinine will increase as the body inability to maintenance metabolism and keep fluid and electrolyte balance [(5)]. Additionally, kidney failure caused endocrine disorder and metabolic disorder, so it needs hemodialysis or kidney transplantation [(5)]. Hemodialysis is needed to remove metabolic residual from the blood such as water, sodium, potassium, hydrogen, urea, creatinine, uric acid, and others substance through semi-permeable membranes [(6)]. Hemodialysis also assists to maintain fluid balance, but the patients have to control their fluid regularly.

Patients with hemodialysis need to be trained to calculate fluid balance within 24 hours so they can control the fluid based on their needs. The fluid restriction will prevent fluid excess, because fluid excess can cause disruption of function in other organs, such as lung and cardio [(7)]. Another consequence is interdialytic weight gain, edema, wet rheumatism in the pulmonary, swollen eyelids and shortness of breath [(5)].

Patient with hemodialysis is required to do self-care independently, it refers to self-care. Self-care is an individual effort to fulfill their needs by optimizing intellectual abilities, behavior and utilizing the environment[(8)]. Self-care can be achieved by applying Dorothea E. Orem's nursing self-care theory. According to Orem's theory, every individual with a certain age

and condition has the ability to treat, protect, control, minimize and maintain the body to get healthy and well-being as well as optimal life both healthy and sick, or recovering from illness [5].

Self-care deficit in managing fluids can cause an increase in body weight between two dialysis times due to increased body fluid volume, it refers to interdialytic weight gain [9]. Interdialytic weight gain is one of the complications in patients with chronic renal failure who undergo hemodialysis caused by the inability of the renal excretion function. Increasing the value of the interdialytic weight gain will cause a negative effect such as hypotension, muscle cramps, hypertension, shortness of breath, nausea vomiting [10], also cause hypertension, peripheral edema, pulmonary edema, and increase the risk of dilatation and cardiac hypertrophy [7]. The problem in this study was to measure the relationship between self-care of fluid limitation and interdialityc weight gain among patients with chronic renal failure and hemodialysis in Ratu Zalecha Hospital Martapura.

Method

Participants and Settings: All of the procedures of this study got permission from Institutional review board in one of University in Indonesia. This study used cross-sectional design to analyze the correlation between self-care for fluid limitation and Interdialytic Weight Gain. The Dependent variable was self-care for fluid limitation and the independent variable was Interdialytic Weight Gain.

Data were collected from patient with hemodialysis in Ratu Zalecha Hospital Martapura, South Kalimantan, Indonesia, and used total sampling. We collected the data from Januari until February 2018. Total patients with hemodialysis in this hospital were 81. It produced 60% respond rate, so the final sample was 50 respondents.

Instruments: We used self-report questionnaires to collect the data.

Self-care for fluid limitation: We developed this questionnaire based on self –care concept from Orem theory (11, 12). It had 3 dimensions self-care maintenance, self-care management, and self-care confidence with total of 20 items. Self-care maintenance refers to knowledge regarding decision–making with true-false question (7 items), self-care management refers to behavior regarding health maintenance (7 items), with Likert scale (always-never), and self-care confidence regarding self-efficacy (6 items) with Likert scale (strongly disagree-strongly agree). The score between 51-80 means high score in self-care, and score between 20-50 means low score in self-care. This questionnaire had good convergent validity (r> 0.2) and adequate internal consistency with cronbach alpha= 0.839.

Interdialytic weight gain (IDWG): This is an observational instrument and measure body weight before hemodialysis, body weight after hemodialysis. We used Nerbass theory to determine the different bodyweight as well as the percentage of body weight (13). If the percentage of bodyweight < 5% refer to normal.

Statistical analysis: We used SPSS for windows to analyze the data (p value of < 0.05 are considered to describe statistically significant differences). Descriptive statistics (frequency and percentage) were used to calculate all variables. A spearman correlation was used to explore the relationship between self-care for fluid limitation and Interdialytic Weight Gain. Regarding response rate we used the recommendation from the previous study, that was 60% response rate [14].

Findings:

Characteristic of Respondents:

Table 1 shows the characteristic of participants, included in this study: age, gender, and length of hemodialysis. Regarding age, 34% of participants were 45-55 and 56 -65 years old, the proportion of male was 54% and female was 46%. Length of hemodialysis showed that 54% of participants undergo hemodialysis around 12-24 months and 40% of participants undergo hemodialysis > 24 months.

Table 1. Demographic characteristic of participants

Characteristic	N	%
Total = 50		
Age (years)		
18-40	3	6
41-45	8	16
46-55	17	34
56-65	17	34
>65	5	10
Gender		
Male	27	54
Female	23	46

Characteristic	N	%
Length of Hemodialysis		
<12 months	3	6
12 – 24 months	27	54
>24months	20	40

Descriptive statistics among variables: Table 2 shows 58% participants had good self-care for fluid limitation and 42% had low self-care for fluid limitation. In term of Interdialytic Weight Gain, 58% participants had normal Interdialytic Weight Gain and 42% participants had abnormal Interdialytic Weight Gain.

Table 2. Statistical Description of variables

Variables	N	%
Total = 50

Discussion

Self-care for fluid limitation among patients with hemodialysis in Ratu Zalecha Hospital Martapura

Patients with hemodialysis generally have complex problems and require to fulfill their needs. One of their needs was related with ability to care themselves. Patients with hemodialysis must have ability to maintain their fluid intake to achieve optimum quality of life. Self-care in this study used Orem theory [11, 12, 15]. Based on this study, 58% of respondents had good self-care for fluid limitation (table 2). Most respondents showed higher self-care maintenance (knowledge) followed by self-care confidence (self-esteem) and self-care management (behavior). Previous study noted that quality of life could be achieved by increasing self-care [3].

This study also showed most of the respondents had low self-care management to manage the fluid intake. The patients did not calculate the fluid intake and urine output a day. They consume 2-3 glasses of water in a day, with urine output 500 ml/24 hours and also manage thirst by brush their teeth and gargling. However, they did not know that they must restrict salty food that induces thirstily. Previous study mentioned about the obstacle of self-care management among patients with hemodialysis was internal and external factors. Internal factors were low of motivation to diet and fluid restriction during activity. External factor was cost of hemodialysis [16]. Fluid restriction is needed to give comfort to patients before and after conducting hemodialysis [5].

Interdialytic weight gain among patients with hemodialysis in Ratu Zalecha Hospital Martapura: Interdialytic weight gain is related to the patient's fluid restriction. Fluid restriction is one of the treatments for end-stage renal disease (ESRD) to prevent worse conditions. The amount of fluid was determined for a day, and it depends on kidney function, the patient's edema and urine output [17]. This study showed that 58% participants increased of body weight and it was normal range. 42% of participants were an abnormal range (table 2). Fluid intake among patients with chronic renal failure related to Interdialytic weight gain. This study was similar to previous study [17]. We assumed that Interdialytic weight gain due to thirsty condition among participants, it was similar to Black and Hawks theory [18].

Increased interdialytic weight gain exceeding 5% of dry weight can cause several of complications such as hypertension, interdialytic hypotension, left heart failure, ascites, pleural effusion, congestive heart failure, and also can lead to mortality. Many factors contribute to interdialytic weight gain, such as internal factors (thirst, stress, and self-efficacy) also external factors such as family support and fluid intake [19].

Relationship between self-care for fluid limitation and Interdialytic weight gain among patients with hemodialysis in RSU Ratu ZalechaMartapura

In this study showed 82.8% respondents had high self-care for fluid restriction experienced an increase in normal interdialytic weight gain and the remain was respondents with low self-care for fluid restriction experienced an increase in abnormal interdialytic weight

gain. This study also showed that self-care for fluid restriction was statistically significant with interdialytic weight gain (table 3) with moderate correlation (r= 0.589). This study was similar previous study about significant relationship between fluid intake and interdialytic weight gain [17].

Limitation: This study had some limitation. This study used cross-sectional study and relatively small sample size. Therefore, the results may be generalized carefully. Further study is needed to increase self-care for fluid limitation among patients with hemodialysis to prevent Interdialytic weight gain.

Conclusion

Besides the limitations, this study produced enough response rate. We are confident that self-care for fluid limitation related to interdialytic weight gain. This study suggests evidence to increase self-care for fluid limitation to prevent Interdialytic weight gain.

Abstract

Objective: To evaluate the value of human epididymis protein 4 (HE4) in predicting endometrial pathology in women with postmenopausal bleeding (PMB).

Method: A cohort study included 100 women with PMB. Women with endometrial thickness (ET) >5mm were subjected to hysteroscopic guided fractional curettage (FC) followed by total abdominal hysterectomy and bilateral salpingo-oophorectomy with or without pelvic lymphadenectomy.

After exclusion of 10 patients, the value of serum HE4 was tested in 90 patients for the ability to predict endometrial pathology based on hysterectomy specimen.

Results: Level of HE4 showed a significant difference among women with different endometrial pathologies. HE4 showed a significant positive correlation with the severity of the endometrial lesion, with mean values of 38.33±27 pmol/L for atrophic endometrium (11 cases), 51.26±28.59 pmol/L for simple endometrial hyperplasia (SEH,51 cases), 148.4 ±67.34 pmol/L for atypical endometrial hyperplasia (AEH,16 cases) and 390.9±351.72 pmol/L for endometrial carcinoma (EC,12 cases) Using the cut-off value of 69.5 pmol/L for preoperative HE4 yielded a sensitivity of 75% and a specificity of 88.5% in prediction of EC.

Conclusion: HE4 can predict endometrial pathology in women with PMB with a high specificity and a fair sensitivity.

Keywords: *Human epididymis protien4 (HE4); postmenopausal bleeding; endometrial carcinoma; endometrial pathology.*

Introduction

Endometrial carcinoma accounts for 20% to 30% of malignant tumors in the female reproductive system. As a consequence to increased obesity, hypertension, diabetes, and prolonged life expectancy, the incidence and mortality of endometrial carcinoma have risen lately, with a tendency for onset at a younger age [1]. The prognosis is closely related to the disease stage. If the diagnosis is during stage I, then the survival rate is about 90%[2].

There are no specific tumor markers for endometrial carcinoma. CA-125 was detected in 1983 by Bast et al.[3] as the epithelial ovarian carcinoma antigen. However, CA-125 is less effective in the diagnosis of EC compared with the diagnosis of other gynecological carcinomas.

CA-125 can only produce obvious effect in diagnosing some common tumors in advanced stage[4].

HE4 biomarker has been recently studied. It was identified in the epithelium of the distal epididymis and was predicted to be a protease inhibitor involved in sperm maturation [5]. In 2003, HE4 was approved by the FDA as a serum tumor marker for ovarian carcinoma and attracted great attention [6]. Recent studies indicate that HE4 is highly expressed in ovarian and endometrial carcinoma tissues with increased serum level in these patients as well [7].

Materials and Method

This prospective cohort study included 100 women with PMB who were recruited from Kasr Al Aini Hospital, Cairo University, Egypt between June 2014 and August 2016. An informed written consent was obtained from all participants prior to inclusion.

All patients included in the study had single or multiple episodes of PMB with an ET of more than 5mm. Exclusion criteria were having history of other malignancies, history of intake of chemotherapy or radiotherapy, the use of hormone replacement therapy, and being unfit for surgical intervention.

Full history was taken (including the duration of menopause, the number of episodes of PMB, and previous investigations and current medications), general examination was performed (including blood pressure measurement, calculation of body mass index (BMI= weight (kg)/[height (m)]^2, and the presence of any signs of systemic diseases), and local examination was performed for all patients.

Transvaginal ultrasound (TVS) done by the same observer to nullify the effect of interobserver variability.

For the level of HE4: 5 ml of venous blood were withdrawn from all patients. The samples were left to clot. The separated sera were stored at -20˚ until all samples were obtained. Frozen samples were allowed to reach room temperature prior to use. Samples were then mixed thoroughly by gently inverting multiple times before analysis. HE4 was quantitatively assayed using the enzyme immunoassay (EIA) method (Fujirebio Diagnostics, Inc. Göteborg, Sweden). The functional sensitivity of the HE4 EIA is ≤ 25pM. The analytical specificity is 100 ± 15%.

All patients were then submitted to hysteroscopy under general anesthesia and guided endometrial biopsy.

Definitive management was later performed in the form of total abdominal hysterectomy, bilateral salpingooophrectomy, with or without pelvic lymph nodal dissection and histopathological examination.

Results

Women with malignancy had significantly older age, lower parity, higher BMI and longer duration of menopause when compared to those with non-malignant lesion (table 1).

ET of the malignant group was significantly higher than that of the non-malignant group (20.33 ± 7.4 versus 12.68 ± 4.22mm, p: <0.001), level of preoperative serum HE4 was significantly higher in the malignant group as compared to the non-malignant group (390.92 ± 351.72 versus 61.25 ± 31.65pmol/L, p: <0.001) (table 1).

The level of HE4 in different endometrial pathologies of the cases group is presented in (table 2).

A scale was proposed in which the endometrial pathologies were arranged in a descending manner according to the severity of the lesion, where malignancy was the severest, followed by AEH, then SEH, and atrophic endometrium being the least severe form. Hence, correlation between the preoperative HE4 level and the severity of the endometrial lesion could be evaluated. This study showed that there was a significant strong positive correlation between the preoperative level of HE4 and the severity of the endometrial pathology (r= 0.735, p: <0.001).

ROC curve was generated to evaluate the performance of the preoperative level of HE4 in distinguishing malignant from non-malignant endometrium (figure1).

Using the cut-off value of 69.5 pmol/L for preoperative HE4 yielded a sensitivity of 75%, a specificity of 88.5% and an AUC-ROC of 0.933 (table 3).

All malignant cases (12 cases) were of the endometrioid type, 5 were stage Ia, 5 were stage Ib, and 2 were stage II. All were operable and a total abdominal hysterectomy and bilateral salpingo-oophorectomy with pelvic lymphadenectomy was performed for all.

For the degree of differentiation, 2 cases were grade 1 (G1), 8 cases were grade 2 (G2), and 2 cases were grade 3 (G3).

Multivariate stepwise linear regression for factors with significant differences between malignant and non malignant cases as age, parity, and duration of menopause are shown in table 4.

The level of HE4 in the malignant cases according to the tumor stage, grade and lymph node involvement is described in table 5.

Discussion

In this study, we focused on examining the role of HE4 in distinguishing malignant from non-malignant lesions of the thickened endometrium in women with PMB through histopathological examination of hysteroscopic directed endometrial curettage followed by hysterectomy, and to correlate HE4 level with the endometrial lesion.

The prevalence of EC in the present study was 13.3%. This is similar to that reported in previous studies[8].

HE4 is a new detection index. Being highly expressed in ovarian and endometrial carcinoma cells [7].

In this study, the preoperative level of HE4 was significantly higher in the endometrial carcinoma cases than its level in the non-malignant cases.

HE4 actually exists in normal tissues e.g. male vas deferens, mammary gland epithelium, female genital tract including the endometrium [9]. So its level is suspected to increase with increased endometrial thickness. As suspected its level is increased in cancers arising from these tissues [10].

The National comprehensive cancer network in 2012 signified the value of HE4 as a tumour marker for epithelial ovarian tumors and as both the uterus and the ovary share a common embryological origin so HE4 can be used as a marker for endometrial tumors [11].

In the present study, upon examining the diagnostic performance of HE4 in predicting the presence of EC among patients with PMB, using the cut-off value of 69.5 pmol/L for preoperative HE4 yielded a sensitivity of 75% and a specificity of 88.5%, and an AUC-ROC of 0.933, Having more serious consequences separating AEH and EC patients from SEH and atrophic endometrium cases, HE4 was significantly higher in the former group 218.14 ± 273.46 versus 54.2 ± 22.45, $p < 0.001$ with a new cut off value calculated to help differentiation of AEH and EC cases, HE4 value of 62.5 pmol/L yielded a sensitivity of 85.9% and specificity of 62.9% with AUC of 0.832 .

Similar to our findings, previous study on 2015 reported the sensitivity and specificity of HE4 in distinguishing EC patients from healthy females were 62.2% and 95% respectively, with an AUC of 0.996 . Another one on the same year reported a sensitivity of 72.4% and a specificity of 75.4% for the cut-off 76.5 pmol/L [15]. Also, Capriglione et al in 2015 [16] reported sensitivity and specificity that are near to ours in detecting EC patients 83.3% and 96% respectively.

An earlier study on 2013 has reported that the sensitivity of HE4 in detecting malignant cases was 75% and the specificity was 65.5%, and that the sensitivity was improved after combining HE4 with other markers (CA-125, CEA, and serum amyloid –A) to be 84% [13].

Another publication in the same year revealed that the sensitivity of HE4 in detecting malignant endometrium was 59.4% with 100% specificity for the cut-off value of 70pmol/L. After adding CA-125, the sensitivity was elevated to be 60.4%. The authors concluded that HE4 at cutoff of 70 pmol/L yields the bestsensitivity and specificity [12]. The lower sensitivity of the marker in their study compared to ours might be due to that they took into consideration other types of EC while all our cases were of the endometrioid type.

Previous study on 2016 have reported that HE4 was significantly higher in grade 3 (G3) carcinomas compared with grade 1 (G1) and 2 (G2), and that patients who needed lymphadenectomy had significantly higher HE4 level than those who had no indications for this procedure[14].

A recent study on 2017 stated that preoperative serum HE4 is significantly correlated with primary tumor diameter and depth of myometrial invasion, but not with tumor grade or cervical involvement and lymphovascular infiltration and that serum HE4 levels could be useful in identifying EC patients at high risk of lymphatic spread who would benefit from lymphadenectomy[17].

A meta-analysis done in 2014 reported that HE4 is the most accurate and sensitive EC marker identified to date. In particular, this new marker seems to have a good performance in diagnosis. The best cut-off of HE4 in diagnosis ranges between 50 and 70 pmol/L, resulting at least in 78.8% of sensitivity and 100% of specificity in all stages. Another important aspect to consider is HE4

capacity in predicting the stage of disease and myometrial involvement, which can help scheduling the appropriate timing of imaging and surgery in a more individualized fashion and as indicator of patient prognosis[18].

Our study confirmed the known fact that malignancy is suspected to be found in women with postmenopausal bleeding when they are older, lower parity, higher BMI and have longer interval between menopause and presentation.

ACOG confirmed these findings by stating that the clinically identified risks for carcinoma endometrium include age and high body fat [19].

The present study is strengthened by its prospective nature, and that it depended on hysterectomy specimen for diagnosis of different endometrial pathologies as well as malignancy, beside the analysis of positive results of lymphadenectomy.

The main limitation of the study is the small sample size included which resulted in a limited number of malignancy cases with the resultant limited variations in malignancy stages and pathological subtypes. Larger number of participants would have better detected the value of the studied marker (HE4) in diagnosis and prognosis of endometrial malignancies. Nevertheless, the study highlighted the presence of this new marker and pointed to its possible value in diagnosis of the disease and the prediction of its occurrence at certain cut-off value with the reported sensitivity and specificity.

Table (1): Characteristics of the studied population

	Malignant group (n=12)	Non-malignant group (n= 78)	P value

Impact of Cervical Infection with Bacteria Ureaplasma Urealyticum to Interleukin-1α-Expression in Pregnant Women

Aimen A. Ahmed[1], Sabah M. Salih[2], Ayoub A. Bazzaz[3]

[1]Directorate of Health, Kirkuk, Clinical Laboratory, Directorate of Health, Baghdad Road, [2]Faculty of Nursury, Assistant Professor, Vice Dean of Faculty of Pharmacy, University of Kirkuk, [3]Department of Anatomy, Faculty of Veterinary Medicine, University of Kirkuk, Iraq

Abstract

Pregnant women could be at risk of developing complications in genital tract when infected with the bacteria *Ureaplasma urealyticum*. The objective of this study was to assess the impact of genital infection in pregnant women, in Kirkuk city, relevant to both gestational age and level of Interleukine (IL-1α). Fifty five pregnant women were involved whose ages ranged between 18-45 years. Double swab samples from cervix were collected i.e. the first swab used to detect *U. urealyticum* while the second to assess the level of IL-1α cytokine. Only 45% of pregnant women were infected with *U. urealyticum*, with the highest positive *U. urealyticum* infection among age group (18-31 years) (40%), while the older women had less infection frequency (5%). The significantly highest ($p \leq 0.05$) distribution percentage was amongst third trimester gestation (33%). Genital expression of IL-1-α had significantly ($p \leq 0.05$)elevated during the infection (189±3.3pg/mL) in comparison with non-infected pregnant women. The level of IL-1α was elevated significantly($p \leq 0.05$) among women in third trimester of pregnancy in comparison with second and first trimester, respectively. A significant correlation between *U. urealyticum* infection and elevationin the level of IL-1αis established.

Keywords: *Bacteria Ureaplasma urealyticum, Gestational age,interleukine IL-1α, pregnant women.*

Introduction

Bacterial vaginosis (BV) is one of the most common genital tract infections among reproductive age-group worldwide, in some cases, for unknown reasons. They are parasitic bacteria which need a host i.e. a human or animal to survive. Both social and sexual factors can contribute to the development of bacterial vaginosis[1]. The bacteria may exist almost in every woman but as a friendly and in nonpathogenic status. The bacteria *Ureaplasma* (family Mycoplasmataceae)have been found in both men and women with infertility problems. The bacteriumis part of the body's bacterial population, and they live in balance, without causing a problem, in most cases; however, they can increase in population, causing infection and health complications. The *Ureaplasma*, itself, is a bacterium commonly found in people's urinary or genital tract and can ***cause fertility problems in both genders which*** can be passed during sexual contact. It may also be found in women who have never been sexually active but might be higher among women who had multiple sexual partners. These bacteria may also be passed to a fetus or newborn if the mother has *Ureaplasma* infection during pregnancy[2].

Many species of mycoplasmas, do exist but only four are recognized as human pathogens; however, this study deals with only one species e.g. *Ureaplasmaurealyticum*. There are other species isolated from humans'genital tract, but their role in disease is not well established yet *e.g. Mycoplasma. genitalium* and *Ureaplasma parvum* that may reach colonization rates of up to 80% in healthy, sexually active women[3]. These species can be detected within vaginal flora in 40% of sexual inactive and 67% of sexually active women at reproductive age and in 25% of postmenopausal women[4]. The known transmission routes involved sexual contact or maternal infant transfer[5].

The *Ureaplasma* lacks the cell wall that makes it unique among bacteria represented in its resistant to some common antibiotics, including penicillin while it can be treated with others. The *U.urealyticum*, is also an important opportunisticpathogen during pregnancy[6]. These reproductive tract infections are implicated in medical conditions, i.e. pelvic inflammatory disease, preterm premature rupture of membranes, preterm birth, pregnancy loss, postpartum and postabortal sepsis[7,8,9]. *Maternal genital colonization with U.urealyticum promotes preterm delivery: association of the respiratory colonization of premature infants with chronic lung disease and increased mortality*[10]. The health condition of females is commonly checked by swab samples taken from cervicovaginal tract includes cytokines. The cervico-vaginal fluid proteome reflects the local biochemical milieu and is influenced by the physical changes occurring in the cervix and adjacent overlying fetal membranes[11,12]. Hence, it can be an excellent media to test the health condition in the female.

Cytokines represent a broad and loose category of peptides i.e. interleukins which cannot cross the lipid bilayer of cells to enter the cytoplasm but are involved in signaling as immuno-modulating agents. They are produced by a broad range of cells, including immune cells like macrophages, B-lymphocytes, T-lymphocytes and mast cells, as well as endothelial cells, fibroblasts, and various stromal cells[13]. The cytokines, similar to hormones, do act through receptors, and are especially important in the immune system as well as in health and disease, specifically in host responses to infection, i.e. immune responses, inflammation, trauma, sepsis, cancer, and reproduction[14]. Interleukine-1 (IL-1) is a central mediator for innate immunityand inflammation which includes7 ligands with agonist activity, three receptor antagonist and an anti-inflammatory cytokine (IL-37). Interleukine-1(IL-1) could therefore play a key role in checking the urogenital health condition of BV in women particularly in pregnant women.

Due to scanty studies to assess the prevalence of this bacterium and its correlation with the hormone interleukine-1 sequence in pregnant women in Iraq this study has been undertaken to address such acorrelation.

Materials and Method

Only 55 pregnant women involved were attending Azadi teaching hospital for the period of November2016-March 2017. Two cervicovaginalswabs from each pregnant woman were collected i.e. first was tested to diagnose *U.urealyticum* bacteria using mycoview kit (Zeakon diagnostic) (Besancon-france)[15]. The second swab was preserved in phosphate buffer saline and then tested to assess for level of IL-1α using ELISA technique (Diaclone Company, Besancon Cedex, France), and the SPSS (ANOVA) biostatistical analysis wasused.

Results

Only 25 out of 55 swabs (45.5%) collected from vaginal cervix were positive to *U. urealyticum* infection divided between 15 urban (27.3%) and 10 rural women (18.2%)indicating a proportion of 3:2 urban to rural (Table -1). The levels of IL-1α among pregnant women infected with *U. urealyticum* in urbans appeared significantly ($p \leq 0.05$) higher (279.7±17pg/ml) than in rural (246±6pg/ml) as in (Fig. 1).

Table 1: Details of infection with U.urealyticum according to geographical distribution, percentages and interluekine-1 levels(*): p≤0.05.

	Ureaplasmaurealyticum		
GroupsInter-luekine-1α	**Positive pg/mL**	**Control pg/mL**	**Total**
Urban	15(27.3%)* (279±17)	21(38.2%)* (158±5)	36(65.4%)
Rural	10(18.2%) (246±6)	9(16.3%) (146±6)	19(34.6%)
Total	25(45.5%)	30(54.4%)	55(100%)

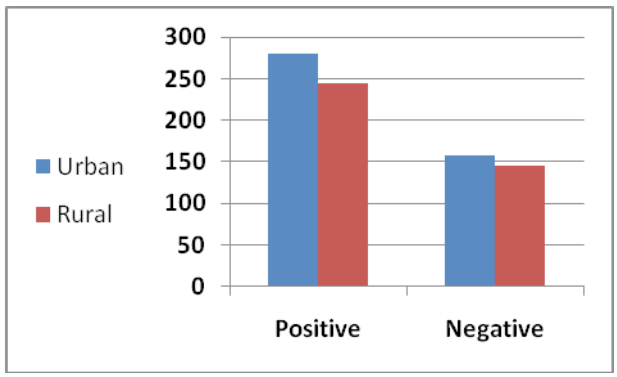

Fig-1: Levels of IL-1α (pg/mL) in both infected with U. urealyticumand control pregnant women from urban and rural districts. Differences were significant (p≤0.0.5).

The highest positive *U.urealyticum* infection was 22(40%), among women whose ages ranged 18-31 years while the older women had less infection frequency 3(5%) [Fig.2]. The significantly highest ($p \leq 0.05$)

distribution percentage was amongst third trimester 18(33%) in comparison with second and first semesters [Fig.3].

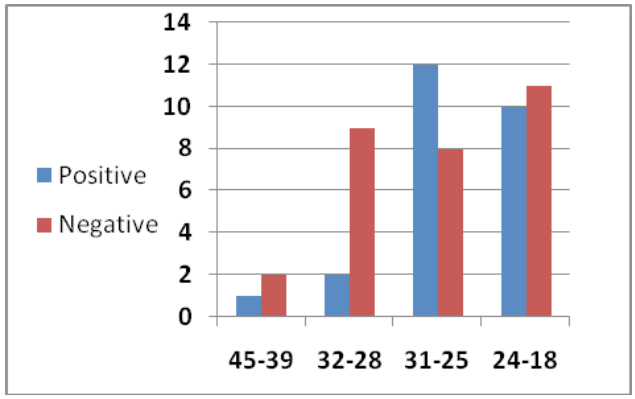

Fig 2: Frequency of U. urealyticum infectionin pregnant women according to age groups. The highest group infected was women aged 25-31 and 18-24 years old.

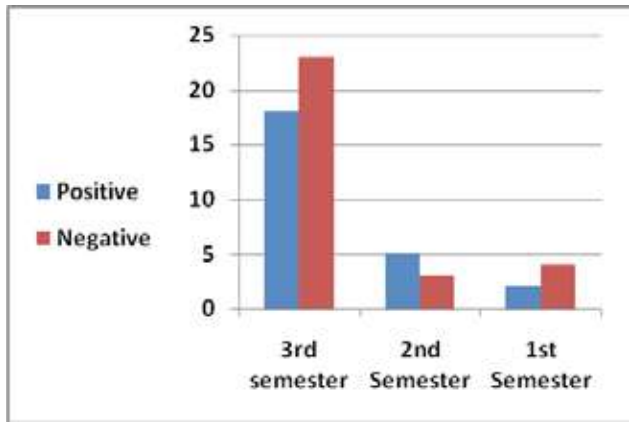

Fig. 3: Frequency of U. urealyticum infection according to gestational trimester of pregnancy. Note the third Trimester recorded the highest ever.

Level of interleukins (IL-1α) has significantly ($p \leq 0.05$) increased inpregnant women infected with *U. urealyticum* that involved almost all age groups. The highest record was at age group 32-38 year old (359±28pg/mL) followed by age group (18-24) years, respectively. However, the elevation in older age groups were less in comparison with control(Table 2).

Levels of IL-1α in different trimester with *U. urealyticum* infection had significantly ($p \leq 0.05$) increased in the third minister (305.74±13.76 pg/mL) in comparison with the second (176.4±3.8 pg/ml) and first trimester, respectively (Table-3).

Table (2): Level of IL-1α with U.urealyticum infection among pregnant women according age groups (* p≤0.05).

Age groups	IL-1α level (pg/ml) against U. urealyticum	
	Infected (pg/ml)	Control (pg/ml)
18-24	239.4±7.3*	160.7±12.9
25-31	193.3±5.5*	141.5±5.8
32-38	359±27*	156± 8
39-45	189.4±8*	144±6
Mean	189.3±3.3*	152± 6

Table 3: Distribution of IL-1a (pg/mL) in different trimester with U. urealyticum infection in pregnant women

Groups	U.urealyticum	
Trimesters	Infective (pg/mL)	Control (pg/mL)
First trimester	187.4±7.3	167.5±4
Second trimester	176.4±3.8	154.6±6
Third trimester	305.7±13.7*	144.5±8

Discussion

Although the total samples of pregnant women is not high enough due to social Iraqi mentality to donate swap samples to male researcher; however, they might, to certain degree, be indicative to the real frequency of infection. The negative samples that showed no infection were used as control for the comparison purposes. The high prevalence of *U. urealyticum* infection was among pregnant women in rural residence which indicates a rather lesser hygienic awareness differences and consequence lower health education level amongst the urban women. Such result is concomitant with most recent work[16]whileother studies had significantly varied in prevalence outcome than ours e.g. 41.1%[17]; 69%[18]. However, further lower percentages (16.13%) were also reported in Northern Greece[19] and in Iran(15%)[20]**.** Much lesser percentage (11.4%) was detected in amniotic fluid samples in a study done on pregnant women in second trimester[21]**.** An Iranian study found that the prevalence of *U.urealyticum* infection in women (spontaneous abortion and normal pregnancy) was 11.92%[22]. while the prevalence was significantly ($p \leq 0.001$) higher in Turkey's (HSD)[23]. Such a differences might be attributed to geographical distribution of the VB or to genetic factors while the health care awareness differences must not be knocked out.

The *Ureaplasmas* bacterium produces an IgA protease and releases ammonia through urea hydrolysis, both of which are considered possible virulence factors, may lead to immunologic response[24]. It seems that the middle age group are more sensitive to the infection than other age groups.

The presence of BV during pregnancy become a matter of concern of physicians/gynecologists due to adverse pregnancy outcomes as they increase the risk of late miscarriage, preterm labor, low-birth-weight infants, chorioamnionitis, postpartum endometritis, and postabortion pelvic inflammatory disease[25]. The BV-associated micro-organisms e.g. bacteria, in amniotic fluid and the placenta originating from the cervicovaginal mucosa are correlated to abortion and preterm labor[26].

When BV is identified before 16 weeks of gestation, the highest rates of preterm labor was detected while BV was responsible for 2 fold risk and 3 fold miscarriage detected of miscarriage in the first trimester[27], respectively. Other studies showed that BV is related to the late miscarriage in comparison with the first trimester pregnancy loss[28]. Almost 40% of pregnant women the BV had caused low-birth-weight infant at the second trimester pregnancy[29]. Other studies contradicted the above findings in fertile women[30].

Theearly age infection in our study is concomitant with a most recent study which was (70.7%) among age group (25-35 years)[31]. Simultaneously, the lower percent of *U. urealyticum* infection of the pregnant women was above 35 years age which may refer to rather a better gynecological experience of sexual transmitted disease prevention in older women than in younger ages. The higher frequency of *U. urealyticum* infection among third trimester might be attributed to the increase in infection rate among age group (25-31) years due to ignorance in health checkout and lack of treatment prior delivery. The latter might burden further risks on pregnant women in defected children e.g. congenital abnormalities. The test of pregnant women for *Ureaplasma* infections, can greatly reduce the chance of any complications by a suitable antibiotic treatment.

The significant increase in the level of IL-1α in pregnant women at the third trimester may be correlated to the increase in the infection intensity. At late pregnancy, the level of IL-1α and β concentrations increase to the peak at 4-14 days prior to labor onset[32] which is concomitant with the present study, however, no correlation was made to address the link between the levels of IL-1α to the intensity of the infection. In other words, the concomitant increase of the interleukine with the infection rate might indicate the involvement of the interleukins in defense mechanisms against ascending infection from the vagina[33]. To the best of our knowledge no correlation studies to relate the level of IL-1α during *U. urealyticum* infection have previously been done to address such a relevancy which may mean that the present study may represent a pioneer one so far.

Conclusions and Recommendation

The BV bacterium *U. urealyticum* infection has relatively high rate among pregnant women represented at third trimester of pregnancy particularly at age groups (25-31 years).Level of IL-1α elevated among age groups (32-38 years) particularly at third trimester of pregnancy. It is recommended to carry out a obligatory survey of BV during the pregnancy all over the country for prognosis with an early treatment to avoid further risk to the pregnant women and their babies.

Acknowledgement: Data are collected anonymously from routine daily hospital checkup for pregnant women attending the state hospital to which the authors acknowledge. There is no conflict of interest in this research.

Ethical Clearance: The results involved routine data from daily hospital checkup procedure for pregnant women attending the state hospital. Ethical clearance, therefore, deems unrequired as the results are taken anonymously from the hospital records where no patient name is disclosed.

Source of Funding: The whole research is done upon results of checkup at state hospital where it is self-funded. Any other fees spent are all from our pocket money. The authors acknowledged in the manuscript the Hospital officers for their co-operation in proving us the data for research purposes.

Conflict of Interest: There is no conflict of interest in this research of other parties at all and I am liable for any claim otherwise.

Short Clinical Outcome of Microscope Assisted Discectomy

Ali Mohammed Abdulhameed[1], Sherwan A. Hamawandi[2]

1Iraqi Board for Medical Specializations, [2]Assistant Professor, Consultant Orthopedic Surgeon, College of Medicine, Hawler Medical University, Iraq

Abstract

Objective: Determine the effectiveness of microscopic assisted discectomy and its application for the patient with disc disease, its efficacy, and its pitfalls.

Materials and Method: A prospective study conducted on 90 patients, which they reviewed prior to the operation by using Oswestry disability index (ODI) and visual analog score (VAS) for the back and leg pain, followed up on a period of 6 months by using the same method which they have been reviewed, all of the patient were operated on by microscopic assisted microdiscectomy discharge on the same day or the day after the procedure.

Results: There was a major improvement of back and leg pain by using VAS, the overall improvement in VAS for back pain was 4.43 points (p-value <0.001) and improvement in VAS for leg pain was 4.51 (p-value <0.001), while the improvement in ODI was 34.85 (p-value <0.001).

Conclusion: Microscopic assisted microdiscectomy offered a successful solution for common health issue with the advantage of small wound better cosmetics, low adverse effect and early rehabilitation and return to daily activity and resume individual function and productivity, good preoperative planning and selection of patient with the meticulous procedure and post-operative care can offer supreme results.

Keywords: *Clinical outcome, microscopic assisted, discectomy, disc herniation, Oswestry index.*

Introduction

Back pain considered an ancient health issue, being describes in the bible and by Hippocrates, it's quite common and international prevalence of back pain reported to be 49-80% annually[1].

Approximately 80% of individuals are affected by the symptoms of lumbar disc herniation at a point in their lives. Impairments of the back and spine are ranked as the most frequent cause of limitation of activity in individuals younger than 45 years old by the National Center for Health Statistics in the united states[2].

Among of many causes of back pain is lumbar disc herniation which is commonly seen in daily orthopedic and neurosurgical practice with wide range of presentation from simple back pain to radiculopathy due to nerve compression[3], in severe cases of lumbar disc herniation depending on the grade of prolapsed disc, leads to numbness weakness saddle anesthesia urinary and bowel incontinence and even foot drop sometimes which is required an emergency decompression surgery for cauda equina syndrome[4].

Conventional open discectomy has been prescribed as an effective remedy for this situation and with the advancement of minimally invasive surgery and its implementation in spine surgery, microscopic discectomy has been gaining popularity among surgeons, with its characteristic of small incision less tissue damage clearer operation field and faster recovery as effective as conventional open discectomy[5].

The objective of this study is to determine the effectiveness of microscopic assisted discectomy in treating patients with symptomatic lumbar and

e-mail: ali.muhammed.86@gmail.com

lumbosacral disc herniation who failed to respond to conservative treatment, follow them up, and determine functional outcomes using ODI and VAS scores for back and leg pain.

Method

Study design: A prospective study designed to follow up the patient according to ODI and VAS for both back and leg pain who underwent microscopic assisted microdiscectomy.

Study setting: The study was conducted in Erbil province in PAR private hospital and Rozhwa emergency hospital (neurosurgical department).

Period of study: The study was carried out between June 2016 and September 2018

Study sample: A total of 90 patients involved in this study a randomized sampling use

Inclusion criteria: Adult patients between 17 and 50 years of age complaining of lower back pain and/or radiculopathy and neurological symptoms, who failed to respond to a 6-8 weeks period of conservative therapy (lifestyle modification, NSAIDs, and physiotherapy).

The diagnosis carried out by using history, and physical examination; MRI was done for the patient to confirm the diagnosis and the level of disc herniation and determine the direction and extent of disc herniation

Exclusion criteria: Subjects with age group (<17 years and >50 years), any other type of disc herniation apart from L3-L4, L4-L5, L5-S1, multilevelpathology, patients with spondylolisthesis, spondylolysis, patients with scoliosis and kyphosis, patients with cauda equina syndrome, patients with previous back surgery, and with no local infection.

Data Collection: A questionnaire form constructed by the researcher which include:

- Demographic data of the patient.
- Level of activity (sedentary or active).
- Symptoms (back pain, leg pain, neurological deficit, or combination of these).
- Duration of symptoms in months.
- Level of disc herniation confirmed by MRI.
- Oswestry disability index before and after the operation
- Visual analog scale for back pain before and after the operation
- Visual analog scale for leg pain before and after the operation

All the patients discharged on the same day of operation or a day after, mobilized soon as they were ready. Patients were reviewed in intervals of 2 weeks, 2 months, and 4 months after surgery using VAS score for low back pain and leg pain and ODI score.

Operative procedure: All the patients were operatedon in a prone position by using bolsters under chest and pelvis and padding to protect pressure areas, all the patients were generally anesthetized, patients were sterilized using stander sterilization method and draping gave a prophylaxis antibiotic (ceftriaxone 1gm) about 30±15 minutes prior to incision. The level of operation was identified using spinal needle and slandered C-Arm available at operation theatre. Make the incision from the midspinous process of the upper vertebra to the superior margin of the spinous process of the lower vertebra at the involved level. This usually results in (25 to 30 mm) skin incision. This incision may need to be moved slightly higher for higher lumbar levels.

Incise the fascia at the midline. Insert a periosteal elevator in the midline incision. Using gentle lateral movements, elevate the deep fascia and muscle subperiosteally from the spinous processes and lamina on the involved side only. Obtain a lateral radiograph with a metal clamp attached to the spinous process to verify the level.Then surgery carried out by using appropriate depth of tubular retractor which helps to minimize the damage to the surrounding soft tissue.

Sequentially dilate down to the bone with enlarging tubular retractors to expose the interlaminar space. Each dilator can be used as a curette to remove soft-tissue attachments from the interlaminar space.

Identify the lamina and by using high-speed drill bit under visualization using a microscope,which is already been draped, remove part of lamina to allow dissection using Kerrison rongeur

Use a Kerrison rongeur to resect the superficial leaf of the ligamentum flavum to allow identification of the critical angle, which is the junction of the leading edge of the caudal lamina and the medial edge of the superior

articular process. Identifying the critical angle is essential in primary micro lumbar discectomy because it has a constant relationship to the corresponding pedicle, traversing nerve root, and target disc. The pedicle is always just lateral to the critical angle, the traversing nerve is always just medial to the pedicle, and the disc of interest is always just cephalad to the critical angle and pedicle. It sometimes is necessary to drill the medial aspect of the inferior articular process to allow adequate visualization of the critical angle.

Once the ligamentum flavum is removed, the medial wall of the corresponding pedicle is identified, the traversing nerve can be found just medial to it and the target disc can be found just cephalad to it small opening can be made using small size scalpel.

When the nerve root is identified, carefully mobilize the root medially. Gently dissect the nerve free from the disc fragment to avoid excessive traction on the root. Bipolar cautery for hemostasis is helpful. When mobilized, retract the root medially.With the nerve root retracted, the disc is now visible as a white, fibrous, avascular structure. Under magnification, small tears may be visible in the annulus as shown in figure 1.Remove the disc material with the appropriate-sized pituitary rongeur or small size curate. Do not insert the instrument into the disc space too deep, to minimize the risk of anterior perforation and vascular injury.

Remove the exposed disc material. Remove additional loose disc or cartilage fragments. Inspect the root and adjacent dura for disc fragments. Forcefully irrigate the disc space using a syringe and a suction tip inserted into the disc space. Maintain meticulous hemostasis.

Washing carried out muscle debrided fascia closed using double thread nylon suture size 0 or 1 or by using absorbable sutures vycril or PDS size 0 or 1, and the skin closed in interrupted vertical mattress technique.

Statistical analysis: Data were analyzed using the Statistical Package for Social Sciences (SPSS, version 22). The student's t-test of two independent samples was used to compare two means. The paired t-test was used to compare the readings of the scales before and after the operation. One-way analysis of variance (ANOVA) was used to compare three means. A post hoc test (LSD) was used to compare means of each two groups (after doing the ANOVA test). Pearson correlation coefficient was used to assess the strength of correlation between numerical variables. A p-value of ≤ 0.05 was considered statistically significant.

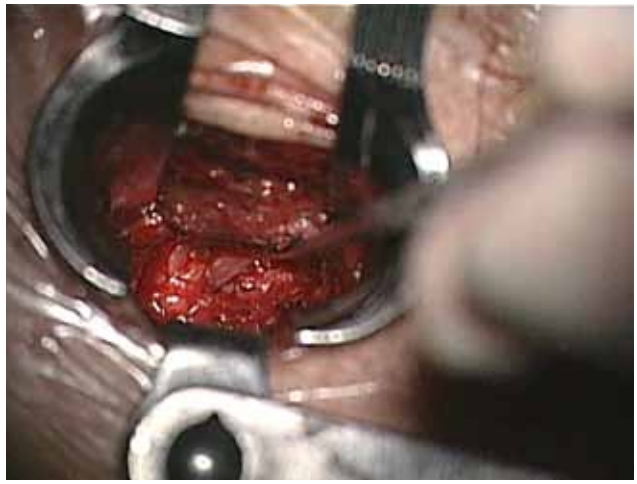

Figure 1: shows retracted nerve root and disc space under microscope magnification

Results

The mean age of patients was 35.67 ± 8.32 years, ranging from 17 to 50 years, 62.2% of the patients were females. More than half (54.4%) of the sample were working in active/manual jobs. Regarding the patients' symptoms, around half (47.8%) of the patients had backache, leg pain, and neurological deficit. The disc herniation level was in L4-L5 in 61.1% of the patients (Table 1).Table 2 shows a significantdecrease in the scores of all the studied indicators after the operation.

There is an inverse significant correlation between age and VAS gain ($r = -0.599$),no significant ($p = 0.868$) association was detected between the VAS leg gain and age, there was a significant inverse correlation between age and Oswestry gain ($r = -0.587$), figure 2.

Regarding the duration of symptoms, it is evident in figure 3 that the more the duration of symptoms, the less the gain in the Oswestry scores ($r = -0.674$, $p < 0.001$). figure 3 shows also an inverse significant correlation between the VAS for back pain gain and the duration of symptoms ($r = -0.461$, $p < 0.001$).

Regarding complication we faced during operation, we had 2 cases of incidental dutal tear while retracting the cord, both making 2.2% of total cases, both tears were small and treated by using fibrin sealant and a 24 hour of supine backrest,2 cases of superficial wound infection making 2.2% of the total number of cases.

Table 1: Basic characteristics of the study sample

Variables	Number	(%)
Age (Years)		
<30	23	(25.6)
30-39	29	(32.2)
≥40	38	(42.2)
Gender

Discussion

The advantage of microscopic discectomy includes, small incision, better outcomes, early mobilization, less analgesics, and short time to return to work the measurement of CPK level and cross-sectional area (by CT scan, MRI) of paraspinal muscle and intraoperative EMG along with pre and post-operative biochemical markers (CPK, IL, CRP) showed less damage[6].

Arts et al study showed frequent retraction and relaxation of tube retractor every 15 minutes resulted in lower CPK value[7], though in another study Mark Arts et al showed no change in cross-sectional areaof multifidus and paraspinal muscle comparing conventional open discectomy and microscopic and tubular discectomy after 1 year follow up[8].

The present study showed that the L4-L5 levels are the most operated level by 61.1%, L3-L4 levels 17.8%and L5-S1 levels were 21.1%, these results are comparable to other studies[4,6,9-13]. While in other studies the L5-S1 level was the dominant level of herniation[3,5,10].

In the present study VAS gain of back pain was about 4.62 points in males and 4.32 in females (p-value 0.190), and VAS gain of leg pain was 4.68 in males and 4.41 in females (p-value 0.132). Additionally, no statistically difference in gain between male and females, in which mean ODI gain in males was 35.74% ± 9.48, and in females 34.32% ± 8.12, p-value = 0.454, mean VAS for back pain gain in males was 4.62 ± 1.13, and in females 4.32 ± 0.38, p-value = 0.190, which is comparable with results reported by Sedighi et al [1].

The resolution of symptoms correlated with level of disc herniation was similar inpatient with L4-L5 with ODI gain 34.24% ± 8.82, and for L5-S1 ODI gain was 34.86% ± 7.32, p-value = 0.337, while the resolution of symptoms with L3-L4 regarding ODI was 40.25% ± 7.44, had significant improvement in compared to L4-L5 with p-value = 0.013 and with L5-S1, with p-value = 0.005,these findings probably occurred because of the more severe herniation correlated to L3-L4 level.

Regarding the VAS score for back pain the gain, was nearly the same through all levels postoperatively. L3-L4 mean gain was 4.69 ± 1.01, L4-L5 gain was 4.38 ± 0.97 and VAS for back pain at L5-S1 was 4.43 ± 0.96, which is comparable with the results reported by Sedighi et al [1].

Conclusion

Microscopic assisted microdiscectomy is safe procedure, it offered high and significant success rate, offered advantages of early mobilization low pain score after procedure, magnified clear flown with minimal blood loss, it can be done on day base surgery for most of the cases, most of the patient tolerate the pain and mobilization because of minimum muscle dissection and less invasiveness to structures that preserve spinal stability, and its showed low complication rate.

Conflict of Interest: None

Ethical Clearance: Informed written consent was obtained from all the participants in the study, and the study and all its procedures were done in accordance with the Helsinki Declaration of 1975, as revised in 2000. The study was approved by the scientific council of the Iraqi Board of Medical Specializations.

Source of Funding: The work was supported by authors only

Hyaluronidase Versus Magnesium Sulphate as Adjuvants to Bupivacaine in Ultrasound Guided Supraclavicular Brachial Plexus Block in Upper Limb Surgeries

Amany K abo Elhusein[1], Mamdouh Hassan[1], Nagat A. Ali[1]

[1]Department of Anesthesiology, Faculty of Medicine, Minia University, Minia, Egypt

Abstract

Introduction: Aim of this trial was to assess the effect of hyaluronidase and MgSo4 when added separately or in combination to bupivacaine on the onset of sensory and motor block, quality of block and effect on duration of action.

Method: Eighty ASA I, II patients of either sex undergoing upper limb Surgery under ultrasound-guided supraclavicular brachial block were recruited in this prospective randomized double blinded controlled study and divided in to four groups each group contain 20 patients. First group received (28 ml 0.5% bupivacaine and 2 ml 0.9% normal saline). Second group received (28 ml 0.5% bupivacaine and 1000 unit hyaluronidase dissolved in 2 ml 0.9% normal saline). Third group received (28 ml 0.5% bupivacaine and 2 ml of MgSo4 containing 200 mg). Fourth group received (28 ml 0.5% bupivacaine and 2 ml of MgSo4 containing 200 mg mixed with 500 unit hyaluronidase).

Results: Hyaluronidase fastened the onset but didn't affect the duration however MgSo4 prolonged the duration of postoperative analgesia without effect on the onset of block

Keywords: *Regional, brachial plexus; local anesthetics, bupivacaine, equipment, ultrasound machines; hyaluronidase; $MgSO_4$.*

Introduction

Supraclavicular nerve block is ideal for procedures of the upper arm, from the mid humeral level down to the hand. It has a rapid onset, with a dense and predictable level of pain control **[1].**

Hyaluronidase, the mucolytic enzyme which acts on the muco-polysaccharide hyaloronic acid, is generally considered to be "spreading factor". When used with local anesthetics, hyaluronidase hastens the onset of analgesia and shortens its duration of effect **[2].**

Magnesium sulphate acts as an adjuvant in analgesia due to its properties of calcium channel blocking and N-methyl-D-aspartate antagonism. Magnesium has been shown to decrease peripheral nerve excitability and to enhance the ability of lidocaine to raise the excitation threshold of A-beta fibers **[3].**

Ultrasound guidance has dramatically improved nerve localization and offers several advantages as direct visualization of nerves and anatomical structures, facilitated visualization of local anesthetic spread in real time, produced good compensation for anatomical variation, reduced incidence of complications **[4].**

Method

This prospective, randomized, double blind controlled clinical study was carried out after obtaining the local ethics committee of El-Minia university hospital approval and written informed consent was taken from the patients. It was done between September

2017 to December 2018, 90 patients of both sexes, ASA I and II, aged between 18-65 years old scheduled to undergo elective and urgent distal arm, forearm and hand surgeries under ultrasound guided supraclavicular brachial plexus block, 80 patients were enrolled in this study and ten were excluded due to block failure.

Preoperative Assessment and Preparation: A careful assessment of medical history was done. Routine preoperative general examination and local examination of the site of injection for signs of infection or any other pathology were carried out. Routine investigations were done. Explanation of visual analogue pain scale was done VAPS is consisted of a straight, vertical 10-cm line; the bottom point represented "no pain"= (0 cm) and the top "the worst pain you could ever have. Two mg midazolam IV was given as a premedication 5 minutes before the block.

Equipments: The ultrasound device Sonosite, micromaxx, Lubricating gel, 21-gauge 50 mm length short bevel insulated stimulating needl, 10-ml syringes for injection, Sterile gloves, 25-gauge needle for skin infiltration, Sterile towels and sterile antiseptic solution (Povidone-iodine 10%).

All medications were prepared in similar sterile coated bottles and coded then passed to the anesthesiologist who is blind to its manner. In this prospective randomized double blinded controlled study 80 bottles numbered from 1 to 80 were prepared and divided in to four groups each group containe 20 bottles. Then the patients were randomly assigned to study groups.

Group (I): Received 28 ml bupivacaine (0.5%) + 2 ml saline (0.9%).

Group (II): Received 28 ml bupivacaine (0.5%) + 1000 unit hyaluronidase dissolved in 2 ml saline (0.9%).

Group (III): Received 28 ml bupivacaine (0.5%) + 2 ml MgSo4 containing 200 mg.

Group (IV): Received 28 ml bupivacaine (0.5%) + 2 ml MgSo4 containing 200 mg mixed with 1000 unit hyaluronidase.

Block technique: A 20 G intravenous cannula was inserted in a peripheral vein of unaffected upper limb and standard monitoring was provided.Patient lie down supine with head turned to the contralateral side and ipsilateral arm adducted gently by the assistant. Skin was sterilized and infiltrated with 1-2 ml of lidocaine 2% at the needle entry site.

The brachial plexus was visualized by placing ultrasound probe in the sagittal plane in the supraclavicular fossa behind the middle-third of the clavicleas 3 hypoechoic circles with hyperechoic outer rings or as a grape like cluster of 5 to 6 hypoechoic circles, lateral and superior to the subclavian artery between the anterior and middle scalene muscles at the lower cervical region.

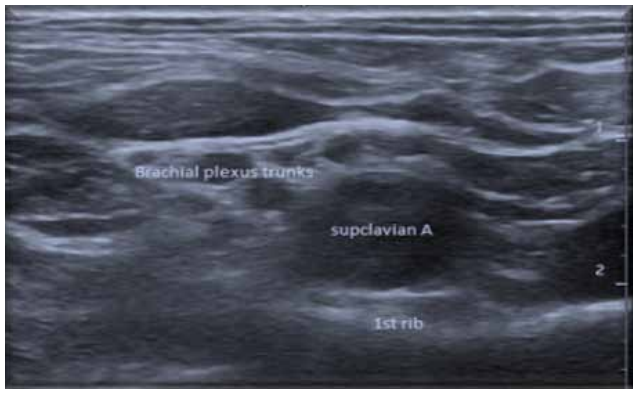

Fig (1): Ultrasonographic imaging of brachial plexus

Parameters assessed: The anesthesiologist who gave the block recorded the onset of sensory and motor block and recorded intraoperative data then the postoperative care physician recorded the duration of block and postoperative data.

The hemodynamic variables were assessed and recorded 5 minutes before the block as a baseline value, immediately after the block 0,10,20,30,60, 90 minutes during the operative time then 1,2,4,6, and 12 hours after the end of operation. Quality of sensory block was assessed by pin prick test using a 3-point scale [5] Grade 0 = normal sensation, Grade 1 = loss of sensation of pin prick (analgesia), and Grade 2 = loss of sensation of touch (anesthesia).

Also motor block quality was determined by thumb abduction (radial nerve), thumb adduction (ulnar nerve), thumb opposition (median nerve), and flexion of elbow (musculocutaneous nerve) according to the modified Bromage scale 1997 [6] on a 3-point scale. **Grade 0:** Normal motor function with full flexion and extension of elbow, wrist, and fingers. **Grade 1**: Decreased motor strength with ability to move the fingers only. **Grade 2:** Complete motor block with inability to move the fingers.

Pain intensity was assessed using VAPS. It was

measured before starting the nerve block then 15, 30, 60, 90, 120 minutes after nerve block. When it is more or equals 4 cm we gave analgesia or sedation using fentanyl and propofol during operation. Then Patients were asked to rate their pain intensity at 2, 4, 8, 12, and 24 hours postoperative and if it was more than four paracetamol 1000 mg bottle was given. Time of first analgesic request: The time from supraclavicular brachial plexus block administration to the patient's first request for analgesic medication by hours. Total analgesic requirements in 24 hours: The total amount of intravenous paracetamol which was given to the patient as a rescue analgesia or maintenance during 24 hours. Adverse effects: any adverse effects such as hypotension (i.e. 20% decrease relative to baseline), bradycardia (HR <50 beats/ min), nausea, vomiting, hypoxemia (SpO2 <90%), local hematoma, hemothorax, pneumothorax,recurrent laryngeal nerve block, intravascular injection, Horner's syndrome and signs of local anesthetic toxicity were recorded during the operation and for 24 hours postoperative.

Results

During studying hemodynamic data changes among groups, The Mean Arterial blood pressure (mmHg) and arterial oxygen saturation changes during intraoperative or postoperative period were statistically insignificant between the four groups. As regard the Heart rate (beat\ min) we found it was lower in group (II, IV) than the other two groups (I, III) at time intervals of 10,20,30 and 60 minutes intraoperative but these changes were statistically insignificant.

Sensory, motor block onset and density of block were faster in groups (II & IV) than in groups (I & III) but the duration of sensory and motor block was found to be longer in groups (III & IV) than in groups (I & II) as presented in fig (2, 3, 4).

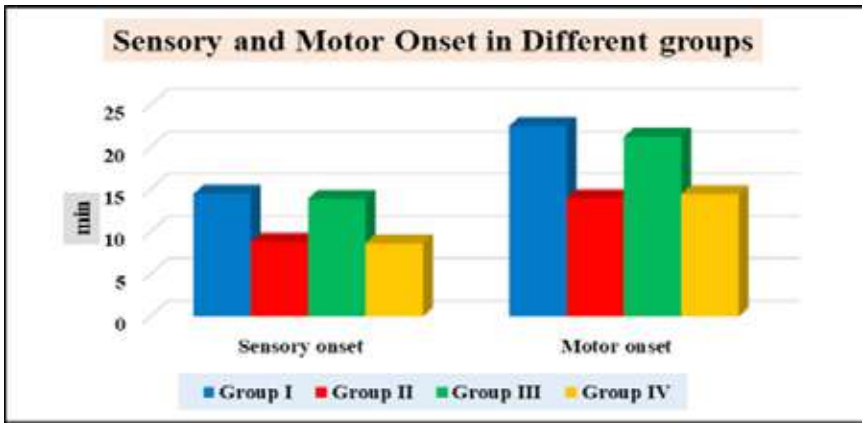

Fig (2)

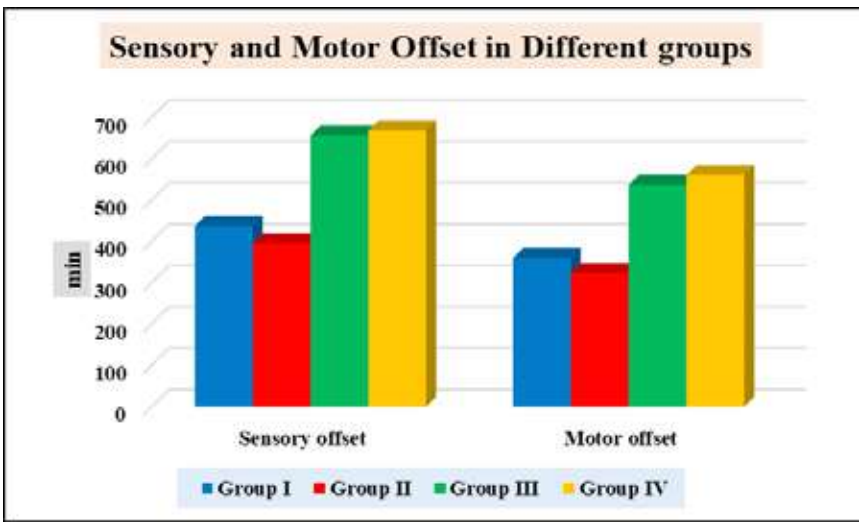

Fig (3)

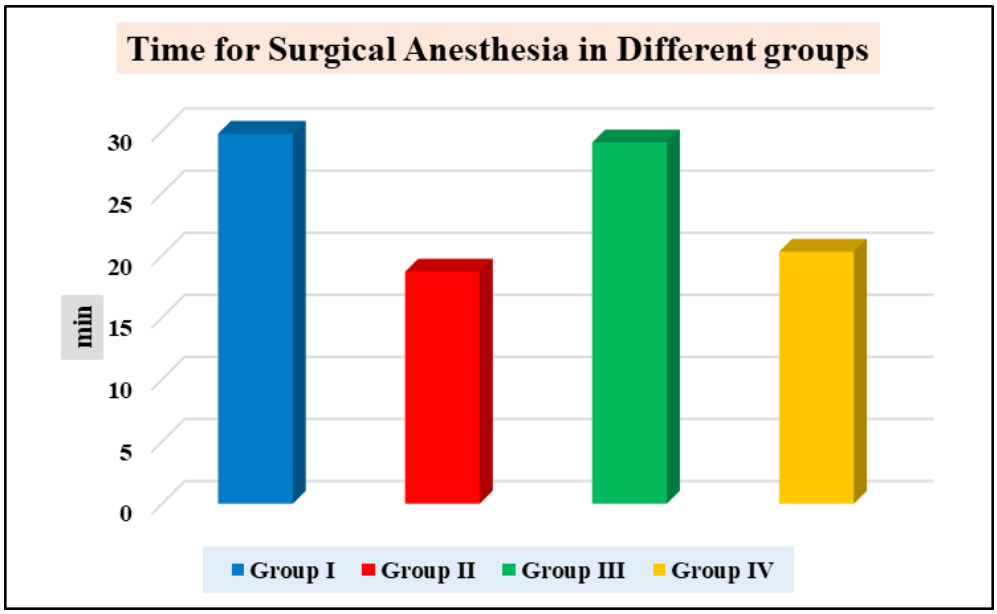

Fig (4)

Pain measurement presented by VASP during intraoperative period at 15 min post injection the pain score was significantly lower in patients received hyaluronidase in groups (II & IV) than in groups (I & III) but no significant difference was found after that during operation. In the postoperative period the VASP was significantly lower at 4, 8, 12, 24 hours in patients received $MgSO_4$ in groups (III & IV) than in groups (I & II).

Intraoperative need for sedation and fentanyl was insignificantly different between the four groups. But the mean time of for postoperative 1st analgesic (minutes) request was significantly longer in groups (III & IV) (360-900) and (540-950) minutes in comparison to groups (I & II) (300-620) and (300-700) minute. And total analgesic requirement (mg) in groups (III & IV) was less than groups (I & II).

