The Factors Associated with Incomplete Vaccination among Children below 4 Years in Holy Karbala/Iraq

Zahraa Khudhair Abdul Alabass[1], Shahrazad Shamki A.L. Jobori[2], Anwer H. Al-khafagi[3]

[1]Student in High Diploma of Family Medicine, College of medicine, University of Kerbala, [2]Tutor in Department of Family and Community Medicine, College of medicine, University of Kerbala, [3]Family Medicine Specialist, Center Sector Karbala/ Karbala Health Directorate, Karbala, Iraq

Abstract

Background: Vaccines has an essential role for the prevention of infectious diseases. It has an important role in promoting child survival, several reasons are related to incomplete vaccination of children.

Objectives: To find out the reasons related to incomplete vaccination among children under five years in Karbala city.

Method: A cross sectional study, convenient sample of 400 children was approached who attended primary health care centers in urban and rural areas in Karbala city. Data collection done between the first of March to 30th of June, 2019 through direct interview using a questionnaire adapted from similar researches. Statistical Package for the Social Sciences (SPSS) program version 24 was used for data analysis and P value of a level < 0.05 considered significant.

Results: The most (22.2%) reported reason for incomplete vaccination that are related to the health centers was unavailability of vaccine.

Child sickness (33.5%) and fear of adverse effects (31.5%) were the most reported reasons for incomplete vaccination that are related to the family and child.

Conclusions: Unavailability of vaccine, child sickness and fear of adverse effect were the most reported reasons for incomplete vaccination.

Keywords: *Immunization, incomplete vaccination, reasons.*

Introduction

Childhood immunization is the induction of immunity throughout vaccination[(1)]. Human beings have profited from immunization for more than two centuries[(2)]. Immunization is a core constitute of the human right and recognized as an individual, community and governmental responsibility[(3)]. Vaccines are so special as it's: promote health, have an expansive reach, have rapid impact and save lives and costs[(4)]. Clinical studies are conducted to assess the safety and efficacy of a vaccine before it can be brought to market[(5)]. The chance of any adverse response is almost one in a million dosages given, they proceed to be observed carefully even after consent[(6)]. False thoughts and rumors with no scientific background about their possible negative response may prevent people from being vaccinated, with the consequent risks for the health of the population[(7)]. In 1985, the Expanded Program of Immunization was established nationwide[(8)]. It is necessary to understanding factors that affect the immunization coverage to increase routine immunization coverage rates[(9)]. Factors that commonly influence vaccination programme performance are either health-system-related (e.g. quality of services, distance,

e-mail: aljanabizahraa2@gmail.com

security, waiting time, reliability of vaccination session schedule) or user-related (e.g. family characteristics, parental attitudes and knowledge)[10]. Family characteristics include: poor-income status, residence in rural areas, extremes of maternal age, high parity, low maternal education level, larger families, residence in the area for < 1 year, mother working outside the home, lack of knowledge about vaccine-preventable diseases, transportation difficulties, lack of health insurance and presence of disease among the children[11]. Factors like low education, age, poor access to health facilities, single parent, inadequate antenatal care, ethnicity and no belief in vaccination associated with low immunization uptake around the world[12]. In Iraq, few studies had done to assess the factors that affect vaccination coverage [13-15], Some studies had done to assess the awareness towards childhood vaccination[16-18].

Subjects and Method

Study design, setting and time: A cross sectional study was carried out at 4 primary health care centers (PHCCs) in urban and rural areas in Karbala city from the first of March to 30th of June, 2019.

Study population and Sampling technique: The study included a sample of 400 children born from 1/ 1/ 2016 and above according to the time of introduction of the new vaccination schedule who attended PHCCs for vaccination, health problems or accompanied by their caregivers and agree to participate in this study. The sample was selected conveniently from four PHCCs, which were selected by simple random technique. Two randomly selected from the urban areas (Al Mulhaq and Al Nidal) and Two PHCCs were selected from the rural areas (Aon bin abdulla and Husseiniya PHCC).

Inclusion Criteria:

- Children born from 1/ 1/ 2016 and above according to the time of introduction of the new vaccination schedule in Iraq.
- Children resident in Karbala.

Exclusion criteria:

- Completely vaccinated children.
- Internally displaced children.
- Children from other cities rather than Karbala.
- Very ill and mentally retarded caregiver.

The questionnaire included the following data:

- Demographic factors of the child, which included:

  (Age, gender, sequence in the family, place of birth, family size, house ownership and residence)

- Socio-demographic factors of the caregiver:

  (Marital status, mother age, mother's educational status, mother's occupational status, father age, father's educational and occupational status)

Other related factors: Walking time to reach healthcare center, means of reaching healthcare center, source of the information on vaccination in general, presence of immunization card.

Causes for incomplete vaccination among children: The last part of the questionnaire contained the possible reasons incomplete vaccination among children which incuded the followings:

Causes related to health center: Unavailability of vaccine, absence of vaccinator, poor health staff motivation, inconvenient time of immunization, long waiting time, child illness –not given vaccine by vaccinator and others (specify).

Causes related to the family and child: Unaware of need for immunization, unaware of need to return for subsequent dose, no belief in immunization schedule, fear of adverse effects, rumors about vaccine such as vaccine causes diseases, the belief that vaccination campaigns are adequate, child sickness(child ill – not taken to health center), busy mother, mother forgetfulness, family problems including illness of mother, and others (specify).

Under vaccinated child (or child with an incomplete vaccination schedule): "Child aged <5 years lacking one or more of the vaccines in the national schedule, including boosters" [19].

Operational definitions for vaccinated children should be provided by age and vaccine and should include vaccine boosters. New vaccines that have been recently introduced in the country should also be considered[19].

Table 1: Basic national vaccination schedule by age that must be given to the children to be completely

Age	Basic Schedule
From birth to one month	BCG + OPV0 + Hep B1
2-3 months	BCG + OPV0 + OPV1+ pneumococcal1 + rotavirus 1+ Hexa 1 (DTaP□-IPV□ -Hib□-HepB□)
4-5months	BCG + OPV0 + OPV1+ OPV2+ pneumococcal1+ pneumococcal2 + rotavirus 1+ rotavirus 2+ Hexa 2 (DTaP□-IPV□ -Hib□-HepB□)
6-12 months	BCG + OPV0 + OPV1+ OPV2+ OPV3+ pneumococcal1+ pneumococcal2+ pneumococcal3+ rotavirus 1+ rotavirus 2+ Hexa 3 ($DTaP_3$-IPV_3 -Hib_3-$HepB_3$)+ measles
12-23months	BCG + OPV0 + OPV1+ OPV2+ OPV3+ pneumococcal1+ pneumococcal2 + pneumococcal3+ rotavirus 1+ rotavirus 2+ measles+ MMR
18-23 months	All vaccines + Boosters doses
Measles→ 12 months MMR→24 months Boosters →24months	

Ethical Consideration:

1. Study protocol was approved by the ethical committee in collage of medicine/Kerbala University.
2. Written agreement was obtained from Karbala health directorate with facilitation letter to the PHCCs where the study was conducted.
3. Verbal consents were obtained from the mothers prior to interviewing after explaining the objectives of the study to them.

Results

Distribution of variables of children with incomplete vaccination: The mean age of children was 18.49±10.77 ranging from (3-41) months. In terms of gender, females outweigh males (females accounted for 53.0%, while males accounted for 47.0%). Over half (52.5%) have a third birth order or more, the other half (19.8% and 28.2%) are either first or second in birth order. 88.2% of the children were born in maternity hospitals and 87.5% have vaccination card present.

Table 2: Distribution of variables of children with incomplete vaccination

Variables	Mean±SD	Range
Current age (Month)	18.49±10.77	(3-41)
Gender		
Male	188	47.0%
Female	212	53.0%
Total	400	100.0%
Birth Order		
First	79	19.8%
Second	113	28.2%
Third or more	208	52.0%
Total	400	100.0%
Place of Birth		
Maternity hospital	353	88.2%
Home	47	11.8%
Total	400	100.0%
Presence of Immunization Card		
Yes	350	87.5%
No	50	12.5%
Total	400	100.0%

Distribution of source of information on vaccination: Figure 1 shows that (97.3%) of the source of information regarding vaccination comes from health centers, the other sources of information are (family, television and internet) in a percentage of (2.3%, 0.2% and 0.2%) respectively.

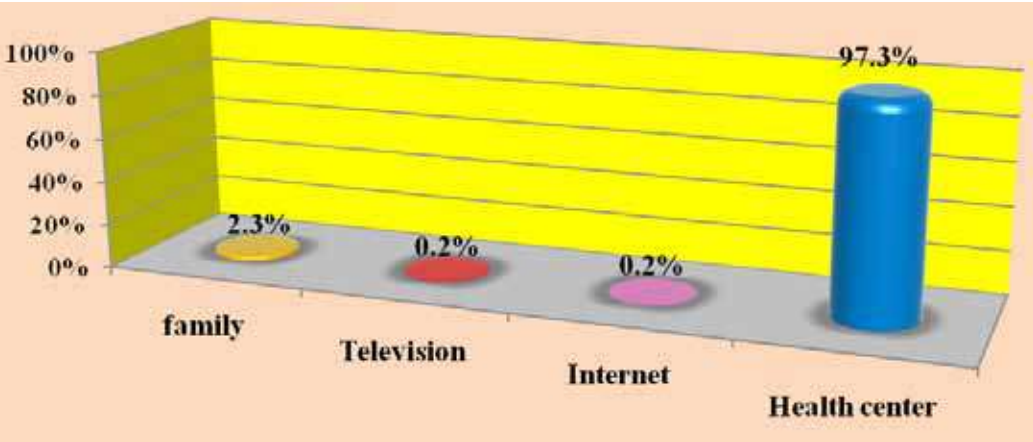

Figure 1: Distribution of source of information on vaccination.

Distribution of incompletely vaccinated children by type of missed vaccines: In the first week of life, the percentage of missed vaccines was low: 5% for BCG, 5% for oral polio vaccine (zero doses) and 1% for Hepatitis B vaccine (first dose). Other missed vaccines are shown in table 3

Table 3: Distribution of incompletely vaccinated children by type of missed vaccines

Vaccine Type	Number	Percent
One week after birth		
BCG	20	5%
Oral polio vaccine (zero dose)	21	5%
Hepatitis B vaccine(first dose)	4	1%
Two months		
Oral polio vaccine (first dose)	131	30%
Rota vaccine (first dose)	278	69%
Pneumococcal vaccine (first dose)	146	36%
Hexa vaccine (first dose)	130	32%
Four months		
Oral polio vaccine (second dose)	189	47%
Rota vaccine (second dose)	366	91%
Pneumococcal vaccine (second dose)	205	50%
Hexa vaccine (second dose)	190	47%
Six months		
Oral polio vaccine (third dose)	207	60%
Pneumococcal vaccine (third dose)	223	64%
Hexa vaccine (third dose)	207	60%
Nine months		
Measles	256	88%
Fifteen months		
MMR*vaccine(first dose)	131	83%
Eighteen months		
Oral polio vaccine (first booster dose)	14	90%
Penta vaccine (first booster dose)	14	90%

*MMR Measles, Mumps and Rubella. * children may missed more than one vaccine

Reasons for incomplete vaccination that are related to the health center: Figure 2 shows that (22.2%) didn't vaccinate their children because the vaccination is not available in health centers. Other related reasons are shown in figure 2.

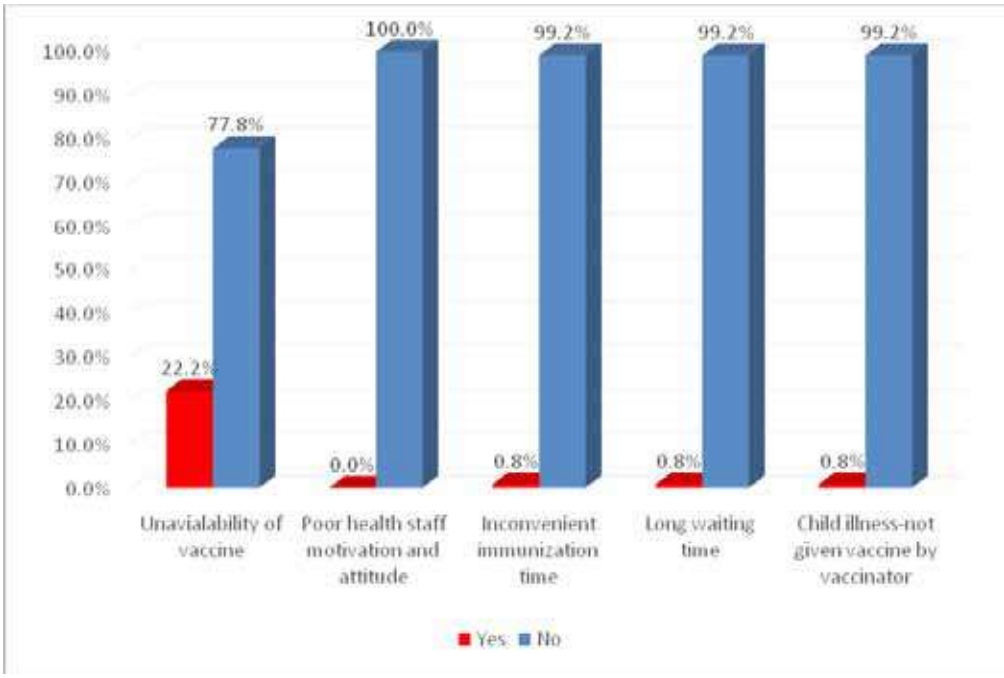

Figure 2: Reasons for incomplete vaccination that are related to the health center.

Reasons for incomplete vaccination that are related to the family and child: Figure 3 shows that being not aware of the need for vaccination was (6.0%), although being not aware of the need for subsequent vaccination was not cited at all as a reason for incomplete vaccination, other related reasons are shown in figure 3.

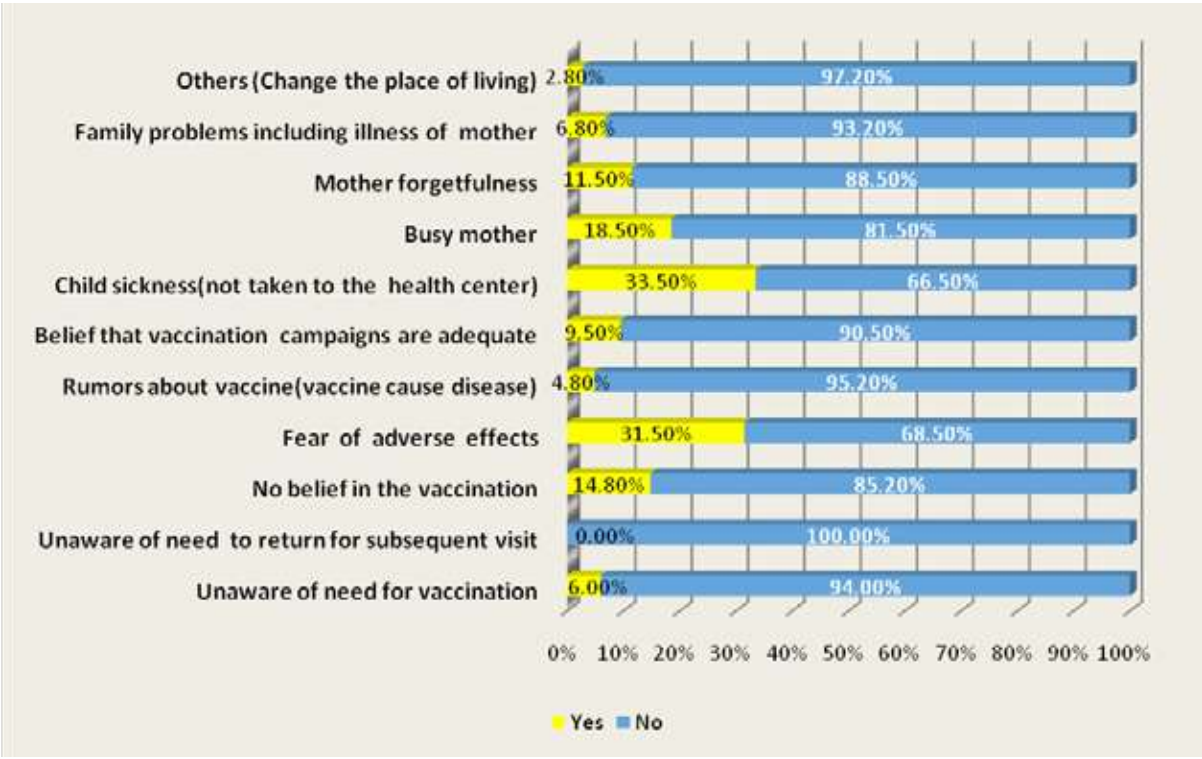

Figure 3: Reasons for incomplete vaccination that are related to the family and child.

Discussion

Vaccination is a very effective way for preventing certain infectious diseases. Routine immunization programs protect most of the world's children from a number of infectious diseases that previously claimed millions of lives each year [20].

The prevalence of incomplete vaccination is a main public health issue because it continues to sustain a high spread of vaccine-preventable diseases in some countries[21].

Regarding to birth order, most (52.5%) of incompletely vaccinated children in this study had a third birth order or more rather than first (19.8%) or second order (28.2%), While in other studies birth order has no effect on vaccination status[22-24].This might be attributed to increase family size that made the parent busy and forget the vaccination schedule.

Regarding to the source of information towards vaccination, it was shown that 97.3% come from health centers. In another study done in Ethiopia, It showed that the major (88%) sources of information were health workers and health extension workers[25]. Another study done in Baquba city showed that most (87.2%) of the information about vaccination comes from physicians or health care workers[18].

The percentage missed vaccines in this study were more when the child get older in age i.e the percentages of missed vaccines At age 18 months and more [Oral polio vaccine (first booster dose)(90%) and Penta vaccine (first booster dose)] were more than that in the first week of life) [BCG (5%), Oral polio vaccine(5%) (zero dose), hepatitis B vaccine (1%) (First dose)] except for Rota doses (start high percentage from the begning) as the permitted period for Rota is too short(Children should receive all doses of rotavirus vaccine before they turn 3 months old (child aged 91 days and more will be prohibited form the vaccine)[26].

This variation may be related to the country's policy in Iraq that birth certificate is not permitted until the child takes BCG vaccine, HBV1 and OPV0 vaccines are taken at the same time. Then when the child get older, there will be a several reasons (it will be mentioned later) for missing vaccination schedule.

In addition, there was a concept that the first week vaccines is the crucial one and the parents or caregivers must brought their neonate to gain that vaccines in a timely manner.

Vaccination coverage start high in percentage in the first week schedule then declines gradually as the child proceed in age as reported in the studies done in Iraq [13-15].

According to the reasons for incomplete vaccination that are related to the health centers, the mostly mentioned reason was unavailability of vaccine (22.2%).

In a study done by Al Lela et al. 2013 in Iraq, It was found that lack of vaccine was considered to be a barrier for vaccination by the greatest proportion 42.4% of the participants[27]. Absence of vaccinators or vaccines was the found as the second most (17.7%) common cause for incomplete vaccination in the study done in Pakistan by Riaz et al. 2018 [28].

According to the reasons for incomplete vaccination that are related to the family and child: child sickness (33.5%) and fear of adverse effects (31.5%) were the most reported reasons for incomplete vaccination. In a study done by Kadhum 2015 in Baquba city, the most reported barriers for immunization were child illness(58.8%) followed by lack of mother knowledge concerning the place and date of vaccination(23.5%)[18].

Conclusion

- Unavailability of vaccine was the most reported reason for incomplete vaccination that are related to the health centers.
- Child sickness and fear of adverse effect were the most reported reason for incomplete vaccination that are related to the family and child.

Chipping Resistance of Nanosilica Treated Zirconia Cores Veneerd with Porcelain after Thermocycling and Cycling Loading

Hanaa F. Mahmoud[1], Yaser F. Gomaa[2], A. Nour A. Habib[3]

[1]Assistant Lecturer of Dental Material, Biomaterials Department, Faculty of Dentistry, Minia University, [2]Professor of Dental Materials, Head of Biomaterials department and Dean of Faculty of Dentistry, Minia University, [3]Professor of Dental Materials, Cairo University

Abstract

Aim: This study was conducted to evaluate the effect of nanosilia surface coating of pre-sintered zirconia on chipping of veneered zirconia crowns after thermocycling and cyclic loading.

Method: Twenty zirconia cores were subjected to nanosilica slurry treatment before sintering then veneered and fired to produce crowns. The crowns ere cemented by resin cement on their epoxy dies and 10 crowns were subjected to 10000 thermocycles and 10000cyclic loading. All crowns were loaded till chipping of veneer layer then the chipped surfaces were examined by SEM/EDX.

Results: Crowns which were subjected to thermocycling and cyclic loading gave lower chipping resistance than the non-aged crowns.

Conclusions: Treatment of zirconia cores with nanosilica before sintering and after thermal and mechanical aging didn't increase the chipping resistance of the veneer layer.

Keywords: *Nanosilica, Zirconia,Chipping,Veneer.*

Introduction

Yttria-stabilized tetragonal zirconia polycrystal (Y-TZP) became the most ceramic material used for production of fixed partial dentures. The successful outcome of Y-TZP has been associated with the intrinsic material toughening mechanism that occurs through phase transformation from tetragonal to monoclinic crystalline form[1,2].

Due to the relative opacity, zirconia substructure needs to be veneered for better esthetic performance. Veneering porcelains are used to coat the surface of zirconia to enhance the natural appearance of prosthesis. Porcelain-veneered zirconia restorations are subjected to failure by the fracture of the veneering layers which dominant clinically observed failure mode and it is called chipping[3].

Studies proved that nano silica had performed greatly in many branches of dentistry[4,5] .Modifying zirconia surface in its pre-sintered stage is an effective technique to change the properties of zirconia based dental restorations[6].

Many previous studies documented that thermal and mechanical aging for the prediction of restorations durability is recommended as they simulate oral conditions in thermal and mechanical fluctuations with less period of time and they have great effect on the chipping resistance[2,7,8].

Hypothesis: The treatment of zirconia core surface with nanosilica before sintering may increase the chipping resistance of the veneer layer.

Aim of the study: To evaluate the effect of nanosilia surface coating of pre-sintered zirconia on chipping of veneered zirconia crowns after thermocycling and cyclic loading.

Method

A model acrylic tooth (Typodont, Columbia)

simulating mandibular first molar was prepared after imbedding vertically in a cylindrical Teflon mold with self-cured acrylic resin(Trayresin™, Dentsply sirona, USA) to obtain a full anatomy ceramic crown preparation having the dimensions of 1.5mm Axial walls reduction, 2mm occlusal surface reduction and 1mm gingival margins reduction using a high speed hand piece (NSK, Tokyo, Japan), size 010,012 tapered diamond stones with flat end and size 012 flame shaped stone (Dentsply, sirona, UK). The angle of convergence was 6°-8° and all line angles were rounded to prevent stress concentration.

Twenty silicon impressions (Speedex®, Coltène/ Whaledent AGAltstätten,Switzerland)were recordedfor the preparedacrylic tooth by using double mix 2 steps technique (heavy and light). Impressions were poured by epoxy resin die material (Kemapoxy 150, CMB international, Egypt) and the resulted dies dimensions were measured by a digital caliper (APT, china). Dies with dimensions exceed the range of error ±0.1mm were discarded.

Each die was coated with a thin layer of optical reflection spray (Occlutec Spray, Renfert Dental Corp, USA) and optical impressions were recorded using a scanning machine (Ceramill map400, Amnn Girrbach, Austria). Twenty zirconia cores (Ceramill zirconia, Amnn Girrbach, Austria)were designed and milled by the aid of computerized milling machine (Ceramill map400, Amnn Girrbach, Austria) with a uniform thickness of 1mm and with cuspal inclination of 30°. Milled cores were air dried with oil free air for 1 minute.

Nanosilica slurry was prepared by mixing the nanosilica powder of average size 40 wt% (Jiangsu, Mainland, China) with ethyl alcohol (Elahram, Cairo, Egypt) by ratio 4:1 wt%. The slurry was applied to the outer surface of zirconia cores with porcelain brushes size 4 and 6(Koli, Bredent, Germany).Surface treated zirconia coreswere sintered in a sintering furnace (Ceramill therm, Amnn Girrbach, Austria) following the manufacturer instructions.

A full-contour wax pattern with cuspal inclination 30° was built up onto one of the copings to mimic the final veneer layer dimensions; silicon impression was recorded for the pattern. This silicon key provided a uniform thickness and shape of the veneer layer for all specimens. Veneering porcelain (GC® Initial, Illinois, America)was sequentially built up by the same technician following the manufacturer's instructions with the help of the silicon key, followed by firing according to manufacturer instructions. The thickness of the crowns was measured with a digital caliper to ensure uniformity among all specimens.

Fired crowns were cemented to their corresponding dies using resin cement(Rely™ x ultimate 3M Deutschl and, Germany). The cement was mixed and applied to the fitting surface of the crowns according to manufacturer instructions. The crowns were seated firmly and 1 kg weight was applied to the occlusal surface for 3 minutes to ensure equal pressure for cementation of all specimens. That was followed by light curing (LED blue phase, Ivoclar Vivadent, Germany) from each side for 10 seconds. The specimens were left undisturbed for 15 minutes and were stored in distilled water for 24 hours.

The specimens were divided into 2 groups (n=10). Group I was the control and group II was subjected to thermocycling and cyclic loading before chipping resistance test. Thermocycling was done in thermocycling machine (Robota automated thermal cycle; Bilge, Turkey). Thermocycling was performed for 10000 cycles intermittently with a 300 cycles per day in a water bath; dwell times were 25 seconds in low temperature point of 5C° and the high temperature point was 55 C° with the lag time of 10 seconds.

The thermocycled crowns were stored in distilled water for 24 hours and then they were transferred to chewing simulator (Robota, ad-tech technology, Germany) to receive 10000 successive compression loads with 200N. All specimens were stored in distilled water for 24 hours.

For chipping resistance test each cemented crown was fixed in the lower jaw of the universal testing machine (Instron, 3345L8741, Assembled Canton, USA). Compressive load was applied directly to the central fossa of crowns by a steel ball (5mm in diameter) with rate of loading 0.5mm/min. A piece of polyethylene sheet was placed between the ball and the crown in order to properly distribute the load.

The area of loading was calculated by the help of articulating paper (Zogear, China) to determine the points of loading between cusps and the steel ball. As the cuspal inclinations were tangential to the steel ball in certain points so the line between two opposing points is the diameter of the formed circle. 3D CAD design software (Solid works 2015)[9] was used to help in drawing the circle and calculating the area (Figure 1,2,3);

so by knowing the diameter of the drown circle; the area could be calculated through the following equation:

$$A = \pi r^2$$

Load was applied until chipping of the veneer layer took place. The load at chipping for each specimen was recorded and the compressive chipping stresses were calculated using the following equation:

$$\text{Chipping stress (MPa)} = \frac{\text{Load at chipping (N)}}{\text{Stress area (mm}^2\text{)}}$$

Fractured surfaces were coated with gold by gold sputtering machine (JEOL, JFC-1100E, Fine coat, USA.) then examined by scanning electron microscope (SEM) (JSM-IT200, JEOL ltd, Tokyo, Japan) and elemental analysis was performed by using energy dispersive x ray spectroscopy (EDX) in order to reveal the presence or absence of silica and its percentage.

Results

I. Chipping Resistance: There was a significant difference between both groups in chipping resistance (p value was<0.05).GroupI showed higher mean of chipping load which was 1300.404±340.361N with chipping stress of 413.877MPa. Group II mean of chipping load was 820.913±396.200N with chipping stress of 261.270MPa.

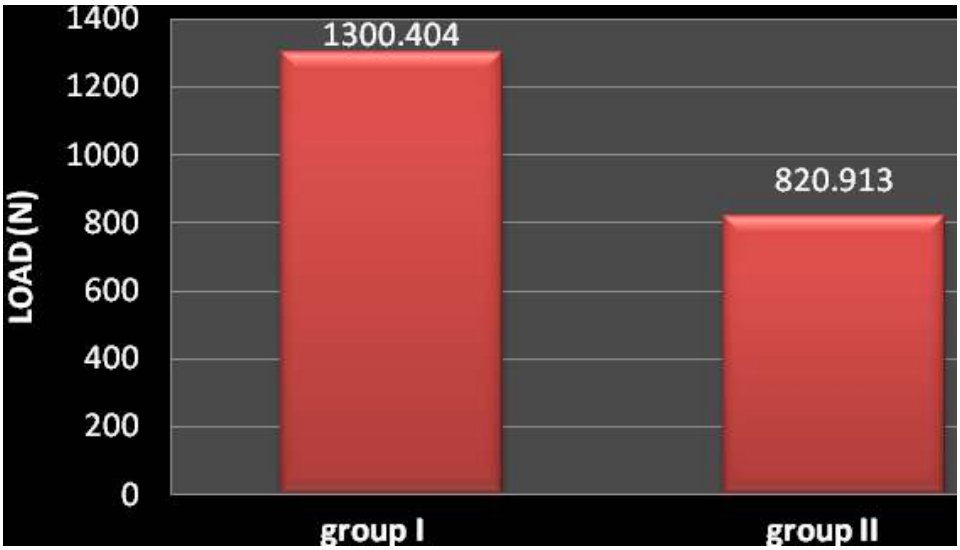

Fig. 2: Means of load at chipping of both groups.

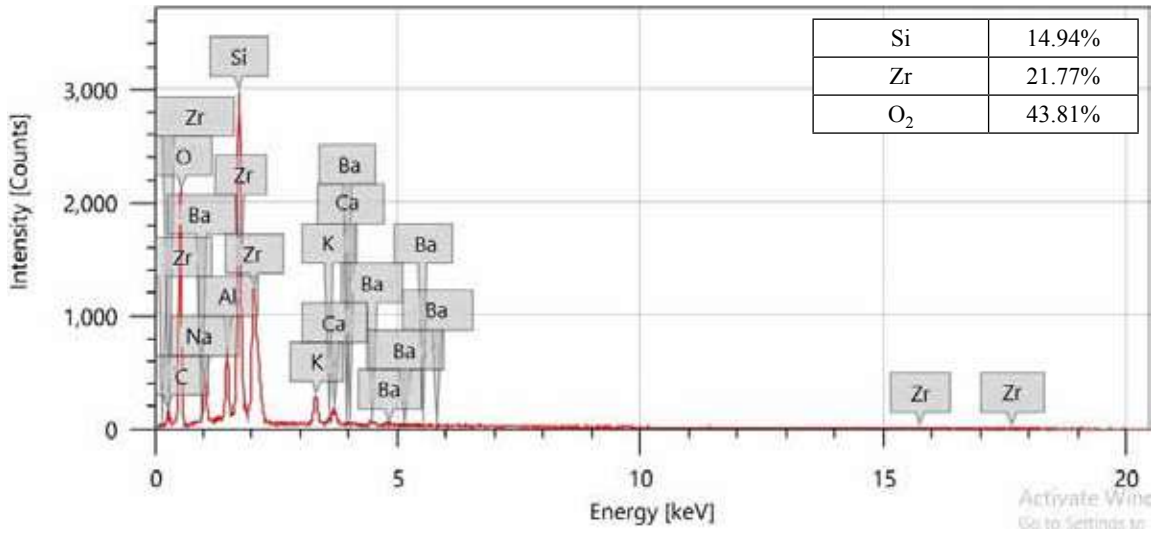
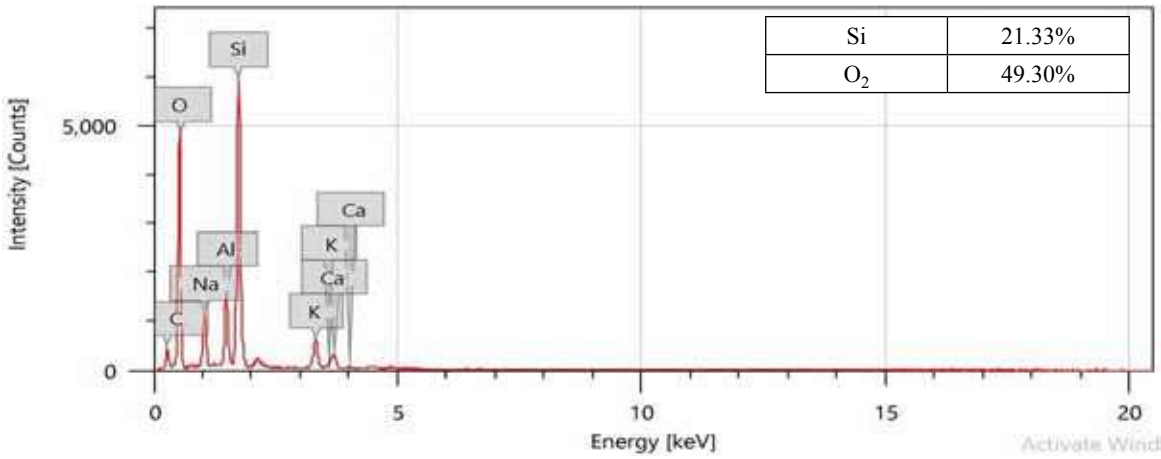
II. SEM and EDX Results: Scanning electron microscope examination and EDX analysis showed that the mode of failure was mainly mixed (70% of specimens)in group I in which there was areas of zirconia not covered with nanosilica in EDX analysis. The failure was mainly adhesive (70% of specimens) in group II in which the zirconia surface was completely covered with nanosilica revealing that the fracture was between nanosilica layer and veneer layer (Figure 3, 4).



Si	14.94%
Zr	21.77%
O_2	43.81%

Fig.3: EDX analysis of zirconia surface of group I(Mixed mode of failure).



Si	21.33%
O_2	49.30%

Fig.4: EDX analysis of zirconia surface of group II (adhesive mode of failure).

Scanning electronmicrographs of chipped zirconia showed areas ofdetachment in the mixed mode of failureandempty holes on the chipped veneers surface. In the adhesive mode of failure there were no empty holes (Figure5).

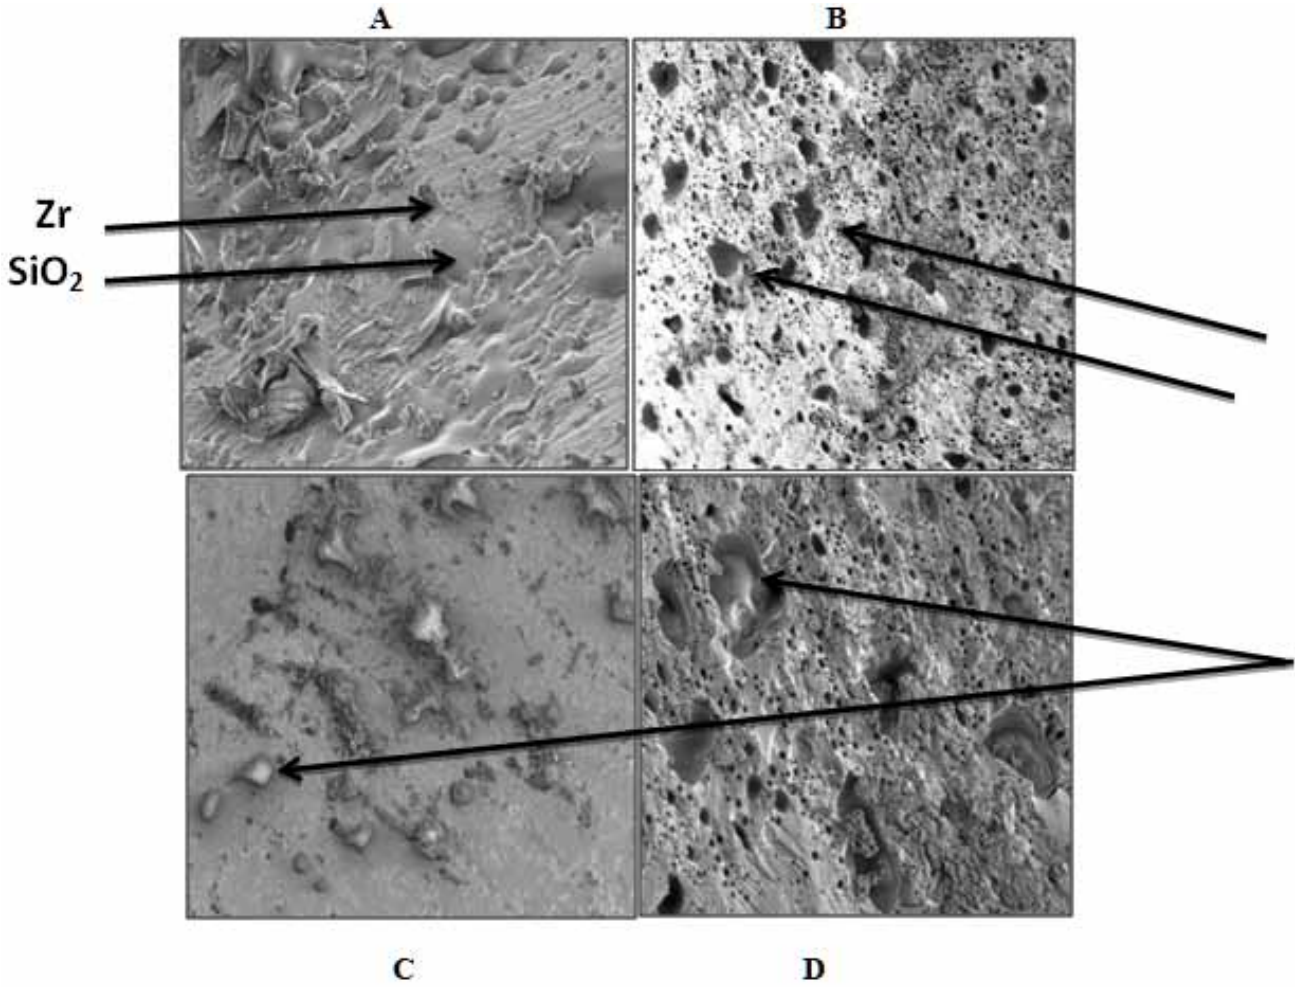


Fig.5: SEM (800X) micrographs show the surface topography of zirconia core of group I (A); arrows refer to elevations. The opposing porcelain veneer surface of the same sample (B) after chipping; arrows refer to empty holes (Mixed mode of failure). The surface topography of zirconia core of groupII (C) and the opposing porcelain veneer surface of the same sample (D) after chipping; arrows refer to silica rich areas (adhesive mode of failure).

Discussion

The incidence of veneering porcelain fracture when a zirconia core is used became a major complication that has been reported in the dental literatures. The cause of veneer chipping is complex material factors, including differences in coefficient of thermal expansion between veneer and core, likely create residual stresses which enhance veneer chipping[10-12].Evaluation and comparing chipping resistance of veneered zirconia crowns had been conducted in several previous studies[2,10].

This study was conducted to evaluate the chipping resistance of nanosilica treated zirconia-porcelain interface after thermocycling and cycling loading.

According to ISO 11405, the use of 500 thermal cycles between 5°C and 55°C is considered to be suitable to simulate short-term aging of dental materials[13]. In addition, *Gale and Darvell*[14]supposed that 10,000 cycles might represent approximately 1 year of *in vivo* functioning, with 20 to 50 cycles considered equivalent to a single day.

There is a large variation between number of cycles and the vertical loading applied in aging studies in the literature. Combining both thermocycling and cyclic loading is more clinically relevant protocol and might give prediction of longer time service[2,15,16].

The resulted load which cause chipping of veneers of group I was comparable to the results of previous

studies with slight non-significant difference. This may be attributed to different techniques of veneering, different core design or thickness and different testing methodology[17-19].

Group II showed lower chipping resistance than previous studies; however it is important to consider that both groups showed higher loads than the maximum chewing forces reported in literature of previous studies. Studied showed that the average maximum biting force of healthy and young adults is approximately from 400 -700N[20,21]. Therefore, the results indicated that the load at chipping of both tested groups in this study may withstand the clinical services without failure.

Mode of failure in group II was mainly adhesive failure between silica and veneer. As stated by many researchers[22-24] that chipping mainly occurred due to difference in coefficient of thermal expansion which lead to unfavorable thermal stresses at the interface between silica and porcelain veneer layer. However, the SEM and the EDX results indicate the strong bond between the silica coat and zirconia.

The difference in coefficient of thermal expansion between silica and porcelain may be the cause of veneer chipping and lower chipping resistance than the control. This may draw a tension to the possibility of using a veneering ceramic compatible with the nanosilica coat.

Conclusions

Within the limitations of this study it was concluded that:

1. The treatment of pre-sintered of zirconia cores with nanosilica before sintering without aging lead to high chipping resistance.
2. Aging decreased this resistance to chipping but it is still within acceptable limits of human maximum biting force.

Recommendation:

1. Nanosilica layer thickness, particle size and shape play great role and should be subjected for further research.
2. The results of this study did not support the hypothesis but revealed that surface treatment of pre-sintered zirconia with nanosilica is a potential cause increasing chipping resistance if the composition of the veneering ceramics is modified to be compatible with the coefficient of thermal expansion of the nanosilica.

Ethical Clearance: Was taken from Faculty of Dentistry, Minia University.

Source of Funding: Was self-funding.

Conflict of Interest: Nil.

Assessment of Fracture Force of CAD-CAM-fabricated Occlusal Veneer Restorations with Different Thicknesses

Hanaa Saber Rabeae[1], Cherif Adel Mohsen, Prof[2], Shams Waaz Amgad[3]

[1]Assistant Lecturer, Fixed Prosthodontics Department, [2]Professor and Chairman of Fixed Prosthodontics Department, [3]Lecturer, Fixed Prosthodontics Department, Faculty of Dentistry, Minia University, Minia, Egypt

Abstract

Purpose: To evaluate the fracture force of occlusal veneer restorations using ceramic material (Lithium di-silicate) and hybrid ceramic (VITA Enamic) Computer Aided Desingn/Computer Aided Manufacturer (CAD/CAM) material at different thicknesses after thermocycling.

Material and Method: Thirty CAD/CAM occlusal veneer restorations were fabricated from group E (IPS e.max CAD), V (VITA Enamic) and divided into subgroups according to thickness 0.3, 0.6, 1 mm. The occlusal veneers were luted to epoxy dies (n=5). The specimens were subjected to thermocycling test then they were subjected to load until fracture using a computer controlled materials testing machine. Data were tabulated and statistically analyzed using Two-ways analysis of variance (ANOVA).

Results: There was no significant difference in the fracture force between the two materials regardless the thickness. The fracture force increases with the increase of the thickness.

Conclusion: VITA Enamic hybrid ceramic material is closer to IPS e.max CAD ceramic material in the fracture force. With the increase of thickness, it leads to increase of fracture force.

Clinical Implication: Within the limitation of this in-vitro study, hybrid ceramic (VITA ENAMIC) and IPS e.max CAD are clinically applicable as occlusal veneer restoration with thickness 0.6 mm and more.

Keywords: *Hybrid ceramics, Fracture force, CAD/CAM.*

Introduction

Ceramics are the materials of choice as long term functional indirect restorations, due to their properties esthetic, biocompatibility and high strength. Nowadays dental technologies such as CAD/CAM are in continuous evolution offering both, the dentist and the patient. All ceramic restorations are cemented by using resin cement as they provide low solubility and they have high bond strength and better esthetic. Due to high bond strength of resin to tooth structure and complicated bonding between ceramic and tooth structure, resin was added to ceramic material to make a new compound structure called hybrid ceramics. Resin bonding is required for clinical success of indirect restorations at long time. With the use of CAD/CAM indirect restorations, there is a need for successful bonding for new hybrid ceramic materials.(16) All ceramic materials are superior to composite in its physical and mechanical properties. The hypothesis of this study, that there is a significant difference between all ceramic and hybrid ceramic occlusal veneer restorations; the fracture force of all ceramic is better than hybrid ceramic.

Materials and Method

The materials were used are: IPS e.max CAD ceramic blocks; low translucency, shade A2 and size C14 (Ivoclar Vivadent/ Italy), VITA ENAMIC Innovative ceramic blocks; low translucency, shade 2M2 and size C14 (VITA Zahnfabrik spitalgasse 3 D-79713 Bad Säckingen Germany), and RelyX™ Ultimate adhesive dual cured resin cement (3MESPE, Seefled, Germany).

Sample Size Calculation for Fracture Force Test: A sample size of 15 samples in each group was determined to provide 80% power for independent samples T test at the level of 0.05 significance using G

Power 3.19.2 software. So we made our study on 15 samples for each material (5 samples for each thickness). (Figure 1).

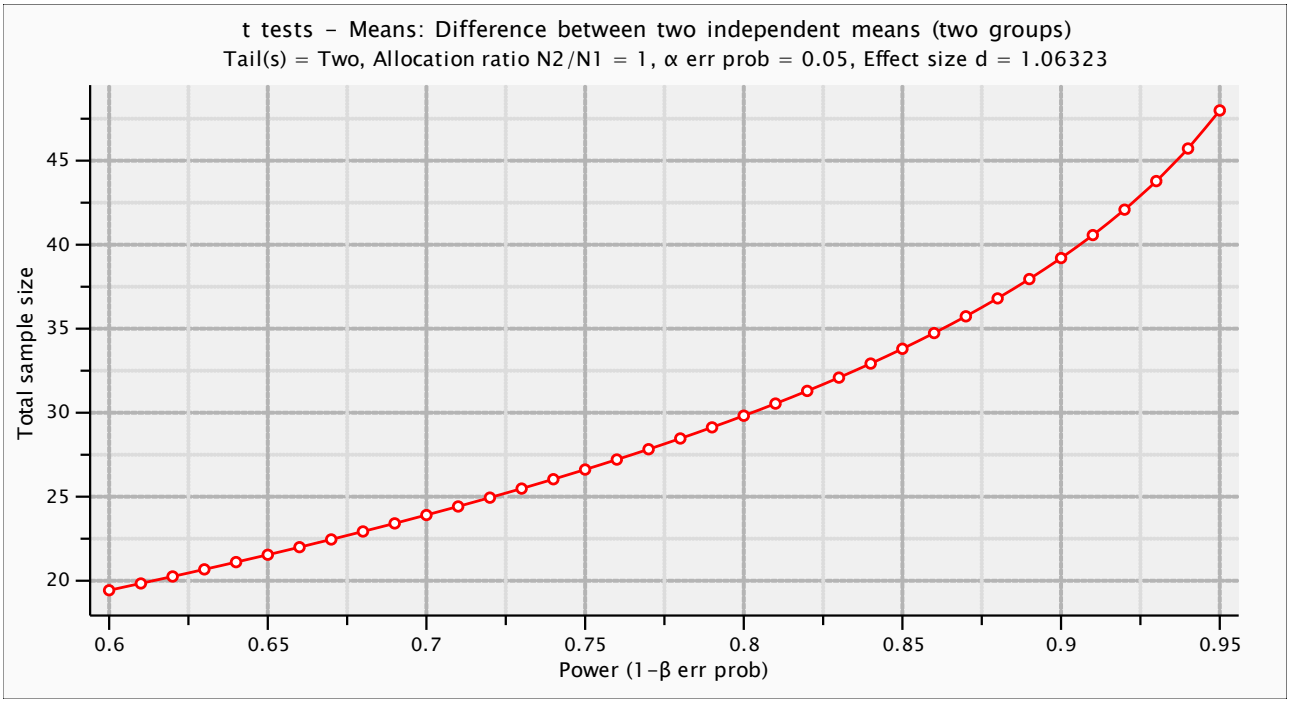

Figure 1:

Maxillary molar teeth with occlusal dimension average size (6mm x 5mm) were collected from the outpatient clinics of faculty of Dentistry Minia University. Teeth were freshly extracted, free from caries, restorations and fracture. The teeth were ultrasonically cleaned (Coltene Whaledent, Biosonic UC50 Ultrasonic, USA) of any surface debris then they were ready for use for samples construction.

Proper powder/ liquid ratio of self-curing acrylic resin (cold cure acrylic resin, Acrostone, Egypt) was mixed according to the manufacturer's instructions. As it reached the dough stage, it was poured into customade split Teflon mold with (2.5cm diameter x 2.5cm height). The roots of the tooth were inserted into the center of the mold till 2 mm apical to the cement enamel junction. With the use of customade paralleling device (Egypt), to centralize the tooth in the mold. The excess of the acrylic resin was rapidly removed with metallic wax carver (Miltex. Stainless steel. pakistan). After complete polymerization of acrylic resin, the split Teflon mold was removed. The samples were subjected to uniform occlusal reduction with diamond cutting tools (Komet Dental. Gabr. B raseler GmbH & Co.KG Trophagener Weg 25.32657 Lemgo. Germany.) to produce a uniform preparation. Before preparation, condensation silicone rubber base (Speedix putty Ivoclar Vivadent, Liechtenstein) indices were made for tooth to aid in standardization of preparation thickness Silicone indices made by hand mixing of putty paste with catalyst according to manufacturer's instructions and loaded into a custom made metallic perforated tray. After impression setting, the index was removed[12].

The molar teeth were prepared manually using diamond cutting stones size 14 with high speed handpiece (W & H Dental Work, Burmoos, Austria) under water cooling. The occlusal surface reduction was 0.3 & 0.6 & 1.0 mm at the central fossa[19].

The preparations resulted were flat occlusal reduction without finish line (butt joint preparation). The three different preparation thicknesses were checked using a digital caliper (Miltex, stainless steel, Pakistan) with the silicon guide on the preparation.Epoxy resin dies construction; by the use of custom made perforated tray that has an internal diameter of 20 mm and 25 mm height[24].

Thirty impressions of prepared teeth were made using condensation silicone rubber base impression

material (Speedix, Ivoclar VivaDent, Liechtenstein) by hand mixing according to manufacturer's instrucitons. The impression was loaded into the tray, prepared tooth was embedded in the impression and after setting the tooth was removed. The impression was poured by epoxy resin (kemapoxy 150, CMB, Egypt). The method was repeated to create sixty epoxy dies. One size of epoxy paste and 1.5 size of activator were mixed under vibration (Vibromaster Bego Bremer, GmBA, Germany) for two minutes then it was leaved ten minutes before pouring to become homogenous mixture. The mixture was poured into the impression and leaved to set for 48 hours in order to reach complete setting and dimensional stability. The dies were removed from impressions, then was finished by low speed straight hand piece (Sirona Dental systems GmbH Fabrikstra Be 31 64625 Benesheim Germany)and polished by pumice (Dental Lab Pumice, Dentsply, USA) with smooth electronic brush (Miltex. Stainless steel. Pakistan).

Occlusal surfaces were surface roughened by low speed wheel stone (Komet Dental. Gabr. B raseler GmbH & Co.KG Trophagener Weg 25.32657 Lemgo. Germany) and it was ready for occlusal veneers construction (Figure 2).

Figure 2: Epoxy die

Designing, milling and crystallization of occlusal veneers;all occlusal veneers (IPS e.max CAD & VITA ENAMIC) were fabricated according to the direction of manufacturing companies for each fabrication system. Epoxy dies were scanned sequentially with camera system without powder (Cerec Omnicam 4.4.4 by Dentsply Sirona).Designing of all occlusal veneers were carried out using a standard protocol, on the computer software.

The thickness of occlusal veneers was 0.3 mm, 0.6 mm and 1.0 mm.

The integrity of the structure was visually checked before crystallization. The IPS e.max ceramic occlusal veneers were placed into the oven (programat P310 by ivoclar vivadent) for crystallization. At the end, the veneers were removed from the oven when it reached at room temperature. (Figure 3)

Figure 3: Visual veneer in position

Cementation of the occlusal veneers to the corresponding epoxy resin dies; occlusal veneers were etched using hydrofluoric acid gel 9.5% (*BISCO-Schaumburg U.S.A*) for 60 seconds, for VITA ENAMIC and 90 seconds, for IPS e.max CAD according to manufacturer instructions. After etching, the veneers were washed with water and dried using air spray (dental chair Roson. China). Then, veneers were brushed by silane coupling agent (BISCO-Schaumburg U.S.A) and wait for 30 seconds then it was dried with air syringe according to manufacturer instructions. Epoxy dies were left clean dry; bonding agent (Adper Single Bond 3M ESPE U.S.A) was brushed to the epoxy dies and light cured (Denjoy, China) for 20 seconds.

Rely X-Ultimate dual cured resin cement clicker was used. One click applied on the veneer and applied on the die and loaded by the loading device 6 N load[9]

Under load, the excess was removed then curing of the samples for 40 seconds.

After complete cementation of all occlusal veneers, the samples were ready for the tests. (Figure 4).

Figure 4: Sample after cementation

Thermocycling Procedures: In this study the number of cycles used was 1000 cycles representing nearly 2years clinically. Dwell times were 25s in each water bath (Robota automated thermal cycle; BILGE, Turkey) with a lag time 10s. The low-temperature point was 5°C. The high temperature point was 55°C.

Fracture Force test: According to manufacturer instructions,samples were secured to the lower fixed compartment of testing machine by tightening screws. Fracture test was done by compressive mode of load applied occlusally using a metallic rod with spherical tip (5.6 mm diameter) attached to the upper movable compartment of testing machine (Model 3345; Instron Industrial Product, Norwood, MA, USA) travelling at cross-head speed of 1mm/min. The load at failure manifested by an audible crack and confirmed by a sharp drop at load-deflection curve recorded using computer software (Bluehill Lite Software Instron Instruments). The load required to fracture was recorded in Newton.

Results

There was no significant difference in the fracture force between the two materials regardless the thickness. There was significant diffirence between different thicknesses regardless the material type. There was no significant difference between the two materials at thickness of 0.3mm. In the group with 0.6and 1mm mm thicknesses, there was a significant difference and IPSe.max CAD had higher strength than VITA Enamic. The fracture strength increases with the increase of the thickness in both materials.

1. Fracture Force Measurement:

Table 1: Effect of material, thickness and interaction between both on Fracture force

Fracture force	F	P Value
Material	12.89	0.001*
Thickness	92.98	<0.001*
Material * Thickness	1.49	0.245

Two-ways-ANOVA test, *: Significant level at P value < 0.05

Table 2: Comparison of fracture force between the two materials regardless the thickness

		Material		P value
		E-max N=15	Vita Enamic N=15	
Fracture force	Range Mean ± SD Median	(632.5-2310) 1329.5±552.9 1292.5	(547.3-1723) 1096.5±418.3 1049	0.272

One-way ANOVA test for parametric quantitative data between the three groups followed by post hoc analysis between each two groups, Superscripts with different small letters refer to a significant difference between each two groups, *: Significant level at P value < 0.05

Discussion

Egbert J S, et al (2015) stated that in case of patient with severly worn dentition, CAD/CAM occlusal veneer restoration made of hybrid ceramic is an alternative to full coverage restorations. The failure load of teeth restored with full coverage with 1.5- 2.00 mm was to be 771-1183 N[(3)], that is lower than this study (1727-2415). This fracture strength was reported to be higher than human masticatory forces (585-880) ***Kikuchi M et al, 1997.***

In accordance to **Chen C, et al (2014)**reported that with increase the thickness of IPS e.max CAD, the fracture resistance increased. There is no change between 0.5 mm and 1.5 mm thickness but sharp increase occurred at 2.0 mm. Tha normal occlusal load is 100 N-200 N in the molar area and 965 in accidental bite. 1000 N is required for clinical longivety. This requirement was achieved in the test specimens of Chen et al, 2014 and also at 0.5 mmor 1.0 mm thickness.(4 & 5 & 6).

Stawarczyk B et al (2016) reported that the fatigue resistance of occlusal veneers was increased by CAD/CAM composite in comparison with lithium disilicate ceramics (schlichting et al., 2011). Results of their study (stawarczyk)CAD/CAM revealed higher flexural strength than VITA Enamic, but lower than lithium disilicte ceramic.

Hamburger J T, et al (2014): Using a total-etch adhesive system improved the resistance to fracture(7). Normal occlusal forces are 50-300 N and reaches to 1200 N in case of clenching(8). E.max CAD showed minimal occlusal thickness 1.5 mm. In the study of **Hamburger J T, et al;** Direct composite restorations give good properties at high occlusal load.

The hypothesis of this study was partially rejected that there was no significant difference between IPS e.max and VITA Enamic materials in fracture force test but there was a significant difference between the two materials at 0.6 mm thickness.

Conclusion

Within the limitation of this study:

1. IPS e.max CAD and VITA Enamic are clinically applicable for occlusal veneer restorations and they are closer to each other in the fracture force.
2. Thickness has great effect on the restoration force, as with increase of the thickness the force increases.
3. Thin thickness as 0.3 has questionable survival in the oral environment. In case of patients with bruxism, it is advised to use restoration thickness not less than 0.5 mm.
4. Occlusal veneer restorations are advised to be used as a conservative approach and accepted force.

Antibacterial Activity of Sappan Wood (Caesalpinia Sappan L.) against Aggregatibacter Actinomycetemcomitans and Porphyromonas Gingivalis

Hendrik Setia Budi[1], Pratiwi Soesilowati[1], Mitha Jati Wirasti[2]

[1]Department of Oral Biology, [2]Undergraduate Student, Faculty of Dental Medicine, Universitas Airlangga, Surabaya, Indonesia

Abstract

The aim of this study was to find the Minimum Inhibitory Concentration (MIC) and Minimum Bactericidal Concentration (MBC) of sappan wood ethanol extract *(Caesalpinia sappan L.)* toward the growth of *A. actinomycetemcomitans* and *P. gingivalis*. The randomized posttest only control group design was applied to this study. The sappan wood ethanol extract was conducted with maceration method using 96% ethanol. Diluted to 50%, 25%, 12.5%, 6.25%, 3.125%, 1.56%, 0.78%, and 0.39% concentration. The MIC and MBC values of sappan wood ethanol extract toward *A. actinomycetemcomitans* and *P. gingivalis* was then known via the evaluation for Colony Forming Units (CFUs) in MH medium. The MIC and MBC of sappan wood ethanol extract toward *A. actinomycetemcomitans* and *P. gingivalis* was at 1.56% and 3.125% concentration. The ethanol extract of sappan wood reduces the number of bacterial colonies significantly at p=0.00. This study concluded that the growth of *A. actinomycetemcomitans* and *P. gingivalis* can be inhibited by sappan wood ethanol extract *(Caesalpinia sappan L.)* at MIC 1.56% and MBC 3.125% concentration.

Keywords: *Sappan Wood Ethanol Extract, MIC, MBC, Aggregatibacter actinomycetemcomitans, Porphyromonas gingivalis.*

Introduction

Periodontal disease is a chronic inflammatory disease that affects the gum tissue and bone supporting the teeth, which is indicated by gingival inflammation and periodontal pockets (periodontitis) and the second most common dental disease suffered by the world population. Periodontitis is a chronic infectious disease caused by microorganisms. Its key features include periodontal pocket formation, loss of connective tissue attachment, alveolar bone resorption, and gingival inflammation. The studies states that periodontal disease occurs in 20-50% of the entire population, and can increase the risk of cardiovascular disease by 19%; this risk increases by 44% at the 65 years old.[1,2,3] It is not yet known for sure of the complications that can happen in patients with untreated caries or periodontal disease. Those conditions can cause pain, distinction, bad appearance, and disruption of everyday activity.[4,5]

Periodontitis can be treated mechanically, surgically, and with supportive treatment. *Chlorhexidine* is one of the mouthwashes often recommended for supportive treatment to treat periodontal disease because of its antibacterial and antiplaque effect. Extended usage of *chlorhexidine* could lead toward changes in tooth color and dorsal part of the tongue, increasing the buildup of calculus, change the taste perception and drying of the oral mucosa.[6,7] Antibiotic can be used as a supportive treatment because of its ability to decrease the bacterial growth that still exists after mechanical therapy. But, even so, the inaccurate and extended administration of antibiotic could lead to bacterial resistance, this has created the need for a therapy using natural ingredients with antibacterial effects to be developed.[8,9]

Sappan (*Caesalpinia sappan* L.*)* is a plant from the *Febaceae* family which grows in tropical region and the stem of the plant has been used as traditional medicine since previous times.[10] Sappan wood contains active compounds in the form of flavonoids, which are homoisoflavonoid, brazilin, protosappanin and chalcone, saponin, terpenoid and tannin.[11] Brazilin acts as an antibacterial agent to inhibit the synthesis of amino acid and cellular proteins in bacteria. Thus, Brazilin has a high antibacterial efficacy toward *S. mutans*, a caries-triggering bacteria and *P. intermediate, a* negative gram bacteria that causes periodontal diseases.[12,13] In previous study, sappan wood was proven to be able to inhibit bacterial growth such as *S. typhi, K. pneumonia, E. coli, B. subtilis, P. aerogenosa* and *S. aureus*.[14] Sappan wood extract has an antibacterial effect against *E. faecalis, S. salivarius, S. sanguinis* and *A. viscosus.*[15] The aim of this study was to find the Minimum Inhibitory Concentration (MIC) and Minimum Bactericidal Concentration (MBC) of sappan wood ethanol extract *(Caesalpinia sappan L.)* toward the growth of *A. actinomycetemcomitans* and *P. gingivalis* which caused periodontal infections.

Materials and Method

The bark from sappan wood which has been crushed to a powder was collected by 1650 gram, then macerated twice with 96% ethanol, then inserted to a digital shaker with the speed of 50rpm for 24 hours and then filtered with a cloth filter to obtain filtrate. The filtrate was then evaporated using Rotary Vacuum Evaporator at the temperature of 40^0C for 13 hours until a thick extract with 100% concentration was obtained.[16]

A colony of bacteria that was taken from the stock using sterile inoculation loop was inserted to the BHIB. After that, the bacterial culture in the BHIB medium was inserted to an anaerobic jar in an anaerobe state and incubated inside an incubator at the temperature of 37^0C for 24 hours. Then, the culture's turbidity was observed to be equalized with the 0.5 McFarland standard (1.5 x 10^8 CFU/ml). Eleven sterile reaction tubes were prepared and labeled with numbers 1-9, (+) for the positive control group and (-) for negative control group. The number 1 sterile tube was filled with 10ml of 100% sappan wood ethanol extract, and, in tube numbers 2-9, the positive control tubes and negative control tubes were filled with 5ml of BHIB medium. Then, 5ml of solution from tube 1 was added into tube 2, thus, half the concentration of sappan wood ethanol extract was obtained by mixing 5ml of BHIB and 5ml of 100% sappan wood ethanol extract. After that, 5ml of mixture was taken from tube number 2 and inserted in tube number 3 to obtain 25% concentration of ethanol extract. The procedure was repeated until tube number 9 so that a group of sappan wood ethanol extract with 12.5%, 6.25%, 3.125%, 1.56%, 0.78%, and 0.39% was obtained. The positive control tubes contained BHIB medium and bacteria, and the negative control tubes only contained BHIB medium; 0.1ml bacteria was then inserted into tube numbers 1-9 and the positive control tubes. All tubes were incubated at the temperature of 37ºC for 24 hours to observe the turbidity after the procedure. Results from the dilution technique were then cultivated in the *Mueller Hinton* medium with streak method to obtain MIC and MBC number.[17] In order to obtain a more accurate result, 0.1 ml of bacteria from each tube, including positive and negative control, was subcultured with spreader method on a *Mueller Hinton* medium to count the number of bacterial colonies that had grown. The calculation of growing colony in each concentration was manually counted three times, each with a different observer.

The data of the bacterial colonies was analyzed statistically using SPSS version 13.0 (IBM, Armonk, New York, USA). We performed Anova to compare CFU between groups concentration and the post hoc analysis was performed using Tukey Honest Significant Difference Test (HSD).

Findings: According to the qualitative phytochemical analysis of the sappan wood ethanol extract, contents of flavonoid, alkaloid, saponin, and terpenoid active substances were discovered to have antibacterial potential (Table 1).

Table 1. Phytochemical Test Result on Sappan Wood Ethanol Extract

Active Substance	Phytochemical Test Result
Flavonoid	+
Tannin	+
Terpenoid	+
Saponin	+
Alkaloid	+

+ it means contains active compounds

Dilution method was carried out in order to find the antibacterial potential of sappan wood ethanol extract, (*Caesalpinia sappan*), hence, its Minimum Inhibitory Concentration (MIC) and Minimum Bacterial Concentration (MBC). This method was done by adding

sappan wood ethanol extract into BHIB, in which after, *A. actinomycetemcomitans* and *P. gingivalis* were inserted to be tested. The result of the dilution method continued with cultivation in each tube with streak method in a *Mueller Hinton* medium to obtain MIC and MBC (Figure 1).

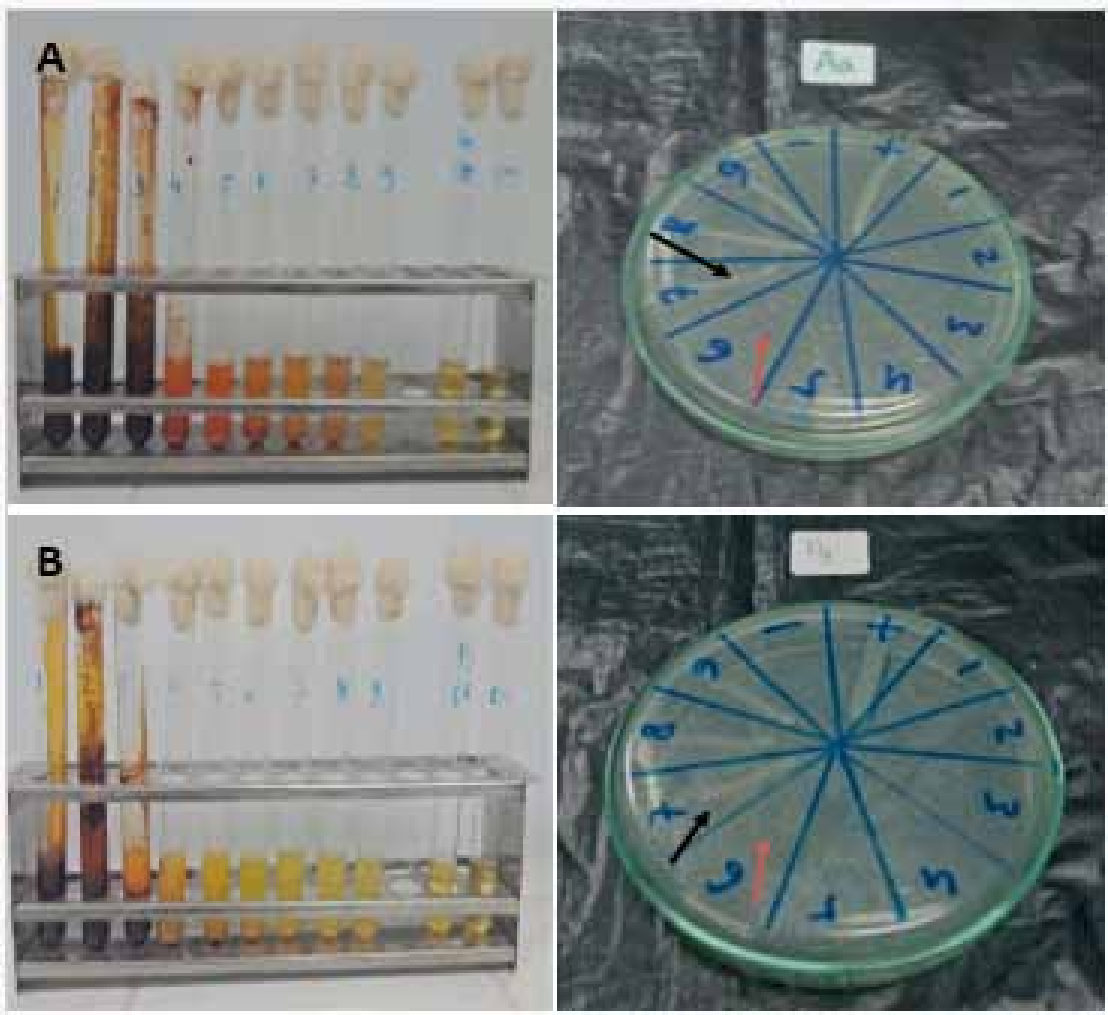

Figure 1. Sappan Wood Ethanol Extract Antibacterial Potential toward A. Actinomycetemcomitans bacteria and P. gingivalis. Annotation: A. Observation of turbidity with dilution method and B. Observation of bacterial colony on the Mueller Hinton using streak method. Tube Number 1-9 consecutively with 100%, 50%, 25%, 12.5%, 6.25%, 3.125%, 1.56%, 0.78%, and 0.39%. Tube with (+) mark was positive control and (-) mark was negative control. The area indicated by red arrow did not show growth of bacterial colony, area indicated by black arrow showed growth of bacterial colonies.

The cultivation of sappan wood ethanol extract in each concentration which had been administered with bacteria *A. actinomycetemcomitans* and *P. gingivalis* were conducted in *Mueller Hinton* medium with three replications. The result showed that, in the positive control, an average of 139 *A. actinomycetemcomitans* colonies was spotted, meanwhile, in the sappan wood ethanol extract with 100%, 50%, 25%, 12.5%, 6.25%, and 3.125% concentration and negative control, no bacterial colony growth. In 1.56% concentration, an average of 12.667 colonies. Meanwhile, in each of the 0.78% and 0.39% were 31.67 and 42 colonies. The result from the calculation of *P. gingivalis* colony in positive control averaged at 138,667 colonies, at 100%, 50%, 25%, 12.5%, 6.25% and 3.125% concentration and negative control, there was no growth of *P. gingivalis* colony. The number of colonies on 1.56% concentration was 11,667 colonies and at 0.78% and 0.39% were 32,334 and 49,667 colonies, respectively (Table 2).

Table 2. Average amount of bacterial colony growth

Groups (Concentration)	n (Repetition)	A. actinomycetemcomitans (CFU)	P. gingivalis (CFU)
100%	3	-	-
50%	3	-	-
25%	3	-	-
12.5%	3	-	-
6.25%	3	-	-
3.125%	3	-	-
1.56%	3	12,67[a]	11,67[a]
0.78%	3	31,67[b]	32,33[b]
0.39%	3	42,0[c]	49,67[c]
Positive Control	3	139,0[d]	138,67[d]
Negative Control	3	-	-

The values with different superscript letters in a column are significantly different ($p<0.05$).

Discussion

A. actinomycetemcomitans and *P. gingivalis* have a relationship to pathogenesis of the periodontal tissue. The ultrasonic scaling and laser therapy are efforts to decrease the severity of a disease, thus requiring other modes of therapy.[18] The result of sappan wood study revealed contents of active substances such as flavonoid, saponin, alkaloid, tannin and terpenoid. Flavonoid can disrupt the formation of cell membrane and damage the permeability of bacteria's cell walls and inhibit the function of the cell membrane.[19,20]

Other study has also revealed that flavonoid can inhibit expression of inflammatory cytokine by lipopolysaccharide,[21] which are one of the main components from negative gram bacteria virulence, such as *A. actinomycetemcomitans*.[22] *Brazilin* was included into the flavonoid group that had the potential as anti-inflammatory, antioxidant and antibacteria.[23] The tannin mechanism can inhibit DNA synthesis in the *A. actinomycetemcomitans* bacteria. Tannin can deactivate cellular adhesion of the *P. gingivalis* which, in turn, inhibits the enzyme that triggers protein transport, rendering it disrupted inside the inner membrane of the microbial cell.[24]

The effectivity of saponin as antibacterial agent worked by triggering leakage of protein and enzymes inside the cell and reducing the stability of the cell membrane. The active substance, terpenoid, can disrupt the formation process of cell walls and membranes; this caused the stability of the cell walls to be disrupted and killed the bacteria.[25,26,27] High quantities of alkaloids were found in various tissues of C. sappan twig. Alkaloids and their derivatives are used for analgesic, antispasmodic and antibacterial effects, anticancer activity and anti-inflammatory activity.[28,29]

The flavonoids, alkaloids, tannins, saponins, and terpenoids are active substances from sappan wood ethanol extract with each of its working mechanisms working in synergy to combat *A. actinomycetemcomitans* and *P. gingivalis* bacteria. Those mechanisms caused a decline in the physiological activity of the bacteria, which caused an inhibition toward the bacteria's growth, and, in turn, killed the bacteria.[30]

The result showed that 1.56% concentration of sappan wood ethanol extract expressed an inhibitory effect toward the growth of *A. actiomycetemcomitans* bacteria at 90.887% toward the positive control group. This showed MIC value at the concentration of 1.56%, which according to the study conducted by Khan et al. (2016).[31] The MIC value of sappan wood ethanol extract toward *P. gingivalis* was obtained at 1.56% concentration at 91.587% inhibition rate toward the growth of *P*. gingivalis in positive control group.

Sappan wood ethanol extract was capable of killing A. actinomycetemcomitans at 3.125%, as it was observed that bacterial growth was halted at this concentration. The MBC value of sappan wood ethanol extract toward *P. gingivalis* was also at 3.125% because, at the appropriate concentration, there was no longer bacterial colony growth observed. The MBC was defined as the lowest concentration needed for an antimicrobial agent to kill 99.9% of bacteria.

Increased concentration of sappan wood extract provides more active antimicrobial substances. Therefore, giving a higher concentration have a potential in inhibiting microbial growth. There were no differences observed in the sensitivity of the bacteria from sappan wood extract between *A. actinomycetemcomitans* and *P. gingivalis*. This study concluded that the growth of *A. actinomycetemcomitans* and *P. gingivalis* can be inhibited by sappan wood ethanol extract *(Caesalpinia sappan L.)* at MIC 1.56% and MBC 3.125% concentration.

Hormonal Regeims Using for Early Puberty Induction of Iraqi Female Lambs

Hussein Abbas Khamees[1], Jawad Khadim Taher[2] , Haider Rashash Abbas[3]

[1]Assistant Lecturer: Department of Surgery and Obstetrics, Collage of Veterinary Medicine Al-Muthannah University, [2]Lecturer: Department of Surgery and Obstetrics Collage of Veterinary Medicine–DhiQar University, [3]Assistant Prof: Department of Surgery and Obstetrics Collage of Veterinary Medicine–Basrah University

Abstract

This study was accompanies on thirty-six female lambs in addition, six rams of proven fertility were used in the present study in a private flock at Samawa/Iraq in breeding season at November 2018. The ages of lambs ranging from 8-12 months and weighing 30 to 35 kg were used in the study. All ewe lambs are awassi breed. The experimental lambs were divides into three groups randomly each group have twelve lambs. Groups 1, 2 and 3 received intra-vaginal sponges containing 20 mg of fluorogestone acetate FGA (Chronogest, Intervet®) for 14 days, the lambs were given intramuscularly 200 IU (group 1, n= 12), 300 IU (group 2, n=12) and 400 IU (group 3, n= 12) of PMSG (Intervet®, Holland) after removing of intravaginal sponges within 14 h . Estrous was monitored every 6h from 12 to 120 h following injection of PMSG. The lambs were considers in estrous when they were mounts by the rams. The pregnancy of ewes was determined after one month by using of ultrasonography and after 3 months depended to abdominal distention and then waiting until time of parturition. The results showed that the all ewe lambs in the group 2 of treatment (T_2) (FGA+300IU PMSG), but only two ewes lambs and one ewe lamb were not appear estrus from group 1 of treatment (T_1) (FGA+200IU PMSG) and group 3 of treatment (T_3) (FGA+400IU PMSG) respectively. The study showed that the estrus response, pregnancy rate and lambing rate were not significantly differences between the three treatments groups at ($P<0.05$). Estrus response in three groups was 83.3%, 100%, 91.6% respectively. Pregnancy rate in three groups were 100%, 83.3%, 90.9% respectively .Lambing rate in three groups were 100% in all groups. The result showed there are no significant differences between the treatments groups in litter size and number of lambs ($P<0.05$).This study appeared single lambing were 100%, 90%.100% respectively while twins lambing were zero, 10%, zero respectively and this study did not appear triple lambing.

Keywords: *Early puberty, Induction, Lambs, Hormonal Regimes.*

Introduction

The Studies on puberty in Iraqi sheep are very limited. Puberty is the age when first estrus accompanied by spontaneous ovulation occurs [1]. The onset of puberty in sheep is influence by genetic and environmental factors such as breed and strain differences. Workers on age at puberty agree that the early age is associated with the time of birth and the nutritional planes [2]. Suppose, for example that the breeding season in a highly seasonal breed is March to June and the earliest age at which puberty is possible in well-fed lambs in 8 months.

The lambs from ewes which conceive in March to May reach to puberty at few months of age, but those from ewes which do not conceive until June cannot reach puberty until they are 16 months old [3].First estrus occurs in ewe lambs at 30-50 kg of body weight 50-60% of adult weight [4, 5, 6].Recently, progesterone or its analogues are generally use to synchronize and induce estrus during the breeding and non-breeding season [7]. Administration of gonadotropins such as human menopausal gonadotropin (hMG) [8],pregnant mare serum gonadotropin (PMSG)[9], follicle stimulating hormone (FSH) and mixed with gonadotropins [10] after stopping progestagens treatment, causes increasing rate of ovulation. [11, 12] demonstrated the positive relationship between the dosage of PMSG (250– 500 IU) and the percentage of ovulation, reproductive performance of

ewe lambs. The treated ewe lambs with PMSG induce follicular growth and increased secretion of estrogens. The purpose of this study were induce early puberty in Iraqi ewe lambs by using progesterone intra-vaginal sponges and different doses of PMSG.

Materials and Method

This study was accompanies on thirty-six female lambs in addition, six rams of proven fertility were used in the present study in a private flock at Samawaprovince inbreeding seasonat September 2018.The ages of lambs ranging from 8-12 months and weighing 30 to 35 kg were used in the study. All ewe lambs are awassi breed. The lambs were grazed daily for 6-8 h on a pasture in addition; these ewes received 1-1.5 kg of mixture feed during the entire period of study. The experimental lambs were divides into three groups randomly each group have twelve lambs.Groups 1, 2 and 3 received intra-vaginal sponges containing 20 mg of fluorogestone acetate FGA (Chronogest, Intervet®) for 14 days, the lambs were given intramuscularly 200 IU (group 1, n= 12), 300 IU (group 2, n=12) and 400 IU (group 3, n= 12) of PMSG (Intervet®, Holland) after removing of intravaginal sponges within 14 h.Estrous was monitored every 6h from 12 to 120 h following injection of PMSG. The lambs were considers in estrous when they were mounts by the rams.

The pregnancy of ewes was determined after one month by using of ultrasonagraphy and after 3 months depended to abdominal distention and then waiting until time of parturition after that recorded number of lambs, the following parameters were records:

1. Estrus response: number of ewes showing estrus/ total ewes treated in each group × 100 [13].
2. Pregnancy rate: number of pregnant ewes⁄ number of mated ewes in each group × 100.
3. Lambing rate: number of ewes lambing⁄number of pregnant ewes in each group ×100[14].
4. Litter size: number of total lambs ⁄ number of lambing ewes.

Statistical analysis: Estrus response and reproductive performance were analyzed using the chi–square test (SPSS 10.0.1 software program) was use for all statistical analysis[15]. Differences were considered significant at level of $p< 0.05$.

Results

The results showed that the all ewe lambs in the group 2 of treatment (T_2) (FGA+300IU PMSG), butonly two ewes lambs and one ewe lamb were not appear estrus from group 1 of treatment (T_1)(FGA+200IU PMSG) and group 3 of treatment (T_3) (FGA+400IU PMSG) respectively (Table 1).

The study showed that the estrus response, pregnancy rate and lambing rate were not significantly differences between the three treatments groups, ($P<0.05$) were presents in. Estrus response in three groups were 83.3%, 100%, 91.6% respectively. (Table 1).

Pregnancy rate in three group were 100%, 83.3%, 90.9% respectively .Lambing rate in three groups were 100% in all groups. The result showed there are no significant differences between the treatments groups in litter size and number of lambs ($P<0.05$).This study appeared single lambing were 100%, 90%.100% respectively while twins lambing were zero, 10%, zero respectively and this study did not appear triple lambing (Table 2).

Discussion

In all groups of these study; only two ewes lambs and one ewe lamb were not appear estrus from group 1(FAP+200IU PMSG) and group 3 (FGA+400IU PMSG) respectively. Contrast with group2 (FGA+300IU PMSG) which is all appear estrus, and this results concurrent with [16], that show no advantage to using a higher dose of PMSG in ewes with a natural relatively high fecundity.The result showed no significant differences between these group in litter size and number of lambs (P<0.05) concurrent with [17] which show the differences in conception rates were not evident between the various treatment groups (0, 250, 500 or 750 IU pregnant mare serum PMSG).This study appeared single number of lamb were100%, 90%.10% respectively while twins were zero, 10%, zero respectively while this study did not appear triple birth comparative with [17] which is show a significantly higher (P < 0.05) litter size followed the use of the 750 IU. PMSG dose.

This study in conclusion indicate that primary P4 and PMSG is a beneficial adjunct to the breeding of sheep by AI at progestagens-synchronized estrus and administration of 300 IU PMSG at sponge withdrawal is more effective for increasing the reproductive performance in ewes in breeding season concurrent with [18].Treatment with PMSG increased the total number of lambs born per ewe lambing from mating at induced estrus compared to that of ewes lambing from a spontaneous estrus[19].Sixty-four percent of ewes that lambed had twins and was greater than the 36% (5/14) of ewes that had births of singles[19]concurrent with our study that show the percent of twins less than single lambing. Boland and Gordon (1973) reported that increased number of multiple ovulation and higher lambing rate following progestagens-PMSG treatment in anestrous ewes [20].Results concurrent with [21] that showed that all ewes (100%) in each treatment group with progesterone sponges and PMSG responded to treatments and exhibited estrus signs reflecting no significant effect of treatments on estrous rate of ewes during the breeding season. Results concurrent with [22] who found that estrous response of Dammar ewes treated with CIDR for 12 days + eCG or 6 days + eCG was 100% for both treatments. Injection of 500 IU of PMSG following the treatment of ewes in the breeding season with vaginal sponges containing 30-40 mg of FGA resulted in 90% and 85% estrus and conception rates, respectively [23].Pregnancy rates in ewe lamb receiving the same dose of PMSG and MGA were higher than in the controls, but there was not significant effect on estrus rate concurrent with [24].

The pregnancy rate in the present study was higher; the percentages of estrus and conception were 100% was consistent with that reported by some other researchers, whereas the conception rate was higher than the reported one[24]. The different reproductive performance may be associated with using animals of different breeds andage, nutritional factors or type of insemination. In the presented study, the percentages of estrus and pregnancy rates are 100% concurrent with [25].

Conclusion

The purpose of this study was to accelerate the arrival of Iraqi lambs using progesterone vaginal sponges and various doses of PMSG because of the economic importance of these animals and part of the livestock in the region and accelerate puberty means increasing the number of births in a shorter period of normal puberty. The results showed that using (FGA + 300IU PMSG) combination is better for accelerating puberty and the appearance of estrous in all treated lambs compared to using other combinations of treatment. During the study, the pregnancy rate was not related to the quality of treatment used and there were no statistically significant differences between the three treatment groups. Results also showed no statistically significant differences

between treatment groups in litter size and number of lambs.

Evaluation of Angiopoietin One and Angiopoietin Two with Missed Abortion

Hussien Saeed Masood[1], Sami Akreem Zbaar[2], Bushra Mustafa Mohamed[3]

[1]Lecturer, Department of Biochemistry, College of Medicine, Tikrit University, [2]Lecturer, College of Medicine, Tikrit University, [3]Lecturer, Ministry of oil, North Oil Company, K1 Hospital, Iraq

Abstract

Missed abortion (MA) is a type of miscarriage, refer to pregnancy in which there is fetal demise without intervention, and also uterine that may expel the product of conception prior to 20 weeks of gestation to assess the role of ANG1 and ANG2 level in early pregnancy and compare these level with healthy pregnancy women, ANG1 play role in new blood vessels maturation and stabilization, the inhibition of endothelial apoptosis and reduction of vascular permeability in stable environment. ANG2 is an antagonist of ANG1 and it known to enhance the plasticity, destabilization and permeability of blood vessels and vascular remodeling site. A prospective cross - study, all women were attended to obstetrics and gynecology outpatient**,**and this study was carried out from Jan 2019 to July 2019. Sixty Women with missed miscarriage fetus heart negative 6-8 weeks were screened to participate in the present study group, Ages were between 18 – 35 years old, and they were from center and the periphery of Kirkuk city to comparative forty apparently health women with early pregnancy fetus heart positive a control groups. A serum level of ANG1 and ANG2 was measured by ELIZA. The result shows that the mean serum level of Angiopoietin one was significantly decrease in missed mischarge compared to control women (2.92±2.4 *vs*. 5.6±3.2 ng/ml) respectively at a $P < 0.05$. And this study showed that there was the significant decrease serum level of angiopoietin two in missed miscarriage patients compared with the control group women (8.12±3.5 *vs*. 16.81 ±12.3). This study showed that there were the positive correlations of Angiopoietin one and two with missed miscarriage. It can be conclude that the level of serum Angiopoietin -1 and level of serum angiopoietin -2 in missed abortion decrease and it is can be used as an early and effective biomarker for diagnosis of missed abortion.

Keywords: *Angiopoietin -1, Angiopoietin -2, missed abortion, Biomarker.*

Introduction

Spontaneous abortion in the ending of pregnancy by removal or expulsion of an embryo or fetus before it can survive the uterus; an abortion without intervention is known miscarriage or spontaneous abortion. Spontaneous abortion can be divided into various subtypes: threatened, inevitable, incomplete, complete, and missed abortion.(1) When deliberate step are taken to end the pregnancy it called an induced abortion or less frequently induced miscarriage. Miscarriage also known spontaneous abortion is the intentional expulsion of an embryo or fetus before the 24 week gestation. Missed abortion is defined is a condition with retained products of conception, with no cardiac activity but the uterus is still silent making no attempt to expel the fetus or unrecognized intrauterine death of the embryo or fetus without expulsion of the product of conception it is constitutes approximately 15% of the clinically diagnosed pregnancies(2). Accurate differentiation between normal pregnancy and pregnancy loss in early gestation remains a clinical challenge; it is estimate that approximately 30-40% of implanted pregnancy result in spontaneous abortion during first trimester (3). Clinical feature in the typical instance .early pregnancy appearance to be normal .with amenorrhea, nausea, vomiting, growth of uteruses and breast change after fetal death there may or may not be vaginal bleeding, abdominal pain, cramping, vaginal spotting .other symptoms denoting missed miscarriage many woman have no symptoms during this period except persistent amenorrhea. No symptoms for missed abortion appear for several weeks and if appear, these vary from spotting

to heavy vaginal bleed and loss of pregnancy symptoms. Signs of missed abortions include loss of fetal heart sounds and closure of cervical[4]. The etiological factors for missed abortion include chromosomal abnormalities, maternal, fetal and embryonic malformations, placental and uterine anomalies, history of recurrent abortions, sexually transmitted diseases, thyroid disease and maternal diabetes.[5] Complications of missed abortions may include pain, Fever, hemorrhage, retained products of conception, septic shock, bladder, bowel and uterine injuries and perforation [6]. Angiopoietin 1 encodes a 484 amino acid with M.W 57 KD, has ability to form higher order multimers though it super clustering. However not all structure can interact with tyrosine kinase receptor, the receptor can be only be activity at the tetramer level or high[7]. ANG1 act as chemo attractant for endothelial cell while also promoting endothelial cell sprouting and facilitating tissue invasion by nascent blood vessels through activation MMPS[8]. It plays critical role in mediating reciprocal interaction between the surrounding matrix and mesenchyme and inhibits endothelial permeability protein also contribute to blood vessel, maturation and stability and may be involved in early development of the heart[9]. Angiopoietin 2 encodes 466 amino acid polypeptides with mocular weight 75 KDa. AGPT2 are secreted glycoproteins that play a complex role in angiogenesis and inflammation, ANGPT2 is widely expressed during development, but it is to restricted postnatal to high angiogenic tissue such as placenta, ovaries and uterus.[10] The aim of this study is to estimate the level of angiopoietin 1 and angiopoietin 2 in patient missed abortion. Furthermore, the current study objectives are:

1. To determine the serum angiopoietin one with patient missed abortion.
2. To determine the serum of angiopoietin two with patient missed abortion.
3. To determine the serum angiopoietin one and two with pregnancy women.
4. Find correlation and level angiopoietin one and two with patient with missed abortion and compared with pregnancy women as control group.

Materials and Method

Study Design: A prospective cross–sectional study, hospital based study the protocol of this study was approved by the scientific committee of Tikrit University College of Medicine, the agreement of attendance to Azadi Teaching Hospital, Kirkuk General Hospital and Kirkuk Department of Obstetrics and Gynecology Center, that approved by Kirkuk Health Directorate, to collect the samples from the patients.

This study was carried out from March 2019 to august 2019. The patients admitted Department of Obstetrics and Gynecology, unit in hospitals Kirkuk City-Iraq. An interview was carried out with these patients using questionnaire form designed by the investigator including their name, age, etc.

Study Population:

Patient and Control: Sixty women with missed abortion were screened to participate in the present study. Men ages were between 18–35 years old, and they were from center and the periphery of Kirkuk city. Sixty–case with missed abortion were considered as study group, while thirty woman normal pregnancies as control group.

Patient sample were inclusion criteria:

1. Woman in the age between 18 -35 years
2. Natural conception
3. History of positive pregnancy test
4. Intrauterine pregnancy
5. First attendance in the pregnancy

Patient sample were Exclusion criteria:

1. Pregnant women who refuse to participate in this study
2. Gestation age less than 6 weeks or more than 8 weeks
3. Multiple gestations
4. Ectopic pregnancy
5. Previous history of infertility
6. History of autoimmune or endocrine diseases (D.M, ALP, POS)
7. Smoker patient
8. Patient with recognizable cause of recurrent missed abortion

Sampling: Five ml of blood sample were taken by vein puncture from each subject enrolled in this study. Blood samples were placed into disposable gel test tubes, after 20 minute blood clotting, centrifuged at 5000 rpm

for 15 minute and the obtained serum were aspirated using mechanical micropipette and transferred into clean test tubes which labeled and stored in deep freeze at –80°C for biochemical measurement of the levels of angiopoietin one and angiopoietin two were measured.

Result

This study includes ninety pregnant women and in there is first trimester they were divided into two groups:

1. First group represent 60 pregnant women with missed miscarriage were considering studies group F.H (-ve).
2. Second group represent 30 pregnant with normal intrauterine pregnancy .were considered as control group F.H (+ve).

There ages were ranged between 18 -35 years, were investigation for determination Angiopoietin one and Angiopoietin two in both group.

Serum level of angiopoietin one in missed miscarriage and the

Control Group: As show in the table (1), the mean serum level of angiopoietin one was significantly decreased in women compared to control women. (2.94 ± 2.4 *vs* 5.6 ± 3.2 ng/ml*)* respectively at a p< 0.05**.**

Table 1: The mean and standard deviation of serum Angiopoietin one in missed miscarriage and control group

Angiopoietin One (ng/mL)	Missed Miscarriage Women	Control Group
No	60	30
Mean	2.94	5.6
SD	2.4	3.2

t.test 4.02 p. value < 0.05 Highly Significant

Serum level of angiopoietin two in missed miscarriage and the

Control Group: As show in the table (2), the mean serum level of angiopoietin two was significantly decreased in women compared to control women (8.12 ± 3.5 *vs* 16.81 ± 12.3 ng/mL) respectively at a p < 0.05**.**

Table 2: The mean and standard deviation of serum Angiopoietin two in missed miscarriages and control group

Angiopoietin two (ng/mL)	Missed Miscarriage Women	Control Group
No	60	30
Mean	8.12	16.81
SD.	3.5	12.3

t.test 3.79 p. value < 0.05 Highly Significant

Correlation between angiopoietin one and angiopoietin two in missed miscarriage women: This study showed strong positive correlation between angiopoietin one and two with missed miscarriage women figure (1).

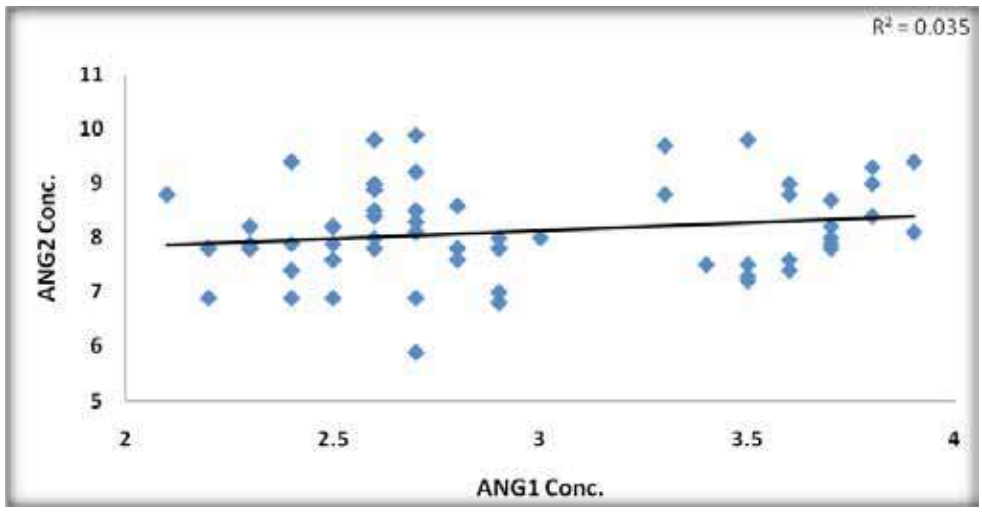

Figure 1: Correlation between angiopoietin one and two with missed miscarriage women

Discussion

Serum level of angiopoietin one in missed miscarriage and the Control group: This study showed that there was a significantly decrease serum level of Angiopoietin one in missed miscarriage compared with that of control group(intrauterine pregnancy)women same gestational age 6–8 weeks.

The result of study was agreement with Daponate *et al*[11] their study showed that optimal levels of serum Angiopoietin -1 were around 963.5 pg./ml (793.9–1277.6) in normal pregnancy women with gestation age 6-8 weeks, and 810 pg/ml (595-767.9) in women with missed miscarriage. The current study showed that these value relatively higher level of angiopoietin one in normal pregnancy compared with women failed pregnancy, angiopoietin one is responsible for vascular growth and maturation of placenta, so deceased levels lead of angiopoietin one leads to increase chance of failure of pregnancy because of the defective vascular formation,when the every step of vessels formation is impaired starting from sprouting of vessels to maturation, then the chance of survival of the fetus decease due to lack of exchange of nutrient and waste product, impaired placental vascular development is related to imbalance in angiogenic factor, as implicated in pathological pregnancy .

Schneuer FJ, Roberts CL, Ashton AW, [12] studies conducted high level Angiopoietin one is mainly expressed in perivascular sertoli cell including pericyte, vascular smooth muscle cells,it binds specifically to the TIE2 receptor on peripheral endothelial membrane through paracrine function, causing phosphorylation of its receptor and subsequent signal transmission.

Serum level of angiopoietin two in missed miscarriage and the Control group: This study showed that there was a significantly decrease serum level of Angiopoietin two in missed miscarriage compared with that of control group(intrauterine pregnancy)women same gestational age 6–8 weeks.

The hypothesis of this study were compromised fetal growth is the result of compromised placental development and potential markers in maternal blood can detected those pregnancies risk, in view of it control role of angiogenesis we hypothesized that ANG2 maternal blood vessels would be increased at the first trimester when both maternal uterine vascular remodeling and placental branching angiogenesis take place, and level would be lower than normal in pregnancy destined for abnormal pregnancy.

This study shows it agreement with GevaE, *el at*[13] for angiopoietin -2 significantly decrease in missed miscarriage patient and recorded high level in normal pregnancy, and this result ANG-2 observed in women at 6-8weeks gestation may indicated that ANG-2 plays an important role in early placental angiogenesis, particularly in maternal vascular remodeling the lower maternal serum level of ANG -2 observed in women whose fetus subsequently developed IUGR may indicate compromised placental angiogenesis early pregnancy well before any clinical evidence of IUGR.

High level angiopoietin -2 in the normal pregnancy that ANG-2 mat also target fetal endothelial cell which also express the TIE-2 receptor thus potentially facial ting branching angiogenesis, and affect placental villous vascular change, interestingly TIE-2 is also express in endovascular trophoblast invading the uterine spiral arteries suggesting that an interaction between ANG-2 and TIE-2 may play significantly role in trophoblast behavior placental development.

Correlation between angiopoietin one and angiopoietin two in missed miscarriage women: This study showed strong positive correlation between angiopoietin one and angiopoietin two with missed miscarriage women. Angiopoietin -1 and angiopoietin -2 are both expressed in the placenta from the very early stage of pregnancy and they mediate number of endothelial and non-endothelial effect that are thought to be pivotal for proper placental development, ANG-2 stimulation an increase in trophoblast synthesis, ANG-1 act as a potent chemotactic factor for trophoblast .ANG-1 expression was restricted to the perivascular stroma of stem villi surrounding large blood vessels, supporting the hypothesis that angiopoietin -1 play role in maturation and maintenance of the placental vessels in contrast ANG-2 was expressed by the perivascular stroma of all placental villi. Furthermore this study show that level of ANG-1 and ANG-2 were significantly reduced in missed miscarriage and suggests that this decreased expression may therefore contribute to be reported poor angiogenesis.

Seval *el at*[14] with agreement with study a few previous in site hybridization studies have described the localization pattern of angiopoietin in the placenta in different stage of pregnancy in very early human

placenta (as early as the 4 the week) ANG-1 protein was localized only in the cyncytiotrophoblast while ANG-2 was localized primarily in the cyncytiotrophoblast and less lesser extent in the cytiotrophoblastic layer of placental villi.

Previous study Dunk *el at*[15] demonstrated that ANG-1 and TIE-2 were detected in the trophoblast bilyar of first trimester placenta, where ANG-2 was restricted to cytotrophoblast in same study ANG-1 and ANG-2 were show to be implicated the regulation of trophoblast behavior through different mechanisms and to promote the growth and migration of trophoblast in vivo, which ANG-1 and ANG-2 and TIE-2 localized to the trophoblast, suggestion that the angiopoietin may play an autocrine role in the trophoblast function.

Conclusion

Serum angiopoietin -1 and angiopoietin -2 levels decrease during pregnancy failure. The measurement angiopoietin -1 and angiopoietin -2 can be used first tool, to support the conformation of diagnosis of missed miscarriage.

Cellular Phone and Laptop Radiation Effects on Subjective Complaints in Informatics Students

Isna Qadrijati[1], Haris Setyawan[1], Seviana Rinawati[1], Tutug Bolet Atmojo[1], Rizka Andhasari Santoso[2], Akbar Fadilah[2], Realita Sari[2]

[1]Occupational Health and Safety Department, [2]Student, Faculty of Medicine, Universitas Sebelas Maret

Abstract

The increasing use of cell phones and laptops in today's modern society has a negative impact on health; one such impact is on informatics students, who struggle with the use of cell phones and computers in their daily activities. This study aimed to determine the relationship between radiation exposure to cell phones and laptops with subjective complaints in the form of sleep quality, headache, dry eye syndrome (DES) and concentration disorders.

The research is analytic observational and cross-sectional approaches. The study used simple random sampling to select 112 respondents, all of which were informatics students of Universitas Sebelas Maret (UNS). The Pearson correlation test results were obtained from cell phone and laptop radiation exposure with sleep quality ($p < 0.05$; $r = 0.192$), headache ($p < 0.05$; $r = 0.510$), dry eye syndrome ($p < 0.05$; $r = 0.1950$) and disturbances concentration ($p < 0.05$; $r = 0.406$).

Keyword: *Radiation exposure, sleep quality, headache, dry eye syndrome, disturbances concentration*

Introduction

Cell phones and laptops are very essential in today's world, and their use is inevitabel. However, for all the benefits associated with their use, they also have downsides. For example, cell phones and laptops are major sources of electromagnetic pollution, which has unpleasant effects on public health. The results in 2015 showed that 54% of the world's total population or 3.996 trillion of the 7.476 trillion people on earth have cell phones, and most users are 18-34 years old[(1)], while in America, cell phone use is mostly among adolescents aged 8 to 18 years[(2)]. In 2015, cell phone use in Indonesia is currently at 56.92% of the total population[(3)]. The use of laptops has also become a lifestyle in the community, especially among students and employees. In 2013, the majority of laptop users in the UK were 14-24-year olds, and they accounted for as much as 70% of the total users[(4)]. Meanwhile, in Indonesia, the number of laptop users reached stood at 42% of the total population, and consisted mostly of students, entrepreneurs and housewives[(5)].

The increasing use of cell phones and laptops has an adverse effect on health. Based on the research in Sweden, young adult cell phone users complained of subjective complaints in the form of stress, depressive symptoms, and decreased sleep quality[(6)]. The study showed that sleep disturbances were experienced by 19.2% of students and concentration disruption was experienced by 14.5% of the students due to exposure to cell phone radiation[(7)] and an effect on the pattern of Electroencephalograph (EEG) and human sleep patterns[(8)]. Cell phone usage disrupts the pattern of sleep at night and also affects the quality of sleep if one's phone is still turned on[(9)]. Decreased sleep quality is associated with cellular phone radiation exposure due to metabolic and cardiovascular disorders which have an effect on the occurrence of insomnia and decreased sleep duration[(10)].

Exposure to cell phone radiation in the form of electromagnetic waves acutely causes headache, eye disorders, fatigue, and sleep disorders. According to the NIOSH, it is reported that 88% of those who use laptops for at least 3 hours will experience fatigue and dry eye syndrome[11]. Dry eye syndrome could be in the form of sensitive eye, feeling discomfort when exposed to bright light, the eyes feeling itchy and sandy, eye aches, blurred vision and reduced vision.

The body can recognize cell phone radiation exposure as a carrier of information that disrupts the body's metabolism and biochemical reactions by interfering with the body's physiological processes and which cause an increase in intracellular free radicals, genetic damage, inter-cell communication disorders, leakage in the blood-brain barrier, and the risk of tumor. However, exposure to radiation from cell phones does not directly causeharm to one's health, but rather triggers biochemical responses in cells so that the manifestations of the disorder usually occur for a long time, as carcinogenic and has the potential to cause interference with various organs of the body[12].

Exposure to electromagnetic radiation from cell phones can cause physical stress where the body responds by secreting hormones from the hypothalamus. Increased hormone secretion in the hypothalamus results in increased levels of glucocorticoid hormones, which increases cortisol levels and causes a decrease in the levels of HMG-CoA reductase. The decrease in the level of HMG-CoA reductase will cause a decrease in the rate of endogenous synthesis of cholesterol. A decrease in endogenous synthesis will cause a decrease in plasma cholesterol levels.

Any physical and psychological stress on the body for just a few minutes can lead to an increase in ACTH secretion. Consequently, there will be an increase in the secretion of glucocorticoids and cortisol. Glucocorticoids play an important role for catecholamines to fully implement the effect of free fatty acid mobilization. Increased secretion of glucocorticoid hormones will also increase the secretion of the hormone epinephrine which can increase the rate of lipolysis in adipose tissues, and norepinephrine, which can increase the use of circulating lipoproteins, so that cholesterol levels in the plasma will decrease. The secretion of cortisol is higher when the body is exposed to stress, both physical and psychological. Cortisol can modulate the immune system because all leukocytes have receptors for cortisol. Increased cortisol levels will cause a decrease in the levels of HMG-CoA reductase. Decreasing levels of HMG-CoA reductase will cause a decrease in the rate of endogenous synthesis of cholesterol. The decrease in endogenous synthesis will cause a decrease in cholesterol levels in the plasma which results in subjective complaints in humans[13].

Material and Method

The research is observational analytic with cross-sectional approaches to analyze the relationship between radiation exposure from cell phones and laptops with subjective complaints by students. The study utilized simple random sampling to select 112 UNS informatics students from a population of 155 students. The respondents were adjusted to the inclusion criteria in the form of UNS informatic students who used cell phones and laptops every day, while the exclusion criteria were: 1) Students who consume sleeping pills, antiarrhythmic agents, corticosteroids, diuretics, and theophylline; and 2). Students who consume coffee or soft drinks 6 hours before going to bed.

The independent variable was the duration of exposure to electromagnetic radiation from cell phones and laptops as revealed by a questionnaire, with the results indicating the average duration cell phone and laptop usage each day, expressed in minutes. The questionnaire used scale measurement in ratios.

The dependent variable was subjective complaints in the form of:1) Sleep quality, measured using the Pittsburgh Sleep Quality Index (PSQI) questionnaire which had 7 main components with a score range 0-21. A score of 0 indicates that sleep quality is getting better, while a score of 21 indicates that sleep quality is very poor. For the sake of statistical analysis, sleep quality was grouped into two, namely good sleep quality (score <5) and poor sleep quality (score> 5)[14]; 2) Headache, which was revealed using a questionnaire containing the description/degree of headache with a score range of 0-10, so that the scale of measurement was a ratio; 3) Dry eye syndrome, which was revealed using the Ocular Surface Disease Index (OSDI) questionnaire. OSDI scores were obtained using the formula: total number of scores x 25. OSDI scores were categorized into four, namely: normal (score 0-12), mild (score 13-20), moderate (score 21-32) and severe (score 33-100)[15] and 4) Headache symptoms which was revealed by a questionnaire about headache symptoms that had undergone validation and reliability. Disturbance concentration, which was revealed using the

Grid Concentration Test. Grid Concentration Test scores were categorized into two, namely: normal (score > 10), severe (score 0-10).[16] Pearson correlation test was used to determine the relationship between cell phone and laptop radiation exposure and subjective complaints, at a significance level of 0.05.

Findings:

Table 1: Distribution of repondents' characteristics

Characteristic	Amount (n)	Percentage (%)
Gender		
Male	50	44.3
Female	62	55.7
Duration of radiation exposure		
High (> 2 hour)	105	93.75
Low (< 2 hour)	7	6.25
Subjective complaint:		
Sleep quality		
Good	42	37.50
Bad	70	62.50
Headache		
Tense muscle headache	78	69.64
Migraine	26	23.22
Cluster	8	7.14
Dry eye syndrome		
Normal	27	24.10
Mild	19	16.96
Moderate	31	27.68
Severe	35	31.26
Concentration disorder		
With	68	60.72
Without	44	39.28

Table 2: Variable correlation test for exposure to cell phone and laptop radiation and subjective complaints

Subjective Complaints Variables	Correlation Coefficient (r)	p Value
Radiation cell phones and laptops exposure with sleep quality	0.192	0.042
Radiation cell phones and laptops exposure with headache	0.510	0.000
Radiation cell phones and laptops exposure with dry eyes syndrome	0.195	0.034
Radiation cell phones and laptops exposure with concentration disturbance	0.406	0.020

Discussion

Based on research data, 93.75% of the research subjects used cell phones and laptops for more than 2 hours per day. This shows that, in terms of cell phone and laptop usage, UNS informatics students are in the high intensity category, in accordance with the research of Saxena; 57% of their respondents use cellphones and laptops for more than two hours each day.[17]

The results of the Pearson statistical test showed a significant relationship between exposure to cell phone and laptop radiation and sleep quality in UNS informatics students ($p = 0.042$; $r = 0.192$). The results of other Pearson statistical tests also show a significant relationship between exposure to radiation from cell phones and laptops and interference with concentration among UNS informatics students ($p = 0.020$; $r = 0.406$). This situation is consistent with the research in which there was a positive correlation between cellphone use and deteriorating sleep quality among medical students[16]. Exposure to radiation from cell phones and laptops can disrupt the diurnal rhythm; reduce the production of melatonin hormone in the pineal gland which can reduce sleep onset, thereby reducing sleep; and encourage the secretion of cortisol hormone which can affect the metabolic cycle, the sleep-wake cycle, and of sleep quality in the REM phase.[18]

Concentration is defined as a person's ability to maintain attention in a long period. Attention involves parts of the brain called alerting, orienting, and attention executives.[19] Orienting as a process of directing attention to sources of stimulation involving visual orienting functions. The anatomical structure associated with orienting is the parietal and frontal lobes which produce neurotransmitters acetylcholin and play a role in the process of orienting. The function of acetylcholin is to help communicate between the nerves and muscles of the eye and the process of storing and recalling memories and attention. Physical environment such as radiation exposure can affect the production of acetylcholin so that it can cause interference with concentration in a person.

The results of the Pearson statistical test showed a significant relationship between radiation exposure to cell phones and laptops and headache among UNS informatics students ($p = 0.000$; $r = 0.510$). The resulting headache is related to the occurrence of electrical hypersensitivity resulting from oxidative damage in brain cells. Brain cells will change the electrical activity of the brain, followed by changes in the blood-brain barrier permeability, resulting in the disruption of the active transport of Na+ and K+ ions, and the release of Ca ++ ions by cellular membranes.[20] When the cell experiences stress, there is a regulatory disorder so that the Ca ++ ion undergoes regulation opposite to that of Ca ++ ions going into the cell and triggering focal ischemics in the brain region, thus causing complaints of headache.[21] The exposure to radiation for one hour caused a stress response to the cell endothelium in the form of a change in phosphorylation status of certain types of proteins namely Heat shock protein 27 (Hsp 27). This will facilitate the elements of albumin, ions, metal, chemicals and viruses to pass through so that microedema and inflammation occur, thus causing complaints of headache.[22]

The results of the Pearson statistical test showed a significant relationship between exposure to radiation from cell phones and laptops and the incidence of dry eye among UNS informatics students ($p = 0.034$; $r = 0.195$). This is consistent which states that dry eye syndrome results from continuous radiation exposure to the eye, resulting in hyperosmolarity in the tear layer, which causes irrigation in the eyeball to be disrupted, thus causing inflammation on the eye surface.[21],[23] The severity of dry eye syndrome can be influenced by different eye distances to the monitor, as well as the brightness level of the monitor and the different light conditions around the location.[24] Exposure to cell phone radiation increases the concentration of free radicals such as reactivity oxygen species (ROS) in cells. The high level of ROS results in oxidative stress and injury to the cell, namely Lipid peroxidation in membranes is characterized by increased levels of malondialdhyde (MDA).(21) Long radiation exposure can cause damage to cell structures, resulting in decreased function and death of cells.[25]

Conclusion

Exposure to electromagnetic radiation from cell phones and laptops causes subjective complaints such as decreased sleep quality, headache, dry eye syndrome and impaired concentration among UNS informatics students.

The Correlation Analysis between Hypertension Controlling Factors and Blood Pressure in the Elderly Living in Griya Werdha Retirement Home, Surabaya

Jaka Surya Hakim[1], Harmayetty[1], Laily Hidayati[1]

[1]Department of Nursing, Faculty of Nursing, Universitas Airlangga, Jalan Dharmahusada Permai No. 330, Mulyorejo, Surabaya, East Java 60115

Abstract

Background: Hypertension is a condition when the blood pressure in blood vessels increases chronically. Living a healthy life has been shown to reduce blood pressure and reduce the risk of cardiovascular diseases. The reduction of body weight and mental stress, low sodium diet, and increased physical activities can also reduce the risk of hypertension.

Objective: To analyze the hypertension controlling factors of the elderly's blood pressure living in Griya Werdha Retirement Home in Surabaya.

Method: In this study, the method used was descriptive analytical design with cross-sectional approach by using purposive sampling technique. This study involved 18 elderly with the following inclusion criteria: elderly who had systolic blood pressure of more than 120mm Hg and diastolic blood pressure of more than 80 mm Hg. The independent variables in this study were the food diet and body mass index, while the dependent variable was the blood pressure. The collected data was analyzed by using Spearman's Rho correlation test with a significance level $\alpha < 0.05$.

Results: The research results found that the majority of elderly people were 60-75 years old, female, had stayed for more than 12 months and had a history of hypertension of 5 years or more. the analysis results of reaearch variables using the Spearman's Rho correlation test indicated that the p-value for the variables of DASH dietary, body mass index, stress and physical activities were all more than 0.05.

Conclusion: DASH diet, body mass index, stress and physical activities did not have correllation with blood pressure, thus, no variables were associated with controlling hypertension on the elderly living in UPTD Griya Werdha Retirement Home in Surabaya.

Keywords: *Hypertension, elderly, diet, lifestyle.*

Introduction

Hypertension is a condition when blood pressure in blood vessels increases chronically[(1)]. One in three adults in the USA suffers from hypertension or is treated for hypertension, and their life expectancy is shortened. According to Joint National Committee on Prevention, Detection, Evaluation, and Treatment on High Blood Pressure 8, or JNC 8, one billion people of the world's population, or 1 in 4 adults, suffers from hypertension. The criteria used in determining hypertension refers to the diagnosis criteria for JNC VII 2003, which is the measurement results of systolic blood pressure ≥140 mmHg or diastolic blood pressure ≥90 mmHg. *The World Health Organization* **(**WHO) recommends the use of a non-pharmacological approach to treat hypertension[(2)]. Living a healthy life has been proven to reduce blood pressure and reduce the risk of cardiovascular diseases. the reduction of body weight and mental stress, low sodium diet, and increased physical activities can also reduce the risk of hypertension[(3)]. Most of the elderly population who experience hypertension are at the age of above 60. in 2025, people with hypertension will

reach 1.6 billion[4]. According to the National Basic Health Survey (2013) the prevalence of hypertension in Indonesia based on age groups are as follows: 45.9% at the age of 55-64 years; 57.6% at the age of 65-74; and 63.8% at the age of above 75. Hypertension can lead to heart disease and stroke, heart failure, peripheral vascular diseases, kidney disorders, retinal bleeding and visual impairment[5]. The basic mechanism that causes hypertension is the loss of distensibility and elasticity of large arteries. This stiffness of the arteries can increase progressively based on age. Blood vessels thickening and widening are the main changes that occur in the aging process. The factors that play a role in the stiffness of great arteries in the aging process include collagen, reduced elastin and classification. This study aimed to analyze the hypertension controlling factors of the elderly's blood pressure living in Griya Werdha Retirement Home in Surabaya.

Method

This study utilized descriptive analytical design with cross-sectional approach while the data was collected through purposive sampling technique. The research collected information and identified the factors related to hypertension control in the elderly living in Griya Werdha Retirement Home in Surabaya, which included dietary factors, body mass index, stress, and physical activities. This study involved 18 elderly people who met the inclusion criteria of having systolic blood pressure >120mmHg and diastolic blood pressure >80 mmHg. On the other hand, the exclusion criteria included elderly who had serious hearing loss, aggressive physical behavior and the elderly who were sick during the study. The independent variables in this study included the food diet and body mass index, while the dependent variable was the blood pressure. The instrument utilized was the DASH from NHLBI diet observation sheet (2015)[6] to find out the diet of food consumed by the elderly. The diet observation was done through measuring the food intake that had been adjusted with the age and physical activities, while the measurement of salt intake was consducted by measuring the total grams included in the elderly's food by the kitchen attendants. The stress data was collected by using the DASS 42 questionnaire (Lovibond & Lovibond, 1995) which had been modified by adding questions related to stress. The physical activity observation sheet was the modified version from Riskesdas (2013) questionnaire and demographic questionnaire to determine body mass index and general description of the condition of the study respondents. The measurement of blood pressure as the dependent variable used standard operating procedures from Perry & Potter (2005) and JNC 8 (2014) [7] which had been modified. The collected data was analyzed by using Spearman's Rho correlation test with a significance level (α) of less than 0.05. From the Spearman's Rho correlation test, the correlation coefficient value was determined. Then, the significance between the two variables was determined by comparing the rho-value with rho's critical value table.

Results

Respondents demographic characteristics: The respondents' demographic data regarding the demographic characteristics of the 18 respondents in this study based on age, sex, length of stay and history of hypertension can be seen in Table 1 as follows.

Table 1: Respondents' Demographic Characteristics

No.	Respondents Characteristics	Category	F(x)	%
1	Age (Years)	45-59	1	5.5
		60-75	11	66.7
		76-90	5	27.3
		>90	1	5.5
2	Sex	Female	11	61
		Male	7	39
3	Length of stay	0-6 months	1	5.5
		7-12 months	4	22.2
		>12 Months	13	72.3
4	History of hypertension	<5 years	4	22.2
		≥5 Years	14	77.8

Based on Table 1, out of 18 respondents, the demographic characteristics of the respondents suggested that the majority of respondents were the elderly in the range of 60-75 years old, and were female. The respondents were dominated by those who stayed more than 12 months and those who had hypertension medical history of more than 5 years.

Table 2. The Corellation between Dependent and Independent Variables

Variables	Blood pressure				Total		p-value
	Not match the hypertension treatment target		Match the hypertension treatment target				
	f(x)	%	f(x)	%	f(x)	%	
DASH Diet							
Insufficient	0	0	0	0	0	0	-
Sufficient	7	39	11	61	18	100	
Good	0	0	0	0	0	0	
Body Mass Index							
Overweight	1	5.5	1	5.5	2	11	0.432
Thin	1	5.5	5	27.7	6	33.2	
Normal	5	27.7	5	27.7	10	55.4	
Stress							
Severe stress	1	5.5	0	0	1	5.5	0.633
Heavy stress	0	0	1	5.5	1	5.5	
Moderatestress	0	0	1	5.5	2	11	
Mild stress	1	5.5	0	0	1	5.5	
Normal	5	27.7	9	50	14	77.7	
Physical Activities							
Insufficient	0	0	0	0	0	0	-
Good	7	39	11	61	18	100	

The analysis results of the correlation between the DASH diet and elderly blood pressure indicated that most of the respondents had sufficient DASH diet with blood pressure in accordance with the target of hypertension treatment. Further statistical test results indicated that p-value was undefined. It can be concluded that H1 was rejected, meaning that there was no corellation between the DASH diet and the elderly blood pressure. From the results of the observations on the corellation between body mass index and elderly blood pressure, the researchers found that almost half of the respondents who had normal body mass index range suffered from blood pressure and did not belong to the hypertension treatment target. Mean while, the respondents who were not in the hypertension treatment target, or within the normal range,reached almost half of the respondents. Further statistical test results indicated that the p value amounted to 0.432. There fore, it can be concluded that H1 was rejected, meaning there was no corellation between body mass index and elderly blood pressure. The analysis results of the corellation between stress and elderly blood pressure suggested that almost half of the respondents who were within the hypertension treatment target had normal stress level. Further statistical test results obtained p value of 0.31. The analysis results of the corellation between physical activities and elderly blood pressure indicated that most of the respondents who belonged to good physical activity criterion suggered from hypertension in accordance with the hypertension treatment target.

Discussion

DASH diet, body mass index, stress and physical activities did not have any corellation with blood pressure. Therefore, there were no dominant factors associated with controlling hypertension and the elderly living in Griya Werdha Retirement Home in Surabaya. Lifestyle modification could be a treatment option for

hypertension for the elderly [8].Inthis study, there was an influence by Griya Werdha Retirement Home policy in applying the lifestyle modification for the elderly. The aforementioned lifestyle modification was not all applicable in GriyaWerdha because the elderly had already stopped consuming alcohol and quit smoking. Therefore, the results of the hypertension control factors that could be studied were the food diet using the recommended DASH diet, weight control by measuring body mass index, stress control, and physical activities.

In the elderly group, there was a decrease in the elasticity of peripheral blood vessels due to the aging process[9]. The mechanism of increasing blood pressure is induced by sodium, a component in salt, which is excreted through the kidneys. When the kidneys cannot excrete sodium as a result of damage to the nephron, sodium retention will occur [10]. Low-salt food intake can be promoted through DASH diet by avoiding the occurrence of adipocyte cell hypertrophy due to lipogenesis processes in white fat tissue. If this situation continues, it will cause narrowing of the arteries causing increase in blood vessels [11]. High intake of fruits and vegetables can increase the concentration of K^+ in the intracellular fluid which can result in fluid transfer to extra cellular fluid and lower the blood pressure [12]. High fruit and vegetable intake, as a part of healthy diet, has beneficial effects on controlling hypertension [13]. the DASH diet aims to reduce blood pressure by increasing a diet rich in fruits, vegetables, whole grains, low-fat dairy products, nuts, low-salt food and low sugar intake[14]. The results of the study regarding the DASH diet could be obtained because the respondents' food consumption was scheduled and had the same diversity for each respondent. Male and female respondents received the same portion.

The corellation between body mass index and blood pressure in elderly hypertension suggested that almost half of the study respondents were in the category of normal body mass index and were included in the hypertension treatment target. The results of the Spearman's Rho statistical test indicated that there was no corellation between body mass index and elderly blood pressure. Overweight and obesity are risk factors for hypertension [15]. Obesity is an abnormal or excessive accumulation of fat in adipose tissue, reaching a level that can cause health problems. Obesity is influenced by a number of factors, including food intake, neuroendocrine, genetic, social and lifestyle factors [16]. The aging process is experienced by everyone. This process is not a disease but the process of growth and development that organisms will pass. In this stage, the body will experience various conditions, including muscle atrophy and decreased food appetite. Elderly people who experience muscle atrophy and decreased food appetite will have a constant weight.

Stress with pressure is body response or reaction to events outside the body and responses from within the body. Stress is also related to hypertension because it can activate sympathetic nerves, so that the blood pressure increases intermittently. Stress increases peripheral vascular resistance and cardial output so it will stimulate sympathetic nerve activity. The responses caused by the body include muscle tension, increased heart rate, and increased blood pressure. These reactions are prepared by the body to react quickly.If not used, it will cause diseases including hypertension. There is a meaningful corellation between stress (based on personality type) and hypertension [17]. Impatience, ambition, competitive perfectionism, and irritability contribute a greater risk of developing hypertension. Psychological stress has a corellation with hypertension. This gap can occur because the response of each person is very individual. Individuals who cannot adapt to stressors can cause physical or psychological disorders. Stressors that can be managed properly can have a positive impact on individuals.

The corellation between physical activities and blood pressure in elderly hypertension indicated that all study respondents were in a good range in carrying out activities with blood pressure according to the target of treatment for hypertension. Spearman's Rho statistical test results suggested that there was no corellation between physical activities and elderly blood pressure. Physical activities affect the occurrence of hypertension where people with lack of activities tend to have a higher heart rate, causing the heart muscles work harder and lead to hypertension. Hypertension causes an increase in blood pressure and causes complications such as stroke, coronary heart disease for the heart blood vessels and heart muscles[15]. Good and routine physical activities will train the heart muscles and peripheral resistance which can prevent an increase in blood pressure. Regular exercises can stimulate the release of endorphins which cause an euphoria effect and muscle relaxation,stopping the blood pressure from increasing[18]. Physical activities result in changes in plasma renin activity level, serum aldosterone concentration, and meaningful converting enzyme angiotensin activities. Therefore, moderate and

heavy physical activities can decrease blood pressure. Physical activities can be carried out for 30 minutes with moderate and heavy intensity[16].

Conclusion

The DASH diet, body mass index, stress and physical activities did not have any corellation with blood pressure. Therefore, no dominant factors were associated with controlling hypertension and the elderly living in Griya Werdha Retirement Home in Surabaya. This research is expected to develop nursing science in controlling hypertension so that the mortality and morbidity rate due to hypertension can decrease.

Abstract

Cervical cancer is one of the most frequently diagnosed malignancies representing the fourth leading cause of cancer-related death in females' worldwide, with approximately 500,000 new cases diagnosed and 280,000 deaths occurring each year. Mxi1, an antagonist of c-Myc, maps to human chromosome 10q24-q25, a region altered in a substantial fraction of prostate tumors, in prostate cancer, where a high frequency of loss and mutation of the *MXI1* gene has been reported. The aim of present study was to find out the possible association of exon deletion of MXI1 gene with incidence of cervical abnormalities and cancers in some Iraqi married women. The present study include collection of 120 scraping cervical cells samples from women clinically diagnosed with cervical abnormalities and cancer, and 30 scraping cervical cells samples from apparently healthy women and all these samples were submitted for cytological and histopathological examination. DNA was extracted from all these samples, and then the singleplex PCR was performed with primers targeted the exon1, 2, 3, 4, 5 and 6 of MXI1 gene. The results of cytological examination showed that 30(25%), 21(17.5%), 15(12.5%), 11(9.16%), 2(1.66%), 1(0.83%), 22(18.33%) and 18(15%) out of 120 scraping cervical cells samples were detected for ASCUS, LSIL, HSIL, SCC, AGUS, cervicitis, and cervicitis with squamous metaplatia, respectively. Also the results of histopathological examination showed that 32(26.66%), 19(15.83%), 17(14.16%), 11(9.16%), 1(0.83%), 22(18.33%) and 18(15%) out of scraping cervical cells samples were detected for CINI, CINII, CINIII, SCC, adenocarcinoma, cervicitis, and cervicitis with squamous metaplatia, respectively. The results of singleplex PCR revealed that the positive singleplex PCR samples were identified by presence of 240, 140, 210, 200, 260, 300 bp amplicons of the exon1, 2, 3, 4, 5 and 6 of MXI1 gene respectively. The PCR results exhibited that 57(47.5%) out of 120 scraping cervical cells samples were showed deletion in the exon5 represented by 22(38.59%), 11(19.29%), 8(14.03%), 7(12.28%) and 9(15.78%) out of 57 positive deletion samples that were detected for ASCUS, CINI, CINII, CINIII and SCC, respectively. In addition, the results showed that 22(73.33%) out of 30 ASCUS, 11(34.37%) out of 32 CINI, 8(42.1%) out of 19 CINII, 7(41.17%) out of 17 CINIII, and 9(81.81%) out of 11 SCC were had exon5 deletion. Whereas 63(52.5%) out of 120 scraping cervical cells samples were didn't show any deletion in the exon5 of MXI1 gene.

Conclusion: The exon deletion of MXI1 gene was clearly associated with the exon5, whereas other exons of MXI1 gene didn't show any deletion, and the results revealed there was remarkable association between the exon5 deletion and the incidence of precancerous stages include ASCUS, CINI, CINII, CINIII and cancerous stage represented by SCC.

Keywords: *Cervical abnormalities, cervical cancer, married women, MXI1 gene.*

Introduction

Cervical cancer is the third most common cancer worldwide and a major fatal malignancy among women, causing about 275,000 deaths annually worldwide, mostly in developing countries. It can be a preventable disease if identified at its early (precancerous) stages and

treated by ablation[1,2]. Max interactor 1 gene (MXI1) is a transcription factor that belongs to the mad family of Myc antagonists, which encode proteins that are highly homologous to c-Myc. Mxi1 opposes the growth-promoting activity of c-Myc by repressing transcription of c-Myc activated target genes. Mxi1 inhibits the ability of c-Myc to transform cells in vitro, and its expression is associated with cellular differentiation[3]. The MXI1 gene has been localized to chromosome 10q24-25 [4], a region demonstrating deletions or rearrangements in 60-97% of human glioblastomas and up to 30% of human prostate cancers. Although loss of heterozygosity for MXI1 is seen in a substantial fraction of glioblastoma tumors (64%), no MXI1 coding sequence mutations have been seen in these tumors[5]. Furthermore, a majority of studies have failed to demonstrate MXI1 mutations in prostate tumors[6]. By counteracting c-Myc, MXI1 functions as a growth suppressor, resulting in reduced cell proliferation in vitro[4,5,7], previously localized the human MXI1 gene to chromosome 10q24-q25. Deletions resulting in loss of alleles in this region of chromosome 10 are observed in 30±50% of human prostate tumors[8].

Materials and Method

Samples Collection: During the period of study, from beginning of March 2017 to the end of September 2017. 120 scraping cervical cells samples were collected from Iraqi women clinically diagnosed with cervical abnormalities and cancer, and 30 scraping cervical cells samples from apparently healthy women who attended to Baghdad Medical City and Al-Elwiya Maternity Teaching Hospitals in Baghdad City, Patients' ages ranged from 20 to 70 years of age. This study was carried out after obtaining the approval from the Institute of Genetic Engineering and Biotechnology for Post Graduate Studies/ Baghdad University and Ministry of Health/ Iraq.

Extraction of DNA: The DNA was extracted from scraping cervical cell samples using DNA-Sorb-A nucleic acid extraction kit (Sacace Biotechnologies/ Italy), according to the manufacturer's instructions.

Agarose gel electrophoresis: After extraction of DNA carrying out, agarose gel electrophoresis was adopted to confirm the presence and integrity extracted genomic DNA [9].

Detection of MXI1 gene by using PCR: The PCR was adopted to detect the exons 1, 2, 3, 4, 5 and 6 of MXI1 gene in the extracted DNA of scraping cervical cells from clinically diagnosed women with cervical cancer. To select PCR primers that can give specific amplification for exons 1, 2, 3, 4, 5 and 6 of MXI1 gene. The (MXE1-F/MXE1-R) for exon 1, (MXE2-F/ MXE2-R) for exon 2, (MXE4-F/MXE4-R) for exon 4, (MXE5-F/MXE5-R) for exon 5, (MXE6-F/MXE6-R) for exon 6, were used according to[10], the (MXE3-F/ MXE3-R) for exon 3 was used according to[11]. The general properties of these primers were checked by using Oligocalc Oligonucleotide Porperties Calculator program, the name and sequence of these primers are listed below in table (1).

Table 1: The name, sequence and product size of PCR primers for exons of MXI1 gene

Name of primer	Sequece of Primer 5'-3'	Size of Product (bp)
MXE1-F	ATGGAGCGGGTGAAGATGAT	240
MXE1-R	GCACTGCCGAAAAAGATTAG	
MXE2-F	GGGTCAATGGATTTGGGTAC	140
MXE2-R	TAAGCGTTCCCAGCTTGCTA	
MXE3-F	GCAACAAAGCATGGCTAATG	210
MXE3-R	TTCACAATGGGCTATACATCTGA	
MXE4-F	TAACCAGACTGTGCTGATTTG	200
MXE4-R	ACCAGAACTGAGGGAATTGTG	
MXE5-F	TGTTTGTACTGGACTATACAC	260
MXE5-R	ATGTTTAGTATTTCATTAGAGAAG	
MXE6-F	GTTAGTTTTTGAAGGTGCGC	300
MXE6-R	TGTTATGTCATGCTGGGTTC	

The PCR reactions for detection of exons of MXI1 gene were performed in 25 µl volumes containing, amplification of exons of MXI1 gene was carried out with initial denaturation at 94°C for 1 minutes, followed by 35 cycles of denaturation at 94°C for 30 seconds, annealing at 66, 65, 55, 66, 65 and 56°C for F and R primers of exons 1, 2, 3, 4, 5 and 6 respectively for 1 minute, and extension at 72°C for 1 minutes. The thermal cycles were terminated by a final extension for 5 minutes at 72°C[11]. The PCR products were resolved by electrophoresis. Chi-square test was used to significant compare between percentage (0.05 and 0.01 probability) in this study[12].

Results

Agarose gel electrophoresis was adopted to confirm the presence and integrity of the extracted DNA**.** The results of PCR showed that samples of present study gave positive result for PCR of exon 1, 2, 3, 4, and 6 of MXI1 gene products with 240, 140, 210, 200 and 300 bp molecular weight, whereas no amplification was observed with exon5 (260bp) in 57 out of 120 samples and negative control (Figures 1).

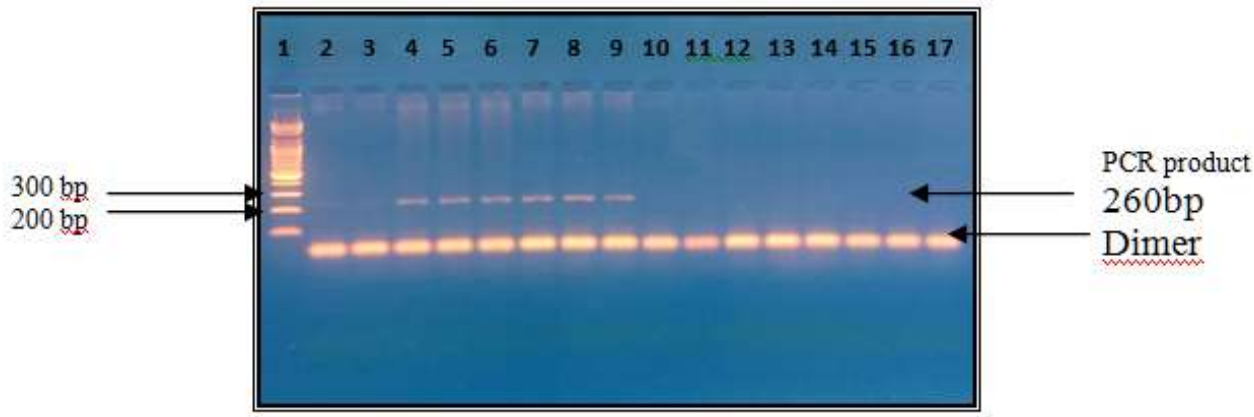

Figure (1): Gel electrophoresis of singlplex PCR products of exon 5 of MXI1 gene on 1.5% agarose gel at 10volt/cm for 1 hour. Lane 1: 100 bp DNA ladder, lane 2-17: PCR products of exon 5.

The patient group was divided to eight groups according to cytology examination; i) Atypical squamous cells of undetermined significance (ASCUS) 30 samples, ii) low grade squamous intraepthelial lesion LSIL 21 samples, iii) high grade squamous intraepthelial lesion HSIL 15 samples, iv) squamous cervical cancer 11 samples, v) atypical glandular cells of undetermined significance 2 samples, vi) adenocarcinoma 1 sample, vii) cervicitis 22 samples, and viii) cervicitis with squamous metaplatia 18 samples. The samples were also including 30 specimens (scraping cervical cells) of healthy women used as a control (Table 2).

Table (2): Distribution of samples study according to cytological examination.

Cytological examination	No. of cases	Percentage of cases (%)
ASCUS	30	25.00
LSIL	21	17.50
HSIL	15	12.50
Squamous cervical cancer	11	9.16
AGUS	2	1.66
Adenocarcinoma	1	0.83
Cervicitis	22	18.33
Cervicitis with squamous metaplasia	18	15.00
Total	**120**	**100%**
Chi-square value	---	9.074 **
P-value	---	0.0005

** (P<0.01).

ASCUS: Atypical squamous cells of undetermined significance, **LSIL:** Low-grade squamous intraepithelial lesion, **HSIL:** High-grade squamous intraepithelial lesion. **AGUS:** atypical glandular cells of undetermined significance.

Also the results of histopathological examination showed that 32(26.66%), 19(15.83%), 17(14.16%), 11(9.16%), 1(0.83%), 22(18.33%) and 18(15%) out of scraping cervical cells samples were detected for CINI, CINII, CINIII, SCC, adenocarcinoma, cervicitis, and cervicitis with squamous metaplatia, respectively (Table 3).

Table (3): The distribution of sample study according to the histopathological examination.

Histological examination	No. of case	Percentage of case (%)
CIN I	32	26.66
CIN II	19	15.83
CIN III	17	14.16
Squamous cervical cancer	11	9.16
Adenocarcinoma	1	0.83
Cervicitis	22	18.33
Cervicitis with squamous metaplasia	18	15.00
Total	120	100%
Chi-square value	---	9.261 **
P-value	---	0.0003

** (P<0.01), **CIN:** Cervical intraepithelial neoplasia.

A total of 120 cases of cervical abnormalities were studied, the MXI1 deletion were identified in 57/120 (47.5%) and 63/120 (52.5%) not deleted table (4).

Table (4): Distribution of the study sample according to deletion of exon5 of MXI1.

PCR	Number	Percentage (%)
Positive	57	47.5
Negative	63	52.5
Total	120	100%
Chi-square value	---	2.071 NS
P-value	---	0.0966

NS: Non-Significant.

The PCR results exhibited that 57(47.5%) out of 120 scraping cervical cells samples were showed deletion in the exon5 represented by 22(38.59%), 11(19.29%), 8(14.03%), 7(12.28%) and 9(15.78%) out of 57 positive deletion samples that were detected for ASCUS, CINI, CINII, CINIII and SCC, respectively (Table 5).

Table (5): Correlation samples of study and deletion of exon5 of MXI1 according histopathological examinatin.

Cytology	Number	Percentage (%)
ASC-US	22	38.59
CINI	11	19.29
CINII	8	14.03
CINIII	7	12.28
Squamous cervical cancer	9	15.78
Total	57	100%
Chi-square value	---	6.944 **
P-value	---	0.0078

** (P<0.01).

In addition, the results showed that 22(73.33%) out of 30 ASCUS, 11(34.37%) out of 32 CINI, 8(42.1%) out of 19 CINII, 7(41.17%) out of 17 CINIII, and 9(81.81%) out of 11 SCC were had exon5 deletion.

Discussion

Extension of our study to include *MXI1,* located at 10q24-45, identified mutations in 2 cell lines but no detectable change in exon sequences of this gene in bladder tumors. This finding is consistent with *MXI1* mapping outside of the critical region of loss on 10q in bladder tumors (13), where mutations in *MXI1* do not play a role in urothelial neoplastic progression. These results contrast with observations in prostate cancer, where a high frequency of loss and mutation of the *MXI1* gene has been reported (6).

Wang and colleges have found no evidence for loss or mutation of *MXI1* in bladder tumors, in contrast to findings in prostate carcinomas (11). We have found deletion in MXI1 gene in precancerous stages of cervical cancer in Iraqi married women.

Conclusion

Presence of exon deletion in exon5 of MXI1 gene whereas other 5 exons didn't show any deletion in scraping cervical cell samples that collected from some Iraqi women clinically diagnosed with cervical abnormalities and cancers.

The exon5 deletion was found with high variable percentage in precancerous stages included ASCUS, CINI, CINII, CINIII and cancer stage represented by SCC. whereas the exon5 deletion didn't present in cervicitis and Cervicitis with squamous metaplasia as well as the result revealed high (81.81%) incidence of exon 5 deletion in SCC comparing with other precancerous stage include ASCUS, CINI, CINII, CINIII.

According several points that mention above can be conclude that there is a strong association between the exon5 deletion and the incidence in cervical abnormalities and squamous cervical cancer in marred women which can refer to possible use the exon5 deletion of MXI1 gene as early molecular marker for cervical abnormalities and squamous cervical cancer detection in marred women.

Curcumin and 6-Shogaol Increase Hemoglobin F Levels by Inhibiting Expression of STAT3 mRNA Gene in K562 Line Cell

Joko Setyono[1], Ahmad Hamim Sadewa[2], Edy Meiyanto[3], Mustofa.Mustofa[4]

[1]Department of Biochemistry, Faculty of Medicine, University of Jenderal Soedirman, Purwokerto, [2]Department of Biochemistry, Faculty of Medicine, Public Health and Nursing, University of Gadjah Mada, Jogjakarta, [3]Cancer Chemoprevention Research Center, Faculty of Pharmacy, University of Gadjah Mada, Jogjakarta, [4]Department of Pharmacology, Faculty of Medicine, Public Health and Nursing, University of Gadjah Mada, Jogjakarta, Indonesia

Abstract

One of the approaches for beta-thalassemia therapy is the induction of the Haemoglobin F (Hb F). Curcumin and 6-Shogaol are empirically known to induce HbF, but the signalling cascade has not been widely explained. This study aims to uncover the potential of Curcumin and 6-shogaol in inhibiting the expression of STAT3 mRNA gene.This study uses the K562 erythroleukemic line cell model with an experimental design post-test only with a control group. There are 5 groups, each group has 3 replications, named the control group without treatment, the positive control group with Hydroxyurea treatment (75 μM), the combination treatment group of Curcumin (2 μM) and 6-Shogaol (10 μM), the single curcumin (2 μM) treatment group and a single 6-Shogaol (10 μM) treatment group. Test samples were taken in 72-h and 96-h time series, then RNA extraction from the cell line was continued by cDNA synthesis. The expression of STAT3 mRNA gene was measured using the qRT-PCR technique; then, the Hb F level was measured by the ELISA method. Statistical analysis using ANOVA test with significance level $p < 0.05$. In the 72-h time series, there was a significant decrease in STAT3 Gena mRNA expression ($p < 0.05$). The lowest single curcumin group ($p < 0.01$) followed by a single 6-Shogaol group ($p < 0.05$) compared to the untreated control group, while the positive control group with hydroxyurea treatment and the Curcumin and 6-shogaol combination treatment groups are not significant. Hb F levels, there was an increase in 96-h time series ($p < 0.05$) respectively from highest to lowest in the curcumin group ($p < 0.05$), 6-shogaol ($p > 0.05$) compared to the control group, but in the positive control group ($p > 0.05$) and the combination group ($p > 0.05$) it is lower than the control group without any treatment. Curcumin and 6-shogaol increase Hb F levels through inhibition expression of STAT3 mRNA Gene on K562 cells. The results of this study could be the basis for further research in vivo to reveal the signalling pathway in Hb Finduction therapy.

Introduction

β-Thalassemia is a group of heterogeneous recessive autosomal hereditary genetic diseases associated with point mutation or small deletion resulting in the absence or reduction of β-globin chain protein synthesis, resulting in haemoglobin deficiency. There are alternative therapies that can be developed to overcome the severity of this disease by inducing Fetal Haemoglobin (Hb F). The globin-ϒ chain, which is similar to the globin-β chain, is produced during pregnancy when it joins with globin-α chain, is to form Fetal Hemoglobin ($\alpha_2\Upsilon_2$). Hence, one of the potential current therapeutic approaches to haematological disorders, including β-thalassemia, is the stimulation of induction of fetal haemoglobin production [1-4].

One of the transcription factors that play a role in the production of Hemoglobin F is the phosphorylated STAT3 protein. This protein, which is the dominant-negative regulator, which acts in the 5'-untranslated globin-ϒ promoter region bound to AϒSTAT3, thus inhibiting the expression of globin-ϒ-dependent concentrations [5]. Therefore, it is necessary to have a potential inhibitor to STAT3 in the framework of globin-ϒ induction. Curcumin is a STAT3 inhibitor in the SH2 domain. Inhibition of the SH2 domain, not only disrupts activation but also dimerization of transcription factors [6]. Other active compounds of herbal ingredients that have molecular targets related to the regulation of Hemoglobin F are Shogaol. 6-shogaol is the most potent inhibitor of STAT3 activation when compared to analogues such as 6-gingerol, 8-gingerol and 10-gingerol[7]. The purpose of this study was to uncover the potential of Curcumin and 6-shogaol on the expression of STAT3 mRNA as one of the induction signals for Hemoglobin F.

Material and Method

Provision of Curcumin and 6-shogaol and Hydroxyurea: Curcumin (BioBasic, Canada) with > 95% of purity, 6-shogaol (Fortopchem, China) with >98% purity and Hydroxyurea (HU) (Sigma-Aldrich, USA) with approx >98% of purity. Curcumin, HU and 6-shogaol are dissolved in 100% dimethyl sulfoxide (DMSO) to reaches the final concentration of curcumin 271,000 µM, 6-Shogaol 361,000 µM, and HU 1,315,000 µM as a stock solution, then stored at -20ºC.

K562 cell culture: Erythroleukemia K562 cells obtained from CANCER CHEMOPREVENTION RESEARCH CENTER (CCRC) Faculty of Pharmacy in the University of Gadjah Mada was cultured with RPMI 1640 supplementary media (without phenol red) with 10% Fetal Bovine Serum (FBS) and 50 U/ml - 50 µg/ml penicillin-streptomycin (pen-strep). Culture was maintained under atmospheric humidity with 95% air/5% CO_2 at 37ºC with cell densities between 2 x 104 to 1 x 105 cells/ml.

Cytotoxic test with MTT method assay 24 hours, 48 hours and 72 hours: Cytotoxic tests were performed to obtain IC_{50} values following the protocol of CCRC Faculty of Pharmacy in the University of Gadjah Mada. The results of the IC_{50} values of each sample were taken from 24 hours, 48 hours and 72 hours incubation. The IC_{50} values obtained were 60 µM curcumin, 6 µm 40 µM shogaol and 300 µM HU, respectively.

Combination Test: K562 cells were distributed into 96 wells as much as 100 µL and incubated for 24 hours. Enter the Curcumin and 6-shogaol concentration series into the wells of 50 µL with five series of concentrations each consisting of ½ IC_{50}, ¼ IC_{50}, 1/8 IC_{50}, 1/16 IC_{50} and 1/32 IC_{50}. Incubation for 24 hours. Cells were counted by using a haemocytometer so that the number of living and dead cells in each well was obtained. The highest number of living cells is an indicator of the best combination dose, named Curcumin 2 µM, 6-shogaol 10 µM, and for HU it is determined by treatment of 75 µM (¼ IC_{50}).

ELISA test to measure Hb F levels: K562 cells that have been given the appropriate treatment in their groups are then carried out protein extraction by the procedure of the M-PER Kit (Thermo Scientific, USA). The lysate obtained was used for examination of Hb F levels measured by the Human HBF Cat ELISA kit. No: EH3213 (Fine Test, China) according to the manufacturer's instructions.

Analysis of STAT3 Gena mRNA expression: Total K562 RNA cells were extracted at different times depending on the treatment, using # RB100 (Geneaid, Taiwan), 1 µg of total RNA from each sample was carried out reverse transcripts to cDNA using the cDNA Synthesis Kit (Toyobo, Japan). Real-time PCR is done by machine (ABs) using the SensiFAST SYBR Lo-ROX Kit (Bioline, Germany). The relative mRNA levels of the target gene are normalized to the mean of the internal control gene, β-Actin.

Primary mRNA with STAT3, forward: 5'-ATC ACG CCT TCT ACA GAC TGC-3 ', reverse: 5'-CAT CCT GGA TCT CTA CCA CT-3 '. β-ACTIN forward: 5 '-ACG GCC AGG TCA TCA CCA TTG-3', reverse: 5 '-GGC GTA CAG GTC TTT GCG GAT-3 TT'. The STAT3 gene expression between treated and untreated samples was calculated as $2^{-\Delta\Delta Ct}$ relatively to the reference gene, β-actin.

Statistic analysis: Data is displayed in mean ± SD and statistical analysis using one way ANOVA test followed by post hoc LSD. The test results are considered significant if $p < 0.05$ and 95% confidence intervals.

Findings: In this study, the impact of Curcumin, 6-shogaol and their combination on the interpretation of STAT3 mRNA expression were measured by the qRT-PCR method, and the results can be seen in Figure 1.

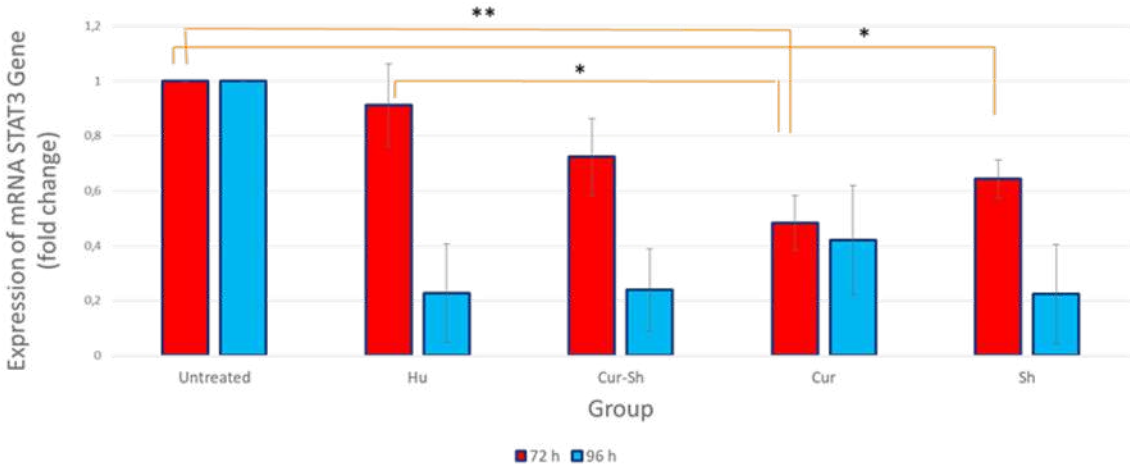

Figure 1: Differences in fold changes of STAT3 mRNA between groups after incubation of Curcumin (Cur), 6-Shogaol (Sh) and Hydroxyurea (Hu) on serial K562 cells for 72 and 96 h. Curcumin showed the strongest expression followed by 6-Shogaol compared with the control group without treatment (* p <0.05, ** p <0.01).

The results showed a decrease in STAT3 mRNA expression in all treatment groups in both the 72-h and 96-h time series compared to the untreated group. In the 72-h time series, the results are significantly different $p < 0.05$. Then followed by post hoc LSD test, in the Curcumin treatment group, the lowest expression of STAT3 mRNA gene was 0.48 ± 0.1 ($p = 0.008$) which was significant compared to the control group without treatment. Next, in the 6-Shogaol treatment group, the expression of STAT3 mRNA gene (0.64 ± 0.07, $p = 0.045$) was significant compared to the control group without treatment. In the combination group of Curcumin with 6-shogaol, the expression of STAT3 mRNA gene (0.72 ± 0.14) was lower than the positive control group but higher than the curcumin and 6-shogaol group. In the 96-h time series, the results did not have significantly different ($p = 0.098$) between the treatment group and the control group without treatment. So, in the 96-h time series, there was a decrease in STAT3 mRNA expression, which was not significantly different.

The effect of Curcumin and 6- shogaol on haemoglobin F levels measured by the ELISA method can be seen from Figure 2. The results show that in a 96-h time series, Hb F levels were the highest in the curcumin group (1.6 ± 0.15; $p = 0.015$), then followed by the 6-shogaol group (1.11 ± 0.29). In the positive control group hydroxyurea and the combination of Curcumin + 6-shogaol, Hb F levels were consecutively (0.85 ± 0.16), (0.41 ± 0.01) lower than those in the untreated control group. The combination group of Curcumin with 6-shogaol was the group with the lowest Hb F level compared with the treatment group and the control group without treatment ($p < 0.05$). In the 72-h time series, the Hb F level of all treatment groups was lower than the control group without treatment. Based on the one way ANOVA test, the 72-h treatment did not differ significantly ($p > 0.05$), but in the 96-h treatment, there was a significant difference ($p < 0.05$). So, in the 96-h time series, the highest Hb F level occurred in the curcumin group, and the lowest Hb F level occurred in the combination group of Curcumin with 6-shogaol.

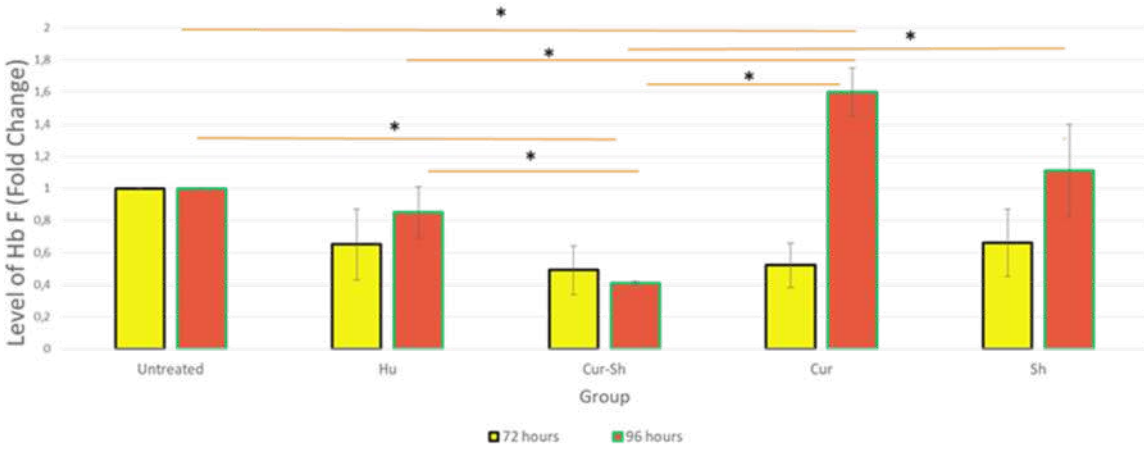

Figure 2: Differences in fold changes of HbF levels between groups after incubation of Curcumin (Cur), 6-Shogaol (Sh) and Hydroxyurea (Hu) on 72 and 96 h serial K562 cells. In the 96-h time series, Curcumin showed the highest effect on changes in HbF levels followed by 6-Shogaol compared to the control group without treatment (* p <0.0).