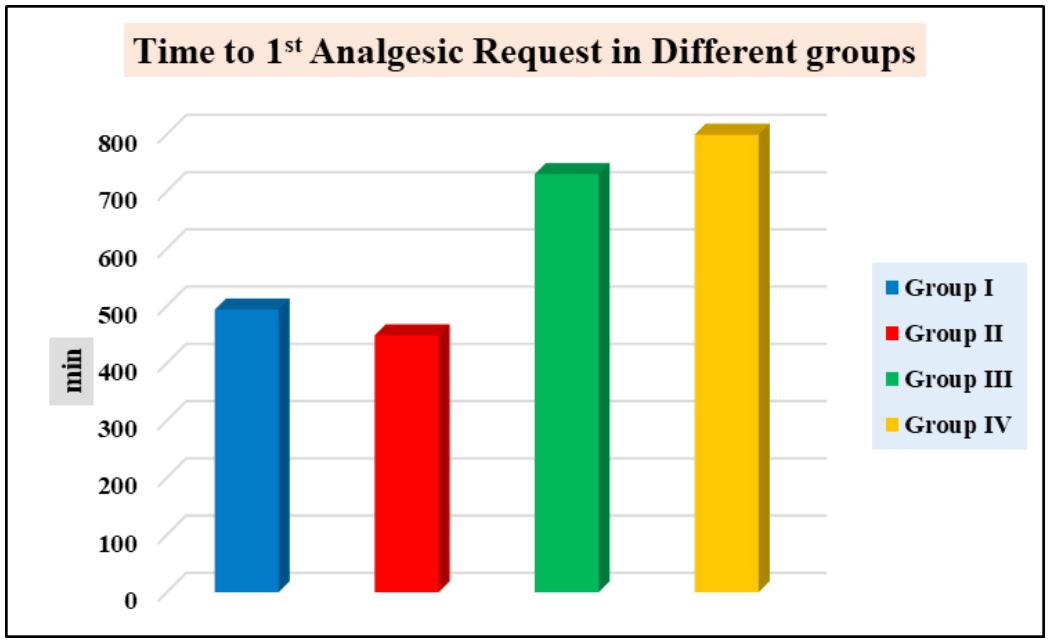

Fig (5)

As regard complications happened during the study no significant differences were found between the four groups.

Discussion

Brachial plexus block is a safe reliable anesthetic technique for upper limb surgery with fewer complications, especially with the introduction of ultrasound which decreased the complications dramatically.

Hyaluronidase the mucolytic enzyme which acts on the muco-polysaccharide hyaloronic acid, is generally considered to be "spreading factor". When used with local anesthetics, hyaluronidase hastens the onset of analgesia and shortens its duration of effect [7].

A number of studies have shown that addition of hyaluronidase during ocular blocks has beneficial effects including higher quality of anaesthesia and improved success rates.

In a study done by Koh et al investigated the hypothesis that addition of hyaluronidase to ropivacaine may reduce the time to achieve complete sensory block after axillary brachial plexus block. The patients were randomly assigned into a hyaluronidase group (n = 24) and a control group (n = 24). The hyaluronidase group received ropivacaine 0.5% with 100 IU.ml_1 of hyaluronidase, and the control group received ropivacaine alone. The primary endpoint was the time to achieve complete sensory block. The hyaluronidase group demonstrated significantly shorter mean (SD) sensory block onset time (13.8 (6.0) min) compared with the control group (22.5 (6.3) min), $p < 0.0001$). Addition of hyaluronidase to ropivacaine resulted in a reduction in the time needed to achieve complete sensory block [8].

Another previous study by Keeler et al reported the effect of the addition of hyaluronidase to bupivacaine 0.5% for axillary brachial plexus blocks. In that study, 3000 IU hyaluronidase mixed with bupivacaine significantly reduced the duration of the sensory and motor block, and had no effect on the number of patients experiencing a complete sensory block after 30 min while the duration of sensory anesthesia was significantly shorter in the hyaluronidase group and the duration of motor block showed a shorter trend [9].

In our study hyaluronidase had obvious effect on decreasing the sensory onset that recorded by pinprick test at 5 min interval after performing the block till complete sensory block occurred and motor onset detected by detection of complete thumb block also detected at 5 min interval after the block in comparison with control group and Mgso4 group. The mean sensory onset was (8.9 ± 3.3) minutes in hyaluronidase group in comparison to the mean sensory onset (14.5±4.5), (14± 3.8) minutes in control and Mgso4 groups respectively. The mean motor onset was (14±5.1) minutes in hyaluronidase group in comparison to the mean motor onset (22.5±4.9), (21.3±5) minutes in control and Mgso4 groups respectively, and both results were significant with p value < 0.001. However it didn't affect the duration of sensory or motor block or the postoperative analgesic requirement in comparison with other groups.

Mgso4 can act as an adjuvant in analgesia due to its properties of calcium channel blocking and N-methyl-D-aspartate antagonism. Magnesium has been shown to decrease peripheral nerve excitability and to enhance the ability of lidocaine to raise the excitation threshold of A-beta fibers [10].

Haghighi et al. in Guilan, Iran, in 2014, investigated the effect of Mgso4 in axillary brachial plexus block when added to lidocaine in upper limb surgeries, and reported that the addition of Mgso4to lidocaine significantly increased the duration of sensory and motor blocks in comparison with the use of lidocaine alone **[11].**

Rao et al, found that The addition of MgSo4 to 0.5% bupivacaine increased the duration of motor and sensory supraclavicular brachial block in the upper extremities during surgeries when compared to the use of 0.5% bupivacaine alone,The mean sensory block duration in the group MgsSo4 was 249±9.36 and in control Group was (160±5.62) ($p<0.39$). The mean motor block duration in the group MgsSo4 was (232±9.64) and in control group was (147±26.52) (both $p<0.32$). The mean onset of sensory block in group MgsSo4 was (15.5±2.16) and the onset of block in control group was (12.73±1.18) ($p<0.4$) statistically not significant). Alsothe mean onset of motor block in group Mgso4 was (23.5±1.1) and the onset block in control Group P was 41±3 ($p<0.53$; statistically not significant) **[12]**

In our study the addition of Mgso4 to 0.5% bupivacaine in supraclavicular brachial plexus block for upper limb surgeries increased the duration of sensory and motor blocks with mean sensory block duration (643.1±144.8) in Mgso4 group vs (423.5±89.4) in control

group or (387.2±78.3) in hyaloronidase group and mean motor block duration (546.6±99.8) vs (337.5±77.6) in control group or (310±84.9) in hyaloronidase group with (p value <0.001) for both. Also Mgso4 decreased the postoperative pain with mean VAPS at 4, 8, 12, 24 (0-2.8), (0-3), (2-6), (5-6) vs (2-3), (4-6), (6-7), (7-7.8) in control group vs (2-3), (3.3-6), (6-7), (6-7.8) with (p value <0.001) for all. Also Mgso4 reduced total analgesic requirements in comparison with the use of 0.5% bupivacaine or bupivacaine plus hyaluronidase with mean total analgesic requirement (1-2) in Mgso4 vs (2-3) in both control and hyaluronidase groups and the change was statistically significant with (p value <0.001). However MgSo4 didn't affect the onset of sensory or motor block when compared to the control and hyaluronidase group.

The most recent in our study is the addition of both MgSo4 and hyaluronidase to bupivacaine 0.5% which resulted in significant decrease in the onset of motor and sensory block and also significant increase in the duration of the block which produced rapid surgical anesthesia, reduced postoperative pain and decrease postoperative analgesic requirement, the mean sensory block onset was (8.7±2.7), the mean motor block onset was (14.5±4).mean VAPS at 4, 8, 12, 24 hours was (0-0), (0-2), (2.3-5), (5-6) which was significant in comparison with control and MgSo4 groups with p value < 0.001. Mean sensory duration was (660.3±94.9), Mean motor duration was (546.6±99.8) both was significantly increased than control and hyaluronidase groups with p value < 0.001. Mean total postoperative analgesic request was (1-1.8) also it was significantly less than control and hyaluronidase groups.

Conclusion

The present study shows that the use of hyaluronidase reduces the time to reach complete sensory and motor block and therefore shortens the total anesthetic time before operation, hyaluronidase has no influence on the total analgesic duration or the consumption of postoperative analgesics.

Also the study shows that the use of Mgso4 increases the duration of motor and sensory block, increases the analgesic duration and reduces the postoperative analgesic consumption. However MgSo4 has no effect on the sensory or motor onset of block.

Last conclusion was that the combination of both MgSo4 with hyaluronidase as adjuvants to bupivacaine produces significant effect on reducing the time to reach complete sensory and motor block and therefore shortens the total anesthetic time before operation, increases the duration of motor and sensory block, increases the analgesic duration and reduces the postoperative analgesic consumption.

The Institutional Ethics Committee approved this study of the School of Medicine, Minia University, Egypt, and all patients gave informed consent before participation in this study. The study conducted in accordance with the ethical guidelines of the 1975 Declaration of Helsinki and International Conference on Harmonization Guidelines for Good Clinical Practice.

Abstract

Introduction: Asthma attacks all age groups but often starts in childhood. Asthma is a chronic disease characterized by recurrent attacks of breathlessness and wheezing, and occurs in people of all ages. It is the most common chronic disease among children. Many publications have shown an association between severity of asthma symptoms and obesity in children and adults. The aim of the study is to assess the symptoms of asthma and the relationship to obesity among secondary school students in Fallujah City.

Method: A cross-sectional study was done during March 2018. We assessed 47 students with asthma from nine secondary schools across Fallujah city, Anbar governorate, Iraq. Simple random sampling technique has been used to select the nine schools.

Results: With a total of 47 subjects with asthma, 20 (42%) male and 27 (57.4%) female subjects have been included in the study. The age of subjects was between (15-23 years with mean 17 +-1.8).

With a total of 47 participants with asthma, 33 (70.2%) participants had attacks of cough or wheeze more than a couple of times per week in the last month. The corresponding weight categories of those 33 participants were as follows: six were obese, nine of over-weight,14 were normal-weight and four of under-weight.

Those who had attacks of cough or wheeze less than a couple of times per week in the last month were 14 (29.8%) participants and their corresponding weight class were: None of them were obese, four were over-weight, eight of normal-weight and two were under-weight.

Conclusion: Obesity could be a risk factor for severe asthma symptoms among the subjects.

Recommendation: Further national study is needed for assessment the association between obesity and severity of asthma symptoms among students in secondary schools.

Keywords: *Asthma, obesity, high school students, Fallujah City.*

Introduction

Asthma is a chronic disease characterized by recurrent episodes of wheezing and breathlessnes[1]

It is a common chronic disease starting in childhood. World Health Organization (WHO) estimates that 235 million people worldwide have asthma[1]

Affected individuals may experience asthma symptoms several times in a day or week, and in some people the symptoms worsen during periods of physical activity or at night. A substantial burden to individuals and families is the result of asthma being under-diagnosed and under-treated, and this possibly restricts individuals' lifetime activities.[1]

Obesity is defined as Body Mass Index (BMI) ≥ 30 kg/m^2. Pre-obese individuals are those with BMI = 25 – 29.99 kg/m^2. Further classification of obesity includes obesity class I, BMI from 30.0 to 34.9; obesity class II, BMI from 35 to 39.9; and obesity class III, BMI ≥ 40.0.[2]

Many publications have shown an association between obesity and asthma in children and adults.[3-6]

A study that conducted on Canadians examined the association between asthma prevalence and BMI, it showing that each 1 unit increase in BMI was associated with an increase of about 6% in the risk of developing asthma in women and a 3% increase in the risk in men.[7]

Obesity was found to be associated with more asthma symptoms, missed days of work, increased rescue bronchodilator use and an increase in asthma severity overall.[8] With obesity, it s less likely to achieve a good control of asthma and there is a reduced response to current asthma treatment[8-10]

Aim: The aim of the study is to assess the symptoms of asthma and their relation to body weight amongsecondery school students in Fallujah city.

Method

A cross section study was done during March 2018. We assessed 47 students from nine high schools across Fallujah city, Anbar governorate, Iraq. Considering equal gender participation and avoiding the selection bias, simple random sampling technique has been used to select the nine high schools with five secondary schools for girls and four secondary schools for boys. The study included only the subjects who stated that they were diagnosed with asthma, and are being treated with a chronic drug usage with or without occasionally seeking an emergency medical help for their asthma exacerbations. To minimize confounding by other conditions in which asthma-like symptoms have been reported, those who did not have the asthma diagnosis card and who stated that their symptoms have diminished and undergone remission for many years were excluded from the study.

The assessment has been made through questionnaire-based interviews which carried out by a committee of highly qualified and trained staff from College of Medicine, University of Fallujah.

The questionnaire, derived from the National Institutes of Health, Pediatric Asthma Center at Children's Hospital of Pittsburgh[11] and certified by a community medicine specialist at the faculty of College of Medicine, University of Fallujah, and consisted from 5 main sections; these included sociodemographic questions, school's information, details on asthma symptoms and medications, family and social history, and certain anthropometric measurements.

The sociodemographic questions included age, sex, address, school's name and study level. Questions for asthma consisted from the date of diagnosis and asthma events during the last month including the frequency of asthma symptoms, frequency of nighttime asthma symptoms, frequency of exercise-induced symptoms, frequency of missing school, frequency of rescue medication usage, frequency of flare-ups, and patient's physical activity between flare-ups.

At the end of the interview, the patient's weight and height were measured using a battery-powered digital weight scale with the shoes unworn and a height measuring scale while the patient in the upright position, respectively and Body Mass Indices [BMI (kg/m^2) = weight (kg)/height (m) squared (ht × ht)] were determined.

After the students with asthma were gathered from the high school classes, they have been grouped together in the meeting room of their respective school and interviewed by the committee using the standard questionnaire.Each interview took an average of 15 minutes. To maintain the privacy of the information collected from the subjects, each interview consisted from one interviewer and one subject and was done in a separateplace from other groups of subjects.

After fully explaining the specific objectives of the research, the way of carrying out the study, and verbally informing the participating students that the collected information will be highly secured and only be used for the purpose of researching, appropriate patient and school administrations approvals were obtained.

Statistical analysis: The data collected on the questionnaire-based interviews was computerized using the Microsoft Office Excel 2007 and SPSS version. 20. Chi test has been used as a statistical test and a P value < 0.05 was considered significant.

Results

Table (1) shows the frequency of gender in the study; with a total of 47subjects with asthma (diagnosed and known cases of asthma), 20 (42%) male and27 (57.4%) female subjects have been included in the study. Ages of subjects were between 15-23 years with mean 17 ± 1.8.

42 (89.4%) of the study subjects experienced coughing or wheezing frequently during or after exercise

in the last month while only 5 (10.6%) subjects did not (Table 1).

For the frequency of coughing and wheezing, the results have shown that 33 (70.2%) subjects coughed or wheezed more than a couple of times per week during the last month while 14 (29.8%) subjects experienced coughing and wheezing less frequently in the last month (Table 1).

By measuring the Body Mass Indices (BMI) for the 47 young high school respondents, the results showing the following: Obese (6 people, 12.8%), over-weight (13 people, 27.7%), normal-weight (22 people, 46.8%), and under-weight (6 people, 12.8%) (**Table 2**).

The results have shown that the number of subjects who stated that rescue medication hasbeen used more than a couple of times per week in the last month for flare-ups of coughing, wheezing, and chest tightness was 37 (78.7%) mainly among obese subjects (100%), over-weight (100%), normal-weight (63.6%), and under-weight (67%).

While those who did not need to use rescue medications more than a couple of times per week in the last month were 10 (21.3%) subjects and their parentages (%) in regard to weight categories were as follows: Normal-weight (36.4%), under-weight (33%), and percentage of those who were obese and overweight was (0%) for both weight classes making significant association between obesity and the usage of rescue medications more than couples of times per week among asthmatic patients, p value of 0.034 (**Table 3**).

For the frequency of missing school as a severity indicator for asthma symptoms in the study participants, the results have shown that a total of 19 (40.4%) subjects were obligated to missing school because of their asthma symptoms; In regard to weight categories, their percentage were as follows: obese (50%), over-weight (69.2%), normal-weight (31.8%), and under-weight (0%), there was statistically significant association, p value = 0.024 (**Table 3**).

Table 1: frequency of gender and coughing or sneezing attacks among the participants

		n	%

Discussion

The obesity is considered as a serious global problem that may associate with several health disorders and have an economic burden on the individuals and communities. The current study attempted to assess the effect of obesity on symptoms of asthma among adolescents . Obese subjects (BMI $\geq$ 30 kg/m^2) have been found to have much more severe asthma symptoms than who had a normal-weight (18.5 < BMI $\leq$ 24.9 kg/m^2). The parameters used in our study to describe a severe asthma included asthma symptoms more than twice per week, using rescue medications more than twice per week, frequent school missing, coughing in sleep for more than twice per month, and frequent asthma symptoms during or after exercise.

In a relationship between weight categories and the frequency of asthma symptoms during the last month, the results revealed that all obese subjects while 63.6% of normal-weight subjects had asthma symptoms, such as coughing, wheezing, and chest tightness with more than twice per week and they used rescue medications more than two times per week. There was statistically significant association between the obesity and using rescue medications more than two times per week, this finding was consistent with what reported in the literature as many studies showing a relationship between severity of asthma symptoms and frequency usage rescue medication for asthma with obesity and high body mass index (BMI).[9-14]

A nation-wide cross-sectional study carried out on Korean children has recognized high body mass index (BMI) as an important risk factor for asthma.[12] In a study that conducted among adolescents with asthma in UAE, sleeping disturbances due to wheezing, frequency of nocturnal symptoms, wheezing during or after exercise and rate of inhaler use were all apparently higher among obese and overweight asthmatic children [15] .

The results demonstrated that there was significant association between the severity of asthma and obesity with missing school which was consistent with what reported in literature as the obesity and asthma had bad effect on heath and performance of the subjects[8-10]

Conclusion

Asthma is a serious disease. Obesity has bad effects on asthma symptoms among high school students, especially on rescue medications usage.

Recommendation: Further national study is needed for assessment of association between obesity and severity of asthma symptoms among students in secondary schools.

Conflict of Interest: Nill

Source of Funding: No source of funding.

Ethical Consideration: Ethical approval for this study was obtained from the Scientific Committee of the College of Medicine, University of Falluja. Participants were given the choice to participate in the study .Verbal consent was obtained from the participants, who were permitted to respond in their own time and privacy.

Acknowledgments: Thanks to the Faculty of Medicine in the University of Falluja,many thanks also to the students of the Medical College, University of Falluja for their assistance during data collection especially: Zainab Shaban Rajab, Abdulhameed Suliman Jubair, Mohammed Sadoon Daham, Rose Ismail Ibraheem, Hiba Mabad Fayad.

Findings of Cranial Magnetic Resonance Imaging in Neonatal Seizure

Amjaad M. Hameed[1], Dergham M. Hameed[2], Hamid Sh. Dhahir[3], Thuraya H. Farhan[3], Senia A. Kadim[4]

[1]Researcher, Collage of Medicine, Al-Qadisiyah University, [2]Researcher, Collage of Nursing, A-Muthanna University, [3]Researcher, Maternity & Pediatric Teaching Hospital, Al-Dywanyia, [4]Researcher, Department of Pharmacology, Collage of Medicine, Al-Qadisiyah University, Iraq

Abstract

Aim of study to know the findings of brain MRI in neonates present with seizure. A retrospective study was done in Maternity & pediatric teaching hospital in Al-Dywanyia city in Iraq, from May 2014 to June 2018. All included neonates diagnosed to have seizure, all of them had cranial magnetic resonance imaging. The standard MRI used protocol T1, T2, diffusion weighted image, gradient echo. Included patients had general anesthesia only 5 patients didn't have anesthesia or sedation as they were in deep sleep during MRI examination. The results that more than half of neonate (58.5%)was male & (41.5%) was female. Term neonate (60.4%) was more than preterm neonate (39.6%).High significant association between preterm & term neonate with MRI findings also there is high significant association between age of neonate at time of 1st attack of convulsion & positive brain MRI findings, abnormal l brain MRI was more common in neonate who had 1st onset on seizure in the 1st week of his life.

Keyword: *Cranial MRI of neonate, neonatal seizure.*

Introduction

Seizure(convulsion) is the commonest central nervous system manifestation during e neonatal life(the first 28 days of life)[1], it can define as attack of alternation in neurological function and usually it shows an underlying problem in the brain[2], due to brain damage and developmental defect in the central nervous system[3]. There is high morbidity (25-35%) and high mortality rate in neonatal convulsions although there is no guide line in diagnosis of neonatal convulsion[4], magnetic resonance imaging (MRI) regarded as the standard imaging technique in diagnosis of development brain disorder[5], its rapidly became study of choice for diagnosis of central nervous system dysgenesis, MRI provide excellent diagnostic imaging technique in evaluation brain disorder superior to cranial computed tomography & ultrasound[6]. Immature brain in preterm baby seem to prone to seizure more than mature brain in term baby[7,8], convulsions are more common in the period of neonate than during other time throughout life & it regard as a commonest neurological emergency especially during 1st days of life[9,10,11], in contrast to convulsion in childhood most neonatal convulsion are acute with suspected specific causes, relatively few neonatal convulsions are idiopathic. The etiology & presentation of neonatal convulsion is different to seizures in childhood & adult[12,13].It's important to detect neonatal seizures causes as early as possible for treatment planning & to know the prognosis, as the prognosis of the neonatal seizure depending on the etiology, for example prognosis after hypocalcaemic attackis excellent. Symptomatic hypoglycaemia and meningitis have a 50% chance of survivors[14]. Overall survivor in hypoxic ischaemic encephalopathy is 30-50%, while central nervous system dysgenesisare generally associated with poor outcome. Preterm neonates with clinical seizures have a higher incidence of impairment than preterm infants without seizures[15].Aim of studyto know the value of brain MRI in neonate present with convulsion in addition to other laboratory investigation

Materials and Method

A retrospective study was done in Maternity & pediatric teaching hospital in AL Dywanyia city in Iraq in a period from May 2014- June 2018. The study included 53 notates all of them diagnosed to have seizure by pediatrician when the neonate had sudden repeated involuntary movement, abnormal tonic movement. EEG

was done to 27 patients. 1st attack of seizures occurred at different time of neonatal period, all of them had brain MRI at a period few hours – 3days from the onset of seizurewhen the neonate became stable,only 5 patients didn't have anesthesia or sedation as they were in deep sleep during MRI examination. We exclude the patients when his family refused MRI or refused anesthesia or sedation also we exclude the patient that was not fit for anesthesia according to the recommendation of anesthetic or not stabilized neonate.

MRI system & protocols: We used Philips - Ingenia 1.5 Tesla system & routine MRI sequences were obtained, axial & sagitalspine echo T1 weighted images (TR/TE = 460/10, slice thickness = 4mm, gap = 1mm), axial T2 weighted image (TR/TE 5500/120, slice thickness = 4mm & gap = 1mm), gradient-echo(GRE) sequences (TR/TE/FLIP angle = 800/40/40), axial diffusion weighted image(DWI) (TR/TE/b factor = 5075/84/1000), MRA (magnetic resonance angiography & MRV(magnetic resonance venography) were done not for all cases only when vascular insults like ischemia or hemorrhage are suspected.Brain MRI findings were evaluated by two radiologist to have final diagnosis this findings are classified to normal brain MRI & abnormal brain MRI than abnormal brain MRI classified to different causes.

Statistical analysis: SPSS version 22.0 and Microsoft Office Excel 2010 were used to analyses the data. The numeric variable was expressed as mean ± SD & categorical variables were expressed as number & percentage, the level of significance was considerable at P- value of 0.05.

Results

Table 1: Distribution of study sample of neonate according to the gender

Gender	No. (%)
Male	31(58.5%)
Female	22(41.5%)
Total	53(100%)

According to table 1more than half of neonate (58.5%)was male & 41.5%) was female.

Table 2: Number & percent of preterm & term neonate in our study

Term & Preterm neonates	No. (%)
Preterm neonates	21(39.6%)
Term	32(60.4%)
Total	53(100%)

Table 2 showsterm neonate (60.4%) was more than preterm neonate (39.6%).

Table 3: Age of neonate at time of fit

Age of fetus at time fit	No.(%)
0-7 days	28(52.7%)
8-14 days	11(20.8%)
15-21 days	11(20.8%)
22-30 days	3(5.7%)
Total	**53(100%)**

Nearly half of fetus (52.7%) have 1st attack of fit at about 1st week of life swing between few hours to 7 days.

Table 4: Cranial MRI of the neonate present with fit.

Cranial MRI Findings	No.(%)
Normal MRI	31(58.5%)
Abnormal MRI	22(41.5%)
Total	53(100%)

Table 5: The association between cranial MRI findings & gender of the neonate.

Cranial MRI findings	Gender		Total
	Male	Female	
Abnormal MRI	10	12	22
Normal	21	10	31
Total	31	22	53
Chi-square=2.633	DF=1		P=.105

According to table 5 there is no significant association between gender & cranial MRI findings in neonatal convulsion.

Table 6: The association between cranial MRI findings with preterm & term neonate in neonatal convulsion.

Cranial MRI findings	Preterm neonate	Term neonate	Total
Abnormal MRI	2	20	22
Normal MRI	19	12	31
Total	21	32	53
Chi-square=14.656	df=1	P value =.000	

High significant association between preterm & term neonate with MRI findings.

Discussion

The susceptibility of seizure recurrence was extremely low with an absence of major cerebral lesions on MRI, for this reason MRI has a value not only diagnosis the etiology but also for predication of neurological outcome[16].In this study neonate male (58.5%) present with convulsion slightly more than female (41.5%) with no significantly association(p=.105) which is go with many study like Moayedi et al[17], Taghdiri et al[18], Sanjeev et al[19], Amjaad et al[20] & Weeke[21]but there is no explanation for this variationMoayedi et al[17].

Percent of term baby (60.4%) was more than preterm baby (39.6%) that's go with many other studies Moayedi et al[17] & Sanjeev et al[19] while Al-Zwaini I et al[22]reported that preterm newborn exhibits higher risk for neonatal seizures than term newborn and this difference may be interfere with other factors like body weight, natal & postnatal complication that affect the occurrence of seizure[23], in this study hypoxic ischemic encephalopathy (40.9%) was the commonest cause which related to the natal complication.

Firstonset of seizure in the neonate most often occur at 1stwk of life[6,20,21], in our study about half of neonate (52.7%) have 1st attack of fit at 1st week of life at a period swing between few hours after birth to 7 days with a high significant association (p value =.000) between age of neonate at time of 1st attack of convulsion & MRI findings.

Less than half of our patient (41.5%) have abnormal brain MRI scan of different etiology & (58.5%) of neonate have normal brain MRI, the most common abnormality seen in neonate was hypoxic ischemic encephalopathy (40.9%) follow by brain dysgenesis(36.4%) which is go with many study like Amjaad et al[20],Snehalatha et al[6] & Shafi M et al.[24].

All patient who have normal brain MRI were undergo to laboratory investigation to detect cause of seizure, in those patient metabolic disorder was the commonest cause (38.7%) follow by kernikterus (35.5%) & unknown etiology was in 12.9%. which is go with many study like Tekgul et al[1] & Ronen et al[2] .

Conclusion: MRI is indicated with other tests to diagnose underlying brainpathology in neonatal seizure.

Conflict of Interest: None

Funding: Self

Ethical Clearance: Not required.

Recommendation: Further study is recommended included follow up these neonate to know whether there is recurrence of fit in future. Further study using MRI spectroscopy to predict the severity & prognosis of patients with neonatal seizure.

Abstract

Efforts to inhibit the growth of oral Burkitt's lymphoma cells require an effective strategy, one of that uses Papua's ant nest plant (*Myrmecodia pendens*) which are natural medicinal plants. In the present study, induction of cell cycle arrest and apoptosis of an oral Burkitt's lymphoma cell (Raji cell)-mediated by an ethyl acetate fraction of Papua's ant nest plant through down regulation of cyclin E-CDK2 complex was examined. For detection of cell cycle arrest was evaluated by flow-cytometer. Induction of apoptosis was detected by colorimetric assay caspase-3, -8 and -9. The level of cyclin E and CDK2 was carried out by Elisa kit. The results revealed the active fraction of the ant nest was markedly induced the cell cycle arrest in the G0-G1 phase according to increased concentration followed bythe induction of apoptosis characterized by elevated of proteolytic activity of caspase-3, -8 and -9. Cyclin E and CDK2 level was significantly decreased in cell treated with ant nest fraction. These results suggest the ethyl acetate fraction of the ant nest plant had a strong potential antitumor activity of oral malignant Burkitt's lymphoma cell proofed by the induction of cell cycle arrest and apoptosis through down regulation of cyclin E-CDK2 complex.

Keywords: *Burkitt's lymphoma, cell cycle arrest, apoptosis, ethyl acetate fraction, cyclin E, CDK2.*

Introduction

Burkitt's lymphoma (BL) is one of the aggressive oral cancers derived from lymphoid with a percentage of events ranging from 3-5% of all lymphoma cancers. BL is a high-stage B cell neoplasm, commonly found in the population of children aged 7-11 years.[1] Almost 40% of BL occur in children includes the type of Non-Hodgkin lymphoma.[2] The highest incidence is found in endemic areas in the equatorial regions of Africa and Papua-New Guinea in the amount of 50-70% of all malignancies in children.[3] Interestingly, Epstein-Barr virus (EBV) has an important role in the occurrence of BL and most commonly occurs in the maxillary or mandibular regions.[4]BL causes a lot of deaths in the children population in developing countries due to inadequate treatment or coming to health institutions in advanced stages. So, the effective and potential treatment strategies to suppress the Burkitt's lymphoma malignant cell growth are still very necessary, one of it uses plants medicine is made from natural ingredients that are cheap, easily available and are local products and are widely grown in the tropic areas, namely ant nest plant (*Myrmecodia pendens*) whose its antitumor potential has been empirically and scientifically observed.

Ant nest plants contain active compounds of flavonoids, polyphenols and tannins, which function

as antioxidants that can prevent the growth of various types of human cancer cells and effectively suppress carcinogens.[5] Ant nest plants also contains tocopherol and alpha-tocopherol, substances with high activity that can inhibit free radicals.[6] It was reported that ant nest plants are toxic to several human cancer cells including cervical uterine cancer cells (HeLa), breast cancer cells (MCM-B2),[6] and oral carcinoma cells (KB).[7] The mechanism of growth inhibition of cancer cells with ant nest plants is reported through barriers to signaling factors transduction of NF-kB, IL-8 and Vascular Endothelial Growth Factor (VEGF).[8]

In the present study, the ethyl acetate fraction of the ant nest plantinduces cell cycle arrest and apoptosis of an oral malignant Burkitt's lymphoma (Raji) cell through down regulation of cyclin E-CDK2 complex was evaluated.

Materials and Method

Cell and cell culture: Raji cells (ATCC CCL-86 B lymphocyte, USA) were cultured in Dulbecco's modified eagle medium (Sigma-Aldrich, St. Louis, MO, USA) supplemented with 10% fetal calf serum, and 100mg/ml streptomycin, 100 U/ml penicillin (Moregate BioTech, Bulimba, Australia). The cultures were incubated in a humidified atmosphere of 95% air and 5% CO2 at 37°C.[9]

Ethanol Extract of Papua's Ants Nest Plants: Ant nest plants (Wamena, Papua, Indonesia) were washed and dried in an oven at 55°C until it dries and was ground to powder (simplicia). Maseration was done by soaking the simplicia into 96% ethanol (Brataco, Indonesia) and stirred for 30 minutes, then incubated for 5 days. The immersion liquid was filtered to separate the pulp and ethanol extract. The macerated extract was collected in one section and evaporated using a rotary vacuum evaporator at a temperature of 70°C. Thus, the existing water content was removed by heating it in a water bath with a temperature of 70°C.

The process of fractionating ant nest plants: Fractionation is the process of separation between liquid and liquid which is carried out in stages based on the level of polarity, namely from non-polar, semi-polar and polar. The puremethanol (Brataco, Indonesia) extract was suspended with methanol: water (1:1) and partitioned using hexane solvent, producing a hexane fraction. Repeated until the hexan fraction obtained was clear. The n-hexane (Nacalai, Japan) fraction was partitioned using n-hexane solvent obtained by n-hexane extract. The n-hexan fraction was partitioned with ethyl acetate (EtoAc): Aquades (1:1) to obtain the ethyl acetate fraction. The results of the partition of the fractions were evaporated at a temperature of 30-40^{0}C until fractions were obtained. Furthermore, the fraction obtained can be used for phytochemical tests.

Cell cycle analysis with flow cytometry: Cell cultures were inserted in a 24-well with a concentration of 2,5x10^5 cells/well and incubated for 24 hours. The treated cells (concentration 37.5, 75, 112.5, 150 and 300 µg/mL) were collected in a flow cytometer tubes and centrifuged at 1500 rpm for 5 minutes, then the supernatant is removed. Cells were fixed with 500 µL of 70% ethanol cold, stored at 4ºC for 15 minutes and centrifuged for 5 minutes. Cell pellets were suspended with 900 µL PBS and 100 µl Propidium Iodide (Sigma Aldrich, USA), dye analysis of DNA content, and homogenized. Suspended cells were incubated in the dark for 30 minutes and analyzed for cell cycles with flow cytometry (Beckmann coulter, USA).

Apoptosis induction analysis by caspase -3, -8 and -9: Caspase-3,-8 and -9 activities were measured using the colorimetric assay kit according to the manufacturer's directions. Briefly, equal amounts of cell extracts prepared from Raji cell treated with ethyl acetate fraction with concentration 37.5, 75, 112.5, 150 and 300 µg/mL were incubated with the substrate (DVED-pNA and LEHD-pNA; BioVision colorimetric assay kit, CA, USA) in the assay buffer for 2h at 37^{0}C. Absorbance was measured at 450 nm using a microplate reader (Bio-Rad Laboratories, Hercules, CA, USA). Each determination was conducted in triplicate.[10]

Cyclin E and CDK2 analysis using Elisa kit: All reagents and samples were prepared in 4ºC storage. Fifty micro liter of all sample were added to appropriate wells and 50 µL of the Antibody cocktail was also added to each well. Seal the plate and incubate for 1 hour at room temperature on a plate shaker set to 400 rpm. Each well was washed with 3x350 µL 1X wash buffer. Wash by aspirating or decanting from wells then dispensing 350 µL 1X wash buffer into each well. 100 µL of TMB substrate were added to each well and incubate for 10 minutes in the dark on a plate shaker set to 400 rpm. Further more, 100 µL of stop solution were added to each well. Shake plate for 1 minute to mix and measured at 450 nm.

Statistical analysis: Data was evaluated with Stat View 4.5 (Abacus Concepts, Berkeley, CA) using one-

way ANOVA and *t-test*. The significance level was set at 5% for each analysis.

Results

Proteolytic activities of caspase-3,-8 and -9: The activity of caspase-3,-8 and -9 in Rajicell treated with various concentrations of ethyl acetate fraction (EAF) were investigated. Raji-EAF 112.5 to 300 µg/mL revealed increased the proteolytic activities of caspase-3, -8 and -9 as compared with that ofcontrol. Proteolytic activities of caspase-3 in Raji-EAF 300 µg/mL was found at 1.42 fold increase compared withthat of control (Figure 1A). Furthermore, proteolytic activities of caspase-8 in Raji-EAF 300 µg/mL was detected at 1.75 fold increased (Figure 1B). Moreover, caspase-9 proteolytic activities in Raji-EAF 300 µg/mL was confirmed at 1.83 fold increase (Figure 1C). Increased caspase-3, -8 and -9 expressions were followed by in increased in ethyl acetate fraction of M. pendens concentration. These results showed that apoptosis can appear through intrinsic (chemical induced apoptosis) and extrinsic (receptor induced apoptosis) pathways. Interestingly, induced apoptosis through the intrinsic pathway was detected stronger than extrinsic pathway in oral Burkitt's lymphoma cells.

Cell cycle analysis: Cell cycle arrest was examined by flow cytometry. As seen in Table 1, Raji-EAF 150 µg/mL had a potential to arrest of cell cycle in G0-G1 phase by 13.75% and in G2-M phase at 8.54%. However, Raji-EAF 300 µg/mL was only inhibited the cell cycle in G2-M phase.

Level of cyclin E and CDK2: Cyclin E and CDK2 was evaluated by Elisa kit. As seen in Figure 2A and 2B, cyclin E and CDK2 level were significantly decreased according to increased concentration of Ethyl acetate fraction of ant nest. The suppression of cyclin E and CDK2 level in Raji cell treated with EAF 300 µg/mLwas found at 68%and 57%, respectively.

Figure 1. Proteolitic activity of caspase-3, -8 and -9 evaluated by colorimetric assay. A. Fold increase in caspase-3. B. Fold increase in caspase-8. C. Fold increase in caspase-9 (*, P < 0.05)

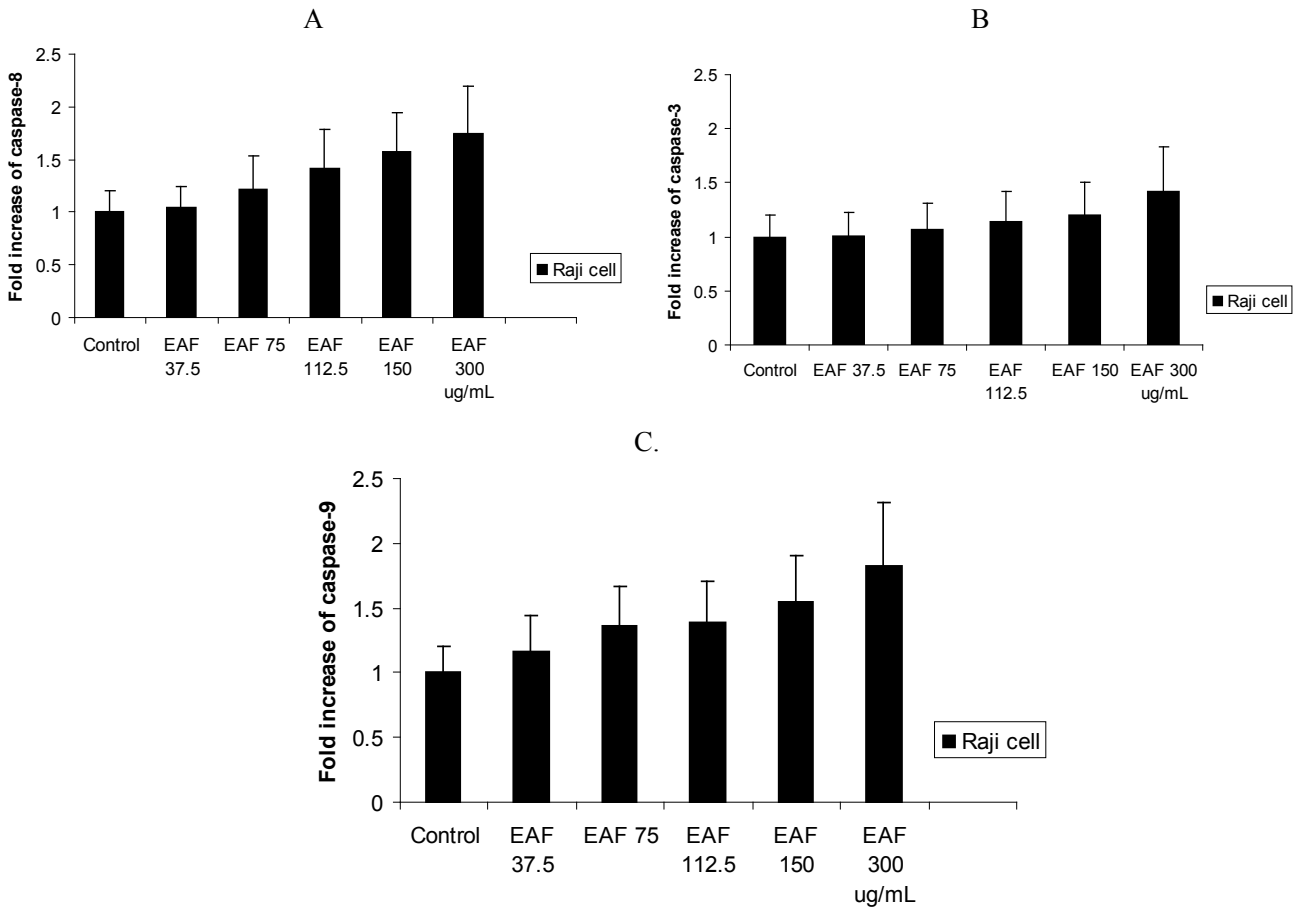

Table 1: Cell cycle arrest was examined by flow cytometri. Raji cell was treated with various EAF of ant nest

	Control (%)	EAF 37.5 (%)	EAF 75 (%)	EAF 112.5 (%)	EAF 150 (%)	EAF 300 (%)
G0-G1	61.31	52.71	48.84	50.82	**75.06**	45.63
S	18.80	20.62	18.99	21.59	13.56	40.47
G2-M	20.08	26.67	31.84	27.60	**11.54**	**11.95**

Discussion

The cell cycle requires a delicate balance between positive and negative regulatory factors. Any alteration in this balance can result in abnormal cell proliferation and apoptosis reduction which may contribute to cancer. Cancers of the oral cavity present a major health problem, as indicated by their high incidence in many parts of the world.[11] These highlights the necessity for continued efforts to improve the treatment modalities one of them uses superior herbal medicine products in Indonesia, Papua's ant nest plant (*Myrmecodia pendens*).In the present study, active fraction of ethyl acetate was employed to investigate the effect of cell cycle arrest and apoptosis induction on oral Burkitt's lymphoma cells. Treatment of various concentration of ant nest into cultured Raji cell was induced the cell cycle arrest and apoptosis effect. In addition, higher concentration of ant nest revealed stronger effect in both examined. These results clearly showed that cell cycle arrest and apoptosis induction was increased by the ant nest effect and not by non-specific effects such as ethyl acetate toxicity. Furthermore, cell cycle arrest in G0-G1 and G2-M phases was showed in Raji cells treated with ethyl acetate fraction of ant nest at concentration150µg/mL. Interestingly, cell cycle arrest in G2-M phase was only detected at concentration 300 µg/mL. These data suggest the most effective concentration inhibits the cell cycle was 150-300 µg/mL. Recently reported that phytochemical species of ant nest plants have relatively similar active compounds include tannin, tocopherols, alkaloids and flavonoids.[6] Flavonoids were reported to have antioxidants effect that activating the cancer cell apoptosis pathway. The mechanism of cell apoptosis in that theory is a result of DNA fragmentation. This fragmentation begins with the release of the proximal DNA chain by reactive oxygen compounds such as hydroxyl radicals. Second, flavonoids as cancer inhibitors are one of them by inhibiting the activity of protein kinase so that it inhibits the signal transduction pathway from the cell membrane to nucleus. Third, flavonoid is inhibiting tyrosine kinase receptor activity because the increased receptor activity of tyrosine kinase plays a role in the growth of malignancy.[12] Recently, Dehay and Kennedy[13] reported cell cycle control is carried out by CKI which acts as a negative regulator of activation of the cyclin/CDK complex during the G1 and S phases.Cyclin/CDK regulation at each cell cycle phase including the cyclin D/CDK4/6 complex plays a role in the initial transition until mid-phase G1. The beginning of the S phase is characterized by the formation of the cyclin E/CDK 2 complex. In this study, we showed ant nest fraction was markedly induced cell cycle arrest

through down regulation of cyclin E-CDK-2 complex protein. This data was in accordance with the results of this study that induction of cell cycle arrest in G0-G1 or G2-M phases followed by down regulation of cyclin E-CDK-2 complex protein.

As expected from the cell cycle arrest effect, apoptotic induction was also occurred in cells treated with ethyl acetate fraction of ant nest at concentrations of 75-300 µg/mL g/mL. Increased in proteolitic activity of caspase-3, -8 and -9 suggest that apoptosis can occur through the extrinsic and intrinsic pathways. In both pathways there was activation of cystein aspartyl-specific proteases (caspase) which play a role in breaking down cellular substrate which causes changes in cell morphology and biochemistry as a characteristic of apoptosis.[14]Intrinsic pathways had the proteolytic activity stronger than extrinsic pathways. It means the ethyl acetate fraction of ant nests was more potent elevating intrinsic pathways which are chemical-induced apoptosis than receptor-induced apoptosis. Moreover, increased activity of caspase-3, -8 and -9 strongly suggest that apoptosis occured in those cultures.Activation of caspase-3, an executioner caspase in apoptosis pathway, leads to the cleavage of PARP and DNA fragmentationindicating that caspase-3 targets cellular proteins for proteolytic cleavage resulting in cell death.[15] Caspase-3 activity can be activated by either an extrinsic apoptosis pathway, by the activation of caspase-8, or an intrinsic apoptosis pathway, by the release of cytochrome-c from mitochondria. Activated caspase-8 can directly cleave and activate the executioner caspases, such as caspase-3, or it can cleave one of the Bcl-2 family members, such as Bid, to induce the release of mitochondrial cytochrome c, which also leads to activation of caspase-3 via formation of a pop to some consisting of Apaf-1 and caspase-9.[16]

In conclusion, the ethyl acetate fraction of the ant nest plant had a strong potential antitumor activity of oral malignant Burkitt's lymphoma cells proofed by the induction of cell cycle arrest and apoptosis through down regulation of cyclin E-CDK-2 complex..

Space-Time Analysis for Dengue Surveillance: A Case Study in Sleman, Yogyakarta, Indonesia

Sulistyawati Sulistyawati[1], Anang Suyoto[1,2]

[1]Special Health Section and Health Insurance, Sleman District Health Office, Sleman, Indonesia,
[2]Department of Public Health, Universitas Ahmad Dahlan, Yogyakarta

Abstract

Introduction: Surveillance is a dynamic activity that needs a continuous update to perform their function such as monitoring, evaluating, identifying high risk and supporting disease policy making. Geographic Information System (GIS) is a system for capture, store, analysis and visualise a phenomenon related to the geographical position including related particular disease. This tool is claimed powerful to support disease surveillance.

Objective: This study aims to apply retrospective space-time analysis using GIS on dengue cases to identify the clustering that may occur during the data period for supporting dengue surveillance.

Method: This research was a descriptive study by employed GIS technique-Satscan retrospective space-time permutation model. 159 confirmed dengue case sourced from Sleman District Health Office (Sleman DHO) between January 2017 to September 2018 was used as an input data. Geographical Positioning System (GPS) was employed to collect the coordinate location of the cases. The map was generated using Arc GIS.

Results: A most likely cluster and eight secondary clusters were detected in this study. The most likely cluster was found in Depok subdistrict during the middle of March to the middle of April 2018.

Conclusions: GIS shown as a powerful tool for dengue surveillance. Identification of space and time related to dengue is an alarm for related stakeholder on dengue prevention to prepare and prevent outbreak occurrence.

Keywords: *Dengue, Scan statistic, Space-Time cluster detection, GIS, Sleman, Indonesia.*

Introduction

Dengue is caused by DEN virus that transmitted by female Aedesaegypti that it is estimated responsible to 390 million infections each year[1]. Dengue is an infectious disease that closely associated with environmental condition and time pattern. In Sleman dengue-related to environmental aspects such as land cover, humidity and rainfall[2].Understanding the space and time pattern is essential for surveillance action on monitoring and preventing the dengue transmission.

Geographical Information System (GIS) is an instrument for capture, store, analysis and visualise a phenomenon related to the geographical position of particular object[3,4]. GIS is a powerful tool on surveillance activity, as stated by some researches before. John Snow introduced this tool in 1854. On that time, he used GIS to study cholera outbreak in London[5]. Since then, GIS is widely used in public health study in many diseases' cases. A review from Jennifer et al. discussed the role of GIS for surveillance purpose[6], for example, recognising the triggers of dengue by assessing the correlation among the variable visually and geographical phenomenon. The important of GIS also said by another review that GIS could support dengue control program, such as by generating the vulnerable risk map[4].

According to Sleman government information, Sleman is divided into seventeen subdistricts that located in the north of Yogyakarta province, Indonesia. This district spreads over 574.82 Km^2, with more than 800.000 resident living over there[7]. Dengue in this district has been receiving attention from the local authority. The case number fluctuated throughout the year from 2013 to the middle of 2018 (Figure 1). Dengue case information in Sleman is captured through Integrated Disease Surveillance System or called as Surveilans Terpadu Penyakit (STP) and Hospital Information system or called as (SIRS). All of which are based on the patient visit in the hospital, primary health centre and other health facilities. A monthly report was generated from this activity to calculate the top 10 disease status[8].

Space-time permutation statistic is an algorithm which required case date of illness and coordinate position. This formula is a promising tool for early detection of particular disease outbreak[9]. Currently, information about the place and time of the disease occurrence is pivotal for preparing the disease prevention program by the stakeholder involved. There is growing evidence the usage of GIS method in disease-related environmental. However, information regarding space and time simultaneously is lacking, particularly in dengue. This research aims to apply retrospective space-time analysis using GIS on dengue cases to identify dengue cluster that may occur during the data period for supporting dengue surveillance.

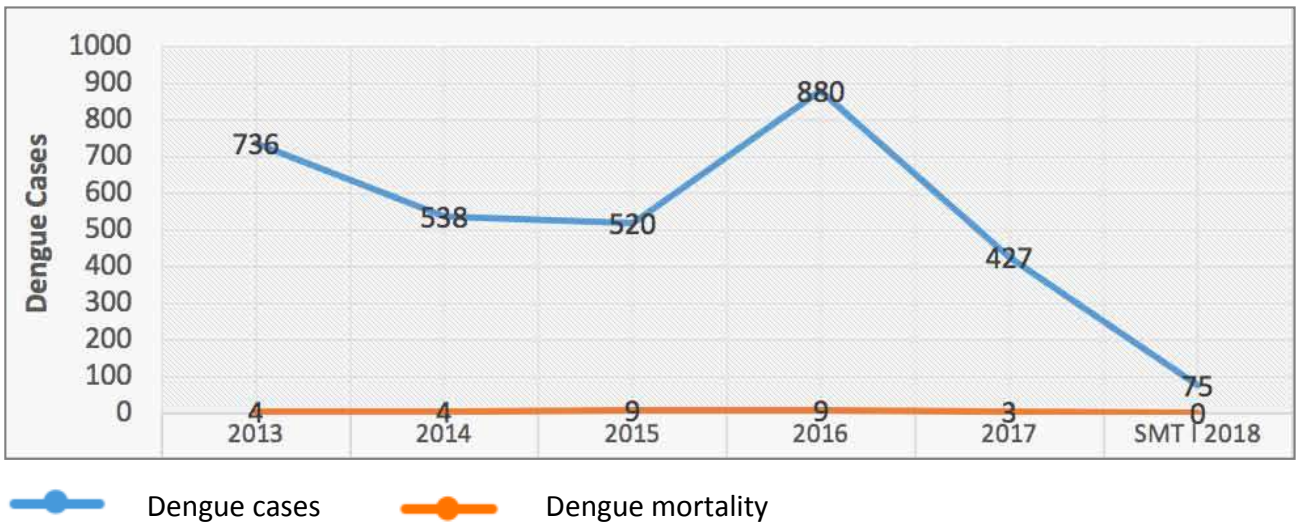

Figure 1: Dengue case and mortality in Sleman district from 2013 to the middle of 2018

Material and Method

This research is a descriptive study to detect space and time cluster of dengue cases in Sleman, Yogyakarta (January 2017 to November 2018). Data collection and analysis was done in the end of 2018. Secondary data from Sleman District Health Office (Sleman DHO) was collected as input data of the study. Of 159 confirmed dengue cases who had a complete home address and date of illness was included. Geographical Positioning System (GPS) was employed to collect the coordinate location of the cases. For analysis purposes, we used the Retrospective Spatial Scan Statistic (Satscan) software. The Kulldorf space-time permutation model was used to discover the dengue cluster by using five days of Time Aggregation Length. The map was generated using Arc GIS.

Results

According to our research, space-time analysis can be used on dengue surveillance study to inform where and when the dengue transmission potentially occurred. This information is essential to influence dengue program stakeholder to determine appropriate prevention of dengue outbreak.

During the data period - from January 2017 to November 2018, Satscan statistics detected nine clusters of dengue cases in Sleman, Yogyakarta. Among which, one cluster was significant (p-value ≤ 0.05). This cluster

centred at Depok subdistrict, in adjacent with the city of Yogyakarta and some other district in Central Java Province. The other eight clusters are spread over the Sleman, and they were not significantly space time associated. Complete information is summarised in Table 1 and Figure 2.

Table 1. Cluster detection according to retrospective space time permutation model

Cluster ID	Data range	Cluster locations	Cluster radius (km)	Actual cases	Expected cases	P-value
1	3/12/18-4/15/18	-7.78311, 110.3928	2.34	8	1.19	0.022*
2	7/5/17- 9/2/17	-7.80071, 110.2959	2.78	13	3.65	0.176
3	7/30/17-8/18/17	-7.69815, 110.4208	1.57	3	0.11	0.337
4	1/1/18- 1/10/18	-7.66529, 110.3271	7.95	6	0.82	0.36
5	6/5/18- 6/19/18	-7.81873, 110.4561	1.80	2	0.03	0.471

Discussion

Geographic Information System (GIS) is a highly recommended tool on disease surveillance to monitor, control and prevention. Currently, many researchers use this method to study disease pattern to support the decision maker for taking the policy. However, dynamic and continuous analysis is needed to update the disease situation because of Dengue as one of environmental disease that changes over time. Identification following space and time will facilitate the development of dengue

monitoring and may improve the response to the dengue outbreak.

In this study, we measured the using of space-time GIS analysis to identify dengue cluster that may occur during the data period. Through Satscan, we found 9 clusters; one of them significantly associated with space and time. Our study in Yogyakarta city also found a similar result, that dengue case was corresponding to space and time[10]. In Sleman during 2017-2018, a significant dengue cluster is detected centred in Depok sub-district from March 12 to April 15 of 2018. Since several years, Depok has received attention about dengue transmission in this area. According to Sleman DHO information, this area has been predicted as a vulnerable subdistrict in 2019 due to the high population density[11,12]. The previous study proved about the correlation between dengue incidence and population density, one of which in Sri-Lanka[13]. While in São Paulo-Brazil, dengue incidence clustered in an area that has a high population density because it increases the possibility of contact between infected mosquito and human[14].

The most likely cluster in Depok was at March 12 to April 15 of 2018. This occurrence is guessed coincided with the rainfall intensity in this location. According to the Meteorology Climatology and Geophysics Council, on March 2018. Depok subdistrict had high-intensity rainfall (301-400 mm)[1] while in April 2018 had medium rain between 150-200 mm[1]. A combination of high-intensity precipitation and proper temperature highly contributed to increasing dengue risk[17]. Rainfall is an essential aspect of Aedes development as they need stagnant water for breeding[18], rain builds breeding sites for larvae develop before it grows to adult mosquitos[19]. From this information shows when high-intensity rainfall occurred, it could potentially increase of dengue incidence if the prevention system is not ready.

Three clusters were detected in Gamping sub-district, while Mlati, Tempel, Ngaglik, Berbah and Kalasan subdistrict, on each of them was found one secondary cluster. Even though it was not significant, this result needs to pay attention for the stakeholder involved as part of dengue prevention. In our observation, there was also unique spot that we found dengue cases in high altitude that is> 500–999 m above sea level 2, namely in Tempel and Turi subdistrict. This information needs to be considered as part of climate change phenomenon that potential to extent the vulnerable area for Aedes development due to temperature increases[21], including in high altitude which is in a normal situation having a lower temperature. When the temperature is rising, it has implication to mosquito growth rate, reduces the interval on blood feeds, shortens the incubation period and contributed to virus evolution rate[22,23]. Accordingly, this information also provides an early warning on dengue transmission in the future.

Conclusion

From this paper, we can see the power of GIS through space-time permutation analysis on surveillance activity. Cluster detection can help on dengue surveillance to providing early detection of dengue outbreak by knowing the association both space and time. This identification can lead to seeking the possible aspect that in uences the incidence. Future study is proposed to conduct a research related to the dynamic of rainfall and the association with dengue incidence. Secondly, to do research related to the changing of temperature and vector longevity in the research area.

Influence of Social Cultural Capital and Marketing on Skin Whitening Products Use among Higher Education Female Students in the Northeast of Thailand

Anawat Phutongnak[1], Wongsa Laohasiriwong[2], Kittipong Sornlorm[3]

[1]Doctor of Public Health Program, Faculty of Public Health, Khon Kaen University, Thailand, [2]Faculty of Public Health, Khon Kaen University, Thailand, [3]Thakhantho District Public Health Office, Kalasin Province, Thailand

Abstract

Introduction: There have been increasing trends of skin whitening products use globally. Social cultural capital has been identified as one of a significant determinants of skin whitening products use. However, there was no study on these issues in Thailand. Therefore, this study aimed to identify skin whitening products use situation and the association between social cultural capital, marketing, and skin whitening products use among female higher education students in the Northeast of Thailand.

Method and Materials: This cross-sectional study was conducted in the Northeast of Thailand among 1,143 female higher education students. Data was collected using a self-administered structured questionnaire. The Generalized Linear Mixed Model (GLMM) was used to identify the associations between social cultural capital, marketing and skin whitening products use when controlling other covariates.

Results: Most of the respondents ever used skin whitening products (84.95%: 95%CI: 82.88–87.03), of which 52.66% (95%CI: 49.77–55.57) were current users, and 17.41% (95%CI: 15.21–19.61) were inappropriate use. The social cultural capital factor that were associated with skin whitening products use were those who were not satisfied with skin colors (Adj. OR=3.48; 95%CI=2.18–5.55; p<0.001), had friends using skin whitening products (Adj. OR=2.63; 95%CI=1.71–4.04; p<0.001, had thin to normal figures (Adj. OR=2.53; 95%CI=1.54–4.15; p<0.001), and had family members using skin whitening products (Adj. OR=1.86; 95%CI=1.10–3.15; p=0.020), studied in humanities and social sciences (Adj. OR=2.07; 95%CI=1.25–3.45; p=0.005) and product marketing (Adj. OR=1.92; 95%CI=1.15–3.20; p=0.012). Moreover, other factors that were also associated with skin whitening products use were family monthly income.

Conclusion: Majority of the higher education female students were current skin whitening products users of which about one-sixth was inappropriate users. Both social cultural capital, marketing had influence on skin whitening products use.

Keywords: *Skin whitening, Social cultural capital, Marketing, Female students.*

Introduction

Skin whitening products use is an ancient and widespread practice in many cultures [(1)], and is one of the most popular products of the global beauty industry, particularly in Asia. Marketing forecasters predict the business will be worth about USD 31.2 billion by 2024[(2)]. In several Asian countries, particularly India, Japan, Korea, China, and Thailand, women face pressure to lighten their skin due to the social perception that light skin is considered to be a cultural marker of beauty, class, and wealth, and has been reflective of high social status for many decades[(3-4)]. The social cultural capital refers to social, political, economic, cultural assets, and imperceptible health resources[(5-6)], with a growing recognition of the socioeconomic

Faculty of Public Health, Khon Kaen University, Thailand
e-mail: drwongsa@gmail.com

status and social determinants of health[7]. It has been described as a feature of trust, norms, networks, skill, cultural knowledge, and education that can improve the efficiency of society by facilitating coordinated actions[8]. In addition, previous studies reported that the advertising industry has recently created a market on notions of beauty, and enhance social cultural capital for the improvement in confidence and career prospects through the use of products advertised to promote white skin[9].

However, skin whitening products frequently contain toxic ingredients that are directly associated with adverse health and skin problems[10]. A study on the use of skin whitening products among university students indicated that 70.7% of females reported using skin whitening products[11] of which their use was associated with adverse skin effects, lack of personal control, risky sexual behaviors, and low social support[12]. In Thailand, as well as the Northeast region, the country biggest region both in term of land areas and population, there are still lack of research specifically concerned with social cultural capital, skin whitening products use, and their relationship to female higher education students.

Hence, this study aimed to describe skin whitening products use situation and to identify the association between social cultural capital, marketing, and skin whitening products use among female higher education students in the Northeast of Thailand. The findings of this study will provide evidence for health, education and relevant sectors to formulate appropriate measures to improve inequalities in health and reduce the use of skin whitening products.

Method

This cross-sectional analytical study was conducted between March to July 2019. The population were female higher education students in the Northeast of Thailand. The inclusion criteria were female higher education students aged 18 years old and older, currently studying for a bachelor's degree in universities of the Northeast of Thailand, able to verbally communicate, and agreed to participate in the study with written informed consent. The sample size was calculated by using the formula to estimate the sample size for a logistic regression analysis of Hsieh [13]. The estimated sample size was 1,143. We recruited students from 18 universities of the Northeast by using a multi-stage random sampling method. The sampling frame was all 18 universities in the Northeast of Thailand. The first stage was a random selection of 4 universities, followed by randomly selecting 3 fields from each university. Then, one faculty from each field was randomly selected. Therefore, a total of 12 faculties were included in the study. Simple random sampling was applied to select participants proportional to the size of the estimated total samples. A total number of 1,143 individuals were chosen to participate in this study.

Research Tools: A structured questionnaire was developed based on the research questions and relevant literatures. The structured questionnaire consisted of 4 parts including: 1) Demographic and socioeconomic: age, university level, field of study, residence, allowance, family monthly income, adequacy of expense, and family members. 2) Skin whitening products use included; Have you ever used skin whitening products in your lifetime? Do you currently use skin whitening products? Inappropriate use was assessed by using a list of dangerous cosmetics from the FDA (Food and Drug Administration, Ministry of Public Health, Thailand), defined as those who reported any use of dangerous cosmetics. 3) Social cultural capital included; satisfied with skin color, have a friend using skin whitening products, have any family members using skin whitening products, Figures were assessed by using BMI (Body Mass Index). The scores were categorized into four groups according to the WHO (World Health Organization) [14] for Asian-Pacific cutoff points, as follows: Underweight (<18.5 kg/m^2), Normal (18.5–22.9 kg/m^2), Overweight (23–24.9 kg/m^2), and Obese (≥25 kg/m^2). Finally, the scores were dichotomized as thin/normal (<23) and overweight/obesity (≥23). 4) Marketing: Product, Price, Place, and Promotion. Using the 5 scores (Very Low, Low, Moderate, High, Very high). After summing up the total marks, according to Best's theory, the scores were categorized into 3 groups (Low, Moderate, High). Finally, the scores were dichotomized as low/moderate (<3.68) and high (≥3.68) by using the mean as the cutoff point.