Reduced hexahydro-bisdemethoxycurcumin (HHBDMC) reduced curcuminoids were most effective in inducing gamma-globin mRNA (3.6 ± 0.4 fold) and Hb F (2.0 ± 0.4 fold) in erythroid primary precursor cells for seven days[8]. Curcumin works to reduce the expression of STAT3 genes so, the decrease in STAT3 gene expression will increase the production of Hb F. The role of 6-shogaol in Hb F induction through the activation of the p-p38 MAPK signal[9] whereas p38 MAPK is reduced by two weeks of curcumin activation[10].

Discussion and Conclusion

In beta-thalassemia patients there is an imbalance in the number of globin-α/globin-β chains, due to the lack or absence of globin-β synthesis, resulting in precipitation of free globin-α chains in erythroid precursors which results in the maturation and damage of erythrocyte cells, causing prolonged anaemia [11]. Therefore the best choice for the treatment of thalassemia patients is reactivation/ induction of globin-ϒ, so that replaces globin-β to join globin-α to form fetal haemoglobin and ultimately there is no excess free globin-α chains [12]. Individuals with elevated Hb F levels (> 8.6%) show a reduction in symptoms and increase patient life expectancy; hence, the induction of Hb F has the potential as a therapy in beta-thalassemia patients. Of the current therapeutic options, Hb F induction through pharmacological agents is the most feasible therapeutic choice[8].

Other transcription factors that play a role in the production of haemoglobin F are the phosphorylated STAT3 protein. Therefore, it is necessary to have a potential inhibitor to STAT3 in the framework of gamma-globin induction. Pharmacological inhibitors targeting STAT3 can be done in 5 ways, namely inhibition of STAT3 DNA-binding domain, abrogation of the STAT3 N-terminal domain, suppression of the STAT3 SH2 domain, inhibition of the STAT3-importin interaction, and/or blockage of upstream kinase activit [13].

The active compounds of the following herb, Curcumin, have broad molecular targets related to various molecular and biochemical cascades interacting directly on the target protein and epigenetic modulation of the target genes. Curcumin, as an epigenetic agent, functionally in modulating multiple biological processes, occurs at low concentrations. Curcumin plays a role in the expression of genes through direct interaction with transcription factors such as nuclear factor kappa-light-chain-enhancer of activated B cells (NF-kB), epigenetic modulation through inhibition of DNA methyltransferase I (DNMT1), histone acetyltransferase (HAT), histone deacetylase complex (HDAC) [14]. Various molecular targets of Curcumin include inflammation, kinase activity (MAPK, PKA, JAK), transcription factors (CREB, STAT3, PPARϒ), enzyme activity (COX- 2, INOS, MMP), and others (VEGF, adiponectin, ROS) [15-16]. The 6-Shogaol are other active compounds of herbal ingredients that have molecular targets related to the

regulation of Hemoglobin F. The 6-shogaol suppresses the expression of the products governed by STAT3. It was also reported that 6-shogaol caused the activation of JNK, p38 and ERK, as well as downregulating the expression of p38 MAPK, NF-κB and COX-2 [17]. Therefore, 6-shogaol can play a role in the induction of Hemoglobin F.

Hydroxyurea (100 μM) has a link between the regulator of globin-ϒ expression (MYB, BCL11A and KLF-1) with specific miRNA, and reveals the mechanism of Hb F production through inhibition of HU-induced miRNA [18]. Treatment with HU combined with HDAC2 knockdown increases gamma-globin expression. It was also reported that CD34 + cells treated with HU and MS-275 (HDAC inhibitors 1,2 and 3) had a relative induction of gamma-globin expression [19].

Curcumin is a decreasing expression of STAT3 mRNA gene and increases Hb F levels compared to 6-shogaol on K562 cells. While the combination of the two substances was not significant either in inhibiting STAT3 expression or HbF levels. The results of this study could be the basis for further research in vivo to reveal the signalling pathway in Hb F induction therapy ($\alpha_2\Upsilon_2$).

Vernadsky Crimean Federal University, Simferopol, Russia

Abstract

The efficacy of using probiotic preparations of the yogurt type was studied in 136 patients with lymphogranulomatosis, suffering from intestinal dysbiosis while taking antibiotic therapy and polychemotherapy (BEACOPP-II protocol). It was found that probiotics of this type are highly effective for the treatment of dysbiotic disorders of the intestines in cancer and hematological patients. Their use significantly reduces the risk of complications such as an unpleasant aftertaste in the mouth, belching, heartburn, diarrhea, constipation, flatulence, discomfort or periodic abdominal pain. It is recommended that prolonged therapy with a probiotic of the yogurt type be used in these groups of patients.

Keywords: *Probiotic, dysbiosis, eubiosis, dyspepsia, lymphogranulomatosis, polychemotherapy.*

Introduction

Every year, the problem of dysbiotic conditions of the gastrointestinal tract is increasing among the world's population in general and among Russian citizens in particular [1]. Along with other reasons, the use of antibacterial drugs is one of the main causes of intestinal dysbiosis. Currently, observed dysbiosis is mainly of natural microbial origin. This is due to a violation of homeostasis of the natural microflora of the gastrointestinal system, leading to the occurrence of intestinal dysbiosis (dysbiosis). The prevalence of this clinical condition among all age groups in the human population exceeds more than 90% and is constantly increasing[2]. This negatively affects the clinical course, diagnosis and treatment of various nosologies, leading to the aggravation of various diseases and their pathomorphism [3,4].

Nowadays, lymphogranulomatosis has become one of the few highly liable diseases in the hematological practice. According to the German Hodgkin Study Group, achieving complete remission in patients with advanced stages is possible in 70-90% of cases, using effective polychemotherapy regimens in combination with or without radiation therapy [5]. Thus, polychemotherapy regimes in lymphogranulomatosis is very important and such regime usually given with antibacterial therapy leads to dysbiosis. Traditionally, the correction of dysbiotic conditions is achieved by introducing microbial associations of a healthy person in the form of probiotics into the patient's digestive system [6]. But most modern drugs all over the world are created on the basis of a limited number of bacterial strains, which are often poorly effective [7,8]. Probiotics such as yogurt are especially recommended when conducting antibacterial

therapy, taking cytostatics, as well as for correcting the microflora of the digestive system in people with lactase deficiency. Due to the simplicity of their administration and relatively high bioavailability. Probiotics of the yogurt type are widely used in the complex therapy of various pathological conditions, including diseases of the gastrointestinal tract, oncological diseases with long courses of chemotherapy, which are characterized by inhibition of normal microflora with the development of dysbiosis syndrome [9, 10, 11].

Purpose of the study: To analyse the effectiveness of probiotic therapy in patients with dysbiosis initiated by polychemotherapy and antibiotic therapy in conditions of cancer alertness. Also to determine the effectiveness of yogurt-type probiotic preparations in patients with the above conditions.

Materials and Method

The study was conducted according to the results of treatment of 136 patients with lymphogranulomatosis, suffering from intestinal dysbiosis with the background of chemotherapy (BEACOPP-II protocol) and concomitant antibacterial therapy. The study involved patients with excluded organic pathology of the digestive system such as scars, erosion, hernia of the esophagus, gastritis, peptic ulcer of the stomach and duodenum, ulcerative colitis, Crohn's disease, primary tumors of the gastrointestinal tract; diseases leading to excretory insufficiency of the liver and pancreas. Patients underwent a course of polychemotherapy in the Department of Hematology and Chemotherapy of the State Budgetary Healthcare Institution of the Republic of Crimea "Crimean Republican Oncological Clinical Dispensary named after V.M. Efetov" in Simferopol, from April 2015 to March 2017.

The preparation used in the study contained: a lyophilized microbial composition of live strains of lactobacilli (Lactobacillus rhamnosus and Lactobacillus murinus), which differ from other lactobacilli by more pronounced (40–45%) viability in the presence of antibiotics and have higher activity (35–40%) suppression of pathogenic and conditionally pathogenic microflora.

Statistical processing of the results was carried out using the Microsoft Office Excel 2013 program, with the calculation of the t-criterion by the Student method for relative values, the data were considered reliable at t = 2, the reliability was Pt = 95.5%, and the risk of error was $p < 0.05$.

In our study involving all human participants were in accordance with ethical standards of the responsible committee on human experimentation and with the Helsinki Declaration of 1964 and later amendments.

Research Results

136 patients with lymphogranulomatosis (Hodgkin's lymphoma) were examined, who received a course of polychemotherapy and suffered from intestinal dysbiosis that developed while taking antibacterial therapy.

An initial examination of patients revealed that in 47 (34.56%) patients, dysbiosis of the II degree was observed, and in 89 (65.44%) patients there was dysbiosis of the first degree. In 31 (22.79%) patients, dyspepsia/unstable stool type was observed and dyspepsia/constipation was observed in 18 (13.24%) of the examined patients. Flatulence was observed in 32 (23.53%) patients before probiotic therapy. 55 (40.44%) patients complained of discomfort and abdominal pain. Only the most pronounced subjectively and clinically significant syndrome complexes were taken into account.

The results of a retrospective analysis and dynamic examination of 136 patients before and after treatment of intestinal dysbiosis with and without antibiotic, radiation and polychemotherapy was observed (Table 1).

After 2 months of treatment with a probiotic type of yogurt in the study group, it was recorded that; II degree dysbiosis was not detected in the observed patients, but I degree dysbiosis was detected in 42 (30.88%) patients. Unstable stool, diarrhea after 2 months of treatment was determined in 3 (2.21%) patients. Constipation after treatment was observed in 2 (1.47%) patients. Flatulence was detected in 6 (4.41%) patients. Discomfort, abdominal pain were observed in 8 (5.9%) examined patients after the course of the treatment. In 23 (16.91%) patients it was observed that, after 2 months of treatment with a probiotic-type of yogurt, grade I dysbiosis was determined bacteriologically, despite the absence of any clinical symptoms and complaints of the digestive system from patients. In 94 (69.1%) patients, intestinal eubiosis was clinically and bacteriologically determined. The significance of differences for all of the above groups is t = 2, *Pt = 95.5%* and $p < 0.05$.

Table 1: The clinical condition of patients with intestinal dysbiosis before and after probiotic therapy.

Study Period	Prevailing of Clinical Syndromes (Number of Patients)			
	Unstable Stool, Diarrhea	Constipation	Flatulence	Discomfort, Abdominal Pain
Before Treatment	31	18	32	55
After Treatment	3	2	6	8

In the control group, after two months, no statistically significant changes were recorded. The observed patients still noted various disorders of the digestive system, such as belching, heartburn, diarrhea, constipation, flatulence, discomfort or periodic pain in the abdomen.

Conclusion

Probiotics such as yogurt demonstrate high efficiency in the correction of intestinal dysbiosis in oncological and hematological patients on the background of polychemotherapy and concomitant antibacterial therapy.

It has been proven that taking probiotics such as yogurt significantly reduces the incidence of dyspeptic disorders such as an unpleasant aftertaste in the mouth, belching, heartburn, diarrhea, constipation, flatulence, or periodical abdominal pain in patients suffering from dysbacteriosis, which has developed with the use of antibiotics.

Long-term therapy with a drug probiotic such as yogurt, which lasts more than 2 months, makes it possible to correct conditions such as grade I and grade II dysbiosis, contributing to intestinal eubiosis in a significant part of the observed patients.

Influence of Mental Health and Social Relationships on Quality of Life among Myanmar Migrant Workers in the South of Thailand

Kanit Hnuploy[1], Wongsa Laohasiriwong[2], Kittipong Sornlorm[3], Thitima Nutrawong[4]

[1]Doctor of Public Health Program, Faculty of Public Health, Khon Kaen University, [2]Faculty of Public Health, Khon Kaen University, Khon Kaen, [3]Tha Khantho District Public health Office, Kalasin, [4]Faculty of Medicine, Khon Kaen University, Khon Kaen, Thailand

Abstract

Background: Previous studies indicated that mental health and social relationships have influence on quality of life. However, there are limited studies on the association between mental health and social relationshipson quality of life among Myanmar migrant workers in Thailand.

Method: This study aimed to determine the prevalence of quality of life and the influence of mental health and social relationships on quality of life among Myanmar migrant workers in the South of Thailand. This cross-sectional analytical study was conducted among 794 Myanmar migrants who were selected by using a multi-stage random sampling from 2 provinces in the South of Thailand to respond to a structured questionnaire interview. The generalized linear mixed model analysis was performed to determine the association between mental health and social relationships on quality of life when controlling other covariates.

Results: The prevalence of good quality of life among Myanmar migrant workers was 11.46% (95%CI:9.24-13.68). Mental health and social relationships were significantly associated with good quality of life were; no had depressive symptoms (adj. OR=3.83; 95%CI: 2.28-6.43, p-value < 0.001), had good relationship with employers (adj. OR=3.02; 95%CI: 1.71-5.31, p-value < 0.001) and had high level of involvement with peers (adj. OR=1.90; 95%CI: 1.09-3.32, p-value < 0.023). Significant covariates were average personal monthly incomes and received health information. About one-tenth of Myanmar migrant workers had a good quality of life. Mental health, social relationships and access to health information had influenced their quality of life.

Keywords: *Myanmar migrant workers, Quality of life, Social relationships, Thailand.*

Introduction

Quality of life (QOL) is a multidimensional level of an individual life's happiness where they live in societies to achieve their goal in life. QOL consists of 4 domains including physical, psychological, social relationships, and environmental domains[(1)].The concept of QOL is commonly used to describe the well-being among various susceptible populations, such as migrants, refugees, etc.[(2-4)], since QOL describes the degree to which a person enjoys the important possibilities of his or her life[(5)]. There were a number of factors influencing QOL. Social relationships were one of the factors associated with QOL of which it increased the likelihood of survival[(6)]. A study carried out in the Basque Country, Spain suggested that low social support was related to poor HRQOL, of which identifying the social support is a key in understanding health inequalities among immigrants[(7)].

Migrating to a new country is an extremely complex and stressful process because it involves changes in all areas of life-socially, culturally and psychologically[(8)]. Psychosocial factors such as lack of social and emotional support from relatives and friends[(9)] were common among migrant workers. Some studies indicated that migrant workers were refused by local citizens[(10)] and lack of legal migration status in migration processes[(11)].

Depression, one of the most common mental health disorders, was identified as having a positive relationship with occupation injury[12]. Depression imposes an immense social burden which leads to functional impairment, decreased quality of life, low productivity and impaired interpersonal relationship[13].

Thailand economic growth has attracted an increasing number of migrant workers from neighboring countries[14]. Migrant workers in Thailand are mostly involved in the ''3 Ds'' jobs (dangerous, dirty and degrading jobs). These 3Ds conditions push them at risk for health problems. One notable health hazard of migrant workers is the deterioration of mental health, which has been implicated to suicide that is more common among migrant workers than that of local citizens [15].The Office of Foreign Worker Administration of Thailand reported that in July 2019 there were 2.83 million migrants residing in Thailand, and about 1.87 million were from Myanmar. About 358,530 Myanmar migrant workers were in the South region. Most of these migrants worked in the manufacturing sectors, agriculture and animal husbandry,fishery, and construction. Therefore, this study aimed to determine the prevalence of quality of life and the influences of mental health and social relationships factors on quality of life among Myanmar migrant workers in the South of Thailand.

Materials and Method

Study design and sampling: This cross-sectional analytical study was conducted in 2018. The populations were Myanmar migrant workers in the South of Thailand. The sample size was calculated by using the formula to estimate the sample size for logistic regression analysis of Hsieh [16].The estimated sample size was 794. We recruited Myanmar migrant workers from 2 southern provinces by using multi-stage random sampling method.

Questionnaire: A structure questionnaire was developed based on the research questions and relevant literatures. The structured questionnaire consisted of 6 parts: A) Demographic and socioeconomic characteristics,B)Social relationships, C) Health behaviors and physical health status, D) the Perceived Stress Scale (PSS) of Cohen et al. [17], E) The Center for Epidemiology Studies Depression Scale (CES-D)[18], and F) WHOQOL-BREF was used to assess the quality of life. QOL scores were categorized into three groups: a) poor level (26-60 scores), b)moderate level (61-95 scores), c) good level (≥96scores)[1]. The questionnaire was undergone content validation by 5 experts and revised to improve its validity. The Cronbach's alpha coefficient of PSS, CES-D, and WHOQOL-BREF were 0.78, 0.70, and 0.85 respectively.

Statistic Analysis: All analyses were performed using Stata version 10.0 (StataCorp, College Station, TX). Demographic and socioeconomic characteristics of the participants were described by using frequency and percentage for categorical data as well as the mean and standard deviation for continuous data. A simple logistic regression was used for bivariate analysis to identify individual factor associated with QOL. In the bivariate and multivariable analysis, quality of life was classified into 2 groups using the cutoff score of ≥ 95 points which mean 'had a good quality of life'. The independent factors that had p-value <0.25[19] were processed to the generalized linear mixed model (GLMM) analysis to identify the association between mental health and social relationships with QOL when controlling the effect of other covariates and reported the adjusted odds ratio (Adj. OR),95% confidence interval (CI) and p-value<0.05 as the magnitude of effect and statistical significant level.

Results

Majority of the Myanmar migrant workers were male (58.31%) with the average age of 32.79 (±9.00) years old, 69.52% were married and 37.78% finished only primary education. Most of them lived in urban settings (81.74%),75.19% lived with a family and 46.98% lived in a labor camp. The highest proportion worked in manufacturing (29.97%) followed by agriculture and animal husbandry, fishery and construction. Their average personal monthly incomes was 9,201.17(±2,681.29) Baht, of which 3,203.21 (±1,660.17) Baht were average personal monthly expenditures. Almost all had health insurance (99.62%).

Most of the workers worked both indoor and outdoor (64.23%) and the rest (35.77%) worked only indoor. Most of them satisfied with their living and working conditions as well as the relationship with others, except that 58.56% had a limitation on traveling. About one-third were smokers (38.16%), 16.12% were drinkers. More than half of the migrant workers (54.91%) had a physical check-up and 11.08% had chronic diseases. Most of them (88.66%) had a moderate level of stress and more than half (52.77%) had depressive symptoms.

Concerning the quality of life, 85.77% (95% CI: 83.15-88.03) of the migrant workers had a moderate level, 11.46% (95% CI: 9.42-13.87) had a good level and 2.77% (95% CI:1.82-4.17) had a poor level.

Factor associated with good quality of life: Bivariate analysis: The bivariate analysis results indicated that the independent variables that possibly associated with good QOL (p-value<0.25) were;average personal monthly income, physical health check-up, involvement with peers, relationship with employers, relationship with co-workers, relationship with family, received health information and depressive symptoms. These factors have proceeded to the multi variable analysis (Table 1).

Discussion

The findings observed that most of the Myanmar migrant workers perceived of having a moderate level of QOL (85.77%), only 11.46% having good QOL. It might be that the situations where they lived and worked were as they expected. They were not much better. This study also observed that those who had no depressive symptoms had a significantly better quality of life in comparison with those who had depressive symptoms, of which similar with previous studies conducted in China[20, 21]. Besides, those who had a good relationship with employers had a significantly better quality of life in comparison with those who had a poor and average level which was similar with a study conducted in Thailand [22]. It might be that the relationship with peer could result in job security and incomes. The migrant workers who had a high level of peer involvement had significantly better QOL than those who had low to moderate levels of peer involvement which was similar to a study in Sweden[23]. It might be that they could share various issues and able to release their tensions. Concerning personal monthly incomes, this study indicated that those who had average personal monthly incomes ≥9,300 Baht were more likely to have good QOL in comparison with those who had lower incomes. A study conducted in China was also observed a similar finding[20]. Concerning health, migrant workers who received health information were more likely to have a better quality of life in comparison with those who had not received health information. Migrants have usually accessed health information through social networks more than formal health service providers due to language and access barriers[24].

Conclusion

About one-tenth of Myanmar migrant workers in the South of Thailand had a good QOL. After adjusting

for other covariates which were personal monthly income and access to health information;mental health especially depressive symptoms and social relationships including had a good relationship with employers, and high level of peer involvement were found significantly associated with QOL.

Abstract

Background: Low back pain (LBP) is one of the most common musculoskeletal disorders demandinghospital visits. Intervertebral discdegeneration is a known cause of chronic low LBP back pain. The relation between changes in the lumbar spine and lower back pain is controversial.

Objectives: To assess LSS MRI findings in patients with CLBP, and to show the relation of disc degeneration with age and gender.

Material and Method: 218 adult patients with chronic lower back pain (pain more than 12 weeks) did Lumbosacral spine MRI, at Azadi Teaching Hospital/Kirkuk city, from March/2017 to April/2018, those with a positive history of spinal pathology other than osteoarthritis were excluded. The disc degenerative MRI changes at each lumbar disc were assessed and correlated according toage and gender.

Results:146 of patients were male, and 72 of them were female, their age ranged from (16-73 years). Males and elderly patients were affected by disc degeneration more. 92.2% of patients had disc degeneration, followed by disccontour abnormality, facet joint arthrosis, high-intensity zone (HIZ), spinal canal stenosis, Modicchanges (MC), Schmorl's nodes (SN), and spondylolesthesis. L4-L5 disc was the most commonly involved level by disc degeneration, followed by L5-S1disc, the least level was L1-L2.

Conclusions: Most patients with CLBP have DDD. Older males are the most susceptiblepeople to develop DDD which affect most commonly L4-L5 disc level, other findings mayassociate with DDD are MC, SN, HIZ, facet joint arthrosis, spinal stenosis, andspondylolesthesis.

Keywords: *Chronic, lumbosacral, lower back pain, MRI.*

Introduction

Low back pain (LBP) is one of the most common musculoskeletal problems demanding hospital visits, and the main contributing cause of disability in adults. LBP occurs in most of the peopleduring any period of life. [1, 2, 3, 4, 5]Although several causes have been implicated in lowback pain, disc degeneration disease (DDD) is a known cause of this pain.[6, 7]. Chronic pain is defined as pain for more than 12 weeks.[8]

DDD of the lumbosacral spine (LSS) in adults can start in the third decade of life.[6] There are several risk factors related to disc degeneration in the LSS, including age, increased physical loading, obesity, and genetic influences.[4,9,10]

Magnetic resonance imaging (MRI) is often requested and of choice in the management of patients with LBP as different abnormalities can be seen on spinal MRI.[11,12,13] LSS MRI findings of DDD include decreased disc space, decreased signal intensity on T2W images which indicates disc dehydration.

Disc degeneration on T2-weighted sagittal magnetic resonance images of the lumbar spine is appeared and graded as:

Grade (0): Normal No signal changes; Grade (1): the signal intensity of the nucleus pulposus is slightly decreased; Grade (2): seen as hypointense nucleus pulposus with preserved disc height; Grade (3): seen as hypointense nucleus pulposus with narrowing of disc space.[14]

Disc degeneration may be associated with disc bulging/herniation, and high-intensity zone(HIZ). [9, 15] Herniated disk is defined as a "focal displacement of nucleus, cartilage, a piece of annulartissue or fragmented apophyseal bone beyond the space of the intervertebral disc. Disc displacement most commonly is classified into five grades (normal, disc bulge, protrusion, extrusion, and sequestration). [16, 17] (HIZ) represents tear in the annulus fibrosus of the disc, seen as very bright signal intensity on T2 weighted images at the posterior part of the disc.[18] Other findings which associated with DDD include Modic changes (MC), Schmorl's Nodes (SN), facet joint degeneration, spondylolesthesis, and spinal stenosis. [19]

This study was done to assess LSS MRI findings in patients with CLBP, and to show the relation of DDD with age and gender.

Patients and Method

Subjects: Inclusion criteria: Two hundred eighteen (218) adult patients with chronic lower back pain (more than 12 weeks) were sent to MRI department at Azadi teaching hospital/Kirkuk city/Iraq, as a part of the management of lower back pain, over the period fromMarch/2017 to April/2018. Their ages range from 16 to73 years.

Exclusion criteria: Those who had a history of spinal surgery or back trauma, known spinal pathology, malignant diseases,and athletes were excluded from the study. Clinical information was obtained from the documentation of physicians.

Imaging: All lumbosacral spine MRI examinations were done using the 1.5-T unit (Philips Acheiva, Netherl and 2010) with a dedicated lumber coil, imaging protocol was as follows:

1. T1-weighted sagittal Turbo spin echo (TSE) with 8 msec echo time (TE) and 500 msec repetition time(TR).
2. T2- weighted sagittal TSE with 100 msec TE and 4000 TR.
3. T2-weighted axial TSE with 120 msec TE and 4000 TR, and
4. Myelography with 1000 msec TE and 8000 TR.

The images were interpreted by two board-certified radiologists with 7 years experience, any difference in opinion were settled by consensus. Each lumber level of 218 patients was assessed for disc degeneration scoring, disc bulging and herniation, HIZ,presence of MC, SN, facet joint degeneration, spondylolesthesis, and spinal stenosis.

Statistical analysis: It was a cross-sectional analytic study. The study population demographic criteria including age in years, weight in kilograms (kg), and height in centimeters (cm)were expressed as means(SD). Percentage of Disc degeneration at different lumber disc levels was assessed and related to gender and age, total degeneration score was estimated for each patient as average degeneration score of all lumbar disc levels and related to age, using Chi-square test. *P*-value level of less than 0.05 was required for significance. Percentage of disc bulge/herniation, HIZ, MC, SN, sponylolisthese, facet joint arthropathy, and spinal stenosis were also estimated. SPSS software, version 17, was used for the statistical analyses.

Results

The demographic criteria of the study sample were as seen in table 1.

Table 1: The demographic criteria of the study sample

Category	Male ([a]N=146) Mean (SD)	Female (N=72) Mean (SD)	t- value	P value
Age (years)	43.5 (12.1)	42.5 (12.7)	0.5645	0.5730
Height (cm)	174.3 ± 6	161.3 ± 5.8	15.3747	0.0001
Weight (kg)	83.31 ± 14	74 ± 8	5.2332	0.0001

[a] Number.

There were 146 males and 72 females in the study sample; male to female ratio was 2:1, 141 males (96.6%) and 60 (83.4%) of females had disc degenerative changes in their LSS MRI.

Males were significantly more affected than females by disc degeneration (*P*=0.0006). Most of the patients had abnormal MRI findings 201 (92.2%), and only 17 (7.8%) had a normal MRI study. 32 patients were less than 35 years old, 140 patients were 36-55 years old, and 46 patients were more than 55 years old. 68.8% of < 35 years old group, 95% of 35-55 years old group, and All patients >55 years old group had disc degeneration change. The incidence of disc degeneration was significantly increased with advancing age (P<0.001)as seen in table 2.

Table 2: Relation of disc degeneration with age.

Age	Disc Degeneration		Total
	Male	Female	
< 35	17	5	22
35-55	98	35	133
>55	26	20	46

The total number of the affected disc was 588 levels of a total of 218 patients. The mostcommonly affect level was L4-L5 in 32%, followed by L5-S1, L2-L3, L3-L4, and L1-L2 in 21.2%, 19.1%, 18%, and 9.2% respectively as seen in figure 1.

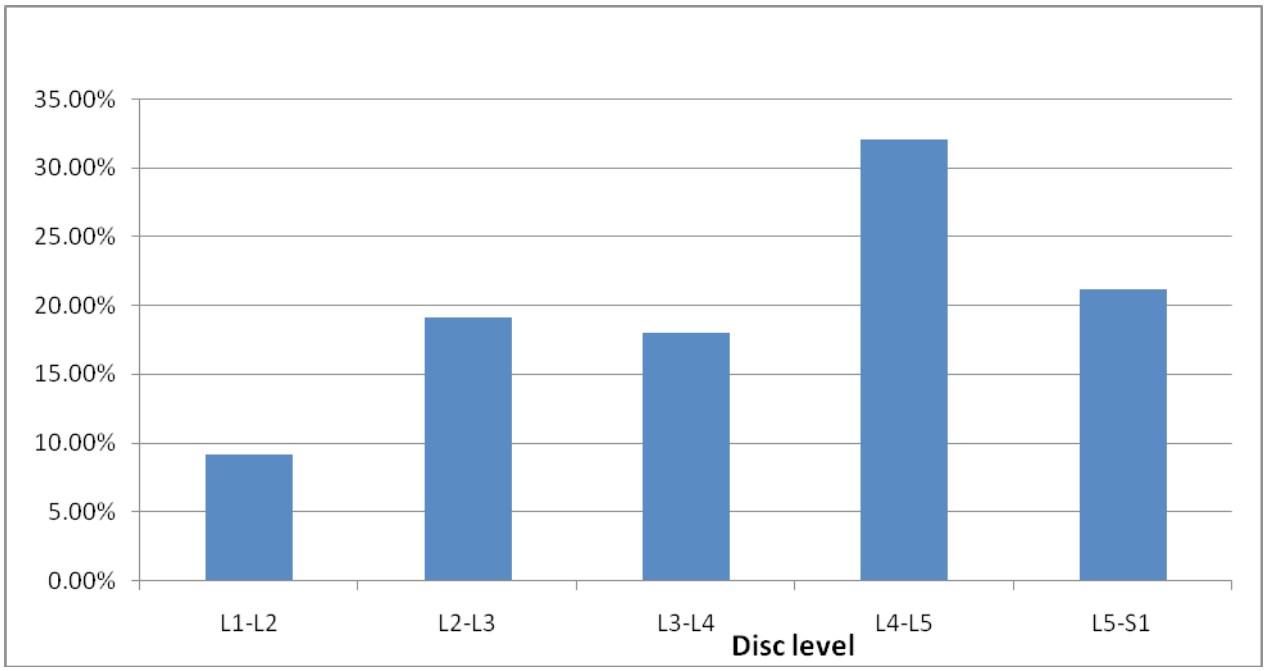

Figure 1- Distribution of disc degeneration according to disc level

Disc degeneration was present at one level in 25%, and multilevel in 75%. The average disc degeneration score of each patient was score 0 in 7.8% (17 patients), score I in 30.1% (66 patients), score II in 37.2 (81 patients), and score III in 24.8% (54 patients) (Table 3).

Table 3: The relation between disc degeneration score and age

Age (Years)	Total Degeneration Score				Total
	0	I	II	III	
>35	10	18	4	0	32
36-55	7	40	61	32	140
55<	0	8	16	22	46
Total	**17**	**66**	**81**	**54**	**218**

Score 3 disc degeneration was not seen in <35 year's age group, and all patients who were <55 years old group had degeneration with different scores, the score of degeneration was significantly increased with increasing age (*P*> 0.001).

Other LSS MRI findings were as the following: disc contourabnormality (70.7%), HIZ (27.8%), SN in (12.9%), MC (19.3%),spinal stenosis (20.4%), facet joint degeneration (45.2%), andspondylolisthesis (6.4%).

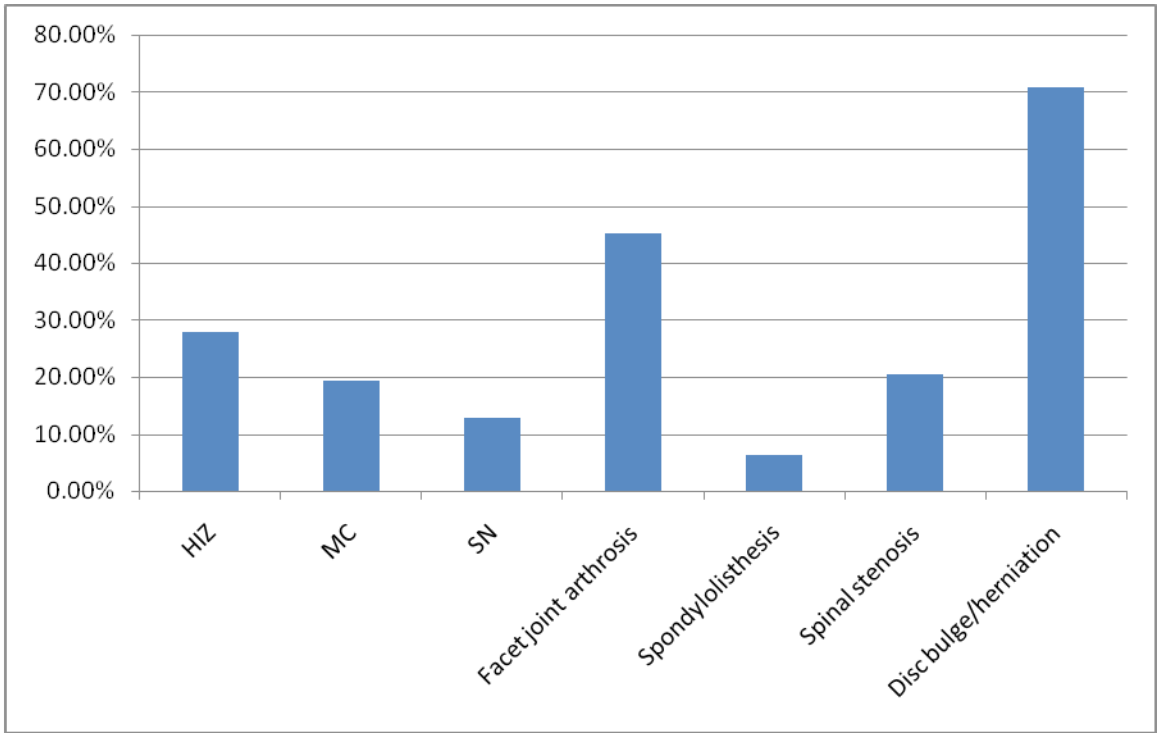

Figure 2: Percentage of MRI changes associated with disc degeneration

Discussion

Degenerative changes were seen in the majority (92.2%) of patients with chronic lower back pain;most of these changes were observed at L4/L5 and L5/S1 levels and lowest rate of involvement was noted at L1-L2 level. Similar outcomes had been perceived in most of the previous studies,due to the highest mechanical strain at these levels[20, 21,22, and 23].

Multiple disc level involvement was common as compared to the single-disc involvement; which was also in line with past studies.[16, 24] In this study the incidence of disc degeneration significantly increased with age, due to aging process which involves decreased vascularization, and decreased delivery of nutrients and growth factors to the disc.[25] This result was similar to several studies.[20, 26] The fewer percentage of DDD that's seen in younger age group also noticed in other studies like us, its exact etiology is not clearly known, but issues like genetic, autoimmune, and biochemical factors may play a role inthe pathogenesis of disc degeneration.[27]

Males were affected significantly more than females in our study which was comparable with other studies,[28,29] as men engage in jobs associated with heavy workload compared with women.[30] Mechanical load that contributes to DDD might also have a role in the pathogenesis of disc contour abnormalities, HIZ, MC, and SN.[31,23,33].

Conclusions

Most of patients with CLBP have DDD. Older males are the most susceptible people to develop DDD which affect most commonly L4-L5 disc level, other findings may associate with DDD including MC, SN, HIZ, facet joint arthrosis, spinal stenosis, and spondylolesthesis.

Early Versus Conventional Postoperative Oral Feeding after Elective Colonic Anastomosis

Kerolos A. Barsoum[1], Sami M. Said[2], Karim K. Maurice[3], Doaa A. Mansour[4]

[1]Assistant Lecturer of General Surgery, [2]Professor of General Surgery, [3]Lecturer of General Surgery, [4]Assistant Professor of General Surgery, Cairo University Medical School, Kasr Alainy, Egypt

Abstract

Objective: The aim of this study was to assess the safety of early oral feeding after elective colonic anastomosis.

Method: The study was conducted upon 40 cases at Kasr Al- Ainy teaching hospital. The cases were divided into two groups: Group 1 (Early feeding): 20 patients began fluids on the first postoperative day and advanced to a regular diet within the next 24–48 h, as tolerated. Group 2 (Regular feeding): 20 patients were managed in the traditional way (nothing by mouth for five days).

Results: Anastomotic leakage was 0% in early feeding group versus 5% in conventional feeding group. Early oral feeding was tolerated in 90% of patients in early feeding group. The time to first passage of flatus was sooner in the early feeding group (1.05 ± 0.22) than the traditional group (1.95 ± 1.05), p= 0.001. The risk of wound infection was significantly reduced with the early feeding group (10.0%) when compared with the conventional feeding group (40.0%), p = 0.028. Length of hospital stay was significantly less in the early feeding group.

Conclusion: Early oral feeding after elective colonic anastomosis is safe and can be tolerated by the majority of patients. Early oral feeding is associated with early return of bowel habits and reduced length of hospital stay. It is also associated with reduced risk of wound infection.

Keywords: *(Early feeding, Colonic anastomosis, Anastomotic leak).*

Introduction

Conventional treatment after colonic anastomosis has typically entailed postoperative fasting with administration of intravenous fluids until passage of flatus, principally due to concerns over post-operative ileus.[1]

This was based on the believe that oral feeding may not be tolerated in the presence of ileus and the integrity of the newly constructed anastomosis may be compromised.[2]

However, small intestinal motility recovers 6–8 hours after surgical trauma and moderate absorptive capacity exists even in the absence of normal peristalsis.[3]

In addition several studies showed that early resumption of an oral diet accelerated gastro intestinal recovery, decreased the hospital length of stay and was associated with lower complication and mortality rate.[4-6]

So oral feeding can be started on the first postoperative day without waiting for the resolution of postoperative ileus. Thus, the patients can be protected from starvation and the related side effects.

Aim of Work: The aim of this study was to compare early and conventional postoperative oral feeding after

elective colonic anastomosis as regards the risk of anastomotic leak, tolerance of early feeding, return of bowel habit, length of hospitalization, wound infection and serum electrolyte disturbance.

Material and Method

The study was conducted upon 40 cases at Kasr Al-Ainy teaching hospital during the period from March 2015 to September 2016.

The patients were then randomized into two groups. Randomization was achieved using sealed envelopes. After carefully explaining the purpose of the study, informed consent was taken from every patient.

Group 1 (Early feeding): 20 patients began fluids on the first postoperative day and advanced to a regular diet within the next 24–48 h, as tolerated.

Group 2 (Regular feeding): 20 patients were managed in the traditional way (nothing by mouth for five days).

In all the cases a detailed history was taken followed by clinical examination and relevant investigations including routine laboratory investigation (CBC, liver function tests, renal function tests), serum electrolytes and tumor markers.

It was assured that serum albumin level was at least 3 g/dl and hemoglobin level was at least 10 g/dl in all patients (for standardization).

Serum electrolytes (Na, K) were done preoperatively and then daily till the date of discharge to detect any electrolyte disturbance. According to the laboratory results correction was undertaken.

The patients were also assessed radiologically by barium enema, abdominal ultrasound, pelvic and abdominal CT, bone survey and chest X-ray in addition to colonoscopy and biopsy for diagnosis of colorectal cancer.

Chemical and mechanical bowel preparation was done for all patients. The anastomosis was done using hand sewn technique, interrupted, 2 layers, using vicryl 3-0. Intra abdominal drain was inserted in all patients.

A nasogastric tube was inserted in all patients during surgery. The tube was removed immediately after surgery, and was reinserted after two episodes of vomiting of more than 100 mL over 24 hours in the absence of intestinal sounds.

The patients were monitored for vomiting, abdominal distension, length of ileus, tolerance of regular diet, length of hospitalization and complications including anastomotic leak, wound infection and electrolyte disturbances.

Findings: Group 1 (early feeding group) included 20 patients, 13 males (65%) and 7 females (35%) while group 2 (conventional feeding group) included 20 patients, 12 males (60%) and 8 females (40%). In group 1 (early feeding group) mean age was 39.4 ± 17.34 years (range 11–65 years) while group 2 (conventional feeding group) mean age was 45.05 ± 13.49 years (range 13–70 years).

Anastomotic leakage was 0% in early feeding group versus 5% in conventional feeding group. Anastomotic leakage occurred only in one patient in conventional feeding group after closure of colostomy and healed after conservative measures.

Early oral feeding was tolerated in 90% of patients in early feeding group. The time to first passage of flatus was sooner in the early feeding group (1.05 ± 0.22) than the traditional group (1.95 ± 1.05), p= 0.001.

The risk of wound infection was significantly reduced with the early feeding group (10.0%) when compared with the conventional feeding group (40.0%), p = 0.028.

Serum electrolyte disturbance was 5% in early feeding group versus 45% in conventional feeding group (p = 0.003).

Length of hospital stay which was significantly less in the early feeding group (5.95 ± 1.00) compared to conventional feeding group (7.70 ± 2.64), p= 0.009.

Table 1: Results of early feeding group

		No.	%
Sex	Female	7	35.0%
	Male	13	65.0%
Age	Mean ± SD	39.40 ± 17.34	
	Range	11–65	
Anastomotic leakage	Negative	20	100.0%
	Positive	0	0.0%
Tolerance of early feeding	Negative	2	10.0%
	Positive	18	90.0%
Time of passing flatus (days)	Mean ± SD	1.05 ± 0.22	
	Range	1–2	
Wound infection	Negative	18	90.0%
	Positive	2	10.0%
Electrolyte disturbance	Negative	19	95.0%
	Positive	1	5.0%
Hospital stay (days)	Mean ± SD	5.95 ± 0.99	
	Range	5–8	

Table 2: Results of conventional feeding group

		No.	%
Sex	Female	8	40.0%
	Male	12	60.0%
Age	Mean ± SD	45.05 ± 13.49	
	Range	13–70	
Anastomotic leakage	Negative	19	95.0%
	Positive	1	5.0%
Tolerance of early feeding	Negative	0	0.0%
	Positive	0	0.0%
Time of passing flatus (days)	Mean ± SD	1.95 ± 1.05	
	Range	1–4	
Wound infection	Negative	12	60.0%
	Positive	8	40.0%
Electrolyte disturbance	Negative	11	55.0%
	Positive	9	45.0%
Hospital stay (days)	Mean ± SD	7.70 ± 2.64	
	Range	5–15	

Discussion

Proper and adequate nutrition has so far been one of the major concerns in postoperative care. However, postoperative fasting until resolution of ileus, known as traditional feeding, is regarded as surgical dogma or doctrine.[7]

This belief was not supported by large number of studies which demonstrated that early feeding is safe, tolerated by most of the patients, reduced length of hospital stay and was not associated with increased risk of complications.[8-12]

This prospective study was conducted in Kasr al Ainy hospital, and comprised 40 patients who underwent elective colonic anastomosis. Patients were divided into two groups; early feeding group (20 paients) and conventional feeding group (20 patients).

In this study, there was no significant difference in the risk of anastomotic dehiscence with the early feeding group when compared with the traditional feeding group. Anastomotic leakage was 0% in early feeding group versus 5% in conventional feeding group. It occurred only in one patient in conventional feeding group after closure of colostomy and healed after conservative measures.

The same result was reported by other studies. El Nakeeb et al. reported that anastomotic leakage was 1.66% in the early feeding group versus 3.33% in the traditional group. Also Le Zhuang et al. reported in their Meta-analysis of RCTs that early oral feeding did not reduce or increase the risk of anastomotic dehiscence compared with traditional oral feeding.[2, 13]

These findings are opposite to the traditional belief that patients should not eat for several days after colorectal surgery in order to avoid anastomotic leakage.

In this study, 18 patients (90%) tolerated early oral feeding while 2 patients (10%) failed to tolerate early feeding and presented with recurrent vomiting and abdominal distension without intestinal sounds. Dag et al. reported similar results where the majority of the patients in the early feeding group (85.9%) tolerated the early feeding schedule.[1]

The time to first passage of flatus was sooner in the early feeding group (1.05 ± 0.22) than the traditional group (1.95 ± 1.05), p= 0.001. The same was reported by El Nakeeb et al where the time to first passage of flatus was seen on postoperative day 3.3 ± 0.9 (2–8) in the early feeding group and on day 4.2 ± 1.2 (2–9) in the traditional group (P= 0.04).[13]

This was reflected on the length of hospital stay which was significantly less in the early feeding group (5.95 ± 1.00) compared to conventional feeding group (7.70 ± 2.64), p= 0.009. Multiple studies reported the same results where early oral feeding was associated with reduced length of hospital stay.[8, 14]

This reduction in the length of hospital stay may be due to that early feeding is associated with reduced length of postoperative ileus and early return of bowel movement, also early feeding is associated with reduced postoperative complications which may lead to decreased length of hospital stay.

In this study the risk of wound infection was significantly reduced with the early feeding group (10.0%) when compared with the conventional feeding group (40.0%), p = 0.028. While El Nakeeb et al, reported that wound complications occurred in 10% in early feeding group versus 11.67% in traditional feeding group. This variation in the incidence of wound infection may be due to variation in the definition of wound infection.[13]

The reduction in the incidence of wound infection among early feeding group may be due to that conventional feeding is associated with increased length of hospital stay so there may be increased risk of hospital acquired infection and wound infection.

In conclusion, early oral feeding after elective colonic anastomosis is safe and can be tolerated by the majority of patients. Early oral feeding is associated with early return of bowel habits and reduced length of hospital stay. It is also associated with reduced risk of wound infection. So, there is no obvious advantage in keeping patients nil by mouth after elective colonic anastomosis.

Joint Effect Obesity and Oral Contraceptive Use towards Hypertension among Women in Thirteen Provinces in Indonesia

Kuuni Ulfah Naila El Muna[1], Helda[2]

[1]Postgraduate Student, Department of Epidemiology, Faculty of Public Health, University of Indonesia,
[2]Department of Epidemiology, Faculty of Public Health, University of Indonesia

Abstract

Introduction: Hypertension complications cause 9,4 million people died in the whole world every year. Hypertension in a woman is more dangerous than man, as they affect mortality and morbidity not only at herself but also the fetus in a pregnant woman. Hypertension is stimulated by many risk factors, some of them were obesity and using oral contraception. The purpose of this study is to evaluate obesity, oral contraceptives use and their joint effect on the risk of hypertension among women in Indonesia.

Method: A cross-sectional study from Indonesian Life Family Survey 5 data, including 10.270 women with age ≥18 years old lives in Indonesia. Weight, Height and Blood Pressure were measured. Hypertensive respondents if the blood pressure ≥140/90 mmHg, while obese defined by body mass index ≥ 27,5 kg/m^2. History of contraceptive used, smoking behavior and age were investigated. The effect between the independent and dependent variables in this study can be determined by Prevalence Ratio (PR) and estimated under Cox Regression Model.

Results: Our study showed that obesity, oral contraceptive used, and age significantly become risk factor of hypertension with PR (95% CI) respectively 2,12 (1,94–2,31); 1,21 (1,10–1,33); and 2,65 (2,42–2,91). Combination OC users and obesity significantly elevated the risk of hypertension by PR 2,149 (1,90–2,42) among women in Indonesia. Compared with OC, Obesity was more strongly associated with hypertension with PR 1,93 (1,74-2,13).

Conclusions: Obesity, OC users and their joint effects significantly increased the risk of hypertension among women in thirteen Provinces in Indonesia. The way better to prevent being obese than preventing using OC in the case of hypertension.

Introduction

Hypertension complications cause 9,4 million people died in the whole world every year.[26] Hypertension in a woman is more dangerous than man, as they affect mortality and morbidity not only at herself but also the fetus in a pregnant woman.[7] Hypertension prevalence in people aged ≥ 18 years in Indonesia continues to increase from 2013 to 2018. Based on the basic health research 2013 and 2018, the prevalence of hypertension in Indonesia is 25.8% and 34.1% respectively.[9,10] The proportion of hypertension in 2018 was 31.34% in men and 36.85% in women.[10]

Hypertension induced by obesity cause of adipocytes in obese people induced increase in renin-angiotensin system which increasing sodium absorption, fluid volume, and also activate sympathetic nervous system. Those adipocytes also induced inflammation and reduced insulin sensitivity which attends to become endothelial dysfunction and arterial stiffness or vasoconstriction which leads to hypertension.[12] Obesity has been defined by the World Health Organization (2000) and The National Heart, Lung and Blood Institute (1988) as a body mass index (BMI) ≥ 30 kg/m^2.[2] This classification not appropriate to describe the association of various diseases due to obesity in Asia, because the percentage of

subcutaneous fat in Asians is more than the Caucasian at the same age, sex and BMI.[2,21,23] In 2004, WHO Expert Consultants suggested the classification of the latest BMI in terms of the risk of cardiovascular disease where the risk cut or point of obesity in the Asian population is ≥27.5 kg/m^2.[23] The prevalence of hypertension in the overweight and obese group is 40.8% while the prevalence of hypertension in the group with normal and thin BMI is 25.3%.[14]

Using oral contraceptives or pills containing estrogen and progesterone causes cardiac hypertrophy and increases the presenting response of angiotensin by involving the renin angiotensin system which causes high blood pressure.[3,15,16] The prevalence of hypertensive patients increased in line with the long duration of oral contraceptive use. It is known that the prevalence of hypertension in women who do not use oral contraceptives, use less than 1 year, less than 2 years and more than 2 years in a row were 14.3%; 13.9%; 21.3%; 22.8%.[16] Oral contraceptives is the second contraceptives most chosen by women 15-49 years old in Indonesia after giving birth to the last child is 8,5%, and the first one is injection every 3 months is 42,4%.[10]

A study using the 2013 basic health research data explained that women of childbearing age (WUS) who had a body mass index of more than 25 kg/m^2 had 2.7 fold risk of developing hypertension.[11] A crossectional study states that those who are obese (>25kg/m^2) have a risk of hypertension of 1,681 times compared to non-obese after being controlled by age variables, a history of family hypertension and physical activity.[18] Hypertensive women and those without hypertension (adjusted) were 1.96 for oral contraceptive use >2 years and 1.22 for use at >1 year.[16] Wang's research in 2011 showed the combined effect of obesity and the use of oral contraceptives at a risk of 8.02 times (OR 8.02, CI 5.05-12.74) greater than hypertension with an addictive interaction of P = 0.039.[21]

Method

This study using cross-sectional design from Indonesian Life Family Survey 5 (IFLS-5) data. IFLS-5 is the fifth survey was held in 13 of 27 province in Indonesia in 2014. This survey used household survey from IFLS data. The subjects of this study including 10.270 women 18-49 years old, live in Indonesia and have complete data for each variable would be analyzed in this study. Weight, Height and Blood Pressure were measured. Hypertensive respondents if the blood pressure ≥140/90 mmHg, diagnosed by health workers, or consuming hypertension pills. While obese defined by body mass index ≥27,5 kg/m^2 this cut off based on WHO Expert Consultant.[23] Oral contraceptive used, smoking behavior and age were investigated. Collecting, editing and analyzing data IFLS-5 using software STATA (v.12, StataCorp). The effect between the independent and dependent variables in this study can be determined by Prevalence Ratio (PR) with confidence intervals (CI) 95% and estimated using Cox Regression Model in constant time.

Results

Sociodemographic characteristic between hypertensive and non-hypertensive cases: Majority women with any kind of characteristic classified as not hypertension case. Our study showed that obesity, oral contraceptive used, and age significantly become risk factor of hypertension with PR (95% CI) respectively 2,12 (1,94–2,31); 1,21 (1,10–1,33); and 2,65 (2,42–2,91). This individual risk factors are shown in (**Table 1**).

Association obesity and the risk of hypertension: After adjustment for age, the obese women have 1,93 fold (PR 1,93, 95% CI 1,74-2,13) increased risk of hypertension compared with non-obese women. This effect less than PR before adjustment (PR 2,16, 95% CI 1,95–2,38) (**Table 2**).

Association oral contraceptive use and the risk of hypertension: After adjustment for age, the obese women have 1,22 fold (PR 1,22, 95% CI 1,07–1,38) increased risk of hypertension compared with non-obese women. This effect is the same with PR without adjustment (**Table 2**). There is association was observed between Obesity and OC users (p< 0,001) (data not shown).

*Adjusted for age

Joint Effect obesity and OC users on the risk of hypertension: As shown in **Table 2**, before adjustment combination obesity and OC users significantly elevated the risk of hypertension by compared to among women in Indonesia with PR 2,4 (2,08–2,76). OC users slightly elevated the risk of hypertension among both obese and non-obese women. The joint effects of obesity and OC users significantly increase the risk of hypertension by 1,11 fold (PR 2,11, 95% CI 1,83–2,43). An antagonism biologic interaction between obesity and OC users was detected (p = 0,0174).

Discussion

From this cross-sectional study we evaluate that obesity, OC users and their joint effects on the risk of hypertension in women of 13 provinces in Indonesia. Our results indicated that Obesity and OC users were all risk factors for hypertension. We suggested a strong effect of obesity (BMI ≥ 27,5 kg/m^2) on hypertension risk, which attribute 35,97% in population. Same study in Chinese population showed effect of increased BMI on hypertension attributed 32,51% of PAR (Population at Risk) with BMI ≥ 24 kg/m^2 vs BMI <24 kg/m^2.[21] There are many studies emphasized whether biologic mechanism obesity induced hypertension,[5,12] also their association around the world. This also proved in the present study, we verified that obesity was the risk factor for hypertension significantly. Therefore, in the future the body mass index (BMI) such as obesity should never be underestimated.

OC use as hypertension risk have attributable risk not as much as obesity was 9,75%. OC used is well known could change blood pressure by few millimeters and 2-3 fold increase incidence of hypertension.[3,24] Both World Health Organization (WHO) and American College of Obstericians and Gynecologists (AJOG) have formally offered that Hypertension was one of contradiction to use COC but AJOG would allow COC use in women with well-controlled hypertension in some circumtances.[4] Low dose COC consist ethinyl estradiol dose less than 50 µg would increase risk of myocardial infraction and ischemic stroke approximately 2 fold in the general population of COC users.[4,21,24] This cross-sectional study also confirmed OC as risk factor of hypertension significantly.

Interestingly we found there is joint effect between Obesity and OC use towards hypertension. Biologic Interaction identified by this study was antagonism although the risk of joint effect was bigger that independent risk of obesity or OC use. In the contrary,a case-control study in China also found joint effects general and central obesity, combined oral contraceptives (COC) use and hypertension, also shown a synergism interaction($p = 0,039$).[21] They found that the higher body mass index and the more longer respondent using COC therefore the risk of hypertension became a lot higher. The risk increased dramatically in combination of COC use with a BMI $\geq$ 28 kg/m^2 or Waist Circumference (WC) $\geq$ 90 cm with OR 8,02 (5,05–12,74) and OR 5,76 (3,65–9,12) respectively.[21]

This research found increasing risk to hypertension in joint effect obesity and OC use but have antagonism interaction. This might be caused by first, the operational definition of OC users had been used in this research was consist of women that using OC; women have used OC in her lifetime with proportion consecutively 11,20% and 10,92%.Women have used OC would have been stop for a long time ago or short time, a cohort study included 2112 hypertension people found that stopping OC in 6,6±7,5 months was an effective antihypertensive intervention in a clinical setting.[13] The study showed there is association between stopping OC and improved prognosis as reduction of at least 10 mmHg in Diastolic Blood Pressure (DBP) or 20 mmHg in Systolic Blood Pressure (SBP) with OR 0,27 (CI 95% 0,06–0,90) adjusted by age, weight and drug prescription.[13] Another study state that COC users would increase 5-6 mmHg of SBP and 1-2 mmHg in DBP.[3] Besides, the period of time women who have a history used OC did not provide by RAND cooperation therefore we did not have information about that. Also as the limitation of our study, we did not identify the period of time using OC.

Second, there are two types of oral contraceptives used in Indonesia which were mini pil (progestin only pill/POP) and pil KB (Combination Oral Contraceptive/ COC), but this study was blinding that because there are no information about that. Although whether POP or COC could increase blood pressure in experimental study in rats, which increasing blood pressures (systolic and diastolic) were higher in COC user that POP.[3] But, contrary in some study literature review and meta-analysis about POP and hypertension drawn conclusion no association POP and increasing blood pressure.[6,8] This two condition affect the risk of OC and their joint effect with obesity towards hypertension become antagonism. However, we found the risk of joint effect still bigger than the risk of obesity or OC users alone.

Conclusions

Our study indicated that obesity, OC users and their joint effects significantly increased the risk of hypertension among women in thirteen Provinces in Indonesia. The way better to prevent being obese than preventing using OC in the case of hypertension. For further research it would have been better if the variable not nominally categorized but depend on the usefulness and richness of the research. Also it would have been wonderful to include the long time using OC and using cohort design study. Besides, we recommend for future research for including waist circumference (WC), if the research conducted in Asian Population.

Comparison between the Antioxidant Activity of Volatile Oil and Hydrosol in Eucalyptus Camaldulensis (Young and Adult) Leaves

Lamiaa A. Gharb

Department of Biology, College of Science, University of Baghdad, Iraq

Abstract

Essential oils have been reported as an important compounds in the pharmaceutical industries for their antibacterial and antioxidant activity. This study was conducted to investigate the antioxidant activity of Eucalyptus *camaldulensis* volatile oil and hydrosol obtained from young and adult leaves. Oil extraction was carried out by using steam distillation method. The antioxidant power was estimated by using the DPPH(2,2-diphenyl-1,1-picrylhydrazyl) and FRAP(ferric reducing antioxidant power) assays. Butylated hydroxy toluene (BHT) was used as positive control. The results show that young leaves of *E. camaldulensis* provide essential oil (2-4%), while in adult leaves the oil percentage was (1-2%). The IC50 of volatile oil in young leaves for the DPPH and FRAP assays was (237.178 and 243.664 µg/ml) respectively while in adult leaves IC50 was not observed. IC50 of hydrosol in young leaves of DPPH and FRAP assays was higher as compared with control and adult leaves. The results also showed that the antioxidant activity of volatile oil and Hydrosol in adults leaves was more than in young leaves. The current study revealed the possibility of using this volatile oil and hydrosol as a natural antioxidants.

Keywords: *Hydrosol, volatile oil, antioxidants, Eucalyptus camaldulensis.*

Introduction

Aromatic plants are used in phytotherapy due to their essential oils and various biological activities such as antioxidant. Exogenous antioxidants can be a natural compounds like vitamins, flavonoids, anthocyanin but it can be also a synthetic like butylated hydroxy toluene[1]. Natural antioxidants are an important compounds to prevent the free radicals during the interaction of oxygen with molecules[2].These radicals are dangerous when they react with DNA and cell membrane[3].Antioxidants delay or inhibit the oxidation processesby affecting the free radical or molecular oxygen[4],so they prevent cellular damage and inhibit the pathway for cancer, aging and diseases[5,6].They also used in foods and cosmetics industries to prevent undesirable oxidation processes. The synthetic antioxidants like butylated hydroxytoluene (BHT) and butylated hydroxyanisole (BHA) are possibly toxicsofinding natural antioxidants has been increased during the last years[7,8].Some herbal extracts and oils formulations have been proved as an important antioxidant agents[9,10] .*Eucalyptus* belongs to Myrtaceae family, it has 500 species endemic to Australia and neighboring territories. Some species have been introduced into Iraq,one of these species is *E. camaldulnesis*[11]. The leaves of this species is sensitive to dust pollution[12] and change as the tree progress from juvenility to adulthood[13], so it can be found as a young (growing tips), Mature (six mo.), aged(12-18 mo.).

The medicinal properties of *Eucalyptus* reside in its oil which is secreted and stored in the sub-dermal cavities[14].The biological effects of this oil include: antiviral,antioxidants, antibacterial, antifungal and treat the respiratory infections as well as sinusitis[15]. The essential oil in association with hydrosol can be obtained through steam distillation process for the leaves of this aromatic plant. The hydrosol contains some of the water-soluble compounds of the essential oil which are the same of those present in volatile oil. Unlike essential oils that should be diluted prior to application attach the skin hydrosol can generally be used directly on the skin without further dilution[16] Hydrosol has been used in different industries such as food and cosmetic as well as to the biological agriculture and soil fertilization[17]. This study was done to determine for the first time, comparison of the antioxidant activity for *Eucalyptus camaldulensis* leaves in Iraq. This work allowed

highlight in the influence of plant leaves maturity on the quantity,activity and chemical composition of essential oil and hydrosol.

Material and Method

Plant collection and extraction: Leaves (young and adult or aged) of *E. camaldulensis* Dehn were harvested in October 2018 from University of Baghdad. These leaves were washed and dried in shade for three days. Dried leaves of this plant were chopped and semi grinded into small pieces and submitted to steam distillation using the Clevenger apparatus for 4 h[18]. Yield percentage was calculated according to the oil ratioequation[19].

$$\text{Extracted oil ratio } \frac{oil\ volume}{sample\ weight} \times 100$$

The (DPPH) assay: 2,2-diphenyl-1,1-picrylhydrazyl: All the chemicals in this study were obtained from Sigma (Sigma-Aldrich GmbH, Germany).2ml of samples at the concentrations (200,400.600,800,1000 µg/ml)were added to the volume(1ml) of theDPPH in methanol solution. The mixture was shaken andstand for half an hourin dark place. Spectrophotometer was used to measure the absorbance of the solution (yellow color) at 517 nm. Percentage (I%) of DPPH was collected as follow :

$$I\% = 100 \times \frac{A\ control - A\ sample}{A\ control}$$

A control=Absorbance of controland A sample is the absorbance of test compound.Butylated hydroxytoluene (BHT) was used as a standard[20].

The FRAP (ferric reducing antioxidant power) method: Volatile oil and Hydrosol reducing powerswere determined according to procedure of[21]. Different concentrations of the extracts were mixed with phosphate buffer and 1% of water solution from potassium ferricyanide. This mixture was kept at 50 °C for 20 min.Trichloroacetic acid was added to the mixture and then centrifuged at 3000 rpm for 10 min. The supernatant was mixed with distilled water and FeCl3 solution.The absorbance was read at 700 nm.

Statistical analysis: The data were reported by using mean±standard deviation for three replicates. The IC50 value µg/ml was calculated by using Excel programme depended on the logarithm(Log.) of each concentration.

Results and Discussion

Plant oil yield: The results show that young leaves of *E. camaldulensis* provide more essential oil (2-4%), while in adult leaves the oil percentage was (1-2%). These leaves provide quantitatively different yields. This result agree with[22] which referred that the aged leaves yield less oil than recently mature. On the other hand the different stages of growth affected the oil yield and its chemical compositions[23].

DPPH scavenging activity and Ferric Reducing Antioxidant power (FRAP) of volatile oil from Eucalyptus leaves: The results show that the antioxidant activity increased by increasing the concentrations.This activity of volatile oil in adult leaves was higher than young leaves in the two different assays (Figure 1 and 2). At the concentrations (200,400µg/ml), the highest value of DPPH activity was obtained from thevolatile oil in adult leaves in addition to its highest FRAP activity for all concentrations as compared with control. On the other hand, the IC50 (the half maximal inhibitory concentration) in both DPPH and FRAP assays was not observed in volatile oil of adult leaveswhile the IC50 of volatile oil in young leaves for the two assays was (237.178 and 243.664 µg/ml) respectively, as compared with BHT(233.001 and 208.855 µg/ml).

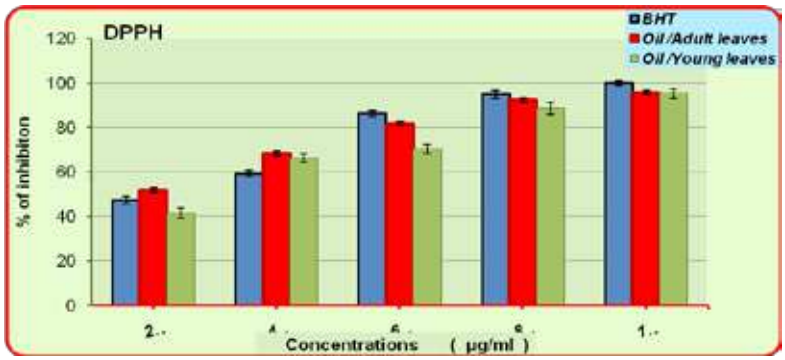

Figure 1: DPPH scavenging activity of E. camaldulensis volatile oil in adult and young leaves.

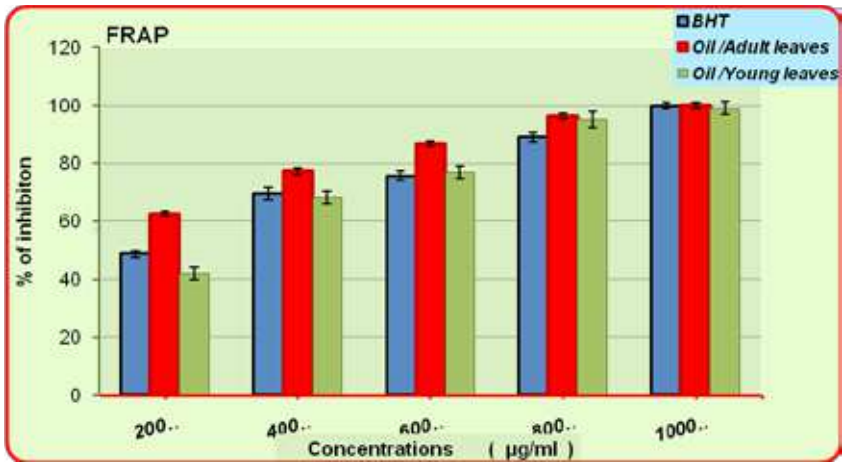

Figure 2: Ferric Reducing Antioxidant Potential of E. camaldulensis volatile oil in adult and young leaves.

DPPH scavenging activity and Ferric Reducing Antioxidant power (FRAP) of Hydrosol from Eucalyptus leaves: (Figure 3 and 4) show that the antioxidant activity of hydrosol in adult leaves was higher than young leaves in the two different assays. At FRAP assay the hydrosol of adult leaves at concentrations (400,600,800) revealed more activity as compared with control.

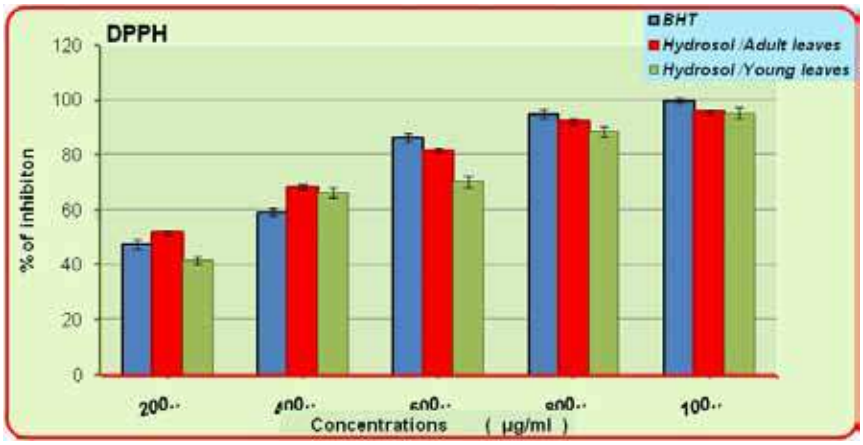

Figure 3: DPPH scavenging activity of E. camaldulensis Hydrosol in adult and young leaves.

On the other hand, IC50 of hydrosol in young leaves of DPPH and FRAP assays was higher as compared with control and adult leaves**.**

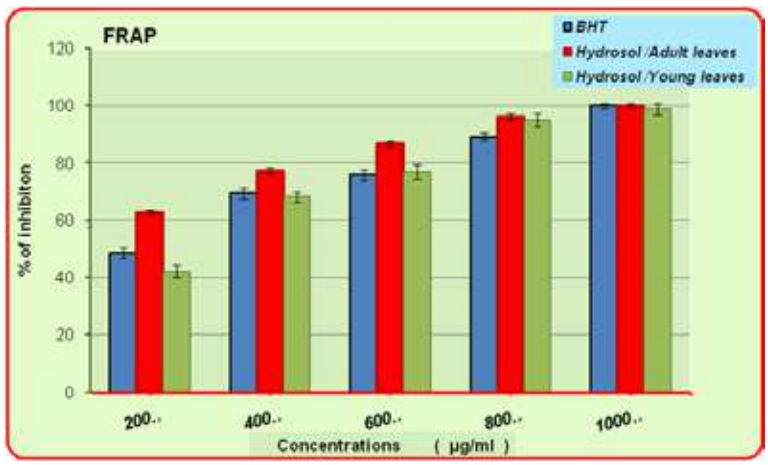

Figure 4: Ferric Reducing Antioxidant Potential of E. camaldulensis Hydrosol in adult and young leaves.

The differences in oils activity found in this experiment between different leaves may be related to the modifications of the oil composition during leaves maturation. The chemical analysis of *E, camaldulensis* essential oil revealed the presence of different compounds including:1.8-cineole, limonene,α-pinene and p-cymene[24]. The antioxidant activity of volatile oil belongs to these compounds and the differences in their concentrations. The stronger free radical inhibitors are active at low concentrations (lower IC50)[25].The disappeared of the IC50 in both DPPH and FRAP assays in volatile oil of adult leaves revealed that it could be appeared in lower concentration than 200 which represented the lower one in this study, so this study indicate that *E. camaldulensis* volatile oil in adult leaves was more active than the control itself.

Conclusion

The volatile oil and hydrosol of *Eucalyptus camaldulensis* can be used as a natural antioxidants. There is an economical importance by using hydrosol as a raw material in the cosmetic industry and food preservation.

E-Health Literacy of Medical Students at a University in Central Vietnam

Lan Hoang Nguyen (Nguyen Hoang Lan)[1], Thuy Bich Thi Le (Le Thi Bich Thuy)[2]

[1]Association Professor. Medical Doctor, PhD, [2]Preventive Medical Doctor, Faculty of Public Health, Hue University of Medicine and Pharmacy, Hue University, 06 Ngo Quyen Street, Hue City, Vietnam

Abstract

Background: The study is to measure eHealth literacy of medical students at a university in central Vietnam and to examine factors influencing their skills.

Material and Method: This is a cross-sectional study. Data were collected through the self-administered structured questionnaire of 410 students who were randomly selected among general medical students and preventive medicine students in the fifth year at Hue University. The eHealth literacy scale was developed on the basis of eHEALS to measure skills for seeking and utilizing sources of eHealth information. Multiple linear regression model was used to identify factors influencing their eHealth literacy.

Results: The study found that the general mean score for eHealth literacy among participants is 27.03 (SD = 3.54). Factors influencing eHealth literacy are genders (p=0.001), training program (p=0.013), computer skills (p=0.031) and purpose of seeking and using medical information (p<0.001).

Conclusions: The findings showed that eHealth literacy of medical students in the study setting is still limited. In order to improve these skills of students, the educators should have relevant teaching strategies that promote the interest and skills of students to locate and evaluate eHealth resources.

Keywords: *eHealth literacy, health resource, medical students, Vietnam.*

Introduction

Along with the development of the digital technology, the internet provides more information than any tool ever to exist. People increasingly expect to interact with health information technology to promote their health.[1] According to Pew Research Center, among 80% of Internet users reported seeking health information online, 58% reported that the information found on their search impacted health decisions and 39% said that the information changed the way to cope with a chronic condition or manage pain.[2,3] Those are referred to as "eHealth" application. Facing information- rich environment, the concept of eHealth has been developed to response to challenges of accessing and effectively using health information technology.[1] Norman and Skinner (2006) defined eHealth literacy as the ability to seek, find, understand, and appraise health information from electronic sources and apply the knowledge gained to addressing or solving a health problem.[4]

eHealth literacy is an important issue for public, therefore health care providers need to have the appropriate skills to assess electronic health information. This will help them identifying issues and misinformation in the electronic resources and therefore improve health education to their target groups.[5] Unfortunately, previous studies report that the level of eHealth literacy of health students was low and that they felt the need for improving their skills in eHealth literacy.[5]

Vietnam's young population and low service costs give the country a higher internet penetration rate than

most of its neighbors in Southeast Asia.[6] According to a statistics, more than 50% of population accessed the internet at least once a month in 2016. Average daily time spent online among internet users in Vietnam was also high compared with neighbor countries.[6] However, eHealth literacy is completely new concept in Vietnam. Scientific researches on this topic are still scarce. This study was conducted at University of Medicine and Pharmacy, Hue University with the aim of measuring eHealth literacy of medical students and examining factors influencing their skills. The findings of the study may provide basic information about eHealth literacy of future healthcare providers.

Material and Method

Site of Study: A descriptive cross sectional survey was conducted in Hue university of Medicine and Pharmacy, Hue University (HUMP). It is located in Hue city that is capital of Thua Thien Hue province, belonging to the central Vietnam. The University is responsible for training health professionals including both graduated and undergraduate levels who served people in all provinces in the central region and central highlands in the country.

Participants: Participants of the study were the fifth year medical students in the year 2017 because this cohort is provided nearly enough basis knowledge and skills of their professional. A sample size of 410 participants including 340 general medical students and 70 preventive medical students were randomly selected using proportional sampling method from a list of 1040 students who enrolled in those training programs. This list was provided from Department of undergraduate student management of the university. Data collection was implemented between July and December 2017.

Instrument: Data were collected using a self-report questionnaire. The questionnaire was structured into 3 parts: part 1 was demographic and socioeconomic profile of students, part 2 included questions about Internet access and electronic health information usage of the participants and part 3 was the eHealth Literacy Scale (eHEALS). eHEALS that was developed from eHEALS suggested by Norman and Skinner is a validated self-report tool to assess the comfort and skills for using electronic resources in health.[7] The eHEALS is an 8-item scale with a 5-point Likert scale ranging from strongly agree to strongly disagree (scores between 1 and 5) was used. The minimum score is 8, maximum is 40, the higher scores correspond to the higher levels of eHealth literacy and vice versa. The reliability of the tool in Vietnamese language was evaluated using Cronbach's alpha by piloting among 50 students (overall Cronbach's alpha was 0.83).

Statistical Analysis: Data was analysed using SPSS software version 16.0. A multiple linear regression model was developed to identify the influence of individual characteristics, learning characteristics, internet accessibility and electronic health information usage on score of eHEALS. A p-value of less than 0.05 was considered statistically significant.

Findings:

Characteristics of Participants: Table 1 descibed that 80% of students aged 23 years old. More than half of them were male. Most of them lived in rented room. 12% of students whose households were classified as poor and near poor according to regulation of Government. The result of previous school year showed that 85.1% of students achieved good level. All students selected English as the foreign language. A few of them studied French as the second foreign language. The majority of students reported their English skills were not good (80.8%). There was 46.6% among them believed that their computer skill was good. Smartphone and laptops were popupar facilities to access to internet.

Table 1. Characteristics of Students

Characteristics		N	%
Sex	Male	184	44.9
	Female	226	55.1
Age (years)	22	328	80.0
	23	73	17.8
	24	9	2.2

Characteristics		N	%
Place of residence	At home with family	34	8.3
	Student's hostel	15	3.7
	Rented room	352	85.8
	House of relatives	9	2.2
Economic condition of household	Near-poor, poor	48	11.7
	Normal	362	88.3
Learning result	Good	349	85.1
	Satisfaction	61	14.9
Foreign Language	English	410	100.0
	French	41	10.0
English level	Good	79	19.2
	Not good	331	80.8
Computer skill	Good	191	46.6
	Not good	219	53.4
Own a facility to access the internet	Yes	408	99.5
	No	2	0.5

eHealth Literacy: The purpose for students to use electronic health information is presented on the table 2. Electronic health information served mainly their learning tasks.

Table 2. Purpose of seeking electronic health information

Purpose	N	%
To look for a solution to health problem	298	72,7
To response to learning tasks	399	97,3
To improve knowledge about health and professional	336	82,0

The average total score on the eHEALS among participants was 27.03 (SD 3.54). Identifying the availability of health resources on the internet achieved the highest score of 3.72 (SD 0.78), followed by skill of finding helpful electronic health resources with mean score of 3.57 (SD 0.84). Skill to define quality of health information on the internet gained lowest score of 2.77 (SD 0.82). The skill of students to use confidently these resources in health decision making got also low score (3.22, SD 0.70) (Table 3)

Table 3. Self-reported eHEALS score of the medical students

eHEALS items	Mean	SD
I know what health resources are available on the Internet	3.72	0.78
I know where to find helpful health resources on the Internet	3.57	0.84
I know how to find helpful health resources on the Internet	3.43	0.84
I know how to use the Internet to answer my questions about health	3.53	0.73
I know how to use the health information I find on the Internet to help me	3.53	0.68
I have the skills I need to evaluate the health resources I find on the Internet	3.25	0.75
I can tell high quality health resources from low quality health resources on the Internet	2.77	0.82
I feel confident in using information from the Internet to make health decisions	3.22	0.70
Total	**27.03**	**3.54**

Factors related to eHealth literacy among medical students

Table 4. Factors related to eHEALS among medical students

Predictors	B (SE)	p-Value	95% CI
Age	-0.01 (0.44)	0.988	-0.86 - 0.85
Sex (Female*)	1.3 (0.4)	0.001	0.55 - 2.10
Economic condition (No poor*)	-0.45 (0.58)	0.433	-1.58 - 0.68
Training program (Preventive medicine *)	1.3 (0.50)	0.013	0.27 - 2.25
Learning classification (Not good *)	0.96 (0.58)	0.096	-0.17 - 2.09
The number of foreign languages studied (one foreign language *)	0.59 (0.46)	0.204	-0.32 - 1.50
English level (Not good *)	0.72 (0.50)	0.148	-0.26 - 1.71
Computer skill (Not good *)	0.89 (0.41)	0.031	0.08 - 1.69
Own a facility to access the internet (Yes *)	- 3.19 (2.65)	0.230	- 8.39 - 2.02
Purpose of seeking electronic health information To look for a solution to health problem (No*)	- 0.04 (0.41)	0.93	-0.85 - 0.78
To response to learning requests (No*)	0.88 (1.13)	0.44	- 1.34 - 3.10
To improve knowledge about health and professional (No*)	1.87 (0.48)	< 0.001	0.93 - 2.80
Constant	24.85 (10.09)	0.014	5.82 - 44.68

* level 0 of dummy variables

Table 4 revealed results of the multiple linear regression analysis. Sex of students, their training program, computer skill and purpose to access health resources on the internet influenced their eHEALS. Mean score of eHEALS in male students is higher 1.3 points than that of females (p = 0.001). Similarly, general medical students showed better level of eHealth literacy than preventive medical students (p= 0.013). The students who were confident of their computer skill gained mean score of 11% higher than others (p= 0.031). The students who accessed electronic health information with the aim at improving their knowledge about health and professional achieved 1.87 points higher than their counterparts (p < 0.001). The study did not find a significant association between eHEALS score with other characteristics of the participants.

Discussion

Mean score for eHEALS of medical students in HUMP was 27.03 (SD= 3.54) which are lower than those in previous studies on health students.[8,9] In Iran, a study revealed that the mean score for eHEALS of the medicine and health science university students was 28.21 (SD=6.95).[5] Park and Lee reported that mean eHEALS score of nursing students in Korea in 2014 was 27.06 (SD= 4.2).[8] The mean eHEALS score of 541 nursing students in Jordan was 28.96 (SD= 4.64).[9] Accessibility to internet and availability of online health information sources are considered as contributing factors to eHealth literacy.[5,10] According to statistics in 2017, the internet penetration rate among population in Vietnam was 53% while this rate was 70% and 73% in Iran and Jordan, respectively.[11,12] In addition, a report of Ministry of Health (2010) revealed that dissemination of health information via the webs were still limited and sharing these sources among electronic libraries of health science universities in Vietnam had restricted because of lack of interconnection system.[13]

Among eHEALS items, skills of participants to differentiate between good and poor quality of health resources was evaluated at the lowest level. This finding was supported by many previous studies.[5,8,9] Authors indicated that health science students could access health related website but they could not identify a trustable information sources.[5] Medical students will be future health care providers who are considered as a reliable health information source. This skill will help them identifying misinformation in the social media, therefore provide better advise to their target groups.[5] Besides, this will meet demand of clients in utilizing eHealth to promote and sustain their health in context of the digital era. Authors suggested that eHealth literacy skills should

be incorporate into the curriculum of health science students in general and medical students in special.[8,9]

Multiple linear regression analysis showed that eHEALS of male students was better than those of females. Our result is similar to that of Dasti et al (2017).[5] In some communities, the young male are more convenient to access internet compared to the female. They had opportunity to spend more time on the internet. Level of access to the internet was suggested to be one of factors improving eHealth literacy.[10] However the relationship between gender and eHealth literacy was found inconsistently among former studies.[14,15,16] The difference in culture of study settings, participants of studies might result in these various findings.

Training program was other factor that influenced eHealth literacy in the study. General medical students had higher eHEALS score than preventive medical students. Compare to training program of preventive medicine, the one of general medicine program is larger. It requires more professional knowledge and skills. More utilization of eHealth resources to respond learning task and improve professional knowledge could result in higher level of eHealth literacy among general medical students.

Levels of proficiency in web usage have direct impact on eHealth literacy because they include capacity to effectively search, navigate using links and scroll in web page. These are essential to develop computer literacy that is one of six components of eHealth literacy.[4,10] Understandingly, good computer skills of participants had positively impact on eHealth literacy.

The current study revealed potential limitations. First, a self-report tool measuring eHealth literacy was adapted for medical students in Vietnamese language. Although pilot research showed that the scale was good internal consistency with Cronbach alpha = 0.83. It is necessary to validate translated tool in the future study in Vietnam. Second, the study included students in the fifth year of two training programs, they are not representative for all medical students in HUMP. However this is the first study measuring eHealth literacy among medical students in the Vietnam, the findings can provide preliminary evidences to enhance eHealth literacy to meet the needs of health care in the new digital era.

Conclusions

This study indicated that eHealth literacy of medical students in HUMP is still limited. It is suggested that eHealth literacy concepts should be introduced to medical students as a topic of subject "health education and communication". Educators should encourage relevant teaching strategies that promote the interest and skills of medical students to locate and evaluate health resources available on the internet.

Conflict of Interest and Funding: The authors have no potential conflict of interest.

This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

Ethics Statement: Approval for the study proposal was obtained from HUMP. In addition, approval for implementing the study at the classes was obtained from Department of Student Management of the University. The self-report questionnaire was given to students with their permission after they were introduced adequate information about the study in a consent form. Ethical principles of research on human subjects such as autonomy, beneficence, and justice were introduced in this form. The vulnerable populations did not present in our study.

Phenomenological Study: Nurses Experiences in Collaboration with Physician and Witch-doctors in Initial Management of Emergency Trauma Patient in Puskesmas of East Sumba Regency, East Nusa Tenggara, Indonesia

Leni Landudjama[1], Lilik Zuhriyah[2], Septi Dewi Rachmawati[2]

[1]Students of Nursing Master Program in Faculty of Medicine, University of Brawijaya, [2]Lecturer in Faculty of Medicine, University of Brawijaya, Malang Indonesia

Abstract

Introduction: Communities in the area of East Sumba in meeting its health is influenced by cultural traditions and handling of traditional treatment. The provision of health services at the community health center (*Puskesmas*) is often referred to health centers requires collaboration among health professionals. Medical collaboration process influenced by the culture and traditions of the people so do also the collaboration process traditionally by witch-doctors in the initial treatment of trauma patients in the *Puskesmas*. The aim of research to explore the nurses experience collaborate with doctors and witch-doctors in the initial handling emergency trauma patients at the *Puskesmas* East Sumba, East Nusa Tenggara.

Method: The research method of qualitative research design using interpretive phenomenological approach. Participants totaled 7 nurse health center, taken by purposive sampling. Collecting data through semi-structured interviews with in-depth interviews and open-ended question. Data were analyzed using phenomenology interpretative analysis (IPA).

Result: The results of this study obtained four themes, namely theme 1: Responsible for performing their duties in collaboration, theme 2: Pros Cons collaborative process with witch-doctors, theme 3: Receiving treatment witch-doctor but under close supervision, and theme 4: Feeling strange but true to the success of the witch-doctor. The process of collaboration between health professionals by nurses and doctors as well as traditional collaboration with witch-doctors in the early treatment of trauma is done in the *Puskesmas*. Traditional treatment options by witch-doctor is a tradition that is believed to be public, proven and successful cure the patient. Nurses as health workers in *Puskesmas* receive the tradition but remains under close supervision by nurse.

Conclusion: Initial management of trauma patients is done in the *Puskesmas* in the process of collaboration between nurses, doctors and witch-doctors to save the patient. Witch-doctor collaboration process in the initial treatment of trauma can not be avoided but successful and remain in the supervision of health workers in *Puskesmas*. Important local cultural considerations in nursing care based on the culture of early trauma treatment in the *Puskesmas*.

Keywords: *Nurses experiences, Collaboration with physician, Collaboration with witch-doctors, Initial management, emergency trauma.*

Introduction

According to the World Health Organization (WHO), trauma has a very high prevalence of more than 9 people die every minute due to trauma and violence. Trauma caused more than 1 million deaths each year and about 20 million to 50 million people suffered severe injuries that trauma is the leading cause of death worldwide(1). In developing countries, significantly more than 90% of accidents occur as a result of a motor vehicle, and projected mortality due to these accidents

increased by 80% in countries of low and middle income[1]. Trauma treatment in East Sumba, East Nusa Tenggara, Indonesia, treated myself as much as 78.3%, traditionally treated as much as 19.8% and treated by medical personnel as much as 19.3%[2].

In Indonesia, there is community health centers called *Puskesmas* as a primary care role to give early treatment in case of such as trauma cases[3]. Nurses in community health centers (*Puskesmas*) in dealing with trauma patients requires collaboration among professionals in the handling of such collaboration with physicians and other health workers in health centers[3]. Initial management of trauma patients in the *Puskesmas* East Sumba influenced by the habits of the local community in deciding the treatment of trauma that would be done medically, traditional and treated themselves. Nursing staff are also required to provide professional nursing care based on cultural characteristics that already exists in the local community[4].

Basic theory of nursing that can be used according to the customs and culture of the local community based Transcultural nursing theory by Madeleine M. Leininger. Nurses provide nursing care to individuals, groups, communities within the context of diverse health decisions and actions have to be traditional treatments, the practice of professionals nursing care or medical-care. It could affect the preservation, negotiation and restructuring of cultural care to improve the health and well-being of the client[5].

Interviews with nurses in *Puskesmas* conducted during preliminary studies in several *Puskesmas* East Sumba, obtained the data that nurses conduct collaborative medical treatment and also traditionally like the handling of closed or open fractures, sprains and dislocations. Massage witch-doctor allow health workers perform simple massage, but do not allow to touch the wound was cleaned.

This is supported by statements of other participants who have ever come across cases of trauma patients, underwent the process of initial treatment in the *Puskesmas* and will be referred immediately but relatives of patients choose traditional treatments. In addition, the patient's family chose to call witch-doctor to treat patients. Furthermore, the families asked the patient is discharged to receive more traditional treatment at home.

Phenomenological study approach to explore more deeply related to the real experience of facing the nursing profession in the health center in the first treatment of trauma patients. Through this approach, the nursing perspective, uniqueness and justification of nursing disciplines ever experienced nurses will not be lost but can be explored more in depth[6]. Therefore, researchers are interested in more depth about the experience of the nurse collaboration with doctors and witch-doctors in the initial treatment of trauma patients in the *Puskesmas*.

Method

This study was a qualitative research approach interpretive phenomenology[7]. The number of respondents were taken by purposive sampling is seven nurses *Puskesmas* in East Sumba, East Nusa Tenggara. Method of data collection using semi-structured interviews with in-depth interview to the participants and used open-ended question. Analysis of the data is interpretative phenomenology analysis (IPA) to the stages of reading and re-reading, initial noting, developing emergent themes, searching for connections across emergent themes, moving the next cases, looking for patterns across cases.

Findings and Discussion

The result of this research is a theme that is generated from the data analysis process research results that there are 4 themes as a result of this research and has been adapted to the purpose of research on the process of collaboration in the initial treatment of trauma patients. The findings of this study four themes along with the discussion are as follows:

Theme 1: Responsible for performing their duties in collaboration: This theme is a process of collaboration between health professionals and an important component in improving the quality of health services in *Puskesmas* as primary basic level that can be reached by the public. This theme is there based on the statements of participants who were interviewed are:

R3: "…the process of teamwork in the ER, we conduct management ... the emergency accident that should be referred…handling pas came we clean the wound, treat wounds, post infusion, the observation first, lest he vomit...check out the state...patients with suspected severe head injury, we observed the first few minutes...usually we will refer the patient to hospital…"

R7: "…an accident..that hit these two girls...we've been working in a team to give early treatment…"

R5: "…from the beginning we have collaboration with doctors...see the general situation…"

R5: "…patients with accident...I help the doctor... sew all her veins...continue straight closed...while it also directly refer…"

R2: "…the decision of the doctor, if the doctor does not exist, remains to be consul to doctor while we handle...doctor who instructed the therapy until the decision to do the referral process…"

The process of collaboration between nurses and physicians in the initial management of trauma in the form of teamwork in the ER. This is done in accordance with the responsibilities of each task and sometimes a nurse helps the doctor or a physician assistant in the treatment of trauma patients such as suturing. Collaboration is woven well and done in the form of teamwork health outposts can meet the needs of the initial treatment of trauma.

Collaboration among health professionals is also necessary to meet the needs of a range of public health services in underdeveloped areas.[8] It collaboration among healthcare professionals in health center practice environment at the primary level as the health center must be run in accordance with the role of each profession so complementary in running nursing practice, medical and traditional. This can be done in accordance with the wishes of the patient and family, or the decision to accept the process of handling.[9] Previous studies also suggested that the collaborative model implemented at all levels of government to empower the community in accordance with the performance indicators of each stakeholders to improve public health in terms of early detection, prevention and control of non-communicable diseases.[10]

Theme 2: Pro Cons collaborative process with the witch-doctor: This theme is based on the statement of the participants in the interviews conducted as follows:

R1: "…we give the understanding...this can be conducted...but we are afraid of there is infection if only massaged…"

R2: "…if the kinds of cons we're afraid if they take home medicine, that we prohibited, we always said should not take the medicine at the same village and medical drugs...we have no control…"

R3: "...not all of our nurses and doctors who allowed so...to deal with witch-doctor...not all cases..."

R2: "…it was hard to talk, knowing already the Sumba right cannot be separated from the village medicine...depending on customs and their beliefs…"

R5: "...we want to oppose but difficult ...if myself received and not received has it...the family wants to sort...responsibility... especially if in the village with the conditions here, it is tradition..."

R5: "...people believe about it...there are herbs that can be affixed and the evidence they recovered ...a trauma patient such as fracture...of the family...ask a masseur or bring a masseur here...it is tradition..."

Collaboration with the witch-doctor performed in the *Puskesmas* to assist in the initial handling trauma patients even though there are pros and cons to it. Nurses have a sense of worry about the complications that may occur as a result of handling witch-doctor on infection and treatment. There is a ban for not taking the drugs simultaneously medical and traditional, but nurses cannot go against the tradition because it was believed by the local communities related to the handling of the witch-doctor. The patient's family or society already believe and trust in the proven tradition of handling quack cure. Tradition witch-doctor handling cannot be challenged by the nurse health center, otherwise the nurse resigned to the tradition of handling witch-doctors believed and proved to cure the patient.

Partnership collaboration culture-based health workers can affect the improvement of health outcomes and involvement of community participation in health services[11], Collaboration traditional witch-doctor tradition of collaboration with real success in handling, restoring and maintaining the health of patients adjusted well to the confidence and trust of the public and health professionals about the culture[5].

Theme 3: Receive witch-doctor handling practices but under close supervision: This theme is in accordance with the statement of the participants are:

R4: "...the only way there should be a collaboration... could not only his own actions...must ask the help of other people…who have other skills...without going through formal education...bring a masseur that helped... to save people...a decision we have to take…"

R4: "...so masseur already we call and it was believable..."

R7: "...there was...family who asked...sometimes closed fracture if any accident they say should be massage...it's tradition...we respect that decision..."

R2: "...sometimes we work together...if only normal trauma, the patient's family asked the witch-doctor to came at the health center to massage...to be in front of the nurse...should not without supervision... calling the witch-doctor or sprayed so...we also conduct collaboration... medicine medical still be served, but the massage with drugs remaining..."

R7: "...there is supervision and we do not let that... his fracture was irregular...it is not allowed..."

The nurse stated that there is a process of collaboration with herbalists traditional massage in cases of trauma such as a fracture or dislocation in the *Puskesmas*. Nurses receive treatment collaboration witch-doctor, knowing that cannot be alone in taking action early treatment. Nurses also need the help of others even though the person is not through a formal health education but is believed to help provide early treatment. Decisions collaboration with the witch-doctor is the only way that can be taken to help nurses initial handling for the sake of patient safety. Nurses accept and respect the decision of the family choose quack but the handling of supervision of nurses in *Puskesmas*. This decision is influenced by family who is used to use traditional treatment.

Collaboration with the witch-doctor has become a habit the local community and is considered a tradition that affect the behavior of people who believe the witch-doctor in cases of trauma such as fractures and dislocations. Behavior in finding where the handling of public health issues is also influenced by the concept of healthy and sick trusted by the local community such as culture and tradition to follow a traditional treatment that affects the concept of beliefs, attitudes and behaviors of people who agreed to elect to undergo the process of handling by herbalists[12].

Theme 4: Feel strange but true to the success of the witch-doctor: This theme is in accordance with the statement of the participants are:

R4: "...we are at odds...with our medical science has...a collaboration that we did...even if one track...but what can we do...yes it is...like a strange thing is not real but it is real...eight trauma patients was massaged and it worked...from the initially hesitant...but all are safe, and also collaboration is also established with good..."

Nurses feel strange for the success of the witch-doctor in dealing with trauma patients. The nurse stated that witch-doctors have another without going through formal education related to the handling of cases of trauma, but strangely or witch-doctor miraculously managed to handle trauma patients. Handling traditionally by witch-doctors massage has become a local tradition in dealing with cases of trauma such as a fracture or dislocation. The success led to nurse feels strange witch-doctor as believers do not believe it but the real observed that witch-doctors successfully handle trauma patients.

Successful handling of witch-doctor profitable and has become a local culture can be preserved, accommodation and re-negotiated or modified in accordance with the Transcultural nursing theory by Madelenie M. Leininger, known as culture-based nursing care[5]. Improvement of health and health behaviors can be done with the involvement of people who are already receiving and trusting culture related to the tradition of handling traditional so it can be developed as an innovative approach to patient care in underdeveloped areas where people still believe in the tradition that is handling or traditional treatment is proven to provide relief for patients[11].

Conclusions

Initial management of trauma patients is done in the *Puskesmas* requires a collaborative process, whether it is a medical collaboration between nurses and doctors or traditional collaboration involving witch-doctor massage. This was done with the aim of saving the lives of patients. The process of initial treatment of trauma involving collaboration with herbalists massage becomes a matter that cannot be avoided, but still in control of health workers in *Puskesmas*. This is due to the strong culture of the people who still believe in the traditional treatment by a witch-doctor, so that their culture be important for consideration by nurses in *Puskesmas* to provide nursing care based on the local culture in the initial treatment of trauma.

Conflict of Interest: There is no conflict of interest in this study.

Source of Funding: Sources of funding in this study were derived from private funds researchers.

Ethical Clearance: This study was approved by ethics committee ethical clearance from the Medical Faculty of Nusa Cendana Kupang, East Nusa Tenggara Indonesia with numbers: 04/UN15.16/KEPK/2019.

Determinant Factors of Alcohol Consumption by Adolescents

Liena Sofiana[1], Suci Musvita Ayu[1], Marsiana Wibowo[1], Erni Gustina[1], Azip Hasbi Asidik[1]

[1]Faculty of Public Health, Ahmad Dahlan University

Abstract

Objectives: The harmful use of alcohol was a causal factor in more than 200 diseases and injury conditions. The percentage of alcohol consumption at age 15-19 years in Indonesian were male (3.4%)and female (1.5%).Alcohol consumption is association with a risk of developing health problems, such as mental and behavior disorder which includes alcohol dependence and mayor non-communicable disease.

Method: This was an analytic observational research with Cross Sectional design. The population were all students of Senior High School or the equal, in Yogyakarta City. Sample size in the research are 380 students. Technic sampling is used Multi-stage random sampling. The Research used questionnaire as the instrument. To analyze the data is used univariate analysis and bivariate analysis (chi-square).

Results: The results show that 40.1% of adolescent in Yogyakarta City consume or once consumed alcohol, while 26.6% were alcohol dependence/harmful alcohol dependence. Bivariate analysis results in the following. Knowledge (p= 0.000; RP=0.541); attitude (p= 0.000; RP 2.510); self-confidence (p=0.001; RP=1.566); family role (p=0.016; RP=1.396); teacher role (p=0.000; RP=1.960); peer role (p= 0.000; RP 2.953); information resources (p=0.436; RP 1.103).

Conclusions: There was relationship among knowledge, attitude, self-confidence, family role, teacher role, and peer role, and alcohol consumption by adolescent. There is no correlation between information sources and alcohol consumption by adolescent.

Keywords: *Knowledge, attitude, self confidence, family, teacher's role, peers, information sources, alcohol consumption, adolescent.*

Introduction

Excessive use of alcohol is the causal factor of more than 200 diseases and injuries. 5.1% of them are caused by alcohol consumption. In addition, it causes disability and fatality. Among the age group of 20-39 years old, 25% of total fatality is caused by alcoholism. In 2012, 3.3 million of death is caused by alcoholism, or 5.9% of the total mortality number.[1] Alcohol consumption in South East Asia of the age group above 15 years old, per capita, is 3.4 liters of pure alcohol. It is projected to increase in 5-10 years along with the increasing number of adolescents. Thus, it increases the potential consumers. In 2010, the proportion of alcohol consumption in Southeast Asia, of the age group of 15-19, showed 5.9% of ex-drinker and 8.2% drinkers.[2]

In 2010, the alcohol consumption per capita in Indonesia showed that male consumed 1.1 liter of alcohol, while female took 0.1 liter.[3] The percentage of alcohol consumption in the country for the age group of 15-19 years old are 3.4% and 1.5% for male and female, respectively. The number is small but it is a clear evidence that Indonesian youngsters consume alcohol.[4]

Alcohol consumption may influence individuals' behavior. Alcohol has encouraged the youth to commit crime, reaching 2%.[5] Juvenile delinquency in Indonesia, particularly in Yogyakarta Special Region Province,

is categorized as severe by the evidence of several incidence, such as school brawling, getting drunk, unwed pregnancy, and so on. Being rebellious is not an only cause of misbehavior. Instead, child rearing or environment may be another factor.[6] This research aims to know the relation among predisposing, reinforcing, and enabling factor and alcohol consumption by adolescents in Yogyakarta.

Materials and Method

This study belongs to observational analytic research with cross sectional design. The research is conducted in all senior high schools, and the equal, in Yogyakarta City, of which all the students become the population, as many as 36.360 students. The samples were taken using Multi-stage random sampling. Sample size among this research is 380 adolescents. The instruments include questionnaires to measure the variables of knowledge, attitude, confidence, family roles, teachers' role, peer roles, and information sources. The research used the instrument adopted from The Alcohol Use Disorders Identification Test published by WHO. The analysis data employed Chi square.

Results

They have low level of knowledge and consume alcohol (27.8%). 129 adolescent (51.4%) who consume alcohol have high level of knowledge. There was relation between knowledge and consume alcohol among adolescent (p=0.000; RP=0.541; CI95%=0.43-0.69). There was relationship between attitude and alcohol consumption (p=0.000; RP=2.510; CI 95%= 1.972-3.196).There was relationship between self-confidence and alcohol consumption (p=0.001; RP=1.566; CI95%=1.25-1.96). There was relation between family roles and alcohol consumption (p=0.016; RP=1.396; CI95%=1.098-1.775).There was relation between teachers' roles and alcohol consumption (p=0.000; RP=1.960; CI 95% = 1.604-2.397).There was relationship between peers' roles and alcohol consumption (p=0.000; RP=2.953; CI95% =2.362-3.692). There was no relation between information resources and alcohol consumption (p=0.436; RP=1.103; CI95%= 0.885-1.374).

Table 1: Determinant Factors of Alcohol Consumption by Adolescents in Yogyakarta City, Indonesia

Discussion

The Correlation between Knowledge and Alcohol Consumption: Adolescents who have low knowledge as a protective factor not to consume alcohol. This situation is because teenagers who do not consume alcohol have no knowledge of the type of alcohol and the aroma of alcohol. While someone who consumes alcohol at least more often see, have physical contact with, know, and obtain the information about alcohol compared to those who do not. They get the information through their senses, particularly sight and hearing.[7]Individual who have learned the effects of drinking will think twice to consume it. Indeed, it is more likely that they will avoid it. Those who take good care of their life will not harm themselves.[8]Previous research showed there is a relation between poor knowledge about the effects of alcohol and the drinking behavior of adolescent where the higher is the score of poor knowledge, the higher is the number of alcohol drinking by adolescence.[9]

The Correlation between Attitude and Alcohol Consumption: Attitude influences alcohol consumption by adolescents in Yogyakarta. Attitude is the second level of behavior before an individual takes an action. Attitude is a readiness to act, but it is not an implementation of a motive. It is a response that involves opinion and emotion.[7]Previous research shows there is a relation between attitude and alcohol consumption by adolescent. The occurrence of those with negative attitude is 14.88 times comparedto adolescents who have positive attitude.[10]Another research show there no relation between attitude and the prevention of alcohol consumptive.[11]

Attitude is part of the process of changing behavior. It means that attitude is not yet operate in an action or behavior. It is not always manifested in a real action. An action can be illustrated by attitude of like-dislike, or agree-disagree. However, the attitude can influence particular behavior, such as preventing alcohol consumption. An individual has the opinion and tendency to avoid alcohol consumption, but pressure, lack of confidence, or other factors may cause the attitude cannot manifest in the real action.

The Correlation between Self-confidence and alcohol consumption: Confidence influences an individual's attitude and behavior. An individual's belief in his capability or confidence will lead him to do what he wants. Meanwhile, those who lack of confidence tend to doubt his action. Indeed, they tend to avoid the action. Self-confidence is the key factor in making an individual feel more optimistic and try to adapt the environment. Nevertheless, self-confidence for conducting negative may harm others. It is supported by the idea that self-confidence is a positive assessment on a self, which raises the individual's motivation to respect himself.[12]

Frequently, adolescents drink alcohol to gain self-confidence and eliminate shyness, stress, and depression. Alcohol belongs to anti-depressant of central nerve system that presses the control shyness and avoidance, as well as influencing the conscience.[13] Thus, drinking individuals cannot control their behavior and conscience, allowing them to gain more confidence. If this continues, the individuals will be addicted and they will experience a kind of mental disorder, leading to other health problems.

Other research that is in line with the result concludes that self-confidence contributes to juvenile delinquency, but it has negative correlation value. It means that the higher the self-confidence, the less the occurrence of juvenile delinquency. Alcohol consumption belongs to one of the mentioned delinquency.[14]

The relation between family and alcohol consumption: In families less participating, the number of alcohol consumption is higher compared to those whose family have greater roles. The family's participation in preventing youth from drinking alcohol is not enough to encourage the youth to leave it. Family role is not the only factor in this case. Theoretically, parents' role will root within an individual to interact with himself or with others.[8] Good interaction will help to shape adolescence's behavior.

The research is supported by another research conducted to underage inmates, ranged from 15 to 18 years old. It shows that children's attachment to their father, particularly when it decreases, lead to improve the numbers of juvenile delinquency.[15] The most influential factor of adolescent alcohol consumption is their parents.[16] The quality of parents-children relationship reflects the level of warmth, security, confidence, positive affective, and response.[17]

The Correlation between Teacher's role and alcohol consumption: In this study, it is known that teacher has not been fully capable of encouraging adolescents not to drink alcohol, apart from other influencing factors, such as environment and peers.The previous research shows that 80.6% of students perform

unhealthy behavior because their teachers do not concern much about them. The relation is significant.[18]Children and adolescents tend to imitate the adults. In this case, teachers are the adults they see at school. It is expected that the policies, regulation, and sanctions arranged by the teachers help the adolescents to behave better.

Teachers can strengthen students in performing good deeds. This strengthening factor is concomitant factor following the behavior, such as giving sanction, incentive, or punishment upon the behavior. Teachers also participate in maintaining or eliminating the behavior.[19] Teachers have the power to influence the values and characters of the students in three ways: be an effective caregiver by loving and respecting the students; be a good model inside and outside the classroom; and be an ethical counselor by providing moral teaching.[20]

The Correlation between Peers and alcohol consumption: The role of friends becomes a reinforcing influence for adolescents to consume alcohol. Previous research show that one of the reasons causing an individual to drink is the environment.[21]Youth who spend their time with peers who drink alcohol are likely to develop drinking habit. Other research supports the results, showing that there is positive and significant relation between peers' attachment and juvenile delinquency. The finding indicates that attachment to peers is the risk factor that causes juvenile delinquency, one of them is alcohol consumption.[15]

Adolescents have more time to spend with their peers rather than to their family. Indeed, it is common that peers come first before the parents, for individuals tend to easily actualize themselves and live their own choices without their parents.[8]Mostly, drinking alcohol becomes the main social activities of male adolescents. It also becomes their social symbol.[22]

Peers are influential social agent for individuals. These individuals are willing to do anything to join their peers in a group, such as smoking, drinking, or any other activities.[23] Previous research shows significant relation between peers giving negative influence and alcohol consumption by adolescents. It reached OR=9.64, meaning that the occurrence of alcohol consumption is 9.64 times bigger in adolescents receiving negative influence than those receiving positive influence.[10]

The relationship between Information Sources and Alcohol Consumption: Information sources do not relationship with alcohol consumption by adolescents in Yogyakarta City. A study shows that the respondents exposed by alcohol advertisement indicate an increase in their willingness to drink compared to those who are exposed to non-alcoholic advertisement. Warning advertisement of the effects of alcohol indirectly contributes to decrease alcohol consumption.[24] Mass media becomes strong influence in shaping public opinion and behavior. Other study found that mass media causes assertive behavior and the tendency of juvenile delinquency.[25] Youth behavior that leads to alcohol consumption can be influenced by advertisement. It results in significant relation between cigarette advertisement and smoking behavior by students of junior high schools.[26]

However, the present study shows that information sources or mass media does not give negative effect. The problem is not on the type or the number of mass media, but from the characteristics (positive or negative) and the attitude of the receiver of information. Conversely, information sources can give positive impact.[27]If the information provided by the mass media is positive, it brings good knowledge which leads to good attitude reflected in the real life. The higher the access to positive information sources, the more knowledge obtained and the more positive the behavior.

Conclusion

There was relationship between knowledge, attitudes, self-confidence, family role, teacher's role, and peer role with alcohol consumption in adolescents. There was no relationship between information sources and alcohol consumption in adolescents in the city of Yogyakarta. Provide understanding to adolescents about healthy living behaviors such as avoiding alcohol consumption and involving parents, teachers and friends in supporting teenagers to avoid alcohol consumption.

The Effects of Infant Massage on the Physical Development of Baby in Indonesian Rural Areas

Lusiana Gultom

Health Polytechnic Medan, Ministry of Health, Medan-Indonesia,
Jamin Ginting Street Km. 13.5 Laucih, Medan, Indonesia

Abstract

Introduction: Infant massage has been a long time and common practice. Mother plays an important role in ensuring the effectiveness of infant massage. This research attempts to find out the effects of infant massage training and education on the infant's physical development for mother in rural areas in Indonesia.

Material and Method: This study was designed to compare two groups, namely, the first group of 17 mothers with infant massage education and training intervention since the third trimester, and the second group of 17 mothers without intervention. Body weight, body length, circumference of the upper arms, suckling frequency and suckling duration of the babies in the two groups were compared one month after delivery.

Results: One month after the group of mothers giving massage to their babies, there were significant differences ($p<0.05$)in body weight, body length, suckling frequency of the babies in the two groups, while none for circumference of upper arms and suckling duration. Comparing the effects of massage on babies before and after giving infant massage, there were significant differences in suckling durations and body weight of the babies.

Conclusion: Our study suggests that, after receiving an education on infant massage, mothers with babies are recommended to give massage to their babies. Infant massage brings various benefits to the babies, and it can be performed in natural contexts, including in rural setting.

Keywords: *Infant massage, baby development, mother-child interaction, rural setting, Indonesia.*

Introduction

The benefits of massage for babies have been long recognized. Massage stimulates babies to have better physical growth and become a powerful stimulus to the early life of a baby[1]. It also creates a closer mother-infant bonding[2]. Newborn babies receiving massage are known to make a quickly health recovery when they are sick[3].

Since mothers in many cultures are responsible for the well-being and care of their babies, then they could play strategic roles in stunting prevention. The data issued by the World Bank reveal that, in 2013, as many as 37% of Indonesian children under five years of age or equal to 9 million children suffered from stunting[4]. The number decreased to 30% in 2018[5]. The data from the Indonesian Ministry of Health show that most cases of child stunting occur in rural areas.

Mothers should be empowered, among others, through infant massage training. Most existing researchers so far have discussed infant message in the contexts of hospitals or other health facilities. As far as the researcher is concerned, a very few studies have been carried out with regard to discussions on the effects of infant massage to infant growth, and how mothers get involved in the activity in the natural contexts of their daily life. This research is then an attempt to examine the effects of mother's involvement in infant massage in the context of rural areas in Indonesia.

Material and Method

This research,involving 34 mothers having pregnancy in their third trimester, was conducted in the Village of Perlis, an area under the supervision of Tangkahan Durian Health Center, and Pangkalan

Brandan, Langkat Regencies, North Sumatra Province in Indonesia. This is a quasi-experimental research[6] by having two groups. The first group, the intervention group, is the mothers who were given infant massage training, a note book and leaflet on infant massage. The second group, the non-intervention group, is the mothers who only had note book with them.

The intervention group received trainings in infant massage for 4 consecutive days. The trainings were led by instructors and the object of massage was infant phantom. Trainings were carried out simultaneously in the village maternity clinic. Leaflet provided extra information about infant massage.

After giving birth, the mothers got the same trainings for 4 consecutive days. The mothers were asked to massage their babies twice a day- when the babies were taking a bath in the morning and in the afternoon- for the duration of 30 days. The researcher supervised the process of infant massage. Before massage was given, the weight, length, and circumference of the upper arms of the babies were measured. The researcher also interviewed the mothers about the suckling frequency and suckling duration of their babies.The data were recorded in the note book distributed to each mother before.

Meanwhile, the non-intervention group received note book and leaflet. The mothers in this group accepted explanation of how important massage is for their babies. However, they did not receive any training in infant massage. The measurements of baby weight, length, circumference of the upper arms, and suckling frequency and duration were made every week until the fourth week.

Infant massage took place for 25 minutes. Massage started in the face area, then chest, stomach, arms, legs, and back of the head. Each area was slowly and gently massaged. When giving the massage, the mother maintained eye contact and "communicated" with her baby. A series of massage was done 6 times for 8 seconds each. Baby oil was used for the infant massage.

The body weight of baby (in grams) was measured with a special weight scale, GEA. The measurement results were converted into NCHS category, namely,standard deviation (SD) <-3 to<-2 and SD -2 to SD 2. The body length of baby (in centimetres) was measured with a paper measuring gauge. The measurement results were also converted also into NCHS category like the body weight. The circumference of the upper arms of baby was measured with an arm gauge for baby, and categorized into >0,5 cm/month or < 0,5 cm/month. Suckling frequency of baby was categorized into >10 time suckling frequency/day or <10 time suckling frequency/day. Suckling duration of baby was categorized into >15 minutes or <15 minutes.

Each group and between the intervention and non-intervention groups were compared and were tests with 95% CI.

Results

This study involved 34 mothers who were in the third trimester of pregnancy. All mothers had safe delivery with the total of 19 male babies and 15 female babies. Most female babies (65%) were from the non-intervention group. Seen from pregnancy interval and mother parity, the profiles of the two groups were similar. The majority of mothers' latest pregnancy interval was 2 years. Most were multiparous women (70.6% of multiparity in each group).In the intervention group, 64.7% of mothers were in their 20-≤30 years of age while in the non-intervention group were little bit older (see Table 1).

Table 2 provides the differences of the two groups. In the intervention group, all mean variable values increase significantly after 4-week intervention. There are increases in body weight as much as 26.8%, body length as much as 5.2%, circumference of uppers arms as much as 11.8%, suckling frequency as much as 44.7%, and suckling duration as much as 61.6% after intervention. All changing conditions are statistically different (p-value <0.05).

The babies in the non-intervention group undergo the following conditions. There are increases in body weight as much as 22%, body length as much as 1%, and circumference of upper arms as much as 11.9%.There are slightly difference in suckling frequency (13.2%) and suckling duration (52.4%). All changing conditions, but body length, in this group have statistical values (p)<0.05.

The differences between the intervention group and non-intervention group come up with different statistical test results. For body weight, body length, and suckling frequency variables, the differences are statistically significant (p<0.05), while circumference of upper arms and suckling duration variables do not indicate any difference.

The differences between the groups are clearly seen in Picture 1. It indicates weekly changes in each variable. Body weights of all babies increase steadily until the third week yet several babies gain significant body weights in the fourth week. The maximum gain weight for several babies in the intervention group is 1000 grams while in the non-intervention group, 700 grams. The same pattern also applies to the body length of the baby. In the first two weeks, the body length reach of the babies in the two groups is relatively the same. However, from the third to the fourth weeks, the babies in the intervention group grow more significantly in body length compared to those in the non-intervention group. Picture 1 part c presents the changes in the circumference of uppers arms. Striking changes are seen in third and then fourth weeks. Suckling frequency and suckling duration of the babies in the intervention groups are much better than those in the non-intervention group when intervention enters the third week.

Table 1. Comparison of mother's demographics and infant characteristics in intervention and non-intervention groups

Characteristics	Intervention group		Non-intervention group	
	n	(%)	N	(%)
Mother's Age				
>30 years of age	6	35.3	9	52.9
20-≤30 years of age	11	64.7	8	47.1

Discussion

Educating mothers about infant massage certainly has beneficial effects on their babies. The best time for mothers to receive infant massage education is during the period of entering the third trimester of pregnancy to one month after delivery. Babies having massage undergo physical development in terms of body weight, body length, and circumference of upper arms. They look comfortable during breastfeeding. This condition indirectly create an intimate connection between mother and her baby.

Previous study reveals that after having one-year massage right after their birth, babies record higher scores for motor and mental development. The babies pain responses are low and have shorter LoS (length of stay) in hospital[3].

This study also suggests that appropriate infant massage techniques performed by the mother stimulate her baby to gain body weight significantly[7,8]. Infant massage and physical exercises could cause rapid weight gain for pre term infants as well[9]. With massage and physical exercises, babies show significant growth

in their bone length as shown in their increasing body length[10].

Babies who are given massage have a better sleep quality than those who are not[11]. Babies need to get enough sleep for healthy growth as shown in their increasing body weight and length. This is possible because infant massage improves blood circulation of the baby[12]. Another hypothesis regarding infant massage is that stroking the muscles of a baby activates a receptor in the baby's body. This receptor is responsible for stimulating effective baby metabolism which in turn promoting rapid physical growth of the baby[13].

In addition, infant massage seems to be closely related to quality of baby suckling. This study reveals that the suckling frequency and suckling durations of the babies of the mothers in the intervention group are better than those in the non-intervention group (see pictures 1d and 1e). Weight and length gain of babies do correlate strongly with breastfeeding at least during the early six months of infancy [14].

However, it is important to recognize the psychological effects created by skin-to-skin contact between mother and her baby. This study finds out that mothers who massage their babies in fact establish positive relationships with their babies. These positive relationships maintain the emotional stability of the mothers which in turn stimulates mothers to improve their breast milk production[15]. Positively psychological condition allows mothers to produce adequate quantity of milk their babies.

The importance of infant massage has been recognized for a long time[12,16]. New studies also confirm that infant massage helps mother to develop affection for her baby[15]. It does not only meet the physical needs of the baby but also facilitates both mother and her baby to build positive relationships[17]. Compared to the mothers who do not participate in infant massage training, those who join the infant massage trainings for 8 weeks report of better self-confidence in fulfilling their role. The trainings help them to build more intimate and positive relationships with their babies[18]. For the mothers, massage could become an activity to channel affection for their babies[19]. A relaxed emotional state enables mothers to have much better sleep quality[11].

Like in other cultures, it is the common and traditional role of Indonesian mothers, especially those living in rural areas, to bath their baby. Therefore, mothers do not need to spare specific time to massage their baby since it could be done during bath time because giving infant massage during bath is a natural process a mother could perform[20]. Since many mothers lack adequate knowledge about infant massage techniques,[21] it is then necessary to train and educate them on infant message from the final phase of their pregnancy to one month after giving birth.

Conclusion

This study proves that infant massage is an effective way to improve baby's physical profiles and suckling quality. It supports the argument that infant massage trainings and education for pregnant women are important to ensure the well-being of both mothers and their babies. This study indicates that mother plays a very important role in ensuring the life quality of her baby in the future.

Relationship between Polishing Techniques and Bacterial Count on Different Denture Base Materials

Mai Salah El-Din[1], Amr Ismail Badr[2], Emad Mohamed Agamy[3], Gehan Fekry Mohamed[3]

[1]Clinical Instructor at Removable Proshodontics Department, Faculty of Dentistry, Alexandria University, Alexandria. Egypt, [2]Assistant Professor of Removable Proshodontics and Head of the Department, Faculty of Dentistry, Minia University. Minia. Egypt, [3]Professor of Removable Proshodontics, Faculty of Dentistry, Minia University, Minia, Egypt

Abstract

Introduction: Wearing of dentures cause alteration in the oral microflora and increasing in number of bacteria and candida. The polished and fitting surfaces of the denture are both affected. Different polishing techniques influence the total count of bacterial accumulation on the denture surface.

Aim: To count the bacterial colonies after polishing three denture base materials before and after six months of denture wearing by different polishing techniques.

Materials and Method: Eighteen patients were randomly selected for construction of maxillary partial denture. They were divided into 3 groups: Group 1: Patients received conventional heat-cured PMMA (Acrostone) denture. Group 2: Patients received thermoformed polyamide (NEWULTRA) denture. Group 3: Patients received thermoformed acetal (Bio Dentaplast) denture. In each group, three patients had their dentures polished by pre polishing with brown rubber disc and fine pumice with wet rag wheel, and the other three patients with the same technique but followed by tripoli compound with dry rag wheel. Evaluation of bacterial counting was conducted before denture wearing and after six months of denture wearing. Swabs were taken from the palate of the patients and bacteria were counted.

Findings: No significant difference was found between technique no. I and no. II in decreasing the bacterial count between the tested materials. Thermoformed polyamide showed the highest bacterial count after six months of wearing denture polished by technique no. II followed by thermoformed acetal and heat-cured PMMA.

Conclusion: The second polishing technique produced less surface roughness and bacterial colonization on the tested materials than the first one.

Keywords: *Polishing techniques, bacterial count, denture base materials.*

Introduction

Wearing removable dental prosthesis (either complete or partial dentures) causes an alteration in the oral microflora[1].

The surfaces of soft and hard tissues of the oral cavity covered with a 0.5-1.5 μm thick layer which consists of: salivary glycoprotein, immunoglobulin and microorganisms that normally formed within about thirty minutes after tooth brushing and is called "pellicle"[2].

Microorganisms found in this pellicle such as: oral streptococci, staphylococci, enterococci[3] and oral yeast which is known as candida albicans.

With many oral environmental factors, salivary pellicle is the strongest factor for microbial colonization

of oral hard surfaces such as teeth, restorations and prosthetic appliances[4].

Bacteria and Candida commonly causes dental caries and less frequently cause more severe disease, such as pneumonia or endocarditis[5]. The medically important diseases maybe caused by the bacterial pathogens; that occasionally colonize the oral cavity[6].

The alteration in the oral microflora considers as a common cause for the development of a particular condition: dental prosthetic stomatitis or denture associated stomatitis. Denture stomatitis is characterized by mucosal inflammation and redness underneath a denture[7]. It is caused by the microbial biofilm on the fitting surface of the denture rather than on the mucosal surface, especially in the maxilla[8].

Available literature makes it known that bacterial and fungal adhesion to the prosthetic materials is a complicated phenomenon and depends on such factors as, coarseness of those materials and their ability to attract water and the proteins in saliva, which facilitate adhesion of micro-organisms[9].

Smooth and highly polished denture surface are of utmost importance for patient comfort and denture longevity, and it is desired for reducing microorganism's retention[10]. It can improve good aesthetical results, oral hygiene and low plaque retention, preventing oral diseases[11].

The aim of the polishing procedure of the denture is to make the denture glassy without changing its contour. For obtaining this aim, all scratches and rough areas must be removed. A series of progressive finer abrasive is used to produce a shiny surface on the denture[12].

Polishing procedure is either mechanical or chemical[12&13]. The mechanical polishing procedure uses abrasives which produces wear of the surface in a selective controlled manner and this reduces the surface roughness of the material[13]. Mechanical polishing is preceded by finishing using stone bur and sand paper in order to make the acrylic denture reach to the final form before polishing[14].

As Manufacturer's recommendations for polyamide suggest the material can be used as partial denture framework including clasps, due to its flexural properties[15].

Mustafa MJ[16] stated that effect of finishing and polishing technique on the surface polyamides have been reported as being difficult to finish and polish due to their low melting temperature, Fraying at the margins of the polyamide specimens was noticed occasionally during polishing of the samples in study, which may have occurred due to overheating of the surface and exposure of fibers.

A study[17] was conducted on the effect of denture cleansers on the formation of candida biofilms on a polyamide resin and a PMMA resin. The study showed that candida biofilms had significantly higher growth on polyamide compared with PMMA indicating that polyamide could present a convenient surface for microbial colonization.

A recent study byMekkawy MA et al[18]; revealed that acetal resin showed the highest mean value of surface roughness after polishing among materials tested, but within the accepted threshold level. Due to the high crystalline feature of acetal resins, which provides excellent properties as it increases the hardness, it might be the cause of the increased surface roughness value[19].

So the aim of this study was to count the bacteria on three denture base materials before and after denture wearing for six months.

Materials and Method

18 patients were selected from Removable Prosthodontics Department. Faculty of Dentistry. Minia University.

Inclusion Criteria: Patients were free from any systemic diseases especially autoimmune disease or patients under corticosteroids therapy. Age ranged between 45 to 55 years (males or females). Partiallyedentulous maxillary arch with recent extractions and completely dentulous mandibular arch. Patients with good oral hygiene, measured by modified gingival index (MGI).

Exclusion Criteria: Sensitive patients (allergic) to heat-cured PMMA or thermoformed materials were excluded. Allergy test was applied for each patient using the patch test[20].No previous history of denture wearing.

Ethical Consideration: Thesis protocol was approved by the research ethical committee. Faculty of Dentistry. Minia University.

Patient Categorization:

Patients were categorized into three groups:

Group 1: Patients received conventional heat-cured PMMA (Acrostone) removable partial denture.

Group 2: Patients received thermoformedpolyamide (NEWULTRA) removable partial denture.

Group 3: Patients received thermoformed acetal (Bio Dentaplast) removable partial denture.

The in-vitro investigations of an earlier study by EldinMS[21] concluded that polishing technique that used pre polishing rubberizing with brown rubber disc 1500 rpm for one minute, followed by fine pumice with wet rag wheel, 1500 rpm for two minutes (technique no. I)[16] and the same technique but followed by tripoli compound with dry rag wheel, 1500 rpm for two minutes(technique no. II)[16]; showed the least surface roughness values forheat-cured PMMA and thermoformed specimens. Accordingly, for each group, three patients had their dentures polished with technique no. I, and the others three patients with technique no. II.

Patient Evaluation: Patients were evaluated by collection of swabs from the palatal mucosa by the aid of sterile cotton swabs (sterile swab stick)[22]. Swabs were taken within area of (2 × 2 cm line) by using a transparent pattern. This transparent pattern was made for each patient. Sterile cotton swab was moistened with phosphate buffered saline (PBS) and then applied using horizontal strokes for one minute to the swabbed areas then recapped again and transferred immediately to the microbiology laboratory for processing. Swabs were taken in the morning between 11 and 12 o'clock.

Evaluation Time:

a. Before denture wearing.

b. After six months of denture wearing.

Bacterial Counting: Bacterial concentration was conducted on blood agar enriched with 5% sheep blood[22]. Samples were prepared under aseptic condition and were incubated for 24 hours at 37°C[23]. Bacteria were counted manually and counting was repeated 3 times. Colonies growth recorded as total colony forming units per milliliter for liquids (CFU/ml)[24].

CFU = (Bacterial Colony Count/ Volume used × Reciprocal of dilution)

Statistical Analysis: Data were presented as mean (μ) and standard deviation (SD). Data were explored for normality using Kolmogorov-Smirnov and Shapiro-Wilk tests. Data showed a parametric distribution. In this study; independent t-test and dependent t-test were used.

Findings: Patients were: ten patients Kennedy's class I, five patients Kennedy's class II, two patients Kennedy's class III with long edentulous area, one patient Kennedy's class IV. They were twelve males and six females.

Table 1 showed that group 1 had no significant difference in bacterial counting after polishing with technique no. Iand II before denture wearing (P value=0.172), but showed a significant higher difference of technique no. I than technique no. II after denture wearing (P value=0.022) with (Mean: 3.88 and 2.49) respectively. Group 2 showed no significant difference in bacterial counting after polishing with technique no. I and II before denture wearing (P value=0.548) and after denture wearing (P value=0.434). Group 3 showed no significant difference in bacterial counting after polishing with technique no. I and II before and after denture wearing (P value=0.073) &(P value=0.208) respectively.

		Techniques				p-value
		Technique I		Technique II		
		Mean	SD	Mean	SD	
GP 1	Before Polishing	4.86	.03	4.47	.52	0.172 NS
	After Polishing	3.88	.89	2.49	.17	0.022*
GP 2	Before Polishing	4.69	.88	4.32	.56	0.548 NS
	After Polishing	3.51	.88	3.01	.59	0.434 NS
GP 3	Before Polishing	5.21	.49	4.41	.55	0.073 NS
	After Polishing	3.45	.21	2.84	.53	0.208 NS

In table 2, it was clarified that dentures that were polished by technique no. I; before and after denture wearing showed no significant difference in bacterial counting for group 1&3; (P value=0.109 and 0.124) respectively. But group 2 had a significant higher difference before wearing denture than after denture wearing (Mean: 4.69 and 3.51) respectively. Group 1 that was polished by technique no. II; showed a significant higher difference before and after denture wearing (Mean: 4.47 and 2.49) respectively. Group 2 that was polished by technique no. II; showed a significant higher difference before denture wearing than after denture wearing (Mean: 4.32 and 3.01) respectively. Group 3 that was polished by technique no. II; showed a significant higher difference before and after denture wearing (Mean: 4.41 and 2.84) respectively.

			Polishing				p-value
			Before Polishing		After Polishing

		GP 2	4.32	.56	3.01	.59	0.004*
		GP 3	4.41	.55	2.84	.53	0.008*

Discussion

Patients selected were free from any systemic diseases as autoimmune disease or under corticosteroids therapy which would cause osteoporosis. Their age range were between 45 and 55 years to assure that the mandibular arch were completely dentulous and the maxillary arch was with recent extraction of the teeth to prevent extreme bone resorption after long time extraction or overerruption of the mandibular teeth.

None of the selected patients were previously wearing dentures to assure that there was no effect of any previous treatment in the results[25].

This present study used a transparent pattern (2×2 cm) for taking a swab from each patient for idealization of the area of swab. Swab that was taken in this study were from the palate only and not from the fitting surface of the prosthesis as within the limitations of Al-AkhaliMA[26] study, it can be concluded that the mucosa under the acetal denture base retains more microorganisms than the mucosa under the metallic denture base. However, the fitting surface of the metallic denture base retains more micro-organisms than the fitting surface of the acetal resin denture base. This difference was found to be non-statistically significant; the adhesion of micro-organisms on mucosa and denture base of either the metal or acetal denture increased by time[26].

The present study revealed that few of the patients had reduced (CFU/ml). However, such a finding was not necessarily indicative of a total absence of microbial presence on the prosthesis and in this study it could be due to the limitations of over swabbing efficiency or due to the small sample size.

This study concluded that no significant difference between technique no. I and no. II in decreasing the bacterial count between the tested materials. However, thermoformed polyamide showed the highest bacterial count after six months of wearing denture polished by technique no. II followed by thermoformed acetal and heat-cured PMMA.

From the research of Glantzet al[27], it arises that acrylic has smaller surface potential, but it absorbs water which causes a significant increase of adhesion strength and adsorption of a relatively large amount of prosthesis plaque.

It was demonstrated that polyamides had rougher surface than other resin materials, and it caused more bacterial and fungal colonization[28].

Ata So[29] reported that, whiteacetal resin was more porous and showed less color stability than pinkacetal resin.

This study was followed for only six months which is a reasonable period to give an idea about the bacterial adhesion on different denture base materials after using polishing techniques.

Conclusion

The use of tripoli compound in polishing different denture base materials caused decreasing in the total count of bacterial adhesion on denture surfaces as it caused less surface roughness of these materials, however this decrease was non-significant.

Conflict of Interest: None.

Determination of Dyspnea in Mechanically Ventilated Patients

Masouda Hassan Abd El-Hamid Atrous[1,2], Khaled Mohamed Al-Sayaghi[3]

[1]Critical Care and Emergency Nursing Department, Faculty of Applied Medical Sciences, Jouf University, KSA, [2]Critical Care and Emergency Nursing Department, Faculty of Nursing, University of Alexandria, Egypt, [3]Critical Care and Emergency Nursing Department, Nursing Division, Faculty of Medicine and Health Sciences, Sana'a University, Yemen

Abstract

Introduction: Although dyspnea is the most common suffering and devastating symptom in the mechanically ventilated patients (MVPs), it is not routinely measured.

Aim of the Study: To assess dyspnea and factors contributing to it in MVPs.

Design: A descriptive research design

Settings: Intensive Care Units of Alexandria Main University Hospital.

Subjects: Forty critically ill conscious adult MVPs

Tool of Data Collection: Dyspnea assessment tool used to collect the data.

Results: 55% of the study sample had dyspnea and 86.4% of dyspneic MVPs had moderate to intense level of dyspnea.

Conclusion: Dyspneais present in more than half of the MVPs. Moderate to intense dyspnea is more frequent in MVPs.

Keywords: *Dyspnea, Mechanical ventilation, Modified Borg Scale.*

Introduction

Dyspnea is a subjective experience of breathing discomfort described as air hunger, heavy breathing or choking.[1,2]It is a common and often debilitating symptom that affects up to half of patients admitted to acute tertiary care hospitals and 25% of patients admitted to acute tertiary care hospitals seeking care in ambulatory settings.[3,4] Presence of dyspnea is a strong predictor of patient's clinical course and mortality and neglecting it cause suffering, complicate and extend length of stay, and counterbalance physiological benefits in terms of clinical outcomes.[4,5,6] Therefore, mechanical ventilation which is a commonly used technological treatment in ICUs,[7]aims to maintain adequate oxygenation, alleviate the patient's respiratory symptoms, reduce the work of breathing (WOB), and improve patient comfort.[1,6]

However and at the same time, patients on MV may experience distressing symptoms such as anxiety, dyspnea, pain or discomfort, confusion, agitation, and sleep disturbances.[8] In other words, dyspnea can persist, reappear, or re- increase after the initiation of MV. This can reveal many complications (such as pneumothorax, pneumonia, cardiac failure, anemia, etc.), air leaks, increased airway resistance, decreased lung compliance, inappropriate ventilator settings, anxiety and pain. [6, 9] Therefore, dyspnea could be used as a useful clinical management tool for the MVPs.[6]

The critical care nurses had an essential role in providing patient-centered care to maintain oxygenation and ventilation adequacy, breathing comfort, and patient-ventilator synchrony.[10] Responsibilities of the critical care nurse related to ventilator management may vary among acute care settings, but no doubt the nurse is the "first-line manager" challenged with MVPs related problems.[9] Therefore, it is very important that they

should do their best effort to develop their knowledge and skills needed for effective management of MVPs. (9)

As dyspnea is the most suffering and devastating symptom.(11) A patient-centered approach of nursing care should include routine assessment for dyspnea using an appropriate instrument.(5,9,12) Unfortunately, dyspnea is still not routinely assessed in critically ill patients, except during patient weaning from MV.(6) During the last decades, manufacturers and researchers increase theirattention on the patient-ventilator interactions.(13) However, dyspnea has not been studied to any great extent in MVPs.(6) In generalcritical care nurses have a sense of security that, because the patients are supported by the MV, they are receiving adequate ventilation and they are not suffering from dyspneahowever, in fact, dyspnea is common and more frequent problem in MVPs. In addition, there is a knowledge gap in the understanding of dyspnea in those patients. Therefore, this study aimed to assess dyspnea in mechanically ventilated patients.

Materials and Method

Design: A descriptive research design was used to assess dyspnea in MVPs.

Sample: A convenience sample of 40 critically ill conscious patients above 18 years old intubated and attached to MV for more than 24 hours

Settings: Casualty and general ICU of Alexandria Main University Hospital.

Instrument: Dyspnea assessment tool used to collect the data and was developed after reviewing the related literature.(5,6,9,14) It consisted of **two parts**. **The first part** consisted of the patients' characteristics, MV parameters and the respiratory distress manifestations associated with dyspnea. Arterial blood gases (ABG), peripheral oxygen saturation (SPO_2) vital signs, anxiety, pain level,blood hemoglobin level (Hb) were also assessed. **The second part** of the tool consisted of the dyspnea scale. The Modified Borg Scale (MBS)(5, 15) was used to assess dyspnea in MVPs. It is a 12-point scale (0, 0.5, 1–10) with numbers corresponding to descriptions regarding the amount of dyspnea, with no dyspnea rated as 0 and worst maximal dyspnea rated as 10.

Data collection: The patient's characteristics and health relevant data were recorded. The manifestations of respiratory distress associated with dyspnea, were continuously observed.

If any abnormality in breathing dynamics was present, dyspnea assessment was done by asking patients first "do you have trouble breathing". If the answer was yes, then they were asked to rate the intensity by telling the patients the items of Modified Borg Scale (MBS) and ask them to select the dyspnea level. Finally mechanical ventilation settings, vital signs, Hb level, ABG and SpO2 were assessed and documented. Pain and anxiety were also assessed by visual analog scales (10-cm VASs to evaluate anxiety ("no anxiety" to intolerable anxiety") and pain (no pain" to "intolerable pain").

Data Analysis: Patient were categorized according to the dyspnea as "present" or ~absent" and therefore defining two groups of patients. The patients groups were compared using Wilcoxon rank sum tests for quantitative variables and the Fisher's exact test for qualitative variables. A multiple logistic regression with a backward stepwise model selection was used to identify factors independently associated with dyspnea. All tests were two sided, and p values < .05 were considered statistically significance. The statistical analyses were performed using SPSS version 17.

Results

Result of this study shows that more than half of the study sample had dyspnea (55%) and the mean age of dyspneic patients was 53.39 ± 17.0. The majority of the study sample (77.5%) was males (90.9% of them were dyspneic). One half of the study sample suffered from pulmonary disorders and 59.1% of them had dyspnea. The mean score of dyspnea modified Borg scale was 6.0±1.8 and this reflect the moderate to intense level of dyspnea. This table also shows that there was significant difference between dyspneic and non dyspneic patients in term of hemoglobin level.

Findings of current study revealed that 31.8% of the dyspneic patients had fever, 27.3% of them had pain and 63.6%% of them had anxiety. Dyspneic patients exhibited abnormalities in breathing dynamics (using of accessory muscle) while, non dyspneic ones did not exhibit any abnormality in breathing dynamics**.** Also dyspneic patients were more attempting to sit up in bed, had higher respiratory rate(RR), higher HR, higher systolic blood pressure (SBP) and diastolic blood pressure (DBP), lower Hb level, lower SpO_2, lower FiO2%, lower Vt, lower flow rate, lower PEEP, higher PS, and higher PAP than non dyspneic patients. There were statistically significant differences between dyspneic and non dyspneic patients

regarding RR, HR, SBP, DBP, Hb level and SpO_2. It was observed that dyspneic patients were on assist control ventilation (ACV) mode and PSV mode while, non dyspneic patients were on biphasic positive airway pressure (BIPAP), synchronized intermittent mandatory ventilation (SIMV), and continuous positive airway pressure (CPAP) modes and there were statistically significant differences regarding ventilator modes, PAP in dyspneic and non dyspneic patients.

Alsoit was found that 86.4% of the patients had moderate to intense level of dyspnea. Of those 50% had moderate dyspnea and 36.4% had intense dyspnea. There were statistically significant differences between dyspnea intensity level (mild, modrate and severe dyspnea) regarding abnormalities in breathing dynamics, RR, HR, SBP, and PAP.

Discussion

Poor patient–ventilator interaction causes discomfort and dyspnea.[16] Optimizing patient comfort is a main concern in the ICU and relieving immediate suffering is indeed a natural mission of all caregivers. [17] Therefore, the aim of this study is to assess dyspnea in MVPs.

Regarding the **presence and intensity level of dyspneain MVPs**, the findings of this study highlight that dyspnea is more frequent in MVPs and our result revealed that more than half of the study sample had dyspnea and the majority of them experienced moderate to intense level of dyspnea. This may be related to assessment of dyspnea in MVPs is neglecteddue to safety feeling of critical care nurses that MV provide support to patients attached to it. In addition, lack of knowledge and skills related to dyspnea in MVPs. These findings are consistent with Bissett et al [18] and Twibell et al[19] findings who reported that patients had moderate and high levels of dyspnea during MV. On the contrary, Decavèle et al[20] and Merchán-Tahvanainen et al [21] results which revealed that MVPs had low to moderate levels of dyspnea.

In relation to**the characteristics of the study sample**, one half of the sample diagnosed with pulmonary disorders. This may be due to that the majority of subjects were adult male and more than one third of them were elderly. This may be due to smoking history and aging which affecting on the lung volume. As people are older, their lung functions start to decline (Veljković,2019).[22]

In our study, Dyspneic and non dyspneic patients did not differ significantly in term of patients' diagnosis. This may be due to presence of many factors which contribute to dyspnea in MVPs. This result is in agreement with Schmidt et al. (2011)[6] who found that intensity, characteristics and prevalence of dyspnea did not depend on the cause of respiratory failure and this result suggests that dyspnea may be caused by pathophysiology of disease. Indeed, patients with pulmonary disorders reported dyspnea that is may be related to the hyperinflation-induced volume restriction as in COPD patients. [17, 23]

Mechanical ventilation and critical illness induce great anxiety and distress in hospitalized patients. **Anxiety and pain** may increase dyspnea by stimulating ventilatory drive. [24]We found that there were no statistically significant differences between dyspneic and non dyspneic patients regarding anxiety and pain in MVPs. This may be due to MVPs may be unable to communicate their distress, anxiety and pain. It was reported by Schmidt et al [6] that pain and anxiety were more frequent in dyspneic than in non-dyspneic MVPs and dyspnea was significantly associated with anxiety.

As **hemoglobin** is a common generator of dyspnea, and at the same time there was an association between anemia and failure of weaning from MV.[25] So, it is of most importance to assess hemoglobin level and correlate it with dyspnea in MVPs. Dyspneic patientshad lower hemoglobin level than non dyspneic patients and there was statistically significant difference between dyspneic and non dyspneic patients in term of hemoglobin level. Multivariate analysis showed that there was no significant association between dyspnea and hemoglobin. This is similar to Schmidt et al. (2011)[6] who found that that there was no association between dyspnea and hemoglobin.

Ventilatory settings might be involved in the genesis of dyspnea, in addition to **ventilatory mode**. In the present study, dyspneic patients were usually on ACV and PSV modes and there were statistically significant differences regarding ventilator modes, PAP in dyspneic and non dyspneic patients. This may be due to higher respiratory rate in ACV which increase inspiratory efforts and hence increase work of breathing. Schmidt et al (6) reported that ACV was the principle cause of dyspnea and found that the ACV mode was independently associated with dyspnea[17]

Regarding **Pressure support ventilation,** there were no statistically significant differences between dyspneic and non dyspneic patients. This may be due to that the mean pressure support in dyspneic patients is to some extentsimilar tonon dyspneic patients. On the contrary, Vaporidiet al (2019)[26] who found low pressure support levels have also been associated with a sense of excessive inspiratory effort and there was a trend toward more dyspnea in those who received a pressure support ventilatory mode with a pressure support level < 15 cm H2O.[6]

Other factor may contribute to dyspnea in MVPs is a low **tidal volume**. We found that there was no statistically significant difference between dyspneic and non dyspneic patients in relation to tidal volume. This may be also related to small variations in the value of the tidal volume in the dyspneic and non dyspneic patients. This is against Rauxet al (2019)[27] found that low tidal volumes were associated with air hunger.

Moreover, the **inspiratory flow** is among the ventilator settings that may be lead to dyspnea. Our findings indicate that dyspneic patients had a lower inspiratory flow than non dyspneic patients. This may be due to that ventilator flow rate is not adjusted to match the high respiratory demands of critically ill patients. Also there was no statistically significant difference between dyspneic and non dyspneic patients in the term of inspiratory flow. These findings are consistent with Schmidt et al.[6]and Binks et al (2017)[28] findings that an inspiratory flow below 1 l/sec equates to a risk of generating dyspnea.

Conclusion

It can be concluded that dyspnea is present in more than half of the MVPs. Moderate to intense dyspnea is more frequent in MVPs. Assessment of dyspnea in the MVPs is feasible and applicable.

Ethical Clearance: The Research and Ethical Committee of the Faculty of Nursing, Alexandria University approved the study, and an ethical clearance was issued. Permissions were requested from hospitals' management and unit's managers. Participation in the study was voluntary and an informed written consent was obtained from patients after explaining aim of the study. The right to refuse to participate or to withdraw from the study was emphasized to patients. Confidentiality of participants was maintained.

The Effect of Self-Regulated Learning Strategy in Motor Hyperactivity and Learning the Performance of Skill of Jump Shot in Basketball for Freshmen High School Students

Mayadah Khalid Jasim[1], Shaymaa Jasim Mohammed[2]

[1]Assistant Professor, [2]Instructor, Department of Physical Education and Sport Sciences, College of Basic Education, University of Mustansiriyah, Iraq

Abstract

The study aims to identify the effect of the strategy of self-regulated learning in the motor hyperactivity and learning the performance of the jump shot skill of the basketball for freshmen high school students. The researchers used the experimental design with the experimental and control groups in pre and post. This study was conducted at Al-Fursan High School, the General Directorate for Education of Al-Rusafa II for the academic year 2017-2018. Male students aged 15-16-years were surveyed using hyperactivity scale to detect the phenomenon that correspond to the study problem. Students who scored (28) on this scale were purposively selected to represent (36.842%) of the original community. They were divided into two equal groups; study and control. Each group included (14) students. The researchers prepared six educational units that are applied in the physical education lesson for the study group. The study results revealed that the self-regulated learning strategy has proved its effectiveness in reducing hyperactivity and its good investment in the physical education lesson. The self-regulated learning strategy proved its effectiveness in learning the performance of jump-shot in basketball for freshmen high school. The researchers recommend that it is necessary to pay attention to the periodic psychometry in the physical education lesson in the high school to detect unwanted behaviors and change them into active and productive behaviors, and training teachers and develop their own abilities in the application of educational strategies in the physical education lesson and caring for the modern of such strategies.

Keywords: *Self-Regulated Learning; Motor Hyperactivity; Jump-Shot*

Introduction

The teaching process should be viewed as a unit that includes (objective, content, and method), and that the lesson; as a whole or parts, is closely linked to these three factors," said Ahmed. "Some of the specialists in the field of physical education teaching that the content of the physical education lesson includes some components, including a compound set of concepts, standards, and facts, and a range of sports performance method(6).

"It is necessary to assess the level of motor development that a student reaches to determine what skills he has learned and what he has not yet learned," said Mona and Jamal. (7)

Pintrichand Zeidner define the self-regulated learning (SRL) strategy as "a meaningful and active process. Learners set their educational goals and then attempt to monitor, organize, and control their cognitive, motivational, and behavioral characteristics, and their orientations in the learning environment".(10)

"The aim of self-regulation is to regulate the personal, behavioral, and environmental factors that influence the learner's performance in learning situations," said Youssef Mohamed. (9)

The learner leaders in the learning groups after roles assignment among them acquire personal and professional skills at a high level, which deepens the concept of learning as the practice facilitates the learning process of the less-experienced students in an organized and supported manner (11).

Hyperactivity is defined as "excessive, inappropriate behavior of the position, no direct goal, inappropriate

development of the child's age, negatively affecting and accumulating behavior and increasing in males more than females."[5]

The academic researcher specialized in motor learning and teaching method should differentiate between the types of these behaviors for the purpose of controlling them by adopting the scientific method. Thus, they can control the system in the lesson and enable the teacher to achieve his objectives, shaping the future student personality, in addition to maintaining the spirit of teamwork and cohesion among students. This calls for continuing the scientific efforts to supply the educational process;particularly the physical education lesson,with specialized research including the psychological studies that deal with the study of behavior at different stages of life. The importance of this study lies in the importance of diagnosing and analyzing hyperactivity among middle school students.

Self-regulated learning involves metacognitive (planning, self-monitoring, evaluation, reflection) and motivational (effort, self-efficacy) processes engaged by learners to reach self-set goals [6].

One of the duties of the school is to create and organize a safe learning environment for students who are inherently descended from different social environments and families. This difference is associated with many factors. Usually,such a difference leads them to seek self-affirmation among their peers. This clearly appears in his behavior of dealing with peers which takes different forms. The researchers; throughout their visits to the schools, noticed different, unwanted behaviors including hyperactivity against others that arises among cohort in the physical education lesson, which allows them to move freely and play unrestrictedly compared to other restricted classroom environments. This enables those meant by exploring to observe these behaviors, which require careful measurement with objective tools within the parameters of the psychometric measurement of the methodology of scientific research to suit the students' characteristics, their age, level, and then the educational institutions service to prepare the programs for it later. The problem of the study lies in the researchers' attempt to achieve this diagnosis to find the scientific answer to the following question: Does the SRL strategy help in investingthe organization of the excessive students' movement in favor of learning the skillful performance of jump-shot in basketball?

The study aims to (1) identify the influence of the SRL strategy on the hyperactivity of freshmen high school students, and (2)recognize the influence of the SRL strategy on learning the performance of jump-shot skill in basketball for these students.

The researchers hypothesized the following:

1. There are statistically significant differences in the hyperactivity and learning the performance of jump-shot skill in basketball between the pretest and posttest between groups.
2. There are statistically significant differences in the hyperactivity and learning the performance of jump-shot skill in basketball between for the posttest time between groups.

Method

An experimental, pretest-posttest design with two groups; study and control, was used to guide this study.

The boundaries of the research community in this study were represented by the high school freshmen. The study included 76 male students,age 15-16-years, who were recruited from Al-Fursan High School in Al-Rusafa side in Baghdad City. for the academic year (2017/2018).The study participants were selected by surveying using a scale for hyperactivity. Students who score 8 or above on this scale would be involved ($n = 28$) who were purposively selected. They represent (36.842%) of this society.Twenty students were assigned in the pilot study to test the modified version of the scale. Participants in the main study sample were assigned using the simple random sample method; 14 students in each group.

Measuring tools and study procedures: In order todiagnose hyperactivity,the hyperactivity scale developed by Abdul- Ameer[2] was adopted. It consists of 15 items with a total score of (15).Minor modifications and adapting it to 20 students to find the scientific bases. The researchers designed a performance evaluation form that includes three sections of performance the jump-shot in the basketball of (10) degrees. This performance is revealed after the students' videotaping and presented to three specialists in basketball tests.

After preparing the measuring tools for the study experiment, the educational units were prepared using the SRL strategy to employ excess energy from excessive activity in the sense of the concept of hyperactivity by

directing the students well according to the determinants of motor performance of the skill. At the same time,the educational units aim to regulate the cognitive information pertinent to that skill and the harnessing of the learner's energy for proper performance since it is not limited to the accuracy of the scoring, but the movement and harmony of the body parts of the requirements of the optimal performance that helps to such an accuracy later. The teacher's duty is to create the educational environment appropriate for applying such a strategy to be a lesson that is free from restrictions, be concerned with the learners' directions and feedback of self-regulation. Such strategies are considered as meaningful and active learning strategies sought by modern learning schools in various sciences. The educational units have been applied among students with hyperactivity for 45-days in an average of one educational unit per week for the academic year 2017-2018 after finishing the formal school time. Data were analyzed using the statistical package forsocial sciences (SPSS) version 24. The statistical measures of percentage, arithmetic mean, standard deviation, independent-sample T-test, and paired-sample T-test were used.

Results

Table 1. The equivalence of the study groups in the pretest

Tests	Study Group (n = 14)		Control Group (n = 14)		t	Sig.	Sig. Level

Tests	Study Group (n = 14)		Control Group (n = 14)		t	Sig.	Sig. Level
	Mean	SD	Mean	SD			
Hyperactivity	4.5	0.65	6.57	0.646	8.453	0.000	S
Performance of jump-shot skill	7.71	0.469	5.29	0.469	13.706	0.000	S

Significant at $p \leq 0.05$ at 0.05, degree of freedom n-2 = 26; S = Significant

Reviewing the results of Table (2) reveals improvements in the values of the variables of the study and control groups. Reviewing Table (3) displays that the students in the study group members outweighed their counterparts in the control group pertinent to the dependent variables. This finding could be attributed to the role of SRL strategy that enabled the students to reorganize their experiences and information, improve excessive and random movement in the class, and guide it towards proper skill performance that requires aesthetic and quality determinants in the three skill sections. Thus, two objectives were met by one action that is positively reflected on the psychological status in its improvement whatever the reasons for such opportunities. At the same time, the skilled performance that requires regulating the experience and information as indicated to regulate the

movement. As well as,it helped to increase the number of units to six for one skill in improving the values of skill improvement for the performance of this skill in basketball. For the students in the control group, the researchers attribute the improvements to the role of the sports education lesson, and it achieves of educational and learning goals.

Al-Busidistated that SRL differs from self-learning developed by Skinner or using computers. In his theory, Deutsch could determine the relationship form between different organizations of mutual social interdependence(1).

Qatami stated that "The aim of Uzbel is to study the cognitive structure of the learner and the higher mental processes in order to achieve a meaningful learning and increase the efficiency of the processes of cognitive processing of the information using multiple cognitive processes and at reasonable times that facilitate the task of storing these knowledge, their transfer,and integration into the learner's cognitive structures" (8).