The questionnaire was undergone content validation by 5 experts and was revised to improve its validity. The Cronbach's alpha coefficient of social cultural capital was 0.80, marketing was 0.87. A self-administer questionnaire was used for data collection. The researcher responded to possible questions raised by the respondents, and assisted them when necessary. The completed questionnaires of each student were placed into an individual envelope, sealed, and put into a box. Confidentiality of all data was fully assured.

Data analysis: The data was analysed using STATA® (ver. 13; College Station, TX, USA: Stata Corp). Frequency and percentage were presented to describe the categorical variables. Continuous variables were described as mean and standard deviation, median and range. The generalized linear mixed model (GLMM) was performed to model the random effects and correlations within clusters. In the modelling, the universities were set as random effects. Bivariate analysis was used to determine the association of each independent variable with skin whitening products use. The variable that had p-value<0.25 were proceeded to multivariable analysis, of which the backward elimination method was used for model fitting. The final model results were presented as adjusted Odds Ratio (Adj. OR), 95% CI, with the levels of significance of 0.05.

Results

The average age of female higher education students was 20.67 ± 1.25 years old. Almost equal proportion of students were form each 4 universities (about 25%) and were from freshman (24.06%), sophomore (24.41%), junior (27.91) and senior: 23.62%. Majority of the student lived in private accommodation. Their median family monthly income was USD 940 with the ranged of USD 163 to USD 6,528. Nearly half of the respondents had adequate financial support but were unable to save any money. Most of respondents (84.51%) had thin and normal figure, and had friends (71.22%) using skin whitening products. Almost one-third had family members using skin whitening products and were not satisfied with their skin colors. Majority of respondents (53.81%) perceived a moderate level of overall marketing strategies and about 60% perceived a high level of product marketing.

Most of the respondents used skin whitening products (84.95%), 52.66% were current use and 17.41% were inappropriate use.

Table 1: Number and percentage of skin whitening products use among female higher education students in the Northeast of Thailand (n = 1,143)

Characteristics	Number	Percent	95%CI
Use of skin whitening products			
Never	172	15.05	13.09 – 17.24
Ever	971	84.95	82.76 – 86.91
Current Use			
No	541	47.34	44.44 – 50.24
Yes	602	52.66	49.76 – 55.56
Inappropriate Use			
No	944	82.59	80.28 – 84.68
Yes	199	17.41	15.32 – 19.72

The bivariate analysis indicated that social cultural capital factor including satisfied with skin colors, had friends using skin whitening products, figures, had family members using skin whitening products, and field of study, product marketing and marketing on place, age, family members, family monthly income, and allowance might associated with skin whitening products use (p-value <0.25). These variable were proceeded to the multiple variable analysis using GLMM. The results indicated that satisfied with skin colors (adj. OR=3.48: 95% CI; 2.18-5.55), had friends using skin whitening products (adj. OR= 2.63: 95% CI; 1.71- 4.04), were thin-normal (adj. OR= 2.53: 95% CI; 1.54- 4.15), studied in the field of humanities and social sciences (adj. OR= 2.07: 95% CI; 1.25- 3.45), had product marketing level (adj. OR= 1.92: 95% CI; 1.15- 3.20), and had monthly family income ≥ 980 USD (adj. OR= 2.13: 95% CI; 1.41-3.20).

Discussion

Skin whitening products use among female higher education students was 84.95%. This finding is consistent with previous studies reporting a high prevalence of skin whitening products use[1,15]. However, this was inconsistent with a study among African women, observed only 60% the respondents using skin whitening products[16]. Our study observed that 52.66% of students were current users, which was higher than the 37.60% found in India. It probably due to the greater range of ages (16-60 years) as well as the cultural setting of the study[17]. About one sixth were using the products inappropriately, a little lower than 46.7% of teenage females reported using harmful cosmetics[18].

The multivariable analysis of this study confirmed that social cultural capital was significantly associated with skin whitening products use. Regarding social cultural capital and satisfaction with skin colors, students who were dissatisfied with their skin colors were 3.48 times more likely to use skin whitening products. This finding was consistent with a previous study [15]. Social and cultural notions connected females using skin whitening products [15]. The presence of social cultural capital among university students was associated with their entire health and individual life [19]. Shroff, H et al suggested enhanced social cultural capital for prevention of use among women [17]. Students who had friends using skin whitening products were 2.63 times more likely to use skin whitening products as well as having family members using skin whitening products were 1.86 times more likely to use them. It might be that both peers and families could have direct communication with the students that could have influence on their behaviors. These findings were consistent with another study [20]. Students with thin to normal figures were 2.53 times more likely to use skin whitening products compared to those in the overweight and obese group. This was in similar with the study in India [17], but inconsistent with the study in Sudan [15]. This might be due to the body image and beauty concerns of female students engaged in weight control. Students who studied in humanities and social sciences were 2.07 times more likely to use skin whitening products than students who studied science and technology. The finding was also consistent with another study [21]. Students with a high level of product marketing were 1.92 times more likely to use skin whitening products, which was similar with a study in United Arab Emirates [22]. Students with family monthly income ≥ USD 980 were 2.13 times more likely to use skin whitening products. This was also similar with a study conducted in Southeast Asia [19]. It might be that they had money to spend on nonessential items.

Conclusion

As high as 84.95% of the higher education female students ever used skin whitening products of which more than half were current skin whitening products

users. About one-sixth was inappropriate users. Both social cultural capital, marketing had influence on skin whitening products use.

Limitation of the study

Since this is a cross-sectional study, it could not identify the causal relationship between independent variables with skin whitening products use.

Conflicts of interest

The authors declare no conflicts of interest.

Ethics clearance

After explaining the study objective, written informed consent was taken from all the participated in the study. Confidentiality of the data was fully assured. The Khon Kaen University Ethics Committee in Human Research approved the exemption for ethical approval of this study (reference no. HE 612343).

Knowledge Management Based Performance Improvement on Certified Health Workers in Health Center of South Sulawesi

Andi Mansur Sulolipu[1], Ridwan Amiruddin[2], Sukri Palutturi[3], Ridwan M. Thaha[4], Arsunan A.A.[5]

[1]Doctoral Program Student,[2]Professor, Department of Epidemiology, [3]Professor, Department of Health Policy and Administration, [4]Senior Lecturer, Department of Health Education and Behavioral Sciences, [5]Professor, Department of Epidemiology, Faculty of Public Health, Hasanuddin University, Makassar, Indonesia

Abstract

Introduction: The aim of this research was to determine the effect of Knowledge Management on improving the performance of health workers force at Primary Health Center of South Sulawesi.

Material and Method: The research used qualitative method. The informants were 12 health workers. Data collection used was in-depth interviews. The tools used were tape recorders and camcorders.

Finding and Discussion: This study found that the Knowledge Management method was relevant to be used in increasing the performance of health workers force in a group of health workers (Doctors, Nurses, Midwives, and SKM (Bachelor of Public Health) who come from different functional health positions) at the South Sulawesi Community Health Center.

Conclusion: Performance of health work force could be done using one method which was knowledge management.

Keywords: *Health workers force, Knowledge management, Performance.*

Introduction

Global Health Workforce Alliance (GHWA) Conference reported that the quality of Human Resources Health is still a problem at the global level. In Indonesia, various efforts to improve the quality of health human resources to achieve sustainable competitive advantage and increase profitability were carried out through education and training. However, the education and training system have been criticized for years. The quality of the results of education and training of health workers in general is still inadequate[1]. According to various studies showed that health workers are the main key in the success of achieving health development goals. Health workers contribute up to 80% in the success of health development. In 2006, WHO reported that Indonesia was one of 57 countries that faced a health HR crisis, both in number and distribution.

Competence is an ability possessed by someone in carrying out a task or a job based on skills and knowledge. The development of human resource competencies in the health sector is a strategic component of health development in order to accelerate the distribution of health services and the achievement of health development goals. The performance of an organization will be determined by one of the main elements, which is the quality of human resources[2].

The implementation of non-quality training will have an impact on the low competency of graduates which ultimately affects the performance of institutions/ organizations. According to Hendry, the practice of improving the quality of human resources (training, job design, employee skills, employee attitudes, work motivation, etc.) has an impact on the performance of various business units[3]. Likewise, Sule findings

showed a significant positive relationship between competency-based training and development and employee performance[4]. Knowledge management is a concern of what is called Knowledge Management (KM). According to Qwaider, Knowledge Management helps manage knowledge individually or in group within organizations or between organizations that can affect the quality and benefits of knowledge[5].

Several studies were conducted on knowledge management related to variables such as performance, competence, training, learning, and others. Research conducted by Tongsamsi discovered the effect of knowledge management and training on manager competencies[6]. Knowledge management positively influences organizational performance. Another study was conducted by Chandavimol, which is the development of a mixed training model by applying the principles of knowledge management and learning actions, in order to develop the design competency of health human resource development staff training programs in the government sector[7]. Furthermore, the working team will form collaboration between participants in education and training [8] . The aim of this research is to improve the performance of the health work force at the Primary Health Center of South Sulawesi. In the era of knowledge-based society in the 21st century, the way people learn has changed. New knowledge is gained by learning from training, work and exchange of experiences. The US Department of Labor estimated that more than 70% of knowledge occurs from experience and 30% from education and training[9].

Knowledge of each individual in the organization or the company is certainly different so it causes the knowledge does not develop evenly with in the environment. Knowledge Management is one solution to assist knowledge processing, so that individuals in training or learning classes can have the same knowledge[9], then with the same knowledge it can help to develop an organization or company. Knowledge management is formed from a knowledge, where knowledge is divided into two types, those are Tacit Knowledge and Explicit Knowledge. This knowledge can be in the form of: books, journals, scientific works, references or others. This knowledge is obtained and developed from the content and information contained in it.

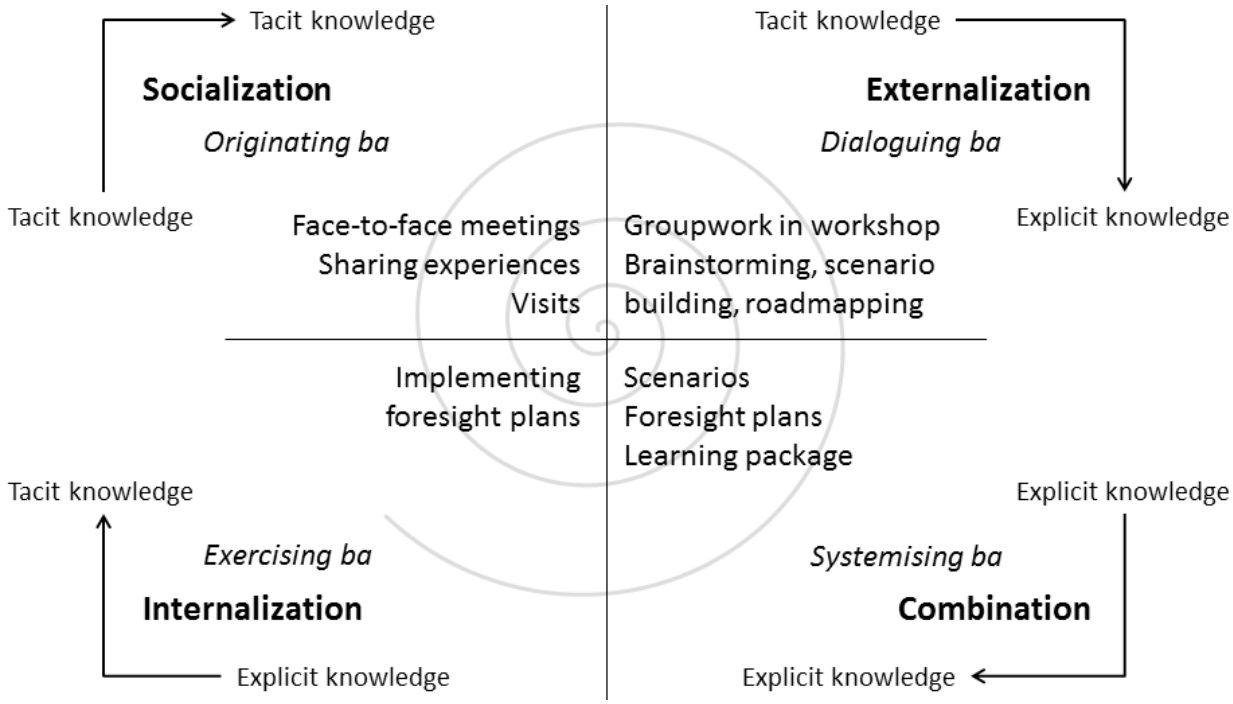

Figure 1. SECI Model

Figure 1 is known as the SECI Model[10], in the figure where there are two types of knowledge, those aretacit knowledge and explicit knowledge. In university education activities, knowledge management can improve administrative services related to the improvement of curriculum, teaching and learning

processes usingtechnology, as well asimproving response by monitoring and combining lessons from student experience and evaluation[11]. Nawaz and Gomez, presented two Knowledge Management Model Concepts. The first model concentrates on how knowledge sources are transformed into strategic knowledge, where the process of converting tacit and explicit knowledge into knowledge diffusion converts it again as the application of knowledge. Participants develop their knowledge by understanding the concept of subject matter and converting it into strategic knowledge. The second model strategic knowledge is a source of knowledge for students, while learning knowledge learners diffuse knowledge and choose strategic knowledge. This enhances procedural knowledge owned by the students, generates core subject skills and algorithms, core subject techniques and method as well as formula knowledge to determine when and how to use appropriate procedures to solve problems. The Strategic Knowledge Model can be implemented in universities, then for Knowledge Models can be implemented in advanced training institutions.

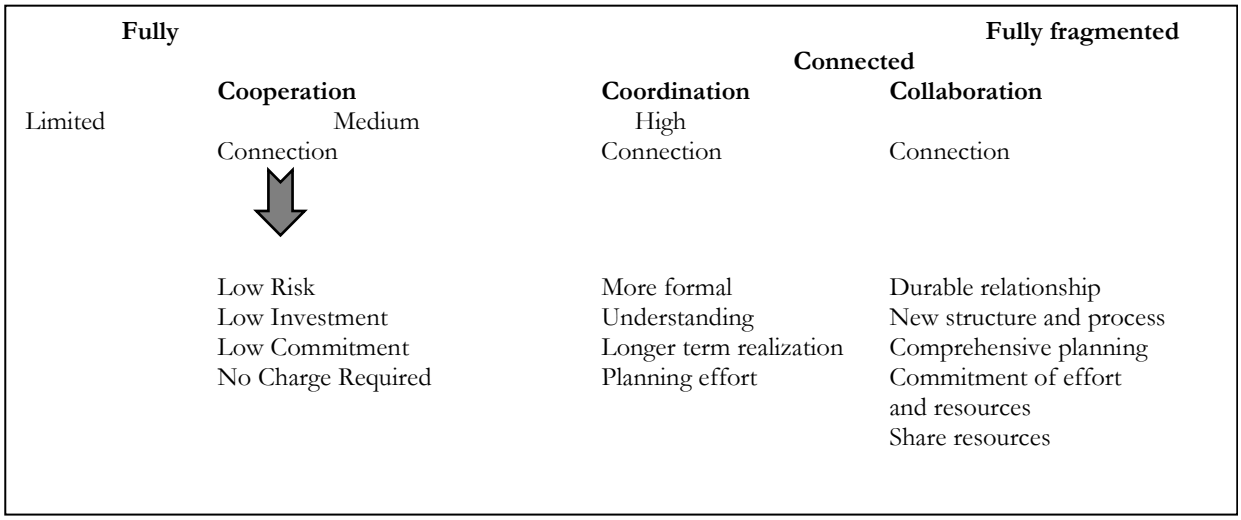

Figure 2. The Victorian council and social services

Knowledge Management strategy is very much needed to cooperate or collaborate, namely Cooperation, Coordination and Collaboration. Simple horizontal integration between cooperation, coordination and collaboration is shown in Figure 2.

Material and Method

Based on the conceptual framework, the variables in this study consisted of: Knowledge Management Strategy as an independent variable, and Enhancing Performance and competency as the dependent variable. This study used qualitative research method to obtain comprehensive, valid and objective data.

Finding and Discussion

The results of in-depth interviews showed that the application of knowledge management in the form of face-to-face socialization had a positive impact and benefits for the health workers in the Primary Health Center. Thus, it was very well implemented for every training attended by the health workers in the Primary Heath Center, sinceknowledge management is very helpful in understanding the management of the health center. In addition it is also able to be directly held.

Knowledge management can improve organizational performance [12] even though not all knowledge resources affect organizational performance directly. However, it cannot be ignored because they work in combination with other supporting sources, including knowledge acquisition and application knowledge that can contribute directly to the organizational success.

Based on the results of research at the Primary Health Center that have implemented knowledge management, it shows that it indirectly affects the performance of health workers so that it can encourage the management of the health center to improve the function of health services. The following are the results of the interview:

- ……*Socialization of training results improved performance, seen from the document management of the health center that had been produced....*

Performance is a work achievement that can be measured based on the standards or criteria set by the Primary Health Center. The completion of basic tasks and functions is the performance of a health worker who is physically and mentally attached.

……*At our place (Primary Health Center),every employee who participated inthe training must be trained to conduct socialization of training in meeting each patient in the Primary Health Center…*

Knowledge Management focuses on the identification, acquisition, distribution and maintenance of substantial and relevant knowledge. Rush (2005) described the term of Knowledge Management related to the exploitation and development of knowledge assets of an organization with the intention of improving the organizational goals. Knowledge management has been implemented in many organizations with the expectation that they will have a positive effect on performance[11].

Conclusion

The results showed that knowledge management had an effect on performance, and it could be concluded that health workers in the Primary Health Center who were committed to organizing had an impact on completing their main tasks and functions as health workers. Knowledge management provides development and the ability to think, work and manage work well so as to produce performance that affects the health services. Furthermore, research on learning strategies and knowledge management are suggested to be combined because they can facilitate the learning well.

Conflict of Interest: There is no conflict of interest to be declared.

Source of Funding: Self or other source

The source of funding for this research came from private funds.

Ethical Clearance: The ethical approval of this research was based on the letter Number: 3598/ UN4.14.8/TP.02.02/2019), Faculty of Public Health, Hasanuddin University, Makassar, Indonesia.

Hearing Impairment among Primary School Children in Nasiriya City/Iraq During 2018

Asaad Adil Mnaather[1], Sarah Noaman Al-Talaqani[2], Ali Abed Saadoon Al-Ghuzi[3], Mushtaq Neamah Al-Malki[3]

[1]Researcher, College of Medicine, Al-Muthanna University, [2]Researcher, Al-Muthanna Health Directorate, [3]Researcher, College of Medicine, Thi-Qar University, Iraq

Abstract

Across-sectional and comparative school-based study was carried out through multistage systematic random sampling for 9 public primary schools in Al-Nasiriya city from 1st of February/2018 -3th of May/2018. Primary information was obtained through prepared questionnaires including the socio-demographic characters of studied pupils. A total of 355 pupils were screened, 228(64.2%) of them were males and 127(35.8%) were female that ratio of male to female was 1.8 :1. Nearly half of pupils were within 6-7 years at (55.2%),and least one were within age group >10 years (15.2%). Majority of pupils were within high socio-economic status (87.6%), and the remaining were within moderate (8.2%) - low class (4.2%). The extent of hearing impairment among pupils in Nasiriya city was 16% .Unilateral (9.2%) was more prevalent than bilateral (7%). of 58 pupils with hearing impairment,52(14.7%) of studied pupils had mild hearing impairment, and 6(1.7%) had moderate hearing impairment. Non showed moderately severe or sever or profound hearing loss. There was significant association between age, socio-economic status of studied population and Prevalence of hearing impairment by logistic regression analysis.

Keywords: *Hearing impairment, primary school children, public school, tuning fork test, screening audiometry, hearing assessment.*

Introduction

Hearing impairment in pediatric is a common and serious disability[1]. Hearing loss can come from inherited problem, some infections affecting ear, infections during pregnancy; complicated birth of child, use of ototoxic medications, chronic, infection of middle ear and excessive exposure for noise[2]. In 2018 WHO estimated disabling hearing impairment to be more than 5% of the world's population which is about 466 million people, 34 million of them are children, and greatest of those were found in Southern area of Asia, Eastern area of Asia and sub-Saharan area of Africa[2] Which was in continuous rising that in 1995, WHO shown that peoples with hearing problems were 120 million[3], in 2000, 250 million people and in 2011 they involved about 360 million with disabling hearing loss; 32 million of them were children within age less than 14 years[4]. South and East Asia and sub-Saharan Africa remain the world regions with the highest prevalence of hearing impairment in both adults and children[5]. Unrecognized hearing loss, even of a mild severity can significantly affect educational achievement, language, social and emotional development of children[6-8]. Hearing impairment can be classified according to its severity of mild, moderate to severe or profound and also classified as conductive, sensorineural and mixed[9]. WHO developed a set of excellent and well-illustrated training guidelines for hearing care, aimed to provide primary health care workers and communities in developing countries with effective and simple method from preconception to adulthood in order to lower the burden of hearing disorders[10]. Early interventions through primary prevention, early detection, and assessing hearing impairment can overcome this problem. Management for children who have hearing problem that showing benefit include earlier identification; hearing aids usage, surgery of cochlear implants; and in educational and communicational field is encouraging use the language of sign and/or comment.

Materials and Method

Study Setting: This study was conducted in Al-Nasiriya; Thi-Qar Governorate's city center about 370Km southeast of Baghdad Where:

Ethical Consideration: The ethical clearance was obtained from committee of Department of Family medicine and Community/Thi-qar university. Thi-qar office of education and head teachers of recruited schools were notified and permission obtained from them to carry out the study. Informed verbal consent was obtained from parents of children, their teachers,and from children themselves, whenever applicable.

The Study Population: They were primary school children of 9 public primary school in Nasiriya City aged between 6-13 years of both sexes.

Inclusion criteria; all pupils aged 6-13 years.

Exclusion criteria; excluded were pupils who refused to participate, and those who were out of studied age group.

The study design: It was a cross- sectional descriptive-comparative school based- study carried out in primary schools in Nasiriya during the period from 1st day of Februry/2018- 4th of May/2018.

Sample size and Sampling process: The sample size was calculated according to the following equation[11]

$N = (1.96)^2 \times P(1-P)/d^2$

Where: N: Sample size, P: Estimated prevalence rate from other studies which would be (8%)[21]

d: Maximum tolerated error, the value of 0.03 was chosen as an acceptable limit.

$N = (1.96)^2 \times 0.08 \times 0.92/ (0.03)^2 \approx 314$

At the initial time in conducting the pilot study, there was a very high unresponsive rate (13%) … even though it might be acceptable to some extent… so the reviewers add a further 41 cases to overcoming this high refusal rate and at the end the sample size estimated totally as 355 pupils. Multistage random sampling was carried out. Firstly Nine primary schools were randomly selected (by simple random sampling from a list of primary schools obtained from Thi-Qar Education Directorate; 5 primary school from the first area and 4 primary school from 2nd area, those were be labeled then) from 9 primary health care sectors in Al Nasiriya city.

Data collection: The research team consisted of the researcher, consultant otolaryngology surgeon, and audiologist with his assistant. The researchers explained the aim of the study to school management and pupils and assured them of data confidentiality. Each selected school pupil was asked a special designed questionnaire (about hearing impairment approved by ethical committee for purpose of the study, before starting the study) and examined by direct observation and a special screening test (Tuning fork test and screening Audiometry).

Data analysis: Statistical analysis was performed using SPSS package (version 23). Descriptive data statistics expressed [in form of frequencies,percentages, and graphs], inferential statistics for testing of association by using tests of significance [Chi-square or Fisher exact test which are used for analysis of variables] .

Results

A cross-sectional, school based-study was conducted on 355 pupils with mean age of 8 years; ranging from 6-13 years and male to female ratio was 1.8:1. According to age and sex distribution of studied population**,** a total of 355 pupils screened; 228(64.2%) of them were male and 127(35.8%) were female. Nearly half of them were within 6-7 years (55.2%), and least one were within age group >10 years (15.2%). No statistically significant difference in the age of the studied population according to sex was found. In respect to socioeconomic distribution with no statistically significant difference,majority of pupils were within high socio-economic status as (87.6%), and the minority one within low class as (4.2%). Regarding family size with no statistically significant difference,most of studied population were within family size <5 as (83.9%) and the remaining were within family size ≥ 5 as (16.1%).

Table 1: Socio-demographic characters of studied population.

Variables		Sex		Total Count (%)	p-value, x2 test
		Female Count (%)	Male Count (%)		
Age	(6-7)years	68(53.5%)	128(56.1%)	196(55.2%)	0.838, 0.354
	(8-10)years	40(31.5%)	65(28.5%)	105(29.6%)	
	>10 years	19(15.0%)	35(15.4%)	54(15.2%)	
Socio-economic status	High	109(85.8%)	202(88.6%)	311(87.6%)	0.340, 2.586
	Moderate	14(11.0%)	15(6.6%)	29(8.2%)	
	Low	4(3.1%)	11(4.8%)	15(4.2%)	
Family size	<5	106(83.5%)	192(84.2%)	298(83.9%)	0.854, 0.034
	≥5	21(16.5%)	36(15.8%)	57(16.1%)	
Total		**127(100.0%)**	**228(100.0%)**	**355(100.0%)**	

Prevalence of hearing impairment according to screening audiometry: Prevalence of hearing impairment in primary school children in Nasiriya city is illustrated in **Figure 1**. Among the 355 studied pupils, 58(16.3%) was with HI, giving the prevalence rate of 16.3%.

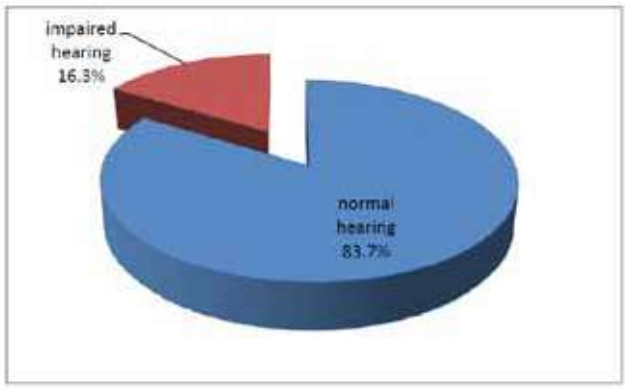

Figure 1.

Prevalence of hearing impairment according to severity based on audiometry: Figure. 2 demonstrates prevalence of audiometric-based severity of hearing impairment. of 58 pupils with hearing impairment, 52(14.7%) of studied pupils had mild hearing impairment, and 6(1.7%) had moderate hearing impairment. Non showed moderately severe or sever or profound hearing loss.

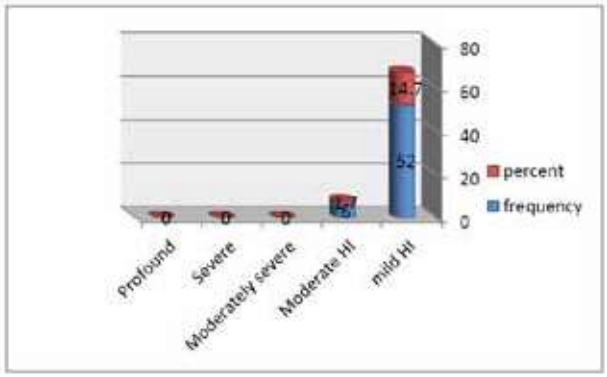

Figure 2.

Prevalence of audiometric-based HI according to selected socio-demographic characteristic: Table 2 shows the prevalence of hearing impairment was highest among pupils aged >10 years (24.1%), and least in pupils aged 6-7 years (13.3%)with no statistically significant association between HI and pupil's age. The prevalence of HI among females (21.3%) was higher than that for males (13.6%), however, the association was statistically not significant.

The prevalence of HI according to socio-economic status was highest among low socioeconomic pupils (46.7%), followed by moderate class (24.1%) . The prevalence of hearing impairment was lowest among those of high socio-economic class (14.1%). The association between socio-economic class and HI was statistically highly significant.

The prevalence of HI according to family size showed a lower prevalence among pupils of small family size (14.4%),compared to those of large family size (26.3%). The association between family size and HI was statistically significant.

Table 2: Prevalence of audiometric-based HI according to selected socio-demographic characteristic.

Variables		Hearing impairment		Total	p-value, x2 test
		Normal hearing	Impaired hearing		
Age (Years)	6 -7	170 (86.7%)	26 (13.3%)	196 (100.0%)	0.138,3.955
	8-10	86(81.9%)	19(18.1%)	105(100.0%)	
	>10	41 (75.9%)	13 (24.1%)	54 (100.0%)	
Sex	Female	100 (78.7%)	27 (21.3%)	127 (100.0%)	0.061,3.504
	Male	197(86.4%)	31(13.6%)	228(100.0%)	
Family size	<5	255(85.6%)	43(14.4%)	298(100.0%)	0.026,4.946
	≥5	42(73.7%)	15(26.3%)	57(100.0%)	
Total		**297(83.7%)**	**58(16.3%)**	**355(100.0%)**	

Table 3. Demonstrated that mild HI was more prevalent in pupils aged 6-7 years (42.3%) but without significant statistical association. It was of equally prevalence in females and in female. Mild HI was more prevalent in high socioeconomic status (75%) and this association was not statistically significant. It was more in pupils living within large family (66.7%) and this association was also statistically significant.

Table 3. Socio-demographic relationship with prevalence of hearing impairment severity according to Audiometry examination

Variables		Mild HI	Moderate HI	Total	p-value, x2 test
Age (Years)	6 -7	22(42.3%)	4(66.7%)	26 (100.0%)	0.078, *7.486
	8-10	91(36.5%)	0(0.0%)	19(100.0%)	
	>10	11(21.2%)	2(33.3%)	13(100.0%)	
Sex	Female	26(50.0%)	1(16.7%)	27(100.0%)	3.467, *2.635
	Male	26(50.0%)	5(83.3%)	31(100.0%)

Total		**52(100%)**	**6(100.0%)**	**58(100.0%)**	

Discussion

Strengths of the study: It is the first study about hearing impairment implemented in Nasiriya city, and it was conducted for three classes (grades) in primary schools of Al- Nasiriya city/Thi-Qar Governorate.

Limitations of the study: The cross-sectional design of this study allowed only for single observation and for short period (limited to school time), to assess the hearing acuity among primary school children, and cannot follow selected pupils with hearing impairment for any changes in prevalence rate over time (it may be with temporary or permanent cause). The referred suspected cases of HI to differentiate them as CHL or SNHL by diagnostic audiometry and tympanometry in Al- Habboby hospital were not attend. Also Prevalence of ear infections associated with hearing impairment were limited mostly for particular season, so this promotes short period for their estimation (underestimation). Screening audiometry is used only for determining prevalence of hearing impairment and hearing threshold,but it wasn't done to determine type of hearing loss whether conductive, sensori-neural or mixed type that could be done only in presence of the diagnostic audiometry which was available in hospital.

Extent of hearing impairment: A cross sectional study extended over 4 months including 355 pupils

of primary school children in Al- Nasiriya city who were selected randomly with male: female ratio 1.8:1 as comparable to study in Port Harcourt, Nigeria13, to estimate extent of hearing impairment among pupils in primary school as 16.3%,as comparable to study which was conducted in Aligarh, Uttar Pradesh, that was found to be 17.9% **14**. It is compared with study conducted in Egypt (20.9%)**15** [total of 555 children aged 6-12 years from both a rural and an urban school in El-Kom District of Egypt] . In Nigeria (29.4%) **13** [the study conducted from January 10th to May 21th); a higher percentage of HI among primary school children than in Al- Nasiriya city. In comparing with study conducted in Tikrit city/ Iraq (5.14%) [it was conducted in period from September through to 15 of December for 1420 pupils and the pure tone audiometry was done for pupils who have HI], a lower than the present estimation for the extent of the problem in Al-Nasiriya city. The extent of unilateral impaired hearing (9.3%) had been higher than extent of bilateral impaired hearing (7%). It is comparable to study done by Obukowho et al and also Khairi et al who reported that unilateral hearing loss as being more common (61.1%)**13**.

Age specific-prevalence of hearing impairment: The Prevalence of hearing impairment was shown to be higher in pupils aged >10 years (24.1%) and least in pupils aged 6-7 years (13.3%) but this was statistically significant by logistic regression analysis. Comparable to study conducted in Nigeria (32.8%)**13**[that was HI more in those aged more than 10 years(32%) than those who aged 5-7 years(24%)]**.**

Sex specific-prevalence of hearing impairment: The present study showed that the prevalence was higher in females (21.3%) than in males (13.6%) and this sex difference is statistically not significant. Comparable to study in Nigeria[13].

Socio-economic status specific- prevalence of hearing impairment: The prevalence of hearing impairment had been more in low socio-economic class(26.7%) and lowest among high class of pupils(7.4%).This association between HI and the socio-economic class was statistically significant. it is comparable to studydone in India 15 (where prevalence of HI was more in those with low standard of living).

Family size specific- prevalence of hearing impairment: Prevalence of hearing impairment was higher in large family size (14%) than in smaller family size (7.7%). This difference is not statistically not significant. This was comparable to study by Parvez et al 15 (that family with overcrowding showed more prevalence of HI that was 18.5%).

Conclusions

This study had shown a high prevalence of hearing impairment(16.3%) among primary school children, higher prevalence in female gender, in pupils aged > 10 years, in families with low socioeconomic class, significant independent association was found between HI and age and socioeconomic status, the most common ear diseases associated with hearing impairment were ear wax impaction and otitis media with effusion, the majority had mild HI.

In Silico Comparative Studies on Cytokine Receptor "Interleukin-11 Receptor" of Human, Rat and Mouse

Ashraf Fadhil Jomah[1]

[1]*Researcher, Science Department, College of basic education, University of Sumer, ThiQar, Iraq*

Abstract

Objectives: Interleukin-11 receptor with an imperative multifunctional role In normal cell signals and also in different pathologies, Interleukin-11 receptor with many statistical method obviously show how this protein is estimated to include possibly disordered regions in association with normal bonding partnerships.

Method: The Interleukin-11 receptor conducted a concise comparative bioinformatic analysis of three different types of human, mouse and rat. The study was conducted using numerous statistical method to examine the function-correlation and structure of their corresponding amino acid sequences and the associated protein sequences. Physico-chemical properties, sequence conservation, and secondary functional details are studied on the basis of specific bioinformatics tools and techniques. Findings: in order to recognize both structural diversity and sequence, different bioinformatics techniques were used. Interleukin-11 receptor's initial sequence analysis showed that they shared 86.1% similarity of the mouse and 81.9% identification of 85.4% and 80.5% identity of the rat similarity. With few exceptions, all sequences presented a high level of sequence survival. The physico-chemical analysis verified that there was no high evolutionary distance between mouse, rats and humans. Analysis of retained domains showed a clear structure of clustering, which also indicated the ancestral of the elationship among mouse, rat and human. The results suggest that IL may have originated from a common ancestor and may have diverged genetically in the course of evolution. Those studies will help the researchers to investigate the IL receptors functional differentiation and substratum binding process. Applications: Understand the evolutionary relationship and the sequence survival among humans, rats and mouse, which may lead to further studies in proteomics.

Keywords: *Silico, Cytokine Receptor, Interleukin-11 receptor.*

Introduction

Interleukins (ILs) are hematopoietic immunomodulatory protein that belongs to the subfamily of cytokines and serve as cytokines diverse immunological functions. Cytokines are biomolecules that play a vital role in infections, hematopoiesis and homeostasis, revealed their multi-functional position in regulating infectious disease reaction and even tumor genesis by growth, cellular sprouting and controlling tissue renewal. Both chronic inflammatory responses and acute, interleukins are involved. These work as a response to specific receptor stimulus conveyed in the cells surfaces, triggering every time a different signalings pathways. Interleukins-11 are followed by itsIL-11 receptors-alpha (IL-11Rα) transmembrane receptor and induces breast neoplastic cell proliferation with the parallel development of primarycancers cell and the diffusion of canceer cell in to distants organs[1]. The cytoplasmic domain of IL-11 predicts to be strongly disordered, and there is a significant volume of dysfunction even in the broad extra cellular protein domain[2]. The ability to bind IL-11 with high affinity (Kd = 300-800 pM). the discovery that some cytokines that associatewith complexes of receptors which contain common components.[345]. In this way, three groups of cytokines are identified. IL-3, IL-5 and GM-CSF are special low-affinity binders a-chains and associate with a common: chain producing a high-affinity signal transduction recepto[35]. Similarly, it is believed that IL-2, IL-4, IL-7, IL-9 and IL-13 bind both to unique receptor chains and to a general subunit, initially isolated as the IL-2 receptor y-chain[4]. The third group is even more complicated with IL-6, IL-11, LIF, OSM and CNTF receptors[6].

An attempt was made here to describe and contrast the properties of 3 types of human, rat and mouse receptors using various bioinformatics method.

Materials and Method

For this study, sequence extraction and evaluation was called three separate forms of IL receptors from three types of mouse, rat and human. NCBI Gen Bank (www.ncbi.nlm.nih.gov/genbank) obtained three sequences in Fast format (NCB Accession Numbers: person (Q14626), rat (Q99MF4) and mouse (Q64385). Protparam was used to measure the physico-chemical properties off selected IL receptor proteins. (http:/web.expasy.org/Protparam) The amounts of aminoacidcomposition are determined in version 6.06 of MEGA. Hydrophobicity/Hydrophobicity Protein research was carried out on the web database Peptide 2.0. (http://peptide2.com/N_peptide_hydrophobicity_hydrophilicity.php) For pair sequence analysis, sequence synchronization and secondary structure estimation EMBOSS (http:/imed.med.ucm.es/EMBOSS/) needle was used.

The arrangement of the amino acid sequence was performed using PROMALS3D (http:/prodata.swmed.edu/promals3d/promals3d.php) to figure out the pattern of preservation and secondary structural information. PROMALS3D generates protein sequence alignments based on sequence database knowledge, secondary structure prediction, accessible 3D structure homologues and user-defined constraints[6].

Conserved domains are calculated to use the NCBI Batch Web CDs Searching features within protein sequences (http:/www.ncbi.nlm.nih.gov/Structure/bwrpsb/bwrpsb.cgi) within an E-Valuecut-off:0.01.

Result and Discussion

The amino acid concentration percentage was estimated and shown in Figure 1. In IL11, for all sequences, the amount of metabolites, including proline, leucine. Serine, Valin residues are lower in rat and can note arginine higher in rat comparing with human and mouse. Alanine is high in human and lowest in comparing with mouse and rat. Glycine is high in human, rat when compared to the mouse. Simultaneously, aspartic acid, Glutamic acid in both rat and mouse higher than human.

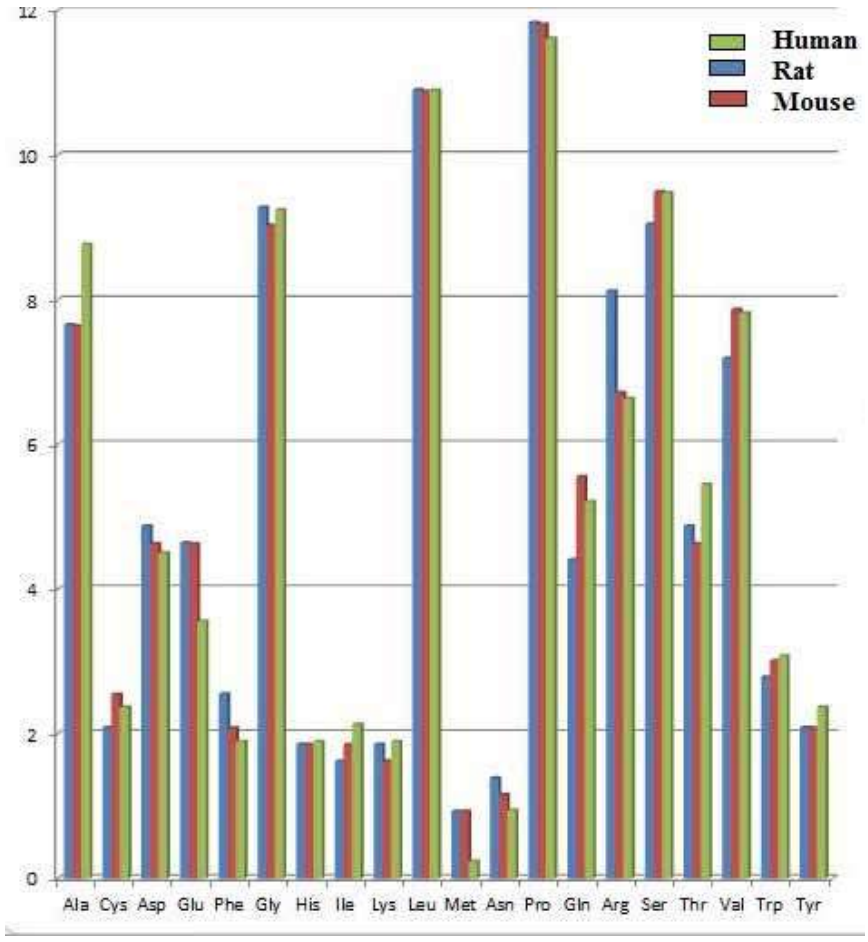

Table 1: Physico-chemical analysis

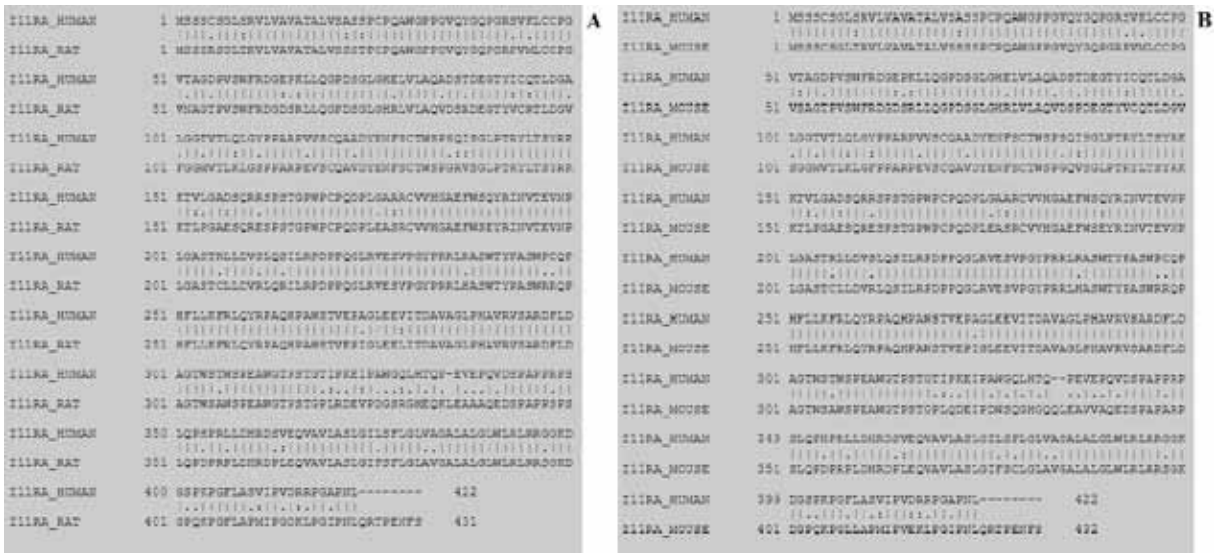
Physico-chemical	**Hu**	**Mouse**	**Rat**
Number of amino acids	422	432	431
Molecular weight	45222.36	46654.94	46784.08
Theoretical pI.	8.03	6.09	8.07
Instability index	51.03	54.23	51.42
Aliphatic index	82.27	80.12	77.38
Hydrophobic residues	46.45%	46.06%	45.48%
Acidic residues	8.06%	9.26%	9.51%
Basic residues	10.43%	10.19%	11.83%
Neutral residues	35.07%	34.49%	33.18%
The total number of residues that have been adversely labeled (Asp + Glu):	304	40	41
The total number of residues positively charged (Arg + Lys):	36	36	43

Table of physico-chemical analysis (1) revealed the hydrophobic existence of the proteins. The expected parameters are given in Table 1 and there is not that much difference in their properties when comparing the physicochemical characters. Isoelectric point (pI) seems to be a pH where the amino acid net charge is null. pI of human 8.03 and rat 8.07 was higher than mouse 6.09. From the Instability Index study, which has found that mouse 54.23, while the rest of the proteins were in lower in rat and human. Therefore, the Aliphatic index (AI) corresponds to the relative amount of a protein that its aliphatic side chains share. The lower the protein Aliphatic level, the more the proteins stable thermally. Human Aliphatic index 82.27, mouse 80.12 and rat 77.38 ranged from 46.45% to 45.48% (hydrophilic).

Secondary Structure: Sequence similarity (Figure 2) indicated a high level of residue retention for amino acids. Among the retained residues (disulfide bonds), the cysteine (C) disulfide bonds in place may have profound effects on the folding mechanism and a protein stability; thus the entropy of the unfolded system, thereby increasing its suitability for survival in the extra cellular Disulfide bonds can stabilize the protein[78]. In addition, they may make the journey to thenativestate smoother when they connect parts of a protein that must come into contact early during a folding reaction and can make it less likely to unravel when they happen in especially labile areas of a protein[9]. Native intra- or inter-molecular disulfide bonds that develop translationally during the folding of secretory pathway proteins well before further protein C-terminal regions join the ER [10]. This can happen if the bonds are formed between neighboring cysteines[1112] or if the protein comprises of autonomously folded domains[13].

These substitutions in il11 structure Mouse compared with human sequence the are (T9, S22, P43, M45, S52, T55, D64, S65,R66, R78, V84, P87, V93, V100, S101, M104, K108, F111, E117, L153, P 154, E157, E161, E176, S178, E190, C206, R211, H237, R247,R248, I274, A306, P319,L320, Q321, D322, D326, S328, G330, G332, Q334,L335, E336, A337, V339, A340, E342, A348, D355, P358, P364,L365, F377, C379, A383,V384, S398, P403,Q404, L408, P411, M412, E416,K417,L418, I421, QRTPENFS).fig(z).



Also these substitutions in Rat sequence compared with human fig (z) (R5, T9,s22, T24, P43, M45,N52,T55, D64,S65,R66,R78,V84,R87,V93,R95,V100, F101, M104,K108,S111, E117,V123, G135,R136,V137, L153, P154, E157, E161, E176,S178, E190, C206,R211,R214, H237, R247,R248, I274,L279, A306, P319,L320,R321, D322,V324, D326, G327,S328,R329, G330, E332, K334,L335, A337, A338, A339, E341,S348, D354, P357, P363,L364, F376, A382,V383, S397, P402,Q403, P410, M411, G414, K416,L417, I420, QRTPENFS). Additionally among substituted residues,a specific residue is replaced with hydrophobic.

Hydrophobic activity is recognized as one of the key drivers for protein folding and is also a key factor in stabilizing single protein, multi-protein, and protein−ligand matrix globular and binding structures[14]. The hydrophobicity in proteins maybe related with the amino acid residues sides chain that are the protein base functional elements, according to previous studies. Differences in amino acid residues of the residue region can reduce or decrease the active site cavity size when substituted by smaller residues or bulkier which may contribute to operational divergence processes [15]. Structural key section. (Z) details are also shown in the organization of different sequences (Figure 3). The generic series of CHS from alfalfa. It is clear from the results that the protein is relatively stable and consists of most beta-strands and less alpha-helices.

Conserved Domains Database (CDD): From 3 protein receptor sequences, they investigate how they consist of a well-annotated series of several sequence coordination templates for ancient domains and full-length proteins. These are accessible as position-specific score matrices (PSSMs) (214653,238020) for rapid recognition by RPS-BLAST of retained domains in protein sequences. CDD material contains NCBI-curated domains[16], that use 3D-structure data to specifically identify domain boundaries and offer insight in to sequence, structure and feature relationships; As well as IG-related domain models such as human sequence 33 to 109, rat and mouse sequence 33 to 95, human and mouse sequence FN3 sequence 216 to 310, superfamily rat sequence 111 to 202 fn3 (cl21522). (Fig. 4).

	Hit type	PSSM-ID	From	To	E-Value	Bitscore	Accession	Short name	Incomplete	Superfamil

4_BOVIN	specific	238020	217	309	4.55927e-07	47.4911	cd00063	FN3	-	cl21522
	specific	214653	33	94	4.50271e-05	41.7221	smart00410	IG_like	-	cl29242

Conclusion

Human, rat and mouse sequence and structural analysis revealed regions that are evolutionarily and structurally related. In addition to the range of retained Residues of amino acids from physico-chemical properties at the active site, Retention at the respective site in a few amino acid substitutions that result in functional divergence. Because interleukin is very essential proteins that play a role in inflammatory conditions, bone homeostasis, hematopoiesis, and fertility, more proteomics work will be supported by the studies on it.

Psychosocial Characteristics of Human Trafficking: A Systematic Review

Awaliyah M Suwetty[1], Asti Melani Astari[2], Titin Andri Wihastuti[2]

[1]Lecturer at the Maranatha Nursing Academy, [2]Lecturer in Medical Faculty University of Brawijaya

Abstract

The phenomenon of human trafficking is one of contemporary issue being seriously concerned. Its characteristics are repressive to human exploitation destination (individual or group)as well as a direct implication on human rights violations. Victim of *trafficking* has characteristics social typical for trading. The purpose of systematic review was to identify the psychosocial characteristics of human trafficking victims. Systematic search on March 12, 2019, in the data of Proquest, Springer Link, Scopus by key word Psychosocial Characteristics of Victims of Human Trafficking during 2013 -2018. The results found 13 appropriate journal that included into inclusion criteria, they were peer-reviewed journals in English, all forms of exploitation, the samples were aged >15 years old. The results based on a). Demographic data Age (adults/children), gender, marital status, education level, place of residence (urban/rural), regional trade (national/international), religion, type of work, economic conditions before trading. b) Variable of exposures (smuggling status, the process of departure, detention in camps, forgery/fraud documents, employment status, obscure country of work, type of work). c) Method of recruitment using social media (Backpage, Facebook, dating website) and invited directly by recruiters. d) Type of exploitation (household slavery, exploitation of labor, financial exploitation, sexual exploitation). e) Characteristics of the exposure (restriction of movement, drug use, sexual abuse, psychological abuse, restriction/confinement, physical violence, the background to the incident trafficking, race, home life, relationships with parents/carers/ family members, economic opportunities, the recruiters-victim relationship, trust in strangers, lack of social support), f).Psychosocial variables as the impact of trafficking (the abuse of alcohol/drugs, involved in crime and a fugitive/police targets). Required a prevention effort to group or individual who had the same characteristics, thus, they did not fall to the incidence of trafficking.

Keyword: *Psychosocial characteristics, Human trafficking.*

Introduction

Crime Human trafficking is a serious problem and became the center of world attention. Trafficking itself very influential impact on the environment social, Human rights violations to one's mental disorders. The crime of trafficking is said to be a form of modern slavery, where exploitation is financially beneficial for the group of perpetrators. The UN has sought to suppress, prevent and punish perpetrators of trafficking crimes by forming units of protection for victims who received exploitation(1). Accepted forms of exploitation including victims of violence, fraud, forced labor and sex workers(2) with the aim of earning a lot of money and the benefits of being an offender profit trafficking(2). The phenomenon of trafficking involving an individual, family, and local network criminal/Supra-regional organized. There are about 45.8 million people in the world of human trafficking with the same psychosocial characteristics(3). Trafficking crime makes vulnerable groups of aspects social and the economy as a operandi target. Indonesia is ASEAN countries included in the Country economic

e-mail :wihastuti.fk@ub.ac.id

range and has a high population[4]. Increasing population effect on increasing employment requirements, so that Indonesia is reported by IOM as the country to 13 with most trafficking cases throughout the year[4]. Various efforts have been made by governments, organizations local and International to address trafficking problems, but these problems do not go over, because it does not touch directly on the subject matter. This study provides empirical evidence of characteristics of human trafficking and networks exploiting victims[5]. Its impact on mental health psychosocial[6]. Psychosocial characteristics of vulnerable victims of trafficking in terms of sociodemographic among others folly, no school, live in rural areas, the lack of global information[4]. Lack of jobs and low of human resources[7]. This systematic review aimed to identify the psychosocial characteristics of trafficking victims were vulnerable to exploitation and trafficking.

Methodology

Search criteria: Systematic search using electronic with NHS evidence (electronic information resources, research, evidence, and best review). Search on March 12, 2019, by databases Proquest, Spinger Link, and Scopus. Health care data bases chosen because it allowed advanced search of relevant articles with keywords characteristics of psychosocial.

Inclusion and Exclusion Criteria: The inclusion criteria were peer-reviewed journals in English by year of publication from 2013 to 2018. Articles include any form of exploitation (sexual abuse, violence, selling organs, etc.). Samples were age 15 to adult. Psychosocial characteristics focused on survivors. Articles that were not selected are Dissertations & Theses (ProQuest), the Conference of COS, ProQuest Index, Conference Proceedings, Citation Index (Thomson Reuters), Thesis & Dissertation website Open Access, OpenGrey, report the results.

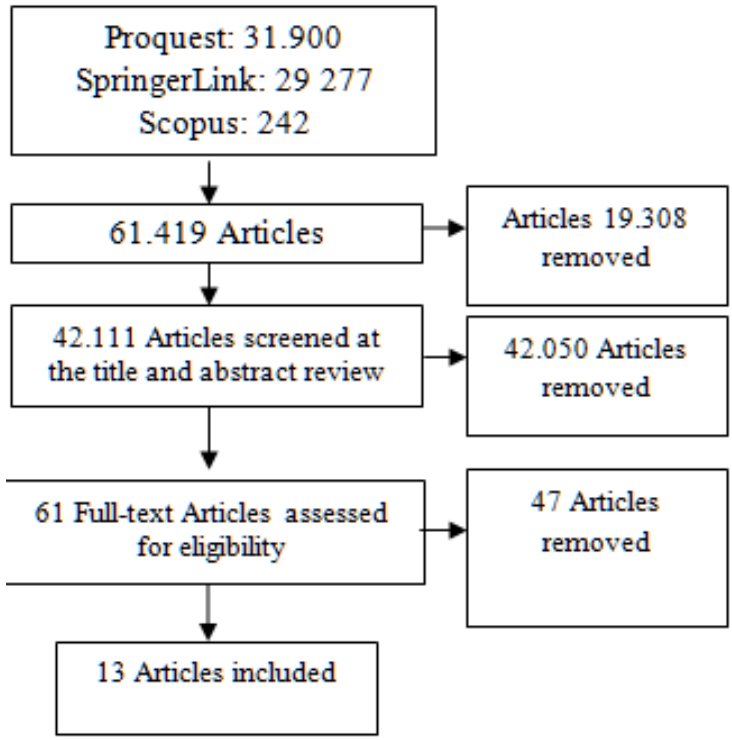

Figure 1: Process of Taking and Abstracting Journal

The initial search was obtained 61.419 articles that consisted of 31.900 of Proquest, 29.277 of Spingerlink and 242 of Scopus. 19 308 articles removed because it did not fit the inclusion criteria. The review process was selected based on reviews of article titles, abstracts and full text. Researcher extracted 61 studies of the titles and abstracts and 47 studies of full-text review. Finally 13 articles selected for this study.

Outcomes Measures:

Summary of Characteristics: The search yielded 13 articles. Five articles using qualitative design, three articles using quantitative designs: cross-sectional and RnD, five articles using cohort study. Total of 455.392 participants consisting of 5.248 direct participants and 450.134 tracked from electronic medical records and database of CRIS.

Characteristics Participants: Characteristics of participants in 13 studies were described as follows: characteristics of study participants in Ethiopia were male and female under the age of 18 years old[8]. Cambodia,Thailand, Vietnamese were male, female, adolescents and children aged 10-17 years [1,7], Moldova special for female aged >18 years[9], Ghana special for girls and female without mentioning age [10], US to keep track of medical records of patients <18 years[6]. South London and East London in search of medical records of children and women up to 30 years [2, 5], India, Laos, Nepal without specifying gender and age, East Nusa Tenggara for women aged 21-37 years[4] and the rest did not mention the place, age, or gender of the participants[11].

Context: The research data was collected in 2006-2012[12], 2006-2012[10]2013[11], 2006-2012[13], 2013[13], 2016[8]. Four were taken using electronic medical records and databases CRIS years 2007-20012[15].

Recruitment and sampling: The sampling method on 13 studies were differentiated by design research undertaken. In quantitative research using consecutive sampling, and cohort was used while using a qualitative research study of medical records in accordance with the criteria of the UN Protocol and purposive sampling. Four studies with a cohort design was conducted by checking the electronic medical record or database CRIS at hospital[16]. 9 studies took the sample directly in places where human trafficking occurred. In-dept qualitative data collection through interviews with open-ended questions in person or over the phone. While quantitative questionnaire or implement interventions to participants.

Study design and analysis: Article qualitative used semi-structured interviews in a special group. Three articles used quantitative questionnaire design and five articles using a cohort study with Electronic Medical Record or database CRIS[16]. Two studies using logistic regression analysis[9,12]. Two studies using SEM[1,8], one study using multiple regression[5], one study using descriptive analysis[6], four studies using thematic analysis[17] and three studies using retrospective interviews with UN standard protocol. Among the studies did not found that reported the normality assumption test and data.

Ethical considerations: There were 13 studies reported ethical approval to use ethical standards of WHO and Recommendations Safety[1]. Ethical approval was obtained from Kings College Research Ethics Committee (CREC/07/08-56) and from the State of N. Testemitanu Institutional Review Board of the Medical and Pharmaceutical University[8],Research Ethics Committee (Oxfordshire C, reference 08/H0606/71)[3] and Ethical approval from the University of South Wales[4]. One study did not report on the ethical approval.

Mains Findings: Human trafficking identified in accordance Optional Protocol to the United Nations (UN), which prevent, suppress and punish trafficking in persons, especially women and children[8]. According to the 13 studies, found the psychosocial characteristics of victims such as: a) The demographic data; age (adults, children), gender, marital status, education level, place of residence (urban/rural), regional trade (national/international[5], religion, type of work, economic conditions before trading. b) Variable of exposure; smuggling status, the process of departure, detention in camps[8] counterfeiting and document fraud, employment status[9] unclear country the purpose of employment, and the type of work presented[5], c) Method of recruitment using mediasocial (Backpage.com, Facebook.com, dating website) and invited directly by recruiters[6], d) Type of exploitation; domestic slavery, exploitation of labor, financial exploitation, sexual exploitation[7], e) Characteristics of exposure to experience during the work; restriction of movement, drug use (shisha, marijuana, alcohol)[8], sexual abuse, psychological abuse, restriction and confinement, physical violence[6]. The background incidence of trafficking, race, home life, relationships with parents/carers/family members, economic opportunities, the recruiters-victim relationship, trust in strangers, lack of social support[8], f) Variables of psychosocial on the impact of trafficking; abuse of alcohol/drugs, engage in crimes that require incarceration, a fugitive/police targets[7].

Discussion

Victims of trafficking are vulnerable to trafficking has characteristics that may be invoked to think of society to recognize the psychosocial characteristics trafficking events that begins from the neighborhood sociodemographic, factor which affects the incidence of trafficking, trafficking process, type of exploitation is accepted[9]. Exposure to events experienced problems as well as the victim is also a psychosocial characteristics that must be observed to prevent mental health disorders[6]. Effort early prevention of the root of the problem by fixing all the characteristics that led to trafficking thereby minimizing the incidence of trafficking and mental disorders.

Conclusion

Psychosocial characteristics of trafficking victim based on the literature search found a few characteristics: a) the demographic characteristics b) variable trafficking process. c) method of recruitment d) exploitation type e) characteristics of the exposure. f) the background of the trafficking g) psychosocial variables that appear. Further research is more focused on prevention through campaigns for the public to minimize the incidence of mental disorders.

Conflict of Interest: None

Risk Factors for Obesity in Patients with Hypertension

Aylinda Wahyuni Putri[1], Ratu Ayu Dewi Sartika[2]

[1]Student of Magister Program of Nutrition Department, [2]Professor of Nutrition Department, Faculty of Public Health, Universitas Indonesia, Depok, Indonesia

Abstract

Introduction: Non-communicable diseases (NCDs) are a leading cause of death worldwide. In 2018, NCDs' prevalence had reportedly increased since 2013. Hypertension was the biggest cause of NCDsdiagnosed in health facilities, from 25.8% to 34.1%. Patients with hypertension and obesity are at increased risk of complications from diabetes mellitus and kidney disease.

Objective: The present study aimed to determine risk factors for obesity in patients aged 25–69 years with hypertension.

Materials and Method: This was an observational study with a cross-sectional design, using secondary data from the 'Cohort Study of Risk Factors of Non-communicable Diseases', conducted in Bogor City, Kebon Kelapa Village in 2017. The population in this study included adult patients with hypertension aged 25–69 years.

Results: The prevalence of obesity in patients with hypertension was 47.4%.Risk factors that were significantly related to obesity in patients with hypertension included age groups 25–44 and 45–59, female gender and excessive energy intake (p = 0.009, 0.050, 0.025 and 0.039, respectively and odds ratio = 2.43, 1.73, 1.85 and 1.85, respectively).

Conclusions: Risk factors associated with obesity in patients aged 25–69 years with hypertension included age, gender and energy intake.

Keywords: *Obesity, hypertension, adult, elderly.*

Introduction

Non-communicable diseases (NCDs) are the leading cause of death worldwide. Around 15 million people aged 30–69 years die each year from NCDs, with 85% occurring in low and middle-income countries.[1] NCDs' prevalence increasedin Indonesia between 2013 and 2018.[2]

Hypertension is a leading cause of cardiovascular disease that can lead to strokes, coronary heart disease, kidney failure and premature death.[3–6] It is estimated to cause 12.8% of deaths worlwide.[7] In 2018, hypertension was the main cause of NCDsdiagnosed in health facilities. Hypertension's prevalence increased from 25.8% in 2013 to 34.1% in 2018.[2]

Studies have reported that the prevalence of obesity among patients with hypertension is increasing. A study by Ford et al. using data from the National Health and Nutrition Examination Survey showed that obesity's prevalence increased from 25.7% from 1976–1980 to 50.8% from 1999–2004 in adults with hypertension.[8] Qin et al. also reported an increase in the prevalence of obesity and central obesity in hypertensive adults in China.[9] A study by Sartika et al. showed that obesity's prevalence in Indonesian patients with hypertension was 40.7% in urban areas and 18.9% in rural areas.[10]

Patients with hypertension and obesity are at increased risk of complications of type 2 diabetes mellitus

and kidney disease.[11,12] Obesity status in patients with hypertension is associated with a significant difference in the average onset age of type 2 diabetes mellitus.[12] In patients with hypertension, obesity and insulin resistance also play major roles in the genesis of kidney failure, which is known as 'nephrosclerotic hypertension'.[11]

Risk factors such as age, gender, education, income, diet, physical activity, hypertension treatment, smoking and stress contribute to the incidence of obesity in patients with hypertension. Risk factors for obesity complications in patients with hypertension vary greatly among regions.

The present study aimed to determine the risk factors for obesity complications in patients with hypertension aged 25–69 years in Bogor City in 2017. This study's results are expected to provide an evidence base for appropriate health programmes to prevent obesity in patients with hypertension.

Materials and Method

The present study was cross-sectional in design and analysed secondary data from the 'Cohort Study of Non-communicable Diseases', conducted by the National Institute of Health Research and Development, Republic of Indonesia, in Bogor City, Kebon Kelapa Village, in 2017. This study's population were all patients with hypertension aged 25–69 years who were respondents in 2017. Hypertension was defined as systolic blood pressure >140 mmHg and/or diastolic blood pressure >90 mmHg, doubling of blood pressure within 5 min under appropriate conditions, diagnosis of hypertension by a health professional or undergoing treatment for hypertension. A population of 489 patients with hypertension aged 25–69 years was selected from the 'Cohort Study of Non-communicable Diseases', conducted in 2017. This research sample was selected using total population sampling. Respondents with heart disease (n = 50), stroke (n = 44), diabetes mellitus (n = 118) and pregnancy (n = 1) were excluded from the study sample. Thus, 318 respondents were included in the study.

The dependent variable in this study was obesity status, with a body mass index (BMI) parameter >27 kg/m². BMI was calculated as body weight in kilograms divided by the height in metres squared and categorised as: underweight (<18.5 kg/m^2), normal weight (18.5–25.0 kg/m^2), overweight (25.1–27.0 kg/m^2) and obese (> 27 kg/m^2).[13] Independent variables were age, gender, education, conversation, nutrition intake, physical activity, hypertension treatment, smoking and stress. Nutrient intake was measured as the amount of energy, carbohydrate, protein, fat and sodium consumed daily compared with dietary recommendations for people with hypertension (DASH).[14] Intake of nutrients was categorised as low (<90%), moderate (90%–119%) and high (≥120%).[15]

Data processing involved cleaning and transforming data and was performed by univariate and bivariate using chi Square test with a 95% confidence interval (CI) (α = 0.05) and odds ratios (ORs).

Results

Characteristics of patients with hypertension: Analysis of nutritional status in patients hypertensive aged 25–69 years showed malnutrition in 1.6%, normal nutrition in 35.3%, with 15.7% overweight and 47.4% obese. The prevalence of hypertension was greatest (53%) among those aged 45–59 years (pre-elderly). The incidence of hypertension was highest (72.6%) among females compared with males. Most (65.1%) patients with hypertension were of low education status. The patients' characteristics are presented in Table 1.

Table 1: Characteristics of patients with hypertension aged 25–69 years

Variables	Category	N	%
Nutritional status	Underweight	5	1.6
(n = 312)	Normal	110	35.3
	Overweight	49	15.7
	Obese	148	47.4
	Missing	6	
Obesity	No	164	52.6
(n = 312)	Yes	148	47.4

(n = 318)	High	159	50.0

Source: secondary data processed

Prevalence and risk factors for obesity in patients with hypertension: The prevalence of obesity in patients with hypertension was quite high (47.4%) and was higher in females compared with males (51.5% vs. 36.5%). Obesity in patients with hypertension mostly occurs in adulthood, from age 25 to 44 years. The prevalence of obesity was higher in patients with a low education status compared with those who were highly educated (50.2% vs. 42.3%). Nutrient intake in obese hypertensive patients showed high energy (58.2%), high carbohydrate (54.8%), adequate protein (61.4%), moderate fat (52.4%) and low sodium (50.3%) intake.

The bivariate analysis showed that factors were significantly related ($p < 0.05$) and the risk factors for obesity in patients with hypertension were age, gender and energy intake. Adult patients with hypertension aged 25–44 years showed a 2.43-fold higher risk of obesity compared with that of elderly patients (aged 60–69 years), and pre-elderly patients (aged 45–59 years) showed a 1.73-fold higher risk of obesity compared with that of elderly patients (aged 60–69 years). There were 1.85 times more female than male patients with hypertension. High energy intake in patients with hypertension was 1.85 times higher than low energy intake. The results of the bivariate analysis of risk factors for obesity in patients with hypertension are presented in Table 2.

Source: Secondary data processed

Discussion

Our results indicate that the prevalence of obesity in patients with hypertension aged 25–69 years in Bogor City in 2017 was high (47.4%). This high prevalence is in line with findings from previous studies by Ford et al. (2008), Qin et al. (2013) and Sartika (2015).[8,9.10] The cause of obesity among patients with hypertension is multifactorial. The level of hypertension, socioeconomic status, residential area, consumption of red meat, physical activity, hypertension treatment, family history of diabetes, hypertension and heart disease, which is associated with obesity among people with hypertension.[9]

In the present study, risk factors for obesity complications in patients with hypertension were found to be age, gender and energy intake. Residential area, consumption of red meat, family history of diabetes, family history of hypertension and family history of heart disease could not be analysed due to limited secondary data.

The prevalence of obesity in patients with hypertension was higher in adults aged 25–44 years than in pre-elderly (45–59 years) and elderly (60–69 years) patients. Under normal conditions, age is associated with obesity as metabolism decreases with age, which increases the risk of obesity. However, in the present

study with a population of patients with hypertension, adults (25–44 years) showed a higher risk of complications of obesity that was 2.43-fold higher than elderly (60–69 years) patients, whereas this value was 1.73-fold higher in pre-elderly (45–59 years) compared with elderly patients.

The prevalence of obesity in female patients with hypertension was higher than that of males. These findings reveal a significant relationship between gender and incidence of obesity in patients with hypertension. Females with hypertension showed a 1.85-fold higher risk of obesity compared with males with hypertension. This study's results are in line with those reported by Qin et al. (2013).[9] They conducted a study in Lianyuangang, China from October 2008 to September 2009 and showed that the prevalence of obesity in females with hypertension was higher than that of males.[9] Females are at greater risk of obesity since they generally have more fat than males, including a higher amount of subcutaneous fat and more fat deposits in the glutaeal–femoral area or peripherals that determine the typical pear-shaped female (peripheral or gynoid type obesity).[16]

Excessive energy intake is related to obesity in patients with hypertension and is associated with a 1.85-fold increased risk of obesity compared with those with low energy intake. When energy intake exceeds energy expenditure, a positive energy balance occurs, leading to an increase in body mass. A 60%–80% increase in body mass is associated with an increase in body fat.[17] An imbalance between excess energy intake and output results in weight gain, both under normal conditions and in patients with hypertension.

Conclusion

The prevalence of obesity in patients with hypertension aged 25–69 years in Bogor City in 2017 was 47.4%. Risk factors that were significantly related to obesity in patients with hypertension included age (adults aged 25–44 and pre-elderly aged 45–59 years), female gender and excessive energy intake ($p = 0.009$, 0.050, 0.025 and 0.039, respectively and OR = 2.43, 1.73, 1.85 and 1.85, respectively). The high prevalence of obesity in patients with hypertension is a health problem requiring appropriate treatment since controlling weight gain is fundamental to improving quality of life in patients with hypertension. Our results are expected to be used to plan appropriate health programmes and prevent obesity in patients with hypertension.

HIV and Zonke-bonke Syndrome in Mthatha Region of South Africa: Case Reports

B. Meel

Professor, MBBS, MD, MPhil HIV/AIDS Management. Research Associate,
Faculty of Health Sciences, Nelson Mandela University, Port Elizabeth 6031 South Africa

Abstract

Introduction: South Africa is an African rainbow nation, not only in its color of population, but also in the mixture of HIV infection. There is all three combinations are of HIV infection such as HIV-1, HIV-2, and both of them. This is matter of concern.

Objective: To highlight the problem of HIV-1 and HIV-2 (combined) infection in Mthatha region of South Africa.

Case History: First time four cases of HIV-1/2, mixed infection were reported within period of 1-year (2009). They were reported at Sinawe Center for examination for their sexually assaulted. The HIV screening tests were carried out for HIV infection. There were four patients were found positive for both HIV1 & 2. Surprisingly, one was a child of 8-years of age. Multiple sexual partners some or other time crossed with West African who were harboring the type 2 HIV could be the cause of this mixed infection. This kind of promiscuous behavior with multiple partners is called as ***"Zonke-bonke syndrome"***. The history, mode of transmission of HIV infection, and the consequences of mixed HIV infections is discussed in this case reports.

Conclusion: There is prevalence of HIV-1 & HIV-2 (mixed) infection in Mthatha region of South Africa. It is a serious matter of concern.

Keywords: *HIV type 1 & 2, Promiscuous behavior, and multiple partners.*

Introduction

South Africa has one of the highest rates of sexual assaults in the world as well as one of the highest prevalence rates of HIV infection.[1] In Bantustan (Transkei), the young people were allowed to come and engage in free sexual experimentation.[2] Young women actively seek partners who are willing to spend money and often-initiate relationships with older men. The girl goes out there and positions herself in a place where she knows she will get the man. They do not see themselves as victims. This is all about power and authority, with teenage boys and girls involved in these relationships on an unequal footing. "The sugar daddy or mommy is in a better position, and is therefore able to entice the young girl or boy. They are reluctant to be identified because "people will think we are doing these things" Although everyone agrees it is a common practice, cross-generational relationships are not often addressed in HIV/AIDS prevention campaigns, despite a growing awareness that they are driving much of the epidemic.[3]

HIV-2 infections are predominantly found in Africa. West African nations with a prevalence of HIV-2 of more than 1% in the general population are Cape Verde, Côte d'Ivoire (Ivory Coast), Gambia, Guinea-Bissau, Mali, Mauritania, Nigeria, and Sierra Leone. Other West African countries reporting HIV-2 are Benin, Burkina Faso, Ghana, Guinea, Liberia, Niger, São Tomé, Senegal, and Togo. Angola and Mozambique are other African nations where the prevalence of HIV-2 is more than 1%.[4]

Differentiating between HIV-1 and HIV-2 infection is the first step to understanding HIV transmission, epidemiology and pathogenesis in geographical areas where both viruses circulate. [5] HIV is a highly variable virus, which mutates very readily. This means there are

many different strains of HIV, even within the body of a single infected person. Both types (HIV-1 and HIV-2) are transmitted by sexual contact, through blood, and from mother to child, and they appear to cause clinically indistinguishable AIDS. However, it seems that HIV-2 is less easily transmitted, and the period between initial infection and illness is longer in the case of HIV-2. Worldwide, the predominant virus is HIV-1, and generally, when people refer to HIV without specifying the type of virus they will be referring to HIV-1. The relatively uncommon HIV-2 type is concentrated in West Africa and is rarely found elsewhere.[6] A recent (2014) study showed that HIV-2 is intrinsically resistant to nonnucleoside reverse transcriptase inhibitors. Therefore it is mandatory to discriminate between HIV types before initiating antiretroviral treatment. Guinea-Bissau has the world's highest prevalence of HIV-2 and HIV-1/HIV-2 dually infected individuals. [7] The purpose of these case reports is to highlight the problem of HIV1 and HIV-2 (combined) infection in this community, and to make aware to the health care professionals for its management.

Methodology

This is a retrospective study done in Sinawe Centre over 1-year (January to December, 2009). This unit is a part of Nelson Mandela Academic Hospital, and caters to a population of about 400 000 in the OR Tambo Municipality area. All the cases of rape, and sexual assaults are reported in this center. It is now a 'One Stop Center' providing a multidisciplinary management of victims of rape and sexual assaults. It is open from Monday to Friday from 08h00 to 16h00. On weekends and after hours, the victims were examined in Accident and Emergency (A & E) section of Nelson Mandela Academic Hospital. It is policy of the center to provide HIV testing after counseling to all victims of sexual assault and rape. Blood for HIV screening is taken with the consent of the victims. It is later confirmed by ELISA test in laboratory. HIV1 and HIV2 (combined) infection in four cases who were presented to the center for an examination. Post-exposure Prophylaxis (PEP) was started at the beginning of 2003, and is offered to all the victims except those who came later than 72 hours after the incident.

Case history 1: AM, a 19 years female presented with history of sexual assault by known person, her boyfriend's cousin. It was happened in morning hours. She was with her boyfriend who was intoxicated in his aunt's home in the guest room. Perpetrator pushed the door, entered in the room, and dragged her in outside bedroom. She tried to resist but the perpetrator assaulted her. He forcefully undressed her and raped her. He used a condom.

The victim has a boyfriend who worked in Cape Town and had a consensual sex in August 2008. She wanted a sex as she met her friend after a long time, but he was drunk. The perpetrator took advantage. The victim had multiple injuries such as lacerations on left knee, and bruises on left hand and on back.

On genital examination, there was old ruptured hymen with fresh tears on 9 O'clock position. There is increased friability with bruised introitus. Rapid test was reactive to both HIV1 and 2. HIV Ag/Ab Combination Assay reactive suggestive of that both HIV antibody and antigen (p24).

Case history 2: PM 26 years old single woman is living 40 kms from Mthatha. A known person has sexually assaulted her on 26.03.2009. This is happened in the perpetrator's bedroom at Qumbu. She was talking with another colleague. The perpetrator has shown a knife and grabs her to his bed. She has a boyfriend and had a consensual intercourse about 2 weeks before. She is having two children of the age 9 and 4 years old.

On genital examination, there were no sign of any injury. There is increased friability, but no whitish discharge visible. Rapid test was reactive to both HIV1 and 2. HIV Ag/Ab Combination Assay reactive suggestive of that both HIV antibody and antigen (p24).

Case history 3: Police with history of sexual assault on 10.04.2009 brought BB 18 year female. She is a learner in standard 10. She was waiting for transport for going to Easter Church Service. Four unknown men were approached her, and asked her name. One of them starts assaulting her, and drag in nearby bushed and raped her. He robbed her R15. BB is having a boyfriend, and had a consensual sex on 2oth March 2009. She had two boy friend earlier as well. They did not use condom. She is menstruating now. There is no injury identified. She was counseled for HIV test in January, and she was negative. HIV screening test conducted on 10 April 2009 at Sinawe Center, and she found HIV positive for both HIV1 & HIV 2. She is stick to only one boyfriend from last 3-years.

Case history 4: IT, an 8-year learner referred

from Ngangelizwe Health Center with history of being sexually abused by a known eight-year-old boy on 03.04. 2009 at about 3 pm. Her grandmother on 24.04.2009 at Sinawe center brought her. Her mother is staying in Johannesburg. She was coming from school, and on the way, she was overpowered by the perpetrator, and raped her. Counseling and reassuring therapy was done.

On examination child is scared of mother. There was yellowish, offensive dark, vaginal discharge with ruptured hymen. Pus swab taken for microscopy and culture. Gram stain showed on microscopy gram-positive cocci, yeast cells with neutrophils. On culture, klebsiella pneumonie extended spectrum ß-lactamase producer and proteus mirabilis.

Rapid HIV test found to be positive for both types HIV-1 and HIV-2.

Discussion

This is believed to be the first case of HIV-2 infection in this region. There is no case as such found in literature reported in South Africa. It provides important information that justifies expanded efforts to initiate and develop a program for the HIV-2 screening in this region. Mthatha (Umtata) was a capital of former Republic of Transkei. Mthatha region is the least developed of the former black homelands. It is also a region where majority of workers go for their earning in far-flung richer areas of South Africa. This has contributed directly the spread of HIV in the rural areas of South Africa.

The sole cause of HIV transmission is the poverty. Older men, who use their power and money in return for sex from younger women, are among the drivers of the HIV and AIDS infections in this region. Several studies showed that there was a positive correlation between HIV prevalence and poverty globally especially in sub-Saharan Africa. The infection is increasing. South Africa. Research organizations dealing with testing and counseling say it is not only men but women, too, who are out to attract younger colleagues. The fact is that older, affluent professionals, previously thought to be at low risk of HIV infection, are increasingly becoming vulnerable to infection because of risky sexual behaviour with younger partners.[4]

Changes in sexual behaviour among the wealthy have led to a worrying swell in HIV and AIDS infections among those who had previously been considered low risk. Several behavioral factors have been aligned to this development, among them inter-generational sex, where older, affluent men and women were having sex with the higher-risk younger group. It is the arrogance, not ignorance that contributing in the spread of HIV infection.[8] In United States, HIV-2 infection was diagnosed in 1987. Since then, the Centers for Disease Control and Prevention (CDC) has worked with state and local health departments to collect demographic, clinical, and laboratory data on persons with HIV-2 infection. of the 79 infected persons, 66 are black and 51 are male. Fifty-two were born in West Africa, 1 in Kenya, 7 in the United States, 2 in India, and 2 in Europe. The region of origin was not known for 15 of the persons, although 4 of them had a malaria-antibody profile consistent with residence in West Africa. AIDS-defining conditions have developed in 17, and 8 have died.[4] It is not known in this area, but there national of almost all African countries are residing in South Africa. There should be a screening system in place before they immigrate to South Africa. These case counts represent minimal estimates because completeness of reporting has not been assessed. Although AIDS is reported uniformly nationwide, the reporting of HIV infection, including HIV-2 infection, differs from state to state according to state policy.[4] There is hardly any estimate available in South Africa despite of the fact that HIV-2 infection is increasing.

Because epidemiologic data indicate that the prevalence of HIV-2 in the United States is very low, CDC does not recommend routine HIV-2 testing at U.S. HIV counseling and test sites or in settings other than blood centers. However, when HIV testing is to be performed, tests for antibodies to both HIV-1 and HIV-2 should be obtained if demographic or behavioral information suggests that HIV-2 infection might be present.[4] The first victim has reported that her boyfriend is working in Cape Town, could be the source of infection with HIV-2. The second case is mutipara young women who have given history of having multiple sexual partners one of them was a West African. The third victim was a school girl, and had relationship with boyfriend without using a condom. Most surprising is the case of child (case 4) who is only 8 years and sexually abused. She was having history of poring foul smelling fluid through vagina. This was notice by her grand mother. The perpetrator could be the close relative of this child as mother is staying in Johannesburg.

Among all HIV-infected people, the prevalence of HIV-2 is very low compared with HIV-1.[4] However, the

potential risk for HIV-2 infection in some populations may justify routine HIV-2 testing for all people for whom HIV-1 testing is warranted. [5] The decision to implement routine HIV-2 testing requires consideration of the number of HIV-2-infected persons whose infection would remain undiagnosed without routine HIV-2 testing compared with the problems and costs associated with the implementation of HIV-2 testing. The development of antibodies is similar in HIV-1 and HIV-2. Antibodies generally become detectable within 3 months of infection. Since 1992, all U.S. blood donations have been tested with a combination HIV-1/ HIV-2 enzyme immunoassay test kit that is sensitive to antibodies to both viruses. This testing has demonstrated that HIV-2 infection in blood donors is extremely rare. All donations detected with either HIV-1 or HIV-2 is excluded from any clinical use, and donors are deferred from further donations.[4]

Little is known about the best approach to the clinical treatment and care of patients infected with HIV-2. Given the slower development of immunodeficiency and the limited clinical experience with HIV-2, it is unclear whether antiretroviral therapy significantly slows progression. Not all of the drugs used to treat HIV-1 infection are as effective against HIV-2.[7] In vitro (laboratory) studies suggest that nucleoside analogs are active against HIV-2, though not as active as against HIV-1. Protease inhibitors should be active against HIV-2. However, non-nucleoside reverse transcriptase inhibitors (NNRTIs) are not active against HIV-2. Whether any potential benefits would outweigh the possible adverse effects of treatment is unknown.[4] Monitoring the treatment response of patients infected with HIV-2 is more difficult than monitoring people infected with HIV-1. Viral load assays used for HIV-1 are not reliable for monitoring HIV-2. Response to treatment for HIV-2 infection may be monitored by following $CD4^+$ T-cell counts and other indicators of immune system deterioration, such as weight loss, oral candidiasis, unexplained fever, and the appearance of a new AIDS-defining illness. More research and clinical experience is needed to determine the most effective treatment for HIV-2.[4]

In conclusion, there is a lack of knowledge regarding HIV-2 infection in Mthatha region of South Africa. It needs surveillance study to know the population infected of HIV-2. This will help in the management of patients as well as to curtain the infection on its grassroots levels. Physicians caring for patients with HIV-2 infection should be empower to initiate antiretroviral therapy after discussing with their patients what is known, what is not known, and the possible adverse effects of treatment. Continued surveillance is needed to monitor HIV-2 in the population because the possibility for further spread of HIV-2 exists. Programs aimed at preventing the transmission of HIV-1 also can help to prevent and control the spread of HIV-2.

Ethical Consideration: Prior consent for HIV testing was taken from all the victims of sexual assaults. Their names and identity has kept confidential, and not allow to divulge to anybody. The author has been have ethical permission for collecting data and publication from ethical committee of University.

Acknowledgment: The author would like to thank all staff of the Sinawe Thuthuzela centre for helping to collect data, and providing information on police stations in this region.

Source of Funding: Self-funded project.

Conflict of Interest: The author declared that no competing interest.

Performance of Midwives with Self Management as a Mediator from the Influence of Individual Factors

Bringiwatty Batbual[1,4], Fendy Suhariadi[2], Nyoman Anita Damayanti[3]; Dra. Linda Augustien Makalew[5]

[1]Doctoral Student, Department of Health Promotion and Behavior Science, Faculty of Public Health, Airlangga University, Surabaya, Indonesia, [2]Lecturer at The Faculty of Psychology, Airlangga University, Surabaya, Indonesia, [3]Lecturer at The Faculty of Public Health, Airlangga University, Surabaya, Indonesia, [4]Lecturer of Midwifery, Polytechnic of Health, Kupang, Indonesia, [5]Lecturer of Medical Laboratory Technology, Polytechnic of Health, Manado, Indonesia

Abstract

The performance of midwives is very influential on the performance of the organization in an effort to achieve its goals optimally. This study aims to prove that individual factors in the form of knowledge and skills with self management as mediation influence the performance of midwives in midwifery services at Kupang District Health Centers. Quantitative research with a cross-sectional study design conducted in 26 Puskesmas in Kupang Regency, with a sample of 220 implementing midwives, using the sampling method by simple random sampling. Descriptive statistical analysis, hypothesis testing with PLS. The results of this study prove that the skills of midwives have a significant effect on self management and midwife performance. Knowledge and skills of midwives with self management as mediation have a significant effect on the performance of midwives. Individual factors (knowledge and skills) directly and indirectly influence the performance of midwives with self-management as mediation.

Keywords: *Performance of Midwives, Self Management.*

Introduction

Health workers who function to provide quality health services are required to play an optimal role according to their main tasks, roles and functions[(1)]. Health workers as health care providers can be measured in performance through various indicators, one of which is through patient satisfaction as recipients of health services[(2)].

Performance is the result of work that has a strong relationship with the objectives of organizational strategy, customer satisfaction and economic contribution. Willingness and skill are not effective enough to do something without a clear understanding of what is done and how to do it[(3)]. Human resources who are talented, qualified, highly motivated and willing to cooperate in teams will be the key to the success of the organization. Therefore the leader must be able to set work goals that will produce high-quality, highly motivated and productive employees. Specific target setting in a certain period of time is not only quantitative but also qualitative. Strategies to achieve performance targets, for example by self-development to master the knowledge and expertise needed with an improved level of competence. One effort to find out the ability of an individual in his work is to measure performance according to competency standards carried out continuously and effectively and efficiently. Performance measurement that is commonly used is the measurement of employee performance assessed by direct supervisor, peer rating and self-rating[(4)].

Midwives as one of the leading health workers are also required to show optimal performance. Midwifery is a science that is formed from the synthesis of multi-disciplines related to midwifery services including medicine, nursing, social, behavioral, cultural, public health, and management.

Kupang Regency with a population of 305,548 people, couples of childbearing age 46,404 couples, the number of pregnant women in 2014 was 8115 mothers. The proportion of village midwives reached 83.33% (289 midwives) with placements that were almost evenly distributed in all villages in the Kupang Regency area. Nonetheless, the coverage of delivery assistance by health workers is still very low at 50.79% with the number of mothers giving birth as many as 7746 people. The low coverage of delivery assistance by health workers can result in high MMR and IMR. Maternal mortality in Kupang Regency in 2014 was 4 people (absolute number) with the cause of death due to post partum bleeding and preeclampsia. While infant mortality in kupang district in 2014 was 52 people (absolute numbers). Causes of death of newborns due to neonatal asphyxia, LBW, aspiration, and congenital abnormalities. It was also reported that K1 coverage was 4760 people (58.66%) and V4 coverage was 3758 people (46.31%). Early detection of risks to mothers and infants by health workers was 679 people (41.84%) and by the public as many as 451 people (27.79%), and referral of neonatal maternal cases was 149 (9.31%)[5].

Human factors are determinants of public service providers in producing quality services. The quality of service to the community is very dependent on the individual and the system used. Doctors and medical and non-medical support staff serving in health services must understand how to serve consumers well, especially for patients and families, because they are the main consumers of health services. Patient and family complaints about the quality of midwifery services can be caused by various factors, among others, one of them is the low performance of midwives. Assessment of performance includes several factors including observation, size, development and assessment of effectiveness. In individual factors which are one of the factors that influence performance, there are self-management factors that are very important to improve their performance, among others: 1) how individuals determine the behavior of the target to be changed; 2) then individuals are able to monitor their own behavior; 3) individuals choose the procedure to be determined; 4) individuals carry out procedures that have been set by themselves and 5) individuals are able to evaluate the procedures they have carried out continuously. Self management is an effort to manage individuals in order to organize themselves in improving their performance to achieve organizational goals.

According to Quintero et al.[6] who examined the self leadership and effectiveness though in self management teams, found that the ability of a person to lead himself was effective against individual work in the team.

According to Young K (2018)[6] there are 18 components of self management skills, namely: self assessment, building self confidence, identifying risk factors, choosing good activities, goal setting, building possession.

Material and Method

This study used an analytical cross sectional design. The target population in this study were all health workers working in the Kupang Regency area. This study took the total population with inclusion criteria: 1) Midwives, 2) worked in the scope of Kupang district health center 3) Willing to be respondents 4) Physical and spiritual health. While the exclusion criteria in this study were respondents who were originally willing to later resign for certain reasons. Sampling using Role of Thumbs, totaling 220 respondents.

Independent variables in this study are individual factors of knowledge and skills. Dependent variable is the performance of midwives in midwifery services including the quality of performance of midwives in the implementation of midwifery care for pregnant women, maternity, newborns and postpartum mothers. Mediator variables are self management, namely self assessment, self analysis, goal setting, self planning, self-implementation, finding social support, self monitoring and self evaluation modified with Varney 7 step midwifery management including the assessment of basic data, interpretation of basic data, anticipate diagnosis/potential problems, immediate action, planning, implementation and evaluation[7]. The tool used for this study was a closed questionnaire. In the closed questionnaire the answers are available, with a blue print. This research was carried out in the Kupang District work area which covered a total of 26 Puskesmas in Kupang District, NTT Province of Indonesia.

Very good knowledge of midwives tends to show very good self management (52.3%), good midwife knowledge tends to show good self management (77.8%), sufficient knowledge of midwives tends to show good midwife self management (87.5%), knowledge of midwives who are less likely to show good midwife self management (36.4%), poor midwife knowledge tends to show balanced good and bad midwives self management (39.2%).

Excellent midwife skills tend to show very good midwife self management (60.5%), good midwife skills tend to show good midwife self management (67.3%), midwife skills that tend to show good midwife performance (70, 3%), skills of midwives who were less likely to show good midwife performance (78.9%), poor midwife skills tended to show poor midwife self management (60.6%).

The knowledge of midwives about excellent self management tends to have excellent midwifery service performance (62.6%), good knowledge, tends to perform very well (63.0%), sufficient knowledge of performance tends to be good (45.8%), lack of knowledge tends to perform very well (45.5%) and poor knowledge of performance tends to be very good (29.4%).

The skills of a very good midwife tend to show very good performance (77.6%), good midwife skills tend to show good performance (47.3%), sufficient skills of midwives tend to perform very well (40.5%), skills midwives who are less likely to perform very well (42.1%), poor midwife skills tend to be balanced between good and very good performance, each (27.3%).

Very good midwife self management tends to midwife's performance in midwifery services is also very good (87.7%), good midwife self-management midwife performance also tends to be good (45.8%), midwife self-management that is quite midwife performance tends to be good (39, 1%), midwives' self-management that lacked the performance of midwives tended to be lacking (40.0%) and poor self management the performance of midwives tended to be very good (40%).

The inner model is including the goodness of fit, which is the value of the R Square of the dependent latent variable as in table 1:

No	Variable	R Square	R Square Adjusted
1	Y. Performance of Midwives	0.792	0.784
2	Z. Self Management	0.795	0.788

The influence between variables is as follows:

a. Knowledge of midwives has a significant effect on midwife's self management, self management has a significant effect on midwife's performance, meaning that knowledge of midwives has a significant effect on midwife's performance through self management. The results of this study indicate that the knowledge of very good midwives tends to influence excellent self-management, which can also influence the tendency of midwives' performance to be very good. This shows that the better the knowledge of midwives about self management can encourage the better implementation of self management, which can influence the performance of midwives to be better.

b. The skills of midwives significantly influence midwife's self management, self management significantly influences the performance of midwives, meaning that the skills of midwives significantly influence the performance of midwives through self management. The results of this study indicate that the skills of very good midwives tend to influence self-management which is very good, which can also influence the tendency of midwives' performance to be very good. This shows that the better the skills of midwives can encourage better self management, which can influence the performance of midwives to be better

c. Self management has a significant effect on the performance of midwives, the results of this study indicate that self management which tends to be very influential also affects the tendency of midwives' performance to be very good. This shows that the better the midwife's self management can encourage the performance of the midwife to be better

d. Knowledge of midwives mediated by self management has a significant effect on the performance of midwives. This shows that the knowledge of midwives mediated by good self management can encourage the performance of midwives to be better.

e. The skills of midwives mediated by self management significantly influence the performance of midwives. This shows that the skills of midwives mediated by good self management can encourage the performance of midwives to be better.

Discussion

Individual factors (knowledge) of midwives about self management, the results of the study showed that the knowledge of midwives about self-management was mostly good. According to Sharma et al (2015)[3] the assessment is based on a criterion that is self-determined or uses existing criteria. In this study the measured knowledge of midwives about self management. The

knowledge of midwives in Kupang District Health Center is mostly good, meaning that most midwives already know about self management, have understood it, have applied it, have the ability to analyze and have the ability to evaluate what they are doing.

The individual factors (skills) of midwives about self management, the results of the study showed that the skills of midwives in implementing self management were mostly very good. Skills are the ability to do a physical or mental work. Allan et al (2013)[8] say that skills are aspects of behavior that can be learned through exercises that are used to fill the workplace; skills not only require training, but the basic abilities that each person has can help produce something more valuable faster. Skills are the capacity needed to carry out a series of tasks that develop from the results of training and experience. A person's expertise is reflected by how well someone is carrying out a specific activity, such as operating an equipment, communicating effectively or implementing a business strategy. Most midwives have excellent skills in implementing self management in carrying out Varney's 7-step midwifery management. This can be interpreted that most midwives already have expertise in solving midwifery problems using their logic.

The influence of individual factors (knowledge) midwives on self management gets pvalues = 0.013, the knowledge ability of midwives to develop self management is very significant, where there are 6 self management skills, namely: problem solving, decision making, resource utilization, the formation of a patien-provider[9] partnership, action planning and self-tailoring, this is in line with those recommended by the International Confederation of Midwives

The influence of individual factors (skills) midwives on self management get pvalues = 0.015, Midwives who have self management will be able to build Building performance skills, do exercises to improve their ability to work. In carrying out the work that is the main task of each employee, performance is displayed in the form of achievement. Effective and efficient performance management is carried out as an activity to help employees discover their potential abilities that are followed up by providing opportunities to make them become achievement through their placement in the field of work or position in accordance with their potential abilities. The performance of individuals is not something that is static, but always dynamic in the sense that it can increase in height or vice versa to decrease or be low. So that everyone wants to achieve progress in work. Progress can only be achieved if someone is able to display satisfactory performance, including higher work productivity.

The influence of individual factors (knowledge) on midwives in implementing self management on the performance of midwives obtained pvalues = 0.02. This is in accordance with the results of the study from Moattari, et al (2012)[10] who wrote that there was a correlation between physiological factors of knowledge, motivational factors, leadership factors, incentive/ reward factors and co-worker factors with midwives' performance in Iranian services.

The effect of individual midwives (skills) in implementing self management on the performance of midwives obtained pvalues = 0.02. In line with the study of Karvande, et al (2018)[11] who wrote that the skills of midwives who are often honed make their self-management fundamentally improve performance

The effect of the implementation of self management on the performance of midwives in the health service obtained pvalues = 0.02. Self management in education, psychology, and business terminology is a method, skill and strategy that can be done by individuals in effectively directing the achievement of the objectives of the activities they perform, including goal setting, planning, scheduling, task tracking, self evaluation, self intervention, self development. In addition, self management is also known as the execution process (decision making).

This study, Varney's 7-step midwifery management was modified with the aim that midwives can provide midwifery services well by doing self-management on their own by modifying self management adapted from Corbin and Charles (2017)[12] consisting of 8 cell steps

Conclusions

Individual factors (knowledge and skills) directly and indirectly influence the performance of midwives with self-management as mediation.

Health Literacy on Weighing Control and Use of Weight Loss Products among Working-age Women in the Northeast of Thailand

Chalee Yaworn[1], Wongsa Laohasiriwong[2], Kittipong Sornlorm[1]

[1]Doctor of Public Health Program, [2]Faculty of Public Health, Khon Kaen University, Khon Kaen, Thailand

Abstract

This cross-sectional study aimed to describe weight loss products' use patterns and identify the association of health literacy on weight control and weight loss products use among working-age women in the Northeast of Thailand. The study was conducted among 1,190 respondents who were multistage randomly selected from 4 provinces of the Northeast region. Data were collected using a self-administered structured questionnaire. The generalized linear mixed model (GLMM) was used to identify the association between health literacy and weight loss products use when controlling the effects of other covariate presenting adjusted OR and 95% confidence interval. The results indicated that 23.19% (95% CI = 20.79-25.59) of the respondents ever used weight loss products, of which 11.60% (95% CI = 9.77-13.41) were current users. Levels of health literacy on weight control was statistically significant with weight loss products use including having; sufficient level of health literacy (adj. OR = 2.62: 95% CI=1.59-4.31, p-value <0.001), problematic level of health literacy (adj. OR = 4.71: 95% CI=2.87-7.72, p-value <0.001) and inadequate level of health literacy (adj. OR = 10.97: 95% CI=6.17-19.51, p-value <0.001) when compared with having excellence level. The significant covariate was had waist circumference ≥ 80 cm. (Adj. OR = 4.12: 95% CI = 2.79-6.11, p-value =0.025), finished lower than bachelor degree (adj. OR = 2.11, 95% CI = 1.78-3.70, p-value <0.001), had average monthly income ≥ 15,000 THB =(adj. OR = 3.08: 95% CI = 2.20-4.31, p-value <0.001), About twenty three percent of working-age womenever used weight loss products. Health literacy was highly associated with used weight loss products.

***Keyword**: Weight loss products, Health literacy, working-age women.*

Introduction

Overweight and obesity cause various health problems all over the world[1], obesity particular is one of the main causes of morbidity and mortality[2] especially cardiovascular disease (CVD). Awareness of the serious health consequences, people turn their attention to weight control to be within the standard[3]. It is wildly accepted that lifestyle modification, such as healthy dietary habits and regular physical activity is necessary for weight control, however, with a long term effort [4]. Therefore, many people use various weight loss products because they are quicker and easier than exercising or dieting[5]. Although this method is dangerous or has many side effects[6], as well as being unable to confirm the weight loss results as to whether or not effective[7]. The main target groups of these products are working women[8]. Because he or she is a person with financial readiness, able to make independent purchase decisions and pay attention to the shape[9].

Health literacy is linked to the ability of individuals to understand and apply health information to practice for disease prevention and health promotion[10]. People with an excellent level of health literacy should be less likely to use weight loss products since they are well aware of their complications than those with inadequate health literacy. Social-cognitive factors also play an important role in behavioral determination[11].

Although different health behavior theories have been used to explain weight management, roles of social-cognitive factors on weight loss remain poorly understood[12]. Also, there is limited evidence concerning the influence of socio-demographic gradients on dieting and attempts at weight loss[13] such as women are more likely to concern about their shape.

The Northeastern region of Thailand is the biggest region both in terms of areas and population. Most of the labor forces of the country are from this region. With the long term continuously economic expansion, there has been an increasing trend of overweight and obesity among northeasterner women. Therefore it is essential to the determinants of weight loss products use among them.

Objective: To describe the weight loss products use and identify the association between health literacy on weight control and weight loss products use among working-age women in the Northeast of Thailand.

Materials and Method

This cross-sectional study was conducted in 2019. The population was working-age women aged 20 to 59 years old in the Northeast of Thailand. The sample size was calculated by using the sample size estimation formula for the logistic regression analysis of Hsieh[14]. The estimated sample size was 1,190. The respondent was recruited from 4 provinces of the Northeast of Thailand by using multi-stage random sampling method to respond to a structured questionnaire.

Data Analysis: All analyses were performed using Stata version 10.0 (Stata Corp, College Station, TX). Descriptive statistics including frequency and percentage to describe categorical data whereas mean, standard deviation, median, and maximum-minimum for continuous data. A simple logistic regression was used to identify individual the association between each independent variable and weight loss products use. The independent factors that had p-value <0.25 [15] were processed to the multi variable analysis using the generalized linear mixed model (GLMM) to identify the association between health literacy and weight loss products use when controlling the effect of other covariates, of which 4 provinces were selected to include as random effects. The magnitude of association was presented as adjusted odds ratio (Adj. OR), 95% confidence interval (CI) and p-value <0.05 as statistical significant level.

Result

Socio-demographic: The average age of the respondents was 39.46 ±10.71 years old, 58.74 were married, 67.15 percent had education lower than a bachelor's degree. the occupation was employee 25.04 percent, an average monthly income 10,000-19,999 baht, average monthly expenditures less than 10,000 baht, normal body mass index 40 percent, waist circumference exceeds the standard threshold 50.25 percent without chronic disease 86.47 and healthy status of 81.26 percent.

Almost a quarter of the respondents ever used weight loss products (23.19%: 95% CI = 20.79-25.59) of which 11.60% (95% CI = 9.77-13.41) were current users. The most common type of weight loss product use were diet pills which were consumed by 7.84% of the respondents, followed by diet coffee (6.68%) and fiber products (4.50%), see table 1

Table 1: Number and percentage of weight loss products use pattern (n = 1,190 people)

Weight loss products use pattern	Number	Percent
1. Weight loss products use		
Currently, use	138	11.60
Used for less than 6 months and stop using	39	3.28
Used for more than 6 months and stop using	99	8.32
Never used but would like to use in the future	90	7.56
Never used and want to use	824	69.24
2.Type of weight loss product use (Can answer more than 1 question)		
Diet pills	101	7.84
Diet coffee for weight loss	86	6.68
Fiber products	58	4.50
Konjac Extract	55	4.27
Wearable products for weight loss	12	0.93
Tea products	11	0.85
A traditional procedure such as massage	10	0.78
Chitosan	9	0.70
Weight loss program	8	0.62
Equipment	7	0.54
Garcinia extract	5	0.39
Increased metabolism products	4	0.31
Other weight loss products	8	0.62
Do not use weight loss products	914	70.96

Association between health literacy and weight loss products use among northeastern working women when controlling other covariates: a multivariable analysis: Association between health literacy and weight loss products use among northeastern workingwomen were identified by using the Generalized Linear Mixed Model (GLMM) to control the clustering effect in each health zone. The results indicated that levels health literacy were associated with weight loss products use including had sufficient level of health literacy (adj. OR = 2.62 :95% CI=1.59-4.31, p-value <0.001), had problematic level of health literacy (adj. OR = 4.71:95% CI=2.87-7.72, p-value <0.001) and had inadequate level health literacy 10.97 times the use of weight loss products for those with excellent health literacy (adj. OR = 10.97: 95% CI=6.17-19.51, p-value <0.001) when compared with those with excellent level of health literacy. The other significant covariates were, those with waist circumference ≥ 80 cm. (adj. OR = 4.12: 95% CI = 2.79-6.11, p-value =0.025), graduated bachelor **degree or higher** (adj. OR = 2.11,95% CI = 1.78-3.70, p-value <0.001), had average monthly income ≥15,000 THB (adj. OR = 3.08:95% CI = 2.20-4.31, p-value <0.001), see Table 2.

Table 2: Association between health literacy and weight loss products use among northeastern working women when controlling other covariates: a multivariable analysis using GLMM

Factors	Number	Percent	Crude OR	Adj. OR	95%CI	P-value
Health literacy						
Excellent	320	9.69	1	1		
Sufficient	407	18.92	2.17	2.61	1.60-4.24	<0.001
Problematic	331	30.32	4.15	4.68	2.88-7.61	<0.001
Inadequate	132	50.00	9.32	10.60	6.04-18.62	<0.001
Education level						
≥ Bachelor Degree	391	18.41	1	1	1.78-3.70	<0.001
<Bachelor Degree	799	25.53	1.52	2.57		
Income per month (THB)						
<15,000	667	15.59	1	1	2.20-4.31	<0.001
≥15,000	523	32.89	2.65	3.08		
Waist circumference(cm.)						
<80	588	10.54	1	1	4.48-8.98	<0.001
≥80	602	35.55	4.68	6.31		

Discussion

This present study observed that about 23% of working-age women ever used weight loss products. This proportion was a little lower than those found in a study in 2015 in Bangkok, Thailand indicated that 27.7% of the respondents used weight loss products[16]. However, it was higher than those found in a study in 2017 in Ratchaburi Province, Thailand that observed that 19.6% of the participants used weight loss products[17]. A possible explanation was that there was a higher level of economic development in Bangkok, people have higher income and might concern about shape more than the northeasterners. Ratchaburi, on the other hand, had a lower income. The multivariable analysis of this study also indicated that higher income had a high influence on weight loss products use (adj. OR = 3.08) which was similar to a study in Sweden [13].

Health literacy (HL) played an important role in weight loss products use. Our finding indicated that those who had excellence level of health literacy on weight control were less likely to use weight loss products when compared to those who had sufficient, problematic, and inadequate levels of HL (adj. OR= 2.61, 4.68, and 10.60 respectively). A study of Cheong et all. Indicated that HL had a positive impact on weight loss behaviors. There was also evidence that interventions focusing on improving knowledge and HL skills could effectively control the weight[18]. HL influences reach and moderates weight effects. These findings underscore the need to integrate recruitment strategies and further evaluate programmatic approaches that attend to the needs of low-HL audiences. HL is necessary and an important indicator when making decisions about weight loss products. Having HL can influence the choice and

decision not to use weight loss products. Therefore, encouraging the public to have good HL will help people to avoid using weight loss products and choose to use the right weight control[19]. Our finding also observed that there were socioeconomic gradients to overall health and showed that those with lower levels of education had poorer health and higher mortality. A previous study of Barbering et.all[13] also indicated that proper dietary regimen and overweight were associated with higher education levels. Similarly a studied of Ball observed that males who were married, living in households with shared income and who had less education were more likely to use weight loss products[20]. Waist circumference(WC) is one of the conditions of metabolic syndrome, which is an important risk factor of cardiovascular disease[21]. Women with higher WC have a bigger belly which made them looked fat. This might lead to more concern about weight loss. They might try to reduce the WC as quick as possible by using weight loss products[22]. Therefore, it requires effective measures to improve health literacy on appropriate weight control especially among those with lower education having a big belly and had a higher income that has more purchasing power.

Conclusion

The study indicated that about 23 percent of working-age womenever used weight loss products. Health literacy was highly associated with used weight loss products when considering the influenced of waist circumference, educational level**,** andincome.

Oko Mama Culture Betel Nut Consuming Habit in Kupang District and its Effect toward Salivary Ph and Flow Rate

Christina Ngadilah[1], Hari Basuki N.[2], Rika Subarniati T.[3]

[1]Doctoral Program of Health Sciences, Faculty of Public Health, Airlangga University, [2]Faculty of Public Health, Airlangga University, [3]Head of Public Health Department, Faculty of Medicine, Wijaya Kusuma University, Indonesia

Abstract

Public health always associated to culture and lifestyle. Lifestyle itself constitutes a concept that commonly used to define "The way people live", reflecting the whole social value, attitude, and activity. One of long-term culture that become personal habit is chewing betel nut. Oko Mama culture is the local culture of the Timorese tribe who consider it as the symbol of philosophy, dignity, enjoyment, beauty, also as a means of communication in society, political means, and delaying hunger. Several studies revealed several unbeneficial of chewing betel nut, such as acute betel nut toxicity, cardiovascular disease, respiratory disorder, and congenital defect. Besides, betel nut may also alter oral health. This study is aiming to analyse the correlation of habitual chewing betel nut toward salivary pH and flow rate. This was an observational analytic study, by means of cross sectional design involving both on male and female aging 17-50 years old in 4 sub-district, consisting of 2 remote areas and 2 urban areas. The correlation between variables was analysed using path analysis by means of Smart PLS 3.2.7. The analysis revealed a positive correlation between Oko Mama culture toward behaviour (p=0.316) and intention (p= 0.454), also a negative correlation between the culture toward oral hygiene knowledge (p=-0.185) and the effect of chewing betel nut knowledge (p = -0.111). A positive correlation also recorded toward perceived norm (p=0.931). While intention had a positive correlation toward behaviour (p=0.429). Regarding oral health, chewing betel nut had negative effect toward salivary pH (p=-0.167) and salivary flow rate (p=-0.210).

Keywords: *Community habit, betel nut, salivary pH, flow rate.*

Introduction

Public health is an integrated matter with the local culture. The society in each region have their own concept of health, as the important part of the culture. Betel nut chewing denotes an old habit of the society in Kupang. A prior study revealed that in Oelnaineno, sub district Takari, Kupang, 94% people aged 17-60 years old chew betel nut. The betel nut usually mixed with betel, areca nut, lime, sometimes the other ingredients were added, such as nutmeg, cloves, and even tobacco[(1)].

The Oko Mama culture, that used betel nut in various occasion in daily life, thus, it can be found in every household in Timor. Oko Mama is the Timorese tribes culture, that chew the betel nut as the symbol of philosophy, dignity, enjoyment, beauty, also as a means of communication in society, political means, and delaying hunger. This culture denotes the factor that drives the society to chew betel nut to date[(2)].

Studies revealed that chewing betel nut might induce oral precancerous lesion which highly tend to become cancer. The areca nut itself has been classified as class I carcinogenic agent by the International Research Agency for Research Cancer[(3)]. Areca nut only, has significant impact toward health, thus, tobacco addition may rise worsen health consequence, even death. After chewing betel nut, several symptoms may appear, such as headache, tachycardia, hot sensation and sweating, epigastric discomfort, hyperventilation, thirst and hunger diminish, relax, and overexcited[(1)].Areca nut contain arecolin, that possibly toxic toward periodontal tissue, thus, may worsen the periodontal status [(4)].

The betel nut is addictive to its chewers. The tint

from betel nut can penetrate into oral mucosa, and teeth, yet may disappear if strongly rubbed by areca skin[5]. The tooth discoloration due to betel nut chewing may prevent tooth demineralization. Several studies had proved that betel nut could reduce the caries prevalence[6][7][8].

Considering the high number of betel nut chewers and its effect toward health, thus, it is important to analyse the Oko Mama culture, related to the habit of chewing betel nut and its effect toward caries. It is expected to be able to help the attempt to reduce betel nut chewers in Kupang, East Nusa Tenggara as it is dangerous to their health, especially their dental health. This research aiming to syntheses a theory of Fishbein Integrated Behaviour Model with Dunn Behavioural theory which including culture as the factor that influence someone behaviour.

Material and Method

This observational analytic study employed a cross sectional design. The sub district South Amfoang and Takari, denotes remote areas, while the urban areas were sub district Nekamese and Kupang Centre. Those selected areas had the most population. The subject of this study were the inhabitants aged 17-50 years old. As much as 363 peoples were randomly chosen from 146.597, calculated using estimated proportion population formula.

The criteria for the respondents were male and female who chewed betel nut, and those who did not from those 4 selected areas. The respondents were asked to fill a questionnaire. The acquired data were analysed by means of path analysis by PLS 3.2.7 to find a correlation among variables. We hypothesized eleven theories; 1) there is a correlation between attitude and intention; 2) there is a correlation between perceive norm and intention; 3) self-efficacy affect the intention; 4) Oko Mama culture affect intention; 5) Oko Mama culture affect behaviour; 6) intention affect behaviour; 7) oral health knowledge affect behaviour; 8) disease knowledge affect behaviour; 9) habit affect behaviour; 10) behaviour affect salivary flow rate; 11) behaviour affect salivary pH.

Results

The respondents participated in this study consisted of 51.5% female and 48.5% male. The total of betel nut chewers was dominated by female (52.8%). Among the population, the betel nut chewers (79.9%) were more than those who do not chew betel nut (20.1%). Mostly respondents were aged 41-50 years old (43.8%), while the respondents aged less than 20 were the minority (11.3%). The younger the respondents, the less they chew betel nut. Most of the respondents were farmers (82.6%), with the last education was elementary school (59.2%).

The habit of betel nut chewing more than 5 times a day were done by 37.5% of the respondents. The average frequency of betel nut chewing was twice a day. A portion of 51.8% the respondents has been chewing betel nut for 10 years or more, with 58.1% of them chewed betel nut with lime and areca nut. The majority of the respondents learn to chew betel nut form their parents (96,9%).

Table 1. Result from Path Analyzes

Path	Original Sample (O)	Mean (M)	SD	T Statistic (|O/STDEV|)	P Values

Similar to TRA/TPB, the most important predisposing factors in Integrated Behaviour Model (IBM) is intention. Intention defined as individual decision indicator to do a certain behaviour. Without intention, behaviour will not be built. The intention itself was determined by attitude, perceived norm, and self-efficacy to start doing betel nut chewing as habit. This study used 4 variables based on the IBM that affect the intention to chew betel nut, that are attitude, perceived norm, self-confidence and Oko Mama culture. Based on the result from table 1, there were 2 rejected hypotheses, that are 1) oral health knowledge have no effect toward behaviour ($p>0.05$), and 2) disease knowledge have no effect toward betel nut chewing ($p>0.05$).

Attitude had significant correlation toward intention as much as 0.278 ($p<0.05$), while perceived norm also had significant correlation toward intention as much as -0.191 ($p<0.05$). Self-confidence significantly affect intention as much as 0.417 ($p<0.05$). Intention had significant effect toward betel nut chewing as much as 0.429 ($p<0.05$). Oko mama's culture significantly affects the intention to consume betel nut at 0.454 (p value 0,000). The Oko mama culture significantly affects the Behavior of consuming betel nut by 0,316 (p value 0,000). The habit of consuming betel nut significantly affects the salivary pH of -0.167 (p Value 0,000). The habit of consuming betel nut significantly affects the salivary flow rate of -0,210 (p value 0,000). The Behaviour Hypothesis influences the Saliva Flow Rate in the habit of consuming betel nut analysed by looking at the Path Coefficients (table 1). This hypothesis is accepted significantly because Path Behaviour to the Saliva Flow Rate has a p-value of 0,000 and the value of t-statistics 3,933 and Path Coefficients -0,210. The hypothesis is accepted because p-value is less than 0.05 and t statistic is more than 1.96. From these results it can be concluded that the Behaviour has a negative effect of -0.210 on the salivary flow rate.

Discussion

The behaviour of chewing betel nut affects salivary flow rate, may possibly due to the reduce in salivary secretion or salivary properties changes while they are not chewing betel nut. This condition may contribute to several oral and dental diseases, that directly affect the quality of life. Several studiesstated that the normal unstimulated salivary flow rate is 0.3-0.5 ml per minute[9][10], while stimulated salivary flow rate is 10ml per minute[11][12]. The significant changes of salivary flow rate affect dental and oral health[12]. The functional changes of salivary gland, is related to oral cavity, throat, oesophagus, neoplasm, nutrition metabolism, inflammation, genetic disease, auto-immune disease, and nervous system damage. The varied salivary flow rate also depends on the time of measurement. Those variations in 24hours depends on the circadian rhythm. Besides, other factors also contribute, such as age and gender.

Several studies recorded that unstimulated normal salivary pH ranged from 5.5 to 7.9, the higher pH, the higher salivary flow rate[12][13]. Salivary pH is controlled by carbonate/bicarbonate acid system, phosphate system, and protein system. A study revealed several rate of salivary flow from chewing 4 kinds of betel nutmixture, and raw areca nut only, which resulted the highest mean of salivary flow rate recorded was 4.18ml in 10 minutes[11]. A decrease of salivary secretion or changes in saliva properties may also contribute to several oral and dental problems, that directly affect the quality of life. Some of those problems are speak and eat difficulty, taste perception changes, increase plaque formation, increase risk of caries, tooth erosion and periodontal disease, increase of plaque formation, mucosal irritation, halitosis, and candidiasis, also decrease the retention of full denture. Those aforementioned oral and dental problems may also affect general health, since the affected individual may experience lost appetite, that leading to malnutrition[14].

There is a significant correlation between chewing betel nut with salivary flow rate. A study revealed unstimulated salivary flowrate in betel nut chewers was basically same to those who do not, yet the when stimulated, the chewer group had a higher flow rate[15]. This is possibly caused by the increase of sensitivityand salivary mechanism due to areca nut and tobacco. There is an opinion, that this also probably due to salivary gland hyperplasia, and masticatory muscle hypertrophy in long-term betel nut chewer[16]. Besides, oral mucosa also become more sensitive due to toxic effect of betel nut [11][15]. However, those changes do not affect masticatory efficacy[15][17]. Another study showed that the salivary flow rate and pH of the carious and free-caries subject were not significantly different[18]. Also no significant differences of salivary flow rate between those subjects. Enamel demineralization may occur in pH <5.5[19]. The mean pH of the respondents chewing betel nut was 6.6, while those who don't was 6.78[18].

There was a significant correlation found between betel nut behaviour with the salivary pH (p=0.000; t-statistic 3.617 and path coefficient -0.167). Behaviour had negative correlation to salivary pH (-0.21). The current study found changes of salivary pH and flow rate in betel nut chewer, which may lead to various oral diseases[20].Betel nut chewing denotes socio-cultural expression (Oko Mama), which significantly affect the perceived norm (0.931). The importance of culture affect how the society will behave. Besides, betel nut chewing also noted as social identifier, to be considered as cultured and ethical individual. Some individuals do betel nut chewing in order to be recognized as the member of society[21].

That the areca nut availability promotes betel nut chewing behaviour. Since betel nut is easily found in every household, makes it easier to consume and mostly the chewer firstly learnt from their parents[22]. That in several cases, betel nut chewing was done due to the social pressure, and the desire to be recognised[21]. WHO summarized that betel nut is correlated to oral cancer prevalence[23]. Oral carcinoma due to betel nut chewing denotes aggressive malignancy that required intensive treatments[24]. While the society have not fully understood about cancer, thus, this need a long-term attempt of prevention. Betel nut chewing was not an oral and pharynx potentially malignant disorder (OPMD) only, but also may be the predisposing factors of other diseases. The high prevalence of betel nut chewing increase the incidence of hepatic cancer. Besides, betel nut chewing also affect cardiovascular, nervous system, digestive system, metabolism, respiratory system, and reproductive system[25].

To date, there has not any global policy regarding betel nut chewing. Multidisciplinary research is required to control this phenomenon, and further studies to get a better understanding in basic biology, mechanism, and epidemiology of betel nut chewing. This may encourage the prevention, also, stop the betel nut chewing for a better health. Those attempts are betel nut uses monitoring, continuous educate the society to stop the habit, by utilizing advertisement board, and increase areca nut tax.

Conclusion

Oko Mama culture affects intention to chew betel nut, and also affect the behaviour to chew betel nut. The betel nut chewing behaviour affects salivary pH and flow rate. The habit of betel nut chewing shows a change in salivary pH and flow rate. Those changes contribute in the occurrence of oral diseases. Complex behaviour of betel nut chewing is reflected in varied salivary pH and flow rate.

Abstract

Introduction: Preeclampsia is one of the complications that occur in pregnancies. This study was aimed to study the factors that affect the of giving ethanol extract with black cumin (Nigella sativa) against sFlt-1 level and VEGF serum on laboratory mice induced preeclampsia.

Method: Laboratory experimental research with posttest only control group design. This study used 30 BALB/C laboratory mice, divided into 6 groups, namely negative controls: pregnant mice injected serum from normal pregnant women, positive controls; mice modeled preeclampsia, and treatment groups 1, 2, 3 and 4 are preeclampsia mice received a dose of 500 mg, 1000 mg, 1500 mg and 2000 mg/kg weight of Nigella sativa ethanol extract for 5 days. Statistical analysis using ANOVA

Result: The mean serum sFlt-1 level in mice modeled preeclampsia and treatment group dose 500mg, 1000mg, 1500mg and 2000mg (2510.3+182.2 pg/mL, 2142.5+171.9 pg/mL, 1309+161.3 p/mL, and 1500+169.9, respectively) pg/mL) showed a significant difference ($p<0.05$) and found a decrease in serum sFlt-1 levels with increasing doses. The mean serum VEGF levels in preeclampsia mice and treatment groups were 500 mg, 1000 mg, 1500 mg and 2000 mg (50.25±2.85b pg/mL, 60.18±4.81c pg/mL respectively, 71.89±2.38d pg/mL, 66.51±1.87 e pg/mL) showed a significant difference ($p<0.05$) and found an increase in serum VEGF levels as the dose increased.

Conclusion: Giving of Black Cumin extract (Nigella sativa) decreases serum sFlt-1 levels and increases serum VEGF levels in preeclampsia mice model and the effect is dependent dose.

Keywords: *sFlt-1, VEGF, Nigella sativa, preeclampsia.*

Introduction

Preeclampsia is one of the complications that occur in pregnancies of more than 20 weeks which is characterized by an increase in systolic blood pressure greater or equal to 140 mmHg or diastolic pressure greater than or equal to 90 mmHg and the amount of proteinuria 300 mg or more than 30 mg/dL per 24 hours[1]. Preeclampsia occurs in about 3-5% of pregnant women worldwide and the number two cause of death for pregnant women. In the United States, 15% of maternal deaths are caused by preeclampsia [2,3].

The pathogenesis of preeclampsia occurs with a variety of mechanisms, but placental ischemia/hypoxia is likely to be a major factor due to disruption of trophoblast invasion[4]. Placental ischemia will stimulate excessive production of sFlt-1 or VEGFR-1. The presence of sFlt-1 as a competitor for surface VEGF receptors (Flt-1), causes VEGF cannot attach to receptors on the cell surface. This situation causes serum VEGF levels

to decrease and induce endothelial cell damage in the glomerulus, producing a urine protein[5,6].

Black cumin has been used as a traditional medicine for thousands of years for various diseases such as asthma, coughing, bronchitis, headaches, fever, and rheumatism[7]. Seed extracts of both water and oil have the potential to be anti-tumor, antioxidant, anti-inflammatory, anti-hypertensive, anti-diabetic and anti-seizure. Thymoquinone (TQ) is the main constituent of Black Cumin essential oil[8,9]. As an antioxidant, thymoquinone synergizes with other compounds such as dithymoquinone and thymol as a free radical scavenger[10]. As TQ Anti-inflammatory inhibits activation of NFκβ. In cases of preeclampsia where placental hypoxia occurs, activation of NFκβ will affect the expression of hypoxia-inducible factor 1-α (HIF1-α)[11] which is a VEGF[12] transactivator.

By referring to the above facts because Black Cumin (Nigella Sativa) has the potential as an antioxidant and anti-inflammatory, it is necessary to conduct research on the molecular mechanism of Black Cumin extract (BC-e) on serum sFlt-1 and VEGF levels in preeclampsia mice.

Design and Method

This research is a laboratory experimental study with a posttest only control group design. This study measured serum sFlt-1 and VEGF levels in the mice model of preeclampsia after being given several doses of Nigella sativa extract. A total of 30 pregnant BALB/C mice were used in this study, divided into 6 groups: pregnant mice injected with serum of normal pregnant women were used as negative controls, preeclampsia mice were as positive controls, and 4 groups of preeclampsia mice were treated with BC-e with a dose of 500 mg, 1000 mg, 1500 mg and 2000 mg/kg of body-weight/day for 5 days. Mice model preeclampsia made by injecting serum of preeclamptic pregnant women on the 10th and 11th days of gestation each 0.1cc intraperitoneally[13.14]. The manifestation of preeclampsia in mice is obtained by finding hypertension and proteinuria on the 15th day of gestation. Maintenance of mice and modeling of preeclampsia were carried out at the Pharmacology Laboratory of the Faculty of Medicine, University of Brawijaya and got standard food and drink.

Mice are terminated at 20 weeks' gestation and blood and kidney organs are collected. Examination of sFlt-1 and VEGF levels in mice serum was measured using an ELISA kit, pg/Ml unit.

Result

The comparison test results showed a difference (p = 0.000 <) the mean serum sFlt-1 level between the negative control group (healthy mice) (579.8 ± 114.8 pg/mL) and the positive control group (preeclampsia mice) (2752.8 ± 188.7 pg/mL)) Likewise there was a significant difference (p = 0.000 <) mean serum VEGF levels between healthy groups (88.56 ± 5.58 pg/mL) with preeclampsia mice model (44.85 ± 2.15 pg/mL). As shown in table 1.