Thorndike stated that "The teacher and the learner must determine the characteristics of the good performance so that the practitioner can be organized to be able to diagnose errors and not repeated them and the difficulty to modify," (4)

Conclusions and Implications:

1. The SRL strategy has proved its effectiveness in reducing hyperactivity and good investment in the physical education lesson among freshmen.
2. The SRL strategy has proved its effectiveness in learning the performance of jump-shot in basketball for freshmen.

The researchers recommend the following:

1. It is necessary to pay attention to the process of periodic psychometry in the physical education lesson in the high school to detect unwanted behaviors and turn them into active and productive behaviors.
2. It is necessary to train teachers and develop their own abilities in the application of educational strategies in the physical education lesson and paying attention to the modern of such strategies.

Conflict of Interest: The researchers report no conflict of interest.

Funding: This study did not receive any funding from any agency.

Ethical Clearance: A permission to conduct this study was obtained from the ethical committee in the College of Basic Education, University of Mustansiriyah

The Influence of Tactical Approach Exercises on the Tactical Behavior of Some the Attack and Defense Skills by Foil (Fencing)

Maysoon Mohamed Nawar[1], Lama Samir Hamoudi[2]

[1]Student, [2]Prof. in the Physical Education and Sport Sciences for Girls from the University of Bagdad

Abstract

The study aimed at identifying the effect of tactical approach exercises on the planning behavior of some offensive and defensive skills of the foil in the research sample. Use the experimental method by designing the experimental and control groups with pre- and post-test on a sample of second stage students. The experimental group that learns the skills under study using the planetary approach exercises. After the implementation of the curriculum and post-test, Then statistical treatments concluded that the tactical approach exercises carried out by the experimental group in learning the skill performance have positively influenced the analysis of the results of the planning behavior of some offensive and defensive skills in the foil better than the control group that did not develop in the analysis of planning behavior. In light of the conclusion, it is recommended to adopt the tactical approach exercises in developing the planning behavior of some offensive and defensive skills in the foil..

Keywords: *Exercises, Planetary Approaches, Planned Behavior, foil.*

Introduction

When teaching or training to the fence, the learner must reach a degree of progress so that you clearly understand the end of the kinetic sentence you perform and why? They must know the purpose of their efforts, they should also be encouraged to control skills, learn about their performance situations and learn how to apply them(1)Therefore, we find several basic elements within the process of learning and training fencing sport and these elements (rapid decision-making, response speed, behavioral planning correct behavior) in order to carry out a kinetic sentence ending with atouch of the competitor, with high flexibility in thinking, where these factors are very important for the player Fencing, and the lack of availability leads to the failure to ensure the fulfillment of technical and tactical duties (technical and planning skills) and the rapid adaptation of the reactions of competitors of different planning behavior(4)

When you look at the exercises approach planners as one of the method used to learn and develop the basic skills, the characteristics of these exercises became clear by creating an atmosphere similar to the atmosphere of competition and close to it, as the learner performs during the performance of these exercises skills and planning, and thus linking learning skills and plans, as it is one The method that gain the learners how to perform the skill in the competition according to gradual steps, and the purpose of using this method is to develop performance in play and interaction to unify the planning and the implementation of the skill in the conduct of the correct plans ends with a legal touch.

Through the above, the researchers considered conducting a study in which they try to pay attention to the planning side along with their interest in the skill side through the use of exercises that make the learners learn in an atmosphere similar to the atmosphere of competition, namely exercises approach approaches to know their role in performing the correct planning behavior of the performance of offensive and defensive skill in the arm For students to improve the educational process for the better.

Search Problem: Through the follow-up and informed the researchers being a teacher of physical education and sports science noticed that there is a discrepancy between learners in learning the planning aspects of some fencing skills, and also found it difficult

to perform learners when linking more than one skill with each other, especially the skills of the foil, and most learners are able to perform Some fencing skills, but they find it difficult to perform the same skills when placed in the atmosphere of competition with associates, and maybe the reasons for this is to pay attention to the physical side and skills and a greater degree than the interest in the planning side and therefore find it difficult learners in choosing the most appropriate plan and Best behavior among several actions.

Therefore, the researchers considered the development of solutions to this problem through the use of exercises approach planners, which urges the learner to perform skills with the implementation of the plans and thus know the role of these exercises in the planning of the performance of offensive and defensive skill in the arm of the foils educated students.

Research Objective: Identify the impact of the tactical approach exercises in the planning behavior of some offensive and defensive skills of the foil at the research sample.

Research hypothesis: Planned approach exercises have a positive effect on the planning behavior of some offensive and defensive skills of the foil at the research sample.

Defining terms:

Planetary Approaches Exercises: It is an encouraging approach to solve the planning tasks and a coherent link between learning and mastering the planning skills and moving within gradual steps that give the learner how to learn the performance of skill in the competition and the purpose of using this method is to develop performance in the game and interaction to unify the planning and implementation of the skill[9]

Planned behavior: It is the achievement of the goal mentally before the performance or is a prediction of the movement coupled with performance, implemented through a movement or a group of movements used to solve a certain duty based on the prediction of the movement of the tool or opponent or colleague and others[3]

Research Methodology and Field Procedure:

Research Methodology: Use the experimental approach with controlled design to design the experimental and control groups with pre- and post-test to suit the nature of the problem to be studied.

Research community and sample: The research community identified the second stage students in the College of Physical Education and Sports Sciences for girls/University of Baghdad for the academic year

(2018-2019) and the number of 106 students distributed over 4 divisions, and through the draw was selected Division (A) number of 26 students representing the experimental group, which learn skills under The study using the planners approach exercises, and Division (C) and the number of 28 students representing the control group, which learnt he skills of fencing according to the usual teaching method followed (skill exercises and physical), and thus the total number of the main experiment sample (54) students and a percentage of (51%) of the total community, Tjan was confirmed O The two samples are valued through pretest.

Analysis of the planning behavior of some offensive and defensive skills of the foil: For analyzing the offensive and defensive planning behavior in the foil for the educated in practice, individual competitions were conducted, each student competing for scientific research, and then the analysis of tribal rivalries by three tribunals after filming, by taking the arithmetic mean of the degrees of the courts according to the competition analysis from approved in previous studies[6]The objective of the analysis of the competition was to identify the level of planning behavior of members of the research sample.

Main trial procedures:

Pre-test: After,the survey was conducted on 25-2-2019 the pre-test of the experimental and control groups was conducted to analyze the planning behavior of some offensive and defensive skills of the Blind weapon through video shooting, on 3-3-2019, according to competitions for scientific research in the fencing hall. The pre-test was used for homogeneity and equivalence of the two research samples as in Table (1) show in pag6.

Prepare an educational curriculum using the Planetary Approach exercises: An educational curriculum has been prepared using the tactical approach exercises for the skills of the fencing weapon in the fencing according to the vocabulary of the sectoral sector.

Therefore, to learn the offensive and defensive skills according to exercises close to the competition conditions. And against any competitor. What are the opponent's weaknesses and strengths? In order to perform this kind of attack or defense movement. The curriculum was implemented from the date of 4-3-2019 to 6-5-2019 on the experimental group; the control group remains the usual way (physical and skill exercises) to learn the offensive and defensive skills of the Blind.

Post-test: The experimental and control groups were analyzed after the experimental and control groups to analyze the planning behavior of some offensive and defensive skills of the Blind on7-5-2019, in the fencing hall. Taking into account all the temporal and spatial conditions conducted in the pretest.

Statistical means: The statistical package (SPSS) was used to process the results according to the following laws:

- Arithmetic mean.
- Standard deviation.
- The law of interconnected samples.
- Law for independent samples discussion of results:

Presentation of the results of pre-posttests in the experimental research group: Table (2) page 6 showed that there were significant differences between the values of the arithmetic media and the values of the standard deviations of the pre and post-tests in the experimental group. This means that there are significant differences in the interest of the post-test in the experimental sample the development of the experimental group is attributed to the use of tactical approach exercises when learning the skills of the Blind weapon. Through the tactical approach exercises, learners generate programs about their behavior that store these programs in memory, which helps to realize the required attitudes and behavioral plans after the stimulus has occurred and in the form of mental processes[8]

In addition, the competing teammates always try to hide as much of their actions as possible. The more it assimilates all the information and analyzes it properly, the more it will be able to react quickly. Therefore, "understanding and analyzing competition is the knowledge of the overall competition relationships, the position of competitors and their strategic objectives[5]

Planned approach exercises place the learners during skill learning in situations that make them think about the action and planning required, in order to develop their mental and cognitive ability by giving them information to organize the competition and to take appropriate action. This theoretical information was applied in the form of exercises that serve the tactical behavior of some offensive and defensive skills in the foil.[7]

Presentation of the pre- and post-test results of the control group and their discussion: Table (3) page 6 showed that there were no significant differences between the values of the arithmetic media and the values of the standard deviations of the pre- and post-tests of the control group. This means that there were no significant differences in the control sample. Asthe information is given to the control group and the skill performance performed emphasizes the skilled technique and is of no value even if performed skillfully during the stages of learning and training, unless the learners can apply what they learn from skills during the actual competition, and they can analyze each new situation, and realize any Of the movements and plans that can or cannot be used in it, for example, if we note "the movement of the arrow in the fencing depends on the element of surprise and speed in performance, and lead when the opponent leads one of the attacks and return to standby, so that the distance between the opponents is large and the attacker initiates Iha.[2]

Table 1: Shows the statistical parameters between the two research groups in the pretest tests for homogeneity and equivalence

Significance of differences	.Sig	T-Test	.Sig	The value of Levin	± p	s		
Immaterial	0.268	1.12	0.758	0.096	1.29	4.65	Expert mental	Analysis of the planning behavior of some offensive and defensive skills
					1.35	4.25	Officer	

Significant at significance level ≤0.05

Table (2) shows the statistical parameters to find the differences between the pre-post tests in the experimental group

Significance of difference S	.Sig	T-Test	P	Q.	± p	S		Analysis of the planning behavior of some offensive and defensiveskills
Moral	0.000	35.4	1.82	12.69	1.29	4.65	before me	
					1.19	17.34	after me	

Significant at 0.05 level

Table 3: Shows the statistical parameters to find the differences between the pretest-posttests in the control group

Significance of difference S	.Sig	T-Test	P	Q.	± p	s		Analysis of the planning behavior of some offensive and defensive skills
Immaterial	0.113	1.87	1.74	0.62	1.35	4.25	before me	
					1.99	4.87	after me	

Significant at 0.05 level

Conclusions and recommendations: After the statistical treatments, it was concluded that the tactical approach exercises carried out by the experimental group in learning the skill performance have positively influenced the analysis of the results of the planning behavior In light of the conclusion, it is recommended to adopt tactical approach exercises in the development of the planning behavior of some offensive and defensive skills in the arm of the Blind, the fact that these exercises give the learner a positive analysis.

Influence Organizational Citizenship Behavior (OCB) on Performance Nurses Public Health Centre in the District Tuban

Miftahul Munir

Chief of Nursing Undergraduate Study Program Institute of Health Science Nahdlatul Ulama Tuban

Abstract

Organization will successfully when employees not only do their tasks anyway but also want to do duty extra as wants to work, help one another, give advice, participate effectively, giving best services, and want to use time it works effectively but not all an employee with like willingly want to do[1]. A nurse having organizational behavior citizenship behavior (OCB) the atmosphere than last year in order to have a comfortable so as to cause a working relationship which harmonious in order to increase performance workers to reach organizational goals[2].

The study was observational analytic, population nurses public health centre in the district tuban were 24 people, a random sampling of sampling simple .Independent variable organizational citizenship behavior and dependent variable performance nurses and research instruments using sheets kuisioner with data analysis spearman use the rank.

Is the organizational citizenship behavior (OCB) of performance nurse.

Keywords: *Organization, citizenship, behavior, performance nurse, public health centre.*

Introduction

Human resources have a very crucial role in addition to the other. owned organization. An organization can run well and get completely as performance produced by every other component running smoothly and mutually supported[3].

One attitude or behavior to improve the performance of nurses in the structure of course behavior that leads to positive things that are known as organizational behavior (ocb) citizenship that is the individual that exceeds demand and the role of. But not all employees voluntarily want to does more their formal task on their job description contains[4]

Corresponding Author:
Miftahul Munir

Contact No.: 081231992611
e-mail: bahranmifanda69@gmail.com

One of the ways to enhance the performance of nurses is by the presence of organizational behavior (ocb citizenship in organization so that it will give rise to the atmosphere a harmonious work[5]. Hence, very important a nurse having organizational behavior citizenship behavior (OCB) the atmosphere than last year in order to have a comfortable so as to cause a working relationship which harmonious in order to increase performance workers to reach organizational goals[6].

Material and Method

This research design of observational analytic, the population is nurses public health centre in the district tuban a total of 24 people, simple sampling technique random sampling .The independent variable citizenship organizational behavior and the dependent variable for the performance of nurses and an instrument the research uses a sheet of the questionnaire was test with data analysis using the spearman rank[7].

Findings:

1. The distribution of respondents ocb nurse

No.	OCB	*f*	Prosentase
1	Height	16	69,6%
2	Medium	4	17,4%
3	Low	3	13,0%
	Total	23	100%

Based on the table above can be seen from 23 (100%) respondents said that the majority of 16 (69,6%) respondents own high of ocb

2. The distribution of respondent based on the nurses

No.	Performance nurse	*f*	Prosentase
1	Good	12	52,2%
2	Medium	10	43,5%
3	Low	1	4,3%
	Total	23	100%

Based on the table above can be seen from 23 (100%) respondents said that the majority of 12 (52,2%) respondents have a good performance.

3. The influence of organizational behavior citizenship (ocb) on the performance of nurses

OCB		Performance Nurse		Total
	Good	Medium	Low	
Hight	11 (68,8%)	5 (31,3%)	0 (0,0%)	16 (100%)
Medium	1 (25,0%)	3 (75,0%)	0 (0,0%)	4 (100%)
Low	0 (0,0%)	2 (66,7%)	1 (33,3%)	3 (100%)
Total	12 (52,2%)	10 (43,5%)	1 (4,3%)	23 (100%)
Value	α = 0,05	*p* = 0,005		r = 0,563

From the table above it can be seen from 23 (100%) of respondents that almost most of which have ocb high with a good track record in 11 (68.8%) of respondents, having ocb being with the performance of being 3 (75,0%) and that has ocb low with the medium of performance 2 (66.7%)

Based on an analysis by using spss for windows with the spearman rank α= 0,05 obtained the p = 0,005 value $p < \alpha$ so variable ocb have significant influence on performance a nurse with the correlation was (r = 0,564) and direction positive correlation means the higher ocb better performance nurse at work.

Discussion

1. **Behavior identification organizational citizenship (OCB) in nurses:** Most of nurses in public health centre in the district tuban having organizational citizenship behavior (OCB) the height.

   Organizational citizenship behavior (OCB) in generally believed that to achieve excellence must have their individual performance of as high as, because basically individual performance influences the performance as a whole ocb organization is the act of someone out kewajibanya not consider the interests of the himself[8].. This behavior have changed in line how passionate organization on welfare levels individual and appreciation organization against their contribution[9]. The majority of respondents having ocb high, because some aspects of: alturism, civic virtue, conscientiousness, courtesy, sportmanship.OCB also is the unique individual activities in working and is the customs or manners performed voluntarily, no formal is part of the job, and indirectly identified by a system of rewards[10] .So it can be concluded that ocb also called the behavior extra role of concurrent given individual exceeds main function[4].

   This research result indicates that there are 16 respondents own ocb high and 3 respondents own ocb. lowIt is in because the willingness of nurses to take the role of (role) that exceeds a lead role in an organization, so called as behavior any extra roles (extra role).It is to achieve the success of an organization when its members not only working on his main job just, but also want to do extra duty, like the will to cooperate, help each other, provide input into, actively involved, provide service extra, as well as wanting to use the hours are effectively.

2. **Identification performance nurse:** Performance is the result of a work or process of an end of a activities. The performance is a motion or action that have been carried out in a conscious geared to achieving a goal or a specific target. The performance was a result of working to the awards by a person or a group of people in accordance with their respective authorities and responsibilities of each party, as forms of businesses in achieving legally organizational goals, not unlawful and in accordance with moral and ethical[11].

   The performance is an illustration of the level of achievement of implementing a program or policy activities in realizing the target, the purpose of, the vision and mission of the organization that was poured through strategic planning an organization .For that reason the performance of individual basically can be influenced by a number of factors such as the quality of, the quantity, the effectiveness of, timeliness and independence[12].

   From the research the majority of respondents having a good track record .It was because the performance of supported by a factor of an external and an internal, the internal factor, that is, that deals with the properties of a person .While the external factor that is the factors that influences the performance someone who originated in the neighborhood[13].

   As behavior, attitude, and the colleague, subordinate or leadership of, work facilities and climate organization .Where factors that might have an impact on working system given by organization or the hospital .Individual ocb influences the performance, and therefore this behavior is leading to the social interaction of members of an organization are more reliable, reducing the conflict, and improve the efficiency[14].

3. **The influence of organizational citizenship behavior (OCB) on the performance of nurses:** The result of this research is the organizational citizenship behavior (OCB) on the performance of nurses. OCB influential positive and significantly to the performance of individual[8]. It is anyone had showed that the of individuals having an attitude of my doubts but towards their job of his colleagues or help with the work of his colleagues the more one is high performance general of the agriculture ministry, of individuals having an inclination to favor the relevant organisation s with the role of and decrease the participation in a central organization, of individuals having the level of consciousness of doing things which includes in this data collection referred to the dispatch priorities the presence of the use of the time of work[15]. The individual had tinggat awareness in working eat, employee performance will be good too individuals having a polite and manners, organization individuals having sportifits in working involving a willingness to tolerate discomfort true and risk jobs without the complaining employees own attitude sportsmanship in working for the good performance these individuals[16].

   Research conducted by researchers from the data can be proved the organizational citizenship behavior (OCB) by means of distributing the sheets for two times a week.This is evidenced by the results of research of 23 (100) percent of respondents said that almost entirely having ocb high performed well 11 (68,8%), respondents having ocb was with performance and 3 (75,0%) and who has low ocb with performance and 2 (66,7%).This karenakan willingness nurse to take the roles of (role) beyond, primary role in an organization so called as the behavior of the role of extra (extra-role).

   It is to achieve the success of an organization when its members not only do, main function of only but also want to do the extra, as a willingness to cooperate,, help each other inform, active, provide service extra, and will want to make use of their working time effectively[17].

Conclusion

The influence of organizational behavior citizenship (ocb) on performance tuban public health centre in the district nurse

Abstract

Background and Objective: This study aimed at assessing the skeletal stability of adjustable miniplates in comparison to conventional miniplates following bilateral sagittal split ramus osteotomy (BSSRO)

Materials and Method: Fourteen patients were divided into 2 equal groups. Patients in both groups underwent BSSRO and mandibular setback. In the study group, the bone segments at the osteotomy site were stabilized using the adjustable plates and four 2.0 mm monocortical screws. In the control group, bone segments at the osteotomy site were stabilized using conventional miniplates and four 2.0 mm monocortical screws. Each patient was assessed in terms SNB, mandibular plane angle (MPA) recorded in degrees (°) and horizontal and vertical changes of the B-Point recorded in millimeters (mm).

Results: Skeletal stability was contemporaneous in both groups with an insignificant difference regarding the assessment criteria. However, adjustable plates showed the advantage of decreasing operative time when occlusion is not perfect at the release stage and adjustments were required.

Conclusion: The choice of the fixation method should combine between sufficient stability for early jaw mobilization and elasticity to allow for intraoperative and early postoperative corrections. Such requirements were met by the adjustable plates.

Keywords: *BSSRO, adjustable plates, fixation.*

Introduction

Dentofacial deformity signifies significant unconventionalities from ordinary scopes of the maxillomandibular complex. In 1907, ***Angle*** described Class III malocclusion as when "the lower first molar is in a mesial positioned in relation to the upper first molar". This type of deformity includes a relatively trivial segment of the regular orthodontic run through. However, these cases are among the most challenging to be treated effectually and productively.(1)

Skeletal class III malocclusions were alleged to be solely accredited to anoutsized and/or prominent mandible, this was till the 1970s. But in reality, it can be the product of mandibular prognathism with a customarily situated maxilla, maxillary retrognathism with a normal mandible or mixture of maxillary retrognathism and mandibular prognathism.(2)

The prime goals of successful orthognathic surgery are the restoration of normal jaw function, optimal facial esthetics, and long-term stability. The most common orthognathic practice is a bilateral sagittal split ramus osteotomy (BSSRO) to setback or advance the mandible. From a surgeon's point of view, long-term stability following BSSRO may be the most imperative thing to accomplish.(3)

Several method of fixation are used to achieve

acceptable postoperative stability, including bicortical screws or miniplates. These meansare used to position the proximal and distal segment after BSSRO. Several studies have been conducted comparing the postoperative skeletal stability between different types of osteosyenthesis.[4]

The presented study is to investigate the postoperative skeletal stability following BSSRO in mandibular setback surgeriesusing adjustable versus monocortical miniplates by identifying the horizontal and the vertical changes of mandibular position through lateral cephalometry.

Materials and Method

Study group: The plates used in our study were the 2.0 Dr. SABOYE adjustable plates on site manufactured by GlobalD, France. The plate was 1 mm thickness and consisted of 2 vertical plates–a long and a shorter one - connected by two adjustable arms. The long plate is was 15mm and the short one was 12mm. The distance between the two plates was 17mm having an adjustable joint in each arm that could be modified using plate-specific pliers accompanying the kit, the joints were either expanded or compressed to achieve the desired result. This was to allow anterior, posterior, clockwise and counter-clockwise directional change.

Comparator Group: Conventional 4-hole with space monocortical miniplates and screws were used.

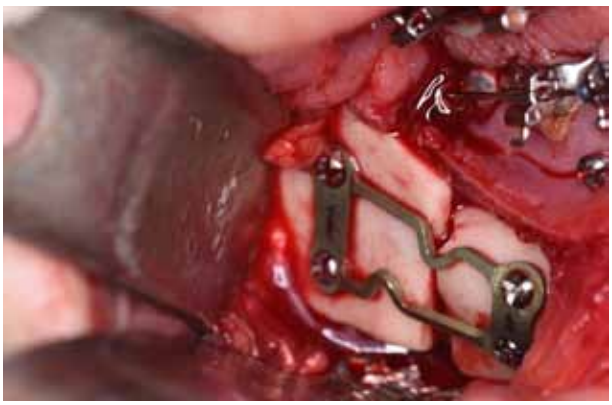

Fig. 1: Adjustable plate placement after osteotomy

Study Population: 14 patients were selected suffering from class III skeletal relationship. The history and detailed medical examination data for each patient was collected in a chart prepared specially for this study. Standard preoperative patients' photographs were taken. Fabrication of intermediate and final dental splint was carried out on the surgical model conventionally.

Clinical data: Mandibular range of motion, occlusion, wound healing, temporomandibular joint dysfunction syndromes and inferior alveolar nerve paresthesia in addition to other complications as infection or facial nerve injury was evaluated for each patient.

Radiographic data: Radiographic follow-up was achieved through lateral cephalometric radiographs. Panoramic radiographs were ordered immediately postoperatively to check the condylar position and the location of plates and screws. Lateral cephalometric radiographs were ordered immediate postoperative (F1), 3 months (F2), 6 months (F3), and 1 year postoperatively (F4) to develop cephalometric analysis which compared that performed preoperatively (F0) to evaluate the surgical changes and the amount of relapse. All radiographs were traced using Dolphin software using Wits and Stiener analysis.

The Data collected included angular measurements, SNB (the angle formed between the anterior cranial base (S-N) and a line drawn through N and B point), MPA (The angle formed between the mandibular plane (Go-Me) and the anterior cranial base (S-N)) recorded in degrees (°) and horizontal and vertical changes of the B-Point (the innermost point on the contour of the mandible) recorded in mm.

Horizontal changes at B-point were measured and calculated by a perpendicular line to Frankfort horizontal plane (FH)(The plane demonstrated by a line through the orbitale and porion) passing through Nasion (N) point. Vertical changes at B-point were measured and calculated from perpendicular to FH line. Changes to these landmarks were recorded at 2 different time intervals, F0-F1 (representing the surgical change) and F1-F4 (representing the amount of relapse). Posterior movement of the mandible was represented by negative values while anterior movement was represented by positive values. On the other hand, superior movement of the mandible was represented by positive values while inferior movement was represented by negative values.

Results

Male to female ratio was 0.75 (6 males and 8 females) with average age group of 24.1 (22–27 y). All patient had class III skeletal relationship, eight required bimaxillary surgery and only six patients required only mandibular setback.

Surgical Results: For all patients, the surgical procedures were performed without any major complications. All inferior alveolar nerves were either embedded in the distal segment or visible but embedded in the distal segments. However, in two cases a bad split occurred on the left side of the mandible in one case and on the right side in the other during splitting and the decorticated fragment was fixed again in place using miniplates.

Clinical Results: The early postoperative period for all patients went uneventful with no significant complications. All patients showed postoperative edema with variable degrees. Patients who underwent single jaw surgery had mild edema which had resolved within 1-2 weeks, while patients who underwent bimaxillary surgery showed severe edema which resolved in 2–4 weeks. Early mandibular function was started for both groups. All patients were satisfied with the esthetic results.

Radiographic Results

SNB and MPA: Concerning SNB, for the mean percentages of relapse showed no statistically significance differences between the two groups at F0 to F4. However, there was a statistically significant difference between the two groups regarding the mean percentages of relapse. Concerning MPA, there was no statistical differences between the two groups regarding the mean percentages of relapse.(Table 1)

Table 1: Comparison of the means and standard deviation values of SNB and MPA in the different time periods

		F0		F1		F2		F3		F4		Relapse %	
		Mean ± SD	P-value	Mean ± SD	P-value	Mean ± SD	P-value	Mean ± SD	P-value	Mean ± SD	P-value	Mean ± SD	P-value
SNB	Group I	84.82±4.20	0.749	79.17±2.74	1.000	79.82±2.85	0.485	80.35±3.16	0.302	80.82±3.35	0.239	2.02±0.72	0.000*
	Group II	86.1±4.93		79.81±4.57		81.34±4.72		82.62±4.58		83.42±4.42		4.55±0.84	
MPA	Group I	34.77±3.06	0.994	31.6±3.0	0.757	32.27±3.1	0.485	32.75±3.0	0.305	33.25±3.01	0.239	4.99±1.0	0.226
	Group II	34.75±3.61		31.65±3.64		32.42±3.72		33.08±3.66		33.75±3.72		6.25±1.76	

Point horizontal and vertical: For B horizontal, the mean percentages of relapse showed no statistically significant differences between the two groups at F0-F1 and F1-F4. In addition, there was no statistical differences between the two groups regarding the mean percentages of relapse. For B vertical, the mean percentages of relapse showed no significant differences between the two groups at F0-F1 and F1-F4. There was a statistical difference between the two groups regarding the mean percentages of relapse (Table 2).

Table 2: Comparison of the means and standard deviation values of B point in a horizontal and vertical direction in the different time periods.

		F0-F1		F1-F4		Relapse %	
		Mean±SD	P-value	Mean±SD	P-value	Mean±SD	P-value
B Horizontal	Group I	-4.87±1.46	0.075	1.47±0.30	0.850	32.76±12.76	0.357
	Group II	-5.02±1.31		1.87±0.45		38.23±8.5

Discussion

BSSRO is the gold standard surgical technique used for mandibular advancement and setback. Postoperative relapse is the most common drawback. With the advent of rigid internal fixation across the osteotomy site, uncontrolled skeletal relapse is unlikely to occur. Skeletal remodeling at the site of osteotomy and the mandibular condylar heads may postoperatively continue up to one year. At the time of the sagittal splitting of the mandible, it is imperative to precisely position the proximal mandibular segment prior to fixation application.[5]

Many factors can influence the postoperative stability of the mandible, including the amount of setback, postoperative re-orientation of the pterygomasseteric sling, the bowing effect of the proximal segments, occlusal disharmony, and positional changes of the mandibular condyle and proximal segment.[6]

Adjustable plates have the advantage of decreasing operative time when occlusion is not perfect at the release stage and adjustments are required. Using the plate-specific pliers accompanying the kit, the joints can be either expanded or compressed to achieve the desired result. This allows anterior, posterior, clockwise and counter-clockwise directional change.

In the current study the age ranged between 22 and 27 years in order to avoid the effect of age on postoperative stability. ***Joss and Vasalli*** in their systematic review did not report post-surgical growth of the mandible after BSSO setback because the age was between 20 and 32 years.(7)

Data was aggregated in the form of mean and standard deviation (SD). 95% CI together with 0.05 P-value will be additionally reported. Data was analyzed using IBM SPSS advanced statistics (Statistical Package for Social Sciences), version 21 (SPSS Inc., Chicago, IL). The stability of mandibular position was described as mean and standard deviation. The Mann-Whitney U test was performed to test the significance between the 2 groups at each time period. Friedman's test followed by multiple comparisons test was performed to test the significance between the 4 time periods within each group. In addition, correction of p-value was done using Bonferroni adjustment to avoid hyperinflation of type 1 error that arises from multiple comparisons. A p-value ≤ 0.05 was considered statistically significant. All tests were two tailed.

For both groups F0-F1 was characterized by posterosuperior mandibular movement. This was accompanied by a decrease in SNB and MPA. Autorotation of the mandibular distal segment resulted during surgery and lead to superior movement of B point. For both groups, F1- F4 was characterized by anteroinferior mandibular movement.

Righi et.al and **Fujioka et.al**concluded a similar anteroinferior mandibular movement which took place during the follow-up period. They proposed that the "shearing force is the most noteworthy load affecting the maxillomandibular system stability after osteotomy". In case of BSSRO, these "shearing stresses" act on the osteotomy site and causes clockwise rotation of the distal segment and counterclockwise rotation of the proximal segment.(8,9)

Lee et al reported that postsurgical skeletal changes after surgery-first approach BSSRO setback were also in the anterosuperior direction.(10) In contrast, **Kim et al** reported that changes were in the anteroinferior direction and they postulated that the possible reasons for this difference were mandibular counterclockwise rotation after surgical splint removal and differences of facial types among patients.(11)

Previous studies fixated on postoperative skeletal stability and the extent of relapse after BSSRO mandibular setback depending on fixation method. **Abeltins et al.** stated that the mean (SD) horizontal relapse at B point was 1.4 mm.(12) **Ballon et al.** reported the point B point horizontal relapse was 1.05 mm.(13) **Landes and Ballon** reported that horizontal relapse at point B was 2.0 mm.(14) These authors all used four-hole sliding plates to fix the mandibular bony segments.

Rao et.al evaluated the skeletal stability after BSSO in advancement and setback cases using miniplates. In the setback group, mandibular plane had a statistically significant change position of 1.4 mm (paired t-test, $p = 0.03$). The SNB angle, remained constant during the follow-up period. In advancement cases, the relapse was seen from the third month postoperative period but in setback cases, the relapse was noted from the sixth month onward and the skeletal relapse in these cases were noticed cephalometrically.(15)

Hsu et.al evaluated mandibular prognathism stability corrected by BSSO comparing bi-cortical osteosynthesis and monocortical miniplates, the percentage of relapse in the miniplates group was 25%.(16) A reasonable explanation for the difference in mean mandibular relapse results is the length of the follow up period (6 months only).

Veyssiere's study on the preliminary effect of an adjustable S-shaped plate on 15 consecutive cases showed good results, with respect to the mechanical reliability of this plate for three months postoperatively corresponding to the bone-healing period. Radiographic observations did not show any significant displacement at the osteosynthesis site. Class III patients showed good clinical results without any occlusal relapse. From the radiographic study of this group, no patient has presented significant postoperative bone movements.(17)

In addition to time saving, the integrity of the bone at the site of fixation was preserved, instead of screws removal and re-drilling which could compromise the integrity of the bone. This is an additional comfort we have chosen to adopt in our study. Finally, the simplicity

of the adjustment of these plates after centric relation check avoids any compromise in occlusion at the end of the surgery.

Other than our results, the choice of the fixation method should combine between sufficient stability for early jaw mobilization and elasticity to allow for intraoperative and early postoperative corrections. We think that the adjustable plates meet these criteria.

Funding: The study was self-funded.

Competing Interests: No conflict of interest.

Ethical Approval: The Ethics and research committee, Faculty of Dentistry, Cairo University approved the study and patients' consent was obtained.

Factors Influencing Rate of Chest Compression in Cardio Pulmonary Resuscitation (CPR) by Nurses as a First Responder

Moch. Sukron Prasetyo N.A.[1], Sanarto Santoso[2], Tony Suharsono[3]

[1]Student of Magister Nursing Program, [2]Lecturer of Faculty of Medicine,
[3]Lecturer of Magister Nursing Program, University of Brawijaya, Indonesia

Abstract

Introduction: Cardiac arrest is a condition of the cessation of blood circulation in the body. First aid cardiac arrest is cardiopulmonary resuscitation consisting of chest compression and ventilation. Chest compression is a factor that affects the return of spontaneous circulation (ROSC) patients. In addition to the depth of chest compressions, the chest compression rate is a major factor that can increase the chances of the patient's life shortly after suffering a cardiac arrest.

Aim: The purpose of this study is to determine the factors that affect the rate of the chest compressions performed by nurses as a first responder.

Method: The method used in this study is analytic cross sectional correlative to 107 respondents. Chest compression rate measurement using a chest compression CPR Help Zoll's Real product was analyzed using an application Rescue Net Code Review.

Finding: Preliminary study results showed that the factors that affect the rate of the chest compression is gender, age, BMI, education, the last time attend to BLS training and the last time giving chest compressions. Based on the results of the linear regression analysis, gender is a factor that most affects to the rate of the chest compression ($\beta = -7.8$). It explains that the male responder provide a faster compression 8x/min compared with female responder.

Conclusion: In conclusion, gender, the last time attends to BLS training and the last time provides chest compression significantly affect to the rate of the chest compression.

Keywords: *Cardiac arrest, Rate, Chest Compression.*

Introduction

Cardiac arrest is a condition in which the cessation of blood circulation caused by heart failure in effectively contract[(1)], Cardiac arrest that persists for ten minutes can result in the death of vital organs in the body. Such conditions require immediate action. If there is a delay in the delivery of the action, the likelihood of success is reduced 7-10% every minute[(2)], The incidence of sudden cardiac arrest in the United States an estimated 200,000 patients annually[(3)], In Indonesia, the incidence of sudden cardiac arrest patients is still not clear data obtained, but it is estimated around 10,000 people in one year or 30 people every day[(4)].

Preliminary studies showed that patients who had a cardiac arrest and need a Basic Life Support (BLS) procedure in private hospital on 1 January 2018 and May 2018 in 38 patients. As for the number of patients who visit the diagnosis of coronary artery disease and are at risk of sudden cardiac arrest as many as 910 patients.

Sudden cardiac arrest can occur in hospital and out of hospital. In hospital cardiac arrest is a major cause of death of patients hospitalized[(5)]. Cardiopulmonary resuscitation (CPR) is an action that should be given to patients with sudden cardiac arrest [(6)].

Cardiopulmonary resuscitation (CPR) consists of chest compression and ventilation. Chest compression

aims to deliver blood to the vital organs such as the heart and brain and stimulate the return of spontaneous circulation (ROSC) in patients[7]. Medical personnel should provide chest compressions as soon as possible when met patients with cardiac arrest. A nurse who on duty for 24 hours is a potential first responder for the patients[8].

Quality chest compressions includes five components, namely the average rate giving chest compressions as much as ≥ 100-120 x/min, chest compression depth around 5-6 cm, the return of the chest, hand position and no interruption more than 10 seconds[9]. Components of rate chest compression is one of the main factor that can increase the chances of the patient's life shortly after cardiac arrest[10]But the quality of chest compressions given today by nurses is below standard[11].

A study reports that there is a decline in the quality of chest compressions in the first minute are only able to provide 98%-quality chest compressions, and in the fifth minute only able to provide 18% of the expected target of chest compressions [12].

Based on a study involving subjects with age 31 years ± 5:34, mentions that there is no correlation between age responder with the quality of chest compressions given[13].

Other studies mention that the responder with a BMI> 24 is able to provide better chest compressions than responder with a BMI <24[14], but other research said that the subject of women with a BMI <26 were able to give chest compressions faster than female subjects with a BMI> 26[15].

Based on the literature, researchers wanted to determine the factors that influence the rate of the chest compression in cardiopulmonary resuscitation (CPR) provided by nurses as a first responder.

Method

The research design used in this study are correlative analytic with cross sectional study. In this study were recruited on voluntary basis, conducted between January and April 2019.

The population in this study was nurses who work in private hospital. The sampling technique used purposive sampling was 107 nurses with the following inclusion criteria: male or female age 21-43 years, minimum education level diploma and maximum bachelor of nursing (BN), respondents had attended training Basic Life Support (BLS) procedure according to American Heart Association (AHA) 2015 guidelines. The exclusion criteria were pregnant and chronic diseases that make the responden weak and disable do physical exercise.

Before the data collection process, the respondents should fill the agreement form. Then, researchers will measure the height and weight of respondents, as well as provide relevant demographic data questionnaire respondents. The next process, researchers will give a presentation case of cardiac arrest in the hospital, and assess the response to the case.

Respondents are expected to provide chest compression for a minute on props. The data has been recorded, stored in CPR Help Zoll's Real product, and then analyzed using an application Rescue Net Code Review.

This study already gets ethical clearance by the Health Research Ethics Commission in Faculty of Medicine, *Universitas of Brawijaya* with number series 54/EC/KEPK–S2/02/2019.

Finding:

Table 1: Distribution Characteristics of Respondents by Age, Body Mass Index (BMI), When Was the Last BLS Training and When Was the Last Giving Chest Compression

Variables	Min-Max	Mean ± SD
Age (Years)	21-43	28.16 ± 4.5
BMI (Kg/M²)	16-32	22.13 ± 3.4
The last BLS training (Month)	1-60	14.26 ± 1.1
Last giving Chest compression (Month)	0-36	8.71 ± 1.2

According to the table 1, it can be explained that the average age of respondents was 28 years, with a minimum age of 21 years and maximum 43 years. Furthermore, the average BMI was 22, with a minimum value of 16 and a maximum value of 32.

The average last training BLS of respondents is 14 months ago, with a minimum last training is 1 month ago and maximum last training is 60 months ago. the averaged last giving chest compressions is 8 months ago, with minimum last giving chest compression is less than 1 month and maximum is 36 months ago.

Table 2: Distribution Characteristics of Respondents by Gender and Education Background Respondents

Variables	N	%
Gender		
Man	36	33.6
Woman	71	66.4
Education		
Diploma	78	72.9
BN	29	27.1

According to the table 2, it can be explained that the gender most are women that are 71 respondents (66.4%), education background of respondents the most is a Diploma as many as 78 respondents (72.9%), but only 29 respondents (27,1%) are diploma.

Table 3: Chest Compression Rate in One Minute

Variables	Min-Max	Mean ± SD
Chest Compression rate	84 -190	139 ± 1.7

Based on table 3, it can be seen that the average rate of the chest compressions is 139x/min. The minimum rate is 84x/min and maximum rate is 190x/min.

Table 4: Linear Regression Analysis of Factors influencing Chest Compression Rate

Variables	R	P	R Square
Gender	-7.88	0,025	.151
Last BLS training	-0.32	0,018	
Last giving Chest compression (Month)	-0.30	0,023	

Based on the linear regression analysis, age, education background and BMI did not significantly influence the compression rate.

According to the table 4, the factors that influence the rate of the chest compression are gender, when the last BLS training and when the last giving chest compression with all p value <0,05. The three factors to explain the variable compression rate of 15.1%.

Any increase in the last 1 month long training conducted by a nurse will reduce chest compression rate of 0,32 after controlling for other variables. If the chest compressions performed by a male nurse will faster 7x/min when compared to women. The last experience giving chest compressions significantly affect the rate of the chest compression. Any increase in the last 1 month long experience of giving chest compressions will reduce the rate of chest compressions as much as 0,30.

Discussion

A study explains that the greater number of chest compression rate will increase the possibility of return of spontaneous circulation or (ROSC)[16],

Based on this study, male nurses provide faster compression when compared to female nurses, it is likely due to greater muscle mass is owned by male nurses, as well as a larger body size than female nurses [17]. However, other studies explained that gender significantly influence the chest compression rate with p value = 0.00, but the study also explains that the female respondents giving chest compressions faster when compared to the male respondents[15].

Other studies mention that the male respondents (20%) were able to give chest compressions is more than 200 times in two minutes when compared to female respondents (0.03%) [18]. The ability of male respondents in providing chest compressions faster when compared to female respondents likely due to the size of the female body that is lighter and shorter than the size of the male body.

BLS training is one of the factors that play a role in improving skills and knowledge of the respondent to provide basic life support in patients with cardiac arrest. One important component in the training of BLS is cardiopulmonary resuscitation (CPR). Cardiopulmonary resuscitation (CPR) is the first aid to be provided by a nurse as the first responden before the code blue team came.

In addition to gender, according to this study, when the last attend to BLS training significant effect on the rate of the chest compression. The longer the respondents did not attend training BHD, it will decrease the rate of chest compressions. This was due to the declining ability and knowledge of respondents about the up to date basic life support.

Another study explains that the skill level of the respondents is 18.7% before training, after training increased to 93.5%. However, after 10 weeks of training this value decreased to 82.5% and after two years of training, the value declined significantly to 36.8% [19]. BLS is the instructional media training that includes knowledge and skills in providing basic life support.

BLS periodic training is expected to enhance the skills and knowledge of nurses, so nurses more confident and competent when faced with a patient with cardiac arrest.

In addition to gender and last BLS training, other factors that affect the rate of the chest compression is when the last experience giving chest compressions. Nurses often give chest compressions on a patient reported to be rapidly exhausted in giving chest compressions[18]. Other study states that the medical officer who works in the emergency room with chest compression condition often do not get tired when giving chest compressions when compared with medical personnel who work in the other room[20].

BLS training must often give to nurses as medical personnel that play a role into the first responden of cardiac arrest in the hospital.

Another study said that rate.

Conclusion

Based on the results of multiple linear regression analysis, there are three factors that influence the rate of the chest compression is gender, when the last BLS training and when the last giving chest compression. All three of these factors have a significant influence with each value -7.88, -0.327 and -0.303. This study can be used as a reference to hospitals and health care workers in an effort to improve the quality of chest compressions, especially on chest compression rate.

Conflict of Interest: In this Study, there is no conflict of interest.

Source of Funding: In this study, a whole funding is accounted on the researcher independently. There are no other funding sources.

Abstract

Objectives: To evaluate and compare the effectiveness of atropine alone and the combined therapy of atropine and glycopyrrolate in treatment of patients with acute organophosphate poisoning (OP).

Patients and Method: Forty patients with history of OP poisoning were included in the study with in the period from 1st of March 2017 to 28th of February 2018. The study is a prospective randomized controlled trial that was carried out on patients admitted to Poison Control Center of Minia University Hospital. These patients were divided in to two groups of 20 patients each. Group I was treated with atropine alone while group II was treated with atropine in combination with glycopyrrolate.

Results: The majority of the patients were females (55%). The outcomes of these two groups were analyzed and compared including percentage of mortality, percentage of recovery, duration of hospital stay, need for mechanical ventilation, incidence of intermediate syndrome and percentage of adverse reactions. The percentage of recovery and percentage of mortality were the same between the 2 groups with p=1. However, there was reduction in hospitalization days and incidence of adverse drug reactions of the used drugs in group II when compared to group I.

Conclusion: The study suggests that treatment with combined therapy of atropine and glycopyrrolate was more effective than therapy with atropine alone regarding the reduction in the duration of hospital stay and incidence of adverse reactions of the used drugs.

Keywords: *Organophosphorus poisoning, atropine, glycopyrrolate.*

Introduction

Organophosphorus (OP) compounds are largely used as pesticides worldwide. Their easy availability and lack of knowledge about their seriousness resulting increase in accidental and suicidal poisoning. According to a World Health Organization (WHO) report, every year three million cases of poisonings with insecticides occur worldwide resulting in approximately 200,000 deaths.[1]

OP insecticides are irreversibleacetyl cholinesterase (AchE) enzyme inhibitors. The clinical manifestations are caused by excess acetylcholine (Ach)at themuscarinic receptors, nicotinic receptors and in CNS. Manifestations of OP poisoning occur in three phases: Acute cholinergic crisis (first 48 hours),intermediate syndrome (IMS) (24-96 hours after poisoning) and OP induced delayed polyneuropathy.[2]

Anticholinergics are competitive antagonist to Achand reverse all muscarinic effects both in CNS and

peripheral nervous system. Glycopyrrolate is a synthetic quaternary amine with peripheral effects similar to those of atropine. It is longer acting drug and doesn't cross the blood brain barrier and therefore, it has lesser effect on CNS.[3]

Aim of the work: The aim of this study is to evaluate and compare the effectiveness of atropine alone and the combined therapy of atropine and glycopyrrolate in treatment of patients with acute organophosphate poisoning (OP).

Patients and method: The study is a prospective randomized controlled trial that was carried out on patients admitted to Poison Control Center of Minia University Hospital. Forty patients were collected within the period from 1st of March 2017 to 28th of February 2018. Written informed consent was obtained from relatives of all patients.

Patients: Forty patients with acute OP toxicity of both sexes aging from 20 to 60 years were included in the study. Diagnosis was made by history of exposure to OP compound, clinical manifestations and by measuring pseudocholinesterase enzyme level. These patients were divided in to two groups of 20 patients each. Group I was treated with atropine alone while group II was treated with atropine in combination with glycopyrrolate.

The cases included in the study were chosen as they have no history of previous diseases including hepatic, renal, cardiovascular, respiratory or CNS illness. Patients were excluded from the study if they had concomitant ingestion of other drugs in a suicidal attempt. Patients with trauma, patients with drug or alcohol abuse and patients presented to emergency department 24 hours after OP exposure were also excluded.

Atropine was given either as a continuous infusion or intermittent dosing (the end-point of atropinisation was drying of secretions, flushing, tachycardia and mydriasis). Continuous infusion was started as 0.02-0.08 mg/kg per hour and intermittent dosing was performed using atropine in the doses of 2 mg IV and then 2 mg after every 5-10 minutes till the signs of atropinisation appeared. After achieving atropinisation, the interval between the doses was increased so as to maintain adequate atropinisation. Atropine was then slowly withdrawn over a period of 3-5 days.

Glycopyrrolate was given at a dose of 7.5 mg infused in 200 ml saline till the desired effects of dry mucous membranes. It has also been given at a dose of 0.2 mg IM and repeated every 6 hours if required.

Outcome: All the patients were observed for short-term outcomes either complete recovery or death and total duration of hospital stay.

Complications: All patients observed for the complications developed during hospital stay e.g intermediate syndrome, respiratory tract infection, need for mechanical ventilation, CNS toxicity and other adverse effects.

Statistical analysis: Statistical analysis was performed using the SPSS software for Windows v. 20 (SPSS Inc., Chicago, IL). For comparing quantitative data, Kruskal Wallis test and Mann Whitney tests were performed. For comparing qualitative data, Fisher exact test was performed. A probability value (p=0.05) was considered statistically significant.

Results

During one year study forty patients with acute OP poisoning were evaluated. The majority of the patients were females (55%).Group I consisted of 20 patients with the mean age of 25.3±6.2 mostly from rural areas(80%). Group II also consisted of 20 patients having mean age of 34.3±13.6 and most of them belonged to rural areas (70%). There was no significant difference in demographic data and time of arrival between the 2 groups. As regard percentage of recovery and percentage of mortalitythere was no significant difference inpatients treated with atropine alone and patients treated with acombined therapy of atropine and glycopyrrolate (P=1) However, there was reduction in hospitalization days in group II when compared to group I (Table I).

There was no significant difference in need for mechanical ventilation and incidence of intermediate syndrome between the 2 groups with P=1 (Table II).It was found that the combined treatment of atropine with glycopyrrolate reduces dose of atropine with P=0.278 (Table III) with subsequent decrease in atropine adverse effects. Incidence of confusion, hallucinations and tachyarrythmias were significantly more in group I when compared with group II with P>0.001 (Table IV).

Table I: Outcome data between the study groups

		Group I	Group II	P value
		N=20	N=20	
Hospital stay	Median IQR	5 (4-6)	4 (3-5)	0.066
Outcome	Recovery Died	18(90%) 2(10%)	18(90%) 2(10%)	1

IQR: Interquartile range, Significant level at P value < 0.05

Table II: Complications between the study groups:

		Group I	Group II	P value
		N=20	N=20	
Ventilation Required	No Yes	16(80%) 4(20%)	16(80%) 4(20%)	1
Intermediate Syndrome	No Yes	18(90%) 2(10%)	18(90%) 2(10%)	1
Respiratory Ttract infection	No Yes	14(70%) 6(30%)	16(80%) 4(20%)	0.465

*: Significant level at P value < 0.05

Table III: Doses of atropine used in treatment between the study groups

		Group I	Group II	P value
		N=20	N=20	
Atropine	Median IQR	55.5 (42-90)	49.5 (31-70)	0.278

IQR: Interquartile range, Significant level at P value < 0.05

Table IV: Adverse effects of the drugs between the study groups

		Group I	Group II	P value
		N=20	N=20	
Confusion	No Yes	2(10%) 18(90%)	14(70%) 6(30%)	<0.001*
Hallucinations	No Yes	2(10%) 18(90%)	14(70%) 6(30%)	<0.001*
Tachyarrythmias	No Yes	0(0%) 20(100%)	10(50%) 10(50%)	<0.001*
Fever	No Yes	6(30%) 14(70%)	12(60%) 8(40%)	0.057

*: Significant level at P value < 0.05

Discussion

Organophosphates are one of the most common causes of poisoning especially in developing countries with mortalityrates reaching up to 10-20%. So early diagnosis and appropriate treatment is often life saving.[4]

The antidotes of OP poisoning are anticholinergic drugs such as atropine and glycopyrrolate, atropine being the older of the two medications. Muscarinic effects of OP poisoning are reversed by these drugs. Conventional treatment with atropine may lead to CNS toxicity, although control of secretions may still be inadequate.[5]

Glycopyrrolate (glycopyrronium bromide) is a quaternary ammonium with anti-muscarinic activity and peripheral actions like to that of atropine, however glycopyrrolate is twice as potent as atropine for peripheral effects. It can be safely use during pregnancy as it doesn't cross the placentalbarrier. Glycopyrrolate can't pass through the BBB so it does not have any detectable central anti-cholinergic effects.[6]

Atropine is universally accepted antidote most frequently used for the patients of OP poisoning. Some of the previous studies revealed that atropine treatment is effective, however it often causes agitation, hallucinations and confusion. Other effects of atropine treatment are hyperthermia, bowel ileus, urine retention and tachycardia, however the use of combined therapy of atropine and glycopyrrolate improves tachycardia with no changes in body temperature and CNS stimulation hence glycopyrrolate can't pass through the BBB.[7] Out of all the forty patients included in the study confusion and hallucinations were seen in 24 (60%) cases and 18 cases of them were from Group I. Incidence of confusion and hallucinations is significantly more Group I when compared to group II with P<0.001.

So it was found that the combined treatment of atropine with glycopyrrolate reduces dose of atropine with P=0.278 and also reduces the central adverse effects associated with it improving the quality of treatment.

Other clinical manifestations seen were intermediate syndrome in 2 (10%) case in group I and 2 (10%) cases in group II. Respiratory infection was seen in 10 patients, 6 (30%) cases of them from group I explaining that combined therapy of atropine and glycopyrrolate provides better control on chest secretions. Out of 40 cases 36 patients recovered and 4 patients died. Incidence of mortality is not statistically significant between both groups.

Our study found that there was no significant difference in mortality between patients treated with

atropine alone and patients received combined therapy of atropine and glycopyrrolate, how ever there was reduction in the duration of hospital stay and incidence of adverse reactions especially CNS toxicity associated with atropine treatment. This agreed with results of a study done by Khalid et al. (2017) and Anju et al.(2011) whom study revealed that both the groups had the same efficacy but atropine showed a very distinct CNS toxicity,[3,7] but it was in contrast with Arendse et al.(2009) who had found that the infusion of a combination of atropine and glycopyrrolate had a lower mortality rate but the occurrence of atropine toxicity was unchanged between the 2 groups.[8]

Conclusion

The study suggests that treatment with combined therapy of atropine and glycopyrrolate was more effective than therapy with atropine alone regarding the reduction in the duration of hospital stay and incidence of adverse reactions of the used drugs.

Implant Materials Used for Orbital Floor Reconstruction

Mohamed EsmailKhalil[1], Mohamed Farag Khalil[2], RaafatMohyeldeen Abdelrahman[2], Ahmed Mohamed Kamal Elshafei[3], Tamer Ismail Gawdat[3]

[1]Assistant Lecturer, [2]Associate Professor, Ophthalmology Department, Minia University, Minia, [3]Professor, Ophthalmology Department, Cairo University, Cairo, Egypt

Abstract

Purpose: To review different available implant materials used for orbital floor reconstruction regarding their indications, advantages and disadvantages.

Summary: Review of literature revealed the presence of a wide variety of implant options for repair of orbital floor defects. They can be broadly classified into biological materials, metals and polymers which are further divided into resorbables and non resorbables. The choice could be based on an algorithm for the defect size, the anatomical location, or the remaining structural support. Small defects may heal solely by the formation of scar tissue, whereas larger defects, especially those associated with enophthalmos, need material of a sufficient strength to support the orbital contents.

Keywords: *Blow-out fractures, Titanium, resorbable polymers.*

Introduction

Fractures of the orbit are seen in many patients who have blunt trauma to the face and skull. The prominent position of the orbit in the craniofacial skeleton predisposes this region to injury. [1]

Blow-out fracture is a special type of fracture of the orbital floor. Rene Le Fort concluded that blow-out fractures occurred through force transmission from the more rigid infraorbital rim to the relatively weak orbital floor, known as the buckling theory. [2] This theory was challenged by Pfeiffer in 1948, who observed a case series of globe-directed trauma resulting in blowout fractures, leading him to propose the hydraulic theory, which states that hydraulic pressure from the globe is transmitted to the bony orbit resulting in fracture of the thin orbital floor. [3]

In the repair of orbital fractures, the value of an implant is to regain function and aesthetic appearance by repairing the traumatic defect and bringing the globe into its correct position. In addition to the timing and method of reconstruction, a third essential factor in orbital fracture surgery is the choice of reconstruction material. [4]

Advances in biotechnology continue to introduce new implant materials for reconstruction of orbital floor fractures. Which material is best fit for orbital floor reconstruction has been a controversial issue. [5]

Characteristics of an ideal orbital reconstruction material[6]:

1. **Stability and fixation:** The implant should be strong enough to support the orbital content and related forces, do not deform (sagging of material into maxillary sinus) under load and can be fixed to surrounding structures
2. **Contouring and handling:** Restores adequate volume to treat enophthalmos and diplopia, easy to shape to fit the orbital defect and regional anatomy and has smooth surface.
3. **Biological behavior:** Ideal implant is biocompatible with no infection, migration, foreign body reaction,

non-allergenic and non-carcinogenic. It should be osteosynthetic and shows high tissue incorporation but easily dissectable in implant removal during secondary reconstruction

4. **Drainage:** Spaces within the implant should be present to allow drainage of orbital fluids
5. **Donor site morbidity:** The implant should not increase surgical complication rate or donor site morbidity (pain, swelling, etc.)
6. **Radiopacity:** The implant should be radiopaque to enable radiographic evaluation without artifacts.
7. **Availability and cost-effectiveness:** Ideal implant should be readily available in sufficient quantities and acceptable costs

Types of materials used for orbital reconstruction:[6]

1. **Biological materials:**
   - *Autografts/autogenous materials:*
     i. Autologous bone: calvarium, iliac crest, rib, mandibular symphysis, maxillary sinus wall
     ii Autologous cartilage: nasal septum or concha, auricle, rib
     iii Autologous fascia: Tensor fascia lata, temporal fascia
     iv Autologous periosteum
   - *Allografts*: Lyophilized dura mater; demineralized human bone, lyophilized cartilage, irradiated fascia lata.
   - *Xenografts and animal-derived materials:* porcine sclera, porcine skin gelatin/Gelfilm, bovine bone or sclera
   - *Biological ceramics (inorganic, non-metallic):* Porous hydroxyapatite (HA) and other calcium phosphates.
2. **Metals:** Titanium, Cobalt alloys
3. **Polymers (plastics):**
   - *Non-porous non-resorbable (permanent) implants*: Silicone, nylon (SupraFOIL; Supramid), polytetrafluoroethylene (PTFE; Teflon, Gore-Tex), hydrogels, PEEK (poly ether ether ketone).
   - *Non-porous resorbable implants:* Hyaluronate/ carboxymethylcellulose (HA/CMC; Seprafilm).
   - *Porous non-resorbable implants*: Porous polyethylene (PE; Medpor)
   - *Porous resorbable (absorbable) implants:* Poly(lactic acid) (PLA), poly(glycolic acid) (PGA), PLA/PGA implants Polydioxanone (PDS), polyglactin 910/PDS implants (Ethisorb)
4. **Composites:**

   HA-reinforced high density composite

   Titanium/PE composite implant (Medpor Titan)

   HA/PLA/polycaprolactone (PCL) sheet

   Bone morphogenetic protein-loaded gelatin hydrogel

Advantages and disadvantages of currently available reconstruction materials:

- **Biological materials:** Biological materials are defined as grafts harvested from the same or another human or animal and include autografts, allo-grafts, and xenografts.[6]

  Since the 18th century, autologous bone has been the 'gold standard' biomaterial for the reconstruction of bony defects in the craniofacial area. [7] Autologous bone grafts are used in orbital surgery because of their strength, rigidity, vascularization potential, and incorporation into the orbital tissues with minimal acute and chronic immune reactivity (i.e. infection, extrusion, collagenous capsule formation, and ocular tethering). [8] Donor site morbidity remains a general drawback for autologous bone harvesting. [6]

  Allografts (homografts) are transplanted tissues (e.g. lyophilized dura mater or banked (demineralized) bone) from another human being. Their advantages include a decreased surgical time, preoperative customizability, absence of donor site morbidity, and abundant availability of banked bone. [4] Lyophilized dura (Lyodura) was a standard in the past for the reconstruction of smaller orbital defects because of its strength and absence of tissue reactions. [9] However, it became controversial following a case of Creutzfeldt–Jakob prion disease in a patient who received dura originating from a cadaver. [10] Consequent to this report, lyophilized dura sterilization was no longer performed with gamma irradiation but with sodium hydroxide. [11] The

disadvantages of allografts include a resorption rate substantially higher than that of autologous tissue, [8] the need for immunosuppressive pharmacotherapy, and the risk of viral transmission, such as hepatitis C virus and HIV. [12]

- **Metals**

Titanium has been used extensively in craniofacial surgery and dentistry in the form of implants, plates, and screws.[13] With its high biocompatibility and physico-mechanical properties, it could be an ideal implant for covering large anatomical defects (categories III–V) and globe malposition if implant-stabilizing surrounding bone or a distal landmark (a 'bony ledge') is absent. [14]

Titanium mesh is strong, rigidly fixable, widely available, and is subject to osseointegration with minimal foreign body reaction. [15] However, titanium is costly and may have irregular edges if not cut properly, which may impinge soft tissue. Furthermore, fibrous tissue will incorporate the mesh-holes, which can make implant replacement technically complex. [15] Late unwanted effects such as infection, corrosion, and toxic metal ion release have been reported with the use of titanium implants. [13] One Randomized Control Trial (RCT) has evaluated the effects of titanium implants as compared to perforated (PDS) foil for small orbital floor fracture reconstruction, and found no significant differences in the clinical outcomes. [16] A pilot study without controls used a low-profile 0.25-mm titanium plate in large defects (categories II and III) and found successful clinical outcomes without complications in 93% of the cases; at the 6-month follow-up, no functional or aesthetic concerns were observed. [14]

- **Polymers:** Polymers (or plastics) are large molecules comprising multiple repeated subunits and can be categorized into absorbable and non-absorbable (permanent) types. [6]

Non-absorbable permanent polymer implants: Porous ultra-high density polyethylene **(PE; Medpor™)** sheets of various sizes and thicknesses (0.4–1.5 mm) have been used widely to cover smaller floor defects since the 1990s. This widespread use is a product of the ability to easily cut the sheets into various shapes and the ability of orbital tissue to move freely over the smooth surface. Connective tissue and vascular components grow into the pores with minimal foreign body reaction. [17] In a prospective cohort study of floor reconstructions, PE sheets showed satisfactory surgical outcomes and infection rates similar to autografts. [18]

Polytetrafluoroethylene (PTFE; Teflon) is biologically and chemically inert, non-antigenic with minimal foreign body reaction, sterilizable, and easily mouldable. However, this polymer has not yet been subject to comparative clinical studies. [6]

Relatively new in orbital floor repair is the use of nylon foil, a non-porous poly-amide. Nylon foil has provided favourable results in preliminary non-comparative studies. [19]

Resorbable Osteosynthesis implants: Although the performance and biocompatibility of metallic and titanium fixation in osteosynthesis has been reported as satisfactory, a number of disadvantages have been associated with its use, including stress shielding of bone or osteopenia [20], impairment in imaging evaluation [21] and its restricted use in certain specific circumstances such as pediatric craniofacial surgery. [22]

Resorbable materials have been used widely for over 30 years in many fields of surgical practice, [23] and are of interest because of their more predictable absorption rates than biological grafts, as well as their high level of customizability and control. [24]

Chemistry and mechanism of action: Bioresorbable polymers are mainly high-molecular-weight aliphatic polyesters with repeating units of α-hydroxy acid (HOCHR-COOH) derivatives manufactured by ring-opening polymerization. The absorption of these polymers begins with depolymerization through the hydrolysis of their ester bonds and subsequent metabolism, probably by macrophages, in the citric acid cycle into water and carbon dioxide. [25]

The first clinically used bioresorbable polymer was polyglycolic acid (PGA), a highly crystalline and high-molecular weight molecule with limited clinical use for osteosynthesis because of its susceptibility to rapid degradation. Approximately 4–7 weeks after implantation, a duration which is insufficient to allow complete bone healing, PGA loses its mechanical strength in vivo. In addition, the side effects of PGA have been detected during its clinical use; these are due to the difficulty in clearing the accumulated acid degradation products. These negative effects have resulted in the minimal use of pure PGA in osteosynthesis. [26]

Polylactic acid (PLA) is another high-molecular-weight bioresorbable polymer; its optically active carbon in lactic acid generates 2 stereoisomeric forms,

namely poly- L -lactide (PLLA) and poly- D -lactide (PDLA). Since the early 1990s, PLLA has been used as an osteosynthesis material. [27] Due to its crystallinity and hydrophobicity, PLLA is fairly resistant to hydrolysis, and thus bioresorption with complete loss of its strength in vitro does not occur within the first 2 years of implantation. PDLA, on the other hand, has a lower crystallinity and is less resistant to hydrolysis. Because of its slower degradation rate, PDLA has been reported to be highly biocompatible, although crystalline particles resistant to degradation may elicit some inflammatory response. [27]

By copolymerization of different derivatives of α-hydroxy acids, a variety of different mechanical qualities and degradation rates can be achieved. Copolymers of L -, D -lactides, for example, SR-P(L/DL)LA 70/30, a copolymer composed of 70% PLLA and 30% PDLA, loses all its strength in vitro after 48 weeks of implantation. [28] Copolymers of L -lactide and glycolide (PLGA) have been extensively used owing to the wide range of physiochemical properties of the components. [29]

Advantages and disadvantages of resorbable implants: The main advantages are easy handling and contourability, smooth surface and smooth edge, do not necessarily require rigid fixation, ideal for pediatric fractures, thin and can be applied in multiple layers in larger orbital volume displacement and without late implant related complications as infection, migration and extrusion. [6]

On the other hand, these materials can be radiolucent on postoperative imaging. [6]Some authors believed it may not provide enough support to orbital contents in large fractures and demonstrated an increase in orbital volume as a late complication. [30]

In a RCT, the administration of an absorbable copolymer of PLA and PGA had functional and aesthetic outcomes and complications similar to auricular cartilage implants in orbital blowout fractures with or without medial wall involvement. [31] In addition, PLA 70/30 plates were studied in a controlled trial and showed similar surgical outcomes and complications as compared to autografts in category II and III floor defects, without MRI evidence of foreign body reaction.[32]

Discussion

Depending characteristics of the different materials of orbital implants, it was feasible to postulate clinical recommendations for materials in specific cases.

Treatment algorithm for orbital wall fractures[6]:

1. Small-sized, low-complexity defects (class I): Most materials are suitable; biological behaviour is most important and resorbables may be used in these cases.
2. Medium-sized, medium-complexity defects (class II): Apart from the bio-logical behaviour of an implant, the experience of the surgeon with specific types of orbital implants will benefit the outcome. Various materials can be used, from autologous materials to alloplasts.
3. Large-sized, high-complexity defects (classes III–VI): Stability and contour become more significant and pre-bent or patient-specific titanium mesh is the preferred reconstruction material.

Conclusion

The debate on the clinical recommendations for orbital reconstruction material will likely continue because of the absence of RCTs and best practice clinical studies. Controversy exists regarding the best material features, which can be defined broadly by whether the implant is: (1) autogenous or allogenic, (2) non-resorbable or resorbable material and (3) malleable or preformed anatomical plates.

Abstract

Purpose: To review different method for management of rhegmatogenous retinal detachment (RRD), different indications, advantages and recent modifications for each technique.

Summary: Rhegmatogenous retinal detachment (RRD) is caused by retinal break which held open by vitreoretinal traction and causes accumulation of liquefied vitreous under the neurosensory retina separating it from the retinal pigment epithelium (RPE). There are three lines for surgical management of RRD; pneumatic retinopexy, scleral buckling and pars plana vitrectomy (PPV) with different new modifications aiming for easier surgeries and better results.

Keywords: *Rhegmatogenous retinal detachment, pneumatic retinopexy, scleral buckle, vitrectomy.*

Introduction

Rhegmatogenous retinal detachment (RRD) affects about 1 in 10.000 of the population each year and may affect both eyes in about 10% of cases. It is characterized by the presence of a retinal break which held open by vitreoretinal traction and causes accumulation of liquefied vitreous under the neurosensory retina separating it from the retinal pigment epithelium (RPE).(1)

One of the most common risk factors of RRD is posterior vitreous detachment (PVD). with age, collagen fibers are fragmented and proteoglycans are aggregated around these fragments and these changes may be responsible for liquefaction of vitreous which can pass into the subhyaloid space and separate the posterior vitreous surface from the internal limiting membrane(ILM) of the retina producing a true PVD.(2)

Other factors that accelerate vitreous liquefaction include enzymatic vitreolysis with ocriplasmin, cataract surgery, high myopia, ocular inflammation, and trauma.(3)

Proliferative vitreoretinopathy (PVR) represents one of the most common complications of RRD causing failure of surgical repair. It develops when RPE cells are dispersed into the vitreous cavity through a retinal break and form membranes on the inner retinal surface which lead to the reopening of retinal breaks or the creation of new ones causing retinal re-detachment.(4)

There are different risk factors for development of PVR as presence of large retinal breaks or giant tears, vitreous hemorrhage, multiple previous eye surgeries, previous ocular trauma, preexisting PVR, prolonged ocular inflammation, viral infections of the posterior segment and prolonged chorioretinitis.(5-7)

There are three lines for surgical management of RRD; pneumatic retinopexy, scleral buckling and pars plana vitrectomy(PPV) with primary success rates of up to 90%.(8)

The purpose of that review is to identify the current management and recent modifications in techniques for treatment of RRD.

Pneumatic Retinopexy: Pneumatic retinopexy is a minimally invasive procedure for correction of RRD. It consists of injecting an expandable gas and applying retinal cryotherapy or laser photocoagulation to close retinal breaks yielding good results in carefully selected patients.(9)

This technique was first described by Rosengren in 1938,then it was widely practiced after the publication of Hilton and Gizzard's seminal paper in 1986, in which they described what was known as modern pneumatic retinopexy.(10)

Pneumatic retinopexy is indicated for uncomplicated RRD without PVR. The ideal cases are those with one break or a group of breaks within 1 clock hour and retinal breaks involving the superior 8 clock hours of the retina.(9)

In appropriately selected patients, outcomes are comparable to alternative techniques, and it has the benefits of reduced morbidity, reduced costs and faster postoperative recovery.(11)

A review of 81 studies including 4,138 eyes undergoing pneumatic retinopexy revealed a single operation success rate of 74.4% and a final success rate of 96.1% after further scleral buckling or vitrectomy procedures.(12)

Careful preoperative examination is essential for that technique, including scleral indentation to examine the far peripheral retina, transconjunctival cryopexy is applied over the peripheral retinal break, or laser retinopexy may be used if the tear was posterior and must be performed 24–48 hours after gas injection, paracentesis, then the gas either C3F8 or SF6 at 100% expansible concentration is injected. Insertion of needle is perpendicular to the sclera directed to the center of the vitreous cavity, then the needle is withdrawn to leave 2–3 mm of it within the globe, then brisk injection of the gas to avoid fish-egg gas bubbles.(9)

Scleral buckling (SB): SB surgery was introduced in 1951 by Charles Schepens, which had a high rate of success and became the treatment of choice for RRD.(13) It is indicated for RRD in young age, phakic eyes, and in limited retinal detachment, particularly with an inferior detachment.(14)

The aim of SB is to reduce the vitreous traction and close the retinal break as the sclera is pressed inward so that the vitreous traction is lessened to close the retinal break.(15)It has several advantages over PPV, including early visual rehabilitation and prevention of cataract formation(15) but there are some difficulties to learn it due to the steep learning curve, declining mastery over indirect ophthalmoscopy and poor ergonomics associated with the surgery, and so there are some modifications to some of the steps of SB to make them safer, more precise and make the process of learning the art of SB easier.(16)

As regards localization of break and retinopexy, chandelier-assisted SB using a chandelier and a wide-angle fundus viewing system has the advantages of better visualization, familiarity to the predominantly vitrectomy trained surgeons and improved ergonomics(17), also an illuminated scleral depressor is a new technique to improve localization.(16)

Sutureless buckling is simple, fast, and safe technique which can be performed in most eyes with RRD specially with localized areas up to 1½ clock hours or ½ a quadrant, also more than one explant can also be placed in multiple quadrants in eyes with multiple breaks.(18)

In eyes with a single retinal break, an intrascleral buckle can be placed by creating scleral pocket to house the silicone segment, then silicone segment is placed in the scleral pocket, and a single suture is used to close the pocket. This is an extremely localized buckle and does not cause much refractive change.(16)

Minimal segmental buckling is also a fast, simple, effective technique for repair of RD and it is suitable for cases with single break or breaks restricted to few clock hours (ideally <3 clock hours). In this technique, a silicon segment is placed either circumferentially for multiple breaks and retinal dialysis or radially for horseshoe tear, then suture bites are oriented parallel to the limbus for circumferential segments and radially for radial segments as the buckling effect is achieved with suture. It is preferable to use this technique in cases with the absence of other lesions which can predispose to RD in rest of the quadrants. Minimal segmental buckling needs minimal manipulation and may have less postoperative pain.(19)

To avoid complications of subretinal fluid drainage, trans-scleral needle drainage technique may be alternative using 26 gauge ½ inch needle to perforate the sclera and drain the SRF with advantage of small entry site decreasing the risk of hemorrhage and incarceration.20

Also, infusion-assisted drainage can be used to prevent the hypotony during drainage by placing a 25G infusion as in vitrectomy and turned on during SRF drainage to ensure maintenance of intraocular pressure during drainage and also assists in draining. The infusion cannula is placed in the same quadrant of drainage site and is placed just before drainage of SRF to avoid inadvertent kinking of the cannula and lens trauma when rotating the eye for visualizing the drainage site.(16)

A new technique has recently been described for suprachoroidal buckling, in which an illuminated catheter is inserted into the suprachoroidal space and directed to any desired location where peripheral breaks are present, and then long-lasting hyaluronic acid filler can be injected to create internal choroidal indentation. This can be performed without or in combination with vitrectomy and has been used successfully for the treatment of RRD.(21)

Pars Plana Vitrectomy(PPV): PPV is currently the most commonly used procedure for the repair of RRD (22). Over last decades, this procedure has been progressively improved due to advanced technology, such as the development of small-gauge instrumentation and the use of intraocular perfluorocarbon liquid, silicone oil, and gases. All of these have played a part in making PPV a highly effective technique for repair of simple and complex RRDs, and new modifications are still being made.(23)

There are multiple risk factors for surgical failure after PPV include longer duration of symptoms, older age, larger extent of RD, macular detachment, inferior detachment, absence of detectable retinal breaks, high myopia, hypotony, and PVR-related risk factors such as pseudophakia, aphakia, uveitis, vitreous hemorrhage, and preoperative PVR.(24)

The internal limiting membrane (ILM) was first named by Pacini in 1845 and represents the barrier between the retina and the vitreous body.(1)

Theinverted ILM flap technique was compared with ILM peeling only in a retrospective study which revealed higher rates of macular hole closure andretinal reattachment, significantimprovement in the final visual acuity withthis technique and it has been suggested that the invertedILM flap may stimulate the proliferation of glial cells that aid inclosing the hole.(25)

Another comparative study has also investigated the effectiveness of combining a macular buckle with PPV and ILM peeling in highly myopic eyes and RD with macular hole and revealed a higher rate of retinal reattachment and macular hole closure in combined surgery group.(26)

For treatment of macular folds, which may complicate RRD surgery and have significant implication on the visual prognosis, induced detachment of the macula can be performed by the subretinal injection of balanced salt solution, as well as the addition of filtered air, under these conditions, the action of gravity of the perfluorocarbon liquid in the vitreous cavity combined with an active globe manipulation may achieve successful flattening of the macula.(27).

Recent studies have evaluated the potential of high-frequency electric welding (HFEW) for creation of immediate chorioretinal adhesion to obviate the need for long-term tamponade and used it in a rabbit model of retinal tear and one study reported that the it was able to create an immediate retinopexy equal in strength to mature laser retinopexy.(28)

Development of ERM is one of complications of PPV for repair of RRDs has been reported to range from 4.4% to 12.8%(29) specially in cases with multiple or large retinal breaks(30), equatorial breaks and a longer duration of macular detachment.(29)

Various studies compared PPV with ILM peeling versus PPV without ILM peeling in patients with RRD and revealed a lower incidence of postoperative ERM in patients with ILM peeling.(31)

For management of severe PVR, soft-shell technique may improve retinal flattening and prevent passage of perfluorocarbon liquid into the subretinal space by injecting ophthalmic viscoelastic devices (OVDs) over areas of retinal folds with possible retinal breaks, this protective layer allowed the perfluorocarbon liquid placed over it to achieve retinal flattening and prevented it from entering the subretinal space.(32)

In recent years, partially fluorinated alkanes (FALKs) were introduced as long-term heavy tamponades, which are heavier than water and may be beneficial especially in the treatment of lower RRD or PVR. A recent study investigated the use of F6H8 in combination with silicone oil, in cases with inferior RRD with PVR, where F6H8 was used to flatten the retina and was later partially mixed with silicone oil

for long-term tamponade. This combination resulted in a clear tamponade allowing postoperative visualization of the retina, with no emulsification, inflammation, or other complications. The best results were reported with F6H8/SO ratios between 50/50 and 30/70.[33]

Two-step surgery is another option for severe PVR as an initial surgery is done first to repair the retinal detachment in which perfluorocarbon liquid tamponade is left for 2 to 3 weeks, followed by a second procedure in which it is removed. A recent study reported good results with this technique in 44 eyes with retinal detachment complicated by grade C PVR.[34]

Conclusion

There are different techniques for surgical management of RRD and every day there are new modifications in these techniques which aim at easier surgeries and more satisfactory results for the patients.

Study the Composition of Fatty Acids in Blood Serum Parts During the Fasting Month (Ramadan)

Mohammed A.H. Alobeady[1], Raghad A.A. Al Hialy2

[1]Asst. Professor, [2]Lecturer, Chemistry Department/College of Education For Pure Science/University of Mosul

Abstract

This study dealt with the measurement of several variables in the blood serum for a group of people in the case of fasting (Ramadan) for (14-16) hours, where the blood serum was withdrawn from people during daylight hours after fasting (5-8) hours and then follow the same people After (15) days of fasting and then after (25) days as well as blood serum samples were collected for the same people one month after the end of the month of Ramadan and the age of people ranged between (19-80)years and both sexes (males and females) are healthy people and do not suffer from any apparent disease. The study focused on measuring the percentage of fatty acids in the three segments separated from serum (cholesterol ester, triglyceride and phospholipids) which were separated by thin layer chromatography and then the esterification of the separated fatty acids was carried out using (BF3/methanol) method. Percentage of fatty acids (SFA, MUFA and PUFA) using a capillary gas chromatography device The results of this study indicated a significant increase in the percentage of saturated fatty acids, a non-significant decrease in the percentage of monounsaturated fatty acids, and a non-significant decrease in the percentage of polyunsaturated fatty acids in The serum cholesterol ester portion of the fasting group compared with the control group The results of this study indicated a significant increase in the percentage (SFA), a non-significant decrease in the percentage (MUFA), and a non-significant increase in the percentage (PUFA) in the Tricyclic serum for serum group The results of this study showed a significant increase in the percentage (SFA), a significant decrease in the percentage (MUFA), and a significant non-significant decrease in the percentage (PUFA) in the serum phosphate fat portion of the fasting group compared with Control group.

Keywords: *Fatty acids, cholesterol ester, fasting,saturated fatty acid.*

Introduction

This study was designed to identify the effect of fasting on the level of chemotactic variables and the percentage of fatty acids in serum. Fasting is an integral part of many religions in terms of the pattern, duration and limits of fasting that differ between different religions [1], and fasting in biochemical conditions is to refrain from eating calories for (12-14) hours (2). Ramadan is the ninth month of the Islamic calendar during this month and it is expected that all healthy adult Muslims, males and females abstain from foods, liquids, oral medications and smoking from dawn to sunset and this type of fasting is addressed in our study, which lasts (29 to 30 days) [3] Fasting affects many metabolic processes in the human body and physiological indicators return to normal after the end of the month of fasting, indicating the safety of fasting for healthy people. [1].The human diet is a complex mixture of reactive components that cumulatively affect health[2]. and fast e An excellent model of how dietary modifications affect lipid profile[3]. studies have shown beneficial changes in serum on chemotactic variables in terms of high variables (HDL) and low variables (TG, TC, LDL) that are considered to be the main risk factors For coronary heart disease and cerebro vascular disease[4].diet modification (fasting) is a treatment for hyperlipidemia and is also taken in conjunction with drug therapy in people with coronary heart disease risk . Fasting also affects the percentages of fatty acids in the three parts of the blood serum, as this effect is positive and the percentage of fatty acids with different varieties is balanced in the three parts of the blood serum.[1]

Materials and Method

Blood samples were collected for healthy people who were fasting after a period days and then follow

up the people themselves after (20) days of fasting and control group where the samples were collected for the period (17/5-16/6 (2018), where (5) milliliters of blood was withdrawn for each person and then the samples are left for Serum is separated . After that, the serum divided into two parts.

Section 1: Measurement GLU, TC, HDL, LDL, TG, PL by Kits and VLDL was theoretically calculate.

The second section kept in freezing at (-18)°C until the start of the analysis of fatty acids.

The percentage of fatty acids of the three parts of the serum (CE, PL and TG) was measured after the separation of each of the three parts using (TLC) technique. These parts are distributed on the used silica gel plate resulting from the separation of serum components blood using a solvent system consisting of (hexane/ether/formic acid) in percentages (2:20:80) (V/V/V). [5]

The fatty acids are then re-esterified for each of the three previously separated parts using BF3/ Methanol (16%)[6] and then diagnosis and analysis of the percentage of fatty acids for each part using standard models.

Percentage of fatty acids: The serum fatty acid content of the above three components was estimated by means of injecting (1) micro-liters of the model prepared for measurement in the (CGC)[7] Figure (1) shows the graph resulting from the analysis and measurement of the ratio of (23) fatty acid standard using the device (CGC).

Table (1): Standard fatty acids

Fatty Acids	Retention Time	Percentage
C 4:0	2.28	0.09
C 6:0	3.62	0.14
C 11:0	6.47	0.15
C 12:0	10.81	0.172
C 14:0	13.23	0.084
C 15:0	15.71	0.18
C 16:0	18.12	0.086
C 18:0	20.51	0.17
C 18:1trans	21:25	0.095
C 18:1cis	22:79	0.036
C 18:2	23:46	0.048
C 18:3	27:47	0.068
C 20:0	25:22	0.363

C 22:0	30.33	0.01
C 22:1	31.48	0.039
C 20:4	33.67	0.178
C 23:0	34.34	0.03
C 22:2	35.70	0.024
C 24:0	37.32	0.323
C 20:5	38.74	0.031
C 24:1	39.23	0.015
C 22:6	40.73	0.099

Statistical analysis: The results were analyzed for the levels of chemotherapeutic variables (Glu, TC, LDL, HDL, VLDL, TG and PL) as well as percentage analysis of fatty acids in the three segments separated from serum lipids. Blood using t-test for groups of equal number and different totals to compare the results of people fasting with the control group in general, where the acceptable probability level is (P> 0.05) [8].

Results and Discussion

The results of this study showed a significant decrease in (Glu) concentration in the fasting group compared with the control group .This may be attributed to lower calorie intake during Ramadan compared to other months as well as the nature of muscular effort and sleep during fasting month. [9]The results indicated a significant decrease in (TC)concentration in the fasting group compared to the control group .This is consistent with several studies that indicated this decrease during fasting. Insulin sensitivity .The results also indicated a significant increase in (HDL-C) level in the fasting group compared to the control group. This corresponds to several studies in the case of fasting. The role of hepatic lipase, which controls the level of (HDL-C) and during fasting, is an increase in the effectiveness of hepatic lipase which leads to an increase in the level of this type of cholesterol during the fasting period and low level of (TC) [10]. This study indicated a significant decrease in (LDL-C) level in the fasting group compared with the control group . This corresponds to a number of studies that indicated the possibility of (LDL-C) level during the fasting period[11]. There was a significant decrease in the (TG) in serum in the fasting group compared with the control group . This can be due to the nature of food intake during the fasting period as the concentration of this type of fat depends on the level of neutral triglycerides, which are directly related to the food [12] .(LDL/HDL) is an important clinical indicators to diagnose the risk of

disease Cardiovascular [13] .The increase or decrease in this ratio is an indication of the progression of metabolic processes within the normal level and the normal ratio should be less than 3.3 [14]. The ratio (TC/HDL) refers to this ratio The risk of developing cardiovascular disease and its probability of occurrence is more specific than the total cholesterol level of serum [15].The results of this study indicated a significant decrease in this percentage of the total fasting compared with the control group, and the ratio (TG/HDL) This is one of the important indicators on the occurrence of atherosclerosis and the higher this percentage increased the probability of developing atherosclerosis[16]. The results of this study showed a significant decrease in this ratio to the fasting group compared to the control group .This indicates the usefulness Fasting affecting the insulin level The results of this study indicated a significant decrease in (PL) in the fasting group compared to the control group. The hepatic lipase enzyme is effective during fasting, leading to increased lipolysis in general and phospholipids in particular [17] . all results shown in Table (2). .

Table (2): Biochemical parameters in control group and fasting grope

Biochemical Parameters	Control	Fasting	P value
N mmol/l	50	50	
Glucose	5.04±0.94 *	4.13±0.78*	0.001 <

* Mean±SD

Fatty acids in the cholesterol ester: The results of this study showed a significant increase in the percentage of (SFA) for the fasting group compared with the control group . A significant decrease in the percentage of (MUFA) for the fasting group compared with the control group. There was a significant decrease in the ratio of (PUFA) to the fasting group compared to the control group as shown in Fig. 2 and Table 3. Lipid triglycerides in adipose tissue (ATGL) that oxidize and metabolize fats, especially cholesterol ester and triglycerides in adipose tissue.[18][19]. Located in For food with their serum levels and give an indication of the usefulness of fasting in affecting the proportion of fatty acids of all kinds in this part of the blood serum [20][21]. .

* Mean±SD

Fatty acids in the triglyceride: The results of this study indicated a significant increase in (SFA) for the fasting group compared with the control group as . This may be due to insulin sensitivity during the fasting period. There is an inverse relationship between insulin sensitivity and fatty acid level.[22].This is due to the effect of fasting on a number of specific enzymes. By removing saturation and elongation which plays an important role in increasing . This may be due largely to food intake in addition to The effect of fasting on enzymes that regulate lipolysis[23] which leads to the formation of a greater percentage of polyunsaturated fatty acids through increased fat oxidation and de-saturation of some short-chain acids and converted to long chain (PUFA) and this

corresponds to a number of recent studies in the field of fasting[24]. The percentage of fatty acids indicates and its installed in triple part of the serum in general to the amount of fatty acids within the existing food intake, as the proportion of fatty acids in this part of the blood serum are highly correlated associated with the nature and the amount of fatty acids present in the intake of food during the fasting period[25].

Fatty acids in the phospholipids: The results of this study indicated a significant increase in the (SFA) of the fasting group compared with the control group . This may be due to the role of the liver during the fasting process as the liver plays an essential role in the formation or demolition of this type of phospholipids by controlling the amount of (SFA) entering or exiting the blood serum to the liver, which affects the percentage of this type of acid as the process of demolition of fat increases during the fasting period and the liver plays a major role in this process [26] and to The presence of a significant decrease in the level of fatty acids This may be attributed to the fact that fasting affects the body mass rate in the first stage by activating the activity of the enzyme lipop utinlayase and thus affecting the rate of formation of triglycerides. The results of this study indicated that there was increase in the percentage of fatty acid (22: 2n6) of serum dimple, fasting group compared with the total This can be attributed to insulin sensitivity, which in turn affects the action of de-saturating enzymes, since the action of these enzymes is closely related to The results of this study indicated that there is a variation in the percentage of fatty acids in this part of the blood serum compared ester cholesterol and triglycerides, which is consistent with many studies in this area. As the proportion of fatty acids in this part of the blood serum.[27]. It is an indication of the importance of fasting by increasing compatibility and hepatogenesis of both (SFA), especially fatty acid (16: 0) and (PUFA) n: 3, as phospholipids are a good vector for recycling fatty acid of fatty proteins it promotes the health of the body through the redistribution and transmission of fatty acids between different parts of the serum [28].

Conclusions

1. The study indicated a significant decrease in serum(TC) level in the fasting group compared to the control group, which indicates the usefulness of fasting in reducing the risk of high serum cholesterol. High serum cholesterol leads to an increased risk of heart disease and atherosclerosis.
2. The study indicated a significant rise in(HDL) level and a significant decrease in LDL level. This proves the role of fasting in controlling metabolism in general and fat metabolism in particular. The body fats fat during fasting as a major source of energy during the fasting period and then the body returns to normal after breakfast.
3. The study indicated the effect of fasting on the level of fatty acids (PUFA/MUFA/SFA) in the three parts of the serum where the effects were different from high percentage of fatty acids and low percentage of (MUFA). The multicomponent compared with control groups demonstrating the role of fasting in influencing the metabolism of all types of fatty acids in different parts of the serum.

Ethical Clearance: All samples were taken from colleges at dept. of chemistry-Mosul university, according to their agreement.

Expression of Amylin and Preptinin Iraqi Patients with Type 2 Diabetes Mellitus

Mohammed I. Hamzah[1], Israa A. Abdul Kareem[2], Mohammed Albayati[1]

[1]Clinical Chemistry, [2]Chemical Pathology, College of pharmacy, Al-Nahrain University, Iraq

Abstract

Diabetes mellitus is one of the most worldwide spread chronic diseases, and its complications are very serious if it is untreated. Type-2 diabetes mellitus (T2DM) is reported to be caused by obesity and sedentary life style. DM plays a role in accelerating the hardening and narrowing of the arteries. Preptin and amylin are pancreatic hormones which participate in glucose homeostasis. In T2DM patientsamylin peptids can be toxic to β-cells of pancreas due to Amyloid deposits within these cells, supporting the idea that islet amyloid might have an important role in the pathogenesis of T2DM.preptin is a peptide hormone that is secreted with insulin and amylin from the pancreatic β-cells.The study planned to investigate the relationship between serum amyline and preptinlevelsin patients with T2DM compared to healthy controls and to study their associations together (preptin and amylin) with serum levels of insulin and HOMA-IR. Sixty-four (64) patients were recruited from the Endocrine Outpatient clinic in Al-Imamain Al-Kadhimain city hospital from March of 2018 to May of 2018. Fasting serum samples were obtained on enrolment. (mean age, (61.73± 8.05) years;mean duration of diabetes, (8.77±2.66) years; mean HbA1c,(8.1 ± 1.7) withT2DM and body mass index (BMI) > 25.1 kg/m^2 underwent examination. Age, sex and (BMI) matched with thirty eight(38) healthy controls were also in ruled,Serum preptin and amylin levels were measured by ELISA technique. There was statistically significant difference between patients and controls serum amylin (p=0.023) and preptin (p=0.01).Patients with T2DM had significantly higher blood glucose (p=0.0001), HbA1c (p=0.0001), insulin (p=0.0001), and homeostatic model assessment of insulin resistance (HOMA-IR) (p=0.001)compared to healthy control,while total cholesterol was positively related (p=0.111) triglyceride, low-density lipoprotein cholesterol values were (p<0.001 for each), and significantly lower high-density lipoprotein cholesterol levels compared with the control group (p<0.0001). The preptin level demonstrated a significant positive association with insulin and HOMA-IR compared with healthy control. (for healthy control group: r=0.381,p=0.146, r=0.133,p=0.438)respectively; for T2DM group: (r=0.411,p=0.02, r=0.332,p=0.003), The amylin level also showed a significant positive correlation with insulin and HOMA-IR compared with healthy control. (for healthy control group: r= 0.188,p=0.309, r= -0.039,p=0.911) respectively; for T2DM group: (r=0.279,p=0.002, r=0.291,p=0.003),Conclusions: There were significant differences between healthy control and patients with T2DM concerning amylin and preptin levels. Serum Amylin and preptin increase in association with insulin in diabetic conditions. The present study suggests a potential role of amyline and preptin in the pathogenesis of T2DM.

Keywords: *Amylin, preptin, type 2 Diabetes Mellitus.*

Introduction

Diabetes mellitus (DM) is a metabolic disorder characterized by chronic hyperglycaemia with disturbances of carbohydrate, fat and protein metabolism resulting from defects in insulin secretion, insulin action, or both[(1)]. Typical presentation of Diabetes mellitus includes symptoms like thirst, polyuria, blurring of vision, and weight loss[(1)].

T2DM results from defect in insulin action in hepatic and peripheral tissues, especially muscle tissues and adipocytes[(2)]. The specific etiologic factors are not known but genetic input is much stronger in T2DM than type 1 diabetes mellitus (T1DM)[(2)]. Human islet amyloid polypeptide (hIAPP) which named as amylin, 37 amino acid, that is co-secreted with insulin from pancreatic islet β cells. This peptide when accumulates and aggregates

forms fibrils, Amyloid deposits is associated with β cells degeneration which considered as a hallmark of non-insulin dependent diabetes mellitus (NIDDM)[3].The prevalence of diabetes for all age-groups worldwide was estimated to be 2.8% in 2000 and expected to be 4.4% in 2030[4]. The total number of people with diabetes is projected to rise from 171 million in 2000 to 366 million in 2030. According to International Diabetes Federation data, there were some 425 million patients with diabetes worldwide in 2017, and this number is estimated to reach 629 million by 2045[5,6,7]. Amylin is produced via gene expression on chromosome 12. It is transcribed as an 89-aminoacid prepolypeptide, which is cleaved to form the mature peptide in the β cells of the pancreas, where it is stored along with insulin and C-peptide in the same granules[8].

Amylin, which is co-secreted with insulin, regulates post-prandial glucose levels in part by inhibiting gastric emptying and suppressing glucagon release while not affecting glucose uptake[9]. Amylin has been shown to mirror insulin secretion in healthy subjects[10], obese subjects, prediabetes (subjects with impaired glucose tolerance)[11,12], and patients with T2DM[10]. These findings suggest an active role for plasma amylin levels in modulating glucose metabolism [13].

As an endocrine peptide, preptin is thought to activate the insulinlike growth factor receptor 2 (IGF2R), and as a result, induces calcium-dependent insulin secretion in association with protein C and phospholipase C when the glucose concentration is high[14]. In addition, preptin has insulin-like effects on bone metabolism, such as boosting cellular differentiation and affecting the functions of osteoblasts and osteoclasts[15]. Preptin is a 34-amino acid peptide hormone co-secretedfrom the cells of pancreas along with insulin, amylin,and pancreastatin[16,17]. Females have higher preptin levelsthan males[18]. Preptin is believed to be a physiologicalenhancer of insulin secretion induced by glucose. There isa strong correlation between obesity, hyper-insulinemia and insulin resistance, and these associations get stronger with increasingbody weight[19]. Therefore, the relationship between BMIand preptin level would be a worth investigation. Hence, this study was carried out to evaluate amylin and preptinin patients with T2DM.

Subjects, Material and Method

Subjects: This study comprised sixty four consecutive patients of T2DM (26 male and 38 female) and 38 healthy control (18 male and 20 female) were recruited from the Endocrine outpatient clinic in Al-Imamain Al-Kadhimain city hospital from March 2018 to May 2018.

All of the patients wereasked to provide socio-demographic data, medicalhistory, and family history. Other questions included were:theduration of disease, age of onset of the disease, anytreatment taken.

Inclusion criteria: Patients who are suffering and diagnosed as T2DM patients.

Exclusion Criteria: T1DM patients., Pregnant women,Presence of other autoimmune disease like Hashimoto's thyroiditis, SLE,patients with liver disease, renal disease, recent history of cardiovascular disorder, hypertension, neurological disease, or, obese subjects with history of acute or chronic infections, any other chronic diseases, under cortisol treatment or suffering from any autoimmune disease, were excluded from the study.

Blood Sampling: Blood samples (7 ml) were collected from T2DM patients diagnosed according to the WHO protocol, and control subjects in serum separatorvacutainers (BD Vacutainer Systems, Plymouth, UK).Sera were separated and immediately stored at −20° Cuntil analysis.

Serum Amylin and preptin: The quantitative determination of Amylinlevels and preptin were conducted by ELISA technique, using acommercial available kit,(human Amylin ELISA kit Catalog No. MBS72142 Mybiosource.com) and (human Preptin ELISA kit Catalog No. MBS764034 Mybiosource.com),respectively.

Statistical analysis: All data were coded and entered using the program statistical package for social sciences (SPSS) version 25 under windows XP. Descriptive data was summarized using mean, standard deviation (SD), $P< 0.05$ were considered statistically significant.

Results

Serum levels of Amylin and preptin were estimated in 64 patients with T2DM, compared with 38 healthy control,age and sex matched. As expected, the patients with T2DM had significantly higher level of Amylin levels than the healthy controls($P=0.023$),as shown in table (1) and Figure(1).

The concentrations of preptinlevel, are presented in Table (1) are significantly higher in T2DM patients as compared with normal subjects(p=0.01).As shown in figure(2), The mean levels of amylin and preptin in normal healthy subjects and T2DM pateints was depicted in Table 1.

Figure (1): Mean levels of Amylin in patients with Type 2 DM compared to healthy controls.

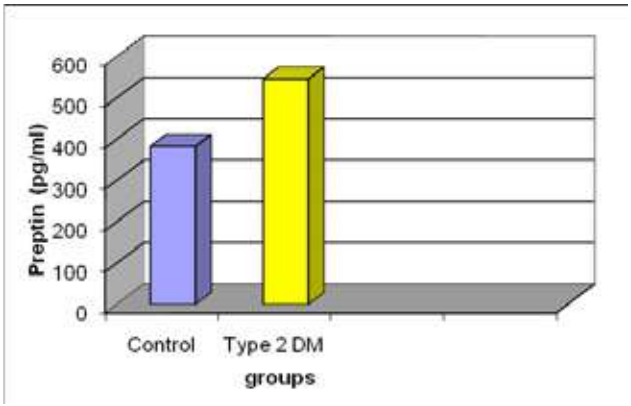

Figure (2): Mean levels of Preptinin T2DM patients compared to healthy controls

The amylin level demonstrated a significant positive correlation with insulin and HOMA-IRcompared with healthycontrol(r=0.279,P=0.002),(r=0.291,P=0.003). Alsopreptin level showed a significant positive correlation with insulin and HOMA-IRcompared with healthy control.(r=0.411,P= 0.02),(r=0.332,P= 0.003)

Discussion

In T2DM, the levels of amylin are raised in parallel with the increased demand for insulin, and this is thought to induce concentration-dependent amylin aggregation[20]. Islet amyloid formation is associated with reduced β-cell mass[21] and human amylin 'oligomers' (small, soluble aggregates) are toxic to cultured islet cells[22] suggesting that they could contribute to progressive islet β-cell failure. Amylin oligomers can disrupt membranes[23] and inflict oxidative damage to cells[24]. In the present study amylin was measured and compared in type 2 DM and control, there was significant statistical difference between type 2 DM and control group where the p-value was 0.023. Researchers mentioned that islet amyloid deposits are found in >90% of T2DM patientsat autopsy[25], and action[26]. Amylin has been. However,the mechanisms and the precise role of amylin in the pathophysiology of T2DM remain unclear.

In the present study The concentrations of preptin level significantly higher in T2DM patients as compared with normal subjects (p=0.01), as illustrated in Table (1). These results agree with other results done by Yang et al.[27] who found higher levels of preptin in T2DM patients compared with control group. Higher preptin levels have also been reported in studies of patients with gestational DM and polycystic ovary syndrome[28-30].

Preptin is a physiological enhancer of insulin secretion induced by glucose. Recent studies have revealed that there is a potential association between preptin and insulin resistance in humans[31]. About diabetes mellitus, this association was also significant and this is confirmed by literature where it was shown that the concentration of preptin levels were higher in DM patients[32].

Statistical analysis revealed that Amylin significantly related to the variations seen in HOMA-IR in the present study, indicating a connection between amylin and insulin resistance in patients with T2DM. In the present study preptin level showed a significant positive relation with insulin and HOMA-IR compared with healthy control. These results consistent with other results that showed strong association between preptin levels and HOMA-IR in obese subjects as previously mentioned[33]. Similar to our research, the preptin level showed a positive correlation with insulin, HOMAIR, glucose, and HbA1c levels in a study conducted by Yang etal.[27]. Therefore, it is expected that a possible relation between amylin and preptin levels might exist.In the present study these two peptides (amylin and preptin) increase independently in T2DM patients; however, both indices demonstrated a positive correlation with insulin levels and HOMA-IR values.

Conclusion

Amylin and preptin may have an important role in the pathogenesis of T2DM, and ultimately in the degeneration and death of pancreatic islet cells. These findings provided a new rationale and opening up additional avenues of research into the etiology, pathogenesis and the treatment of T2DM. The findings of this investigation may provide significant data for in future research.

Clinical Evaluation of Retention of Metallic Versus Thermoplastic Resin Frameworks in Maxillary Distal Extension Cases

Mostafa Elsayed Abdel Haleem F.[1], Ahmed Gamal Ahmed Hassan[2], Emad Mohamed Tolba M. Agamy[3], Gehan Fekry Mohammed[4]

[1]Assistant Lecturer; Prosthodontic Department, [2]Assistant Professor of Prosthetic Dentistr, [3]Professor of Prosthetic Dentistry,and Vice Dean for Student Affairs, [4]Professor of Removable Prosthodontics Department, and previous Dean of the Faculty of Dentistry Minia University

Abstract

Background and Objective: Acetal resin has been introduced as an esthetic partial denture material. However, the retention of this material when compared to cobalt-chromium (Co-cr) frame works still unclear when applied clinically.

Purpose: To evaluate the retention of (acetal resin) as compared to (Co-cr)frame works and clasps.

Materials and Method: The present study is a randomized controlled trial that included 24 healthy patients with Kennedy class I partially edentulous maxilla and dentulous mandibles. The patients were selected from the out-patient clinic (Dep. of Prosthetic Dentistry, Minia University) and divided randomly into two equal groups according to the used denture base material; **Group 1** received maxillary partial denture with (Co-cr) clasps and frameworks. **Group 2** received maxillary partial denture with acetal resin clasps and frameworks. Retention of the prosthesis was evaluated at partial denture insertion, after 3, 6 and 12 months. Paired t-test was used at $p \leq 0.05$ to assess the changes in the above parameter in each group. Student t-test was used to compare between the two groups.

Results: Retentive force mean values of thermoplastic group were significantly lower than metallic group at denture insertion and at all follow up intervals.

Conclusion: Acetal resin frameworks and clasps provide lesser retention values when compared to chrome cobalt.

Clinical Implications: Although there was lesser retention power of acetal resin than Co-cr, further study has to be done regarding various thicknesses and designs of clasps and framework for its successful dental application.

Keywords: *Cobalt-chromium, Removal partial denture, Retention, Acetal resin.*

Introduction

Fabricating an esthetically pleasing removable partial denture presented a challenge to dentists. Among different solutions; acetal resin clasps may be used as a simple and effective means, of improving removable partial denture esthetics.[1]

Lack of retention and poor esthetics are main reasons for not wearing partial dentures. Traditional metal alloy clasps have been shown to exert forces on abutment teeth that exceed those capable of producing tooth movement. In addition, metal display on anterior teeth is often unacceptable.[2]

The thermoplastic resin materials were reported to have superior flexibility and exerted less force than the metals on the abutment teeth. These forces fell within the physiological range of those abutments and considered safe for use. This coupled with their pleasing esthetics made them suitable for use on periodontally compromised teeth, those with deep undercuts and on anterior teeth.[3-4]

Acetal resin is being marketed for the construction of retentive and supportive components of removable partial dentures. The material has a flexural modulus lower than that of polymethylmethacrylate and is sufficiently rigid to be used as a supporting element for partial dentures. Acetal resin clasps may be resilient enough to engage undercuts for the retention of removable partial dentures but the low flexural modulus requires that the resin be used in greater cross-sectional area than metal alloys in order to gain useful retention.[5]

The periodontal conditions of the teeth adjacent to the dentures were poorer than around those not directly involved in its construction due to food stagnation and difficult oral hygiene caused by the removable partial denture components.[6,7] In addition, removable partial denture might sink into the soft tissues causing bone resorption; and bars and clasps might impinge the gingiva.[8]

In this study we tried to evaluate the retention of acetal resin frame work and clasps as compared to cobalt-chromium frame works and clasps.

Patients and Method

Twenty four partially edentulous male patients were selected from the outpatient clinic of the Prosthodontics Department; Faculty of Dentistry, Minia University. **The inclusion criteria** included: patients exhibiting maxillary bilateral distal extension ridge with edentulous area starting from premolar teeth, Dentate mandible or fully restored by fixed restorations, Age: 45-55 years, Angle's class I maxillo-mandibular relationship with sufficient interarch space, The remaining teeth have no, and no previous prosthetic management in the maxillary arch.**The exclusion criteria** included: clenching habits and bruxism, active periodontal diseases or extensive caries, tempro-mandibular disorders, any systemic or debilitating diseases affecting bone metabolism and any intraoral soft or hard tissue abnormality.

All individuals were examined clinically and radiographically. Periapical radiographs were made for all abutment teeth and for the edentulous alveolar ridge. Occlusal analysis was also done to detect any premature contact or over-eruption, which was corrected by selective grinding.

Clinical examination of the maxillary partial denture abutments showed that it was free from caries, gingival inflammation, periodontal pockets, and there was no tooth mobility and by X-ray evaluation the partial denture abutments were free from periapical or periodontal pathosis.

Full mouth scaling and root planning were performed to all patients, and they were instructed for proper oral hygiene and home care using toothbrush and dental floss.

Patient grouping: The patients were randomly divided into two equal groups, twelve in each.

Group 1: The patients received maxillary partial denture with metallic cobalt-chromium frameworks and cobalt-chromium clasps (**Wiront Pellets Co-64%, Cr-28.65%, Si, Mn, Ctrace Bego, GmbH & Co. KG, Germany)**cingulum rest on the canine and mesial rest in first premolar in each side joined to the saddle by antro-posterior palatalstraps.

Group 2: Patients received maxillary removable partial denture with thermoplastic frameworks and acetal resin clasps **(Biodentaplast Cartridges Acetal resin (Poly-Oxymethylene) Bredent, GmbH & Co. KG, Germany)** with the same design of group 1.

Construction of the removable partial denture: Study casts prepared from alginate impressions were surveyed, proximal surfaces of the abutment teeth were prepared parallel to the path of insertion to act as guiding planes. Following mouth preparation, final impressions were made using rubber base impression material in a custom tray Master casts were surveyed, modified and duplicated.

For the first group, wax pattern & casting was completed in the conventional.manner. For the second group,the master casts were duplicated for constructing the wax pattern of the acetal resin frame work and retentive arm direct retainers in conventional manner. Wax pattern of acetal resin direct retainer were made in a special muffle. After the wax pattern was eliminated, the acetal resin material was softened at 260 degree

centigrade & injected into the mold with a special injection gun. Pressure was maintained till the material cools,finished & polished, then seated on the master cast.

The metallic and thermoplastic frameworks were tried for both groups. Maxillo-mandibular relation was recorded, setting up of teeth & denture was tried in the patient's mouth.Lastly at insertion, stress the oral & hygienic measures.

Steps for retention measurement procedure:

Identification of the geometric center: The relative geometric center of the partial denture was identified first; Undercuts in the fitting surface of the partial dentures were blocked by wax. Then a mix of stone was poured in the fitting surface of the parial denture to obtain a cast. The centers of the maxillary tuberosities and the midline were marked on the partiale denture. A cardboard was cut so as to connect these markings, thereby forming a triangle. The intersection of the three lines bisecting the three angles of the triangle was considered as the geometric center (Fig.1). The geometric center of the triangle was then identified based on scientific grounds.

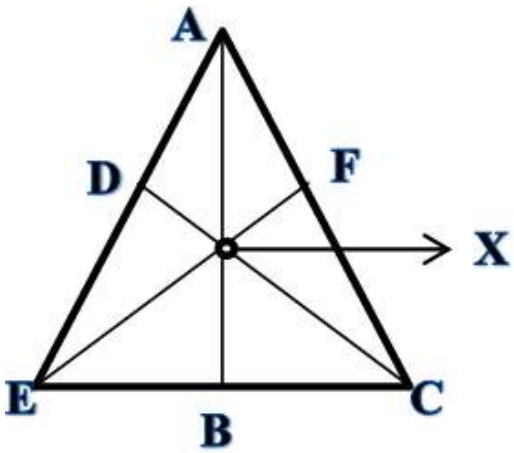

Fig (1): The geometric center of this triangle would be pint X (intersection of AB. CD and EF)

A pin was passed through the cardboard at the geometric center downwards to mark it on the cast. A plastic rod was then fixed to the cast and suspended upwards from the marked point to maintain the location of the predetermined center. Then, three holes were made at the palatal margin of the major connector at the points of emergence of each bisector line of the predetermind triangle.These holes were created 2-3 mm away from the palatal margin to resist fracture.also,these holes were used to assist the passage of wires to resist dislodgement during the retention measurement procedures (Fig 2).

Fig (2): Thermoplastic RPD attached with wires and loop

The wrought wires were 1mm in diameter to resist deformation during testing procedures. The wires were adjusted to run 2cm below the occlusal plane . The end of the 3 wires was bent to form a loop, to be engaged by the forcemeter hook and allow lifting of the denture . with his mouth open and the lips relaxed, the palate and the maxillary ridge were at nearly 45 degree to the floor (Fig. 3).

The hook of force meter was inserted in the hole of frameworks loop then the peak button was turned on and the zero button of the device was pressed when the device screen showed zero reading; measurement was started immediately. A Pullling force was then gradually applied until the framework was dislodged.

Retention force was measured as the maximum force needed to completely dislodge the partial denture. The measuring procedures were repeated 5 times at 5 minute intervals and the average value was recorded (Fig. 3). Measurments of retention were carried out after denture inspection (zero level) and 3,6,9,12 months later.

Fig (3): Digital force gauge device attached to the maxillary partial denture

Results

Measurements of retention were carried out after denture inspection (zero level) and 3,6,9,12 months later using a digital force measurement gauge.Data were collected, revised, coded and entered to the Statistical Package for Social Science (IBM SPSS) version 20. quantitative data were presented as mean, standard deviations and ranges.The confidence interval was set to 95% and the margin of error accepted was set to 5%. So, the p-value was considered significant as the following: ($P > 0.05$: Non significant, $P < 0.05$: Significant and $P < 0.01$: Highly significant).Paired t-test was used at $p \leq 0.05$ to assess the retention values within each group.

Table (1), presents the comparison between the two groups regarding retentive force in Newton. The recorded retentive forces with group I at delivery were more than double that recorded with group II (48.9 ± 4.98 vs 22.1 ± 3.57 N). The results showed that retentive force mean values were significantly lower in thermoplastic group; compared to metallic group, at denture insertion and at all follow up intervals (3, 6, 9 and 12 months post insertion) ($P \leq 0.01$). In group (I), significant reduction in retentive force mean values was noticed at 6, 9 and 12 months of denture insertion to end with 41.1 N that is 84% of the original values. However, a nonsignificant reduction was observed in retentive force values in group (II) along with follow up intervals to end with 19.7 N that is almost 90% of the original values.

Table (1): Comparison between groups regarding retentive force in Newton.

Retentive Force (Newton)	Groups				P. value (Sig.)
	Group (I) Metallic (n=12)		Group (II) Thermoplastic (n=12)		
	Mean	SD	Mean	SD	
At denture insertion	48.9 [a]	4.98	22.1	3.57	<0.01**
3 Months	46.5 [ab]	5.41	21.5	3.14	<0.01**
6 Months	45.4 [b]	4.74	21.4	3.71	<0.01**
9 Months	43.9 [c]	5.37	20.5	3.91	<0.01**
12 Months	41.1 [c]	4.96	19.7	4.18	<0.01**

Independent T-test was used to compare between groups. Paired T-test was used within each group at partial denture insertion, 3, 6, 9 and 12 months from insertion, a, b, c Means in the same column with different superscripts are significantly different ($P \leq 0.05$), ** Significant ($P \leq 0.01$).

Discussion

The possible use of polyacetal resin as a denture base material was considered by Smith over 40 year's ago 30 and was promoted primarily on the basis of superior esthetics, which allowed the clasp to better match the color of the abutment tooth. [9] Acetal as a homo-polymer has good short term mechanical properties, but as a co-polymer has better long-term stability. Acetal resin is very strong, resists wear and fracturing, and is quite flexible. These characteristics make it an ideal material for pre-formed clasps for partial dentures, single pressed unilateral partial dentures, partial denture frameworks, provisional bridges, occlusal splints, and even implant abutments.[10,11]

Retentive clasp arms must be capable of flexing and returning to their original form and should retain an RPD satisfactorily. The tooth should not be unduly stressed or permanently distorted during service and should provide esthetic results. acetal resin have a sufficiently high resilience and modulus of elasticity to allow its use in the manufacture of retentive clasps.[12,13]

The retentive force is dictated by tooth shape and by clasp design. Tooth shape influences retention by determining the depth of undercut available for clasping.[11] The results of this study showed that retentive force mean values were significantly lower in Thermoplastic group in comparison with metallic group at denture insertion and at all follow up intervals. It is worth mentioning that the retentive values of clasps of group I (metallic)was more than double of that of group II (thermoplastic) even at the end of follow up period. This is due to the excessive rigidity of metallic clasps in comparison of the thermoformed ones.

Group (I) showed significant reduction in retentive force values at 6, 9 and 12 months of denture insertion. However, a slight non-significant reduction was observed

in retentive force values in group (II) along with follow up intervals. This is in accordance with the results of[14] that simulated a 36-month clinical use of RPD clasps made of acetal resin and assessed their retentive force and deformation by comparison with similar clasps cast of Co-Cr. The result showed no deformation for the acetal resin clasp after 36 months of simulated clinical use unlike the Co-Cr clasp which presented an increase in the distance between the tips. Their results also showed that the acetal resin clasps require less force for insertion and removal than Co-Cr clasps.

The fact that the thermoformed resin clasp is more flexible than the metallic one; have driven several authors to recommend shorter and thicker resin clasp engaging deeper undercut to produce acceptable clinical retention. This is due to the relatively low rigidity of the thermoplastic resin (elastic modulus; 2.36 GPa for POM as compared to 240 GPa for CoCr alloy.[15] For this reason, thicker acet al resin clasps were used for comparison in this study. A more recent study found essentially the same results as the current study in regards to denture retention.[16] They concluded that; the cobalt chromium clasp has superior retentive forces than the acetyl resin due to significantly higher flexibility of the acetal resin. They recommended its use in deeper undercuts when an aesthetic demand or periodontal health is a primary concern.

Conclusion

Acetal resin provides less retention compared to chrome cobalt. However patients did not complain from retention with thermoformed removable partial dentures. So, further study has to be done regarding various thicknesses and designs of clasps and framework for its successful dental application.

Abstract

Stroke is one of the highest causes of catastrophic death in Indonesia. Lack of knowledge and public awareness about stroke caused the delay of health care and post-disease recovery. So that, they impacted on death or disease complications and even disability. There were needs for prevention efforts and early detection that could be done at home. Today, the early detection was carried out by health workers in health care facilities through skrinning. The use of smartphones could minimize the delay of health care. This would be an opportunity to develop smart phone applications as media for stroke early detection because most people used smartphones in their daily lives. This study aimed to identify the use of smart phones as media for stroke early detection. Comprehensive literature analysis through Google Scholar, Proquest, and EBSCO in the last 5 years, with keywords: *stroke early detection*, *sourceinformation*, *smartphone application*. Inclusion criteria were smartphone application and stroke articles in the past 5 years. Data were analyzed in a table consisted of title, author, year, and result. A total of 21 articles had showed the use of smartphones might provide sign assessment and mild stroke symptoms experienced by individuals effectively and efficiently. These media had been globally used for early detection and information sources about strokes. Smartphone applications became innovative media that could help individuals to carry out early detection and obtain practical information about stroke and be accountable. The results of this literature study could be used as references to determine the form of appropriate intervention ormedia as support toward the efforts of stroke case prevention in Indonesia.

Keywords: *Smartphone application, early detection, stroke.*

Introduction

Indonesia is faced with a triple burden disease situation, where control of infectious diseases has not been resolved but the trend of an increase in non-communicable diseases occurs every year, especially catastrophic diseases. The period of January-June 2014 had increased in the number of cases and the cost of treating catastrophic diseases such as vascular disease (heart disease, stroke), diabetes mellitus, kidney disease, cancer, thalassemia, and hemophilia[(1)]. The management of catastrophic diseases requires higher cost because the numbers of cases have increased and made various kinds of complications and even death. The government needed to design appropriate programs and policies through the management of risk factors and calculate disease financing[(2)]. One of catastrophic diseases that could be minimized through risk factor management was stroke.

Stroke is non-communicable disease that contributes for the highest mortality after heart disease and cancer and is the first cause of serious and permanent disability. This could be prevented through appropriate treatment considering on the risk factors[(3)]. A total of 15 million people worldwide suffered from strokes, 5 million people die from strokes, and 10 million other people survived with permanent disability. This permanent disability

resulted dependence on others[4]. The numbers of stroke cases in Indonesia was 2,137,941 (12.1%) cases. This number have increased 3.8% from the previous year, so that, Indonesia was currently as the country with the highest number of stroke cases in Asia[1].

Stroke stands for *Cerebro Vascular Accident* (CVA) isneurological disorder that occurs due to disruption of blood circulation to the brain for 24 hours or more and tends to be permanent. Clinical symptomsoccured suddenly and progressively, they resulted acute brain damage in focal or global[5]. A total of 87% people had ischemic stroke caused by the blockage of blood flow to the brain and the rest occurred hemorrhagic strokes[6]. Stroke attacks could affect anyone due to unhealthy and instantaneous lifestyle at this time[7].One of the efforts was early detection of symptoms or the risk of stroke.

Currently, early detection was not only implemented conventionally but also in modern way through the advances of health information technology. *E-health* appeared as a form of existence in the health sector that refered to the delivery of information and the provision of internet-based health services and technology. This was supported by the development of smartphone use among communities included in Indonesia from time to time. The numbers of internet users in Indonesia until 2014 reached 88 million people[8](explained that 67.6% used smartphones to access the internet and social media, 87.3% accessed the internet and social media sites for 20-50 hours per week).

Previous research had proven the success of smartphones as accessible media, improved medication compliance, immunization schedule reminders[9]. Monitoring system consisted of website-based server applications and Android-based client applications could help monitor the compliance and development of CD4(clients'HIV/AIDSARV) in order to succeed the implementation of ARV therapy[10]. The *Girl Talk* application increased the knowledge significantly from the baseline level (35.3% vs. 94.1%; $p < 0.001$)[11]. At present, there was no study on the implementation and impact of using smartphone applications as media of information and early detection of stroke in Indonesia.

Based on this phenomena, there was a need for literature review on the use of smartphone technology as efforts to provide information and early detection of stroke in various countries. The results of this study were expected to be used as references in the development of smartphone application-based stroke early detection media. This study aimed to identify research articles that described the use of smartphones as media of information and early detection of stroke.

Research Method

The strategy of searching research articles carried out comprehensively through the databases of Google Scholar, Proquest and EBSCO research journals in the last 5 years, it was obtained 21 articles. The keywords used in the searching for research articles were *stroke early detection, source information, smartphone application*. Searched articles using punctuation "AND" so that the writing "*stroke early detection and smartphone application*" and "*source information for stroke and smartphone application*".

Result

The utilization of smartphone applications in various countries as media for early detection and stroke prevention based on the analysis of 21 articles. The application functioned as screening for clients with risk of stroke, information sources of stroke, detection of abnormalities in the use of walking patterns, routine blood pressure checks, detection of heart problems, stop smoking, checking cholesterol and blood sugar, regular physical activity, and low salt diets.

The results of literature review showed smartphones that were used as media for early detection and prevention of stroke, namely ARM Strokes, FAST-ED (*Field Assessment Stroke Triage for Emergency Destination*), Stroke 119, and mSTOPES. Study result showed that 86 doctors (74%) used the application for patient care process, either for personal use or recommending to patients(12). Doctors used the application to manage stroke risk factors (25%) all of the time. 77% of doctors stated their interests in using the application because it could help their patients managing their risks. 90% of doctors agreed that this application was useful if provided patient care.

The *e-wars* prototype provided additional features about information to reduce the risk of stroke, it consisted of checking routinely blood pressure, detection of heart problems, stop smoking, checking cholesterol and blood sugar (DM clients), regular physical activity, low sodium diet (low salt) (Erawantini et al.,2018). The mSTOPES application was able to identify and improve the AF screening method for stroke prevention. The results of

this trial also provided greater knowledge of arithmetic characteristics (eg frequency, duration, average, and time of day) that associated with symptoms of AF[13].

The ARMStrokes application was developed on iPhone using the *built-in*iPhone sensor (accelerometer, gyroscope, and device orientation sensor) to identify movement speed and user position information (eg *pitch*, *roll*, and *yaw* values) during training. Clients were enthusiastic about using ARMStrokes in their daily lives because the given feedback was right after training[14]. In addition, the FAST-ED (*Field Assessment Stroke Triage for Emergency Destination*) application provided information through short questions to identify age, anticoagulants use, final normal values, motion weakness, visual impairment, and aphasia; stroke center database that provided endovascular care; and *Global Positioning System* to calculate the feasibility of clients of endovascular care and the distance/time of transportation to emergency health care centers[15]. Based on the results of these studies, smartphone applications could help individuals to detect and obtain stroke information easily and practically because it might be accessed anywhere and anytime.

Discussion

Stroke is one of eight types of catastrophic diseases that is included in the National Health Insurance (JKN) financing. This was due to the high cost of treatment, various complications emerged and threatened life. The magnitude of the threat of stroke required prevention and early detection. One of the preventive actions was through the use of information technology in the form of smartphone applications as *early warning system* (e-ways). Based on the literature review of 21 research articles showed various innovations had been developed as media for early detection and prevention of stroke.

Treskes et al through his research on 200 clients by applying *mobile-AF* application in the form of *The Kardia Mobile* for early detection of AF (*Atrial Fibrillation*) and TIA as the cause of cryptogenic stroke. The result showed that *The Kardia Mobile*was non-invasive validated device that was easy to use, low cost and could be used by clients independently[16]. This application had the potential to improve the detection of AF and TIA in cryptogenic stroke populations and prevention of recurrent strokes. Similar study was conducted, through "Stroke 119" application was able to perform stroke screening and information about the nearest hospital. This application provided information about symptoms of stroke, thrombolytic treatment, and action plans for clients at risk of stroke[17]. A study through the development of *stroke mobile pre-detection* application showed that most clients believed this application could increase their awareness of stroke and help them to detect early symptoms of mild stroke[18].

Other studiesalso showed the effectiveness of smartphone applications, among others: "Stroke Riskometer TM" application which was able to detect stroke risk factors. Risk factors for stroke included age, sex, systolic blood pressure, and waist circumference (>89 for men and women)[19]. "Stroke RiskometerTM" application was an easy to use tool because individuals could assess stroke risk independently and comfortably, anytime and anywhere. "Stroke Riskometer" application and showed the results "this could calculate the risk of stroke for normal individuals[20].

The benefits of smartphone applications showed that there was a need to develop smartphone-based application interventions that could be used extensively in the health sector, especially in managing carastrophic diseases. Various problems in health services such as access to service centers, lack of health care providers, long treatment times, and high costs or needs of health care providers both clients and government, made health problems became complex and needed to get solution for designing participatory services[21]. The World Health Organization (WHO) stated that digital technology (*mHealth*) was intended to improve the quality and coverage of care, improved access to health information, services and skills, and promoted positive changes in health behavior to prevent catastrophic diseases[22].

The benefits of smartphone use were also suggested, *mHealth* which was an element of eHealth played important roles in creating health services that were easily accessed through smart telephone communication such as providing health information as effortsto prevent health problems, collect health data and monitor clients[23]. The mHealth (ex: *smartphone*) application facilitated communication among users and the health care systems, monitoring, and access to information regarding medical records and developments[24]. A number of *mHealth* trials on stroke problems had shown greater benefits from the use of smartphones as *early warning system* (*e-ways*) in the early detection and strokes prevention, complications and stroke recurrence prevention. Through this literature review, it was

expected to provide views on the development of health technologies, especially the development of *mHealth* in chronic diseases and catastrophic.

Conclusion and Suggestion

The use of smart phone as an early warning system (e-ways) presented opportunities to reach the wider communities in the effort of early detection and prevention of stroke. In addition, the use of *e-ways* was also able to prevent the recurrence of stroke. Most of the Indonesian people had used smartphone applications, this was enable the development of smart phone applications in health services, especially in the prevention of stroke.

Acknowledgment: We expressed our gratitude for the prayers and support from all parties, especially to the our institutions.

Conflict of Interest: The researcher declare that there are no conflict interests of this study

Abstract

Background: The role of tumor-infiltrating lymphocytes (TILs) in breast cancer has been extensively studied over the last decade; it now believed that they have predictive and prognostic roles in breast cancer.

Materials and Method: We identified 70 patients with primary breast cancers receiving neoadjuvant chemotherapy (NAC); we analyzed pre-and post-treatment tumor-infiltrating immune cells (CD3, CD8) by immunohistochemistry. Immune cell profiles were analyzed and correlated with response and survival.

Results: We identified two tumor-infiltrating immune cell profiles, which were able to predict pathological complete response (pCR) to NAC. A higher infiltration by CD8 and CD3 lymphocytes was associated with occurrence of pCR. Analysis of the immune infiltrate in post-chemotherapy treatment identified a profile of high CD8 and low CD3 infiltration associated with better disease free survival.

Conclusions: Tumor lymphocytic infiltrates play a predictive role for detecting pCR and a prognostic role in detecting the outcome. Further understanding of the mechanisms underlying the distribution of immune cells and their changes after chemotherapy may contribute to the development of new immune-targeted therapies for breast cancer.

Keywords: *Tumor lymphocytic; chemotherapy; neoadjuvant.*

Introduction

Neoadjuvant chemotherapy (NAC) is the standard of care for breast cancer and increases the options for breast-conserving surgery.(1)

Pathological complete response (pCR) after NAC is cosidered as an indicator of good outcome, especially in triple-negative breast cancer (TNBC) and human epidermal growth factor receptor 2 (HER2) breast cancer.(2)Residual cancer cells after NAC may be more aggressive or have poor outcome.(3) However, some patients who fail to achieve pCR after NAC have a relatively good outcome. Therefore, new prognostic markers in residual tumors are needed to identify high-risk patients.

Nowadays, the importance of the immune tumor microenvironment has been reported to play animportant role in predicting outcomes.(4) Various cells of the immune system can play varying roles in tumor progression; for example, cytotoxic T cells (CD8+ T cells), natural killer cells, dendritic cells and macrophages are associated with improved clinical outcomes, whereas regulatory T (Treg) cells and myeloid-derived suppressor cells suppress antitumour immunity. Specific TIL subsets, such as CD3+, CD8+ and forkhead box protein 3 (FOXP3)-positive TILs, has been reported to be clinically significant and reliable in predicting treatment response.(5)

Chemotherapy enhances the immune activity or the reversal of immunosuppression. Some studies revealed that changes in the levels of CD8+ or CD3+ TILs induced by chemotherapy can be used as a prognostic marker in aggressive breast cancer subtypes, such as TNBC and HER 2 breast cancer.(6)

However, the predictive value of changes in lymphocytic subpopulations after NAC in all breast cancer subtypes has not been discussed sufficiently.

The current study investigated the clinical significance and value of changes in the levels of CD8+ TILs and CD3+ TILs before and after NAC in all breast cancer subtypes.

Patients and Method

Patient Background: A total of 70 patients with stage II and III primary infiltrating ductal breast cancer that were treated with NAC at period from January 2015 till May 2016 follow up period extended till May 2019 was done. Tumor staging were stratified based on the TNM Classification of Malignant Tumors, The Union for International Cancer Control Seventh Edition.(7)

Tumors were classified into subtypes according to the immunohistochemical expression of estrogen receptor (ER), progesterone receptor (PgR), HER2 and Ki-67.

Clinical evaluation included physical examinationchest X-ray, mammography, ultrasound breast exam, breast magnetic resonance imaging (MRI) and core biopsy.

In locally advanced tumors bone scintigraphy and body computed tomography were added to the staging workup. For chemotherapy response evaluation, dynamic breast MRI was performed prior to surgery.

Pathology Assessment: Pre-treatment estrogen (ER) and progesterone receptors (PR) status was assessed by immunohistochemistry (IHC), and HER2 status was assessed by either fluorescent in situ hybridization (SICH) or a validated IHC method. Ki67 proliferation index was calculated and 14% was taken as a cutoff point. pCR was defined as the absence of invasive carcinoma both in the breast and the axilla, regardless of the presence of carcinoma in situ.

Tumor-infiltrating lymphocytes assessment: Pre-and post-NCT samples was built after selection of predominantly tumor areas by a pathologist (ACB).

Adequate controls (tonsil and normal breast) were included. For immunohistochemistry, 4 μm sections were cut deparaffinated, rehydrated and processed with standard method using an automatized stainer (Ventana Bench mark, Roch, Germany). Staining was performed simultaneously in all slides to avoid intersection variability. For TIL study, the following antibodies were used: CD8 (Clone C8/144B, Dako), CD3 (Clone DF-T1, Dako).

Microscopic evaluation of CD3+ and CD8+TILs: Scoring of immune stained positive TILs wasdone by the pathologist. CD3+and CD8+ TILs were counted in five randomly selectedhigh power fields at 40X magnification and the countswere averaged. Initially TIL count was recorded as: +(1-25 cells), ++ (26-50 cells), +++ (≥51 cells) in thetumor and the stroma separately. Positive TILs up to25 cells were considered as low TIL count and morethan 25 cells were considered as highTIL count.

Results are expressed as TIL count/mm^2. For each subpopulation, chemotherapy-related relative variation was determined and expressed as a percentage. Tumor lymphocytic infiltrate detected classified into low and high according to cut off point 10%.

Neoadjuvant therapy regimen and surgery: All patients received a TC protocol consisting of six courses of Docetaxel (75 mg/m2) and (600 mg/m2) cyclophosphamide every 3 weeks .(8)

Clinical end points

Therapeutic antitumor effects were assessed according to the Response Evaluation Criteria in Solid Tumors criteria.(9) The pCR was defined as the complete disappearance of the invasive compartment of the lesion with or without intraductal components, including the lymph nodes.(10)

DFS was defined as the time from surgery to death, locoregional recurrence or distant recurrence.

Statistical Method: The collected data were coded, tabulated, and statistically analyzed using **SPSS program (Statistical Package for Social Sciences) software version 25.**

The level of significance was taken at **(P value < 0.05).**

Results

The clinicopathological characteristics of the 70 breast cancer patients were recorded as shown in [Table 1]. The patient's age ranged from 27 to 70 years, 45(64.3%) were premenopausal and 23(35.7%)

were postmenopausal. All patients were invasive duct carcinoma. Patients with grade II carcinoma were 92% while grade III carcinoma was 8%. Patients were of clinical tumor size T231.4%, 48.6% of patients were of T3, and 18.6% were of T4. Patients with positive axillary LN metastasis were 71.4%. ER was positive in 68.6%, PR was positive in 55.7%, and Her 2 was positive in 18.7%, and Ki-67 was 14 or more in 82% of patients. Tumor lymphocytic infiltrate presented as 19 (27.1%) cases were CD3 T lymphocyte high and 27 (38.6%) cases were CD8 T lymphocyte high (Figure 1).

Ten out of seventy patients achieved pCR (14.3%), 5 patients were TNBC, 4 patients were HER2 and one patient was Luminal B.

Table 1: Showing clinicopathological characteristics N=70

Age	Range Mean ± SD	(27-70) 46.4±10.6
Age Group	Premenopausal Postmenopausal	45(64.3%) 25(35.7%)
T	T2 T3 T4	22(31.4%) 34(48.6%) 13(18.6%)
N	N0 N1 N2 N3	20(28.6%) 48(68.6%) 0(0%) 2(2.9%)
ER	+ve -ve	48(68.6%) 22(31.4%)
PR	+ve -ve	39(55.7%) 31(44.3%)

TILs analysis: The 70 patients were categorized into those with low and high TILs grades based on the analysis of pre and post treatment tumor specimens (Fig. 1–2). The degrees of CD8 and CD3 positive TILs were evaluated immunohistochemically.

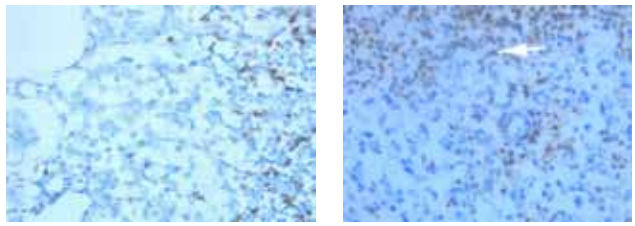

Figure 1: High CD8 and CD3 pre

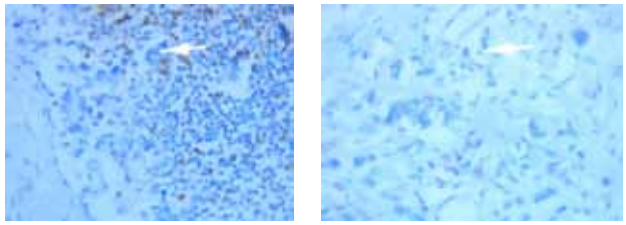

Figure 2: High CD8 and low CD3 post

Predictive value of TIL: Nine of 27 (38.6%) from high CD8 patients and 10 of 19 (27.1%) from high CD3 achieved a pCR (Table 2).

The distribution of TILs grades in the pCR and non-pCR groups is presented in Table 2. The rate of pCR was correlated significantly with TILs grade. The pCR rate in patients with high CD8 TILs grade was 90%, which was significantly higher than that in those with low CD8 TILs grade (1%) ($P = 0.001$) and also the pCR rate in patients with high CD3 was (100%) which was significant than those with low CD3 (0%)($P = <0.001$).

Table 2: Correlation between CD8 and CD3 with pCR

		PCR		P value
		Non pCR N=60	pCR N=10	
CD8	Low High	42(70%) 18(30%)	1(10%) 9(90%)	0.001*
CD3	Low High	51(85%) 9(15%)	0(82.9%) 10(100%)	<0.001*

Prognostic value of TIL

At a median follow-up of 36 months, 30 recurrences (42.9%) were observed after standard NAC and curative surgery.

Tables (3 & 4) illustrates disease free survival (DFS) according to TILs (high and low levels) post-operative proved to have significant prognostic value.

Table 3: Shows High CD8 TIL in post-operative specimens associated with prolonged survival with statistical significance

Means for Survival Time					Overall comparisons	
TIL CD8 post	Estimate	Std. Error	95% CI		X^2	P value
			Lower Bound	Upper Bound		
Low	122.6	9.7	103.5	141.7	5.83	0.016*
High	149.6	9.8	130.4	168.8		

Table (4): Shows Low CD3 in post treatment specimens associated with prolonged survival with statistical significance

Means for Survival Time					Overall comparisons	
TLI CD3 post	Estimate	Std. Error	95% CI		X^2	P value
			Lower Bound	Upper Bound		
Low	149.8	7.2	135.8	163.9	8.45	0.004*
High	102	13.5	75.4	128.5		

Discussion

The current study detects the role of TILs grade in breast cancer revealed that a high TILs grade in the primary tumor was associated with a significantly higher pCR rate and better outcome espically in HER2 and TNBC. Also, the high CD8 TILs grade in the residual tumor who did not achieve pCR was also associated with a significantly better prognosis, compared with the residual tumors with a low CD8 TILs grade.

Denkert *et al*.[11] detected that pathological response rate after preoperative drug treatment was associated with TILs grade in HER2-positive breast cancer. Specifically, they found that the pCR rate was significantly higher in the group with high TILs expression than that with low TILs expression in HER2-positive patients with NAC.

The role of TILs in different subtypes of breast cancer is still unknown. We analyzed the predictive roles of TILs in different subtypes of breast cancer. These results indicated that high TILs detected in pre-treatment biopsy indicated pCR rate increase in triple negative and HER2 positive breast cancer patients, but not higher pCR rate in ER positive patients. Previous studies have mostly supported our results. Ono et al. [12] found a significant association between pCR and the TILs number in triple-negative patients, but not in other breast cancer subtypes. TILs subset in breast cancer, primarily CD3+, CD8 lymphocytes, has also been studied in the relationship of the pCR rate. Since TILs subset have been shown to change after NAC, we found that higher level of CD8+, CD3+ in pre-treatment biopsy were correlated with the pCR rate and these results were similar to meta-analysis that a high number of TILs is a significant predictor of the pCR rate in response to NAC.[13]

Several studies suggested that TILs expression in residual tumors following preoperative chemotherapy might be an important factor in evaluating the sensitivity of cancer to chemotherapeutic agents. In 2014, Dieci *et al*.[14] compared the TILs expression levels before and after NAC among patients who did not achieve pCR and reported significantly better prognosis in the group with high TILs expression in residual tumors than in the group with low TILs expression.

Our results showed that post-NAC TILs are able to prognostically classify patients with good outcome who did not achieve pCR high CD8 and low CD3 in post treatment was found to be of favorable prognostic value for DFS.Many studies stated that high TLI was associated with better DFS and this was similar to our results in high CD8 as Mahmoud et al[15] and Tsiatas et al[16] but high CD3 in post treatment was not associated with better DFS in our results and this was differ with Castaneda et al[17] but similar to García-Martínez et al[18] and Hamy et al[19].

The identification of these high-risk patients, especially in the group with burden residual disease, might lead to adjuvant immune treatments. Our data might be seen as opposite that of a recent report by Dieci

et al. showing those high TILs in post-NAC residual triple negative breast tumor is a predictor of good prognosis [14]. However, given the sample size and the high pCR of TNBC primary tumor in our series, we only identified four patients where TNBC with residual tumor and high TILs infiltration.

Our work has some limitations, the main one being the limited sample size. This fact precluded a more extensive analysis of the interactions between the immune response profile and the tumor subtype. However, other work has shown that prediction of pCR by immune-related signatures is probably not confined to HER2 or TNBC and may also be reliable in luminal breast cancer[20].

Also second limitations is that TILs have many variables we only detect CD3 and CD8 types still there is a lot of variables to be detected as CD4, CD68, FOXP3.

Third limitation is that we did not use trastuzumab in NAC or adjuvant setting in HER2 breast cancer patients and this may affect pCR and DFS.

Conclusions

Despite the above limitations, our findings suggest that TILs could serve as an important marker for predicting the pCR rate to NAC, especially in HER2 positive and TNBC patients.

Also it can be used as prognostic marker for those who did not achieve pCR in detecting their outcome, but still we need more characterization and understanding TILs.

Ethics: This study was conducted at Minia university hospital and Minia Oncology Center. All patients were informed of the investigational nature of this study and provided their written informed consent.

Abstract

Background: Diarrhea is a leading cause of morbidity and mortality in children aged less than five years. Escherichia coli O157: H7 is a highly pathogenic subgroup of Shiga toxin-producing E. coli (STEC) that causes severe human bloody diarrhea and hemolytic uremic syndrome.

Objectives: To determine the rates of detection of E. coli O157: H7 infections in children less than five years of age and to assess the clinical and laboratory criteria of E. coli O157: H7 associated diarrhea.

Patients and Method: Across sectional prospective, hospital-based study was carried out on children with acute diarrhea visiting the outpatientclinics at Children Welfare Teaching Hospital, AL-Kadhymia Pediatric Hospital and AL-Elweya Pediatric Hospital in Baghdad during the period from Sep. to Dec. 2015. E.coli O157: H7 antigen in fecal samples taken from children with acute diarrhea were detected by immunochromatographic assay (ICA).

Results: Escherichia coli O157: H7 antigen was detected in 43/94(45.7%) of fecal samples for children with diarrhea. 55.8% of children with positive stool samples were females and 44.2% were males with a female to male ratio of 1.3:1. Children with acute diarrhea due to E. coli O157: H7 were younger (mean age 17.19 ± 9.572 months) than those without E. coli O157: H7 infection (mean age 30.63 ±19.815 months) and the difference is highly significant. Fever and vomiting were symptoms shared by all the studied children regardless of their E.coli O157: H7 infections. Significant associations between bloody diarrhea, pus and red blood cells in stools and E. coli O157: H7 infections were noted.

Conclusions: E. coli O157: H7 infectionwas a common cause of gastroenteritisin children less than five years in Baghdad.Mainly among infants and young children who presented with acute bloody diarrhea, microscopic pus and red blood cells in their stools.

Keywords: *Children, Escherichia coli O157: H7, Acute enteritis, immunochromatographic assay.*

Introduction

In developing countries, diarrheal diseases are among the most common causes of morbidity and mortality of young children.(1) Two types of E. coli are recognized among isolates from stool samples; diarrheagenic and non-diarrheagenic E. coli. Regarding diarrheagenic E. coli, these pathogens cannot be distinguished on bases of colony morphology or biochemical testing. (2) Genotypic determination is therefore necessary for the identification of these pathogenic strains and for such purposes, various highly sensitive and specific multiplex PCR method have been developed.(3,4,5) On the basis of distinct epidemiological and clinical features, specific genetic virulence determinants, and

association with certain serotypes, diarrheagenic strains of E. coli have been recognized into six main categories; Shiga toxin-producing E. coli (STEC) formerly called Enterohemorrhagic E.coli(EPEC), Enterotoxigenic E. coli (ETEC), Enteroinvasive E. coli (EIEC), Enteroaggregative E. coli (EAEC), and diffusely adherent E. coli (DAEC). Cytolethal distending toxin-producing E.coli (CDT-EC) are also considered one of the diarrheal E. coli group.[6] Shiga toxin-producing E. coli (STEC) strains are important foodborne-zoonotic pathogens of global public health concern, where sheep and their products are important reservoirs for STEC.[7,8] In 1982, E. coliO157:H7 was first recognized as a cause of food-borne outbreak of severe bloody diarrhea and since then in a number of large food and water-borne intestinal disease outbreaks in humans were reported.[9,10] In human, E. coliO157:H7 strains are recognized as highly pathogenic subgroup of STEC that can cause severe outbreaks of gastrointestinal illness, ranging from diarrhea and hemorrhagic colitis to the life-threatening hemolytic uremic syndrome, where most of these outbreaks as well as sporadic cases have been frequently attributed to the STEC O157: H7 strains.[11,12,13,14,15] Specificity of the causative diarrheal pathogens as well as their epidemiology is critical for implementation of their specific interventional strategies. This study was proposed to unravel the rate of Escherichia coli O157:H7 infection in children up to five years of age as well as assessing the clinical and laboratorial criteria of their associated diarrhea in children attending tertiary pediatric hospitals in Baghdad.

Patients and Method

This cross sectional prospective hospital-based study was carried out on 94 children less than 5 years presented with acute diarrhea visiting the outpatient clinics at Children Welfare Teaching Hospital, AL-Kadhymia Pediatric Hospital and AL-Elweya Pediatric Hospital in Baghdad in the period from Sep. to Dec. 2015. Their age ranged from one month to five years. Children with protozoal or parasitic infestations were excluded from the study. Following microscopical and microscopical laboratory examinations of the stool samples, an immunochromatographic assay (ICA) (CerTest Company, Spain) for the detection of E. coli O157:H7 antigen which was applied according to the instructions of the manufacturing company. Regarding E. coli O157:H7 antigen detection, approximately 0.1 gm or 100 microliters of each stool sample was taken in specified collecting tube that contained a diluent. Then 100 microliters of the diluted mixture were dispensed in the (S)-labelled circular window in the card and to wait for 10 minutes for the appearance of red and green-colored bands. This qualitative immunochromatographic assay was done for determination E. coli O175:H7 antigen in fecal samples, where mouse monoclonal antibodies were reacting with E. coli O175:H7 antigens present on the pre-coated test band region. According to the capillary action, the stool samples were allowed to move upward across the membrane to react with the colored conjugate (pre-coated with mouse monoclonal anti-E. coli O175:H7 antigen antibodies-red microspheres which was pre-dried on the specified test region) so as a red colored line then being visible. This mixture again moves upward to another immobilized antibody placed in the control band region to produce a green-colored band, validating then a qualified procedure. Negative results was indicated as an appearance of only one green band (control line) while a total absence of control band, irrespective to other results, was regarded as an invalid result. The T test, Fischer exact and Chi square tests were applied for the analysis of the obtained results using SPSS program (version-20).

Results

From Sep. to Dec. 2015, 94 children with acute diarrhea attended the consultation clinics at three major tertiary pediatric hospitals in Baghdad were tested forthe detection of E. coli O175:H7 antigen in their stools. Their age ranged from 1-60 months with a mean age of 24.48±17.257 months. The E. coli O175:H7 antigen was detected in of 43/94(45.7%) of the fecal samples. Children with acute diarrhea due to E. coli O175:H7 were younger (mean age 17.19 ± 9.572 months) than those without E. coli O175:H7 infection (mean age 30.63 ±19.815 months) and the difference in mean age in relation to E. coli O175:H7 infection was highly significant P= 0.001. Among the studied children, 51 females and 43 were males, with female to male ratio of 1.2:1. The female to male ratio among those with E. coli O175:H7 infection was 1.3:1. Although the gender of studied children with E. coli O175:H7 infection was in favor of female predominance (55.8% of those children who have E. coli O175:H7 antigen-positive diarrhea were females and 44.2% were males), yetthe statistical association between E. coli O175:H7 infection and gender was not scored as seen intable-1. Regarding the relationship between clinical features and stool E. coli O175:H7 antigen detection;all studied children with and without E. coli O175:H7 infections presented with

vomiting. However, there was a significant association between bloody diarrhea and E. coli O175:H7 infections as all the children with acute diarrhea and positive fecal specimens for E. coli O175:H7 antigen had bloody diarrhea compared to 43.1% of those without E. coli O175:H7 antigen. Children with fecal specimens positive to E. coli O175:H7 had more nausea than those without E. coli O175:H7 antigen (79.1%% versus 76.5%%),but the association between nausea and E. coli O175:H7 infection was not achieved. All the children with acute diarrhea and positive fecal specimens for E. coli O175:H7 antigen had fever while 96% of those without E. coli O175:H7 antigen were febrile, and a statistical association between fever and E. coli O175:H7 infection was not scored Children with abdominal pain and fecal specimens positive to E. coli O175:H7 antigen were 62.8% while those without E. coli O175:H7 antigen were 66.7%,thus no significant association was detected between abdominal pain and E. coli O175:H7 infection. Similarly, each of gross fecal pus and mucus scored no significant association with E. coliO175:H7 infections as seen in table-2. Regarding the associations between the stool laboratorial findings and E. coli O175:H7 antigen findings; the stool color,the presence of pus and red blood cells in stools were significantly associated with E. coli O175:H7 infection. While stool consistency, fat drops, and candida in stool were not significantly associated with E. coli O175:H7 infection as seen in table-3.

Table 1: The association between demographic characteristics and E. coli O175 infection in children

Characteristics		E.coli O175 No (%)	Non-E. coli O175 No. (%)	Total No. (%)	P value
Gender	Male	19 (44.2)	25 (49)	44 (46.8)	0.6
	Female	24 (55.8)	26 (51)	50 (53.2)	
Age mo.	1-12	14 (53.8)	12 (46.2)	26 (27.7)	0.001
	13-36	29 (65.9)	15 (34.1)	44 (46.8)	
	< 36	0 (0.0)	24 (100)	24 (25.5)	

Table 2: The association between clinical features and E. coli O175 infection in children

Clinical Features		E.coli O175 No (%)	Non-E.coli O175 No. (%)	Total	P. value
Fever	Yes	43 (100)	49 (96)	92 (79.9)	0.3
	No	0	2 (4)	2 (2.1)	
Nausea	Yes	34 (79.1)	39 (76.5)	73 (77.7)	0.9
	No	9 (20.9)	12 (23.5)	21 (22.3)

Discussion

In developing countries, diarrheagenic E. coli is recognized as an important cause of infantile and young childhood diarrhea. However, in different studies, their incidence have varied from more than 40% as in Bangladesh to less than 30% as in Jordan.[16,17]Furthermore in the last two decades, infection with E. coli O157:H7 has become a significant public health problem in the developed countries.[18] However, data on the etiology of diarrhea in Iraq are scarce.[19] In his study Immunochromatographic assay (ICA) for the detection of E. coli O157:H7 antigen was applied. It is considered as a rapid, sensitive and specific detection method to specify the infection by this pathogenic O157:H7 serotype of E. coli from other counterpart serotypes that have similar cultural as well as biochemical characteristics. The results showed that E. coli O157:H7 antigen was detected in 45.7% of the examined fecal samples. These results are higher than many other Iraqi studies, such as those reported by Al-Awwadi *et al.*(2012)[20] who serotyped E.coli O157:H7 in 4%, Al-Dawmy*et al.*(2013) [8]in 4.8%, Mohmmed *et al.* (2011)[21] in 5.7% and Shebib *et al.* (2003)[22] in 11%. Other studies conducted by Elaine et al (2012)[23] and Vally *et al.* (2013)[24] have also recorded very low rates of infection with E. coli O157:H7 in diarrheal children in Australia and USA, respectively. Different rates in different studies might be attributed to different tests used in each of them. However, by using multiplex PCR, Arif *et al.* (2010)[1] detected target genes of diarrheagenic E. coliin 38% diarrheal stools specimens from children in Sulaimani and Karkuk, Iraq.

In the present study, children with acute diarrhea due to E. coli O157:H7 were significantly younger than those without E. coli O157:H7 infection and the frequency of E. coli O157:H7 infection had increased with advancing age towards 36 months and declined after 36 months of age (Table-1). These findings are in agreement with Tozzi A.E study[25] where the frequency of STEC O157:H7 infections was found to increase with age. Also Ali in 2004[26] found that the E. coli O157:H7 infection rate was higher among children <2 years of age than other age groups, however,the frequency of such infections has begun to decrease in 10-12 years age group, representing a decline curve of this infection in relation to age. Another Iraqi study by Al-Dawmy and Yousif (2013)[8] revealed that most of the EcoliO157:H7 diarrheal cases occurred from first month to 5 years. Delignette et al study (2008)[27] revealed that children less than 5 years are 5 times more susceptible to EcoliO157:H7 infection than those more than 5 years.

Our results showed high prevalence of E. coliO157:H7 infections among females than males as well as in children less than 36 months. While Ali (2004)[26] in Basrah, Iraq, reported that males were more prone to the infection than females. Al-Wgaa and Alwan. (2017)[28] found 3.5% of isolates of human urine samples were E.coli O157:H7 positive and two third of them were females. The age-specific differences could belong to that infants have an immature immune systems as well as are exposed either to contaminated milk formula, foods and environment, which might increase the probability of the infection among children less than 3 years age.[29] In addition, thumbs sucking, dropped dummies or toys, and under supervised hand was hinge may increase the risks of infants and toddlers for such infection. Moreover, family of infants with diarrhea are more likely to seek medical care and to have stool being cultured than older children.[8]

In the present study, each of gross fecal pus and mucus showed no significant association with E. coli O157:H7 infections. However,there was a significant association

between bloody diarrhea and E. coli O157:H7 infections as all (100%) of the children with acute diarrhea and positive fecal specimens for E. coli O157:H7 antigen had bloody diarrhea compared to 43.1% of those without E. coli O157:H7 antigen. An association has been identified between certain host-specific factors and progression risk of enteric E coliO157:H7 infection, where up to 15% of gastrointestinal cases progressed to the hemolytic uremic syndrome (HUS).[19] The onset of HUS was most frequently follow an episode of gastroenteritis that often accompanied by bloody diarrhea.[30] In addition, E. coli O157:H7 infected patients who were at time of presentation have elevated white blood cell counts, fever, or bloody stools have also been noted to have a higher risk of progression to HUS than their counterpart patients without these findings.[31,32,33] Regarding results of bloody diarrhea observed in the present study, the clinical illness caused by E. coli O157:H7 was similar to that noticed previously by Karmali *et al*. and Hughes et al. studies.[34,35] However, bloody diarrhea was not an invariable finding in Ali (2004) study[26] where 44% of the patients had non-bloody diarrhea. Children with acute diarrhea whose fecal specimens were positive to E. coli 0157 antigen did relatively develop fever as those without E. coli O157:H7 antigen In contrast, Ali (2004)[26] in Basrah, noted that this agent causes bloody diarrhea with mild clinical presentation and could be distinguished by the lack of fever.In addition, AL-Musawi*et al.* (2018) [36] provided an evidence of the spread of E. coli O104:H4in Iraq, via the stool and urine of children under 15 year, that causes an illness similar to infection with E. coli O157:H7.In conclusion, this study has highlighted the importance of E. coli O157:H7, in infecting and causing severe intestinal tract infection in Iraqi children aged less than five years and provided useful information on the clinical and laboratorial criteria of their associated diarrhea.