Table 1. Results of comparison of control groups

Variable	Negative Control (Healthy) Mean ± SD	Positive Control (Eclampsia) Mean ± SD	p-value
sFlt-1 serum level (pg/mL)	579.8±114.8	2752.8±188.7	0.000
VEGF serum level(pg/mL)	88.56±5.58	44.85±2.15	0.000

Based on the results of the one way ANOVA test on serum sFlt-1 level data, there were significant differences in the mean serum sFlt-1 level in the five observation sample groups (p-value<0,000). Furthermore, the Multiple Comparisons with the Least Significant Difference (LSD) showed that there was a difference between the mean serum sFlt-1 levels between the positive control group (model preeclampsia mice) (2752.8±188.7apg/mL) and the treatment group gave ethanol extract Nigella sativa doses 500mg (2510.3±182.2b pg/mL), with a dose of 1000mg (2142.5±171.9cpg/mL), with a dose of 1500mg (1309±161.3dpg/mL), and also with a dose of 2000mg (1500±169.9dpg/mL). This means that there is a treatment effect of giving 500mg, 1000mg, 1500mg and ethanol Nigella sativa extracts to serum sFlt-1 levels in preeclampsia mice.

Table 2. The influence of Nigella sativa ethanol extract on mean serum sFlt-1 levels and VEGF levels

Intervention Group	Mean serum sFlt-1 levels (pg/mL)	Mean serum VEGF (pg/mL)
Negative control	579,8	88,56
Positive control	2752,8	44,85
Preeclampsia Mice + Ethanol Extract 500 mg	2510,3	50,25
Preeclampsia Mice + Ethanol Extract 1000 mg	2142,5	60,18
Preeclampsia Mice + Ethanol Extract 1500 mg	1309,0	71,89
Preeclampsia Mice + Ethanol Extract 2000 mg	1500,0	66,51

Based on the results of the One Way ANOVA test on VEGF level data, there were significant differences in the mean VEGF levels of the five observation sample groups (p-value=0,000). Furthermore, the Multiple Comparisons with the Least Significant Difference (LSD) showed that there were significant differences in the mean VEGF levels between the positive control group (preeclampsia mice) (44.85±2.15 pg/mL) and the treatment group administered ethanol extract Nigella sativa at a dose of 500mg, 1000mg, 1500mg and 2000mg (50.25±2.85b pg/mL, 60.18±4.81c pg/mL, 71.89±2.38d pg/mL and 66.51±1.87e pg/mL). There appears to be an increase in serum VEGF levels along with an increase in the dose of ethanol extract except at doses of 2000 mg. If based on the average value of VEGF levels, the treatment group doses 1500mg show the highest value of the average VEGF level (71.89±2.38d pg/mL) compared to the group in other doses and can be considered the fastest dose in increasing VEGF levels in mice models preeclampsia.

The occurrence of a decrease in serum sFlt-1 levels and an increase in VEGF in line levels in increasing doses. The 1500mg dose seems to be the optimal dose of reducing serum sFlt-1 levels and increasing serum VEGF levels.

Discussion

This study showed that sFlt-1 serum levels in pregnant mice injected with pre-eclampsia maternal serum (2752.8±188.7 pg/mL) significantly increased compared with negative control mice. The administration of pre-eclampsia serum intraperitoneal injection with high TNF levels in pregnant mice increase blood pressure and serum sFlt-1 levels[14] which caused by an increase in angiotensin II[15].

The previous study reported that the administration of IgG injection of preeclampsia mothers increase TNF serum levels in pregnant mice. Increased levels of sFlt-1 in preeclampsia patients can reduce levels of free VEGF and PlGF in the circulation resulting in the onset of symptoms of preeclampsia[16,17]. Soluble Fms-like tyrosine kinase-1 (sFlt-1), also known as Soluble vascular endothelial growth factor receptor 1 (sVEGFR-1) which is a soluble receptor for VEGF and PlGF[18] which acts as VEGF and PlGF against by binding and inhibiting interactions both of them against endogenous receptors[19].

This study showed the serum VEGF levels of preeclampsia mice have a significant decrease compared to control mice. The injection of serum for pregnant women PEB in pregnant mice causes pre-eclampsia-like symptoms because TNF-α found in maternal serum binds to TNF type 1 receptors (TNFR-1) mice which in turn activate the NF-κB[20] transcription factor. NF-κβ activation by TNF α may play a role in inducing HIF-1α[21] which is a transcription factor for sFLT formation in the placenta[22]. sFlt does not have a transmembrane domain and membrane[6] cytoplasmic domain, so the bond between VEGF and PlGF to sFlt-1 cannot provide a second messenger for angiogenic and has an antiangiogenic effect[5]. The presence of sFlt-1 as a competitor for surface VEGF receptors (Flt-1) causes VEGF cannot attach to receptors on the cell surface. This condition causes serum proangiogenic VEGF levels to drop by 5/6. Decreasing levels of free VEGF can also indirectly increase in blood. The low levels of free VEGF in serum could decrease in nitric oxide (NO) which cause in blood vessel vasoconstriction followed by an increase in blood pressure.

There was a significant difference in serum sFlt-1 levels in preeclampsia mice with a treatment group given a dose of BC-e dose of 500 mg, 1000 mg, 1500 mg, and 2000 mg. Antioxidant supplements to preeclampsia patients able to reduce serum sFlt-1 levels and increase serum PlGF levels. Black cumin with the main content of Thymoquinone (TQ) has the potential as

an antioxidant so that it can reduce serum sFlt-1 levels in preeclampsia mice significantly[23]. TQ is able to inhibit organ damage caused by free radicals[10]. The antioxidant effects of TQ, dithymoquinone, and thymol be able to inhibit some reactive oxygen species (ROS). TQ and dihydrothymoquinone (DHTQ) have the ability as free radical scavengers with a half inhibitory concentration (IC50) in nanomolar concentrations and micromolar[10]. All ingredients of black cumin have a strong antioxidant effect, where thymol works by quelling single oxygen production, while TQ and dithymoquinone show activities such as superoxide dismutase (SOD)[24].

There was a significant difference in the mean serum VEGF levels of preeclampsia mice with a treatment group that was given a dose of 500 mg, 1,000 mg, 1500 mg, and 2000 mg of BC-e. The effect of BC-e on increasing serum VEGF levels in preeclampsia mice is not fully understood. TQ has the ability to inhibit transcription factors, nuclear factor kappa β (NFκβ) is thought to be the cause. TQ as an inflammatory inhibitor works through anti-inflammatory and proapoptotic action[25].

TQ can inhibit the bonding of NFκβ to DNA through direct interaction with sub-unit p65. TQ will inhibit activation by IkBα kinase which in turn will inhibit degradation and phosphorylation of IκBα thereby inhibiting the activation and translocation of NFκβ from the cytoplasm to the cell nucleus[26]. Barriers to activation of NF-kβ cause decreased HIF1-α expression. In preeclampsia placenta, the inhibition of activation of HIF1-α can reduce the synthesis of sFlt anti-angiogenic factors, and ultimately increase the VEGF angiogenic factor that enters the maternal circulation.

The role of BC-e as an antioxidant is also thought to play a role in increasing VEGF levels. Antioxidant supplementation caused a significant decrease in the concentration of sFlt-1 and increased PlGF in plasma. Whereas in vitro studies showed beneficial effects of antioxidants on VEGF. BC-e has considerable antioxidant properties both in vivo and in vitro[8,24]. In its activity as an antioxidant, thymoquinone synergizes with other compounds such as dithymoquinone and thymol to capture free radicals[10].

The average increase in serum VEGF levels along with the increase in the dose of black cumin extract given and the optimal dose of NS in increasing VEGF levels in serum is 1500 mg. At a dose of 2000 mg, there is a decrease in serum VEGF levels. This is presumably because the effect of hormesis is found in the effects of the response dose[27], where at low doses black cumin ethanol extract has a beneficial effect while at high doses it has a detrimental effect.

Conclusion

Giving of Black Cumin extract (Nigella sativa) decreases serum sFlt-1 levels and increases serum VEGF levels in preeclampsia mice model and the effect is dependent dose.

Biochemical Studies of Oxidative Stress During Ischemia Induce Myocardial Injuries

Deine Majeed Qadir[1], Mohsin Omar Mohammed[2], Mustafa Taha Mohammed[3]

[1]MSc., [2]Assistant Professor, Department of Chemistry, College of Science, Kirkuk University, Kirkuk,
[3]Department of Chemistry, College of Science, Mustansiriyah University, Baghdad, Iraq

Abstract

The study was designed as a biochemical study of the oxidative stress during hypotension caused by cardiac injury, the world's first cause of death, using biomarkers and their role in laboratory diagnosis. The study included three sets of 40 blood samples from each people with myocardial infarction, angina pectoris and healthy people as a control group. Different biochemical variables such as ROS, GPX1, Troponin, C.K, and lipid profile were measured,and the results showed a significant increase in the level of concentration of Reactive Oxygen Species ROS (P-value 0,045) in patients with MI, (7.326 ±1.143ng/mL), and the Angina Pectoris was (6.037 ±1.669ng/mL) compared with the control group (1.046 ± 5.158ng/mL)A significant decrease in the level of Glutathione peroxidase GPX1 at the level of (P-value 0.038) in patients with myocardial infarction (1890 ±391pg/mL) was observed, while in Angina Pectoris was (2109 ±600pg/mL) and in control was (2386±401pg/mL) Furthermore, a varying rises in the level of troponin and creatine kinase in patients with myocardial infarction(29.03±22.99 ng/mL, 110.62±45.71 u/L)respectively, while in patients with Angina was (2.181±2.186 ng/mL, 39.730±12.79 u/L) compared with the control(0.139±0.1717 ng/mL, 16.283±5.133 u/L). The results of the study showed a significant increase of lipid profile (cholesterol, triglycerides, HDL)in patients with MI and AP, with an average concentration (344.6±67.4, 240.3±58.5, 43.00±6.89 mg/dL) for MI and (303.6 ± 86.1, 232.8 ± 65.8, 39.10 ± 5.86) for AP compared with the control group, with an average concentration Mean ± SD (159.2 ± 50.30, 102.9 ± 35.60, 31.00 ± 3.085) respectively.

Keywords: *Cardiac injury, myocardial infarction, angina pectoris, Glutathione peroxidase 1, Reactive Oxygen Species.*

Introduction

Cardiovascular diseases(CVD) are the leading cause of death globally[(1)].This is a fact in all areas of the world except Africa[(1)] Together CVD resulted in 17.9 million deaths (32.1%) in 2015.[(2,3)] Deaths, at a given age, from CVD, are more common and have been increasing in much of the developing world, while rates have declined in most of the developed world since the 1970s.[(4,5)] In the United States, 11% of people between 20 and 40 have CVD.[(6)]

There are many risk factors for heart diseases: age, sex, tobacco, alcohol, obesity, raised hypertension, raised diabetes mellitus, raised hyperlipidemia.[(7-11)]. Myocardial Infarction MI also known as a heart attack,[(12)] it is acute, threatening heart disease. Most MI are caused by coronary artery disease.[(13)] Risk factors include Hypertension, Smoking, Diabetes, and others.[(1,13)] Ischemia [(14)] is a relative or absolute failure or retention of blood supply to body tissues,[(15)] causing oxygen and glucose deficiency needed for cellular metabolism[(16)] Ischemia is usually caused by vascular problems, resulting in damage.

Oxidative stress is an imbalance between free radicals and antioxidants in the body. Free radicals can cause large chain chemical reactions in the body because they react so quickly with other molecules so they can be beneficial or harmful.[(17)] Chemically, oxidative stress is associated with increased production of oxidizing species or a significant decrease in the effectiveness of oxidant defense's, such as glutathione.[(18)] Reactive oxygen species (ROS) is a collective term used for a group of oxidants, which are either free radicals or molecular species capable of generating free radicals.

Uncontrolled generation of ROS can lead to their accumulation causing oxidative stress in the cells.[19]

The study is designed to studying oxidative stress during ischemia caused by the cardiac injury.Find out the presence of oxidative stress and diagnose it by an imbalance between the levels of oxidants (ROS) and antioxidants (GPX1).Know the importance of antioxidants and oxidative damage because of the serious diseases caused by oxidative stress. Identify the importance of cardiac proteins such as troponin and enzymes such as CK-MB as vital indicators for serious heart disease.Predict the severity of high blood lipid levels as risk factors for heart disease.Minimizing serious heart disease by taking care of its risk factors and thus reducing the oxidative stress caused by it, which causes many dangerous diseases.

Materials and Method

1. **Blood Samples:** Forty samples were collected at age (45-90) years (20) of the male and (20) female for both who was had IM and AP after being diagnosed by specialist doctors at Azadi Teaching Hospital and Kirkuk General Hospital. The sample collection period from 1/2 to 30/4 2019.
2. Five mL of blood was withdrawn from the vein and placed in the gel tube and placed in the centrifuge for five minutes at 4000 rpm and then separated the serum divided into three parts and was kept in small plastic pipes dry and clean and kept in freezing at -20 °C until it is used to measure variables.

Measurement of biochemical variables

Measurement of Reactive Oxygen Species (ROS): The ELISA kit uses the Sandwich-ELISA principle. The micro ELISA plate provided in this kit has been pre-coated with samples are added to the micro ELISA plate wells and combined with the specific antibody. Then a biotinylated detection antibody specific for Human ROS and Avidin-Horseradish Peroxidase (HRP) conjugate plate well and incubated. The optical density (OD) is measured spectrophotometrically at a wavelength of 450 nm. The OD value is proportional to the concentration of Human ROS. The concentration of Human ROS in the samples can calculate by comparing the OD of the samples to the standard curve.

Measurement of Glutathione Peroxidase 1 (GPX1)

The same method above was used.

Measurement of Troponin: The test uses a sandwich immunodetection method the detector antibody in buffer binds to antigen in the sample, forming antigen-antibody complexes, and migrates onto nitrocellulose matrix to be captured by the other immobilized-antibody on the test strip. The more complex leads to stronger intensity of fluorescence signal detector antibody, which is processed by instrument for ichroma tests to show Tn-l concentration in the sample.

Measurement of Creatine Kinase (CK-MB): CK-NAC modified reagent contains a polyclonal antibody which so completely inhibits CK-MM activity. Only the activity of the non-inhibited B monomer subunit, representing half of the CK-MB activity, is measured. The method assumes that CK- BB activity in the specimen is essentially zero[20, 21]

Measure of Cholesterol: The enzymatic method described by Allain [22] and al., which is the Cholesterol esters reacts

Measure of Triglycerides: Fossati[23] and Principle method associated with Trinder[24] reaction.

The absorbance of the coloured complex (quinoneimine), proportional to the amount of triglycerides in the specimen, is measured at 500 nm.

Measure of High-Density Lipoprotein (HDL): This reagent is only for the treatment of specimens before determination of HDL-Cholesterol with a reagent for total cholesterol. (LDL), (VLDL) and chylomicrons from specimens are precipitated by phosphotungstic acid (PTA) and Magnesium chloride..[25]

Results and Discussion

Level of (ROS) in Serum of Two Groups of Patients (MI, AP): The results in Table (1) and Figure (1) showed a Rise in the ROS level at (P-Value 0.045) in the serum of the two groups of patients with MI, AP compared to the control group. The reason for the rise is that it has been already established that ROS play a vital role in the progression of CVDs.[26, 27]

Table (1): Level (Mean ±St.d) of (ROS, GPX1, Troponin, C.K) in serum samples for the two groups of patients with MI, AP and control group

Group	ROS	GPX1	Troponin	C.K
Myocardial Infarction	7.326±1.143A	1890±391c	29.03±22.99A	110.62±45.71A
Angina Pectoris	6.037±1.669B	2109±600b	2.181±2.186B	39.730±12.79B
Control	5.158±1.046C	2368±401a	0.139±0.1717B	16.283±5.133C
P-Value	0.045	0.038	0.0008	0.00003

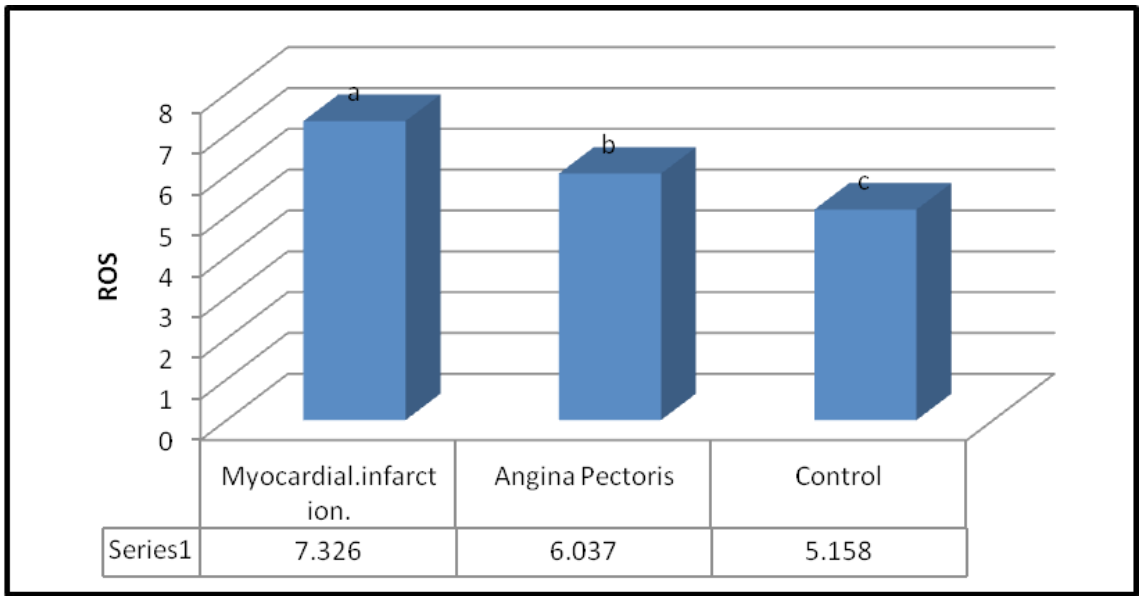

Figure (1): Shows the level of ROS in serum samples for the two groups of patients with MI, AP and control group

Level of Glutathione Peroxidase 1 (GPX1) in Serum of Two Groups of Patients MI, AP Compared to Control Group: The results in Table (1) and Figure (2) showed a Decline in the GPX1 level at (P-Value 0.038) in the serum of the two groups of patients MI, AP compared to the control group and the reason for the decrease in the level of GPX1 denote the increased oxidative stress[28-30].

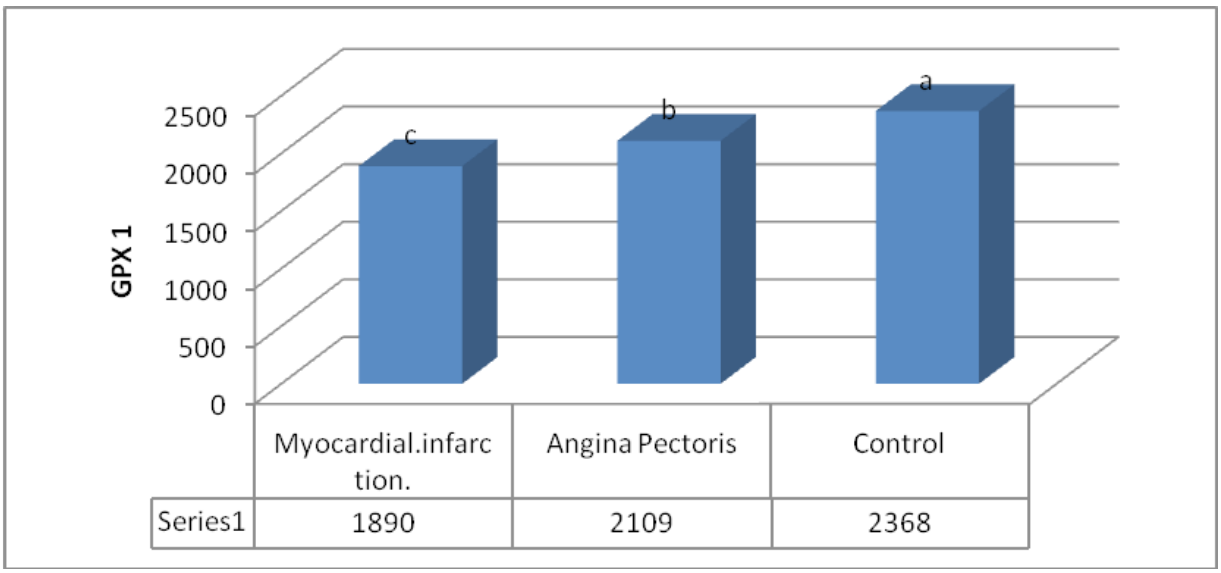

Figure (2): Shows the level of GPX1 in serum samples for the two groups of patients with MI, AP and control group

Measurement of Creatine Kinase (C.K.): The results in Table (1) showed a significant rise in the level of C.K at (P-Value 0.00003) in the serum of patients with MI compared with AP and the control group. The reason is that the enzyme CK -MB regulates adenosine triphosphate within cells to provide increased energy and the measurement of CK - MB was found to detect myocardial infarction and then used as a diagnostic marker for myocardial infarction.(31)

Measurement of Troponin (Tn-I): The results in Table (1) showed a significant rise in the level of troponin at (P-Value 0.0008) in the serum of MI compared to AP and control group, The reason is that troponins excreted into the bloodstream after necrosis of the heart muscle and are free proteins or complicated forms. After that, degradation of muscle fibres continues and once released into the bloodstream; troponin is subject to various biochemical modifications including phosphorylation, oxidative stress and proteolysis. In the case of myocardial infarction, there is an increase in the concentration of troponin when increased demand of oxygen to the heart muscle such as arrhythmias, high heart pressure and reduced oxygen supply as a result of increased tension on the heart muscle. (32)

Measurement of Serum Lipid Levels in Patients with MI, AP comparison with control:

Cholesterol: The results in the table (2) showed a significant rise in the level of cholesterol (P-Value 0.0009) in the serum of the two groups of patients with MI, AP compared to the control group. The reason is that cholesterol contributes to the formation of platelets that begin to clump and take place in the walls of the arteries between the inner and outer layers,(33)The increase in blood cholesterol causes a high risk that leads to the deposition of cholesterol in the blood vessels, causing partial or complete blockage of the vessels and the occurrence of strokes heart or brain.(33)

Table (2): Level (Mean ±St.d) of (Cholesterol, Triglyceride, HDL) in serum samples for the two groups of patients with MI, AP and control group

Group	Ch	T.G	HDL
Myocardial Infarction	344.6±67.4 A	240.3±58.5 A	43.00±6.89 A
Angina Pectoris	303.6±86.1 A	232.8±65.8 A	39.10±5.86 B
Control	159.2±50.30 B	102.9±35.60 B	31.00±3.085 C
P-Value	0.0009		0.0007

Triglycerides: The results in a table (2) showed a significant rise in the level of Triglycerides (P-Value 0.0008) in the serum of the two groups of patients with MI, AP compared to the control group. The reason is due to in the human body, high levels of triglycerides are associated with the risk of heart disease and stroke. This risk can be partially calculated by the relationship between triglyceride level and HDL level (34)

High Density Lipoprotein (HDL): The results in Table (2) showed a minimal rise in the level of HDL at the level (P-Value 0.0007) in the serum of the two groups of patients with MI, AP compared to the control group and the reason is due to an increased HDL in the blood gets a lower risk of heart disease and a very lower mortality rate in cardiovascular disease and that high-density lipoprotein is a protection and its presence prevents LDL oxidation. Epidemiological and clinical trials confirm an inverse relationship between HDL and heart disease risk (35)

Conclusion: ROS rises and GPX1 decline in cases of MI and AP this indicates oxidative stress which gives this test a high importance diagnostic. Troponin and creatine kinase rise slightly or within normal limits in the case of AP while they rise very significantly in the case of MI. Lipid levels are significantly elevated in both MI and AP and may be one of the reasons for these diseases.

Cell free DNA in Maternal Blood as an Indicator of Fetal Complications

Dhelal Qasim[1], Hanan L. Al-Omary[2], Shayma`a J. Ahmed[3]

[1]Lecturer Doctor, Medical College, Al-Iraqia University, [2]Assistant professor, Medical College, University of Baghdad, [3]Professor, Medical College, University of Baghdad

Abstract

Cell-free DNA (cfDNA) is a new biomarker that has been used in different aspects,especially in prenatal diagnosis and pregnancy complications. The aim of the study is to investigate the role of cfDNA in the prediction of fetal complications. Ninety women had been enrolled recruited from AL-Karkh Hospital from March to September 2018. Thirty of with diabetes mellitus and the other 60 with hypertension. The mean age of study sample was 29.7 ±6.33 years. History was taken from all women. Blood samples were collected and cfDNA was measured using PCR. No significant association was found between the primers for autism or the presence of SeritI gene and age or BMI in hypertensive and diabetic patients. It was concluded that there is no difference in the presence of autism gene primers and SitrtI gene primers between different age groups of pregnant women and different BMI index groups except for primer 3 in both hypertensive and diabetic ones.

Keywords: *Cell free DNA, Pregnancy, Fetal complications.*

Introduction

cfDNAis DNA parts which are found outside the nucleus. They are formed by apoptotic or necrotic mechanisms; they are also present in fluids of the body, so they can be used as indicators of pathological states [(1)].

cfDNAs that circulates in the maternal blood of healthy pregnant women is 3.4 to 6.2% of the whole DNA amount in the beginning and the end of pregnancy respectively. The sources of fetal DNA in maternal circulation are from a direct transfer of fetal DNA, placenta and blood cells[(2)].

The cfDNA vanishes from the blood of the mother maternal after labor except for those pregnant women with liver disease where high levels of fetal DNA are seen even after childbirth [(3)].

A possibility of having congenital problem is about 3-4%in all pregnancies[(4)]. So cfDNA is measured as a non invasive prenatal diagnosis especially in chromosomal aneuploidies, sex-linked diseases, blood diseases, fetal RhD type, preeclampsia, and paternally inherited problems[(5)]. Recently, the estimation of cf-DNA is used in clinical practice for the prenatal detection and screening of some fetal aneuploidies [(6)].

The elevation in the levels of cfDNA can predict the complications related to pregnancy before symptoms appear [(7)], although most of the studies showed the increase in cfDNA was early in the disease, but others proved the sustained increase inall stages, so it can be used to predict intrauterine growth retardation, placental previa, preterm labor, and hyperemesis gravidarum[(8)].

The aim of the study is to investigate the role of cell free DNA in the prediction of some fetal complications.

Materials and Method

Ninety pregnant women wereenrolled, recruited from AL-Karkh Hospital fromMarch to September 2018. Women with complicated pregnancy were included in this study (33%) were diabetics (DM) and (67%) were hypertensive (HPT). The mean age was 29.7 ±6.33.

History was taken from all women. Medical examination was done. BMI was calculated by the equation(Wight/(Hight)^2 [(9)]

Blood samples were collected in EDTA tubesand stored in (-20C^0).

Procedure of DNA extraction was done by adding proteinase K and four buffers . The DNA purity was determined by nanodorp spectrophotometer.

Two µl of DNA sample was added, the software calculated the nucleic acid concentration (ng/µl) at 260 nm.

The ratio of absorbance at 260 nm and 280 nm is used to assess the purity of DNA, the accepted ratios must range between 1.8-2.0[10] .

Primers of FMR1, C16, SEZ6L2 (forward F and reverse R) for detection of Autismgene, prepared by adding 100µl of de ionized water to the powder of the primer.

FMR1

Forward	5, _ GCT CAG CTC CGT TTC GGT TTC ACT TCC GGT – 3,	900 bp
Reverse	5, _ AGC CCC GCA CTT CCA CCA CCA GCT CCT CCA -3,	900 bp

C16

Forward	5'- ACT GCC CCA GCG AAG ATG -3'	500 bp
Reverse	5' -CCG ACC ACC CAG ACC -3'	500 bp

SEZ6L2

Forward	5' –CCT CTC TCT TCC CCA CAA AGG- 3'	1000 bp
Reverse	5' - TGG ACA GCC TGG TTC TCT CT-3'	1000 bp

Primers of A allel 1, A allel 2, G allel, G allel 2 (forward F and reverse R), for detection of SIRTI gene were prepared by adding 100µl of de ionized water to the powder of the primer.

A allel 1

Forward	5'- CCC AGG GTT CAA CAA ATC TAT GTT G-3'	900 bp
Reverse	5' – GCT TCC TAA TCT CCA TTA CGT TGA C-3'	900 bp

Forward	5'-GTA GCA GGA ACT ACA GGC CTG -3'	700 bp
Reverse	5'-CTA TCT GCA GAA ATA ATG GCT TTT CTC -3'	700 bp

The PCR mixture was done in a volume of 25 µl containing the DNA extracted primers, and PCR premix (**Accupowder ®** by Bioneer Company).

The Primers DNA were added into the PCR PreMix tube. Ðistilled water was put. The ßlue þellet was dissolved and spin down by þipetting. The reaction was maintained at 4°C and stored at (-20°C). The mixture (8µ) was loaded on gel to analyze the product of PCR.

For Autism gene all forward and reverse primers of C16 and FMR1 were added in one Gold multiplex

PCR Premix tube, the same way all forward and reverse primers of SEZ6L2 were added in another tube.

For SirtI genes all forward and reverse primers of G allel and G allel 2 were added in one Gold multiplex PCR Premix tube, the same way all forward and reverse primers of A allel 1 and A allel 2 were added in another tube.

PCR reaction tubes were centrifuged. The tubes were placed in the thermal cycler where DNA was amplified.

To detect the size of the amplicons, agarose gel electrophoresis was done.

Gel visualized in in gel documentation system/UV transilluminator revealing bands(primers).

All data were analyzed using SPSS 17.0 .All values were in mean ± SD, chi-square test was. A P value of less than 0.05 is significant.

Results

The study included 90 women, 30 of them with diabetic millets and other 60 were with hypertensive.

Table 1 shows no significant difference in age and BMI between hypertensive and diabetic patients.

Table 1: Comparison of age and BMI between pregnant women with diabetes and hypertension

			Disease		Total	P value
			DM	HPT		
Age	18-29 years	Count	13	33	46	0.297
		% within disease	0.28	0.72	0.51

Discussion

Diabetes mellitus and hypertension are two of the commonly seen pregnancy complications that adversely affect fetal outcomes [11].

The results of this study reveal that there is no difference between hypertensive and diabetic women in regard to age and BMI. Unlikeother studies which found that obesity is accepted to affect the pregnancy process

and it is risk factors for perinatal complications [12]. This result may be explained by the number of patients with high BMI in this study that were 54 out of 90 patients.

There was significant association between hypertension and agein increasing the probability of autism especially in primer 3,this was in agree with other studies which show relation of older parental age with the causes of ñeurodevelopmental conditions including autism[13].Also an updated review documented the relation between hypertension in pregnancy and risk of ñeurodevelopmental problems in the children. While parental age associated risk in ASD has been reported in different regions, with a prove that it is a risk for ASD,foundseparately for maternal and paternal age. It was shown that parental age-related risk is at its maximum in children where both the mother and father are old in age, and if the couples with high age differentials [14].

Concerning BMI and what was reached to in this study, the results were unlike that was found by other study which documented that maternal obesity was proposed to affect the brain growth cognition of offspring [15]. Obesity in mothers might affect fetal neurodevelopment, through low-grade neuroinflammation, high oxidative stress, insulin resistance, glucose, and leptin signaling, non regulated serotonergic and dopaminergic signaling, and changed DNA methylation patterns[16]

Concerning diabetic pregnant women the results in this study were similar tothe studywhich does not support the suggestion about the link between diabetes and ASD [17], also another study did not find an increased risk of autism for babies born to women who were already diagnosed with diabetes before getting pregnant. This might be in part because women with diabetes who become pregnant have made lifestyle modifications that keep their sugar levels in check and may also be taking medications to control their blood sugar. Similarly, those diagnosed with gestational diabetes after 26 weeks did not have an increased risk. The study authors speculated that being exposed to untreated high blood sugar during critical brain development early in the pregnancy may have contributed to the autism risk[18].

Studies examining the effect of diabetes in mothers on autism in offspring have shown variable results. A review collecting 16 studies [19] showed additional risk for autism in thepresence of maternal diabetes, while high levels of variation in study outcomes and publication bias were detected; these disappeared when meta-analysis was restricted to case–control studies, with the risk of ASD increasing by 62% among diabetic mothers, compared with non-diabetic mothers. There is evidence that timing might be significant in the association between maternal diabetes and offspring with ASD [20].

There is no significant influence of hypertension and diabetes in relation with age and BMI on the presence of SIRTI gene primers.Although the positive results in primers 1,2,3,4 were much more than the negative results but it is not significant and this may be due to small sample size.

Accumulating studies have revealed that deacetylase Sirtuins exert protective functions against pathologies like diabetes and hypertension [21].

In obesity, mitochondrial dysfunction may direct fatty acid to intracellular lipid accumulation, leading to insulin resistance. SirtI activation can protect the neuron cells exposed to neurotoxic insult. During cerebral hypoxia, the level of ATP and oxygen are lowered, which stimulate bioenergic and oxidative stress leading to Sirti activation[22].This was shown in the results of this study which illustrate the increasing positive number of Autism primers associated with positivity of SirtI gene primers because it is neurodegenerative protective gene.

Conclusion: There is no difference in the presence of autism gene primers and SitrtI gene primers between age groups BMI index groups of pregnant women except for primer 3 in both hypertensive and diabetic ones.

Conflict of Interest: There is no conflict of interest to be mentioned.

Source of Funding: The study was done with personal funding.

Ethical Clearance: The study was approved by the ethical committee of the medical college of university of Baghdad. An informed consent was taken from patients.

Modified Early Warning Score Performance in Predicting the Outcome of Head Trauma Patients in Emergency Department

Didik Mulyono[1], Nurdiana[2], RinikEko Kapti[3]

[1]Nursing Master Program Study, [2]Pharmacology Department, [3]Nursing Department Faculty of Medicine Universitas Brawijaya Malang Indonesia

Abstract

Modified Early Warning Score (MEWS) is a useful scoring system that detects physiological changes in identifying adult medical surgical patients at risk for deterioration and death. Although it is a good predictor of deterioration and mortality in hospitalized patients, the performance of MEWS in the ED and specifically in head trauma patients is still untested. The purpose of this study was to assess the performance of MEWS in predicting the outcome of head trauma patients in ED. We conducted a retrospective observational study at RSUD dr. Soedono Madiun, East Java Province, Indonesia. The sample using the medical record of patients with moderate-severe head trauma adjusted to the inclusion and exclusion criteria and used purposive sampling technique as many as 181 respondents. Multivariate analysis of ordinal logistic regression to determine the MEWS parameters that most influenced the outcome of head trauma patients, while the ability to predict outcomes was assessed using The Area Under Receiver Operating Characteristic (AUROC) analysis. The ordinal logistic regression results show that AVPU parameters show an Odd Ratio (OR) value of =2.89, meaning that the poor AVPU parameter measurement results have a risk of obtaining a death outcome of 2.89 greater than the outcome of moderate disability, severe disability, vegetative state persistence. The AUC MEWS value to predict the outcome of head trauma patients was 0.777 (95% CI; 0710-0,836) so that based on the AUC value the level of accuracy of MEWS's scoring predictions was in good classification. In conclusion, MEWS's ability shows good performance in predicting the outcome of head trauma patients.

Keywords: *ED, Modified Early Warning Score, Outcome of Head Trauma Patients*

Introduction

Head trauma is the third largest cause of death in the world after cardiovascular disease and neoplasm[1]. Head trauma results in high costs in the treatment system. Early detection and proper management will provide optimal results and reduce maintenance costs[2]. The outcome of trauma patients depends on the severity, the accuracy of the initial assessment and the time to reach the place of care. Rapid and appropriate assessment can reduce long-term mortality and disability[3].

The initial evaluation of a patient with trauma is influential for the management of patients with head trauma. Mortality may decrease if head trauma patients are immediately evaluated for proper treatment at the hospital. Preliminary assessments that only use the Glasgow Coma Scale (GCS) to identify the severity of head trauma lack accurate results, so they often fail to detect the risk of worsening conditions in some age groups[4,5]. In recent years, several scoring systems have been developed to determine whether patients need intensive care, medication, and appropriate treatment[6]. Scoring system was also developed to evaluate the severity of patients with trauma and will also provide an objective assessment of the patient's initial clinical condition as part of determining trauma management[7].

MEWS is a simple and fast physiological scoring system that can be applied by nurses. MEWS is performed by summing physiological data which includes systolic blood pressure, pulse, respiration, body temperature and level of consciousness. A higher MEWS score at the time of admission to an Emergency Departement (ED) is correlated with an increase in the need for hospitalization and the risk of death in the hospital[8].

The ability of MEWS to predict prognosis is very

good. MEWS is also used as a communication facility between nurses and the medical team when the patient's condition worsens[9]. The research conducted by Chang et al (2018) stated that MEWS has a good predictive value for the mortality of renal abscess patients. The value of Area Under Curve (AUC) of MEWS in predicting hospital mortality was 07826[10]. Similar results were also obtained from the results of the study from Xie et al (2018), discrimination of MEWS in patients with an AUC value of 0.9, this means that MEWS is very good at predicting mortality in ED[11].

Various studies related to the validity of MEWS score in the trauma population have been carried out. However, as far as the researchers know there has been no research on the validity of MEWS in populations that are specific to head trauma patients. Whereas, head trauma is a type of trauma that most often causes mortality and morbidity compared to other types of trauma. The aim of the study was to determine the validity of the MEWS in predicting the outcome of patients with head trauma in ED.

Material and Method

This study used analytic observational design with retrospective cohort approach in RSUD dr. Soedono, Madiun, East Java, Indonesia, on March 2019. There were 181 medical records data selected by inclusive and exclusive criteria. Samples were obtained using purposive sampling method where researchers choose some samples according to researchers' preference which meet the inclusion and exclusion criteria. The variables of this study were MEWS scoring and the outcome of head trauma patients. Data collected included age, sex, education, occupation, causes of head trauma, MEWS parameters and outcome of head trauma patients. In MEWS calculation, five parameters were each scored from 0 to 3 (table 1). Data was analyzed with the help of SPSS For Windows Version 20 and Medcalc Software. Ordinal logistic regression analysis used to determine the MEWS parameters that most influential to the outcome of head trauma patients. The AUROC was used to assess the ability of MEWS to distinguish good outcomes and poor outcomes.

Table 1: The Modified Early Warning Score

	3	2	1	0	1	2	3
Systolic Blood Pressure	<70	71-80	81-100	101-199		≥200	
Heart Rate		<40	41-50	51-100	101-110	111-129	≥130
Respiration		<9		9-14	15-20	21-29	≥30
Temperature		<35		35-38.4		≥38.5	
Score AVPU				Alert	Reaction to voice	Reaction to pain	Unresponsive

AVPU: A: alert; V: responding to voice, P: responding to pain; U: unresponsive.

Findings:

Table 2: Characteristics

Variable	Classification	N	%
Gender	Male	128	71
	Female	53	29
Age	16-25	41	23
	26-35	21	12
	36-45	20	11
	46-55	37	20
	56-65	36	20
	>65	26	14
Education	No school	1	1
	Elementary School	71	39
	Junior High School	25	14
	Senior High School	72	40
	College	12	7

Variable	Classification	N	%
Job	Unemployed	19	10
	Salesman	4	2
	Employee	66	36
	Entrepreneur	8	4
	Farmer	45	25
	PNS/TNI/POLRI	9	5
	Student	30	17
Cause of Head Trauma	Traffic Accident	155	86
	Falling down	26	14

Table 2 shows most of the patients were male with 128 people (71%). Based on the characteristics of age, the highest respondent age with a percentage of 23% was the age group 16-26 years. The job of respondents with the percentage of 36% from the total respondents was private employees. The cause of head trauma, almost all of which was a traffic accident with the percentage of 86%.

Table 3: Respondent Frequency Distribution Based on the Results of MEWS Scoring

No	Variable	Classification	Frequency (n)	Percentage (%)
1	MEWS	Low Risk (0-2)	33	18
2		Medium Risk (3-4)	72	40
3		High Risk (≥5)	76	42
Total			**181**	**100**

Table 3 shows that out of 181 patients, 76 or 42% included in the high-risk classification, while 33 (18%) included in the low risk classification.

Table 4: Respondent Frequency Distribution Based on the Outcome of Head Trauma Patients

Variable	Classification	Frequency (n)	Percentage (%)
The outcome of Head Trauma Patients	Good recovery	0	0
	Moderate Disability	36	20
	Severe Disability	54	30
	Persisten Vegetative State	3	2
	Death	88	48
Total		**181**	**100**

From table 4, the results show that 88 or 48% of the respondents classified in death, whereas none of the respondents classified in good recovery.

Table 5: Multivariate Test for MEWS Parameters

		Estimate	Std. Error	Wald	Sig.	Odds Ratio
Threshold	[Outcome = 2]	3,850	1,286	8,958	0,003	
	[Outcome = 3]	5,590	1,323	17,853	0,000	
	[Outcome = 4]	5,673	1,325	18,333	0,000	
Location	SBP	0,018	0,006	8,328	0,004	1,02
	PULSE	0,005	0,008	,362	0,547	1,01
	RESPIRATION	0,028	0,027	1,098	0,295	1,03
	TEMPERATURE	-0,005	0,006	0,677	0,411	1,00
	AVPU	1,060	0,184	33,150	0,000	2,89

Table 5 showed AVPU parameter OR = 2.89, meaning that the poor AVPU parameter measurement results have a risk of getting a death outcome of 2.89 greater than the outcome of moderate disability, severe disability, persistent vegetative state.

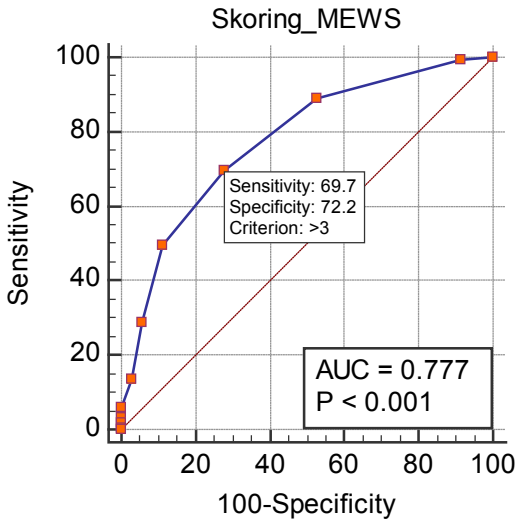

Figure 1: ROC MEWS

Figure 1 showed that the ROC curve is generated from various cut of point values. It can be seen that the ROC curve is above the reference line. The AUC value produced is equal to 0.777 (95% CI; 0710-0,836), therefore, based on the AUC value the level of accuracy of the predictions of MEWS scoring considered as good classification.

Discussion

Based on the results of the study it was found that almost all respondents (128.71%) were male. This result is almost the same as the research conducted by Hartoyo, Raharjo, & Budiyati (2011) which found 75.4% of respondents were male[13]. Factors that may caused high moderate-to-severe head trauma in men include physical activity and work that is riskier than women. But according to Marcolini, et al (2018) the high incidence of head trauma in men was not only due to physical activity and work, there were hormonal factors in men that will trigger stress and lead to risky behaviors of head trauma such as drinking alcohol while driving[14].

The results of this study indicated that moderate-to-severe head trauma is most experienced by the age range of 16-25 years. This finding is in accordance with the findings of previous studies showing that the age group of 15-24 years was the most group experiencing head trauma, in which this is a group of young adults who have high productivity and activity[15]. Motor vehicle accidents are the most common cause of head trauma in the age group 15-19 years and 20-24 years[16]. The high rate of head trauma in this age group due to traffic accidents is possible because of the high mobility and psychological development, where young adults have an unstable psychological development so they often fails to control emotions. This situation caused a lack of awareness in driving.

Based on the type of job, in this study the highest number was private employees with 66 respondents (36%). The results of this study are somewhat different from the results of the study by Krisandi, Utomo, & Indriati (2011) which stated that the type of job of head trauma respondents is students[17]. From the results of the study and the fact in previous research, it can be assumed that the type of job had a connection with the incidence of head trauma, and this can be seen from the factors causing head trauma in this study, most of which were traffic accidents (86%). So, it can be concluded that the more often jobs require activities on the road such as riding motorbikes, cars, rickshaws and pedestrians, the higher the possibility of head trauma.

The multivariate test results, AVPU parameter OR= 2,89, meaning that the poor AVPU parameter measurement results have a risk of getting a death outcome was 2,89 and greater than getting moderate disability, severe disability, and vegetative persistence state.AVPU is a simple method of measuring the level of consciousness and used during initial contact with patients. According to Lumbantobing & Anna (2015) the level of awareness can be used as one of the indicators of emergency and prognosis in head trauma. This decrease in awareness can affect the fulfillment of the patient's basic needs[18]. Maas & Steyerberg (2014) stated that the prognosis model of head trauma using level of consciousness showed good prognostic performance[19].

MEWS discrimination scoring performance in this study is good, indicated by the AUC value of 0.77 (95% CI, 0710-0,836). The AUC value in this study is different compared to the findings in previous studies. In the study of Ghanem-zoubi, Vardi, Laor, Weber, & Bitterman (2011) who examined sepsis patients with predictions of ED mortality, it was obtained AUC score of 0.69 or in the fair prediction category[20]. Bulut et al (2014) who examined the medical case population and surgery for patients who came to the emergency department on mortality received an AUC value of 0.568 [21]. The

same finding was also obtained from the results of the Kruisselbrink et al (2016) study with an AUC value of 0.692[12].

These difference in the performance of discrimination can be explained because the types of cases used in this study were more focused on patients with head trauma. In head trauma patients, physiological status which includes systolic blood pressure, pulse, respiration, body temperature tends to be unstable as a result of auto regulation after experiencing head trauma. Findings that contradict the previous findings provide direction that in the initial assessment of head trauma patients, the doctor cannot only rely on neurological status in determining the degree of mild weight and predictions of head trauma outcomes but also must consider physiological changes.

Conclusion

This study found that MEWS's ability to predict the outcome of head trauma patients showed good performance, so it is necessary to use MEWS scoring as one of the early detection systems or Early Warning Score System (EWSS) in head trauma patients in ED.

Contraception Counseling to Reduce Postpartum Unmet Needs: A Qualitative Study at Samarinda, Indonesia

Dini Indo Virawati[1,2], Yayi Suryo Prabandari[3], Siswanto Agus Wilopo[3]

[1]Doctoral Program, Faculty of Medicine, Public Health and Nursing, Universitas Gadjah Mada, Yogyakarta, [2]Health Polytechnic Kalimantan Timur, Samarinda, [3]Faculty of Medicine, Public Health and Nursing, Universitas Gadjah Mada, Yogyakarta, Indonesia

Abstract

Introduction: Family planning (FP) counseling has a large potential as a strategy for reducing postpartum unmet needs. This study aimed to explore the present-day implementation of FP counseling, and the expectations of providers and recipients of FP counseling.

Method: The research design was a qualitative phenomenological study conducted at Samarinda City, East Kalimantan Province, Indonesia. The research participants were selected with a maximum variation of purposive sampling. The data analysis used thematic analysis.

Results: This study found that FP counseling is currently integrated with ANC. All available method are explained so that clients are confused and forgetful. The choice of method is based on medical questions only. FP counseling is expected to adjust to reproductive needs by cooperation a partner. The clients need more information about the method chosen using practical media counseling. Necessary additional health information and counseling media that can be taken home.

Conclusion: At present there are still weaknesses in FP counselling. It is expected that counseling sessions are more practical, integrated with ANC, concise, easy to remember, meet reproductive needs, cooperation partners and be accompanied by other additional information. The use of a modified Balanced Counseling Strategy (BCS) for pregnant women is a wise and strategic choice.

Keywords: *FP counseling, postpartum unmet needs, balanced counseling strategy.*

Introduction

In developing countries,approximately 214 million women in 2017 at childbearing age wanted to avoid pregnancy but did not use modern contraceptive method.[1] Unmet needs for contraception in Indonesia are relatively low compared to other developing countries. The results of the Indonesian Health Demographic Survey (IDHS) in 2012 showed that unmet needs in Indonesia was about 11.4%, consisting of 4.5% of spacing pregnancies and 6.9% of limiting pregnancy. High unmet need areas in Indonesia are spread in 10 provinces. One of those is Samarinda City in East Kalimantan Province. Based on data from the 2017 Population and FP Control Board (DPPKB), the unmet needs in Samarinda City was 19.7%, consisted of 9.37% of spacing pregnancy and 10.33% of limiting pregnancy.

The largest proportion of unmet needs for contraception was found in women in the first year after giving birth.[2] Two-thirds of postpartum women do not want to get pregnant, but do not use contraception. The average postpartum unmet needs in Indonesia from 2007 to 2015 was 26.4%. However, only 50% of Indonesian women start using contraception after 6 months of labor.[3]

FP counseling has a high potential as a strategy to reduce postpartum unmet needs by improving the service quality. The main element for improving service quality is improving the interaction between clients and FP service providers.[4] So, the best strategy to reduce unmet needs is to improve the quality of FP counseling.

Strategy to reduce postpartum unmet needs through FP counseling has been performed, but there are still women who do not want to get pregnant but do not use contraception. Therefore, needed qualitative study aimed to explore the implementation of FP counseling and identify the expectations of providers and recipients of FP counseling.

Subjects and Method

We used a qualitative phenomenological approach to explore views and opinions about FP counseling in Samarinda City, East Kalimantan Province, Indonesia.

The subjects were 8 people selected by purposive sampling considering the maximum sample variation. The selected subjects represented 3 groups of participants: 1) The policy makers(the head of the publichealthdepartment, the head of the development and FP participation section of the Population and FP Control Board (DPPKB), and the head of the primary health care), 2) The counselors namely the midwife in charge of FP clinic, and 3) The clientsare pregnant womens who have received FP counseling.

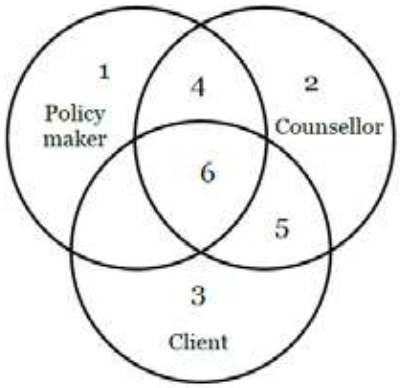

Figure 1: Participants and explored data

Interviews are conducted by someone who works as a midwife and lecturer and has completed education in the field of public health at the master level. Data were collected by interviewer through semi-structured interviews and observing the implementation of FP counseling. The instrument consisted of three interview guides to support the triangulation method. The group of participants and the data collected are illustrated in Figure 1. Data that were explored included: 1) Policy support, 2) Training of FP counselors, 3) Willingness to receive FP counseling 4) Strategies to reduce postpartum unmet needs, 5) Information on contraceptive method, contraceptive needs, cooperation with partners, and addition of other health information, and 6) Expected FP counseling.

The data were analyzed thematically, using the six steps of qualitative data analysis according to Creswell (2014), namely 1) Transcribe of interview recording results and notes of important events during the data collection process, 2) Coding data, 3) Building categories and themes (using OpenCode 4.03), 4) Describing data, 5) Making comparison between findings and literature, and 6) Ensuring accuracy of findings which are validated by applying triangulation and reflexivity.

Results

From the results of interviews, we classified the quotations into two themes are presented in Table 1. and Table 2.

Current FP Counseling: In Samarinda city, FP counseling received support from policy makers through integration with ANC services and written in standard operating procedures (SOP). The counseling about postpartum contraception is not only done in the FP clinic, but is routinely delivered when the ANC conducts pregnant women class. FP counseling is delivered by midwives, however not all midwives have received FP counseling training.

Table 1: Examples of Quotes from Current FP Counseling Theme

Integrated with ANC:
"It has been integrated, we still delivered the postpartum birth control materials at ANC, also in the class of pregnant".(P.3, head of primary health care)
All method are explained:
"All of them are explained, I don't remember, I forgot a little, I was explained but a bit confused actually ". (P.8, pregnant woman)
Basic method selection
a. Medical question: "We asked about age, date of birth, period, how many children, history of illness here we already have it in accordance with the existing form". (P.6, midwife).
b. Reproductive needsare not asked: "Counseling is lacking as needed, so sometimes the goal is not achieved, the pregnancy that is too close is still there". (P.2, Health Office)

The research showed that midwives explained the types and contra indications of various method available at the primary health care. Clients felt that they have received too much information on contraceptive method so that clients felt confused and forgetful. Midwives also felt that FP counseling is currently less effective because the media used seems to require the midwife to explain all the method before helping the clients make choices.

The choice of contraceptive method has not been based on fulfilling the client's reproductive needs. Midwives use medical questions available on the form as the number of children, history of labor, and history of illness. The questions about fulfilling reproductive needs such as "Do clients still want to have more children or not?" were often ignored. The partner cooperation for method selection was not discussed during FP counseling.

FP counseling that is expected: Some participants argued that FP counseling is better delivered since ANC, because when the mother gave birth was constrained by physical changes, and the psychological condition of mothers who gave birth such as breast pain and baby blues. Some mothers were late for post-natal care (PNC). There are mothers who are pregnant again because they think they will not get pregnant before menstruation returns.

Table 2: Examples of Quotes from the Expected FP Counseling Theme

Integrated with ANC "It's better for FP counseling since from ANC because she waits for the menstruation occur, she comes for post-natal care, as soon as we check the pregnancy test, the result is positive". (P.5, Midwife)
According to reproductive needs and cooperation partner "I think it is necessary asking for the purpose of using the methodandcoperationfrom their husbands because it is indeed adjusted, leading to wanting to have more children, yes or no more". (P.6, Midwife).
Counseling material
a. Practical: "I think, the old method may be okay, but it is not implemented well, or maybe there must be a more practical method". (P.4, Head of Primary health care)
b. Compact and easy to remember: "More concisely, she keeps on remembering it, so she can choose it more precisely, because she understands, not because she merely said yes." (P.1, DPPKB)
c. There is additional information: "It could be, we explain the prevention of HIV, or cervical cancer, only if there is a guideline". (P.6, Midwife)
Counseling media can be taken home: "It is necessary, would be happy, so that we can read at home right, so later we will be able to, I mean that it can be thinking about it first". (P.7, Pregnancy women).

The choice of method should be adapted to the reproductive needs of the client (spacing or limiting pregnancy) and cooperation the partner in determining the choice of method. The informant stated that there were still women who did not want to have a child anymore but chose a short-term contraceptive method because they considered only the best method.

Practical counseling is needed so that the information delivered is concise and easy to remember. Information about the additional benefits of FP may increase motivation for FP. Other health information such as HIV prevention and cervical cancer make it possible to add to this. The addition of counseling time is not a problem for clients or midwives because other health information is also needed.

The clients being given print media to learn at home is considered a good idea that makes it possible to try to help clients recall information that has been delivered. The clients also stated that it is necessary and they are happy to be given counseling media to read at home.

Discussion

Current FP counseling: This study found that Samarinda City FP counseling to promote contraception immediately after birth has been integrated with the maternal and child health (MCH) program. MCH program serves as a "gateway" to reach women throughout the reproductive period to increase access and use of contraception.[5]FP counseling at the ANC has repeatedly been shown to increase post-natal birth control.[6]The counseling is given after delivery but the the client planning to use contraception should be identified since the ANC.[7]

This study showed that current FP counseling hasweaknesses. Midwives seem to have explain all available method while clients feel that they receive too much information that is not relevant to the method of choice. Submission of information that is irrelevant by the service provider is one of the barriers to fertility regulation.[8]Thi is a major cause of unmet needs and continuity barriers to contraceptive use.[9-11]

The providers did not discuss the client's wishes in determining the choice of contraceptive method,

but preferred medical questions in the available forms. The provider did not ask about the client's reproductive intentions (the number of children she wants and the willingness of the partner to cooperate).

FP counseling is expected to reduce unmet needs for postpartum: FP counseling is betterbegan since the ANCrather than PNC. Previous studies found a relationship between PNC and postpartum contraceptive use was lacking, this may be due to limited PNC intensity.[12]Promoting the use of postpartum contraception since ANC is an important strategy because ovulation can return as early as four weeks after delivery, and women may become pregnant before menstruation returns.[10]

The clients hope to get more information about the method chosen. Although the duration of counseling is not a problem, service providers should use time efficiently, more practical in assessing client needs, and avoid giving too much information to irrelevant method. The provider must focus on the method chosen by the client and discuss the method in more depth.[13]

The client's reproductive needs for spacing or limiting pregnancy need to be asked, so that the client is able to decide on the appropriate FP method reproductive needs. Intentions to use contraception that were not asked, caused the selection of method to be incompatible with the purpose of contraceptive use and had an impact on the continuity of contraceptive use.[13]

FP counseling needs to cooperation the partner, and this is reasonable.Some men expect to have a discussion before using contraception.[14]In fact, women who were confident of gaining support from their partners were twice as likely to use contraception.[15]Otherwise, 43% of women stop contraception on the grounds that they are opposed by partners.[16]Therefore, questions about the willingness of partners to work together should not be ignored.

Addition of other health information makes it possible to add. Integrating other health information with FP counseling is an ideal strategy to improve the effectiveness of FP programs, improve cost efficiency, and the possibility of clients accessing additional health services.[17,18]

Participant felt the need for counseling media to be learned at home to make it easier for clients to remember information obtained from midwives. The women given leaflets after FP counseling sessions showed there was a significant increase in contraceptive use.[19]

FP counseling that is expected integrated with ANC, practical,information was concise, clear, easy to understand, and easy to remember. The expected FP counseling is similar to the Balanced Counseling Strategy (BCS).[20] BCS has been proven to improve the quality of FP services, increases contraceptive use and continuity of use.[21]

We concluded that weaknesses were still found in the implementation of FP counseling. FP counseling which is expected to reduce unmet need postpartum is similar to BCS. Therefore,we recommend that considering the use of BCS after adjusting for pregnant women is a wise and strategic choice.

Conflict of Interest: Authors declare that there is no conflict of interest whitin researh, publication paper and funding support.

Outbreak of Diarrhea in Pondok Duta Elementary School, Depok, 2018

Djadjuli, HNG.[1] Sudaryo, MK.[2]Budi, DAS.[3]

[1]Magister Study Program of Epidemiology, Faculty of Public Health, Universitas Indonesia, [2]Dept. Epidemiology, Faculty of Public Health, Universitas Indonesia, [3]Indonesian Epidemiologist Association

Abstract

Introduction: Diarrhea is an endemic disease in Indonesia. Diarrhea in Pondok Duta Elementary School, Depok was determined as an outbreak in 2018. The purpose of this study is to define the factor associated with diarrheal incidence and provide a recommendation for the outbreak prevention in the future.

Method: This study is used retrospective cohort design, Chi square test andCox regression Proportional Hazard Regression Model.

Results: 335 students(50,2%) were reported diarrhea in October 2018. Bivariate analysis showed that diarrhea was significantly associated with snack behaviour (RR=1.58,95% CI=1.32-1.89,p=0.000), drinking refilled water (RR=1.3,95%CI=1.11-1.52,p=0.003), use of water from old well (RR=1.24,95%CI=1.06-1.45,p=0.010) and cutting nail (RR=1.21,95% CI=1.02-1.44,p=0.038). In final cox regression model, diarrhea was significantly associated with snack behavior (RR=1.70,95%CI=1.34-2.17,p=0.000)and use of water from anew well (RR=0.70,95%CI=0.53-0.93,p=0.010).Coliform and E.Coli were detected in the refilled water samples.

Discussion: There was a great risk of infectious diarrhea among the students for two weeks. Snack behavior was the strongest factor in students diarrhea. Use of water from a new well was considered to be protective against the incidence of diarrhea. Improvement in providing healthy food at the canteen including maintaining the strict food hygiene, sanitation regulation and practices were essential. This recommendation needs to be followed up by the school administrators and local authorities.

Keywords: *Diarrhea, outbreak, elementary school, water, snack, hygiene, sanitation*

Introduction

Diarrhea is an endemic disease in Indonesia. Diarrhea causes 15-34% of mortality in Indonesia[1]. In 2015, there were 18 times diarrheal outbreaks in 18 districts/cities, with 1.213 people and 30 mortality (CFR 2.47%)[2]. In 2018, the prevalence of diarrhea in Indonesia was 8% and in West Java was 8.6%[3]. Diarrhea cases found and handled in Depok, 2017 were 33,583 cases (69.6%)[4]. Pondok Duta Elementary School as a place of research was due to diarrhea cases being designated as outbreak in 2018.

Method

Design and Subject: This investigation was conducted using a retrospective cohort design. The investigation was conducted from October 14th-18th 2018 in Pondok Duta Elementary School. The number of samples were 677 students. The definition of diarrhea used was the condition of a student defecating with liquid consistency even in the form of water and a frequency of three times or more in one day[5].

Data of outbreak consisted ofsocio-demographic characteristics, illness status, clinical symptoms, onset, and individual behavior for the past two weeks before the investigation.

Environmental Assessment and Laboratory Test: Environmental assessment in school included examination of water from the old well and new well, septic tanks, hygiene of food in the canteen and hygiene of refilled water. Testing of water samples was done to

see biological, physical and chemical contamination. Testing of food from canteen and fecal samples from patient was conducted to confirm the presence of microorganism.

Statistical analysis: All data were imported and analyzed using the Stat a application. The univariate analysis was done to describe case distribution based on characteristic of person, place and time. Bivariate analysis was conducted to determine associations between all risk factors and diarrheal incidence using *Chi-Square* tests. Multivariate analysis was done by using Cox Proportional Hazard Regression Model.

Result

Surveillance data showed an increase of diarrheal cases from late September until mid-October 2018. Within this period, 335 cases of diarrhea were reported. The peak of the curve occurred on October 10th 2018 with 56 cases (Figure 1). Our investigation found that the attack rate of diarrhea was 50.2%. Most predominant symptom was abdominal pain (Table 1).

Further bivariate analysis showed that the incidence of diarrhea was significantly associated with snack behavior in the canteen, drinking of refilled water, use of water from old well, and cutting nail. In the final Cox regression model, snack behavior in the canteen was the strongest risk factors of diarrhea. Use of water from a new well was considered to be protective factor against diarrhea (Table 2).

The foods or drinks for students were brought from home, catering or school canteens. Observation of canteen, snacks were in the form of packaged or ready-to-eat or drink that must be mixed. Canteen used drinking water from the gallon water. Cookware was washed using water from the new well.