The Impact of Healthy Educational Curriculum for Harmonized Exercises in the Development of Some Defense Skills in Handball

Naji Mutashar Azzat Al-Badr

Assist Prof., Department of Student Activities-University of Basra

Abstract

The importance of research to provide of the learner by best level of performance skills defensive hand reel through the integration of interoperability exercises with the educational units of an educational curriculum. The study aimed to identify the impact of the educational curriculum for exercises interoperability in the development of some defensive skills reel hand to sample individuals. The study was used in the study of the experimental method of designing the two groups of pre-tribal and post-test to suit the nature of the problem and the objectives of the research. This study was applied to the students of the third stage in the Faculty of Physical Education and Sports Sciences, University of Maysan for the academic year 2017-2018 of 40 students, Such as the control sample, (19) students such as experimental research sample, two students were dismissed for health reasons. Appropriate method, tools and tests were used, and after the results were obtained from the tests, they were processed statistically by using the statistical bag (SPSS). The study concluded with the most important conclusions: The educational curriculum of the combative exercises has a positive effect on the development of the performance of defense skills (interview, coverage, wall block and handover, receipt) for the students of the research sample. In addition, the educational curriculum for the exercises of compatibility achieved a better effect than the traditional curriculum followed by the teacher on the students of the research sample.

Keyword: *Experimental, Control, Smooth, Speed, Central nervous system.*

Introduction

Learning is a process that is inherent to life, that is, the person is in continuous learning as long as he is alive. Everyone knows that the educational process is affected by many factors, including what is related to the learner himself, others are related to the teacher and the type of learning and the surrounding circumstances them. Some of the special learner genetic factors that have a significant role in the success of learning associated with the type of material educated as possible developed, and thus we get a positive impact in achieving the goal of the educational instruction process, and among these factors kinetic compatibility that significantly affects the performance of many of the motor skills. In most of the skills of different sports, including handball skills, and thus whenever the motor compatibility, which is owned learner by a high level whenever the learner was able to reach the best performance of the motor skills. Compatibility means "the player's ability to integrate the types of movements in one template is characterized by Streamline and good performance". In other words, the motor[(1)].

Compatibility depends mainly on the integrity of the central nervous system, which sends nerve signals to several muscles working simultaneously to perform the motor duty. Thus, whenever increase the higher the accuracy of the sent signals, whenever the higher the motor compatibility, which in turn it is a positive return in the performance of defensive skills in handball that requires a great deal of motor compatibility. Therefore, have to attention it and develop it and here lies the importance of research to deliver the learner to the best level of performance skills defensive handball through the integration of interoperability exercises with the educational units of an educational curriculum.

The students in the Faculty of Physical Education and Sports Sciences must learn the defensive skills of

handball so that they can perform their defense duties during the application of defensive formations; we often notice that they have difficulty learning and not reaching the required level of performance. Although they have no difficulty or problem in receiving information while explaining the skill learned by the teacher of the material.

In an effort to find a solution to this problem, we decided to study the harmonic exercises because of its significant role in the motor performance of the most successful sports skills through application in a curriculum prepared by the researchers[2].

The research aims to identify the impact of the educational curriculum for exercises interoperability in the development of some defensive skills handball to sample individuals.

Research methodology and field procedures: The experimental approach was used to design the two sets of equal and for tests Pre and post the suitability of the nature of research.

The Data: The research community represents the students of the fourth stage in the Faculty of Physical Education and Sports Sciences-University of Maysan for the academic year (2017-2018) and it is scientific, theoretical, and applied branches of the number (40) students.

Students were selected to represent the branches of the research sample, the lot fell on the branch of the theoretical science to represent the control group by 19 students, and a branch of Applied Sciences to represent the experimental group of (19) students was excluded two students for health reasons.

Method and tools used in research:

- Method of data collection (Arab and foreign sources, observation, tests, data dump form for research tests).
- Tools and devices used (handball stadium legal, balls hand number (5), Poling number (10), whistle type (fox40) (2), colored adhesive tapes width (5 cm), video camera type (Sony), Laptop Acer.

Identify the studied skills and tests: It has been identified some defensive skills hand reel that will be studied, namely, (interview, coverage, wall block, handover) were determined. The tests were based on the evaluation of the performance of the skills through their portrayal and presentation to the evaluators to be the evaluation of (10) degrees.

Pre tests: Pre-tests for the research sample in skill tests understudy on Monday, 19/2/2018 at exactly half-past eight o'clock in the morning in the sports hall for the College of Physical Educationand Sports Sciences, University of Maysan with Note the following:

1. Give the sample sufficient time to warm up with all supplies.
2. Provide a detailed explanation for members of the research samplehow the tests are performed.
3. View each test before it is started by the members of the research sample.

Curriculum for harmonized exercises: To achieve the objectives of the research, the units were prepared for harmonized exercises and included (8) educational units, the duration of the unit (90) minutes divided as follows:

Preparatory section: Duration (25) minutes, including (introduction, warm-up and private warm-up).

Main section: Duration (60) minutes and includes two parts:

A. The educational part: In this part, the defense formations of the handball are explained. The duration of this section is 15 minutes.

B. The applied part: In this part, the defense formations of the handball are applied, interspersed with the implementation of consensual exercises. The duration of this part is 45 minutes.

The final section: Duration (15) minutes, including exercises to calm, relax, and greet the departure.

Application of the curriculum: After the completion of the implementation of the curriculum was conducted post-tests for the research sample in skill tests defense understudy on Thursday 12/4/2018 At exactly half-past eight o'clock in the morning in the sports hall for the Faculty of Physical Education and Sports Science-Maysan University. Was subject to conditions and the requirements in which the pretest took place.

Statistical method: The statistical bag (SPSS) was used to derive (arithmetic mean, standard deviation, t-test for the corresponding samples, t-test for asymmetric samples).

Results and Discussions

View the results of the differences between the two measures the pre and post in skills tests for the control group.

Table 1: It shows means and standard deviations and test (t) of the results of skill tests and pre-post control group

tests	Unit	Pre		Post		(t)	Sig	Type of significance
		M	SD	M	SD			
Interview	M	5.79	1.2	6.12	0.76	2.34	0.03	Sig
Coverage	M	5.12	1.17	5.66	0.97	1.12	0.07	not sig
Wall block	M	4.77	2.1	5.33	1.87	1.26	0.07	not sig
Handover	M	4.56	1.43	5.96	1.23	2.44	0.00	sig

* At degree of freedom (18) and probability of error ratio (0.05).

Through the table analysis (1) above, showing the results of the differences between the two measurements pre and post group research control in the test interview and the handover. Have made significant differences in favor of the post-test because of the level of significance value of less than (0.05). While did not show significant differences for test coverage and wall block the probability that the value of the significance level is greater than (0.05).

Discuss the results of the pre and post-tests of the control group: It shows through the presentation and analysis of the results of skill tests under the two measurements pre and post research group control which explained in the table (1). the development of the skills of the interview and the handover, and attributed the reason for this development as a result of its performance repeatedly through the application of formations defense in the educational units of the curriculum of education followed by the teacher.

Present the results of the differences between the pre and post measurements in the experimental tests of the experimental group and analyze them.

Table 2: It shows means and standard deviations and test (t) of the results of skill tests pre and post-experimental group.

tests	Unit	Pre		Post		(t)	Sig	Type of significance
		M	SD	M	SD			
Interview	M	5.79	1.07	7.17	0.73	3.27	0.00	Sig
Coverage	M	4.88	1.18	6.64	1.12	3.34	0.00	not sig
Wall block	M	5.17	1.67	6.73	0.97	2.45	0.00	not sig
Handover	M	4.34	1.41	6.37	1.1	3.32	0.00	sig

* At degree of freedom (18) and probability of error ratio (0.05).

Through the analysis of the table (2) above, the results show that the differences between the two measurements pre and post experimental research group in all skill tests achieved significant differences in favor of the posttest because the level of significance value of less than (0.05).

Discussion the results of the pre and post-testing of the experimental group: Shows through the presentation and analysis of the results of skill tests under the two measurements pre and post-experimental research group that is explained in the table (2).The curriculum of the harmonic exercises and prepared by the

researchers have a positive impact on the development of defensive skills (interview, coverage, wall block, handover), and this is consistent with the imposition of the first search.

This is because the educational curriculum includes harmonized exercises that have a great role in the development of defensive skills in handball (studied). As motor compatibility whenever the good of the individual whenever enables sports movements perform better and a high level, and this was confirmed by [3] as stated, "The higher the accuracy of the implementation of the motor performance indicates that the high level of compatibility. "As well as the nature of the exercises used in the educational curriculum, as given students enough time to repeat the exercise, has pointed out [4] that imposed on the teachers and trainers encourage learners to the greatest possible number of attempts to exercise performance.

Presenting the results of the differences between the control and experimental groups in the post measures of the skills tests and their analysis.

Table 3: It shows means and standard deviations and test (t) of the results of skill tests pre and post-experimental group and control

Tests	Unit	Pre		Post		(t)	Sig	Type of significance
		M	SD	M	SD			
Interview	M	6.12	0.76	7.17	0.73	3.27	0.00	Sig
Coverage	M	5.66	0.97	6.64	1.12	2.93	0.00	sig
Wall block	M	5.33	1.87	6.73	0.97	3.65	0.00	sig
Handover	M	5.96	1.23	6.37	1.1	2.75	0.00	sig

* The degree of freedom (36) and the probability of error ratio (0.05).

Through the analysis of the table (3) above, showing the results of the differences between the measurement of the post between control and experimental groups in all skill tests achieved significant differences in favor of the experimental group because of the level of significance value of less than (0.05).

Discussion the results of the post-test of the control and experimental groups: As shown in Table (3) above, the experimental group exceeds the control group in learning the studied skills, thus achieving the second hypothesis of the research.

The researchers attributed the reason to the fact that the curriculum is more effective than the traditional method followed by the subject teacher, which includes exercises harmonized and have a significant role in the treatment of the problem of excessive arousal of muscle aggregates and non-performance linked, which shows the lack of flow of movement. This contributed significantly to show moral differences, Compatibility motor is linked to the central nervous system, which in turn receives various information on all the positions and movements of the body through sensory neurons and take the decision to issue only commands to the core muscles responsible for motor performance by motor neurons. In addition to the harmonic exercises that have been applied marked by a factor of thrill and excitement, which led to a state of interaction between the teacher and the student and therefore a positive sign by the students during the educational unit. as it confirms [5] that learn any skill by practicing various exercises must To be done through the proper practice of skill and focus on the accuracy of performance by using the optimum time and practice of high efficiency.

In addition, that the training exercises positive yield in the development of the skill and mobility in the students, as the performance skill requires (use the entire body to perform the movement with the utmost proficiency with the ability to change direction and speed in a sound and smooth. In addition, need to be a fitness and compatibility to try to succeed in the integration of several basic skills in one framework or change from skill to another or change of speed and direction. In other words, skill performance is tightly related to motor compatibility, which reflects the level of performance. (Learner initially when he performs defensive duties

that require compatibility, the involvements of muscle groups are not required in the performance of movements, causing unrest and lack of skill performance consistency), and the important things that should be referred to in the events of evolution is the quality of the harmonic exercises that have been implemented and their suitability to the level of the sample in terms of the level of difficulty and consistency that the sample students, (the amount of learning spent by the learner in the exercise is not effective only in the development of learning only, but the quality of the exercise is also within the period specified. As a result, the experimental group students have excelled in the performance of the students of the control group.

Conclusions

Through what was shown from the results we reached the following conclusions:

- The curriculum for the harmonic exercises a positive impact on the development of the performance of defensive skills (interview, cover, block wall and handover) for the students of the research sample.
- The curriculum for the harmonic exercises achieved a favorable influence of the traditional curriculum followed by the teacher on the student's research sample.

The Effect of Different Doses of Green Tea Extract on Hematological and Biochemical Parameters in Adult Male Rats

Omer Mahrouf Ali Shoshin[1], Ahmed Abdulaali Azeez Baker[1], Evan Mohammed Mostafa[2], Noor Abdulaali Azeez Baker[3], Ahmad Salih Helal[3]

[1]Researcher, College of Veterinary, University of Kirkuk, [2]Researcher, College of Science, University of Kirkuk, [3]Researcher, K1 Hospital, North Oil Company, Kirkuk, Iraq

Abstract

This investigates the effects of various concentrations of continuous drinking of green tea in rats. (24) male rats are randomly categorized into four groups: control, which does not receive green tea, GTE5, GTE10 and GTE20 (receive 5g, 10g and 20g GTE, respectively). In hematological parameters analysis, there are no significant variation ($p>0.05$) in the RBC, MCHC and platelet among all groups. Furthermore, Control group presented a considerable decrease ($p <0.05$) in HB, HTC, MCV and MCH as compared with GTE5, GTE10 and GTE20. The biochemical analysis, control and GTE5 groups had high significant decrease ($p<0.05$) in glucose level as compared with GTE10 and GTE20 groups. Analysis of albumin and globulin, control and GTE5 groups had a significant decrease ($p<0.05$) higher than that of GTE10 and GTE20 groups. On the other hand, GTE20 group revealed a highly significant increase variation ($p<0.05$) in total protein than the control, GTE5 and GTE10 groups. In the control group showed a significant increase ($p <0.05$) in values of AST, ALT and ALK as compared with other groups. Therefore, it is recommended that using green tea for a long period leads to inhibition of the free oxygen radical damages in the liver and erythrocyte.

Keywords: *Green tea, Liver enzymes, Glucose, total protein.*

Introduction

The liver in animals, as well as human, is considered to be the site that is continuously subject to various ingested and inhaled chemical substances that might have toxic or non-toxic effects depending upon the uptake of their amounts[1,2]. The ability of herbal plants to render the effects of poisons and microbial infections is well documented recently[3,4,5]. Green tea is among the most common herbal plants that contain xanthine analogues, such as caffeine, theophylline, theobromine, glutamide subordinate and theanine which have direct effects on the immune system[6]. The consumption of green tea might enhance weight loss, promote metabolism, fat burning, reduce cholesterol, protect the heart and arteries and prevent cancer[6]. In addition, green tea acts as hepatoprotective and as antioxidant due to its high content of catechins (e.g., epigallocatechin, epicatechin gallate, epicatechin and epigallocatechin gallate), vitamins E and C which function like co-factor[7,8]. The present study highlights the effect of green tea on some biochemical and hematological parameters in rats.

Materials and Method

Sample investigation: Green tea is made in Turkey and purchased from a local market in Konya governorate, Turkey. Different concentration solutions of green tea (5-10-20 gram) were excreted by boiling each solution in one liter of distilled water. After cooling, the solutions were passed through a piece of gauze and then supplied to rats in their sole wellspring of drinking water[9,10,11].

Animals: Twenty-four healthy adult male (15 week age) of Sprague Dawley albino rats of (250-300 g) weight were housed in the polypropylene cages, 12/12 light/dark, at 23-25 ˚C at College of Veterinary, University of Kirkuk. They were provided with standard rats diet. After seven days, the rats were classified into 4 groups as follows:

Group 1: Provided with normal distilled water for one month (control, n=6).

Group 2: Provided with a prepared solution of 5g green tea/1L of distilled water for one month (GTE5, n=6).

Group 3: Provided with a prepared solution of 10g green tea/1L of distilled water for one month (GTE10, n=6).

Group 4: Provided with a prepared solution of 20g green tea/1L of distilled water for one month (GTE5, n=6).

Collection of blood samples: After completing the experiment, under ether anesthesia, the blood samples were taken legitimately from the heart by utilizing 5 cc syringes with two types of blood collection tube:-

1. EDTA for hematological analysis.
2. Non-coagulant tube for liver enzymes and some biochemical analysis.

The samples were centrifuged at 5000 rpmfor 15 minutes, and the serum was collected and kept freezing at -20˚C for evaluating the liver enzymes, hematological and some biochemical parameters.

Liver Enzymes parameters: The parameters Aspartate amino-transferase (AST), Alanine amino-transferase (ALT) and alkaline-phosphatase (ALK) were estimated using reagent kits manufacturer's instructions, which were purchased from RanDox (United Kingdom).

Hematological parameters: Total Erythrocyte Count (RBC), Hemoglobin HB, Hematocrit (HTC), mean corpuscular volume (MCV), mean corpuscular hemoglobin (MCH), mean corpuscular hemoglobin concentration (MCHC), Total leukocyte count (WBC) and platelets were estimated using Animal blood counter -ABC vet device (Horiba ABX- France).

Biochemical parameters: Glucose was estimated using reagent kits manufacturer's instructions, which were purchased from Ran Dox (United Kingdom). Albumin, globulin, and total protein were measured using reagent kits manufacturer's instructions, which were purchased from biochemical Biolab (USA).

Data Analysis: Statistical analysis was done using a PC program, (SPSS, 23) and one–way (ANOVA) for each parameter.

Results

Impacts of green tea extracts on liver enzymes: As listed in Table 1, the control group presented a considerable increase ($p < 0.05$) in AST, ALT and ALK ($p < 0.05$) in comparison to other groups (GTE5, GTE10 and GTE20).

Table 1: Comparative evolution of liver enzyme between control, green tea 5% (GTE5), green tea 10% (GTE10) and green tea 20% (GTE20) groups.

	Groups			
Parameters	**Control (n=6)**	**GTE5 (n=6)**	**GTE10 (n=6)**	**GTE20 (n=6)**
ALT	41.00±1.63 [a]	40.75±1.25 [b]	39.75±3.30 [b]	38.00±0.81 [b]
AST	43.50±2.08 [a]	39.75±2.06 [b]	39.50±2.16 [b]	39.00±2.16 [b]
ALK	383.75±189.82 [a]	381.00±32.88 [b]	380.75±21.74 [b]	381.25±16.35 [b]

a and b: indicate the significant difference among the groups in the same parameter ($p < 0.05$).

Effects of green tea on hematological parameters: Based on results shown in Table 2, although there is a variation among groups in the RBC count, MCHC and platelet, there was no statistically significant variation among them. The control group has a significant increase ($p < 0.05$) in the level of HB, HTC, MCV and MCH in comparison to the GTE5, GTE10, and GTE20 groups. On the other hand, Control, GTE5, and GTE10 groups have WBC level lower than that of GTE20.

a and b: indicate the significant difference among the groups in the same parameter ($p < 0.05$).

Impacts of green tea extracts on some blood biochemical parameters: As presented in Table 3, control and GTE5 groups demonstrated a highly significant decrease ($p < 0.05$) in glucose level in comparison to GTE10 and GTE20 groups. Furthermore, control and GTE5 groups showed a significant decrease ($p < 0.05$) in albumin and globulin as compared to GTE10 and GTE20 groups. Moreover, GTE20 group showed a significant increase ($p < 0.05$) in total protein level as compared with control, GTE5 and GTE10 groups. On the other hand, a significant decrease ($p < 0.05$) was revealed in the the control group as compared to other groups (GTE5, GTE10 and GTE20). There was no significant variation between GTE5 and GTE10 groups.

Table 3: Comparative evolution of Some biochemical blood parameter between control, green tea 5% (GTE5), green tea 10% (GTE10) & green tea 20% (GTE20) groups.

	Groups

Discussion

Green tea refers to a kind of tea made from buds and leaves of *C. Sinensis*. It has not gone through the same process of oxidation employed in making other types of tea like oolong and black. Green tea has emerged in China. Its generation and assembling have extended to various nations in Asia. Though there are significant studies on the conceivable health impacts of consuming green tea normally, only a few numbers of them have proved that drinking green tea has no effects on health[11].

Epidemiological and research center examinations have announced that green tea presents assorted valuable wellbeing impacts including hematological, biochemical parameters and liver enzymes[12], anti-hyperglycemic, hepatoprotective [13].

The significant increase of liver enzyme function observed in the present study is quite similar to that reported by[13,14,15]. This is possibly attributed partially to that the antioxidant components of green tea could decrease the oxidative stress in liver cells. The free radicals are known to cause damage to the liver cell structures and their organelles which lead to release these enzymes from cytoplasm and mitochondria of the hepatocytes to the blood[15].

The evidence presented in this paper concerning the relative absence of significant changes in RBC count, MCHC and platelets suggests that the polyphenols may interfere with absorption of both heme and nonheme by these cells although polyphenol is considered as one of the most important constituents of green tea[16,17]. These results are parallel to those reported by[12,18,19]. The

significant decrease in hematological parameters (HTC, HB, MCH and MCV) and low variation in white blood cell counts are related well with reports of[20,21,22,23].

The free radicals could act on oxidation of the unsaturated fatty acid to produce malondialdeyde, which causes liver toxicity Green tea, on the other hands, contains catechins compounds which may prevent the growth of bacteria and certain kinds of viruses in the body[24]. The high significant decrease in glucose level among groups is in agreement with results of[13,25,26]. This result could explain the ability of catechins to repress some digestive enzymes, for example, intestinal-sucrase, salivary-amylase and α-glucosidase, which may lead to lowering the level of blood glucoses. Other authors reported that some chemical substance of green tea, such as epigallocatechin gallate, increase the regeneration of pancreatic β-cells. This, in turn, inhibits the gluconeogenesis by inhibition of phosphoenolpyruvate–kinase[27,28].

Also, effects on albumin, globulin and total protein are in agreement with previous reports[25,29]. The hyperalbuminemia and hypoalbuminemia depend on the toxicity level in the body. Hypoalbuminemia is observed to be brought about by a few factors, for example, decreased combination brought about by liver infections, expanded catabolism because of aggravation or tissue harm[30,31].

Conclusion

This article demonstrated that the administration of drinking green tea to the rats for a long period might result in protecting cell ingredients, such as proteins and lipids, decreasing and inhibiting the effect of free oxygen radicals in the liver. Additionally, the administration may also show the useful impact of green tea on common blood cells and plasma compounds.

Conflict of Interest: None of the authors has any conflicts of interest to declare.

Clinical and Radiographic Evaluation of WaveOne Gold Single-File System in Pulpectomy of Primary Molars: A Randomized Clinical Trial

Osama S. Gad El-Hak[1], Nagwa M. Khattab[2]

[1]Assistant Lecturer, [2]Professor, Pediatric and Community Dentistry Department, Faculty of Dentistry, Minia University, Egypt

Abstract

Purpose: The current study evaluates the reciprocal WaveOne Gold single-file system regarding clinical and radiographic outcomes in root canal treatment of primary molars.

Method: This randomized clinical trial was carried out on 70 primary molars on 60 children in the age group from 4 to 7 years. The teeth selected for this study were randomly assigned into 2 groups according to the used endodontic preparation system. Group I: 35 primary molars were instrumented with WaveOne Gold reciprocating single-file system. Group II: 35 primary molars were instrumented with stainless steel K-files. All teeth were evaluated clinically and radigraphically for 12 months with periodic recall at 3, 6 and 12 months.

Results: WaveOne Gold single-file system exhibited higher overall success rate over manual instrumentation, however, the difference between groups was not statistically significant ($P > 0.05$).

Conclusion: Single-file systems are promising instruments that have the power to be an alternative for manual instrumentation in primary molar pulpectomies.

Keywords: *WaveOne Gold, Single-file endodontics, Pulpectomy, Pediatric dentistry*

Introduction

One of the fundamental objectives of pediatric dentistry is conservation of primary teeth in form and function until their normal exfoliation. Premature loss of primary teeth with irreversible pulp pathosis has the potential to destabilize the developing occlusion with space loss, arch collapse, and premature, delayed or ectopic eruption of the permanent successors.(1)

When advanced pulpal degeneration affects a primary tooth, two possible treatment options are available: pulpectomy or extraction. However, the success of pulpectomies in primary teeth has led to a shift in the paradigm of treating pulpally involved teeth.(2-5)

Negotiation and thorough instrumentation of bizarre and tortuous canals encased in roots programed for physiological resorption are the main challenges for pulpectomy.(6)

A practical endodontic treatment for primary teeth should provide short treatment time, effective debridement, and minimal complications**.** Since most hand preparation techniques are time consuming, and may lead to iatrogenic errors, much attention has been directed toward the use of rotary instrumentation in primary teeth.(7,8)

In the bygone decade, all rotary systems were based on the use of a series of files to complete shaping of root canals. Recently, the concept of single-file system has been introduced. This concept requires a minimum

or no glide path, reduces the working time, prevents cross-contamination, and improves safety of the shaping procedures.[9]

Aim of the study: To the utmost of our knowledge, there are no published RCTs about the clinical and radiographic success of primary tooth pulpectomy using the reciprocal single file system; WaveOne Gold (Dentsply Maillefer, Ballaigues, Switzerland). Therefore, the current study was conducted to validate this novel single-file system.

Method

This investigation was a double-blind randomized controlled clinical trial which was designed, analyzed & interpreted according to the Consolidated Standards of Reporting Trials (CONSORT) statement.[10] The sample size was calculated to be 70 teeth (35 teeth for each group) with a power of 80% and type I error of 5% based on a pilot study conducted for 6 months.

Settings and study subjects: The study was conducted on patients who attended outpatient clinic of Pediatric Dentistry Department, Faculty of Dentistry, Minia University. Out of 105 children, 60 patients with 70 necrotic primary second molars indicated for pulpectomy, were enrolled in the study. Their age ranged from 4 to 7 years old.

Inclusion criteria[11]:

- **Clinical:** History of dull toothache over an extended period of time, history of spontaneous pain or pain at night, swelling adjacent to tooth with or without a sinus tract, abnormal tooth mobility, presence of necrotic pulp tissue or purulent discharge when the pulp chamber was accessed.
- **Radigraphic:** Interruption of lamina dura or thickening of PDL space and/or presence of furcation or periapical radiolucency.

Exclusion criteria[12]:

- **Clinical:** Systemic diseases that adversely affect or contraindicate pulp therapy, teeth with non-restorable crowns, tooth with a mechanical or carious perforation of the pulpal floor.
- **Radiographic:** Root canal obliteration, internal or external root resorption, peri-radicular lesion involving the crypt of the developing permanent successor, or presence of underlying dentigerous or follicular cysts.

Randomization and allocation: The selected mandibular second primary molars were randomly assigned to one of two treatment groups by block randomization method using a computer generated sequence. The allocation was done using serially numbered opaque and concealed envelopes opened just after access preparation (allocation ratio was 1:1). The participants and outcome assessor were blinded about the instrumentation technique used.

Clinical procedures: All procedures were performed by the same operator in a standardized treatment protocol regarding: Topical & local anesthesia,isolation using rubber dam and saliva ejector, removal of caries, access preparation & removal of pulp remnants and radiographic working length determination which was maintained at 2 mm short of the root apex.

Then, patients were randomly assigned to one of the study groups.

- **Group I** comprised 35 molars treated with Primary WaveOne Gold (Dentsply Maillefer, Ballaigues, Switzerland) single reciprocating file system in a slow brushing motion according to the manufacturer's instructions.
- **Group II** consisted of 35 molars instrumented with stainless steel K-files (MANI Inc., Tochigi, Japan) with 2% taper in a sequential manner up to size 30 using a quarter-turn-pull technique.

During canal preparation in all groups, EDTA gel 17%, cautious irrigation with 10 ml of 1% NaOCl using side vented needles, a final flush with 5 ml of saline were carried out. Then canal dryness using sterile paper points and Metapex (Meta Biomed Co. Ltd. Chungbuk, Korea) obturation using pressure syringe technique were performed. After root canal obturation, radiographs were taken to determine whether the root canals were completely filled. If not, they were refilled. Finally, all teeth were restored with stainless steel crowns.

Evaluation: All teeth received independent clinical and radiographic evaluations at 3, 6 and 12 months postoperatively by another investigator who was blinded to the instrumentation technique used in each tooth.

Outcome assessment criteria[13]: The pulpectomy treatment was judged as successful if there was none of the following clinical or radiographic criteria:(1) Absence of pain, tenderness to palpation or percussion and abnormal mobility. (2) Presence of healthy soft

tissue (defined as the absence of swelling, redness, sinus tract, or purulent exudate expressed from the gingival margin. (3) Absence of pathological root resorption. (4) Arrest or reduction of bone rarefaction up to 6-12 m postoperatively. (5) Absence of new periapical or furcational radiolucency postoperatively.

Statistical analysis: Statistical analysis was performed using IBM SPSS, version 23 (SPSS Inc., Chicago, IL, USA). Categorical data was displayed as number and percent and analyzed statistically using Chi-squared test where indicated. Probability of less than 0.05 was used as a cut off point for all significant tests.

Results

Seventy necrotic second primary molars in children aged between 4 and 7 years were randomly selected and provided with treatment in this clinical trial. All patients were followed up, with no dropouts, at the 3, 6 and 12 month recall visits. The baseline demographic, clinical and radiographic observations of the selected patients are presented in Table 1.

Table 1: Baseline demographic, clinical and radiographic characteristics of study groups.

Group	Age (Years) Mean±(SD)	Gender		Clinical Signs or Symptoms		Peri-radicular Radiolucency	
		Male N(%)	Female N(%)	Present N(%)	Absent N(%)	Present N(%)	Absent N(%)
WaveOne Gold	5.0±0.55	16(45.7)	19(54.3)	26(74.3)	9(25.7)	21(60)	14(40)
K-File	4.9±0.63	15(42.9)	20(57.1)	25(71.4)	10(28.6)	19(54.3)	16(45.7)
p-value*	0.735	0.969		1.000		1.000	

* p>0.05 indicates no significant difference.

The clinical, radiographic and overall success rates of the 2 groups at 3, 6 and 12 months are presented in Table 2. The overall success rates were 85.7% and 80% for WaveOne Gold and K-file groups, respectively, at 12 months.

Although WaveOne Gold group exhibited higher overall success rate, the intergroup comparison didn't reveal any statistically significant difference at 3, 6, or 12 months (p> 0.05).

Taking into consideration different factors that might have affected the treatment results, the overall success was influenced by presence of preoperative clinical signs & symptoms and pre-operative radiolucency, especially in the k-file group, but without any statistical significance (Table 3).

Table 2: Clinical and radiographic outcomes of the studied groups through the follow up period.

Follow up	Outcome	WaveOne Gold (G I)		K-file (G II)		(p- value)*
		Success N (%)	Failure N (%)	Success N (%)	Failure N (%)	
3 months	Clinical	35(100)	0(0.0)	35(100)	0(0.0)	p: 1.000
	Radiographic	34(97.1)	1(2.9)	34(97.1)	1(2.9)	
	Overall	34(97.1)	1(2.9)	34(97.1)	1(2.9)	
6 months	Clinical	33(94.3)	2(5.7)	33(94.3)	2(5.7)	p: 0.698
	Radiographic	32(91.4)	3(8.6)	31(88.6)	4(11.4)	
	Overall	32(91.4)	3(8.6)	31(88.6)	4(11.4)	
12 months	Clinical	32(91.4)	3(8.6)	31(88.6)	4(11.4)	p: 0.530
	Radiographic	30(85.7)	5(14.3)	28(80)	7(20)	
	Overall	30(85.7)	5(14.3)	28(80)	7(20)	

*p>0.05 indicates no significant difference.

Table 3: Effect of preoperative clinical and radiographic characteristics on overall pulpectomy outcome after 12 months.

*p>0.05 indicates no significant difference.

Discussion

Biomechanical preparation is one of the most important phases of pulpectomy in primary teeth which is mainly aimed at debridement of the canals.[12] Conventionally, root canal preparation was done with endodontic broaches and hand files. However, the current literature reflects a trend towards the use of nickel-titanium (NiTi) automated file systems in pediatric endodontics.[14-17]

The concept of single-file system was recently introduced in endodontics, and its applicability in contemporary endodontic treatment in primary teeth has now been debated.[18-20] Thus, the current study was conducted to compare a reciprocal single-filesystem, WaveOne Gold, with manual K-file regarding clinical and radiographic outcomes of endodontically treated primary molars.

WaveOne Gold (Dentsply Maillefer, Ballaigues, Switzerland) is one of the reciprocal single-file systems which is available in four different sizes (small, primary, medium and large) in lengths of 21mm, 25mm, and 31mm. These variabilities allow the clinician to prepare a wide range of apical diameters and root canal anatomies.[9]

Furthermore, this system is supplied in sterilized packs for single use only which increase safety margin and reduce risk of cross-contamination. With all these facts considered, WaveOne Gold single file system was selected for our study.

To eliminate discrepancies, all clinical procedures were performed by the same operator. Endodontic instrumentation, root canal filling and placement of stainless steel crown were performed in one visit for all patients to avoid contamination from the loss of temporary restorations.[11,21]

The overall pulpectomy success rates, for WaveOne Gold and K-file groups, observed in our investigation were similar to previous studies.[11,21-23]This proves the validity of the used methodology. WaveOne Gold group exhibited higher overall success rates, which may be attributed to the file design providing more efficient cleaning.

The overall success rate for root canals prepared with K-files was 80% by the end of the 12 month follow up period. This result came in conformity with those obtained by Mani et al.[22], Barr et al.[24] and Barcelos et al.[25] who revealed overall success rates of 83.3%, 79.5% and 82.3%respectively.

To the best of our knowledge, this is the first randomized controlled clinical trial to report the application of WaveOne Gold single-file system in endodontic treatment of primary molars. Therefore, there is nothing similar in the literature with which to compare the present results. Thus, the overall outcome was compared with that observed in earlier studies using other engine-driven nickel–titanium instruments.

The 12 month overall success rate obtained for WaveOne Gold, 85.7%, was comparable to those of Kuo et al.[26], Guler et al.[27] and Vieyra and Enriquez[28]. Moreover, the overall success was influenced by presence of preoperative clinical signs or symptoms and radiographic radiolucency especially in the K-file group but without any statistical significance. This finding goes in accordance with earlier studies of Coll and Sadrian[2], Moskovitz et al.[3] and Barcelos et al.[25]

This finding might confirm that necrotic pulps are more difficult to treat[3,25] as well as superiority of reciprocal single file systems over manual instrumentation in cleaning and shaping of primary teeth.

Conclusions

WaveOne Gold single-file system demonstrated favorable clinical and radiographic outcomes in pulpectomy of human primary molar teeth over a 12-month follow up period. Additionally, WaveOne Gold was superior to manual stainless steel K-files, regarding treatment of necrotic primary teeth with preoperative clinical signs & symptoms, or peri-radicular radiolucency.

Intrapartum Translabial Ultrasound to Predict Successful Vaginal Birth in Ladies with Previous Caesarean Section

Ahmed Nageeb[1], Mohammed Hani[2], Ahmed Sameer[2], Momen Hassan[2], Hassan Abdul-Jabbar[3]

[1]Assistant Lecturer, [2]Professor of OB/GYN Dept., University Hospital, Minia, Egypt,
[3]Professor of OB/GYN Dept., King Abdulaziz University Hospital, Jeddah

Abstract

Objective: To evaluate the role of intrapartum translabial ultrasound to predict successful vaginal birth in ladies with previous caesarean section.

Patients and Method: 200 pregnant women with previous caesarean section admitted during the active phase of the first stage of labor.

Results: At a cut-off value 2.5mm the sensitivity of the progression distance was 89.3% and 71.4% specificity in prediction of vaginal delivery. Using 100.5 degree as a cut-off value for the angle of progression to identify patients who deliver vaginally gives 88.5% sensitivity and 74.3% specificity.

Conclusion: Intrapartum translabial ultrasound is a useful tool to predict occurrence of vaginal delivery in women with previous caesarean.

Keywords: *VBAC, intrapartum ultrasound, translabial ultrasound, progression distance, angle of progression.*

Introduction

Witnessing a dramatically increasing rates of CS deliveries mainly due to the practice of defensive medicine [(1)], repeat CS is central to that practice.

Although being the 'gold standard' in obstetric practice, the digital transvaginal examination is a subjective evaluation and has several limitations[(2)].

A growing body of knowledge is accumulating regarding intrapartum ultrasound as a relatively new application of ultrasound. Intrapartum ultrasonography can provide objective information on the dynamics of different stages of labor [(3)], and may also be used to assess labor progression, predict labor outcome and to predict the prognosis for operative vaginal delivery [(4)].

Translabial ultrasound was used to demonstrate pelvic floor structures, it was shown to be fast, safe, reliable, easy to learn and readily available tool [(5)].

Aim of the work: To assess the ability of intrapartum translabial ultrasound to objectively predict the progress of labor and the occurrence of successful vaginal birth in ladies with previous CS attempting for VBAC at term pregnancy.

Patients and Method

This study included 200 pregnant women, All with previous CS. The same operator performed all ultrasound studies, The managing obstetricians were blinded to the ultrasound results.

Inclusion criteria: Full term(37:41weeks) singleton pregnancy, and Spontaneous onset of the active phase of 1st stage of labor as evidenced by regular uterine contractions and dilatation of the internal cervical OS ≥4 cm.

Exclusion criteria: Abnormal fetal presentations, congenital fetal malformations, abnormalities of the amniotic fluid or placenta, maternal spine or pelvic disease or fractures, and complicated pregnancies.

Full history and complete clinical examination were undertaken for all participants.

This approach was to reveal anatomical structures in the 'infrapubic plane': The symphysis pubis, the lowermost parts of fetal skull, and the dorsal part of the birth canal. For standardization the transducer was placed so that the symphysis will be in a horizontal position. In this plane, the progression distance was measured. Described as the minimal distance [c] (in mm) from a line [b] placed vertical to the central axis of the symphysis pubis [a], placed through the infero-posterior symphyseal margin, and the leading edge of the fetal skull. (fig. 1 a)

In the same plane, the angle of progression of the fetal head was measured, described as the angle[b] between a line through the midline of the pubic symphysis [a] and a line from the inferior apex of the symphysis to the leading part of the fetal skull [c] (fig.1 b).

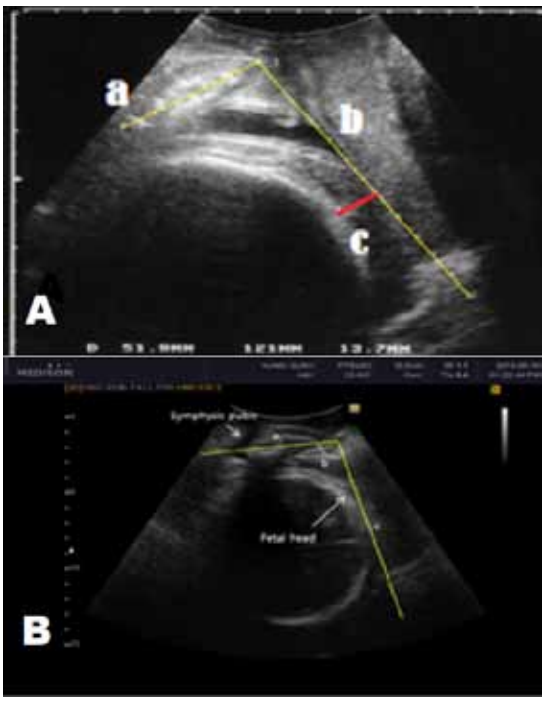

Fig. 1A: Head progression distance[6], B: Angle of progression of fetal head[3]

Results

Mean patient age was 28.2 ± 4.5. Gravidity was ranging from 2:4. The mean gestational age was 38.2 ± 0.8 weeks. By PV digital examination, the mean cervical dilatation was 4.56 ± 0.87 cm (from 4-8 cm), 19% of cases had their membranes spontaneously ruptured at time of examination. 5.5% of patients had trial of VBAC under epidural analgesia.

49 cases had vaginal delivery, 3 of them delivered by vacuum to shorten the 2nd stage

TOLAC ended by CS delivery in 75.5% of cases, 72.84% of them had a CS for non-progressive labor. Failure to progress was stated according to the definition of the American College of Obstetricians and Gynecologists (ACOG) [7].

Intrapartum bleeding reported in one case and delivery was by CS, it was found to have dehiscent uterine scar during CS.

Fetal head position was detected by transabdominal US in 100% of cases. Whilst PV examination failed to detect head position in 16%, No significant agreement between head position detected by US and By TV examination (r=0.123).

The mean PD was 2.9±6.0 mm, ranging from -15:18mm. It differ significantly between the vaginal and the CS groups (p=0.0005), and in turn there was significant difference among CS indicated by failure to progress and CS due to other causes (p< 0.001).(tab1)

Table 1: Values of tested parameters in different groups

Group		PD	AoP
Vaginal delivery	Spontaneous	6.10±6.1 (-13 : 13)	105.9±6.1 (89:115)
	Vontose	-2.33±6.0 (-10 : 2)	103.6±5.5 (99:108)
CS	Failed progress	-9.40±5.1 (-17 : -4)	96.6±7.4 (86:105)
	Other indications	-3.85±5.3 (-15 : 8)	100.4±6.7 (98:112)

In 89.8% of vaginal deliveries, the measured PD was ≥ 2.5 mm while it was ≤ 2.5 mm in 71.5% of CS cases. At a cut-off value of 2.5mm the sensitivity was 89.3% and 71.4% specificity in prediction of vaginal delivery.

At a significant statistical value (AUC=0.833, p<0.001) the same cut off value, the sensitivity and specificity of the PD for detection of "failure to progress" was 91.3% and 78% respectively (fig.2).

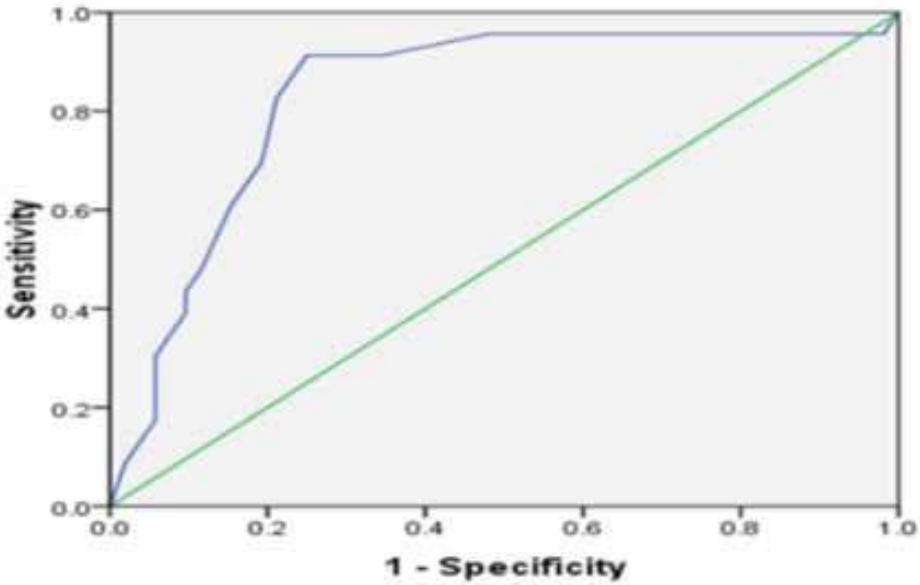

Fig.2: ROC curve PD in the subgroup of "failure to progress"

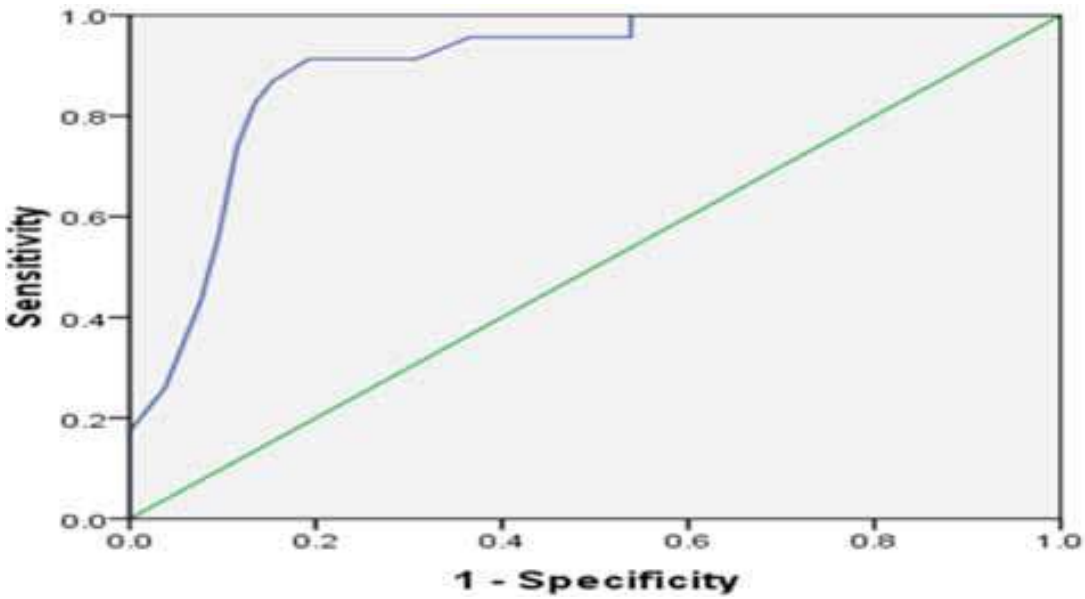
The mean AoP was 100.8 ± 6.97º, ranging from 86 to 115. In women with spontaneous vaginal delivery the mean AoP was 105.0±5.99º, while in women with CS it was 98.4±6.7º, the difference was found to be of good significance (p< 0.001)

A cut-off value of 100.5º, showed the best statistical significance (p < 0.001), such value will have a sensitivity of 80.3% and specificity of 85.6% in detecting the engagement of the fetal head compared to digital PV examination.

The AoP was measured ≥ 100 in 87.7% of patients who had VBAC while it was < 100 in 73.5% of cases who delivered by CS. At a statistically significant level (P= 0.001) using 100.5º as a cut-off value to identify patients who deliver vaginally gives 88.5% sensitivity and 74.3% specificity.

In the subgroup of " failed progression", the same cut off value, gives higher sensitivity (91.3%) and specificity (80.8%) at a statistically significant level (AUC=0.896, P <0.001).



(Fig 3): ROC curve showing the ability of the AoP in predicting failure of progression

There was noticed significant correlation between both wider AoP and longer PD with shorter interval to delivery ($p<0.001$, $p<0.05$ respectively).

Time to delivery was 6 hours+31 min when AoP was below 99º, 5 hours+ 30 min when AoP between 100 and 109, and 4 hours+45 min with angle ≥110). longer PD was found to have similar effect (5 hours+54 min with PD less than o mm, 5 hours+24 min if PD is ≥ 0 mm).

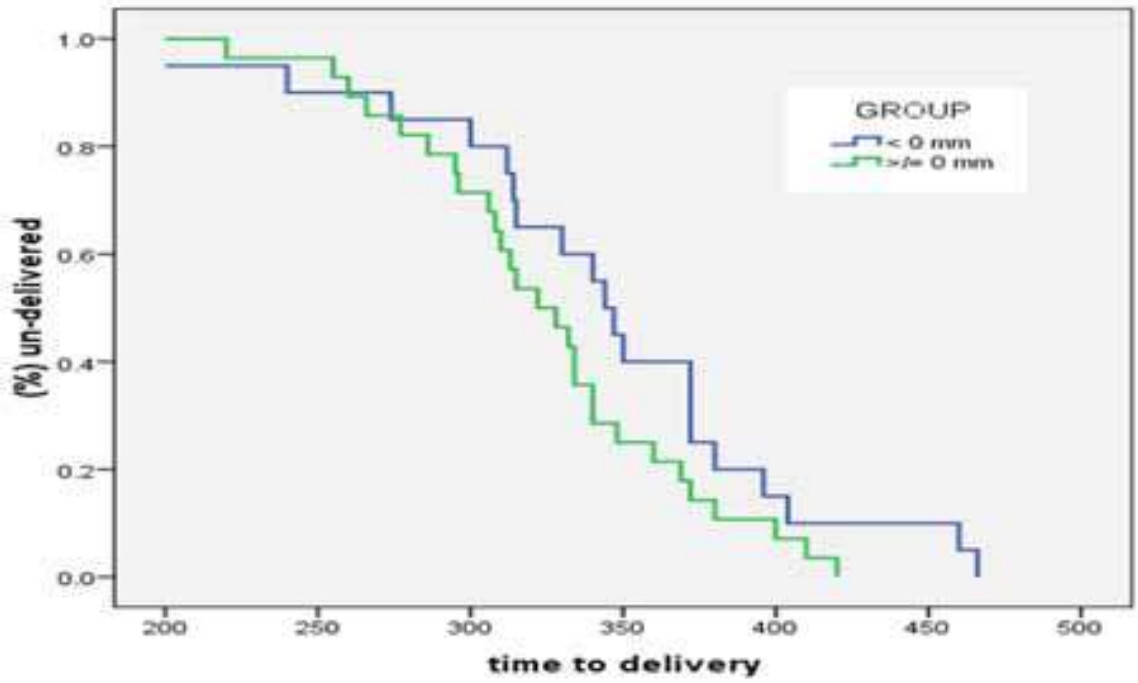


Fig.4: Kaplan-Meier curve of time to delivery in 2 sub-groups according to PD.

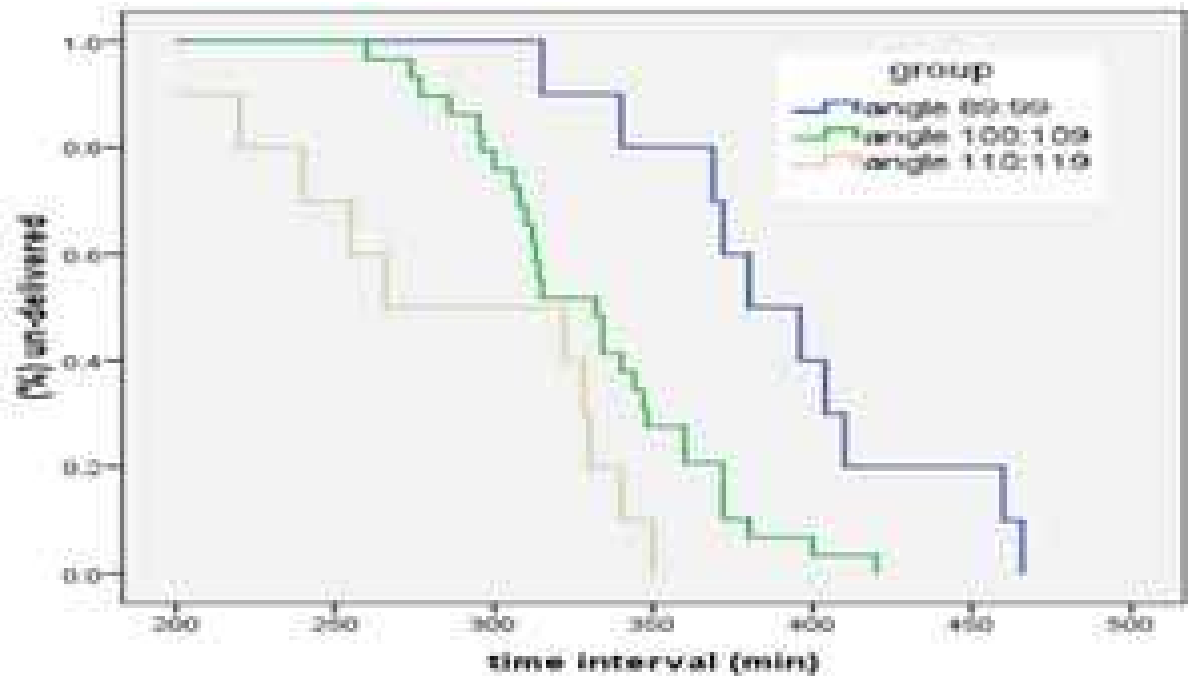

Fig.5: Kaplan-Meier curve of time to delivery in 3 sub-groups according to AoP

Discussion

The identification of the fetal head position by PV was not possible in 16% of cases, no significant agreement was found between the ultrasound and PV examination findings (r=0.123). Many studies observed transvaginal digital examination as being less accurate than ultrasonography for determining the fetal head position during the first stage of labor With high rate of error [8,9]. In a study by Usman et al., Fetal head position was recorded in 99.7% of US and 51.5% on vaginal examination (p<.0001) [10]. Some studies even recommended the routine use of ultrasound in early first stage of labor or prior to instrumental delivery for accurate detection of fetal head position[11].

Several studies have shown that digital determination of fetal head station in laboring women is imprecise even in the hands of experienced examiners [12].

One of the most studded ultrasound parameters to detect fetal head engagement to predict mode of delivery is the angle of progression of fetal head [13]. In the current work we tested a relatively new parameter - the progression distance - in addition for the main purpose.

Dietz et al. first described the PD of the fetal head. They provided evidence that the PD was correlated well with the fetal head station [6].

The studded PD differ significantly among different reports, due to different methodology used in PD measurement and different population groups, also most of the reports focus on PD in prolonged 2nd stage of labor [14].

Our mean PD (-2.9 ± 6.0 mm.)was near to that from the original work of Dietz et al. They reported a mean of -6.7mm. Taking in consideration that their study was on nonlabouring women, it may explain our shorter PD.

The ability of the PD at a cut-off value of 2.5mm to predict VBACK, has sensitivity of 89.3% and specificity of 71.4%. It was raised to 91.3% and 78% respectively when used more specifically to predict unsatisfactory labor progress.

These findings are in agreement with Henrich et al. [15] they used 3D-CT reconstruction of pelvimetric measurements of normal female pelvis in correlation with intrapartum US and confirmed that the infrapubic plane lies cranial to the level of the ischial spines and hence the plane of fetal head engagement.

In a study by Erik et al. [16] PD was found to be significantly longer (p=0.01) in women who delivered vaginally compared to those who had CS for obstructed labor. But due to lack of standardization of the used measurement method, their values were far from ours (2.51 ± 1.71cm and 1.48±1.9cm).

The mean value of the 'AoP' was 105.0±5.99º in cases who delivered vaginally, a lower value was found in cases delivered by CS (98.4±6.7º). This difference was of high statistical significance (p< 0.001).

The same angle was studded by Omar et al. they found similar difference between both groups (104±16.6 and 88.3±14)[17]. Also Lavy et al. found a narrower angle in patients who went for CS (90 vs 104). But the later study was conducted on patients who are not in active labor [18].

The AoP value obtained by this study to identify head engagement (100.5) is apparently lower than the 123 reported by Chan et al. [19], and the 116 reported by Tutschek et al. (8) It is, however, closer to the 101 obtained by Yaw et al. [20]. However, these studies all agree on station 0 typically corresponding to an AoP above 99.

Using the same cut-off value to predict occurrence of vaginal delivery, it gives 88.5% sensitivity and 74.3% specificity at a statistically significant level (P=0.001). and to predict slow labor progress, it gave higher sensitivity(91.3%) and specificity (80.8%).

Some consecutive studies have shown that AoP is more accurate than digital examination in predicting vaginal delivery in nulliparous women with prolonged first stage of labor [21,22].

Several studies with conflicting results have attempted to solve the issue of the correlation between a specific AoP and fetal head station within the birth canal. A MRI study by Bamberg et al.[23] found that an AOP of 120◦ corresponded to a fetal head station of 0. In another study by Barbera et al.(24) developed a geometric model from CT images and from TLUS. they concluded that a TLUS angle of 100◦ correlated with zero station of the fetal head.

The results of the current study agreed with the work done by Barbera et al. as the cut-off for the prediction of fetal head engagement was above 99º. Moreover, cases who delivered vaginally had the mean values above 99º unlike those who delivered by CS [24].

It was noticed that wider AoP were associated with significantly decreased time to delivery. This is in agreement with Ghi et al, [25], and Bianca et al. [26], however, the later reported that the impact on clinical practice seems low.

Conclusion

TLUS is a useful feasible acceptable and safe adjunctive assessment tool in the evaluation of laboring women trying to have vaginal delivery with a prior CS.

The Effect of Isotonic Training Method for the Development of HealthyMuscular Ability and Accuracy of the Performance of Volleyball Skill for Young Players

Ali Hamid Ali[1], Serdar Hkem Mohamed Ameen[2], Saddam Mohammed Ahmed[3]

[1]Lecturer, Ministry of Education, Najaf, Education Directorate. Najaf, Iraq

Abstract

The aim of this research is to develop the muscular ability and its effect on the performance of volleyball and the development of isotonic training method (movement), and the researchers supposed that the impact of the method in the development of muscle capacity and accuracy of the performance of the skill of transmission, they used the experimental method, Al-Muqdadiya Youth Sports Club in Diyala Governorate (15) players were chosen in a deliberate manner. The method was prepared by the researchers and the candidate tests were used. The results were processed using the statistics. The most important recommendations are the use of the isotonic training method to develop the muscular ability of all practitioners of the game. Whether students or professional or amateur, taking into account that the level and the ability of the sample as well as the need to emphasize the conduct of continuous and regular tests to test the physical and skill capabilities of the players to know their level and try to develop them to the best.

Keywords: *Isotonic, Healthy Ability, Performance.*

Introduction

Explosive power is "one of the most important motor skills in volleyball. It depends on two components: muscle strength and speed. The combination of these two components together and their explosive output is evidence of the individual's ability to exercise" [1]. Muscle power plays an important and essential role In the performance of skills in the game of volleyball and vary in importance in varying degrees between skill and other and increasingly important in the offensive skills of the game being critical in achieving the points that require the performance of the maximum force and speed possible any force characteristic of speed or explosive force, and these skills sending and beating Which is characterized by this type of performance where the player uses all his physical and skill to achieve the best achievement of the point, and thus emerged the importance of research in the application of a method designed to train the Isotonic skills to develop muscle and accuracy of the performance of the skill of volleyball for the youth.

Research Problems: Through the observation and the field experience of the researchers as teachers and practitioners of volleyball, noted the weakness of the skill performance of the players, especially in the performance of sending muscle strength and speed, as well as accuracy in performance and the reason for this gap in the educational and training method used for the development of force and their association with other physical qualities that serve the skill performance and one of these gaps is the muscle capacity (explosive power or speed characteristic).

Research Objectives:

1. Preparation of a training method includes the Isotonic training (movement), as a method for the sample of the research.
2. To recognize the impact of isotonic training in the development of muscle strength and accuracy of the performance of the skill of the volleyball for young players.
3. Identify the development of muscle strength and its impact on the performance of volleyball for young people.

Hypothesis of the Research: Isotonic training affects the development of muscle capacity and accuracy of the performance of the volleyball for young people.

Research Areas:

1. **Population:** Muqdadiya players in the junior volleyball class.
2. **Time:** 1/4/2018 up to 1/9/2018
3. **Place:** Al-Muqdadiyah Sports Club Stadium in Diyala.

Research Methodology: The researchers used the two-group experimental approach (experimental design with pre and post control) to suit the research and its objectives.

Sample of The Research: The sample of the research was among the youth players of the Muqdadiya Sports Club in Diyala Province, who were chosen by the deliberate method of (17) players, two players were excluded so the sample became (15) players.

Means, tools and devices used in the research:

Data collection method: Arab and foreign scientific sources, observation and experimentation, testing and measurement.

Tools and devices used: (1 kg, 2 kg, 3 kg, 4 kg, 5 kg), non-stretchable colour stripe, stained-glass wall, chairs, colourful chairs, various wooden benches, Swedish seats, rubber ropes, Iron bar with different weights.

Identification of Variables: The variables of the research were determined by looking at many scientific sources and previous related studies. The variables that were determined are as follows:

1. Muscle Strength Test,
2. The accuracy of the skill of transmission from the top.

Identification of Research Tests: Test the strength of the arm (push the medicine ball of (3) kg by hands in the sitting position).

Purpose of the test: Measure the strength of the arms.

Required tools: Flat space area, medical balls weighing 3 kg, chair, measuring tape, wide belt.

Performance description: The trainee sits on the chair holding the medical ball with hands so that the ball is in front of the chest and below the chin level as the trunk should be attached to the edge of the chair. A belt is placed around the lab's chest so that it is held from the back by an airway. This is to prevent the movement of the trainee forward while throwing the ball in the hands from the top of the head. The movement is done using hands only and as far as possible the trainee is given two attempts and the best is calculated. When the trainee vibrates or moves on the chair while performing one of the attempts. The result is not counted and another attempt is given instead, with a measuring tape to measure the distance of the ball.

Recording: The distance in meters and the distance from the inner edge of the firing line and the closest to the medical ball are measured by the line and the best two attempts are measured by meters and centimetres.

Figure (1) shows the test of throwing the medical ball weighing (3) kg

Test the accuracy of transmission from the top: In the second half of the stadium two parallel lines are drawn to the first side line, four feet from the side line, and the second six feet from the first line (10 feet from the front line). Side) Write in the first rectangle (10), in the second rectangle (5) and in the third rectangle (1) where these numbers represent the trainees cores if the ball falls in any of these three areas as shown in Fig.

Performance Specifications: The trainee stands in the transmission area and performs the transmission skill to the half of the corresponding field. The ball passes the net (without touching it) and tries to drop it in the rectangle in which it is written (10).

Conditions: 1. The type of transmission used shall be agreed in advance. 2. Each individual has ten attempts on the test (consecutive) 3. The trainee shall receive (0) in case of contact with the net whether it falls on or off the field.

Registration: The player gets 10 points if the ball falls in the designated area (the first rectangle next to the side line) and on (5) if the ball falls into the third rectangle (1). If the ball falls on one of the fair lines of the two rectangles inside the lines of the stadium is within the target measures and the final grade represents the set of degrees of the trainee in its ten attempts, i.e.: the final grade of these tests is (10) degrees.

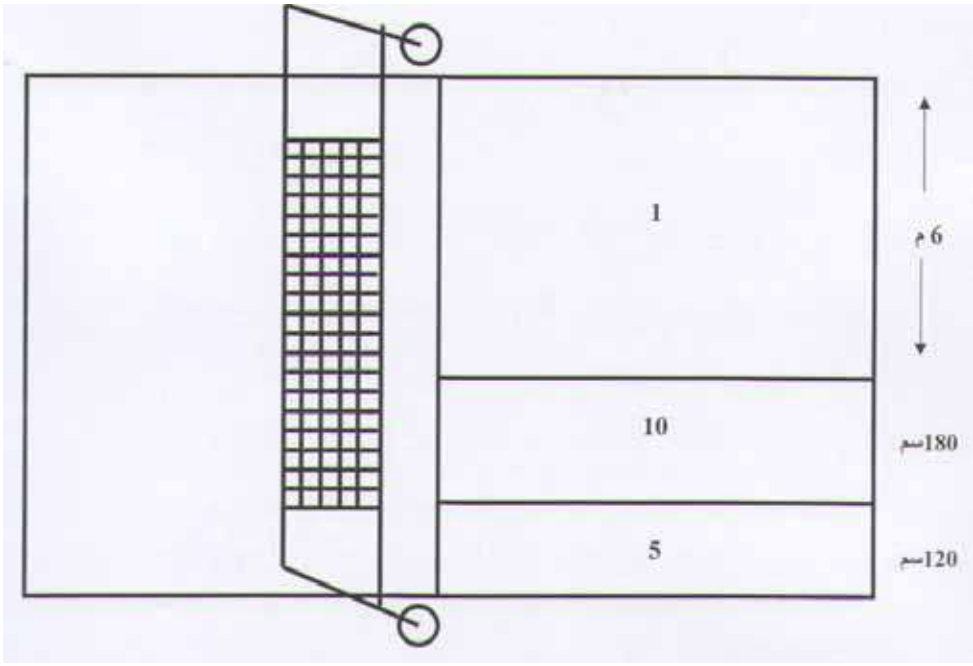

Figure (1): Shows the transmission skill test from the top

Pilot experiment for the two tests:

Exploration Experience: The researchers carried out the pilot test for muscle strength test and transmitter skill test on 26/4/2018 at the Shahrban Sports Club. The researchers applied the test to a sample of 12 players.

The scientific basis for the tests:

Honesty: Is that the test is designed to measure what was put to measure, the field or phenomenon studied (1) was the credibility of the virtual presentation of technical tests to the experts and specialists, as it was agreed by all experts and specialists.

Consistence: The test is the same that gives the same results are close if the test is applied in the same circumstances. The test was applied on 26/4/2018 and returned after seven days on 3/5/2018 and on the same sample to know the stability of the test, the researchers used Pearson correlation coefficient between the results of the first and the second test, and the results showed a "significant" correlation between them.

Pre-Tests: The muscle strength test and the precision test of the skill of the transmitter were conducted on (8/5/2018) on the research sample (15) players and the conditions of the pre-tests were recorded and the possibility of applying them in the post tests.

Implementation of the main experiment: The results of the training course prepared by the team's own trainer, from the remaining vocabulary and time of the training module, were applied to the training module, from 10/5/2018 to 5/7/2018. (8) Weeks and three training units per week as the training time (120 d) was the main part. 80 d). The researchers used a ripple load (2-1) and two high units Low unit (gradient Balhdd) ranging Alhdd in the exercise used (65-100%).

Post-tests: After the completion of the exercises, the tests of the research sample were carried out on 7/7/2018, taking into consideration the temporal and spatial conditions and the means used in the pre-tests and the same auxiliary team.

Statistical Method: Researchers used SPSS to process data.

Presentation, analysis and discussion of the results of physical: To determine the significance of the differences in the results of the physical and psychological the pre and post-tests of the sample, the researchers used the t-test of the sample as shown in Table (1).

Table (1): Shows the mean, standard deviations and the value of (T) of the research sample in the pre and post-tests of the physical and skill tests:

Sr.	Physical & Skilful tests	Pre-Test		Post Test		T-test	level of significance	Type of Significance
		Mean	Standard Deviation	Mean	Standard Deviation			
1	Muscle strength test	6.152	0.705	6.509	0380	2.202	0.03	Significant
2	accuracy of transmissions from the top	7.521	10.986	8.802	8.928	3.201	0.01	Significant

Below the degree of (14) and the level of significance (0.05): From the table above we find that the value of the mean and the standard deviation of the test of throw a ball weighing 3 kg in two hands over the head from the position of sitting on the chair in the pre-test was the value of the arithmetic mean and standard deviation, respectively (6.152), (0.705) (0.509), (0.380), and (t) (2.202) and freedom level (14) below the level of significance (0.05), indicating that there are significant differences in favour of the post-test. The results of the test of accuracy of the transmissions, the value of the mean and the standard deviation respectively are (7,521), (10.986) and for the post test are (8.802), (8.928), the value of t (3,201) and the degree of freedom (41) 0.05), indicating significant differences in favour of post-test.

Discussion

The results show that there are significant differences between the pre and post-tests and for the post-researchers which emphasize that it is not necessary to improve the level of strength and speed to increase the level of accuracy, but that occurred and the practice of Isotonic development of muscle capacity of the arms and trunk, which contributed to generate additional strength of the muscles working and accelerate the movement of the strike arm for the ball allowing the player to hit the ball from the highest point in the air and from the upper corner, thus leading to full control of the direction of hitting the ball and then increase the accuracy of the direction of the ball to the desired location and this is confirmed by DhaferHashim, "that muscle strength For the purpose of performing the transmitter skill requires increasing the horizontal or vertical momentum of the force generated by the body, which increases the hitting of the ball quickly when performing the skill of transmission ".

Conclusions

There are Significant differences in the pre and post-tests for the muscle strength test (using isotonic training (movement) and the volleyball performance skill for the players of the Muqdadiyah Club for young people.

Recommendations:

1. The researchers recommend using the isotonic training to develop the muscular ability of all the practitioners of the game, whether students, professional or amateur, taking into account the method level and the ability of the player.
2. The need to emphasize the conduct of continuous and regular tests to test the physical and skill capabilities of the players to recognize their abilities and try to develop them to the best level.
3. Conduct a similar study using the training method and linking other variables as well as the physical and skill variables under study whether functional variables or biomechanical variables.

The Effect of Use Healthy Acupuncture in Odynolysis Chronic Pain of the Biceps Femoral Muscle of Taekwondo Players

Ali Jasim Kareem[1], Hamid Abdul shaheed Hadi[2], Abbas Mahdi Saleh[3], Salman OkabSarhan[3]

[1]Assistance Professor, University of Basra, College of Physical Education and Sport Sciences, [2]Lecturer, Ministry of Education, Najaf Education Directorate, IRAQ, [3]Professor, University of Al Kufa, College of Physical Education and Sport Sciences, Theoretical Science Branch

Abstract

The importance of the research lies in the use of acupuncture for the spastic muscle (biceps femoral) of taekwondo players in the clubs of Al Najaf Al Ashraf province.

The problem of research is the dealing mistakes with these injuries as many of injured resort to do massage and deep massage, which increases the case of injury in addition to the muscle rupture cases.

The study objectives to achieve, the researchers used the experimental methodology of one group to suit the nature of the problem, the research population identified as taekwondo players with muscle spasms of the femoral biceps muscle, the researchers used acupuncture to relieve muscle spasm and odynolysis the degree of pain caused by a specialist, where tests were conducted on the Taekwondo hall in AL Najaf Al Ashraf Club and after getting of results were treated statistically by using statistical bag spss, and reached the following conclusions result of acupuncture clearly on odynolysis the degree of pain caused by muscle spasm, therefore enable the sample of the research to perform muscle contractions properly and in the light of the obtained results by the researchers, they recommend with the need of acupuncture in of muscle spasm cases.

Keywords: *Acupuncture, Odynolysis, Chronic Pain***.**

Introduction

Interest of sports activity in developed and developing societies alike has become an essential aspect of human resources in order to improve human health. Sport has become a common feature in doctors' advice to diseases prevention that may infect humans at different stages of life.

Injuries related to high effort, poor physical fitness and body building are muscle injuries and muscle spasm, as well as for taekwondo and karate players, this injury is caused by pain, the posterior femoral muscles and connective muscles, and this movement is closely related to the integrity of the ligaments, muscles and in the femoral articulation.

Muscle injuries of all kinds occur in martial artists as most practitioners complain of pain in the connective muscles and the biceps femoral due to the pressure caused by the use of rotational movements during the performance of basic exercises, these pains are usually caused by acute or chronic infect their structures in the articulations or some (cartilages, bones, ligaments, muscles and nerves).

The therapeutic exercises are the main axis and the common factor in the treatment of injuries and is one of the most important ways in removing dysfunction cases of muscles and articulations, as well as interest in understanding (biomechanical) the body movements and healthy body through performing exercises to develop the muscle strength and articulation flexibility and the degree of neurological compatibility to restore normal state.

Acupuncture is one of the physiotherapy method used to restore the balance and internal stability in the human body and way to induce the nervous system responsible for causing pain and where acupuncture play important and effective role in gr rid of pain through the theory of control of pain gate (closing the pain gate), and secretion of stored natural chemicals materials in the

body called (blood opioids), which lead to stop the pain and thus significantly reduce dependence on external analgesics with its harmful effects.

Hence the importance of research in the use of acupuncture in relieving spasm in the biceps femoral muscle of Taekwondo players.

The Research Problem: Taekwondo is one of the games that require great effort and high flexibility for muscles and articulations where these games need fast movements and a high level of muscle flexibility,through the researchers note that the martial artists frequent muscle exposure of biceps femoral muscle to the muscle spasms, and this promoted the researchers to use acupuncture to odynolysis the muscle spasm.

Objectives:

The research aim to:

1. Using the acupuncture in odynolysis the spasm of biceps formal muscle of Taekwondo players.
2. Identify the effect of acupuncture in odynolysis muscle spasm.

Hypothesis: There is a positive effect of acupuncture in odynolysis the spasm of the biceps femoral muscle of taekwondo players.

Methodology: The researchers used the experimental approach of one-group as the most appropriate method to solve the research problem.

Research Population and Sample: The research population was identified as the infected players of the Taekwondo game in Najaf sports clubs, and the number of 8 injured, representing the research population.

Means of collect information, devices and tools used: The researchers used more than one method that can help him to reach the facts, as they use many different research tools to ensure obtaining accurate and correct data to implement the requirements of the research, including:

Means of collect information:

- Foreign and Arabic Sources
- Observation and experimentation.
- Testing and measurement.

Used devices and tools:

- Chinese needles.
- Dynamometer
- Tape measure.

Determination of Research Tests:

First, measure the strength of the biceps femoral muscle and the pain level:

The aim of test: Measuring the maximum strength of the biceps femoral muscle of the affected muscle.

Test Description: From the prone position, the laboratory pulls the dynamometer fixed horizontally with the affected muscle and raises the foot to back with angle of 90 (rear kilometer) and with maximum force, give each experimenter two attempts to calculate the best attempt.

Recording Method: The force is recorded in Newton with the pain level indicated by the player himself according to the pain level test shown in the figure below.

Pre-tests: Researchers conducted the pre-tests of the research sample on Saturday (17/11/2018) at two o'clock in the Taekwondo Hall in Najaf Sports Club.

Main Experience: The researchers used acupuncture by a specialist in physiotherapy and acupuncture of three sessions a week for two weeks (6 sessions) for the purpose of odynolysis the spasm in the muscle of the biceps femoral resulting from high stress on the muscle as the prick muscle affected by spasticity especially from the large measurement for the purpose of reaching the depth of the muscle and in the specified areas for tingling away from the nerve feeding the muscle and the duration of stimulation acupuncture for (5) minutes with manual stimulation and not electrical activity has been used stimulation two method are the method of (lifting and pushing–turnover method) this was effective in odynolysis the pain of infected.

The post- tests: The researchers conducted the post-test for the members of the research sample on Friday (30/11/2018) at exactly 2:00 pm in the hall of Najaf Club also in the same manner of pre- tests.

Statistical method used in the research: The researchers used the spss statistical program and the following Laws.

- Arithmetic mean.
- Standard deviation.
- T test for correlated samples.

Presentation, analysis and discussion of results:

Presentation and analysis of differences between pre and post-tests:

Table (1): The differences between pre- and post-tests in the searched variables of the control group

Sr.	variables	pre		post		T Calculated Value	Sig Value	Significance
		s	h	s	h			
1	The maximum strength of the affected muscle	125.33	10.09	166.75	12.44	11.86	0.00	moral
2	Pain Degree	6.55	0.83	2.5	1.08	7.36	0.01	moral

This indicates that the results of the research showed a significant change in reducing the pain degree of the players, which clearly affected the amounts of muscle strength of the infected muscles, application of therapeutic exercises with acupuncture has a clear effect in improving the effectiveness of the injured muscle because acupuncture play an important role in odynolysis, which is reflected positively on the motor extent, this result is consistent with what (Peter E. Baldry 2005)[1] said that various physical therapies means, including motor rehabilitation (therapeutic exercises), odynolysis spontaneously and significantly affect the reduction of muscle pain besides acupuncture at near and far energy points and leads to Better results, as (70%) of patients suffering from muscles pain and articulations and subject to acupuncture sessions and continuously had a significant impact in odynolysis, increase the flexibility of the joint,increase electrical activity of muscles, and acupuncture is a property in closing the gate of pain, which helps the injured to do the exercises well and properly without pain. This was confirmed by [2].

The results of the [3]study confirm that acupuncture on the anatomical points of the energy pathways in the body leads to an improvement in the electrical activity of the muscles working on this track and improved the functional efficiency of these muscles.

As confirmed by [4]and,[5] that there is evidence of the effectiveness of acupuncture on reducing the degree of pain, and the nerve tissue is considered a bundle of thick and thin sizes. The thin size that transmits the sensation of pain while the thicker transmits other sensations such as touch and can prevent traversal of thin tissues, this is done during the closure of the pain gate, which is in specific neurons in the spine and tingling needles stop the pain by secreting chemicals materials called (Opioids)leads to stop the pain. It was possible to follow the progress of the acupuncture alert from the body contour to the cerebral cortex and record the inhibitory effect of pain by tingling and alerting some points in several areas of the body.

These results are consistent with [1]that acupuncture works to reduce muscle tension, where the muscles within the body have continuous and imperceptible contractions to maintain their mobility in treatment these symptoms not only in the implant area but on continuous inhibition effect of pain sensation of (Contineam Inhibition) There is a reaction similar to pass the pain sensation comes from the mechanical and thermal receptors in the skin affected by the presence of acupuncture that occur mechanical and thermal effect and occur effectively change to any pain sensation comes from the spinal parts of the brain where it is sent continuous nerve signals to discourage pain sensation [6].

As stated by[7] and[8] that on the excruciating pain expresses a deficiency in the natural control system, where new therapeutic method have emerged depend on nervous induction to enhance this control the pain-resistant chemicals are entered, which are natural types of morphine are secreted by neurons during acupuncture, which leads to less pain sensation.

Fate of Dysfunctional Bladder after Pediatric Renal Transplantation

A.M. Fawzy[1], Ehab Tawfiek[2], A. Zaki[3], Hani Morsi[4], Fatina Ibrahim[5]

[1]Lecturer of Urology, Minia Urology & Nephrology University Hospital, Faculty of Medicine, Minia University., [2]Associate Professor of Urology, Division of Pediatric Urology,Minia Urology & Nephrology University Hospital, Faculty of Medicine, Minia University, [3]Professor of Urology, Dean of Urology Department, Minia Urology & Nephrology University Hospital, Faculty of Medicine, Minia University, [4]Professor of Pediatrics, Division of Pediatric Nephrology, Dean of Pediatric Renal Transplantation Unit, Aboul-Riche Children's Hospital, Cairo University, Cairo, Egypt, [5]Professor of Urology, Division of Pediatric Urology, Aboul-Riche Children's Hospital, Cairo University, Cairo, Egypt

Abstract

Introduction: Graft function on long term into patients with LUTD is still a myth, So, we aimed know the natural history of LUTD and graft function into patient with abnormal lower urinary tract.

Patient and Method: The study was conducted by retrospective review of 129 files of pediatric live renal transplant patients;Patients in either group had clinical evaluation of lower urinary tract function and assessment of graft functions at least one year after RT.

Results: On evaluation the magnitude of change of cystometric variables we found 57% improvement of incidence of urodynamic detrusor overactivity and 48% improvement in patient categorized as poor/ decreased compliance. There was 90% increase in the number of patients with adequate capacity. Patients showed 55.5% decrease in the number of patient with high PVR.

Conclusion: Live donor renal transplant into pediatric patients with LUTD due to organic or neurogenic lower urinary tract pathology showed high serum creatinine on long term follow up.

Keywords: *ESRD - Follow up - Serum creatinine.*

Introduction

Recent advances in surgical techniques in pediatric renal transplantation, preoperative and postoperative care, as well as immunosuppressive therapy have contributed to increase patient and graft survival for this population. However, important differences in the pediatric transplantation compared with adult especially for children who have lower urinary tract dysfunction LUTD which represents chronic problem in the context of renal transplantation.[(1)]

Data about the renal allograft function in cases with LUTD is limited and also, results of pediatric renal transplant patients with abnormal bladder have been conflicting. Some showed that these patients are poor candidates for renal transplant with poor graft and patient outcome. In contrast, other studies have shown that renal transplant is a safe and effective treatment for end-stage renal disease in children with lower urinary tract abnormalities. [(2)]We aimed at assessing the impact of lower urinary tract dysfunction on renal allograft function, graft survival and related morbidities.

Patient and Method

Our study included a retrospective cohort of 129ESRD patient received live related donor renal allograft in the periodbetween 2010 and 2016 at Aboul-Riche pediatric University Hospital. Patient was diagnosed for LUTD due to underlying different clinical conditions including PUV (39 patients), primary VUR (32 patients) and neurogenic bladder (20 patients) and urethral stricture disease (1 cases) remaining cases had no obvious LUTD.

Long term assessment of serum creatinine and clinically significant lower urinary tract manifestations were examined. Also, we studied the effect of pre, intra and post-operative variables together with lower tract parameters on last serum creatinine as a mirror of graft functions.

Results

Mean age of live donor was 38 years most of them were mother of the child with ESRD in 61.5%. Mean recipient age at transplantation was 9 years with a mean weight at operation 26.5 Kg.(See table 1)

On comparing magnitude of change of cystometric variables in each group we found 57% of incidence of urodynamic detrusor overactivity and 48% improvement in patient categorized as poor/decreased compliance. There was 90% increase in the number of patients with adequate capacity. Group B patients showed 55.5% decrease in the number of patient with high PVR.

Mean serum creatinine in last follow up was 1.3 with no graft failure or deaths.(See table 2)

Donor and recipient criteria in both study groups

Table 1: 61.5% of recipeints were males with mean age at transplantation of 9.2 years

Parameter		Group B NO. (129)
Donor age	Mean ± SD	38.1 ± 8.5
Donor sex	Male Female	15 (38.5%) 24 (61.5%)
Recipient sex (%)	Males	24 (61.5%)
	Females	15 (38.5%)
Age at renal transplantation	Mean ± SD	9.2 ± 4.1
Weight at renal transplantation	Mean ± SD	26.5 ± 9.9

Graft function outcome in both study groups in the end of the study:

Table 2: Mean serum creatinine at the last follow up was 1.3 mg/dl in 3.6 to 7.8 years of follow up duration (median follow up 6 years).

Parameter		Group B NO.(39)
Last Creatinine (mg/dl)	Mean ± SD	1.3 ± 0.9

Discussion

Our study in considered an a follow up of a second study was done on 123 pediatric renal transplant patient to compare the outcome of renal graft and related complication between two groups; control group of patient with non-urological cause of ESRD and group of patient who developed ESRD due to urological causes including mainly patients with LUTD. However, the above study did not report whether LUTD changes affects graft outcome.

Many studies reported 62.5% live related donors versus 37.5% cadaveric donor, while in our studies only live donor was accepted by law. [(4-13)]

Mean age donor in the studies described before was calculated to be 35.4 years versus 38 year in our study which was similar to us.[(4-13)]

In our series, donor gender distribution between two groups showed no statistically significant difference where most of donor were female (70.5%) of total donors (***See table 1***). However in some studies; males (46.6%) were nearly equal female donors (53.4%) of 296 total donors reported. This difference could be attributed to presence of more cadaveric donor in the mentioned studies and more live related donor in our study where mother is the main donor. [(4-13)]

There were different means of age at transplantation of some of studies ranged from 4.8 to 13.7 years. [(4-13)] similar to our study where mean age at operation in group A was 9 years in our study reflecting that patient with LUTD usually had more time of till development of ESRD more than renal group. But without statistical significance (***See table 1***).

Most of our study patients were males in 71% with no statistically significant difference between study groups. Similar to our study, other studies; males

represented 64% of total cases reported. Also,, mean weight at transplantation of our study cases was 26.5 Kg. Only two studies among those described in table 1 reported weight at transplantation with no statistically significant difference between their groups. [5-6]

In our study, cases showed statistically significant differences on the baseline and final urodynamic parameters which forced us to study the magnitude of changes, on comparing the change of cystometric variables in each group. We found 57% improvement of incidence of urodynamic detrusor overactivity. Patients categorized as poor/decreased compliance showed 48% improvement associated with 44.9% significant increase in mean mL needed to rise detrusor pressure one unit i.e. compliance. There was 90% rise in the number of patients with adequate capacity which was reflected as 63.8% increase in the mean of mL needed to reach MCC. Patients showed 55.5% decrease in the number of patient with high PVR which was associated with 79.9% increase in the mean volume of PVR.

All cases in our study has negative panel reactive antibodies PRA according to standard protocol of the institute. The most common HLA crossmatch pattern in each group was 3 out of 6 with no significant difference in the distribution of different grades of HLA crossmatch between study groups. In a single cohort of pediatric renal transplant recipient done in the same institute of us, median number of HLA crossmatch was 4 out of 6 crossmatch (39% of HLA crossmatch). Also, 42% of HLA cross match was 3 out of 6 HLA pairs similar to us. [3] Also, another comparative study reported no significant difference between the distributions of the number of HLA crossmatch in between both groups of patients, one of them included recipient with LUTD, [13]

Luke et al., 2003 reported increase in mean cystometric capacity by 63% from mean CC at baseline (186 ml). Also, there was a reduction in the mean of detrusor pressure before RT from 40 to 19 cmH2O after RT.[13]

High PVR was estimated in 45 out of 129 cases, there was no significant change in the mean of PVR from baseline towards the post-transplant follow up. In addition, voiding difficulties were expressed in additional (7) non-CIC Non toilet trained patients associated with 33% increase in the need for assisted voiding e.g. CIC after RT

After RT, need for urinary diversion appeared in 8 cases with LUTD reported in studies described in table 1, only 5 patients needed Mitrofanoff procedure mainly due to development of urethral stricture in CIC dependent patients and non-compliance and inadequate urethral drainage in patients with urogenital sinus as mentioned. [6-12]Vesicostomy was needed in two cases one of them was due to urethral stricture development in CIC patient.

Mean UTIs episodes of our cases was 5-6 UTIs episodes yearly occurred ranging from 1 to 11 episode.

Three studies described a significant difference in the incidence of UTIs as for the favor of high UTIs occurrence in LUTD patients.[4, 7, 12] Only 2 studies reported non-significant difference between their study and control group regarding UTIs incidence.[3, 5]

In another study, comparing between pediatric transplant patients with nephrology versus urologic cause for ESRD. There was no significant difference between percentages of patient with UTIs between study groups before renal transplantation but after receiving graft the percentage of UTIs in the urologic group was markedly higher with high statistical significance. Which was similar to what was interpreted in our study that there was increase in the mean of UTIs episode in renal transplant patient with dysfunctional bladder against those with normal LUT.[14]

Serum creatinine at last follow up was high with a mean of 1.3 mg/dl. Only one study by Aki et al., 2015 reported significant difference between its groups regarding last serum creatinine (1.3 vs. 0.9 in LUTD+ve and LUTD-ve group respectively).[7]Despite that remaining studies did not describe a statistically significant difference regarding serum creatinine or eGFR in between their groups, serum creatinine or eGFR usually higher in groups with LUTD.[4-13]

High serum creatinine at the last follow up forced us to seek for predictors of serum creatinine, UTIs was responsible for 45% of last serum creatinine changes. Thus incident UTIs results in 20% change of serum creatinine.

In previous study, results of multiple regression analysis for factors affecting graft function showed that underlying urological pathology have a significant risk for graft function and postoperative complication (OR = 0.2, p= 0.05).[5]

Conclusions

Live donor renal transplant into pediatric patients with LUTD due to organic or neurogenic lower urinary tract pathology showed worse serum creatinine in patients with pathological LUTD. Comparing the effect of different LUT parameters on the net result of serum creatinine we found that UTIs account for 45% of serum creatinine result on the long term after receiving live donor transplantation.

Updated Review on Revascularization in ST-elevation Myocardial Infarction (STEMI)

Ashraf Radi Mohammed Atta[1], Alaa Mohammed Ibrahim[2], Hesham Boshra Mahmoud[3], Tarek M. Abdelrahman[4], Hany Taha Taha[4]

[1]Assistant Lecturer in Cardiology, Faculty of Medicine, Minia University, [2]Professor of Cardiology, Faculty of Medicine, Minia University, [3]Professor of Cardiology, Faculty of Medicine-Beniswif University, [4]Assistance Professor of Cardiology, Faculty of Medicine, Minia University, Egypt

Abstract

Effective and in time reperfusion of the infarct-related coronary artery is essential to optimal treatment for ST-elevation myocardial infarction (STEMI). Now it is established the benefit of primary percutaneous intervention (PPCI) in STEMI over fibrinolysis. While intervention of the non-infarct related artery still a large area of debate with no definite consensus. Here in this review we will highlight the different reperfusion strategies and different ways to reach optimal reperfusion and debate about non-IRA in different situations.

Keywords: *STEMI, Revascularization, primary PCI.*

Introduction

Effective and in time re perf us ion oft he infarct-related coronary artery is essential to optimal treatment for acute coronary syndrome (ACS). In comparison with fibrinolysis, primary percutaneous coronary intervention (PCI) establishes more consistent and predictable epicardial artery recanalization, significantly lowers the risk of intracranial hemorrhage and stroke,reduces recurrent ischemia and reinfarction, and improves survival [1,2].

Early angiography followed by revascularization when appropriate also improves clinical outcomes with the greatest benefits realized in the highest risk patients. Because epicardial artery reperfusion does not guarantee myocardial perf us ion, strategies for cardioprotection and optimization of tissue level reperfusion are also essential[3].

Here we will highlight different reperfusion strategies to achieve faster and more effective epicardial vessel and micro vascular re perf us ion in patients with STEMI as well as temporal and logistic factors that may affect treatment outcomes.

Reperfusion in STEMI: Early reperfusion therapy is the most important issue in the management of STEMI. The greatest amount of infarction occurs inthe first few hours after coronary occlusion[4]. A recent analysis of 12 675 STEMI patients in the FITT-STEMI trial confirmed the strong impact of time delays on mortality, particularly in STEMI patients with cardiogenic shock or out-of-hospital cardiac arrest.[5]

Given this association between shorter time to reperfusion and survival, Door to Ballone (D2B) time became the focus of regional) and national quality improvement initiatives.[6,7]. Several strategies were developed, tested, and formally incorporated into clinical guidelines to shorten D2B times.[8]. By using such evidence-based strategies, there have been significant improvements in D2Btimesacross the country and across different types of hospitals.[9].

Which Reperfusion Method: Primary PCI, defined as percutaneous catheter intervention in the setting of STEMI without previous fibrinolysis, is

the preferred reperfusion strategy[10]. It has replaced fibrinolysis in patients with STEMI, provided it can be performed in a timely manner in high-volume PCI centers with experienced operators and 24 h/7 days week catheterization laboratory activation [11].

In settings where primary PCI cannot be performed in a timely fashion, fibrinolysis should be administered as soon as possible. If first medical contact (FMC) is out-of-hospital, lysis should be implemented pre-hospital (e.g. in the ambulance) [12].

It should be followed by transfer to PCI-capable centers for routine coronary angiography in all patients, and should be performed without delay for rescue PCI in the case of unsuccessful fibrinolysis or within 2–24 h after bolus administration.[13].

Primary PCI: Primary PCI is the preferred reperfusion strategy if a skilled interventional cardiologist and catheterization laboratory is available and if the procedure can be performed within 90 minutes after initial medical contact with the patient. [14-18].

The TRANSFER-AMI study further tested the pharmacoinvasive strategy concept in high-risk STEMI patients. Patients who had at least 1 high-risk feature [greater than or equal to 2 mm of ST-segment elevation in 2 anterior leads, systolic blood pressure less than 100 mm Hg, heart rate higher than 100 bpm, Killip class II to III, 2 mm or more of ST-segment depression in the anterior leads[19], or 1 mm or more of ST elevation in right-sided lead V4 indicative of right ventricular involvement for inferior MIs [20].

Management of Non-infarct Stenosis during Primary PCI: Multi-vessel disease is seen in up to 60% of patients presenting with STEMI and has a worse prognosis compared with patients with STEMI with single-vessel disease. [21]

Previous observational and nonrandomized studies and metaanalyses supporting the strategy of IRA-only PPCI recommended by the 2013 AHA/ACC guidelines[22].

However, then emerging data suggested that PCI of non-IRA in patients with STEMI may be superior to the standard approach of IRA-only PCI. As a result, a focused update on primary PCI was published in 2015 by the ACC/AHA, suggesting that PCI of non-IRAs may be considered in selecetatients[23].

Four major randomized trials-**PRAMI** (Preventive Angioplasty in Acute Myocardial Infarction, **CvLPRIT** (Complete Versus LesionOnly Primary PCI trial),[24], **DANAMI-3-PRIMULTI** (The Third DANish Study of Optimal Acute Treatment of Patients with STsegment Elevation Myocardial Infarction: PRImary PCI in MULTIvessel Disease,and **Compare-Acute**have consistently shown a benefit of complete revascularization (performed immediately or staged) as compared with IRA-only PCI in patients with STEMI and multivessel disease[25]

While in another meta analysis byElgendy et al. showed that the risk of all-cause mortality and spontaneous reinfarction is not different among the various revascularization strategies for multivessel disease. Complete revascularization at the index procedure or as a staged procedure (either during the hospitalization or after discharge) was associated with a reduction of MACE due to reduction in urgent revascularization with no difference between these 3 strategies. [26]

Functional Assessment of Non-Ira Lesions: Recently DANAMI- 3-PRIMULTI trial studied the clinical outcomes by comparing the fractional flow reserve (FFR) guided by complete revascularization with IRA-only PCI in STEMI, and found that the composite rate of all-cause mortality, nonfatal reinfarction, and repeat revascularization was significantly lower in the complete revascularization group, which was mainly driven by a reduction in repeat revascularization and More recently, another randomized trial (COMPAREACUTE) revealed that FFR-guided complete revascularization of non-IRA arteries in an acute setting was associated with a lower risk of the composite cardiovascular outcome [25].

So, updated ACC/AHA guidelines recommended that complete revascularization can be considered either at the time of primary PCI or after the index procedure as a staged procedure.The 2017 European Society of Cardiology guidelines recommended a class IIa recommendation for complete revascularization STEMI patients with MVD. [11].

Recently, the results of COMPLETE trial were released. At a median of three years, complete revascularization reduced the risk of the composite of cardiovascular mortality or MI (HR = 0.74, 95% CI: 0.60-0.91, P = 000.04) driven by a reduction in the risk of MI (HR = 0.68, 95% CI: 0.53-0.86). Complete

revascularization also reduced the risk of the composite of cardiovascular mortality, MI or ischemia-driven revascularization (HR = 0.51, 95% CI: 0.43-0.61, P < 0.0001). ± 2.7). [27]

Table (1) Characteristics of the major trials comparing complete revascularization with IRA only revascularization[27]

Trial	Year	N	Complete revascularization approach	Major adverse cardiac events	All-cause mortality	Re-infarction	Urgent revascularization
PRAMI	2013	234/231	Index	21/53	12/16	7/20	16/46
CvLPRIT	2015	150/146	Index (67%), staged prior to hospital discharge (33%)	15/31	2/6	0/2	7/12
DANAMI-3-PRIMULTI	2015	314/313	Staged 2 days after index PCI	40/68	15/11	15/16	17/52
COMPARE-ACUTE	2017	295/590	Index (83%), staged prior to hospital discharge (17%)	23/121	4/10	7/28	18/103
COMPLETE	2019	2016/2025	Staged: 64% prior to discharge (median 1 day), 36% after discharge (median 23 days)	179/339	96/106	109/160	29/160

Management of Non-IRA in the setting of cardiogenic shock: Cardiogenic shock (CS) in the setting of acute myocardial infarction (AMI) is associated with significant morbidity and mortality [11]

For the treatment of patients with multi-vessel disease, current European guidelines for the management of acute ST-segment elevation myocardial infarction recommend immediate percutaneous coronary intervention (PCI) of both culprit and non-culprit lesions [11]

However, the 30-day results of the Culprit Lesion Only PCI versus Multi-vessel PCI in Cardiogenic Shock (CULPRIT-SHOCK) trial [25] showed that the risk of a composite of death from any cause or severe renal failure leading to renal-replacement therapy was lower with culprit lesion- only PCI than with immediate multi-vessel PCI, thus challenging the guideline recommendations. On the basis of these results, the European revascularization guidelines have now downgraded immediate multi-vessel PCI in cardiogenic shock to a class III B recommendation (i.e., a recommendation that the procedure is not useful and may be harmful, according to evidence from a single randomized trial[19].

In light of the short-term results of the CULPRITSHOCK trial, the use of multi-vessel PCI in patients with cardiogenic shock is now controversial.[11]

Conclusion:The benefit of primary percutaneous intervention (PPCI) in STEMI over fibrinolysis was established, and after small non- randomized studies concluded the advantages of IRA only strategy in STEMI, multiple large trials recently declared the advantage of total revascularization in decreasing the short and long term adverse outcomes, and large randomized trials now are needed to create agreement about the best time for revascularization of residual lesions after dealing with IRA.

Ethical Statement: The material has not been published anywhere. Authors of the manuscript have no financial ties to disclose and have met the ethical adherence.

Abstract

Background and Aim: Diabetic nephropathy is a complication of diabetes mellitus which can lead to kidney failure. Monocyte Chemoattractant Protein-1 (MCP-1) is a protein that is expected to be a biomarker of diabetic nephropathy. The purpose of this study was to examined the relationship of MCP-1 with diabetic nephropathy in Indonesia, especially in Bali therefore the accuracy in detecting diabetic nephropathy can be assessed.

Method: One hundred and sixteen patients with type 2 diabetes mellitus with diabetic nephropathy (n = 37) and without diabetic nephropathy (n = 79) were included in this study. MCP-1 serum was examined using the enzyme-linked immunosorbent assay (ELISA) method.

Result: MCP-1 serum levels were significantly higher in patients with diabetic nephropathy ($p < 0.001$). Analysis of receiver operating characteristic (ROC) curve for diabetic nephropathy detection showed that cut-off point of MCP-1 serum was 436 pg/ml with a sensitivity of 83.7% and 84.8% specificity.

Conclusion: It can be concluded that MCP-1serum can be considered as a biomarker for detection of diabetic nephropathy.

Keywords: *MCP-1 serum, diabetic nephropathy, biomarker.*

Introduction

Diabetes mellitus (DM) is a series of metabolic diseases characterized by hyperglycemia due to defects in the secretion or action of insulin. The prevalence of this disease is increase rapidly throughout the world and becoming one of the major health problems. In 2013, 382 million DM cases were estimated worldwide and will increase to 592 million in 2035[1]. Complications in diabetes are microvascular and macrovascular complication. One of the complication is diabetic nephropathy (DN). Diabetic nephropathy can occur in 30-40% of patients with type 1 and type 2 diabetes mellitus[2].

Various factors have been described to be involved in the pathophysiology of DN, such as hemodynamic and metabolic changes, oxidative stress, activation of the renin-angiotensin system and most recently the role of the inflammatory process that can cause disease progression towards DN[2,3]. The mechanism underlying the regulation of cytokines in the kidney of DM patients is still unclear. Cytokines and chemokines which increase their expression (production) during the inflammatory process in the glomerular membrane of mice with

diabetes are CC-chemokine ligand 2 (CCL2)/monocyte chemoattractant protein (MCP-1), Interleukin 1, 6, 18, TNF-α, TGF -β1, TF, Smads, adhesion molecules and adipokines[2].

Monocyte Chemoattractant Protein-1 (MCP-1) is a protein produced by kidney cells in response to proinflammatory stimuli that specifically attract monocytes and macrophages[4]. High glucose levels can stimulate MCP-1 production in rat and human mesangial cells[5]. Interaction between MCP-1 and its receptor, CCR2 causes an inflammatory process that leads to mesangial cell fibrosis in the kidney[4].

Renal epithelial cells including glomerular podosite and tubular cells also produce MCP-1 in response to increased blood glucose[6,7]. MCP-1 is a chemokine that attracts monocytes from the blood into the kidneys and triggers macrophage activation and releases ROS, proinflammatory cytokines (IL1, TNF alpha) and probiotic growth factor. The MCP-1 signal through CCR2 in mesangial cells activates the NF-kB transcription factor and produces TGF-β1 thereby inducing fibronectin mRNA which acts to induce the occurrence of fibrotic response in glomerular mesangial cells[4,8]. TGF-β1 stimulates the expression of MCP-1 in mesangial cells and allows the amplification of MCP-1[8].

In some previous studies there was controversy in the results of MCP-1 serum. MCP-1 serum can be increased in diabetic patients. It has been found that MCP-1 serum has a significant relationship to macroalbuminuria[9] in mice, while other studies suggest an insignificant relationship[10] in Japan's populations. Researchers would like to examine the relationship of MCP-1 with diabetic nephropathy in populations in Indonesia, especially in Bali to assess its accuracy in detecting diabetic nephropathy.

Materials and Method

Patients and sample selection: This study used a cross-sectional analytical study design in patients with type 2 diabetes mellitus at the Tabanan General Hospital and SanjiwaniGianyar General Hospital, Bali. A total of 116 subjects were included in this study. Patients were selected by consecutive sampling method with regard to the following inclusion criteria: patients with type 2 diabetes mellitus, had type 2 diabetes mellitus for at least 3 years, patients were excluded if the patient had other kidney disease (based on clinical or laboratory evidence), and patients with hematuria.

Laboratory assessments: Subjects were examined clinically and their blood drawn for blood chemistry levels, including blood urea nitrogen (BUN), serum creatinine (SC), total cholesterol and triglycerides at the laboratory of Sanjiwani Hospital and Tabanan Hospital. The patient's body weight and height were used to calculate body mass index (BMI), while serum creatinine, age, sex and body weight were used to calculate eGFR based on the formula from CKD-EPI.

Microalbuminuria examination was done by measuring the urine creatinine albumin ratio. Urine sampling was carried out in the morning as much as 10 ml and then the urine albumin level was analyzed by the immunoturbidometry method, whereas urine creatinine levels were measured by the kinetic method on the integra analyzer (Roche, Basel, Switzerland). Microalbuminuria examination was carried out at the Prodia Clinics Laboratory in Tabanan and Gianyar. The condition of diabetic nephropathy was determined by the ratio of albumin-creatinine in urine (uACR) of more than 30 mg/g.

Examination of MCP-1 serum levels was carried out at the Biochemistry Laboratory of Gadjah Mada University by R & D ELISA kit reagent. The examination was carried out according to the instructions on the ELISA kit. The collected data were analyzed statistically using independent t-test and chi square to analyze bivariately. Multivariate analysis was done by binomial logistic regression.

Results

This study involved 116 subjects with type 2 diabetes mellitus with and without diabetic nephropathy with an average age of 59.2 (9.16) years, period of diabetes 9.2 (6.04) years, and BMI of 24.9 (3, 75) kg/m^2. This can be seen as in table 1.

Table 1: Characteristic of Study Subject

Characteristic	N= 116
Gender (% Males)	55.2%
History of Hypertension (yes/no)	58.6%
Current Hypertension (%)	36.2%
Age in years (mean ± sd)	59.2 ± 9.16
Period of DM in years (mean ± sd)	9.2 ± 6.04
BMI (kg/m^2) (mean ± sd)	27.2 ± 23.99
Triglycerides (mean ± sd)	138.8 ± 83.08
Total Cholesterol (mean ± sd)	190.3 ± 46.51
eGFR ml/min/1,73 m^2 (mean ± sd)	57.2 ± 36.84
MCP-1 (pg/ml) (mean ± sd)	403.1 ± 176.05

Subjects experiencing nephropathy and non-nephropathy were determined based on uACR values. UACR value ≥ 30 mg/g was considered as diabetic nephropathy (DN) while uACR<30 mg/g as non-DN. After being analyzed bivariately, several variables showed significant results when compared between the diabetic nephropathy and non-nephropathy groups. As shown in table 2, gender, history of hypertension, current hypertension, total cholesterol, eGFR and MCP-1 serum levels have a statistically significant differences.

Table 2. Bivariate analysis of categorical and numerical variables in diabetic nephropathy

	DN (37)	Non-DN (79)	p-value
Gender			
Male (freq)	27	37	0.008*
Female (freq)	10	42	
History of Hypertension			
Yes (freq)	35	33	<0.001*
No (freq)	2	46	
Current Hypertension			
Yes (freq)	19	23	0.020*
No (freq)	18	56	
Age in years (mean ± sd)	57.4 ± 10.18	60.1 ± 8.57	0.140
Period of DM in years (mean ± sd)	10.5 ± 5.28	8.5 ± 6.31	0.099
BMI (kg/m^2) (mean ± sd)	25.6 ± 3.66	27.9 ± 28.99	0.633
Triglycerides (mean ± sd)	142.0 ± 88.51	137.7 ± 81.70	0.818
Total Cholesterol	168.0 ± 42.94	197.9 ± 45.46	0.003*
eGFR ml/min/1,73 m^2 (mean ± sd)	19.0 ± 18.88	75.2 ± 28.56	<0.001*
MCP-1 (pg/ml) (mean ± sd)	556.9 ± 153.41	331.1 ± 135.51	<0.001*

Table 3 showed the results of multivariate analysis with binomial logistic regression. After the process of analyzing the model with backward elimination, a final model with two independent variables was obtained, which was eGFR and MCP-1 serum therefore these two variables is a strong predictors for diabetic nephropathy. The last model is shown in table 4.

Table 3. Results of multivariate logistic regression analysis of DN variables

	Variable	Coefficient	p	OR
Step 1[a]	MCP-1	.026	.008	1.027
	eGFR	-.220	.013	.803
	Total Cholesterol	-.008	.684	.992
	Hypertension (Yes)	-3.797	.221	.022
	his_hyp (Yes)	1.930	.247	6.892
	Gender (Male)	1.639	.306	5.148
	Constant	-.771	.877	.463

Table 4. Final models of MCP-1 and eGFR

	Variable	Coefficient	p	OR
Step 5[a]	MCP-1	.021	.001	1.021
	eGFR	-.176	.001	.839
	Constant	-1.069	.538	.343

Table 4 also showed that after adjusting eGFR, there was a significant association between MCP-1 and diabetic nephropathy, where each 10 unit increase of MCP-1, the likelihood of becoming nephropathy increased by 21 percent. The formula that can be drawn from the analysis above is:

$$\text{Odd Ratio Nephropathy} = e^{0.021\ \text{MCP-1}-0.176\ \text{eGFR}-1.069}$$

Hosmer Lemeshow of the model indicates that observed and predictive probabilities are in line (p = 0.852) which means that the model provides a good fit/ prediction.

In Figure 1, it showed that the MCP-1 serum has an area under curve (AUC) of 0.886. This value was classified as very good diagnostic accuracy. These results were followed by determining the cut off point and cross tabulation analysis. Cross tab based on MCP-1 serum cut-off point 436, ie if the MCP-1 serum value was less or equal to 436 then there was no risk of diabetic nephropathy, whereas more than 436 was risky. If the MCP-1 serum variable was supplemented with eGFR and both were included in the diagnostic test model, both of these variables cause an increase in sensitivity and specificity towards the diagnosis of diabetic nephropathy (Table 5.)

Table 5. Diagnostic indicators of MCP-1 serum compared to MCP-1 serum and eGFR for detecting diabetic nephropathy

Cut-off value	Sensitivity	Specificity	PPV	NPV	AUC
MCP-1 >436 pg/ml	83.7%	84.8%	72%	91.7%	0.886
MCP-1+eGFR > 0.500	91.9%	98.7%	97.1%	96.3%	0.989

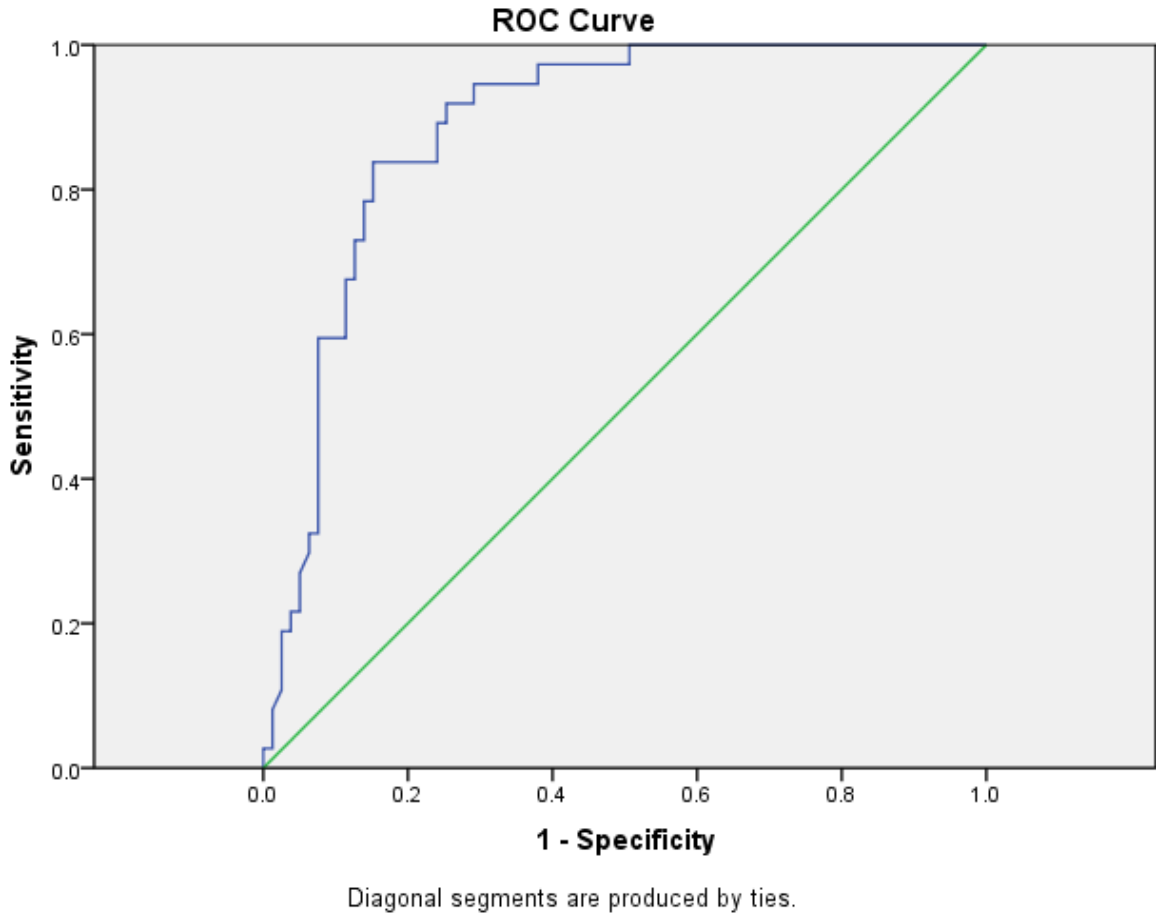

Figure 1: Receiver-operator characteristic (ROC) curves for the prediction model of MCP-1 serum in diabetic nephropathy

Discussion

CCL2/MCP-1 is expressed by various cell types. Large amounts of MCP-1 are found in endothelial cells, fibroblasts and mononuclear cells. In the kidney, MCP-1 is produced by tubular cells, smooth muscle cells, mesangial cells, podocytes, eosinophils and mast cells. MCP-1 is produced in the kidney in response to inflammation[11]. The released MCP-1 has the main effect of attracting other inflammatory cells. In vitro, MCP-1

concentrations can induce chemotaxis from monocytes and attract T cells and natural killer cells. In monocytes, MCP-1 induces not only chemotaxis, but also respiration bursts, rapid induction of arachidonic acid release and changes in calcium concentration. One study found that MCP-1 can reduce the survival of graft by improving the pro-inflammatory environment or MCP-1 itself can be a marker for damaged graft[12].

Diabetic nephropathy is a complication of diabetes mellitus, one of which is associated with inflammation. Several recent studies have shown that the progression of diabetic nephropathy in the affected kidney can be characterized by infiltration of inflammatory cells such as monocytes and macrophages. The macrophage infiltration releases enzymes lysozyme, NO, reactive oxygen intermediates, and TGF-beta which have been reported to play an important role in kidney damage[13].

In this study, it was found that MCP-1 serum was a strong predictor of diabetic nephropathy, which is in line with the results of research from Takebayashi et al. in 2006 which found that MCP-1 in circulation was significantly different in subjects with macroalbuminuria compared to normoalbuminuria[9]. Although it cannot be explained, it is likely because of the expression of MCP-1 in renal macrophages can lead to an increase in systemic levels of MCP-1 which is proportional to the inflammatory and nephropathic stages. Another possibility is that MCP-1 serum levels increase in patients with early nephropathy as a result of activation of dysregulation of systemic leukocytes, although several studies showed deviant production of cytokines and inflammatory chemokines by monocytes and circulating lymphocytes in type 2 DM patients with nephropathy[14].

This study found that MCP-1 serum levels could be a candidate biomarker that could further strengthen the diagnosis of diabetic nephropathy by becoming an additional examination after eGFR. eGFR which is the result of calculation of serum creatinine levels, body weight and age, has often been used to determine the stage of chronic kidney disease, but is less sensitive in predicting diabetic nephropathy, which could be the beginning of chronic kidney disease. These results are in line with research from Sinkala (2017) which found that serum creatinine, urea and microalbuminuria are biomarkers that can still be used to predict acute kidney injury and chronic kidney disease[15].

Several studies have shown that MCP-1 serum levels were not significantly different from kidney function[16,17]. This can be caused by the number of samples in previous studies was greater and the classification of microalbuminuria into 3 groups including normoalbuminuria, microalbuminuria, and macroalbuminuria, while in this study only divided into two groups which were normoalbuminuria and albuminuria (micro and macroalbuminuria). The result differences can also be caused by the different population that used so that there were roles of ethnic, dietary and activity factors that affect metabolism in the pathophysiology of diabetic nephropathy in this study.

In conclusion, MCP-1 serum levels were significantly higher in patients with diabetic nephropathy than those without diabetic nephropathy. Additionally, MCP-1 serum correlates with uACR levels so that it can predict diabetic nephropathy in patients with type 2 diabetes mellitus. The accuracy of diagnosis and cut-off points of MCP-1 serum for detection of diabetic nephropathy has been assessed and compared with eGFR. The result showed that MCP-1 serum can be considered as a diagnostic biomarker for the detection of diabetic nephropathy and will be more accurate when supplemented with eGFR results.

Optimizing Bone Wound Healing Using BMP2 with BDNF in Osteoporotic Rats: Histological Evaluation

Athraa Y. Al-Hijazi[1], Noor Natik Raheem[2], Ali JB Al-Sharki[3]

[1]Professor at Al-Mustaqbal University College/Dentistry Department, Babel, [2]Ass. Lecturer at College of Dentistry, Mustansiriya University, Baghdad, [3]Lecturer at College of Dentistry,University of Baghdad, Iraq

Abstract

Background: Bone is a high vascular tissue and resilient organ with intuitive healing ability. Bone tissue contains multipotent stromal cells which have the ability to differentiate into different specialized cells. Induced stem cells have been developed by various growth factors. Using of biomaterial and growth factor is one of the most commonly used as new tissue engineering strategies.

Aim of the study: To evaluate the effect of application of a combination bone morphogenic protein 2 (BMP-2) with brain-derived neurotrophic factor (BDNF) as biomaterial to enhance bone healing in osteoporotic rat .

Materials and Method: Twenty female Wistar rat(10 normal rat and other 10 induced osteoporotic rat). Bone defects (3mm)was created in femur of each rat,one in the left side that left to heal spontaneously without any application,while the right side with application of a combination of 0.5 µl of BMP2 and 1µl of BDNF .Evaluation of histological changes includes bone cell counting and scoring of inflammation were estimated at different periods .

Results: Histological examination of Bone healing with application of BMP2 & BDNF for normal and osteoporotic rat shows formation of woven bone and bone trabeculae that filled most of bone hole with minimal inflammatory response and with a significant differences value in comparism to inapplicable bone .

Conclusion: The study concludes that application of the combination of BMP-2 & BDNF enhanced bone repair in osteoporotic rat.

Keywords: *BMP-2, osteoporosis, bone defect, bone healing, BDNF, bone cells.*

Introduction

Bone healing is a proliferative physiological process in which new bone formation was illustrated to fill the hole or the fracture site.[1,2]

Three stages involved in bone healing include

1. Inflammatory phase in which blood starts to clot and forms a fracture hematoma
2. Repairing phase represents by formation of spongy bone called trabecular bone that replace the defect.
3. Bone remodeling.

Osteoporosis is one of the most commonmetabolic bone disorder leading to bone fractures. It is also, thought to delay or impair the regenerative response[3,4] osteoporotic fractures remain challenging to treat that needs for new treatment protocol to increase bone regeneration capacity. Among other major risk factors, decreased expression of morphogenetic proteins has been identified for impaired fracture healing in osteoporosis[5,6]. Studies on osteoporotic animals show atrophy of dental tissue and that this atrophy was accompanied by a reduction in the pool of osteoprogenitor cells that associated with significantly slower wound healing[7,8].

Combining of biomaterials such as bone morphogenetic protein 2 (BMP2) with growth factor was implicated in many advanced bone healing studies. Bone morphogenetic proteins BMPs are group of bone-inducing growth factors that used to enhance osseous repair.[9,10]

Brain-derived neurotrophic factor (BDNF) has an influence on the establishment of the bone innervation,and might have morphogenetic effects includes modulating the proliferation or differentiation of developing bone cells[11].In addition, they have also been shown to act as an osteogenic and angiogenic factor, and this neurotrophin can also enhance expression of the other factor, like BMP-2, as well as the major angiogenic factor, VEGF, to promote bone formation, vascularization, and healing of the injury site.[12]

The objective of this study was to evaluate the effect of application of a combining BMP-2 and BDNF in facilitating of bone healing in osteoporotic rat.

Materials and Method

Animals: Twenty female Wistar rats, weighting (0.25–0.30 kg), aged 4-5 months were used and kept in the animal department of (National Center of Drug Control and Research/Iraq) at a constant humidity and temperature of 23°C according to the National Council's guide for the care of laboratory animals. After 2 weeks of acclimatization,rats were randomly allocated to 4 groups (No.5 for each group), include:

Control Group includes

A: Normal rats with bone defect left to heal spontaneously .

B: Induced osteoporotic rats with bone defect left to heal spontaneously

Experimental group includes

C: Normal rats with bone defect that healed with application of BMP-2 & BDNF.

D: Induced osteoporotic rats with bone defect that healed with application of BMP-2 & BDNF .

Materials

- Recombinant bone morphogenic protein-2(rhBMP-2) Medtronic Sofamor Danek,TN/USA.
- Lyophilised BDNF protein 10µg (ab9794)/ Abcam,the protein was reconstitute in water to a concentration of 0.01mg/ml and used for experimental group

Method

Experiment on rats

Induction of osteoporosis: Ten rats were induced for osteoporosis by bilateral ovariectomy, and after 2 weeks postoperatively,the animals were received a systemic daily I.M injection of methylprednisolone hemisuccinate (MPH) at dose (1 mg/kg) for 4 consecutive week.

Surgical procedure: Six weeks after ovariectomy, rats were anaesthetized generally with a mixture of ketamine (50 mg/kg) with xylazine (2.5 mg/kg).Surgical technique was performed in rat femur to prepare two drill-holebone defects (3mm). The left femur was considered for the control group(A & B) of normal and osteoporotic .The holes were left to heal spontaneously without any application,just washed by normal saline and dried gently by air and closed the overlying tissue while the right side was considered for the experimental group(C & D).The holes were restored as previously described but with application ofa combination of 0.5 µl of BMP2 and 1 µl of BDNF, using micro-pipette,allowed for one minute before closing.

Note: Determination of effective dose for BMP2/ BDNF depends on previous studies.[13,14]

Histopathological preparation and analysis: The animals were sacrificed by an overdose of carbon dioxide gas after surgical operation at the periods (7^{th} & 28^{th} day).

Specimen retrieval: Bone hole along with their surrounding bone were excised with a surgical saw right away following the euthanasia. The excess tissue was dissected and the specimens were removed with a margin of surrounding bone of about 5–10 mm. The specimens were immediately put into the 10% formaldehyde solution.

Sample preparation for embedding: The specimens were decalcified,washed and then dehydrated in the ascending graded ethanol solution. Specimens were embedded in wax block and trimmed, the first undefined slice was removed from the saw blade of the sliding microtome (RM2255, Leica Biosystems, Wetzlar, Germany) and the desired serial sections 5-µm

thickness were selected .Mounting and staining of slides by hematoxylin and Eosin (H & E).The stained sections were blindly evaluated by a trained investigator who was previously calibrated with an experienced pathologist. Under a light microscope (Olympus BX53, Olympus, Tokyo, Japan), all samples were evaluated and scored in terms of:

1) inflammatory cell infiltration, 2) bone cells

According to Mestrener et al (2003)[15], the quantitation of intensity of inflammatory response at 7th day was evaluated by counting them in visual field (X10, X20, X40) with subsequent of arithmetic mean for each specimen as follow:

Intensity of inflammatory reaction

I. Absent or very few inflammatory cell.

II. Mild average number less than 10 inflammatory cells.

III. Moderate average number 10-25 inflammatory cells.

IV. Severe average number greater than 25 or necrosis.

Counting No. Of bone cells (osteoblast, osteocyte and osteoclast) for the periods (7th & 28th day) was done too.

Statistical method: Mean values and standard deviations were calculated forthe number of bone cells at different groups and periods with multiple Comparisons by (LSD Method) among all pairs of effect's Parameters. Frequency and percentage of inflammatory response in different groups was recorded. P value <0.05 was considered significant.

Findings

Histological findings revealed the followings: Bone healing for **normal rat (control)**shows bone trabeculae and osteoid tissue at 7th day,and at 28th day shows bone trabeculae filled 2/3 of bone defect. Figure,1(A & B).

Bone healing for **normal rat with application of BMP2 & BDNF(experimental)** shows formation of woven bone,bone trabeculae surrounds by active osteoblast at 7th day, and at 28th day shows bone trabeculae filled approximately the whole bone defect coalesce with basal bone. Figure, 2(A,B & C).

Bone healing for **osteoporotic rat(control)** shows resorpative bone with osteoclast cells with presences of inflammatory cell at 7th day,and at 28th day a thin sparse bone trabeculae with fibrous tissue was illustrated in figure, 3(A & B).

Bone healing for **osteoporotic rat with application of BMP2 & BDNF (experimental)** shows bone trabeculae, woven bone with osteoblast and osteocyte at 7th day,and at 28th day a thin bone trabeculae filled approximately 1/2 of bone defect. Figure, 4(A & B).

Statistical analysis revealed a high significant difference for bone cell count in comparism of normal with osteoporotic,while anon significant difference was recorded between the normal control and the osteoporotic experimental. On other hand,number of whole cells at 7th and 28th day show a significant differences in comparisum of normal with osteoporotic. Table (1).

Frequency and percentage of inflammatory response in different groups at 7th day shows a significant to high significant difference values in comparism of normal and osteoporotic in control and experimental, respectively. Table (2).

Discussion

The present results show that application of a combination of BMP-2 and BDNF as biomaterial for bone defect induce new differentiation of osteogenic stem cell into osteoblast cell that apposed woven bone with enhancement of process of minerlization .Bone trabeculae was found to fill approximately the whole bone defect for the normal and about 1/2 of bone hole in osteoporotic rats.

Many studies found that BMP-2 provides a strong signal for differentiation of osteoblastsand an over expression of BMP2 can promote fracture healing and osteogenic ability in senile osteoporotic fractures through activating the BMP/Smad signaling pathway[16,17].

Animal studies related to post-menopausal estrogen deficient osteoporosis had shown healing to be prolonged with decreased levels of mesenchymal stem cells (MSCs) and decreased levels of angiogenesis[18,19,20].

In present study application of neurotrophin (BDNF) effects on vascular endothelial growth factor VEGF that enhances vascularization and promotes bone formation

The application of combination of BMP-2 & BDNF illustrates that many events has been affected including the recruitment and differentiation of (MSCs) to osteoblast cell andenhancement of angiogenesis with new blood vessels formationin the early bone healing with minimal inflammatory responseand finally formation bone that filled the defect.[21,22]

The present study records frequency and percentage of inflammatory response at 7th day that shows a significant difference value in comparism of normal with osteoporotic,and furthermore,in exp.osteoporotic rat illustrates a decrease in inflammatory cell score in response to presence of BMP-2 & BDNF in bone defect.

Conclusions:The present findings implied that application of combination of BMP-2 & BDNFin osteoporotic bone healing,act as inductive agent that initiates the differentiation of osteoblast cell and formation of new bone and could be taken into consideration when designing a biomaterial for inducing osteogenic tissue engineering.Further researchers should focus on this important topic and provide more data in this field in order to enable a sound clinical use of these materials in osteoporotic subjects.

Macronutrients Analysis in *Ipomoea Batatas L. Poiret* as an Alternative Food in Improving Nutritional Adequacy of Pregnant Women

Awatiful Azza[1], Diyan Indriyani[1], Ika Priantari[2], Hendra Kurniawan[1]

[1]Faculty of Health Science, [2]Faculty of Education and Sciences, University of Muhammadiyah Jember

Abstract

Background: Adequacy of nutritional intake in pregnant women is needed in order to deliver healthy babies. Inability to provide nutritional needs due to financial problems is a common issue. Diversification of cheap and affordable food is needed for pregnant women so they will be avoided for various pregnancy complications. The objectives of this study are conducting a nutritional content analysis of *Ipomoea batatas L. poiret* as an alternative food to improve the nutritional status of pregnant women as well as examine the pattern of macronutrient consumption during pregnancy with the growth of the pregnancy.

Method: There are two designs used in this study (1) a field quantitative with completely randomized design, a laboratory experimental design, and (2) retrospective correlational design with cross-sectional study. The study samples are *Ipomoea batatas* and pregnant women in the second and third trimester with simple random sampling. Data analyses used in this study are proximate analysis in *Ipomoea batatas* and chi-square in pregnant women.

Results: The macronutrients content of 100 gr dry *Ipomoea batatas* are 84.08 carbohydrates, 1.00 gr proteins, and 2.22gr fats. Macronutrient consumption analysis obtained p-value 0.03 for carbohydrates, 0.02 for proteins, and 0.14 for fats which means that there is a correlation between carbohydrates, proteins, and fats with an increase of body mass index in pregnant women.

Conclusion: *Ipomoea batatas* can be an alternative macronutrient source for mother's needs during pregnancy.

Keywords: *Ipomoea batatas, nutrition, pregnant women.*

Introduction

Issues in nutrition are still a major public health problem in Indonesia[(1)(2)]. Malnutrition in mothers and babies has contributed to around 3.5 million deaths annually and approximately 11% of disease globally as well as reaching 30% of the total world population[(3)(4)]. According to Ethiopian Demographic and Health Survey (EDHS) for developing countries, the malnutrition problem in Kerala (India) is around 19%, while same number of 34% in Bangladesh and the slums area of Dhaka[(5)]. Anemia during pregnancy and chronic energy deficiency (CED) are an impact of malnutrition and can increase the risk of born prematurely and low birth weight babies[(4)(6)].

Basic health research (riskesdas) in Indonesia (2013) showed that CED is still the main problem in pregnant women since there is a 7.2% increase in the prevalence from 31.3% in 2010 to 38.5% in 2013[(7)(8)]. The main cause of chronic energy deficiency in pregnant women is an unbalance between the need for food during pregnancy and food intake in sufficient quantities[(9)(10)]

with several indirect factors are socioeconomic, short birth interval, parity or number of babies born, early age of first pregnancy, and low education[11].

Mothers need adequate nutrition during pregnancy. Diversification of cheap and affordable food is needed to avoid various pregnancy complications[10][12]. Nutritional needs that must be fulfilled include energy, protein, vitamins, folic acid, calcium, iron, iodine, zinc, flour, and its amounts must be adjusted to the gestational age[12][13].

Rice consumption standards according to Food and Agriculture Organisation is 60-65 kg/capita/year[5][14][15]. The national social-economic survey by the Indonesian central bureau of statistics (2017) reported that Indonesian people consume 114.6 kg/capita/year of rice from 2002 to 2017, that is why Indonesia is categorized as Asia's number one consumption of rice as a staple food. This number needs to be reduced by decreasing the dependence on rice consumption through diversifying food consumption[4][15].

Ipomoea batatas is one of the main sources of carbohydrates and has an important role in providing an alternative food and opportunity to replace rice as the main foodstuff of Indonesian people[16][17]. The concept of food source substitution will have an important role in food diversification and can be processed into a variety of products that can encourage the development of agro-industry[18][12]. One of the benefits of products made from *Ipomoea batatas* is improving the nutritional adequacy of pregnant women since it contains vitamin A, C, E, betacarotene, magnesium, potassium and antioxidants[19].

This study aims to conduct a nutritional content analysis of *Ipomoea batatas L. poiret* as an alternative food to improve the nutritional status of pregnant women as well as examine the pattern of macronutrient consumption during pregnancy with the growth of the pregnancy.

Material and Method

a. Study design and setting: There are two designs used in this study (1) a field quantitative with completely randomized design, a laboratory experimental design to identify macronutrients content in *Ipomoea batatas*, (2) retrospective correlational design with cross-sectional study to assess macronutrients consumption habits in pregnant women by food frequency questionnaire (FFQ) for 3 months related to pregnancy growth through body mass index (BMI).

b. Sample: The main sample in this study was *Ipomoea batatas* with two times of test in a fresh and dried condition in the form of flour.

1. Materials and tools to analyze macronutrient contents in *Ipomoea batatas.*

   The materials used in this study were local *Ipomoea batatas* which have been washed with tap water. The chemicals used were HCl (Merck), NaOH (Merck), aquadest, H2SO4 (Merck), Na2SO4 (Merck), K2SO4 (Merck) and n-Hexan (Merck).Tools used in this study were scales, knives, plastic containers, slicers, abrasion peeler, dryer cabinet, 80 mesh sifter, freeze dryer, and oven. The tools for physic and chemical identification were analytic scale, spectrophotometer UV-VIS 200S, and HPLC waters e2695 separations module.

2. **Women pregnancy:** Macronutrients consumption habits assessment in pregnant women were those in the second and third trimester with the criteria including the mothers do not experience with hyperemesis, chronic infections, and willing to join assessment program for daily nutritional consumption for the last 3 months. The sampling technique used in this study was simple random with the number of participants were 100 pregnant women in the district of Jember-Indonesia.

c. Data collection and instrument: Data collection techniques are carried out using a structured interview form and questionnaire about sociodemographic characteristics, pregnancy history, and food consumption during pregnancy. Daily macronutrient consumption habits collected using FFQ which was modified to assess eating habits in the last 3 months. BMI of mothers obtained through weight and height measurement.

d. Data analysis:

1. **Analysis of Ipomoea batatas for laboratory experimental design** Laboratory testing is carried out using proximate analysis in *Ipomoea batatas* to identify macronutrient content.

2. **Analysis of micronutrients consumption in pregnant women** Statistical analysis used in this

study is chi-square to assess the consumption habits of macronutrients in pregnant women with a BMI.

Findings

1. **Study result in Ipomoea batatas:** Proximate analysis in this study used to identify carbohydrate, protein, and fat content in 100 gram *Ipomoea batatas L.*

Table 1. Macronutrients composition in 100 grams *Ipomoea batatas* by proximate analysis

No	Macronutrient content	Fresh Ipomoea batatas			Dry Ipomoea batatas		
		UI 1	UI 2	Rata2	UI 1	UI 2	Rata 2
1	Carbohydrate (gr)	25.80	25.18	25.49	84.00	84.16	84.08
2	Fat (gr)	0.4	0.6	0.5	0.94	1.07	1.00
3	Protein (gr)	0.70	0.90	0.80	2.31	2.14	2.22

Ipomoea batatas also has macronutrients such as carbohydrates, protein, and fats which needed to help the growth of the fetus. Based on proximate laboratory tests it was found that the highest carbohydrate content was found in dried *Ipomoea batatas* with an average rate of 84.08 grams. While the fat composition of about 1% in dried *Ipomoea batatas* and 2.22 grams of dried *Ipomoea batatas* protein content.

2. **Study result in pregnant women**

a. **Respondent characteristics**

Table 2. Respondent characteristic based on age, education level, occupation of mother, and pregnant status (n=100)

Variables	n	Percentage
Age of mothers		
< 20 years old	24	24
20-30 years old	57	57
> 30	19	19
Education level		
Elementary school	17	17
Junior high school	47	47
Senior high school	23	23
College	3	3
Occupation		
Housewife	65	65
Private sector	16	16
Labor	19	19
Pregnant status		
Primigravida	49	49
Multigravida	51	51

Based on the frequency data, it was found that most of the pregnant women were 20-30 years of age, junior high school education and were not working.

b. **Macronutrient consumption analysis with the growth of pregnancy**

Table 3. Carbohydrate consumption with body mass index (n=100)

BMI	Carbohydrate consumption		Total	OR95% CI	P value
	Not fulfilled	Fulfilled			
Not appropriate	75	25	100	4.286	0.03
Appropriate	41.2	58.8	100	1.683–10.9127	
Total	52	48	100		

There is a relationship between carbohydrate consumption with BMI of pregnant women with OR 4.286 that means the mothers whose carbohydrate consumption patterns are not fulfilled have a 4.286 times chance of having an appropriate BMI.

Table 4. Fat consumption with body mass index (n=100)

BMI	Fat consumption		Total	OR95% CI	P value
	Not fulfilled	Fulfilled			
Not appropriate	46.9	53.1	100	3.403	0.14
Appropriate	20.6	79.4	100	1.370-8.453	
Total	29	71	100		

There is a relationship between fat consumption with BMI in pregnant women and OR analysis found that mothers whose fat consumption was not fullfiled had a 3.403 times chance of having an appropriate BMI.

Table 5. Protein consumption with body mass index (n=100)

BMI	Protein consumption		Total	OR95% CI	P value
	Not fulfilled	Fulfilled			
Not appropriate	45,1	54,9	100	4,371	0,02
Appropriate	19,6	80,4	100	1,76 - 10,857	
Total	29	71	100		

There is a relationship between protein consumption with BMI and OR analysis found that mothers whose protein consumption was not fulfilled had the opportunity to have 4.37 times appropriate BMI.

Discussion

Macronutrients are substances needed by the body in large numbers to provide direct energy[20][21]. In pregnant and lactating women, intake of macronutrients acts as forming organs and fetal cells[14][21]. The results of this study about macronutrient consumption habits in mothers showed an association with pregnancy growth as measured by BMI[22][23]. Macronutrients are very important in pregnant women to get balanced nutrition and growth of the fetus[24][25]. Rice is the number one consumption of Indonesian people as a staple food, even though there are many cheaper and have complete nutritional content from other sources of macronutrients.

Ipomoea batatas is one of Indonesia's agricultural products which has high carbohydrate content to provide the nutritional needs of pregnant women[18][16]. Mothers need additional 300 kcal of nutrients per day during pregnancy from macro and micronutrients[26][12]. Additional macronutrient requirements are 20 gr/day protein, 10 gr/day fat and 40 gr/day carbohydrate.84.08 grams carbohydrate content in 100 grams dry *Ipomoea batatas* is bigger than in fresh one that just 25.49 grams. The increased in macronutrients need during pregnancy is used to provide the need for metabolic changes and fetal growth[15]. This result suggests that *Ipomoea batatas* is very potential to replace rice as a source of food. Carbohydrate has an important role to maintain circulation and protein synthesis during pregnancy[19][27]. Anemia during pregnancy and CED can increase the risk of born prematurely and low birth weight babies[28][4].

Ipomoea batatas also has protein content that needed for fetal growth as well as a source of calories, synthesis of enzymes and hormones, muscles and other body tissues, blood cell formation, growth of the placenta and brain development[6][12]. The result of proximate analysis showed that dry *Ipomoea batatas* has 2.22 grams/100 gram protein content which can help to provide 15% of protein needs. Indicator for the maternal protein adequacy assessment can be measured through maternal weight and fetal growth[29]. Chronic energy and protein deficiency during pregnancy can reduce the nucleus in both DNA and RNA that affect to disruption of the maternal nutrients transfer to the fetus and lead to low birth weight babies and intra uteri growth retardation (IUGR)[9][29].

Fat, especially omega 3 and 6 are important to increase birth weight and fetal growth as its main role in providing metabolic energy. Saturated and unsaturated fatty acids have resulted from fat metabolism[9][30]. Docosahexaenoic acid (DHA) and arachidonic acid (AA) is a long-chain unsaturated fatty acid derived from diffused lipids and useful for the growth and development of the fetus[2][15]. *Ipomoea batatas* which has an optimal content of fat indicates that this food is safe for pregnant

women daily consumption since the result of proximate analysis is 1 gram/100 grams fat content[27][16].

Ipomoea batatas is local food sources that are able to be an alternative food source in providing the adequacy of nutrition in pregnant women[5]. The complete macronutrient content and some of the micronutrient contents in *Ipomoea batatas* make this food feasible and safe for pregnant women to consume and can be a food substitute for rice[31][29].

Conclusion

As a cheap source of carbohydrates, *Ipomoea batatas* have great potential as ingredients that can provide the nutrition of mothers during pregnancy. *Ipomoea batatas* also has macronutrients such as carbohydrates, protein, and fats which needed to help the growth of the fetus.

Statistically showed that there is a significant relationship between macronutrient consumption of pregnant women with fetal growth as measured by BMI.

Abstract

Purpose: To assess the relationship of Prothrombin G20210A gene mutations as a risk factor for idiopathic repeated pregnancy loss. The focus has been on Prothrombin G20210 Amutation that may predispose women to microthrombosis during the stages of embryo implantation and placentation.

Method: A total of 70 women with recurrent pregnancy loss, mean age 31.1±4.2 years, were involved in the study. As a control group, 70 women [mean age 32.2±3.3y ears with at least two live-born child and no history of abortion were included. We used real-time polymerase chain reaction (PCR) to determine the frequencies of Prothrombin G20210 Agenotype.

Results: The frequency of heterozygotes for *F2* was significantly higher in women with repeated pregnancy loss compared to women without abortion ($p = 0.0001$).

Conclusion: In summary we found an association of prothrombin G20210A mutation with recurrent pregnancy loss .we recommend for prothrombin G20210A screening in cases with repeated pregnancy loss so they can start anticoagulant therapy more earlier .

Keywords: *Prothrombin G20210A; pregnancy; PCR.*

Introduction

Recurrent miscarriage (RM) -defined by ESHRE guideline as ≥2 consecutive pregnancy losses before 20 weeks post menstruation affects approximately 1% of couples trying to conceive[(1)]. Current diagnostic procedures can identify etiologic factors in approximately 50% of these couples, such as uterine defects, advanced woman age, parental karyotype abnormalities, embryonic aneuploidies, infections and thrombophilia disorders[(2,3)]. While the role of acquired thrombophilia has been accepted as an etiology of RM, the contribution of specific inherited thrombophilic genes to this disorder has remained controversial[(4)].

The balance between coagulation and fibrinolysis is an essential part in early pregnancy, and thrombophilia has been postulated to be a contributor to the pathophysiology of recurrent pregnancy loss. Pregnancy is a hypercoagulable state with an increase in procoagulant factors and a decrease in the levels of anticoagulants [(5)].

Among the causes of these adverse pregnancy outcomes, three in particular are considered as the major factors of recurrent pregnancy loss and other adverse pregnancy out comes including: (i) structural and numerical chromosomal abnormalities, (ii) inflammatory and autoimmune disorders, and (iii) allelic polymorphisms of some pro-thrombophilic genes [(6)].

Mutation G20210A in 3` untranslated region of Prothrombin gene is associated with an increase level of plasma Prothrombin and consecutive excessive thrombin generation [7]. The aim of this study was to investigate association of prothrombin G20210A with recurrent pregnancy loss in a group of women of the Egyptian population.

Study Design:

Patients: This study included 70 patients who were selected from the Gynecological and Obstetric Clinic, Faculty of Medicine, Minia University Hospital, Minia, Egypt during the period from December 2018 to June 2019. Patients were further categorized into two Subgroup **Ia**, had the following characters: 23 women with history of two consecutive recurrent pregnancy loss and subgroup **Ib** 47 women with history of more than two times abortions either consecutive or not.

We Included women with two or more recurrent pregnancy loss consecutive or not before 20 weeks gestation and excluded women having Anti phospholipid antibody syndrome, Diabetes mellitus, chronic liver disease, chronic kidney disease, patients with thyroid diseases, dyslipidemia, local uterine abnormalities, patients with polycystic ovary syndrome or luteal phase defect and patients with self-induced abortion.

The control group consisted of 70 apparently healthy women with matched age to the patient groupattended to the same institutions for regular follow up .They had normal obstetric history with no history of abortion..All subjects volunteered to participate in the study .They were subjected to thorough history taking,clinical and radiological examination, Routine laboratory investigations included blood count, Prothrombin concentration(PC) and INR, activated partial thromboplastin time (PTT),Special laboratory investigations involved:Lupus anticoagulant screening test(PTT LA),D-Dimer and qualitative analysis of prothrombin gene A20210G.

Method

All participants were screened for antiphospholipid syndrome by sensitive APTT reagent(KACZOR D.A.,BICKFORD N.M 1992), The kit was supplied by DIAGNOSTICA STAGO SAS, France. The reading was obtained via (CoaDATA2001,Germany). The principle of the PTT-LA test is based on the measurement of plasma recalcification time in the presence of cephalin and activator .The presence in the test plasma of lupus anticoagulant prolongs the clotting time. Sensitization of the reagent specially enhances the prolongation of the clotting time due to the LA in the plasma.

All participants were screened for any thromphophilic manifestation or presence of microthrombus through D.Dimer .It was measured by enzyme immunoassay method (EIA) by Humareader plus 3700-1272 Germany. The kit was supplied by Wuhan EIAab Science Co., Ltd,**China.**

Principle: The micro-titer plate provided in this kit has been pre-coated with an antibody specific to D.Dimer. Standards and samples are then added to the appropriate micro-titer plate wells with a biotin conjugated antibody preparation specific for the target protein.Next, Avidin conjugated to Horseradish Peroxidase (HRP) is added to each microplate well and incubated. Then a TMB substrate solution is added to each well. Only those wells that contain target antigen, biotin-conjugated antibody and enzyme-conjugated Avidin will exhibit a change in color.The enzyme-substrate reaction is terminated by the addition of sulphuric acid solution and the color change is measured spectrophotometrically at a wave length of 450 nm . The concentration of D.Dimer in the samples is then determined by comparing the optical density (O.D.) of the samples to the standard curve**.**

Molecular study: DNA extraction was performed usingPROBA-NA DNA mini kit from DNA-Technology company. One ml in ethylene diamine tetra acetic acid (EDTA) containing tube for genotyping technique. DNA extraction was done from fresh whole blood samples then DNA was stored at -20 ºC till amplificationby real time PCR.

Real time PCR was performed using TaqMan Gene Expression Assays followed by melting curve analysis, The Kit were supplied byDNA-TECHNOLOGY(catalog no.334-1), Russia.

Procedure: The following were left to thaw, completely re-suspended by doing gentle vortex, then were briefly centrifuged to bring liquid to the bottom of the tube: Taq-AT-polymerase, DNA samples, Probes, PCR buffer. The required number of 0.2 mL PCR-tubes were marked for each mutation to be tested.The PCR master mix was prepared as following:

For each sample, the following were pipetted into a nuclease free 1.5 mL microcentrifuge tube:

- 10×(N+1) µL of PCR-buffer;
- 0.5×(N+1) µL of Taq-AT-polymerase;

N—number of the marked tubes.

20 µL of corresponding PCR-mix were added into the marked tubes . Vortex of the tubes with PCR-buffer and Taq-AT-polymerase were performed for 3-5 seconds, then spinning for 1-3 seconds was done to collect the drops.10 µL of PCR-buffer and Taq-AT-polymerase mixture was added into each PCR-tube. Then 20 µL of mineral oil were added in each PCR-tube. The tubes were closed tightly .Finally, each tube was opened and 5.0 µL of DNA sample were added into corresponding PCR-tubes, then the tube was closed again before proceeding to the next DNA sample . The tubes were spun for 1–3 seconds to collect the drops.

The tubes were set to Real-time PCR instrument (DNA-TECHNOLOGY, Russia).

Prothrombin A20210G genotyping by REAL-TIME PCR

Statistical analysis: The collected data were tabulated and analyzed by Statistical Package for Social Sciences program (SPSS) software version 20. Descriptive statistics were done for numerical variables by mean, standard deviation, median and interquartile range, while they were done for qualitative variables by number and percentage.

Mann-Whitney test was used to determine the statistical difference between the two groups for normally distributed quantitative variables and independent samples **t-test** for not normally distributed quantitative variables. **Fisher's exact** were used to determine the statistical difference between the two groups for **Prothrombin A20210G gene** variable.

Pearson's and **Spearman's** correlation were used to correlate between different variables. According to (r) ranged from (0±1), the degree of correlation was determined (0-0.24 weak, 0.25-0.49 fair, 0.5-0.74 moderate and ≥0.75 strong). The level of significance was taken at **p value** less than or equal to 0.05 as significant.

Results

All groups in our study showed similar age There was no statistical significant difference between the studied groups as regard age (p=0.08). Frequency of abortion among cases ranged from 2-10 times with mean ± SD 3.6±1.8,while the control group (group II) had no abortion . There was highly statistical significant difference between the studied groups as regarding frequency of abortion (p=0.0001*).

Table (1): Comparison between studied groups regarding HB, WBCs and platelets.

	Group I N=70	Group II N=70	P value
HB: (g/dl)			
Mean ± SD	12.1±0.9	12.4±1.1	0.1
Median	12	12.5	
Range	10-14.8	10-15	
WBCs: ($\times 10^3$/µl)			
Mean ± SD	6.8±2.1	6.5±1.7	0.4
Median	6.7	6.2	
Range	4.-12	4-10.8	
PLT: ($\times 10^3$/µl)			
Mean ± SD	282.5±60	281.5±62	0.8
Median	279.5	283	
Range	167-400	153-400	

Regarding HB, WBC's and platelet count, there was no statistical significant differences were found between the studied groups (p= 0.1,0.4,0.8 respectively).

Table (2): Comparison between studied groups as regarding PC, INR and aPTT.

Group I N=70		Group II N=70	P value
PC:%			
Mean ± SD	93.5±8.4	87.1±9	
Median	99	88	0.0001*
Range	72-100	70-100	
INR			
Mean ± SD	1.04±0.05	1.09±0.07	
Median	1	1.08	0.0001*
Range	1-1.17	1-1.25	
aPTT :(Sec)			
Mean ± SD	30.1±5.9	27.3±3.6	
Median	29.4	27.8	0.008*
Range	18.6-41	17.9-38.6	
PTT.LA: (Sec)			
Mean ± SD	32.9±5.1	30.9±3.5	
Median	33.1	30.9	0.01*
Range	21.3-39.5	22.3-37.9	
D.Dimer:(ng/ml)			
Mean ± SD	40.5±83.9	24±24.8	
Median	9.7	13.5	0.03*
Range	5.3-400	5-106	

Prothrombin concentration in group I ranged from 72-100% with mean ± SD93.5±8.4, In group II prothrombin concentration ranged from 70-100% with mean ± SD87.1±9. There was statistically significant difference between the studied groups (p=0.0001).

INR showed statistically significant increase in group II when compared with group I (p=0.0001).

Activated partial thromboplastin time in group I ranged from 18.6 -41 second with mean ± SD 30.1±5.9. In group II it was ranged from 17.9-38.6 second with mean ± SD 27.3±3.6. There was statistically significant increase in group I when compared with group II as regarding the aPTT (p=0.008).

Partial thromboplastin time lupus anticoagulant

in group I ranged from 21.3-39.5 second with mean ± SD 32.9±5.1. In group II it was ranged from 22.3-37.9 second with mean ± SD 30.9±3.5. Partial thromboplastin time lupus anticoagulant showed statistically significant increase in group I when compared with group II (p=0.01).

D. Dimer in group I ranged from 5.3-400 ng/ml with mean ± SD40.5±83.9, in group II it was ranged from 5-106 ng/ml with mean ± SD 24±24.8 .There was statistically significant increase in group I when compared with group II as regarding D. Dimer (p=0.03).

Table (3) Comparison between both groups as regarding Prothrombin A20210G expression

	Group I N=70	Group II N=70	p value
Pro thrombin A20210G Wild			
G/G	57 (81.4%)	70 (100%)	0.0001*
Heteromutant A/G	13 (18.6%)	0 (0%)	

The expression of prothrombin A20210G was higher in group I in comparing with group II as 13 cases of group I (18.6%) were heteromutant (A/G) while group II were all wild type (A/A). There was statistically significant increase in the expression of prothrombin A20210G mutation in group I when compared with group II (p=0.0001).

We compared HB, WBCs,platelets, PC., INR., aPTT., PTTLA., and D.Dimer between group I subgroups (Ia and Ib) there were no statistical significant difference between group I subgroups (p= 0.5,0.3,0.5 0.4,0.5,0.2, 0.8,0.1)respectively.

Table (4) Comparison between group I subgroups (Ia and Ib) as regarding Prothrombin A20210G expression .

	Group Ia N = 23	Group Ib N = 47	P value
ProthrombinA20210G Wild			
G/G	23 (100%)	34 (72.3%)	0.003*
Heteromutant A/G	0 (0%)	13 (27.7%)	

ProthrombinA20210G mutation was higher in group Ibwhen compared with group Ia as 13 cases (27.7%) of group Ib were heteromutant (A/G) while the group Ia were all wild type (A/A). There was statistically significant increase in the expression of prothrombin A20210G mutation in group Ib when compared with group Ia (p=0.003) .

Discussion

We examined the relationship between unexplained RPL and thrombophilia gene mutations.

Spiral artery thrombosis and infarction occurs, and as a result of these, uteroplacental insufficiency may be the final common pathophysiologic pathway in RM and later pregnancy complications associated with inherited thrombophilia become possible[8].

A central factor of coagulation cascade is coagulation factor II or thrombin coded by prothrombin gene. Its precursor is prothrombin which is cleaved and thus activated through the action of coagulation factor X [(9)]. It may increase the risk for pregnancy loss but many individuals heterozygous or homozygous for the 20210G>A polymorphism never develop thrombosis, while most heterozygotes who develop thrombotic complications remain asymptomatic until adulthood [(10)].

In our study we found that the prevalence of ProthrombinA20210G mutation was higher in the studied cases in comparing with the control group

as 13 cases (18.6%) were heteromutant (A/G) while the control group were all wild type (A/A) and it was statistically significant in cases when compared with the control group (p=0.0001). Although Sehirali et al. [11] found the association between the *F2* 20210A allele and pregnancy loss in Turkish women ($p < 0.05$). AlsoFinanet al.[12] reported that 13.64% of women with recurrent pregnancy loss carried the Prothrombin G20210A mutation, compared to 2.99% carrier rates among control group which was statistically significant. Similarly a study made by Pihuschet al.[13] reported that heterozygous Prothrombin G20210A mutation is more common in patients with abortions in the first trimester.

In our study prothrombinA20210G mutation was higher in group IB in comparing with group IA as 13 cases (27.7%) were heteromutant (A/G) while the control group were all wild type (A/A).This was in agree with Barut M.U. et al[14]who reported that when patients with 2 prothrombin G20210A heterozygous abortions and patients with 3 or more abortions were compared.

In the other hand Pickering et al. [15] reported that the prevalence of the G20210A Prothrombin mutation is not increased in women with recurrent pregnancy loss, although it was only found in women who had suffered early pregnancy losses. Finally, a literature review performed by Ghee et al.[16] claimed that there is no evidence to support an association of Prothrombin G20210A mutation with RM.

Conclusion

Prevalence of prothrombin gene mutations is significantly increased in patients having recurrent miscarriages.

The Institutional Ethics Committee approved this study of the School of Medicine, Minia University, Egypt, and all patients gave informed consent before participation in this study. The study conducted in accordance with the ethical guidelines of the 1975 Declaration of Helsinki and International Conference on Harmonization Guidelines for Good Clinical Practice.

The Role of Trust and Social Networking in the Use of Long Term Contraception Method in Kampung KB

Bella Kartini Rochmania[1], Shrimartirukminidevy[2], Rachmathargono[3], Iswari Hariastuti[4]

[1]Health Promotion and Behavior Sciences, Master Program of Public Health Sciences Faculty of Public Health, Airlangga University, [2]Department of Health Promotion and Behavioral Sciences, Faculty of Public Health, Airlangga University Surabaya, [3]Department of Health Promotion and Behavioral Sciences, Faculty of Public Health, Airlangga University Surabaya, [4]Population Agency and family Planning national representative of East Java, Surabaya, East Java, Indonesia

Abstract

The demographic bonus is a nation's challenge that needs to be managed. Data from the Department of Population Control, Women's Empowerment and Child Protection (DP5A) shows in 2016 the new long term contraception method user in Surabaya City reached 7.70%, in 2017 to 5.16%, and 36.29% in 2018 of the total contraception method participants from every year. The data shows that there is an increase of member oflong term contraception method. The new member of long term contraception method in 2018 is 63.71%, greater than short term contraception method. Utilize of long term contraception method in 2018 is increase, but it cannot compete with short term contraception method especially injection contraceptive method. This research is a descriptive study using a qualitative approach using a phenomenological study approach. Data collection is held at Kampung KB and non-Kampung KB Tambaksari District of Surabaya City. Informants in this study consisted of key informants and informants. Trust and social networking are used as an effort to improve the family planning program in utilizing a long term contraception method at Kampung KB. While trust and social networking have not been utilized to improve family planning program in utilizing a long term contraception method at non-Kampung KB.

Keywords: *trust, social networking, family planning.*

Introduction

Demographic bonus is a nation's challenge that needs to be managed. Indonesian projected population was estimated at 5% every five years. National Medium-Term Development Plan (RPJM) has a target to be achieved at Population Control Family Planning for five years, which is to realize Balanced Growing Population (PTS) with the achievement of Total Fertility Rate 2,1 in 2019[(1)]. It shows that there is a health-oriented development will be carried out by the government to control population growth. Development as an effort for people's welfare in terms of population growth regulation is manifested in reproductive health, one of which is family planning.

The seventh target of Sustainable Development Goals third objective explains that by 2030 ensuring universal access for sexual and reproductive health services, including for family planning, information, education, and integrating reproductive health into strategies and national programs[(2)].

Kampung KB is stands for Kampung Keluarga Bencana (Village of family planning), Kampung KB as a forum that can be used to overcome problems that arise related to an area based on studies that have been identified previously. active participation of the community is key to implementing empowerment. The program incorporated in the Kampung KB as an implementation of the integration of existing programs in improving the welfare of the community. The cross-sector role in the concept of health-oriented development is expected to be able to make a positive contribution to the formation of the environment and healthy behavior.

Data of 2017 SDKI about birth planning based on the age of womans giving birth in 2017 is known that the age of womans is 35-39 years who want to have children 75.2% and have children later 6.4%, the age of 40-44

years old womans who want to have children soon 63,4% and have children then 3,5%, womans aged 45-49 years who want to have children 59,0% and have children later 5,5%[1]. This shows the desire to have children is still high both who want to have children immediately and who want to have children later. Therefore the need for pregnancy planning so that family planning can be achieved. Long term contraception method as an appropriate contraceptive tool to control pregnancies namely implants and Intra Uterine Device (UID).

Data from the Department of Population Control, Women's Empowerment and Child Protection (DP5A) shows that in 2016 the new long term contraception user in Surabaya was 7,70%, in 2017 decrease to 5,16%, and in 2018 there were 36,29% of the total contraception method participants from every year. The data shows that there is an increase in new long term contraception user. The new contraception method user in 2018 is still greater in use at short term contraception method, which is 63,71% of contraception method participants[3]. Participation in the Family Planning Program shows that there needs to be support and further efforts to be able to encourage and improve the achievements of the long term contraception method.

Popularity of the way of work and the effectiveness of the long term contraception method are still lacking compared to short term contraception method. The usage of long term contraception method in 2018 has increased, but it is still less than short term contraception method, especially the method of injection contraception. Based on this background the researchers wanted to descripted more through about the role of trust and social networking in usage of long term contraception method in Kampung KB of Surabaya City.

Materials and Method

This research is a descriptive study using a qualitative approach using a phenomenological study approach. Place of data collection in Kampung KB and non Kampung KB Tambaksari District Surabaya City. Informants in the study consisted of informants and key informants by taking data through indepth interviews. Data analysis techniques through the process of selection, focusing, simplifying, and abstraction that is done during the research process takes place through the selection of data. So, the data can be more concise and can be classified in one or more patterns. Drawing conclusions through data triangulation in the form of focus group disscussion.

Result

Each couples of reproductive age has a person who is trusted in obtaining information about family planning. Couples who use long term contraceptive method believe that the person who provided the information needed. The following are statements from several informants:

"Cadres who understand about family planning have experience here. Initially I consulted about complaints using injection contraception method. Then the cadre suggested giving an IUD. I got an explanation from the cadres. Cadres in this village also did not hesitate to assist couples who wanted to use contraception" (W1).

"Cadres are trusted people who provide information about family planning. Because cadres have experience handling family planning. The cadre assured me not to be afraid to use the implants, and this was an comfort birth control program" (W2).

Most of couples are aware that family planning is needed, especially financial and physical readiness that can affect to their life. Traditions that have been expanded by the generation in the selection of contraception make couples used to be a role model. Couples makes succes of the family planning program by helping people who want to use the long term contraception method as a form of maintaining tolerance.

Short term contraception method informants in non-Kampung KB claimed that the cadre leader had convinced to use long term contraception method in cadre associations only. The informant's fear was because some friends who had been asked about the IUD had failure of that device that caused an unplanned pregnancy. This makes informants not use contraceptives, especially long term contraception method. Other reasons for not using contraception are incompatibility with previous contraceptive device and fear of using other contraceptives. The following supporting quotes are based on discussion forums:

"Sometimes at PKK group meetings there is a information about the installation of contraception is free of charge. Leader of PKK gave that information about free charge of contraception, but rarely gave out information of contraceptive method. I have never known information about family planning" (SK, FGD7).

Trust in long term contraception method in couples can be obtained based on knowledge. Couples knowledge comes from information held through

learning or experience from others. Couples who do not use long term contraception method have no knowledge about long term contraception method. Family planning counselors from DP5A said that popular contraceptive method in the community are pills and injection contraception. Couples feel embarrassed and afraid to use long term contraception method. Challenges in the selection of contraceptives were also conveyed by DP5A Surabaya that indeed the use of contraceptives in the community requires attention. The selection of the right method is promoted through the Kampung KB's program. Following are supporting statements from key informants:

"The main thing is that trust needs to be utilized as a strength in society. Special attention is needed so that people can choose the right method. Most people, carelessly choose the method of contraception. The common ones are injections, pills, that's all. From the data, we can see interest in method for short-term contraception method is more than long-term contraceptive method, especially injection" (HAI).

Community organizations or groups that exist in the Kampung KB are able to provide easy access to all couples regarding long term contraception method. Most informants mentioned that there are community associations that often discuss about family planning at the Posyandu at the Family Empowerment and Welfare Association (PKK: Pemberdayaan dan KesejahteraanKeluarga). In addition to explaining the choice of contraception, socialization also facilitates the data collection of Couples who want to use the long term contraception method. The following is a supporting statement from informan:

"There is a family empowerment and welfare group, the PKK, and also a Posyandu, usually the leader of the small group of family (RT: RukunTetangga) and their cadres. Every 1 month there is a PKK meeting and it is always announced about family planning. Those involved in the selection of contraceptive method are cadres, leader of medium group of family (RW :RukunWarga), and of course couples who want to use an IUD and implants. Cadres also often collect data door to door at their neighbours and offer couples to use longterm contraception method" (W4).

Whereas community organizations or groups in the non-Kampung KB just giving of information when they need to carried out surveillance of free of charge of contraception installation. Short term contraception method informants mentioned that they had never used and knew of the failure of family planning in their social networks, so they were not satisfied. Non contraception method participant informants also conveyed the same thing related. Non contraception method participant social network that has experienced a case of family planning failure. Social networks in non-Kampung KB have not been utilized in an effort to increase the use of long term contraception method. The following is a quote that supports the statement:

"Usually during PKK meetings, cadres provide information on who wants to use implantable contraceptive method and IUD. Just like that, so offer installation of contraceptive method. Nothing is explained again" (WA2).

Family planning counselors stated that there were differences in family planning activities. The Kampung KB often gets program exposure. Whereas program in non-Kampung KB is less than the KB family. Following the supporting statements from key informants:

"Indeed different. In the Kampung KB, they have active cadres, the family planning program is indeed focused there. That's why in Kampung KB there is more exposure to the community. Kampung KB receives funds that are used to provide stimulus through a series of activity agendas to solve problems in the village. Many activities carried out in the Kampung KB such as monitoring, meetings, and various cadre support training. This is one of them being used to accelerate the use of long-term contraceptive method in couples" (NIM).

Discussion

The use of long term contraception is an effort to manage pregnancy plan in family planning. Pregnancy planning needs to be done so that pregnancy becomes the desired process and is carried out with good planning. The use of long term contraception method is also like using other contraceptives as a preventive program in family planning so that it can reduce the number of deaths due to problems in pregnancy, childbirth, and unsafe abortion, prevent pregnancy too early, and distance the pregnancy[4].

Trust as a dimension in social capital has a role in providing the value of mutual trust between community members and the community. Trust is the determinant

of social relations, as the smallest belief needed to start social interaction. The role of trust is decisive in social society.

Couples beliefs in family planning programs related to long term contraception method consist of feelings of identity of trusted people, belief systems, expectations, and performance of people who provide information about family planning. Each couples has a person who is trusted in obtaining information about family planning. Couples in the Kampung KB will seek information about family planning in the cadre. Couples seek information from that person because they are considered to have experience and understand more about family planning. Whereas the non-Kampung KB also has a trusted person, namely the neighbors. Trust can arise by believing that the person can provide the information needed. The role of trust in as a bridge in determining expectations and goals to be achieved is obtaining information.

Other research states that cadres are workers from the community, chosen by the community, and work voluntarily to foster and improve community welfare. The role of family planning cadres is to carry out the processing and guidance of population and family planning programs at the village level or below[5].

Theory states that trust is a cognitive component of socio psychological factors. Belief in this case is the belief that something is right or wrong. Trust is often rational and irrational. Trust is formed by knowledge, needs, and interests[6]. Other research states that there is a relationship between knowledge and the choice of contraceptive method[7].

Information obtained with complete confidence can be a reference in choosing a contraceptive method. The trust of cadres in long term contraception method users that the information obtained becomes trusted information. Couples trust is used as a strength in organizing family planning programs in Kampung KB.

The source of the strength of social capital is the ability of a group of people to build associations and the way people in an organization or associations involve themselves in a network of social relations[4]. Social network will strengthen the cooperation of members and benefit from the participation of its members. High levels of community participation in the courage to argue with their leaders and the many residents who use the opportunity to deliver their aspirations[8].

Couples who use Long term contraception method are satisfied because they feel the benefits gained. While short term contraception method and non used contraception method user were not satisfied with the existence of long term contraception method. Social networks in social capital as a strong source in both Kampung KB and non-Kampung KB. Community activities are known to provide easy access to family planning services, especially long term contraception method. The free long term contraception method program is an effort to bring people closer to becoming acceptors. This access is known by most informants, especially women of reproductive age.

The ability of the community in a group to work together to build a network to achieve common goals. Social capital places more emphasis on group potential and is an important variable in achieving public health[9]. The source of the strength of social capital is the ability of a group of people to build associations and the way people in an organization or associations involve themselves in a network of social relations[4]. Couples who are in Kampung KB know that in village activities such as the family welfare empowerment movement (PKK) and Posyandu they are always informed about free method of implant and IUD. Even cadres did not hesitate to deliver prospective acceptors directly to health services. Whereas the women of fertile age in non-Kampung KB who are better informed through PKK activities or who are cadres can get it from the cadre management association. Whereas in non-Kampung KB the existence of social networks has not been utilized in increasing the use of long term contraception method.

Suggestion: Couples of reproductive age has trust in others about the use of long term contraception method. Trust is influenced by the knowledge possessed. Social networks in the community are resources that can be used for family planning programs, specially the use of long term contraception method. Trust and social networking are used as an effort to improve the family planning program in the use of couples in the Kampung KB. While trust and social networking have not been utilized in improving family planning programs in the use of couples in non Kampung KB.

Acknowledgments: On this occasion the author would like to thank the informants, key informants, and discussion participants who have honestly explained in depth and have taken the time for in-depth interviews and discussions.

Conflict of Interest: All authors have no conflicts of interest to declare.

Source of Funding: Personal researcher and assistance research funding from the National Population and Family Planning Institute Representative in East Java Province.

Relationship among Cervical Cancer Risk Factors with Pap Smear Results in Medan North Sumatera

Diah Lestari Nasution[1], Fatwa Imelda[1]

[1]Faculty of Nursing, Universitas Sumatera Utara, Medan, Indonesia

Abstract

Objects: To identify relationship among cervical cancer risk factors with pap smear results in Medan North Sumatera.

Method: The study was a correlative descriptive. The samples were 60 respondents. Data were collected using a questionnaire and analysis using the Chi Square test at an error rate of 0.05.

Results: The result showed that there were no significant correlations among education (p>0.484), employment (p>0.329), age at first sexual intercourse (p>0.410), history of pregnancy (p>0.204), and use of vaginal cleansers (p>0.569) with the results of pap smears. There was a significant between using contraceptive with pap smear results with p-value 0.00 (p<0.004).

Conclusion: It is hoped that women need increase the knowledge about the importance of early detection of pap smear examination in reducing the number morbidity and mortality of cervical cancer in Indonesia.

Keywords: *Cervical Cancer, Risk Factors, Pap smear.*

Introduction

New cases of cervical cancer are the number one most attacking the reproductive health of women in Indonesia. Cervical cancer ranks second as the leading cause of death due to reproductive age in developing countries. In Indonesia there are 15,000 new cases with 8,000 deaths annually. This cancer is the most common cancer in Indonesian women. This cancer appears without causing symptoms and is very difficult to detect so that the disease is often diagnosed at an advanced stage [(1)].

In Indonesia, the prevalence of cancer is also very high. The prevalence of tumors/cancer in Indonesia is 1.4 per 1000 population, or around 330,000 people. The highest cancers in Indonesia in women are breast cancer and cervical cancer. The incidence of cervical cancer in Indonesia is 17 per 100,000 women[(2)].

In the early stages, symptoms that arise such as menstrual disorders, vaginal discharge, vaginal bleeding outside the menstrual period, complaints of pain in the lower abdomen, bleeding during sexual intercourse, and infection of the bladder tract. If this continues at a higher stage, the patient will feel pain in the pelvic area, bleeding that smells fishy, lost appetite, drastic weight loss, and anemia with bleeding[(3)].

To reduce the morbidity and mortality of cervical cancer prevention efforts need to be made, which consists of several stages, namely: 1. Primary prevention carried out at this stage is the promotion, education and vaccination of HPV (Human Papilloma Virus). 2. Secondary prevention is early detection. 3. Tertiary Prevention is treatment for cases that are found in early detection and prevent complications and early death[(4)].

The problem of the high incidence of cervical cancer in Indonesia is due to the lack of cervical cancer screening measures, namely cervical cytology and acetic acid reviews, late diagnosis at an advanced stage, general weakness, low socioeconomic status, limited resources, limited facilities and infrastructure, the type of histopathology, and the degree of education involved in determining the patient's prognosis[(5)].

Prevention of cervical cancer can be done by minimizing the existing risk factors by familiarizing yourself with a healthy lifestyle, making early detection

by doing a pap smear for women who are sexually active. Therefore the earlier the early symptoms of cervical cancer are known, the easier the treatment and treatment [6].Early detection in Indonesia is done by pap smear tests, colposcopy, ginescopy, cervicography, speculoscopy, autoion (IVA) inspection method. Pap smear test coverage is estimated to be less than 5%. To fulfil tmated screening cytology, liquid based cytology/ thin prep, HPV tests and visual acetate acid inspecthis, an alternative Pap smear test with IVA is sought, which is expected to get wider coverage[7].

Pap smear is a simple and quick examination to determine the presence of abnormal cells in the cervix by taking a smear of cells in the cervix, and then examined under a microscope to see whether or not the cells are abnormal. This examination can be done at any time, except during menstruation. All women who have had sexual intercourse are encouraged to have regular Pap smears, once a year/at least 3 years. For women who have gone through menopause, a Pap smear can be done until the age of 65 years[8].

Method

This study used a cross sectional study design with a study design by measuring or observing research subjects at the same time or once, measurement of independent variables (education, employment, age at first sexual intercourse, history of pregnancy, use of vaginal cleaners and using contraceptive) and the dependent variable (results of Pap smear) without a repeat visit. This type of research is "descriptive correlative", which is research that aims to explain the relationship, estimate, test based on existing theories. In this study, researchers used a consecutive sampling technique with a total of 60 respondents. Data were analyzed by using the Independent T Test.

Results

Table 1. Frequency distribution base on variables

Variables	Frequency normal pap smear	%	Frequency abnormal pap smear	%	Frequency sample	%
Educations						
Junior high school	1	1.7	0	0	1	1.7
Senior high school	19	31.7	17	28.3	36	60
College	9	15	14	23.3	23	38.3

Table 1. Shows that the majority of samples with a history of high school education were 36 samples (60%) with normal pap smear results of 19 people (31.7%) and abnormal pap smear results of 17 people (28.3%).The majority of samples with work history as housewives were 48 people (80%) with normal pap smear results of 23 people (38.3%) and abnormal pap smear results as many as 25 people (41.7%).The majority of samples with a history of first sexual intercourse, namely the age of 17-25 years were 44 people (73.3%) with normal pap smear results of 20 people (33.3%) and abnormal pap smear results of 24 people (40%). The majority of samples with a pregnancy history of 2 children were 21 samples (35%) with normal pap smear results of 10 people (17.5%) and abnormal pap smear results of 11 people (18.3%).The majority of samples with a history of using non contraception were 46 samples (76.6%) with normal pap smear results of 26 people (43.3%) and 20 abnormal pap smear results (33.3%). The majority of samples with a history of using vaginal cleaner did not use as many as 43 people (71.7%) with normal pap smear results as many as 22 people (36.7%) and abnormal pap smear results as many as 21 people (35%).

Table 2. Relationship among cervical cancer risk factors with pap smear results

Model	Unstandardized Coefficients		Standardized Coefficients	T	Sig.
	B	Std.Error	Beta		
(Constatnt)	3.326	1.347		2.469	.017
Education	.037	.108	.051	.341	.734
Employment	-.149	.116	-.301	-1.288	.204
Age at first sexual intercourse	-121	.145	-.122	-.830	.410
History of pregnancy	.112	.093	.295	1.207	.233
Using contraceptive	-.278	.091	-.395	-3.041	.004
Use of vaginal cleaners	-.082	.143	-.074	-.574	.569

Table 2. Shows that the relationship of education with pap smear results with a t value of 0.705 and Beta value of 0.108 and a significant level of 0.484 means greater than 0.05 (p> 0.05) means that there was no significant relationship between education with pap smear examination results. Shows that the relationship of work with Pap smear results with a value of t = -0985 Beta value -0.156 and a significant level of 0.329 means greater than 0.05 (p> 0.05) means that there was no meaningful relationship between pap smear results. Shows that the relationship between age of sexual intercourse with the results of pap smear with a value of t = -0,830 Beta value -0.122 and a significant level of 0.410 means greater than 0.05 (p> 0.05) meaning that there was no meaningful relationship between age of having sex with pap smear results. Shows that the relationship between pregnancy history and pap smear results with a value of t = 1,207 Beta value of

0.295 and significant level of 0.233 means greater than 0.05 (p> 0.05) meaning that there was no significant relationship between pregnancy history and pap smear results. Shows that the relationship between the use of vaginal cleansers with Pap smear results with a value of t = -0.574 Beta -0.074 value and a significant level of 0.569 means greater than 0.05 (p> 0.05) means that there is no significant relationship between the use of vaginal smears with Pap smear results. Shows that the relationship between contraceptive use and pap smear results with a value of t = -3.041 Beta value -.395 and a significant level of 0.004 means greater than 0.05 (p> 0.05) means that there is a significant relationship between the use of contraception with pap smear results.

Discussions

The results of this study obtained the majority of educated middle and above so the results obtained that the relationship of education with pap smear results with a significant value of 0.484 means greater than 0.05 (p> 0.05) meaning that there is no significant relationship between education with pap smear examination results. Based on supporting theories, research results, and previous research, the researcher believes that the higher the level of formal education, the better the mother's knowledge, especially about pap smears.

The relationship of work with the results of Pap smear with a significant level of 0.329 means greater than 0.05 (p> 0.05) meaning that there is no significant relationship between work with Pap smear results. Housewives are light work that is small at risk of cervical cancer, whereas heavy work that is at risk of cervical cancer can be seen from the results of pap smears, where women who work as manual laborers and farmers show a greater chance of developing cervical cancer than women who work light workers like housewives stairs.

The results of this study indicate the majority of samples with a history of age having first sexual intercourse, namely the age of 17-25 years with the majority of pap smear results abnormal. In accordance with the etiology of the infection, women who start sexual intercourse at a young age will increase the risk of cervical cancer because cervical columnar cells are more sensitive to metaplasia during adulthood, women who have sex before the age of 18 will be five times at risk of cervical cancer [(9)]. At a young age, mucosal cells in the cervix are immature. That is, still vulnerable to stimulation. So it is not ready to accept stimuli from the outside. Including chemicals carried by sperm. Mucosal cells can change the nature of becoming cancerous where mucosal cells are no longer too susceptible to change [(10)].

The results of this study indicate the majority of pregnancy history as much as 2 times with a significance level of 0.233 meaning greater than 0.05 (p> 0.05) meaning that there is no significant relationship between pregnancy history with pap smear results. A woman who often gives birth (many children) belongs to a high risk group for cervical cancer, the higher the parity of the mother, the less good the endometrium. This is caused by reduced vascularization or atrophic changes in the decidua due to past labor, which can lead to complications in the reproductive organs. With the frequent birth of a mother, it will have an impact on the frequent occurrence of injury to her reproductive organs which ultimately the impact of the injury will facilitate the emergence of Human Papilloma Virus (HPV) as a cause of cervical cancer.In line with the results of Hidayat study, that parity of more than> 3 is 16.03 times at risk of developing cervical cancer than people who have a number of parities <3[(11)].

Women with high parity associated with cervical columnar epithelial eversion during pregnancy which causes new dynamics of immature meta-plastic epithelium that can increase the risk of cell transformation and trauma to the cervix making it easier for HPV infection. Dangerous parity is to have children more than 3 or the distance of pregnancy is too close, it is because it can cause changes in abnormal cells in the cervix that can develop into malignancy[(12)].

According to ACS women who have experienced 3 or more pregnancies in the full term have an increased risk for cervical cancer. Research has shown that hormonal changes during pregnancy may make women more vulnerable to HPV infection or cancerous growth[(13)].

The results of this study indicate that the majority of samples with a history of non-family planning contraceptive use. The use of hormonal contraception for more than 4 or 5 years can increase the risk of cervical cancer 1.5-2.5 times[(14)].

According to ACS states that the risk of cervical cancer is doubled in women who take birth control pills for more than 5 years, but the risk returns to normal 10 years after they stop. Combined oral contraceptives are a mixture of synthetic estrogens such as ethinylestradiol

and one of several C19 steroids with progesterone activity such as noretindron. This contraception contains a fixed dose of estrogen and progesterone. The use of estrogen can be risky because it stimulates the thickening of the endometrial walls and stimulates endometrial cells so that it changes properties[13].

The results of this study found a significant level of 0.569 means greater than 0.05 (p> 0.05) meaning that there is no significant relationship between the use of vaginal cleansers with pap smear results. A healthy vagina must contain Lactobacillus bacteria, which is a good bacterium to maintain the acidity of the vagina so that germs do not easily infect. The habit of using vaginal fluid (douching) will eradicate the Lactobacillus bacteria, so that the vagina is more susceptible to infection. One of them is a Human Papilloma Virus (HPV) infection, which causes cervical cancer[15].

Pap smear examination should be done routinely and regularly on women who have sexual intercourse, Pap smear examination is the easiest and cheapest way to detect cervical cancer early. This examination can be done in the menstrual cycle, during childbirth or post-miscarriage which can be done at any time and can be done on women with suspected or known STI or HIV/ AIDS.

Conclusion

The result showed that there were no significant correlations among education (p>0.484), employment (p>0.329), age at first sexual intercourse (p>0.410), history of pregnancy (p>0.204), and use of vaginal cleansers (p>0.569) with the results of pap smears. There was a significant between using contraceptive with pap smear results with p-value 0.00 (p<0.004).

Suggestions: Increase education and health promotion activities on cervical cancer prevention by holding seminars or examinations of cervical cancer detection in the form of Pap smear examination, IV examination and IHC examination.

Hair Mercury Exposure and Hypertension among Community Artisanal and Small Scale Gold Mining in Banten, Indonesia

Budi Hartono

Department of Environmental Health, Faculty of Public Health, Universitas Indonesia, 16424 Depok, Indonesia

Abstract

Background: Mercury was a heavy metal that persistent in the environment and harmful to human health and still used by Artisanal Small Scale Gold Mining (ASGM), especially in Indonesia. Cimanggu was one of ASGM in Banten province who still active using mercury and had found high levels of mercury that exceed the threshold in wastewater and human hair. Mercury exposure can affect human health, such as hypertension. This research aimed to determine the levels of hair mercury, hypertension, and individual characteristics such as age, sex, and smoking habits. And also determine the association between hair mercury with hypertension among communities in ASGM.

Material and Method: Design studies in this research using cross-sectional design. The data from BBTKLPP Jakarta datasheet "Analysis of Potential Impact of Risk Factors Environment Based for Disease Outbreaks on Interest Mining Society". Retrieved data was hair mercury that analyzed in the laboratory BBTKLPP Jakarta using Mercury Analyzer (MA) 3000 with cold pavor method and blood pressure were measured directly two times using sphygmomanometer merk ABN and individual characteristics taken through a questionnaire. Totaling 100 samples analyzed were taken by quota sampling.

Findings: Univariate test showed that most of the respondents had abnormally hair mercury levels (55%), hypertension 29%, woman 78%, smoking 23%, and > 40 years 46%. Chi-square test showed no significant association between hair mercury levels and hypertension (P value=1, OR= 1.01, 95% CI = 0.42-2.40).

Conclusion: Respondents who had normal or abnormally hair mercury levels had the same odds to have hypertension risk. Further research is needed by using a larger sample with high-intensity process mercury use to clarify the association of hair mercury levels with hypertension.

Keywords: *Mercury; hypertension; Artisanal and Small Scale Gold Mining (ASGM).*

Introduction

Mercury emissions in the environment can from human activities such as fossil fuels burning, solid waste burning, and Artisanal Small Scale Gold Mining (ASGM)[1]. In the ASGM, mercury used to extract gold from the seeds by forming an amalgam. The widespread of mercury use in ASGM because simple to use, can be done individually, and relatively quick to separate the gold. Globally around 15 million people, including 3 million women and children participate in ASGM in 70 countries[2]. Based on the survey results consisting of 800 ASGM in Indonesia with estimated 250,000 miners and 1 million, whereas women and children[3]. ASGM had an increase in Indonesia. It's in line with many studies have shown that mercury pollution has occurred the sea, sediments, water wells, fishes, plants, and communities have an impact on public health[4–6]. Such as Hartono research which found mercury exposure in fish in Buyat Bay and Teluk Ratotok which has improved health for people who consume air from the Ratotok River Estuary,

e-mail: butoniv73@gmail.com, budi_h@ui.ac.id

Buyat River Hulu, and clean water/drinking water storage PT. Newmont Minahasa Raya[7]. The results of a study conducted in ASGM Gorontalo showed that the concentration of hair mercury respondents had exceeded the established standard of 2 with an average concentration of hair mercury in 5.0480 ppm[8].

ASGM donate 37% of mercury emissions in air and water. Mercury vapor present in the air around ASGM always high and the mercury pollution in water almost exceeds the quality standards by WHO. Continuously exposure can affect the central nervous system, the reproductive system and the cardiovascular system[2].

The last few years, the impact of mercury on the cardiovascular system, especially hypertension has become a concern. Hypertension has been proved as a major risk factor for cardiovascular disease triggers. The incidence of hypertension has increased for the last three decades. Besides food consumption which high salt intake and obesity, exposure to mercury in the environment also one important factor driving the incidence of hypertension. Epidemiological and experimental studies showed association between mercury exposure and increased blood pressure. Chronic mercury exposure levels in humans can be determined by examining the hair biomarker are considered most suitable for chronic exposure, easy to collected, and non-invasive[9]. Several studies in the world showed an association between mercury exposure to increased blood pressure among the gold miners who use mercury were found significant increased sistolee blood pressure ($P < 0.01$) correlated with lipid peroxidation and oxidative stress ($P < 0.01$)[10].A case-control study showed the incidence of gold miners who have hypertension 46% greater than the control group. Other studies showed that a significant correlation between hair mercury levels with hypertension[11].A study of 251 people in the Brazilian Amazon showed that blood pressure was associated with higher levels of total mercury in the hair where an increased in blood pressure sistolee along with the increased amount of mercury in the hair of <10 lg/g[12]. In Indonesia research about association between hair mercury exposure with hypertension is still not received attention by researchers.

This research aims to determine the levels of hair mercury, blood pressure as well as individual factor characteristics (age, sex, and smoking habits) and determine the association between hair mercury with hypertension in communities around ASGM Cimanggu, Pandeglang, Banten Province. Cimanggu was an area of the ASGM who around a residential area that still used mercury to gold processing and has operated for approximately eight years. Balai Besar Teknik Kesehatan Lingkungandan Pengendalian Penyakit (BBTKLPP) Jakarta in 2017 had found mercury in wastewater in the processing of gold and mercury hair on people living around ASGM above the predetermined quality standards[13].If it continuously happened could have a negative impact on human health one of hypertension disorders due to exposure to mercury.

Material and Method

This study was conducted using a quantitative method with cross-sectional study design and use secondary data derived from datasheet "Analysist of Potential Impact of Risk Factors Environment Based for Disease Outbreaks on Interest Mining Society" conducted by BBTKLPP Jakarta. This research will describe mercury levels in the hair and it's association with hypertension in community living around ASGM, Cimanggu, Pandeglang, Banten.

The population in this study was communities who live around ASGM in Cimanggu with total of 5442 people, the samples in this study were communities who selected based on inclusion criteria among men or women have equal opportunity to participate, length of stay ≥1 year around ASGM, in good health and willing to become respondents signed an informed consent. Calculation of sample size using the formula Lemeshow sought, in order to obtain a maximum sample is 100 sample. Sampling was conducted using quota sampling.

This study will use Univariateanalysist to describe Hair mercury level, blood pressure, and individual characterictics respondents, and bivariate analysist used a chi square test to show association between hair mercury with hypertension. Hair mercury analyzed in the laboratory BBTKLPP Jakarta using Mercury Analyzer (MA) 3000 with cold pavor method and blood pressure were measured directly two times using sphygmomanometer merk ABN and individual characteristics taken through a questionnaire.

Findings: Based on Table 1 showed that of the 100 respondents who checked his blood pressure, only 29% who have hypertension, that was systolic≥140 or diastolic pressure ≥90[14]. Respondents who had hair mercury levels above the quality standards that have been established by UNEP (2 ppm) is 55%. Individual

characteristics show that respondents >40 years old only 46%, which wasman 22%, and smokers only 23%.

Table 1: Distribution of Hair Mercury, Hypertension, and Individual Characteristics Around ASGM in Cimanggu 2018

Variables	Total	Presentation (%)
Hypertension		
No (<140/90)	71	71
Yes (≥140/90)	29	29
Hair Mercury Levels		
Normal (≤ 2ppm)	45	45
Abnormally (> 2ppm)	55	55
Age		
≤ 40 years	54	54
> 40 years	46	46
Gender		
Woman	78	78
Man	22	22
Smoking Status		
Do Not Smoke	77	77
Smoking	23	23

The association showed There is no association between hair mercury levels and hypertension (P-value=1, OR= 1.01, CI 95%= 0.42-2.40). OR=1.01 that means respondents with abnormally hair mercury level have equal odds to have hypertension with normally hair mercury with 95% confidence interval hair mercury respondents between 0.42-2.40 ppm. Mercury exposure in society was measured using hair as a biomarker because can explain mercury levels long term in the body, hair mercury also quite persistent even not lost when washing with shampoo and coloring, and hair mercury levels 250 times in blood[15]. Hair will be examined using Mercury Analyzer (MA) 3000 and cold vapor method with the results of measuring parts per million (ppm) with quality standards set by UNEP (2 ppm)[16].

The analysis showed most of the respondents have hair mercury level abnormally. Abnormally hair mercury level in ASGM communities related to their exposure to mercury from combustion processes and the separation of gold which exposes humans through intermediary of water, air, and land for a long time, in additionally the hair shaft grows to combine mercury from the blood[17]. This result same with previous studies conducted around ASGM in KruengSabee, Aceh, 90.28% of respondents contains mercury levels above the quality standard value 10 μg/g set by the WHO. Fillion found 67.9% of the population living around the Amazon River containing hair mercury levels ≥ 10 mg/g[12].

Hypertension was defined as increasing systolic blood pressure or diastolic after at least 2 times measurement. Hypertension in this study defined as blood pressure that had systole pressure of 140 mmHg or diastolic pressure of 90 mmHg[14].This study showed just a few respondents with hypertension. This result was lower than research conducted by Valera et al. that showed 53.9% of people living around the mining have hypertension[18]. And about 46% of miners in Europe have hypertension[10].Many factors can lead to hypertension such as age, sex, smoking, obesity, lack of exercise, excessive salt consumption, and stress[19]. And from this research, we can show that most of the respondent had a low risk of hypertension, because most of the respondents were woman, ≤ 40 years and do not smoke.

In this study showed no significant association between hair mercury levels and hypertension with OR = 2.072. It's not in line with Bautista et al. where people with high levels of hair mercury was four times more at risk for hypertension (p value= 0.02)[17]. The same results also proved by Fillion et al. and Valera who reported a positive association between mercury levels and hypertension[12,20]. In recent years there had increased attention to mercury effects on cardiovascular system like atherosclerosis, cardiac arithema, and renal dysfunction[21,22]. The mechanism of mercury affecting blood pressure cannot be explained with certainty, but the accumulation of mercury can affect endothelial function by inhibiting NO synthesis[23]and increasing oxidative stress, lipid peroxidation, and TNFα and interculin[17,24,25]. Increased oxidative stress from lipid peroxidation and decrease in antioxidants can trigger endothelial and renal dysfunction, which can increase the risk of hypertension and atherosclerosis, and result increase in blood pressure and pulse[22,23,25].

The same result with this study showed by Rajaee who cannot found association between mercury levels with blood pressure around communities ASGM[26]. The lack of association between hair mercury levels with hypertension because there had many factors causing hypertension behind mercury contaminants such as age, smoking, obesity, alcohol consumption, high natrium consumption, and low physical activities[27]. Besides that small sample size and low hair mercury levels can effect significance result study. Therefore need further

verification by using a larger sample with high intensity process mercury use. Although statistically there's no association between hair mercury and blood pressure, mercury exposure continuously for a long time can had a negative impact on health, one of them is hypertension, so monitoring of mercury use in ASGM areas should be monitored and conducted routine health monitoring in the community around ASGM.

Conclusion

The study concluded that most of (55%) respondent had abnormally hair mercury level, but only 29% had hypertension with the characteristics age >40 years old 46%, man 22%, and smoking 23%. There's no significant association between hair mercury and hypertension (p value = 1) with OR = 1.01 means respondents with abnormally hair mercury level have equal odds to have hypertension with normally hair mercury.

Conflict of Interest: The authors declare they have no conflict of interest.

Abstract

Radiation induced dermatitis is a significant adverse effect of radiation therapy occurring in the majority of patients treated with this modality such as mastectomy. No standard treatment has been recommended for the prevention of this side effect. This article is a report of a study evaluating the effect of Aloe Vera gel on severity of radiation induced dermatitis among patients after mastectomy. A time-series nonequivalent quasi-experimental research design was utilized, hence, a convenient sample of 132 adult female patients receiving radiation therapy after mastectomy were equally assigned randomly to either a study or a control group. Data were collected using two tools: 1) Demographic and Medical Data Sheet, and 2) Radiation Induced Skin Reaction Assessment Scale (RISRAS). The study results revealed statistical significant reduction in radiation induced dermatitis severity scores among the study group compared to the control group. It was concluded that the use of Aloe Vera gel is effective in reducing the severity of radiation induced dermatitis among patients after mastectomy.

Keywords: *Aloe Vera Gel; Radiation Therapy; Radiation Induced Dermatitis; Mastectomy.*

Introduction

Radiation therapy is one of the main modalities in the management of breast cancer; along with chemotherapy and surgery to provide maximum damage to tumor cells.[1] Despite new improvements in irradiation skin-sparing techniques, most patients still experience a variety of short-term and long-term side-effects. Radiation induced dermatitis is a prominent clinical problem that affects the majority of patients receiving radiation therapy.[2]

Radiation induced dermatitis is defined as "an acute or chronic inflammation of the skin caused by exposure to radiation therapy". This reaction is a result of radiation therapy disrupting the normal process of cell division and regeneration in the basal cell layer of the skin, resulting in cell damage or cell death. [3]Acute radiation induced dermatitis exhibit varying degrees of severity, including erythema ranging from mild to severe, followed by dry desquamation which may proceed to moist desquamation and necrosis. These side effects interfere with quality of life, patient compliance, and may cause treatment cessation.[4]

The severity of the radiation induced dermatitis depends on many factors including; treatment-related and patient-related factors. Treatment-related factors include higher total dose, higher dose per fraction, the use of concurrent chemotherapy and field size, in addition to patient-related factors such as obesity, older age and chronic sun exposure. [5]

The radiation oncology literature contains no evidence for prevention or treatment of radiation induced dermatitis, so that it remains an unsolved problem.[6] Natural products, especially herbal medicines, have found great attentions in the recent decades to solve this problem as they are assumed to have less adverse effects; it includes chamomile cream, almond ointment, topical vitamin C, calendula cream, corticosteroid cream and Aloe Vera.[7]

Aloe Vera (AV) as a plant-based remedy is cheap, cost-effective and easily available. The pharmacological action of AV gel includes anti-inflammatory, antibacterial, antifungal, antioxidant, immune-boosting and wound healing properties.[8] It also contains vitamins A, C, E, B12 and folic acid. Vitamin C, which is involved in collagen synthesis, increases concentration of oxygen at the wound site because of dilation of blood vessels. Furthermore, AV penetrates and dilates capillaries going to an injured site, which improves healing.[9,10]

The findings of this study might help to improve the quality of patient care and establish evidence based data that can promote nursing practice and research. Therefore, the aim of the current study is to evaluate the effect of Aloe Vera gel on severity of radiation induced dermatitis among patients after mastectomy.

Research Hypothesis:

H: There is statistically significant difference between the severity of radiation induced dermatitis mean scores of the study group participants who receive Aloe Vera gel application when compared to the control group who receive the routine hospital care throughout measurement time.

Method

Selection and description of participants: A convenient sample of 132 adult female patients receiving radiation therapy after mastectomy were included in the current study from the Radiology Unit of a selected university hospital in Cairo, Egypt. Participants were equally randomly assigned to either a study group receiving Aloe Vera gel application or to a control group receiving routine hospital care. All the studied participants didn't receive any medical treatment regimen regarding prevention of radiation induced dermatitis either before or during radiation therapy, except if moist desquamation occurs, then medical ointmentwas prescribed.

The study sample was calculated based on statistical power analysis; considering r =1,α error was 0.05 (one sided), effect size (0.25) and G- power version 3.1.1, the power at 95%, the sample size for each group would be 66 participants.

Inclusion and exclusion criteria: Participants having the following criteria were eligible to participate: (1) Undergo radiation therapy after modified radical mastectomy through linear accelerator and receiving fractionated dose of 2 Gray, (2) Not sensitive to natural AV gel or its products. While exclusion criteria were:(1) Co-morbid disease as diabetes mellitus, hypertension, infectious diseases, auto-immune diseases, (2) Presence of skin diseases in the radiation area, (3) Anemic patients, (4) Old age (more than 60 years), (5) Previous exposure to radiotherapy on the present irradiated area, or concurrent chemotherapy.

Data Collection tools: Two adapted tools were utilized to collect data pertinent to study variables. The first one was Demographic and Medical Data Sheet; it was designed by the researchers to collect the baseline characteristics of the participants such as age, marital status, education and duration of disease.

The second tool was Radiation Induced Skin Reaction Assessment Scale (RISRAS) to measure radiation induced dermatitis severity.[11] Cronbach's alpha of this tool was 0.95. It consisted of two parts: **Part 1:** Signs of radiation induced dermatitis, **Part 2:** Patient symptoms of radiation dermatitis**.**

Part1: Health care professional visual assessment ***(Radiation induced dermatitis***) scale. This include four observations to measures the extent and severity of erythema, dry desquamation, moist desquamation, and necrosis. The total scores of this part ranged from 0–16. Score zero was assigned for no dermatitis, score 1 ≤ 4 represent mild dermatitis **(Grade 1),** score 5 ≤ 8 represent moderate dermatitis **(Grade 2)**, score 9 ≤ 12 represent severe dermatitis **(Grade 3)** and score 13 ≤16 represent life threatening condition **(Grade 4).**[12]

Part 2: ***Patient symptoms scale.*** .It is composed of four questions which focus on skin tenderness, itching, burning, and functional activity with four-point likert scale responses quantifying symptoms reported by patients started from 0-3.

The total scores of this part (2) ranged from **0-12**. Score zero was assigned for no symptoms, score from **1 ≤ 4** indicate mild symptoms, score from **5 ≤ 8** indicate moderate symptoms, and score from **9 ≤12** indicate severe symptoms.

Scoring system of Total RISRAS: The summation of health care professional assessment scale scores 0-16, and total patient's symptoms scale scores 0-12 gives the total combined RISRAS severity scores which, can be expressed in the range of 0-28, with 0 representing no

changes, 1 ≤ 7 represent mild severity, 8 ≤ 14 represent moderate severity, 15 ≤ 21 represent severe and score 22 ≤ 28 represent life threatening condition.

Procedure: The designed study intervention was conducted on three phases; preparatory, intervention, and evaluation phase.

Preparatory phase: Participants who met the inclusion criteria for the study were approached by the researchers; individualized interview session was conducted to collect data related to the demographic and medical data.

All participants were scheduled for 20 fractionated dose of external beam radiotherapy through linear accelerator; it was taken 5 fractionated doses per week (in 5 consecutive days in a week with 2 days rest from radiotherapy each week) for 4 weeks.

Intervention phase: The researchers provided each participant in the study group with an adequate amount of fresh AV gel. Written instructions for usage and storage of AV were provided, as following; Wash the irradiated area by using distilled water and applying AV gel with gentle massage twice daily for 6 weeks starting from first day of radiation session. Aloe Vera gel container should be stored in sterile, dark container in refrigerator for direct use.

Evaluation phase: All participants were followed up for 6 consecutive weeks. Weekly assessment of radiation site was performed using the Radiation Induced Skin Reaction Assessment Scale (RISRAS) for four weeks during radiation therapyand 2 weeks after completion.

Results

Table (1): shows that there were no statistically significant differences at demographic characteristics among the two groups; this means that the two groups of the study were homogenous groups. Furthermore, the highest percentages of both groups were university educated, married, and their age ranged between 40-60 years.

Table (1) Comparison between Study and Control Groups' Demographic Characteristics (N=132).

Variables	Study (n= 66)		Control (n= 66)		Test	P-value
	No	%	No	%		
Age:

Figure (1): Percentage distribution of Study and Control Groups Regarding duration of Disease (N = 132).

Figure (1) Illustrates that the majority of the participants in the study and control groups have disease duration less than one year.

Table (2) demonstrates statistically significant differences between the study and control groups as regard grades of radiation induced dermatitis by the end of 2nd, 3rd, 4th and 6th weeks of intervention. No dermatitis occurred in the first week in both groups. As can be seen from the table, the highest percentage of the participants in the study group had Grade 0; also, there is no observable Grades 3 of dermatitis severity in the study group along the study period compared to the control group.

Table (2) Frequency, Percentage distributions and comparison between the Study and Control Groups Regarding Grades of Radiation Induced Dermatitis along the Study Period (N= 132).

Measurement time	Grades of skin reactions (RTOG-Grades)	Study group (n=66)		Control group (n=66)			
		No	%	No	%	χ^2	p-value

Discussion

The present study findings revealed that the participants were predominately university educated, married, and had age ranged between 40-60 years. Furthermore, there was statistically significant reduction of the mean severity dermatitis scores among the study group when compared to control group, indicating improvement of the radiation induced dermatitis severity condition in the study group after AV gel application.

This finding is supported by several studies that demonstrates Aloe Vera as an anti-inflammatory, moisturingin addition to the pharmacological actions which include antibacterial, antioxidant, immune-boosting and wound healing properties.[9,10,13,15] Also it was founded that the severity of dermatitis was significantly reduced among the study group who applied Aloe Vera gel at the radiation site.[5,7,13,15]

The results of this study might be interpreted in the light of the fact that the application of Aloe Vera natural gel increases the collagen content of the wound and also alters the collagen composition, increasing the collagen cross linking. It improved wound healing by increasing blood supply and increasing oxygenation, which results in increased fibroblast activity and collagen proliferation. The most important component of AV gel is the polysaccharide acemannan, which reduce opportunistic infections, and stimulates wound healing, and also it has anti-inflammatory action; carboxypeptidase, which inhibits prostaglandin synthesis and arachidonic acid, thus it is a potent anti-inflammatory agent.[15] The moisturizing effect of AV gel appears as result of mixing of water and polysaccharide constitutes. In addition, the antimicrobial effects have been attributed to the plant's natural anthraquinones; providing analgesic, antibacterial, antifungal and antiviral activity.[15, 16]

Also, application of Aloe Vera gel; twice daily for six consecutive weeks in the current study allowed sufficient time for interaction, and enhanced much better action and consequently improvement in radiation induced dermatitis severity.

Conclusion and Recommendations

The current study concluded that Aloe Vera gel application could be effective in reducing the severity of radiation induced dermatitis.

The study recommended the following:

- Aloe Vera gel application needs to be endorsed in the nursing management of patients receiving radiotherapy post mastectomy.
- Replication of the research study is recommended with using a larger sample size from different geographical areas in Egypt in order to provide generalization of findings.
- Longitudinal study should be designed to determine the long term effect of AV gel for this group of patients over a long period of time.

Conflict of Interest: The authors declare no conflict of interest.

Source of Funding: it is a self-funding.

Ethical Clearance: A written initial approval was obtained from the ethics and research committee of the Faculty of Nursing - Cairo University. Written informed consent was obtained from each participant after explaining the nature & purpose of the study. Patients were informed that participation in the study was entirely voluntary and anonymity and confidentiality of the data were assured.

Effect of Lavender Oil Massage on Pain among Patients with Knee Osteoarthritis

Enas Mahmoud El Sayed[1], Hanan Ahmed Al Sebaee[2], Heba Ahmed Mohammed[3], Zeinab Osman Nawito[4]

[1]Clinical Instructor, [2]Professor, [3]Assistant Professor, Medical Surgical Nursing, Faculty of Nursing, [4]Professor of Rheumatology and Rehabilitation, Faculty of Medicine, Cairo University, Egypt

Abstract

Osteoarthritis (OA)is a progressive chronic joint disease with global relevance with up to 250 million people being affected from knee OA worldwide. The aim of this study was to evaluate the effect of Lavender oil massage on pain among patients with knee osteoarthritis. A convenient sample of 60 adult male and female patients who admitted to Rheumatology and Rehabilitation unit affiliated to Cairo University hospital in Egypt with confirmed diagnosis of knee OA divided into experimental (study) and control group. A quasi-experimental Time Series pre-post testnonequivilant interrupted control design was utilized in the current study. Data was collected using Personal and Medical Background Information Form, Pain Numerical Rating Scaleand Lequesne Algo Functional Index of Severity. The study findings revealed that there were significant statistical differences of pain intensity score and OA severity between study and control group after application of lavender oil massage.

Conclusion: Lavender oil massage was proved in this study to be effective on pain and OA severity among patients with knee osteoarthritis.

Keywords: *Lavender oil massage, pain, Patients with osteoarthritis.*

Introduction

Osteoarthritis is one of the most common musculoskeletal diseases, with an estimated prevalence of 12% to 22% worldwide[1]. In Egypt OA is the third leading cause of disability just after heart disease and back disorder; 1.6 million people were affected by OA in Egypt[2]. According to the American College of Rheumatology, OA is defined as a group of conditions which are associated with the defective integrity of articular cartilage result in changes in the underlying bone and articular margins[3].

Knee OA is divided into two types either idiopathic (primary) or secondary (post-traumatic). The primary OA is a gene-dependent disease, while secondary OA occurs after a traumatic event. Clinical characteristic of knee OA include pain, swelling,stiffness, crepitation and loss of movement that results in functional limitation, physical disability and reduced health-related quality of life[3].

Aromatherapy is one of complementary and alternative therapy (CAT) uses essential oils and herbal essences for improving mental health or relieving physical symptoms. Previous studies have examined the effect of aromatherapy on anxiety, pain and wound healing[4]. As result of its simplicity and affordability, aromatherapy has been used as an optional choice in some medical settings, either alone or together with standard pain control protocol[5].

Nursing practices for patient with osteoarthritis should be focused on performing regular follow up, training, and determining the most effective symptom management method. Aromatherapy and massage are among the non-pharmacological method which nurses may directly and independently use to control pain

so they should increase their knowledge and skills regarding aromatherapy massage like recognizing the pharmacological actions of the essential oils and how to apply aromatherapy massage properly[6].

Method

Aim of the Study: The aim of the current study was to evaluate the effect of Lavender oil massage on pain among patients with knee osteoarthritis. To fulfill the aim of this study the following research hypotheses were tested:

H1: Total mean score of pain of OA patients who receive lavender oil massage will be different from total mean score of pain of OA patients who receive routine protocol of care.

H2: The severity of osteoarthritis in OA patients who receive lavender oil massage will be different from the severity of osteoarthritis in OA patients who receive routine protocol of care.

Research Design: Quasi-experimental time series pre-post testnonequivilant interrupted control design was utilized in the current study.

Sample: A convenient sample of adult male and female patients with confirmed diagnosis of OA of the knee, their age ranged between 18 and 50 years. All patients admitted to rheumatology unit and met the inclusion criteria throughout 6 months from July 2018 to January 2019 were allocated to either study or control group starting with control group.

Setting: The current study was conducted in a selected Rheumatology and Rehabilitation unit, at Cairo university hospital, Egypt.

Data Collection Tools:

1. Personal and Medical Background Information Form (PMBIF): It is consisted of two parts: (a) Personal data sheet (b)Medical data sheet related to disease onset, duration, medical treatment, etc.
2. The pain Numerical Rating Scale (NRS): It is an 11-point scale (0-10). Pain intensity can be classified into mild, moderate, and severe levels based on the NRS score.
3. Lequesne Algo Functional Index of Severity: it is a disease questionnaire related to severity of OA. It consists of three scales with eleven items. Its scoring system 0= none, 1-4 mild, 5-7 moderate, 8-10 severe, 11-13 very severe and >= 14 extremely severe

Validity & Reliability: Tools were validated by a panel of five experts in the field of Medical-Surgical Nursing and modifications were carried out. Reliability was tested using Cronbach's alpha with value of 0.98.

Procedure: Patients were randomly divided into study and control group. Participants in the study group were instructed to massage their affected knee joint for 20 min 3 times per week for 3 weeks using 5 ml lavender essential oil diluted in sweet almond oil at a concentration of 3% and continued to receive conventional drugs. While the participants in the control group receive similar conventional drugs described by the rheumatologist.

Results

Section I: Demographic characteristics and medical data of the study and control groups.

The age of 60% of the study group and 56.6% of the control group ranged from41-60 years old and the mean age was 41.83 ± 6.828. Female gender constituted 83.3% of both study and control group.86.7% and 93.4% of study and control group respectively were married. Less than half of study group (40%) and around one third of control group can read and write,66.6% in both groups were housewives and 73.3% were rural areas' inhabitants.

According to medical data, around two thirds and 63% of study and control group respectively had gradual onset of osteoarthritis. 73% and 77% of study and control group respectively had no chronic diseases.60% and 43% of study and control group respectively had no family history of osteoarthritis.

Section 2: Delineates hypothesis testing for being supported or not among study and control groups.

Table (1): Comparison between pain intensity score at four time points of both study and control group (N=60).

Pain intensity		Study group		Control group		X^2	P value
		No.	%	No.	%		
Base line	Mild	1	(3.3)	0	(0)	1.355	0.508
	Moderate	5	(16.7)	7	(23.3)		
	Severe	24	(80)	23	(76.7)		
First week	Mild	5	(16.7)	2	(6.7)	5.540	0.063
	Moderate	13	(43.3)	7	(23.3)		
	Severe	12	(40)	21	(70)		
Second week	Mild	11	(36.7)	3	(10)	7.251	*0.027
	Moderate	8	(26.6)	7	(23.3)		
	Severe	11	(36.7)	20	(66.7)		
Third week	Mild	13	(43.3)	3	(10)	9.583	*0.008
	Moderate	7	(23.4)	7	(23.4)		
	Severe	10	(33.3)	20	(66.6)		

*significant at P≤ 0.05.

Table (1) denotes that there was significant statistical difference between study and control group along study period.

Table (2)Comparison between levels of algofunctional index score at four time points of both study and control group (N=60).

Disease severity		Study group		Control group		X^2	P value
		No.	%	No	%		
Base line	Severe	5	(16.7)	3	(10)	.605	0.739
	very severe	7	(23.3)	7	(23.3)		
	extremely severe	18	(60)	20	(66.7)		
First week	mild	1	(3.3)	0	(0)	8.865	0.065
	Moderate	4	(13.3)	0	(0)		
	Severe	11	(36.7)	7	(23.3)		
	very severe	7	(23.4)	8	(26.7)		
	extremely severe	7	(23.3)	15	(50)		
Second week	mild	4	(13.3)	0	(0)	11.910	*0.018
	Moderate	4	(13.3)	0	(0)		
	Severe	10	(33.4)	9	(30)		
	very severe	6	(20)	6	(20)		
	extremely severe	6	(20)	15	(50)		
Third week	mild	5	(16.7)	0	(0)	13.001	*0.011
	Moderate	4	(13.3)	0	(0)		
	Severe	10	(33.3)	9	(30)		
	very severe	5	(16.7)	6	(20)		
	extremely severe	6	(20)	15	(50)		

*significant at P ≤ 0.05.

Table (2) clarifies that there was significant statistical difference between study and control group along study period.

Figure 1: shows that there was statistical significant difference in pain score among study and control group (ANOVA test: 46.229, p-value: *0.000) respectively along the study period. Alsothere was a statistical significant difference in pain score between study group when compared to control group in the 1st, 2nd, and 3rd weeks of intervention.

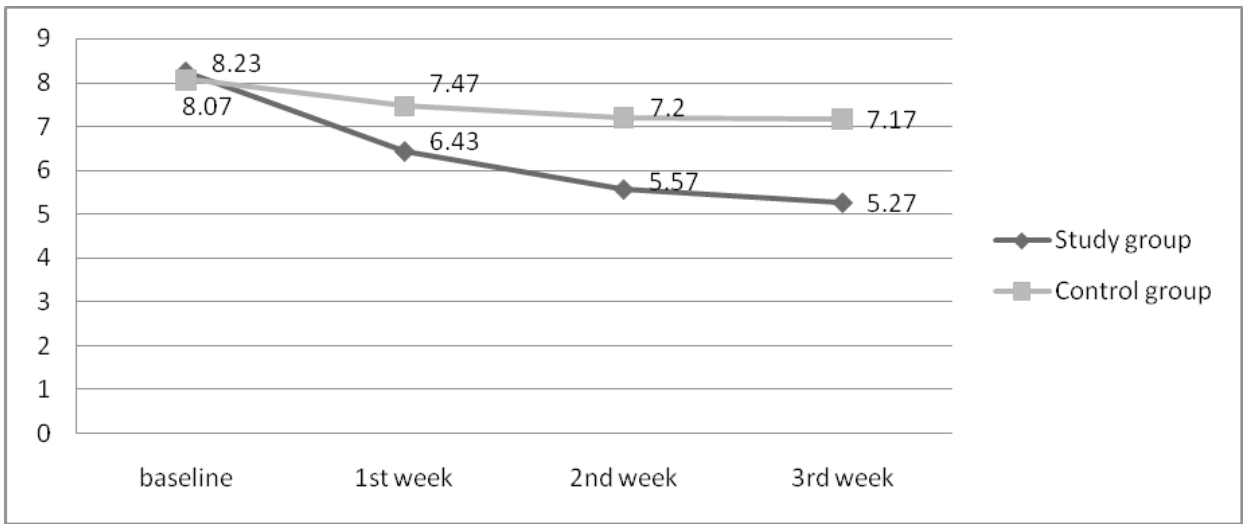

Figure 1: Differences of pain score between study & control group at four time points.

Figure 2: clarifies that there was statistical significant difference algofunctional index score among study and control group (ANOVA test: 52.260, p-value: *0.000) along the study period. Also there was a statistical significant difference in algofunctional index score between study group when compared to control group in the 1st, 2nd, and 3rd weeks of intervention.

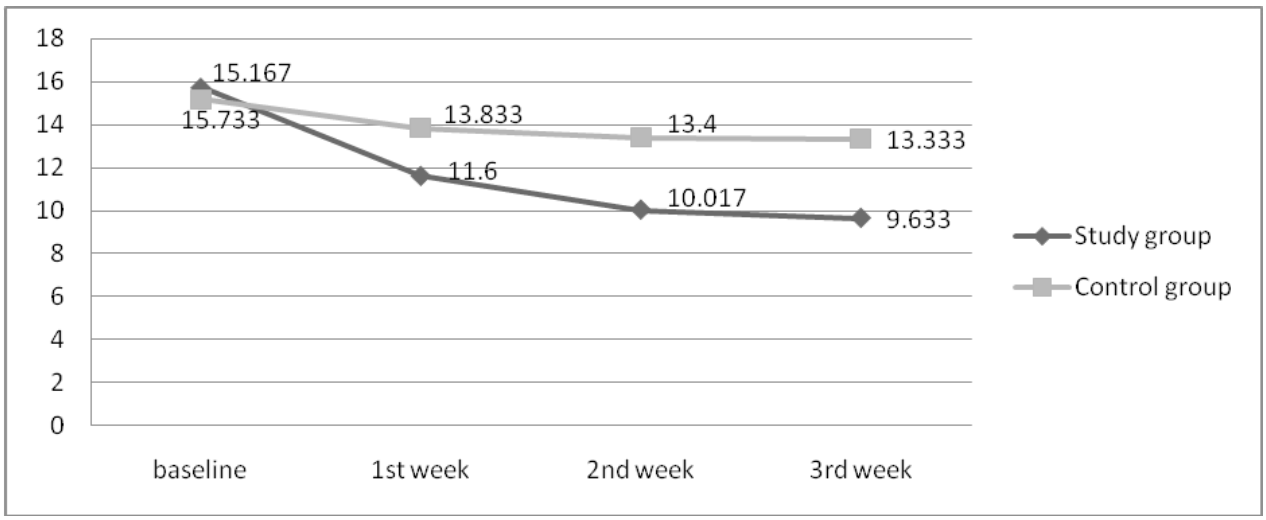

Figure 2: Differences ofalgofunctional index score between study & control group at four time points.

Discussion

The current study revealed that, the majority of the study participants aged between 41-60 years old withmean and standard deviation of age 41.83 ± 6.828. This finding is almost consistent with Arslan, Kutlutürkan and Korkmaz, (2019)[7],the majority of their study participants were 35-64 years old. The findings can be explained with the fact that OA development

starts much earlier than originally thought, and ranked among the top 20 diseases in the 40–45 years age group.

Regarding gender, more than half of the participants were females. This finding is congruent with the findings of the studies by Nasiri and Mahmodi, (2018); Arslan, Kutlutürkan and Korkmaz (2019) & Pehlivan and Karadakovan, (2019)[8,7,6] all affirmed that the majority of their study participants were females. In addition, Mahajan and Patni, (2018)[9] confirmed that OA strikes women more often than men and it increases in prevalence, incidence and severity after menopause. The majority of study participants were housewives. These findings were relatively congruent with Nasiriand Mahmodi, (2018); [8]. The finding that the majority of the participants were housewives could be explained that the majority are females and reside from rural areas.

More than two thirds of study participants had gradual onset of disease.This could be explained with that OA develops slowly and that's why it takes time to induce symptoms that appears gradually starting with pain which worsens overtime.The majority of study participants had no comorbidities as diabetes and hypertension. In contrast Swain et al., (2019)[10] reported that 67% of patients with OA had at least one other chronic condition, being 20% higher than those without OA. In addition, Hawker et al., (2017)[11] mentioned that 77% of their study sample had hypertension, added that OA-related difficulty walking was a significant and potentially modifiable risk factor for diabetes complications.The mean age of the current study participants was 41.83 ± 6.828 years old that could be the reason why the majority of study participants had no co morbidities as the prevalence of co morbidities increases with advancing age.

The findings of the present study revealed that a significant reduction in the mean score of pain 5.27 ±2.083and OA severity9.633±5.0085after application of lavender oil massage on knee jointcompared to the control group 7.17±1.802 and 13.333±3.4996 respectively. This finding supports the effectiveness of lavender oil massage on pain and OA severity among patients with osteoarthritis. The findings of the present study are consistent with other study conducted by Nasiri & Mahmodi, (2018); Nasiri et al., (2016)[8, 12].The findings showed that pain severity reduced significantly in the group undergoing massage with lavender oil compared tocontrol group. This finding could be explained in the light of fact that the direct pharmacological effects of lavender oil is possibly because of lynalyl acetate and linalool, which can effectively decrease pain and inflammation, prevent muscle spasms and reduce tensions, leading to improve pain and physical function.

In this respect, other study conducted by Seda Pehlivan (2018)[6], reported that there were significant differences in pain score in the aromatherapy group when compared with the massage and control group. Other study done by Arslan et al.'s (2019)[7]revealed that aromatherapy massage performed in patients with osteoarthritis had positive effect to reduce knee pain scores, morning stiffness, and improve physical functioning status and considered that complementary treatment modalities are useful for nurses who can perform aromatherapy massage for symptom management in OA.

In the current study, there was a statistical significant difference in mean score of pain between study group when compared to control group in the 1st, 2nd, and 3rd weeks of intervention. This findings is consistent with Nasiri and Mahmodi, (2018); Nasiri et al., (2016);[8, 12]who reportedthat pain severity differed significantly immediately, 1 week, and 4 weeks after the intervention with p value (<0.001) compared with placebo and control groups.

On the same stream, another study findingbelongs to Zhang et al., (2018)[13] revealed thatpatients with bilateral knee OA has been demonstrated that lavender oil aromatherapy massage, significantly reduced the patients' knee pain, tenderness, and morning stiffness. Furthermore, other study conducted by Won andChae, (2011)[14], reported that aromatherapy massage could be recommended as an effective intervention to decrease pain and to increase stride length in the elderly with knee osteoarthritis. Atkins and Eichler (2013)[15]added aromatic massage therapywas more beneficial than massage alone among knee OA patients.

Conclusion

Lavender oil massage was proved in this study to be effective on pain among patients with knee osteoarthritis.

Implications: The complementary therapy is useful to healthcare providers who can learn, apply, or recommend aromatherapy massage techniques as a component of care for symptoms management of OA patients.

Recommendations:

- Replication of the study using a larger probability sample selected from different geographical areas in Egypt.
- Longitudinal study should be designed to determine the long term effect of lavender oil massage for this group of patients over a long period of time.

Ethical Clearance: A research approval was obtained from the Research and Ethical committee at Faculty of Nursing - Cairo University and official permission was obtained from the administrators at study setting. Written informed consent was obtained from each patient.

Conflict of Interest: The authors declare that there is no conflict of interest.

Source of Funding: Self-funding.

An Empathy of Family for Reducing Stigma on People with HIV/AIDS: A Case Study in North Coastal of Central Java

Ernawati[1], Nursalam[2], Aric Vranada[3]

[1]Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia; Faculty of Nursing and Health Sciences, Universitas Muhammadiyah Semarang, [2]Faculty of Nursing Universitas Airlangga, [3]Faculty of Nursing and Health Sciences, Universitas Muhammadiyah Semarang, Indonesia

Abstract

People living with HIV/AIDS (PLWHA) faces powerless. Those aggravated with social problems from the family and community. Support from family allows them to have greater acceptance related to the disease. The Aimed of study to explore family stigma from PLWHA perspective in the North Coastal of Central Java. Method of research used qualitative with case study approach was conducted at Kudus district. Purposive sampling was applied to recruit participant. In-depth interview with semi-structured questions was attempted to 15 migrant workers also been carried out to families and case manager for triangulation. Thematic of manual content analysis was used. The stigmatization among gender showed different result in the context of family. Families were more tolerance and accepted the males with HIV/AIDS without any stigmatization. The culture of lower class of family have good attitude which potentially to be developed such as skills of understanding, being empathy and willing to care. There are specific programs needed which could encourage family empowerment to develop integrated community-based care for PLWHA.

Keywords: *Empathy, Stigma, PLWHA, Reducing Stigma, HIV/AIDS.*

Introduction

People living with HIV/AIDS (PLWHA) faces several powerless circumstances related to physical, psychological and social problems. The major social problem in Indonesia are self-stigmatization and difficulty to find someone to share about the disease.[1] Stigma issue is complicated it is not only associated with PLWHA but also impacted to their family.[2] While PLWHA and close family member (CFM) being stigmatized by others, but CFM also spreads stigmatization to PLWHA.[3,4]

The stigma becomes the main reason for the global epidemiology among HIV/AIDS. A recent study conducted in Central Java Indonesia by 2017 founded 3.731 PLWHA. Kudus district has a greater increasing number of HIV/AIDS cases compared to the previous years. As many 114 cases, more than half were migrant workers' family. Migrant workers are classified as a high-risk group for HIV.[5,6]

Stigmatization among PLWHA was still widespread in Indonesia.[7,8] Stigma has a negative impact on PLWHA and their families.[9] It contributes for low access of healthcare services, HIV screening test,[10–12] increases the risk of transmission.[13] 40-51%PLWHA overdue of receiving HIV treatments,[14]poor quality of life.[15] The stigma can eliminate someone's position in the family and community.

The support from a big family is necessary needed in accepting the condition of PLWHA and also willingness to provide care for them, [16] improve their physical and psychological well-being.[17] This study is aimed to explore family stigma from the perspective of PLWHA among migrant workers in the northern coastal of Central Java.

Method

A qualitative research method with a case study approach was performed in this study.

Sample: Purposive sampling method was applied to recruit the participant with the inclusion criteria: (1) Male and female with HIV positive; (2) Recently worked as a migrant worker or been experiencing in the past; (3) Permanent resident in Kudus district. Amount of 15 migrant workers (12 males, 3 females) participated in this study.

Setting: The research setting is North coastal at Kudus district, Central Java province, Indonesia. The interview takes place at the case manager's house. The interviewers rapport building with participants along with confidential issues.

Data Collection: Formal written informed consent was provided to the participants along with demographic data. Interviewers also clearly explained that participants have the right to dismiss the interview process whenever participants feel uncomfortable. In-depth interview method with open semi-structured questions about feeling of PLWHA after they have been diagnosed with HIV/AIDS, perceive about family respond and stigma. Field notes and MP3 recorder were used to perform complete documentation. It was about 45 to 60 minutes. All participants received transportation fee as the amount of IDR 100.000 after fulfilling the interview session.

Data Analysis: Analyse the data used a "thematic analysis".The descriptive table presented to describe the demographic data. Inductive content analysis was used to analysed narratives contents.

Results

Participants' Characteristics: 15 PLWHA who identified has experience working as a migrant worker outside of the city or overseas with a range of age 23-70 years old (Table 1).

Table 1: Participants' demographic data

Demographic Information	n	Range
Gender		
- Male	12	
- Female	3	
Education Degree		
- Low Education	9	
- Middle Education	8	
Occupation, return home period of time dan Income:		
- Construction worker	7	Every 4 to 6 months (IDR 300.000–400.000)
- Household worker	3	Every 2 to 3 years (IDR 10-30 million)
- Inter-city or inter-island driver	5	Every 5 to 7 days (IDR 250.000).
Period of time of recognizing as an HIV sufferer	15	(1 to 4 years)

All participants was married, but 2 participants have divorce status with their spouse because of financial problems. 7 from 15 participants started heading their work to the big city since they were graduate from junior high school, as stated:

I was getting married at my young age, when my child was turning 3 months old, at 2012 I divorced with my husband because of financial problem which cannot afford my our living expense, then I stayed back with my parent and started working overseas at Malaysia through Indonesian Labor Service Company Kendal district branch…(Mrs. R, 23 Years old, Household worker)

I started working since long time ago when I have graduated from yunior high school in the year 1996. I was working as a construction labor at Jakarta. I just followed my friend who has worked before, because in my village it was very difficult to find a job… (Mr. R, 25 years old, construction worker)

Research Themes: Thematic analysis generated four themes, such as:

a. There was no stigma and discrimination by a big family, as stated:

"My family, nephew, and others also stated that my disease is an ordinary disease which can occur when my wife left me, it's already happened, just let it flew. (Mr. S, 55 years old, Construction worker)".

b. Family showed different responses among gender. Female with HIV/AIDS mostly associated with morality. They also become more introvert with their HIV status, as stated:

"It showed a result that I diagnosed with HIV positive. After that, I was departed back to Indonesia. When a question been asked "who are you having sexual intercourse with?."then I was not answering that question.." (Mrs. R, 23 Years old, household worker)

c. Male are more tolerated to buy sex while they have long hours of working and away from their wives (e.g. when they were leaving their wives working overseas) as stated:

"..when my wife knew that I suffer this disease, she accepted me… she god mad in the beginning and she totally fine if I would like to find a new wife… but now, she totally being acceptance person.." (Mr.E, 37 years old, construction worker).

d. An Empathy from their family accepted male with HIV/AIDS without stigmatization, they also redefine the meaning of healthy as "back to work as usual" as stated:

"...now the important thing is being healthy and back to work as usual.. (Mr. S, 55 years old, construction worker)".

Discussion

Families feel 'suffering' when they experiencing stigma related to HIV/AIDS on their family members, an interesting phenomenon explored in this study that from all of the participants in Kudus district were not reported any stigmatization and discrimination from a big family.

Stigma is defined as a social process, experience or anticipation, characterized by exclusion, rejection, blame or devaluation which detrimental to a person or group [18]. Three main causes of family stigma, such as (a) negative perceptions, attitudes, emotions and avoidance behaviors of among others to family; (b) people's beliefs that family with HIV/AIDS are dangerous, unhealthy, have a negative effect or have differences from general social norms; and (c) people's beliefs that family members are directly or indirectly contaminated by another family member with HIV/AIDS. So it considered dangerous, unhealthy, and have negative effects on others.[19]

That stigma occurred due to lack of adequate information related to the diseases, and low education among community,[20]Stigma and discrimination have contributed to the breakdown of kindship. Moreover, it also contributed PLWHA did not disclose their HIV status to their sexual partner and dissolution of families in Nigeria.[20]

Female participants feel embarrassed to express their feeling related to their HIV/AIDS to their big family. Female PLWHA in China also showed higher significant internalization stigma experience than male ($p<0,001$). There are gender differences in HIV-related stigma especially for internal stigma.[21] Female PLWHA is mostly associated with cultural value as "bad sexual behavior" and "promiscuity".[22] As many as 77.7% women living with HIV/AIDS in 27 countries experienced stigma by community, regardless of the severity condition of illness.[8] Study in Nepal discovered there were differences in stigma related to sexual behavior among migrant workers. 43.5% among them had sex with their partner and 26% among them had sex with a prostitute. All of those criteria had an average or high stigmatization.[5]

Male are more tolerated to buy sex while they have long hours of working and away from their wives. Gender inequality and poverty have increase women's vulnerability to risk beahaviour and exposure [23]. This is the big problem situation in Indonesia, the highest number of cumulative AIDS sufferers is housewives and the highest percentage of AIDS risk factors from not safely sexual behavior in heterosexual (71%).[24]

An Empathy from their family accepted male with HIV/AIDS without stigmatization, they also redefine the meaning of healthy as "back to work as usual". The English Oxford Dictionary mention that empathy means the ability to understand and share the feeling of another. An Emphaty helps others to feel the same way that they understand and tend to provide good care,[25] eliminate stigma and being acceptance to PLWHA will strongly support care and treatment.

The culture of the lower class of family at North Coastal of Central java have good attitude which potentially to is developed skills. Consistent with previous studies in Nigeria,[26] family are willing to care

for a relative with AIDS which goes to show the level of empathy toward PLWHA. Likewise, a study in Nepal found 63% level of stigma about HIV/AIDS among migrant workers.[5] In Turkey found low prevalence of HIV/AIDS because were almost no stigma from families member. Their cultural value tends to support and become an important facilitator of internal stigma.[17] In Nigeria found higher level of education and those higher wealth index seem to be more compassionate toward PLWHA. More than 70% in the population are willing to care for relative with AIDS.[26]

People tend to be more empathetic to family members, group members, close friends, and people who have personal needs and problems as the same as their own needs and problems [27]. Family redefine the meaning of health as "back to work as usual". Family concerns become an important social attachment which builds the feeling that family has a role and responsibility to accept and care their family members with HIV/AIDS.

Everyone has a role to eliminate the stigma and make meaningful contributions to help to cure someone's health problems by building self-esteem. It can be successfully done through small changes in the way of thinking, feeling and acting surrounding the home environment. Social support by providing psychological motivation for PLWHA can improve their mental health condition as a necessity for comprehensive health status.[28] Social support influence mental health condition and quality of life better.[28] The specific participants PLWHA-migrant workers as the limitation in this study. Need more assessments of family stigmatization to other risk group in the community.

Conclusion

This study found good practice family willing to care for relatives toward PLWHA. In order to combat HIV/AIDS epidemic in the region, issues pertaining to stigma and discrimination need to be addressed. The family acceptance of the health condition among their family members with HIV/AIDS is reflecting of the function in carrying out of family health care. It can influence the family system as a morality culture of the community. Overcoming psychosocial needs through family support can help PLWHA overcome the problems of HIV infection and also stress associated with HIV infection properly. An Empathy can be used as an approach in one of the stigma reduction interventions. Finding from this study have implication to develop integrated community-based care for PLWHA.

Ethical Clearance: The study protocol was approved by the Faculty of Nursing Science of Universitas Islam Sultan Agung Semarang.

Source of Funding: This study received funding support from the Ministry of Research, Technology and Higher Education of Indonesia number 033/UNIMUS/PJ.PG/2016.

Abstract:

Introduction: *Ravenala madagascariensis* (Sonn.) family Strelitziaceae, commonly called traveler's tree or palm; it is used traditionally in India as tea made from young leaves for treatment of diabetes. On the other hand its seed found to have antiseptic properties.

Objective: Phytochemical investigation and isolation as well as testing the antioxidant and antimicrobial activities of the crude total and different successive fractions.

Material and Method: The leaves total ethanol extract was subjected for phytochemical screening. The *n*- BuOH fraction was fractionated using chromatographic isolation. Total phenolics and flavonoids and antioxidant activity of the crude total ethanol extract as well as *n*-hexane, CH_2Cl_2, EtOAc and *n*- BuOH successive fractions were determined using ABTS assays. On the other hand the antimicrobial of the crude total ethanol was carried out against 13 microorganisms using agar well diffusion method.

Results: Phytochemical screening showed the presence of flavonoids, tannins and sterols. Three phenolic compounds were isolated from the *n*- BuOH fraction and they were identified using different spectroscopic techniques. The different fractions showed high antioxidant activities especially EtOAc fraction that showed 88.96% for ABTS inhibition. Crude total ethanol extract showed selective moderate antimicrobial activity against the tested strains of *Cryptococcus neoformans*, *Bacillus cereus* and *Serratia marcenscens*.

Conclusion: The ethyl acetate fraction showed significant antioxidant activity probably due to presence of the flavonoids contents.

Keywords: *Antimicrobial, Antioxidant, Flavonoids, Phenolics, Ravenala.*

Introduction

Replacement of synthetic products with natural products is our aim nowadays for safe life. Free radicals (especially oxygen free radicals) which generated by oxidation reactions of exogenous factors (like protein and lipids) are the cause of start chronic diseases like diabetes and cancer[(1)]. Inhibition of these oxidation reactions by antioxidants is targeted to reduce free radicals and its effects on our bodies. Thus, antioxidants are useful for prevention of harmful diseases caused by free radicals[(2)]. Searching of new source is important because of the increase in antibiotics resistance for developing antimicrobial agent. Due to low level of toxicity of plants, the priority to choose plants for treatment of the infectious diseases[(3)].

Ravenala madagascariensis, commonly called traveler's palm or traveler's tree, is one of nature's most distinctive and remarkable plants for the arrangement of its leaves in a fan shape[(4)]. The common name is thought to refer to how travelers could be refreshed in

an emergency by drinking the water that has collected in the cup-like leaf bases. The traveler's palm (not a true palm) has been described as being part banana plant and part palm tree. Although it's called a palm, this plant is not a member of the palm family (Arecaceae); it actually belongs to the bird-of-paradise family, Strelitziaceae [5, 6]. *Ravenala madagascariensis* is native to Madagascar, the African island renowned for its many endemic plant and animal species. Also present in other tropical countries which it is easily cultivated as an ornamental tree[7, 8]. The tested extracts (hexane, carbon tetrachloride, chloroform and aqueous) of the leaves of *R. madagascarinsis* exhibited moderate antimicrobial activity with zone of inhibition ranging from 2.0 to 9.0mm against microbile strains while the crude methanol extract 9.0 mm zone of inhibition against *Escherichia coli*[9]. Beside these tested fractions and methanol extract exhibited significant thrombolytic activity[10]. Ethanolic extract was found effective in hypolipidaemic activity and improve the renal morphology and reduce lesions associated with diabetes induced by alloxan[7, 11]. Ethanol extract of the leaves of *R. madagascarinsis* has proved to be effective in inhibiting the growth (i.e. showed a bacterioststic but not bactericidal at 200 mg/ml) of enteric bacteria such as *Shigella flexneri* ATCC 12022, *Serratia marcescens* ATCC 39006, *Klebsiella pneumoniae* ATCC 13883, *Proteus mirabilis* ATCC 25933, *Serratia marcescens*, *Klebsiella pneumoniae*, *Proteus mirabilis*, *Citrobacter freundii* which are among the causative agents of diarrhea[5].

Material and Method

Plant Material: The leaves of *Ravenala madagascariensis* (Sonn.) were collected from the plants cultivated in El-Orman garden, Egypt, August 2015. The plant was authenticated by Ibrahim Ahmed El-Garf, professor of Botany, department of Botany and Microbiology, Faculty of Science, Cairo University, Giza, Egypt. The leaves were air-dried, powdered, weighed and kept in amber-colored, well-closed glass container, at low temperature for phytochemical and biological studies.

Chemicals: Methanol, gallic acid, sodium carbonate (Na_2CO_3), Folin-Ciocalteu (FC) reagent were obtained from Fluka (Milwaukee, WI, US). Aluminum chloride ($AlCl_3$), sodium nitrite ($NaNo_2$), rutin. 2, 2'-azinobis (3-ethylbenzothiazoline-6-sulfonic acid) diammonium salt (ABTS), potassium persulfate, butylated hydroxyanisol (BHA). All chemicals and standards were provided from Sigma-Aldrich (St Louis, MO, USA).

Preparation of plant extract: The powdered leaves (1.7 kg) were exhaustively extracted with 70% ethanol by maceration, on cold, and at room temperature then concentrated to yield 400g. An aliquot of the ethanol extract (200g) was resuspended in distilled H_2O and successively fractionated with solvent of increasing polarity: *n*-hexane, CH_2Cl_2, EtOAc and *n*-BuOH.

Phytochemical screening: The total ethanolic extract of *R. madagascariensis* leaves was screened for the presence of carbohydrates and/or glycosides, tannins, flavonoids, saponins, sterols and/or triterpenes, alkaloids, anthraquinones and cardiac glycosides. It was carried out in accordance with the method described by Pandith[12] and Pandey[13].

Extraction and isolation: The powdered leaves (1.7 kg) were exhaustively extracted with 70% EtOH on cold by maceration at room temperature and concentrated to yield 400g. An aliquot of the ethanol extract (200g) was resuspended in distilled H_2O and successively fractionated with solvent of increasing polarity: *n*-hexane, DCM, EtOAc and finally *n*-BuOH. The *n*-butanol extract (25g) was subjected to a polyamide column (100 × 5 cm, 250 g) chromatography, gradient eluting with MeOH: H_2O in a way of increasing polarity by 10% increment. Fractions (100 mL each) were collected, evaporated under reduced pressure and screened by TLC using different systems. Similar fractions were pooled to yield 12 subfractions. The 1th fraction was chromatographed by a Sephadex LH_{20} column (38 × 3 cm, 40 g) chromatography, isocratic eluting with saturated *n*-BuOH to give 6 subfractions, from which the 4th subfraction was subjected to a silica gel column (60 ×3 cm, 100 g) chromatography by gradient eluting with DCM: MeOH followed by sephadex LH-20 column (38 × 3 cm, 40 g) chromatography which eluted with 80% MeOH to give (**1**, 5 mg), (**2**, 10 mg) and (**3**, 10 mg).

Hexyl glucose[14], ^{1}H-NMR (400 MHz, MeOD): δ 4.2 (1H,d,*J*=8Hz,H-1'), δ 3.9 (1H,q, CH_2), δ 3.87(1H,dd,H-6'), δ 3.76- 3.5 (4H,m), δ 3.6 (1H, m, H-5'), δ 3.25- 3.14(4H,m,), δ 3.43 (1H,dd,H-4'), δ 1.92 (1H, s,), δ 1.19 (3H,t, CH_3), δ 0.95 (1H, t, CH_2). **^{13}C-NMR**: (100 MHz, MeOD), 14.29, 16.95, 17.54, 34.91, 58.88, 60.55, 63.04, 63.27, 64.84, 65.54, 67.51, 68.07, 69.93, 70.07, 71.00, 72.51, 73.53, 75.54, 75.79, 76.50, 77.11, 81.87, 82.50, 103.50,

Ethyl β-D-glucoside[15, 16], ^{1}H-NMR (400 MHz,

MeOD): δ 4.3 (1H,d,*J*=8Hz,H-1'), δ 3.9 (1H,q, CH_2), δ 3.86 (1H,dd,H-6'), δ 3.71 (1H,dd,H-3'), δ 3.6 (1H, m, H-5'), δ 3.55(1H,dd,H-2'), δ 3.41 (1H,dd,H-4'), δ 1.25(3H,t, CH_3). ^{13}**C-NMR** (100 MHz, MeOD): 14.29, 61.18, 65.13, 70.15, 73.60, 76.35, 76.68, 102.51.

(3S,5R,6R,7E,9S) megastigmane-7-ene-3,5,6,9-tetrol 9-O-B-D-glucopyranoside[17], ^{1}H-NMR (400 MHz, MeOD): δ 6.2(1H,d,*J*=16 Hz, H-7), δ 5.66(1H,d,*J*=6.6Hz,H-8), δ 4.56(1H,*J*=6Hz,H-9), δ 4.41(1H,d,*J*=8Hz,H-1'), δ 4.07(1H,d,*J*=16Hz,H-4), δ 3.87 (1H,d,*J*=12Hz,H-6'b), δ 3.68 (1H,d,*J*=12Hz,H-6'a), δ 1.14(3H,s,H-11), δ 1.26(3H,s,H-13), δ 1.47(1H,d,*J*=12Hz,H-2 eq), δ 1.6- 1.9(m, H-4ax, eq), δ 0.93(3H,s,H-12). ^{13}**C-NMR**: (100 MHz, MeOD), 20.95, 24.92, 25.58, 26.68, 39.34, 44.12, 45.01, 61.24, 63.7, 70.14, 73.45, 74.05, 76.41, 76.7, 77.87, 99.2, 131.72, 134.14.

Total phenolics content: Total phenolics content was determined using method described by Zhang et al. 2006 [18] to each of the 96 wells, 75 µl of DDW was added, followed by 25 µl of either sample or standard and 25 µl of Folin–Ciocalteu reagent (diluted 1:1(v/v) with DDW). Then mixed and left for 6 min, 100 µl of 75 g/L Na_2CO_3 was added to each well. The solutions were mixed again and the plates were covered and left in the dark for 90 min, absorbance was measured at 765 nm. Each standard and sample solution was analyzed in triplicate. Gallic acid was used as a standard at 0.78 - 200 µg/ml to produce a calibration curve.

Total flavonoids content: Total flavonoids *content* was determined using method described by Herald et al. 2012[19]. Distilled water (100 µl) was added to each of the 96 wells, followed by 10 µl of 50 g/L $NaNO_2$ and 25 µl of standard or sample solution. After 5 min, 15 µl of 100 g/L $AlCl_3$ was added to the mixture; 6 min later, 50 µl of 1 mol/L NaOH and 50 µl of distilled water were added. The plate was shaken for 30 s in the plate reader prior to absorbance measurement at 510 nm. All samples and standards were measured against a methanol as blank. Rutin was used as a standard at 15 - 2000 µg mL^{-1} to generate a calibration curve.

Biological activity study:

Antioxidant assay: The free radical scavenging capacity of extracts was also studied using the ABTS radical cation decolorization assay[20]. ABTS was dissolved in deionized water to 7 mM concentration. ABTS radical cation ($ABTS^{+\bullet}$) was produced by reducing ABTS solution with 2.45 mM potassium persulfate and allowing the mixture to stand in the dark at room temperature for 12-16h before use. For the study, the $ABTS^{+\bullet}$ solution was diluted in deionized water to an absorbance of 0.7 (±0.02) at 734 nm. After the addition of 100 µL of methanolic plant extract solution to 3 ml of $ABTS^{+\bullet}$ solution, the absorbance reading was taken at room temperature 10 min after intial mixing(A_1). All determinations were carried out in triplicate. Butylated hydroxyanisol was used as a standard at 15–250 µg/ml to generate a calibration curve (average R^2 =0.9999, fig.7). All samples and standards were measured against a methanol reagent blank.

Inhibition activity was calculated using the following formula:

$$\% \text{ inhibition} = (A_o - A_1)/A_o \times 100$$

Where A_o is the absorbance of the control, A_1 is the absorbance of the standard/extracts.

Antimicrobial activity: Organisms used in this study were obtained from the antimicrobial activity unit of the Regional Center for Mycology and Biotechnology of Al-Azhar University and Microbiology Department of MUST and consisted of the fungi *Candida albicans* ATCC 10231, *C. glabrata* (RCMB 0049010), *Cryptococcus neoformans* (RCMB 0049001), *Aspergillus flavus* (RCMB 002002), *Aspergillus niger* (RCMB 002005) and *Aspergillus fumigatus* (RCMB 002008) and the bacteria *Staphylococcus aureus* ATCC 25923, *Serratia marcenscens* (RCMB 029), *Escherichia coli* ATCC 25922, *Pseudomonas aeruginosa* ATCC 27853, *Bacillus subtilism* (RCMB 015), *Bacillus cereus* RCMB 027, *Klebsiella pneumoniae* (RCMB 0100223-5) and *Cryptococcus neoformans* (RCMB 0049001). Antimicrobial sensitivity was tested using the agar well diffusion technique according to[21]. The plant extract was dissolved in DMSO with concentration 200 mg/ml. Muller Hinton agar (MHA) plates were inoculated with bacterial suspension with a density adjusted to that of 0.5 McFarland standard under aseptic conditions and wells with diameter 6mm were filled with 50 µl of the plant extract (dissolved in DMSO with concentration 200 mg/ml), positive and negative controls. The latter were applied using Gentamycin (4µg/ml), Ketoconazole (100µg/ml) and DMSO, respectively. When 70% ethanolic extract of (200mg/ml) is placed on agar, it will diffuse into the agar. The solubility of the chemical and its molecular size will determine the size of the area of

chemical infiltration around the well; if it susceptible to the chemical. This area of no growth around the well is known as a zone inhibition or clear zone. The zone diameter was then measured with slipping calipers.

Results

Phytochemical screening: Phytochemical screening of *R. madagascariensis* leaves total ethanolic extract revealed the presence of carbohydrates and/or glycosides, sterols and/or triterpenes, tannins, saponins and flavonoid aglycone/glycosides.

Identification of purified compounds: Structure elucidation of the purified compounds was based on their physicochemical and chromatographic properties, spectral analyses (UV, ESI-MS, ^{1}H NMR and DEPT–Q) and compared with authentic samples and literature. The isolated compound **1** was identified as **hexyl glucose[14],** compound **2** as **ethyl β-D-glucoside[15,16]** and compound **3** as **(3S,5R,6R,7E,9S) megastigmane-7-ene-3,5,6,9-tetrol 9-O-B-D-glucopyranoside[17]** which these were isolated for the first time from ***Ravenala madagascariensis*** **(Sonn.)**.

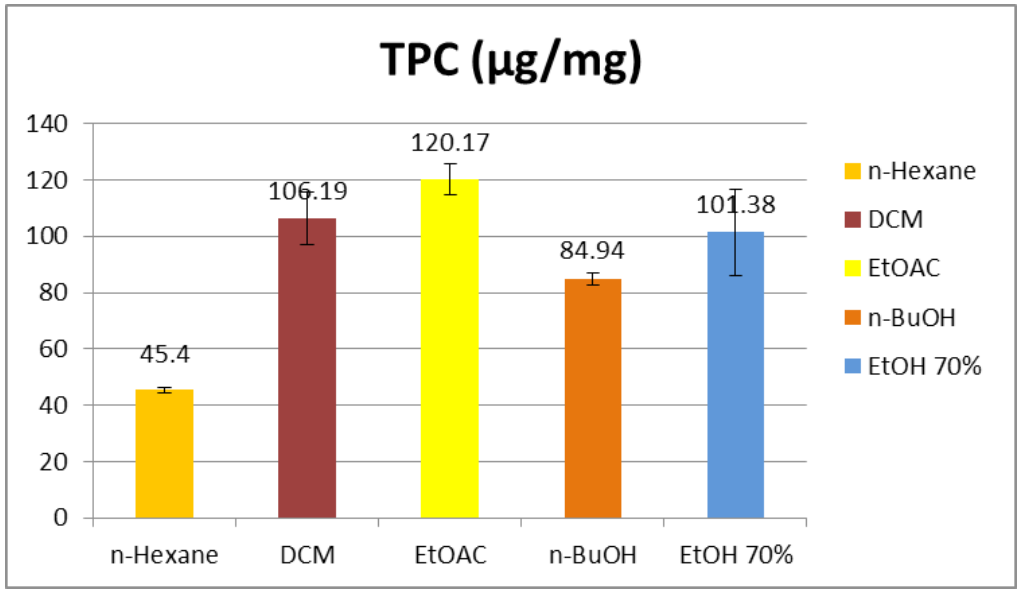

Figure 1: Total phenolic content (TPC) of different fractions of R. madagascariensis leaves.

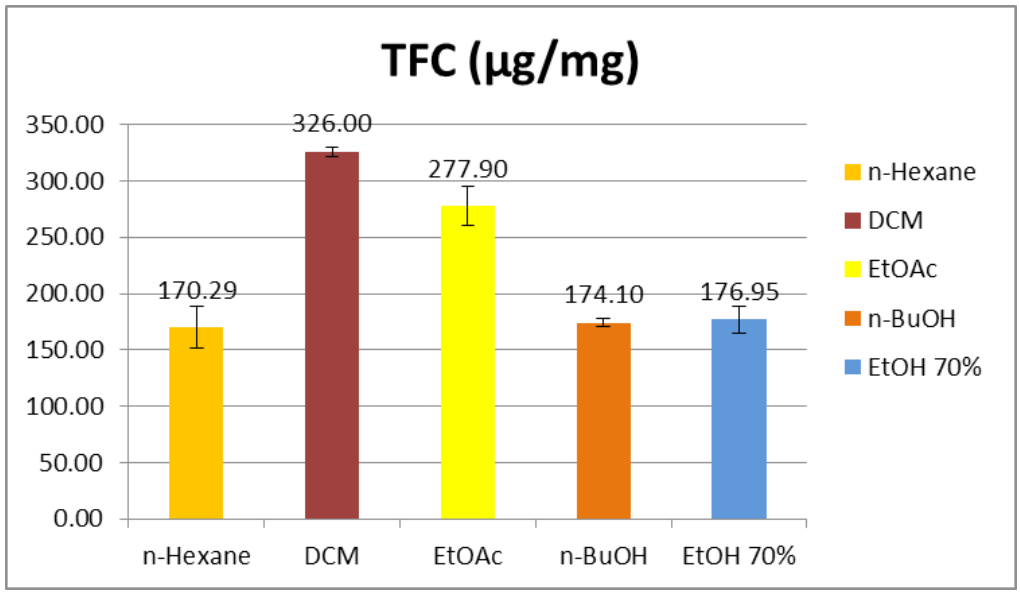

Figure 2: Total flavonoid content (TFC) of total ethanol 70% and successive fractions of R. madagascariensis leaves.

Antioxidant activity: ABTS is used for testing the radical scavenging activity of antioxidant compounds or plant extracts. The $ABTS^{\bullet+}$, generated from oxidation of ABTS by potassium persulfate, is presented for determining the antioxidant activity of hydrogen donating antioxidants and chain breaking antioxidants. The ABTS scavenging capacity of different fractions of *R. madagascariensis* leaves were expressed as inhibition capacity and the results are presented in figure 3.

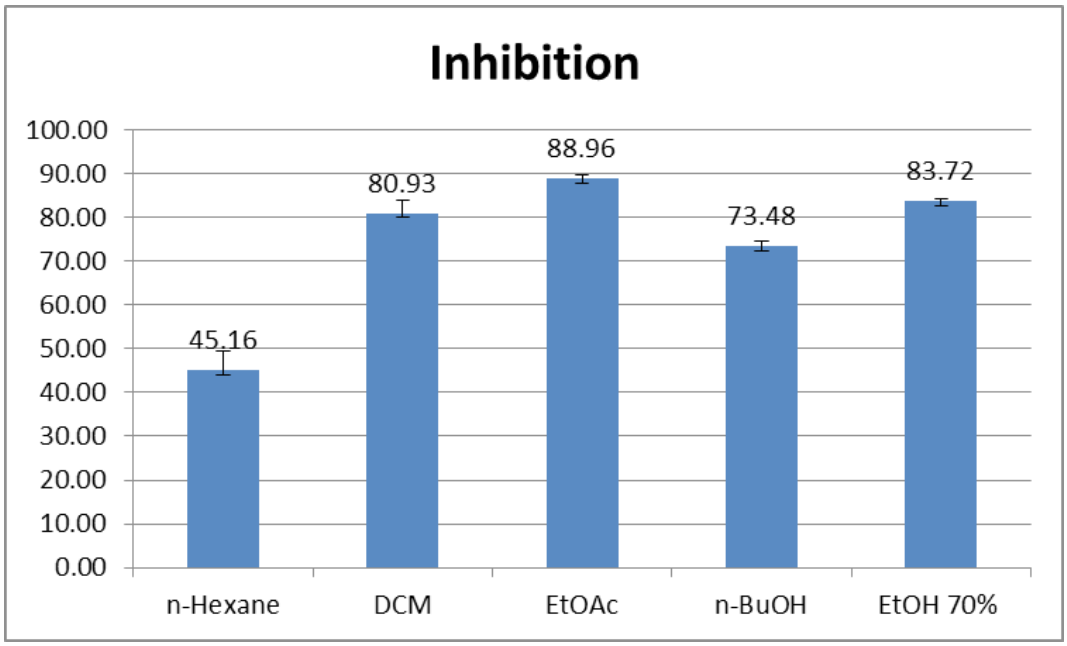

Figure 3: Inhibition activity of total ethanol 70% and successive fractions of R. madagascariensis leaves using ABTS assay.

Antimicrobial activity: The total ethanolic 70% extract showed selective antimicrobial activity against tested strains of the fungus of *Cryptococcus neoformans* (RCMB 0049001), the gram negative bacteria *Serratia marcenscens* (RCMB 029) and the gram positive bacteria *Bacillus cereus* (RCMB 027) with zone of inhibition (13mm, 12mm, 15mm) respectively, the results are presented in Table 1.

Table 1: Antimicrobial effects of crude total ethanol 70% extract (200 mg/ml) R. madagascariensis leaves extract against different organisms

Test organism	Zones of inhibition (mm)		
	+ ve control	DMSO	Ethanol extract
Gram negative bacteria

Discussion

Based on scarce reports about the traveler's palm and according to the results of phytochemical screening which showed the presence of sterols, triterpenes, carbohydrates, glycosides, tannins and flavonoids compounds in total ethanol extract of *R. madagascariensis* encourage phytochemical and biological studies of the mentioned plant. These phytochemical classes encouraged us to evaluate the antioxidant activity[5] of the crude total ethanol extract as well as *n*-hexane, CH_2Cl_2, EtOAc and *n*-BuOH successive fractions and antimicrobial activity of crude total ethanol. Due to results of antioxidant activity, the *n*-butanol fraction was subjected to different chromatographic method which led to isolate three phenolic compounds which identified as **Hexyl glucose, Ethyl β-D-glucoside** and **(3S,5R,6R,7E,9S) megastigmane-7-ene-3,5,6,9-tetrol 9-O-B-D-glucopyranoside**. Concerning the antimicrobial activity against different microorganisms, it was found that the total ethanol extract of *R. madagascariensis* has selective antimicrobial activity against the tested strains of *Cryptococcus neoformans* (RCMB 0049001), *Bacillus cereus* (RCMB 027) and *Serratia marcenscens* (RCMB 029).

Conclusion

The ethyl acetate fraction of *R. madagascariensis* leaves showed significant antioxidant activity probably due to presence of the total phenolic contents. The total ethanol extract has selective antimicrobial activity against the tested strains of *Cryptococcus neoformans* (RCMB 0049001), *Bacillus cereus* (RCMB 027) and *Serratia marcenscens* (RCMB 029).

New Approach of Hyaluronic Acid Bound Spermatozoa-ICSI in Iraqi Infertile Patients

Ezdehar N. Ali, Hayder A.L. Mossa

High Institute of Infertility Diagnosis and Assisted Reproductive Technologies, Al-Nahrain University, Baghdad, IRAQ

Abstract

Background: Ability of spermatozoa to binding to hyaluronan is related to sperm membrane maturity and fertilizing potential, thus it has been suggested that sperm selection using Hyaluronic acid (HA) could increase the implantation rate in Intracytoplasmic Sperm Injection(ICSI). Basically Physiological -ICSI (PICSI) is a scientific technique used in ICSI, is a specialized form and more filtered way of selecting the best competent sperm for fertilization process. Despite the fact that conventionally spermatozoa are selected for ICSI based on their morphology and motility.

Objective: To evaluate whether (PICSI) has the potential to improve the fertilization rate and embryo grading.

Patients, Materials and Methods: Fifty-three infertile couples subjected to an *in vitro* fertilization stimulation program; Thirty-five underwent (ICSI) cycle and eighteen underwent (PICSI) cycle, assessed the fertilization rate and embryo grading at cleavage stage then the results were statistically analyzed.

Results: In spite of the fertilization rate of PICSI group was better than ICSI group but statistically no significant difference was noticed between both of them. In regarding to embryo grading at cleavage stage, there was a significant increase($P<0.05$) in Grade 1 and Grade 2 for PICSI group as compared to ICSI group.

Conclusions: The percentage of fertilization for PICSI group is better than for ICSI group. In regarding to statistical analysis, there was no significant differences between two groups. Regarding to embryo quality at cleavage stage, the PICSI cycle significantly improves embryo quality(Grade 1 and Grade 2) at day 2 and day 3 of development as compared to the ICSI cycle.

Keywords: *Hyaluronic Acid Bound Sperm, ICSI,PICSI, infertile men.*

Introduction

Infertility is a complex disorder and a unique medical condition,it involves a couple, rather than a single individual with significant medical, psychosocial, and economic problems[1].

Male infertility is usually caused by either sperm production or its transport disorders[2]. Semen analysis has two major quantifiable attributes: the total number of spermatozoa which reflects sperm production by the testes and the patency of the post-testicular duct system and the total fluid volume formed by the various accessory glands which reflect the secretory activity of these glands [3].

In Vitro Fertilization (IVF) is an assisted reproductive technology in which spermatozoa and oocytes are combined outside of the human body in a laboratory dish. The main steps in any IVF cycle are controlled ovarian hyperstimulation, retrieval of oocytes, fertilization, embryo culture and embryo transfer[4].

The conventional IVF could not help the couples with severe male factor infertility including very low sperm count, motility impairment and abnormal sperm morphology as they leading to failure of fertilization[5]. The ICSI proceduremean" entails the deposition of a single spermatozoon directly into the cytoplasm of the oocyte, thus bypassing the zona pellucida and the

oolemma"[6]. Up to 15% of all couples of reproductive age have been diagnosed with infertility and about one-third of them have male factor infertility as a contributing factor, ICSI has confirmed to be precious for couples with severely compromised semen parameters [7].

Another proposed indication for the use of ICSI includes: unexplained infertility, poor quality oocyte, advanced maternal age, low oocyte yield, prior fertilization failure with conventional IVF, Pre implantation genetic diagnosis, fertilization after *in vitro* maturation, and fertilization of cryopreserved oocyte [8].

Hyaluronic acid (HA) is the main component of the cumulus oophorus; it plays a role in the natural selection of mature spermatozoa during in vivo fertilization. Therefore, the sperm ability to bind to hyaluronic acid and subsequently to the zona pellucida can be used as the basis for *in vitro* sperm selection. Since HA is a physiological component of the cervix, cumulus cells and follicular fluid, it should pose no additional safety risks when used for sperm selection[9]. Huszar and colleagues discovered that sperm bound to hyaluronic acid *in vitro* have markers of cellular maturity, minimal DNA fragmentation, normal shape, and low frequency of chromosomal aneuploidies[10].

In the past few years, both HA-mediated devices, the sperm HA- binding assessment in the Andrology laboratory, and the ICSI sperm selection device, the PICSI dish (an IVF Petri dish that carries an HA spot), has been increasingly accepted and used worldwide[11].

The PICSI dish may take only a few minutes. Further, the PICSI dish provides a spacious area for sperm selection. It's equipped with lines of orientation, and all spermatozoa are within the same level of microscopic focus range. Thus, the embryologist has a good opportunity to compare the available spermatozoa with respect to shape (morphology) and also HA binding, as well as the important specific response of the fully developed sperm to HA contact [12,13].There are now several laboratories that have initiated HA mediated sperm selection. It's important that none of the groups practicing the HA sperm selection reported any adverse effects regarding fertilization or embryo development[14].

Patients, Materials and Methods

A prospective study conducted in High Institute of Infertility Diagnosis and Assisted Reproductive Technologies/AL-Nahrain University. Fifty-three infertile couples subjected to IVFstimulation program; Thirty -five infertile couples underwent (ICSI) cycle, and eighteen underwent (PICSI) cycle.Fifty-three infertile couples subjected to:

- Full history taking (age of women, type of infertility, duration & causes of male and female infertility, and number of previous IVF trials).
- Measurement of the body mass index (BMI).
- Baseline hormonal assay was performed at day 2 of the menstrual cycle include serum Follicle stimulating hormone (FSH), Luteinizing hormone (LH), Estradiol (E2), Prolactin and Thyroid stimulating hormone (TSH)) for each woman.

The study included women that underwent to controlled ovarian stimulation (antagonist protocols) their age ranged between (20-40) years. The cases of infertile male with spermatozoa retrieval from testicular biopsy and frozen spermatozoa were excluded.

Oocytes retrieval was performed using a transvaginal probe 34-36 hours after the hCG injection just prior to the rupture of follicles. The procedure usually took 20-30 minutes. After that, the patients were given antibiotics, analgesics, and luteal phase support. All follicles within both ovaries are aspirated by ovum aspiration needle and follicular fluid given directly to the embryologist to identify the quality of the retrieved cumulus-oocytes complex[15].

After recovery, the oocytes were washed free of the follicular fluid, the hyaluronidase concentration and exposure must be kept to a minimum, mechanical dissection of cumulus oophorus and corona radiate was done. After denudation, to remove traces of hyaluronidase, oocytes should be thoroughly washed. Grading of the oocytes into germinal vesicle, metaphase I (MI), and metaphase II (MII), also classified into normal or abnormal oocyte. Later on transferred into drops of IVF media overlaid by paraffin/mineral oil in an incubator at temperature 37°C with 5% CO_2, and at 95% humidity. Finally, those ova which have been extruded the first polar body (metaphase II) and morphologically intact were suitable for microinjection[16]. The oocytes inseminated for 4–6 hours after aspiration and the spermatozoa must be prepared during this time. [17]. After insemination, zygotes observed for 18-20 hours to check for the presence of 2 pronuclei. At day 1, the presence of 2 pronuclei considered as a good prognostic sign. After that, evaluation of embryos at day 2 and day

3. The embryos with(4 cells at day 2) or with (7-9 cells at day 3) and containing <10% of cytoplasmic fragments are considered as good quality embryos [18]. Embryo transfer generally done at day 2,or at day 3 or at day 5 post ICSI procedure depending on patient's age, embryo quality, and the number of embryos available [6].

Luteal phase was supported since day of oocyte retrieval by vaginal progesterone (Cyclogest®400mg twice: or Crinone,® 8% progesterone gel) and continued daily. Serum ß-hCG assay was done on day 14 after the embryo transfer[19].

The Sperm Selection Device (PICSI) provides a means to select mature sperm based on their ability to bind to hyaluronan hydrogel. It's a polystyrene culture dish with three microdots of hyaluronan attached to the interior bottom. The device is sterile, free of endotoxin and non-toxic to embryos, the spermatozoa will be added to the pre-hydrated microdot in a volume equal to or greater than that used to pre-hydrate the dot (approximately 10 µl). Then the tip of the micropipette containing the sperm will be touched to the edge of the hydrating drop at the dish under the oil and expel the sperm. Once bound, hyaluronan -bound sperm are easily identified, they exhibit no progressive migration despite vigorous tail beating. Sperm binding begin normally in 5 minutes or less. However, some microdots may require 30 minutes or more to reach full binding capability. The captured sperm will be expelled into a Polyvinylpyrrolidone (PVP) drop to process them for ICSI, from the PVP droplet, select and load single, processed sperm for injection into the oocytes according to your standard injection protocol[10,20].

Statistical analysis was done by using SPSS (statistical package for social sciences) version 20.For analysis, basic characteristics and hormones profile were analyzed using independent sample t-test. Chi square test was used to reveal the significant comparison among percentages of the fertilization rate, and embryo grading in this study.

Results

The current study illustrated that the percentage of infertile couples with primary infertility was (62.264%),while infertile couples with secondary infertility was (37.735%). All infertile couples who were enrolled in this study had different causes that led them to be infertile. The most common cases of males was oilgoasthenoteratozoospermia and for females was polycystic ovaries syndrome. The statistical analysis in table (1) showed no significant differences for the female age, infertility duration, BMI and basal hormonal profile level at cycle day 2 between infertile couples underwent ICSI cycle and infertile couples underwent PICSI cycle.

Table (1): Basic characteristic and hormonal profile at cycle day 2 for both groups.

Parameter	ICSI group	PICSI group	P-value
Age (Year)	30.685 ± 0.853	28.555 ± 1.207	0.922
Duration of infertility (Year)	6.514 ± 0.600	5.944 ± 0.697	0.261
BMI (kg/m^2)	29.153 ± 0.592	28.762 ± 0.586	0.052
FSH (mIU/L)	6.278 ± 0.449	6.647 ± 0.720	0.552
LH (mIU/L)	7.139 ± 0.985	6.901 ± 1.391	0.984
Prolactin (mIU/L)	13.195 ± 1.401	14.380 ± 1.782	0.513
E_2 (pg/ml)	45.136 ± 1.755	43.477 ± 2.621	0.997
TSH (mIU/L)	1.477 ± 0.081	1.555 ± 0.117	0.936

The fertilization rate for PICSI group higher than for ICSI group. In regarding to statistical analysis, there was no significant differences between both groups, p-value = 0.207.

Assessment of embryo quality at cleavage period, according to number and size of cells and the percentage of fragmentation .Therefore, the grading of embryo divided into three grades (Grade 1, Grade 2 and Grade 3). The embryo with grade 1 represent the best embryo,while the worst embryo with grade 3. The statistical analysis showed significant increase in embryo grading (Grade 1 and Grade 2) for PICSI group, while no significant difference for Grade 3 for both groups, as shown in table (2).

Table 2: Comparison between ICSI group and PICSI group in main clinical embryological variables.

Chi square	P-value	PICSI group	ICSI group	Parameter	
1.596	0.207	78.378	63.385	Fertilization rate	
5.444	0.020	86.206	58.024	Grade 1	
13.889	0.000	10.344	35.802	Grade 2	Day 2
1.000	0.317	3.448	6.172	Grade 3	
5.321	0.021	82.758	55.555	Grade 1	
11.520	0.001	13.793	37.037	Grade 2	Day 3
1.600	0.206	3.448	7.407	Grade 3	

Discussion

In the current study there was no significant difference in basic characteristic and hormonal level at cycle day 2 for both groups to eliminate any variations that may affect the reproductive results.

Even though in this study the patients were treated with the same controlled ovarian stimulation regimen and ICSI was performed by the same embryologist, using the same instruments and media for gamete handling and culture. This study revealed that injection of HA-bound spermatozoa (HA-ICSI) determines a statistically significant improvement in embryo quality in day 2 and day 3 when performing HA- ICSI on a limited number of oocytes (between 1 and 3). It didn't observe a statistical significant difference in fertilization rate, in spite of the percentage of fertilization to selection of HA-bound spermatozoa group was higher than that for ICSI group .However,it's difficult to analyze the insignificant difference when HA-ICSI was performed on a limited number of oocytes and low number of patients which warrants further study to be carried out as a clinical trial.A statistically significant improvement in reproductive terms like fertilization rate, embryo quality and a reduction in the number of miscarriages were observed by Worrilow *et al*. Performing PICSI ® (MidAtlantic Diagnostic) versus conventional ICSI, in a study of 240 patients[21]. Recently, Nasr-Esfahani *et al*. have published a study (performed on 50 couples) observing a higher fertilization rate when injecting oocytes with HA-selected spermatozoa[22]. Against this, in two studies with a small number of patients involved [44 patients Van Den Berg *et al*, and 18 patients Sanchez *et al*.], no differences in fertilization[23,14].Use of hyaluronan-facilitated sperm selection did not exert any observed harmful effects to the recipient oocytes or resulting embryos. Consequently, the use of hyaluronan binding sperm in ICSI may directly influence the genetic integrity of the paternal contribution to the conceptus, minimizing the potential risks inherent to ICSI [20].

Conclusions

The percentage of fertilization for PICSI group is better than for ICSI group. In regarding to statistical analysis, there was no significant differences between two groups. Regarding to embryo quality at cleavage stage, the PICSI cycle significantly improves embryo quality(Grade 1 and Grade 2) at day 2 and day 3 of development as compared to the ICSI cycle.

Authors Contribution Statement: This research was done by Dr.Ezdehar N. Ali as a part of her Ph.D. thesis under the supervision of Assist. Professor Dr. Hayder A.L. Mossa (corresponding author).

Depression and Meaning of Life of Middle-Aged Women: Mediating Effects of Self-Esteem and Social Network

Hae Kyung Chang

Professor, Department of Nursing, Hanseo University,Seosan, Republic of Korea

Abstract

Purpose: This study aims to verify the mediating effects of self-esteem and social network on the relation between depression and meaning of life of middle-aged women.

Method: The data was collected from total 119 middle-aged women in 40-64 years old. The data was analyzed using the descriptive statistics, Pearson's correlation coefficient and stepwise multiple regression by using the SPSS 22.0 Program.

Results: The meaning of life showed the significantly negative correlation with depression(r=.-52, p<.001) while it showed the positive correlations with self-esteem(r=.74, p<.001) and social network(r=.56, p<.001). In the relation between depression and meaning of life, the self-esteem and social network were the significant mediating variables.

Conclusion: This study could be used as the basic data for the development of integrated nursing intervention programs that could improve the quality of life of middle-aged women.

Keywords: *Middle-aged women, Depression, Meaning of life, Self-esteem, Social network.*

Introduction

As the most active period in lifetime, the middle age is the period to get ready for the upcoming new old age by bearing fruits of efforts so far and giving a new meaning to life.[1] However, in case of middle-aged women, they go through diverse emotional changes and physical symptoms as their ovarian function gets declined around the menopause.[2] Out of them, the depression of middle-aged women is an important health problem required for nursing intervention as it is related to the degree of life goal and achievement under the emotional confusion and wandering together with doubts about the meaning of life and the substance of themselves in the middle of their lives.[1]

Corresponding Author:

e-mail: hkchang@hanseo.ac.kr

As an important variable having effects on the meaning of life of middle-aged women, the self-esteem is a variable having direct effects on the depression,[3] and the depression has a correlation with the meaning of life of middle-aged women,[1] so that it is verified as a variable related to the meaning of life of middle-aged women. As an environmental variable, the social network has direct/indirect effects on individual's health by meeting the sociality which is a basic desire of human, providing information to individuals, and also motivating them to act for the enhancement of health.[4] Thus, based on the preceding researches reporting the correlation between depression and meaning of life, the depression would have effects on the meaning of life of middle-aged women, and also the self-esteem and social network would work as mediating variables on the relation between those two variables. As a result, the quality of life after the middle age could be decided depending on how successfully the individuals adapt themselves to changes and loss in accordance with physical aging. Thus, it would be necessary to review the meaning of life by strengthening the establishment

of social network, growing the self-regulating ability through the self-esteem enhancement training, and also enhancing the depression management ability.

Thus, this study aims to provide the basic data for the development of nursing intervention programs that could improve the quality of life of middle-aged women by verifying the mediating effects of self-esteem and social network on the relation between depression and meaning of life of middle-aged women.

Method

Subjects: This study selected the middle-aged women in 40-64 years old. Regarding the number of samples in this study, when setting up the medium-level effect size (.15), significance level (.05), and three predictor variables to secure the 95% statistical power for the correlation analysis and regression analysis by using the G*Power 3.12 Program, the number of minimum samples was calculated as 119. Thus, after distributing the questionnaires to 140 people, total 119 questionnaires were used for the final analysis.

Instruments

Depression: This study used the K-CESD-R (Korean version of Center for Epidemiologic Studies Depression Scale-Revised), verified for the validity and reliability by Lee et al.[5] This tool is composed of 20 questions based on the 5-point scale (0-4point). The higher score means the higher degree of depression. Cronbach 's α = .93 in this study.

Self-esteem: This study used the self-esteem scale, developed by Rosenberg.[6] This tool is composed of 10 questions based on the 4-point scale. The higher score means the higher degree of self-esteem. Cronbach 's α = .83 in this study.

Social Network: This study used the K-LSNS-R based on the LSNS-R (Social Network Scale-Revised) by Lubben et al.[7] verified for the validity and reliability by Hong et al.[4]This tool is composed of 12 questions based on the 6-point scale (0-5point). The higher score means the higher degree of social network. Cronbach 's α = .92 in this study.

Meaning of life: This study used the Korean version of meaning in life scale by Won, Doo-Ri et al.[8] This tool is composed of total 10 questions based on the 7-point scale. The higher score means more subjective meanings in life. Cronbach 's α = .96 in this study.

Data collection: The data was collected from July 2018 to August 2018. The researcher collected data from middle-aged women visiting the bus terminal, sports and shopping. After explaining the purpose and objective of this study to the voluntary participants, they were asked to fill out the written consent form.

Ethical consideration: For the ethical consideration of subjects, this study submitted the research plan to the Public Institutional Review Board under the Ministry of Health and Welfare, and then received the deliberation exemption approval (P01-201806-21-017) before starting this study.

Data analysis: The general characteristics of subjects, and depression, self-esteem, social network, and meaning of life were determined by descriptive statistics using the SPSS/WIN 22.0 Program. The correlations between variables were analyzed through the Pearson's correlation coefficients. Also, the mediating effects of self-esteem and social network on the relation between depression and meaning of life were analyzed using the regression and Sobel test.

Results

General characteristics of subjects: The subjects in 40-49 years old were the most (n=55, 46.2%). In the degree of education, the graduation of college or up was the most (n= 78, 65.5%). Total 96 subjects (80.7%) had a spouse, and total 72 subjects (60.5%) had a religion. And total 67 subjects (56.3%) had an occupation. Regarding the economic status, total 95 subjects (79.8%) responded that they were in the middle status. In case of health status, total 61 subjects (51.3%) responded that they were in the normal status (Table 1).

Table 1. General characteristics of subjects (N=119)

Characteristics	Categories	n (%)
Age (Years)	40~49	55(46.2)
	50~59	54(45.4)
	60~64	10(8.4)
Education	≤High school	41(34.5)
	≥College	78(65.5)
Spouse	Yes	96(80.7)
	No	23(19.3)
Religion	Yes	72(60.5)
	No	47(39.5)
Occupation	Yes	67(56.3)
	No	52(43.7)

Characteristics	Categories	n (%)
Economicstatus	High	12(10.1)
	Middle	95(79.8)
	Low	12(10.1)
Healthstatus	Good	44(37.0)
	Normal	61(51.3)
	Bad	14(11.7)

The degree of depression, self-esteem, social network and meaning of life in subjects

The mean scores of depression and self-esteem of subjects were .63(±.69) and 2.94(±.43) respectively. The mean scores of social network and meaning of life of subjects were 2.43(±.81) and 4.65(±1.30) (Table 2).

Table 2. The degree of depression, self-esteem, social network and meaning of life

Variables	M±SD	Min	Max
Depression	.63±.69	0	3.90
Self-esteem	2.94±.43	1.90	4.00
Social network	2.43±.81	.33	4.25
Meaning of life	4.65±1.30	1.90	7.00

Correlations between depression, self-esteem, social network and meaning of life in subjects: The meaning of life had the significantly negative correlation with depression(r=.-52, p<.001) while it had positive correlations with self-esteem(r=.74, p<.001) and social network(r=.56, p<.001). In other words, when the degree of depression was lower, and when the degrees of self-esteem and social network were higher, the degree of meaning of life was higher(Table 3).

Table 3. Correlations between depression, self-esteem, social network and meaning of life

Variables	Depression r(p)	Self-esteem r(p)	Social network r(p)
Depression	1		
Self-esteem	-.51 (<.001)	1	
Social network	-.38 (<.001)	.49 (<.001)	1
Meaning of life	-.52 (<.001)	.74 (<.001)	.56 (<.001)

The mediating effects of self-esteem and social network on the relation between depression and meaning of life in subjects: First, the mediating effects of self-esteem on the relation between depression and meaning of life of middle-aged women are as follows(Table 4). In the first step, the depression as an independent variable had statistically significant effects on the self-esteem as a mediating variable(β=-.51, p<.001), and the explanatory power of self-esteem was 26%. In the second step, the depression as an independent variable had significant effects on the meaning of life as a dependent variable(β=-.52, p<.001), and the explanatory power of meaning of life was 27%. In the third step, in the results of conducting the regression analysis by taking the depression and self-esteem as predictor factors and the meaning of life as a dependent variable to understand the effects of self-esteem as a mediating variable on the meaning of life as a dependent variable, the depression(β=-.19, p=.007) and self-esteem(β=.64, p<.001) were the significant predictor factors on the meaning of life. In other words, when taking the self-esteem as a mediating variable in the third step, the depression was significant on the meaning of life. As the non-standardized regression coefficient was decreased from the absolute value .98 of the second step to the absolute value .36 of the third step, the self-esteem partially mediated.

Second, the mediating effects of social network on the relation between depression and meaning of life of middle-aged women are as follows(Table 4). In the first step, the depression as an independent variable had statistically significant effects on the mediating effects of social network(β=-.38, p<.001), and the explanatory power of social network was 14%. In the second step, the depression as an independent variable had significant effects on the meaning of life as a dependent variable(β=-.52, p<.001), and the explanatory power of meaning of life was 27%. In the third step, in the results of conducting the regression analysis by taking the depression and social network as predictor factors and the meaning of life as a dependent variable to understand the effects of social network as a mediating variable on the meaning of life as a dependent variable, the depression(β=-.36, p<.001) and social network(β=.42, p<.001) were the significant predictor factors on the meaning of life. In other words, when taking the social network as a mediating variable in the third step, the depression was significant on the meaning of life.As the non-standardized regression coefficient was decreased from the absolute value .98 of the second step to the absolute value .68 of the third step,the social network partially mediated.

In the results of Sobel test for the test of significance on the mediating effect size of the self-esteem and social network, the self-esteem and social network were the significant mediating variable on the relation between depression and meaning of life (Z=-5.26, p<.001, Z=-3.47, p<.001).

Table 4. Mediating effects of Self-esteem and Social network on the Relation between Depression and Meaning of life

Step	Variables	B	β	t	p	R^2	Adj. R^2	F	p
Step 1	Depression → Self-esteem	-.322	-.512	-6.452	<.001	.262	.256	41.630	<.001
Step 2	Depression→Meaning of life	-.983	-.521	-6.609	<.001	.272	.266	43.685	<.001
Step 3	Depression, Self-esteem → Meaning of life					.576	.569	78.831	<.001
	1) Depression	-.363	-.192	-2.733	.007				
	2) Self-esteem	1.926	.642	9.125	<.001				
Sobel test : Z=-5.26, p<.001									
Step 1	Depression→Social network	-.442	-.377	-4.401	<.001	.142	.135	19.366	<.001
Step 2	Depression→Meaning of life	-.983	-.521	-6.609	<.001	.272	.266	43.685	<.001
Step 3	Depression,Social network→ Meaning of life					.426	.416	42.995	<.001
	1) Depression	-.682	-.362	-4.763	<.001				
	2) Social network	.681	.423	5.575	<.001				
Sobel test : Z=-3.47, p<.001									

Discussion

The cut-off score of this depression tool was 13, and the mean score of depression of subjects was .63(mean 12.7). Compared to the optimal cut-off score(16) of a foreign tool CESD-R, this tool shows the lower cut-off score. As the final score could be influenced by situations or method presented by the tool, and this result might reflect the sociocultural background of Korea, the developer emphasizes that there should be sufficient consideration of depression even when the score is relatively low.[5] The mean score of self-esteem was 2.94. The self-esteem of female adults was lower, the prevalence of depression got higher. Thus, it was verified as a predictor factor of depression, which supports the results of this study.[9] The mean score of social network was 2.43(mean 29.11), and in a research targeting the subjects in mean 57.58 year old, by the tool developer Hong et al,[4] it was 30.53. Like this, the degree of social network shows a bit of differences and the differences in the degree cannot be compared, so that it would be necessary to have further researches. The mean score of meaning of life was 4.65 out of seven. A research targeting the middle-aged men and women by using the same tool, by Chang[10] showed a bit higher score (4.81) than the result of this study. Considering the results of a study by Chang & Sohn[1] reporting that the middle-aged men showed the higher score of meaning of life than the middle-aged women, this might be because this study targeted only middle-aged women.

In the correlations between depression, self-esteem, social network, and meaning of life, the meaning of life showed the significantly negative correlation with depression while it showed the positive correlations with self-esteem and social network. As the factors having effects on the meaning of life, the physical factors having direct effects on health and functions, personal factors like hardiness, environmental factors like social support, cognitive factors like self-esteem, and the emotional factors like depression and stress were mentioned,[11] which supports the results of this study. According to a research by Oh & Oh,[12] the low self-realization and interpersonal relationship have effects on the meaning of life in the middle age, and the social support works as a buffering agent of psychological symptoms such as stress or depression of middle-aged women,[13] which supports the results of this study.

On the relation between depression and meaning of life, the self-esteem showed the partial mediating effects. In other words, even though the depression of

middle-aged women had direct effects on the meaning of life, the meaning of life could be positively influenced by self-esteem showing the mediating effects. According to a research by Choi,[14] the most influential variable on the meaning of life is self-esteem, so that there should be further researches on the causality if the self-esteem would work as a mediating variable. On the relation between depression and meaning of life, the social network showed the partial mediating effects. In other words, even though the depression of middle-aged women had direct effects on the meaning of life, the meaning of life could be positively influenced by social network showing the mediating effects. According to a research targeting elderly women by Oh et al.[15] the social network has significant effects on the depression, which supports the results of this study. However, there should be further researches targeting middle-aged women.

Conclusion

As a result, the quality of life after the middle age could be decided depending on how successfully individuals adapt themselves to changes and loss in accordance with physical aging. Thus, it would be necessary to review the meaning of life by strengthening the establishment of social network, growing the self-regulating ability through the self-esteem enhancement training, and also enhancing the depression management ability.

Abstract

In 2017, many schools were not yet equipped with good sanitation facilities. In Indonesia, 1.5 million children under five die of diarrhea every year. This community partnership program aims to increase students' knowledge about environmental sanitation and improve environmental sanitation behavior. The method used quantitative and qualitative method. Quantitative method is resultant from questionnaires data and qualitative method used to direct observation through Focus Group Discussion (FGD. The data of students' knowledge and behavior were analyzed using bivariate analysis. The results of this activity showed that at the pretest, the elementary school students' knowledge was 90.62%, which was in the good category, and the peer educator's knowledge was 82.14%, which was in the good category. At the posttest, the elementary school students' knowledge increased to 94.08%, which was in the good category, and the peer educator's knowledge increased to 90%, which was in the good category. The elementary school students' sanitation behavior was 67.60%, which can be categorized as good. Correlation test results showed no significant relationship between students' knowledge and behavior ($p > 0.05$). It can be concluded that there was an increase in students' and peer educators' knowledge about environmental sanitation after the implementation of community partnership program. Unfavorable sanitation behaviors were seen in the behaviors of littering, not washing hands before eating, and consuming unhealthy snack. Meanwhile, good sanitation behavior was seen in the behavior of bathing twice a day and defecating in the toilet/water closet.

Introduction

Health status of a person or a community in a society is the result of the interaction of various factors, i.e. internal and external factors[1]. Internal factors include psychological and physical factors. External factors include factors of community culture, physical environment, social, education, politics, economics, and so on[1]. Broadly speaking, health status is influenced by four factors, namely environment (45%), lifestyle/ behavior (30%), health services (20%), and genetics/ heredity (5%). Health status is a unity of various conditions, including physical, mental and social health[1]. Therefore, each factor has a significant role in creating public health status. Environmental factor has major impacts on human health, one of which is waste management. Waste is considered as one of the urban problems. The existence of waste is considered as a source of disease, it also damages the city's aesthetics. One of the easiest ways to deal with it is to dispose it in a place far from the settlement[2]. The other environmental factor is sanitation facilities. One of three schools in Indonesia does not have access to water, 12.09% or 25,835 schools in Indonesia do not have water closets, 35.19% or 75,193 schools in Indonesia do not have hand washing facilities, and one of two schools in Indonesia does not have water closets that separate male students and female students[3].

Based on the results of previous research, the water quality around Bantargebang, especially for microbiological parameters in the Ciketing Udik Urban Village in 2019, was below the quality standard[4]. The results of previous research also illustrated that the amount of waste that entered Bantargebang Integrated Waste Management Site for the period 2014-2015

fluctuated every month. The maximum amount was in December 2015, which was 214,972.08 tons/month, and the minimum amount was in June 2014, which was 151,770.58 ton/month[5]. The results of previous research also showed that the most medical expenses spent by the people in the three villages were for URTI, followed by diarrhea and malaria. The number fluctuated every month. The results showed that water sanitation in Sumur Batu area was classified as low, specifically the clean water and drinking water services. The results of observations and interviews showed that some residents and scavengers around the Waste Management Site did not have sanitation facilities that met the requirements[6].

Method

The program was implemented at Elementary School of Dinamika Indonesia located in Bekasi Bantargebang Integrated Waste Management Site, Ciketing Udik Urban Village, Bantargebang Sub-District. The primary targets in this program were the students of Dinamika Indonesia Bantargebang and the secondary targets (peer educator) in this program were the staff in the school environment, including the headmaster, teachers and the educational community. The students and peer educators took a pretest on knowledge about sanitation and questionnaire on elementary school students' behavior.

The pretest and posttest given to students and peer educators consisted of 10 questions. Students' and peer educators' knowledge were categorized based on the questionnaire. There were 3 categories of knowledge:

a. Poor, if the correct answers were < 56%,

b. Moderate, if the correct answers were 56%─75%,

c. Good, if the correct answers were 76-100%.

The percentages were obtained by dividing the number of correct answers by the number of respondents then multiplied it by 100%. After calculating the percentage, the results can be categorized[7]. Environmental sanitation behavior categories were assessed using a hypothetical mean formula. The results of questionnaire on students' knowledge and behavior were then analyzed using bivariate analysis. The results were previously tested using normality test. Normality test results showed that the data were not normally distributed so the correlation test was conducted using Kendall's Tau-b test.

Results

Results of students' pretest are presented in Table 1.

Table 1. Results of Elementary School Students' Pretest

Number of Students	Total score per question										Total
	1	2	3	4	5	6	7	8	9	10	
96	93	90	94	95	94	93	44	80	94	93	870

Mean obtained from the questionnaire was 9.062.

Results of peer educators' pretest are presented in Table 2.

Table 2. Results of Peer Educators' Pretest

Number of Peer Educators	Total score per question										Total
	1	2	3	4	5	6	7	8	9	10	
14	11	14	12	14	13	12	13	13	12	1	115

Mean obtained from the questionnaire was 8.214.

Results of students' posttest after the familiarization to elementary school students are presented in Table 3.

Table 3. Results of Elementary School Students' Posttest

Number of Students	Total score per question										Total
	1	2	3	4	5	6	7	8	9	10	
71	69	71	69	70	71	70	56	55	68	69	668

Mean obtained from the questionnaire was 9.40.

Results of peer educators' posttest are presented in Table 4.

Table 4. Results of Peer Educators' Posttest

Number of Peer Educators	Total score per question										Total
	1	2	3	4	5	6	7	8	9	10	
13	12	13	13	13	13	13	13	12	13	2	117

Mean obtained from the questionnaire was 9.

Table 5. Frequency Distribution of Elementary School Students' Sanitation Behavior

Category	Total	Percentage
High	48	67.60%
Medium	23	32.40%
Total	71	100%

In the posttest results, it can be seen that the total correct answers was 870. It was divided by 96 and multiplied by 10 questions. The result was multiplied by 100%. The percentage obtained was 90.62%, which means that students' knowledge was in the good category. Categories of elementary school students' knowledge about sanitation are presented in Table 6.

Table 6. Categories of Elementary School Students' Knowledge

	Pretest Category	Posttest Category
Students	90.62% (Good)	94.08% (Good)
Peer educators	82.14% (Good)	90% (Good)

Relationship between students' knowledge and behavior variables was tested using Kendall's Tau-b test. Bivariate test results showed no significant relationship between student's knowledge and behavior ($p = 0.992$ or $p > 0.05$).

Discussion

Referring to Table 6 above, it can be seen that students' and peer educators' knowledge was in the good category even before the familiarization. The implementation of familiarization to elementary school students and training of peer educators seemed to increase knowledge, as evidenced by an increase in the percentage of correct answers by elementary school students and peer educators. Bivariate analysis results showed no relationship between environmental sanitation knowledge and behavior. These results were not in line with the results of previous research, which found a positive correlation between environmental knowledge and behavior[9]. In addition, the results of previous research also indicated a correlation between students' knowledge and behavior[10]. Environmental education was proven to increase students' knowledge about the environment[11]. Good student behavior can be formed through daily practice. It was in line with the results of previous research, which found that good practices in waste management must be applied in the school environment in order to change students' behavior[12].

Based on Table 5, elementary school students' sanitation behavior was quite good, but there were some behaviors that were not good enough. One of the bad behaviors was consuming unhealthy snack. Behavior of consuming street food had the highest percentage, 14.85% of students answered always and 56.34% of students answered often. It happened because there were no canteen facilities at Dinamika Indonesia. Therefore, students bought snacks on the roadside near the school. Some teachers had taken precautions so that students did not buy unhealthy snack by asking them to bring lunch box from home. Healthy eating behavior can be

improved by providing knowledge of the importance of healthy food to students and parents[13]. Hence, the need for policies regarding the promotion of healthy food in the school environment emerges[14]. In addition, schools must provide healthy canteens. Healthy canteens can support the availability of healthy food for students[15, 16].

Behavior of disposing waste properly was always done by 57.74% of students. The rest answered often, sometimes and never, which meant that 40% of students did not always dispose waste properly. It might be caused by the lack of waste containers provided by the school or the poor wastemanagement. Waste was not transported to the Waste Management Site regularly, causing waste containers full and waste scattered around containers because they can no longer accommodate the waste. This scene was witnessed by the researchers when they visited the school several times. Adequate disposal facilities can influence the habit of disposing waste properly[17]. In addition, it is necessary to provide environmental education, such as disposing waste properly as early as possible to elementary school students[18].

Behavior of washing hands before eating was always done by 67.60% of students. The rest answered often, sometimes and never, which meant that approximately 33% of students did not always wash their hands before eating. It might be caused by the far distance to toilet facilities. Elementary school students whose classrooms were located on the 2nd floor must go down to the 1st floor to wash their hands in the lavatory. The lavatories were located only on the 1st floor. Moreover, Dinamika Indonesia had no sink. This was in line with the results of previous research, which stated that students' behavior of washing hand was influenced by hand washing facilities[19, 20, 21]. In addition, it was necessary to conduct regular hand washing training to build students' good behavior of washing hand. [22].

Behavior of defecating in the toilet/water closet and bathing twice a day were always done by > 80% of students. The result was supported by the previous research, which mentioned that most families living around Bantargebang Integrated Waste Management Site owned shared facilities for bathing and defecating[4]. The available facilities supported behavior of bathing twice a day and defecating in the toilet/water closet.

Conclusions

Elementary school students' and peer educators' knowledge increased after the implementation of community partnership program, 2) elementary school students' and peer educators' knowledge about sanitation were in the good category, 3) Poor sanitation behaviors were seen in the behavior of littering, not washing hands before eating and consuming unhealthy snack, 4) good sanitation behaviors can be seen from the behavior of bathing twice a day and defecating in the toilet/water closet.

Recommendations that can be given as follows: 1). Dinamika Indonesia should be equipped with healthy canteen facilities, 2) Dinamika Indonesia should be equipped with toilets on each floor and sinks in front of classrooms for washing hands, 3) Dinamika Indonesia should increase the number of waste containers at students' gathering points.

Competing Interest: This research is part of the Community Partnership Program of the Ministry of Research, Technology and Higher Education of the Republic of Indonesia and the University of Indonesia, thus there is no competition in running this program.

Ethical Clearance: This program is approved by the Institutional Review Board (IRB) of the Faculty of Public Health and School of Environmental Science, University of Indonesia.

Source of Funding: This research is funded by the Ministry of Research, Technology and Higher Education of the Republic of Indonesia.

Acknowledgement: The researchers would like to express their gratitude to the Ministry of Research, Technology and Higher Education of the Republic of Indonesia and the Directorate of Research and Community Service at the University of Indonesia (DRPM UI) for the Community Partnership Program. The researchers would also like to express their gratitude to Yayasan Dinamika Indonesia and Serambi Inspirasi for participating in this program.

Abstract

Background and Objectives: A Posyandu is an integrated health post as an extension unit of Puskesmas (community health center) providing several under-five child health programs, especially regular weighing every month, basic immunization and vitamin A supplementation and additional food provision. Monitoring of child growth in Posyanduis a very important activity in order to know early child growth faltering. Data of National Basic Health Research (RISKESDAS) 2010,proportion of regular weighing was only 49.4%.

Method: A cross-sectional study was conducted to interview 96 mothers of under-five children randomly selected from 7 neighborhood blocks in sub-district of Kelapa Gading, Jakarta. The multivariable analysis was done to analyze strength of association (using odds ratios) between some potential determinants and the regularity of mothers to weigh their children in Posyandu. Weighing 4 times or more within the past 6 months was considered to be regular.

Findings: The proportion of mothers weighing their children regularly in Posyanduin sub-district Kelapa Gading was 47.9%. The older the mothers, the lesser the probability to weigh regularly their children. Mothers who knew that Posyandu could provide Vitamin A and basic immunization freely for their children, were 2.7 times and 4.3 times respectively more likely to weigh their children regularly, as compared to mothers who did not know. Closer distance between mother's house and Posyandu gave the mothers higher probability to weigh their children regularly, as much as 18.5 times, as compared to farther distance. The likelihood of working mothers to weigh their children regularly, were 18.3 times, as compared to the likelihood of housewife mothers.

Conclusions: Mother's age, knowledge about the programs of Posyandu, distance between mothers' house and Posyandu, and mother's occupation status were important determinants of likelihood to weigh their children regularly in the Posyandu.

Keywords: *Posyandu,regularity of weighing, under-five children.*

Introduction

Weighing children under five years old regularly every month is one of the vital activities in monitoring health and nutrition status. With regular monthly weighing, growth faltering can be identified early so that growth promotion can be done to prevent the occurrence of malnutrition[1,2]. By monitoring intensively, if the child's weight does not rise or if a disease is found, recovery and prevention efforts could be made immediately in order to prevent malnourished. Quick and appropriate handling of malnourished children will reduce the risk of death so that mortality due to malnutrition can be suppressed, therefore, growth monitoring of children aged under five years is very important[1-4]. Parents are recommended to weigh their children especially in the early weeks and months of life with health professional.

If a child gains weight steadily this means that the child is growing satisfactorily. The World Health Organization (WHO) states that Growth Monitoring and Promotion (GMP) measures and graphs the child's weight and the result will be informed to the parent for advice, so that they can take action to improve child's growth in order to prevent malnutrition. Measurements begin at birth and must be done every month, accurately recorded on a growth chart and interpreted[3]. In Indonesia mostly growth monitoring activity is carried out in Posyandu (integrated service post)[4]. Posyandu is an Indonesian government program which is one of the Community-Based Health Efforts carried out by cadres who are part of the community with guidance from health workers in Puskesmas (Community health center). Posyandu has five main activities, consist of maternal and child health, family planning, immunization, nutrition improvement through weighing regularly and diarrhea therapy[5,6]. The role of Posyandu in growth monitoring and promotion has decreased. Various obstacles faced by the Posyandu include insufficient health services and equipment in Posyandu, low skilled of Posyandu's cadres, lack of public awareness of mothers to weigh their children. Based on RisetKesehatan Dasar/Riskesdas(National Basic Health Research) 2007: infants weighed regularly (4 times or more) was 45.4%, while those weighed 1-3 times and never weighed were, 29.1% and 25.5% respectively[7]. In Riskesdas 2010, the percentage of regular weighing increased slightly becoming 49.4%[8] however the percentage of children aged 6-59 months who had never been weighed in the last six months was likely to increase from 25.5% (2007) to 34.3% (2013)[9]. According to the Minister of Health Regulation No. 43 of 2016 concerning Minimum Service Standards that in addition to administering vitamin A capsules twice a year and giving complete basic immunizations, every toddler must also receiveweighing at least 8 times a year and measurement of length/height at least twice a year. Based on Riskesdas 2018, the percentage children who was weighed ≥ 8 per year was 54.6%[10]. This study objective was to determine the factors related to the regular weighing of children under five in Posyandu at sub district KelapaGading in North Jakarta

Method

A cross-sectional study was conducted in 2010to interview 96 mothers of under-five children randomly selected from 7 neighborhood blocks in sub-district of KelapaGading, Jakarta. Mothers who became a sample were those who had KMS (Kartumenujusehat/ Card towards health) and came to Posyandu in the last 3 months.The questionnaire used in the data collection was firstly tested in order to improve the questions so that it can bemore understandable by the respondents and thereby can maintain the good validity of the data resulted from the interview. Ethical Clearance was obtained from YARSI University. Analysis of the data comprised univariate, bivariate and multivariate analysis. The Chi-Square test was used in bivariate analysis. Multivariate analysis using cox regression model was done to analyze the strength of association (using prevalence ratio) between several potential determinants and regular weighing in Posyandu. Weighing 4 times or more within the past 6 months was considered as regular weighing.

Result and Discussion

This study revealed that the proportion of mothers weighing their children regularly in Posyanduin sub district Kelapa Gading was 47.9%.This result was almost the same as in Riskesdas 2010, 49.4 percent children aged 6-59 months who were weighed routinely during the last six months (4 times or more)[8]. The frequency of weighing > 4 times slightly decreased in 2013 (44.6%)[9]. In Riskesdas 2018 regular weighing, which was stated as at least done 8 times a year, increased significantly 54.6%. This maybe because of the definition of regular weighing was changed from at least 4 for the last 6 months to minimum 8 times in one year[10]. In this study, there were 15.6% of children had only one time weighing in the last 3 months and there was no child had not been weighed. This result was better as compared to data in Riskesdas. Children aged 6-59 months who have never been weighed in the last six months increased from 23.8% in Riskesdas 2010 to 34.3% in Riskesdas 2013. However, there was no data in Riskesdas 2018[8-10].

In bivariate analysis we found some potential factors related to regular weighing to Posyandu such as mother's age, mother's formaleducation, mother's workingstatus, family income/socio-economic level, mother's knowledge, child's age, distance to Posyandu, and cadre's attitude (table 2). In Multivariate analysis using Cox Regression, we found that there were two determinants in regular weighing of children under five years in Posyandu, which were mother's knowledge and mother's working status (see table 2). Mothers who did not work were 2.1 times more likely to weigh regularly their children in Posyandu, as compared to working mothers (PR= 2.12; p-value=0.030). Mothers with

higher knowledge were 2.78 times more likely to weigh their children regularly as compared to mothers with lower knowledge (PR= 2.78; p-value=0.002).

Table 1. Potential Determinants associated to Regular Weighing

Determinant Factors	Regular Weighting				PR (Prevalence Ratio)	95% CI	p
	Regular		Irregular				
	n=46	%	n=50	%

In Indonesia, Posyandu is a very important place of weighing children under five so that its existence is needed both by the community and by health workers. Posyandu is a form of community participation in health development, but the role of Posyandu in growth monitoring and promotion has decreased in scope.

Various obstacles faced by the Posyandu included insufficient equipment, low skilled of Posyandu cadre, lack of public awareness to weigh their children and health services in Posyandu were not yet optimal[2]. The community activeness in monitoring growth of their children in the Posyandu continued to decline[3,11]. One of the reasons that mothers did not take their children to weigh regularly was that they felt that weighing children in Posyanduwas not important (20.8%). This perception was especially from working mothers which might affect the decrease of the weighing of the children under five in Posyandu. One factor driving this was the mother's ignorance of the benefits of weighing her child at the Posyandu, leading to reluctance to bring their children to Posyandu. Other reasons comprisedPosyandu was not regularly scheduled (29.2%), the mothers were working (31.3%) and children were weighed in other health services (18.8%)[12]. In Riskesdas 2018 it was stated that the reasons for children not to be weighed: children were already old (≥1 years) 14.1%, children had immunization (10.8%), children did not want to be weighed (8.1%), lazy (15.1%), forget/did not know the schedule (12.8%), there was no place for weighing (2.8%), the place was far (6.8%), busy/hassle (28.3%), body scale was not available (1.3%)[10].

There was such a tendency that the higher age child group, the lower the scope of routine weighing (≥ 4 times during the last six months). Conversely the higher the age of the child the higher the percentage of children who had never been weighed. This study revealed that younger age (< 24 months) tend to be weighed 2.3 times as compared to older age (PR=2.3; see table 1). The same pattern was also found in Riskesdas 2018[10].

A very significant relationship between the level of maternal knowledge with the frequency of weighing children under five in Posyandu (PR=2.121). This result was similar to what Ariyani et al. found in their research in Posyandu Desa Pilangrejo[16]. The same result was also related to mother working status. Ariyani et al. found a significant relationship between mother's work and the frequency of weighing children under five in Posyandu, Pilangrejo Village, Wonosalam District, Demak Regency. Mother who did not work were more frequently weigh their children in Posyanduas compared to mothers who worked[13]. These results were very compatible with the theory from Green about health behavior which states that a person's behavior is motivated by 3 factors, one of which is a predisposing factor that contains knowledge[14]. Mother's knowledge is very important for mothers in order to get optimum results in growth monitoring program.

In Ethiopia most of mother did not know immediately about growth monitoring unless the topic was raised simultaneously with issue of immunization. Therefore, their awareness of growth monitoring was low as compared to attention to immunization. Most mothers mentioned that a regular growth monitoring program was mainly provided for children below two years of age[3].

Based on research by Kusumawati et al. there was a significant relationship between the attitudes and behavior of cadres to the frequency of weighing toddlers[15]. However according to Trintrin et al 2003, knowledge of cadres in interpreting the growth curve in the growth chart was very low; it was only nine percent of cadres that were ableto interpret the growth curve correctly. There was 98% of cadres did not know that the weight change in monthly weighing should be told to mother in nutrition counseling[16].

Conclusions and Recommendation

Mother's knowledge about the programs and mother's work status were very important determinants of weighing children regularly in Posyandu.

Recommendation:

1. Increase awareness of mothers through cadres to more actively and regularly weigh their children, in order to decrease nutritional problem of under five children.
2. Strengthening CIE (communication, information and education) program in Puskesmas to increase mother's knowledge about the importance of monitoring the child growth through regular weighing to prevent growth faltering.
3. Health workers should provide information to the mothers through counselling in which mother can communicate and interact actively,so that mothers can take action to promote child growth. This is the way also to make them aware of the benefits of weighing at the Posyandu.

Acknowledgment: The author would like to thank to the head of the Community Health Center of Kelurahan Pegangsaan IIB and all cadres that helped the study in the area.

Conflict of Interest: Nil

Source of Funding: No funding source for the research

Molecular Sequencing Study of Salmonella spp Which Isolated from Cattle Meat and Human Stool

Hiba Shehab Ahmed[1], Wafaaabdalwahed Jheel2, Saba Falah Klaif[3]

[1]Lecturer, [2]Assistance Professor, AL-Qadisiyah University- College of Biotechnology,
[3]Assistance Lecturer, AL-Qadisiyah University- Veterinary Medicine

Abstract:

Aim of our study is investigation of the genetic relationships between *Salmonella spp* isolates which taken from human stool isolates and *Salmonella spp* isolates which taken from cattle meat. The total number of study isolates is one hundred (50 cattlebeef and 50human stools. Bacterial isolation and bacterial identification are used for testing the samples for culturing and examined by biochemical tests then detected by using 16S rRNA gene in PCR that designed by NCBI and make DNA sequencing for two positive isolates. Our results revealed that percentage of *Salmonellaspp* was 8/50(16%) which isolated from cattle beef and was 10/50(20%) which isolated from human stool. The PCR was demonstrated highly specific and sensitive. DNA sequencing of part of 16S rRNA was show highly similarity with NCBI-Blast data and the phylogenetic study was reveal genetic homology at (0.5 genetic change) between animals and human isolates and then the gene sequence deposited into NCBI-Genbank accession numbers accession numbers (MN523665.1) and (MG388337.1). In conclusion, our study is done for first-time in Iraq of the genetic correlating between *Salmonellaspp* which isolated from cattle meat and human stool. So, it is important to know the cattle meat is significant source for spreading infection between human and animals.

Keywords: *Sequencing, Salmonellaspp, Cattle, Human stool.*

Introduction

Salmonellais negative gram bacteria causing of contamination of food products, which is a way of transmitting pathogens to humans[1&2] this pathogen Itcan hide in the digestive tract of healthy animals and the environment[3].

The significant loss of economic production in the food and animal industries is associated with moderate and severe salmonella disease and mortality in field animals[4], Salmonella bacteria cause various syndromes of diseases and host specificities based on its antigenic effects, intestinal *Salmonella* is considered the leading cause of food diseases in animals and humans worldwide[5-7].

Serotypes of salmonella are divided to (3) groups (bacteremia, enteritis and typhoid fever)[8].

Materials and Method

Samples Collections: (100) samples divided into (50) fresh beef meat, provided from slaughterhouse and butchers in different sites of Al- Qadissyia province and fifty stools of Human samples. All the samples were keeping in cold box then sent to microbiology Laboratory. In Vet Med. College for swabbing then submitted to culturing and biochemical test for culture and identifying of *Salmonella spp.*

Salmonella spp isolation and identification: The samples were inoculated in nutrient *salmonella* differentiated from other enterobacteriacea bacteria. The single pure colony was cultured Salmonella-Shigella agar and XLD agar to identification *Salmonella* from another lactose fermententerobacteriaceain figure (1) (2).

Figure (1) and (2): salmonella colony on SS agar and XLD agar.

Genomic DNA Extraction: Genomic DNA of *Salmonellaspp* isolates was extracted by using a kit called (mini genomic DNA. China. Geneaid Company). 1ml of new bacterial growth (for overnight) in the nutrientbroth was put in the microtubes (1.5) ml. These tubes were centrifuged for one minute at 10 thousand rpm. The DNA extracted from bacterial cells based on company instruction. For determining purification and concentration, Nanodrop spectrophotometeris used for this purpose then the product kept in freezer (-20)°C.

PCR: It was doneby using a designedprimer at (880)bp of (16s rRNA) gene in all (F) primer (TG ATC GTT TAC GGC GTG GAC),and(R) primer (A ATA CCA AGT CTC AAG AGT G) were provided by (Korea, Bioneer co.). Preparation of PCR master mix is done by using a kit called (Korea, Bioneer Company, AccuPower® PCR PreMix). Compositions of the premixtube are:

1. Polymerase enzyme
2. dNTPs
3. KCl
4. Tris-HCl
5. MgCl2
6. Stabilizer
7. Stain

Preparation of PCR master mix was done depend on kit directions in total volume (20) µl by mixing with DNA (5) µl and F primer (1.5) µl and R primer (1.5) µl, then adding PCR premix tube bywater for (20) µl then shaking by vortex (Korea Bioneer). All stage of the reaction is done into thermocycler (Germany Eppendorf) as:

1. The first stage five minute at (95)°C.
2. The second stage (denaturation stage) at 95°C for (30) cycles for (30) second.
3. The third stage (annealing stage)thirty seconds in (60)°C
4. The fourth stage (extension stage) thirty seconds in (72)°C
5. The fifth stage (final extension stage) ten minute in (72)°C.

The products were prepared in electrophoresis on agarose gel (1.5)%, and then Ethidium bromideis used for dyeing then putting under (UV)light apparatus for visualized.

DNA Sequencing: It was done for confirmative detection,and Phylogenetic relationship of *Salmonellaspp* depended on (16s rRNA)gene by analysis of phylogenetic tree (MEGA 6) program. (880) bp PCR product was placed in agarose gel by using extraction kit called (EZ EZ-10 Spin Column DNA Gel, made in Canada Biobasic company). The PCR product which contains(16s rRNA) gene was sent to Korea in Bioneer Com. for doing DNA sequencing.