Refilled water from school was taken from a vendor. In early October, the school took an initiative to replace vendor because there was dirt in the gallons of refilled water.

Sources of clean water for students were from the old well that had been used more than 25 years and a new well that has been used for two years. Clean water is used for the purposes of ablution, hand washing, and toilet. On October 9th, students complained that the tap water of ablution produced smelling water. The old well had not been used and the distortion of the water has been diverted using water from a new well.

The samples of clean water were taken directly from both wells. Food sampleswere taken from the canteen. A refilled water sample was taken from an previous vendor. Stool samples were taken from patients who were still sick.

The septic tank was ±8 meters from the old well and ±25 meters from the new well. The soap for washing hands was often not available.

Laboratory results of water from old well showed E.coli were still below the threshold value of clean water. Chemical and physical parameters of water from the old well were still in normal value but pH of water was below normal value. Laboratory results of refilled water and water from new well showed total coli form and E.coli. Vibrio cholera and Salmonella were not found. The results of biological culture (food and stool samples), E.coli, Vibrio cholera and Salmonella were not found (Table 3).

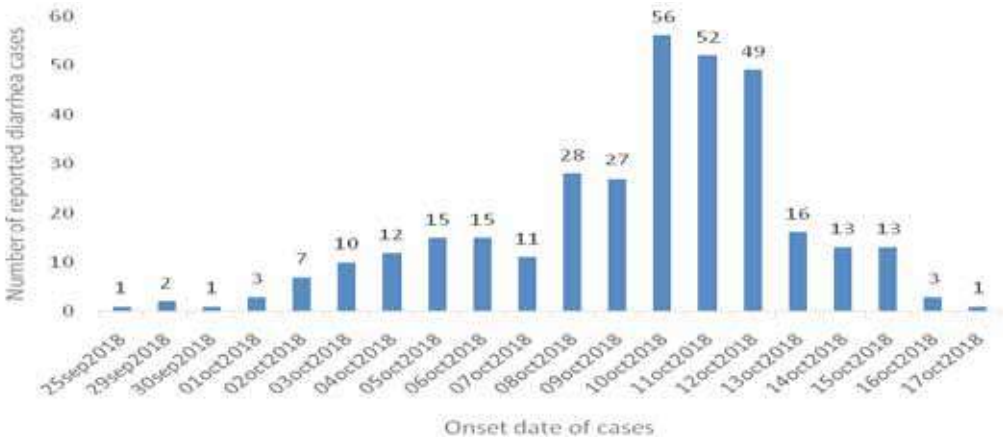

Figure 1. The EpidemicCurve of Reported Diarrhea

Table 1: Population Characteristic of Outbreak Respondens

	Overall (n=667)	**%**
Age–median (years) mean min-max	9 8.9 5 - 12

Discussion

Snack behavior was the strongest factor in students diarrhea. It's like the studies of Dyna, Lambu, Nita and Almanfaluth, there were association of snack with diarrhea in Pekanbaru ($p = 0.01$)[6], Banjarbaru ($p<0.05$)[7], Mraggen ($p=0.06$)[8] and Banyumas ($p=0.002$)[9].

Contaminated food is defined as food which if consumed by humans will cause disease; foods that contain pathogenic microorganisms cause disease; foods that have decreased in quality from standards; foods that have experienced physical deviations that exceed the limits of quality standards, include irregularities in aspects of color, texture, smell and forms[10]. The selection of food ingredients is usually not guaranteed quality, besides the method of storing food is not done properly so as to cause contamination from bacteria and viruses[11]. Colonies of microorganism were not found in biological cultures. It could be caused by volume and various of food samples were limited and the students got diarrhea had antibiotic treatment before.

Drinking refilled water was the factor of students diarrhea too. It's like studies of Yulviana and Ayuningrum, there were association of refilled water with diarrhea in Birobuli ($p<0.05$)[12] and East Java (OR 4.41; $p=0.042$).[13] Coliform and E.coli should not be found in drinking water[14]. This can be caused by lack of sanitation hygiene in the process or transportation. The result of Lipinwati study showed there were 38,10% samples of refilled water contained fecal coliform, and 64,29% samples contained non-fecal coliform[15].

The preference of refilled water vendors must consider the legal aspects such as distribution permit and the protocol of quality inspection. The presence of microrganisme prove the existence of contamination in the process of supplying drinking water. Hygiene and sanitation in the process of refilled water need to be improved and evaluated. Laboratory examination of refilled water parameters must be done routinely to ensure the quality of government standard.

Like the studies of Putra and Bumulo in Karangnyar (OR=3.232,95% CI=1,294-8,074,p=0.018)[16], and Gorontalo (OR= 1.61,95% CI=1,15-2.26,$p<0.05$)[17], clean water supply was the factor of students diarrhea.

The distance of 10 meters between septic tanks and wells has become common knowledge in community. The reason is water from well is not contaminated with septic tank water by pathogenic bacteria that can interfere with health[18]. The old well as a source of clean water has the risk of diarrhea due to the distance less 10 meter from the septic tank. Indonesian National Standard (SNI) 03-2916-1992, the horizontal distance of the well upstream from groundwater flow or source of septic tank is more than 11 meters, while the well distance for communal septic tank to housing is more than 50 meter[19].

Septic tanks are dirt and rarely sucked can seep into the surrounding soil and groundwater. Pipe systems are susceptible to contamination due to leakage and negative pressure caused by irregular supply[20]. Septic tanks should be given a layer of cement, becoming waterproof so as not to contaminate the surrounding soil. The well excavated must be coated until the cement is at least 3 meters deep to prevent bacterial contamination. Drainage of sediments in reservoirs is also needed to reduce soil deposits contaminated with pathogenic bacteria from septic tanks[19].

pH of this water was lower than the standard. Pure water is neutral, with it's pH at 25 ° C set as 7.0. There is no relationship between pH in drinking water and its effect on health. The pH of stomach fluid is with a mean of approximately 2.0. There is a range of commonly encountered foods that are also of low pH. A direct relationship between human health and the pH of drinking water is impossible to ascertain, because pH is so closely associated with other aspects of water quality; acids is weak and usually very dilute[21].

The use of water from a new well for all bathrooms and ablution faucets must be maintained because it is considered to be protective against the incidence of diarrhea. However, clean water from both wells must not be consumed because it contains small amount of coliform and E.coli.

There were significantly association of cutting nail with students diarrhea. Sutanto and Nita studies, cutting nail was the factor of students diarrhea in Sukoharjo ($p=0,004$)[22] and Mraggen ($p=0.02$)[8]. Nails can be a nesting place for germs and where germs breed. Biting nails can cause microorganisms move into the mouth and into the digestive tract which will cause various digestive problems such as diarrhea[22]. It is recommended that each student cuts his nail every week to prevent diarrhea[23].

We can see that the basic problems triggering the outbreak was about hygiene and sanitation. Food hygiene is a way of handling food ingredients to prevent damage and food poisoning. Kitchen hygiene is a

requirement for kitchen buildings to prevent rodents, insects, and cockroaches from entering the kitchen area. Individual hygiene is a way to maintain personal hygiene and performance requirements of a processor and food waiter. Equipment sanitation is to choose cleaning materials and sanitary materials, selection of cleaning tools, and equipment cleaning techniques. Room sanitation and furniture are preparing cleaning materials and sanitary materials, cleaning and sanitizing techniques, and cleaning schedules[10]. No hand washing, less clean and unhygienic snacks, can increase the incidence of diarrhea by 52%. This supports the results of the study that has been done[24].

The results of this investigation certainly cannot be fully prevented from various limitations in such way that it may affect the validity and precision of the study. These limitations were information bias. In this study, data collection using a questionnaire was very subjective, so the correctness of the data was very dependent on the honesty of the respondents and the sensitivity of the interviewers at the time of observation.

Conclusion

We concluded that risk factors significantly affected diarrhea in this outbreak were snack behavior in the canteen, drinking refill water, use of water from the old well and cutting nail. Use of water from a new well was considered to be protective against the incidence of diarrhea.

Recomendation: Improvement in providing healthy food at the canteen including maintaining the strict food hygiene, sanitation regulation and practices were essential and necessary to be followed up by the school administrators and local authorities.

Conflict of Interest: There is no confict of interest.

Source of Funding: Self-funding.

Ethical Clearance: Ethical approval number 124/ UN2.F10/PPM.00.02/2019 from The Research and Community Engagement Ethical Committee Faculty of Public Health Universitas Indonesia

Acknowledgments: The author thanked the Head of the Depok City Health Office and staff for support for outbreak investigations and laboratory examinations. The author also thanked the Principal of Pondok Duta Elementary School for her cooperation in this outbreak investigation.

Abstract

Objective: Metabolic syndrome may cause bad prognosis on diastolic or systolic function of the left ventricle. Thus, this research aimed to recognize the possible effect of metabolic syndrome on systolic and diastolic function of left ventricle using ECHO.

Study Design: Prospective case-control study.

Place and duration of study: Soad Kafafi Hospital, Egypt, from May 2016 to March 2018.

Methodology: This research included forty patients with metabolic syndrome (18 male, 22 female, mean age=54.13±6.33 years) and forty control matching age and sex volunteers without history of metabolic syndrome disorder (15 male, 25 female, mean age=52.20±5.27).MS was defined according to ATP-NCEP III criteria. Waist circumference will be measured to all participants at the start of study inclusion. Height and weight was measured to calculate Body mass index using standardized formula. Participants underwent laboratory investigations and complete echocardiography. Left ventricular function of the heart was assessed using Echocardiographic examination.

Results: There was a statistical significant difference regarding Left atrial (LA) diameter, Inter ventricular septum and posterior wall thickness in metabolic syndrome patients than normal control persons. The incidence of diastolic dysfunction was significantly higher in metabolic syndrome group compared to control.

Conclusion: MS may cause LV diastolic dysfunction although systolic function was preserved.

Keywords: *-metabolic syndrome, diastolic dysfunction, diabetes, hypertension, left ventricular function.*

I Introduction

Metabolic syndrome is defined as a group of interacted risk factors which includetruncal obesity,type II diabetes mellitus (DM), hypertension,high triglyceride level and low high densitylipoprotein level[1]. The component of metabolic syndrome may be the cause development of cardiovascular disease (CVD) [2]. Its prevalence is further growing in both males and females due to a life style characterized by high calorie consumption and low physical activity[3,4]. Plandevall et al. recommend routine waist circumference measurement to determine metabolic syndrome and its related diabetes and coronary heart disorders [5]. Interestingly it was found that metabolic syndrome components(diabetes, obesity,and hypertension develop before the development of cardiovascular disease[6]. Previous studies demonstrated that heart failure may occur as a result of diastolic dysfunction although ejection fraction was normal[7]. The mechanisms by which Left Ventricular diastolic dysfunction developed to heart failure were not completely identified. Some proposed mechanisms are that metabolic syndrome may alter function and geometry of the left ventricle which may results in coronary heart disease. Some studies have shown that LV dysfunction independently to metabolic syndrome components. However,some studies have shown relation between hypertension as a component

of metabolic syndrome and increased left ventricular mass in MS patients. Further studies might conduct to define different mechanisms for the development of cardiovascular disease as a result of metabolic syndrome[8].

Methodology

This research included forty patients with metabolic syndrome (18 male, 22 female, mean age=54.13±6.33 years) and forty control matching age and sex volunteers without history of metabolic syndrome disorder (15 male, 25 female, mean age=52.20±5.27). Patients were recruited from the outpatient department at soad-kafafi hospital. Diagnosis of metabolic syndrome was performed according to IDF criteria. According to this criterion MS diagnosed with waist circumference ≥80 cm for women or ≥90 cm for men plus abnormal two parameters of the following: High density lipoprotein cholesterol≥50 mg/dL for women or ≥40 mg/dL for men; triglyceride levels ≥150 mg/dL and random blood glucose levels ≥100 mg/dL, blood pressure ≥130/85 mmHg.

At inclusion medical history of all subjects was taken then echocardiographic examination was done for all subjects included in the study. Blood pressure was measured by available sphygmomanometer. Height and weight was measured to calculate Body mass index using standardized formula. Complete lipid profile test, random blood sugar, liver and renal function test and urinalysis using standard operating procedures.

The study approved by ethical committee of Soaad-Kafafi hospital. The exclusion criteria include; Patients suffer from MI, cor pulmonale, atrial fibrillation, cardiomyopathy, valvular heart disease,atrioventricular block hypothyroidism and renal failure.

Echocardiographic examination wasdone with available machine (GE Vingmed, Horten, Norway) with a 1.5 or 3.2 MHZ phased array transducer. Patients were lying in the left lateral position and breathing gently. A comprehensive echocardiographic study following standardized protocols was carried for all subjects[9]. Participants are asked to perform passive expiration the whole cardiac movement.

Statistical analysis: Statistical package SPSS version 21 was used for entered of statistical data. Data was summarized using number and percentage for qualitated variables,mean and SD for quantitative variables which are normally distributed while median and interquirtile range formula were used for quantitative variables which are not normally distributed. Independent sample t-test was used for quantitative variables which are normally distributed while non-parametrical Mann-Whitney Test was used for quantitative variables which are not normally distributed. P value<0.05was considered statistically significant. Normality was checked by Shapiro test.

Results

Table 1: Clinical characteristics of the study groups.

Variables	Metabolic Syndrome	Control	P-Value
Age	54.13±6.33[a]	52.20±5.27[a]	.143*
BMI	36.22 ± 7.53[a]	25.55±4.96[a]	<.001*
WC (cm)	119.65±14.36[a]	83.03 ± 7.24[a]	<.001*
SBP	142.50 (130:160)[b]	114.50 (110.00:120.00)[b]	<.001**
DBP	90.00 (80.00:95.00)[b]	76.00 (75.00:80.00)[b]	<.001**
RBS	97.00 (83.00: 143.00)[b]	87.00 (81.00:90.00)[b]	.003**
TG	146.50 (120.00:210.75)[b]	131.00 (113.00:144.75)[b]	.003**
HDL	43.68±8.47[a]	53.10 ±6.56[a]	<.001*

BMI: Body mass index; WC; waist circumference; SBP: systolic blood pressure; DBP: diastolic blood pressure; RBS: random blood sugar; HDL: high density lipoprotein cholesterol.

Indicates a significant p-value ($p < 0.05$). mean ± standard deviation ([a]), median (IQR) ([b]), P value by independent sample t-test (*); P value by Mann-Whitney Test (**).

Table 2: Sex distribution among control and metabolic syndrome groups

Sex	Metabolic Syndrome		Control		P-Value
	N	%	N	%	
Female	22	55.0	25	62.5	0.496
Male	18	45.0	15	37.5	

Both gender and age were not significantly different among the two studied groups (Table 1a & b).Regarding clinical parameters, the result shown that both body mass index and waist circumference were found to be significantly higher in patients with metabolicsyndrome group compared to normal control group. The prevalence of hypertension was found to be significantly higher in group I (metabolic syndrome group) compared to group II (normal control group) (Table 1a). Among laboratory investigations, triglyceride level and random blood sugar were statistically significant higher in metabolic syndrome group compared to control group. However, HDL-cholesterol level was found to besignificantly higher in control group compared to metabolic syndrome group compared to (Table 1a).

Table 3: Comparison of standard echo cardiographic parameters between metabolic syndrome group and normal control group

Variables	Metabolic Syndrome Group	Control	P-value
LVED(mm)	47.58±5.08a	46.48±4.96a	.330*
LVES(mm)	29.90±4.83a	28.33±4.03a	.118*
EF%	68.58±8.48a	67.68±5.50a	.575*
FS%	37.30±6.26a	38.58±8.67a	.453*
LA(mm)	38.53±3.83a	27.98±3.77a	<0.001*
AO(mm)	29.83±4.90a	28.23±4.69a	.140*
IVS	10.00 (10.00:11.00)b	9.00 (9.00:10.00)b	.002**
PW	11.00 (10.00:12.00)b	9.00 (9.00:10.00)b	<0.001**

LVED: left ventricular end-diastole; LVES: left ventricular end-systole; EF%: ejection fraction; FS: fractional shortening; LA: left atrium; AO: Aortic root dimension, IVS: Interventricular septum; pw: Posterior Wall thickness.

Mean ± standard deviation ([a]), median (IQR) ([b]), P value by independent sample t-test (*); P value by Mann-Whitney Test (**).

LVED, LVES,and LV ejection fraction LV fractional shortening were shown to be within normal ranges and no statistically significant difference was detected between both studied groups regarding the previously mentioned ECHO features (Table 2). Additionally, AO was found to be normal within the two groups with no significant difference (Table 2). However, Left atrial anteroposterior diameter, posterior wall thickness and Inter ventricular septum and were found to be statistically significant higher in metabolic syndrome group compared to normal control group (Table 2).

Table 4: Effect of controlled and uncontrolled hypertension on diastolic dysfunction ofthe left ventricle

Diastolic Dysfunction	Hypertension						P-Value
	Absent		Controlled		Not Controlled		
	N	%	N	%	N	%	
Present	1	16.7	0	0.0	14	87.5	<0.001
Absent	5	83.3	18	100	2	12.5	

Uncontrolled hypertensive patients show echocardiographic features of diastolic dysfunction which was found to be significantly higher compared to controlled hypertensive patients and normotensive patients.

Table 5: Effect of controlled and uncontrolled diabetes on diastolic dysfunction of the left ventricle

Diastolic Dysfunction	Diabetes						P-Value
	Absent		Controlled		Not Controlled		
	N	%	N	%	N	%	
Present	6	30	1	10	8	80	0.003
Absent	14	70	9	90	2	20	

Uncontrolled diabetic patients show echocardiographic features of diastolic dysfunction which was found to be significantly higher compared to controlled diabetic patients and patients with no diabetes.

Table 6: Effect of controlled and uncontrolled dyslipidemia on diastolic dysfunction of the left ventricle

Diastolic Dysfunction	Dyslipidemia						P-Value
	Absent		Controlled		Not Controlled		
	N	%	N	%	N	%	
Present	5	37.5	3	23.1	7	53.8	.281
Absent	9	64.3	10	76.9	6	46.2	

This table shows that there is no difference in the frequency of diastolic dysfunction among the three studied groups.

Discussion

The term metabolic syndrome (MS) represents a clustering of components including truncal obesity,hypertension,diabetes mellitus anddyslipidemia. Eachcomponent of metabolic syndromemay be considered as important risk factors for the development of cardiovascular disease [10].Previous literatures study the impact of both insulin resistance and obesity on left ventricular function; however, there islack of studies that show the impact of MS on left ventricular function. Furthermore, some studies demonstrated that individuals with idiopathic dilated cardiomyopathy were diagnosed with insulin resistance;these studies concluded that MS may cause coronary heart disease[11]. Thus, the present study was conducted to evaluate the impact of metabolic syndrome on left ventricular performance using ECHO.

In the current study, all components of metabolic syndrome were found to be significantly higher in patients with metabolic syndrome compared to normal control group. The analysis of traditional echocardiographic parameters showed that both ejection fraction and fractional shortening which represents left ventricular systolic function were not different among MS patients and normal control group. The major finding of the current study was that metabolic syndrome causes diastolic dysfunction as assessed by standard echocardiographic measurements. Previous studies have demonstrated the effect of metabolic syndrome on the function of left ventricle, but consensus is still lacking. A study by [12] has examined the impact of metabolic syndrome on diastolic function of left ventricle in American Indians using ECHO. They noticed altered of both left ventricular relaxation and of left ventricular diastolic function which is consistent with the current study. Also they concluded that American Indians with the metabolic syndrome had greater posterior wall thickness, left atrial diameter and diastolic dysfunction which are consistent with the current study [12]. In the present study, left atrial diameter of metabolic syndrome group was increased compared to control group, which corresponds to results from other literature[13],[14] Have shown that left ventricular diastolic function was impaired in MS patients; however ejection fraction and fractional shortening (left ventricular systolic function) is preserved which corresponds to the findings of the present study. [15]Also have shown that only left ventricular diastolic function altered in patients with MS although systolic function is preserved. In contrast,[16] some studies demonstrated that metabolic syndrome is associated with global left ventricular dysfunction (diastolic and systolic) in subjects with MS but no CVD. Previous studies have demonstrated that diastolic function observed in the current study may be as a result of

hypertension. Arterial Stiffness, caused by hypertension may be results in cardiovascular abnormalities [17].In contrast, another study demonstrated that hypertension and obesity were not associated with left ventricular diastolic dysfunction.

Watcher et al.,demonstrated that left ventricular diastolic dysfunction occurs at a higher percentage in diabetic patients (80.6%) when compared with patients with no diabetes (69.2%). furthermore, diabetes cause serious effect on the left ventricular diastolic function[18]. In the current study the incidence of diastolic dysfunction rise significantly. The rate of Prevalence of diastolic dysfunction was found to be significantly higher among uncontrolled diabetic patients (80%) compared topatients under glycemic control(10%) and patients with no diabetes (30%). Both studies are comparable. Control of glycemiaby drug or life style modification in diabetic patients can help in maintaining normal diastolic function. According to the Strong Heart Study there was a relation between degrees of glycemic control and diastolic function [19]. However, in the present study glycemic control markers were excluded from the research.

The potential limitations of the present study are a small sample size and lack of randomization.

A Comparative Study of Vitamin D Levels and Some Biochemical Parameters between Healthy and Breast Cancer in Iraqi Females

Dunia Abdul Jabbar[1], Amer Hasan Abdullah[2], Bushra Hameed Ali[3]

[1]M.Sc. Student, [2]Assist. Prof, Chemistry Department, Science College, Mustansiriyah University, Baghdad-Iraq, [3]Professor, Chemistry Department, College of Education for Pure Sciences/Ibn AL-Haitham, Baghdad University, Baghdad, Iraq

Abstract

Breast cancer is one of the most widespread cancers,depending on World Health Organization, cancer calculated for approximately 7.6 million incidences in 2008, whoever expected elevation in incidence is about 13.1 million in 2030. So that the current research investigates vitamin D role in the occurrence of this disease and explains if vitamin D has a positive effect on the incidence of disease, as well as measuring parathyroid hormone and estrogen levels. Three groups were included in this analysis: control healthy women, benign and malignant breast tumor women. All cases that were selected at the beginning of the disease diagnosis. According to statistical values vitamin D showed highly significant ($P<0.001$) decrease in benign (3.74±2.33) ng/ml and malignant (4.38±3.12) ng/ml tumor patients compared with healthy group (24.96±7.24) ng/ml. Also a high significant increase was shown for PTH values in benign (208.37±132.5) pg/ml and malignant (133.9±60.02)pg/ml tumor patients compared with healthy group (67.04±25.6) pg/ml. Furthermore, results revealed non-significant difference in estrogen levels between benign group (54.11±22.93) pg/ml, and control group (64.85±22.18)pg/ml, while there were a significant difference in levels of estrogen between control and malignant tumor groups (52.4±18. 09) pg/ml.

As a results, we found that all patients had sever vitamin D deficiency compared with healthy group, as well as high levels of parathyroid hormone as evidence of vitamin D deficiency, while estrogen levels where within normal levels.

We concluded that all patient groups were suffering from vitamin D deficiency and elevation in parathyroid hormone that gives evidence of the role of vitamin D as anti-cancer agent.

Keywords: *Breast cancer, Estrogen, Parathyroid hormone, Vitamin D.*

Introduction

Breast cancer (BC) is one of the most widespread cancers around the world and it is the second main reason of death after lung cancer among women [(1)]. Many reports demonstrated reverse correlation between vitamin D concentration and occurrence of 15 types of cancers, including breast, lung, kidney, colorectal, and pancreatic cancer[(2)].

Vitamin D is synthesized in human by more than one step. The first step start when UVB (290-315nm) reaches the skin and stimulates conversion of 7-dehydrocholesterol to pre-vitamin D3 [(3)], approximately 90% of vitamin D comes from endogenous production under the skin, which transported to the liver to produce 25-hydroxyvitamin this step induced hydroxylation by vitamin D-25-hydroxylase enzyme encoded by (CYP2R1)[(4)] then undergoes another hydroxylation step in the kidney toyield1,25-dihydroxyvitamin D (1,25(OH)2D) by the 25(OH)D-1α-hydroxylase enzyme which encoded by (CYP27B1), (1,25-dihydroxyvitamin D3) [(5)]. The active form of vitamin D, has a short half-life of about 15 hours, while 25-hydroxyvitamin D3 has a half-life of about 15 days[(6)]. The active form of vitamin D,

1,25(OH)2D, plays many important biological function such as modulation of immune responses, impact on hormone excretion, regulate of cellular proliferation and differentiation. Also, anticancer actions for example anti-proliferation, anti-inflammation, induces apoptosis, prompting of differentiation, inhibition of metastasis, and angiogenesis for different malignant cells[7].

However, VDR signaling has been noticed to impact on the expression of more than 200 genes[8]. Therefore the levels of 1,25(OH)2D is regulated tightly by phosphorus, calcium and parathyroid hormone (PTH)[9].

In recent years an anti-cancer mechanism of vitamin D was discovered, so the influences of vitamin D that restrain of mammary tumors are mediated through estrogen pathway by reduce systematization of intracellular estrogen receptors (ER) [10]. Many studies recorded hypo-vitamin D among patients with breast cancer contrasted with healthy group [11].

Aim of the Study: The present study aimed to analyze vitamin D laboratory test results obtained from healthy and breast cancer Iraqi females, in addition to evaluation of estrogen and parathyroid hormone and their relationship with active form of vitamin D.

Materials and Method

Study Groups: All blood samples were collected from Al-Eluia Hospital for Woman Care, Oncology Teaching Hospital and Amel Hospital for Tumors in the period from October 2018 to April 2019. This analysis includes healthy group and breast tumor cases. Samples were divided as three groups (control G1, benign tumor G2 and malignant tumor G3), each groups comprised of 30 blood specimens of Iraqi females in premenopausal stage at age ranged between 32 to 45 years.

Blood Sampling: Five milliliters of blood were withdrawn from healthy and patients subsequently put in gel tube and left to coagulate at room temperature then centrifuge at 3000 rpm for 5 min. After that the serum collected was divided into five sections and put in eppindorftubes and stored at-20 ºC in order to be used for vitamin D, PTH and estradiol (E2) levels measurement by ELISA technique**.**

Parameters Measurement: Evaluations of direct 25(OH) vitamin D and E2 were achieved by Sequential Competitive Method, while determination of PTH was achieved by Sandwich equilibrium Method.

Statistical Analysis: The results were obtained as a mean ± SD (standard deviation). P-value of <0.001 and <0.05 expressed as a highly significant and significant respectively, as well as Pearson's correlation coefficient was utilized to determine the correlation between two continuous variables.

Results

In our study, we enrolled 90 participants. The median age of the patients at diagnosis ranged between (32-45) years old. The study demonstrated a contributory relationship between vitamin D deficiency and breast cancer occurrence, however the results reveled very low concentration of vitamin D in breast cancer women group compared with healthy women group that suggests inverse association between decrease level of vitamin D and increase risk of breast cancer with many different mechanisms as many recent research suggested. The results of vitamin D, PTH and E2 in G1 healthy group, G2 benign tumor and G3malignant tumor are shown in table (1) that revealed a highly significant (P<0.001) decrease in vitamin D levels in benign (3.74±2.33)ng/ml and malignant(4.38±3.12)ng/ml tumor patients, respectively compared with healthy group(24.96±7.24)ng/ml, while there is a non-significant difference (p>0.05) between G2 and G3.

Also a high significant increase (P<0.001) was shown for PTH values in benign (208.37±132.5) pg/ml and malignant (133.9±60.02)pg/ml tumor patients compared with healthy group (67.04±25.6) pg/ml, respectively. Also, there was a significant difference in PTH levels between benign and malignant groups.

Furthermore, results revealed non-significant difference in E2 levels between benign group (54.11±22.93) pg/ml, and control group (64.85±22.18) pg/ml, while there were a significant difference in levels of estrogen between control and malignant tumor groups (52.4±18. 09) pg/ml, as well as a non-significant difference between G2 and G3 groups.

Table 1: Comparison among vitamin D, PTH and E2 levels in control,benign and malignant groups

Parameters	Control(G1) Mean ± SD	Benign(G2) Mean ± SD	Malignant(G3) Mean ± SD	P-Value G1 vs. G2	P-Value G1 vs. G3	P-Value G2 vs. G3
Vit. D	24.96 ± 7.24	3.74 ± 2.33	4.38 ± 3.12	H.S	H.S	N.S
PTH	67.04 ± 25.6	208.37±132.5	133.9 ± 60.02	H.S	H.S	S.
E2	64.85±22.18	54.11 ±22.93	52.4 ±18. 09	N.S	S	N. S

H.S. Highly significant, S. Significant, N.S. Non-significant

In addition to that mentioned have been demonstrated in table (2) highly significant negative correlation between vitamin D and other parameters which include PTH and E2 in benign group that explained in figures 1 and 2. While in malignant patients we demonstrated a highly significant positive correlation distributed of vitamin D with PTH otherwise the study appeared a highly significant negative correlation between vitamin D and E2 were showed in table (2) and figures 3 and 4.

Table (2): Illustrates the correlation between PTH and E2 in benign and malignant groups.

	Benign group		Malignant group	
Parameters	**R**	**P-value**	**R**	**P-value**
PTH	-0.09	H.S	0.16	H.S
E2	-0.05	H.S	-0.08	H.S

H.S. Highly significant

The following figures explain the correlation between vitamin D, E2 and PTH in benign and malignant groups.

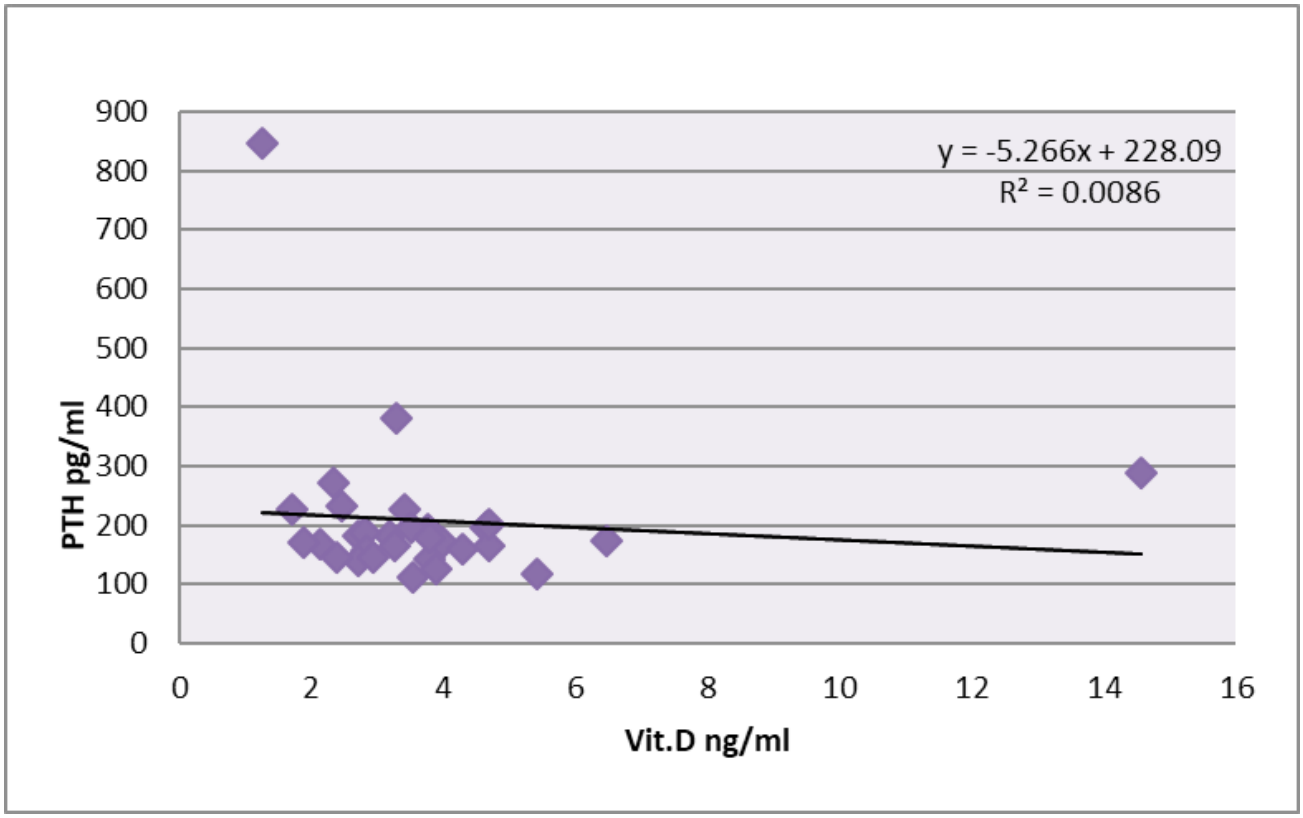

Figure (1): Vitamin D vs. PTH in benign patients

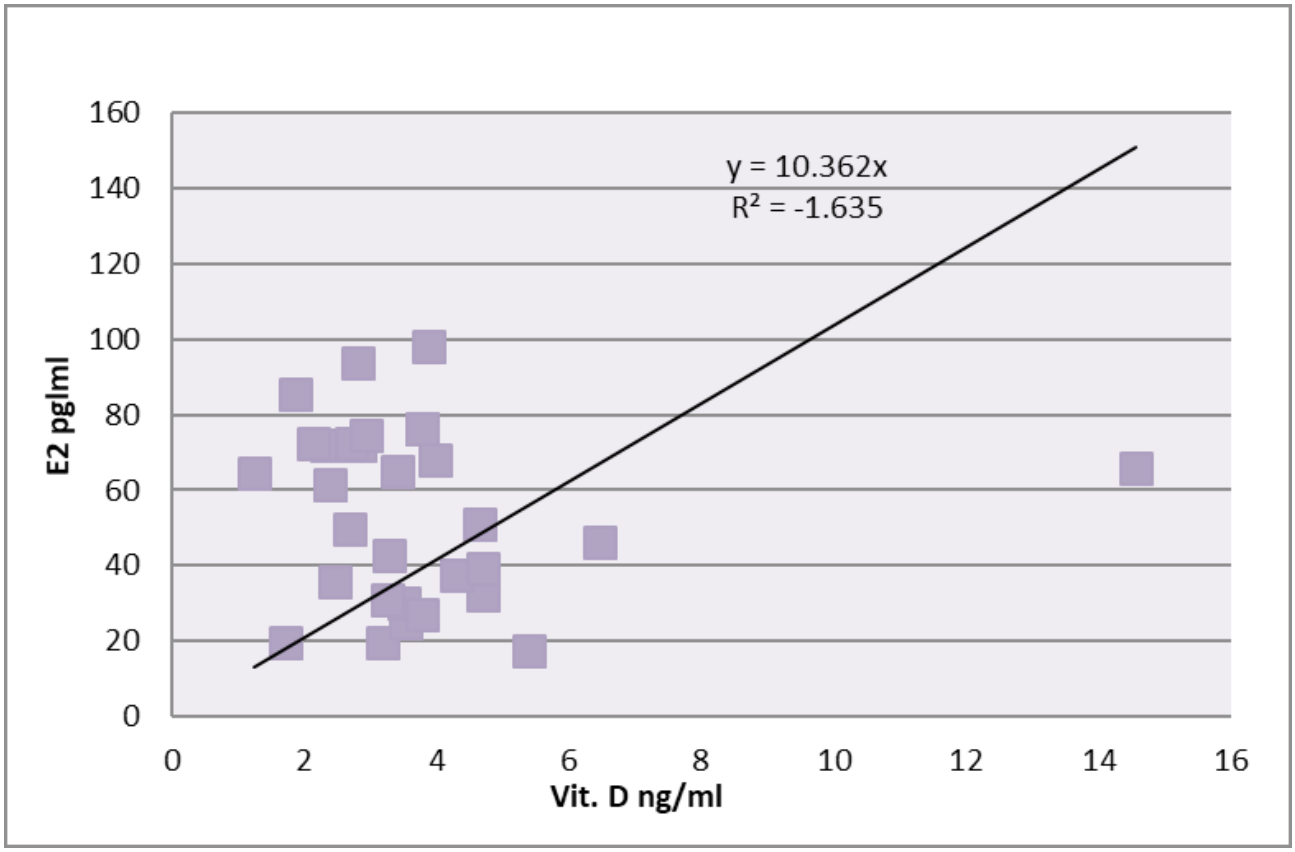

Figure(2): Vitamin D vs. E2 in benign patients

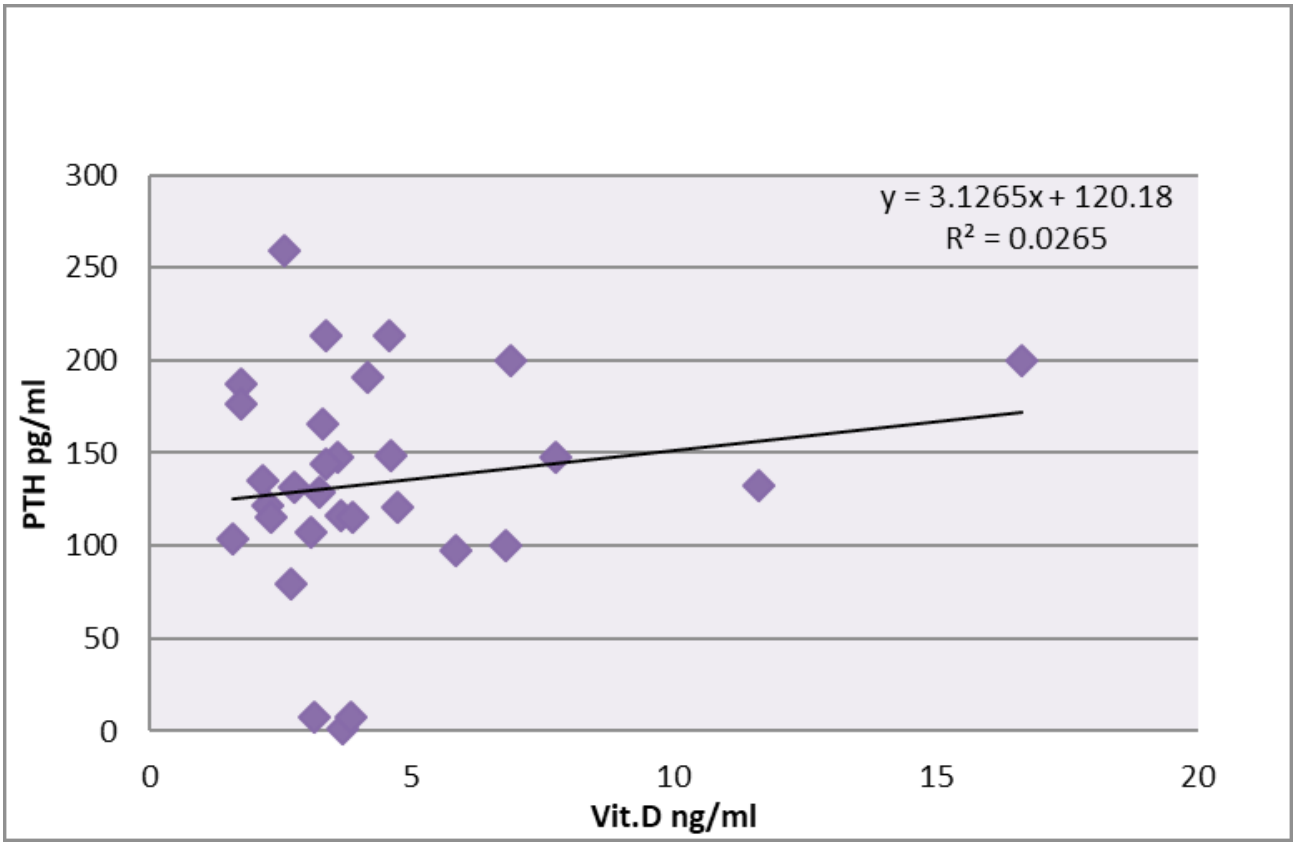

Figure (3): Vitamin D vs. PTH in malignant patients

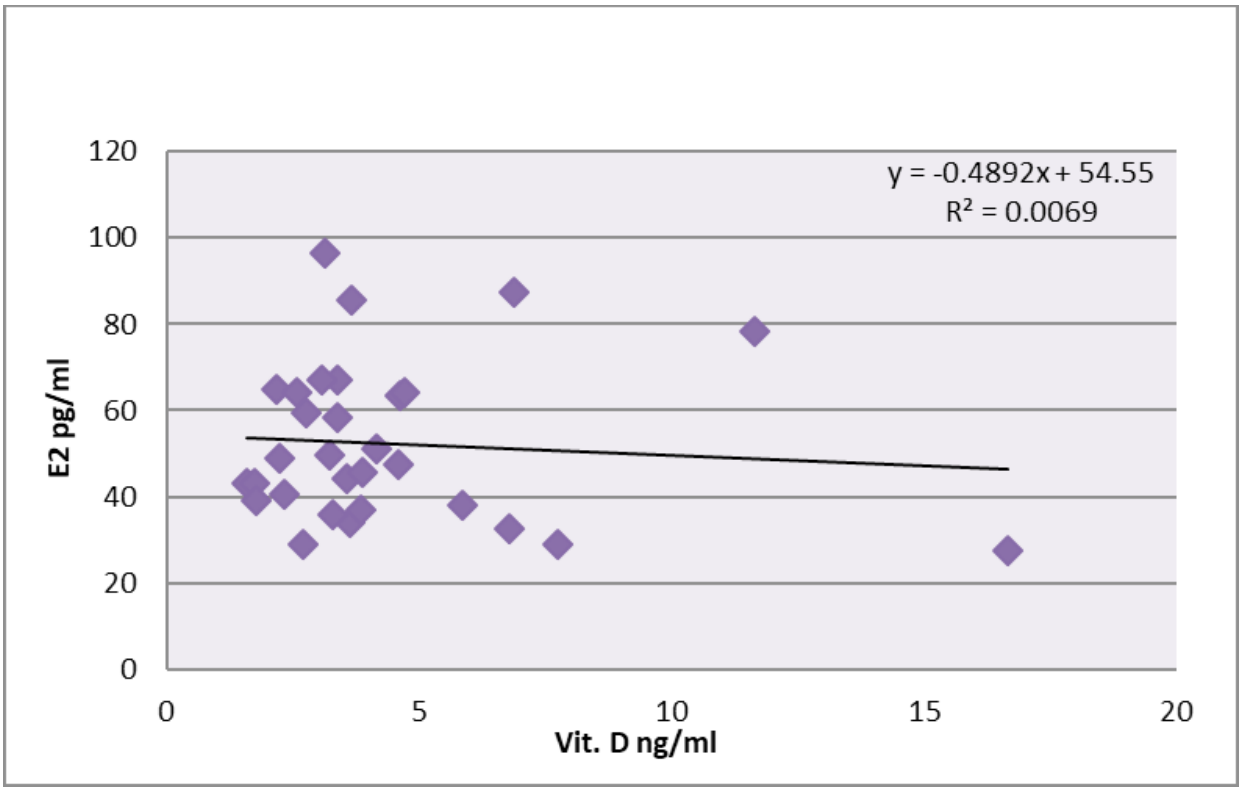

Figure (4): Vitamin D vs. E2 in malignant patients

Discussion

The present study demonstrated a contributory relationship of vitamin D depletion in relation to breast cancer occurrence, however the results of vitamin D levels for the pool of women with breast benign and malignant tumors were very low compared with the group of healthy women that suggests increase risk of breast cancer with various mechanisms. According to some sources the normal values of vitamin D ranged (30-100) ng/mL considered as sufficient[12]. The decrease in vitamin D levels is divided into three sections; levels of 25(OH)D below (<10 ng/ml) that represents severe deficiency, mild deficiency (10-25 ng/ml) and sufficiency > 30ng/ml,the decline is considered acceptable to a society suffering from a lack of vitamin D levels for men and women according to local studies. Another research that agrees with our study found that 90% or more of people with breast cancer have vitamin D deficiency[13]. Since the lack of vitamin D is linked to the disease in more than one course. Firstly, the natural levels of vitamin D regulate more than 200 genes [14]. The role of 1,25(OH)2D3 is to regulate some genes involved in cell cycle organization and apoptosis such as p21-activated kinase (PAK1), p53(TP53) insulin-like growth factor [14]. On the other side vitamin D has a role through its effect on estrogen receptor, Estrogen has been found to play a vital role in breast cancer inducing the chest cell to occur uncontrolled division and thus tumor where the low level of vitamin D consider positive effect by increase of estrogen receptor therefore vitamin D has an estrogenic effect on the spilt of chest cell to form tumor [15]. The proposed third effect of vitamin D is by influencing on the aromatase enzyme, where 1,25(OH)2D3 decreases expression of aromatase enzyme (CYP19), which catalyzed estrogen synthesis[16]. Although there are other factors that contribute to increase positive gene expression of this enzyme such as fatty tissue, which is a source of estrogen, the higher of fatty tissue increase the Nα F and IL-6 thus lead to increased conversion of testosterone to estrogen[16]. Either the fourth effect of vitamin D by its effect on generation of reactive oxygen species, mitochondrial disruption and eliminate cytochrome C[17].

Finally another research proposed a mechanism comprising of angiogenesis is process of generation new blood vessels from existing vasculature and is a crucial step which causes progression, and metastasis of tumors[3].

According to our results, the estrogen levels were within normal limits. The genetic expression of the enzyme aromatase that converts androgens into estrogen, which occurs as a result of a decrease in vitamin D levels, has been excluded because the levels of estrogen were within normal limits;Estrogen plays a role through estrogen receptors, promoted cell proliferation and initiates mutations that occur as a function of errors during DNA replication[18]. A second mechanism of estrogen role in breast cancer can be explained by direct effect by formation of oxygen free radicals which have role in the genetic changes in cell chest[19].

Almost 5–10% of patients are suffering from genetic changes related to breast cancer[20]. According to a previous study more than 75% of breast tumors occur through estrogen receptors (ER), suggesting that the vast majority of breast cancers are hormone-dependent and grow in response to the hormone estrogen[21].

On the other hand, some studies indicate carcinogenic effect and tumorstimulation of parathyroid hormone. Other previous cohort studies agreed with our results that found an association between higher levels of parathyroid hormone and breast cancer risk[22]. Increase risk of breast cancer in women with hyperparathyroidism[23]. One of the conditions of hyperparathyroidism types is the expansion of one or more of the parathyroid glands which cause excessive hormone production called primary hyperparathyroidism the second condition that leads to high levels of parathyroid hormone is called secondary hyperparathyroidism[24]. It is well established that there is an inverse relationship between serum 25-hydroxyvitamin D (25-OHD) and serum PTH[25]. Decrease in vitamin D levels causes rise in parathyroid hormone levels. Therefore, high levels of parathyroid hormone stimulate excretion of calcium (Ca^{2+}) from bones into the bloodstream to fill lack of blood calcium levels (hypercalcemia),and increase the risk breast cancer incidence. Some evidence study found that high extra cellular calcium levels have a similar effect of estrogen "estrogen like" effect in vitro[26]; so all cases of patients with the incidence of benign tumor and malignant where in pre-menopause ages[27].

The Role of Mean Arterial Pressure (MAP), Roll Over Test (ROT), and Body mass Index (BMI) in Preeclampsia Screening in Indonesia

Dwi Putri Rahayu Tampubolon[1], Lilik Herawati[2], Nursalam[3], Ernawati[4]

[1]Student in Midwifwery Program, [2]Physiology Department Faculty of Medicine, [3]Faculty of Nursing, [4]Obstetrics and Gynecology Department Faculty of Medicine Universitas Airlangga

Abstract

Objective: To evaluate the role of MAP, ROT, and BMI in preeclampsia screening in low resources setting.

Method and Material: This is a retrospective study conducted on 1011 pregnant women who had an antenatal care at Public Health Center in Indonesia. Data taken from public health medical report. The sample groups were 45 preeclampsia patients who have had complete screening of MAP, ROT and BMI. The control groups were normal pregnant women who attained same inclusion criteria.

Results: The preeclampsia group had positif MAP and obesity result respectively 95.6% and 40% of patients, but in control group only had 40% and 11.1% of patient have positive MAP and obesity respectively. Statistical test illustrates a significant association between MAP and BMI screening with the incidence of preeclampsia (p 0.0001, OR = 32.250 and p 0.002, OR = 5.333).Whereas positive ROT showed in 40% PE groups and 57.8% control group. There is no association between ROT screening and the incidence of preeclampsia (p 0.092).

Conclusion: MAP and BMI can be used as baseline screening tools of preeclampsia in low resources setting. But ROT is not associated with the incidence of preeclampsia.

Keywords: *Preeclampsia Screening, MAP, ROT, BMI.*

Introduction

Preeclampsia (PE) is a complex medical disorder, who is is responsible for neonatal and maternal deaths worldwide. It is also becomes the biggest cause of high Maternal Mortality Rate (MMR) in Surabaya Indonesia from 2013-2017[1]. Accurate prediction and aggressive prevention allowed to elude this pregnancy complication. Effective screening to predict PE in the first trimester of pregnancy is important to identify women who are at risk of developing PE so that early enough prevention treatment could start to prevent or reduce the frequency of its occurrence.

Preeclampsia screening vary from clinical to biomolecular level depend on the resources availability. In low and middle income countries where resources are limited, variations of the first-trimester combined test can be considered but difficult to reached. The baseline test which is possible to do are combine of maternal risk factors with Mean Arterial Pressure (MAP) and Roll over Test (ROT). In the absence of other biomarker(s), risk calculation can still be done but the detection rates will be reduced .

MAP and ROT are a method to describe hemodynamic conditions in patients with preeclampsia. ROT is not a perfect predictor, but it still have advantages

to use in populations with high PIH associated maternal and perinatal mortality, mostly in low resources setting[2]. It has been used in many contries but some literature shows that ROT is not related to the incidence of preeclampsia[3]. The purpose of this study is to determine the effectiveness of preeclampsia screening (MAP, ROT, and BMI) to the incidence of preeclampsia in Indonesia.

Material and Method

This is a retrospective study conducted on 1011 pregnant women who performed an antenatal care at Sidotopo Wetan Public Health Center (*Puskesmas Sidotopo Wetan*), Surabaya, Indonesia from October 2017 to October 2018. Et Data taken from public health medical report. The sample groups were 45 preeclampsia patient during that period time who fulfilled inclusion criteria: patients in the first and second trimesters who have had complete screening of MAP, ROT and BMI. The control groups were normal pregnant women who attained same inclusion criteria. It was takenby consecutive sampling. Positive result noted if MAP is > 90 mmHg. ROT classified as positive result if there were different of diastolic pressure between supine and lateral position more than 15 mmHg[3]. The values on BMI screening classified as obesity if the result >30. The samples were traced retrospectively to see the MAP, ROT and BMI screening history and demographic data.

Finding:

Table 1. Demographic Characteristics

Age (Year)	PE group	Control group	Total
	n (%)	n (%)	n (%)
< 20	0 (0)	3 (6.7)	3 (3.3)
20-35	37 (82)	38 (84.4)	75 (83.3)
> 35	8 (18)	4 (8.9)	12 (13.3)
Parity			
Primi	9 (20)	13 (28.9)	22 (24.4)
Multips	36 (80)	32 (71.1)	68 (75.6)
Risk Factor			
Anemia	3 (6.7)	0 (0)	3 (3.3)
Gestational Diabetes	5 (11.1)	2 (4.4)	7 (7.8)
History of Preeclampsia	1 (2.2)	0 (0)	1 (1.1)
Obesity	16 (35.6)	5 (11.1)	21 (23.3)
Tuberculosis	2 (4.4)	0 (0)	2 (2.22)
HbsAg (+)	1 (2.2)	0 (0)	1 (1.1)
History of IUFD	1 (2.2)	0 (0)	1 (1.1)
Under Nutrition	1 (2.2)	6 (13.3)	7 (7.8)

Baseline demographics of study participants are presented in Table 1.Most pregnant women in both groups are in reproductive ages. It also worked on parity data, which is multips showed have larger number than nulips. Obesity has the highest rank in PE risk factor in this study. It counts a percentage of 35.6% obesity cases. Followed by Gestational diabetes and anemia.

Table 2. MAP, ROT, BMI and the Incidence of Preeclampsia

Screening	PE group	Control Group	Total	P	OR
	n (%)	n (%)	n (%)		
MAP (-)	2 (4.4)	27 (60)	29 (32.2)	0.0001	32.250
MAP (+)	43 (95.6)	18 (40)	61 (67.8)		
ROT (-)	27 (60)	19 (42.2)	46 (51.1)	0,092	-
ROT (+)	18 (40)	26 (57.8)	44 (48.9)		
Obesity (-)	27 (60)	40 (88.9)	67 (74.4)	0,002	5.333
Obesity (+)	18 (40)	5 (11.1)	23 (25.6)		

The MAP test in this study pointed out that 95.6% preeclampsia samples have a value of positive MAP, while only 40% samples of control groups have a positive MAP. This study in accordance with another study by Gasse et al in 2017, which is showed that first-trimester MAP is a strong predictor of gestational hypertension and preeclampsia in nulliparous women[4].

Table 2 also showed that 60% preeclampsia patients have negative ROT screening and are inversely proportional to control group that most of them have positive ROTscreening with p value 0.092 which means that there is no association between ROT measurement and the incidence of preeclampsia.

The results of BMI measurement and the incidence of preeclampsia in this study showed that 40% preeclampsia patient are obese but only 11.1% control group patient recorded obese. Statistical analysis noted p value 0.002 which could be explained that there is a relationship between BMI and the incidence of preeclampsia.

Discussion

Baseline data in this study discordant with the theory of preeclampsia and other study which is reproductive ages and multips are low risk group to have hypertension in pregnancy. It could be explained that reproductive age in this study has preeclampsia risk factor ie gestational diabetes, obesity, history of preeclampsia and infection. Another study from Indonesia also pictured that more than 50% patients who experienced preeclampsia are between 20 to 35 years old[5].Parous women without prior history of PE have lower risk of PE; however, this protective effect will change when they have different conception partner[6].

MAP test showed strong relationship with incidence of preeclampsia in this study, it revealed odd ratio 32.25. This data inline with Poon study in 2008 which reported first study on MAP measurement using validated automated blood pressure devices according to a standardized protocol and maternal variables in 11+0 to 13+6 weeks pregnancy can predict PE.Maternal blood pressure was measured in 5590 singleton pregnant women. the detection ratesfor PE, at 10% false positive rate, were 38% and 63%, respectively for MAP alone and in combination with maternal history[7].

MAP is a reflection of hemodynamic perfusion pressure from vital organs. Another follow-up study on MAP measurement of more than 9000 pregnancies at 11–13 weeks of gestation compared the screening using systolic blood pressure, diastolic blood pressure, and MAP.MAP performed best as a marker, with an increasing of detection rate for early onset PE from 47% (based on maternal factors alone) to 76% (based on MAP and combination of maternal factors) at 10% false positive rate[8].MAP screening in first-trimester is a strong predictor of gestational hypertension and preeclampsia[9,10].

The value of roll-over test has advantages in its simplicity. It requires simple equipment and no special skill. ROT is performed by positioning the patient in a lateral state and then a blood pressure measurement is made until there is no change in blood pressure. Then, the tension is measured in the supine position and the tension results are recorded again.

Some study showed roll-over test are highly variable among different investigators and also inconsistent reproducibility in the same patient. Literature review reveals sensitivities varying between 0 to 93% and specificities between 54–91% and false positive results up to 90%. Walia et all study in 2015 also reported roll-over test performed at 24 weeks had negative in all

study cases. So, it is clear that ROT has no role as early predictive in preeclampsia[3].

The relationship between preeclampsia and obesity has been greatly studied. Obesity prevalence has increased over 25 years it is similar to preeclampsia prevalence. This study showed obesity has correlation with incidence of PE. It revealed OR 5.3 in obesity cases compare non obesity cases.

This data support substantial evidence which is show that obesity (BMI ≥30 kg/m^2) confers a higher risk for PE[10,11,12]. Obesity also state as meta inflammation, associated with chronic stress and inflammatory response. The inflammatory response was found to increase in obese women and contribute to vascular targets and vascular changes induce endothelial dysfunction and placental ischemia in turn exaggerated maternal inflammatory response and induce preeclampsia[13,14,15].

This study in line with FIGO guideline on preeclampsia screening where state that if it is not possible to measure biomarker (PLGF) and/or uterine artery doppler, combination of maternal risk factor and MAP has advantages than maternal risk factor alone. Simple method to measure in Public health will increase awareness, access, affordability, and acceptance prenatal screening of preeclampsia[16].

Conclusion

MAP and BMI can be used as baseline screening tools of preeclampsia in low resources setting with OR = 32.250 and 5.333. But ROT is not associated with the incidence of preeclampsia.

Abstract

Introduction: Older people generally experience an overall functional decline and that may cause high dependence upon their families. The object of this study is to devise The Cordial Older Family Nursing Model in order to improve the quality of family care on them. Material and Method This study used an operational research design that passed through three steps of research.

Findings: The results of this study, were as follows: 1.) Step I: Informational support and coping strategies Acquiring Social Support were the predominant variables of older persons abuse. 2.) Step 2: The results of The Cordial Older Family Nursing Model with module, worksheet, and training curriculum 3.) Step III: There was a significant difference between family support (both informational and instrumental, family strategy, coping criteria and the incidence of elder abuse inter measurement.

Discussion: The cordial older family nursing model testing indicated improvement of mean value of total family support before and after treatment on intervention group which means the capability of family in providing support in elderly care giving were improving. This was carried out during a trimester after the application of the model between interventional and control groups.

Conclusion: The replication of models in cities across Indonesia Continuous training for nurses, health carers, and caregivers while taking care of homebound older adults

Keywords: *The Cordial Older Family Nursing Model, family support, health status of older persons, older persons abuse.*

Introduction

The population of elderly people in the world increases each year. *World Health Organization* (WHO) (2002), stated that the elderly people in Indonesia in the coming 2020 will reach 11.34% or 28,8 million people. Although the percentage of elderly in Indonesia is relatively smaller than the elderly in many countries, yet the real number is actually quite great. This is because of the large population of Indonesia that places the elderly of Indonesia in the fourth place after China, India, and USA[1].

BPS RI–Susenas 2009, in National Commission on Older Persons/Komisi Nasional Lansia, stated that the average percentage of older persons of the population in Indonesia was 8.37% hence it could be said that the population of Indonesia could be categorized as elderly structured population. There were 11 provinces in Indonesia with more than 7% older persons in the population, namely Daerah Istimewa Yogyakarta/ Special Region of Yogyakarta (14.02%), Central Java (10.99%), East Java (10.92%). BPS RI, in Older Persons Population Profile/Profil Penduduk Lansia compiled by the National Commission on Older Persons/Komisi Nasional Lansia described that West Java was one of the provinces with older persons population because the percentage of its older persons population was 7.95% of its total population amounting as many as 41,902,385 people[2].

Biological risk occurs with biological change in the elderlies due to ageing process. According to Miller's Theory of Consequence health problems in the elderlies may occur due to various biological changes in the elderlies. Lifestyle risk is health values realized by healthy behaviors[3]. The elderly as part of a family adopts the believed healthy behaviors in the family. Environmental risk covering social and economy environment occurs due to the elderly's social status change in the society, such as loosing main occupation (retiring). Previously working elderly has to adapt to retirement when the previously employed elderly has to adapt to retirement in which income decrease occurs, while medical cost increases due to the increasing health problems[4].

The family, as the closest social unit to the elderly, is the main support to the elderly. The family is expected to be able to facilitate the elderly in coping and executing the development task, so as to increase the health, comfort, and welfare of the elderly [5]. Nursing model developed by Sahar verified that *Family Carer's Training Program (FCTP)* has positive impact on the elderly health status through the increasing capability of the family in taking care of the elderly[6]. The family as service provider at home can affect the elderly's health status. The family will give positive effect when the capability as needs provider is improved by attending *Family Carer's Training Program.* Riasmini focused on a model to make family independent in nursing the elderly. Both models have not specifically given the reference for mistreatment issue on the elderly; nevertheless both have verified the importance of family role in supporting the welfare of the elderly[7].

Mistreatment might occur when the elder's level of dependency is very high hence nursing provider can show hostile and aggressive behavior which might harm the elderly. Psychopathology theory suggested that people with mental problems, substance addiction, or mentally disabled are abnormal people and do not have the capability to control their behavior [8]. The theories mentioned earlier explained various factors that might create mistreatment on the elderly. Knowledge about those factors is expected to enable health workers early detect mistreatment and take precautionary efforts so that the elderly living with a family will not experience mistreatment[9].

Hanson stated that the family functions as social support by seeking and conveying information, emotional support by assisting in emotion control, diect support in providing financial support as well as child and elder care support. The lack of support provided by the family might create mistreatment on the elderly[10]. Emotional support is a dominant factor on the occurrence of abandonment on the elderly living with a family. Hence various supports which are given by the family can prevent the occurrence of elder mistreatment. Prevention of elder mistreatment's occurrences can increase the health degree of elderly living with families[11].

Depok as part of West Java province has elderly population of 106,159 consisting of 55,120 male elderly and 51,039 female elderly[12]. Based on the experience and observation results during supervision in the area of Depok, the family should actually be able to participate in improving the health and welfare of the elderly. An illustration of family support that was not optimal in elderly care was that more than half (55.6%) of the families were not aware of abandonment of the elderly; the family had not yet considered various aspects related to abandonment[13]. Until the present day, the number of mistreatment in Depok has not been identified. Puskesmas (the Community Health Center) has not had intervention program that is available in the community relating to mistreatment happening to the elderly in the family. Based on the description, the researchers are interested in developing cordial older family nursing model in the efforts to improve the quality of family care on the elderly.

Material and Method

The research was carried out by applying operational research approach. The implementation was carried out in three (3) phases. Phase 1 was to identify the scale of the problem by applying Cross Sectional design with 135 respondents in Kelurahan/Village of Harjamukti area, Kecamatan/District of Cimanggis, Depok city; Phase 2 was to develop a model based on the results found in phase 1, literature studies, and inputs fron the experts and; Phase 3 was to validate the model developed in phase 2 by applying *quasi experiment pre-posttest with control* design, Harjamukti village as intervention group with 54 respondents and Mekarsari village as control group with 54 respondents.