The Results: One hundred of study samples(50) are cattle meat and (50) human stool are cultured of clinical samples and examine by Conventional PCR. Only 8/50 (16%) of cattle beef and 10/50 (20%) samples of human stool which appeared positive for *salmonella spp* at (880) bp PCR product of (16srRNA) gene on agaroseelectrophoresisas a table (1) and Figure (3).

Table (1): Number and percentage of study samples

Sample	Total N.	Positive	Positive Percentage	Negative	Negative Percentage
Cattle Meat	50	8	16%	42	84%
Human Stool	50	10	20%	40	80%
Total	100	18	18%	82	82%

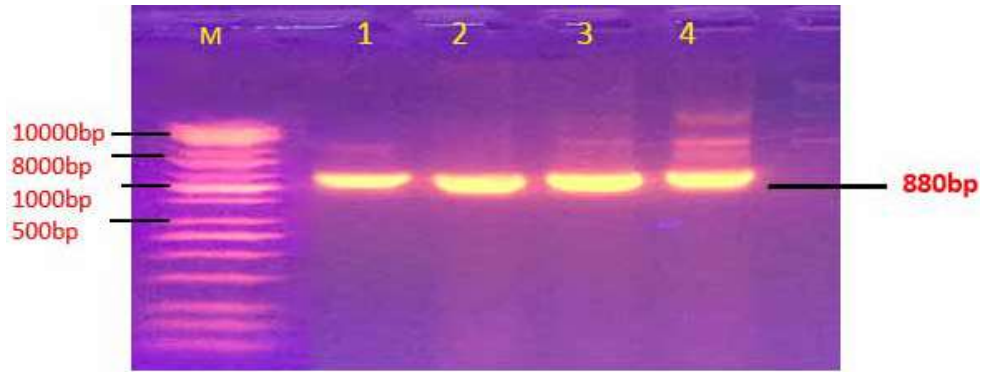

Figure (3):band on Agarose gel by using electrophoresis device represent partial 16S rRNA gene of salmonella sp.

Sequence analysis was donetodeterminingthe results of PCR. These sequences formthe conserved region of 16s rRNA of the *Salmonellaspp* provided accession numbers (MG388337.1) from beef cattle at NCBI. Analysis of DNA sequencing of (16s rRNA) gene by many sequence alignment (BLAST-NCBI) reveals detection of the results of phylogenetic analysis in most of the Iraqiisolates that grouped mainly with the same branch *salmonella sppentericaserovar Typhimurium*. South Korea, only one clone in this study clustered in the same branch of Jordanian in clade A. while bat corona virus, SARSV and neoromicacorona viruswere out group clustered in the separated branch as Fig(4).

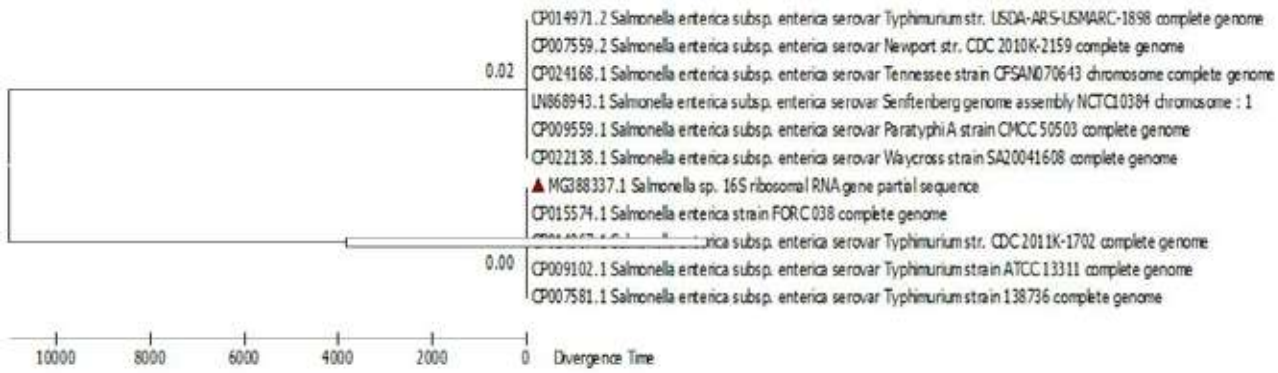

Figure (4): Phylogenetic tree of my isolates with references world salmonella sp and their accession no.

Discussion

According to our results, percentage of *salmonella spp* that isolated from cattle meat samples by using polymerase chain reaction was (16)%, that close to results of [9]and [10] were (17.5)% and (20)% respectively in beef meat by using PCR. While [11] and[12] are recorded (55)% and (100)% respectively in meat beef by using PCR and that was more than rates of results.

Some the studies founded low rates of *salmonella spp* by using PCR in meat beef such as[13-15] wherever they founded (6.7)%, (6.5)% and (4.35)% respectively.

The prevalence of *salmonella spp* is varied due to several causes such as rate of contamination, hygienic management, general cleaning, sterilization techniques in meat factories and butcher shops, also depends on temperature degree of meats store. All these; causes lead to different rates of contamination and spreading the pathogen [16].

Depending on our results, percentage of *salmonella spp* that isolated from a human stool by using polymerase chain reaction was (20)%, wherever (10) found prevalence of *salmonella spp* in children stool was

(10.7)% by using PCR, and that considered less than our results.

While [17] recorded a higher percentage than our rates, it was (95)% of *Salmonellaspp* by using PCR which isolated from faeces of children.

Prevalence of infection of *salmonella spp* depended on several factors such as degree contamination water and food by bacteria, immune status of the host, season (because environment temperature degree has significant role), host type and age, vaccination and sterilization techniques which applied[18 & 19].

Our report studied sequencing of two samples (one sample from human stool and one sample from cattle feces), and confirm the accession number of 16S ribosomal RNA gene of *salmonella spp* in NCBI-Genbank website, wherever our study founded that great match of sequencing of nucleotides of 16S ribosomal RNA gene of *salmonella spp* with sequence confirmed in NCBI-Genbank company, This explains the concomitant epidemic of disease in the animal and humans simultaneously, The same isolates cause disease in both animals and humans.

Many studied,and reports provided same of our results which included great similarity between salmonella isolates samples and data of NCBI between human and animals in many genes such as [20-22].

Finally, *Salmonella spp* isolates which isolated from animals is essential to source of spreading the pathogen to human.

What is New about Magnetic Resonance Imaging of Multiple Sclerosis?

Hosny Sayed Abd El Ghany[1], Enas Ahmed Mohamed Abdel Gawad[1], Mohamed Mamdouh Mohamed Esmaeel[2], Mahmoud Mohamed Moneer[3], Alaa Wagih Fathy[4]

[1]Professor of Radiology, Radiology Department, [3]Lecturer of neurology and Psychiatry Department, [4]Lecturer of Radiology, Radiology Department, [5]Assistance Lecturer of Radiology, Radiology Department, Faculty of Medicine, El Minia University-El Minia-Egypt

Abstract

Background: Multiple sclerosis (MS) is a demyelinating disease of the central nervous system. Magnetic resonance imaging (MRI) has an important role in early diagnosis of MS.

Patients and Method: Thirty patients with clinically diagnosed to have MS according to McDonald criteria were included and referred to department of radio-diagnosis, Faculty of Medicine, Minia University. Imaging was performed on a 1.5T Philips MR system using double inversion recovery (DIR), fluid attenuated inversion recovery (FLAIR), T2-weighted, T1-weighted and susceptibility-weighted imaging (SWI) sequences with the parameters including field of view (FOV), matrix, slice thickness and voxel size. They were done after the approval of ethical committee of our institution. Data analysis was performed using the SPSS version 20 and p-value as well as comparative study were gained.

Results: The detection rate of white matter lesions in T2 was (88%); while for grey matter lesions was (10%). In FLAIR sequence, we found that; the detection rate of white matter lesions was (96%); while for grey matter lesions was (25%). As regarding DIR sequence, the detection rate of white matter lesions was (90%); while for grey matter lesions was (95%).Comparative study between serial MRI sequences (T2,FLAIR and DIR) revealed; significant increase in detected number of grey matter lesions; in DIR-MRI sequence ($p < 0.0001$). In SWI, a central vein sign was detected in 96 lesions (66 in periventricular lesions and 30 in subcortical lesions).

Conclusion: From this study we concluded that new imaging modalities of MRI as regarding DIR and SWI are a valuable MRI sequences in imaging of multiple sclerosis; thus, we recommend adding DIR and SWI sequences in routine MR protocols for MS patients.

Keywords: *MRI, multiple sclerosis, Double inversion recovery (DIR), SWI, T2, FLAIR.*

Introduction

Multiple sclerosis (MS) is chronic autoimmune, inflammatory demyelinating disease of the central nervous system (CNS). It is recognized as the most common cause of progressive neurologic disability in young adults worldwide with higher rates in females compared to males.(1) It poses a major personal and socioeconomic burden as the average age of disease onset is 30 years which is a time that is decisive for work and family planning.(2) The advances in non-conventional magnetic resonance imaging (MRI) techniques show a more global MS pathology and it is believed that MS may not be truly characterized by ‘‘multiple’’ areas of sclerosis but rather a ‘‘diffuse’’ representation of sclerosis. The acknowledgment of grey matter (GM)

involvement in the disease has led to the incorporation of juxtacortical lesions in the recent diagnostic criteria for MS as well as increased interest in the role of normal appearing grey matter (NAGM) damage in determining cognition and disability. (3) Detection of cortical lesions by conventional MRI techniques is difficult. So it is important to detect different types of cortical lesions using new imaging technique as double inversion recovery (DIR) sequence which is used to image the gray matter by nulling the signal from white matter and cerebrospinal fluid (CSF). (4) Double inversion recovery (DIR) imaging provided higher image contrast ratios between lesions and normal-appearing gray matter (NAGM) in all anatomic locations compared with fluid attenuated inversion recovery (FLAIR) and T2WI imaging (fig1). Moreover, DIR imaging provided better delineation of the white matter lesions with higher contrast between the lesions and normal-appearing white matter. (5)

On other hand, susceptibility-weighted imaging (SWI) is another new imaging modality used to assess damage of the brain by iron in multiple sclerosis which might be related to oxidative stress with release of free radicals that has been specifically seen in the vessel walls of veins giving the perivascular relationship with MS (perivenular lesions) with the characteristic central vein sign. (6)Susceptibility-weighted imaging (SWI) has the potential to recognize the presence of iron in MS lesions based on the advantage of the T2*-shortening effect of deoxyhemoglobin in venous blood. (7 & 8)

Aim of the work: The aim of this study is to assess the efficacy of variable magnetic resonance imaging techniques in assessment of multiple sclerosis as regarding degree of severity by highlighting the role of DIR in imaging the gray matter lesions and presence of central vein sign using SWI.

Patients and Method

Study design and population: In a prospective study 30 patients with clinically diagnosed to have MS according to McDonald criteria were included diagnosed in neuropsychiatry department and they were referred to department of radio-diagnosis, Faculty of Medicine, Minia University. The study was done between December 2018 to September 2019. They underwent MRI imaging after meeting the inclusion criteria. All patients signed a written informed consent before MRI examination.

Inclusion and exclusion criteria: All patients included in this study were diagnosed with MS (clinical and laboratory), age of the patient varying between 18 years and 50 years and expanded disability status scale (EDSS) scoring system varying from 1-7. However, general contraindications to MRI as the presence of any paramagnetic substances such as pacemakers, metallic clips or claustrophobic patients were excluded from the study. Also patients with age above 50 years old or less than 18 years and patients with concomitant neurological disease in conjunction with MS were excluded.

Method

MRI technique: MR imaging was performed using 1.5 Tesla MR Scanner (Ingenia, Philips Healthcare, Netherlands). All patients were imaged in the supine position using standard quadrate head coil. The MRI examination was conducted on the brain including conventional MRI sequences; axial T2 weighted images utilizing the following parameters:, repetition time (TR) of 4800 msec/echo time (TE) of 110 msec, slice thickness of 5 mm, number of signal averages (NSA)=3, matrix 512x 512, gap 1–2 mm, flip angle=90 º and field of view (FOV)= 230mm. Axial and sagittal FLAIR images utilizing the following parameters: repetition time (TR) of 6000 msec/echo time (TE) of 140 msec, slice thickness of 5 mm, (NSA) 3, matrix 512x 512, gap 1–2 mm, flip angle=90 º and FOV = 230mm. Axial DIR images utilizing the following parameters: repetition time (TR) of 96 msec/echo time (TE) of 25 msec, slice thickness of 3 mm, matrix 512x 512, gap 1–2 mm and FOV = 230mm. Axial SWI images utilizing the following parameters: repetition time (TR) of 43 msec/ echo time (TE) of 25 msec, slice thickness of 3 mm, matrix 300x300, gap 1–2 mm, flip angle=20 º and FOV = 230mm.

Data processing and image interpretation: The images were transformed to Philips 881030 Intelli-Space IX/LX Workstation. Each MR sequence findings were evaluated as following:

Image interpretation: Conventional and advanced MRI sequences were evaluated for: the total number of the lesions in T2, FLAIR, DIR and SWI. Lesion location (White matter: including peri-ventricular and subcortical regions- Grey matter: including basal ganglia and cortical regions - infratentorial: including brainstem and cerebellar regions) in T2, FLAIR and DIR. Number of cortical lesion in FLAIR, T2 and DIR.

Number of lesions in white matter (deep white matter and subcortical regions) in T2, FLAIR and DIR. Number of lesions with central vein sign in SWI. Each lesion appears in FLAIR in periventricular and subcortical regions were correlated with its similar on SWI and it was assessed if a central vein present or not.

Statistical analysis: Statistical analysis was performed using the SPSS software for Windows v. 20 (SPSS Inc., Chicago, IL). Tests of significance (Repeated measures ANOVA, Cochran's Q tests, Kappa statistics and ROC Curve analysis). P-values less than 0.05 (5%) was considered to be statistically significant. Mean, standard deviation (± SD) and range for parametric numerical data, while median and inter-quartile range (IQR) for non-parametric numerical data. Frequency and percentage of non-numerical data.

Results

Our study included 30 female patients with multiple sclerosis according to McDonald criteria. We found that; the mean age of all patients was (36.24) years and as regarding gender of the patients (84%) of patients were females and (16%) were males. (65%) of patients had visual disorder, (57%) had tingling and numbness; (40%) had muscle weakness and (9%) of patients had hemiparesis. We found that detection rate of white matter lesions in FLAIR sequence was (100%); and of grey matter lesions was (36.6%). In DIR sequence, the detection rate of white matter lesions was (96.6%) while for grey matter lesions was (100%). In T2, it was (90%) for white matter lesions and (20%) for grey matter lesions. Comparative studies between T2, FLAIR and DIR sequences revealed significant increase in sensitivity and specificity of detection of grey matter lesions in DIR sequence with highly significant statistical difference ($p < 0.001$) as in (table I). However, no significant difference in detection of white matter lesions could be detected between three pulse sequences ($p > 0.05$) as in (table II). Double inversion recovery (DIR) was significantly superior to FLAIR sequence in detection of infratentorial lesions ($P<0.001$). As regarding detection of overall MS lesions in whole brain, DIR sequence showed significant increase in sensitivity and specificity of detection of the total lesions over T2 and FLAIR sequences ($P=0.004$). In SWI, a central vein was detected in 96 lesions (66 in periventricular lesions and 30 in subcortical lesions). In FLAIR, a central vein was detected in 55 lesions (40 in periventricular lesions and 15 in subcortical lesions). Comparative studies between FLAIR and SWI sequences revealed significant increase in sensitivity and specificity of detection of periventricular lesions with central vein sign in SWI sequence with highly significant statistical difference ($p < 0.0001$).

Table I: detection of grey matter lesions in each pulse sequence using Roc-curve analysis:

Variable	AUC	P value	SE
Grey matter lesions in FLAIR	0.720	0.0001	0.047
Grey matter lesions in DIR	0.987	<0.0001	0
Grey matter lesions in T2	0.497	0.015	0.032

SE= Standard Error, AUC= Area under curve, ROC =Receiver operating characteristic.

Table II: Comparison between 30 MS patients in multiple MRI sequences as regarding detection of white matter and grey matter lesions:

Variable	T2-MRI sequence	FLAIR-MRI sequence	DIR-MRI sequence	Cochran's Q test
				P value
Detection rate of grey matter lesions	6(20%) ^^	11(36.66%) ^^	29 (96.6%) ^^	= 0.097 #
Detection rate of white matter lesions	27 (90%) ^^	30 (100%) ^^	29 (96.6%) ^^	= 0.097 #

^^% per total of 29 patients, # Cochran's Q test.

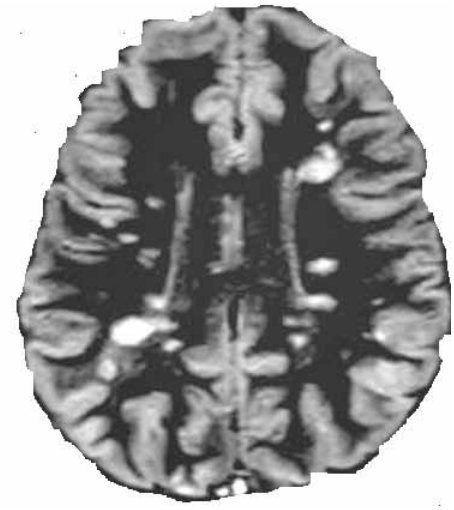

Figure 1: Axial DIR shows cortical lesions (intracortical and juxtacortical) as well as white mater lesions (subcortical and periventricular).

Figure 2: Axial DIR shows cortical lesions (intracortical and juxtacortical lesions).

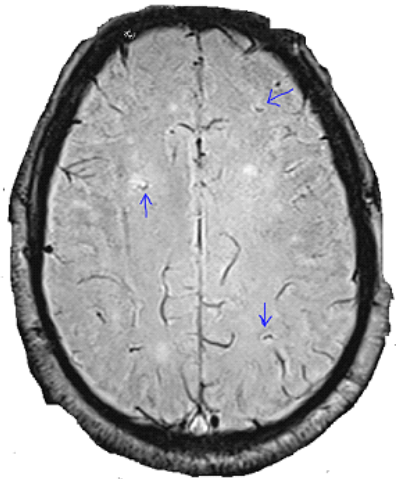

Figure 3: Axial SWI: shows central vein signal within the lesions.

Discussion

Multiple sclerosis is chronic inflammatory autoimmune disease. MRI has been part of the International Panel criteria for the diagnosis of MS since 2001 and its use has become increasingly vital as reflected in the last changes by the committee guidelines. It plays major role in elucidating the mechanisms underlying disease progression and in monitoring the accumulation of abnormal features underpinning disability. Multiple sclerosis has heterogeneous clinical and imaging manifestations which differ between patients and change within individual patients over time. So these caveats should be borne in mind as conventional MRI cannot explain the wide heterogeneity of the clinical outcomes of the disease so recent researches emphasizes the importance of non conventional MRI to allow visualization of its various pathophysiological mechanisms. The acknowledgment of grey matter (GM) involvement in the disease has led to the incorporation of juxtacortical lesions in the recent diagnostic criteria for MS as well as increased interest in the role of normal appearing grey matter (NAGM) damage in determining cognition and disability. From this point of view, it is important to detect cortical and deep grey matter lesions using DIR which used to selectively image the gray matter by nulling the signal from white matter and cerebrospinal fluid. Detection of perivenular lesions in the brain (the "central vein sign") is also important as it improves the pathological specificity of MS diagnosis.[9] Our study aims to assess grey matter lesions in patients known to have multiple sclerosis using DIR, FLAIR and T2 as well as detect central vein sign using SWI which increase diagnostic accuracy of MS. This study included 30 patients were diagnosed to have MS according to MacDonald's criteria and their age varying between 25 to 40 y. Most of our patients were females (84%) and the most affecting symptoms were visual disorders and numbness.

In the current study DIR was the most important sequence in detection of grey matter lesions (cortical or deep grey matter lesions). Double inversion recovery (DIR) allows visualization of juxta-cortical (which just abuts the cortex) and intracortical lesions.[10] An assessment of cortical lesions (CL) contributes to the identification of patients with CIS who are at risk of evolution to definite MS. [11,12] We are in agreement with several authors as De Graaf et. al. and Simon et. al studies who reported that the DIR showed more intra-cortical lesions compared to FLAIR and T2WI sequences (fig 2).

We agree with M.P. Wattjes et. al. study who stated that total number of the lesions were higher in DIR sequence than FLAIR and T2 sequences. In addition, we agree with him that DIR has higher sensitivity for the infratentorial region compared with the FLAIR sequence.

Central vein assessment, provided by susceptibility-based MRI, significantly improves the diagnostic accuracy and specificity of MS diagnosis as it can differentiates MS from vasculopathies involving CNS which are difficult to diagnose accurately as they have clinical and radiological presentations very similar to MS. As concerning radiological findings of central vein sign in SWI, we agree with Lane JI et al, who stated that there is significant increase in sensitivity and specificity of detection of periventricular lesions with central vein sign in SWI sequence over FLAIR sequence (fig3).

Conclusion

Finally, in our study we were in agreement with the findings reported by the other studies regarding the greet value of DIR sequence in detecting grey matter lesions particularly cortical lesions over other sequences (T2WI and the FLAIR sequences) and its vale to detect more MS lesions than other sequences. In this issue we also detect that central vein sign in SWI increase diagnostic accuracy of MS. Future implementation of automated imaging post-processing techniques (i.e., central vein sign detection) should allow direct translation of the central vein sign into the everyday clinical practice.

Parenting Style on School Age Children that Addicted to Mobile Phone (A Phenomenology Study)

Natar Fitri Napitupulu[1], Wisnu Barlianto [2], Septi Dewi Rachmawati[2]

[1]Master Program of Nursing, [2]Lecturer of Nursing Department, Faculty of Medicine, University of Brawijaya, Indonesia

Abstract

Nowadays, the development of technology is progressing in various sectors, one of which is felt by society is the development in the communication sector through the availability of advanced communication tools, known as mobile phones. Nowadays, mobile phones are used more as a companion or friend living at all ages, both children and adults. Currently, parents provide mobile phones to children to facilitate communication and as a tool for education, but without any special supervision of parent causes the child addiction that disrupts the development of children. This study purposed to explore the experience of parents in caring for children who addicted to mobile phone. The method used is a qualitative research design with interpretive phenomenological approach. Data collection techniques obtained through in-depth interviews with semi-structured interview guide to explore the understanding and experience of participants. The number of participants in this study there were 6 women with inclusion criteria: mothers with school-age children (6-12 years) who are addicted to mobile phones that have been diagnosed by a psychiatrist/psychologist, living together and getting therapy more than >1 month. Selection participants conducted by researchers using purposive sampling technique that involves participants in accordance with the criteria.Based on the results of data analysis in this study, it was found the following themes: making the rules of the use of mobile phones, full time assisting children and compact implement rules for using mobile phones. Children have freedom in using mobile phones cause the child to fall on the condition of dependency or addiction that makes a child can not be separated from mobile phones so that parents set rules that must be followed when children use mobile phones. In addition, assistance is one way parents in assisting children who are already addicted. Parents also must be compact in implementing the rules and shall be the prime example for children in using of mobile phones. Need for setting rules from parents to children in terms of the use of mobile phones to prevent mobile phone addiction. Thus,parents need to provide special assistance to children in order to prevent adverse effects of mobile phones and continues to regard development of the child.

Keywords: *Parenting style, school age children, mobile phone addiction*

Introduction

Parents give mobile phones to children as a tool for communication and education. At school, in an atmosphere of learning always involves the Internet to find resources in the completion of task. School-age children still have an emotional response and self-control that are still unstable, given the opportunity to use mobile phones without the assistance and supervision would make the child wrong in using it. Children will use it as they please without any understanding of the negative impact on development. Parents also provide entertainment applications such as games which are very interesting cause children will spend more time playing games than studying or doing other activities. Children who experience addiction to mobile phones is a child who is unable to control the desire to play the game and affect emotions, behavior and social relationships of children[(1).] Based on the results of the asian parent insights survey revealed that 98% of children are mobile phone users and used it to access games[(2)]. Data of Riskesda 2013 recorded approximately 9.5% to 14.2% of preschool children in the area of Yogyakarta has emotional social issues that negatively impact the development and

school readiness[3]. In the Regional Mental Hospital of Dr. RM. Soedjarwadi Klaten recorded from the month of June 2017 until July 2018, there were 7 cases of children who are addicted to mobile phones.

Parents realize that the impact of the freedom given to children in the use of mobile phones caused problems, either physical, psychological or mental influence children development. Parents make rules for using mobile phones is to provide guidance, oversight and limitation of time such as a day children are only allowed to play for an hour with features that correspond to the child's age. Supervision in accessing the services in the mobile phone becomes the responsibility of parents. Parents should have a variety of ideas and knowledge in order to prevent children in the use of excessive gadget, one of which is to train a consistent discipline for children and parents themselves in the use of any related gadgets that can and can not be accessed[4].Parents should put the phone away from the reach of children or not laid carelessly allowing the child to use it without parental consent[5]

The family is responsible for shaping the personality, affection, attention, harmony and health are the parents. To create a good environment in the family needed good parenting, according to[6]there are three parenting style in family, namely: a) Authoritarian, Authoritarian is a type of family environment restrictive and do not allow freedom at all, all the rules of the parents should be followed, without thinking about the willingness and ability of the children; this resulted in the inability of children in developing potential and ability. b) Democratic. Democratic environment is an environment in families that provide flexibility for children to develop all the potential of the child by not rule out the family rules and norms that have been established by parents c) Permissive or free. Free is kind of parenting style that giving occassion to children in acting and behaving without rule and norm that should be obeyed by children, thus children are easy to trap into negative things[6]. Parenting is important for the psychological health of children and parenting is a pattern of interaction between parents and children that include parental attitudes and behavior in children, how to apply the rules, values, norms, concern and affection for the children.

Purposes: This study purposes to explore the experiences of parents in caring for children who addicted to mobile phones.

Material and Method

This qualitative study using interpretive phenomenological approach to parents with children who are addicted to mobile phones. Participants of six people who were selected through purposive sampling with the following inclusion criteria: 1) women who have school-age children (6-12 years old) with addiction mobile phone that has been diagnosed by a psychiatrist/ psychologist. 2) the biological mother who lives with children who are addicted to mobile phones. 3) The school-age children with addiction mobile phone is getting therapy more than >1 month. Data were obtained through in-depth interviews using a semi-structured interview guidelines, all the data recorded by utilizing a recording applications found on mobile phones. Data were analyzed using Interpretative Phenomenological Analysis (IPA).

Results

The results of this study illustrate the meaning of each utterance participants related to changes in parenting of mothers to children with mobile phone addiction. The themes described on these results, among others, make rules for use of mobile phones, full time assisting children and compact implement rules for using mobile phones.

Theme 1: Making the rules for the using of mobile phones.

Parents used to provide freedom that means there are no rule of the parents in the use of mobile phones, children access the mobile phone freely without supervision of a parent but now parents together establish rules for using mobile phones. Here are excerpts of participants according the statement above:

"... Using mobile phone and they used it every day whenever " (smiling) (P4)

"... My son used to used mobile phone all day. (pointing towards her son) "(P3)

The rule of mobile phone usage here is everything that has been set up and assigned parents to be implemented by the child. Participants submit the matter through the following quote:

"Should be monitored, they should reduce to use their mobile phone… I limit the time in using the mobile phone, five minutes. (P1)

"There are limits to use it... after learning I give them allowance to operate mobile phone only thirty minutes" (P3)

Theme 2: Full time accompany children in the use of mobile phones

Parents need to accompany children in the use of mobile phones. Mentoring is carrying out when children use mobile phones to learn and play. Here's an excerpt of participants:

"... We accompany them ... when they playing mobile phone" (P3)

"... I always monitor them while operating mobile phone, even during learning" (P6)

"Yes it is not to be authoritarian or be like this but it needs to provide guidance during they operating mobile phone" (P4)

Theme 3: Compact implementing rules for using mobile phones

Parents must agree in implementing rules that have been established in the use of mobile phones. Here's an excerpt from the statement following participants:

"...the vision and mission of parents ... exemplifies of children not to use the phone ... there are the same rules, should be applied to parents both father and mother to be compact in educating children, especially in using mobile phone" (P1)

Discussion

Rule is a provision agreed to by more than one person with tying goal. Similarly, in the enforcement of rules on children's use of mobile phones. The incidence of mobile phone addiction in children exists because parents failed in supervising the use of mobile phones. Learning from this experience, the parents finally create a statute or rules that apply to all members of the family to minimize the incidence of addiction to mobile phones[7].The use of devices (mobile phones) in children is very necessary role of parents to supervise. The child will grow and develop in accordance with the environment where the child is, in this case the parents who provide education about the pros and cons of using mobile phones. Children will use it well when parents provide proper education on its use. In contrast, children will incorrectly use the phone if the parents do not either provide education in its use, there is no specified rules such as time limits and always provide guidance by not removing the child to play alone[8]

Mentoring is an act accompanied. Children who have experienced addiction desperately need help from others to be able to restore it in this case the parents who play an important role in its success. Participants said that all would be conduct to make her recover and currently do give a lot of time with children, especially when children use mobile phones.

The role of parents should always be done should not replace by providing a mobile phone as a friend of children playing. How that should be carried out by parents is to control every site where your kids on the phone, fill spare time with the child to discuss or question and answer session on the experience every day. With discussion or tell stories with children will make your child comfortable and confident to express all the creative ideas he has in mind[9]

Parents also need to understand the principles of parenting in the age of technology. The principle that should be known by parents are when children need it, their observations and communications while using, determine the punishment if the child broke a promise, give understanding to the children on the rules created and explain what sites should be seen and not to be opened[10]Parents who give consent for children to use mobile phones, subject to the mentoring and supervision of parents. Monitoring carried out by asking what is seen or opened in the mobile phone child. Attitudes of children who are given permission to use the phone more open is to tell and show about what they see. In mentoring parents already make clear rules that previously disepakatin such as school achievement should not be decreased and the use of mobile phones in the time of no-school hours and no more than one hour. While the nature of the child's psychological as more open communication between parents and children continuously interwoven, creating closeness and harmony[11]

Parenting also affect to children using mobile phones freely. Permissive parenting with free or bear children who are addicted to mobile phones. Parents who are adopting a child has a permissive will shape attitudes can not control yourself, do not obey and do not like to get involved with the activities of the surrounding environment. By nurturing that gives freedom will have a negative impact on children, namely children tend to

be less independent, less confident, selfish and socially immature. While applying authoritarian parenting children become cantankerous, happier alone, had no creativity, introverted, not very talkative and when dealing with parents always tried to be obedient, but if they are behind parents of children to be rebellious[12]

With the freedom that children using mobile phones cause the child to fall on the condition of dependency that makes a child can not be separated from the phone, thus the parents set commands that should be followed when children use mobile phones. The same thing was delivered by the participants that there are the same rules that should be applied by parents, both father and mother are compact in terms of educating for children to use mobile phones. In addition, participants also say parents should still not be allowed to change in forbid children to use mobile phones and not at random to put down the mobile phone,thuschild is not easy to use without parental consent.

The willingness and the need for direct involvement by parents are fathers and mothers in anticipation for any child in the use of mobile phones. The means used by parents are making the same goals and rules to do with the child. Parents are responsible to provide guidance and oversight and ensure children use mobile phones to disclose information that related with the learning and in accordance with the age of the child[13]. Parenting behavior will greatly affect a child's behavior. In his research, parents are required to fulfill the established rules for children to follow or imitate what is done by the parents as the scheduled time not to watch or activate the mobile during study hours[14]. Parents are required to be the prime example for the their child in using a mobile phone and prudent in applying discipline in children.

Conclusion

This study purposed to explore the experiences of parents in parenting the children who addicted to mobile phone answered on the firest theme; make rules for the use of mobile phones, second; full time to assist children in the use of mobile phones, three; implement rules for using mobile phones compactly.

Conflict of Interest: There is no conflict of interest in this study.

Flowcytometric Determination of T-lymphocyte Expression of $CD4^+$ and $CD8^+$ Cells in Systemic Lupus Erythematosus

Nehal Ibrahim Abbas[1], Ashraf Mohamed Osman[1], Amal Mahmoud Kamal El-Din[1], Emad Allam Abdel-Naem[1], Manal Mohamed Saber[1]

[1]Clinical Pathology Department, Faculty of Medicine, Minia University, Egypt

Abstract

The Purpose: Flow cytometric analysis to quantify the T-lymphocyte expression of $CD4^+$ and $CD8^+$ cells.

Patients and Method: This study was conducted along the period from March 2018 to March 2019 on patients diagnosed as having systemic lupus erythematosus. The patients were selected from those who attended Rheumatology and Nephrology outpatient clinics, Minia University Hospital, Egypt.

Group I: It consists of 40 apparently healthy women to serve as a control group.

Group II: It comprised 40 SLE women.

Results: The area under ROC curve of lymphocyte expression of $CD4^+$ and $CD8^+$ were 0.815 (95% CI= 0.712-0.893, p<0.001), at a cutoff value of < 32% and 0.675 (95% CI= 0.561-0.776, p=0.004) at a cutoff value of < 18.8, respectively. CD4 lymphocyte expression exhibited sensitivity, specificity, PPV, NPV, and accuracy of 77.5%, 87.5%, 86.1%, 79.5% and 82.5%, respectively, whereas those of CD8 were 32.5%, 100%, 100%, 59.7% and 66.2%, respectively.

Conclusion: We provided more scientific insights into the flow cytometric analysis to quantify the T-lymphocyte expression of CD4+ and CD8+ cells.

Keywords: *SLE; CD4; CD8.*

Introduction

SLE is a systemic autoimmune condition characterised by a wide spectrum of clinical manifestations, partly related to the disease itself, but also linked to its comorbidities and drugs adverse reactions. Following the previous annual reviews, we focused on new insights in SLE clinical features, pathogenic pathways, biomarkers of specific organ involvement and therapeutic strategies. Finally concentrated on SLE aspects that could significantly influence patients' quality of life and that need to be investigated in detail through the development and validation of diseasespecific patient-reported outcomes.[(1)]**.**

Rate of SLE varies between countries from 20-70/100,000 [(2)]. Women are affected about 9 times more than men[(3)], begins between the ages of 15 and 45[(4)] SLE is an autoimmune disorder caused by a complex combination of genetic, epigenetic and environmental factors that lead to altered gene expression and function of several molecules which lead to abnormal T cell responses[(4)].

Aim of the work: In this study we aimed to provide more scientific insights into the flow cytometric analysis to quantify the T-lymphocyte expression of $CD4^+$ and $CD8^+$ cells.

Patients and Method

This study was conducted along the period from March 2018 to March 2019 on patients diagnosed as having systemic lupus erythematosus who were compared with a group of apparently healthy volunteers. The patients were selected from those who attended

Rheumatology and Nephrology outpatient clinics, Minia University Hospital, Egypt.

Therefore, the current study included two groups:

Group I: It consists of 40 apparently healthy women to serve as a control group. Their ages ranged from (18-35) years with mean + SD of (26.8 + 5.4) years.

Group II: It comprised 40 SLE women. Their ages ranged from (16-37) years with mean + SD of (24.7 + 5.3) years.

The diagnosis of SLE was done according to Systemic Lupus Erythematosus International Collaborating Clinics (CLICC) 2018 and SLE sheet and systemic lupus erythematosus diseases activity index Selene modification (SLEDAI Score)

Exclusion criteria: We excluded patients with rheumatic disease other than SLE, SLE patients who had prior treatment with monoclonal antibodies or other biological drugs, malignant tumours and ongoing infections.

All patients and controls were subjected to careful History taking, Clinical Examination,routine investigations including *complete blood count (CBC),* Erythrocyte sedimentation rate (*ESR); Liver function tests, Renal function tests, Urine analysis, 24 hour urine proteins, Rheumatoid factor(RF),C-reactive protein(C-RP)*

Patients with systemic lupus erythematosus diagnosed by Anti-nuclear antibody (ANA), Anti double strand DNA, Complement 3 (C3) and Complement 4 (C4).

All patients and controls were subjected to special investigations including Flow cytometry

Flow cytometricanalysis for identification and enumeration of cluster differentiation (CD) 4 and CD8 T-lymphocytes was done by Flowcytometry, BD FACS canto^{TM} USA.

A. Staging procedure of flow cytometry:

1. Whole blood was collected in evacuated tubes containing EDTA.
2. For each sample, two tubes were prepared labeled 1 & 2 (control and test).
3. 100 µl of blood sample was added to the tubes.
4. 10 µl of anti CD4 FLTC conjugated was added (only two the test tube) and vortex.
5. 10 µl of anti CD8 PE conjugated was added (only two the test tube) and vortex.
6. Cells were incubated for 15-20 minutes at room temperature in the dark.
7. Cells were washed by PBS twice to remove any unbound antibodies.
8. Followed by red cell lysis using 2 ml lysing solution then incubated for 10 min at room temperature in the dark.
9. Cells were centrifuged for 5 minutes, supernatant was discarded and 2 ml of PBS were added.
10. Wash by PBS was repeated twice then the cells were resuspended in 400µl of PBS for final flow cytometric analysis.

Statistical Analysis: Analysis was carried out using a (PD-FACS FLOW Argon Laser U.S.A.) Flow cytometry at 515 nm.

Comparisons between two categorical variables were made with Mann Whitney test for non-parametric quantitative data (expressed as median) between the two groups

*: Significant level at P value < 0.05

All statistical analyses were performed using IBMSPSS Statistics version 17 (SPSS for Windows,Chicago, IL).

Results

Concerning the percentage of CD4 lymphocytes expression it was statistically significantly lower in SLE patients than controls (30.5 (27.3-32) vs. 35.9 (33.6-38.3)%, p<0.001). Similar trend was observed for CD8 lymphocytes expression (22.1 (16.1-25.1)% for SLE patients vs. 25.4 (21.3-29)% for controls, p=0.007).

Table 1: Results of flow cytometric analysis in the study groups

Variable		Control N=40	Cases N=40	P value
Lymphocytes CD4 expression (%)	Median IQR	35.9 (33.6-38.3)	30.5 (27.3-32)	<0.001*
Lymphocytes CD8 expression (%)	Median IQR	25.4 (21.3-29)	22.1 (16.1-25.1)	0.007*

Apart from a significant correlation between CD4 and CD8 lymphocyte expression (r=0.847, p<0.001), no significant correlation could be detected between either CD4, CD8 and any of the studied parameters.

Table 2 : Correlation between CD4 lymphocyte expression and different studied parameters in systemic lupus erythematosus patients

Variable	CD4 lymphocyte expression (%)	
	r	P value
Age (Years)	0.088	0.591
Duration of disease (years)	0.112	0.491

C-reactive protein (-ve/+ve)	-0.237	0.141
Proteinuria/24hour (mg)	0.053	0.746

Table 3 shows no significant correlation between CD8 and other parameters

Table 4: Results of proteinuria in the studied groups

Variable		Control	Cases	P value
		N=40	N=40	
Proteinuria/24 h (mg)	Median IQR	30 (0-50)	800 (50-1000)	<0.001*

SLE patients had a statistically significantly higher values of proteinuria/24 hour(800 (50-1000) vs. 30 (0-50) mg, p <0.001)

Discussion

SLE is recognized as chronic, often severe autoimmune disease with largely unknown etiology [(4)].

In this study we found significantly lower levels of $CD4^+$ lymphocyte expression in patients with SLE compared to healthy volunteers ($p<0.001$). Similar trend was observed for $CD8^+$ lymphocyte expression ($p=0.007$)

Although there was no significant correlation between% of lymphocyte expression of either $CD4^+$ or $CD8^+$ with any of the studied parameter, we noticed a significant positive correlation between $CD4^+$ and $CD8^+$ ($p<0.001$). We found that the area under ROC curve of lymphocyte expression of $CD4^+$ and $CD8^+$ were 0.815 (95% CI= 0.712-0.893, $p<0.001$), at a cutoff value of < 32% and 0.675 (95% CI= 0.561-0.776, $p=0.004$) at a cutoff value of < 18.8, respectively. CD4 lymphocyte expression exhibited sensitivity, specificity, PPV, NPV, and accuracy of 77.5%, 87.5%, 86.1%, 79.5% and 82.5%, respectively, whereas those of CD8 were 32.5%, 100%, 100%, 59.7% and 66.2%, respectively.

In our study, proteinuria/24 hours was reported in our SLE patients as evident by statistically significantly higher levels of proteinuria/24 hours in lupus patients compared with healthy controls

These results go hand with hand with those **Zahran et al., [(5)]** who studied the effects of royal jelly (RJ) supplementation on regulatory T cells in 20 SLE children received 2 g of freshly prepared RJ daily, for 12 weeks and resulted in children with SLE, before treatment there was an observed imbalance between CD4+ and CD8+ lymphocytes; this may be explained by the immune dysregulation in cases of SLE. Their results showed that patients with SLE (both before and after RJ treatment). The frequency of CD4+ T lymphocytes was significantly increased after RJ treatment versus baseline value. This was not true for CD8+ T lymphocytes as it did not show any significant changes with RJ treatment or any difference between the SLE children and normal control group.

Our results are in accordance with what was found by **Zhang et al. [(6)]** who examined the levels and

function of peripheral blood immunoregulatory T-cell subpopulations in SLE. They found normal percentages of CD8+ T cells in peripheral blood in all SLE patients. Interestingly, about CD4+, they found about half of the SLE patients had markedly depressed CD4+ cell levels and in turn significantly lower CD4+/CD8+ cell ratio, whereas the remaining half of the patients had normal levels of CD4+ cells (normal CD4+/CD8+ cell ratio)[5].

Effect of Black Seed (Nigella Sativa) Extract on Release of Some Minerals from Human Enamel: An in Vitro Study

Nibal Mohammed Hoobi[1], Raya R. Al-Dafaai[2], Baydaa Hussain[1]

[1]Assist. Professor College of Dentistry, University of Baghdad, [2]Assist. Professor College of Dentistry, Ibn Sina University of Medical and Pharmaceutical Sciences, Iraq

Abstract

Background: Black seed of *Nigella sativa*has been used for centuries to promote health due to its anti-microbial, anti-oxidant and anti-inflammatory effects. This study was conducted to evaluate the ability of black seed water extract to reduce the release of potassium and zinc ions from enamel after acidic attack.

Materials and Method: Twenty five maxillary human premolars were prepared and divided into five groups. The test solutions were included, black seed water extract in three concentrations (3%, 5%% and 7%), sodium fluoride (0.05%) as control positive and de-ionized water as control negative. The teeth in each group were immersed separately in 40 ml of the test solution for two minutes, once daily and for twenty days. The teeth then prepared for subsequent etching and analysis by atomic flame spectrometer to measure the concentration of the released potassium and zinc ions.

Result: The highest mean value of dissolved potassium ion was found in de-ionized water group followed by 3% water extract of black seed while the lowest one was recorded in 7% black seed water extract. The statistical difference between the five groups was highly significant ($p<0.01$) by using ANOVA test. The highest mean value of dissolved zinc ion was found in de-ionized water group followed by 0.05% sodium fluoride and 3% black seed extract while the lowest one was recorded in 7% water extract of black seed. The statistical difference between the five groups was also highly significant ($p<0.01$).

Conclusion: Water extract of black seed has the ability toreduce the dissolution of potassium and zinc ions from the tooth and might increase tooth resistance against acid attack.

Keywords: *Nigella Sativa, potassium ion, zinc ion.*

Introduction

There is a worldwide increasing interest on the use of herbs or plants in the treatment of various diseases especially in developing countries. Black seed of *Nigella sativa*is an annual flowering plant that widely used in nutrition and medicine. This seed is rich in phenolic compounds, essential fatty acids, proteins and bioactive compounds[(1)]. Previous studies had searched for its anti-oxidant, anti-cancer, anti-inflammatory and anti-microbial activities of this miracle seed[(2,3,4)].

Enamel is the hardest tissue in the human body. Dental enamel is 95% mineral, 4% water and 1% organic matter by weight percentage. The minerals are composed mainly from calcium and phosphate in addition to the presence of small quantities of other elements[(5)]. Zinc is essential trace element. It accumulates in the surface structures of teeth and occurs in low concentrations in subsurface material. Zinc can reduce enamel demineralization and increase enamel resistance to acid dissolution[(6)].Regarding potassium ion, enamel content of this ion is very low in comparison with calcium and phosphors contents [(7)]. However, little data are available about the relation between tooth resistant to acid attack and potassium content. A possible relationship between enamel minerals content and caries susceptibility has been advised[(8)]. No previous study was conducted for the effect of water extract of *Nigella sativa* on the release of zinc and potassium ions from human enamel, so this study was conducted.

Materials and Method

Extracted maxillary first premolar teeth from patients aged 10-13 years old were selected from orthodontic department (college of dentistry, university of Baghdad). The total number of teeth was 25. The teeth were cleaned by using conventional hand piece and rubber cup with non-fluoridated pumice and deionized water. After cleaning, the teeth were stored in 0.1% thymol solution at 4º C until use tominimize microbial growth. This step also was done to prevent the dryness and brittleness of teeth. The water extract of black seed was prepared by the modified method of Ibraheem et al[9]. The teeth were divided into five equal groups; each group consisted of five teeth. The test solutions were included, water extract of black seed in three concentrations (3%, 5%% and 7%),sodium fluoride (0.05%) as control positive and de-ionized water as control negative. The teeth in each group were immersed separately for two minutes, once daily,for twenty days in 40 ml of the test solution. After each immersion, the specimens were washed in de-ionized water for 5 minutes and then stored in de-ionized water withthymol (0.1%)at room temperature till the next immersion.

After the treatment period (20 days), a rounded area (3 mm in diameter) were prepared on buccal surface of each tooth by applying adhesive disc and avoiding hypo plastic areas or microscopic cracks. The rest of enamel for each tooth was covered by a sticky wax, leaving only the rounded area (window) exposed for subsequent etching. The windows were etched for ten seconds in separated polyethylene tubes. Eachtube is containing five ml of 2NHCL[10]. The concentrations of released potassium and zinc ions were determined calorimetrically byusing flame atomic absorption spectrometer.

Statistical analysis: The data was processed using SPSS version 20 statistical software. Means and standard deviation were calculated for each group. One way ANOVA and Dunnett T3 (post hoc test) were used to evaluate the significance of difference between the five groups. Probability values less than 0.05 were considered statistically significant (P<0.05). Values less than 0.01 were considered highly significant (P<0.01).

Results

Concentration of potassium ion release (mean,standard deviation and statistical analysis of ANOVA are illustrated in Table 1. The highest mean value of dissolved potassium ions was found in de-ionized water group followed by 3% water extract of black seed while the lowest mean was recorded in 7% concentration of black seed. The statistical difference between the five groups was highly significant (p<0.01). Table 2 is showing the mean differences of dissolved potassium ions concentrations between each two agents. No statistical significant differences were found between the de-ionized water and black seed extract in concentrations:3%, 5% and 0.05% of sodium fluoride. No significant difference was found between 5% black seed extract and 0.05% sodium fluoride.

Concentration of zinc ion release (mean, standard deviation and statistical analysis of ANOVA are illustrated in Table 3. The highest mean value of dissolved zinc ion was found in de-ionized water group followed by 0.05% sodium fluoride and black seed extract 3%, while the lowest mean was recorded in water extract of black seed 7%. The statistical difference between the five groups was highly significant (p<0.01).Table 4 is showing statistical mean differences of dissolved zinc ions concentrations between each two agents. No statistical significant difference was found between the black seed extract in 5% and 7%. No significant difference was found between 3%black seed extract and 0.05% sodium fluoride.

Table 1: The released potassium ion concentrations among the selected agents

Selected Agents	No	Mean ± SD	F value	P value
Water black seed extract 3%	5	0.910±0.07	19.44	0.00**

Discussion

In dentistry, the extract of black seed was tested in many studies to verify its oral effects due to the interested organic and inorganic constituents. The black seed showed its antimicrobial action against *Streptococcus mutans*, *Streptococcus mitis* and other types of bacteria isolated from the oral cavity [11,12]. In addition to that, *Nigella Sativa* extract had an obvious effect on the healing process of oral ulcer[13].In previous Iraqi study, water extract of black seed was able to decrease the dissolution of inorganic phosphorous ions from teeth [14].In the current study, the water extract of black seed was tested in three concentrations to approve its ability to decrease the dissolution of zinc and potassium ions

from the tooth surface and thus increase the hardness of the tooth and the resistant to acid attack. Sodium fluoride was used as control positive due to its effect in inhibiting demineralization and enhancing remineralization of tooth surface. It is able to react with the outer enamel surface resulting in the formation of calcium fluoride[15].

The study showed that the release of potassium ions was the least for the 7% extract and the highest release was recorded in deionized water group. The effect of sodium fluoride 0.05% in reducing the release of potassium ion was better than that reported for 3% extract.

The study also reported that the release of zinc ions was the least for the 7% extract and the highest release was recorded in deionized water group. The effect of 3% extract was almost equal to the effect of sodium fluoride 0.05% in reducing the release of zinc ions. This may indicate that the application of black seed water extract can decrease the demineralizing effect of the acid used. It was also obvious from this study that, if the concentration of the extract increases, there mineralizing effect of the water extract will increase. These results approve the findings of other studies regarding the effect of black seed water extract to improve the hardness of the tooth [14,16]. This effect could be attributed to the chemical composition of black seed and its mineral contents (calcium, phosphorous, potassium, sodium, zinc and iron)which was reported by previous studies[17,18]. However, the finding of this study is needed to be confirmed by further investigations and larger sample size before the application of this extract in the above mentioned concentration as mouth wash in preventive dentistry.

Conclusion

Acknowledgment: The authors are grateful to the teaching staff in the orthodontic department and preventive department in the college of dentistry, university of Baghdad to their help in conducting the current study. Authors thank the medical staff in poisons center of medical city in Baghdad to their efforts in data readings.

Water extract of black seed or *Nigella Sativa* has the ability to reduce the dissolution of potassium and zinc ions from the tooth. This effect might increase tooth hardness and its resistance to acid attack.

Effect of Zinc, Vitamin A-Based School Snack and Nutritional Status on Diarhheal Morbidity among Children Aged 5-7 Years in Tuban: A Crossectional Study

Nikita Welandha Prasiwi[1], Diffah Hanim[2], Adi Magna Patriadi Nuhriawangsa[3]

[1]Nutrition Postgraduate Student, [2]Public Health Postgraduate,
[3]Department of Animal Husbandry Postgraduate, Sebelas Maret University, Surakarta, Indonesia

Abstract

In many developing countries, about 25% of children deaths were due to diarrheal disease. Diarrheal infection and malnutrition have always been intricately related. Micronutrient deficiencies have increased susceptibility to infection, and infection caused food intake disorder, nutrient malabsorption, and intermediary metabolism. Among children ages 5-7 years, school snacks provide almost 40% of the daily intake. This study aimed to determine the effect of zinc and vitamin A containing on school snacks and nutritional status on episodes of diarrheal among children 5-7 years in Tuban. This was an analytical observasional study with crossectional design. This study was conducted in Tuban from March until May 2018. From 521 kindergarten in Tuban district, 11 kindergarten were randomly selected, and 113 children aged 5-7 years were sampled. The data were collected by 3x24 hours food recall, and a set of questionnaire. The data was analyzed used Spearman test with a significance value of $p < 0.05$. This study found that there were no effect between zinc ($p=0.336$) and vitamin A ($p=0.492$) contained on school snacks with episodes of diarrhea, but there was significantly effect of nutritional status on episodes of diarrhea ($p=0.013$). This study conclude that zinc and vitamin A contained on school snacks has no effects on episodes of diarrhea, but nutritional status was significantly related with episodes of diarrhea.

Keywords: *Diarrhea, school snacks, zinc, vitamin A, nutritional status.*

Introduction

Diarrhea is defined as a change in stool consistency and increased frequency of defecation. It caused by various bacterial, virus, and parasitic organism contaminant. Nearly 90% of diarrheal disease is attributed to inadequate sanitation such as contaminated food, lack of safe drinking water, lack of sanitation and hygiene, as well as poorer overall health. Diarrheal disease is a major public health problem globally, and particularly in low- and middle-income countries. Diarrhea among children under 5 years of age causes considerable morbidity and contributes to child mortality for about 525 million children every years around the worldwide.[1] The mortality of diarrheal disease were more abundant than the mortality of AIDS, malaria, and measles disease.[2] In Indonesia, diarrhea is an endemic disease which is still become a potential disease of extraordinary events that often occurs with a fairly high Case Fatality Rate (CFR) and it is still become a problem that government need to be solved. In 2017, it is seen that the CFR of extraordinary incidences of diarrhea which often accompanied by children death is still quite high (1,97%), thus nationally the government program did not reach the target yet.[3]

Based on the East Java health profil data, the service coverage target for diarrhea patient who come to the health facilities in 2011 and 2012 was 69%, 72,43% respectively from the estimated number of diarrhea sufferers. It still far away under the national target

which 100%. Tuban district is one of the district which did not reach the national target of service coverage for diarrhea patient. In East Java, there were only 7 districts/ city which reach the national target (100%) such as Bondowoso district, Situbondo district, Mojokerto district, Sampang district, Kediri city, Pasuruan city and Mojokerto city.

Based on Riskesdas (2013), the prevalence of diarrhea among children ages of 5-14 years was 7.2%, and Tuban district health facilities only covered of 12.8% services of children affected by diarrhea.[4]

In the group age of 5-7 years, the children commonly study at kindergarten schools. In this group of ages, snacking provide almost 40% of the daily intake. Listiyorini et al.[5] found that incidence of diarrhea closely associated with food hygiene which bought from schools canteen or roadside snack. It is also closely related with nutritional status, due to related to food intake disorder, nutrient malabsorption, and intermediary metabolism. Based on previous study conducted by Clifton et al.[6] the increasing of episodes of diarrhea among the children, significantly caused deficiency of zinc and vitamin A. Fedriansyah[7] concluded that zinc and vitamin A status on the body related with episodes of diarrhea. Deficiency of Vitamin A closely related to diarrheal infection, and supplementation of vitamin A 60 mg RE can decreased the morbidity of diarrheal infection case.[8] Vitamin A can repair the damaged of intestinal epithel due to acute infections. Vitamin A has an important role on cell proliferation and cell differentiation which increasing immune system respond through increase the production of B-limphocytes. So that, the deficiency of Vitamin A caused decreasing of immune system respond which depend on limphocytes as cellular immune.[9] Besides vitamin A, zinc also plays main role on peripheral tissue and needed in oxidative process of vitamin A become retinal oxidase. Deficiency of zinc can causes disruption of vitamin A metabolism, and several immune system metabolism such as the maturation of limfosit T and interleukin-2 production. Zinc is the precursor of tymulin hormone which plays an important role on immune system and the activity of tymulin hormone are closely related with zinc concentration on serum. So the deficiency of zinc will impact on vitamin A concentration cause a disruption on immune system such as, differentiation of lymphocyte T and lymphocyte B, apoptosis inhibition, and malfunction of maintain the integrity and function of mucosal surfaces.[7]

Based on the background above, the researcher is interested to conducting study about the effect of zinc and vitamin A containing in school snacks and nutritional status on diarrheal morbidity among children 5-7 years of age, in Tuban.

Material and Method

This study was carried out in Tuban Regency, East of Java, Indonesia. This study was conducted from March until May 2018. This study was an analytical quantitative observational with crossectional design. Subjects were sampled by simple random sampling techniques. From 521 Kindergarten schools in Tuban Regency, 11 kindergarten schools were selected among 11 village in sub-district of Tuban.

The inclusion criteria in this study such as (1) age of children 5-7 years in kindergarten residing in Tuban City; (2) Their parent agreed to participate in this study proven by informed consent, while the exclusion criteria in this study; (1) The children were absent when the study conducted; (2) consumed worm medicine during 6 month ago.

Primary data was obtained directly from the subjects of the study, which are the interviews from the mothers or caretaker of the subjects guided by a validated questionnaire. Primary data consisted of: characteristics of subjects, data of snack intake from recall of 3x24 hours, data of episodes of diarrhea occurrences and nutritional status data from anthropometric measurements (height and weight).

Secondary data was data from the Health Profile Data and the Education Profil to find out the number of kindergarten students in Tuban Regency and the highest prevalence of diarrheal infection.

IBM SPSS statictics v.23 software was used for statistical analyses. The characteristics of subjects described with descriptive analyses, and the bivariate analyses using Spearman test with a significance value of $p<0.05$.

Findings: This study involved a total of 113 subjects from 11 kindergarten in several sub-district in Tuban Regency. There was no subjects whom dropped out from this study. Age of subjects, zinc containing on snacks, vitamin A containing on snacks, and nutritional status were assessed by the current study. The majority (60%) subjects were 6 years of age. About 40.7% of the

subjects had a severe deficiency of zinc from snacks intake and approximately 62.8% of subjects had a severe deficiency of vitamin A from snacks intake. The majority (50.4%) nutritional status of the subjects were normal while 18.6% subjects were underweight and 14.2% were obesity. The episodes of diarrhea of subjects showed that majority of subjects (65.5%) had never diarrhea, but 19.5% subjects had twice episodes of diarrhea within a month (Table 1).

Table 1. Frequency distribution based on the Characteristic of subject

Characteristics	N= 113		
	n	%	Mean
Age of Years			
5 years	26	23	5.9 years
6 years	68	60	
7 years	19	16.8

Overweight	19	16.8	
Obesity	16	14.2	
Episodes of diarrhea***			
Never	74	65.5	
1 times diarrhea	17	15.0	
2 times diarrhea	22	19.5	

Notes: *: categorized by provision of Health Ministry (1996) with criteria >120%: excessive, 90-119%: normal; 80-89%: mild deficit; 70-79%: moderate deficit; <70%: severe deficit, **: categorized by Supariasa (2017) with criteria <-3 until -2 SD; normal: -2 until +2 SD; overweight > +2 SD; obesity: > 3 SD, ***: categorized by Listyorini (2012)

The results showed the subjects who suffered severe deficit of vitamin A, 14 of them had twice episodes of diarrhea within recently month, while the subjects who suffered severe deficit of zinc, 11 of them had twice episodes of diarrhea. The subject who had underweight nutritional status, 10 of them had twice episodes of diarrhea (Table 2).

Table 2. Correlation between zinc and vitamin A containing school snacks, nutritional status with episodes of diarrhea

Variables	Episodes of Diarrhea			Total
	Absent of Diarrhea	Once	Twice	
Vitamin A intake				
Excessive	16	1	4	21
Normal	7	2	2	11
Mild deficit	3	0	1	4
Moderate deficit	3	2	1	6
Severe deficit	45	12	14	71
Zink Intake				
Excessive	31	6	7	44
Normal	10	2	4	16

Variables	Episodes of Diarrhea			Total
	Absent of Diarrhea	Once	Twice	
Nutritional Status				
Underweight	9	2	10	21
Normal	39	11	7	57
Overweight	13	3	3	19
Obesity	13	1	2	16

Notes: *: categorized by provision of Health Ministry (1996) with criteria >120%: excessive, 90-119%: normal; 80-89%: mild deficit; 70-79%: moderate deficit; <70%: severe deficit, **: categorized by Supariasa (2017) with criteria <-3 until -2 SD; normal: -2 until +2 SD; overweight > +2 SD; obesity: > 3 SD, ***: categorized by Listyorini (2012)

The results showed that there were correlation between vitamin A intake with zinc intake (p= 0.000), and nutritional status (p= 0.002), but there were no correlation between vitamin A intake with episodes of diarrhea (p= 0.492). Similarly, the zinc intake also correlated with vitamin A intake (p=0.000), and nutritional status (p= 0.007), but there were no correlation between vitamin A intake with episodes of diarrhea (p= 0.336). While nutritional status correlated with vitamin A intake (p=0.002), zinc intake (p=0.007), and episodes of diarrhea (p=0.013) (Table 3).

Table 3. Analyze of zinc and vitamin A containing school snacks, nutritional status with episodes of diarrhea

Variabel	Vitamin A intake	Zink intake	Nutritional Status	Episodes of diarrhea
Vitamin A intake		0.000*	0.002*	0.492
Zink intake	0.000*		0.007*	0.336
Nutritional Status	0.002*	0.007*		0.013*
Episodes of diarrhea	0.492	0.336	0.013*	

Notes: Spearman's rho test; α = 0,05, *: statistically significant

Discussion

The results of this study showed that the incidence rate of diarrheal morbidity among children age 5-7 years was quietly high (34.5%). This prevalence higher than prevalence of diarrhea in India which only 12.43% [10] and higher than prevalence of diarrhea in Italia which only 26.1% [11].

The younger children are most vulnerable with the incidence of either acute or chronic diarrhea due to weakened immune system.[12]

This study showed that nutritional status closely associated with the episodes of diarrhea. Childhood malnutrition was associated with dehydrating diarrhea. The association between malnutrition and the diarrheal morbidity was bidirectional and has been reported for the past decades.[13] Malnutrition after diarrheal illness caused anorexia, reduced absorptive function, and mucosal damage as well as nutrient exhaustion associated with episodes of diarrhea. Diarrheal illness affects the weight reducing as well as height gains.[14] On the other side, malnutrition leads to reduced the children performance, inadequate physical growth and development, decreased of immune system function which increased the opportunity to be infected and worsen the frequency, duration, and severity of diarrheal episodes.[15] Food-based intervention and nutritional dietary improvement among severe-malnourished children should be done rather than only treating the diarrheal infection.[16]

In this study, zinc containing on schools snacks did not related with the episodes of diarrhea among children 5-7 years in Tuban. This finding, did not supported by mostly previous study which concluded that zinc plays an positives effect of zinc intake during acure diarrhea.[17-18] Even WHO recommends zinc supplementation for children in developing countries who have acute or

persistent diarrhea at a dose of 20 mg in infants daily for 10-14 days. It is more necessary for malnourished children as they already have a zinc deficienct, which predisposes them to diarrhea and worsens it.[19]

Zinc's mechanism of action for the treatment of diarrhea is not fully understood, but it might be zinc is crucial for many cell function, such as protein synthesis, and cell growth and differentiation.[17] Zinc also plays a role for regulation of intestinal fluid, mucosal integrity and modulation of expression of genes encoding important zinc-dependent enzymes like cytokines, which play important roles in immune system and in modulation of oxidative stress.[18]

In this study, vitamin A containing on school snack also did not showed significantly associated with the episodes of diarrhea. This finding, opposite with previous review that conclude and indicating that vitamin A supplementation is associated with large and important reduction in morbidity and mortality of diarrhea in low and middle income countries.[20] Vitamin A deficiency may caused by maternal undernutrition, poor dietary quality, and losses during infection such as diarrhea, while the other side it is increases vulnerability to a range of illnesses such as diarhhea. Vitamin A deficiency can leading causes of mortality when infection compounded by coexisting malnutrition.[21] Vitamin A refers to a subclass of retinoic acids long understood to help regulate immune function and reduce morbidity and mortility of infectious disease such as diarrhea.Vitamin A mainly required for normal function of the visual system, maintenance of cell function for growth, ephitelial intergrity, production of red blood cells, immunity, and reproduction.[22]

The difference results of this study might be caused this study just analyzed zinc and vitamin A intake from school snack which approximately only 20-40% of total daily intake.

Conclusion

There were no effect of zinc and vitamin A containing on school snacks on the episodes of diarrhea. There was a significantly effect of nutritional status on the episodes of diarrhea. A well nourished children will decreased the vulnerability of illnesses such as diarrhea. Limitation of this study was bias memorize because the parents or caretakers have to reminded what the children ate for 3 days past.

Abstract

Background: Brain-derived neurotrophic factor (BDNF), recognized to be involved in differentiation and proliferation of specialized cell such as endothelial cell and osteoblast cell.

Aim of the Study: The study was designed to identify the effect of exogenous BDNF on development of jaw and on neural marker expression.

Materials and Method: Twenty pregnant rats,ten injected (I.M) with normal saline,other ten injected (I.M) with 0.1 ml of BDNF that received three doses at intervals (0,7,14 day of gestation period).Embryos at 16th and 18th intra-uterine life were used for histological and immunohistochemical evaluation for the development of prenatal jaw .

Results: Illustrate an enhancement of bone development during proceeding embryonic periods for both study groups .Moreover, the experimental group shows a high significant difference in the mean of bone cell count at the period 18th day in comparisum to 16th day IUL,and in comparisum to control at 18th day IUL. Results show positive expression of neuronal marker by proliferating nerve cells in control and experimental groups with significant difference.

Conclusion: The study suggest that BDNF contributes to promoting the differentiation of bone cells and enhancement of bone formation by increasing expression of neuron marker.

Keywords: *Brain derived neurotrophic factor, bone, embryogenesis, osteogenic cell, bone stem cell, rat development.*

Introduction

Neurotrophins and their receptors are important molecules that have a rolein the development and maintenance of nervous organs and have been recognized to be involved in regulating of organogenesis of skeletal tissues[1,2]. Studies have shown that neurotrophins are widely expressed in skeletal tissues, and shared in chondrogenesis, osteoblastogenesis, and osteoclastogenesis.[3,4] They illustrated to be involved in regulating skeletal tissue formation and in healing events[5].Moreover,BDNF stimulates and controls growth of new neurons from neural stem cells (neurogenesis) [6,7], and BDNF protein and mRNA have been identified in most neural areas of developing tissues.[8,9]

This study used Brain-derived neurotrophic factor (BDNF)to investigateit's potential roles on expression of neural marker in developing bone of prenatal rat jaw.

Material and Method

Twenty pregnant Wistar rats,aged (11–12-week-old)with weight (220–270 g) were used and maintained in the animal department of (National Center of Drug

Control and research/Iraq) under control conditions of temperature, drinking and food consumption and all experimental procedures were carried out in accordance with the ethical principles of animal experimentation .The animals divided randomly into 2groups, each consisting of 10 animals.

Group I, control group received 0.1ml(I.M injection) of distilled water.

Group II, experimental group received 0.1 ml BDNF (I.M injection).Both groups received 3doses at gestation interval periods (0,7,14 day).

Five rats from each group were sacrificed at 16th and 18thday of gestation date respectively and their embryos were obtained.

Materials

- A lyophilised BDNF protein 10 µg (ab9794)/ Abcamwas reconstitute in water to a concentration of 0.01 mg/ml and used for experimental group.
- Anti-Neu N antibody [1B7] - Neuronal Marker (ab104224) ABCAM

Method

Histological Examination: Embryo jawwas resected, fixed by 10% buffered formalin, dehydrated, and embedded in paraffin, 5µm section was stained with Hematoxylin and Eosin (H & E). The histological examination was done under light microscope by examining four microscopical fields for each slide and counting the number of the bone mesenchymal stem *cells* (BMSCs), osteocytes, osteoblast. Mean readings were calculated and used in statistical analysis .

Immunohistochemistry on tissue sections: The Neuronal Marker (ab104224) ABCAM was used. Preparation and characterization of these monoclonal antibody has been described and verified according to the manufacture data sheets.

Positive peroxidase staining produces brown color on light microscopy,the percentages of positively stained cells were counted at 5 representative fields (40X).

Immunohistochemical scoring: Quantification method of Immuno-reactivity was estimated for positive cell that expressed neuronal Marker .It was assessed by identifying and scoring 100 cells in five fields (X40) along examined area of different sections,the scoring is:

(Score 0, none; score 1, <10%; score 2, 10-50%; score 3, 51-80%; score 4, >80%).[10]

Radiological examination: All the embryo's head were radiographed by Plain X-ray with standard dental radiographic film.Voltage(kV)=60, Current(mA)=70, Exposure(s)=0.08 statistic analysis

The data were analyzed using one-way ANOVA test with multiple comparisons by (LSD Method).

Findings:

1. **Histological and immunohistochemical results:** Control group at 16th IUL shows new apposition of thin trabeculae surrounding by proliferating bone stem cells,at 18th day histologic section shows bone trabeculae with osteoblast on it's surface.

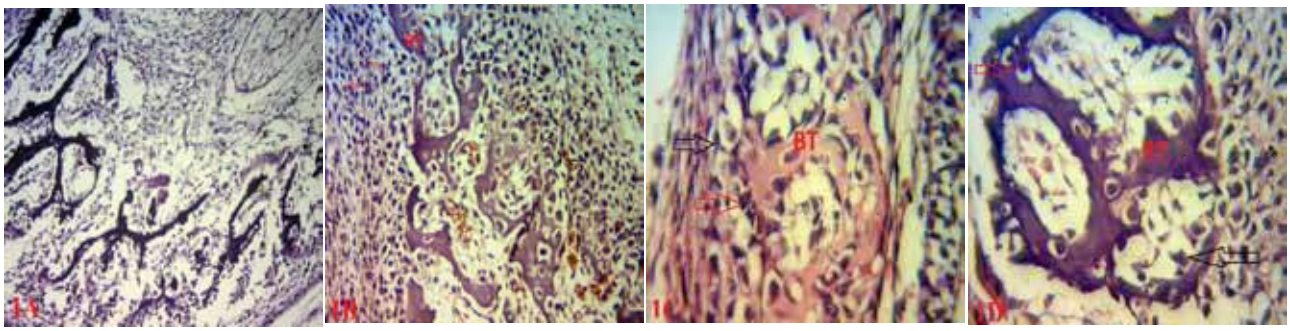

Figure (1): Embryonic bone at 16th & 18th IUL 1A: Control at 16th IUL H & E x10 1B: Embryonic bone (control) at 18th IUL shows Bone trabeculae (BT),bone mesenchymal stem cell.(arrows). H & Ex20 1C: Exp. At 16th IUL, shows bone trabeculae (BT); osteoblast (red arrow) Mesenchymal cell (black arrow). H & Ex40 1D: Embryonic bone (exper.) at 18th IUL, bone trabeculae (BT); osteocyte (red arrow) osteoblast (black arrow) H & Ex40

Experimental group at 16th IUL shows bone trabecule with osteoblast, proliferating bone stem cell was detected around the trabeculae.At 18th day of gestation period illustrates well, thick organized trabeculae surrounding by osteoblast and osteocyte cell trapped inside the trabeculae. Figure (1).

Immunohistochemical expression of neuronal marker for embryonic bone (control & exp.) at 16th & 18th IUL shows positive DAB stain by proliferating neural cells in developing jaw,score 1 for control and score 2 for experimental figure (2).

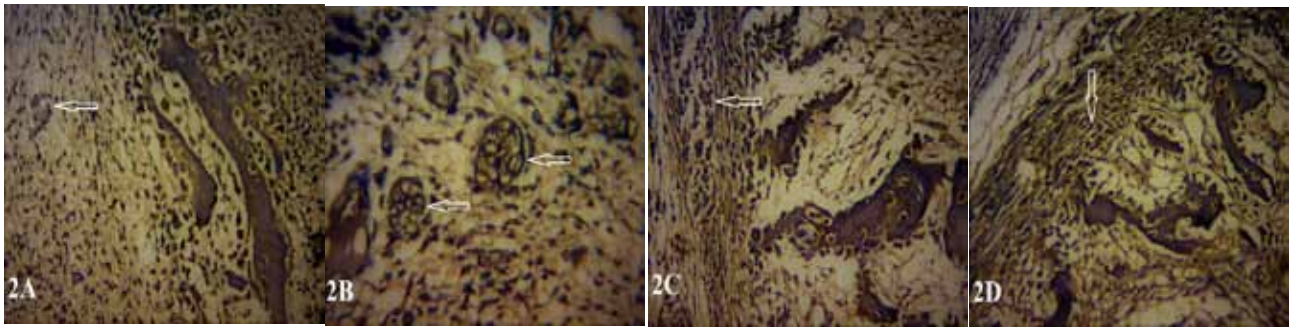

Figure (2): Immunohistochemical expression of neuronal marker for embryonic bone (control & exp.) at 16th & 18th IUL, 2A: Control at 16th IUL shows positive expression of neural cells (arrow).DAB stain x10, 2B:Control at 18th IUL shows positive expression of neural cells (arrows).DAB stainx20, 2C: Exp. at 16th IUL, shows positive expression of neural cells (arrow).DAB stainx20, 2D: Exp. at 18th IUL, shows positive expression of neural cells (arrow).DAB stainx10

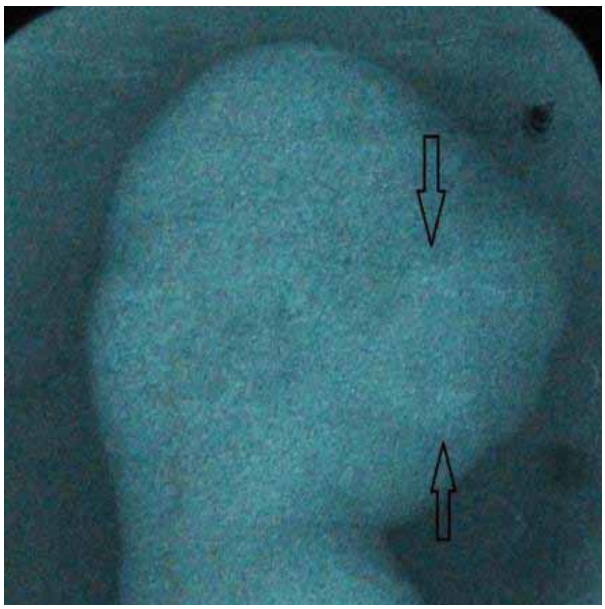
2. **Radiological Results:** Radiographic evaluation for the study groups of embryos at 18th IUL illustrated that control group shows faint streaky radio-opacity in upper and lower jaws,while experimental group shows more organized,linear radio-opacity in upper and lower jaws. Figures(3,4)



Figure(3): Stippled, streakyopaque radio-density represented upper and lower jaw (arrows) For control group at 18th IUL.

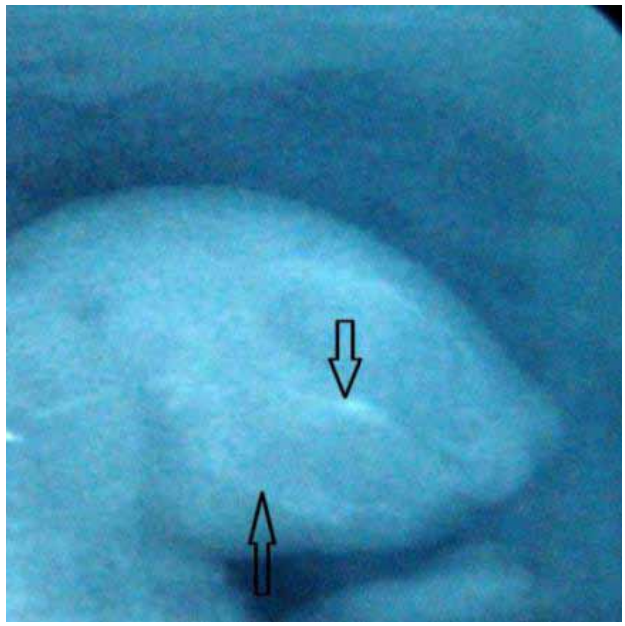


Figure (4): Linear opaque radio-density represented upper and lower jaw(arrows) for Experimental group at 18th IUL

3. **Statistic analysis:** Table (1) illustrates mean of bone cell (osteoblast and osteocyte) with bone mesenchymal stem cells for control and experimental groups at the 16th and 18th gestation periods. Multiple comparisons by (LSD Method)

of bone cells and BMSC count shows a high significant value for the experimental group at the period 18th day in comparisum to 16th day IUL,and in comparisum to control at 18th day IUL .

Table (2) illustrates mean of neuron cells that expressed positive neuron marker .The results show a high record in the mean of positive cells in experimental for both periods in comparisum to control with a high significant value. On other hand,the mean record for experimental group show to be high at period 16th in comparisum to 18th period that reversed the result in control.

Discussion

The study focused on jaw development of rat model to confirm how concurrent use of brain-derived neurotrophic factor can affect formation and aggravation of bone.

Recent studies have found that neurotrophins and Trk receptors are expressed in mouse osteoblastic cell lines[11,12].

In our animal model, it appeared that using of exogenous BDNF play a role in development of the

jaw as appeared inhistological, immunohistochemical investigations and radiologic examination.

The results can be explained as followings:

First: BDNF is a key molecule which controls neuronal differentiation and survival, synaptic formation and plasticity, as well as activity-dependent changes in synaptic structure and function [13].

Second: BDNF promotes the differentiation of bone cells,as the present results show that the mean of bone cell (osteoblast and osteocyte) with bone mesenchymal stem cells for experimental group were higher in comparisum to control[14,15].

Third: Enhancement of bone formation,by the action of the increment of expression of neuronal marker that affected on mesenchymal stem cell and formative bone cell [16,17].

In experimental group, we observed that new bone trabeculae formation starts at 16th day proceeding the control group with a coincidence of an increment for expression in neuron marker and at 18th day of gestation period a well,thick organized trabeculae surrounding by osteoblast and osteocyte was detected histologically and the result was confirmed radiologically as the radiographic film showed a linear opaque radio-dense demarcated the jaw.

Conclusion

Brain-derived neurotrophic factor (BDNF) has neurological Andnon neurologicalaffecton bone formation and may act as osteoinductiive agent by increasing expression of neuronal marker with increment of the number of bone progenitor cells and bone forming cells.

Efficacy of Catharanthus Roseus Extract against Dengue Virus Type 2 Infection in Vitro

Noor Zarina Abd Wahab[1], NorefrinaShafinaz Md. Nor[2], Nazlina Ibrahim[3]

[1]Lecturer, Faculty of Health Sciences, Universiti Sultan Zainal Abidin, [2]Lecturer, Faculty of Science and Technology, Universiti Kebangsaan, [3]Associate Professor, Faculty of Science and Technology, Universiti Kebangsaan Malaysia, Malaysia

Abstract

Catharanthus roseus, known as Madagascar periwinkle is an herbal and traditional plant used for treatment of various diseases.A study was carried out to test the cytotoxicity and antiviral effects of methanol extract from the leaves of *C. roseus*. The leaves of *C. roseus* were extracted using methanol to produce crude methanol extract. *In vitro* cytotoxicity test was performed to determine the concentration value of the extract causing 50% cell death (CC_{50}) using MTT assay. The antiviral activity has been confirmed by conducting foci forming unit reduction assay (FFURA) which involved post-treatment, pre-treatment and virucidal tests. Cytotoxicity test was performed on Vero cells indicates the CC_{50} value for *C. roseus* extract towards Vero cells was 0.13 mg/mL. The 50% Effective Concentration, EC_{50} of *C. roseus* extract was 0.025 mg/mL. Selectivity index of *C. roseus* extract against DENV-2 was 5.2. Three treatments were used in the antiviral test; 1) post-treatment, 2) pre-treatment, and 3) virucidal. The results revealed that the post-treatment was more effective in inhibiting viral replication compared to pre-treatment and virucidal. The results of this research showed that *C. roseus* extract has good potential for prospective nature-based antiviral drug.

Keywords: *Catharanthus roseus, Antiviral Activity, Dengue Virus Type 2, MTT, FFURA.*

Introduction

In this study, we investigate the cytotoxicity and antiviral properties of *C. roseus* to explore its potential as anti-DENV-2 agent. *Catharanthus roseus* (L.) G. Don (Apocynaceae) a perennial herb plant is widely used as an ornamental species in many *tropical countries.* It is more commonly known as Madagascar periwinkle. In Malaysia its known as *Kemuningcina*. This plant produces a combination of pink, purple and white flowers. These flowers are often grown for their attractive appearance and to decorate shady areas[1]. Methanol extracts of *C. roseus* has been reported to exhibit significant anti-cancer activity against different cell types *in vitro*[2.] Crude extracts of *C. roseus* showed antibacterial activity against Gram-positive and Gram-negative bacteria[3]. In addition, *C. roseus* extract also showed antifungal properties against *A. fumigatus*, *C. albicans*, *A. niger* and *F. moniliforme*[4].

Dengue virus (DENV) is a positive-sense, single-stranded RNA virus with a genome size of at least 10.7 kb. It is a member of the Family Flaviviridae, genus Flavivirus. There are four different DENV serotypes (DENV-1, DENV-2, DENV-3, and DENV-4) which are primarily transmitted between humans by the mosquito vector *Aedes aegypti* and *Aedes albopictus*[5,6]. Dengue virus can cause asymptomatic infection to mild dengue fever or severe dengue hemorrhagic fever and dengue shock syndrome[7.] All DENV serotypes are widespread geographically throughout the tropics. The incidence of dengue has grown dramatically around the world in recent decades[8]. Recovery from infection by one serotype provides lifelong immunity against that particular serotype. However, cross-immunity to the other serotypes after recovery is only partial and temporary. Secondary infection by other serotypes increase the risk of developing severe dengue[9].

Materials and Method

Plant Material and Extraction: Leaves of *C. roseus* were washed under running tap water and finally rinsed with distilled water then air dried for 48h,

homogenized into a fine powder and stored in air-tight plastic containers. Dried leaves were finely ground and then extracted in a soxhlet extractor using methanol solvent. After that, the extract was evaporated to dryness using a rotavap. Lastly, freeze dry technique was performed to lyophilize the extract.

Cell and virus: Vero cell from American Type Culture Collection (ATCC) CCL-81 was used for both cytotoxicity and antiviral test. Dulbecco's Modified Eagle's Medium (DMEM) supplemented with 5% fetal bovine serum (FBS)was used for Vero cell maintenance throughout the experiment. C6/36 cells maintained in L-15 medium supplemented with 5% FBS were used for virus propagation. Dengue virus type-2 (DENV-2) used in this study is a prototype of the New Guinea C strain, a kind gift from the Faculty of Biosciences and Medical Engineering, UniversitiTeknologi Malaysia. Briefly, the virus was propagated in C6/36 cells, harvested and the virus titer was determined by focus forming assay using Vero cells[10].

Cytotoxicity Test: Cytotoxicity of *C. roseus* extract against Vero cells was determined using the MTT assay[11]. Briefly, a confluent monolayer of Vero cells in 96-well cell culture microplate were treated with increasing concentrations of *C. roseus* extract triplicates with starting concentration of 10 mg/mL. After 48 h of incubation, 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT) was added into each well and was further incubated for 3 h. After removing excess MTT, 100 µL of dimethylsulfoxide (DMSO) was added. The absorbance values of the wells were measured at 570 nm using a 96-well plate reader. Dose-response curve was plotted using Graph Pad Prism 5 and the half maximal cytotoxic concentration (CC_{50}) of *C. roseus* extract was determined from the plot.

Foci forming unit reduction assay (FFURA): FFURA was done to screen for anti-DENV-2 activity of *C. roseus* extract with different concentrations. Infected Vero cells which were treated with *C. roseus* extract was incubated for 4 days post infection in growth medium supplemented with 2% FBS and 1.5% carboxymethyl cellulose. The number of DENV-2 foci was counted using a stereomicroscope and the virus titer was expressed as Foci Forming-Unit (FFU). Antiviral activities of the compounds were determined by calculating the percentage of foci reduction (%RF) compared against the controls using the following formula:

$$RF(\%) = (C\text{-}T) \times 100/C$$

where, C is the mean of the number of foci from triplicates treatment without extract added and T is the mean of the number of foci from triplicates of each treatment measures with the extract[12].

Antiviral Activity: Antiviral assays composed of post-treatment, pre-treatment and virucidal assays. **Pre-treatment:** In order to determine the prophylactic effects of *C. roseus* extract against DENV-2 replication, different concentrations of *C. roseus* were added to the confluent Vero cells (2.0×10^5 cell/well) in 12-wells microplate after 5 h of virus infection. The treatment medium was removed and the treated cells were washed twice with PBS. The cells were then infected with 200 FFU of DENV-2 and incubated at 37°C for 4 days, 5% CO_2. After 4 days of infection, antiviral activity was determined by the reduction in foci number as previously described. **Post-treatment assay:** Vero cells (2.0×10^5 cell/well) grown into 12 well plate were infected with 200 FFUof DENV-2. Cells were incubated for 1.5 h to allow virus adsorption. After adsorption period, cells were washed twice with PBS to remove any residual unbound viruses. This was followed by the addition of different concentrations of *C. roseus* extract. The cells were then infected with 200 FFU of DENV-2 and incubated at 37°C for 4 days in the presence of 5% CO_2. After 4 days of infection, antiviral activity was determined by the reduction in foci number as previously described. **Virucidal assay:** A viral suspension containing 200 FFUofDENV-2incubated with equal volume of the different concentrations of *C. roseus* extract for 1.5 h at 37°C. After incubation, all tubes were diluted and titrated. Then, Vero cells were infected with the diluted treated viral suspension. Cells were washed twice with PBS after 1.5 h adsorption at 37°C and cells were overlaid by 1.5% CMC containing DMEM supplemented with 2% FBS. After 4 days of incubation, direct virucidal activity of *C. roseus* extract was determined by foci reduction as previously described.

Statistical Analysis: Values were expressed as means ± standard errors of the mean. Significance difference, determined as $p< 0.05$, was calculated using Student's t-test (Microsoft Excel).

Results and Discussion

To determine the nontoxic dose, Vero cells were exposed to twofold serially diluted *C. roseus*

methanolextract at concentrations ranging from 1 to 0.03 mg/mL. In this assay, the CC_{50} value of *C. roseus* extract was determined at 0.13 mg/mL. Figure 1 shows the percentage of cell viability versus concentration of *C. roseus* extract. Thus, maximum concentration that was used in the subsequent antiviral studies was fixed at 0.078 mg/mL.

Figure 2 shows the result obtained from antiviral assays using *C. roseus* extract. In post-treatment assay, more than 60% foci reduction was observed in *C. roseus* extract at the highest concentration (0.078 mg/mL). The lowest concentration (0.005 mg/mL) of *C. roseus* extract still exhibited mild reduction which was more than 30%. The antiviral activity of *C. roseus* extract was observed to be concentration dependent as the percentage of foci reduction is reduced with reducing *C. roseus* extract concentration. For pre-treatment assay, *C. roseus* extract showed weak activity which was less than 2% foci reduction at highest concentration (0.078 mg/mL). In virucidal assays, exposure of DENV-2 to the *C. roseus* extract at highest concentration (0.078 mg/mL) reduced more than 30% of foci reduction. This result confirms the mild virucidal activity observed in *C. roseus* extract.

The EC_{50} value of the SPD tested against the DENV-2 was 0.025 EC_{50} (mg/mL), as shown in figure3. The effectiveness of the *C. roseus* as an anti-DENV-2 expressed as selectivity index (SI). *Catharanthus roseus* possessed a moderate anti-DENV-2 activity with SI value of 5.2. Any antimicrobial agent that has SI values higher than 10 (SI>10) ensures the potential to be developed as an agent of antiviral drug. Meanwhile, SI value less than 1 are considered to be weak antiviral agent. SI value above 1 have moderate activity as antiviral agent[13].

Catharanthus roseus is an important medicinal plant distributed all over the world. The interest in this plant are due to the reports thatmore than 130alkaloids and severalof them exhibit potent pharmacological propertiescan be found in *C. roseus*[14].Based on phytochemical analyses, *C. roseus*has been proven to be rich n secondary metabolites such as alkaloids, flavonoids, phenols, tannins, saponin, terpenoids, quinines and cardiac glycosides[15,16]. *Catharanthus roseus* have been reported by many researchers to be rich in alkaloid[17,18,19]. Alkaloid from *C. roseus* inhibited simplex herpes virus (type I) and showed an antiparasitic effect against Trypanosoma[20]. Flavonoids groups have been reported by several researchers to exhibit a wide range of biological activities such as antimicrobial, antioxidant, anti- analgesic, anti-inflammatory, anti-cancer and anti-allergic[21].There have been reports on flavonoids from plant inhibited dengue virus type -2 (DENV-2) in Vero cell via Foci Forming Unit Reduction Assay (FFURA)[22]. Flavonoids from *C. roseus* were found to cause maximum antimicrobial activity towards Gram positive and Gram negative bacteria[23]. Thus, the richness of alkaloid and flavonoid in *C. roseus* may contribute to anti-DENV-2 properties.

Conclusion

This study demonstrates the variable effects of *C. roseus* extract on DENV-2 replication in Vero cells. Extract had mild antiviral activities and low prophylactic function. In order to elucidate the mechanisms of inhibition, further studies are required to determine the underlying mechanisms that contribute to its antiviral activity.

Psychometric Evaluation of a Feedback Conception Scale: Building Positive Feedback Practises of Charge Nurses in Public Hospitals

Nor Hasnida Che Md Ghazali[1], Mahizer Hamzah[1], Norazilawati Abdullah[1], Zahari Suppian[1]

[1]Lecturer, Faculty of Human Development, Universiti Pendidikan Sultan Idris, Malaysia (UPSI)

Abstract

Charge nurses who have a good level of understanding on feedback conceptions will be able to practise feedback effectively towards their staffs. The purpose of this pilot study was to provide the evidence of psychometric evaluation of 'Teachers' Conceptions of Feedback (TCoF) scale of charge nurses using the Rasch Measurement Model. There are 9 constructs with 37 items altogether. One hundred and sixty-three (N=163) charge nurses from three states had completed the questionnaire. The content validity was checked by three experts in the field of measurement and medical health. The findings revealed that most items fit the model as their MNSQ values are between 0.60 and 1.40 except for four items. PMC value for all items are more than 0.20 except for three items. Two items showed a negative value of PMC. Most items are in a same direction so the item discrimination is good. Item reliability and item separation is 0.87 and 7.29 respectively, while person reliability and person separation is 0.81 and 2.81 respectively. The reliability value for item and person is high and acceptable. The separation index for item and person are also acceptable. In total, five items were deleted. The statistical analysis provides strong evidence to support the validity and reliability of the scale. The findings show that sample selection is appropriate. Hence, this instrument could be adapted or adopted by other researchers in the Malaysian health care system context.

Keywords: *charge nurse,feedback conceptions, validity, Rasch Measurement Model.*

Introduction

Feedback is one of the most influences on someone's achievement. Feedback, by definition is any information given to someone by teachers, peers, parents, books, self or experience in providing knowledge, skills and attitude[10]. What type of information are we talking about? It could be an alternative strategy, a clarification of ideas or the correctness of a response. Feedback can be accepted, modified or rejected[11]. And, feedback which is gained from learners could make teaching become more effective as it can be used to adjust teaching approaches[19]. On the other hand, feedback is incapable in reinforcing someone or initiating further action of someone. Feedback might threaten someone if the information given is not familiar or obtrusive to them. Before we go into detail, let us look at the 'conception' of feedback. One's conceptionsare the beliefs, attitudes and intentions that someone has[4]. So, in this study, conception of feedback refers to the charge nurses' beliefs, attitudes and intentions towards feedback. These feedback conceptions could influence their feedback practises towards their nursing staffs while they are on duty as[1] stated that one's conceptions contribute a lot to one's behaviour. In general, the aim of feedback is to improve achievement. Feedback is also conducted to develop confidence of learners to do peer-assessment or self-assessment, to ensure that learners are actively engaged in their own learning and to promote learning[6]. It should not be something personal or confidential but it has to based on real evidence. To gain this, a feedback has to be constructive. [2]has listed few characteristics of a constructive feedback which are the goal and standard

Corresponding Author:
Nor Hasnida Che Md Ghazali
Department of Educational Studies, Universiti Pendidikan Sultan Idris, Malaysia (UPSI)
e-mail: hasnida@fpm.upsi.edu.my

of the feedback has to be clear, exact and not vague, the information given to learners must be in a descriptive form. Next, a good feedback must be action-oriented and also solution-oriented. In addition, it has to be strictly confidential as to maintain trust between the assessor and the one being assessed. The least effective way is to give grade to the staff under them[21]. By giving only grades, the students are not able to determine what they are supposed to do to improve towards their goals. The best ways to give feedback is to provide an information on the correct answers plus some explanation and specific activities for improvement.

Problem Statement: Every day, charge nurses will face various kinds of challenges when dealing with staff nurses such as specific assignments requested by staff nurses or the challenges in increasing staff satisfaction[17]. And, one of the five main principles listed by The American Nurses Association is to assess staff skills. When assessing staff skills, not only the clinical skills that the charge nurses have to consider, but it is more than that. The whole scope of practices have to be considered such as the staff nurses characteristics, competencies, years of experience, culture and emotional intelligence and so on. When assessing, feedback will come into play as feedback could serve as a medium to enhance thinking skills[8] of staff nurses. An effective feedback might give opportunities for staff nurses to change their skills which they have previously misinterpreted or to change their motivational beliefs and self esteem[23].In addition, interviews have been conducted with few of charge nurses in public hospitals and they agree that they do not really understand the concept of feedback elements like peer and self-feedback, timeliness of feedback and things that they are supposed to focus at when giving feedback to staffs. Lack of understanding in feedback conceptions might be the reason why they are sometimes confused when it comes to assessing their staffs formatively. Hence, the researchers decided to gain data using this exclusive set of questionnaire from New Zealand researchers which has been tested in few countries[5]. Since this instrument was to be used in the Malaysian health care context, this instrument has to go under pilot study to check for validity and reliability of the instrument as only valid and reliable instrument can be used for real study.

Method

This study is using a quantitative approach which involves 163 charge nurses randomly selected from three states. The instrument used is 'Teacher Conceptions of Feedback (TCoF) inventory adapted from[9]. It consists of 9 constructs altogether with 37 items. They are Conception-Irrelevance (Students Ignore)–4 items, Conception-Improvement (Student Use)–4 items, Conception-Accountability (Expected)–3 items, Conception-Encouragement + Self Type (Praise)–6 items, Task Type–3 items, Process Type–4 items, Self-Regulation Type–5 items, Peer & Self Assessment–3 items and Timeliness–5 items). An example of item from the second construct is 'Staff uses feedback given to improve his/her work', item from the fourth construct is 'Peers are the best source in giving feedback'. The scales were measured using a 6-point Likert scale ranging from strongly disagree to strongly agree. Using Rasch, the data was analysed to determine the validity and reliability of the TCoF. Initially, the data was not fit at all. When using data from 163 person, the value for raw variance explained by measures is -440.0% and the value for unexplained variance in 1st contrast is 69.4% which does not agree with what suggested by[13]. 58 data were deleted and it left with 105 data only and the data was analysed again. The report of the findings was discussed below.

Findings: The analysis was conducted to test item fit, item polarity, unidimensionality and local independance, items and respondents' reliability and separation index.

Item Fit: The item fit statistics (infit and outfit MNSQ) is the degree of equality between the response pattern and the expected model for each item for all respondents[3]. The misfit item due to the high value of MNSQ or Z-value could affect the unidimensionality of subscales (Linacre, 2007). According to Smith et al. (2006), MNSQ is more stable than Z-std value. According to[14], item with high value of MNSQ is a threat to validity compared to low value of MNSQ. For this study, the accetable range of values for the infit and outfit MNSQ measures are in the range of 0.6 to 1.4[14]. The range for Z-std is -2<Zstd<+2.All items which stay within this range is a productive items. If the items are not within this range, it is suggested to eliminate the items. The Rasch model prepare a fit statistics which could help researchers to come out with important decisions about the data[18]. Table 1 shows most MNSQ infit and outfit values are less than 1.0 which means that there is a lack of variation from the model. All of the items laid between 0.6 to 1.4 except for four items (item A2, A4, E18 and I37). Most items have a good overall

fit and they are retained. Four items are deleted. Looking at the Z-std value, the same thing is concluded. All the four items deleted are not in the range of -2 to +2 so it is better to delete those items.

Table 1: Item measure (INFIT, OUTFIT) MNSQ and Point Measure Correlation

Entry Number	Measure	Standard Error	INFIT MNSQ	INFIT ZSTD	OUTFIT MNSQ	OUTFIT ZSTD	PTMEA CORR	Item
1	1.05	.13	1.28	2.1	1.29	2.2	.27	A1
2	1.66	.12	1.82	5.1	1.88	5.1	.09	A2
3	2.53	.17	1.37	2.2	1.34	2.1	-.08	A3
4	2.18	.17	1.77	4.2	1.70	3.6	-.03	A4
18	-0.04	.13	1.66	3.6	1.58	3.7	.41	E18
35	1.35	.13	1.40	3.4	1.40	3.5	.31	I35
37	0.16	.13	1.88	5.2	1.88	5.7	.29	I37

Item Polarity: Item polarity is an indicator showing that the items moving in one direction as intended by constructed constructs. Point Measure Correlation (PMC) is a statistical item showing the correlation results between one points and scores for all candidates. Item polarity analysis using PMC is an early detection method for construct validity. The positive value shows that the item is in the same direction with the construct. However, if the value is negative, it shows that something has to be done by the researcher as it indicates that the item or the respondent contradict with the variables[12]. However, the acceptable value is 0.2 or more. In this study, the PMC value of all items are more than 0.2 except for the three items which are item A2 (PMC=0.09) A3 (PMC=-0.08) and item A4(PMC=-0.03). All the three items are deleted. So, most items have a good discrimination value.

Unidimensionality and Local Independence: This two measures are important as they are interconnected with each other[10]. Unidimensionality refers to a condition where items are measuring in one dimension[21]. Furthermore, unidimensionality and local independence allow us to detect whether an item is showing a different dimension or not, the item is understood or not and whether the response shows the respondents' special skills. Principal Component Analysis is used to detect unidimensionality and local independence. A good unidimensionality is when the raw variance explained by measures is more than 40%[2] or more than 60% [16]. The unexplained variance in the 1st contrast must be less than 15%[2] or less than 5%[16]. [2] states that for raw variance explained by measures, values higher than 40% is a strong dimension, higher than 30% is a moderately strong dimension and if it is more than 20%, it is a moderate dimension. The raw variance explained by measures show a value of 52.0% (higher than 40.0%) and the unexplained variance in 1st contrast is 5.2% (less than 15%) (Table 2). So, it is clear that items are not confusing with a strong dimension measures. When unidimensionality assmptions are fullfilled, then the local independence caharacteristics would be fulfilled automatically[16].

Table 2. Standard residual variance (in Eigenvalue units)

	Empirical			Modeled
Total raw variance in observations	70.6	100.0%		100.0%
Raw variance explained by measures	32.1	52.0%		51.4%
Raw variance explained by persons	6.1	10.3%		10.0%
Raw variance explained by items	26.0	36.8%		36.7%
Raw unexplained variance (total)	38.0	52.0%	100.0%	52.2%
Unexplained variance in 1st contrast	3.5	5.2%	11.1%	
Unexplained variance in 2nd contrast	3.2	5.2%	9.4%	

Reliability and Separation: Reliability of an instrument is precision. Item reliability indicates whether items are interacting well with one another showing the same attibutes[21]. On the other hand, person reliability shows reproducibility as expected if the samples are measuring the same construct in a set of items[22]. This is the same as the Cronbach Alpha value. Next is the item and person separation index. Item separation index shows the separation of item difficulty level whereas person separation index shows the separation or the difference of individual following different capability. For both measures, as long as it is more than 2.0, the the measures are good. The summary of statistics of person and item are shown in Table 3. For summary of 37 measured item, item reliability is 0.87. For summary of 102 measured person, person reliability is 0.81. This shows that the reliability values are high and acceptable[15]. [14]also stresses that for an instrument to be reliable, the reliability value has to be more than 0.80. Furthermore, it shows that person factor is stable and consistent when measured. The instrument separation should at least be more than 1.0 and a value less than that shows that there might be an overlapping items or less person variability in the trait. In this study, item separation index was 7.29 which indicated the existance of 7 to 8 item strata while person separation index was 2.81 which indicated the existance of 3 people strata. However, as stated by[13], for both measures, as long as it is more than 2.0, then the measures are good.

Table 3. Summary of person and item measure

Summary of Person Measurement					
		INFIT		**OUTFIT**	
	Measurement	**MSQ**	**ZSTD**	**MSQ**	**ZSTD**
Mean	0.33	1.00	-0.1	1.00	-0.1
SD	0.67	0.37	1.9	0.39	1.2
Separation	2.81				
Person Reliability	0.81				
Summary of Item Measurement					
Mean	0.00	0.99	-0.2	1.00	-0.1
SD	1.05	0.36	2.5	0.29	2.7
Separation	7.29				
Item Reliability	0.87				

Discussion and Conclusion

This study aims to validate an instrument in assessing feedback conceptions amongst charge nurses in public hospitals in Malaysia using Rasch Model. The findings suggested that most items fit the model as their MNSQ values are between 0.6 to 1.4 except for four items, items A2, A4, E18 and I37 which have MNSQ infit and outfit more than 1.5. Three items do not agree with the item polarity accepted range. Two items show a negative value and the other one item has a value of less than 0.2. So, all the three items are deleted. Unidimensionality is not really an issue as it shows a good unidimensionality when the raw variance explained by measures is 52.0% which is more than 40.0%. This indicates that all the nine constructs are quite different from one another. This instrument with 37 items which represents 9 constructs shows good and acceptable indices of item and person reliability. This shows that items are consistent. After going through data analysis, finally five items were deleted. The overall item quality was good. The instrument is capable in assessing charge nurses' conceptions of feedback in the Malaysian health care system context. However, a more detailed analysis is needed, if possible. Maybe an Item Response Theory could be used for further investigation. In conclusion, for any instrument to be used in real study, it has to go through pilot testing to check for its validity and reliability. The development of this instrument in a different context cannot be assumed that it could fit with any other samples.

Cytotoxic Activity and Selectivity Index of Solanum Torvum Fruit on T47D Breast Cancer Cells

Nunuk Helilusiatiningsih[12], Yunianta[2], Harijono[2], Simon Bambang Wijanarko[2]

[1]Faculty of Agriculture, Universitas Islam Kadiri, [2]Faculty of Agriculture Technology Universitas Brawijaya Malang

Abstract

Solanum torvum has antioksidan. This study aimed to analyse cytotoxic activity and selectivity index of *Solanum torvum* on T47D breast cancer cells invitro. Identification of *Solanum torvum* fruit chemical compounds with LCMS containing Clorogenic acid, 4-O-caffeoylquinic acid, 3-O-caffeoylquinic acid, 3-O-feruloyquinic acid, 5-O-feruloylquinic acid, 3-O-feruloylquinic acid, 3,4 - O dicaffeoylquinic acid, 3,5-dicaffeoylquinic acid, 3-O-feruloylquinic acid, 5-O-feruloylquinic acid, putative dicaffeoylquinic lactone. Cytotoxic assays showed that the *Solanum torvum* Without Fermentation were IC_{50} (IGT) 1111.62µg/mL, IC_{50} (MGT)1889.20µg/mL, IC_{50} (EGT) 1171.90µg/mL, IC_{50} (FEGT) 305.98 µg/mL. Cytotoxic assays showed that the treatment of fermentation was IC_{50} (IBT) 1760.36 µg/mL, IC_{50} (MBT) 1631.06 µg/mL, IC_{50} (EBT) of 1111.58 µg/mL, IC_{50} (FEBT) 39.17µg/mL, IC_{50} (FHBT) 85.58 µg/mL. Index of selectivity (IS)*Solanum torvum* (without fermentation) were IS (IGT) 5.23, IS (MGT) 0.61, IS (EGT) 1.06, IS (FEGT) 1.45. Index of selectivity of *Solanum torvum* (fermentation treatment) were IS (IBT) 2.41, IS (MBT) 0.78, IS (EBT) 0.18, IS (FEBT) 4.64, IS (FHBT) 1.67. The best results are treatment of ethyl acetate fraction of *Solanum torvum*(FEBT) has IC_{50} was 39.17 µg/mL and Index selectivity was 4.64, declared safe/not toxic to normal cells, thus potentially developed as T47D breast anticancer cells.

Keywords: *Cytotoxic, T47D Breast Cells, Selectivity Index, Solanum torvum.*

Introduction

Solanum torvum in Indonesia in fertile soils has antioksidan. *Solanum torvum* contains steroids, terpenoids, saponins, tannins, alkaloids, fatty acids, 3-o-acetyl-stigmasta-5, 25-diene-2, 3-diol, methyl stearate, 21, 25-dimethylmelianodiol[(1)]. *Solanum torvum* extraction on seeds and fruit peel has compounds of flavonoids, sterols and saponins[(2)]. Solanum torvum has alkaloids, flavonoids, saponins, tannins, glycosisides[(3)]. *Solanum torvum* has constituent chemicals such as neochlorogenin 6-O-β-D-quinovo-pyranoside, neochlorogenin 6-O-β-D-xylopyranosyl- (1 → 3) -β-D-quinovopyranoside, 6-O-α-L -rhamnopyranosyl- (1 → 3) -Dbeta quinovopyranoside, solagenin 6-O-β-D-quinovopyranoside, solagenin 6-O-α-L-rhamnopyranosyl (1 → 3) -β-D-quinovopyranoside, .isoque-rcetin, routine, kaempferol and quercetin[(4)]. The wild eggplant fruit (Solanum torvum) in Indonesia was relatively used by the population because ithas not been cultivated. *Solanum torvum* containing sesquiterpen functions immunosuppressive[(5)]. Clorogenic acid serves to prevent and treat anti-inflammatory diseases[(6)]. Chlorogenic acid is a polyphenol compound proven to stimulate anti-inflammatory, antibacterial and antioxidant activities as agents for clinical treatment of hepatic I/R injuries[(7)]. Carcinogenesis is the process of the occurrence of multi-stage cancer that undergoes genetic changes and progressive transformation of normal cells into malignant cells[(8)]. The biggest cancer causes of death in the world are breast, cervix, colon, lung and stomach cancer[(9)]. The most common causes of death for women are cervical cancer and breast cancer. T47D breast cancer cells used in this study have unlimited replication ability, high homogeneity and was easily replaced with frozen stock in the event of contamination[(10)]. This was supported by research that states that the methyl cafeat compound in Solanum torvum fruit functions as an anti-cancer[(11)]. The study aimed to analyze antioxidant compounds found in *Solanum torvum* fruit extracted with various solvents

to function as cytotoxic and selectivity index for T47D breast cancer cells.

Materials and Method

Solanum torvum: *Solanum torvum* was obtained from Sumber Manjing village Malang . Fruit wild eggplant was sorted, washed, drained. In the next stage processing into dry powder using 2 types of treatment. Treatment 1 was the fruit that has been cleaned in a small chunk and then vacuum dryer temperature 50^0 C for 14 hours. The two treatments were fermented, namely 5 days curing, 6.18 hours fermentation time, 50^0 C drying temperature and 14 hours drying time, thus there stored on main raw material.

Chemical materials: Materials include, water, aquabides, methanol pa, ethanol pa, n hexane pa, ethyl acetate (p.a.), DMSO, alcohol, T47D cells and vero cells,RPMI, M199 media, FBS, PS, trypsin-EDTA, SDS in 0.01 N HCL, MTT, and PBS, Rnase, ethanol, 2 N hydrochloric acid, lead (II) acetate 0.4 M, isopropanol, chloroform, Molish, 2 N hydrochloric acid, iron (III) chloride reagent, Liebermann-Burchard, n-hexan, DPPH 0.1 mM, methanol, Folin-Ciocalteai, Gallic Acid, AICI3, Quercetin, Sodium Nitrite, Diethyl ether, Na2CO3. Chemicals obtained from the parsitology laboratory of the UGM medical faculty jogjakarta.

Analyzing Solanum Torvum using LCMS: UHPLC The brand of ACCELLA type 1250 made by Thermo Scientific which consists of vacuum degassers. Solvents A = 0.1% wet format in water and B = formic acid in Acetonitrile. A mobile phase gradient with a speed of 300 µl/minute with the following settings: 0.0-0.6.00 minutes 5% B, 0.6 - 3.0. is 2 µL at 160^0C. The column is controlled at 30ºC, and the autosampler compartment is set to 16ºC. UseLCMS/MS Triple minutes 75% B, 3.0 - 3.5 minutes 75% B, 4.0- 5.5 minutes 5%. The injection volume in the TSQ Quantum Access Max spectromethermic acid LC from Thermo Finnigan with an ESI ionization source is controlled by TSQ Tune software which is operated in negative mode. The ionization conditions of ESI are as follows: 3.0 kV spray voltage; evaporation temperature of 250ºC; capillary temperature of 300ºC; nitrogen as sheath gas pressure 40 psi, and 10 psi pressure aux gas with argon gas (12)

Preparation of breast cancer cellsT47D (13)

Ethanolextraction: Samples weighed 10 grams plus 80% ethanol as much as 100 ml then placed on elenmeyer diprasi for 24 hours while being shaken. The results of the extract were filtered put in an impermeable container, the sample was again macerated with 80% ethanol solvent which was repeated until 3 times. The results of the ethanol extract put together are concentrated with a rotary evaporator vacuum temperature of 40^0C until concentrated, then stored in bottles that are impermeable to drying with nitrogen gas until the solvent evaporates, stored in a safe place.

Methanol extraction: 10 grams of the test sample were extracted with 100 ml of methanol concentration of 95% with 24-hour maceration. The extract was filtered with Whatman no 1 filter paper. Then evaporator until thick and with nitrogen gas until dry, stored in a safe place.

Water extraction: 10 grams of the test sample were each extracted with 100 ml of hot water in an infusion pan for 15 minutes. The extract was filtered with Whatman filter paper No. 1. The dirotarievapore extract until thick and the results stored in a bottle then dried with frezee drying, stored in a safe place.

Hexane fractionation: Ethanol extract of Solanum torvum fruit powder was inserted in a separating funnel, added hexane and water each 50 ml (1: 1) shaken so that 2 layers were formed. The hexane layer is collected, the water layer is extracted again with hexane up to 3 times. The results are applied with a vacuum rotary evaporator until thick and dried with nitrogen gas so that stored in a safe place.

Ethyl acetate fractionation: Ethanol extract of the test sample was put in a separating funnel added with ethyl acetate and 50 ml (1: 1) of water each shaken to form 2 layers. Ethyl acetate layer is accommodated, the water layer is extracted again with ethyl acetate up to 3 times. The results are applied with a vacuum evaporator until thick and dried with nitrogen gas, thus stored in a safe place.

Citotoxic analysis via MTT: Citotoxic analysis in T47D breast cells with 9 samples treatment *Solanum torvum* were 31,25 ppm, 62,5 ppm, 125 ppm, 250 ppm, 1000 ppm with ELISA *reader* (Bencmark Bio Rad), wavelength 595[(13)].

Index selectivity analysis: The principle works the same as cytotoxic analysis but the complete media uses M199. The test sample concentrations were 1000ppm,

500ppm, 250ppm, 125 ppm, 6.25 ppm, 31.125 ppm. The results of Selectivity Index formula was (13).

Selectivity index = IC_{50} Cells Vero/IC_{50} Cells T47D

Result

Identification of chromatographic chemical compounds with LCMS: The results of the identification of chemical compounds in the Solanum torvum fruit (without fermentation treatment) can be seen in Figure 2 and Table 1.

Tabel 1: Chemical components of Solanum torvum

9. Solanum torvum Fruit Hexane Fraction (Fermentation Treatment) FHBT	1,67	Non-Selective

Discussion

Identification of *Solanum torvum* fruit chemical compounds with LCMS containing Clorogenic acid, 4-O-caffeoylquinic acid, 3-O-caffeoylquinic acid, 3-O-feruloyquinic acid, 5-O-feruloylquinic acid, 3-O-feruloylquinic acid, 3,4 - O dicaffeoylquinic acid, 3,5-dicaffeoylquinic acid, 3-O-feruloylquinic acid, 5-O-feruloylquinic acid, putative dicaffeoylquinic lactone. This was supported by opinions[14]The results of phytochemical analysis of *Solanum torvum* fruit extraction with organic solvents contained alkaloids, indole alkaloids, saponins glycosides, flavonoids, phenols, sterols, proteins, carbohydrates, alkaloid lepac, vitamin A, Vitamin C, Vitamin E, polyphenols. The results of research that have a good selectivity index are samples IGT and FEBT (Table 5).The selectivity index value greater than 3 indicates that extract is selective and not toxic, and vice versa if the selectivity index is less than 3, meaning that the extract used is not selective and has a toxicity to normal cells[15]. Antioxidants in small concentrations can prevent or slow down the rate of free radical oxidation or lipid oxidation. These antioxidant compounds can function as free radical scavengers, forming complexes with metal elements as antioxidants and functioning as reducing compounds [16]. Antioxidants were useful in preventing tumors and cancer, premature aging[17]. The best cytotoxic activity in this research wasethyl acetate fraction of *Solanum torvum* fruit (Fermentation Treatment) IC_{50} value of 39,17 µg/mL. Doxorubicin as a positive control has an IC_{50} value of 36.76 µg/mL[18]. A very effective anticancer agent for breast cancer metastesis was doxorubicin[19]. The criteria for compounds that have antiproleferative potential are $IC_{50} \leq 100$ µg/ml[20]. The research Chromatographic

analysis of *Solanum torvum* containing Clorogenic acid and derivative. That clorogenic acid functions to prevent and treat anti-inflammatory diseases [21]A new clorogenic oxide called oxovanadium complex has the potential for antioxidant agents and anti cancer (human breast cancer) [22].

Conclusion

The results of Chromatographic analysis containing Clorogenic acid, and derivative. So the best research results as cytotoxic activity of Solanum torvum ethyl acetate fraction having IC_{50} which was 39.17 µg/mL and index selectivity of 4.64 which means it was not toxic to normal cells, thus potentially developed as T47D breast anticancer

The Relationship between Father Involvement with Growth and Social-Emotional Development in Preschool Children

Nur Hijrah Tiala[1], Fitri Haryanti[2], Akhmadi[3]

[1] Student of Master Program in Nursing, [2]Lecture, Department of Child and Maternity Nursing, [3]Lecture, Department of Psychiatric and Community Nursing, Gadjah Mada University, Indonesia

Abstract

Background: Growth and social-emotional development in preschool children must have cared for parents. Although evidence exists of the association between them, especially mothers' involvement, only a few studies have examined fathers' involvement in parenting.

Method: This research uses Cross sectional study design. It has 106 pairs of fathers and preschool age children selected using consecutive sampling technique. Those fathers complete the questionnaire on father's involvement in parenting and questionnaire on Age Stages Questionnaire Social Emotional (ASQ-SE) based on their child's age. Furthermore, the Z-score is calculated based on the child's Body Weight/Body Height index to assess their growth. The data are analyzed using chi-square test at significance level of $p<0.05$.

Result: Father's involvement in parenting is relatively good at 51.9%. In terms of child growth based on the calculation of Z-score from Body Weight/Body Height index, 77.4% of the children are found to have normal growth. Most of the children have the risk of experiencing socio-emotional issues at 58.5%. In terms of the association between father's involvement in parenting and preschool children's growth,a value of $p>0.05$ is obtained, and in terms of the association between father's involvement in parenting and socio-emotional development of preschool children,a value of $p<0.05$ is obtained.

Conclusion: This research finds that father's involvement in parenting is not associated with preschool age children's growth,yet it has a significant association with preschool age children's socio-emotional development.

Keywords: *Father involvement, parenting, growth, social-emotional, Preschool.*

Introduction

The initial stage of a child's growth and development determines the conditions in the next stages. Preschool is the period when the father's involvement with their children is at peak than when children are still in their infancy or at elementary school.[1]In Indonesia, according to the result of nutritional status monitoring in 2018,it is reported that infants in Indonesiaexperience growth issues, i.e. being highly thin and thin at 10.2% and obese at 8%.[2] In addition to growth, child development issues are as extremely important for child welfare as social development which plays a role in child's health.[3]

Father's involvement in positive aspects of their child's life will promote positive achievement as well in children at their preschool years.[4] These positive achievements include positive social behavior, nutritional status improvement,[5]and low obesity occurence.[6]

Pleck identifies some components of father's involvement which consist of positive engagement activities, warmth and responsiveness, control along, indirect care, and process responsibility.[7] In developing countries, the role of a father in their child's health has not received adequate attention. The role that a father

Corresponding Author:
Fitri Haryanti
Lecture, Department of Child and Maternity Nursing, Gadjah Mada University
e-mail: fitriharyanti@ugm.ac.id

plays in child's growth and development has not been a frequent topic for research. Some studies emphasize that mothers play an important role in their children's liveand fathers are treated fairly shallowly by merely emphasizing their economic status on child's health.[8,9]

Therefore, a further study is needed to see the association between father's involvement in parenting and preschool age children's growth and social-emotional development.

Method

Research Design: This research was conducted in the area of Puskesmas Nglipar I, Gunung Kidul Regency on April-May 2019. It used cross sectional study design and its population was all pairs of father and preschool age child in the area of Puskesmas Nglipar I, Gunung Kidul Regency. This research had obtained a clearance from the ethical committee of Medicine, Public Health and Nursing Faculty at Gadjah Mada University under number KE/FK/0380/EC/2019.

Sampling: Pairs of father and preschool age child (3-6 years old) living within the area of Puskesmas Nglipar I and willing to sign the informed consent. The father should be literate (capable of reading and writing). The exclusion criteria in this research were children who had developmental disorders, sych as mental retardation, autism, or cerebral palsy and fathers with physical disability ad mental emotional disorder. To assess the mental emotional disorder, a screening was done using Self-Reporting Questionnaire-20 (SRQ-20)

Instrument:

1. Questionnaire of father's involvement in parenting of preschool children. This questionnaire was prepared by the researcher for the purpose of this research, consisting of 28 statements using Likert scale. From the result of validity test, the construct was declared valid, i.e. r statistic > r table (0.361). From the reliability test result, the value of cronbach's alpha was found to be 0.732 > 0.60. The father's involvement in parenting was divided into 2 categories, namely good (total score ≥ 72) and poor (total score <72).
2. Age and Stage Questionnaire Social Emotional (ASQ:SE): The research used ASQ:SE,particularly questionnaire of 36, 48, and 60 years of age. This questionnaire had been tested for its validity and reliability in Indonesia in Indonesianlanguage by Ariyani (2017). From the validity test, the value of r statistic was (0.241-0.694), which was greater than r table. The reliability test value with cronbach's alpha was 0.743 > 0.60.
3. The instruments used to measure the child's growth status were microtoice as the body height measuring instrumentand digital scale as the body weight measuring instrument. The value of Z-score of body weight per body height based on age was calculated using WHO Anthrosoftware.

Procedure: Those fathers who qualified the inclusion and exclusion criteria were given an explanation on the research procedure and asked for their consent by signing an informed consent. The father completed demographic questionnaire, questionnaire on father's involvement in parenting, and the child's growth and development questionnaire according to the child's age as calculated in months by the researcher. The correctly completed questionnaires were then submitted. The child's body height and body weight measurements were done by coming to the schools or posyandu (integrated service post) of the children whose fathers had agreed to be involved in the research.

Statistic: The statistical test used was correlation test, i.e. chi-square test with the level of confidence used being 95%.

Result

106 pairs of fathers and children of 3-5 years old served as the research respondents. Most of them were male (63 or 59.4%). Most of these fathers had higher education (54 or 53.8%). They mostly had formal occupations (64 or 60.4%) and most of their mothers were unemployed at 73.6%. Most of these families had low monthly income at 55.7% or below the City Minimum Wage of Gunung Kidul Regency.

From the completed questionnaire on father's involvement in parenting,it was found that 55 (51.9%) fathers had a good involvement and 51 had a poor involvement, meaning that 48.1% were less involved in parenting. The correlation betweenf father's characteristics and their involvement in parenting could be seen in Table 1.

The result of data analysis showed that father's education variable with a p value of 0.002, mother's education with a p value of 0.001, mother's occupation with a p value of 0.018, and family income with a p

value of 0.017, had significant correlations with father's involvement in parenting.

The physical growth of preschool age children was measured based on anthropometric method with body weight per body height index. The body weight was measured using a digital scale and the body height was measured using microtoice. From the 106 children measured, 1 child was found highly thin, 14 children were thin, and 9 children were fat. Furthermore, for the purpose of bivariate analysis, those children with growthsother than normal one (highly thin, thin, and fat) combined to be an abnormal growth category, hence in the bivariate analysis, the growth variable was divided into 2 categories, i.e. normal and abnormal.

The correlation between father's characteristics and child's growth could be seen in table 2. The data analysis result indicated that the family income variable with a p value of 0.016 had a significant correlation with the child's growth.

Tabel 4. Relationship of Father's Involvment in Parenting with Growth

Variable		Growth				p-value
		Normal		Abnormal		
		n	%	n	%	
Father Involvement	Well	47	85,5	8	14,5	0,063
	Less	35	68,8	16	31,4	

Table 3 showed the analysis result where the mother education variable with a p value of 0.019 and mother's occupation variable with a p value of 0.034 were found to have a significant correlation with the child's socio-emotional development.

The bivariate analysis result of father's involvement in parenting with preschool age children's growth using Chi-square test could be seen table 4.47 children raised by fathers who were well involved in parenting and 35 children raised by fathers who were poorly involved in parenting were found to have a normal growth. In terms of the children experiencing abnormal growth which was an accumulation of highly thin, thin, and fat ones, 16 of them were raised by those fathers who were poorly involved in parenting and 8 of them were raised by those fathers who were involved well in parenting. From the statistical test result, a significance value of 0.063 (p value> 0.05) was obtained, meaning that there was no correlation between father's involvement in parenting and preschool age children's growth.

Table 5: Relationship of Father's Involvement in Parenting with Social-Emotional Development

Variable		Social-Emotional Development				p-value	Odd Ratio	95% CI
		Not at risk		Risk				
		n	%	n	%			
Father Involvment	Well	33	60,0	22	40,0	0,000	5,455	2,313-12,865
	Less	11	21,6	40	78,4			

Table 5 showed the result of statistical test where a significance value of 0.000 (p-value< 0.05) was obtained, meaning that there was a correlation between father's involvement in parenting and the socio-emotional development in preschool age children.

The value of odd ratio was found to be 5.455,meaning that those children raised by fathers with poor involvement in parenting had 5.455 times risks of having socio-emotional issues than those children raised by fathers with a good involvement in parenting. The confidence interval values range from 2.313 to 12.865,meaning children raised by father's poor involvement had at least 2.313 times and a maximum of 12.865 greater risks of having socio-emotional issues.

Discussion

Most fathers had a good involvement in parenting. Nevertheless, the difference in number of fathers with good and poor involvements was shown not too substantial, i.e. 51.9% had a good involvement and 48.9% had a poor involvement. It was found that father's involvement in parenting had no correlation with child's growth as seen from the body weight per body height status based on the child's age (p value> 0.05).

Child's growth served as a direct impact of the intake of food in a long run and the child's health. The better the quality and quantity of food that the children consumed and their health, the better they will grow. In addition to food intake and disease, parents' presence also played a certain role in the child's growth.

Parenting became an indirect factor in child's growth. The parenting process was not just done by the mother, rather the father also needed to take part. However, the mother played an important role in providing and serving nutritious foods in the family, thus it had an influence on child's growth.[10] Thus, when the father was less involved in parenting,yet the mother could meet this direct factor, then it would allow the child to have a good growth.

This research also found that most children had the risk of encountering socio-emotional development issues at 58.5%. The analysis in this research showed that father's involvement in parenting had a correlation with socio-emotional development in preschool age children (pvalue = 0.000).

The father played an important role in their child's socio-emotional development and behavior.[11,12] When the father was actively involved in parenting, their children were less likely to have behavioral problems.[13] An improvement to the quantity and quality level of father's involvement gave a positive influence on the child's social and emotional development.[14] Parenting during preschool period significantly influenced the child's social and emotional competence.[15]

Research limitation: This research used cross sectional method. The research result would be better if it used a longitudinal study method to see the father's involvement in parenting from time to time and its influence on the child's growth and social-emotional development.

Conclusion

From the discussion above, it could be concluded that there was no correlation between father's involvement in parenting and preschool children's growth, yet it had a significant correlation with preschool children's socio-emotional development.

Conflict of Interest: None

Funding: This research was personally funded by the researcher.

Ethical Clearance: Obtained from the ethical committee of Faculty of Medicine, Public Health and Nursing, Gadjah Mada University.

Factors Associated with Hypertension among Adults in West Java, Indonesia

Nurul Wahyu Wadarsih[1], Ratu Ayu Dewi Sartika[2]

[1]Postgraduate Student, [2]Professor, Department of Public Health Nutrition, Faculty of Public Health, Universitas Indonesia, Depok, Indonesia

Abstract

Background: Hypertension is influenced by various factors including genetic, environmental and lifestyle factors.

Objectives: We aimed to identify factors associated with hypertension among adults in West Java, Indonesia.

Material and Method: The study design was a cross-sectional approach using secondary data from the 'Cohort Study of Non-Communicable Diseases (NCD)' conducted in Kebon Kalapa Village, Bogor City, Indonesia in 2017. This descriptive study used a structured questionnaire to collect primary data distributed to respondents after obtaining their consent. Nutritional status and blood pressure data were collected from participants. A 24-h dietary recall was conducted to collect nutrient intake data. Data were analysed using IBM SPSS software version 24.0.

Results: The prevalence of hypertension in this study was 34.2% and 23.9% of respondents were hypertensive. Bivariate analysis revealed that age 45–59 years, female gender, history of hypertension, overweight, and obesity were associated with hypertension status (P values = 0.0005, respectively, and odds ratios = 2.59, 2.37, 40.06, 7.60 and 10.04, respectively).

Conclusions: Factors associated with hypertension among adults in West Java, Indonesia included older age, female gender, history of hypertension, and nutritional status.

Keywords: *hypertension, factors, adults, cross-sectional.*

Introduction

Hypertension is a disorder of blood pressure (BP) regulation due to increased cardiac output or total peripheral vascular resistance.[1] Late diagnosis of hypertension can lead to various other diseases, such as heart disease, stroke and kidney failure.[2]

The prevalence of hypertension in Indonesia based on the Indonesian Basic Health Research 2018 was 34.1%. Based on these data, among the 34.1% of people who experienced hypertension, only 1 in 4 were diagnosed and only 54.4% took regular medication for hypertension.[3]

Many studies have identified the main risk factors for developing hypertension to be male gender,[4-5]older age,[4,6,7]overweight,[4,8,6] obesity,[4,8,6,9]retirement, smoking habit,[4,10] illiteracy,[4,10,7]upper socioeconomic status, alcohol consumption, marriage,[4,5] smoking habit,[4,9]lack of physical activity,[9]and diabetes.[7,9]

The major risk factors for hypertension and the extent of their contribution remain unclear. Overcoming hypertension is challenging, given the high prevalence and lack of awareness of its long-term clinical impact. Furthermore, hypertension increases the risk of future health impact if it is not detected and treated early.

Studies have shown that targeting factors associated with hypertension is one of the best preventives that can be considered when determining intervention strategies for hypertension. Therefore, the present study aimed to identify factors associated with hypertension among adults in West Java, Indonesia.

Materials and Method

The study design was a cross-sectional approach using secondary data from the 'Cohort Study of Non-Communicable Diseases (NCD)' conducted in Kebon Kalapa Village, Bogor City in 2017. The population included permanent residents aged 25–59 years which was registered in the cohort study 2017. The study sample was selected by total sampling, and included individuals with and without hypertension.

There were 1186 initial respondents in total. We excluded respondents with heart disease, stroke and pregnant (n = 118), age ≥ 60 years (n = 49), users of hormonal contraception (pills, injections, implants) (n = 132) and outliers based on nutrient intake (n = 160). A final total of 727 respondents were included in the study.

The dependent variable was hypertension status. The independent variables were age, gender, smoking habits, family history of stroke, physical activity, history of hypertension, medication compliance, nutritional status, and nutrient intake.

Systolic and diastolic blood pressure (SBP and DBP) were measured using a digital tensimeter. Hypertension status was determined based on an average SBP ≥ 140 mmHg and/or DBP ≥ 90 mmHg[11] and/or taking anti-hypertensive drugs.[12]Body height was measured using a height measuring device with 0.1-cm accuracy, while body weight was measured using a digital weighing device with an accuracy of 0.1 kg. Nutritional status was categorised based on body mass index (BMI) as follows: underweight (<18.4 kg/m^2), normal (18.5–25.0 kg/m^2), overweight (25.1–27.0 kg/m^2) and obese (≥27 kg/m^2).[13]

Characteristics of study participants were collected using a questionnaire developed specifically for NCD cohort studies. Age was divided into two groups: 25–44 and 45–59 years.

Food consumption data was collecting using 24-h dietary recall. Nutrient intake was calculated based on the Indonesian recommended dietary allowance in the normal population, while intake in the hypertensive population was calculated based on the Dietary Approaches to Stop Hypertension (DASH) recommendations.[14]Nutrient intake was grouped as low (<90%), moderate (90%–119%) and excessive (≥120%).

Data were analysed using IBM SPSS software version 24.0 including univariate and bivariate analysis. Bivariate analysis was used to determine the relationship between each independent variable and dependent variable using the chi-square and Fisher exact test. Risk was calculated using odds ratios (ORs). A simple logistic regression test was used to calculate *P*-value and OR for independent variables with more than two categories.

Results

The average age, SBP, and DBP in the hypertensive group was higher than that in the normal population. Fat and sodium intake was higher in the normal population compared with that of the hypertensive group. The distribution of numerical variables of the participants is presented in Table 1.

Table 1: Distribution of numerical variables of study participants

Variable	Normal population		Hypertensive population		Total	
	N	Mean ± SD (min–max)	N	Mean ± SD (min–max)	N	Mean ± SD (min–max)
Age (Years)	553	45.97 ± 7.83 (30–59)	174	50.82 ± 6.30 (31–59)	727	47.13 ± 7.77 (30–59)
SBP (mmHg)	459	120.77 ± 13.89 (87.50–167.00)	150	148.11 ± 19.75 (103.50–207.00)	609	127.50 ± 19.49 (87.50–207.00)
DBP (mmHg)	459	79.15 ± 9.48 (55.50–109.50)	150	94.77 ± 11.94 (69.70–141.30)	609	82.99 ± 12.17 (55.50–141.30)
Weight (kg)	459	59.76 ± 11.61 (32.80–100.30)	150	64.59 ± 12.83 (36.50–97.20)	609	60.95 ± 12.09 (32.80–100.30)

Variable	Normal population		Hypertensive population		Total	
	N	Mean ± SD (min–max)	N	Mean ± SD (min–max)	N	Mean ± SD (min–max)
Height (m)	459	1.56 ± 0.08 (1.33–1.81)	150	1.52 ± 0.06 (1.38–1.69)	609	1.55 ± 0.08 (1.33–1.81)
BMI	459	24.76 ± 4.74 (14.51–39.54)	150	27.94 ± 5.15 (17.03–42.33)	609	25.54 ± 5.03 (14.51–42.33)
Nutrient intake:						
Energy (kcal/day)	458	2034.85 ± 619.26 (719.88-3571.42)	150	1652.42 ± 478.89 (748.29–2729.62)	608	1940.50 ± 610.12 (719.88–3571.42)
Protein (g/day)	458	63.22 ± 21.16 (16.25–119.14)	150	52.95 ± 16.84 (16.18–101.33)	608	60.69 ± 20.65 (16.18–119.14)
Carbohydrate (g/day)	458	274.66 ± 91.71 (87.83–508.33)	150	228.68 ± 73.35 (75.54–429.34)	608	263.32 ± 89.70 (75.54–508.33)
Fat (g/day)	458	77.55 ± 31.81 (8.14–161.34)	150	58.77 ± 21.82 (16.78–107.41)	608	72.91 ± 30.73 (8.14–161.34)
Sodium (mg/day)	458	2374.47 ± 1195.38 (221.98–5495.63)	150	1839.63 ± 839.56 (205.57–4092.47)	608	2242.52 ± 1151.11 (205.57–5495.63)

The prevalence of hypertension in the present study was 34.2%, and 23.9% of respondents were hypertensive. Excessive fat and sodium intake was observed in 247 (40.6%) and 371 (60.1%) participants, respectively. Bivariate analysis revealed that age 45–59 years, female gender, history of hypertension and nutritional status were found to be associated with hypertension status.

Respondents aged 45–59 years showed a 2.59-fold higher risk of hypertension compared with those aged 25–44 years. Females showed a 2.37-fold higher risk than males, and respondents with a history of hypertension showed a 40.06-fold higher risk. Nutritional status was a risk factor for developing hypertension, and was 7.60-fold higher for overweight and 10.04-fold higher for obese individuals compared with those with normal nutritional status.

While excessive fat and sodium intake showed a 0.46 and 0.53-fold lower risk, respectively, compared with low fat and sodium intake.

The results of the bivariate analysis between characteristics of participants with and without hypertension status are presented in Table 2.

Discussion

The results of the present study revealed that hypertension was influenced by age. High incidence of hypertension was associated with increasing age, caused by changes in the structure of large blood vessel, such as narrowing of the lumen and stiffening of blood vessel walls, as a result of increased SBP.[15] Another factor related to hypertension was female gender. This finding is consistent with the findings of some studies.[16,17] In this study, most respondents in the age 45–59 years and hypertensive groups were females. In women, incidence of hypertension increases after menopause. Before age 50, women show a lower prevalence of hypertension compared with men, but after age 55, women show a greater age-related increase in proximal aortic stiffness, leading to a higher incidence of systolic hypertension. Women have two other features that tend to reduce DBP and widen pulse pressure. First, short stature causes a faster return of pulse waves to increase peak systolic pressure, and second, a faster heartbeat produces a shorter diastolic period.[15] However, other studies found that hypertension is more common in men.[4-10]

Hypertensive respondents tend to experience high BPmore frequently due to inelastic blood vessels. Other factors may also play a role, such as lifestyle, medication compliance and nutritional status. Although medication adherence helps to control BP, this still requires a healthy lifestyle.[18]In the present study, medication compliance data was not sufficient to explain this finding.

Overweight and obese respondents had a higher risk of hypertension than those with normal nutritional status. An association between excessive activation of the sympathetic nervous system and the renin–angiotensin–aldosterone system (RAAS) was shown in obese people, increasing the risk of high BP.[19] High RAAS has been shown to increase sodium reabsorption which carries water so that the body tends to be hypervolemic, which ultimately increases cardiac output and BP.[20]

In the present study, excessive fat and sodium intake showed less risk compared with low fat and sodium intake. This could be due to hypertension being affected by many risk factors. Alternatively, respondents with low fat and sodium intake may have had a history of hypertension. People with hypertension tend to decrease their sodium and fat intake to prevent disease complications. This diet pattern would affect the outcome of the relationship between fat and sodium intake with hypertension status. This relationship may be affected by weight status or presence of metabolic disorder.[21] In the present study, most respondents with low fat and sodium intake were overweight and obese.

There is conflicting evidence about the effect of dietary fat intake on BP. Some studies have shown a positive correlation between dietary cholesterol intake and BP, while others found no significant correlation.[21] In another study, the relationship between dietary cholesterol and SBP was slightly stronger in the non-hypertensive group. Possible mechanisms include dietary cholesterol related to endothelial dysfunction and reduced nitric oxide bioavailability, which may lead to functional arterial stiffening leading to high BP.[22]

Conclusion

In the present study, the prevalence of hypertension was 34.2%, and 23.9% of respondents were hypertensive. Older age, female, history of hypertension and nutritional status were associated with hypertension status.

Our findings may help to determine suitable interventions to overcome and prevent the incidence of hypertension and also to find further strategies to prevent uncontrolled hypertension complications. Further studies are required to alleviate hypertension from year to year based on factors that influence the incidence of hypertension.

Symptoms and Activities of Daily Living in Patients with Chemotherapy-induced Peripheral Neuropathy

Ok-Hee Cho[1], Kyung-Hye Hwang[2]

[1]Associate Professor, Department of Nursing, College of Nursing and Health, Kongju National University, Gongju, [2]Associate Professor, Department of Nursing, Suwon Science College, Hwaseong, Republic of Korea

Abstract

Objective: To compare symptoms and impairment in activities of daily living (ADL) between faller and non-faller patients with chemotherapy-induced peripheral neuropathy (CIPN).

Method: Participants were 247 cancer inpatients of the hematology-oncology department at the university hospital in Korea.

Results: Among participants investigated, 11.7% had fall experiences due toCIPN symptoms. The faller group showed higher rates of metastasis, radiotherapy, and items in ADL impairment than the non-faller group. The faller group also experienced higher degree of sleep disturbance, depression, and peripheral neuropathy symptoms.

Conclusion: This study provides directional relationship between negative effects on ADL and falls in patients with CIPN. It suggests that more attention is needed to develop fall prevention programs for patients with CIPN who has history of metastasis or radiotherapy to improve their ADL capability.

Keywords: *Falls, Peripheral neuropathy, Activities of daily living, impairment, cancer.*

Introduction

Patients with cancer who undergo chemotherapy experience various adverse effects such as loss of sensation in extremities, weakness, nausea, vomiting, pain, loss of appetite, and fatigue during and after treatment due to widespread cell destruction induced by chemotherapy[1]. Treatment with cisplatin, paclitaxel, and vincristinechemotherapyagentsmay cause chemotherapy-induced peripheral neuropathy (CIPN) that can have serious consequences such as immune dysfunction and discontinuation of treatmentdue to side effects related to neurologictoxicity[2-4]. However, medical teams tend to pay moreattention tochemotherapy-inducedbone-marrow suppression orother major organ damage than to symptoms of peripheral neuropathy[5].

Symptoms of peripheral neuropathy manifest assensory, motor, and autonomic neuronaldamages, with sensory symptoms such asnumbness in hands or feet (a burning or stabbing sensation) andanesthesia (a loss of sensation) being the most prominent. When motor nervesare involved,corresponding musclescan be weakenedor atrophy sometimes.It is difficult to peripheral neuropathy without a neurologic examinationbecause it may beovershadowed bythe presence of other symptoms such asfatigue,depression, andcachexia[6]. Symptoms associated with damageto the autonomic nervous system includeconstipation, orthostatic hypotension, and urinary incontinence[7-9]. The degree of paresthesia or hyperalgesia experienced by patients is increased with increasing treatment duration, cumulative doses, and

the frequency of chemotherapy. In addition, diminished muscle strength in patients can lead to difficulties in performing ADLs and decreased quality of life [4,8,10].

Previous studies have reported that patients with CIPN show decreases in walkings peed and changes in walking pattern[11,12]. The decrease in mobility can affect the independence of patients and impair their sense of balance on postural sway, thus increasing their risk of falling[13]. Patients with cancer frequently experience falls while undergoing high-dose chemotherapy[14]. These falls occur more frequently in patients who have severeneuropathic symptoms. They are directly associated withthe degree of impairment in sense of balance and the number of chemotherapy sessionsin patients[11]. Gewandter et al.[15] reported that 11.9%of cancer survivors who experienced CIPN symptoms answered that they had fallen within the last three months. They concluded that the presence of motor neuropathycould increase the risk of falls.Death rate was also increased in cancer patients who experienced injuries caused by falling during treatment[16]. To promote the safety and security of patientswho receive chemotherapy, it is important to confirm the development of peripheral neuropathy,verify the severity of symptoms,and definefactors associated with falls in these patients. Previous studies investigating falls in patients with CIPNhadmainly discussed theirfunctional disorders[13,14,17], injuries[18], factors associated with walking[12], and quality of life[8]. Few studies have investigated the directional relationship between impairment of ADL and falls in patients with CIPN including its severity.

Materials and Method

Study Design: Descriptive correlational research design was used to investigate the severity of CIPN and define the relationship between its negative effect on ADL and falls in patients with CIPN.

Setting and samples: Participants included convenient samples of 247 patients with cancer who were inpatients in the Department of Hematology-Oncology at the University Hospital located in Seoul, South Korea. Selection criteria were: aged 18 years or more, with a history of undergoing platinum or taxane-based chemotherapy, ability to walk, and experienced symptoms of numbness or tingling in hands or feet after undergoing chemotherapy. Patients were excluded if they had mental and cognitive disorders or nervous and musculoskeletal system disabilities such as cerebral infarction, osteoporosis, or multiple sclerosis.

Measurements: Sociodemographic characteristics such as age, gender, education, marital status, occupation, economic status, and body mass index were evaluated for all patients included in this study. Disease-related characteristics including types, stages, chemotherapeutic agents and cycles, presence or absence of metastases, history of radiotherapy,and any adverse event were graded according to the National Cancer Institute-Common Toxicity Criteria (NCI-CTC, version 2)[19]. Stages of peripheral neuropathy were measured by the NCI-CTC before distribution of questionnaires for self-administered surveys.

Patients were categorized into the faller group who answered "yes" to the following question: "Have you ever fallen or slipped because of numbness or tingling in hands or feet after chemotherapy within 3 months?". Those who answered "no" were classified into the "non-faller group."

Symptoms of peripheral neuropathy were measured according toneurotoxicity symptom areas from the Functional Assessment of Cancer Therapy/Gynecology Oncology Group/Neurotoxicity (FACT-GOG/NTX)[20]. This scale had 11 questions. Each question was answered on a 5-point scale(0-4), with higher score indicating more severe peripheral neuropathy symptoms. The Cronbach alpha coefficient of the instrument reliability in the present study was .91. The presence or absence of impairment of ADLs was assessed using the modified version of the Patient Neurotoxicity Questionnaire (PNQ)[23]. These 11 questions were applied to patients of this study. Each question was answered "not disturbed" or "disturbed" to measure the level of ADL. Data were collected from August 2015 to March 2016.

Data analysis: All datawere analyzed using SAS for Windows (ver. 9.2). Falloccurrence rates, sociodemographic characteristics, disease-related characteristics were reported with descriptive statistics. Differences in all variables of peripheral neuropathy symptoms and level of ADL impairment between the faller and non-faller groups were verified with the following tests: t-test, χ^2-test, Fisher's exact test, and Wilcoxon rank sum test.

Results

Sociodemographic characteristics between the

faller and non-faller groups: Among 247 participants, 29 (11.7%) had experienced falls due to the presence of symptoms of CIPN. The mean age of all patients was 56.7 years, showing no significant difference between the faller and non-faller groups. Three (10.3%) participants in the faller group had occupations, which was less than the number in the non-faller group in which 68(31.2%) participants had occupations (p=.020).

Disease-related characteristics between the faller and non-faller groups: Twenty-two (78.6%) participants in the faller group and 127 (58.8%) participants) in the non-faller group(p = .044) had metastasis. Seven (24.1%) patients in the faller group and 23(10.6%) in the non-faller group (p=.035) received radiotherapy.

Peripheral neuropathy symptoms between the faller and non-faller groups: Patients in the faller group scored 15.10 of 44 for experiencing symptoms of peripheral neuropathy. This score was higher than the score of 10.00 for patients innon-faller group(p=.002). Regarding the sensory domain, numbness or tingling in hands (p=.027), numbness or tingling in feet (p=.001), discomfort in hands (p=.050),and discomfort in feet (p=.005) were more severe in the faller group than those in the non-faller group. In the dysfunction domain, difficulties in buttoning clothing (p<.001) and feeling the shape of small objects were more severe in the faller group than those in the non-faller group (p=.002) (Table 1).

Impairment of ADLs between the faller and non-faller groups: The rate of participants with impairment of ADLs in the faller group was higher than that in thenon-faller group for all daily activities. The faller group demonstrated the highest rates of impairmentin ADLs for climbing stairs and walking (p<.001)[at 72.4% (21 participants) and 69.0% (20 participants), respectively],followed by impairment for working (p=.002), buttoning clothes (p<.001),using chopsticks (p<.001), and writing (p=.004).

Table 1: Comparisons of Peripheral Neuropathy Symptoms Between Faller and Non-faller Groups. (N=247)

Characteristics	Faller (n=29,%=11.7)	Non-faller (n=218,%=88.3)	z	*p*

Discussion

In this study, 11.7% of patients fell or slipped due to the presence of symptoms of CIPN. This rate well matched with that of a previous study showing that 11.9% of patients with CIPN had survived falls[15]. The rate of patients who were employed was lower in the

fallergroup than that in the non-faller group.This might be because patients in the fallergroupdid not have adequate recovery of health to permit them to return to work. As returning to work is an important socioeconomic aspect influencing quality of life in patients with cancer, future studies are needed to investigate correlationsamongthe severity of CIPN, episodes of falling, and loss of employment.

Patients in the faller group experienced more severesymptoms of peripheral neuropathy than those in the non-faller group. Numbness or tingling in hands and feet can cause difficulty in grasping, lifting, or driving. Impaired sensation in the lower extremities can make it difficult to maintain balance and a steady walking pace, thereby increasing susceptibility to injuries related to falling[12].Patients with CIPN experience numbness or tingling in the hands and feet the most. Severe symptoms can decrease their quality of life[22]. Therefore, periodically evaluating and managing symptoms of CIPN are necessary.

This study showed that more patients in the faller group had difficulties with buttoning clothing or feeling the shape of small objects. In aprevious study, foot-touch perceptionin patients with CIPNwas negatively correlated with difficulties in buttoning clothing[22].

Patients in the faller groupwere found to experience greater impairment of ADLs than those in the non-faller group. Similarly,Gewandter et al.[15]have reported that survivors with CIPNshow difficulties in shopping or doing moderate housework and that levels of sensory or motor-associated symptomsare more severe in the faller group. Patients with impairment in ADLsbecome dependent on others and exhibit increased risk of falling[13]. Therisk of fallingwas decreased in a group of high-risk patients, including patients with peripheral neuropathy, when theyreceived training to enhancetheirmuscle strength and their capability to maintainbalance[14].

In this study, many patients had difficultiesin walking and ascending stairs. Inpatients with peripheral neuropathy, the speed of walking was decreased so much that it took twice time to walk compared to normal adults. Postural swayis also increased in these patients, which widens their stride and increases the risk of falling because of gait instability even during slow walking[12,13]. Thus, patients with CIPN need to be trained to use more muscle strength in the lower limbs while walking or ascending stairs to avoid fall.

This study has limitation to define a relationship between the cause of fall and CIPN level. In addition, we could not count the number of falls in patients. However, this study was meaningful in that patients with CIPN were divided into faller and non-faller groups and their symptoms and interference with ADLs were investigated. This could provide basic data for the development of interventions to prevent falls in such patients.To provide proper nursing to patients with CIPN, it is very important to prevent falls. Medical team's attention change and new program are required to prevent falls.

Conclusion

Our results suggest that history of metastases or undergoing radiotherapy, severity of sleep disturbance, and depression in patients must be considered when developing programsto preventfalls in patients with CIPN. Furthermore,training to enhance endurance, strength, and sensorimotor skill must be emphasized while taking the severity ofnumbness or tingling sensation in handsand feet, the degree of impairmentin activities (namely, walking, ascending stairs, working, and buttoning clothing)into consideration.

Biliary Atresia Outcome in Egypt a Descriptive Study

Omar N Abdelhakeem

Professor Gamal H Eltagy MD, Professor Alaa A El Sayed MD, M M Khedr MD.

Abstract

Biliary atresia is a rare disease that affects children and neonates, nowadays the current management of BA is portoenterostomy with or without liver transplantation, in this study we described the outcome of BA in single center.

We included 48 patients in this study with type 3 BA and measured the incidence of clearance of jaundice and cholangitis the incidence of clearance of jaundice was 43%and cholangitis was 20% also the mean age was 74.6±21.8 days which is quiet high.

We concluded that early diagnosis and centralization is the key point for getting best outcome for patients of BA

Keywords: *Biliary Atresia, Portoentersostomy, Jaundice clearance, cholangitis.*

Introduction

BA is an obstructive cholangiopathy, an inflammatory process that affects both intra and extra hepatic bile ducts causing obliteration of the bile ducts ends up to cirrhosis and liver cell failure if left untreated[(1)].

Although it is an uncommon disease occurring in 1/10000- 1/15000 live births worldwide it It is rare but with obvious geographical variation as in Europe and North American for example it has an incidence of 1 in 15–,20,000 live births and by contrast can be sensationalistic births in Taiwan and presumably mainland China. It is nota homogenous,uniform disease and within the umbrella term ares ever al variants which have separate and distinct causes and different outcomes. These make comparison of treatment options difficult but not impossible[(2)].

Corresponding Author:
Omar Nagy Shaker Abdelhakeem
Egypt, Minia, Minia University Hospital
e-mail: omar.nagy@mu.edu.eg
Contact No.: 00201002873241

The etiology of BA I unknown but thought to be multifactorial, currently there is 3 main types of BA; cystic type of BA, isolated BA and syndromic BA which is thought to be congenital in nature [(3)].

The first porto enterostomy was done by Prof Moro Kasai 1953 by chance while he was dissecting in the porta hepatis and noted bleedind then he put the dudenum for hemostatsis then the patients stool got coloured since then many modifications has been done to this operation and became the first line of treatment of BA with or without liver transplantation [(4)].

There are many factors that affects the outcome of Kasai procedure, the most important factor is patients age at time of operation, the second is the type of BA the best in prognosis is cystic type of BA while the worst is the syndromic BA, attacks of cholangitis also affects the outcome also adjuvant therapy may play a role in improving the outcome [(3)].

The prognosis of BA has dramatically changed in the last decades: before the Kasai operation most BA patients died,while nowadays with the sequential treatment with Kasaioperation, with or without liver transplantation, BA patient survival is close to 90%. Early diagnosis is very important since the chances of success of the Kasaiprocedure decrease with time[(5)].

In Egypt and due to limitation of liver transplant inpatient with BA below one year of age we have to do our best to increase the success rate of the porto-enterostomy inpatient with BA including both clearance of jaundice and the percentage of native liver survival

Patients and Method

48 patients were included in this trial we included all cases of BA type 3 after investigations were done including Lab investigations which showed direct hyper bilirubinemia, elevated GGt and Alkaline phosphatase, ultrasound showed absent or non contractile gall bladder, liver biopsy showed marked inflammation and bile duct proliferation .

All cases were operated and managed at Cairo University Children Hospital (CUPSH) and after referral to the surgical department the case is admitted 48 hours before surgery and preoperative labs were done, blood crossmatching and preoperative antibiotics were given .

On the OR patients were anasthesized supine with endotracheal intubation and sonar guided CVL.

The infant was positioned supine to ensurea non obstructed view for cholangiography, which was not routinely required. surgical exploration commenced through anextend edkocher`s incision centered to the right. This incision could be extended across the midlineifbiliary reconstruction was required . he the left upper quadrant was examined to determine splenic anatomy.

Liver consistency was noted and the port a he pat is inspected. Cholangiography has a distinct role in this patients. If the gallbladder had a lumen, diluted contrast material (diatrizoate Hypaque) was injected to determine the continuity of the biliarytree between the liver and duodenum. Complete extra hepatic duct patency was confirmed when contrast appears distally in the duodenum and proximally in the liver radicles. The size of the ducts is assessed by cholangiography to determine whether biliary hypoplasia or obstruction to bile flow from inspissation was present. If the contrast material moved only distally into the duodenum and not into the liver,gently occluding the distal common bile duct while reinjecting the gallbladder to encourage proximal ductal filling, although this maneuver rarely succeeded. If extra hepaticbiliary patency is demonstrated, regardless of whether the ducts were of normal caliber or diminutive, a liver biopsy is performed and the incision closed.

If ductal patency was not confirmed, portal dissection and biliary reconstruction was performed (the Kasaiprocedure).