Findings:

Table 1: Support, coping strategy, family burden, elderly health status, and family ability in preventing mistreatment after Model implementation between groups (n=108)

Variable	Intervention (n=54)		Control (n=54)		Value p
	Mean	Median	Mean	Median	
1. Family Support					
- Informational	27.61	28.00	26.28	25.50	0.020
- Appreciation	29.56	31.00	30.74	31.00	0.181
- Emotional	29.87	31.00	30.17	31.00	0.594
- Instrumental	31.46	32.00	27.24	27.00	0.000
- Total	118.50	119.50	114.43	115.00	0.014
2. Family Coping Strategy					
- Acquiring Social Support	29.57	29.00	27.20	27.50	0.015
- Reframming	33.07	33.00	31.07	32.00	0.000
- Passive Appraisal	18.50	18.00	17.28	18.00	0.047
- Seeking Spiritual Support	17.93	18.00	16.33	16.00	0.000
- Mobilizing family to acquire and accept help	20.02	20.00	18.87	20.00	0.001
- Total	119.09	119.00	110.76	110.00	0.000
3. Family Burden	7.78	4.00	10.28	6.00	0.132
4. Elderly Health Status					
- Physical	27.35	28.00	28.48	29.00	0.728
- Mental	21.00	22.50	21.46	22.00	0.219
- Total	48.35	51.50	49.94	50.50	0.747
5. Mistreatment					
- Physical	19.67	20.00	19.07	19.00	0.001
- Financial	15.41	16.00	15.06	15.00	0.006
- Psychological	14.74	15.00	14.09	14.00	0.049
- Abandonment	15.78	16.00	15.22	16.00	0.012
- Total	65.54	66.00	63.44	64.00	0.000

Results of Phase 1 Research are as following: The characteristic of the elderly was most of them are aged between 60-69 years old (51.1%). This indicated that the elderly was categorized as young elderly. They should actually still live actively and be able to be independent in meeting their own basic needs. More than half of the elderly were female (55.6%), almost all of the elderly's income was below the City/County Minimum Wages or UMK (91.9%) and more than half of the elderly were of Betawi ethnic group (57.0%).

Results of Phase 2 Research: Based on the result of phase 1 research, literature study and inputs from experts, a Cordial Older Family Nursing Model was compiled to improve the quality of family nursing on the elderly in phase 2 research. The model developed referred to the philosophy of the research that is improvement of family support on the elderly, coping strategy, and lowering the burden felt by families hence the occurrence of mistreatment can be minimized and the elderly health status can be optimized.

Results of Phase 3 Research: Phase 3 researches illustrated the effectiveness of Cordial Older Family Nursing Model on the supports, coping strategy, and family burden in nursing the elderly, health status of the elderly, and capability of the family in avoiding mistreatment on the elderly.

Discussion

Results of the cordial older family nursing model testing indicated improvement of mean value of total

family support before and after treatment on intervention group which means the capability of family in providing support in elderly care giving were improving. Statistics test results indicated differences (value of p=0.000) in total family support prior to and after the implementation of cordial older family nursing model on intervention group. Based on test on the difference between intervention group and control group a result was drawn that there was a difference (p=0.014) in total family support between intervention group and control group after the implementation of cordial older family nursing model. This indicated that cordial older family nursing model was effective in improving total family support in nursing the elderly.

The research carried out by Zulfitri had similar results with this research, i.e. there was a significant relation between family support and the behavior of the elderly in controlling their health in the service are of Melur Pekanbaru Community Health Center (Puskesmas)[14]. This means by improving family informational support in health related information provision, the elderly health behavior would be improving. Willis (2009), stated that one of the reasons for lack of communication in a family was each of its members was busy with their activities hence they did not have time to listen to each others' wishes and complaints. Such condition was also found in this research. There were families who did not have enough time to listen to the elderly's complaints due to their hectic working hours(15). Family counseling is an assistance effort provided to invidual family members so as their potential can be developed optimally and the problems resolved based on their eagerness and love for the family. This is in line with the research of Zulfitri which stated that the most dominant family support that was related to the behavior of elderly with hypertension was emotional support[16].

The results of family instrumental support questionnaires filled in by caregivers stated that most families did not prepare special saving for the elderly needs, this was caused by the priority of family financial management was still put on meeting the family basic needs (food, clothing and housing). In other questionnaire's anser related to instrumental support was that there were families who did not give the elderly a chance of socializing due to financial constraint[17]. Most of the respondents and familie in this research had income that was below Depok city minimum wage (upah minimum kota/UMK). Family income is an important aspect for the family and affects the family life [18]. Excellent family income is expected to provide better instrumental support in accordance with the needs of the elderly because the family is the greatest supports source for the elderly.

Widiastuti in her research revealed that a respondent experienced a stress in nursing her spouse who was suffering from Alzheimer. In this case, the respondent dealt with her problem by controlling her emotion first to adapt with existing situation. The coping strategy used by the respondent can be categorized as Reframing coping strategy[19]. This complied with the result of this research where the family did not always consider problems as an unexpected thing and many families always sought for the blessing in any problems or incidents experienced so they did not cause desperation. The result of chi-square test gave an illustration that elderly with families that did not apply good reframing coping strategy experienced greater mistreatment compared to those with families who applied good reframing coping strategy[20].

Conclusion

The results of the research showed that:

1. Family informational, instrumental, appreciation, and emotional supports in nursing the elderly have not been optimal. There were relations between appreciation and emotional support to the occurrence of mistreatment on the elderly.
2. Family coping strategy in nursing the elderly that was mostly used was *seeking spriritual support* coping strategy. Families have not implemented the entire existing coping strategies adequately.
3. Most of the families stated that there had not been any burdens in nursing the elderly. There was no relation between caregiver's burdens to the occurrence of mistreatment on the elderly.
4. The health status of the elderly had not been optimal. There was a relation between mental health status to the occurrence of mistreatment on the elderly.
5. The occurrence of mistreatment was found on the elderly in the form of physical, financial, psychological and abandonment mistreatment types
6. Cordial older nursing model was compiled

Conflict of Interest: The researcher declare that there are no conflict interests of this study

Source of Funding: This study was supported by the Universitas Indonesia fund.

Ethical Clearance: The ethical clearence taken from Universitas Indonesia committee

Early-Onset Neonatal Sepsis in Low-Birth-Weight and Birth-Asphyxia Infants at Haji Hospital Surabaya, Indonesia

Euvanggelia Dwilda Ferdinandus[1], Berliana Devianti Putri[2]

[1]Department of Maternal and Child Health, Faculty of Public Health, Universitas Airlangga, [2]Department of Health, Faculty of Vocational Studies, Universitas Airlangga, Kampus C Universitas Airlangga, Kec. Mulyorejo, Kota Surabaya, Jawa Timur 60115

Abstract

Introduction: The incidence of early-onset neonatal sepsis is still high, therefore special attention is needed early detection of risk factors for early management. Many risk factors could affect early-onset neonatal sepsis such as birth-weight and birth-asphyxia.

Aim: This study explored the risk factors for early-onset neonatal sepsis among neonates at Haji Hospital, Surabaya City, Indonesia.

Method: This study was observational analytic with a cross-sectional design. The data used retrospective document review was conducted in NICUs of Haji Hospital, Surabaya City, Indonesia. 1.461 infants were born from January 2018 to December 2018. The data analysis of this study was the Chi-Square Test and Multiple Logistic Regression Test using SPSS for windows v.17.

Result: This study involved 1.461 infants with one hundred seventy-eight suffered of sepsis. The study found out that low-birth-weight and birth-asphyxia were significantly associated with neonatal sepsis ($p<0.001$). Last, the result of multiple regression analysis showed that early-onset sepsis was influenced by low-birth-weight ($p<0,001$; RR: 10.405; CI: 6.346 to 17.061) and birth-asphyxia ($p<0.001$; RR: 17.038; CI: 10.644 to 27.271).

Conclusion: The neonatal sepsis was influenced by low-birth-weight and birth-asphyxia. Based on these results we recommend to focus on the intensive treatment for infants who suffered asphyxia and had low-birth-weight.

Keywords: *Neonatal sepsis; low-birth-weight; birth-asphyxia.*

Introduction

Infant Mortality Rate (IMR) is an indicator that reflects the state of health in society including Indonesia and is a sensitive benchmark of all management efforts undertaken by the government, especially in the health sector[1]. IMR in Indonesia in 2015 was still high at 22.23 per 1,000 live births while in East Java the IMR in 2014 reached 26.66 per 1000 live births[2]. IMR in East Java decreased compared to the previous year but it was not significant, namely in 2013 several 27.5 per 1000 live births. IMR in the city of Surabaya in 2015 amounted to 6.48 per 1000 live births. This figure has increased compared to 2014 which was 5.62 per 100 live births. The United Nations set this indicator on the 2030 Suistanable Development Goals (SDG's) at point 3, namely in 2015-2030, which is to reduce the infant mortality rate to at least 12 per 1,000 live births.[3].

According to WHO in 2016 neonatal deaths account for 45% of child deaths under 5 years. The majority of all neonatal deaths (75%) occur in the first week of life, and between 25% to 45% of neonatal deaths occur within the first 24 hours. Almost all (98%) of five million neonatal deaths occur in developing countries. Neonatal sepsis accounts for nearly 80% of neonatal deaths[4].

Sepsis was initially defined as a suspicion or proven infection accompanied by clinical conditions of SIRS (Systemic Inflammatory Response Syndrome) but the

definition is now abandoned. As per the consensus regarding the latest sepsis, sepsis is defined as a state of life-threatening organ dysfunction/failure, caused by an unregulated host response to infection. The cause of early onset neonatal sepsis is different from the cause of slow onset neonatorum sepsis. The cause of SNAD is microorganisms that are transmitted vertically from mother to baby, both before and during labor[5].

As per the consensus regarding the latest sepsis, sepsis is defined as a state of life-threatening organ dysfunction, caused by an unregulated host response to infection. Neonatal sepsis is divided into two namely early-onset neonatal sepsis (age <72 hours) and advanced (age> 72 hours)[6]. Early-onset neonatal sepsis causes high morbidity and mortality in newborns. The incidence of early-onset neonatal sepsis is higher in developing countries (1.8 to 18 per 1000 live births) than in developed countries (1 to 5 per 1000 live births). The case fatality in EONS ranges from 16.7% to 19.4%[7]. The incidence rates of neonatal infection in several referral hospitals in Indonesia is approximately 8.76%–30.29% with the mortality rate is 11.56%–49.9%. The incidence rates of neonatal sepsis in several referrals hospital in Indonesia is 1.5%–3.72% with the mortality rate is 37.09%–80%[5].

In Haji Hospital Surabaya there was an increase in cases of newborn infections in 2015-2017 to 21.50%. Several factors of mother, babies, and environment are contributed to the infection exposed and non-optimal of NM immunologic response so as the newborn become susceptible to be infection[8]. The objective of this study is to explore the risk factors for early-onset sepsis among neonates at Haji Hospital, Surabaya City, Indonesia.

Material and Method

This study was observational analytic with a cross-sectional design. The data used retrospective document review was conducted in NICUs of Haji Hospital, Surabaya City, Indonesia. 1.461 infants were born from January 2018 to December 2018. The independent variables of this study were birth-weight and birth-asphyxia. The dependent variable of this study was early-onset sepsis.

This study used SPSS Statistics 17.0 for data analysis. Bivariate analysis was correlated using cross-tabulations and Chi-Square Test with α=0.05. A multivariable logistic regression model was created to examine the causal association between independent variables and breast milk production using Multiple Logistic Regression with α=0.05. This study was received ethical approval from the Health Research Ethics Committee, Faculty of Medical, Universitas Airlangga.

Findings:

Most of the 928 infants (63.51%) were female while almost half were 533 infants (36.48%) were male. Almost entirely, 1353 babies (92.61%) were born with clear membranes while only a small portion, namely 108 babies (7.39%) were born with turbid green membranes.

Furthermore, almost 1350 babies (92.40%) were born full term and a small part, namely 107 babies (7.30%) were born with a premature period as well as babies born over time (postdate) only a small portion, 4 babies (0.30%). Other data show that almost all 1340 infants (91.72%) had no low birth weight (LBW) while only a small portion, 121 babies (8.28%) were born with LBW.

The data of asphyxia in infants shows that almost all of 1333 infants (92.61%) were born not asphyxia while only a small proportion of 128 infants (8.76%) experienced asphyxia. And it shows that almost all 1420 babies (97.19%) were single born and only a small portion, 41 babies (2.81%) were born twin (multiple)

Based on data which fulfill our inclusion criteria. These are the result.

Table 1. Bivariate analysis between independent variables and early-onset sepsis

Variables	Early-Onset Neonatal Sepsis				Total		p
	EONS		Non-Sepsis				
	n	%	n	%	n	%	
Birth-weight							
Low(< 2500 gram)	76	42.7	45	3.5	121	8.3	< 0.001*
Normal (> 2500 gram)	102	57.3	1238	96.5	1340	91.7	
Asphyxia							
Yes	87	48.9	41	3.2	128	8.8	< 0.001*
No	91	51.1	1242	96.8	1333	91.2	

* Significantly correlate using Chi-Square Test ($p < 0.05$)

Table 2. Summary of multiple logistic regression

Variables	B	SE	P	RR
Birth-weight				
Low	2.342	0.252	< 0.001*	10.405
Normal (reference group)				
Asphyxia				
Yes	2.835	0.240	< 0.001*	17.038
No (reference group)				

* Significantly associate using Multiple Logistic Regression Test ($p < 0.05$)

This study involved 1.461 infants with one hundred seventy-eight suffered of sepsis. As shown in **Table 1**, there was a correlation between LWB and neonatal sepsis ($p<0.001$). Most of infants who had normal weight (96.5%) did not suffer sepsis than infants who had LBW. In contrast, almost half of participants (42.7%) who had LBW were suffer early onset sepsis highly than infants who had normal weight. It could be concluded that the early onset sepsis was more suffered by infants who had low-birth-weight (less than 2500 gram).

Table 1 also shows that there was a correlation between asphyxia and neonatal sepsis ($p<0.001$). Only 3.2% (n=41) infants who are getting sepsis were infants who had asphyxia. In contrast, almost half of participants (48.9%) who had asphyxia were suffered early onset sepsis highly than normal infants. It could be concluded that the sepsis was more suffered by infants who had asphyxia.

Table 2 shows that the results of multivariate analysis with Multiple Logistic Regression Test ($\alpha = 0.05$). The result showed that neonatal sepsis was influenced by low-birth-weight ($p<0,001$; RR: 10.405; CI: 6.346 to 17.061) and birth-asphyxia ($p<0.001$; RR: 17.038; CI: 10.644 to 27.271)

The infants who had LBW were at risk for getting early onset sepsis 10.405 times greater than infants who had normal weight. Then, infants who suffered asphyxia were at risk for getting early onset sepsis 17.308 times greater than infants who not suffered asphyxia. So that, asphyxia most likely has an influence.

Discussion

Following approval from the institutional ethical committee, almost half of participants (42.7%) who had LBW were suffering early onset sepsis highly than infants who had normal weight. It could be concluded that the early onset sepsis was more suffered by infants who had low-birth-weight (less than 2500 grams).

The results of this study are in line with the results of a research namely LBW has three times the risk of developing sepsis than non LBW[9,10]. This is in line that infants with sepsis had more low birth weight (85.7%)[11]. The central regulation of breathing is not perfect, the respiratory muscles and ribs are still weak in LBW infants resulting in less oxygen entering the brain, if oxygen is lacking, anaerobic germs easily develop which causes easy infection. In contrast to research conducted by Rahmawati in Dr. M. Djamil Padang Hospital, the

results showed that there was no statistically significant relationship between birth weight in the form of low and normal categories with the incidence of neonatal sepsis. A significant relationship appears in LBW infants with prematurity where the maturation of their organs (liver, lungs, enzymes, digestion, brain, immune system against infection) is not perfect, so LBW babies often experience complications that end in death[12,13].

Then, infants who lived asphyxia were at risk for getting early onset sepsis 17,308 times greater than infants who didn't live asphyxia. So that, asphyxia most likely has an influence to. Neonatal asphyxia facilitates systemic infections. This is due to inhibited leukocyte activity because it requires energy (ATP) for cytoskeletal microfilament contractions. The state of hypoxia will also inhibit the microbicidal activity of polymorphonuclear cells[14]. Neonatal asphyxia increased the risk of EONS with a positive blood culture result 4-fold (RO = 4.102; 95% CI 1.04-16.14)[15,16].

Neonatal asphyxia was assessed by examining APGAR scores. A low APGAR score increases the risk of EONS. Research conducted by Muhammad et al in 2015 found that Apgar scores <7 in the first minute had a risk of 14.05 times (95% CI 5.487-35.987) for EONS events[17]. APGAR scores <7 in the first minute were also reported by Shah et al., which were significant with each OR being 5.7 for EONS eventsc. In general, the first minute APGAR score is associated with Potential Hydrogen (pH) umbilical cord blood and intrapartum depression and is not related to the results, whereas the APGAR score then reflects changes in the baby's condition during resuscitation[10,18].

Asphyxia neonatorum is very closely related to health problems of pregnant women, including infections. Babies with asphyxia neonatorum appear unfit and have a history of fetal distress before birth. Neonatal asphyxia facilitates systemic infections. Neonatal asphyxia increases the risk of early onset neonatal sepsis with positive blood cultures. In addition, low birth weight babies, including this risk group. Most problems occur in infants who weigh less than 1500 grams with high mortality and require special medical care and treatment for infants at 2.75 times higher risk of neonatal sepsis[10,13,16].

The diagnosis of early onset neonatal sepsis is very important in the management and prognosis of the patient. Delay in diagnosis can potentially threaten the survival of the baby and worsen the patient's prognosis. The prognosis of neonatal sepsis depends on diagnosis and therapy. The prognosis of neonatal sepsis is good if the diagnosis is made early and the therapy is given appropriately. Mortality rates can increase if clinical manifestations and risk factors for neonatal sepsis are not well identified. Midwives and doctors play an important role in efforts to improve the health of mothers and children, especially in clinical cases[19,20].

Conclusion

The neonatal sepsis was influenced by low-birth-weight and birth-asphyxia. Based on its conclusion, it is suggested to Health Service Centre to focus on the intensive treatment for infants who had low-birth-weight and suffered asphyxia. It is also suggested to society, especially for husband, to keep supporting the pregnant-mothers for check their pregnancies regularly.

Conflict of Interest: There was no conflict of interest in this study.

Comparative Study between Elastic Nail Versus Plates and Screws in the Treatment of Diaphyseal Both Bone Forearm Fracture in Children

Farouk Makkie Abdulkareem[1], Las Hwaizi[2]

[1]Lecturer, Iraqi Board for Medical Specializations, [2]Asst. Prof., College of Medicine, University of Erbil, Erbil, Iraq

Abstract

Objective: Compare between titanium flexible nail and plate fixation for fracture both radius and ulna regarding the operation time, time of union, functional outcome and complications for each method.

Materials and Method: A prospective comparative study, involved 44 children with displaced fractures of the radius and ulna were reviewed. Group1; (23 patients)underwent closed reduction-intramedullary fixation. Whereas, Group2; (21 patients)underwent open reductioninternal fixation with plates. Patients were followed up for 24 weeks.

Results: Both treatments achieved excellent clinical outcomes and union rate, flexible intramedullary nailing showed better cosmoses, shorter operating and discharge times but the disadvantage is radiation exposure.

Conclusion: Both titanium elastic nail and compression plates and screws can be expected to yield excellent results and are proper for treating pediatric forearm shaft fractures. Intramedullary nailing was safe, effective, and easy to do in the management of both-bone forearm shaft fractures in children.

Keywords: *Forearm shaft, fracture, titanium elastic nail, plates, scores, Price score system.*

Introduction

Pediatric diaphyseal fracture of the radius and ulna commonly referred to as both bone forearm fractures are the third most common fracture in pediatric population, and account for 13 to 14% of all pediatric fracture[1]. Most of these fractures treated with non-operative management. Recently, however, there has been a trend toward increased surgical management of these fractures in an effort toward increased functional outcome[2]. The purpose of the operative intervention is to prevent future angular and rotational deformity and maximize functional outcome[3].Many epidemiologic studies have shown that 18% of children will experience a fracture by the age of 9, with children between the ages of 5 and 14 having the highest fracture incidence[4].

In recent years the proportion of pediatric forearm fractures treated with internal fixation had increased, with a particular rise in the use of intramedullary nailing (IMN). This increase might be driven by improved understanding of the functional implications of mal-union, technological advances, societal expectations or fear of litigation. Traditionally, internal fixation of unstable pediatric forearm fractures had been achieved by open reduction and rigid internal fixation with plate and screws with good results. IMN with Kirschner wires or elastic stable intramedullary nails has become popular due to improved cosmetics, shorter operative time, less soft tissue dissection and ease of removal, with good results reported[5].

Open reduction with compression plate and screw fixation offer full stability if performed properly. The

method had been reported as a possible choice in adolescents approaching skeletal maturity. It is also a useful method in cases of re-fracture as the intramedullary canal may be obstructed[6-8].

Titanium elastic nails system (TENS), has recently become the primary method of surgery in forearm shaft fractures in children. It has produced results equally good as plate and screw fixation in cases of unstable fractures, with several advantages when compared with plate and screw fixation[9]. In theory, ESIN was based on three-point stabilization by means of opposite tension of two parallel implants in the same intramedullary canal. In the forearm both bones are fixed separately with single nails. Therefore, stability is dependent on the two nails mandatorily orientated with the tips towards each other. In the forearm, the two separate nails in two separate bones together form opposing elastic concavity at the level of the fractures, for this reason both bones should be fixed [10], regardless of opposing reports supporting single bone nailing. ESIN will not fill the medullary canal, in contrast to rigid intramedullary implants. The flexibility of using ESIN facilitates callus formation by enabling minimal movement in the fracture. It is still strong enough to maintain satisfactory alignment[11].

The present study aimed to compare titanium elastic nail and plate fixation for treatment of fracture both radius and ulna regarding the operation time, time of union. also, to evaluate the functional outcome and complications for each method.

Method

Study Design: A prospective comparative study between two surgical techniques for the treatment of both forearm bone fracture, the first one was fixation by titanium elastic nail and the second one is fixation by plate and screws.

Study Setting: The study was conducted at the orthopedics department of Erbil teaching hospitals.

Period of the Study: The study was carried out between October2016 and November 2017

Study Sample: A total of 44 patients were included in the study. A random sampling technique was usedby including every other patient in the study.

Inclusion Criteria: Age from 4-14 years old, unstable fracture, failure of conservative treatment, and open fracture (Gustilo type 1).

Exclusion Criteria: Distal metaphyseal fracture, fracture dislocation (Galeazzi and monteggia fracture), associated arm fracture on the same side, and associated radial neck fracture.

Written consent was obtained from the family of each patient before participation in the study, A semi-formed Questionnaire was constructed by the researcher, the questionnaire includes:

Socio-demographic characteristic of the participants, side and site of injury, mechanism of injury, operative time, time of union, intraoperative complications and any postoperative complications like infection (superficial and deep,insertion site pain, need of nail trimming or removal and loss op reduction) each patient was followed up by 2nd, 6th, and 12thweek postoperatively. The duration of the interval between injury and surgery was 1 day to 1 week.

Overall, the number of patients presented to our department with displaced diaphyseal fracture of radius and ulna at that duration was (124)children. Only (44) of them required open reduction and internal fixation.

Patients: Group 1: (23 patients), 17 boys (73.9%) and 6 girls (26.1%), their mean age were (9.43 ± 3.23) ± SD years, underwent closed reduction-intramedullary fixation by titanium elastic nail.

Group 2: (21 patients), 14 boys (66.6%) and 7 girls (33.4%), their mean age were (11.04 ± 1.82) ± SD years underwent open reduction internal fixation with plates and screws. The patient and method of fixation were chosen randomly.

Statistical Analysis: T-test concerning two means of un-paired group was used to find out if there are significant differences in the duration of the operation of both method. Pearson Chi-square test was used to see if there was a significant difference in functional outcomes of both method. The data were analyzed statistically by using statistic package for social science (SPSS) version 18. A p-value < 0.05 considered to be statistically significant.

Results

Table 1 illustrates most of the characteristics of the patients involved in the study. The mean duration of the operation was significantly higher in group 2 compared to group 1, while duration of hospitalization, functional outcomes and time to unite was not statistically different between both groups, as illustrated in table 2.

Discussion

The functional outcome following bone pediatric forearm fracture is one of the main considerations for a surgeon to decide between operative and conservative management[12]. Most of these fractures can be treated non-operatively with full restoration of forearm function, due to the presence of a tout periosteum, and the very good remodeling capacity of children[12].

This study showed a significantly high proportion (70.45%) of male children with both bone fracture of forearm compared to females (29.55%). This may be because male children are more involved in playful activities like bicycling and this finding correlated with the studyby Mohammed et al[13].

The most common mechanism of injury fellon outstretched hands duringplaying at school (79.54%), while fracture incidence by car accident was low(9.09%) and this agreed with another study [14].

The indications for open reduction and internal fixation of such fractures were; unstable (29.54%), still displaced after a trial of manipulation (18.18%), re-displaced (22.72%), neglected (15.9%), compound fracture(4.5%), multiple(4.5%), segmental(2.2%), neurovascular injuries and compartment syndrome (2.2%), which is similar to a study by Greenbaum [15].

Concerning the time of operationfixation by titanium flexible nail take a significantly shorter time in comparison to the fixation by plate and screw, this agreed with Koseet al study [16].

There wasfewer complications rate in titanium elastic nail than those treated by plate and screws, but it did not reach statistical significance, which was in agreement with other studies like that done by Reinhardtetal[17].

The fracture union complications in the forearm have been shown to be rare in several previousstudies[18]. Those treated with IM nailing healed within 3 months (78.26%) and (21.73%)healed within six months. By using plate fixation healing within 3 months was (57.14%) and (42.85%)within 6 months, no significant differences between IM nailing and plating in terms of fracture union at 3 and 6 months after surgery.

The functional outcomes were graded according to Price et.al. study[12]. The result showed in titanium elastic nail group had excellent outcome (78.26%) and (21.74%) had good result, while for group 2 which used plate and screws in fixation the result showed (66.66%) excellent and (33.33%) good result, there were no fair or poor graded noticed in this study, although there was a little difference in the two groups that's of no statistical significance. Seyfettinogluet al found that surgical treatment gave excellent and good results in 82% of the patients[19].

Ozkayaet al study recorded that 85.7% had excellent, 14.3% had good results according to Price et al Criteria. The follow-up period in their study was 37 months and the method of treatment was closed reduction and intramedullary nailing. They concluded that intramedullary nailing was safe, effective, and easy to perform in the management of unstable both-bone forearm fractures in children[20].

Conclusion

Both techniques have good functional outcome and union rate, flexible intramedullary nailing is a useful method to treat unstable forearm fractures in young children, compression plating is a useful method to treat unstable forearm fractures in late childhood, titanium elastic nail is superior to plate and screws fixation because: the procedure is easier and quicker, skin incisions are smaller, less soft tissue dissection and stripping of the periosteum is avoided, these allow shorter operative time and decrease the risk of prolonged anesthesia, and easier removal without significant complication.

Conflict of Interest: None

Ethical Clearance: Informed written consent was obtained from all the participants in the study, and the study and all its procedures were done in accordance with the Helsinki Declaration of 1975, as revised in 2000. The study was approved by the Iraqi Board of Medical Specializations.

Humanoid Robot Integration in Rehabilitation of Musculoskeletal Conditions

Fayz S. Al-Shahry[1], Rayan F. Al-Shehri[2]

[1]Assistant Professor COAMS,KSAU-HS, Consultant Rehab,KAMC, [2]Engineering Student, KSU, Riyadh

Abstract

Robots find numerous applications in medical/health domains and are extensively used in commercial as well as domestic applications to support daily life activities. Human robot (HR) has widened their wings to be used in rehabilitation applications. Interest in robots that provide health care is growing as one of the upcoming fields of next generation. In this study we investigated the Robot-patient performance in physical rehabilitation. A group of musculoskeletal patients diagnosed with pain in muscles or joints or both, aged 20 to 65 years was chosen for the study. The robot was programmed to instruct and guide the patients for physical rehabilitation activities for three trials of 30 minute sessions on different days. The sessions involved interaction with a humanoid robot. Robot was programmed for a set of active exercises with a classified sequences that are time and motion managed. Verbal communication between the robot and patients allowed for re-start, stop, resume and replay functions. The whole performance was filmed and reviewed from the perspectives of the impact on the patient as well as the performance of the robot. The whole process was validated by performing the same procedure on a trial basis with healthy individuals to ensure the setup is operated smoothly. The performance of each variable was evaluated in three successive sessions. Evaluated functions include clarity, therapy sequence, interaction, voice, timing, independency, operation, technical performance and degree of freedom. Results were computed as percentages by an external assessor. Results demonstrated dynamic learning in the 1st and 2nd sessions which showed a remarkable improvement in the 3rd, 4th and 5th sessions. The overall average of the performance for the last 3 sessions was 91+%. Referring to this outcome, it could be concluded that the robot may have the potential to influence the physical therapy imitation. However,to establish the extent of this influence affirmatively, a bigger sample will be needed with a wider variety of patients.

Keywords: *Humanoidrobot, interaction, integration, rehabilitation, musculoskeletal.*

Introduction

Robots are being designed to complement human skill sets, reduce workload and enable professionals to focus on more important activities that have a greater impact on patient care delivery. As this technology advances and becomes more affordable, we can expect more health care institutions to adopt robotics.

Robots are still not a replacement for human interaction. Hospital operations are complex and involve uncertainty. Robots are good for performing repetitive tasks and tracking data, but this technology should only be used to make the clinicians' workflow easier so that they may focus on the most critical part of their jobs, which is caring for patients.

Advanced humanoid robots are employed in a variety of applications in medical/health domains and are also used extensively in commercial establishments as well as in the home support for daily life activities. Beyond the traditional scope, robot can be engaged in the rehabilitation process and it is poised to become one of the most important technological innovations of the 21st century. Literature showed specific uses with elderly patients and some pediatric applications.[1,2]

In this article, we offer a trial study on the possible uses of robots in rehabilitation, particularly in the management of musculoskeletal conditions.

Human Robot (HR) has widened their wings to be used in rehabilitation. Interest in health care robots is

growing as one of the upcoming fields of next generation in this smart industry, especially as assistive tools in rehabilitation[1]. It is believed that humanoid Robot promises excellent experience for CP children to learn motor tasks[3]. Many studies involving CP children investigated robotic exoskeletons[4] to replace or support function. There is still a lack of intervention therapy which involves complicated functional tasks.

Some of the robotic technologies were designedto assist the user primarily through social rather than physical interaction[5]. For example, a previous study[6] has established Kindergarten Assistive Robotics (KAR) as a tool for learning and development for normal children in preschool education. KARhas increased children's motivation and communication during the interaction. Robots have been successfully introduced into physical therapy and rehabilitation of children with disabilities[7,8,]. Thus, KAR is suggested to be applied for CP children. One of the studies involved KAR as a Robotics Agent Coach for CP motor Function (RAC CP FUN)[9] which is designed to improve their motor functions and activities associated to daily living. Further, another study[10] employed a mobile robot named "Neptune" and used a toy robot named "Cosmobot" and the derived results showed that robot can become a social mediator for learning. The results of a study[11,12] that used Lego Mind storms robots[13] for CP children's play activities demonstrated that the children reacted positively toward the robots, while some children increased their attention span and could be better engaged when they used the robots. However, most explored robotic systems earlier were mainly in the form of toys, and not in humanoid form. Thus, this study is designed to use a humanoid robot to instruct patients in physical therapy sessions with musculoskeletal problems. An expert software programmer and a physiotherapist jointly developed the therapy program. Details of the therapy were tailored specifically to meet the needed conditions, interact with the patients, with the mode and specificationcapable of offering several options.

Methodology

The intended group is a set of musculoskeletal patients diagnosed and referred for P.T clinic. A strengthening exercisewas prescribed and endorsed by a licensed physiotherapist specialized in the musculoskeletal disorders, This particular group was for improving the back strength, with age range between 20 to 65 years. Other inclusion criteria were no physical or mental disability, no hearing and vision deficiency, and a cognitive ability to follow simple commands in English. Signed informed consent was obtained from the participants. Five trials, each of 30 minutes session were performed on different days. The sessions involved interaction with humanoid robot. The experiment protocol was approved by the Occupational Therapy Association Research Board. The robot was programmed for a set of active exercises with a classified sequence managed in time and motion. Verbal communication between the robot and patients allowed re-start, stop, resume and replay functions. The robot was equipped with 4 cameras and programmed to take photos of the patient's face and voice print to enable individual recognition in order to recall the personal therapy program and update the patient information at the end of the session. The whole performance was filmed and reviewed from the perspectives of both the patient and robot. The whole process was validated by performing the same procedure on a trial basis with healthy individuals to ensure the setup is operated smoothly.

Patients were educated about the robot and the study aim. An introduction session was made to familiarize the group(robot, patient, operator and the assessor) with the study methodology. The study was conducted in a simple gym, with the exercise mat laid on the floor for the patients and the NAOwas placed on the non-slippery floor. The performance assessment will use met partially me or not met.

NAO has 23 degrees of freedom: 2 degrees of freedom for head, 4 degrees of freedom for each arm, 1 degree of freedom for pelvis, and 5 degrees of freedom for each leg.

Result

The aim of this robotic-patients application is to instruct patients with musculoskeletal problems for several pre-structured and programmed exercises. The overall aim is to measure several factors that govern the robot-patient performance, e.g. clarity, sequence, interaction, voice, timing, independency, operation, technical performance, and degree of freedom. The assessment is expressed by% of excellence for the three times and then the% average is gathered for all patients. The total for each parameter in each session and the total for the five patients for each session is presented. The data in the table below is the grand total for the three sessions for five patients and expressed in%.

Item	Trial sessions		3rd session	4th session	5th session	Average%
	1st session	2nd session				
Clarity	50%	70%	90%	95%	95%	93+
Therapy sequences	30%	60%	90%	90%	100%	93+
Interaction	20%	60%	95%	95%	95%	95
Voice	70%	70%	80%	90%	95%	88+
Timing	40%	60%	100	95%	100%	98+
Independency.	60%	80%	80%	90%	90%	86+
Operation	70%	90%	90%	90%	95%	91+
Technical performance	90%	90%	90%	90%	95%	91+
						Grand 91+

Table 1: The data here is representing the% of performance of each item. The performance of the last three visits are averaged in the last column and the grand average for the overall performance (91+) is also presented. The 1st and 2nd sessions were considered as learning sessions.

Consequently, there are few points to be highlighted and discussed. The data presented represent the external assessor evaluation of the performance. It is clear that the 1st session is a learning step which shows low levels of performance. Second session showed remarkable improvement and a continuous improvement is recognized in the 3rd session. The overall impression is supporting the fast and reliable interaction integration. The total performance related to the robot therapy assignment is seen as highly satisfactory and manageable with the patient acceptance of the whole process.

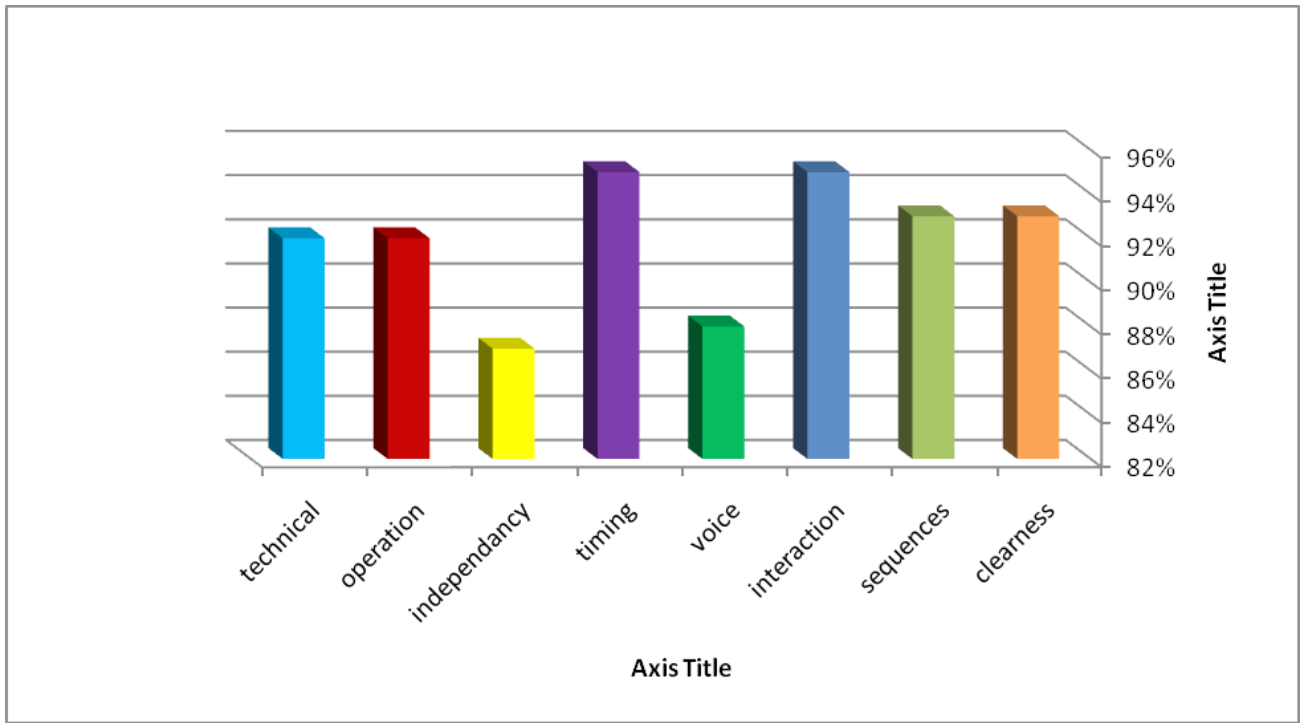

Fig. 1: Shows the representation of various performance parameters. This indicates the average percentage of the last three sessions

Fig 2: A, and B, The robot is oppositely facing the patient to assure face to face communication, both in lying position. The robot NAOasks the patient to imitate each movement. NAOstarts to perform the exercise and patient is expected to follow, patients should match the time in a steady sequence and follow and repeat for several times matching the robot command. The robot is watching the patient through the cameras and has the capability to stop, rectify, adjust and resume.

Discussion

The set up of this robot rehab program was made to serve patients at the clinic or at home. The overall performance was great, smooth and relatively reliable in this small trial group. This work encourages interest groups to proceed with robot rehab therapy. The available data from this trial study showed the robot-patient performance and the technical performance as well as the operational performance. The imitation of movement simultaneously with the robot confirmed the possibility of independent execution of serial therapy program in the rehab clinic or at home particularly for chronic conditions. The total percentages core of the last three sessions was around 92. However, further optimization of the robot programming and proper prescription of exercise program and careful selection of patients could make the work performance highly efficient. Each of the eight parameters of this study were assessed in five different sessions. These parameters are believed to be the most important factors to govern the implementation. Optimizing them will enable the robot to work independently with the patients at the clinic or at the home and this will enable to personalize this technology and the outcomes[7,8] are in line with this result.

It is worth saying that the interaction was very successful and the options of stop, resume, restart were

used many times to cater to patients' requests, and this was considered healthy. The clarity of steps and voice level was perfect and the patient'sfollow-up on sequence was also maintained to a high level. Progressing with time is a notable and clear indicator which means that the patient-robot relation is supporting the level of confidence of the patient as well as the therapist, and this matches earlier reported outcomes[13]. This is an improvement of the technology with a friendly perspective. The overall satisfaction of the patient and the acceptance were high and very promising. The grand total performance of all eight parameters was very high(almost 92%) which substantiates its applicability in the clinical robotic industry in line with the[16,17,18].

This article is meant to cover solutions at different stages of applications. Thereafter it is up to the developer to commercially make it ready and available in the market or to look to some alternative or to go for more phases of research and experimentation. The existing data provides examples and pointers to proceed to clinical applications and other major ingredients for the success of these applications as well as the main issues surrounding their adoption for a wide range of everyday physiotherapy use are to be developed further. We have examined how robotics could partially fill in some of the identified gaps in current telehealth-carethrough internet connectivity since the robot is equipped with 4 Cameras and can recognize individuals by face and by voice tone. Introducing a tele control can pave the way for program modification and alteration based on instantaneous robot-patient interaction and would bring in a possibility of remote sharing with a third party or more in audio-visual mode.

We conclude with a brief glimpse at a couple of emerging developments and promising applications in this field that are expected to play important roles in the future. Readers should note that this paper is intended to be read mainly by non-roboticists, with little or no background in the field. Specifically, the paper is meant to ignite the interests of conventional health informatics and telemedicine/telehealthcare specialists and clinicians, physiotherapists and rehabilitation professionals into such emerging possibilities. It would also be of interest to experts in robotics who are interested in its potential applications, especially about how robotics may help users in the healthcare and social care sectors. This also my facilitate investments and businesses in the long-term to commercialize use of robotics in health sectors, both in health care centers and in homes.

Conclusion/Recommendations

This trial outcome is highly supportive to the use of robot in rehabilitation of patients. More focus may be needed to improve the friendly interaction and flexible sequence between exercises. Logistic support may be included e.g. refreshment time, rest, short breaks may be considered upon patient request.

There is also a need to address some challenges encountered in the set up. The degree of freedom for all joints was of acceptable level except the pelvic rotation. There is a need to improve on the robustness of the pelvic movement.

The issue of the NAO system getting heated up during the performance causing an interruption in the session needs to be investigated and resolved.

Based on this trial, it is recommended that this work be continued with a larger sample and varying conditions to ensure consistent approach and reliable outcomes.

Validity of the Fast Scan for Diagnosis of Intra-Abdominal Injury in Blunt Abdominal Trauma

Asaad Abd El Rahman abd El Aziz[1], Salah El-Din Abd El-Razik Mahmoud[2], Ashraf Mohamed Hassan El-Sherif[3], Ahmed Mohamed Kamal El-Din[4], Ashraf Abdel Azeem Mohamed[4]

[1]Assistant Lecturer of General Surgery Department, [2]Professor General Surgery Department, [3]Professor of Radiology Department, [4]Assistant Professor General Surgery Department, Faculty of Medicine-Minia University, Egypt

Abstract

Objective: To determine the validity of FAST scans in the diagnosis of bluntabdominal trauma in keeping with findings on CT scan and laparotomy.

Methodology: This study was carried out at Department of Accident and Emergency, Minia University Hospital, from August 2017 to August 2019. FAST scan was performed as part of the primary or secondary survey of the trauma patient in the emergency department in all patients with suspected bluntabdominal trauma.

Results: Our study included 150 patients with suspected blunt abdominal trauma who underwent CT abdomen or exploratory laparotomy or both CT abdomen and exploratory laparotomy. The mean age was 32.3±14.4 years. Forty-four patients (29.3%) were hemodynamically unstable and 106 (70.7%) were hemodynamically stable.

Conclusion: FAST scan has good diagnostic accuracy. It can beroutinely utilized to triage the blunt abdominal trauma patients for laparotomy,however, a multi-institutional research study in our setup is required to further validate the findings of our study.

Keywords: *CT; Abdominal injury; abdominal trauma*

Introduction

According to WHO: by the year 2020, trauma will become the first or second leading cause of "loss of productive years of life" for both developed and developing countries [(1)].

Trauma has been called the neglected disease of modern society, despite its close companionship with man. World over injury is the 7th cause of mortality. Abdominal injuries require surgery in about 25% of cases. 85% of abdominal traumas are of blunt character[(2)].

Abdominal trauma ranks the third in prevalence after head and chest traumas, with majority of cases being non-penetrating or the so called blunt abdominal trauma (BAT)[(3)].

Major abdominal trauma, both blunt and penetrating, is commonly seen nowadays, being particularly difficult to manage due to the frequent altered mental status of the patients and severity of associated injuries [(4)]. Early diagnosis and treatment can reduce mortality by up to 50% [(5)].

Blunt abdominal trauma (BAT) accounts for about 80% of abdominal injuries seen in patients referred to the emergency departments [(6)].

Ultrasonography can demonstrate variety of post traumatic abdominal organ pathologies including hematomas, contusions, lacerations, and hemoperitoneum [7].

Ultrasonography (US) is really valuable in the early assessment of a polytrauma, regardless of haemodynamic status; in fact, owing to its high sensitivity in the identification of intra-abdominal free fluid, it has largely replaced peritoneal lavage, becoming the first method used for this purpose, especially in haemodynamically unstable patients[8].

The need for a prompt diagnostic technique that could be used in the emergency setting led to the introduction of FAST in emergency departments in the 1990's. It is undertaken after the primary survey in order to identify the presence of free fluid in the peritoneal cavity [9].

FAST has become the common initial screening modality in the majority of trauma centers in the United States and worldwide, and it is included in the Advanced Trauma Life Support program for evaluation of the hypotensive trauma patient. [10].

FAST consists of a non-invasive ultrasound examination that can be quickly performed by the patient's bed, aiming to clarify specific clinical issues, regardless of the trauma mechanism that affected the patient [11]. FAST is a rapid, low-cost examination that can result in valuable prognostic information in patients who are hemodynamically stable or not [12].

Patients and Method: After approval by hospital ethical committee and taking consent, this cross-sectional study was conducted on 150 patients with blunt abdominal trauma who were admitted to the Minia University Hospital, during the period between August 2017 to August2019 . Patients consists of 111 males and 39 femals, with an age ranged from 6 to 69 years old .

Both patients whom underwent CT scan and patients who were haemodynamically unstable, were concluded in the study. Patients with penetrating abdominal injuries on history and indeterminate (inconclusive) FAST scans due to patient size, subcutaneous emphysema, or limited sonographic windows were excluded.

FAST was performed as part of the primary or secondary survey of the study population in the emergency department. An emergency ultrasound was performed by a radiologist within 1 hour of the patient arriving in the hospital. An ultrasound machine with live 2-D mode (rapid B-mode) and transducer frequencies between 3-6 MHz was used. Optimal depth settings depended on patient body habitus. The four standard views obtained with the patient in supine position were pericardial, perihepatic, perisplenic, and pelvic.

All patients in the study underwent a FAST scan. All of them also underwent either CT or exploratory laparotomy depending on their clinical conditions. FAST examination results, which were recorded as positive or negative and were compared with the findings on CT and/or exploratory laparotomy, which were considered definitive. All exploratory laparotomies were performed by the same surgical team consisting of a surgeon with at least 5-years clinical experience and the trainee as the assistant.

Data Analysis: The data was analyzed using SPSS 12. Categorical variables like gender and true positives were presented as frequencies and percentage. For numerical variables like age, mean $\pm$ standard deviations were presented. The diagnostic accuracy was calculated using the 2 x 2 table.

Sensitivity, specificity, positive predictive value, negative predictive value and diagnostic accuracy for the FAST scan will be determined by using the following standard formulas.

- Sensitivity = TP/(TP + FN) x 100
- Specificity = TN/(FP + TN) x 100
- PPV (Positive Predictive Value) = TP/(TP +FP) x100
- NPV (Negative Predictive Value) = TN/(FN + TN) x 100
- Diagnostic accuracy = (TP + TN x100)/(TP + TN + FP + FN)

Results

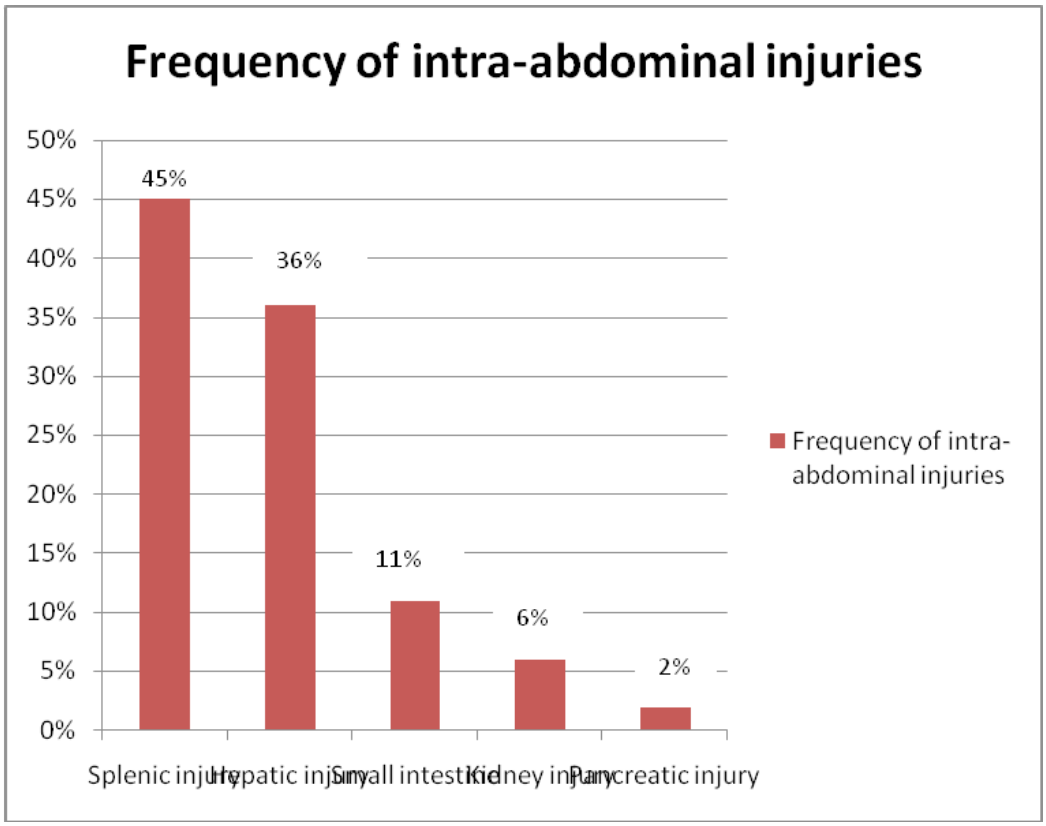

Figure 1: Frequency of intra-abdominal injuries in patients with intra-abdominal injuries.

Our study showed that 40 (45%) of cases with intra-abdominal injuries had splenic injury, 32 (36%) had hepatic injury, 10 (11%) had small intestine injury, 5 (6%) had kidney injury and 2 (2%) had pancreatic injury. Figure 2 exhibits the frequency distribution of intra-abdominal injuries.

Among 72 FAST scan positive in hemodynamically stable patients, 69 had confirmed blunt abdominal trauma on CT scan and 3 had negative CT scan. Among 34 FAST scan negativein hemodynamically stable patients, 4 had confirmed blunt abdominal trauma on CT scan and 30 had negative CT scan. Hence patients with a positive FAST scan had a statistically significant probability of a confirmed blunt trauma on CT scan. P<0.0001. Table 1 illustrates the comparison of FAST Scan and CT Scan Abdomen for stable patients.

Sensitivity of FAST scan in stable patients was calculated as 94.5%, Specificity 90.9%, positive predictive value 95.8%, negative predictive value 88.2% whereas the overall diagnostic accuracy of FAST Scan in stable patients was calculated to be 93.4%. Table 2 gives a comparison of diagnostic accuracy of FAST scan with CT scan in stable patients.

Among 19 FAST scan positive in hemodynamically unstable patients, 15 had confirmed blunt abdominal trauma on exploratory laparotomy and 4 had negative exploratory laparotomy. Among 25 FAST scan negative in hemodynamically unstable patients, 1 had confirmed blunt abdominal trauma on exploratory laparotomy and 24 had negative exploratory laparotomy. Hence patients with a positive FAST scan had a statistically significant probability of a confirmed blunt trauma on exploratory laparotomy. P<0.0001. Table 3 illustrates the comparison of FAST Scan and exploratory laparotomy for unstable patients.

Sensitivity of FAST scan in unstable patients was calculated as 93.7%, Specificity 85.7%, positive predictive value 78.9%, negative predictive value 96% whereas the overall diagnostic accuracy of FAST Scan in unstable patients was calculated to be 88.6%. Table 4 gives a comparison of diagnostic accuracy of FAST scan with laparotomy scan in unstable patients.

Table 1: Chi square test comparing the results of FAST scan and CT Abdomen

			CT Scan Abdomen For stable patients		Total	P value
			Positive	Negative		
FAST scan	Positive	Count	69	3	72	<0.0001
		% of Total	65.1%	2.8%	67.9%

Total		Count	16	28	44	
		% of Total	36.4%	63.6%	100%	

Table 4: Diagnostic accuracy of FAST scan in comparison of Laparotomy in unstable patients

		Unstable patients with BAT (as confirmed on Laparotomy)		
		Positive Laparotomy	Negative Laparotomy	
FAST	Positive FAST	(TP) 15	(FP) 4	PPV=TP/(TP+ FP) = 15/19= 78.9%
	Negative FAST	(FN) 1	(TN) 24	NPV=TN/(TN+FN) =24/25= 96%
		Sensitivity =TP/(TP+FN) =15/16 =93.7%	Specificity =TN/(FP+TN) =24/28 =85.7%	Diagnostic accuracy =TP+TN x 100 TP+TN+FP+FN =15+24x100 =15+24+4+1 = 88.6%

Table 5: Diagnostic accuracy of FAST scan in overall patients

		Patients with BAT (as confirmed on CT or laparotomy or both)		
		Positive laparotomyand CT	Negative laparotomy and CT	
FAST	Positive FAST	(TP) 84	(FP) 7	PPV=TP/(TP+ FP) = 84/(84+7) = 92.3%
	Negative FAST	(FN) 5	(TN) 54	NPV=TN/(TN+FN) =54/(54+5) = 91.5%
		Sensitivity =TP/(TP+FN) =84/(84+5) = 94.4%	Specificity =TN/(FP+TN) = 54/(7+54) = 88.5%	Diagnostic accuracy =TP+TN x 100 TP+TN+FP+FN =84+54 X100 = 84+54+7+5 = 91.4%

Discussion

The abdomen is the third most common injured region, in 25% of cases who require surgical interference. Penetrating abdominal trauma is easily diagnosed, while blunt trauma complications can be missed if the clinical signs are not evident[7].

Focused abdominal sonography for trauma (FAST) is a fast examination method that could demonstrate intraperitoneal fluid. Several studies found this technique to be sensitive (79–100%) and specific (95.6–100%), particularly in hemodynamically unstable patients [7].

In our study, out of 150 cases; 111 (74%) were males and 39 (26%) were females with a mean age (32.3±14.4) years. The young aged males were the most common victims of blunt abdominal trauma.

There was an increase in incidence of abdominal trauma in males (74%), this is seen to be a similar pattern in other studies as males are more involved in violent and traumatic experiences, involving abdominal injuries.

Ozpek et alimplemented a multivariate inquiry of patients with abdominal injuries and the responsible factors affecting mortality and in his study he had (78.9%) being males and (21.1%) being females with a mean age of 36.7 ±16.97 years (3-80 years) [13]. In America census and statistics of 2011 they report that roughly (90%) of patients with invasive trauma are males[14].

In our study, the commonest cause of blunt abdominal trauma was road traffic accidents 112 (74.7%), followed by fall from height 29 (19.3%) followed by violence 9 (6%).

Our study found FAST to be 94.4% sensitive and 88.5% specific with positive predictive value 92.3%.

Our study found FAST in hemodynamically stable patients to be 94.5% sensitive and 90.9% specific with positive predictive value 95.8%.

While we found FAST in hemodynamically unstable patients to be 93.7% sensitive and 85.7% specific with positive predictive value 78.9%.

A Cochrane systematic review found that the sensitivity for detecting hemoperitoneum in trauma patients was 85-95% and the specificity higher. In blunt trauma studies investigating FAST scanning, outcomes have demonstrated an average specificity of 90-99% and sensitivity of 86-99%. Fleming et al. conducted a retrospective study to compare FAST scan with CT scan or a laparotomy within two days in 100 patients with BAT. The accuracy of FAST in BAT was 59.2%; in these 43.7% were confirmed by CT and 15% by laparotomy. There were 40.8% inaccurate FASTscans, all confirmed by CT. FAST had a specificity of 94.7% (95% CI: 0.75-0.99) and sensitivity of 46.2% (95% CI: 0.33-0.60).positive predictive value of 0.96 (0.81-0.99) and Negative predictive value of 0.39 (0.26-0.54). Fisher's exact test showed that positive FAST was significantly associated with Intra-abdominal pathology (p= 0.001). Positive FAST results had an accuracy of 75% (95% CI: 57%-87%) [15].

Our study showed that 40 (45%) of cases with intra-abdominal injury had splenic injury, 32 (36%) had hepatic injury, 10 (11%) had small intestine injury, 5 (6%) had Kidney injury and 2 (2%) had pancreatic injury.

Out of total patients of blunt abdominal injury, 90 patients were operated and 60 patients were treated conservatively. Out of these 90 operated patients, most common operative procedure was splenectomy in 35 (38.9%) patients. Second most common operative procedure was repair of liver laceration in 17 (18.9%).

The secondly more commonly injured-organ is liver in all patients with blunt-abdominal injury. Incidence being 21.3% of patients with abdominal trauma. Mechanism of injury: Blunt injury results from direct-blows, compression between the lower rib on the right side and the spine or shearing at fixed point due to deceleration.

In present study, post-operative complications were reported in 10.7% pt. Wound infection was the most common post-operative complication present in 8 cases. Respiratory complication was present in 5 cases, biliary fistula in 2 cases, and pancreatic fistula in one case followed by splenectomy.

Two patients died in the present study, One was due to severe haemorrhage from lower limb compound fracture with liver injury and the other one was due to splenic avulsion. Since out of total patientstwo patients die, mortality rate was about 1.3%.

- Srivastava et al study was 2%.
- Di Vincenti et al study was 23%
- The mortality rate in Davis et al study 13.3%.
- Cox et al study reports a mortality rate of 10%.

Out of total 89 patients of abdominal injury, 76 patients were improved and discharged, 2 patients died, 3 patients escape from the hospital and 8 patients were discharged on personal request.

1 patients escape from the hospital while kept on conservative treatment and another 2 patient escape in post-operative period.

8 patients were discharged on request. They were followed and improved while 3 escaped patient could not be traced due to lack of communication.

Conclusion

- Road traffic accident form the most common mode of injury. Though conservative management is successful in carefully selected patients, operative management remains the main stay of treatment
- Plain x-ray abdomen in erect posture is valuable investigation taken for gastrointestinal injuries.

Abstract

Type 1 diabetes is an inflammatory disease of the pancreatic is lets due interaction of activated T-cells and proinflammatory cytokines in the immune infiltrate**.** Vitamin D has vital immunomodulatory properties that help in prevention of occurrence of T1DM.IL-6 is a multifunctional cytokine which has role in the pathogeneses of type 1 diabetes. This study was conducted to evaluate levels of vitamin D and IL6 in type 1 diabetic children and their relation to RBS, glycemic control and c-peptide level.

Keywords: *Type I diabetes, vitamin D, Il-6, immunomodulatory process.*

Introduction

Diabetes mellitus is mainly an error of carbohydrate metabolism associated with hyperglycemia(and disturbance of protein and fat metabolism[(1)].Type I diabetes(T1DM) defined as a complete or near-complete insulin deficiency due to an immune-mediated selective destruction of the insulin producing-cells in the islets of Langerhans. Type 1 diabetes can be considered an inflammatory disease of the pancreatic islets in which a process of programmed cell death (apoptosis) is elicited in the-cells by interaction of activated T-cells and proinflammatory cytokines in the immune infiltrate[(2)]

Vitamin D has vital immunomodulatory properties that help in prevention of occurrence of T1DM animal models[(3)]. It activates human macrophages, antigen-presenting cell maturation and inhibits dendritic cell differentiation as well as affects cytokine production by interacting with most immune cells [(4,5)], one of these cytokines is interleukin 6 (IL-6).

IL-6, a multifunctional cytokine is secreted by T cells and macrophages to stimulate immune response during inflammation and infection. Numerous epidemiological, genetic, rodent, and human in vivo and in vitro studies have investigated the putative role of action/lack of action of IL-6 in the pathogeneses underlying obesity, insulin resistance, cell destruction, type 1 diabetes, and type 2 diabetes[(6)]. These studies suggest both protective and pathogenetic actions of IL-6 in diabetes. In this review, we briefly evaluate vitamin D level and IL-6 level among T1DM patients and investigate the association between concentration of vit D and IL6 in relation to FBG, C-peptide, glucose control among type 1 diabetic patients.

Subjects and Method

This study was conducted on 105 children, divided in to 2 groups, control group 35 apparently healthy children selected from outpatient pediatric clinic. Another 70 children with T1DM (**according to ADA criteria 2019)**were selected from pediatric endocrinology clinic (**Maternity and Children Minia university hospital, Minia, Egypt**). Both groups were matched in age and sex. About 8 ml of venous blood was collected from each patient by sterile venipuncture under complete aseptic conditions. This sample was divided as follow: Two ml in sterile ethylene diamine tetra acetic acid (EDTA) containing tube for HbA1c and six ml into one plain tubes. Blood was left to clot

in the incubator then centrifuged. The expressed serum was used for measurement of serum levels of RBG, C-peptide, 25(OH) vitamin D and IL-6. Vitamin D was determined by detecting the level of 25 OH vitamin D using ELFA technique (Enzyme linked fluorescent Assay) by (MiniVidas, Biomerieux, France), IL-6 was determined by enzyme linked immunosorbent assay (EIA) (Human IL6 EIA Bioassay technology laboratory, China).

Results

Comparison between studied groups regarding laboratory data: Laboratory data of type 1 diabetic children found that statistically significant elevation in IL-6 level among T1D patients when compared to healthy subjects. The mean ±SD of IL6 was 10.9±1.5 in control group, 165.1±111.4 in diabetic group. Regarding serum vitamin D level the study subjects were categorized into three subsets based on their detected vitamin D: Study subjects with vitamin D levels <20 ng/ml were labeled as having deficiency", subjects with vitamin D levels between 21-29 ng/ml were classified as having "vitamin D insufficiency" and the ones with vitamin D levels 30-100 ng/ml were considered as having "vitamin D sufficiency". Vitamin D defiency was found in 87.1% in diabetic patients and 14.3% in control group, there was significant difference between both groups. 11.4% of diabetic patient had insufficient level of vitamin D and 14,3% of control group were suffient, only 1.4% of diabetic patients had sufficent vitamin D level while 71.4% of control group had sufficient level (table1) (figure 1),(figure 2).