According delivery oft he liver some surgeons preferred to deliver the both lobes oft he liver from the abdominal cavity after dividing both triangular ligaments, some preferred to deliver the left lobe only andminority prefer not to deliver either lobes and doing the portoenterostomyinsitu.

Figure 1: liver delivery before dissection

The fibrous common duct was ligated distally with non absorbable suture and transected. Gentle traction applied to the remnant facilitates dissection toward the porta, where a cone of fibrous tissue anteriortothe bifurcating portal veinisencountered.

When there was discontinuity of the biliary tree, exploration of the tissue overlying the portal vein bifurcation will almost invariably reveal the fibrous cone. Placingasuturein this fibrous tissue will facilitate establishing the plane above the portalvein.

Once dissection was complete, finestay sutures were placed at the lateral margins of the fibrous cone. While maintaining moderate tension, the fibrous cone was sharply transected,

There sectedbiliary structures with attached gallbladder remnant are sent for pathologist to measure

the size of the biliary ductules for later prognostic evaluation.

Recently we standardized our technique by making wide portal plate extending from Rexfossatothegallbladderfossa (innominatefossa) for allowing maximum drainage of bile through the porto-enterostomy.

The porto-enterostomy was done retrocolic through an incision in the transverse mesocolon just to the right of the middle colicartery.

The prto-enterostomy was done end to side by making an incision of the anti-mesentric border of the rouxlimb 1-2 cm of its distal end to avoid blind pouch and then the anastomosis is done using parachuting technique for the posterior wall which allows better vision.

After completing the porto-enterostomy the rouxlimb was sutured to the glisson`scapsule and transversemeso colon to decrease the tension on anastomosis.

Drain was usually inserted and removed on the 5th day postoperative .

Regional anaesthesia (TAP block) is injected at the lateral border of rectus sheath to decrease postoperative pain, the dose was calculated through the anesthesia team.

Abdomen was closed in 2 layers and Subcuticular closure for the skin was done.

Postoperative management: Patient was kept on the ICU on nasal oxygen if needed with proper analgesia, Ivfluids and postoperative CBC was done routinely to detect any need for blood transfusion.

Gradual feeding was introduced once intestinal motility was regained

Patient was followed up through CBC with differential and CRPto detect earlysepsis and upgrade antibioticline accordingly.

Discharge: Patients was discharged when they reached their full feeding with no fever and no laboratory signs of sepsis.

Outpatient follow up: After discharge Patients were followed up regularly at the hepatology clinic for followup,

At day 12 postoperative, 1,3 and 6 months postoperative.

General medical examination was done,jaundice is detected recording of any complication such as cholangitis,etc,..

The following data were recorded: Hepatosplenomegaly Presence of jaundice, Colour of stool Fever andcholangitis

Results

Concerning our patients the range of age was **(30-118)** with a mean age was **74.6±21.8**. 25 were males (52%) while 23 were females (48%)

In our study 25 cases were male (52.1%) and 23 cases were female (47.9%)

In our study 21 cases (43.8%) were jaundice free with in the first 6 months postoperative .

27 cases **(56.3%)** were still jaundiced at 6 months postoperative. 35 cases (72.9%) has coloured stool while only in 13 cases (27.1%) clay coloured stool have persisted.

The median preoperative bilirubin was 9.8 mg/ dlwhile the median bilirubin after 6 months were 5.1 mg/dl.

Discussion

Although our study seems to be intermediate inn umber of cases and this limits the presence of statistical significance oft he data but this happened however this happened due to relatively short duration oft he study which was only 2 years, Davenport made his trial over 11 years and the START trial was done over 6 years.[(1)].

Concerning age in our study theme an age was 74.6±21.8 (30-118), 14 cases were less than 60 days(29.2%),23 cases were 60-90 days (47.9%)and 11 cases were 90-120 days(22.9%).

By comparing theme an age with theme an age oft he similar studies that discuss the use of steroids theme an age oft his study is the oldest age, in the study of Tyraskis and Davenport *2016* the mean age was reaching 46 days (12-70)days[(1)]. while In the START trial done be Bezzera 2014 the mean age was 69 days[(6)], also at the study of Escobar 2006 the mean age was 43 days[(7)],

theme an age oft he study of *Petersen 2008* was 62 days[8].*Chung 2008* also at has a mean age of 70 days[9].

From the previous data we can conclude that the youngest age was at Davenport study (45 days(12-70))and we think that this could be achieved by the centralization system that the NHS provide to allow early detection and management of those cases and due increased awareness of this disease among pediatrician[1].

On the other hand in EGYPT and due to lack of awareness of this disease among pediatrician and due to lack of ability of differentiation between BA and physiological jaundice there is a delay in the management of these cases, In our study we excluded the cases aged above 120 days due to controversy about benefit of porto-enterostomy for those patients and if we didn't exclude those cases the mean age would be much higher .

Conclusion

For achieving best outcome for patients of BA two main factors should be present the first is early diagnosis and management of biliary atresia either by screening or increasing awareness of this disease between pediatricians the second factor is centralization which should increase surgical success.

Registration Accuracy between Maxillary and Mandibular Teeth for Fixed Restoration Construction

Hossam Atef Abd El-Samad[1], Cherif A. Mohsen[2]

[1]B.D.S (Misr University For Science and Technology, 2009), MSc (Ain Shams University, 2015), [2]Vice Dean and Professor of Fixed Prosthodontics Department Faculty of Dentistry,Minia University, Department of Fixed Prosthodontics, School of Dentistry, Minia University, Egypt

Abstract

Objectives: This study was carried out to evaluate the dimensional accuracy of conventional bite registration material and CAD/CAM bite registration material in patients with a single missing tooth.

Method: Twenty patients with one missing tooth (who needed a fixed partial denture) were selected and included in the present study. A full veneered preparation was done. The patient bit on bite registration material in centric and eccentric movement. A wire "3 cm in length "was bonded with composite on adjacent teeth to the preparation. The length of wire impression on bite registration material was measured and after 24 hours to evaluate the possible effect with time factor.

Results: The effect of duration on the dimensional accuracy of bite registration materials at horizontal centricand eccentric occlusion was statistical significant between immediate and later who recorded higher values with both types of bite registration materials tested. Also a statistical significant differences between the two types of occlusion irrespective to the duration, type of restorations and types bite registration materials, as eccentric occlusion recorded higher values.

Conclusions: Futar D and Futar scan bite registration materials provided accurate records with no differences between them. Dimensional accuracy was influenced by time factor of the recording materials.

Keywords: *Registration accuracy, conventional bite registration material,CAD/CAM, centric, eccentric, immediate, late.*

Introduction

The Bite Registration is aninterocclusal record which defined as an accurate and precise recording of maxillo-mandibular relationship [1]. The importance of bite registrationin recording the maxillo-mandibular relationship is to transfer the relationship to the articulator so laboratory procedure on the casts will correspond to the patient's mouth[2]. There are various method of recording maxillomandibular relationships graphic, functional, cephalometric and direct interocclusal recordings [3]. Direct interocclusal records are most commonly used to record maxillomandibular relationships because of their simplicity. The arches are brought into a relationship with or without tooth contact, and a space is created between the teeth. The recording material, which is initially soft, fills the spaces between teeth, hardens, and records the specific relationship of the arches. The hardened material is then transferred onto casts to be mounted on an articulator [4]. Therefore, an ideal registration material and technique combination would allow the placement of an indirectly fabricated prosthesis intraorally with minimal occlusal adjustment [1].The ultimate accuracy in relating maxillary and mandibular dental casts is dependent on the accuracy and dimensional stability of the material used to record the interjaw relationships[5]. Futar D and Futar D Fast have different setting times; and both materials have different final hardness from Futar Scan. The latter can be scanned using an optical scanner as required for CAD /CAM system because of its matte surface which makes it suitable for collecting three-dimensional data[6]. An ideal interocclusal recording material should be able to represent the maxillomandibular relationships

accurately and should also be dimensionally stable over some days of storage [7]. The purpose of this study was to evaluate the dimensional accuracy of conventional bite registration material and CAD/CAM bite registration material in patients with Single missing tooth.

Materials and Method

Ethical regulation: Full detailed explanation of the procedures to be done will be offered to the patient and will be asked to sign an informed consent before commencing the treatment. This study was made to evaluate the accuracy of different bite registration materials used for recording the interocclusal relation.

I. Materials:

1. Vinyl polysiloxane bite registration cream " Futar D Fast" (Conventional bite registration material)
2. Vinyl polysiloxane bite registration cream (scannable) "Futar Scan" (CAD/CAM bite registration material)

II. Method:

1. **Preparation of teeth:** Twenty patients with one missing tooth (who needed a fixed partial denture) were selected and included in the present study.

Crown preparation to the tooth in the fully dentate patient will be done using depth cutter stone on the occlusal surface to provide 2mm occlusal clearance to allow placement of 2mm thickness of registration material.

The other patients with one missing tooth, a full veneered preparation to the two abutments will be done.

The patient will bite on bite registration material in centric and eccentric movement.

2. **Preparaing a wire as a guide to calculate dimensional changes:** A wire "3 cm in length ", which will be measured by stereo microscope and then will be bonded with composite on adjacent teeth to the preparation in a horizontal position to be recorded on the bite registration material and after setting of bite registration material (according to the manufacturer instructions). The length of wire impression on bite registration material was measured and after 24 hours to evaluate if there was effect with time factor [(5)].
3. **Method of measurement:** Using stereomicroscope (light stereomicroscope BX60, Olympus, Japan).
4. **Statistical analysis:** Statistical analysiswas performed by Microsoft Office (Excel) and Statistical Package for Social Science (SPSS) version 20.

Data were presented as mean and standard deviation (SD) values.

The significant level was set at $P \leq 0.05$.

Anova for repeated measurement was used to assess effect of time and material over accuracy of bite registration material

Univariate anova was used to assess effect of material over accuracy of bite registration material

Results

Table (1): Effect of duration on the dimensional accuracy of bite registration materials at horizontal centric occlusion

Types of Restoration	Duration (immediate)		Duration (later)	
	Types bite registration materials			
	Futar D Fast (Mean ± SD)	Futar Scan (Mean ± SD)	Futar D Fast (Mean ± SD)	Futar Scan (Mean ± SD)
Three Units (one missing tooth)	2.9234 [a] (± 0.4321)	2.5160 [a] (± 0.5231)	2.6283 [b] (± 0.5792)	2.6946 [b] (± 0.4732)

Same letter denotes no significant difference: The effect of duration on the dimensional accuracy of bite registration materials at horizontal centric occlusion is represented in table 1. Results showed statistical significant differences between immediate and later who recorded higher values with both types of bite registration materials tested.

Table (2): Effect of duration on the dimensional accuracy of bite registration materialsat horizontal eccentric occlusion

Types of Restoration	Duration (immediate)		Duration (later)	
	Types bite registration materials			
	Futar D Fast (Mean ± SD)	Futar Scan (Mean ± SD)	Futar D Fast (Mean ± SD)	Futar Scan (Mean ± SD)
Three Units	2.9341 (± 0.2109)	2.5262 (± 0.5214)	2.7182 (± 0.5321)	2.8078 (± 0.2895)

Same letter denotes no significant difference: The effect of duration on the dimensional accuracy of bite registration materials at horizontal centric occlusion is represented in table 2. Results showed statistical significant differences between immediate and later who recorded higher values with both types of bite registration materials tested.

Table (3): Comparison between the two types of occlusion irrespective to the duration, type of restorations and types bite registration materials regarding horizontal occlusion

Centric occlusion	Eccentric occlusion
2.7435[a]	2.5922[b]

Same letter denotes no significant difference: Comparison between the two types of occlusion irrespective to the duration, type of restorations and types bite registration materials is represented in table 3. Results showed a statistical significant differences between the two types of occlusion irrespective to the duration, type of restorations and types bite registration materials, as eccentric occlusion recorded higher values.

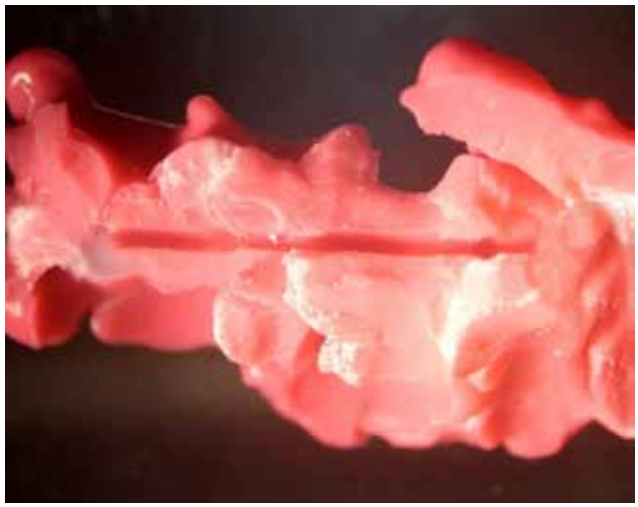

Figure 3: Wire impression on futar d fast bite registration material

Discussion

An interocclusal record is a precise recording of maxilla mandibular position[8]. A n accurate transfer of the interocclusal relationship to the articulator is essential for the fabrication of prosthesis. The accurate articulation of working casts results in less time spent adjusting

occlusion. This has a direct effect on the quality of the restoration and the operational cost of treatment[9] .The precise assessment of a patient's maxilla-mandibular relations is a key aspect of diagnosis and complex restorative therapy in oral rehabilitation[10]. However, this assessment is insufficient without mounting the maxillary and mandibular casts in accordance with the recorded jaw relation on the articulator [11]. The interocclusal record is a registration of the positional relationship of the opposing teeth or arches and has become the most popular method of transferring maxillomandibular relations from the mouth to the articulator[12]. The Bite Registration is aninterocclusal record which defined as an accurate and precise recording of maxillo-mandibular relationship[13]. The importance of bite registrationin recording the maxillo-mandibular relationship is to transfer the relationship to the articulator so laboratory procedure on the casts will correspond to the patient's mouth[14]. There are various method of recording maxillomandibular relationships graphic, functional, cephalometric and direct interocclusal recordings. The recording materials whenever possible were automatically mixed with gun so as to give a proper, consistent and homogenous mix free of void. This study was carried out to evaluate the dimensional accuracy of conventional bite registration material and CAD/ CAM bite registration material in patients with a single missing tooth. In the present study; two materials were chosen for recording interocclusal registration (Futar D Fast and Futar scan). Twenty patients with one missing tooth (who needed a fixed partial denture) were selected and included in the present study. A full veneered preparation was done. The patient bit on bite registration material in centric and eccentric movement. A wire "3 cm in length "was bonded with composite on adjacent teeth to the preparation. The length of wire impression on bite registration material was measured and after 24 hours to evaluate the possible effect with time factor.Injection technique for recording interocclusal relationship was used as it is the most popular technique used in dental work and produces a homogenous consistent mix which is free of voids[15]. All the specimens were stored in sealed dry polyethylene bags at room temperature (28 + 2) as dimensional changes of elastomers can be reduced by storage in a sealed dry containers at room temperature as moisture caused considerable expansion of elastomeric impression materials[16].In the present study; there was no statistical significant difference between the two tested types of bite registration materials for 2 types of restorations at horizontal centric or eccentric occlusions either immediate or late among the included cases. Also there was no statistical significant differences between the two tested types bite registration materials irrespective to the duration, type of restorations and type of occlusion. On the other hand; regarding the effect of duration on the dimensional accuracy of bite registration materials at horizontal centric and eccentric occlusions, there was statistical significant differences between immediate and later who recorded higher values with both types of bite registration materials tested. A statistical significant differences was found also between the two types of occlusion irrespective to the duration, type of restorations and types bite registration materials, as eccentric occlusion recorded higher values. It was also found that; no significant effect on dimensional accuracy of recording. These were in agreement with *Wieckiewicz et al*[17] who compared the dimensional stability of interocclusal registration materials between dentate and partially dentate and concluded that; there was no statistically difference significant between them and concluded that increasing volume of the material did not affect closure yet, closure would be dependent on the viscosity of the material. Regarding the effect of ***time of storage*** on dimensional accuracy of the recording materials, it was found that time of storage had a significant effect on the dimensional accuracy of both recording materials. This finding was in accordance with *Anup* ***et al*** [18] who studied the effect of time of storage on dimensional accuracy of elastomeric materials and concluded that the dimensional stability decreased with increase in time and was influenced by both material and time factor. It was also conducted that, for VPS recording materials, there were no statistically significant differences in dimensional changes immediately and after one week. This result was with agreement with the experimental findings of *Persson* et al [19] who studied the physical properties of interocclusal recording media and concluded that addition silicone materials showed little dimensional change in a horizontal plane. *Ghazal and Kern* [20] who studied the detail reproduction and dimensional stability of elastomeric impression materials and explained that; the setting reaction of polymer-based materials started as soon as the base and catalyst pastes come into contact with each other. This continuous process of polymerization and cross-linking resulted in molecular densification and shrinkage. As for VPS this polymerization reaction continued resulting in negative change in dimension after 24h. ***For the materials effect*** on dimensional accuracy, it was found that there was no statistically significant differences

between both materials. These results was in agreement with *Michalakis et al* [21] who compared the dimensional stability of different interocclusal materials and concluded that no significant difference between them.

Conclusions

Futar D and Futar scan bite registration materials provided accurate records with no differences between them. Dimensional accuracy was influenced by time factor of the recording materials.

Conflict of Interest: No conflict of interest.

The Relationship Consumption Patterns of Pokea Clams (Batissa Violaceavar. Celebensis, von Martens, 1897) and Lipids with Total Cholesterol Levels and Triglycerides in Patients with Hypertension

I Putu Sudayasa[1], Bahtiar[2], Hartati[3], Arimaswati[4], Andi Zilfiah Lantani[4], Ni Putu Cecilia[4], La Ode Alifariki[5]

[1] Departement of Public Health and Community Medicine, Medical Faculty, [2]Faculty of Fisheries and Marine Sciences, [3]Integrated Laboratory, Medical Faculty, [4]Department of Medicine, Medical Faculty, [5]Departmen of Epidemiology, Medical Faculty,University of Halu Oleo, Indonesia

Abstract

Introduction: The purpose of this study was to determine the relationship between pokea clams and lipid consumption patterns with total cholesterol and triglyceride levels in hypertensive patients in the Sampara District.

Method: This study uses an analytic observational with a case control design the population of this research is the people who consume pokea clamps. Sample of this research amount 60 people, divided into 30 cases and 30 control. The sampling technique uses purposive-sampling method. Data taken by using a questionnaire consumption pattern of pokea clamps, questionnaire of Semi Quantitative Food Frequency Questionnaire (FFQ-SQ) and the blood pressure were taken by using a mercury sphygmomanometer. Data analysis use the calculation of Odds Ratio.

Results: Statically, p values and OR value that is obtained from the consumption pattern of pokea clamps (Batissa violacea var. celebensis von Marten, 1897) (p value = 0,342; OR = 1,750; CI 95% = 0,548-5,586), pattern of lipid consumption (p value = 1,000; OR = 1,027; CI 95% = 0,247-4,273) to total cholesterol level in Sampara district region. Statistically, p value and OR value from all respondents with the pokea consumption pattern (von Marten, 1897. Batissa violacea var. celebensis) by control and cases group (p value = 2,05; OR = 2,31; CI 95% = 0,72-7,4). The statistical result of lipid consumption pattern between the control and cases group (p value = 0,47; OR = 0,44; CI 95% = 1,00-1,97) agains triglyceride levels in the Sampara District.

Conclusion: There is no relationship between consumption pattern of pokea clamps and pattern of lipid consumption with total cholesterol and triglyceride levels in hypertension patient in Sampara district region.

Keywords: *Pokea Clamp, Lipid, Total Cholesterol, Triglyceride, Hypertension.*

Introduction

Hypertension or high blood pressure is a condition of increasing blood pressure above normal which can increase the amount of morbidity and death[(1)]. Hypertension is an increase in systolic blood pressure of more than or equal to 140 mmHg and diastolic pressure of more than or equal to 90 mmHg[(2)].

Based on the results of the measurement of the prevalence of hypertension in Indonesia in 2013 at the age of ≥18 years the results were obtained with a percentage of 25.8%. The highest prevalence of hypertension is in Bangka Belitung Province (30.9%) and the lowest is

Corresponding Author:
La Ode Alifariki
Perumahan Pelangi Residence Kelurahan Poasia Kota Kendari, Propinsi Sultra, Indonesia
e-mail: ners_riki@yahoo.co.id

in Papua (16.8%). The prevalence of hypertension in Indonesia obtained through a questionnaire diagnosed by health workers is 9.4%, which was diagnosed by health workers or is taking medicine at 9.5%, this means that there are 0.1% who take their own medication. Respondents with normal blood pressure but taking hypertension medication were 0.7%[3].

During visits to service units such as the Puskesmas and its network, it was found that the population aged> 18 years was 82,425 (8%) and those who experienced an increase in blood pressure or hypertension were 31,817 (38.60%) people. Judging from the gender of the respondents, the incidence of hypertension was more common in men (50.32%) than in women (34.67%)[4]. Based on the top 10 most diseases in the Sampara Health Center, hypertension was in 4th position in 2017[5], where of 3,061 people, there were 312 people (10.2%) suffering from hypertension[5].

Factors that influence the incidence of hypertension are divided into two major groups, namely unmodifiable factors such as gender, age, genetics and modifiable factors such as diet, exercise habits and others[6]. Hypertension can be associated with abnormalities of total cholesterol lipids. Dyslipidemia can increase the risk of hypertension[7]. Various factors can increase the risk of hypertension, including age, sex, genetic, obesity, stress, physical activity, smoking, consumption alcohol and nutrient intake.One of thefactors that can be controlled is the intake of nutrients, such as intake of protein, saturated fat, sodium, potassium, calcium, magnesium and fiber. National and local hypertension control policies and strategies have been implemented that include 3 components, namely surveillance and monitoring, prevention and reduction of risk factors, early detection, timely and continuous treatment. One of the factors that play an important role in controlling hypertension is dietary factors, especially low-fat food diets. Fat intake can be described in the profile of dysilipidemia which includes total cholesterol, LDL, HDL, and triglycerides.

In the human body, cholesterol derived from daily food is classified as exogenic cholesterol and cholesterol resulting from synthesis in the body as endogenic cholesterol[8]. According to Soleha[9], high level of cholesterol or hypercholesterolemia can be a trigger for hypertension due to blockages in peripheral blood vessels that can reduce blood supply to the heart.

Dyslipidemia results in hypertension through the mechanism of endothelium dysfunction which can increase the production of the release and activation of nitric oxide in blood vessels resulting in changes in the structure of enlarged arteries that follow the process of atherosclerosis. According to the theory, triglycerides play an important role in the pathophysiological mechanism of increasing blood pressure.

One of the factors that influence cholesterol levels in the body is the individual's consumption patterns. The consumption pattern is the composition of food which includes the type and amount of foodstuffs on average per person per day, which is generally consumed by people in a certain period of time. The type of clams that is considered to have a high cholesterol content is the type of Batissa violacea (Pokeaclams) which is considered to be a cause of various cardiovascular diseases[10]. Pokea clams is bivalves that live in several rivers in Southeast Sulawesi that is unique compared to similar species from other regions[11].

For the Sampara community, clams are the main nutritional intake and often consumed. clams is one of the main sources of animal protein with good protein content and high biological value. Clams protein is categorized as complete protein due to its high essential amino acid levels. In addition, clams also contains fat and water soluble vitamins as well as a major source of minerals that the body needs[10].

Material and Method

This research uses observational analytic method with case control design. The study was located in Andepali Village, Andadowi Village, Pohara Village, Polua Village, Totombe Village, and Konggamea Village in the coastal area of the Pohara River, Sampara District, Konawe District, from March to July 2019. Using a purposive sampling method, a total sample size was determined. The 60 samples divided into 30 cases and 30 controls. Primary data were obtained from interviews about the consumption patterns of meat consumption of pokea clams, and lipids using the Semi-Quantitative Food Frequency Questionnaire (FFQ-SQ), and blood pressure examination with mercury sphygmomanometers while sampling blood is carried out by clinical laboratory personnel. Secondary data was obtained from service profile data at Puskesmas Sampara.

Findings:

Table 1. Analysis of the Relationship between Consumption Patterns of Pokea clams Meat with Total Cholesterol Levels in Sampara District

Consumption Pattern of Pokea Clams	Total Cholesterol level						p value	OR	95% CI	
	Abnormal		Normal		Amount					
	n	%	n	%	N	%			LL	UL
Sufficient	6	10	11	18,3	17	28,3

Discussion

Pokea clams (Batissa violaceav var. Celebensis von Martens, 1897) is a type of bivalvia of the Corbiculidae family that has a dark brown to blackish-purple shell and has a slightly flattened and rounded shape[10].This type of clams has become one of the sources of community livelihoods around the Pohara River, Konawe Regency, and Southeast Sulawesi. These clams are usually sold in the form of fresh whole, fresh peeled, and satay. Pokea clamsnare usually consumed in the form of stew by the local community[10].

The study is in line with research conducted by Yeni et al[10] regarding the effect of boiling on the content of fatty acids and cholesterol in pokea clams. The results in his research showed the fatty acid content of Pokea clams after boiling was relatively stable. Fresh and boiled

clam meat is identified as having fatty acids consisting of Saturated Fatty Acid or SFA, Mono Unsaturated Fatty Acid or MUFA and Poly Unsaturated Fatty Acid or PUFA. The highest total fatty acid content in fresh and boiled clam meat is SFA type of fatty acid which is dominated by palmitic acid.

In contrast to Sudayasa et al[12] conducted research on the relationship of pokea clams consumption toward blood pressure in Pohara coastal communities. Based on the interview results, most of respondents consumed pokea clams meat by frying.In this study, most of respondents consumed pokea clam meat by boiling.

Apart from the consumption patterns of Pokea clams, factors that can affect total cholesterol levels are physical activity and obesity. Physical activity can be in the form of exercise and daily routine activities can reduce the risk of cardiovascular disease by maintaining the stability of the heart's pumping system and balancing blood cholesterol levels[10].The more physical activity is carried out, the more ATP needs and will cause a lack of total cholesterol formation and Low Density Lipoprotein (LDL) cholesterol and an increase in High Density Lipoprotein (HDL) cholesterol[10].

The results of bivariate analysis OR = 1.027, can be interpreted that respondents who consumed lipids were at 1,027 times greater risk of an increase in total cholesterol levels compared to respondents who did not consume lipids.Based on the respondents' characteristics, it is found that the comparison of respondents with normal total cholesterol levels with respondents with abnormal total cholesterol levels is 1: 1, which indicates that lipids affect the total cholesterol level in the body.

Based on the results of interviews with respondents using the FFQ-SQ questionnaire that was converted into the Nutrisurvey application (2007), the highest lipid consumption value was 142.2 g (risky or> 67 grams/ day) and the lowest lipid consumption value was 4, 3 gr (no risk or ≤67 gram/day). The types of food that most influence the total value of lipid consumption are palm oil and chicken eggs.

Frequent consumption of high-fat foods is a major cause of increased total cholesterol in the blood. The high cholesterol level in the blood is a serious problem because it is one of the risk factors for various non-communicable diseases such as heart disease, stroke and diabetes mellitus[4].

The results of this study are in line with research conducted by Yoentafara and Martini[4] regarding the effect of diet on total cholesterol levels. The results of his study showed the value of p = 0.285 (p> 0.05), which showed no relationship between high-fat diets with total cholesterol levels. This research is inversely proportional to the results of a study conducted by Septianggi et al(13), where the value of p = 0.026 (p <0.05), which shows that there is a positive relationship between fat intake and total cholesterol levels in outpatient of coronary heart disease in the Tugurejo General Hospital Semarang in 2013.

The results of the study by Gayet-Boyer et al[14] found no linear relationship between consumption of fat with HDL, LDL and total cholesterol levels. This is different from research conducted by Prabowo et al[15] where the results of p value = 0,000 (p <0.05) means that there is a significant relationship between diet and cholesterol levels both positive correlations the higher correlation of foods based on fatty diets, the higher the cholesterol level.

The meaninglessness in the results of the statistical test of this study might be because people in the Sampara area have a risk-free lipid consumption pattern or within safe limits in accordance with standard which states that lipid consumption is risky if the levels are> 67 grams/ day and not at risk if the levels are ≤ 67 gram/day. Based on the results of interviews conducted during the study, most of respondents have reduced the consumption of foods with high fat content because it is related to their blood pressure.

Communities in Sampara Subdistrict, especially those who live around the Pohara River, often consume pokea clams (Batissa violacea celebensis von Marten, 1897). This clam is endemic because it is only found in the Pohara River, Konawe Regency, Southeast Sulawesi, about 25 km towards the estuary at a depth of 1-9 meters. Pokea clams have become an important commodity for the communities around the Pohara River, because they can be sold in the form of fresh, fresh peeled and satay so that they have the potential to become one of the regional primary products[10].

Based on the results of bivariate analysis, there was no relationship between the pattern of consumption of Pokea clams on triglyceride levels in patients with hypertension in the District of Sampara. Based on the results of interviews, people more often process pokea

clam meat by boiling 2-3 times before consumption and then fried or sauteed. The use of cooking oil can add fatty acids in processed Pokea clams meat consumed by the communities.

Free fatty acids in coconut oil are saturated fatty acids that will be the ingredients of the formation of triglycerides and cholesterol in the blood. If consumption is carried out continuously for a long period of time it can cause blood fat levels to increase, resulting in the accumulation of a layer of fat in the blood vessels that makes blockages in blood vessels and causes blood pressure to increase[16].

This is not in line with research conducted by Sudayasa et al[16] which states that there is a relationship between Pokea clams consumption patterns and blood pressure in the coastal communities of the Pohara River, Sampara District. That is caused by differences in the processing of pokea clam meat by respondents. In a study conducted by Sudayasa et al[12], most of respondents consumed Pokea clams meat by frying, while in this study, most respondents consumed pokea clam meat by boiling.

Repeated boiling can affect the meat content of Pokea clams. As stated by Yeni et al[10] regarding the effect of boiling Pokea clams on the content of fatty acids and cholesterol, the content of fatty acids after boiling is relatively stable.Fresh and boiled clam meat is identified as having fatty acids consisting of Saturated Fatty Acid (SFA), Mono Unsaturated Fatty Acid (MUFA) and Poly Unsaturated Fatty Acid (PUFA). The highest total fatty acid content in fresh and boiled clam meat is SFA type of fatty acid which is dominated by palmitic acid. The total MUFA and PUFA content of fresh and boiled clam meat is higher than the SFA composition. MUFA and PUFA have an important role in reducing cardiovascular disease, type 2 diabetes, inflammatory diseases, and immune disorders.SFAs with a lower content have a role as triglycerides in the blood with a possibility of fatty acids suppress inflammation by inhibiting the biosynthesis pathway of leukotriene, which is unsaturated fatty acids that contain carbon released during the inflammatory process[10].

Although in this study no relationship was found between consumption patterns of Pokea clams with increased levels of triglycerides in patients with hypertension, but there were more respondents in the case group who consumed less meat but experienced an increasing blood pressure. These needs to get more attention considering there are some respondents who are still teenagers and have experienced increased blood pressure. The increasing blood pressure is not only influenced by the consumption pattern of pokea clam meat. Family history is one of the factors causing the increasing blood pressure in adolescents.

According to the research of Henuhili et al[17], hypertension genes are dominant in every individual. Hypertension is in every generation. Even if someone does not inherit hypertension it will still be possible to have offspring who have hypertension. Inheritance of hypertension is not X-linked, meaning that genes on the genital chromosomes of either fathers or mothers can bequeath male or female offspring.

In addition, other factors that can also affect triglyceride levels are lifestyle such as lack of sports activities, lack of drinking mineral water, smoking, consuming alcohol and irregular eating patterns can result in higher levels of free fatty acids.The results of the bivariate analysis showed that there was no relationship between lipid consumption with triglyceride levels in hypertensive patients in Sampara District. According to Fentiana(18), fat intake is the most dominant factor associated with obesity. Fat can affect health, including causing coronary heart disease, increased blood cholesterol levels and increased blood lipid levels.

Data from the measurements of height and weight of respondents in this study found the average body mass index is not normal (in the categories of less or more, and obesity) more than the normal category.However, in the results of interviews people do not like to consume foods that contain excess fat such as fried foods or coconut milk because many of the respondents are aged ≥35 years whose consumption patterns should be maintained, either those who have experienced complaints and those who have no complaints.

In line with research conducted by Hidayati[19] which shows that there is no significant relationship between fat intake and triglyceride levels. Apart from fat intake, another thing that can increase triglyceride levels is an increase in carbohydrate intake wherein the formation of pyruvate and acetyl-CoA will cause an increase in the formation of fatty acids from acetyl-CoA. These fatty acids will be esterified with triphosphate which is produced from glycolysis and becomes triglycerides.

This research is inversely proportional to the research conducted by Nisa et al[20] that fat intake has a relationship with triglyceride levels (ρ = 0.030) and with a correlation coefficient of 0.299 which shows that increasing fat intake increases triglyceride levels. In accordance with the multivariate test, it was found that increasing 1 gram of fat intake would increase triglyceride levels by 0.311 mg/dL. These results are in line with previous research which states that fat intake is associated with triglyceride levels (ρ = 0.001) with each increase of 1 gram of fat/day will increase triglyceride levels by 0.109 mg/dL.

Although in this study there was no relationship between patterns of lipid consumption with triglyceride levels in hypertensive patients in Sampara District, but there are several other factors that influence the formation of triglycerides in the blood and can cause an increase in blood pressure.The results of the bivariate analysis showed that there was no relationship between carbohydrate consumption with triglycerides in hypertension in Sampara District.

The unrelated variables analyzed can be caused by blood pressure in addition to being influenced by consumption of Pokea clams and lipids, but can also be influenced by many factors. Another factor that can affect blood pressure is body mass index. Being overweight can increase the risk of hypertension five times higher than normal weight[21].

Conclusion

There is no relationship between the consumption pattern of pokea clam meat (Batissa violacea var. Celebensisvon Martens, 1897) and lipids with total cholesterol levels and triglyceride levels in hypertension patients in Sampara District.For future researchers, it is recommended to use a different research design from this study by adding and reviewing other variables, such as cross sectional or cohort studies by examining other factors to better support of the research results.

Conflict of Interest: In this study there is no conflict of interest.

Source of Funding: This research uses private funds.

Modification of Ames Test According to Phenotype Features of Prototrophic Escherichia Coli

Ibraheem Abdulrahman Eltaif[1], Dunia Kamal Salim[2], Sundus Jassim Muhammad[3]

[1]Professor, Tikrit University, College of Sciences, Department of Biology, [2]Lecturer, [3]Professor, Department of Biology, Facultyof Sciences, University of Tikrit, Tikrit, Iraq

Abstract

Background: Iraq is an oil country in addition to an agricultural economie so the using of pesticide has raised very dramatically to cater the food demands of increasing population. Thus, a continuous examination of pesticides is required. Ames test is a standard method for determining the carcinogenic compounds by induce back mutations in auxotrophic strain of *Salmonella typhimurium*- histidine negative (his^-) and biotin-negative (bio^-), but in our country-Iraq, this bacterial strain was unavailable in most time. However, this study designed to guess the possibility of employment prototrophic *Escherichia coli* according to phenotype features instead of *S. typhimurium*.

Method: A prototrophic *Escherichia coli* was sensitive to amikacin, erythromycin, chloramphenicol, ciprofloxacin, tobramycin and trimethoprim. The strain was exposed to different concentration of Chlorpyrifos (CPF)as a mutation inducer. The potentiality of mutagenesisof CPF was detected according to phenotype featuresusing antibiotics susceptibility test (AST).

Result: Our result showed that the mutations were induced in some chromosomal genes of *E. coli* when exposed to CPF in high concentration 80-100%, while con. 10-70% were not. These genes encoded resistance to erythromycin, trimethoprim and tobramycin.

Conclusions: The modified Ames test can consider as a predictive tool for screening a potential carcinogenicity. The potential of genotoxic of the CPF has been detected.

Keywords: *Mutagenic, carcinogenic, prototrophic Escherichia coli, chlorpyrifos.*

Introduction

Our using and exposure to a wide diverse of chemical materials has increased significantly during the past decades. Oncological epidemiologists strongly suspected that the intrusion of these chemical compounds in the form of industrial pesticides, pollutants, food additives, hair dyes, cigarette smoke, and the like may play a influence role in the cause of malignant tumors in human[1].

Mutagenic chemical compounds are capable of causing cancers, and this interest has led to bulk of the programs of mutagenicity testing[2]. Previous researches have revealed that some insecticides have mutagenic effectiveness in many biological test programs[3]. According to a genetic feature there is clear proof relationship between mutagenicity and carcinogenicity. One study detected that approximately 90% of the chemical compounds demonstrated to be carcinogen are mutagen, they cause cancer by inducing mutations in somatic cells[1]. Mutation may be can caused in gene "point mutation" and this type of mutation was defined as "just a one base is altered or single or a relatively some bases are deleted or inserted", as large deletion or rearrangement of DNA as chromosomes break or rearrangement, or as gain or loss of whole chromosome[4]. These reports increased perception of the mechanisms of mutations and their function in cancer has stimulated efforts to identify environmental carcinogens agents that cause cancers[4].

The observation that many carcinogens also are mutagens was the basis for development of the Ames test by Bruce Ames in the 1970. Dr. Bruce Ames and

his colleagues, studying the operon of histidine in *Salmonella typhimurium*, observed that histidine (−) auxotroph mutants were reverted to histidine (+) upon exposure to a mutagens[5], so this test represent as a investigating method for the revealing of carcinogenic chemical compounds by testing the capability of chemical compounds to stimulate mutations in bacterial cell[6,7].

When exposed bacteria to a chemical agent and culturing in medium deficient-histidine, the average ofback mutation (reversion) to prototrophic cell is detected by counting the number of bacterial colonies that are seen on the medium deficient-histidine[6,8]. However, proving that a substance causes mutations in bacteria does not prove that it does so in human cells[9], whereas some chemicals tested may not be mutagenic unless they are transformed into another, more active form. In animals, such transformations occur in the liver. Indeed, many known carcinogens are not actually carcinogenic compounds even they are altered by enzymes in the liver that function to destroy toxins and other materials that may be circulating in the blood. However, in some cases, these enzymes transform chemicals into more dangerous forms. For this reason, the extraction of a mammalian liveris added to the molten top-agar prior to plating the bacterial cells used in the Ames test (Fig. 1)[5], however, several variations of the Ames test are possible[8].

Chlorpyrifo (CPF): Chlorpyrifos (O,O-diet hylO-3,5,6-trichlor-2-pyridyl phospherothioate; is a broad spectrum organophosphate insecticide used on animals, crops,, and buildings, and in other placements, to inhibit and/or kill a many of pests, that including worms and insects[10].In1965 was first of introduce CPFinto the market-place, has been used globally as an pesticides to control the harmful insects of agriculturally and in the homes[11]. CRF acts on the nervous system of peststhrough inhibiting the acetylcholenesterase enzymes. World Health Organization WHO considered CPF is moderately hazardous to humans the based on its acute toxicity[12]. On the other hand, when humans exposure to high level of CRF that surpassing recommended amount has been related to persistent developmental disorders,neurological effects and autoimmune disorders[13].

Materials Method

1. Overnight tryptic soy broth culture of prototroph *Escherichia coli* which resistant to (amikacin, erythromycin, chloramphenicol, ciprofloxacin, tobramycin and trimethoprim).
2. Filter paper disks, sterile in Petri dish.
3. Muller Hinton agar.
4. 5 ml sterile tryptic soy broth in a test tube.
5. Chlorpyrifos in concentration 10%, 20%, 30%, 40%, 50%, 60%, 70%, 80%, 90% and 100%.

Procedure:

First Period:

1. For confirmation of *E. coli* sensitive to amikacin, erythromycin, chloramphenicol, ciprofloxacin, tobramycin and trimethoprim. Antibiotic susceptibility test (AST) were applied according to ((Schwalbe *et al.,* 2007 and Ferraro *et al.,* 2006)[14,15].
2. 0.1 ml of overnight culture *E. coli* were poured and spread on Muller Hinton agar, then leave at room temperature for 20 seconds.
3. With sterile forceps a sterile filter paper disk was placed perpendicularly at the center of the medium as shown in Figure 2.
4. With a sterile Pasteur pipette, enough of CPF were deposited just on the upper edge of the filter paper disk to saturate it, after that, the disk was pushed over with the pipette-tip onto the agar surface so it lies flat.
5. All four plates were incubated for 48 hours at 37°C.

Second Period:

1. The plates were examined.
2. When we observe a clear halo of revertant bacterial colonies surround the disk on the medium, within the inhibition zone, this may be due to mutations were occurred, Figure 3.
3. The scattered colonies were taken individually and cultured in new tryptic soy broth tube.
4. In new previous culture, the antibiotic susceptibility test was repeated, to confirmation if a mutation was accorded and to detect the site of mutation.
5. All the plates were incubated for 24 hours at 37°C.

Results

An application of our modified method to Ames test showed significant effect regarding the high

concentration of test compound CPF. Appearance of colonies within inhibition zone, may be indicator to obtain mutant strain. Furthermore, the number of apparent colonies relatively with concentration of CPF. However, the con. 10 to 70% of CPF were insignificant. Tab.1, present data of antibiotic susceptibility test (AST) before and after exposure to different concentration of CPF.

In con. 80%and 90% *Escherichia coli* strain gained the ability to resistance to erythromycin and trimethoprim. In con. 100% gained the ability to resistance to erythromycin, trimethoprim and tobramycin.

Table 1. effective con. Of CPF according to modified method.

Antibiotics	Inhibition zone before exp./mm	Inhibition zone after exp./mm	CPF effect
	Co. 80%		
Amikacin	19/S	20/S	No

Discussion

In our country (Iraq), some things were much difficult to obtain, due to wars and their results. One of these is an auxotrophic strain of *Salmonella typhimurium* which employs in standard Ames test. Furthermore, in the last years, Iraq became open market to different unguaranteed materials and compounds, in addition, it is an agricultural economie so the using of pesticide has raised very dramatically to cater the food demands of increasing population.So that, we needed to modified method a test these compounds and passing this problem.

In our modified method, some steps of standard Ames test were ignored, such as using plates contain two layers of glucose–minimal salts agar and top agar. This traditional Ames test is quite fatigued and required long time for initial monitoring of mutagenic chemical compounds[16]. The Ames system has been continuously improved, such as the addition of an*rfa*mutation at the 48´mark of the *S. typhimurium* genomic map (strains TA1535, TA1537 and TA1538) to increase the membrane permeability to chemical compounds[7].

(Boogaard et al. 2012)[17], suggested modified Ames test as an indicator of the carcinogenecity of residual aromatic extract (RAE), and concluded that their modified Ames test can be used as a screening tool for assessing the potential carcinogenicity activity of RAEs. Since a cut-off value was determined to distinguish between carcinogenic and non-carcinogenic RAE samples. Their data demonstrate that RAEs with a mutagenicity index > 0.4 demonstrated potential carcinogenic activity to mouse skin following chronic exposure. RAEs with a mutagenicity index < 0.4 did not demonstrate a carcinogenic potential. However, the assay is not highly specific, which may result in a large number of false positives and identification of mutagens that are not necessarily carcinogens[7].

The standard method to test chemical compounds for mutaginesis has been to measure the rate of back mutationsin strains of auxotrophic bacteria. According to the Ames test a strains of *Salmonillatyphemurium,* which is auxotrophic for "histidine negative" - (can notgrow and be alive in the medium does not contain histidine)[6]. Furthermore, the *Salmonella* strain whichapplied in this test have varioustypes of mutation in different genes at the operon of histidine, each of these mutations is engineered to be responsive to mutagenic-compounds that act byvarious mechanisms, since the mutations were designed in to these bacteria to make them more sensitive to a wide diverse of compounds[4], while our method depending on inducing a new mutation in bacterial genomic, and measure its frequency. Our result revealed that *E. coli* strain gained the ability to resistance to erythromycin, trimethoprim and tobramycin, it seem that mutation may be happened in the genes responsible to for resistance to these antibiotics. however, these mutations may be accorded spontaneous[1]. (Ameena S. 2010 and Hoeksema et al. 2019)[18,19], Proved that the genes administrator for to the following antibiotic resistance were located on the nucleotides of plasmid : ampicillin, amoxiclav, amoxicillin, cefixime, cephalexine, cefotaxime, gentamycin, doxycyclin, nalidixic acid, rifampicin, nitrofurantoin, tetracycline and streptomycin. while the genes encoding resistancesto the following antibioticswere located on the chromosomal nucleotides: chloramphenicol, erythromycin, amikacin, tobramycin, trimethoprimand ciprofloxacin. Furthermore, (Amira et al. 2018)[20], concluded that the genes related with resistance to macrolide antibiotic (*mph*A, *mrx, ere*A) were detected nine phenotypically resistants train *E. coli* to erythromycin and proved that the *dfr*A and *sul* genes related with resistance to sulphonamides-trimethoprim were identified in 13 and 16*E. coli* isolates, respectively.

In another hand, the genotoxic features of Chlorpyrifohave been reported in a different of tests in the previous years, but the study's results were not agree contradictory. Whereas there is increasing interest about the presence of genotoxin in the environments, the development of sensitive biomarker for identification of genotoxic influences in variety of organisms has gained importance, although, WHO presented report in specifications and evaluations for public health pesticides, and refer that CPF was non-mutagenic for organisms in low concentration, some studies confirmed that[12]. The present study, modified Ames medium application test with the different concentrations of Chlorpyriforevealed that a mutagenic-compound responsible with *E. coli* tester strain. Dose-quantity associate with increase in the number of revertant colonies of*E. coli* strains werereported. Furthermore, the number of spontaneous back mutations in negative control were less than all ofthe different treatment average of CPF. Several studies has been reported that CPF was genotoxic in Chaannapuncteatus. The exposure to 0.08 lg/l of Chlorpyrifocaused genital weakness in Daphenia magnia[11]. Additionally, (Kamilia et al. 2012)[21], refer that CPF caused distortions in meiotic and mitotic chromosomes of mice as previously mentioned, the morphological distortions of sperms observed here might be because of stimulated modifications in testes DNA and sperm chromatin structures. These concepts of insecticide inflicted sperms toxicity may be supported by the high positive association observed between sperm-toxic and mutagenicity influences in mice.

Conclusion

This study refers to possibility of using a prototrophic *E. coli* strains *in vitro* instead of auxotrophic strain of *S. typhimurium* and application other method to detect a carcinogens, or the modified Ames test can consider as a predictive tool for screening a potential carcinogenicity. The potential genotoxic of the CPF has been detected.

Central Venous and Arterial Gases Level Versus Lactate Clearance as an Indicator of Initial Resuscitation in Septic Patients in Intensive Care Unit

Ibrahim Abas Youseif[1], Ahmad Hasaneen Mohammed[2], Rehab Mohammed Farghly[3]

[1]Professor and Founder of Anesthesia, [2]Assistant Professor of Anesthesia, [3]Assistant Lecturer of Anesthesia, Intensive Care and Pain Management, Faculty of Medicine, Minia University, Egypt

Abstract

Objective: Aim of this study was to compare the central venoarterial carbon dioxide difference/arterial-central venous oxygen difference (P(va)CO2/C(a-v)O2) ratio versus lactate clearance as an indicator to evaluate the steps of initial resuscitation in septic patients.

Patients and Method: Our study was conducted in the ICU,Minia University Hospital. Eighty patients with severe sepsis or septic shock

Results: There was improvement in CVP, MAP, or Scvo2 at T8 after early resuscitation with no significant differences between group 1 and group 2 and inside each group. There were no significant difference in P(v-a)CO2/C(a-v)O2 ratio at T0 and at T8 at group 1. However there was higher lactate level at T0 and exhibited significantly lower at T8 in group 2.

Conclusion: Further clinical trials are needed to conclusively establish lactate clearance as a resuscitation endpoint and an outcome measure to be targeted during the most proximal phases of severe sepsis and septic shock

Keywords: *CVP; MAP; Scvo2.*

Introduction

Sepsis is one of the most common causes of death in the intensive care unit (ICU). It is difficult to be diagnosed due to multiple comorbidities and underlying diseases in these patients [1, 2].

Sepsis is considered a complex syndrome characterized by presence of organ dysfunction mediated by different mechanisms of cell damage resulting in more than 30% mortality rate[3,4]. Although sepsis involve microvascular anomalies and constitute a central element of such organ dysfunction through decrease in oxygen supply and/or deficient utilization of the available oxygen[5].

Severe sepsis and septic shock is a life-threatening condition for patients of intensive care unit (ICU) [6,7]. Promoted practice for septic shock therapy is largely based on a study by Rivers et al. which developed a protocol known as early goal-direeted therapy (EGDT)[8].

The initial resuscitat ion of the septic patients includes anticipation for the need for fluid resuscitation, antimicrobials, and possibly vasoactive medications (vasopressors)[9,10].

In a cellular hypoxia anaerobic carbon dioxide increases as hydrogen ions generated by anaerobic sources of energy are buffered by bicarbonate[11]. Consequently, a rise in the respiratory quotient (VCO2/

VO2 ratio) reflects the presence of global anaerobic metabolism[12].

The P(v-a)CO2/C(a-v)O2 ratio is calculated from several parameters based on a known formula that mainly involves ScvO2, hemoglobin (Hb), arterial oxygen saturation (SaO2), and P(v-a)CO [13]. Therefore, a simple and rapid method for identification of a high P(v-a)CO2/C(a-v)O2 ratio would be of substantial benefit, and the factors contributing to a high P(v-a) CO2/C(a-v)O2 ratio are worthy of consideration in the clinical setting[14].

Sepsis is a disease characterized by hypercatabolism with increased demand for oxygen due to elevated consumption in tissue[15]. Early therapy with optimization of blood volume, hemoglobin levels and/or use of inotropic agents favors the patient's prognosis[16].

Despite questioning relating to the mechanisms of hyperlactatemia,[17-19] this is a well-recognized instrument for diagnosing hypoperfusion and occult tissue hypoxia, and it is also used as a prognostic index among septic patients [20]. However, although hyperlactatemia is generally measured in the arterial blood, the ideal collection site has not been clearly established[21].

Patients and Method

Our study was conducted in the ICU,Minia University Hospital. Eighty patients with severe sepsis or septic shock were divided into two groups: group 1, resuscitated to normalize CVP, MAP, and (P(va)CO2/ C(a-v)O2) ratio; and group 2, resuscitated to normalize CVP, MAP, and lactate clearance. Whereas mortality was followed up for 28 days.

Inclusion Criteria:

- Septic adult patients who were sequentially admitted to ICU and required central venous catheters for resuscitation and met the criteria of sepsis were eligible for the study.
- Age: ≥ 18 to ≤ 65 years
- Sex: male and female

Exclusion Criteria:

- Patints less than 18 years or more than 65 years
- Patients who were unable to complete the assessment tools
- Patients with no relatives to sign the consent
- Patients admitted to intensive care unit not due to sepsis
- Patients had a contraindication to central venous catheterisation
- Pregnancy

Parameters to be assessed:

- The admission characteristics, pre-existing conditions and acquired complications in the intensive care unit will be recorded.
- The inclusion time (T0) and study enrollment will be defined as the moment at which central venous pressure (CVP) monitoring begin after intensive care unit (ICU) admission.
- The demographic characteristics including the Acute Physiology and Chronic Health Evaluation II (APACHE II) score, the Sequential Organ Failure Assessment (SOFA)score, use of inotropes and type of organism.
- The global hemodynamic including HR, MAP, CVP, arterial, and central venous blood gas analyses were simultaneously performed on the T0 and T8.
- Measurements in this study included determination of the following variables: -Pao2
- Arterial carbon dioxide tension (Paco2) -central venous oxygen tension (Pvo2) -central venous carbon dioxide tension (Pvco2) -Sao2, and Scvo2 -The Hb and lactate level were measured from the arterial blood. -The arterial oxygen content (Cao2) =(1.34 × Sao2 × Hb) + (0.003 × Pao2) -central venous oxygen content (Cvo2) =(1.34 × Svo2 × Hb) + (0.003 × Pvo2) -arteriovenous oxygen content difference (C(a-v)O2) -venoarterial CO2 tension difference (P(v-a)CO2) -P(v-a)CO2/C(a-v)O2 ratio -Lactate clearance rat = (T0 lactate − T8 lactate)/(T0 lactate) × 100%

  - Prediction of ICU mortality at day 28.

Statistical Analysis: The patients were divided into 2 groups: group 1; P(v-a)CO2/C(a-v)O2 ratio group and group 2; Lactate clearance group . A descriptive analysis was performed. All data are expressed as the mean s ± SDs and medians (25th-75th percentiles) unless otherwise specified. Mann-Whitney tests were used to compare the groups in terms of the continuous variables, and $\chi 2$ and Fisher exact tests were used to

compare the categorical variables between groups. Pairs of continuous variables were analyzed using linear regressions. All comparisons were 2 tailed, and P < .05 was required to exclude the null hypothesis. Statistical analyses were performed with the SPSS 13.0 software package (SPSS Inc, Chicago, Ill) and MedCalc 11.4.3.0 software (Mariakerke, Belgium).

Results

The relevant hemodynamic and global oxygen metabolic parameters at T0 and T8 for the LC and non-LC groups are shown in Tables 1 and 2, respectively. There was improvementin CVP, MAP, or Scvo2 at T8 after early resuscitation with no significant differences between group1 and group 2 and inside each group. There were no significant difference in P(v-a)CO2/ C(a-v)O2 ratio at T0 and at T8 at group 1. However there was higher lactate level at T0 and exhibited significantly lower at T8 in group 2.

Table 1: Hemodynamic and related variables in group 1 at T0 and T8

Variables	T0	T8	P
HR (beats/min)	98 ± 27	99 ± 22	0.563
MAP (mm Hg)	89 ± 21	85 ± 14	0.512
CVP (mm Hg)	10 ± 3.5	9.7 ± 4	0.089
$Scvo_2$ (%)	76 ± 9	75 ± 13	0.123
$C(a\text{-}v)O_2$ (mm Hg)	3.48 ± 2.05	3.7 ± 1.6	0.132
$P(v\text{-}a)\ CO_2$ (mm Hg)	6.4 ± 5.1	7.3 ± 4.5	0.978
$P(v\text{-}a)\ CO_2/C(a\text{-}v)O_2$ ratio (mm Hg/mL)	1.87 ± 1.55	2.1 ± 1.0	0.538
No. of patients with NE (%)	20/34 (59)		0.797
NE dose ($\mu g\ kg^{-1}\ min^{-1}$)	0.18 ± 0.25	0.32 ± 0.6	0.588

HR indicates heart rate; CVP, central venous pressure; MAP, mean arterial pressure; (P(v − a)co2) veno-arterial gradient in carbon dioxide tension,(C(a − v)O2) arteriovenous gradient in oxygen content;NE, norepinephrine, P value is significant if less than 0.05

Table 2. Hemodynamic and related variables in group 2 at T0 and T8.

Variables	T0	T8	P
HR (beats/min)	98 ± 22	92 ± 21	0.123
MAP (mm Hg)	90 ± 17	90 ± 15	0.215
CVP (mm Hg)	9 ± 3	8.5 ± 3	0.334
$Scvo_2$ (%)	72 ± 11	77 ± 9	0.760
Lactate (mmol/L)	2.9 ± 2.2	1.3 ± 0.8	0.007*
No. of patients with NE (%)	28/50 (56)		
NE dose ($\mu g\ kg^{-1}\ min^{-1}$)	0.15 ± 0.25	0.24 ± 0.31	0.904

HR indicates heart rate;CVP, central venous pressure; MAP, mean arterial pressure; NE, norepinephrine, *P<0.05 is significant between T0 and T8 inside group 2

Discussion

Severe sepsis and septic shock are leading causes of death in the world [22]. mortality rate remains high in septic shock [23]. There is a need to test the prognostic value of factors that could be used for guiding therapy after the initial resuscitation.

The results of our study reported that a protocol targeting lactate clearance of at least 10% or more, as an evidence of adequate tissue oxygen delivery and a measurement of total body oxygen metabolism and was compared with the $P(v\text{-}a)CO_2/C(a\text{-}v)O_2$ ratio when resuscitating the septic patients at time of admission and 8 hours after the initial resuscitation.

Our results on P(v-a)CO2/C(a-v)O2 ratio dem onstrated that, although the target indicator of the initial resuscitation of P(v-a)CO2/C(a-v)O2 ratio around 1.68 or lowwas achieved in 85% of patients in group 1, 45% mortality was recorded, with no statistically significant difference between survivors and nonsurvivors ($P > 0.05$).

Our results demonstrated that target indicator of lactate clearance of 10% or more was achieved in 70% of patients in group 2. On comparing it with P(v-a)CO2/C(a-v)O2 ratio as goals of the initial sepsis resuscitation, we found that targeting lactate clearance of at least 10%, as evidence of adequate tissue oxygen delivery and a measure of total body oxygen metabolism when resuscitating patients with severe sepsis and septic shock.

The present research showed discrepancy between lactate and P(v-a)CO2/C(a-v)O2 ratio as regards their correlation with mortality and, as we demonstrated, the target goal of lactate clearance of 10% or more was achieved in 70% of patients in group 1, but with a mortality of 30%. Hence, this group had 15% lower in-hospital mortality than those resuscitated to P(v-a) CO2/C(a-v)O2 ratio around 1.68 or low(30 vs. 45%, respectively), with a statistically significant difference.

In our study, basal lactate was significantly higher ($P < 0.05$) in nonsurvivors compared with survivors.

Monnet et al [24] also reported that the P(v-a)CO2/C(a-v)O2 ratio is predictive of increases in VO2, but the Scvo2 value is not. These authors demonstrated that a P(v-a)CO2/C(a-v)O2 ratio greater than 1.8 is predictive of VO2 increases of more than 15% in response to increases in DO2 when the Scvo2 is greater than 70%.

The arterial lactate level is well known to reflect ongoing metabolism and serves as an indicator of anaerobic metabolism, and LC is associated with mortality in critically ill patients [25,26]. Although the use of LC is limited to a certain degree, it has generally been accepted for use as an indicator of oxygen debt in clinical practice, and LC is particularly well accepted for this purpose. Therefore, it was relatively reasonable to use LC as an indicator of anaerobic metabolism in our study .Thus, VO2/DO2 dependence has been considered to be a hallmark of tissue hypoxia and the activation of anaerobic metabolism [25,27], although it has been challenged because of the methodological limitations (mathematical coupling) in the VO2/DO2 relationship assessment [28].

Conclusion

Lactate clearance provide useful information for assessing the initial resuscitation of the septic patients in ICU after 8 hours, than P(v-a)CO2/C(a-v)O2 ratio. in addition to its simplicity in measurement away from miscalculation of P(v-a)CO2/C(a-v)O2 ratio assessment parameters. Further clinical trials are needed to conclusively establish lactate clearance as a resuscitation endpoint and an outcome measure to be targeted during the most proximal phases of severe sepsis and septic shock.

Hematological Study and Estimation of Trace Elements in Patient with Thalassemia

Khalid H. Gathwan[1], Shatha Q. Jawad[2]

[1]Professor, [2]Asiistant Professor Dr. College of Dentistry, University of Baghdad, Baghdad-Iraq

Abstract

Anemia is a deficiency of red blood cells which can be caused either by too rapid loss or by too slow production of red blood cells. Blood sample from thalassemia and normal were collected, serum analysis. The concentration of hemoglobin, white blood cell count was lower in-patient group than normal. The level of nickel, magnesium in serum of patient were 0.213±0.001µmole/ L, 15.44 ±/ 1.77µmole L While in normal 0.0321 ± 0.0035 and 13.34 ± 1.92µmol /L erespectively

Keywords: *Thalassemia, Serum, Nickel. hematology.*

Introduction

Thalassemia is anherniated disorder by a normal hemoglobin, in normal hemoglobin, the number of α and β chain is equal, in thalassemia the number of these chains is not equal, this causes of the precipitation of the polypeptide chains leading to defective formation of RBCs [(1)]. Thalassemia is problem of complex causes and is related with many factors, is an indicator of poor health and nutrition, hemoglobin is transfer in circulation with RBC [(2)]. The uptake of oxygen is affected by smoking and altitude and physiological factor and the body can alter blood volumes and hemoglobin concentrations to conciliate the necessity for oxygen.[(3)]

The aim of this study was to estimate hematological parameter in thalassemia Patients in comparing with healthy control.

Materials and Method

Thirty patients (15 males, 15 females) with thalassemia enrolled in this study with age from (30–42) years.

Data were collected from patient including name, gender, family history and other systemic diseases, while control group 20 (10 males, 10 females) and they were in healthy condition with age range from (30–45) years.

Sample of blood were collected from patient & healthy control for hematological parameters. Twenty µl of blood was added for 5 ml of Drabkinssolution, mixing and incubated for 5 meant at 37°C and results were estimated by using Hb meter at 450 nanometers wavelength [(4)].The content of trace element was determined by atomic absorption spectrophotometer [(5)].

The results were analyzed using T–Test and level of significant at $p<0.05$.

Result and Discussion

The present study describes that the number of thalassemia patient and normal group. The gender differences between male and female as a behavior, nutrition, lifestyle or stress, the present study was no significant $p<0.05$ differences between male and female Table 1, the result contrast with result of Al–jifrri 2017[(6)].

Table 1: Age mean average in thalassemia and normal group

Sample	No. of Males	Mean Year	No. of Females	Mean Year	Total
Normal	10	37.1	10	36.6	20
Thalassemia	15	38.2	15	39.1	30

The result obtained indicated that very different between patient and control with different metals by using atomic absorption, there was significant decrease in concentration of nickel and magnesium in patient as compared with control. Table 2. The deficiencies of trace elements might be a contributing factor development of iron deficiency anemia in this study Table 2, show that there was significant decrease concentration of nickel and magnesium among thalassemia patient as compared with control group, this result contrast with result of Abass in 2013 [7] and Gathwan in 2016 [8], they found the concentration of magnesium in saliva lower that in control group and Abd in 2017 [9] they found lower concentration of nickel and magnesium in anemic patient as compared with control .

Table 2: Nickel and magnesium comparison between patient and control (Mean ± SD)

Metal	Thalassemia Group (Mean±SD) µmole/L	Control Group (Mean±SD) µmole/L	P–value
Nickel	0.023 ± 0.001	0.032±0.0035	p<0.05
Magnesium	15.44±1.77	13.34 ± 1.92	p<0.05

In addition,there was significant decrease in concentration of hemoglobin and white blood cells count in blood of patient as compared with control Table 3 and this result contrast with result obtained in 2012 by Akinbami[10].

Table 3: Total hemoglobin and White blood cells comparison between patient and control (Mean± SD)

Sample	Thalassemia Group (Mean±SD) µmole/L	Control Group (Mean±SD) µmole/L	P–value
HB (gm/100 ml blood)	9.73± 1.72	13.1± 1.91	p<0.05
Total WBC (cell/µL)	4.88±2.7	5.78± 2.1	p<0.05

In conclusion of this study the changes of hematological and metal parameter can be depended on in diagnosis of anemia.

Assessment of Survival and Function of Heterotopic Auto-transplanted Thyroid Tissue after Total Thyroidectomy for Non-toxic Multinodular Goiters

Lamis Hammad Mohamed El Hadad[1], Amr Abdallah Mohsen[2], Mostafa Nagy El Sanadeky[2], Khaled Mahran[2]

[1]Assistant Lecturer of General Surgery, Faculty of Medicine, Minia University,
[2]Professor of General and Laparoscopic Surgery, Faculty of medicine, Cairo University, Egypt

Abstract

Background/Objective: Limited animal and human studies have shown function, albeit inadequate, of implanted thyroid tissue in muscles. This work aimed to ascertain results in a larger number of patients, finding practical method for implantation, studying the effect of changing weight of implant and effect of passage of time on its function. Method: Forty patients had total thyroidectomy for simple multinodular goiters. A piece of the excised gland was finely minced, mixed with saline as emulsion, and injected in thigh muscles. Twelve patients had 5-g implants, while 28 patients had 10-g implants. Four parameters were studied at 2 months, 6 months, and 12 months: technetium isotope uptake by the implant; thyroid stimulating hormone (TSH); free T3 (FT3); and free T4 (FT4). Results: All auto transplanted thyroid tissue survived and functioned. After 12 months, mean values (_ standard deviation) of isotope uptake, TSH, FT3, and FT4 of the 5-g implants were 0.44 _ 0.16%, 27.74 _ 30.4 UI/mL, 3.07 _ 1.10 pg/mL, and 1.01 _ 0.3 ng/dL, respectively. Those for the 10 g implants were 0.71 _ 0.20%, 22.78 _ 19.7 UI/mL, 3.92 _ 1.2 pg/mL, and 1.05 _ 0.3 ng/dL, respectively. Ten-gram implants showed significantly higher isotope uptake than 5-g. TSH, FT3, and FT4 significantly improved over the period of 1 year.

Conclusion: Injection of thyroid tissue suspension is a simple method for thyroid auto transplantation. TSH was elevated in the majority to maintain normal or near normal thyroid hormones. Ten-gram implants showed higher isotope uptake than 5-g, although this difference was not reflected by thyroid hormone profile. The implant seemed to function better with the passage of time from 2 months to 12 months.

Keywords: *Multinodular goiter; thyroid auto transplantation; thyroidectomy.*

Introduction

Whenever surgery is indicated for a simple multinodular goiter, the current trend is to do total thyroidectomy.[1,2] Inevitably this makes the patient dependent on replacement therapy for life. Although it seems relatively easy to control hypothyroidism by levo-thyroxine, from the patient's point of view, a daily dependence on it and regularvisits to hospital to check hormone levels are burdensome. Other problems that may interfere with reaching a euthyroidstatus using replacement therapy are malabsorption[3] and noncompliance of patients.[4] The clinical application of transplantation in the endocrine field, by auto transplantation of endocrine organs for hormone replacement has already been established in the field of parathyroid surgery. Before applying the same principles on the thyroid gland in humans, studies have been done on animals. Autologous transplantations were found to be successful in 70% of cases and histological

examinations showed normal thyroid architecture.[5-8] Very few studies have addressed this issue in humans. The number of patients in each study was very small,[9-12] the largest study including only 15 patients.[12] Furthermore, the study methodology was not consistent.

The aims of the current work were to ascertain these results in a larger number of patients, find a practical method of ransplanting sizable thyroid tissue, and study the effects of changing weight of implant and passage of time on its function.

Patients and Method

This case series study was conducted at Minia University Hospital and included 40 patients with simple multi nodular goiters who were indicated for total thyroidectomy because of compression manifestations, and where nodularity extended to both lobes. Children, unwilling patients, and those who had any clinical or ultrasound suspicion of malignancy were excluded. Similarly,those with a family history of thyroid cancer and history of neck irradiation were excluded because they constitute a high risk of developing thyroid cancer. The study included 36 women and four men. Written informed consent was obtained from all patients, stressing the importance of regular follow up. Preoperative evaluation followed the same standard protocol and included a thorough history,examination, thyroid function tests, neck ultrasound, and fine-needle aspiration cytology of a dominant or suspicious nodule.

Total thyroidectomies were performed under general anesthesia. During post excision hemostasis and closure a member of the operating team performed the auto transplantation preparation at a side table. The healthiest looking part of the thyroid was chosen. The slightest gross suspicion of malignancy led to termination of the implantation procedure. Intraoperatively, two patients were excluded from the study on gross picture suspicion of malignancy. Neither showed cancer on histological examination of postoperative paraffin sections.

The initial 12 patients received 5-g implants, while the remaining 28 received 10-g implants. The tissues to be transplanted were very finely divided using a pair of scissors and made into an emulsion by adding them to saline in a 20-mL syringe. This was attached to a 2.4 mm-caliber needle. A 3-mm incision was made in the anterolateral aspect of the middle third of the thigh. Through this incision thethyroid tissue emulsion was injected in 8e10 sites in the thigh muscles by changing the direction and depth of needle introduction.

Results

Apart from minor complications, postoperative courses were uneventful. Temporary recurrent laryngeal nerve occurred in one patient and resolved spontaneously in 4 weeks. Temporary hypoparathyroidism occurred in 11 patients and was controlled by oral calcium and vitamin D. The condition resolved within 3e7 weeks. There were no complications related to the auto transplantation site. None of the excised thyroids showed histological evidence of malignancy.

12 mo	27.74 ± 30.4	16.6	22.78 ± 19.7	3

SD = standard deviation.

Discussion

The purpose of heterotopic thyroid auto transplantation is to leave thyroid tissue in the body that might be able to avoid or reduce severity of post-thyroidectomy hypothyroidism in noncompliant patients. In the meantime, if recurrence occurs it would not be in the neck, thus avoiding compression on the trachea and avoiding dangerous reoperation in the neck. Reports on its clinical application are very scarce in the literature, with few patients in each study. Furthermore, none of these studies focused on simple multinodular goiters; the majority were directed to Graves' disease. The only well documented study that addressed this issue with a few multi nodular cases was that of Roy et al[12]who included eight multi nodular goiters among their studied 15 patients.

In the best documented technical description, that of Shimizu et al,[11] the workers implanted 2.5e3.5 g per patient with Graves' disease. For the current work, the implanted tissue was expected to be less active and hence at the start of the study 5-g implants were implanted for the first 12 patients. As functional results of these patients were found to be suboptimal, the weight of implanted tissue was raised to 10 g. The problem with implanting suchsizable amount of tissue was that many muscle pockets are made; they would be over-packed with the implanted thyroid tissue, a factor that may hinder the graft take. The procedure would also take an unacceptably long time. In 2000, Gauger et al[13] described the technique of injecting parathyroid emulsion in the sternomastoid. Their technique was adopted in this work for thyroid tissue implantation using a 20-mL syringe with saline. This technique simplifies the implantation of sizable tissues, in a short time (w15 minutes), and leaves a small, barely visible scar. With this technique all implants survived and functioned.

In the literature there is no previous mention of the effect of time passage on the function of thyroid auto transplant. In the current work, however, this point wasinvestigated. Analysis of variance showed that the levels ofFT3 and FT4 increased with time, and likewise TSH showedsignificant move towards normalization, i.e., reduction ofits levels. Even though isotope uptake showed also a tendencytowards elevation, it did not reach statisticalsignificance.

Conclusion

Injection of thyroid tissue suspension is a simple method for thyroid autotransplantation. TSH was elevated in the majority to maintain normal or near normal thyroid hormones. Ten-gram implants showed higher isotope uptake than 5-g, although this difference was not reflected by thyroid hormone profile. The implant seemed to function better with the passage of time from 2 months to 12 months

Somatic Manifestations of Depression in Patients of Nineva Province

Mahfoodh Sulaiman Hasan[1], Faris Mahmode Lolan[2], Abdullah Shakier Mahmood[2]

[1]Assist. Professor, 2Lecturer, Ninevah University, College of Medicine, Department of Internal Medicine

Abstract

Objective: To understand the somatic manifestations in patients with depression in Mosul area.

Method: In this study 234 patients with depression attending a civil psychiatric clinic in Mosul City in the period between 22nd of January 2017 to 22nd of November 2018 diagnosed according to the Diagnostic and Statistical manual of the American Psychiatric Association VIR (DSMVIR) as depression were examined for somatic manifestations, and any other medical disorders.

Results: Joints and muscles pain was the most common feature in the depressed patients, it was found in (52.1%) of the patients. Headache was the next common, (51%), followed by abdominal discomfort which was found in (47.8%) and chest pain in (44.4%), then the generalized weakness in (22.5%). Menstrual dysfunction was found in (33.8% of female patients) and sexual dysfunctions were found in (28.2% of male patients).

The higher incidence among females is due to the social roles of gender, the lower educational levels among females, and probably to avoid the stigma.

Conclusion: Identifying somatic manifestations among depressed patient is important in diagnosis, planning a successful management and in prognosis.

Keywords: *Depression, Somatic manifestation.*

Introduction

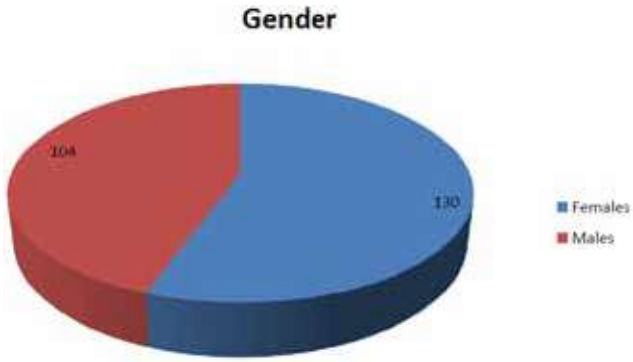
Depression is one of the most common psychiatric illness, most of these patient complaint from somatic manifestation formerly known as a somatoform disorder, is any mental disorder which manifests as physical symptoms that suggest illness or injury, but which cannot be explained fully by a general medical condition or by the direct effect of a substance, and are not attributable to another mental disorder (e.g. joint and muscle pain, headache, abdominal pain and chest pain)

Aim of the Study: To understand the somatic manifestations in patients with depression in Mosul area.

Patients and Method: 234 patients with depression attending the private clinic in the period between 22nd of January 2012 to 22nd of November 2013 diagnosed according to the Diagnostic and Statistical Manual of the American Psychiatric Association VIR (DSMVIR) as depression were examined for somatic manifestations, and any other medical disorders. The results were analyzed using standard deviations and Chi square.

Results: During the 11 months 234 patients with depression were examined.

Gender: Most of the patients were 130 females and 104 males (55.5% and 44.5% respectively). There is no significant difference between the two ($p<0.05$). Figure 1.



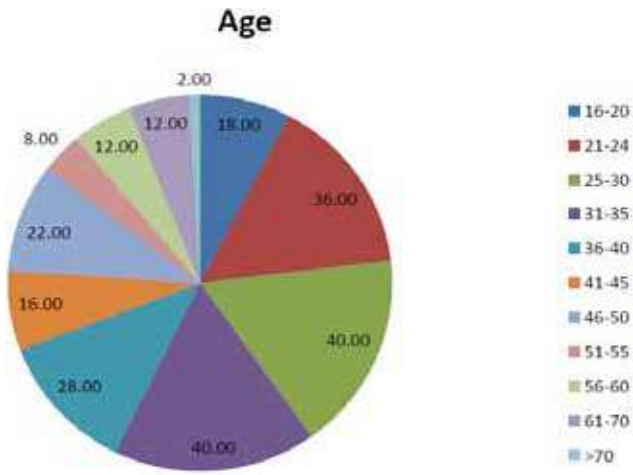
Age: Four patients were 16 years old and 2 patients around 70 years.

The other 228 patient's ages range between 17 and 67 years.

The table below shows the age groups according to No. of patients. Mean =35.63 SD=10.34

The difference is highly significant between the working age group (25-45y) and the non-working age group (16-24y and 46-70y) at P<0.05. Figure 2

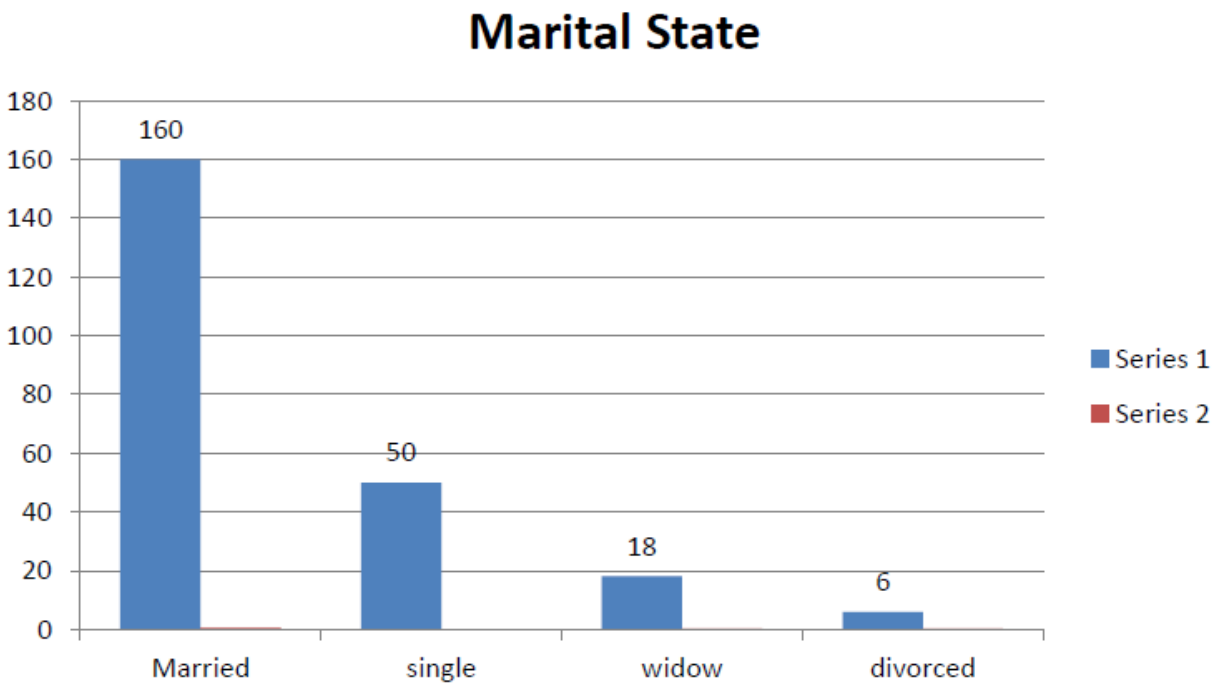
Figure 2 Age:



Marital State: The married patients were 160 (68.4%), fifty were single (21.4%), eighteen were widowed (7.7%) and the divorced were the least 6 patients representing (2.5%).

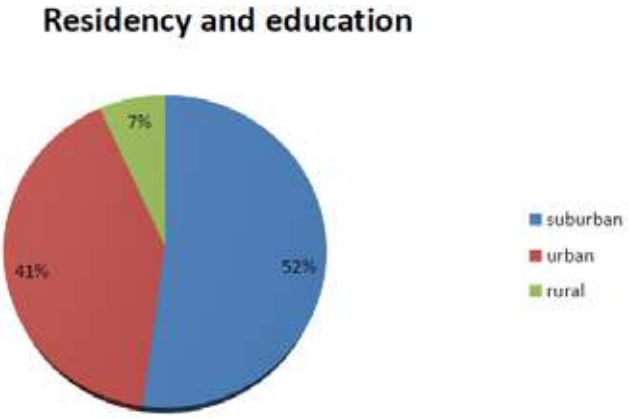
The difference between and married and other groups is highly significant. P<0.05. Figure 3

Figure 3 Marital State:



Residency and Education: Most of the patients (122) were from the suburban areas representing (52.1%), then the urban citizens 96 patients (41.1%), patients from rural areas were the least (16) representing (6.8%).

With significant difference between urban and non-urban areas. P<0.05. Figure 4



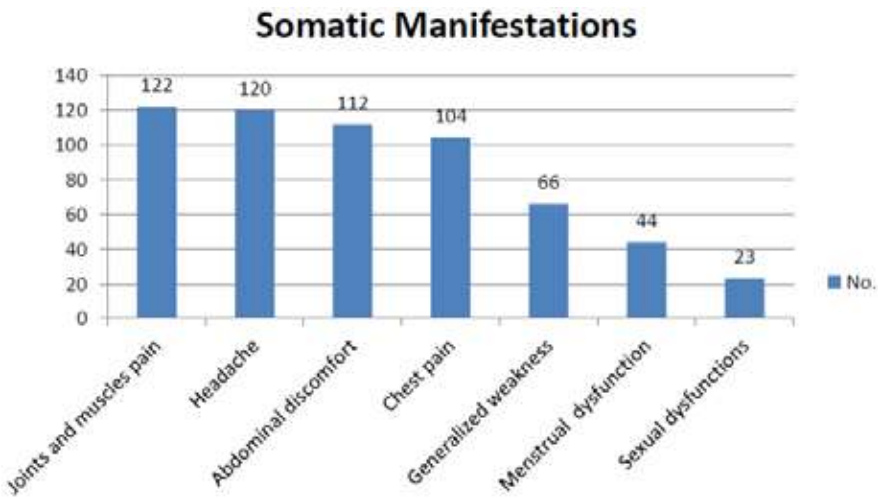
Previous History: Most of the patients (164) representing 70% had no previous history of depression while 70 (22 females and 48 males) patients representing (30%) had such history.

With significant difference between the two. P<0.05. Figure 5

Somatic Manifestations:

The somatic manifestations found in our patients are as follow: Joints and muscles pain was the most common feature in the depressed patients, it was found in 122 patients (52.1%). Headache was the next common, 120 patients (51%), followed by abdominal discomfort which was found in 112 patients (47.8%) and chest pain in 104 patients (44.4%), then the generalized weakness in 66 patients (22.5%). Menstrual dysfunction was found in 44 females (33.8% of female patients) and sexual dysfunctions were found in 23 males (28.2% of male patients). Figure 6

Figure 6 Somatic Manifestations:



Discussion

Headache abdominal pain musculoskeletal pain and sexual dysfunction are common in patients with depression, beside those patients with depression often present with somatic manifestations, usually seen by general practitioners and family doctors before psychiatrists [1].

Recognizing such patients in proper diagnosis and effectively treating them will improve their quality of life and may reduce their current excessive use of health care resources. Somatic symptoms identified by the general practitioner may be useful indicators for predicting major depression[2]. It is important to remember that depression is one of the leading health

burdens and usually the patient will present his illness with psychological and somatic complaints although in primary care somatic complaints dominate[3].

Probably the primary health care unit is the ideal place to diagnose depression, but not uncommonly the somatic symptoms may lead to miss diagnosis[4 & 5].

Some researchers showed that headache Musculoskeletal complaints and dizziness, gastrointestinal, cardiovascular and genitourinary symptoms are the most common somatic features in depression[3].

The similar features are found in our study. Musculoskeletal complaints and headache the prominent somatic manifestations, usually the patient told about the distress caused by these symptoms and the inability to explain their causes.

While abdominal discomfort was explained as having irritable bowel syndrome, either by the patient himself, a medical staff, or sometimes by a physician. Commonly these patients were under treatment of irritable bowel syndrome and or even duodenal ulcer.

Chest pain or precisely discomfort, generalized weakness, menstrual dysfunction and sexual dysfunction, more or less were understood by the patients as direct effects of their low mood and bad temper[6].

Depressive symptoms and syndromes are common in the medically ill, although they are frequently unrecognized and untreated[5&9].

In our study 30% of the patients have comorbidity especially diabetes and it is known that depression is not uncommon among diabetic patients and the relationship between the two disorders is bidirectional[7].

Most of the studies stated that incidence of depression is higher among females than males [3, 4, 6] in our study females outnumber males (130 vs. 104) although with no significant differences reflecting the transcultural variation, in expressing stress and psychiatric disturbances. Difficulties of the life during the years of war and the nature of stresses shared by the whole society may explain this point.

Somatic manifestations in depression seem to be more often in ages associated with social and occupational responsibilities. In this study the main bulk of patients fall in the age range of 25-45 years, maturity, decline, life-cycle stage, survival, and historical trend play important role in depression in such ages. Other studies found somatic manifestations specially appetite change are more common among older patients[8&9].

In Iraq residency reflects the socio-educational status, citizens of the cities usually of higher education and better economic facilities, although the life difficulties are more or less similar in both urban and non-urban areas.

Women are more frequently subjected to depression for genetic, hormonal and environmental causes[10,11&12] beside that they have less chance for higher education than men, and this may explain why most of our patients with somatic manifestations are women from sub-urban areas.

Internal migration for security reasons could be considered as another cause.

Sex Determination in a Sample of Egyptian Population based on Outer and Medullary Metacarpal Measurements. A Multi-Detector Computed Tomographic Study

Mennatallah Mahmoud Ahmed Mohamed[1], Hala Mohamed Ahmed and Osama Abdelaziz Hassan[2], Moustafa Abdelkader Abdelwahab[3], Rehab Hosni Abdelkareem Younis[4]

[1]Assistant Lecturer of Forensic Medicine and Toxicology, [2]Professor of Forensic Medicine and Toxicology, [3]Assistant Professor of Radiodiagnosis, [4]Assistant Professor of Forensic Medicine and Toxicology (Minia University–Faculty of Medicine-Egypt)

Abstract

Prediction of sex from incomplete and decomposing skeletal remains is vital in establishing the identity of an unknown individual. The purpose of this study is to assess the applicability of outer and medullary parameters of third and fourth metacarpals using multi-detector computed tomography in sex determination in Egyptian population. All measurements showed significant sexual differences ($P < 0.05$). By simple discriminant analysis, mediolateral diameter of midshaft of the third metacarpal showed the highest percentage of accuracy (69%) in sex determination. This study concluded that metacarpals are useful bones for sex determination and also it imposes new forensic standards for determination of sex in Egyptian metacarpals using various discriminant formulae.

Keywords: *Sex Determination; Metacarpals; Multi-detector Computed Tomography*

Introduction

Sex determination is the classification of an individual as either male or female. To achieve an assignation of sex, anthropologists use biological characteristics that vary between both sexes [1].

The personal identification from extremities becomes very important in cases of mass disasters where there are a recovering hands separated from the body [2]. There extensive uses are because of the high incidence of recovery of these compact bones in both forensic and archaeological situations [3,4].

The real advance toward a more extensive and effective use of imaging techniques in forensic medicine was prompted by the discovery of computed tomography (CT) due to its capability to provide 3D representation of the body structures in a few minutes [5].

The metacarpals are favored because they are the largest, remain complete in most damaged conditions and most easily identifiable bones of the hand [6]. Therefore, the aim of this study was to assess the relationship between the outer and medullary measurements of metacarpals and sex and to allow the sex of an individual to be diagnosed from these measurements in a sample of Egyptian population by using a multi-detector computed tomography (MDCT) scanning and developing a set mathematical models from discriminant function analyses.

Subjects and Method

This study was conducted on 200 patients (100 males and 100 females) with age ranged from 25 to 65 years at the Radiology Department of Minia University Hospital. These patients were subjected to MDCT for their third and fourth metacarpal bones of right hands. Patients with metacarpal fractures or deformities

(acquired or congenital), skeletal immaturity, bone tumors, growth disorders, connective tissue diseases and previous orthopedic surgery of metacarpal bones were excluded from the study.

Axial cuts were taken on the Rt. hand including the metacarpals from MDCT and then reconstructed coronal and sagittal images were generated as well as the 3D reformatted images that were used to obtain the following measurements. The measurements have been modified from Basir [7] and Nathena et al. [8] as follow:

- Maximum metacarpal length (ML): Is described as the overall external dimension of a metacarpal in its longitudinal direction. Two transverse lines were first drawn touching the distal and proximal ends of the bone. The distance from the mid-point of the transverse line to the mid-point of the other line was taken to be the maximum metacarpal length.
- Medio-lateral diameter of mid shaft (MLDM): Is described as the widest part of mid shaft of the metacarpal in the transverse direction which was shown in medio-lateral view.
- Medullary length of the metacarpals (MdL): Two longitudinal lines were drawn touching the distal/proximal dorsal aspect and the distal/proximal volar aspect respectively.

The collected data were coded, tabulated and statistically analyzed using SPSS program (Statistical Package for Social Sciences) software version 24. Descriptive statistics were done for numerical data by mean, standard deviation and minimum & maximum of the range.

Results

The mean age of tested cases was 49.01 years with standard deviation (SD) ±10.02. Descriptive statistics of different measurements of the right third and fourth metacarpals among all cases and independent-samples t test revealed highly significant increase in males when were compared with females ($P < 0.05$). Table 1 and Table 2.

Simple discriminant functional analysis for sex prediction using right third and fourth metacarpal measurements revealed that the highest accuracy was obtained with usage of MLDM of third metacarpal (69%).

Discussion

Sex determination is one of the crucial steps when it comes to establish an individual's biological profile. A significant problem with relying on these bones is that they can be fragmented, damaged or poorly preserved which makes it necessary to search for new bones to identify the individual [9].

All the studied subjects were adult because sex differences become evident only after the end of puberty when the skeleton has completed its growth [10]. Sex differences in the shape, size and appearance of bones arise during development according to individual genetic markers and in response to sex hormones during puberty [11].

The current study is in acceptance with Navsa et al.[12] who conducted a study on 200 hand bones from sex-race group (50 white males, 50 black males, 50 white females and 50 black males) (age 21-80 years) from a South African population.

These results are in harmony with that of Eshak et al.[13] who measured the lengths (2D measurements) of all metacarpal bones and the volumes (3D measurements) of the 2nd and 4th metacarpal bones from 122 Egyptian individuals (60 males and 62 females). They stated that males presented with significantly greater mean values than females for the lengths of metacarpal bones and the accuracy was ranged from 71.4% to 92.9%. They also proved that the 2nd & 5th metacarpals had the highest accuracy.

The mentioned results correspond with previous results of Khanpetch et al. [14] who used 249 skeletons (154 males and 95 females) from a Thai population. Six measurements were taken on each metacarpal, namely maximum length, medio-lateral base width, antero-posterior base height, medio-lateral head width, antero-posterior head height and mid-shaft diameter.

These results are consistent with the results of Singh et al. [15] who studied 143 metacarpals after obtaining x-ray of both hands from North Indian population sample.

The present results go with this of Ameri et al. [16] who investigated the possibility of estimating

gender using metacarpals dimensions in 200 Iranian adult persons (100 male and 100 female) without any background of specific disease. The length metacarpal was measured in millimeter and reported in ratio.

The current study comes in conjunction with what was mentioned by Kusec et al. [17] who conducted a morphometric analysis of six metacarpal bones (second, third and fourth of right and left hands) on hand radiographs of 434 male (aged between 19 and 86 years) and 549 female (aged between 19 and 79 years).

The reverse was found by Zanella & Brown [18] who estimated the applicability of discriminant function analysis comparing the correspondence results of the equations of previous studies based upon measurements from metacarpals. They used 23 adult cadavers and data were subjected to regression equations and linear discriminant analysis.

Conclusions

The present study proved that the right third and fourth metacarpals have a considerable value in predicting sex among Egyptian population by using discriminant function analysis. These will help in medico-legal cases for establishing the identity of an individual when only some remains of the body are found. This study has decreed new significant parameters of third and fourth metacarpals to be used in forensic medicine.

Predicting Patient Survival after Pancreaticoduodenectomy for Malignancy Based on Histopathological Criteria

Michael Remon Roshdy[1], Abu Bakr Mohammad Mohie EL-Din[2], Khaled Aly Abou EL-ella[3], Nasser Mohammad Zaghloul[4], Motassem Mohammad Ali[5]

[1]Assistant Letterer of General Surgery, Faculty of Medicine-Minia University, [2]Professor in General Surgery and Hepato Pancreato Biliary Surgery, Faculty of Medicine-Minia University, [3]Professor in Hepato Pancreato Biliary Surgery, National Liver Institute- Menoufiya University, [4]Professor in General Surgery and Laparoscopy, Faculty of Medicine-Minia University, [5]Professor in General Surgery and Hepato Pancreato Biliary Surgery, Faculty of Medicine-Minia University, Egypt

Abstract

This Study Aimed to identify histopathological variables that might contribute to survival, mortality of patients,and serious complications after pancreaticoduodenectomy.

Patients and Method: This is prospective hospital based study that been done on all patients who underwent pancreaticoduodenectomy in National Liver Institute and Minia university hospital between the first of January 2015 till the end of December 2016. in the surgical department, National Liver Institute, Menoufiya University and Minia university hospital.

Results: We found that perineural infiltration and lymphovascular invasion were independently significant in multivariate analysis, the effects of combining them in terms of predicting longterm survival is very important .Smaller and well-differentiated tumours were associated with significantly better patient survival ($P < 0.03$ and $P < 0.01$, respectively). Positive lymph nodes were associated with reduced survival ($P < 0.003$).

Conclusion: The analyse the histopathological parameters influencing longterm patient survival after pancreaticoduodenectomy focusing on perineural infiltration and lymphovascular invasion as predictors of longterm survival.

Keywords: *Pancreaticoduodenectomy; histopathological; tumours.*

Introduction

Pancreatic malignancies overall are associated with poor longterm prognosis. Five-year survival rates following pancreatic resection for pancreatic adenocarcinoma remain low (<20%), even in large-volume institutions. This cohort had a median follow-up of nearly 5 years and an actuarial survival of 27%, which is comparable with the recently published MD Anderson series. (1).

Historically, pancreaticoduodenectomy (PD) has been associated with high rates of mortality and morbidity. The mortality rate was higher than 30%. Recently, several high-volume centers have reported markedly improved mortality rates, as low as 1–2%. Postoperative morbidity, however, remains common (2).

Pancreaticoduodencetomy is a therapy indicated for malignant diseases localized in the periampullary region, Furthermore, patients with benign lesions of this area in

which a malignancy cannot be ruled out preoperatively may also benefit from this surgery [3].

Aim of the Work: We aimed to assess prognosis and predict patient survival following pancreaticoduodenectomy based on lymphovascular invasion, perineural infiltration,lymph node status and lymph node ratio in patients candidate for Whipple operation for malignancy.

Patients and Method: Patients presented with pancreatic head mass or periampullary carcinoma candidate for whipple operation from january 2015 to December 2016, in the surgical department, National Liver Institute, Menoufiya University and Minia university hospital on .

This study included 40 patients of presented with pancreatic head mass or periampullary carcinoma candidate for whipple operation of either sex with age not less than 18 years old; operated by open exploratory maneuver through bilateral subcostal incision.

Operative Technique: All exploratory procedures were done under general anesthesia and naso-gastric tube was inserted to diminish the size of the stomach and to reduce the distension of small bowel. A Foly's urethral catheter was inserted to be removed in the recovery room.

Our technique utilizes a bilateral subcostal incision (Chevron incision). The liver and peritoneal surface is carefully examined to exclude the presence of metastatic disease, and intraoperative ultrasonography of liver and pancreas is performed. Adequate exposure is essential for proper Whipple's operation. Good retraction with self-retaining retractor makes assistant's hands free to help the surgeon during surgical procedure. Bipolar cautery, ligaseal, harmonic scalpel are of benefits including staplers to divide stomach and duodenum. Initial mobilization is done by reflecting the hepatic flexure and transverse colon downwards; then extended Kocherisation is done by lateral duodenal ligament which exposes SMV, IVC and aorta partly. Invasion or encasement of these vessels will prevent from proceeding with resection; just essential bypass will be sufficient. Middle colic vein when traced will help in identifying the SMV.

Gastrojejunostomy is done 20 cm distal to the hepaticojejunostomy as an antecolic anastomosis. As already stomach is transected with stapler earlier during procedure, gastrojejunostomy is done using linear stapler device just proximal and posterior to the stapled line. Single layer 3-zero vicryl hand sewn anastomosis also can be done.

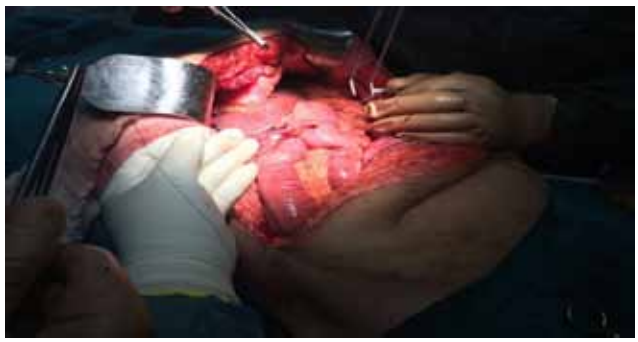

Fig. (1): Gastrojugenostomy anastomosis

Fig. (2): The specimen after removal

Statistical Analysis: All collected data were tabulated, graphed and mathematically analyzed. Numerical data expressed as mean±SD and categorical data were expressed as number and percent (%). T-student test was used to compare numerical data, and Chi-square test was used to compare categorical data. P-value was considered to be significant if it was less than 0.05

Results

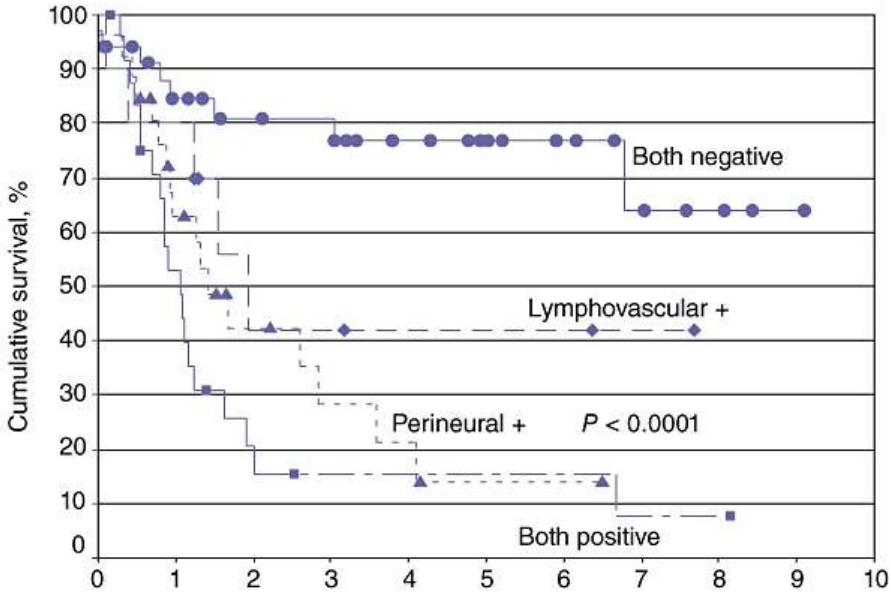
This study included 40 patients presented with pancreatic head mass or periampullary carcinoma candidate for whipple operation of either sex with age not less than 18 years old; operated by open exploratory maneuver through bilateral subcostal incision from january 2015 to December 2016, in the surgical department, National Liver Institute, Menoufiya University and Minia university hospital.

**Multivariate analysis:

**When all the significant histopathological parameters on univariate analysis were assessed using

a multivariate regression model, perineural infiltration ($P< 0.03$) and lymphovascular invasion ($P= 0.05$) were the only independent factors prognostic for longterm survival.

****Prognostic modelling using perineural infiltration and lymphovascular invasion:** perineural infiltration ($P< 0.03$) and lymphovascular invasion ($P= 0.05$) were the only independent factors prognostic for longterm survival. As these two factors were independently significant in multivariate analysis, the effects of combining them in terms of predicting longterm survival were analysed. The 40 patients with malignancies were divided into four categories consisting of those who were positive for both parameters, those who were positive for either one of the parameters and those who were negative for both. Figure 3 illustrates that patients who were negative for both parameters had significantly better survival than the other groups ($P < 0.0001$).



No. at risk (n = 96)											
Both negative	35	25	21	20	15	12	8	5	3	1	0
Lymph vascular +	10	8	3	3	2	2	2	1	0	0	0
Perineural+	26	14	7	4	3	1	1	0	0	0	0
Both positive	25	12	3	2	2	2	2	1	1	0	0

Figure 3: Cumulative patient survival in the presence or absence of perineural infiltration and lymphovascular invasion after resection. Survival is significantly improved if both features are absent on microscopic examination

Table (1): Five-year survival rates after pancreaticoduodenectomy for pancreatic malignancies in patients positive and negative for perineural infiltration and lymphovascular invasion (n= 40)

	Perineural −	**Perineural +**
Lymphovascular −	77%	14%
Lymphovascular +	42%	15%

Likewise, when these parameters were appliedto patients with pancreatic adenocarcinoma, those who were negative for both parameters had an excellent actuarial 5-year survival of 71% compared with the other three groups

Discussion

We studied the effect of different variables on patient's outcome within the first 6th months and first

two year survival after pancreaticodudenectomy. The 6th month's time was chosen because the majority of the major complications and mortalities after pancreaticoduodenectomy have been reported to occur within this period.

Identification of key variables will be essential if improved clinically acceptable models are to be built in the future. Although many variables that are clinically assumed to be important in survival may not reach statistical significance in multivariable models, the ability to test the effect of clinically relevant variables will increase the face value of statistical prediction [4]

The 5-year survival for patients who underwent pancreaticoduodenectomy for periampullary malignancies other than pancreatic adenocarcinoma was 61%. This result is also in line with previously published results for periampullary carcinomas, including a recently published series from Birmingham which reported an actuarial 5-year survival of 60% for ampullary carcinoma following resection. [5] .

Also the results of our study are agree with the results of the study done by Chen JW et al which shows that Patients who underwent resection had 1-, 3- and 5-year survival rates of 70%, 46% and 41%, respectively. The 1-, 3- and 5-year survival rates for periampullary cancers other than pancreatic adenocarcinoma were 83%, 69% and 61%, respectively; those for pancreatic adenocarcinoma were 62%, 31% and 27%, respectively ($P < 0.003$).[6]

In our study we confirmed that smaller and well-differentiated tumours were associated with significantly better patient survival ($P < 0.03$ and $P < 0.01$, respectively) and Positive lymph nodes were associated with reduced survival ($P < 0.003$) this is agree with the study done by[6]which confirms that Poor tumour differentiation ($P < 0.02$), tumour size >3 cm ($P < 0.04$), margin <or=2 mm ($P < 0.02$), nodal involvement ($P < 0.003$), were associated with poorer prognosis.

In our study we confirm that Smaller and well-differentiated tumours were associated with significantly better patient survival ($P<0.03$)

In our study presence of histopathologically positive perineural infiltration and or lympho vascular invasion carries poor prognosis regard to survival this matches with the results of the study done by [6] which confirms that perineural infiltration ($P < 0.0001$) and lymphovascular invasion ($P < 0.002$) were associated with poorer prognosis. In a multivariate analysis .

Conclusion: We concluded that The absence of malignant perineural infiltration andlymphovascular invasionwas associated with highly significantly improved survival .

Assessing Adverse Cardiac Effects of Direct Antiviral Agents in Hepatitis C Virus Infected Patients

Mohamed Abdel Azem Mohamed[1], Mohamed Fathy Abbas[1], Ahmed Hefnawy Abbas[2], Meriam Nabil Nasseif Rezk[2]

[1]Professor of Clinical Toxicology, [2]Assistance Lecturer of Clinical Toxicology, Forensic Medicine & Clinical Toxicology, Minia University, Minia, Egypt

Abstract

Objective: To evaluate the effect of the direct antiviral agents (DAAs) which are recently involved in treatment of hepatitis C virus (HCV) patients on the cardiac function.

Patients and Method: The study conducted on one hundred subjects with hepatitis C virus (HCV) and treated with doses of sofosbuvir (SOF) plus daclatasvir (DCV) only or in addition to weight-based ribavirin (RBV) for 12 weeks. Level of human plasma B type naturetic peptide (BNP), and left ventricular ejection fraction (LVEF) measured by echocardiography were evaluated to all subjects included before starting treatment and at the sixth week and after the twelfth week of the treatment.

Results: There were significant differences in levels of BNP and LVEF measurements through different times compared.

Conclusion: The patients included in the study with affected LVEF did not have heart failure symptoms. Statistically significant differences between parameters measured remained within the normal range.

Keywords: *Cardiotoxicity, hepatitis C virus, direct antiviral agents.*

Introduction

Chronic hepatitis C virus (HCV) infection affects more than 3% (170 million) of the world's population and is a major cause of liver cirrhosis and hepatocellular carcinoma.[1]

National Egyptian health project survey held in 2015 which was performed to describe the prevalence of hepatitis C virus (HCV) infection. The study showed that in the 15–59-year age groups, the prevalence of HCV antibody was found to be 10.0% (95% CI 9.5–10.5) and that of HCV RNA to be 7.0% (95% CI 6.6–7.4). In children, 1–14 years old, the prevalence of HCV antibody and HCV RNA were 0.4% (95% CI 0.3–0.5) and 0.2% (95% CI 0.1–0.3) respectively.[2]

Additionally, 3.7 million Egyptian citizens were suffering from chronic HCV infection in the age group 15–59 in 2015. The Egyptian government started a national project aiming to diagnose and cure HCV through whole Egypt.[2,3]

Food and Drug Administration (FDA)has approved new regimens for HCV treatment involving direct-acting antivirals (DAAs) that target different steps in the HCV life cycle which created a breakthrough in HCV combatting.[4,5]

The new DAAs include SOF, sold under the brand name sovaldi, which is recommended with some combination of ribavirin, peginterferon-alfa, simeprevir, ledipasvir and/or daclatasvir. The declared cure rates reached 30 to 97% depending on the type of hepatitis

C virus involved. The pronounced side effects included feeling tired, headache, nausea, and trouble sleeping.[6,7]

Lately, after the FDA announcement of the possible effect of DAAs on heart,ongoing surveillance of DAAs for cardiotoxicities may be beneficial, especially among patients at higher risk for cardiovascular disease.[7, 8]

Aim of the Work: To study the possible cardiotoxic effects associated with direct antiviral agents (DAAs) used in HCV infected subjects treatment.

Patients and Method

Study design and population: This study was carried out over a period of 22 months; from 1st May 2017 till 31 th March 2019 on 100 subjects diagnosed as infected by hepatitis C virus (HCV) and treated with doses of SOF plus DCV only or in addition to weight-based RBV for 12 weeks. They were recruited from two centers in Minia governorate. These centers were the western medical center at Minia city and El-yom EL-wahed hospital at Samalout city. The study was conducted on Minia university hospital. Their ages were between 42-59 years. Both sexes were included in the study. History and clinical examination were recorded on a standardized report forms involved age, sex, vital signs and physical exams. They were 56 males and 44 females. Subjects were selected according to inclusion and exclusion criteria.

Inclusion Criteria: Patients diagnosed with HCV by positive polymerase chain reaction (PCR) and their ages ranged between 18- 60 years old.

Exclusion Criteria: Patients with Child´s classification grade C cirrhotic patients, Hepatocellular carcinoma (HCC), except 6 months after intervention, or extra- hepatic malignancy except after two years of disease-free interval (in cases of lymphomas and chronic lymphocytic leukemia). Pregnant patients and patients unable to use effective contraception were excluded. Inadequately controlled diabetes mellitus (HbA1) patients and patients with liver disease other than HCV infection were excluded. Patients with QTc interval ≥450 ms or a personal or family history of torsades de pointe were excluded. Patients were excluded if their investigations included one of these findings: Platelet count <50,000/mm^3, Creatinine clearance <50 mL/min, serum creatinine ≥1.5, and or human immunodeficiency virus (HIV) infection.

Method

It included transthoracic echocardiographs (TTEs), and B-type natriuretic peptide (BNP) levels. Parameters were assessed before beginning of the treatment (week 0), sixth week of the treatment (week 6), after ending the treatment (after week 12).

Human plasma B type naturetic peptide (BNP): For BNP (a sensitive marker of myocardial stress), one cm venous blood sample was collected from each subject in a syringe and was sent to the laboratory of clinical pathology, Minia University Hospital. The kits used were bought from Glory Science Company in China.

The patient's BNP level was considered normal if normal if less than 125 pg/ml. [9]

Left ventricular ejection fraction (LVEF): Assessing LVEF was done by echocardiographic studies which were performed using Echocardiograpy, MECANSET, High Class Trolley 3D 4D Color Doppler Ultrasound, CHINA. Each subject was examined in a semisupine left lateral position. Images were obtained at end expiratory apnoea and stored in cine loop format from three consecutive beats. All echocardiographic measurements were performed according to the recommendations of American Society of Echocardiography/European Association of Cardiovascular Imaging (ASE/EACVI) guidelines[10] by a specialized cardiologist.

Left ventricular ejection fraction (LVEF) measurements were divided according to American Herat Association into 3 groups: normal 50%-70%, borderline: 41%-49%, reduced 40% or less. [11]

Statistical Analysis: All data were checked, coded, entered, tabulated and analyzed by using SPSS (Statistical Package for Social Sciences) version 20.0 software. Statistical method included: Friedman test for non-parametric quantitative data and ordinal qualitative data between the different times. Wilcoxon signed rank test for non-parametric quantitative data and ordinal qualitative data between each two times. Descriptive method included: median and range were used to quantativedata. Qualitative data were summarized as number and percentage. $P < 0.05$ was considered significant and $P > 0.05$ was considered insignificant.

Results

Regarding BNP, there was high significant difference between BNP levels at week 0, week 6 and after week 12. There was high significant increase in frequency of abnormal BNP levels at week 6. The interquartile ranges of BNP at week 6 and after week12 were less than 125 Pg/ml (Table 1).

Regarding LVEF measured by echocardiography. There was high significant increase in frequency of reduced LVEF at week 6 and after week 12. There were 6 cases with borderline LVEF and 15 cases with reduced LVEF at week 6. After week 12, there were 12 cases with borderline LVEF and 9 cases with reduced LVEF (Table 2).

Table (1): Showing BNP levels (Pg/ml) difference at week 0, week 6 and after week 12 of treatment regimen.

		At week 0	At week 6	After week 12	P value
		N=100	N=100	N=100	
BNP	Median IQR	24.6 [a] (18.8-33.1)	72.4 [c] (56.8-98.9)	57.4 [b] (47.3-83.3)	<0.001*
BNP	Normal Abnormal	100(100%) [a] 0(0%)	88(88%) [b] 12(12%)	98(98%) [a] 2(2%)	<0.001*

Superscripts with small letters indicate significant difference between each two times., *: Significant level at P value < 0.05., IQR:interquartile range., N=number of cases.

Table (2): Showing LVEF difference at week 0, week 6 and after week 12 of treatment regimen

		At week 0	At week 6	After week 12	P value
		N=100	N=100	N=100	
Left ventricular ejection fraction	Normal Borderline Reduced	100(100%) [a] 0(0%) 0(0%)	79(79%) [c] 6(6%) 15(15%)	79(79%) [b] 12(12%) 9(9%)	<0.001*

Superscripts with small letters indicate significant difference between each two times, *: Significant level at P value < 0.05.

Discussion

Application of newly developed drugs on large scale of population may reveal unexpected adverse effects. DAAs cardiotoxicity may be evident when these drugs were recently introduced to markets as HCV curing agents.More accurate studies to monitor DAAs cardiotoxic effects were needed. [8]

The first report was published by Ahmad et al., who evaluated BNP retrospectively from frozen serum collected before and after treatment discontinuation, discovered increase in BNP in patients with severe and moderate systolic cardiomyopathy and in patients with normal LVEF. Abnormal BNP levels was recorded in 5 of 6 cases with LVEF< 30% and 4 of 8 patients with LVEF 30%-49%, and 2 of 20 cases with LVEF ≥50%; Although plasma BNP levels were raised over baseline, in most cases, were not significantly elevated above normal reference ranges. Most cases exhibited recovery of cardiac function showed recovery in most cases after treatment discontinuation however, and no patients had elevated troponin levels. It was concluded that those biomarkers likely have little utility as screening method.[8]

Regarding LVEF, Ahmad et al. evaluated LVEF in 34 patients who received DAAs for approximately 1-6 weeks. Fourteen (39%) treated patients were noted to have LVEF <50%: 6 had LVEF <30% and 8 had LVE30%-50% at one or more evaluations in the 6-month period. Ahmad et al. considered that cardiac dysfunction was dose related as higher doses of DAAs were associated with higher incidence of cardiac dysfunction.[8]

The accepted explanation of different results in this study may be due to wide range difference in sample sizes and time of samples evaluation.

El-Adawy et al. in Egypt included 390 HCV infected patients divide into 4 groups of 4 different regimens of

DAAs. They observed significant elevation of BNP level in all groups of their study especially in the group of (SOF+DCV+ RBV) (P value <0.001).El Adway et al. evaluated cardiac function in by cardiac magnetic resonance (CMR), There was significant difference LV dysfunction especially in group received SOF, DCV and RBV group with P<0.001.[12]

Mazzitelli et al. who assessed cardiac dysfunction by longitudinal strain (GLS) in 82 patients received DAAs observed statistically significant worsening of GLS in the group of patients treated for 12 weeks; however, EF measured did not change significantly. Their results suggested that SOF based treatment could have a negative impact on cardiac function they recommended assessing biomarkers (such as TN-I, BNP, and micro-RNAs) for long term studies. [13]

On contrary, Biomy et al. study no significant differences in systolic and diastolic function parameters in patients between the beginning and after 6 months.[14]

But the difference in results could be easily explained by wide time range Biomy et el. used to assess patients. The results of the current study showed that the number of patients developed cardiac dysfunction decreased by time (15 cases of reduced LVEF at week 6 declined to 9 cases after week 12).

Pathological analysis made by Ahmad et al. of explanted heart of a case died during the research revealed diffuse elongation and thinning of ventricular cells accompanied by fine interstitial fibrosis, very limited areas of necrosis, and limited small areas of mononuclear inflammation. Severe biventricular dysfunction was not considered as the level of myocarditis was insufficient which was considered consistent with, but not diagnostic, of a toxic cardiomyopathy. As a result, Ahmad et al. changed the regimens for the next cases in their study. [8]

Pathological examination by Ahmed et al. also suggested mitochondrial dysfunction with minimal myonecrosis and myocardial injury.[15]

The first case of myo-pericarditis 3 days after initiating DAAs was reported by Schlegel et al. in a patient on DAAs. The patient was a 55 year old male with non is chemiccardiomyopathy and, normal blood pressure and no renal complications. The patients developed myo-pericarditis 3 days after initiating treatment. Endomyocardial biopsy showed with myopericarditis.[16]

The obvious from the current study results that there were some element of cardiac dysfunction that was going to improve after treatment discontinuation. Most of the means changes measured in this study were within normal range. Most of changes measured were at sub clinical level.

Ahmad et al. study showed that cardiac function was returning normal over time especially after the first 10 weeks after DAAs cessation.[8] The transient effects discovered suggested that the cardiomyocytes injury is not permanent.

The actual mechanism is still unknown. Although some potential changes in cardiac energy utilization were proved, the mentioned studies revealed that DAAs were less possible to be a direct mitochondrial toxicant.[17] In vitro studies showed that the effect of DAAs on human cardiomyocytes was associated with concentration- and time-related cytotoxicity.[18] Direct effect of SOF should be considered. Additionally, a random effect, an effect of concomitant drugs, or an indirect effect of HCV eradication mediated by inflammatory changes may be accepted explanations.[19] Concentration and time related cytotoxicity in human cardiomyocytes, in association with mitochondrial injury was proved.[15,18]

Conclusion

From this study it could be concluded that most of the patients included in the study with affected LVEF did not have heart failure symptoms.Statistically significant differences between BNP and LVEF measured at different weeks were obvious but most of them remained within the normal range and none had significant abnormalities. The alteration of cardiac energy generation or utilization could be the exact cause of cardiotoxicity related to DAAs. Studies using different parameters would be helpful in assessing DAAs cardiotoxicity.

Abstract

This study was to evaluate and investigate the effects of using different drugs on reducing the frequency and severity of Post- ERCP pancreatitis. The study was done on 90 randomized patients with extrahepatic cholestasis and divided into three groups. Post ERCP pancreatitis was diagnosed by laboratory investigations, ultra-sonography and triphasic abdominal CT criteria of pancreatitis. The results of this study showed that there was a statistically significant difference in the percentage of knife precut between the studied groups. There was a statistically significant difference in the degree of post ERCP pancreatitis during comparison the control group with each studied drug group, in which allopurinol has a protective role in the occurrence of post ERCP pancreatitis by regression analysis. It is concluded to use allopurinol before ERCP procedure.

Keywords: *ERCP, pancreatitis, knife precut, Allopurinol.*

Introduction

Endoscopic retrograde cholangiopancreatography (ERCP) is one of the most commonly performed endoscopic procedures. The recent shift towards interventional uses of ERCP is largely due to the emergence of advanced imaging techniques, including magnetic resonance cholangiopancreatography and ultrasonography[1].

ERCP is used primarily to diagnose and treat conditions of the bile ducts and main pancreatic duct, including gallstones, inflammatory strictures (scars), leaks (from trauma and surgery) and cancer[2].

Complications of ERCP can be broadly divided into short-term (within 3 days of the procedure) and long term (> 3 days after the procedure) complications. The reported incidence of ERCP-specific complications ranges from 5% to 40%, depending on the complexity of the procedure, the underlying diagnosis and patient comorbidities[3].

According to Cotton's criteria, acute pancreatitis which occurs after ERCP is diagnosed in patients who experience abdominal pain after the procedure with a concomitant ≥ 3 fold increase in blood serum amylase activity that persists 24 hours after ERCP and who require hospitalization[4,5].

Post ERCP pancreatitis is believed to be multi-factorial involving a combination of chemical, hydrostatic, enzymatic, mechanical and thermal factors. Although there is some uncertainty in predicting which patients will develop acute pancreatitis following ERCP, a number of risk factors acting independently or in concert have been proposed as predictors of post-ERCP pancreatitis[6].

Allopurinol plays a part in the prevention of post-ERCP pancreatitis through the reduction of oxygen free radicals[7]. Topical application of epinephrine on

the papilla may reduce papillary edema by relaxing the sphincter of Oddi or by decreasing capillary permeability. They are also inexpensive drugs for prevention of post-ERCP pancreatitis[8].

Patients and Method

Patients: This study was conducted on 90 randomized patients with extrahepatic cholestasis subjected to ERCP. The patients were selected from tropical medicine department and general surgery department of EL-Minia University hospital. The patients were selected for this study according to the following inclusion and exclusion criteria:-

Inclusion criteria:

The patients of either sex; male or female, of age range from 27-78 years old and had to have extra-hepatic or intrahepatic biliary dilatation diagnosed by ultra-sonography and triphasic abdominal CT.

Exclusion Criteria: Patients with pancreatitis diagnosed by laboratory investigations, ultra-sonography and triphasic abdominal CT criteria of pancreatitis (e.g. enlargement of pancreas, inflammatory changes in pancreas and peripancreatic fat, ill-defined single peripancreatic fluid collection and two or more poorly defined peripancreatic fluid collections) were excluded.

The patients were divided into 3 groups as follow: **Group I (control group that included 30 patients):** patients were not given any drugs before or after ERCP. **Group II (Allopurinol treated- group):** included 30 patients, allopurinol (600mg) was taken orally one hour before ERCP. **Group III (Epinephrine- treated group):** included 30 patients were given 20 ml of 0.02% epinephrine sprayed on the papilla during ERCP.

Method: All patients in this study were subjected to the following:

1-Full history taking 2- Full clinical examination 3- Laboratory investigations serum amylase (normal 25-125 unit per liter) **[9].** The serum amylase level was evaluated before ERCP and 6, 24, 48 hours post-ERCP. INR, total leucocytic count, random blood sugar, liver function tests, blood urea and serum creatinine**.**

Endoscopic retrograde cholangiopancreatography (ERCP) technique: Before ERCP, the patients were prepared by fasting at least 8-12 hours and instructed regarding the associated medical history. They were instructed to stop concurrent used medication that lead to bleeding and correction of any bleeding tendency.

During ERCP, the patient lies on prone position and general anesthesia was performed under supervision of an anesthetist. ERCP was performed using Pentax EPM-3500, where side-viewing duodeno-scope is introduced to the stomach till the pylorus then passed to the duodenum and its papilla was visualized for mass or any abnormality.

Management was done according to the pathology as in case of calcular obstruction, stone extracted by ballon dilatation or mechanical lithotripsy followed by stent implantation. If large stone > 1cm, fragmentation of stone occurred by mechanical lithotripsy followed by stent implantation. After ERCP, the patients were followed up for possible complications by clinical examination and investigation.

Statistical Analysis: The data were analyzed by SPSS (statistical package for social sciences) program version 24. The significance of differences for parametric quantitative data was calculated by using One-way ANOVA test. Kruskal Wallis test was used for non-parametric data. Fisher exact test was used to calculate the significance of qualitative data between the five groups. Univariate and multivariate regression analysis were used for predicting pancreatitis. For all tests, $P < 0.05$ was considered significant.

Results

Diagnostic and therapeutic ERCP were done to all studied patients with obstructive jaundice. **Table 1** showed indications of ERCP in all studied patients, 10 (11.1%) patients had stricture (4 patients in group I, 2 patients in group II, 4 patients in group III), 51 (56.7%) patients had calcular obstructive jaundice (18 patients in group I, 17 patients in group II and 16 patients in group III. Malignant obstructive jaundice occurred in 29 (32.2%) patients. It was diagnosed as cancer pancreas in 20 patients (5 in group I, 7 in group II, 8 in group III)

Hepatic focal lesions occurred in 3 patients (one patient in group I, 2 in group II) and enlarged porta hepatis, para aortic and pre pancreatic lymph nodes in 6 patients (2 in group I, 2 patients in group II, 2 patients in group III). There was a statistically significant difference in diagnosis of causes of obstructive jaundice between studied groups **(table 1).**

Table 2 showed the details of ERCP procedure for all studied groups. The mean± SD of the procedure time in all groups was shown in this table. The least mean procedure time (min.) was in group II (12.5± 7.1) and the longest mean procedure time was in group III (20.1±9.3). All patients were received pre ERCP antibiotics. The least number of patients that underwent stone extraction was in group III (16 (55.53%) patients). The biggest number of patients was in group I (18 (60%) patients. Biliary stent insertion and biliary sphinctrotomy were done to all studied patients. Knife precut was done in 25 patients (9 in group I, 7 in group II and 9 in group III). There was a statistically significant difference in the percentage of knife precut between the studied groups.

Table 3 showed the incidence of post ERCP hyperamylasemia in control and all drug groups. It was found that there was no statistically significant difference in post ERCP serum amylase level at all different times in all groups. Epigastric pain occurred in 40 patients underwent ERCP (15 in group I, 12 in group II and 13 in group III). There was a statistically significant difference between all studied groups ($P < 0.05$) **(table 3).**

There was a statistically significant difference in the degree of post ERCP pancreatitis during comparison the control group with each studied drug group, in which, the degree of pancreatitis is statistically significant decreased after drug intake. Group II showed the least number of patients that developed post ERCP pancreatitis (12 Patients only) **(table 3).**

Univariate regression analysis was done to factors associated with post ERCP pancreatitis, only precut and drug intake Before ERCP are statistically significant by regression analysis to predict the risk factors and protective factors of post ERCP pancreatitis. Precut ERCP was a risk factor for the development of post ERCP pancreatitis (OR was 10.5 and 95% confidence interval (CI) was 4.6-23.7. Drug intake before ERCP has a protective role (OR <1). It was noticed that Allopurinol was the best drug which can decrease the incidence of occurrence of post ERCP pancreatitis (OR= 0.362 & 95% CI was 0.074-2.121) **(table 4).** This finding was confirmed by multivariate regression analysis which revealed that combination of these 2 factors only that can predict or decrease the occurrence of pancreatitis (precut ERCP (OR= 22.3) which means it is a risky and drug intake especially Allopurinol that has the least OR in all drugs (OR=0.426) which also means it has a protective role in the occurrence of post ERCP pancreatitis **(table 5).**

Discussion

ERCP is a direct contrast technique of the pancreaticobiliary system. It is useful in the diagnosis and management of diseases involving the pancreas and bile ducts such as stones, benign and malignant strictures and developmental anomalies. Also, intra-hepatic bile duct pathologies can be treated by ERCP using occlusion cholangiography. Pathology in the gallbladder and cystic duct abnormalities can be visualized by ERCP[12].

The major complication of an ERCP is the development of pancreatitis which can occur in up to 5% of all procedures. This may be self-limited and minor but may need hospitalization and rarely to be life-threatening. Those at additional risk for pancreatitis are younger patients, females, procedures that involve cannulation or injection of the pancreatic duct, patients with previous post-ERCP pancreatitis and those with sphincter of Oddi dysfunction[13].

The pathophysiology of PEP is not well explained. Mechanical, hydrostatic, chemical, cytokine, oxidative, enzymatic, allergic, thermal and microbiological factors have all been discussed as being its causes. PEP may result from mechanical trauma which causing injury to the papilla or pancreatic sphincter and leading to swellof the pancreatic duct and obstruction to the flow of pancreatic enzymes[14,15].

Post-ERCP pain with marked elevation of serum amylase and/or lipase especially when the values are greater than 1,000 IU/L, it is strongly suggestive of pancreatitis. In cases of diagnostic doubt especially when severe pancreatitis is predicted, radiologic imaging should confirm the diagnosis. Early recognition of post-ERCP pancreatitis may be possible by evaluating serum amylase or lipase within a few hours of the procedure[16,17].

The degree of pancreatic inflammation and serum hyperamylasemia was decreased after pretreatment with allopurinol in pancreatography induced pancreatitis [18].

Post-ERCP pancreatitis should be managed and treated as other causes of acute pancreatitis. This is sometimes complicated because it is difficult to distinguish mild from severe disease during the early stages of the disease. In acute pancreatitis, close monitoring for signs of organ dysfunction is essential[19].

It was found that there was no statistically significant difference in post ERCP serum amylase level at all different times in all groups. Epigastric pain occurred in 40 patients underwent ERCP (15 in group I, 12 in group II and 13 in group III). There was a statistically significant difference between all studied groups (P < 0.05).

Univariate regression analysis was done to factors associated with post ERCP pancreatitis. Precut ERCP was a risk factor for the development of post ERCP pancreatitis (OR was 10.5 and 95% confidence interval (CI) was 4.6-23.7. Drug intake before ERCP has a protective role (OR <1). It was noticed that Allopurinol and Epinephrine can reduce the incidence of occurance of post ERCP pancreatitis but allopurinol was preferred than epinephrine in this study to decrease the incidence of occurrence of post ERCP pancreatitis (OR= 0.362 & 95% CI was 0.074-2.121).

Contrary to the results of the current study is that mentioned by **Kamal et al.[20]** who reported that the incidence of PEP in indomethacin alone group was

6.4% as compared to 6.7% in the combination group. Severe PEP was found in 12% versus 16% of patients in the indomethacin alone and combination groups respectively. The combination of papillary spray of epinephrine and rectal indomethacin does not reduce the incidence of PEP compared to rectal indomethacin alone in high risk patients.

On the other hand, **Xu et al.** [21] studied 941subjects undergoing diagnostic ERCP and demonstrated a reduction in PEP incidence by epinephrine which sprayed directly on the papilla at the time of ERCP. Prevention of PEP was occurred through relaxation of the spincter of oddi and reduction of papillary edema by decreasing capillary permeability.

The results of this current study were agree with that mentioned by **Akshintala et al.** [22] who studied the beneficial effect of epinephrine in the prevention of PEP. Topical epinephrine could reduce the risk of PEP by 75% compared to controls on sensitivity analyses (OR 0.25, 95% CI 0.06-0.66).

The present study is against with **Hatamia et al.** [23] who stated that 66 patients were randomized to the epinephrine group (group A), 68 cases to the indomethacin group (group B) and 58 individuals to the indomethacin-epinephrine group (group C).They concluded that the single application of epinephrine and the combination of epinephrine and indomethacin significantly reduced the risk of PEP.

General measures for prevention of PEP includes proper training of endoscopist, maintaining proficiency, adequate disinfection, avoidance of diagnostic ERCP, avoidance of repeated cannulation and injection of PD, careful use of electrocautery and avoidance of balloon dilation especially in higher risk patients such as younger patients who are anicteric [24].

The present results were not agree with this of **Mosler et al.** [25] who analyzed 701 patients. They were randomized to receive either allopurinol or placebo 4 hours and 1 hour before ERCP. The overall incidence of pancreatitis was 12.55%. It occurred in 12.96% of patients in the allopurinol group (and in 12.14% of patients in the control group. Prophylactic oral allopurinol did not reduce the frequency or the severity of post-ERCP pancreatitis.

There was significant reduction of post-ERCP pancreatitis by allopurinol (OR= 0.362 & 95% CI was 0.074-2.121) when compared to epinephrine which in disagreement with those of **Romagnuolo et al.** [26] who studied 586 subjects. The crude PEP rates were 5.5% (allopurinol) and 4.1% (placebo) (95% confidence interval 2.1%-4.8%).

The results of the current study are not in accordance with the study of **Bai et al.** [27] who showed no significant difference in the incidence of post-ERCP pancreatitis between allopurinol treated and allopurinol untreated groups (8.9 vs. 9.7%, P=0.68, RR 0.86, 95% CI 0.42-1.77).

The current study is agree with **Katsinelos et al.** [28] who showed that the frequency of acute pancreatitis was significantly lower in the allopurinol vs the placebo group. The protective effect of allopurinol was also apparent in the diagnostic ERCP and the biliary sphincterotomy subgroups when the frequency of post-ERCP pancreatitis was analyzed after stratification by procedure.

Conclusion

Owed to our results in this current work, it is concluded that acute pancreatitis is the most common complication after ERCP. Also, it is concluded that precut ERCP was a risk factor for the development of post ERCP pancreatitis and dministration of allopurinol can decrease the incidence of PEP. And so, it is advised to give allopurinol before ERCP and make further scientific researches to find another drugs that can ameliorate post ERCP pancreatitis.

Abstract

Background: The advent of new magnetic resonance imaging (MRI) techniques has improved acute stroke diagnosis. Susceptibility weighted imaging (SWI) has an important role in the management of cerebro-vascular strokes.

Patients and Method: The study was conducted upon 50 patients clinically diagnosed with cerebro-vascular strokes and referred to department of radio-diagnosis, Faculty of Medicine, Minia University. Computed tomography (CT) was done at first then magnetic resonance imaging was performed on a 1.5T Philips MR system using conventional MRI sequences as fluid attenuated inversion recovery (FLAIR), T2-weighted, T1-weighted and advanced sequences as susceptibility-weighted imaging (SWI) with the parameters including slice thickness, voxel size, field of view (FOV) and matrix,. They were done after the approval of ethical committee of our institution. Informed written consents were taken from the patients or their relatives.

Results: In our study, we found that 35 patients presented with acute non hemorrhagic infarction even on SWI and 15 patients presented with hemorrhagic infarction noted in SWI. Only ten of those patients with hemorrhagic infarction detected in CT. We found that detection rate of hemorrhage in SWI sequence was (100%). Detection rate of hemorrhage in CT was (33.3%). In SWI as regarding detection of different signs of acute ischemic strokes we found that of hemorrhage was (88%), detection rate of prominent cortical veins in vicinity of infarct was (62%) and detection rate of dark vessel sign was 6%. Comparative studies between them were done revealed that hemorrhage was the most important sign detected at SWI.

Conclusion: From this study we concluded that new imaging SWI MRI modality is a valuable MRI sequence in imaging hemorrhagic transformation in ischemic stroke.

Introduction

Stroke or cerebrovascular accident (CVA) is a clinical term which represent a sudden neurological insult persisting for more than 24 hours as a sequel of an alteration of normal blood supply to the brain. Stroke is the third leading cause of mortality worldwide with significant morbidity rate among survivors. In hemorrhagic stroke, bleeding occurs directly into the brain parenchyma. The usual mechanism is thought to be leakage from small intra-cerebral arteries damaged by chronic hypertension. Imaging of stroke is used to differentiate ischemic from hemorrhagic stroke, arterial from venous infarction and to distinguish anterior and posterior circulation strokes. [(1)] Non-contrast head CT (NCCT) is the first-line diagnostic test for emergency evaluation of acute stroke due to its speed

of imaging, widespread availability and low cost. In CT small infarcts are less likely to be visible and detect parenchymal hemorrhage with near 100% accuracy only within 5–7 days of stroke. From this point of view, magnetic resonance imaging (MRI) is increasingly being used in the diagnosis and management of acute ischemic stroke and is sensitive and relatively specific in detecting changes that occur after such strokes. Magnetic resonance can detect acute hemorrhage within ischemic area through the first six hours. [2] Routine MR sequences remain specific for hemorrhage in 90% of patients. [3] In the remaining 10% detection of hemorrhage may be difficult as low signal caused by haemosiderin not visible on spin echo T2 MR and other sequences vary in their sensitivity to the presence of haemosiderin. So it is imperative to use new imaging technique as susceptibility weighted imaging (SWI). It is a magnetic resonance (MR) technique that is exquisitely sensitive to paramagnetic substances such as deoxygenated blood, blood products, iron and calcium. Susceptibility weighted imaging (SWI) used to asses ischemic area in patients with acute ischemic infraction based on elevation of deoxy-hemoglobin to oxy-hemoglobin ratio in venous system of the ischemic brain tissue with hypo-perfusion which contributes to the magnetic susceptibility difference between veins and the surrounding ischemic brain tissue. [4,5] Deoxy-hemoglobin within the veins lead to visualization of prominent vein (which appear hypointense) over the affected cerebral hemisphere on susceptibility-weighted imaging (SWI) called prominent vein sign. This property accounts for the blood oxygen level dependent (BOLD) effect. [6] Susceptibility-weighted imaging can detect spontaneous hemorrhagic transformation of ischemic stroke earlier than CT scans as it is more sensitive in detecting minute amount of hemorrhage within infarction than CT. [7,8] However, the ability of SWI to detect recurrent hemorrhage has not been assessed. It detects microbleed which may be a marker for patients at risk for intra-cerebral hemorrhage. Early detection of bleeding within ischemic area is very important as hemorrhage is a contraindication to the use of anticoagulant and thrombolytic therapy in the acute stroke setting. Also SWI used to assess intravascular clots as it detects thrombus within intracranial artery which appear dilated and hypointense in comparison with the other side giving what is called blooming artifact. SWI sequences also have the potential to assess tissue viability. [9,10]Assessment of ischemic penumbra is essential for predicting evolution or deterioration in patients with acute ischemic infraction.[10]

Aim of the work: The aim of this study is to assess the role of susceptibility-weighted imaging in assessment of hemorrhagic transformation in patients with acute ischemic infraction.

Patients and Method

Study design and population: In a prospective study 30 patients with clinically diagnosed to have acute stroke were included diagnosed in neuropsychiatry department and they were referred to department of radio-diagnosis, Faculty of Medicine, Minia University. The study was done between October 2018 to September 2019. The examination was done after the approval of ethical committee of our institution. Informed written consents were taken from the patients or their relatives

Inclusion and exclusion criteria

Inclusion criteria:

- All patients included in this study were diagnosed clinically having acute stroke.
- Age older than 18 years.
- Stroke symptoms lasting >1 hour.
- National Institutes of Health Stroke Scale (NIHSS) score is more than 4.

Exclusion criteria: General contraindications to MRI as the presence of any paramagnetic substances such as pacemakers, metallic clips or claustrophobic patients were excluded from the study. Patients with an NIHSS score less than or equal to 4 were excluded.

Method

CT scanning: CT was performed with a CT HiSpeed 16 slice scanner (GE Medical Systems, Milwaukee, WI) in the hospital emergency department using the non helical scanning technique: 120 KV, 300 mA, 1-second scanning time, and 5 mm section thickness.

MRI technique: MR imaging was performed using 1.5 Tesla MR Scanner (Ingenia, Philips Healthcare, Netherlands). All patients were imaged in the supine position using standard quadrate head coil. The MRI examination was conducted on the brain including the following MRI sequences; Axial T1 images utilizing the following parameters: repetition time (TR) of 800 msec/ echo time (TE) of 30 msec, slice thickness of 5 mm, (NSA) 3, matrix 512x 512, gap 1–2 mm, flip angle=90 º and FOV = 230mm. Axial T2 weighted images utilizing

the following parameters:, repetition time (TR) of 4800 msec/echo time (TE) of 110 msec, slice thickness of 5 mm, number of signal averages (NSA)=3, matrix 512x 512, gap 1–2 mm, flip angle=90 º and field of view (FOV)= 230mm. Axial FLAIR images utilizing the following parameters: repetition time (TR) of 6000 msec/echo time (TE) of 140 msec, slice thickness of 5 mm, (NSA) 3, matrix 512x 512, gap 1–2 mm, flip angle=90 º and FOV = 230mm. Axial SWI images utilizing the following parameters: repetition time (TR) of 43 msec/echo time (TE) of 25 msec, slice thickness of 3 mm, matrix 300x300, gap 1–2 mm, flip angle=20 º and FOV = 230mm.

Data processing and image interpretation: The images were transformed to Philips 881030 Intelli-Space IX/LX Workstation. They were evaluated as following:

Image interpretation: All patients were imaged by CT and evaluated for presence of hemorrhage within infarct areas and evidence of early ischemic changes (EIC) (using stroke window width of 30 HU and center level of 35 HU) which was defined by the presence of one or more of the following findings: sulcal effacement, hyperdense MCA/basilar artery sign, basal ganglia/subcortical hypodensity and loss of gray-white differentiation. Then patients had MRI using conventional sequences to evaluate site, size and extension of infarct area as well as signal intensity at different pulse sequences. Presence or absence of infarction using SWI and other sequences as well as type of hemorrhage either macro-hemorrhage (more than 50% of infarct area) or pitechial hemorrhage (less than 50% of infarct area) were assessed. Detection of dark vessel and prominent cortical veins in vicinity of infarct area was also done using MRIcro software to assess venous structures in 5 consecutive sections around the level of the lateral ventricles from just above the level of basal ganglia to the highest section because these sections include most of the cerebral vein. Bilateral venous voxel counts were computed and the asymmetry index (ratio of voxel numbers of cerebral veins between the ipsilateral and contralateral side) was calculated. Each infarct area in each patient appears in CT was correlated with its similar on SWI.

Statistical analysis: Statistical analysis was performed using the SPSS software for Windows v. 20 (SPSS Inc., Chicago, IL). Tests of significance (Repeated measures ANOVA, Cochran's Q tests, Kappa statistics and ROC Curve analysis). P-values less than 0.05 (5%) was considered to be statistically significant. Mean, standard deviation (± SD) and range for parametric numerical data, while median and inter-quartile range (IQR) for non-parametric numerical data. Frequency and percentage of non-numerical data.

Results

Our study included 50 patients with acute stroke diagnosed in our neurological department. The mean age of all patients was (36.24) years and as regarding gender of the patients (84%) of patients were females and (16%) were males. Total of 35 patients had no acute hemorrhage even on SWI and 15 patients had hemorrhagic infarction. Ten of those patients with hemorrhagic infarction detected in CT and 5 patients of those patients with hemorrhagic transformation detected in SWI and not in CT. We found that detection rate of hemorrhage in SWI sequence was (100%). Detection rate of hemorrhage in CT was (66.6%). Comparative studies between CT and SWI sequences revealed significant increase in sensitivity and specificity of detection of hemorrhage in SWI sequence with highly significant statistical difference ($p < 0.001$) as in (table I). In SWI as regarding detection of different signs of acute ischemic strokes we found that of hemorrhage was (88%), detection rate of prominent cortical veins in vicinity of infarct was (62%) and detection rate of dark vessel sign was 6%. Comparative studies between different sign in SWI was done revealed that SWI had significant increase in sensitivity and specificity of detection of hemorrhagic transformation over detection of other signs with highly significant statistical difference ($p < 0.0001$) as in table II. No significant difference was found in detection of intravascular clot in SWI in comparison with CT ($p > 0.05$).

Table I: detection of hemorrhagic transformation in ischemic stroke in CT in comparison to SWI using Roc-curve analysis:

	AUC	P value	SE
Hemorrhagic transformation in SWI	0.987	<0.0001	0
Hemorrhagic transformation in CT	0.497	0.015	0.032

SE= Standard Error, AUC= Area under curve, ROC =Receiver

operating characteristic.

Table II: Comparison between different signs of ischemic stroke in SWI in 30 patients with ischemic stroke:

Variable	Detection rate of dark vessel sign	Detection rate of prominent cortical vein	Detection rate of hemorrhage	Cochran's Q test
				P value
SWI	(6%) ^^	(62)^^	(88%) ^^	= 0.097 #

^^% per total of 15 patients, # Cochran's Q test.

Figure 1: Axial CT image of same patient show right sided subacute infarction with no definite hemorrhage noted.

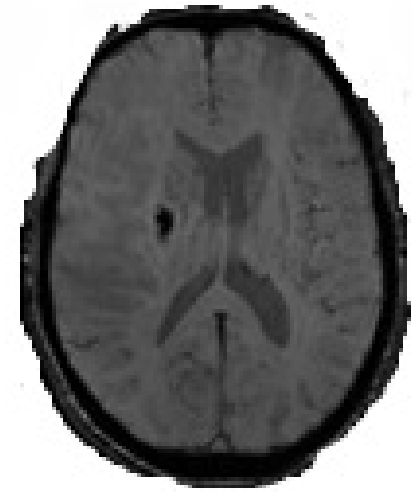

Figure 2: Axial SWI shows blooming signal seen at right parietal region denote hemorrhage .

Discussion

SWI is as an important sequence that detect critical information as regarding hemorrhagic transformation and intravascular clot of ischemic stoke. It has demonstrated advantages over conventional MRI sequences and CT imaging in detection of hemorrhagic events in the vicinity of infarction due to its exquisite sensitivity to paramagnetic substances such as deoxyhemoglobin. SWI venography allows clear visualization of cerebral veins. Shortly after arterial occlusion in patients with acute stroke, there is an increase in deoxyhemoglobin and a decrease in oxyhemoglobin within cerebral veins leads to a signal drop along the course of cerebral veins on SWI venography. SWI venography may thus provide the oxygen metabolic information about ischemic brain tissue by the noninvasive estimation of blood oxygen level. .[11] The acknowledgment of this lead to a revolution in detection of hemorrhagic transformation in ischemic stroke and increased interest in SWI. Our study aims to assess presence of hemorrhage in patients with ischemic stroke using different MRI sequences including SWI and CT imaging. Most of our patients were females (84%).

We are in agreement with several authors as Deepti Naik and Sanjaya Viswamitra Studies who reported that SWI was an important sequence in detection of hemorrhagic transformation in infarct area over CT and other MRI sequences. Chronic hemorrhages in a patient with stroke may reflect the vulnerability of the vascular system and has been suggested as a predictor for future bleed particularly in patients undergoing thrombolytic therapy. We agree with Haacke EM and Tang J et. al. study who stated that SWI can demonstrate venous changes at an infarct which appear as multiple prominent hypointense veins in the vicinity of infarct.

Conclusion

Finally, in our study we were in agreement with the findings reported by the other studies regarding the greet value of SWI in assessment of ischemic stroke. SWI has the ability to identify several parameters such as hemorrhage which may be of prognostic value in making therapeutic decisions. Based on our study, future implementation of adding the SWI sequence beside the conventional MR sequences as a routine modality in

patients with ischemic stroke is important.

Risk Factors for Pediatric Intensive Care Admission among Asthmatic Children in Aseer, South-West Saudi Arabia

Mohammed Abdullah Alshehri[1], Mohannad Mohammed Al gossadi Alsheri[2], Reema Mohammed Al gossadi Alsheri[3], Renad Mohammed Al gossadi Alsheri[3]

[1]Professor, Department of Child Health, [2]Medical Intern, [3]Medical Student, College of Medicine, King Khalid University, Abha, Saudi Arabia

Abstract

Background: The burden of childhood asthma continues to rise with increasing rates of asthma prevalence, severity, and death. Asthma is the one of the most chronic pediatric disorder and is frequent caused for hospitalization and pediatric intensive care unit (PICU) admissions.

Objective: To determine risk factors for PICU admission in children with asthma.

Patients and Method: The study used a retrospective case-control design. The cases included children admitted to the PICU and controls were children admitted to the hospital general ward.

Results: A total of 320 charts of asthmatic children were reviewed: 72 (22.5%) admitted to the PICU and 248 (77.5%) admitted to the general ward. Univariate analysis indicated that asthmatic children admitted to PICU were more likely to be older ($p<0.001$), have longer asthma duration ($p<0.001$), higher use of: inhaled corticosteroids ($p<0.0001$), cromolyn ($p=0.03$), long acting β_2 agonists ($p=0.001$), and poor adherence to treatment ($p=0.002$). However, multivariate analysis revealed that longer duration of asthma ($p=0.03$), use of inhaled corticosteroids ($p=0.01$), and non-compliance with therapy ($p=0.02$) were associated with an increased risk of PICU admission. **Conclusions**: this study identified a significant number of risk factors associated with PICU admission. Early recognition could help to develop preventive strategies, improve efficacy of treatment and reduce admission to PICU.

Keywords: *Asthma, Risk factors, Children, Pediatric intensive care.*

Introduction

Bronchial asthma is a common and potentially serious health problem globally, with estimated 300 million affected individuals, with great variation between countries[1]. The incidence and prevalence of asthma have increased during the last 20 years[2,3]. Asthma is considered one of the most common chronic disorders in the Kingdom of Saudi Arabia as 2 million Saudis suffer from asthma[4]. It imposes a substantial burden on family, health care services, and society as a whole[5].

Asthma can cause episodic coughing, wheezing, shortness of breath, chest tightness and exacerbations that sometimes require urgent health care services and may be fatal. Around 30% of asthmatic exacerbations attended to the emergency department of a hospital require hospitalization and up to 20% require intensive care management[6,7]. In the past two decades, hospital admissions for asthma have been increasing despite improved knowledge about the disease and the availability of better treatment modalities. Severe acute asthma in children is associated with substantial morbidity and may require Pediatric Intensive Care Unit (PICU) admission. Understanding the risk factors

for hospitalization for asthma is important for treating and reducing their effects on society[8]. This study was designed to determine the potential risk factors for PICU admission in Saudi children with asthma.

Patients and Method

We performed a retrospective case-control study at the Abha Private Hospital, Abha, South-west Saudi Arabia between January 2014-December 2018.

Study Design: The inclusion criteria were as follows: all children aged 2-14 years who admitted to the PICU with acute asthma which was previously diagnosed by pediatricians or pulmonologists before PICU admission were eligible as cases. The admission criteria to PICU were clinically predefined and did not change during the study period. They included respiratory failure, imminent exhaustion, no clinical benefit after continuous nebulization of bronchodilator drugs, and/or the need for mechanical ventilation. The control group included patients aged 2-14 years diagnosed with asthma who admitted to the General Pediatric Ward of the Hospital with an acute asthma exacerbations. Controls were recruited during the same period of the study.

The Exclusion Criteria: Patients younger than 2 years were excluded because bronchiolitis an acute wheezing illness occurring mainly in children younger than 2 years, closely resembles asthma and may affect our data. Patients admitted to the Hospital whose diagnosis code changed to non-asthma during hospitalization also were excluded. Children who had not been diagnosed with asthma prior to their admission and presented with their first asthmatic attack were excluded from the study because defining controls would not be feasible.

Materials

The medical records of patients and controls were reviewed and the following information extracted: Demographic variables: age, gender, number of siblings, and consanguinity. Disease variables: age at first symptoms of asthma, duration of the disease, previous admission to the PICU, and family history of asthma. Variables related to medications: inhaled/ oral corticosteroids, cromolyn, long-acting β_2 agonists, leukotriene receptors antagonists, and compliance to therapy. Variables related to exposure and atopy: history of parental smoking, inhaled allergens, eczema and presence of pets in the home.

Statistical Analysis: Data were analyzed using the Statistical Software Package SPSS 19 (SPSS, Inc., Chicago, IL). Quantitative data were presented as mean+ standard deviation (SD), while qualitative data were demonstrated as frequency and percent (%). Differences between cases and controls were analyzed by Student's *t*-test for continuous normally distributed variables. Categorical data were assessed by chi-square test. The dependent variable was PICU/General Pediatric Ward admission. Variables found to be significant on univariate analysis were subsequently evaluated by multiple logistic regression. For all analysis, statistical tests were two-sided, and $p < 0.05$ was regard as significant.

Results

A total of 320 asthmatic children were enrolled in the study: 72 (22.5%) were admitted to PICU, and 248 (77.5%) to the General Pediatric ward. The mean age was statistically older in patients who admitted to PICU than in those who admitted to the General Pediatric ward (6.3 + 0.4 vs 4.6 + 0.3 respectively, $p < 0.001$). Females were preponderance in both groups but this finding was statistically non significant. Cases and controls were matched in terms of breast fed for 6 months, number of siblings, and first degree consanguinity (table 1).

Disease characteristics and risk factors in the two groups are shown in (table 2). Disease features: the duration of asthma was significantly longer in the PICU group than in the General Pediatric Ward group (25.1 + 0.2 months vs 21.0 + 0.7 months respectively, $p < 0.001$). Parental smoking and exposure to inhaled allergens were significantly reported more frequently in the group with PICU admission, $p < 0.05$).

Medications: significant differences between the two groups were noticed including higher use of inhaled corticosteroids ($p < 0.0001$), cromolyn ($p = 0.03$), and long acting β_2 agonists ($p = 0.001$) in the PICU group. More patients in the PICU group had poor compliance with therapy (40.3% vs 22.2%, Odds ratio (OR) = 2.36, Confidence interval (CI) (1.35-4.13), $p = 0.002$). Other factors: asthmatic children who admitted to PICU had more frequent prior admissions to the PICU ($p = 0.0003$).

Multivariate analysis (table 3) revealed that longer duration of the disease ($p = 0.03$), use of inhaled corticosteroids ($p = 0.01$), and non-compliance with therapy ($p = 0.02$) were significantly associated with an increased risk for admission to the PICU compared to the General Pediatric Ward.

Table 1: Demographic characteristics of asthmatic patients admitted to PICU and General Pediatric ward

Characteristics	PICU (n = 72)	General Ward (n = 248)	OR (95% CI)	p-value
Age (Year)[a]	6.3 ± 0.4	4.6 ± 0.3	1.30 (1.78-1.61)	< 0.001
Gender[b]				
Male	30 (41.7)	106 (42.7)	0.95 (0.56-0.61)	0.9
female	42 (58.3)	142 (57.3)		
Breast-fed 6 months[b]	29 (40.3)	102 (41.1)	0.97 (0.57-1.65)	0.8

Factors	OR (95% CI)	p-value
Duration of asthma	2.17 (1.23-4.30)	0.03
Use of inhaled corticosteroids	3.01 (1.48-5.90)	0.01
Non-compliance with therapy	1.46 (1.01-1.07)	0.02

OR: odds ratio; 95% CI: confidence interval

Discussion

The impact of childhood asthma on the health care system is considerable. As one of the most chronic diseases of children, bronchial asthma is frequently caused for emergency room visits and hospital admission[3]. An admission to PCU with asthma is potentially life threatening and is a recognized risk factor for subsequent death[9].

This retrospective study was conducted to identify risk factors for PICU admission. Our study showed that asthmatic children who were admitted to the PICU were significantly older than those who admitted to the General Pediatric Ward. Children in the PICU group were approximately 2 years older than the control group.

The possible explanation may be due to the severity of the asthmatic attack and PICU admission were related to a longer duration of asthma in older children and perhaps the development of remodeled airways. This explanation is supported by the longer history of asthma in children with PICU admission. Many studies reported a longer duration of asthma in children admitted to ICU suggesting a link between asthma duration and severity that may account for the findings[10-12]. Female gender was pronounced as a risk factor for hospitalization and readmission in studies conducted by Nunez et al[13] and Kargar et al[14]. In our study although there was a female preponderance but statistically was non-significant.

Previous admission to the PICU was higher in group admitted to the PICU and the difference was statistically significant (p = 0.0003). This finding is consistent with previous studies that reported previous admission to emergency department and PICU were also linked to hospital readmission[15-17]. However, other studies did not reported significant differences.[10,13] Parental smoking and inhaled allergens have adverse influences on asthma and hospital admission[18]. In the present study, parental smoking and exposure to inhaled allergens were significantly reported more frequently in children with PICU admission ($p < 0.05$). This confirms the previous reports in which a history of exposure to smoking and being in continuous contact with allergens have been known as risk factors for morbidity, asthma severity, and hospitalization for asthma[19-21].