Correlation between Vitamin D and different parameters in type 1 diabetic patients: There was moderate positive correlation between vitamin D level and c-peptide level, while there was strong negative correlation between vitamin D with both RBS and HbA1c (Table 2).

Correlation between IL 6 and different parameters in type 1 diabetic patients: There was strong positive correlation between IL6 with both RBS and HbA1c while there was strong negative correlation between Il6 and c-peptide level. There was moderate negative correlation between IL6 and vitamin D (Table 3).

Discussion: T1DM is a T-cell mediated disease that completely destroys the body's ability to synthesize and secrete insulin (7), (8) Vitamin D plays an immune-modulatory effects in T1DM prevention(9) by decreasing the proinflammatory cytokines expression involved in T1DM pathogenesis, thus making pancreatic β cells less liable to inflammation with subsequent reduction in T-cell recruitment and infiltration so suppression of the autoimmune process(10).

Serum vitamin D level in our study among T1DM revealed that 98.5% of cases have abnormally low vitamin D status (vitamin D deficiency and insufficiency). This was in line with a study done in Egypt [11], which found that most of diabetic patients had vitamin D insufficiency. Also, another study done among Egyptian children with T1DM by Abd-Allah et al[12]reported that 75% of T1DM exhibited vitamin D deficiency or insufficiency. Liu etal[13] in their meta-analysis study suggested that low vitamin D level is associated with T1DM children. Also, Rasoulet al,[14]reported significant frequency of vitamin D insufficiency and deficiency among T1DM children and concluded that serum vitamin D status is a major contributor in T1DM prevalence among Kuwaiti children. However some studies disagree with our study as a study done in Pakistan[15]that showed non-significant difference between diabetic and control group regarding vit D. Another research conducted in Chile by Garcia, et al., R(2007)found no difference in 25 (OH) D level in type 1DM and healthy control[16]. Contrary to some reports [17]. The findings of the current study revealed more significant decreased vitamin D levels among those having higher RBS and HbA1c level. Additionally, C-peptide level was more significantly lower in T1DM children with lower serum level of vit. D. These findings can be explained thatthe vitamin D has strong role in improving β-cell function, inhibiting β-cell apoptosis and increasing β-cell replication thus influencing insulin secretion and increasing insulin sensitivity thus improving glycemic control [18]**.** Similar results were obtained in study done by Ahmed et al (2019) who reported inverse correlation between serum 25(OH)D and HbA1c in T1DM patients with poor glycemic control among diabetic patients having vitamin D deficiency [19].

Regarding IL-6, current study showed significantly increased serum level of IL-6 among T1DM children, these results were consistent with meta-analysis done by (Chen yietal)(2016) where level of IL-6 among diabetic patients where significantly higher than control subjects[20], another study done among Egyptian T1DM children [21] revealed serum IL-6 concentrations where significantly higher in diabetic children however other

studies reported no difference[22] or even decreased[23] IL-6level in type 1 diabetic patients. Observed positive correlation between IL-6 with both RBS level and HbA1c in T1DM patients in our study agrees with several studies[24],[25] this can be explained by the fact, that persistent hyperglycemia contributes to the formation of advanced glycation end products which has important role in the development of chronic inflammation. However study done among Egyptian type1 diabetic children shows no correlation between HbA1c and IL6[21] Regarding correlation between Vit. D level and IL-6 our study revealed moderate negative correlation which may indicate an association with vitamin D deficiency and inflammatory state, represented by elevated circulating IL-6, these results agrees with study done by Shih et al 2014[26]

Table (1): Comparison between studied groups regarding laboratory data:

p value	Control No=35	Cases N=70	Variable
0.001*	70-122 92.1±14.1	200-580 323.1±79.5	Blood glucose Range (mg/dl) Mean± SD

Vitamin D	-0.71	0.001*

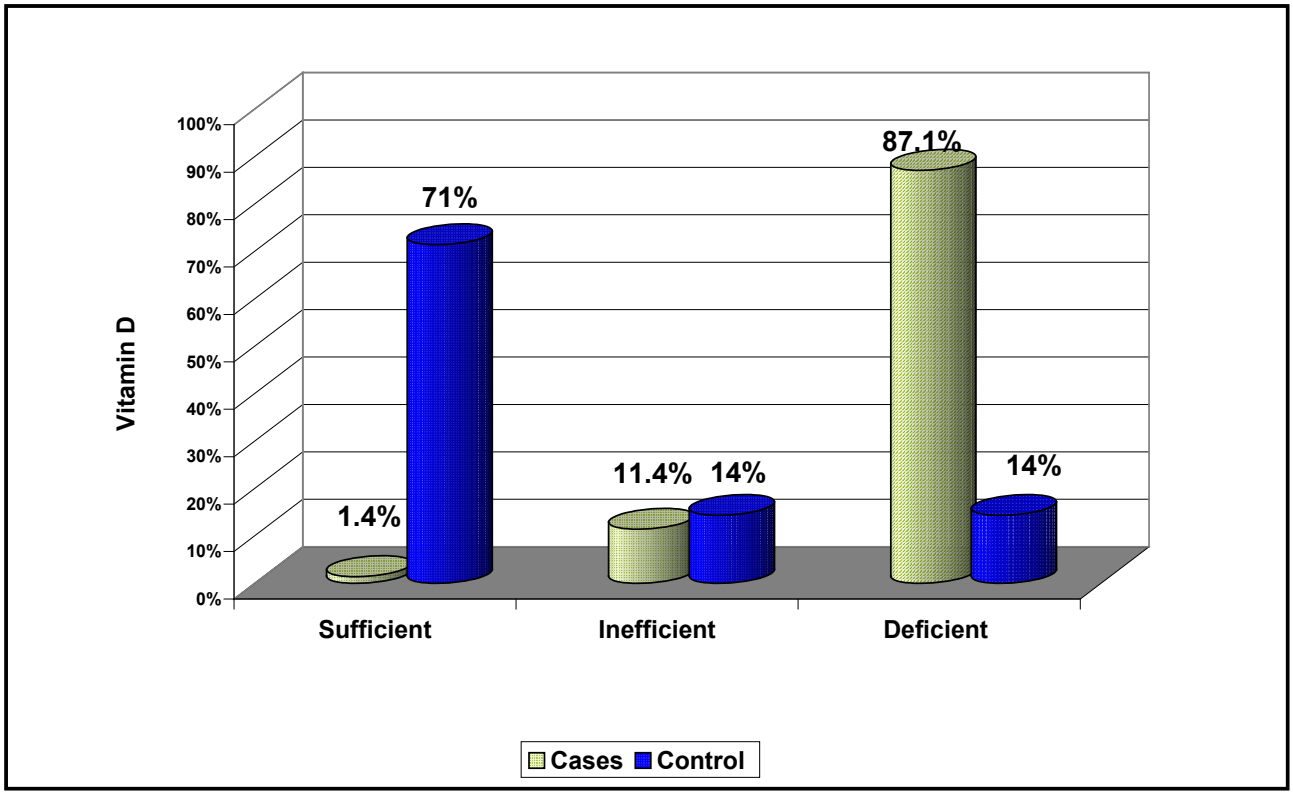

Figure (1): Vitamin D level in diabetic patients and control group

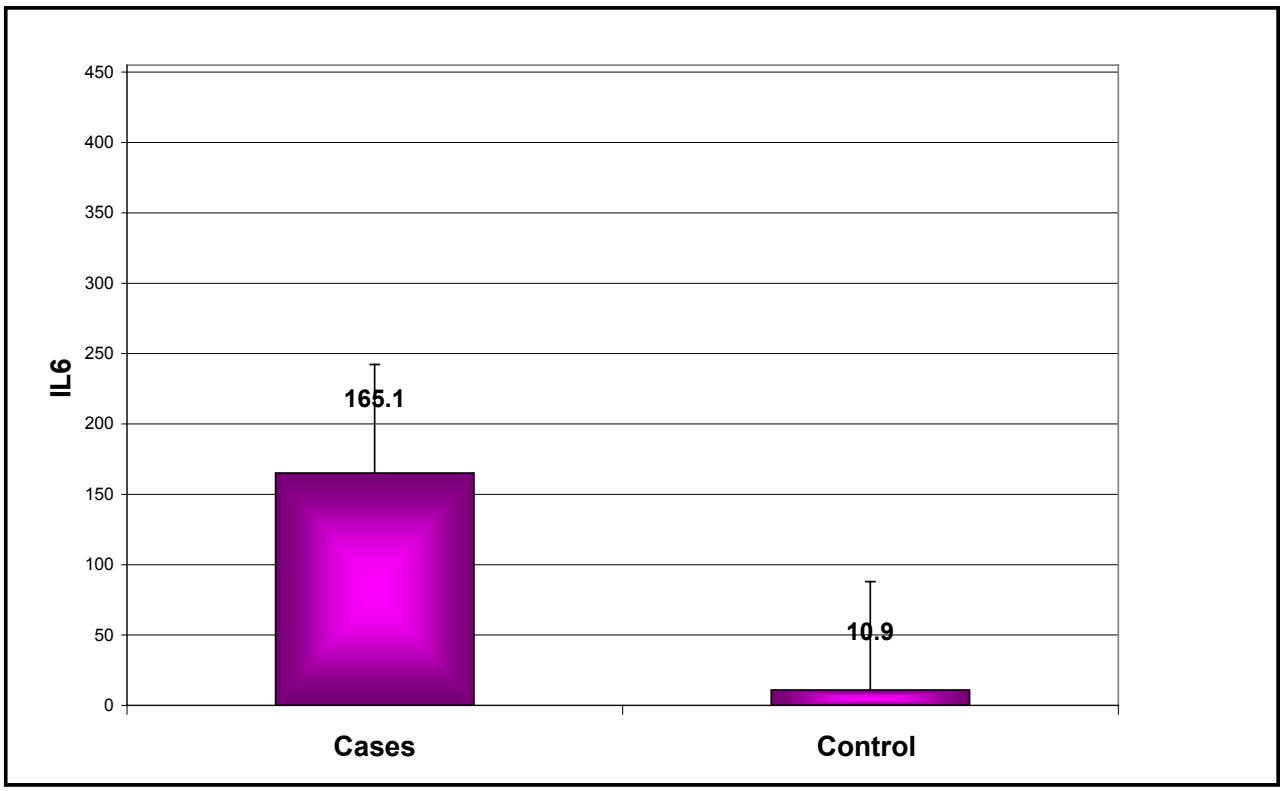

Figure (2): IL6 level in diabetic patients and control group.

Conclusion

The current study support the important role of vitamin D level in type I diabetes and its different level of deficiency with the level of RBG and HbA_1c. Also, our study show the correlation between IL-6 with both RBS level and HbA1c in T1DM patients. This suggest the role of IL-6 as inflammatory marker in T1DM.

Abstract

Breast Cancer is one of the leading cause of death in Indonesia after cervical cancer. Indonesian Breast Cancer patients should get managed well in order to make eficient and sufficient treatment without reducing the quality. The National Health Insurancewell known as *Jaminan Kesehatan Nasional* (JKN) supporting Breast Cancer treatment via BPJS stands for *Badan Penyelenggara Jaminan Sosial* (Indonesian Government Insurance Coverage). Generally, the payment method in BPJS are divided based on INA CBG's and outside INA CBG's which the payment depends on hospital class. INA CBG'S packages including consultation, accommodation, medical, medical treatment (operation andnon-operation). Packages outside of INA CBGS'S include anticancer drugs, health aids, chronic drugs, ambulances and CAPD. This package encourages hospitals to be able to make efficiencies so it is not going to make financial loss for Hospital. The research goal is giving best treatment to Breast Cancer patient without financial loss for the hospital. Measurement Used Time Driven Activiy Based Costing. Moreover The Benefit of this research are (1). Reducing cost (direct and indirect) without decreasing patients quality treatment. (2). Reducing patient treatment time at the hospital since the patient get direct doctors' therapy. To date The Results of this reseach are (1). Day care treatment can be compressed into two days and (2) Reducing length of stay.

Keywords: *The National Health Insurance Coverage (JKN), Hospital Cost Reduction, Time Driven Activity Based Costing, Chemotheraphy Unit.*

Introduction

Health financing plays important role in the implementation of the Indonesian Government Insurance Coverage (JKN). Health financing at a healthcare facility are obtained by health insurance providers payment for health services provided for Indonesian citizens which are aimed in promoting quality improvement, encouraging patient-oriented services, promoting efficiency by not rewarding providers whom do over-treatment, under-treatment or adverse events and encourage team services. With the right financing system is expected to achieve the above aims.

The implementation of Indonesian Government Insurance Coverage or JKN begins in 2014 via the Indonesian Health Ministry. The JKN program is organized by the Social Security Administering Agency (BPJS) based on Indonesian Law number (UU) no 24 year 2011. The purpose of JKN is to help financing the health of Indonesian citizens. The implementation is when citizens using JKN is done on one stageto other stages higher as an example: fromHealth Facility 1 (Faskes 1) to the higher Health Facility, when the disease can't be treated by Health Facility 1 (Faskes 1). Rates applicable to patients using JKN are arranged with the pattern of payment based on Indonesian Case Based Group (INA-CBG's). The payment package is based on grouping the type of disease called the Casemix System. Casemix is a disease grouping which integrate the treatment cost with the type of disease in the hospital.

Catastrophic disease is a disease which its therapy requires special skills, uses sophisticated medical equipment and or requires lifelong healthcare. As a result, catastrophic disease needs higher health claims. The catastrophic diseases at the household level include renal failure, cardiovascular disease (which requires either invasive or noninvasive operation), cancer, and blood disorders, thalassemia and hemophilia[1]. Catastrophic disease is a chronic and degenerative disease. Called chronically because the disease is latent that takes a long time to manifest, often unconscious, and takes a long time for healing or takes a lifetime to control it. Called degenerative because the disease more often occurs with age. Since it is needed higher claim led to the emergence of the terminology of catastrophic disease.

According to World Health Organization (WHO), cardiovascular disease is the leading cause of death worldwide. In 2012 an estimated 17.5 million people die because of cardiovascular disease (7.4 million of them are caused by coronary heart disease and 6.7 million deaths caused by stroke. Over one per third of deaths from cardiovascular disease occur in low-and middle-income countries. Meanwhile, cancer is also a major challenge of morbidity and mortality worldwide, with an estimated 14 million new cases and 8.2 million cancer deaths in the same year. In Indonesia, the RISKESDAS report shows that the prevalence of chronic renal failure, stroke, coronary heart disease and cancer increases with age and the highest increase occurs in the ≥75 age group[2]. While based on gender, cancer patients, diabetes mellitus, heart failure and coronary heart disease more commonly found in women[3].

World Nation Against Cancer (UICC) data shows that the incidence of cancer will increase sharply by 200-300% over the next decade, and 60-70% of these cancers will be present in developing countries, including Indonesia. Viewed from the economic side, data from the Ministry of Health shows that state spending on cancer includes the highest expenditure of the country along with cardiovascular disease and hemodialysis. The countryss expenditure on cancer in 2012 amounted to 144.7 billion rupiah, and in 2014 the Social Security Administering Agency (BPJS) spent 905 billion rupiah on cancer. High expenditures are among others due to workload and treatment modalities that need to be issued to cancer patients, especially when treatment is done at local and advanced stage. On the other hand, UICC claims the danger of this cancer is 43% can be prevented with a clean and healthy lifestyle, and one third can be cured if found at an early stage with appropriate treatment.

Given the high rates of cancer incidence and the magnitude of state expenditure for medical expenses, especially since some are already in an advanced stage, then cancer prevention and cancer discovery activities in the early stages are very important. In the level of health services, from primary care, it should be done healthy life promotion activities to avoid cancer, and early detection, as also presented in this guide. Healthy lifestyle tested according to World Health Organization (WHO) and UICC criteria are actually summarized in CERDIK, i.e. C (routine health check), E (awake smoke), R (physical exercise), D (balanced diet) I (adequate rest), and K (Manage stress). Early detection can be done on several types of cancer, such as cervical cancer, breast, rectal, and cancer in children. By performing early detection, it is expected to change the trend of disease discovery from advanced or advanced local stage, into an early stage. In the treatment of cancer treatment, which now has been divided into primary, secondary, and tertiary referral system, it is expected that every health services facility can perform in accordance with their respective functions and roles, so that cancer treatment can be done quickly, accurately and no long-term oncology handling queue.

In the era of JKN patient service, chemotherapy must be managed well arranged in such a way that the service remains efficiency without reducing the quality of service. The method of payment for BPJS services is generally divided into payments according to the CBG'S INA package and outside the CBG'S INA package, whichrate is in accordance with the hospital class. Here is a package of chemotherapy services for cancer in Type B Hospital. This CBG'S INA package includes consultation, accommodation, medical, medication, medical (operative and non-operative) activities. Packages outside of INA CBGS'S include anticancer drugs, health aids, chronic drugs, ambulances and CAPD. Method of payment by system This package encourages hospitals to be able to make efficiencies in order not to make high loss to hospital.Health financing is an important part in the implementation of the JKN. Health financing at a health facility is obtained by payment by health insurance providers for health services provided to participants, aimed at promoting quality improvement, encouraging patient-oriented services, promoting efficiency by not rewarding providers who

over-treat, under-treat or adverse events and encourage team services. By the right financing system is expected to achieve those aims.

Hospital as a health facility is required to perform efficiency in order not to make financial lost, so the accuracy of cost calculation is very important for the continuation of the hospital. Airlangga University Hospital is a B class education hospital in Surabaya and it is necessary to make a proper cost calculation because the number of patients at the hospital are increasing every year. In order to count hospital unit cost, there is a method of determining the basis of an activity designed to overcome the distortion in traditional cost accounting called the Time Driven Activity Based Costing. Hospitals that serve patients using BPJS are required to perform efficiency. So the solution to the problem is to use Time Driven Activity Based Costing.

Method

This type of research is quantitative descriptive. Quantitative descriptive research in this study is to analyze and interpret the meaning contained in the documentation and interview data that has been collected[4]. The quantitative descriptive approach in this study was used to explain the savings in the cost of chemotherapy treatments for the treatment of breast cancer patients in the JKN era. The subjects in this study of Airlangga University Hospital. The object of this study is the cost incurred or unit costs on chemotherapy measures at the Airlangga University Hospital on breast cancer to see if it can be done cost reduction in the JKN period.

The data use in this research are primary and secondary data. Data then analyzed by using time driven activity based costing. Primary data is data obtained directly from sources related to research subjects, namely conducting interviews with the finance department to obtain data on unit costs related to chemotherapy for breast cancer patients, in addition to conducting interviews with nurses and doctors who are doing chemotherapy treatment for breast cancer patients. Researchers also conducted direct observations of the chemotherapy action space to find out the length of the preliminary observation to breast cancer patients until the chemotherapy action was completed and how much it would take to carry out a series of chemotherapy treatment measures.

Finding and Discussion

Time Driven Activity Based Costing

The basic Hospital can use Time Driven Activity Based Costing because it is included in one criterion to provide value added services to consumers[5], among others:

1. Producing and stocking a greater variety of products
2. Customizing products and services to individual customer preferences
3. Supporting more order-entry and order tracking channels
4. Producing and delivering in smaller order sizes
5. Delivering directly to customers end use locations, often in expedited and narrow time time
6. Providing specialized technical application support

Time Driven Activity Based Costing is a simpler, more powerful path to profitability[6]. The Time Driven Activity Based Costing model requires for each groups of resources only two parameters estimates[7]:

1. The cost rate of supplying resource capacity
2. The consumption of resource capacity (typically unit times) by the activities performed by the resource's products, services and customer

Time-driven ABC starts by identifying the various groups of resources performing activities. For example, customer administration resources include the front-line employees who receive and respond to customer-related requests, their supervisors, and the support resources they require to perform their functions–space, computers, telecommunications, furniture, and, potentially, resources in other support departments (Information technology, human resources, technology, etc.).

18	Lab & Radiology	Package	1	109.000idr	109.000idr
19	Doctor	Medical treat	1	1.218.000idr	1.218.000idr
20.	Hospital contribution			61.016 idr	61.016 idr
	Total			**3.012.600 idr**	**3.012.600 idr**

Source: AUH data processing, Total amount is about: 3.012.600 idr

Comparison between Normal Claim and Airlangga University Hospital Claim is 6.010.200 idr: 3.012.600 idr (2 : 1). To date Airlangga University Hospital can save 3.012.600 idr as of BPJS claim and can get benefit 61.016 idr

1. Activities :
   - Diagnosing : 150
   - Preparing : 150
   - Intervening : 150
   - Recovering : 150
2. Capacity Cost Rate

= Cost capacity supplied/Practical capacity of resources supplied

Cost capacity supplied

= 50 patients/months x 3.012.600 idr

= 150.000.000 idr x 3 (quartely)

= 450.000.000 idr

Practical capacity cost rate = 22 days/month x 6.5 hours x 60 minutes

= 8580 per month x 3 (quartely)

= 25.000 minutes per quarter x 20 employee

= 500.000 minutes

Capacity cost rate

= 450.000.000 idr/500.000 minutes

= 900 idr/minutes

Unit Time Estimate

1. Activities:
   - Diagnosing : 60 minutes
   - Preparing : 120 minutes
   - Intervening : 240 minutes
   - Recovering : 360 minutes

Table 3. Activity Performed Cost Driver Rate

No	Activity	Unit Time	Cost Driver Rate @900/minutes
1	Diagnosing	60	54.000 idr
2	Preparing	120	108.000 idr
3	Intervening	240	216.000 idr
4	Recovering	360	324.000 idr

Then apply these cost driver to the three different activity performed.

Table 4. Activity Performed and Total Cost

No	Activity	Unit Time	Quantity	Total Minutes	Total Cost
1	Diagnosing	60	150	9.000	8.100.000 idr
2	Preparing	120	150	18.000	18.200.000 idr
3	Intervening	240	150	36.000	32.400.000 idr
4	Recovering	360	150	54.000	48.600.000 idr
5	Used capacity		150	117.000	107.300.000 idr
6	Unused capacity			383.000	342.700.000 idr
	Total			**500.000**	**450.000.000 idr**

The analysis found that only 23.4% of the practical capacity (117.000/500.000) of the resources supplied during the period was used for the productive work : hence only 23,4% of the total expenses of 450.000.000 idr are assigned to customers for this period. By specifying the unit times to perform each instance of the activity, the organization gets a valid signal about the cost and the underlying efficiency as well as the as the quantity (383.000 hours) and cost (342.700.000) of the unused capacity in the resources supplied to perform the activity. In Indonesia, the determination of unit cost in each service is not easy if considering the tariff for BPJS

patient services in accordance with PMK No. 50 of 2014 the rate of health services in hospitals is determined based on the density between BPJS Health and the Association of Health facilities based on the standard tariff of INA-CBG's[8]. Hospitals in the JKN era must really consider the cost of treatment claims by calculating unit costs more carefully so that the implementation and planning of costs to national health insurance patients can be well served.

In Indonesia, determining unit costs in each service is not easy when considering the rates for BPJS patient services in accordance with PMK No. 50 of 2014 the rate of health services in hospitals is set based on the density between the Health BPJS and the Association of Health facilities based on the INA-CBG'S tariff standard. Hospitals in the JKN era must really consider the cost of treatment claims by doing a more careful unit cost calculation so that the implementation and planning of costs to national health insurance patients can be well served.

Conclusion

Based on unit cost counting that has been done by Airlangga University Hospital, if the patient is on private treatment, the treatment that they follow as: 1) diagnosing, 2) laboratory checking, 3) radiology checking, 4) diagnosing, 5) preparing, 6) intervening, and 8) recovering with the total cost spend 6 million IDR. While on BPJS and based on INA CBGs then the treatment as follow: 1) laboratory checking, 2) radiology checking, 3) diagnosing, 4) preparing, 5) intervening,and6) Recovering with total cost spend 3 million IDR.

For all those treatments then Airlangga University Hospital still having hospital margin 61.000 IDR. Time Driven ABC can be used on medical treatment which one of them is the determinant factor the unit cost. By using 23.4% from the source, so the hospital can save 76.6% of the time Comparison Normal Claim and Airlangga University Hospital Claim.6,000,000 idr: 3,000,000 idr is equal to 2: 1, so far Airlangga University Hospital can save 3,000,000 idr according to BPJS claims and can get 61,016 idr benefits.

Conflict of Interest: The authors declare that there is no conflict of interest.

Abstract

Cancer requires various treatment modalities based on realistic goals that can be achieved for each type of cancer. Chemotherapy has advantages over other therapies because chemotherapy drugs are able to have a systemic effect in damaging cancer cells even though the cancer cells undergo metastases far spread from their original place. Cancer patients during chemotherapy experience sleep disorders and fatigue complaints. This study aims to determine the relationship of sleep quality with fatigue in cancer patients undergoing chemotherapy. The design of this study is quantitative using a cross sectional approach. The method of sample collection is purposive sampling. The study sample was 30 cancer patients who underwent chemotherapy. The measurement of sleep quality uses the Pittsburgh Sleep Quality Index (PSQI) instrument and the measurement of fatigue uses the Brief Fatigue Inventory (BFI) instrument. Chi square test results showed that there was a significant relationship between sleep quality and fatigue (p-value=0.001). Conclusion nursing intervention is needed for the quality of sleep in an effort to overcome fatigue in cancer patients.

Introduction

Cancer is one of the causes of world death. Every year there is an increase in the number of cancer sufferers. Based on the international agency for research on cancer (IARC), in 2012 there were 14.67 million new cases of cancer and 8,201 million cancer deaths worldwide.[1] In 2018 an increase in new cases of cancer to 18.08 million with 9.5 million deaths.[2] The number of new cancer cases in Asia was 6.763 million and 4.499 million deaths from cancer. While the population of cancer patients in Indonesia in 2012 amounted to 2,447 million with 194,500 deaths.[1] Based on 2013 basic health research data (Riskesdas), the prevalence of cancer in Indonesia is 1.4 per 1000 population.[3] Increased to 1.8 per 1000 population in 2018.[4]

Cancer is a cell disease, where changes in cell cycle regulation become uncontrolled.[5] Cancer requires various treatments based on realistic goals that can be achieved for each type of cancer. Cancer treatment aims to cure, inhibit the growth of cancer cells, or eliminate symptoms associated with the cancer process.[6] Cancer treatment consists of surgery, radioactivity, biotherapy, and chemotherapy.[5,7]

Chemotherapy had advantages over other therapies because it was able to have a systemic effect in damaging cancer cells. Although cancer cells spread from their original place. Chemotherapy drugs work to disrupt the reproduction of cancer cells directly or indirectly. So that cancer cells can be controlled and eradicated.[7] Giving chemotherapy using a combination of drug classes and given in several cycles.[5]

During chemotherapy cancer patients often experience sleep disorders.[8,9] Some sleep disorders during chemotherapy were often awake at night (49%-56%), inability to sleep within 30 minutes (50%-73%) and woke up early (49%-65%).[9] Sleep disturbance can be measured using the global Pittsburgh sleep quality index (PSQI) score. The PSQI instrument consists of 19 questions and 7 score components. The seven score components were global PSQI scores ranging from 0-21.[10,11] A global PSQI score of ≥ 5 indicates poor sleep quality.

Giving chemotherapy can provide fatigue complaints. The National Comprehensive Cancer Network states that about 70% -100% of cancer patients experience Cancer related fatigue (CRF). CRF as a subjective feeling of physical, cognitive, emotional or fatigue related to cancer or cancer treatment. Fatigue that was felt was not comparable with activities that have just been done.[12] Individuals describe fatigue using different words, including fatigue, lack of energy, weakness, lethargy, boredom, being unable to sleep, or having sleep disorders. Fatigue in cancer patients can range from mild to severe.[13]

Fatigue measuring devices in cancer patients can use a variety of instruments. One of them is brief fatigue inventory (BFI). BFI is a specific measurement tool for rapid assessment of the level of fatigue in cancer patients. BFI is a measurement scale for fatigue, in the form of a simple, easy to do assessment.[14] BFI is a short, valid and reliable instrument for assessing fatigue in cancer patients.[15] BFI assesses the level of general fatigue in individuals and fatigue disorders in daily activities in the past 24 hours such as general activity, mood, ability to walk, work activities, relationships with others and enjoy life.[14-16]

Method

The design of this study is quantitative using a cross sectional approach. The population in this study were cancer patients undergoing chemotherapy in the chemotherapy service unit at Jend. Ahmad Yani Hospital Metro City. The independent variable of this study was cancer patients and fatigue as the dependent variable. This research was conducted at Jend. Ahmad Yani Hospital Metro City with a sample of 30 respondents who met the inclusion criteria. The inclusion criteria in this study were cancer patients undergoing chemotherapy, experiencing fatigue complaints and experiencing sleep disorders. Data collection tool in this study using the PSQI and BFI questionnaires.

The Pittsburgh Sleep Quality Index (PSQI) was developed by Buysse et al (1989) at the University of Pittsburgh's Wasren Psychiatric Institute and Clinical, with a Cronbach alpha coefficient of 0.83. Test the validity and reliability of the Indonesian version showed that the Cronbach alpha coefficient is 0.79 and the content validity shows 0.89.[10]Based on the global PSQI score can be categorized ≥5 shows poor sleep quality and global PSQI score <5 indicates poor sleep quality.[11] The BFI instrument was developed by Mendoza et al (1999) at MD Anderson Cancer Center, with a cronbach alpha coefficient value of 0.93. Test the convergent validity by comparing the BFI score with the MOS SF-36 subscale ($p < 0.001$) and the language version reliability test. Indonesia shows that the Indonesian version of Cronbach Alpha is 0.956.[15] Based on the scores obtained, fatigue can be categorized for no fatigue if the scores obtained are 0 (NCCN, 2014), mild fatigue with scores obtained: 1-3, moderate fatigue if scores: 4-6, and severe fatigue if scores are obtained: 7-10.[14] Data collection was carried out by the researchers themselves. The data obtained were analyzed using SPSS version 21 by univariate and bivariate (chi square).

Results

Respondent characteristics data obtained showed that the average age of respondents aged 54.47 years with the youngest age is 28 years old and the oldest age is 77 years old. Univariate analysis of variable data on sex, cancer type, sleep quality, and fatigue based on frequency distribution, can be described as follows:

Table 1. Distribution of respondent characteristics based on the, cancer type, sleep quality and fatigue in Jend. Ahmad Yani Hospital Metro.

Characteristics	Frequency (n=30)	%
Sex		
Male	11	36.7
Female	19	63.3
Cancer type		
Breast cancer	11	36.7
Lung cancer	2	6.7
Colorectal cancer	8	26.7
Lymphoma	4	13.3
Bladder cancer	1	3.3
Nasopharyngeal cancer	4	13.3
Sleep quality		
Good	3	10
Poor	27	90
Fatigue		
Mild	7	23.3
Moderate	23	76.7
Severe	0	0

Table 1 showed that female sex (63.3%) was more than male (36.7%). The most dominant type of cancer was breast cancer (36.7%). The client's sleep quality showed that the majority of the client's sleep quality was poor (90%). Whereas variable fatigue showed that

the majority of clients experience moderate fatigue (76.7%) The results of the analysis of the relationship of sleep quality with fatigue in cancer patients undergoing chemotherapy, were described in table 2 below.

Table 2. Relationship between sleep quality and fatigue in cancer patients who took chemotherapy in Jend. Ahmad Yani Hospital Metro

Characteristics	Fatigue				OR (95%CI)	p value
	Mild		Moderate			
	n	%	n	%		
Sleep quality						
Good	3	10.0	0	0.0	0.15 (0.06-0.36)	0.001
Poor	4	13.3	23	76.7		
Total	**7**	**23.3**	**23**	**76.7**		

Table 2 showed that respondents with good sleep quality a small portion experienced mild fatigue (10.0%) and respondents with poor sleep quality mostly experienced moderate fatigue (76.7%). Chi square test results found that there was a relationship between sleep quality with fatigue (p-value = 0.001). From the analysis results obtained OR value = 0.15, meaning that good sleep quality provides a protective effect against fatigue of 85.0%.

Discussions

This study identifies the relationship of sleep quality with fatigue in cancer patients who took chemotherapy. Chi squared analysis results obtained the results of a relationship between sleep quality with fatigue (p value = 0.001). This is relevant to the results of previous studies which state that there is a relationship between sleep disorders and fatigue in cancer patients during chemotherapy (p value <0.01).[17]

The sleep-wake cycle and sleep stages are the result of interactions among the nervous system, sleep-on neurons and sleep-on neurons rapid eye movement. The defense system involves a system of reticular activity (RAS) in the brain stem and special neurons in the hypothalamus. Neurons secrete hypocretin neurotrasmiteroutonomically, continuously and keep conscious and alert. Sleep on neurons located in the hypothalamus induce slow wave sleep (NREM sleep). REM sleep-on neurons are the centers of REM sleep located in the brain stem.[7] A person can go through 4-6 sleep cycles when sleeping.[18] Changes in the wake-up sleep cycle that the patient feels during chemotherapy can cause complaints of fatigue.[13,17,19,20,21] Savard et al (2009) state that the cancer patient's sleep-wake cycle is disrupted during the first week of each chemotherapy cycle (week of chemotherapy administration), and it gets worse each cycle of treatment.[20]

Based on the results of data analysis showed that the majority of respondents have poor sleep quality. Poor sleep quality of respondents can be known from the total Pittsburgh Sleep Quality Index (PSQI) score. The total PSQI score is an accumulation of seven assessment components consisting of the subject's sleep quality, sleep latency, sleep duration, efficiency of sleep habits, disturbance during sleep, use of sleeping pills and dysfunction during the day.

Subjective sleep quality is a person's view of the quality of sleep. In the component of sleep quality, most respondents stated poor sleep quality. Sleep latency is the amount of time needed to fall asleep after lying in bed and or after the sleep light is turned off.[10,11] In the sleep latency component, respondents need> 30 minutes to fall asleep. Prolongation of sleep latency will affect sleep both in quality and quantity. A normal conscience is needed to start sleeping for about 20 minutes.[22]

Sleep duration is the amount of sleep time measured from starting to sleep at night until waking up in the morning.[10,11] In the sleep duration component, respondents stated that the duration of sleep was <5 hours. Signs of insufficient sleep were not enough time to sleep and too much time awake. There were several factors that affect sleep, including physical symptoms (eg pain, physical discomfort); emotional stress, and environmental influences (eg lighting, noise, room temperature).[18]

Sleep efficiency is the amount of sleep in the period of time filled with sleep and is the ratio between the amount of sleep time and the amount of time spent in bed.[10,11] In the component of sleep efficiency the respondent is <65%. While disturbance during sleep is a disorder that causes a person to not be able to sleep or wake up during sleep at night. In this component most respondents stated that experiencing sleep disturbances in the form of waking up at night and difficult to go back to sleep. Sleep disturbance contributes to energy loss or fatigue. Quality sleep functions to store energy. During sleep skeletal muscles relax progressively and there is no contraction of chemical energy storage muscles for cellular processes.[18] Quality REM sleep maintained mental and mood.[7]

Based on the results of univariate analysis showed that the average age of respondents was 54.47 years. This showed that the respondents were included in the elderly. Based on previous research that older people experience sleep problems such as waking up early, having trouble sleeping at night, often waking up at night and having trouble falling asleep at night.[22]

Conclusions

The results of this study indicated that there was a relationship between sleep quality and fatigue in cancer patients who took chemotherapy (p value = 0.001). And good sleep quality provides a protective effect against fatigue of 85.0%. Based on the results of this study, nurses need to provide independent nursing interventions by enhancing a supportive environment for sleep, providing comfort measures such as providing backmassage, aromatherapy to improve sleep quality and reduce complaints of fatigue in cancer patients undergoing chemotherapy.

Acknowledgment: Researchers on this occasion would like to thank the respondents who were willing to participate in this study to the Director, Education and Training Section, Head of Internal Medicine A (RPD A) and nurses Jend. Ahmad Yani Hospital Metro. We thank you profusely for agreeing to give permission to conduct research at the place where you work. Thank you to the Dharma Wacana Education & Culture Foundation. Thank you for the permission and funding support. Thank you to the Director, Pudir I and the head of LPMI for the permission, support.

Funding: This study was supported by Academy of Nursing Dharma Wacana Metro.

Ethical Clearance: Not required.

Conflict of Interest: Nil.

Post-Traumatic Growth with Police Officer: System Review (Focused on Korean and Foreign Studies)

Seung Woo Han

Dept. School of Emergency Medical Technology, Kyungil University. 50 Gamasilgil Hayangeup, Daegu, Korea, College of Emergency Medical Technology, Kyungil University

Abstract

Purpose: The purpose of this study was to analyze literature related to post-traumatic growth with police officer. Method: Systematic review of studies published were conducted through a vatiety of databases such as Ovid-Embase, Ovid-Medline, The cochrane library, Pubmed, RISS. The research terms included Police officers, Police, Trauma, Posttraumatic growth, Growth. Results: All studies were correlation analysis. In the Korean researches, PTG was positively correlated with self-esteem, problem focused coping, emotion focused coping, social support, self-disclosure and deliberate rumination. In the foreign researches, PTG was correlated with thriving, resilience, events involving threat, personal relationship stress, trauma severity, life stress, and gratitude. Demographic variables such as Female, White were also associated with PTG. Conclusion: To improve post-traumatic growth of police officers, strategies to increase stress coping, social support, are needed. Strategies to decrease stress, trauma and PTSD symptoms should be developed.

Keywords: *Police officers, Police, Post-traumatic, Growth, Review literature as topic.*

Introduction

The increases in crime and violence in Korea may have a great impact on the life and safety of police officers, and according to the statistics of the National Police Agency, of 9,552 on-duty-injured people for the last five years, the assaulted injuries, traffic accidents, and negligent accidents accounted for 97% of the total number of on-duty-injured people.[1]Particularly, these traumatic events will be directly linked not only to the police officers' lives but also to the protection for the lives of the people. In DSM-IV (1994) of the American Psychiatric Association, the trauma cases were extended to direct or indirect experiences that may threaten physical well-being, including life threats, serious injuries, striking events and so on.[2]The experiences of various traumatic events, such as witnessing of the murder scene, usage of guns, and violence during the suppression process, which should be undergone on duty, cause the anxiety, pain, and trauma to the relevant event. These various traumatic experiences lead to Posttraumatic Stress Disorder (PTSD).

Accordingly, in the meantime, the studies on post-traumatic stress have been actively conducted, which have focused on negative physical and psychological experiences and symptoms, accompanied by traumatic events, such as depression, anxiety.[3] However, not all people will be led to the post-traumatic stress after experiencing traumatic events, and even if they experience the same trauma, most people will overcome it well, sometimes experiencing physical and mental growth.[4] In other words, they may experience positive psychological changes that would be perceived after the traumatic event or crisis, and such changes are called as the posttraumatic growth (PTG).[5] The positive psychological change, mentioned here, may mean a genuine positive change that transcends the psychological functioning level and the self-awareness level of life – simply beyond physical and psychological functioning levels prior to trauma.[6] Further, rather than the focus on the physical and pathological symptoms which have been induced by the event itself, mentioned in PTSD, the posttraumatic growth implies a more comprehensive concept focusing on the psychological and subjective response, the individual internal-strengths and adaptive aspects, which would be experienced in the event experiences.[7]

These positive changes had been diversely interpreted by each scholar, which had been used in various terms,

such as discovery of benefits, stress-related growth, etc., by the 1990s, but Calhoun and Tedechi suggested the terminology of 'Posttraumatic Growth', different from their concept.[8,9] Examining the research trend on the posttraumatic growth in the meantime, the initial studies on posttraumatic growth have been performed in the field of psychology, but in recent years, the research has been actively conducted in nursing, medicine, etc., as the interest in prevention of diseases and health promotion increases.[3] In most precedent studies, the studies concentrating on the posttraumatic growth for specific disease subjects including cancer patients, women experiencing physical violence, the subjects who have experienced war have been conducted. However, the posttraumatic growth studies for high-risk occupational groups experiencing various traumatic events, like police officers, fire-fighting officers, and prison officers, are in very short.

Thus, this study is going to search for and then, systemically investigate various variables related to the posttraumatic growth of police officers.

Study Method

Selection of Searching Database: In terms of searching, the literature search started from 1996, when the posttraumatic growth was developed and the term of the original author began to be used, and all the literature associated with the related keywords and the like were searched by January 2018 based on the search date. In order to conduct the systematic literature review of this study, researcher collected studies focusing on the posttraumatic growth aimed at police officers. In this study, Pubmed, Ovid-medline, Ovid-Embase and The cochrane library were used as the overseas database and RISS (Korean/English) as the Korean one. The research objects included Police officers, Police, Trauma, Posttraumatic growth, and Growth. In addition, the literature search was limited to articles providing abstract and full text.

Literature Screening and Quality Assessment: Based on the literature search strategy, all literature retrieved by each database was merged and then, the duplicate literature was removed. After the elimination of duplicate literature, the studies that did not satisfy the core questions of this study were excluded through the titles and abstracts of the primary study. The primary study, which was unclear to judge whether it might be selected or excluded or which fully met the selection criteria, based on the title and abstract, was judged by securing the full text.

As all the primary studies included in the literature review of this study are the study analyzing correlations, the quality evaluation on the literature was conducted by utilizing the 'Quality Assessment and Validity Tool for Correlational Studies' which was used in the existing study of Wong and Cummings.[10]

Results

Based on the literature search criteria of this study, the total number of retrieved literature was 2683 units, and of these, 420 duplicate literature units were excluded. Among 2263 theses by excluding 420 theses, 351 theses related to PTSD and 407 literature units were left by excluding 505 literature units which were not related to the subject, after reviewing abstract, titles and contents. Of them, in the posttraumatic growth, by excluding 322 theses which were studied on the samples not related to police officers of the subject of this study, 8 review theses, 18 qualitative research theses, 23 experimental theses, 4 non-English theses, and lastly, 11 literature units which were retrieved as the poster-presented literature, the final 24 theses were selected. 24 literature units were systematically analyzed by 2 researchers, and if the exclusion was not identical, they discussed it until they reached the agreement.

Discussion

In this study, with respect to the correlations between variables related to posttraumatic growth of police officers, it was found in Koreanstudies that self-esteem, problem-centered coping, emotion-centered coping, self-exposure, social support, and intentional rumination had a significant correlation with posttraumatic growth. These results are in agreement with the study[21] that the higher self-esteem becomes, the higher posttraumatic growth is, and since self-esteem correlates with positive cognition control strategies, it is considered that it has the significant correlation with posttraumatic growth, as a factor of protection and internal growth to control negative emotions in the process of accepting events after experiencing traumatic events. In other correlation studies, problem-centered coping and emotional-centered coping also showed a significant correlation with posttraumatic growth of police officers. This suggests that the adaptive mechanisms and responses will vary depending on the stress coping strategies used by individuals, even if they may experience the same

trauma. In the precedent study[22], they stated that if the negative emotions, such as trauma and stress, was controlled well, and the emotion-centered coping was well exerted after the traumatic experience, so that problem-centered coping, one of the active coping strategies, was utilized more, it would be in charge of the responses for well-understanding of their own psychological emotions and expression of their emotions. Therefore, the stress coping strategies, such as problem-centered coping and emotional-centered coping, after traumatic events, will be served as important variables to induce the posttraumatic growth. Self-exposures were also established to have a significant correlation with posttraumatic growth, and in the precedent study[15], it was said that those who actively engaged in self-disclosure were more likely to participate in cognitive processes related to growth than those who did not. It was confirmed that self-exposure was statistically related to posttraumatic growth as an important factor of psychological recovery in the growth of trauma experience. In the precedent studies[15,16,17], social support and intentional relativity also showed a significant correlation with posttraumatic emotions. In precedent research[23], when social support was well supported after experiencing the traumatic event, it was considered to be an important factor in well coping with stress situations and functioning for the psychological adjustment in adverse situations, which was regarded as an important parameter to induce posttraumatic growth after experiencing the traumatic event. Finally, intentional rumination was found to have a significant correlation with posttraumatic growth, which was considered as an important parameter to promote posttraumatic growth to bythinking carefully about the cast through that event and discovering the positive meanings or benefits from that case, rather than that the trauma experience was not just regarded as a negative event[23]. As a result of precedent studies of such Koreanstudies, the valuables significantly correlated with posttraumatic growth was found to be self-esteem, problem-centered coping, emotion-centered coping, self-exposure, social support, and intentional rumination. By getting out of these phases to explore the relations with valuables, the future research will provide the baseline data for developing programs to promote a positive and healthy direction and posttraumatic growth of police officers, and be helpful as an important factor in conducting a more realistic and multifaceted research. In overseas theses, as the posttraumatic growth-related variables, prosperity and resilience, appreciation, traumatic event threatening the personal life, stress induced from human relations, severity of trauma, PTSD symptoms, relationship stress, working stress, and depression were identified. It suggested that in overseas studies, Positive variables, such as prosperity and resilience, and negative variables, like stress and trauma, were found to be more variously related to posttraumatic growth than in domestic ones, as a variable related to posttraumatic growth of police officers. Prosperity and resilience were found to be significantly correlated with posttraumatic growth in the precedent theses. In the positive psychology, the constructively adaptive ability, well-being, and individual strengths focused on the prosperity of humans, and in the self-formation and prosperity theory, Frederikson[24] argued that the positive emotions, such as prosperity, would undergo a process to promote posttraumatic growth. In addition, referring to resilience as one of coping abilities when confronting a crisis after generally experiencing a traumatic event, he stated that this had a static correlation with posttraumatic growth causing less psychological trauma in crisis. Finally, the appreciation, as a positive variable, corresponded to the study results[25]suggesting that the higher the appreciation tendency, the higher the posttraumatic growth.

Conclusion

The purpose of this study was to investigate and explore the precedent literature on posttraumatic growth aimed at police officers, to establish the variables related to the posttraumatic growth of Korean and abroad police officers, and at the same time, to provide baseline data for the development of programs that can promote posttraumatic growth. In the present study, as a result of investigating the literature that have been created since 1996 when the term of posttraumatic growth was firstly used, in the Korean theses, self-esteem, problem-centered coping, emotion-centered coping, self-exposure, social support, and intentional rumination were identified and in overseas theses, prosperity and resilience, appreciation, stress caused by traumatic events threatening the individual live and human relationships, severity of trauma and PTSD symptoms, relation stress, work stress, and depression were confirmed.

Abstract

Background: Type 1 Diabetes mellitus (T1DM)is one of the most widely seen chronic disease in child hood and its prevalence rate till age of 18 is approximately one in every 300 and its late complications responsible for reduced life expectancy and major health coasts.

Aims: To assess the quality of life (QOL) among children and teenagers with T1DM and its determinants and to compare their QOL to that of healthy peers.

Subjects and Method: A case-control study was carried out in Al Imam Hussain Medical City in Holy Kerbala / Iraq. The sample size included 164 diabetic child as case group and 330 healthy child as a control group. The participants were selected by consecutive convenience sampling technique; the information were collected by using specific questionnaire through direct interview with the participants. The study was performed during the period from 1st of December 2018 to 31th of August 2019.

Results: There were a significant difference in each domain and in all quality of life between the study groups; In addition to that there was a significant association between QOL of diabetic children and certain variables like gender, birth order, number of siblings and paternal education. The study also concluded a negative correlation between the age of the child and QOL there is no significant association between QOL and residence or economic state.

Conclusion: Iraqi children and teenagers with T1DM who live in Kerbala governorate and aged between 5-18 year had poorer QOL than healthy peers. The QOL is associated in all or some domains with certain factors and not associated with others.

Keywords: *Quality of life, Children, adolescents, Type I diabetes mellitus.*

Introduction

Type 1 Dibetes Mellitus is a heterogeneous disorder that usually develops during adolescence and childhood, this disease characterized by a deficit of insulin production secondary to destruction of pancreatic B-cells(1).

Type 1 diabetes mellitus is one of the most widely seen chronic disease in child hood,numbers do not present for the real total population with T1DM, but estimates mention that they may represent 5% of the total diabetes burden(2), its prevalence rate approximately 0.25% furthermore the incidence of T1DM continues to increase in most studied populations by 3-5% per year(3).

The main aims of diabetes care are to fulfill optimal glycemic control in order to delay or prevent complications and preserve normal development. Most of guidelines on diabetes care focus on the medical aspects of management and winking other issues which are of great importance to the patient(4)

Diabetes is highly demanding disease approximately affects every day life so the patient expected to hold out much of the responsibilities for making decisions which may affect his entire health[5].

The most essential feature of measuring theQO Lis to capture the individual's subjective assessment of their QOL and not what others imagine it to be. Progressively it has been acknowledged that it is an important health outcome measure in pediatric medicine [6].

When the child has poor glycemic control and has a lot of episodes of ketoacidosis this can have a serious effect on growth and development[7].For adolescents, the metabolic control of patients with T1DM often worsens during the pubertal years because this stage is the time of rapid physical,emotional and psychological growth[8]. Regarding the physical changes,the most important one is the growth hormone that cause a lean body mass to be twice in the first 2 to 5 years of puberty[9]

The studies regarding QOL and T1DM is controversial, some showed that QOL of T1DM patient is lower than that of healthy peer. others showed that there is no difference in QOL between diabetic child and healthy one.

Subjects and Method

A case-control study was carried out in Al Imam Hussain Medical City in Holy Kerbala / Iraq, the study was performed during the period from 1st of December 2018to31th of August 2019. The sample included 164 diabetic child for case group and 330 healthy child for control group. Consecutive conveniencesampling technique was used . The cases were collected from Al Hassan center which is the only specialized center for diabetes and endocrine glands in holy city, these cases are matched for sex, age, residence and school level to control group which was collected from the consultancy clinics like the clinic of ophthalmology, dermatology and the clinic of ear, nose and throat (ENT).

Inclusion criteria and the exclusion criteria: Inclusion criteria are: the diabetic type 1 cases and the control are aged between 5-18 years while the exclusion criteria are: Any diabetic case with other chronic disease like comorbid autoimmune disease, any heamoglobinopathy or other chronic condition like asthma, heart disease, epilepsy and who was mentally retarded,Cases diagnosed with T1DM since less than one year, Control group with any chronic diseases. The diabetic and control groups with a history of recent physical trauma or surgery.

The Questionnaire: The questionnaire consists of three parts: the first part is related to demographic information, the second part is related to the disease like duration of disease, history of DM in immediate family (parents or siblings) and last HbA1c within the last month the forth part is pediatric quality of life inventory; version 4.0 generic core scale.

The Pediatric Quality of Life Inventory TM; was originally developed in the English language by Varni et al, the generic module evaluates four dimensions: Physical functioning (8 items), emotional functioning (5 items), social functioning (5 items) and school functioning (5 items), for a total of 23 items using a five-point Likert scale The responses ranged from never, almost never, sometimes, often and almost always. Items are reversed scored and linearly transformed to a 0-100 scale 0=100, 1=75, 2=50, 3=25, 4=0[10].

PedsQL 4.0 Cut-Off Point Scores: One standard deviation below the population mean (control mean) was explored as a meaningful cut-off point score for an at-risk status for impaired QOL relative to the population sample. [11]

Ethical consideration:

- The study obtained approval from kerbala health directorate and from al immamhussian medical city.
- Verbal consents were obtained from all participants.

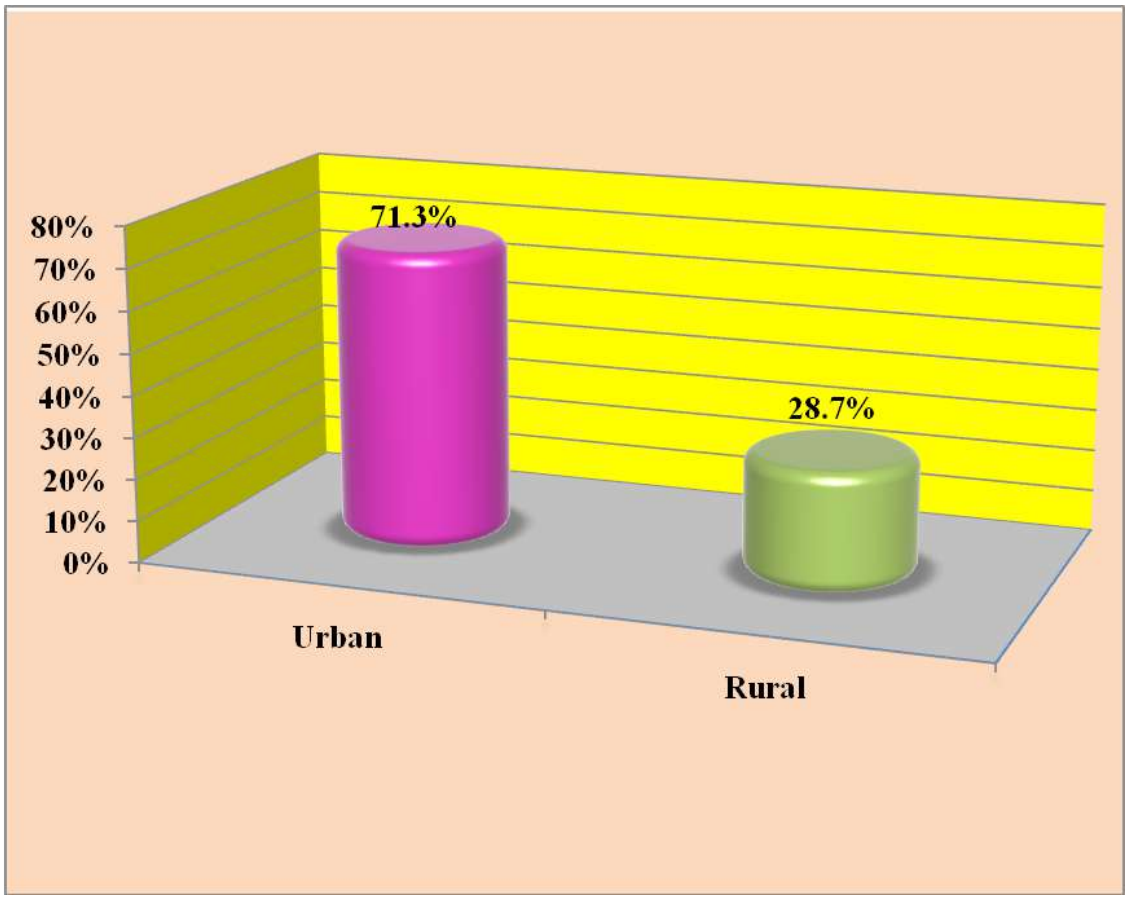
Statistical analysis: Data analysis was done using statistical package for social sciences version 24.

T-test and F test(ANOVA) was used to determine the mean differences between groups, P value of ≤ 0.05 was considered as statistically significant.

Results

Distribution of diabetic children according to residence. Figure 1 shows that the majority of diabetic children were part of urban households which represented 71.3%.

Figure 1: Distribution of diabetic children according to residence



Distribution of diabetic children according to crowding index: Figure 2 shows that socio economic status measured by level of crowding index which is good (9.1%), intermediate (61.6%) and poor (29.3%).

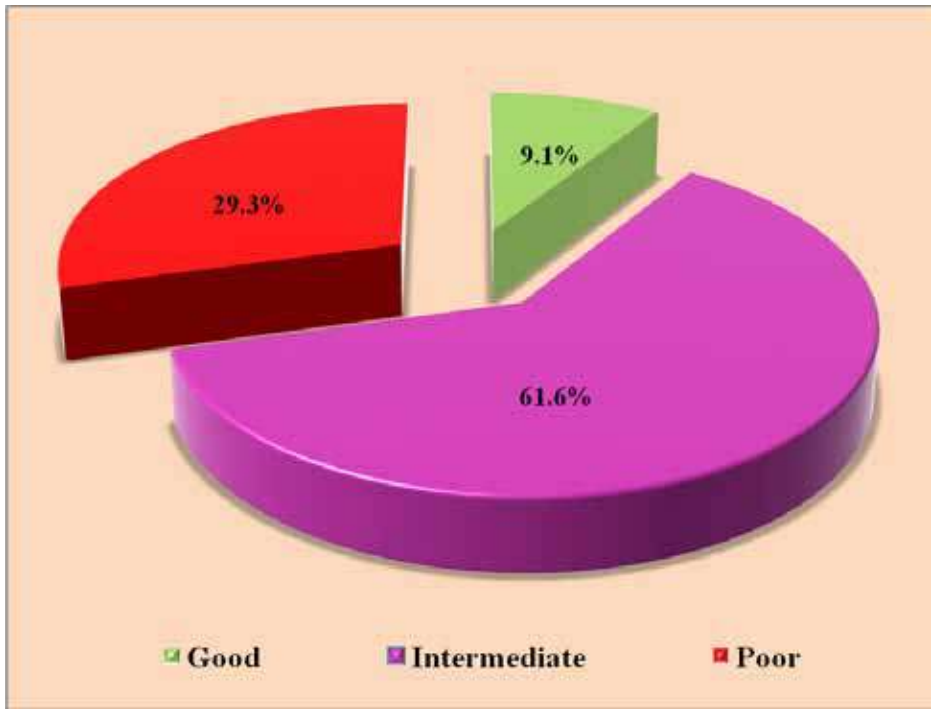


Figure 2 Distribution of diabetic children according to crowding index.

Table 1. shows that t test was conducted to show a mean differences of quality of life domains in case and control group.

There is a significant mean differences in all domains and total score according to study groups.

Table 1: Mean difference of quality of life between study groups

Study variable	Study group	N	Mean ± SD	t-test	P –value
Physical functioning	Case	164	75.72±19.22	-9.760	<0.001*
	Control	330	91.20±9.28		
Emotional functioning	Case	164	66.13±18.54	-12.347	<0.001*
	Control	330	85.59±11.29		
Social functioning	Case	164	90.09±12.68	-2.908	0.004*
	Control	330	93.30±8.79		
School functioning	Case	138	80.72±15.58	-4.505	<0.001*
	Control	272	87.38±10.69		
Total score	Case	164	74.97±15.81	-7.655	<0.001*
	Control	330	85.52±11.10		

Distribution of quality of life cut-off point in four domains: Table 2 shows the quality of life cut-off point according to four domains and total score the cut-off points are 81.92,74.3,84.51,76.69 and 74.42 respectively.

Table 2: Distribution of quality of life cut-off point in four domains in diabetic children.

Variable	Quality of life cut-off point	Number(%)
Physical functioning	<81.92(at risk)	76(46.3%)
	≥81.92(HRQOL)	88(53.7%)
Emotional functioning	<74.3(at risk)	100(61.0%)
	≥74.3(HRQOL)	64(39.0%)
Social functioning	<84.51(at risk)	30(18.3%)
	≥84.51(HRQOL)	134(81.7%)
School functioning	<76.69(at risk)	52(37.7)
	≥76.69(HRQOL)	86(62.3)
Total score	<74.42(at risk)	68(41.5%)
	≥74.42(HRQOL)	96(58.5%)

Mean difference of quality of life according to diabetic children's socio demographic factors: Table 3 shows that t and F test was conducted to show a mean difference of quality of life domains and total score according to some sociodemographic factors of diabetic children.

Table 3: Mean difference of quality of life according to diabetic children's socio demographic factors

Correlation between quality of life and age in diabetic children: Table 4 shows that correlation test is conducted between age of diabetic child each one with the four domains of quality of life.

Table 4: Correlation between quality of life and age in diabetic children

Variable	Study group	N	Mean ± SD	R	P –value
Age (Year) (Mean± SD) 12.11±3.004	Physical functioning	164	75.72±19.22	-0.213	0.006*
	Emotional functioning	164	66.13±18.54	-0.156	0.046*
	Social functioning	164	90.09±12.68	-0.059	0.450
	School functioning	138	80.72±15.58	-0.064	0.455
	Total score	164	74.97±15.81	-0.117	0.135

Discussion

The current study proved the negative impact of T1DM on all domains of QOL for diabetic children so their quality of life was impaired when compared it to their healthy peers. This probably due to the facts that the high number and complexity of different tasks involved in managing T1DM place a hard burden on the children, or because in Iraq the main technique in administration of insulin is by using daily insulin injections while other countries introduced insulin pump as one of treatment options which proved in many studies its role in improving the QOL as it is considered beneficial by children and parents alike as they experienced more treatment flexibility and comfort than with daily insulin injections[12,13], The current study found large percentage of risky patients in those whom have impaired QOL from diabetic children.

our finding regarding QOL is consistent with many studies like of, Kalyva et al,,Abdul rasoul et al,Arabiat et al,Sabri et al,Rivera et al,Samardzic et al and Gadallah et al.[6,15-20]at the same time our results are different from other studies like of laffel et al,Emmanouil et al,Rozemarijn et al,Mills et al,and Murillo et al.[21-25].

This study showed that female gender was not impacted in all domains except in physical functioning

which is inconsistent with many studies that conclude female have impaired QOL when compared to male like the study of Hoey et al, Albuhairan et al, Murillo et al,kalyva et al, Frøisland et al,,Abdul rasoul et al[6,,14,24-27]. Alower physical activity among girls in comparison to boys can be explained according to our culture by weaker utilization of this activity due to the poor support given from school and parents with little encouragement to girls to participate in community sports, our result regarding the gender similar to what has been concluded by Chen et al[28]. Other studies showed no difference in qol between male and female as reported by Jawad et al, Samardizic et al,Emmanouil et al[5,17,21].

The negative correlation of the Qol with the age which found in this study may be due to the following: the role of developmental changes that occur at school-age children whom grow in to adolescence,the individual differences in caloric intake related to growth spurts and participation in sports, and adolescent mood swings, menses in female adolescents all these contribute to the lower score of physical and emotional QOL.Our result regarding this correlation is in line with the result of Jawad et al,Murillo et al [5,24]and not in line with result of Özyazıcıoğlu et al and Abdu rasoul et al[2,6].There is other studies which said that there is no association between them at all as Samardizic et al,Emmanouil et al and Gadallah et al[16,17,21].

It is found that there is no association between Qol with both residence and the economic state that is because in Iraq even a child who comes from lowincome households or rural region he is able to access the recommended treatment by receiving it from the official primary health centers.

Conclusions

The current study concluded that Iraqi children and teenagers with T1DM who live in Kerbala governorate and aged between 5-18 year had poorer qol than healthy peers.