Atopy is a recognized risk factor for severe asthma[1]. We found that eczema was not linked to PICU admission possibly because of small patients number. Serum IgE levels provide a quantitative definition of atopy and may have been a better measure to use, but serum IgE were not recorded in a sufficient number of patients files for analysis.

In their systemic review, Alvarez et al[22] reported that the use of inhaled corticosteroids measured in a dose-independent fashion did not significantly increase or decrease the risk for near fatal and fatal asthma in adults. Some studies in children observed that inhaled corticosteroids prophylaxis is effective controlling symptoms and reducing hospitalization and death[23-25]. These findings are in contrast to our results. The difference would be explained by greater severity of asthma and non-compliance with therapy in the PICU group. Similar findings were noted in a comparable study of asthmatic adults[26]. Similarly, the higher numbers of patients receiving treatment with long acting β_2 agonists, the use of asthma management plans, and asthma management by a respiratory specialists are factors likely to be related to asthma severity and PICU admission[12]. Differences between the routine patient care, respective guidelines for treatment of asthma, age and other characteristics of the patients complicate the comparisons between these studies.

Our study noted that asthmatic children admitted to PICU were significantly had poor compliance with therapy. This finding is consistent with several studies that have suggested that poor adherence with asthma management predisposes asthma patients to more severe attacks and death[12]. The barriers to adherence to asthma management may be the medications (steroids), the patients, their families, and physicians[27,28].

Previous admission to emergency department, general Ward and PICU admissions were linked to higher hospital readmission in studies by Lasmar et al[16], Visitsumthorn et al[17] and Kargar et al. [14] In the present study, previous admission rate to PICU was higher in group admitted to PICU and the difference was statistically significant (p = 0.0003). After multivariate analysis, 3 risk factors remained significant for PICU admission in children with asthma. These included, longer duration of the disease, use of inhaled corticosteroids, and non-compliance with therapy.

A limitation of the present study is that we used a retrospective study design, with information collected from the medical records. For this reason, several variables could not be analyzed reliably such as quality of the home, and instructions by a specialized nurse.

In conclusion, this study identified duration of asthma, use of inhaled corticosteroids, and non-compliance with therapy as significant risk factors for PICU admission in Saudi children with asthma. Future prospective standardized studies are needed to validate these results. Early identification of children at risk for PICU admission may result in development of preventive strategies, improvement of efficacy of treatment and thus in a reduction of PICU admission for asthma.

Evaluation the Prevalence of Association between Cranial Congenital Fetal Anomalies and Extra-Cranial Congenital Fetal Anomalies

Mohammed Yahia Mohammed Ahmed[1], Hossam El-Din Shawky[2], Mohamed Ehab Ali Salet[2], Saad Abd El-Naby Ahmed El-Gelany[2], Mahmoud Hosni Ibrahim[3]

[1]Assistant Lecturer, [2]Professor, [3]Assistant Professor, Obstetrics & Gynecology, Faculty of Medicine, Minia University, Egypt

Abstract

The purpose of this study evaluated the Percentage of association between cranial congenital fetal anomalies and extra-cranial congenital fetal anomalies. Patients and method: The study conducted for two years in Minia University Fetomaternal Unit 2018-2019, We examined 2091 cases referred to us from all Minia regions because of congenital anomalies risk,263 cases detected carrying different types and numbers of anomalies . Results: The number of congenital anomalies in this study was 263 with percentage (12.5%) but when these number of congenital anomalies linked to all Antenatal care cases that attached to Minia University hospital in two years with average number (40,000) cases in two years we found percentage was (0.65%).In this study the top affected system was the central nervous system with percentage 32.7%,then the renal system 18.6%, then the cardiovascular system 14.8%,then the chest 8%, then the musculoskeletal system 7.2% then hydrops fetalis 6.5% followed by GIT 5.7% then the neck 5.3%, followed by face which was the least prevalent Anomalies which the percentage was 1.1%.Conclusions: We found that CNS was the most common system affected and the most rare system affected was the face. The ratio of congenital anomalies in Minia Governorate was 0.65% Which was less than the global percentage.

Keywords: *Prevalence, Cranial, Anomalies, CNS.*

Introduction

Congenital fetal anomalies are structural or functional aberration from normal Including metabolic abnormalities, present postnatal. These abnormalities may be a result of defective embryogenesis or intrinsic defects in the development process. Birth defects can be single or included in A Syndromic manner also may be a leading cause of the neonate disability or even mortality.(1)

Antenatal care designed mainly for Detection of congenital fetal anomalies. Healthy baby outcome postnatally a leading indication to use ultrasound in pregnancy. Risk factors for congenital anomalies are multifactorial, they include advanced maternal age, previously anomalistic baby, family history of birth abnormalities, consanguinity, maternal diseases, drug abuse, infections as viral infections and Ionized radiation exposure. The detection of birth defects can be the cornerstone of regional health records for future use in the preventive programs.(2)

The control of genetic linked abnormalities should be based on A Well integrated and comprehensive plane, including the best possible curative and prevention measures like community education screening programs, genetic counseling, and the availability of early detection measures. Efficient Screening programs (registries and databases) and continued investment in genetic research are the cornerstone of any successful public health intervention, particularly in low–resource communities.(3)

Prenatal screening using the ultrasound for detection the fetal anomalies should be started at 12-14 and 18-22 weeks of pregnancy. Although routine fetal anomalies scan if very helpful in detection of fetal anomalies but there are limitations to detect every anomaly, as not all anomalies are evident at these scan

age when the ultrasound tool had been used, also the scan itself is operator dependant and widely based on the available efficient machines. Some fetuses are difficult to be scanned clearly, because of many reasons as oligohydramnios or maternal obesity[4]

Patients and Method

Study design: cross sectional observational prospective study **Setting:** Al-Minya University maternity hospital, Department of Obstetrics and Gynaecology, Fetomaternal unit which is a tertiary governorate maternity hospital that covers 9 local areas with people about 5.5 millions and these hospital accept referral from all governorate hospitals. Time and sample size : The study extends from may 2017 to may 2019(2 years). **Methodology:** The study will be conducted according the general ethics and principles that approved by the department committee. **Step 1**

Ascan survey for those patient that referred for Cranial anomalies which will include the following items: Skull Examination of integrity and normal shape, and measurement of biparietal diameter and head circumference. **Brain** Examination of cerebral ventricles, choroid plexuses, midbrain, posterior fossa (cerebellum and cisterna magna), and measurement of the anterior and posterior horns of the lateral ventricles. **Face** Examination of the profile, orbits and upper lip **Neck** Measurement of nuchal fold thickness. **Spine** Examination both longitudinally and transversely. **Heart** Examination of rate and rhythm, four-chamber view, and outflow tracts. **Thorax** Examination of the shape of the thorax, the lungs and diaphragm **Abdomen** Examination of the stomach, liver, kidneys, bladder, abdominal wall and umbilicus, and measurement of abdominal circumference. **Limbs** Examination of the femur, tibia and fibula, humerus, radius and ulna, hands and feet (including shape and echogenicity of long bones and movement of joints), and measurement of femur length. **Step 2 Categorizing the patient into 2 main group** Group 1 includes patients with isolated cranial anomalies Group 2 includes those which show any extra cranial anomalies association with cranial anomalies. **Step3** Compare between group 1 and group 2 to detect the percentage of association collectively. **Step 4** Each cranial anomaly will be compared with each extracranial anomaly to detect the percentage of association. Each association will be linked with the patient age and gestational age also baby gender.

The collected data were coded, tabulated and statistically analyzed using SPSS program (Statistical Package for Social Sciences) software version 24. Descriptive statistics were done for numerical data by mean, standard deviation and minimum & maximum of the range. Analyses were done for parametric quantitative variables between the two groups using independent sample *t* test. Simple, multiple and multiple stepwise discriminant functional analyses were used to determine the equations that predict the sex using different metacarpal internal measurements.

Results

This study was conducted at Al-Minya University maternity hospital, Department of Obstetrics and Gynaecology, Fetomaternal unit which is a tertiary governorate maternity hospital that covers 9 local areas with people about 5.5 millions and these hospital accept referral from all governorate hospitals from May 2017 to may 2019.

Group 1 includes patients with isolated cranial anomalies Group 2 includes those which show any extracranial anomalies association with cranial anomalies.

Discussion

These study designed to outline the prevalence of congenital anomalies through advanced Ultrasound fetal scan of referred cases of high suspicious in Minia Governorate that located in the north of upper Egypt to set up the start of the first regional register of congenital anomalies in our governorates such baseline data will be apart of planning and evaluation programs.

The frequency of congenital anomalies in this study was 263/2091 with percentage (12.5%) but when these number of congenital anomalies linked to all Antenatal care cases that attached to Minia University hospital in two years with average number (40,000) cases in two years with percentage (0.65%) this results do not match with the global incidence of prevalence of Congenital anomalies which is between (3-5%)[5] also this prevalence not match with other Egypt previous regional studies like Giza that was found (3.17%)[6], Alexandria was found (1.6%)[7].

However a study that had been carried out in Turkey and included 22 University hospitals was found the total prevalence (3.65%)[8].

The higher frequency in live borns in Egypt may be due to either inclusion of all minor anomalies in the study or inclusion of fetal anomalies in stillbirth[9].

In this study the most common affected system is the central nervous system with percentage 32.7% followed by the renal system 18.6% followed with the cardiovascular system 14.8%, followed by the chest 8% followed by the musculoskeletal system 7.2% followed by hydrops fetalis 6.5% followed by GIT 5.7% followed by neck 5.3% followed by face which is the least prevalent anomalies with percentage 1.1%.

Our results disagree with [4] that show the most common affected system is the musculoskeletal 16.66% and the least represented anomaly is neck 4.1% .

Our results agree in the common and least represented anomalies but differ in percentage with [10] that show the most common affected system is theCNS 26.5% and the least represented anomaly is face1.5%.

Our results disagree with [11] that show the most common affected system is the CNS 30% and the least represented anomaly is GIT 3%

Conclusion

We concluded that CNS was the most frequent system affected and the least system affected was the face.

Abstract

The immune-compromised condition due to type 2 diabetes mellitus (T2DM) can increase the risk of treatment failure in patients with drug resistant-tuberculosis (DR TB). This study aims to determine the effect of T2DM and treatment regimen on the success of DR-TB treatment in Riau Province in 2014-2018.

The design of this study was retrospective cohort using data of DR TB which were recorded in 01 DR TB form, 03 DR TB form, DR TB medical records and e TB manager at the DR TB referral hospital of Arifin Achmad Regional General Hospital and 7 sub-referral hospitals in Riau Province in 2014-2018. The independent variables were the type 2 DM and treatment regimen. The covariate variables were demographic factors namely, age, sex, marital status, occupation, education, residence category, clinical factor of previous TB treatment history, and medication adherence. The dependent variable was the success of DR TB treatment. The samples of this study were 146: 50 samples of exposed group (T2DM) and 96 samples of non-exposed group (Non T2DM). The survival analysis was used for data analysis. The results showed that 54.79% patients were successfully treated. The probability of 50% success of treatments in both T2DM and nonT2DM using old regimen (conventional method) occurred on the 729th day. While, the probability of 50% treatment success in both T2DM and Non T2DM groups using new regimen (STR/ shorter regimen) occurred faster on the 272th day.

The risk of T2DM group with the new regimens in the treatment of DR-TB was 10.66 times (95% CI 3.23-35.12). Whereas, the treatment on NonT2DM group with old regimen with marital status that was controlled showed a significant statistic value with value $p< 0.001$.

Conclusion: The use of new regimen accelerated the healing time and increased the successful treatment of patients with T2DM with DR TB.

Keywords: *Type 2 diabetes mellitus (T2DM), regimen, drug-resistant tuberculosis (DR-TB).*

Introduction

Drug-resistant tuberculosis (DR-TB) still has been a major public health problem globally, including in Indonesia. Indonesia is at the 7th position of countries with the most common cases of DR-TB. Data show there are 23,000 new cases of rifampicin-resistant TB

Corresponding Author:
Musfardi Rustam
Epidemiology Doctoral Candidate, Faculty of Public Health, Universitas Indonesia, Depok, Indonesia

(RR-TB) or multi-drug resistant TB (MDR-TB) with additional resistance to isoniazid surfaces every year globally.[1]

Treatments of drug-resistant tuberculosis (DR TB) are considered to be successful when treatment results show that the patients are cured and the treatments are complete. On the other hand, treatments of DR TB are considered to be unsuccessful when treatment results show that the patients are uncured, die, drop out of taking drugs, losing in follow-up and are not evaluated[2]. The success rate of DR-TB treatment in Indonesia (patients are cured and the treatments are complete) is still considered low. Compared to the success target of DR TB treatment that must be achieved in 2020, that is 90%[3], the results of treatment in 2016 showed that only 48% patients were cured[4]. Control of DR-TB must be conducted through thorough treatment and quick comprehensive action supported by strong political policies and decent regional budget[5]. The increase of DM cases extremely influence the failure of DR-TB treatments[6].

The prevalence of T2DM continues to increase in developing countries including Indonesia. T2DM on adults occurs approximately 90-95% of all DM cases[7]. The influence of T2DM towards the success of TB-RO treatment was caused by longer time to conversion, drug side effect and drug interaction[7][8][9]. The DR-TB treatment became more difficult because DM can cause changes in oral absorption, reduce the binding of drug proteins in the body, and the renal insufficiency and fatty liver cause the impaired clearance of drugs that brought about longer treatment time, ≥ 20 months[10]. Pharmacologically the interaction of DR TB drugs and DM drugs causes a low success in the treatment of patients with T2DM of DR TB[11]. The implementation of T2 DM of DR-TB treatment is more difficult because there is an interaction of DR TB and DM drugs resulting suboptimal drug concentration. Therefore, the treatment success is less likely to be achieved[2].

Since the beginning of January 2014 until the end of September 2017, the treatment of DR-TB in Riau Province used the old regimens or conventional method with the intensive period at least 8 months and 12-month of follow-up phases. Since October 2017 up to present time, the treatment in Riau Province has been using a new blend of regimens with an intensive period of 4-6 months and 5-month of follow-up phases. STR is usually used for 9 to 11 months treatment and it is shorter than the old regimens[12][13]. The use of new regimens was able to accelerate the final conversion of sputum culture and the treatment success[14][15].

There is only a few research on the influence of T2DM and treatment regimens on the success of DR- TB treatment. The purpose of this study is to determine the effect of T2DM and treatment regimens on the success of DR-TB treatment in Riau Province in 2014-2018.

Materials and Method

Material: The type of data collected in this study is secondary data about demographic data namely, age, sex, marital status, occupation, education, residence category, clinical factors of T2DM status, history of previous TB treatments, medication adherence and treatment regimens.

The method of data collection was determined by the researchers and enumerators who had received previous training. Data was collected at the DR-TB referral hospital and DR-TB sub-referral hospitals by the researchers involving enumerators to ensure the data validity and to prevent data bias.

The data that had been collected was processed manually as well as by computers through the stages of data checking, coding, data entry and processing and cleaning data. Data analysis was made using STATA version 15 with a survival analysis. The outcome in this study was in the form of the treatment starting time until the success of DR-TB treatment.

Research Method: This study used a quantitative research with retrospective cohort through DR TB secondary data of Riau Province in 2014-2018. Samples were taken from all adult ≥ 30 years old DR TB patients who underwent treatments at a DR TB referral hospital of Arifin Achmad Regional Hospital and 7 DR TB sub-referral hospitals in Riau Province in 2014-2018. This study used secondary data of DR TB 03, DR-TB 01, medical records and *e TbManager* of patients from the DR TB referral hospital of Arifin Achmad Regional Hospital and 7 DR TB sub-referral hospitals in Riau Province in 2014-2018.

Sample population of 216 respondentswere all TB RO patients who underwent treatments at the DR-TB referral hospital of Arifin Achmad General Hospital and 7 DR-TB Sub-Referral Hospitals in Riau Province. The subjects of this study 146 respondents, were ≥ 30

years old DR-TB patients who underwent treatments at the DR-TB referral hospital of Arifin Achmad General Hospital and 7 DR-TB sub-referral hospitals in Riau Province. Since the beginning of the DR-TB treatment program in 2014 until February 2018, there were 146 DR-TB patients whose end of treatments had been identified.

Results

Frequency distribution based on Type 2 DM and treatment regimen on the success of treatments

Table 1: Frequency distribution based on Type 2 DM and treatment regimens on event status (The Success of DR-TB Treatment) in 2014-2018 in Riau Province

No	Variable	Sensor		Success of Treatment (Event)		Total	P
		n= 66 (45, 20%)		n=80 (54, 79%)		n= 146 (100%)	
		N	%	N	%	n	%
1.	**DM Status and regimen**						
	• Non DM and old regimen	29	19,86	42	28,76%	71	48,63
	• DM and old regimen	21	14,38	15	10,27%	36	24,65
	• Non DM and new regimen	6	4,10	19	13,01%	25	17,11
	• DM and new regimen	10	6,84	4	2,73%	14	9,57

Based on the table above, among 146 patients, 80 patients (54.79%) were successfully treated and 66 patients (45.21%) were unsuccessfully treated. 71 patients (48.63%) were not in Type 2 DM and they were treated using old regimens. In the univariate analysis, it was found that the success of treatments using old regimens on DR-TB patients with nonT2DM was higher than treatments using old regimens on DR-TB patients with T2DM (28.76% vs. 10.27%). Whereas, treatments using new regimens on DR-TB patients with nonT2DM were more successful than treatments using new regimens on DR-TB patients with T2DM (13.01% vs. 2.73%).

Final Model of Multivariate Survival of Effect of Type 2 DM and regimens on the success of DR-TB treatments.

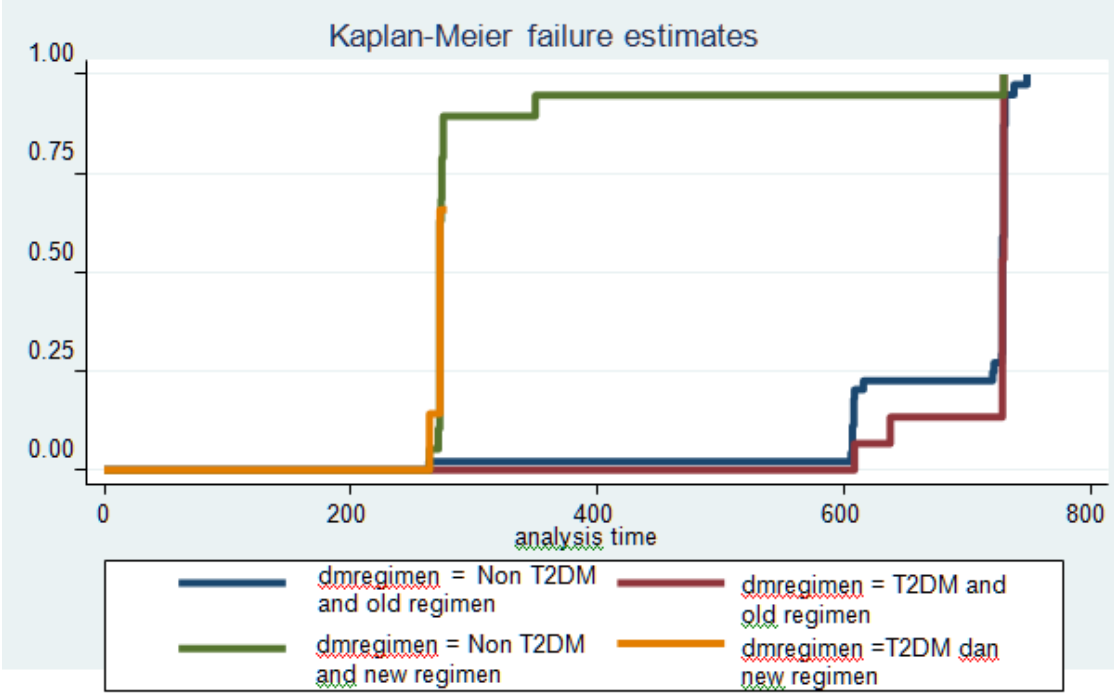
Table 2: Results of Final Model of Effect of Type 2 Diabetes Mellitus and treatment regimens on the success of DR-TB treatments in Riau Province in periods of 2014-2018

No	Variable	Coef (B)	SE	P value	HR Adj	95% CI
1.	Status DM and regimen					
	• Non T2DM/old regimen	-	-	-	-	ref
	• T2DM/old regimen	0,02	0,32	0,93	1,02	0,54-1,92
	• Non T2DM/new regimen	1,95	2,24	<0,001	7,06	3,79-13,16
	• T2DM/new regimen	2,36	6,48	<0,001	10,66	3,23- 35,12
3.	Marital Status					
	• Married	-	-	-	-	Ref
	• Not Married	0,52	0,57	0,12	1,69	0,86-3,31
	• Widow/Widower	0,49	0,87	0,35	1,64	0,57-4,65

Based on the table above, the probability of successful DR-TB treatments on T2DM group using new regimens was 10.66 times higher (95% CI 3.23-35.12) compared to the Non T2DM group using old regimens after marital status is controlled with statistically significant at p value <0.001. Probability of successful treatments on T2DM

group using new regimens is bigger than probability of successful treatments on Non T2DM group using new regimens and T2DM group using old regimens.

Influence of type 2 DM and treatment regimens on the success of DR-TB treatment: The 50% probability of treatment success on T2DM and non T2DM patients using the old regimen occurred on the 729th day. Whereas, the 50% probability of treatment success on T2DM and non T2DM patients using new regimens occurred more quickly on the 272th day as shown in the figure 2.



The Figure of Kaplan Meier Survival Analysis shows that DR-TB treatments on T2DM and Non T2DM patients using old regimens have a longer median survival level than DR-TB treatments on T2DM and Non T2DM patients using new regimens (729 days vs. 272 days).

Discussion

There are several weaknesses in this study that affected the results of the study, such as information bias. The limitation of this study is that information bias may occur due to incomplete and inaccurate data recording on DR-TB 01, DR-TB 03, medical record records and data of e TB manager which was filled out by the staffs of DR-TB referral general hospital and sub referral hospitals.

The strength of this study is that the study can examine the sequence of causal events where causes precede effects so that the temporal time relationship can be assessed. Time survival can be included in a cohort study with survival analysis so that time can be taken into account on all samples until observations are finalized. In this study, the T2DM factors and the regimens precede the effect on an event status (treatment success) so that the effect of causality on the results of this study is relatively good.

The time element shows that the treatment adherence decreases in DR-TB patients using old regimens that influence the side effects of the drug taken[11]. DR-TB patients who also have DM have greater risk of undergoing treatment compared to DR-TB with non T2DM[2].The late conversion from T2DM status also results in the increase of treatment time[16].

The treatment of DR TB patients both with T2DM and NonT2DM groups using new regimens is significantly more successful compared to that of DR-TB patients in T2DM group and NonT2 DM groups

using old regimens. The research results in 9 African countries showed that new regimens were very effective in increasing the success of DR-TB treatment by 77.4% to 91.8%[17][18]. Based on research in Jakarta, the success of treatment using old regimens was 39.8% and using new regimens was 48.9%[18]. However, this study did not consider the exposure status of T2DM or NonT2DM.

The management of DM control is very important in observing the severity and adequate treatment response on DR-TB patients who also suffer T2DM(20)(21). The low adherence of T2DM patients who undergo the DR-TB treatments can affect the success and duration of the treatments. A good collaboration of DR-TB and T2DM programs needs to be made to improve the success of DR-TB treatment on T2DM patients and to reduce the burden of DR-TB among DM patients and the burden of DM patients among DR- TB patients[2][17].

Observational studies performed in countries that implemented new treatment regimens (STR) i.e. in Bangladesh, Benin, Burkina Faso, Burundi, Cameroon, Central Africa, Congo, Nigeria, Switzerland and Uzbekistan showed that the success rate of STR treatment was 84% (95% Cl; 70-87%). Meanwhile, the success rate of treatment using long-term standard regimens only reached 62% (95% CI; 53% -70%). The use of new regimens/STR became a potential effort to shorten treatment time and to make treatment simpler and more effective[18][5][22][15]. The limitation of this study is that this study cannot see the effect of group of serious-categorized T2DM patients or group of mild-categorized T2DM patients and the treatment regimens on the successful DR-TB treatment.

Conclusion

This study proved that DR-TB treatment on DR-TB patients in T2DM group and nonT2DM group using new regimens resulted in a greater chance of successful treatment and a faster recovery time than DR-TB treatment using old regimens.

Role of Vitamin C in Endothelial Dysfunction in Patients with Type 2 Diabetes Mellitus Introduction

Nermien Abd El Rahman Ibraheim[1], Fatema El Zahraa Sayed Bukhary[1], Yehia Zakareia Mahmoud[1], Mahmoud Ragab Mohamed[1], Salama Rabei Abdel-Rahim[2]

[1]Internal Medicine, Internal Medicine Department, [2]Internal Medicine, Biochemistry Department, Faculty of Medicine, Minia University, Egypt

Abstract

Background: To investigate the relationship between ascorbic acid level in serum and anti-oxidant parameters in blood with type 2 diabetes mellitus patients.

Patients and Method: The study was conducted on 85 subjects,25 as a control and 60 with type 2 diabetes

Results: The current study was done in the period between January 2016-December 2018. The study included 60 patients with type 2 DM. The duration of diabetes ranged from one month to 240 month with mean 74.2±64.8

Conclusion: T2-DM patients with more severe diabetic nephropathy had lower vitamin C levels

Keywords: *Type 2 diabetes mellitus; Vitamin C; endothelial dysfunction.*

Introduction

In severe Oxidative stress (OS) cell damage may occur due to the low expression of antioxidant enzymes, is particularly sensitive to reactive oxygen and nitrogen species (RONS) [(1)]. These molecules may act on different substrates in the insulin intracellular signaling cascade, causing cell damage [(2)].

This process is probably the common event for DM-2 complications with the hyperglycemia being the probable biochemical key involved in the induction of such pathways [(3)]. For Monnier & Colette [(4)], both the activation of the OS and the excessive glycation of proteins caused by hyperglycemia appear as important components in the emergence of diabetic complications.

Aim of the Study: To investigate the relationship between ascorbic acid level in serum and anti-oxidant parameters in blood with clinical, and duplex findings of brachial artery of patients with type 2 diabetes mellitus.

This prospective Cross sectional case control study was conducted in the period between (from January 2016-December 2018) at MINIA university hospital from the out-patient clinic.

The included subjects of the current study were 85 subjects: 63 females and 22 males and their ages ranged from 41-72 years old.

Group 1: The control group (25 volunteers) will be selected as healthy participants of matched age and gender having no past history of any chronic medical illnesses.

Group 2: Sixty (60) diabetic type 2 patients will be included among those attained to the MINIA university hospital out-clinic.

- Patients with other chronic medical illnesses,
- Those with secondary diabetes or other endocrinal

pathologies.

- Mental health problems (senile dementia and Alzheimer's disease, among others) will be excluded, as they configure vulnerable groups, beyond the scope of this study.

Laboratory studies; Duplex study; Echocardiography.

Statistical Studies: The collected data were coded, tabulated, and statistically analyzed using SPSS program (Statistical Package for Social Sciences) software version 25.

The level of significance was taken at (P value < 0.05).

Results

Table 1: Echocardiographic parameters comparative analysis:

		Control	DM	P value
		N=25	N=60	
Ejection fraction of left ventricle	Range Mean ± SD	(59-78) 65.4±4.9	(59-76) 65±4.2	0.678
left ventricular diameter in diastole	Range Mean ± SD	(3.1-5.1) 4.3±0.6	(3.2-6.3) 4.6±0.6	0.034*
left ventricular diameter in systole	Range Mean ± SD	(2.1-3.5) 2.8±0.4	(2.1-3.7) 2.9±0.4	0.060
Left ventricle hypertrophy	Yes No	0(0%) 25(100%)	9(15%) 51(85%)	0.053

In this table:

1. **The Ejection fraction of left ventriclewas** ranged from (59-78), the mean was 65.4±4.9 in control, while in Diabetic group the range was (59-76) and the mean was 65±4.2.
2. **Left ventricular diameter in diastole** ranged from (3.1-5.1cm), the mean was 4.3±0.6 in control, while in Diabetic group the range was (3.2-6.3cm) and the mean was 4.6±0.6.
3. **Left ventricular diameter in systole was** ranged from (2.1-3.5cm), the mean was 2.8±0.4, while in Diabetic group the range was (2.1-3.7cm) and the mean was 2.9±0.4.
4. **Left ventricle hypertrophy was found 15% in diabetic, while not in 85%of diabetic group.**
5. As shown in this table regarding **Echocardiographic parameters**. There were statically significant difference between control and diabetic group regarding to **left ventricular diameter in diastole.**

Discussion

Persistent hyperglycaemia in diabetes mellitus increases the production of reactive oxygen species (ROS) and activates mediators of inflammation as well as suppresses antioxidant defense mechanisms, ultimately contributing to oxidative stress which leads to endothelial dysfunction (ED) in diabetes.Furthermore, there is increasing evidence that ROS, inflammation and fibrosis promote each other and are part of a vicious connection leading to development and progression of CVD and kidney disease in diabetes [(5)].

In the current study; 35% of diabetic patients showed manifestations of peripheral ischemia and 30% of them showed diabetic retinopathy (P <0.001). They showed raised Systolic B.P. and diastolic B.P. highly significantly level (P=0.009 & P<0.04 respectively) than control.

Endothelial dysfunction is one of the initial key steps in atherosclero-genesis in diabetic subjects. Several risk factors, such as hypertension, dyslipidaemia, inflammation, oxidative stress, and AGEs, are associated with atherosclerosis and micro- and macro-vasculopathies[(6)]. The mechanism of endothelial dysfunction (ED) in type 2-DM may be due to increased inactivation of endothelium-derived nitric oxide by oxygen-derived free radicals [(5)].

Relationships between oxidativestress markers and antioxidants, point to vitamin C as a potential prognostic indicator of diabetic microangiopathy. All patients with long-standing diabetes used oral hypoglycemic drugs or insulin or both, and most of them were taking antihypertensive and cholesterol-lowering drugs, they showed the highest imbalance between the antioxidant status and increased concentrations of oxidative damage markers[5,7].

In the current study; plasma levels of ascorbate, SOD, catalase and glutathione were highly significantly decreased, while plasma lipid peroxidation levels were highly significantly raised in patients' group than those of control (P= 0.001). Urinary ACR, plasma total cholesterol and LDL were highly significantly raised in patients' group than that of control group (P= 0.001). The Plasma TG was insignificantly raised in diabetic patients' group (P=0.67).

These results agreed with those of [8]whoshowed that T2-DM patients with the highest Urinary ACR (greater than 300 mg/g) had the lowest levels of vitamin C and the highest urine albumin concentration. They found also that vitamin C levels correlated negatively with serum creatinine, urine albumin and UACR. Overall they concluded that T2-DM patients with more severe diabetic nephropathy had lower vitamin C levels.

Concentration of vitamin C was significantly lower in patients with metabolic syndrome (MS) than in the control group. Gender and age did not affect either the mean concentrations of vitamin C.[6]

In Type-2 DM, reduced serum antioxidant activity correlates with worsened glycemic control. Increased oxidative stress and low vitamin C levels were correlated with severity of diabetic neuropathy. SOD and vitamin C prevent the rapid inactivation of NO by superoxide anion [7].

Ethical Statement: The material has not been published anywhere. Authors of the manuscript have no financial ties to disclose and have met the ethical adherence.

Effectiveness of Providing Self-Management Education to Deal With Emesis Gravidarum on Decreasing Nausea Vomiting Pregnancy (NVP) at Private Practice Midwives Puskesmas IV Denpasar Selatan Work Area

Ni Nyoman Deni Witari[1], Ni Made Dewianti[1]

[1]Diploma III Kebidanan, Politeknik Kesehatan Kartini Bali, Jalan Piranha No 2 Pegok Sesetan Denpasar Bali Indonesia

Abstract

Data shows that 50-90% of pregnant women experience nausea in the first trimester. Excessive gravida emesis will gain weight into hyperemesis gravidarum and can disrupt the mother's metabolism including dehydration, weight loss, alkalosis, and hypokalemia. Non-pharmacological therapy is a type of complementary therapy that can be used as an intervention to treat nausea including hypnotherapy, acupressure, acupuncture, relaxation, and therapy. Self-management is regulating personal activities to live a better and healthier life. Emesis gravidarum self-management education adopts the concept of Corbin and Straus in Kate and Halsted (2003), which is outlined in a module that aims to enable pregnant women to educate themselves to be able to regulate their own lives, set goals, and provide self-reinforcement in dealing with nausea, vomiting experienced. The purpose of this study was to determine the effectiveness of providing self-management education to deal with emesis gravidarum on decreasing Nausea Vomiting Pregnancy (NVP). This is an analytical study with a pre-experimental research design (quasi-experiment design) with one group pre-test-post test design. This study was conducted at Private Practice Midwives (hereafter: PMB) Puskesmas IV Denpasar Selatan Work Area. The population of this study was pregnant women who came to PMB in the work area of Puskesmas IV Denpasar Selatan. The sample of this study was pregnant women who experienced nausea and vomiting in the first trimester who met the inclusion criteria where the sampling technique in this study was accidental sampling. Analysis of the data in this study was conducted t-test to test the differences between the two pre and post-test distributions before self-management education was given and after the providing of self-management education was faced with emesis gravidarum. The results of the study showed that the average value of PUQE 24 hours before the self-management module was given was 9.5, the standard deviation value was 2.591, the minimum and maximum values were 6.0-14.0. The average value of PUQE-24 hours after the self-management module was given was 7.1, the standard deviation value was 2,273 with minimum and maximum values of 3.0-12.0. The conclusion of giving self-management module is effective to decrease nausea and vomiting in first-trimester pregnant women.

Keywords: *First-trimester pregnant women, emesis gravidarum, self-management education.*

Introduction

Pregnancy is the growth and development of the fetus in intra-uteri starting from conception and ending until the beginning of labor. The process of pregnancy causes changes in the body of the mother. These changes are largely due to the influence of hormones, for instance the hormones estrogen and progesterone. Increased hormones estrogen and progesterone in the body cause

physiological discomfort in the mother such as nausea, vomiting, fatigue, and enlargement of the breast. The process of pregnancy causes various changes in the entire body system such as cardiovascular, respiratory and gastrointestinal systems influenced by the pregnancy hormone HCG (Chorionic Gonadotropin Hormone)[1].

Physiological adaptations to the gastrointestinal system cause discomfort in the form of nausea and vomiting. Pregnant women who have this will experience interference with their activities. Psychologically, nausea and vomiting during pregnancy affect more than 80% of pregnant women and have a significant effect on the quality of life[2].

Nausea and vomiting are one of the earliest, most common and most stressful symptoms in early pregnancy. About 50 - 90% of pregnant women experience nausea in the first trimester and about 25% of pregnant women experience nausea and vomiting problems. Nausea and vomiting most often occur in young pregnancies from the 6th week after the first day of the last menstruation. 50% of pregnant women who experience nausea and vomiting can overcome at the age of 14 weeks and 90% can overcome until the age of 22 weeks[3]. Nausea and vomiting during pregnancy, known as morning sickness, occurs in the first trimester of pregnancy and some continue until the second trimester. The frequency of occurrence of morning sickness is not only in the morning but can be daytime even at night[4].

According to the Lacase report of 367 pregnant women, 78.47% experienced nausea and vomiting that occurred in the first trimester; 52.2% experienced mild nausea and vomiting, 43.3% experienced moderate nausea and vomiting and 2.5% experience severe nausea and vomiting. In the second trimester, most pregnant women still experienced nausea and vomiting by 40% with the following details 63.3% experienced mild nausea and vomiting, 35.9% experienced moderate nausea and vomiting, 0.8% experienced severe nausea and vomiting.

Excessive emesis of gravidarum will become hyperemesis gravidarum which can disrupt the mother's metabolism, dehydration, weight loss, alkalosis, and hypokalemia. Impact on the fetus such as abortion, LBW, premature birth, and malformation in newborns[5].

Most pregnant women who experience nausea and vomiting in the community use pharmacological therapy. Some just left alone. The use of pharmacology for pregnant women needs to be considered because there are changes in pharmacokinetics and pharmacodynamics of drugs during pregnancy[6]. Non - pharmacological therapy, type of complementary therapy that can be used to treat nausea such as hypnotherapy, acupressure, acupuncture, relaxation, and therapy.

Nausea and vomiting during pregnancy are mild disorders; this condition can be overcome by self-control. In addition to self-control, nausea and vomiting can also be overcome by creating behaviors to reduce complaints[7]. Handling of nausea and vomiting in pregnant women needs to be done to improve maternal health status, one of them is by creating behaviors to reduce complaints. Creating behavior for a healthy life according to the patient's condition is part of self-management[8].

Emesis gravidarum self-management education adopts the concept of Corbin and Straus in the 7th, which is outlined in the form of a module that aims to enable pregnant women to educate themselves to be able to regulate their own lives, set goals and provide self-reinforcement in dealing with nausea and vomiting experienced

Material and Method

This study was held at PMB Puskesmas IV Denpasar Selatan's Work Area; six PMB in total. The design used in this study was a quasi-experimental with one group pretest-posttest design. The type of data collected is secondary data, obtained from the visitation register of pregnant women at PMB, Puskesmas profiles and primary data obtained directly from interviews with respondents about the characteristics, knowledge, and data on the level of nausea and vomiting. The instrument used was a questionnaire to determine the characteristics of respondents, and a questionnaire (PUQE-24 hours) to measure the severity of nausea and vomiting. The pregnant women as the respondents ware provided self-management modules and standard operating procedures to deal with emesis gravidarum. The population in this study was all pregnant women who had antenatal visits in PMB Puskesmas IV Denpasar Selatan work area in 2018. The sample of this study was pregnant women who experience nausea and vomiting who visited and met the study inclusion criteria. Criteria for inclusion; first-trimester pregnant women who experience nausea and vomiting are willing to be respondents and have not experienced complications in pregnancy. Exclusion

criteria are first-trimester pregnant women who experienced complications, hyperemesis gravidarum, and gastritis. The sampling technique used was accidental sampling, by taking respondents who happened to be present or at the time of the study. This was conducted for four months in BPM Region Puskesmas IV Denpasar Selatan. Severity measurement of nausea and vomiting on pregnant women with a questionnaire (PUQE-24 hours) was carried out twice; first, before being given self-management education (pretest) and second, two weeks after giving self-management education (posttest) modules. Data analysis used Paired T-test with a 95% confidence interval and a significance level of P <0.05.

Findings: The results of the analysis in this study are as follows:

Table 1: Frequency Distribution of Nausea and Vomiting before Providing the Self-Management Module at PMB Puskesmas IV Denpasar Selatan working area in 2019

No.	Nausea and vomiting	Frequency (f)	Percentage (%)
1	No symptoms	-	-
2.	Mild	10	25
3.	Moderate	22	55
4	Severe	8	20
	Total	**40**	**100**

Source: Primary Data Research in 2019

Based on table 1 shows that from 40 respondents before providing self-management module; 10 respondents (25%) showed mild symptoms, and 8 respondents (20%) showed severe symptoms, almost half of the respondents, 22 people (55%) showed moderate symptoms.

Table 2:Frequency Distribution of Nausea and Vomiting after Providing the Self-Management Module at PMB Puskesmas IV Denpasar Selatan work area in 2019

No.	Nausea and vomiting	Frequency (f)	Percentage (%)
1	No symptoms	3	7.5
2.	Mild	16	40
3.	Moderate	21	52.5
4	Severe	-	-
	Total	40	100

Source: Primary Data Research in 2019

Table 2 shows that from 40 respondents after providing self-management module; 3 respondents (7,5%) showed no symptoms of nausea and vomiting, almost half of respondent; 16 people (40%) showed mild symptoms, and more than half respondents; 21 people (52,5%) showed moderate symptoms, and no respondent showed severe symptoms.

Table 3: Pregnancy Unique Quantification of Emesis and Nausea (PUQE)-24 hours Score Before and After Providing Self-Management Module at PMB Puskesmas IV Denpasar Selatan Work Area in 2019

Variable	Mean	SD	Minimum	Maximum
Pretest	9,5	2,591	6,0	14,0
Posttest	7,1	2,273	3,0	12,0

Based on table 3 the mean of PUQE-24 hours before providing self-management module is 9.5, SD is 2,591, minimum and maximum are 6,0-14,0. Mean of PUQE-24 hour after providing self-management module is 7,1, SD is 2,273, minimum and maximum 3,0-12,0

Wilcoxon test was used due to not eligible data for parametric test

Table 4: Wilcoxon Signed Ranks Test

Ranks				
		N	Mean Rank	Sum of Ranks
Post_Modul - Pre_Modul	Negative Ranks	31[a]	16.00	496.00
	Positive Ranks	0[b]	.00	.00
	Ties	9[c]		
	Total	40		

a. Post_Modul < Pre_Modul, b. Post_Modul > Pre_Modul, c. Post_Modul = Pre_Modul

Test Statistics	
	Post_Modul - Pre_Modul
Z	-4.886[b]
Asymp. Sig. (2-tailed)	.000

a. Wilcoxon Signed Ranks Test, b. Based on positive ranks.

Based on table 4 shows that *Asymp. Sig.(2-tailed)* with error rate 0.5%;p-value (0.000), ($p < 0.05$) So the Ho is declined and Ha is accepted. This means there is effectiveness in providing self-management module to decrease nausea and vomiting.

Discussion

The results of this study illustrate the tendency for a decrease in PUQE-24 scores from before and after providing the module. The mean PUQE-24 score decreased by 2 points, 9.5 with a standard deviation of 2.591 before treatment, and 7.1 with a standard deviation of 2.273 after treatment. The results of statistical analysis with the Wilcoxon test showed the number of 31 respondents (76%) had decreased PUQE-24 scores with p-value =0,000. This proves that there is a significant effect on providing self-management modules on dealing with morning sickness. Kohen et al. (2005) categorize the severity of nausea and vomiting in pregnancy into 3 categories. The score of 0-3 has no symptoms, the score of 4-6 is mild, the score is 7-12 moderate, and the score is ≥ 13 severe categories.

Based on the characteristics of the frequency of morning sickness, before treatment there were 25% of respondents experiencing mild nausea and vomiting, 55% experienced moderate nausea and vomiting, and 20% of respondents who experienced severe nausea and vomiting. After treatment, respondents who did not experience nausea and vomiting (7.5%), those who experienced mild nausea and vomiting became 40%, and those who experienced moderate vomiting nausea 52.5%. Wilcoxon statistical test results showed a significant difference between PUQE scores before giving morning sickness self-management modules and after administration. This shows that there is an effect of morning sickness self-management module on the decrease in the frequency of nausea and vomiting in pregnant women. Value p = 0,000 so that it can be concluded that this self-management module is effective in dealing with morning sickness in pregnant women.

The use of morning sickness self-management module to decrease the frequency of nausea and vomiting in pregnant women was only investigated by Latifah L (2014) where the results of the study showed that differences in the pretest and posttest values were analyzed using the Wilcoxon test, so that a significance value : 0,000 ($p < 0.05$) was obtained[9]. There is a difference in the PUQE score before and after giving the morning sickness self-management module. The morning sickness self-management module is effective in dealing with morning sickness in pregnant women. The previous study did not measure respondents' prior knowledge and used a minimum of 30 respondents.

The self-management module has been applied to several independent treatments for cardiovascular disease and schizophrenia. Self-management treatment method have been investigated for their effects on chronic diseases such as cardiovascular disease, diabetes mellitus, chronic obstructive pulmonary disease, and schizophrenia. Diabetic patients who follow the self-management program are shown to have significantly improved their clinical conditions (decreased blood sugar), can achieve self-care targets, and are satisfied with health care[9]. Research on the chronic obstructive pulmonary disease (PPOM) has also shown equally positive results. Patients who participated in the self management program experienced a decrease in the severity of the disease by 39.8%, a decrease in the number of hospital visits by 57.1%, a decrease in the number of visits to the doctor incidentally by 58.9%, and a decrease in visits to the emergency department by 41% [10].

Self-management is one of the most common terms used in health promotion and patient health education. Self-management is very useful for patients, especially patients with chronic diseases where only patients who can be responsible for the treatment of the disease daily during his illness. Patients with chronic diseases besides experiencing physical disorders, usually also experience psychological disorders and well-being. Therefore, self-management programs often focus on improving self-perspective and patient welfare[7].

Morning sickness self-management module contains several interventions to overcome nausea and vomiting during pregnancy, including the consumption of ginger drinks, food management, gradual mobilization during the morning, acupressure, and relaxation. Several studies have proven that ginger products which can be in the form of drinks or extracts are proven to overcome nausea and vomiting during pregnancy[12]. McKinney

et al. (2009) mentioned that eating arrangements by eating small but frequent portions, avoiding oily foods, consuming more protein compared to carbohydrates, and separating eating and drinking can reduce the incidence of nausea and vomiting during pregnancy[11]. Wentorf and Dykes (2001) and Artika (2006), found that acupressure by suppressing the P6 point (Neiguan point) was significant in reducing nausea and vomiting during pregnancy[13]. During the study, there were no respondents who complained about the difficulty in implementing the tasks and recommendations in the morning sickness self-management module.

Conclusion

Providing Self-Management Education to Deal Emesis Gravidarum Effective on Decreasing Nausea Vomiting Pregnancy (NVP) at PMB Puskesmas IV Denpasar Selatan Work Area

Detection of Single Nucleotide Polymorphisms in IL-1B gene in Iraqi Patients with Hepatitis B

Noor AL-Hamid[1], Aliaa Mohammad Hadi[2], Mohammad Saad Majeed[1]

[1]Assist. Lecturer University of Baghdad, College of Science, Department of Biotechnology,
[2]Assist. Lecturer Middle Technical University/AL-Mansoor Technical Medical Institute

Abstract

Host genetic factors play an important role in the pathogenesis of hepatitis B virus (HBV) infection. However, the role of interleukin 1 receptor, type I (IL-1B) gene in HBV infection and breakthrough infection in people remains unclear. The aim of this study was to detect a SNP in IL-1B in HBV infection in Iraqi people.

Keywords: *Nucleotide, Hepatitis B, Polymorphisms.*

Introduction

Hepatitis B virus (HBV) infection, a viral infection spreading through the blood and body fluids, is a global health problem affecting more than 2 billion people globally (Liaw and chu CM,2009). Worldwide 240 million people are infected with chronic hepatitis B virus (CHB), resulting in an estimated 650000 death each year. Almost 80-90% of people infected during the first year of life and 30-50% of people infected before the age of 15 develop chronic infection respectively. The infection with HBV < 5% 0f them will develop chronic infection and 20-30% of chronic infected patients will develop cirrhosis and/or liver cancer [(1)].

Hepatitis B vaccine (HB vaccine) has been approved for preventing transmission of HBV since 1982. At present, HB vaccine has been added into the national immunization program in almost all countries[(2)]. Without immunoprophylaxis, about 90% of people infected by their mother with hepatitis B antigen (HBeAg) and with high viral load would develop chronic HBV infection[(2)].China used to be a hyper endemic region for HBV infection. To raise the coverage rate of HB vaccine, the Chinese government has provided all people with recombinant HB vaccine free of charge since 2002. Vaccination with a three dose provide long term protection[(3)]. It was reported that the prevalence of HBsAg in china was decreased[(4)]. In addition the infants born of HBsAg positive mothers have been able to receive hepatitis B immunoglobulin (HBIG) within 24 hours after birth for free since 2010[(5)]. HBV breakthrough infection is influenced by immunological factors, viral factors, environmental factors and host genetic factors [(6)] . Host genetic factors play an important role in the pathogenesis of HBV infection 12. A number of studies have reported the associations between HBV infection outcomes and polymorphisms11. Being involved in the inflammatory cytokine network, interleukin-1 family (IL-1 family) plays an important role in the pathogenesis of HBV infection. IL-1 family includes: IL-1A, IL- 1B, IL-18, IL-33, IL-36, IL-37, and IL-38 et al 13. Genetic variants in IL- 1 family (such as IL–1 B and IL-18) were reported to be associated with persistent HBV infection or HBV clearance[(7)] demonstrated that the polymorphisms of the promoter region of the IL-18 gene at position _607 and _137 were closely associated with susceptibility to CHB14. [(8,9)]. indicated that another IL-1 family member, IL–1 B gene polymor- phisms, were associated with the clinical outcomes of HBV infection in Eastern Indian population12. We aimed to explore the association IL-1B, single-nucleotide polymorphisms (SNPs) and breakthrough infection of HBV in children through a case-control study[(10,11)].

Materials and Method

DNA extraction that used in this study: Approximately (2ml) of blood was taken from each patient by sterile syringe and places EDTA tubes.

1. Each blood sample was placed into 15 ml tube.
2. Cell lysis solution was added to the sample about 6 ml.
3. Blood and cell lysis were mixed together by

inverting the tubes several times and incubate them for 10 minutes in room temperature.

4. Samples were centrifuged at 10000 rpm for 20 minutes.
5. The supernatant was discarding by using a pipette to avoid losing the pellet.
6. Add 2 ml of nucleic lysis buffer to the samples.
7. The mixtures were mixed by inversion.
8. Then 2 ml of protein precipitation solution was added then vortex the samples for 20 seconds.
9. Centrifuged the samples at 10000 rpm for 10 minutes.
10. After the centrifugation, the supernatant were transfer to new tubes that contain Isopropanol about 2 ml.
11. The mixtures were centrifuged at 10000 rpm for 20 minutes.
12. Then discarded the supernatants and add 2 ml of 70% ethanol.
13. Centrifuged the sample again at 10000 rpm for 10 minutes.
14. Aspirated the ethanol and dry the pellet for 10–15 minutes.
15. The final step is (100µl) of DNA rehydration was added to the samples and storage them overnight at 4 ºC
16. At the next day the samples were taken to estimate the DNA concentration by Nanodrop.

Blood Samples: The samples were collected from Medical City Hospital in Baghdad, using EDTA tubes and sterile syringe which consist of 50 patients (20 controls, 30 patients). The samples were transferred to the laboratory for DNA extraction.

Amplification of DNA by PCR technique:

Specific primers and their preparation: There are variant SNPs in the *IL-1B* gene that examined and used in this study .

One pairs of specific primers were provided by (Alpha DNA–Canada) for detection of SNPs in IL-1B gene. The details of these primers which including sequence and their gene locations are presented in table (1). Which provided in lyophilized form and dissolved in sterile distilled water to have the final concentration of 10 pmol/µl

Table (1): The details of this primer

Primer	Sequence
IL-1B	CTCATCTGGCATTGATCTGG (FORWARD) GGTGCTGTTCTCTGCCTCGA (REVERSE

Then amplified the gene with PCR program that contain (Initial Denaturation at 95C° for 5 minute, Denaturation at 94C° for 30 seconds, Annealing tempreture at 60C° for 30seconds, Extension at 72C° for 1 minute and final extension at 72C° for 7 minutes).

The quantity and amplification size of PCR product were confirmed by Agarose gel electrophoresis of 5 µl of amplified DNA on 2% Agarose gel (1 hour and 0.5 X Tris Borate Buffer). The gels stained with Ethidium bromide and visualized by U.V transilluminator and then were imaged by gel documentation system. The specific size of PCR products were estimated by comparing with the ladder bench top PCR markers (100bp) . There were some problems appeared on the gel such as:

1. Primer dimmer
2. Unspecific product.

The suitable solution for avoiding these problems by using optimization PCR reaction which consist:

1. Changing in annealing temperatures: That means using different temperatures less than the original temperature (58ºC less than 60ºC) and three temperatures more than the original (62ºC, 64ºC, 66ºC more than 60ºC), to know at which temperature that the primer work well and can give a sharp band as shown in table(2)
2. Using 0.7 µl of primer volume instead of 1µl illustrated in PCR master mix (optimization).

Table (2): Shows Optimization PCR Programme

Steps	Temperatures	Time
Initial denaturation	95ºC	5 min (35 cycle)
Denaturation	94 ºC	30 sec.
Annealing	55ºC 57ºC 59ºC 61ºC 63ºC	45 sec.
Extension	72 ºC	1 min
Final extension	72 ºC	7 min

3. Changing in time of annealing temperature by using 45 sec. instead of 30 sec.

Then the quantity and amplification size of PCR product were confirmed by Agarose gel electrophoresis of 5 µl of amplify DNA on 2% Agarose gel (1 hour and 0.5 X Tris Borate Buffer). The gel stained with Ethidium bromide which visualize the PCR product by U.V trans illuminator and then were imaged by gel documentation system. The specific size of PCR products were estimated by comparing with the ladder bench top PCR markers (100bp).

Results

Fifty human blood samples were collected from Medical City Hospital in Baghdad province, from consisting of 30 samples infected with hepatitis B that have different ages ranged between 20-35 years. The samples were extracted by miniprep kit for frozen blood.

The amplification of IL-1B gene was done using specific PCR which is couple of specific primers. In the first PCR experiment, a standard concentration of 10 Pmol of each primer, 100 ng of template DNA was added and 35 cycles were preformed. The PCR yield were bands of the desired product so; all reaction components were kept at the same concentration as indicated in figure (1). Concerning molecular genetic studies, hepatitis B is one of the most extensively studied in patients and attention has been given to liver with special focus on the ***IL-1B*** gene.

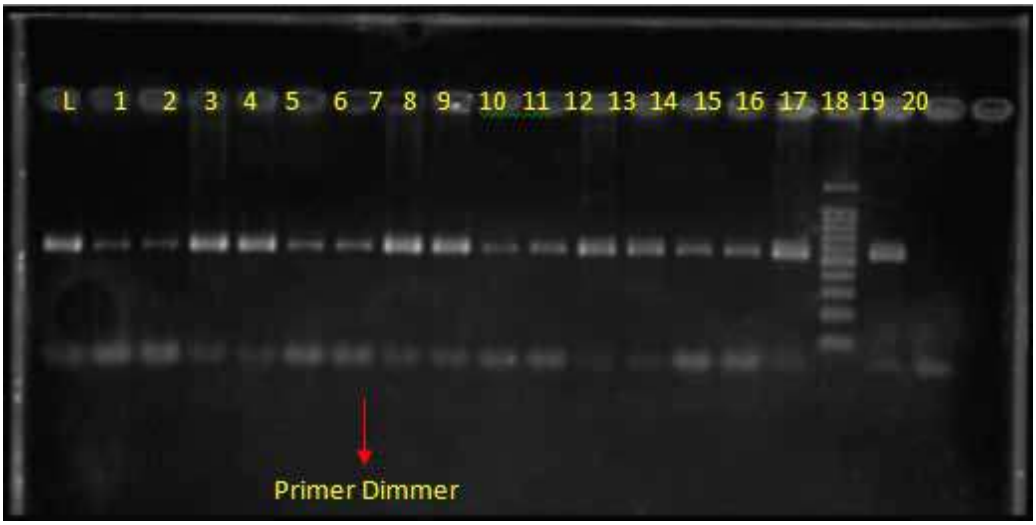

Figure (1): Agarose gel electrophoresis of the IL-1B gene in DNA samples by specific PCR.

The achieving balance between reaction components is optimization of conditions were done by using different runs to improve the performance of the method as indicated in figure (2).

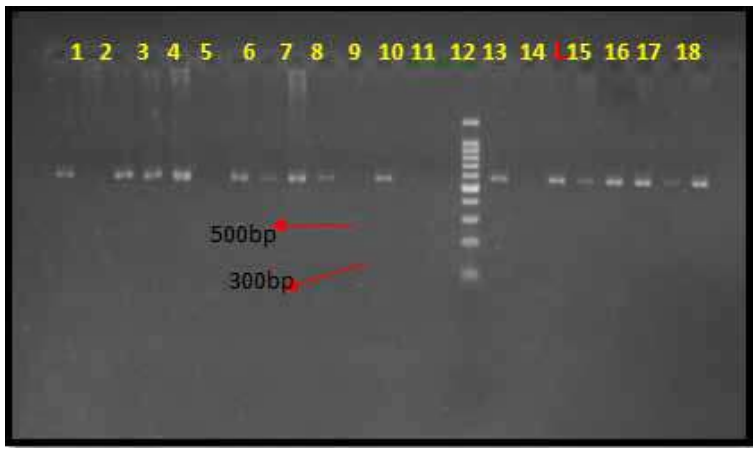

Figure (2):Agarose gel electrophoresis of the IL_1B gene in DNA samples after optimization reaction of general PCR.

From all these experiment we found that there is a SNP in all the patients which leading to have hepatitis B which concern from the symptoms of the disease.

Discussion

Hepatitis B is the most important infectious diseases in china. In recent years, genetic factors such as cytokine and human leukocyte are reported to play important role in HBV infection. in the present study we evaluated whether the genetic variant of IL-1B could influence HBV infection in people. The results showed that strong significant differences were found in the distribution of genotypes for polymorphisms of IL-1B gene SNP. In the present study we identified one SNP in IL-1B.

Conclusion

This study provides further evidence to confirm that genetic factors may play important roles in breakthrough infection of HBV in Iraqi patients. Our results suggest that the SNP in IL-1B gene is probably a risk factor for immune response, leading to breakthrough infection of HBV in Iraqi patients still needs further investigation based on a large population.

Abstract

Introduction: This study aims to determine the relationship between the consumption pattern of pokea clam and protein with LDL and HDL levels in patients with hypertension.

Method: This study used an observational analysis method with a case control study design. Research location in the area of the Sampara District. The number of samples was 60 people consisting of 30 case samples and 30 control samples using purposive sampling technique. The data was taken using a questionnaire pokea clam consumption pattern, Semi-Quantitative Food Frequency Questionnaire (FFQ-SQ) questionnaire and blood pressure data using mercury sphygmomanometer. Result of the data obtained were processed by analysis of Chi-Square test data with a value of $p<0.05$ accompanied by an Odd Ratio value.

Results: Statistical analysis showed that the relationship between pokea clam consumption patterns (ρ=0,604; OR=1,408) and protein consumption patterns (ρ=0,218; OR=2,051) with LDL levels. Statistical analysis showed that the consumption patterns of pokea with HDL levels (OR= 1.259,p=0.704) and protein consumption patterns with HDL levels (OR=0.889, p=0.839).

Conclusion: There were no correlation between pokea clam consumption pattern and protein with LDL and HDL levels in hypertensive patients of Sampara District.

Keywords: *Batissa violacea ceebencus, LDL, HDL, Hypertension, Pokea clam, Protein*

Introduction

Pokeaclam (Batissaviolaceacelebensis, von Martens 1987) is bivalves that live in several rivers in Southeast Sulawesi.It has special characteristic compared to similar species from other regions. The typical characteristics of pokea clam can be seen from the morphological and ecological conditions of the origin waters(1). Compared with the same genus, Pokea clam has more shape form and live at very low salinity. Meat of Pokea clam is used as a comestible containing proteinby the people of Sampara District, Konaweregency(2).

Pokeaclam or Batissaviolaceavar. celebensis, von Martens, 1897 is bivalves belonging to the Corbiculidae family, and it is one of the main types of freshwater clam located in the Southeast Sulawesi region(2). A kind of Pokea clamis scattered in several large islands in Indonesia such as (West Papua, Sumatra, Sulawesi, Java). Pokeaclam spread out in Sulawesi especially in Southeast Sulawesi waters, and it is mainly in large rivers such as the Pohara River, Lasolo River, Roraya River, Laeya River(3).

Based on Yenni et al's research on proximate analysis of pokea clam meat, showed that meat of pokea clam contain protein 50.48%, 6.86% of fat, 29.13% of carbohydrate, 5.53% of fiber, and 2.70% of water. Based on its dry weight, pokea clam contain the highest levels of protein which is more than 50%, medium fat content more than 5%, and carbohydrate content more than 20%. The nutritional content of Pokea clam is equivalent to several types of mollusca. It is empirically believed to be aprodisiac, increase reproductive vitality, treat fever, jaundice, and reduces blood pressure or overcome hypertension[1].

The incidence of hypertension ranked first in the 10 highest of non-communicable diseases in Southeast Sulawesi, compared to acute respiratory infections cases. Hypertension ranked third most diseases in Kendari City[4][5].

Pokea clam meat has macro content in the protein form (50.48%), fat (6.86%), carbohydrate (29.13%), ash (10.67%), fiber (5.53%), and water (2.70%). Protein consists of 9 essential amino acids and 11 non-essential amino acids. Fat divided into cholesterol, triglycerides and phospholipids also contains 27 types of fatty acids consisting of 12 types of SFA, 6 types of monounsaturated fatty acids or MUFA and 9 types of polyunsaturated fatty acids or other PUFA. The other form Contained in Pokea clam is cholesterol but in lower level than in the chicken's meat. Micro content of Pokea clam in the form of Phosphorus (P) Selenium (Se) Copper (Cu) Zinc (Zn) Cobalt (Co) Chrome (Cr) Iron (Fe)[1][6].

Protein, fat and cholesterol content in the Pokea clam, and sources of protein and lipids (triglycerides, cholesterol, phospholopids) from other foods will enter the body. Lipids in blood plasma that insoluble in plasma fluid need to be modified by protein to be able transported into the blood circulation. Cholesterol, triglycerides and phospholipids bind to proteins and this bond is called apoprotein. Apollipoprotein plus lipids becomes lipoprotein. Lipids (cholesterol, triglycerides, and phospholipids) and proteins with apoprotein are the basic ingredients for the formation of lipoprotein, in the form of high density lipoprotein (HDL), Low Density Lipoprotein (LDL), very low density lepoprotein (VLDL), intermediate density lipoprotein (IDL)use to carry out its function as a carrier of cholesterol from peripheral tissues to the liver[7].

Material and Method

The type of research is observational analytic with a case-control study design conducted in March-August 2019, in the District of Sampara. Using a purposive sampling technique, 60 respondents is selcted consisting of 30 case samples and 30 control samples. Data source of hypertension patients obtained from the Sampara Health Center. Confirm of blood pressure is measured with sphymomanometer. The research instrument was in the form of pokea clam meat consumption pattern, Semi-Quantitative Food Frequency Questionnaire (FFQ-SQ). LDL and HDL levels were measured through venous blood collection and examined at the Prodia Kendari clinical laboratory.

Findings:

Table 1: Distribution of Sample Frequency by Gender, Age, Low Density Lipoprotein, Consumption Pattern of Pokea Clam Meat, and Protein Consumption Pattern

Respondent Characteristics	Respondent Category				Total	
	Control		Case

Discussion

In this study, there is no relationship between consumption patterns of PokeaClam meat with levels of LDL. This can be caused by the processing method of pokeaclam before consumption. In general, people are more likely to process pokeaclam by boiling, although there are also some respondents processingpokeaclam meat by frying or sautéing[8]. According Purwaningsih et al [9] that the effect of processing by steaming, boiling without salt and boiling with salt on red-eye snails (Cerithideaobtusa) causes a decrease in macro and micro mineral content, except for the content of sodium and magnesium processed by boiling with the addition of salt.

This study is not in line with previous studies which found that there was a relationship between

consumption patterns of pokea clam meat (p = 0.002 and OR = 5.06) with blood pressure in the Sampara District community[10]. The study stated,fried Pokeaclam meat can affect the incidence of hypertension.

Protein intake functions are primarily as a catalyst, a carrier, activator, regulator of genetic expression, neurotransmitter, structural booster, immune booster and for growth[11]. In statistical test found there are no significant differences between the mean levels of LDL and HDL, in patients with level of adequacy protein mild deficit and more. If the level of protein adequacy is calculated based on the nutritional adequacy rate (RDA) compared to the level of protein adequacy based on actual needs, then the distribution of samples in the category of protein deficit adequacy level becomes more[12].

The results of this study indicate that there is no relationship between protein consumption patterns with LDL levels in the District of Sampara. This is caused by the fulfillment of fiber intake in the community of Sampara District. According to Samudra[12] that fiber has an important role in reducing blood cholesterol level. Consuming at least 28 grams of fiber per day can reduce cholesterol levels up to 15-19%. Epidemiological study that examines entire fiber states that there is a relationship between fiber intake and total cholesterol levels because the mechanism of fiber has an ability of lowering blood cholesterol. Some studies show that soluble fiber can reduce LDL levels without reducing HDL cholesterol levels.

The results of this study are not in line with research conducted by Safitri[13]who founda correlation between soy protein consumption with serum cholesterol levels with a weak negative patterned correlation. It is proven by the statistical test results which obtained p value of 0.048 ($p < 0.05$). That is caused soy is not only rich in vegetable protein but also contains dietary fiber, thus increasing total daily fiber consumption and decreasing fat consumption. One example is in 100 grams of BDD (edible weight) fried *Tempe* containing 9.7 grams of dietary fiber.

Most of the people of Sampara tend to consume foods rich in vitamin A, vitamin E contain in many grains, nuts and fruits including beans, brown rice, white rice, bread, peanuts, green beans, bananas and others. It is known that vitamin E can modulate the activity of the enzyme nitrite oxide synthase 3 gene in producing nitrite oxide (NO). NO itself is a compound that can cause vascular relaxation released by endothelial blood vessels. Vitamin E works as an antioxidant because it is easily oxidized, vitamin E will be taken up by LDL thereby improving endothelial function by reducing LDL sensitivity to the oxidation process, so as to increase the amount of NO production[14].

Pokeaclam (Batissaviolaceacelebensis) are a type of freshwater clam located in the Pohara River. The kind of this Freshwater clam are consumed by many people in the SamparaDistrict area in the form of satay, boiled clam meat, stir-fried clam meat and so forth. Pokeaclam are rich in carbohydrates, fats and proteins(8). Based on studies of fat and carbohydrate content in pokea clam meat when it enters the body, it will be absorbed in the intestine, and then it is brought into extra hepatic tissue or fat tissue and undergoes hydrolysis. The results of this hydrolysis are then carried to the liver by LPL enzymes through capillaries and chylomicrons as lipid transport to enter the liver which will be synthesized into HDL and VLDL. Then VLDL is converted into IDL and LDL to distribute LDL cholesterol to tissue cells and then LDL cholesterol will be transported back to the liver by HDL and will be secreted into bile acids[15].

Cholesterol in LDL contains the most cholesterol which is about 45% of all types of lipoproteins, so it can be said that LDL is the main carrier of cholesterol in the blood. The body's tissue cells receive cholesterol from LDL cholesterol, but the amount of cholesterol the cells can receive or absorb is limited. Consuming saturated fats or foods contains many cholesterol can increase LDL levels in the blood[16].

Table 3 shows the normal group the HDL content with the consumption of pokeaclam in the normal category only 6 respondents (10%) and the low group in the HDL level were 13 respondents (21.7%). This situation can be caused by many things; one of it is physical activity.

The physical activity can be in the form of sports and activities carried out on a daily basis that can reduce the risk of cardiovascular disease[17]. The results are also in line with the description of the population in the Sampara District area that has a source of livelihood as a farmer which is majority in Sampara District. This illustrates that most of Sampara's community is in lower classes, and have a lot of physical activity[18].

Besides physical activity, another factor that has an influence is daily eating patterns. Food consumed will

undergo metabolic processes in the body and produce an energy or Adenosine Triphosphate (ATP). ATP is formed in the body in accordance with the needs of the body itself, but in its formation the food consumed is not all converted to ATP but can be stored in the form of cholesterol. Increasing physical activity is carried out, so that more ATP is needed and will make a little formation of total cholesterol, Low Density Lipoprotein (LDL) and increased High density Liporpotein (HDL)[19].

Based on data of this research shows that some of the respondents in the study did not carry out physical activity on a regular basis, with the most category being female respondents as housewives (IRT). This can be one of the factors that cause no increasing in HDL levels. In this study not all of the respondents who did regular exercise for example such as aerobics, in other words there is a possibility that this situation could affect HDL cholesterol levels in respondents who did not experience an increasing.

Adequate or good nutritional intake can increase HDL levels in the body if accompanied by adequate exercise. A study conducted by Maulida in (20) said that regular exercise such as aerobic exercise for 6 months could significantly increase HDL cholesterol levels. This routine exercise will improve the function of ApoA-1 as a receptor of HDL to help reduce cholesterol in the blood vessels to the liver[20].

This is in line with the results of this study that showed there is no relationship between protein consumption patterns with HDL levels in patients with hypertension in the Sampara sub-district. The Chi square test results obtained p-value of 0.839 (p> 0.05). Based on Table 5, the results obtained are normal groups of cholesterol levels in high protein consumption patterns that are 12 respondents (20%) and in normal groups HDL levels of low protein consumption patterns in 7 respondents (11.7%) which show no relationship between proten consumption patterns with HDL levels in patients with hypertension in the Sampara District area.

Conclusion

There is no relationship between the consumption pattern of pokeaclam meat (Batissaviolacea var. Celebensisvon von Martens, 1897) and proteins with low density lipoprotein (LDL) and high density lipoprotein (HDL) in patients with hypertension in the coastal areas of Sampara district.

Conflict of Interest: In this study there is no conflict of interest.

Source of Funding: This research uses private funds.

The Correlation between GPX-1 Serum and Hearing Threshold of SLE Patient Post Prednison Therapy

Ratna Anggraeni[1], Sally Mahdiani[1], Nindya Pratita[2]

[1,2]Lecturer of Departement of Otorhinolaryngology Head and Neck Surgery, Universitas Padjajaran-Hasan Sadikin General Hospital Bandung, West Java, Indonesia, Faculty of Medicine UNPAD: Jl. Raya Bandung Sumedang No.km 21, Hegarmanah, Kec. Jatinangor, Kabupaten Sumedang, Bandung, East Java, Indonesia 4016, Hasan Sadikin General Hospital: Jl. Pasteur No. 38, Pasteur, Kec. Sukajadi, Kota Bandung, East Java, Indonesia 40161

Abstract

Introduction: Systemic Lupus Erythematous (SLE) is a disease characterized by the involvement of antibodies in the immune system-mediated inflammation, including the auditory system. One of the things that causes hearing loss in SLE is the occurrence of vasculitis and the process of oxidative stress which results in decreasing the activity of Glutathione Peroxidase (GPx) which is one of the important antioxidants in the human body against ROS. Provision of Prednisone therapy in SLE patients with hearing loss will improve hearing. It is expected that there will be an increase in GPx-1 levels along with hearing improvement in SLE patients with hearing loss after receiving prednisone.

Objective: To determine the correlation of hearing threshold with changes of serum GPx-1 levels in systemic lupus erythematosus patients who receiving prednisone therapy.

Method: A comparative analytic study conducted with pre-post design which analyzed the correlation between elevated serum GPx-1 levels and hearing threshold of SLE patients receiving prednisone therapy.

Results: This study found significant changes in GPx-1 levels after SLE patients with hearing loss received prednisone therapy. Comparison of serum GPx-1 levels of SLE patients who experience sensorineural hearing loss before and after prednisone therapy. The statistical test used is the Wilcoxon test and significant if p value <0.05. Comparative test of GPx-1 levels showed a significant number ($p < 0.001$) with increase difference about 3.69U/g Hb. There is significant correlation between the increased serum GPx-1 levels with a decreased hearing threshold shown at high-frequency frequencies at 10,000 Hz and 14,000 Hz ($p < 0.05$).

Conclusion: There is a correlation between improved hearing threshold in increased serum GPx-1 levels in patients receiving prednisone therapy.

Keywords: *GPx-1, Hearing Loss, Oxidative Stress, Prednisone, ROS, SLE*

Introduction

Systemic Lupus Erythematosus (SLE) related to the deposition of autoantibodies and the formation of immune complexes that cause tissue damage.[1] SLE occurs due to disruption of immune regulation which causes an increasing of excessive autoantibodies causing disruption of the reticulo-endothelial system which eliminates antigen-antibody complexes.[2]

As many 10,6% of SLE cases from Sardjito Hospital Yogyakarta from 2015 to 2016, about 10.5% of SLE cases from Rheumatology Department of Internal Medicine Hasan Sadikin Hospital in Bandung (RSHS) in 2015.[2] Mutiara in 2012 conducted a study at the Department of Rheumatology Internal Medicine RSHS Bandung and found 6 of 23 LES patients (26%) had sensorineural, symmetrical, and bilateral hearing loss. There were two people had mild-degree hearing loss and four people moderate-degre hearing loss.[3,6]

ROS has one or more unpaired atoms and ROS is produced when oxidative metabolism occurs in the body.[8,9]GPx-1 enzyme is widely found in all cell parts such as cytosol, mitochondria and peroxisomes. In the cochlea, GPx-1 has very high activity in cortical organs, spiral ganglion, vascularis stria, spiral ligaments and supporting cells.[8,9,17]In SLE patients, The decreasing of GPx activity can cause destruction of antioxidant enzyme activity and increase ROS production and oxidative stress occurence.[8,9]

Management of hearing disorders in SLE since 60 years ago is corticosteroids.[11]Prednisone is the preferred because they have an anti-inflammatory mechanism through the inhibition of the phospholipase enzyme that converts phospholipid into arachidonic acid.[12] In 2015, Cavaleriu study showed a significant decrease in MDA levels of SOD and GPx.[13]Currently at RSHS Bandung, the management of low-grade SLE is giving prednisone oral 0.5 mg/KgBW/day in accordance with the SLE management therapy protocol.[14]

This study aims to determine the correlation of hearing threshold with changes of serum GPx-1 levels in systemic lupus erythematosus patients who receiving prednisone therapy.

Method

The design of this study was a comparative analytic study with pre-post design that analyse the relationship between increased serum GPx-1 levels and hearing status of SLE patients receiving prednisone therapy in 19 samples. The study was conducted from May 2018 to July 2018 in Hasan Sadikin Hospital. The Inclusion criteria of sample were patient with Mild-degree SLE, Age ranged and patient 18-50 years old, patient had Type-A Timpanogram in both ear but exclusion criteria were patient with noise exposure *(NIHL)*, patient with congenital malformation in ear, head trauma and hearing disorder and had hypertension story.The statistical test used is the Wilcoxon test and significant if p value <0.05.

Findings: Study about the correlation between serum GPx-1 levels and hearing status of LES patients who received prednisone therapy had been conducted with sequential study sampling according to patient arrival. The number of subjects were 120 people and were mild-degree SLE patients from May 2018 to June 2018. After screening, 19 subjects were taken. Subject characteristics included gender, age, and no complaint of vertigo and tinnitus during history taking.

Table 1:Characteristic of Study Subject

Variable		Number
1. Age (Years)		
Mean (SD)	33.9 (8.6)	
Range	22 - 48	
2. Gender		
Female		19 (100%)
3. Additional Complaint		
Vertigo		5 (26.31%)
Tinitus		4 (21.05%)
Vertigo and Tinitus		9 (47.30%)

All study subjects were SLE patients who complained of hearing loss. Based DPOAE examination, 19 subjects were referred before prednisone therapy and after prednisone therapy, 18 subjects were pass with 1 subject were still referred.

The bold number indicates a significant p value in statistical tests. In the right ear, it is found to be significant at low and high frequencies, except in the frequency of conversation (1000 Hz, 2000 Hz,4000 Hz). But in left ear, it is found to be significant except in the frequency 250 Hz, 1000 Hz, 2000 Hz.

Information about the number of study subjects with sensorineural-type hearing loss before and after prednisone therapy. McNemar test, one of the nonparametric statistical tools, used to test the differences between two groups of study subjects to measure GPx-1 levels and hearing status before and after prednisone therapy with a significant p value of <0.05.

Majority subjects experienced hearing loss on the right ear at high frequency before prednisone therapy with a value of p <0.05. While on the left ear, Majority subjects, in right ear, as many as 17 people (89.5%) experienced hearing loss at frequency of 14,000 Hz and in left ear as many as 15 people (78.9%) at a frequency of 12,500 Hz and 47.4% at a frequency of 11,200 Hz with meaningful statistical value (p = 0.016). The results of the statistical comparative test of GPx-1 levels showed significant value (p<0.001) with the difference in increase about 3.69 U/g Hb. The mean level of GPx-1 before therapy is 1.92 with mean level of GPx-1 after therapy is 5.61 U/gHb.

The correlated Between DPOAE result With Increase Of Gpx-1 Serum Value. In the right ear, it is

found to be not significant in the frequency500 Hz, 2000 Hz, 4000 Hz, 8000 Hz, 9000 Hz, 11.200 Hz, 12.500 Hz But in left ear, it is found to be not significant in all frequencies

Discussions

Productive age considered to be exposed to sunlight and ultraviolet light. High exposure to cigarette smoke and the reproductive system that is still productive are risk factors for weighting SLE at a young age. A meta-analysis study from At Stadio and collagues in 2017 said that the highest age of SLE patients from all over the world is 20-49 years and in Asia the age range is 20-39 years.[4]

All study subjects were young adult women. Abbasi said that SLE can affect men and women of all ages but 90% of people diagnosed with SLE are women.[7] Female incidence is around 90% of the total SLE patients. This is related to the estrogen hormone which is known to increase the expression of the immune system while androgens work to suppress the expression of the immune system.[1,3,4]Estrogen activates polyclonal B cells resulting in excessive autoantibody production in SLE patients.[5]

In this study, complaints of tinnitus, vertigo and 47% complained of both. In some literature, sensorineural hearing loss occurs in SLE patients accompanied by disturbances of balance and other internal ear disorders.[1] That is similar with study conducted by Maciaszczyk and colleagues who found an increase in the prevalence of inner ear disorders such as vertigo and tinnitus in SLE patients who experienced sensorineural hearing loss. In the inner ear, high-frequency auditory stimuli are transduced to the tip of the cochlear basal and low-frequency stimuli occur at the apical end. Endolimatic hydrops processes that increase the stiffness of the structure vibrate the inner ear and cause dysfunction of the outer hair cells. [1,4,5,7]

The patient's hearing threshold with sensorineural hearing loss decreased between the frequency of conversation to high frequency, similar to the symptoms that occur at presbyacusis, namely hearing loss in SLE patients at high frequencies.[10-12,13]DPOAE examination is used to confirm hair cell damage in the study subject and one of the examination method that can be used to determine cochlear hair cell function objectively.

In the right ear of 12 frequencies examined, there were 9 frequencies that increased in intensity, especially at high frequencies, which was indicated by a meaningful statistical test, where the value of $p < 0.05$. In the left ear 8 frequencies that experience improvement are indicated by a significant statistical test.This is consistent with the study conducted a study at the Polyclinic Rheumatology Department RSHS Bandung and obtained 6 people (26%) from 23 SLE patients experiencing sensorineural, symmetrical, and bilateral hearing impairments.[6] Characteristics of internal ear disease due to autoimmune diseases are described as progressive, bilateral, sensorineural type usually occurs in high frequency, the majority attacks young adults and is associated with vestibular complaints.[5,13] This is related to the accumulation of immune complexes in the auditory arteries reducing the diameter of blood vessels by decreasing blood flow. This reduction in blood flow induces an oxygen deficit followed by the release of oxidative molecules responsible for damage to hair cells. Hair cell damage in the basal part of the cochlea, decreases the auditory function in capturing high notes.[13]

The anti-inflammatory and immunosuppressive effects given are considered to provide maximum results against improvement of the hearing threshold.[11]In this study the preferred drug was prednisone.[12]The dose used in various studies is 1 mg/KgBW for 4 weeks with a maximum dose of 60 mg/day obtained hearing improvement as in the study of Mutiara, Wijana, and Anggraeni on 26 SLE patients with sensorineural hearing loss given prednisone for 4 weeks. After administering therapy for 4 weeks, 24 patients experienced improvement in hearing to normal and 4 patients did not experience improvement. Prednisone has a mineralocorticoid effect that plays an important role in endolymphatic homeostasis and maintains endococcal potential. Prednisone improves hearing by interfering mineralocorticoid receptors that improve endolymphatic homeostasis.[11] In addition, Prednisone increases blood flow in the cochlea, reduces vascular stria degeneration, and has antioxidant effects.[11]

From 19 subjects in the right ear, 16 people (84.2%) experienced sensorineural hearing loss at a frequency 14,000 Hz, 17 people (89.5%) at frequency 12,500 Hz and 15 people (78, 9%) at frequency 11,200 Hz and all three are measurements before being given prednisone therapy. After 4 weeks of therapy there were 12 people

experiencing improved hearing in the right ear at a frequency of 14,000 Hz, 16 people at frequency 12,500 Hz, and 10 people at a frequency of 11,200 Hz in the right ear, and in the left ear a statistically significant improvement was only shown in frequency 11,200 Hz.

All study subjects experienced an increase in GPx-1 levels accompanied by hearing improvements after both total and partial treatment with an average increase of 3.69 U/gHb. GPx-1 examination selected in this study because it is one of the most dominant cellular antioxidants in the defense process against ROS when oxidative stress reaction occurs in the cochlea. In the cochlea, GPx-1 activity will increase in the cortical organ area, vasculary stria and spiral ganglion.[8,9] The main risk factor for microvascular damage is due to a decrease in GPx-1 levels during atrophy of the vasculature stria. In addition, the increased ROS oxidative stress in sensorineural hearing loss could suppresses GPx-1 production which is natural antioxidant.[9]

The correlation between improvement in hearing and an increase in GPx-1 levels in blood in SLE patients From this study, it was found that the right ear had more significant improvement in hearing threshold than in the left ear, which was shown by the number of subjects and improved hearing-threshold difference. However, statistically, a significant correlation occurred at a frequency of 10,000 Hz and 14,000 Hz in the right ear which meant a relationship between the function of increased hearing and an increase in the level of GPx-1 in the blood dominated in the right ear even though it did not occur at all frequencies.

Conclusion

There is an increase in GPx-1 levels accompanied by increased hearing in SLE patients who experience sensorineural hearing loss after receiving prednisone therapy, especially in high frequency.

Conflict of Interest: There was no conflict of interest in this study.

Ethical Clearance: The ethical clearance is granted from KEPK, Dr. Hasan Sadikin General Hospital, Bandung

Abstract

This article aimed to summarize environmental risk factors that can cause leptospirosis in human. Leptospirosis is one of the zoonotic diseases. Zoonotic diseases are infectious diseases of animals that cause diseases when transmitted to humans. The bacteria that cause leptospirosis are *Leptospira*. *Leptospir*a is pathogenic bacteria that are transmitted from animals to humans, directly or indirectly. Leptospirosis mainly found in the human who comes into contact with the urine of infected animals, urine-contaminated surface water, and soil in the environment or drinking water and food that contaminated with *Leptospira.* This review retrieved articles from four science databases, namely ProQuest, Scopus, Pubmed, and ScienceDirect. A systematic review was conducted using a predefined protocol based on PRISMA. The searching process utilizes three main keywords that include leptospirosis, risk factors, and humans in various combinations. During the initial search from four science databases (ProQuest, Scopus, Pubmed, and ScienceDirect), there were 506 articles retrieved. During the screening process, 59 articles excluded due to duplication, 403 articles excluded based on title and abstract incompatibility with inclusion criteria, 14 articles excluded due to not match of article content with inclusion criteria, and seven articles excluded because of the ineligibility with the study In the final screening process 23 articles were chosen to be analyzed. This review found the environmental risk factors that cause leptospirosis in humans are flooding, sanitation, household environment, and the presence of animal reservoir. Prevention is needed by improving the environment and dealing with flood problems properly

Keywords: *Infectious disease; Leptospirosis; risk factors; environment; human.*

Introduction

Leptospirosis is one of the zoonotic diseases. Zoonotic diseases are infectious diseases of animals that cause diseases when transmitted to humans. It spread to humans by ticks, mosquitoes, fleas, or contact with animals infected [1,2]. The bacteria that cause leptospirosis are *Leptospira*[1]. *Leptospir*a is pathogenic bacteria that are transmitted from animals to humans, directly or indirectly. The bacteria enter the body through cuts or abrasion on the skin, or the mucous membrane of the mouth, nose, and eyes[1,3]. Leptospirosis mainly found in the human who comes into contact with the urine of infected animals, urine-contaminated surface water, and soil in the environment or drinking water and food that contaminated with *Leptospira*[1,3].

There are so many factors that can increase the incidence of leptospirosis, such as behaviour, geographic, demographic, socio-economic, and environment. Factors related to socio-economic, sanitation and risky behaviour showed a consistent pattern of being associated with increased leptospirosis risk [4]. There have been many studies that have been conducted on the risk factor of leptospirosis in humans. However, there is still little research that focuses on environmental factors.

This article aims to summarize ecological risk factors that can cause leptospirosis in humans

Method

Search Strategy: Data sources taken from four science databases, namely ProQuest, Scopus, Pubmed, and ScienceDirect, were published last ten years. A systematic review was conducted using a predefined protocol based on PRISMA[5]. The searching process utilizes three main keywords that include leptospirosis, risk factors, and humans in various combinations.

Inclusion and Exclusion Criteria: All scholarly articles published last ten years, written in English, subject with at least one of the following terms (public health, environmental science, and medicine), full-text, the open-access journal included. Review articles, outbreak reports, case reports, brief communication, systematic review, and articles that not discuss environmental factors excluded.

Data Extraction and Management: All articles were identified base on title and abstract by two reviewers. Data selected from eligible studies included first authors, title, study period, published, country, design study, method, independent variable, and outcome related to risk factors (Odds Ratio). Data synthesis will be planned using narrative synthesis. Environmental risk factors divided into related to water and unrelated to water. The risk factor related to water is all risk factors that cause leptospirosis through water contaminated by *Leptospira* bacteria. Risk factors unrelated to water are variables that cause leptospirosis originating from contaminated environments other than water. Such as soil, food, and other environmental conditions that can increase the risk of leptospirosis. The Odds Ratio (OR) value will be analyzed based on statistical analysis. OR value will find out how much the risk of these variables can increase the incidence of leptospirosis.

Result

Articles Characteristics: A total of 506 eligible articles were obtained from four databases using inclusion and exclusion criteria (Proquest: 266, Pubmed: 60, Scopus: 121, and ScienceDirect: 59 articles). During the screening process, 59 articles excluded based on duplicate, 403 articles excluded based on title and abstract, 14 full-text articles excluded because of research reason (review, case report, outbreak report, brief communication, systematic review, and not written in English), seven articles excluded because of ineligibility (not discuus enviromental factors) with the study. In the final process, 23 articles were chosen to be analyzed.

Based on 23 articles that have been analyzed, it is known that the most study period was carried out in 2010 (n=4) and published in 2014 (n=5) and 2018 (n=5). Of the 23 articles, five articles conducted in Brazil. In the eligible articles, 11 articles using a cross-sectional study, six articles using case-control study and the other articles using cohort, ecological, retrospective study, and experimental study. Most of the eligible articles using questionnaires, Geographic Information System (GIS), and laboratory test (Microscopic Agglutination Test) to collecting data and using secondary data to be analyzed.

Risk Factors: There is an environmental risk factor related to water and unrelated to water. Of the 23 eligible articles were analyzed, 11 articles found the association between environmental risk factors related to water with leptospirosis incidence. The risk factor consists of working in waterlogged fields (OR=4,6)[6], flooding(OR=3,35)[7], access to water(OR=2,79)[8], cleaning clogged sewer (OR=3,82)[7], contact with sewage water(OR=2,83)[7], drinking water in public tap(OR=6,51)[9], agricultural worker(OR=1,8)[9], exposed in stagnant water(OR=2,01)[9], detected with cattle urine(OR=1,2)[10], unsafe water (OR=1,82)[11], and rainfall (OR=13,77)[12].Based on risk factors related to water, rainfall has the most significant effect on leptospirosis disease. An area that has high rainfall has 13,8 times greater risk of leptospirosis than an area with low rainfall.

Environmental risk factor related to water analyzed in 19 eligible articles. The risk factors consist of storage of cow dung in or surrounding house, residence in the house-made up of cow dung, a household with the access of food to rodent (OR 3)[6], built-up area[13], hight coverage of grassland tenure[13], heavy sabulous clays in the soils[13], and a wet climate[14]. Also, the risk factor include the socio-economic problem[14], presence of *Rattus norvegicus* feces (OR=4,95)[8], presence of positive pathogenic Leptospira (OR=4,15)[15], rodent burrow(OR==2,80)[8], un-plastered walls (OR=2,71)[8], presence of garbage dumping in the farm (OR=2,40)[15], having higher numbers of piggeries around the home, the higher density of piggeries above the house, contact with mud, contact with garbage, the living below-median altitude of the village, living at lower altitudes, dwelling

near water bodies, outdoor labour,living on clay soil (OR=3,11)[16] etc.

Discussion

Leptospirosis is an endemic disease in several regions, especially in the tropics and subtropics area[1,17]. Leptospirosis may present with a wide variety of clinical manifestations. These may range from mild flu-like illness to a serious and sometimes fatal disease. The common symptoms in leptospirosis are icterus (jaundice). Many risk factors can increase the incidence of leptospirosis. These factors consist of the environment, behaviour, individual characteristics, medical history, socio-economic, topography, demographics, access to health service, etc.[6,13,14,18]. Environmental risk factors consist of risk factor related to water and unrelated to water. The risk factor that related to water that has a significant association with leptospirosis is flooding. In the rainy season and flood, the incidence of leptospirosis usually increases and endemic [17]. Rainfall is one factor that can increase the incidence of leptospirosis. This is because the high rainfall intensity causes inundation and flooding in some flood-prone areas. Flooding can be contaminated by *Leptospira* bacteria. Flooding has a very important role in the transmission of leptospirosis in epidemic and endemic areas[19]. Flood causing material losses and also cause various health problems. Flooding is a medium for spreading leptospirosis through water contaminated with *Leptospira* bacteria and entering the human body through wounds[19]. In a study stated that a confirmed leptospirosis outbreak in Guyana occurred after severe flooding[20]. In flood-prone areas, the community has a risk of leptospirosis because the community makes contact with water, either by cleaning puddles, submerged in puddles, and through mud carried by floods.

Risk factors unrelated to water consist of sanitation, household environment, and the presence of an animal reservoir. Poor hygiene, like the presence of cow dung landfills surrounding houses and contact with garbage, can increase the incidence of leptospirosis[6,7]. An animal-like reservoir rat contaminated litter. The urine contaminated garbage and entering the human body through wounds and food. People who come into contact with waste and don't apply healthy living behaviours such as washing hands with soap and not using personal protective equipment when making contact with garbage will be a risk for leptospirosis. Contact with waste is related to occupational environment and leptospirosis[21].

The household environment is an important transmission determinant in urban slum areas[22]. House environment like un-plastered walls can cause leptospirosis disease[8]. This environment is because rodent, especially rats as reservoir animal, can enter the house and contaminate food or direct contact with the human. Owning a farm around a house can increase the presence of *Leptospira bacteria*. Leptospira bacteria can survive in soil and reservoir animals like goats, cow, in a farm can contaminated soil around the house [23]. Therefore the house environment is important to note. The controlling house environment will be able to help reduce the incidence of leptospirosis. Other than that, environmental improvement is very necessary, especially in the slums area that is endemic to leptospirosis. Controlling the house is to reduce morbidity and mortality.

In addition, the home environment also affects the presence of rat. The environment around the house that is not clean and moist becomes a habitat that is preferred by rats. House conditions that are not impermeable to rats will make it easier for rats to enter the house. one example of the condition of a house that is not impermeable as the un-plastered walls. Houses that un-plastered walls can increase the incidence of leptospirosis. Where people who live in houses where un-plastered walls have a risk of 2.71 greater than people who live in houses that have plastered walls[8]. Another example of a home environment that can increase leptospirosis is living in an agricultural area. The agricultural area is one of the rat habitats. Moist and muddy farming areas are the place that rats like to live and breed. One species of rats that have habitat in agricultural areas is Rattus norvegicus[24].

There are many kinds of animals that carry the *Leptospira* bacteria, such as cattle, pigs, goats, buffalos, horses, dogs, rodents and wild animals[3]. Pigs are one of the animals that can also cause leptospirosis. People at risk are pig farmers. Apart from direct contact with animals infected with *Leptospira* bacteria, leptospirosis can also enter the human body through livestock meat infected with leptospirosis. Therefore, it is very important to control the health of livestock. Rodents recognized as the most common reservoir leptospirosis in human. A study shows that out of 128 patients who displayed leptospirosis like symptoms, 70% reported having seen a rodent in their houses and 29,6% of them owned dogs (25). A rat infestation has a significant association with leptospirosis. Exposure to rodent urine is associated with

acute leptospirosis. Humans that exposed to rodent are having 1,7 time higher risk for severe leptospirosis than those who are not detected (26).Based on the result of a systematic review, it estimated that the animal reservoir of leptospirosis is cattle, pig, cow, rodent, and rat. These animals can cause leptospirosis in human through urine, faeces, and direct contact with an infected animal.

For the future research is needed meta-analysis to identify the environmental risk factor with using Odds Ratio (OR)And carried out research based on continents. So we get an overview of risk factors that affect leptospirosis in each continent.

Conclusion

Many factors influence the incidence of leptospirosis, especially in terms of the environment. Flooding, sanitation, household environment, and the presence of animal reservoir have a significant association with leptospirosis

Abstract

Background: Aluminium chloride ($AlCl_3$) is a known potent environmental neurotoxic agent causing progressive neurodegenerative changes in the brain. Increasing evidence suggests that oxidative stressis strongly related to $AlCl_3$ neurotoxicity. Endothelial nitric oxide synthase (eNOS) is aniso form of the nitric oxide (NO) synthases family.

Aim of the Work: The current study was carried out to investigate the profile of the expression of eNOS in differentbrain regionsfollowing chronic aluminium chloride administration.

Materials and Method: Twelve adult male albinorats were divided equally into two groups. Group I was the untreated control, groups II was given $Alcl_3$(100 mg/kg body weight) orally daily 42 days. At the end of the experiment, rats were killed by decapitation under anaesthesia. The brains were removed and processed for immunohistochemistry using antibody raised against eNOS.

Results: By comparison to the untreated control, $Alcl_3$treated rats showed significant ($P<0.001$) increase of eNOS expression in capillaries of cerebral cortex, hippocampus and cerebellum. In addition, there was significant ($P<0.001$) increase of eNOSexpression in hippocampus when compared to cortex and cerebellum.

Conclusion: These data provide further evidence that chronic exposure to aluminium chloride potentiate oxidative stress with subsequente NOS induction in different brain regions with more hippocampal affection.

Keywords: *Aluminium chloride, neurodetoxicity, eNOS, oxidative stress, brain, hippocampus.*

Introduction

Aluminium (Al) is considered as the most abundant metal in the earth's crust[(1)]. It is found in salt, corn, yellow cheese, tea, herbs, spices, some cosmetics, aluminium containers and drinking water [(2)]. Al induces neurodegenerationby increasing Fe accumulation and reactive oxygen species production in different brain regions[(3)]. There are many reports of decreased performance on cognitive examinations of aluminium-exposed industrial workers, indicating that aluminium contributes to neurodegeneration[(4)]. Aluminium chloride ($Alcl_3$) has been documented to have negative effects on the behavior of Wistar rats[(5)]. The daily intake of aluminium is reported to be approximately 10–20 mg from food additives, medicines such as antacids,

cooking utensils and deodorants[6]. Al exacerbates brain oxidative damage[7], causes neuro-inflammation and induces amyloid-β and neurofibrillary tangles deposition. In addition, it exacerbates oxidative stress caused by iron and other metals, and has been shown to induce apoptosis[8].The hippocampus is considered as one of the earliest brain region affected by $Alcl_3$ [9].

Materials and Method

Animals: A total of 12 adult male albino rats (200 gm) were used in this study.

Materials: Aluminum chloride ($Alcl_3$), anti-endothelial nitric oxide synthase **(anti-eNOS)** (polyclonal rabbit antibody) (Catalog Number N3893) was obtained from Sigma Aldrich Company, Egypt.

Experimental Protocol: The protocol of this study has been approved by the ethical committee of Faculty of Medicine, Minia University. In this study 12 adult male albino rats weighing 200 gm and of 6weeks were housed in clean plastic cages for two weeks before study. They were fed standard laboratory diet and were allowed free access to water.

Animals were randomly divided into two equal groups (6 rats each): **Group I:** received distilled water by a gastric tube for 42 days and served as control. **Group II:** received 100 mg/kg body weight/day of $Alcl_3$[10] whichdissolved in water by a gastric tube for 42 days.

Samplingand Histological Study: All rats were sacrificed at the end of this experiment by decapitation, the brains were obtainedthen sagittaly divided into 2 hemispheres using a sharp blade in order to obtaincortical, cerebellar and hippocampal tissues for immune- histological studies**.**

Immunohistochemical staining for anti-endothelial nitric oxide synthase (anti-eNOS): The immunocytochemical staining was performed using anti-eNOS which is a polyclonal rabbit antibody. Immunohistochemistry was performed on formalin-fixed, paraffin-embedded tissue.5 μm brain sections were cut for immune-labelling. The procedure was done according to the manufacture instructions. Briefly, sections were deparaffinized in xylene, rehydrated in descending grades of alcohol then immersed in 0.1% hydrogen peroxide for 15 minutes in order to block the endogenous peroxidase activity. Then the sections were washed by phosphate buffer then incubated in an ultra-vision block for 5 minutes at room temperature to block the non-specific background staining. The primary antibodies anti-eNOS were diluted at 1:100 in antibody diluent. Sections were incubated in the primary anti-eNOS antibody 15 minutes at room temperature. The reaction was visualized using; Ultravsion one detection System, HRP Polymer & DAB Plus Chromogen. After completion of the reaction, counter staining was done using hematoxylin and dehydrated by passing through ascending concentrations of alcohol then cleared by xylene. Cover slip using permanent mounting media is put at last [11].

The changes in the immunohistochemical reaction in different brain regions of the treated animals were detected through a comparative examination of the corresponding tissues of the normal control animals.

Morphometric Analysis: The cerebral cortex, cerebellum and hippocampuswere examined using bright field microscopy. Image analysis software; Image J (http://rsbweb.nih.gov/ij/; NIH, Bethesda) was used to assess eNOS immunopositivity under 40 high power field. Immunopositivity was assessed by measuring the surface area covered by the positive staining. The analysis is automated and was performed by the software. In each animal six sections with 250um distance in between were used for measuring the area fraction of eNOS immunoreactivity.

Statistical Analysis: Quantitative data has been analyzed using SPSS (IBM Corp. Released 2010. Windows, Version 20.0). The mean and standard error (SE) was calculated for each group. Values were expressed as means ± SE. One-way analysis of variance (ANOVA) test was used to detect significant differences between different groups, followed by the use of Tukey-Kramar as a post hoc test. The results were considered statistically significant when the p- values were <0.05.

Results

Immunohistochemical staining for anti-endothelial nitric oxide synthase (anti-eNOS):

The positive immunoreactivity appeared as brown cytoplasmic staining of the immunoreactive cells.

A. Control Group (Group I): Sections of the control group displayed faint eNOS immunoreaction in the endothelial cells of the hippocampal blood capillaries (Figure 1).

B. Aluminium chloride ($AlCl_3$) (Group II): This group showed strongly positive eNOS immunoreaction inthe endothelial cells of blood capillaries of cerebral cortex (Figure 2A), cerebellum (Figure 2B) and hippocampus (Figure 2C).

Morphometric analysis of area fraction of eNOS: There was a significant increase in the area fraction of eNOS immunopositivity in cerebral cortex, cerebellum and hippocampus of $Alcl_3$ group compared to the control group ($p < 0.001$). Comparing eNOS expression in these regions, we noticed significant increase in the hippocampus when compared to cerebral cortex and cerebellum(all $p < 0.01$)(Table 1).

Table 1: The area fraction of eNOS immunopositivity in the studied groups.

Groups	Mean ±SD	P-value
Control group	0.82± 0.1	
Cerebral cortex of $Alcl_3$ group	1.8± 0.1	$<0.001^{c*}$
Cerebellum of $Alcl_3$ group	1.5± 0.1	$<0.001^{c*}$ $<0.109^{cc}$
Hippocampus of $Alcl_3$ group	2.2± 0.3	$<0.001^{c*}$ $<0.010^{cc*}$ $<0.001^{cer*}$

^{c}versus the control group, ^{cc}versus the cerebral cortex of $Alcl_3$ group and ^{cer}versus cerebellum of $Alcl_3$ group, $*p \leq 0.05$ is significant.

Discussion

Aluminium (Al) is considered as an environmental factor which contributes neurodegenerative disorders. Occupational exposure of Al can occur through diet by food processing and storage in aluminium vessels, foil and cans, drinking water, medicines such as antacids, vaccines and cosmetics. The population who expose routinely to Al may have higher chances of neurotoxicity[12]. The repeated exposure toAlcould cause severe oxidative stress and pathological changes. It acts as a pro oxidant and with continuous exposure, itaccumulates in hippocampus, cortex and other different brain regions, where it induces reactive oxygen species (ROS) formation and result in oxidative damage[13].

In our study, the intensity of staining ofeNOS immunoreaction increased in the capillary endothelium of different brain regionsin $Alcl_3$ group as compared to control group and the maximum affection was noticed in hippocampal capillaries.

Some studies found increased activation of eNOS in neurodegenerative diseases[14]. It isdocumentedthat the activity of eNOS was elevated in spinal cord injury [15] streptozotocin induced diabetes [16].

However, other studies demonstrated a significant negative correlation between capillary expression of eNOS and extent of brain pathological changes[17].

Nitric oxide (NO) is formed by a family of NO synthases (NOS) [18]. Three isoforms of NOS have been identified as: endothelial NOS (eNOS), inducible NOS (iNOS) and neuronal NOS (nNOS). In addition to NO, it is reported that NOS can produce superoxide anion. This phenomenon is called NOS uncoupling as superoxide production mainly occurs if NOS is not coupled with its substrate [19].Superoxide is documented to has a prominent role in mediating neuronal dysfunction in addition to learning and memory deficits of $Alcl_3$ toxicity[20]. During oxidative stress, superoxide and its derived oxidants production induce eNOS uncoupling leading to the formation of eNOS-derived superoxide instead of NO[14]. Chronic traumatic encephalopathy (progressive neurodegenerative disease) is recently reported to causes excessive superoxides production by eNOS uncoupled in the endothelial cells. These superoxides can react with the NO formed by microglia or astrocytes forming peroxynitrite, which in turn can increase phosphorylated tau expression in neurons [21].Oxidative stress result from imbalance between oxidation and antioxidant system which occur due to excessive production of free radical molecules as ROS and NO or depletion of antioxidant components[22].[23] reported strong correlation between memory dysfunction and oxidative stress in the hippocampus. Some studies eNOS inhibition caused reduction of BBB disruption [24].Several studies documented BBB breakdown in $Alcl_3$toxicity leading to loss of neuronal connectivity, synaptic dysfunction and neurodegeneration [25]. Some studies revealed that aluminium concentration increases in the cerebral cortex and hippocampus of rat with aluminium chloride neurotoxicityand the aluminium concentration is reported to be more in hippocampus when compared to cerebral cortex[26].

Conclusion

These data provide further evidence that chronic exposure to aluminium chloride potentiate oxidative stress with induction of eNOS with subsequent increase of oxidative stress and neuronal cell degeneration in different brain regions with maximal affection of hippocampus.

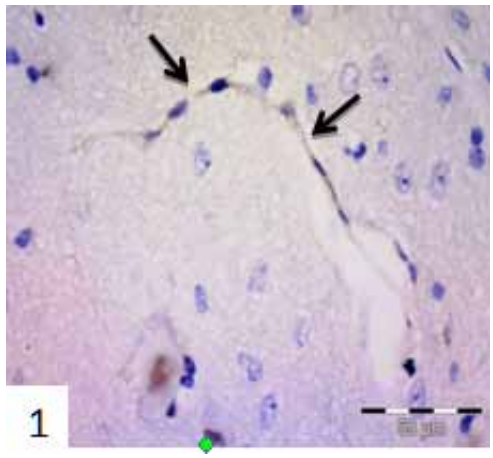

Figure 1: A representative photomicrographin rat brain of the control group showing faint immune reaction of eNOS in the endothelial cells of a longitudinal blood capillary (arrows). Alcl3 group (B) showing strongly positive eNOS expression inthe endothelial cells of numerous longitudinal blood capillaries (arrows) as compared to control group. Inset is cross section in blood vessels.

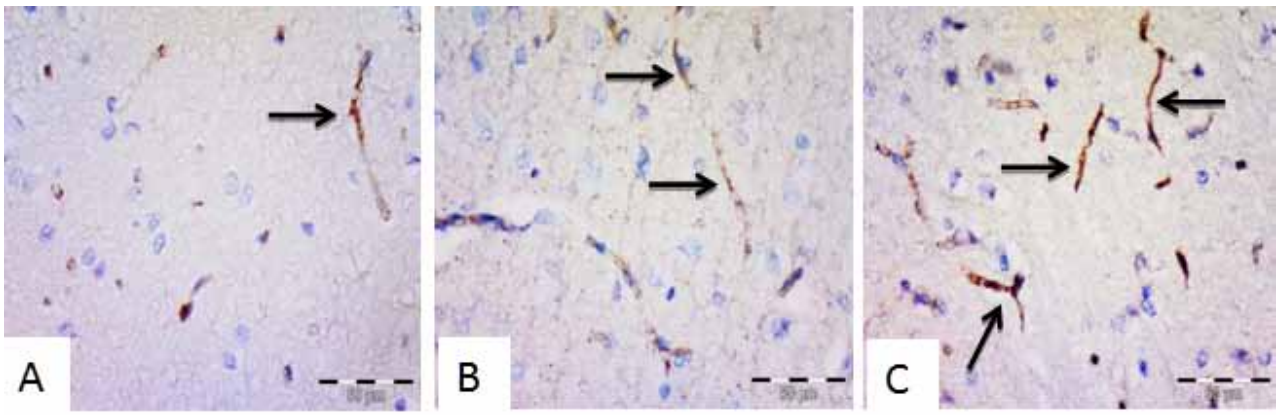

Figure 2: Representative photomicrographsin rat brain of the Alcl3 group showing positive eNOS expression in the endothelial cells of the blood capillaries (arrows) in cerebral cortex (A), cerebellum (B) and hippocampus (C). Notice increase number and intensity of staining of capillary endothelium in hippocampus (C).

Nutritional Evaluation on High Protein Supplement Diet by Biological Assay in Wistar Rat

Sakphisutthikul C.[1] Sanchaisuriya P.[1]

[1]*Faculty of Public Health, Khon Kaen University, Khon Kaen-40002, Thailand*

Abstract

Enteral nutrition is the best way to feed or supplement the diet when gastrointestinal tract functions of patients are partially or totally preserved. Whenever total enteral nutrition is needed, it represents the only source of nutrients for patients. Thus, it is mandatory to ensure that high biological value proteins are included in enteral formula.

Objective: To investigate the nutritional effectiveness of protein blend constituted intended to be used in enteral nutrition products.

Materials and Method: 27 male Wistar rats, with initial body weight of 60±5 g, where divided into three groups and feed for 28 days with: Group A were fed ONS-ST, Group B were fed ONS-HP, and Group C were fed ONS-PF. Enteral diet was fed 30 g./day during 4 weeks and consumption was recorded every day. Observation on body weight and food consumption were determined during the Study. Growth study(PER and NPRR) and digestibility study (TD, BV and NPU) where calculated. ***Results***: The obtained results for growth study and digestibility indicated that the supplement prepared with local food was a good protein source, especially when protein-mix was added.Experimental (Group B) and standard(Group A)had similar values for all analysed indices (PER, NPRR, TD, BV and NPU). These indices where also similar Group C, but lower than experimental and standard groups.

Conclusion: The nutritional effectiveness of ONS-HP versus ONS-ST when administered for 4 weeks to rats were compared. There were no differences between the ONS-HP group and ONS-ST group in body weight and nitrogen balance. Additionally, there were no adverse effects associated with administration of ONS-HP. These results suggest that ONS-HP is as nutritionally effective as ONS-ST, and as useful for nutritional management as conventional enteral nutrition formulas, even in a lower administration volume.

Keywords: *Nutritional Evaluation, High Protein, Supplement diet, Biological Assay, Wistar Rat.*

Introduction

Enteral nutrients are widely used for nutritional supplementation in patients after surgery and in patients who have long-term difficulty with oral ingestion, due to factors such as sequelae of stroke, neurological intractable diseases, and severe motor and intellectual disabilities[1-5]. Approved enteral nutrition formulas are designed to satisfy the daily vitamin and mineral requirements of adults consuming approximately 1,500 kcal/day in Thailand. Therefore, patients who require long-term nutrient administration and who have low activity, with maintenance energy requirements of approximately 1,200 kcal/day, need to adjust their intake volume to meet the recommended daily caloric intake. However, such adjustment may result in deficiency of some vitamins or trace elements[6-8]. It has also been reported that deficiency may result from administration of enteral nutrition formulas that do not contain trace elements (iodine, selenium, chromium, and molybdenum) newly categorized as essential in "Thai Dietary Reference Intakes (Thai DRIs)[9-13].

In addition to these nutritional management issues, the following goals must be met in clinical practice: reduction of volume to lower the risk of aspiration, securing time for rehabilitation by shortening administration time, and use of oral nutritional

supplements for nutritional treatment[14-18]. Therefore, a high-concentration enteral nutrition formula that allows efficient ingestion of energy and nutrients in smaller volumes is required. In this study, ONS-HP and ONS-ST were administered to Wistra Rats for 4 weeks, and their effects on nutritional status were compared to evaluate the nutritional effectiveness of ONS-HP.

Material and Method

1. **Enteral diet formulas:** ONS-HP and ONS-ST were prepared at Queen Sirikit Heart Center, Faculty of Medicine, Khon Kaen University. Thailand. The composition of each enteral diet formula is shown in Table 1.

2. **Animals and Experimental Diets:** Male Wistar rats (n = 27), 6-weeks old were provided by Northeast Laboratory Animal Center (NELAC), Khon Kaen University. Thailand. All the assays described in the present work adhered to the Principles of Animal Care and were approved by Institutional Animal Care and Use Committee of Khon Kaen University (IACUC-KKU).The rats were fed commercial laboratory chow and were allowed drinking water ad libitum for about 3 days before the experiments began.

   The animals were individually housed in stainless-steel cages in the animal house at a constant temperature (23°C ± 2°C) and humidity (30-60%), on a 12-h light/12-h dark cycle (lights on at 07:00 a.m.). All animals were weighed daily at 08:00 a.m. At that time, the water and the non-ingested food were weighed and withdrawn from the cages; the new food was weighed and offered to the animals in a specific receptacle inside the cages. During the remaining time, the animals received food and water ad libitum. As such, this schedule ensured that animals of all groups had the same time of feeding.

   Rats were divided into three groups: Control group were fed ONS-ST, Experiment group were fed ONS-HP, and Basal group were fed ONS-PF. Enteral diet was fed 30 g/day during 4 weeks and consumption was recorded every day.

3. **Analysis of Physiological Parameters:** Diet, carcass, and feces were analyzed for nitrogen (N) content according to the method described by([19]). All parameters were determined following the method described by([20]).

   Protein efficiency ratio (PER) was extrapolated by relating the weight gained to the amount of protein eaten-up, see equation 1.

$$PER = \frac{\text{Increase in body weight (g)}}{\text{Weight of protein consumed (g)}} \quad ...(1)$$

The net protein Ratio (NPR) was calculated estimating the body weight differences between the test group and the basal (protein free) group, using equation 2.

$$NPR = \frac{\text{weight gain on test diet (g)} - \text{weight loss on basal diet (g)}}{\text{protein ingested by the test group (g)}} \quad ...(2)$$

The true digestibility (TD) was determined based on the nitrogen that was eaten-up and fecal nitrogen using equation 3.

$$TD = \frac{\text{Nitrogen Intake} - (\text{Fecal Nitrogen output on test group} - \text{Fecal Nitrogen output on basal group})}{\text{Nitrogen Intake}} \times 100 \quad ...(3)$$

The biological value (BV) was using equation 4.

$$BV = \frac{\text{Nitrogen retained (g)}}{\text{Nitrogen absorbed (g)}} \times 100 \quad ...(4)$$

The Net Protein Utilization (NPU) was using equation 5.

$$NPU = \frac{BV \times TD}{100} \quad ...(5)$$

4. **Experimental Design:** The growth, and digestibility studies were carried out using the Completely Randomized Design (CRD). Rats were randomly assigned to the treatments based on their weights. The results are expressed as means ± SD. Statistical analysis was performed using one-way ANOVA. The frequency of recorded fecal conditions in each group was calculated and a DMRT test was conducted. P values less than 0.05 were considered statistically significant.

Results and Discussions

Analysis of Physiological Parameters: The biological assay comprised weight gain (g) by estimating animals feed consumption (g) (Table 2), feed efficiency, protein quality indexes, Protein Efficiency Ratio (PER), Net Protein Ratio (NPR) True Digestibility (TD) rates, Biological Value (BV) and Net Protein Utilization (NPU) (Table 3), derived from the experimental diets with chemical composition described in Table 1.

There was no significant difference in the initial

animal weight for the three diet groups since no difference was above 0.50 g. However, during the experiment, the animals of control group (ONS-ST) had a significant increase in body weight. Further, when compared the animals of the group fed on ONS-HP also weight more increased than fed on ONS-ST (Table 2). On the other hand, the basal group (ONS-PF) had a constant weight loss till the 14th day of the experiment. Weight gain in Wistar rats of the ONS-HP group reached 49.70±0.94 g. on the 14th day and 166.80±2.19 g. on the 28th day, whereas ONS-ST animals had a weight gain of 44.60±0.71 g. (14th day) and 96.20±4.31 (28th day) (Table 2).

Nitrogen Balance: Results had no difference among the experiment and standard groups when compare to the protein efficiency ratio (PER). Among the groups treated, no difference at ($p < 0.05$) was observed in the net protein utilization (NPU). Also, there was no significant difference in the net protein ratio (NPR) among the groups treated ($p < 0.05$). The true digestibility (TD) of the experimental animals had no observable differences among the groups treated at $p < 0.05$. The biological values (BV) of all the groups were significantly different from each other with the reference diet.

To explore the details of protein nutritional status, the nitrogen balance was assessed period, from Day 7 to Day 13. Nitrogen intake was about 180 mg higher in the OSN-HP group than in the ONS-ST group, and fecal nitrogen excretion was higher in the ONS-HP group than in the ONS-ST group (Table 3). The biological value and nitrogen retention rate were not significant difference during in the ONS-HP and ONS-ST group. Results show that digestibility of ONS-HP is lower than that of ONS-ST due to the former having a higher concentration of anti-nutrition factors, which decrease digestibility. However, a good quality protein mixture provides good digestibility and adequate proportions of total nitrogen and essential amino acids, not synthesized by the organism ([21]).

Conclusion

Weight is often used to measure nutritional status because it is strongly influenced by the changes of food and nutrient conditions. It will go down with decreasing food and nutrient intake ([10]), and at the time of food intake and nutritional conditions fulfilled, the weight will increase to normal weight.In the present study, the effectiveness of a novel highly concentrated enteral nutrient, ONS-HP, was compared to that of an approved one, ONS-ST, in rats. There was a significant between-group difference in weight gain in the ONS-HP group. Several studies have reported that dietary fiber causes hypertrophic changes increases fecal volume in rats, without causing toxicity ([22]). The water-soluble dietary fiberwhich is present in ONS-HP, may therefore have caused the increased weight in the ONS-HP group.

In regard to nitrogen balance, the biological value and nitrogen retention rate were significantly higher in the ONS-HP group than the ONS-ST group. It has been reported that differences in protein content among enteral nutrition formulas are associated with differences in urinary nitrogen excretion in rats, and that the biological value and nitrogen retention rates change in relation to these differences ([23-25]). Therefore, the differences in the biological value and nitrogen retention rates in the present study may be attributable to the use of two enteral nutrition formulas with different protein content.

In summary, the nutritional effectiveness of ONS-HP versus ONS-ST when administered for 4 weeks to rats were compared. There were no differences between the ONS-HP group and ONS-ST group in body weight and nitrogen balance. Additionally, there were no adverse effects associated with administration of ONS-HP. These results suggest that ONS-HP is as nutritionally effective as ONS-ST, and as useful for nutritional management as conventional enteral nutrition formulas, even in a lower administration volume.

Table 1: Composition of the diets (% w/w). Control(ONS-ST); Experimental(ONS-HP) and Basal (ONS-PF)

Ingredients	Diets/Groups		
	ONS-ST	ONS-HP	ONS-PF
Casein 1	12.50	-	-
Salt mixture 2	5.00	5.00	5.00
Vitamin mixture 2	1.00	1.00	1.00
Soybean oil	8.00	8.00	8.00
Choline	0.04	0.04	0.04
Cellulose	1.00	1.00	1.00
Corn starch	72.46	51.00	84.96
Protein-Mix	-	25.96	-

[1]Casein contained 80.00% w/w protein, [2]According to AOAC, 1975

Table 2. Weight evolution and feed ingestion of recently-weaned rats fed on control diet (ONS-ST), experiment diet (ONS-HP) and compare diet (ONS-PF).

Diet Group	14 Days			28 Days		
	Weight gain (g)	Food Intake (g)	Protein Intake (g)	Weight gain (g)	Food Intake (g)	Protein Intake (g)
ONS-ST	44.60±0.71^{a}	137.40±2.83^{a}	14.49±0.49^{a}	96.20±4.31^{b}	311.30±1.47^{ns}	32.81±0.97^{ns}
ONS-HP	49.70±0.94^{a}	142.60±5.18^{a}	15.60±0.52^{a}	166.80±2.19^{a}	313.50±4.86^{ns}	34.30±1.32^{ns}
ONS-PF	-10.40±0.65^{b}	64.90±3.44^{b}	0.55±0.07^{b}	-	-	-

Different letters in each column indicate significant difference at $p<0.05$.

Table 3. Nitrogen balance by biological assay in rats

Diet Group	Nitrogen (mg)			PER	NPR	TD	BV	NPU
	Intake	Urine	Fecal					
ONS-ST	2,317.76±3.88^{a}	231.85±3.67^{a}	201.41±0.31^{a}	2.02±0.56	3.87±0.86	94.04±0.51	91.93±0.97	86.45±1.21
ONS-HP	2,496.16±2.91^{a}	359.46±2.44^{a}	237.56±1.98^{a}	3.14±0.32	4.12±0.21	92.93±0.67	86.78±0.63	80.65±0.87
ONS-PF	88.32±4.87^{b}	43.33±0.27^{b}	62.34±0.14^{b}	-	-	-	-	-

Results except nitrogen intake are shown as the mean ± SD (n = 9/group). Statistical significance was determined using one-way ANOVA ($p < 0.05$).

The Impact Using Healthy Training Method to Develop Some Physical Abilities and Integrated Skills Performances of Futsal for the Deaf and Mute

Salah Bresem Salih[1], Lecturer, Maytham Mohsin Habeeb Alhamdi[1], Mahmood Abd ALjaleel Abd[2]

[1]Lecturer, Ministry of Education, Missan Education Directorate. Missan, [2]Lecturer, Ministry of Industry and Minerals, Najaf, Iraq

Abstract

We have noticed in the recent years that there is a clear improvement in the practice level of football in general and Futsalinparticular, Which consider the product of the scientific development of modern multi-purpose training method, which all world countries seek to prepare their trainers in a scientific way to aim of improving their athletes to reach the international levels,Scientific research is the best method which to check of the various scientific theories in the sports field and benefit from them to serve and develop sport.

In view of the development of science and knowledge in many sports fields, including football, the game has received a large share of the attention researchers, which reflected on the development of play styles, plans and laws that contributed to give aesthetic in the players performance and increase the enthusiasm of the public, and from among those method is Futsal, which is one of the game method being a basic pillar for its development, as well as its skills, plans, events and unexpected positions in the game works to excite everyone and excitement towards practice and viewing because of the ease of law and small stadium space, the small of players number and similar of the basic skills with the football skills (Soccer), which led to practice by a large number of players.'

Keywords: *Deaf, Mute, Integrated skills.*

Introduction

It was explained by(1) that explains that the skill performances in the football game means all the necessary and purposeful movements that lead to a specific purpose within the framework of the football law, whether those movements with ball or without the ball, and the player's proficiency is determined by the level of his handling of the ball and how to run and control The mastery of basic skills and the players ability to control and use the ball efficiently is the first basis to implement the plans, whether offensive or defensive, whenever the proficiency level of the player higher for the skill performance whenever high his value in the team, football is a collective educational sport requires that each player's performance complement the performance of the rest of his teammates, and this also applies on the basic skills till became each team fully diversified in the performance level of its players and thus become a good level of team. Also(2)agrees that there is a clear and abbreviated division of the skill performances with the ball are:

1. Individual (single) performances
2. Composite performance (integrated)

The only skill performances are performed individually and have a definite beginning and end, the effect and the introductory movement role in accomplishing the main duty of the skill are evident, These skills appear in the player's performance of the control skill on the ball (suck, mute, receipt), theside glide, throw ball out of bounds, passes, free kicks and corner and penalty.

Composite skill performances: They represent models of different forms of a set of individual skill performances that merged with each other and overlap

their end stages to form the beginning of the next skill performed by the player in a particular game position to achieve a specific goal according to his requirements. The motor activity of the football player is not only a single skill, but a set of individual skills that merged to become a multi-skill performance that is connected and interdependent among them, where the distinguished players direct to integrate process and melting individual skills inside the only integrate skill such as control the ball and runningthen pass where this includes integrated skills, ie abbreviated in terms of total time and the total area to perform thus become more connected performance [3]. There are some skill performances that depend mainly on the technique and technical style of performances and some other skills depend on the player's ability to respond to external stimulants related to others in actual competition situations and this is what happens in football as we note the emergence of some players are highly skilled in training but fail to show the same superior level during matches because they are unable to respond properly to different playing situations[4].

After conducting an analytical study to identify the most important of these composite skill performances (integrated), a number of (10) composite skill performances are:

1. The Direct pass from the movement (running).
2. Receiving and passing (receiving and passing from movement).
3. Receiving then run the ball and then pass.
4. Receiving then dribbling and passing.
5. Receiving with dribbling and passing.
6. Receiving with dribbling then running the ball and passing.

7 - Receiving then running the ball then dribbling then passing.

8. Receiving then dribbling then running the ball then passing.
9. Receiving then running the ball then dribbling then run and pass.
10. The same previous skill sentences but ending with the correction[5].

It is clear from the above that the physical preparation is an important pillar and an essential duty in Futsal and the modern football requires high capacity, where the players movementon the playground requires a great deal of physical abilities, in addition to the ability of accomplishing and control the ball throughout the periods of dealing with the ball, and to achieve the futsal's player the highest level of performance during the matches the player must be considered a completely physical preparation in the light of playing the game. because the good preparation of physical players has a closely related to his mastery of the basic skills of the game and makes him perform competitions in a distinctive way because the skill and planning performance depends largely on the Physical competence of the player due to many factors, including the game nature, the game time, the size of the stadium space and the large duties lies on the player.

Research Problem: The studying process of any problem requires extensive knowledge and especial realization of the problem type and basing on scientific grounds aimed at reaching the player to the highest levels, and in order to reach the player to high levels of sports in the performance of sports activities in general and futsal in particular, it requires a high level of skill performance and physical abilities, Through the researchers experience in the futsaltraining field have noticed that there is a very obvious weakness in physical and skills abilities of the players, and may be the reason is not to rely on scientific training programs to develop the physical qualities and skills and using the correct scientific evaluation for address these problems, therefore, the researchers see the need to develop effective training programs with using training means (Pleomorphic)and circular and cross training in order to develop some of the physical and skills abilities of futsal players for the deaf and mute.

Research Importance: The importance of the research is to identify the impact of the various training method (Pleomorphic, circular, cross) in the development of some physical abilities and integrated skills of futsal players, and through the reference research and access to Arabic and foreign studies within the researchers' knowledge limits, it was found that there are no studies have the various training method to develop some physical abilities and integrated skills of the players of the Paralympic Committee in Maysanprovince of futsal, this prompted the researchers to try to identify the impact of these method on the futsal players in Maysan and the relation of physical and developing the skill side of the players, which are clearly affecting the level of their performance while playing in the league.

Research Objective: The research aims to develop some of the physical abilities and skills performance of futsal players through:

1. Identify the impact of using the different training method to develop the physical abilities of the futsal players.
2. Identify the impact of using the various training method to develop the skills performance of the futsal players.

Research Hypotheses:

1. There are statistically significant differences between the pre-measurement and post-measurement of the members of the experimental group in favor of post-measurement in the development of special physical abilities of the futsal players.
2. There are statistically significant differences between the pre - measurement and post-measurement of the members of the experimental group in favor of post-measurement in the development of the skill performance of the futsal players.

Biometric Training Mean: It is a training method through which a sudden lengthening (ie, decentralized contraction) which precedes the maximum central contraction where the muscle is lengthened and shortened and helps to develop and improve the explosive capacity, and this type depends on the muscle rubber to give them great kinetic energy, and plyometric exercises are divided into (exercises related to the limb) Lower body and upper limb) and may be performed by using or without tools and include (partridge, jump, leap) and other free exercises, which is a sudden lengthening of the muscle and then followed by shortening them(6).

Cross Training Method: It means doing different things for a lot of people. For some, it may mean the effect of training one side of the body on the other,for others it is an activity used to give active rest from an organized training program,for some, it means using things related to the main activity to avoid the negative results in organized training.

Circular Training Method: It is a regulation of physical effort to achieve a state of adaptation, where it operates through a predetermined path, with a group of activities and performances of the momentary stop at each training station to perform a specified number of repetitions of exercises, free activities, tools or weights according to a specific system.

Futsal: It is the term used internationally for the game, which is derived from the Spanish and Portuguese language and is an abbreviation word of (football) which means football in Spanish and the word (sala) its internal meaning to be the term is football for the halls, and this term is an alternative to the previous term, which is called five-way football. (21)

Research Methodology: The researcher used the experimental method to design two experimental groups and the other controlled by using pre and post measurements to suit the type and nature of the research.

Research Fields:

The Human Field:

1. **Research population:** The research population is represented by (44) players of the Paralympic Committee in Maysan governorate of futsal for the season 2017-2018
2. **Research sample:** The research sample was selected by deliberate random method from the players of the Paralympic Committee in the Maysanprovince of futsal for the season 2017-2018 and the number (30) were divided into two groups (control group, experimental group) The number of each group (15) players were taken into account in the selection of the sample in accordance with the following conditions.

Sample selection conditions:

1. Age between 15 and 17 years.
2. The player's height and weight shall be Proportional with the stage of the age under study.
3. Hearing degree should be 91 decibels (deep loss).
4. Free from diseases that effect of performance.
5. To be committed and continuing in training without interruption.
6. Paralympic Committee officials agree to conduct the experiment on the players.

Spatial Field: The application of scientific transactions to calculate the validity and reliability of the test and the proposed program of the basic research sample on the stadium of the closed hall in the Technical Institute of Technology in Maysan

Time Domain:

1. Scientific transactions were applied to calculate

the validity and reliability of the test on Saturday, 4/11/2017

2. The test was repeated on Tuesday 14/11/2017
3. Pre- tests were applied on Thursday 23/11/2017
4. The basic study of the proposed program was conducted on Sunday 26/11/2017 until Wednesday 24/1/2018
5. The tests were conducted on Thursday 25/1/2018.

Histopathological Findings in Patients with Abnormal Uterine Bleeding

Thuka Tahsseen Yahya[1], Wasnaa Abdulkareem Elias[1], Huda Mahmood Faisal1, Salwa H. Al Mukhtar[2]

[1]MB.ch.B–F.I.B.M.S.path, MB.ch.B–M.S.C.path, Al Khanssa teaching Hospital, Mosul, Iraq, [2]PhD, CHN, Professor, Department of Clinical Nursing Sciences, College of Nursing, University of Mosul

Abstract

Background: Uterine bleeding, which affects a woman between menstrual periods, indicates several hormonal phenomena, which are uterine bleeding outside regular menstrual periods, usually associated with menstruation without ovulation, which is usually the cause of uterine bleeding. The purpose of this study was to describe the prevalence of the AUB among Mosul women.

Methodology: Study design: A prospective study was applied in the Mosul city, Iraq. All cases of abnormal vaginal bleeding procured between October, 2018 and October, 2019, at Al-khanssa teaching hospital, in Mosul city, Iraq. A total of 152 cases were included in the study. For each case, representative slides were reviewed and the pattern of uterine histopathological changes identified and classified according to age groups.

Results: Total of (233) women abnormal uterine bleeding was studied from October 2018 to October 2019. Women' age ranged from 15-55 years. Structural cause of chronic abnormal uterine bleeding consisted of 35.42% of cases, whereas nonstructural cause of chronic abnormal uterine bleeding consisted of 64.58% of cases. Ovulatory dysfunction was the most common finding among women with chronic AUB, accounting for (57.7%) cases. Polyp was found in (16.2%) women, Leiomyoma in (12%) patients, Adenomyosis in (4.94%) patients, Endometrial in (2%) patients, malignancy and hyperplasia in (1.9%) women, and Coagulopathy in (1%) women. The highest rate of Ovulatory dysfunction was belonged to age 25-29 years (19.9%).P prevalence was recorded at the highest rate among women belonged to age (40-44).The prevalence of A & L increased by the age. The prevalence rate was 42.3% among women aged (40-44)(45-49) years respectively. The majority occurrence of AUB found in women belonged to age group()years and those who were multiparous.

Conclusion: The study concluded that our college students still need intensive training in critical thinking and problem solving techniques, and that the teachers of training and teaching should follow advanced method of teaching their students.

Keywords: *AUB, Bleeding, Uterine.*

Introduction

Abnormal uterine bleeding (AUB) is a significant clinical entity. AUB and its sub group, heavy menstrual bleeding (HMB), are common conditions affecting 14-25% of women of reproductive age[1,2] and may have a significant impact on their physical, social, emotional and material quality of life[3]. AUB is mainly caused by an imbalance in the sex hormone balance in a woman's body, which is due to a combination of factors such as polycystic ovary syndrome (POCS), Endometriosis, and Uterine polyps. Chronic AUB was defined as 'bleeding from the uterine corpus that is abnormal in

volume, regularity and/or timing that has been present for the majority of the last 6 months'[4]. AUB may be the symptom of endometrial carcinoma in 8–50% of cases.[5,6] Adenocarinoma of the endometrium is often preceded by proliferative precursor lesions "endometrial hyperplasia". Thus, early accurate diagnosis and proper treatment of endometrial hyperplastic lesions are essential to prevent progress to endometrial cancer and preclude unwarranted hysterectomy without definitive diagnosis.[7]

Aim of the Study: The purpose of this study was to describe the prevalence of the AUB among Mosul women.

Method

Ethical Considerations: This study was approved by the Council of College of Nursing at University of Mosul, Iraq. Study participants were not exposed to harm in any ways whatsoever. Anonymity, privacy and dignity of student were prioritized. No any conflicts of interests and no any advantages were given to the student. Formal Consent was obtained from the student before the study and the protection of them were ensured.

Study Design: A prospective study was applied in the Mosul city, Iraq.

Study Sample: All cases of abnormal vaginal bleeding procured between October, 2018 and October, 2019, at Al-khanssa teaching hospital, in Mosul city, Iraq. A total of 152 cases were included in the study.

Procedure: The cases were classified according to age and causes For each case into three category. The first category includes women with AUB because of non-structural causes includes (Secretory endometrium, Proliferative endometrium, Atrophicendometrium, Disordered proliferative endometrium, Decidual reaction Hormonal imbalance). The second category includes patients with abnormal uterine bleeding due to structural causes (Endometrial polyp, Endometritis, Low grade endometrial hyperplasia, Endometrial carcinoma, Pregnancy-related conditions and Cervical lesions). The third category includes women reproductive age (< 40 years), women of latter reproductive age or perimenopausal age (40-55 years), and finally postmenopausal women (55 years and older)

Statistical Analysis: Data was entered in Microsoft excel 2010 for graphical representation and managed in statistical package for the social sciences (SPSS) version 19. Analysis was done in the form of percentages and proportions and represented as tables where necessary.

Results

Total of (233) women abnormal uterine bleeding was studied from October 2018 to October 2019. Women' age ranged from 15-55 years.Structural cause of chronic abnormal uterine bleeding consisted of 35.42% of cases, whereas nonstructural cause of chronic abnormal uterine bleeding consisted of 64.58% of cases. Ovulatory dysfunction was the most common finding among women with chronic AUB, accounting for (57.7%) cases. Polyp was found in (16.2%) women, Leiomyoma in (12%) patients, Adenomyosis in (4.94%) patients, Endometrial in (2%) patients, malignancy and hyperplasia in (1.9%) women, and Coagulopathy in (1%) women. The highest rate of Ovulatory dysfunction was belonged to age 25-29 years (19.9%).P prevalence was recorded at the highest rate among women belonged to age (40-44).The prevalence of A & L increased by the age. The prevalence rate was 42.3% among women aged (40-44)(45-49) years respectively. The majority occurrence of AUB found in women belonged to age group()years and those who were multiparous.

Table (1): Distribution of abnormal bleeding according to types

Types	No	%
Polyp	42	18.03
Adenomyosis	15	6.44
Leiomyoma	36	15.45
Malignancy and hyperplasia	10	4.29
Coagulopathy	8	3.43
Ovulatory dysfunction	112	48.07
Endometrial	10	4.29
Total	**233**	**100**

Table (2): Distribution of abnormal bleeding according to types and age.

Types/age	15-19y	20-24y	25-29y	30-34y	35-39y	40-44y
Polyp	0%	0%	18%	22%	27%	33%
Adenomyosis	0%	0%	1%	2%	43%	54%
Leiomyoma	0%	0%	0%	0%	46%	54%
Malignancy and hyperplasia	0%	0%	0%	0%	33%	67%
Coagulopathy	12.6%	14.4%	23.9%	20.2%	18.6%	10.3%
Ovulatory dysfunction	22%	20%	25%	12%	11%	10%

Discussion

In the present study the finding shown that the ovulatory dysfunction is most common case (48.07%). Ovulatory dysfunction can contribute to the genesis of AUB, generally manifesting as a combination of irregular timing of bleeding and inconsistent quantity of flow (AUB), which in some cases results in HMB [(8)]. "In many regions, particularly (but not limited to) the USA, ovulatory disorders comprised the huge cases encompassed by the now-discarded term "DUB." Disorders of ovulation may present as a spectrum of menstrual abnormalities ranging from amenorrhea, through extremely light and infrequent bleeding, to episodes of unpredictable and extreme HMB requiring medical or surgical intervention. Some of these manifestations relate to the absence of predictable cyclic progesterone production from the corpus luteum every 22–35 days, but in later reproductive years many relate to unusual "disturbed" ovulations, which have been labeled as "luteal out-of-phase" events"[(9,10)].

Polyp consisted (18.03%) of the cases in the current study. There seems to be little controversy regarding the inclusion of endometrial and endocervical polyps. These epithelial proliferations comprise a variable vascular, glandular, and fibromuscular and connective tissue component and are often asymptomatic, but it is generally accepted that at least some contribute to the genesis of AUB [(11)]. The lesions are usually benign but a small minority may have atypical or malignant features[(12.13)]. A similar incidence was found by Gopalan U (1.1%), Muzaffar M et al (1.2%), Khan S et al (0.6%), and (1.3%) Baral R et al.[(14,15,16,17)]

Furthermore, the study finding revealed that Leiomyoma consisted (15.45%) of cases. Benign fibromuscular tumors of the myometrium are known by several names, including "leiomyoma," "myoma," and the frequently used "fibroid." "Leiomyoma" is generally accepted as the more accurate term and was selected for use in the present system. The prevalence of these lesions (up to 70% in Caucasians and up to 80% in women of African ancestry [(18)], their spectrum of size and location (subendometrial, intramural, subserosal, and combinations of these), and the variable number of lesions in a given uterus require that they be afforded a separate categorization in the system. Like polyps and adenomyosis, many leiomyomas are asymptomatic, and frequently their presence is not the cause of AUB. Furthermore, leiomyomas have widely varying rates of growth, even in a single individual[(19)]. Previous studies had indicated that AUB caused by AUB-L was more severe and the incidence is 14%-25%.[(19,20)] However, our study has found that the bleeding pattern of women with AUB-L was mainly HMB, which accounted for 51% and 44% of length-period prolongation, and the menstrual cycle was regular. Previous study suggested that uterine myoma and endometrial causes of bleeding are associated with increased surface area and brittleness of the blood vessels, resulting in endovascular blood flow increase to overcome platelet aggregation.[(22,23)] In addition, AUB-L was associated with age.[(24,25)] The study found that the incidence of AUB-L increased with age, reaching a peak between 45 and 49 years.

Conclusion

Abnormal uterine bleeding is one of the most common health problems facing women and a change their quality of life. In Mosul, this problem wasn't previously highlighted only through this study, which concluded that

Nutritional Education Regarding Ante Natal Care: Improving Knowledge, Attitudes, and Behaviors of Health Cadres

Sri Achadi Nugraheni[1], Martha Irene Kartasurya[1], Nur Endah Wahyuningsih[1], Naintina Lisnawati[1]

[1]Faculty of Public Health, Diponegoro University, Jl. Professor Soedharto SH, Tembalang, Semarang, Central Java, Indonesia

Abstract

Background: Health cadres have a significant role in helping improve the health of pregnant women. Therefore, providing education supported by comprehensive tools to increase cadres' competence and knowledge of ante natal care (ANC) for pregnant women is a strategic action. The aim of the study was to analyze the effect of conducting nutrition education using "*Bumil-Kit*" media as a comprehensive tools on knowledge, attitudes, and behavior of the cadres in performing ANC.

Method: The quasi-experimental research with one group pre and posttest design was used to analyze 40 cadres as subject working in the area of Lebdosari Community Health Center. Cadres were trained by the nutrition workers the procedures for using "*Bumil-Kit*/Pregnant Mother-kit" consisting of weight scales, mid-upper arm circumference (MUAC) ribbon, microtoise, ANC books, chart of pregnancy growth, and booklets as well as conducting ANC. Knowledge, attitudes, and behaviors were measured before and after a given intervention using a structured questionnaire and data gathered were analyzed using Wilcoxon Signed Rank Test.

Result: The results showed that most cadres (45%) had 6-20 years of working experience. There was an effect of nutritional education on knowledge ($p = 0.001$), attitudes ($p = 0.001$), and behavior ($p = 0.038$) regarding ANC. The increased score of knowledge, attitudes, and behaviors before and after intervention was 7.15%, 6.53%, and 6.43%.

Conclusion: Providing nutrition education using "*Bumil-Kit"* media as a comprehensive tool increases knowledge, attitudes, and behavior of health cadres regarding ANC.

Keywords: *Knowledge, attitude, behavior, health cadres.*

Introduction

Maternal mortality is one of the health problems having been considered a major concern by a country, as most of the maternal mortalities is caused by labor and other factors during pregnancy. According to a survey conducted by Indonesian Basic Health Research, the maternal mortality rate (MMR) in Indonesia fell from 359 per 100,000 live births in 2012 to 305 per 100,000 live births in 2015. Despite the decline, the figure is still relatively high compared to that in other countries in Asia. Even when compared to one of the Sustainable Development Goals (SDG's) targets in 2030, reducing MMR to 70 per 100,000 live births, the gap is still high and therefore more comprehensive efforts are extremely in need. Compared to MDG's target in 2015, which failed to be accomplished, the current target, 102 per 100,000 live births, is still low.[1]

Ante natal care (ANC) has been implemented as a strategy in reducing MMR in several countries, including

Indonesia.[2] ANC service is an integrated program by which pregnant women will receive comprehensive services related to pregnancy care, prevention of babies' low birth weight (LBW), and high-risk prevention for pregnant women; thus, this program provide a positive impact on maternal and fetal health.[3] To achieve these objectives, cooperation among stakeholders, one of which is health cadres, is required. However, the cadres have to have a certain competence to implement the program. Therefore, cadres' competence associated with ANC needs to be improved by providing them nutritional education related subject. In addition, to support the effectiveness of the education, a comprehensive media supporting training, such the "*Bumil-Kit*", is needed. The objective of this study was to analyze the effectiveness of nutritional education using "*Bumil-Kit*" media as a comprehensive tool on the knowledge, attitudes, and behavior of the health cadres regarding ANC of the pregnant women.

Method

The quasi-experimental research with one group pre and post test design was used to analyze 40 cadres as subject working under the administration of Lebdosari Community Health Center. The subjects were given an intervention in the form of nutritional education using "*Bumil-Kit*" media as a comprehensive tool in ante natal care (ANC). The "*Bumil-Kit*" consisted of weight scales, mid-upper arm circumference (MUAC) ribbon, microtoise, ANC books, growth chart of pregnancy, and booklets about how to use "*Bumil-Kit*", Pregnant Mothers Health and Prevention of Low Birth Weight (LBW), Exclusive Breastfeeding Management, and the Role of Husband in the Health of Pregnant Women and Prevention of LBW.

The concept of nutritional education was in the form of socialization and training provided by the Nutrition Workers conducted in Lebdosari Community Health Center for one day. The variables of knowledge, attitude, and behavior regarding ANC of the subjects were measured before and after intervention using a structured questionnaire. Data were analyzed using univariate and bivariate. Univariate is used to determine the characteristics of the subject, while bivariate is used to analyze the impact of providing nutrition education on the subject's knowledge, attitudes, and behaviors regarding ANC. Bivariate data analysis in this study was Wilcoxon Signed Rank-Test. Subjects' participation was voluntary proven by signing of informed consent; in addition, all research data collected was confidential. This research has passed the ethical review from the Health Research Ethics Commission of the Faculty of Public Health, Diponegoro University with Ethical Clearance Number: 224/EA/KEPK-FKM/2018.

Results and Discussion

Subject Characteristics: Most of the subjects were cadres having long working experiences, possessing high school education (SMA), and belonging to productive age.

Table 1: Frequency Distribution of Age, Last Education, and Working Experience of Cadre

Variable	n	%
Age		
a. 20 years–35 years		
b. 36 years–50 th	1	3.5
c. More than 50 years	24	59.0
Last Education	15	37.5
a. Elementary School	0	0
b. Junior High School	9	22.5
c. Senior High School	20	50.0
d. Vocational High School	7	17.5
e. Diploma1	1	2.5
f. Diploma 3	2	5.0
g. Under graduate	1	2.5
Working Experience of Cadre	16	40.0
a. 1–5 years	18	45.0
b. 6–20 years	6	15.0
c. More than 20 years		

Table 1 shows that the subjects of the research belong to age ranging from 36-50 years (59%) are higher than those over 50 years (37.5%), and most of them completed senior high school and only a small percentage completed tertiary education either diploma 1 (2.5%), diploma 3 (5.0%), or undergraduate (2.5%). The working experience of the subjects as cadres is relatively long; 6-20 years (45%), 1-5 years (40%), and more than 20 years (15%).

Health cadres in *Posyandu* are a group of people who voluntarily participate in *Posyandu* activities and have a very important role, one of which is as a motivator of the community in achieving good health status. As *Posyandu* has become a pillar in improving public health through sociocultural approach, the active role of health cadres determines *Posyandu* activities and health programs within the region to be better. In *Posyandu,* the role of health cadres is not only taking

care of toddlers, but also assisting pregnant women in doing ANC compliance.[4]

The result of the analysis showed that as most of the subjects had relatively long work experiences, they had to have a good related competence, yet needed to be updated all the time including increasing knowledge related nutrition. Knowledge is the basic capital in health assisting activities in the community, so providing education is very important.[5] A study in Sidoarjo showed that the activeness of cadres can be identified from their knowledge related competence under which status health programs in the community including *Posyandu* depend on.[6] In this study, the intervention for cadres applied was nutrition education consisting of counseling and practice using media "*Bumil-Kit*" in order to increase cadres' knowledge and competence in ANC.

Effect of Nutrition Education on Knowledge, Attitudes, and Behavior: Cadres' knowledge was measured using a structured questionnaire containing questions regarding pregnancy care, LBW prevention, and high risk prevention for pregnant women. Questionnaires observing pregnancy care covered the number of pregnant women having checked during pregnancy, taking pills containing Fe, recommended and not recommended intake for pregnant women, immunization, smoking history and cigarette smoke exposure, and breast care during pregnancy. Meanwhile, LBW prevention, a component in the knowledge questionnaire, covered LBW definitions and cut-off points, age affecting the occurrence of LBW, factors influencing and preventing LBW. In addition to the two components, other components included in the questionnaire observing knowledge were of high-risk prevention for pregnant women consisting of marriage and pregnancy age, interval and number of pregnancies, signs and symptoms of high-risk pregnant women, and smoking habits as well as drug consumption.

Moreover, the attitude of the cadres in relation to ANC was measured using a structured questionnaire consisted of questions observing pregnancy care, LBW prevention, and high-risk prevention of pregnant women. The pregnancy care component contained questions asking cadres' perceptions about the number of examinations pregnant women had in the first trimester (<20 weeks), recommended and not recommended foods for pregnant women, and activities that might or might not be carried out by pregnant women. In the LBW prevention component, the questionnaire contained questions asking cadres' perceptions about the efforts that should be taken in preventing LBW including examining toxoplasmosis, recommendations for family planning, monitoring the history of pregnant women, and intake and things or activities recommended for mothers during pregnancy. The component of high risk prevention for pregnant women contained questions about maternal perceptions related to encouragement or advice to have health checked when an abnormality occurred during pregnancy, advice to avoid pregnancy at a young age (less than 20 years) and to deliver at home, monitor maternal pregnant conditions during pregnancy, dan suggestions for joining pregnancy exercises.

Similar to knowledge and attitude variables, the behavioral variable also consisted of three question components, namely pregnancy care, LBW prevention, and high risk prevention for pregnant women. The pregnancy care component contained some questions about actions taken by cadres in providing advice to pregnant women to do consultation regarding pregnancy issues, helping organize classes of pregnant women, suggesting to do stimulation for the fetus in the womb, and suggesting what to be done during pregnancy, such as suggestions regarding food intake, lifestyle, and body position when resting.

The LBW prevention component contained several questions regarding recommendations for ANC treatment, attending counseling activities on pregnancy health conducted by health workers, and suggesting intake that may be consumed as well as activities that may be done by pregnant women. Meanwhile, the pregnancy risk prevention component contained several questions regarding cadre actions in giving advice to pregnant women to have health checked at least four times during pregnancy, Tetanus Toxoid (TT) immunization, regular exercise, as well as giving advice on intake and activities that should be consumed and carried out by pregnant women.

The results of the analysis of the effect of providing nutrition education regarding ANC care to health cadres can be seen in Table 2.

Table 2: Effect of Nutrition Education on Knowledge, Attitudes, and Behaviors of Health Cadres regarding ANC Care for Pregnant Women

Variable	Mean ± SD		p[a]
	Pre-test	Post-test	
Knowledge	38.74 ± 2,86	41.51 ± 2,05	0.001*
Attitude	38.26 ± 2,65	40,76 ± 1,64	0.001*
Behavior	38.85 ± 9,90	41.35 ± 5,28	0.038*

[a]Wilcoxon Signed Rank Test, *Intervention significantly influences the three variables ($p < 0.05$)

The results of the analysis showed that nutrition education regarding ANC of pregnant women affected cadres' knowledge, attitudes, and behavior ($p < 0.05$). The increased score of knowledge, attitudes, and behavior was 7.15%, 6.53%, and 6.43%, respectively. Meanwhile, the purpose of the intervention in the form of socialization and practice using "*Bumil-Kit*" media was to make the content of the material taught easy to understand and apply by cadres. This result of this study was in line with the one of a study in Egypt by providing health education for one month to patients with kidney failure and having hemodialysis treatment showed that health education succeeded in increasing knowledge and compliance in relation to fluids and limited sodium consumption.[7]

Other research results in several cities in Europe showed that providing nutrition education can reduce weight loss and improve cognitive function in Alzheimer's patients. The nutrition education conducted in nine sessions and consisted of socialization and practice was given to caregivers of Alzheimer's patients.[8] However, a study in Iran showed that nutrition education for four weeks to patients with kidney failure with hemodialysis treatment increases the score of knowledge, but do not change the practice of food selection, as other factors may influence behavior; it takes a long time for nutritional education to affect the patient's food selection behavior.[7]

Furthermore, the results of the interview after being educated was that all cadres (100%) had a good understanding of the consumption of milk, Fe tablets, no smoking or exposure to cigarette smoke, and prevention of anemia and hypertension in pregnant women, while only a few cadres (62.5%) knew the definition of ANC. Cadres also had a good perception related to ANC examinations in the first trimester, monitoring case history of the pregnant women, pregnant women should consume high protein, and assisting pregnant women when experiencing hyperemesis during pregnancy. Meanwhile, the majority (75%) of cadres did not have a good understanding of family planning and childbirth in health facilities. In this study, cadres did not only have knowledge and understanding related to ANC, but also had taken several actions in the context of giving advice to pregnant women regarding balanced nutrition intake, physical activity, and personal hygiene.

Conclusion

Ante natal care (ANC) is one of the strategies or efforts in overcoming maternal mortality that need intense support from related stakeholders one of which is health cadres. For this reason, nutrition education assisting ANC pregnant women using media "*Bumil-Kit*" as a comprehensive tool is very important for cadres, as this education has proven to have a significant effect on knowledge, attitudes, and behavior of the cadres.

The Effectiveness of Progressive Muscle Relaxation with Benson Relaxation on the Sleep Quality in Hemodialysis Patients

Theresia Uli Porman Purba[1], Ridha Dharmajaya[2], Cholina Trisa Siregar[2]

[1]Master Program, Faculty of Nursing, [2]Lecturer, Faculty of Medicine, Universitas Sumatera Utara, Medan, Indonesia

Abstract

Objects: To identify effectiveness of progressive muscle with benson relaxations on the sleep quality in hemodialysis patients.

Method: The study used a quasi-experimental with comparison of pre and post-tests without control groups. The samples were selected by consecutive sampling technique based on criteria inclusion. The sample size was 48 patients. Sleep quality was measured by applying Pittsburgh Sleep Quality Index. Data analysis used Wilcoxon signed rank and Mann-Whitney U test.

Results: the result showed that there was effect of muscle relaxation with benson relaxation on the sleep quality in hemodialysis patients with p-value 0.00 ($p<0.005$).

Conclusion: The intervention of progressive muscle relaxation and benson relaxation have same effectiveness to improve the sleep quality of the hemodialysis patients with sleep disorders so that nurse should apply this intervention to improve the sleep quality patients with hemodialysis.

Keywords: *Progressive Muscle Relaxation, Benson Relaxation, Sleep Quality, Hemodialysis.*

Introduction

Hemodialysis is one of the method of treatment of end-stage kidney failure that is considered to be able to save lives [(1)]. This therapy is also a stressor for patients because it requires some lifestyle restrictions and modifications that negatively impact physical and psychological well-being[(2)]. Hemodialysis patients are considered to be very vulnerable to psychological problems due to chronic stress associated with client dependence on hemodialysis machines, duration of dialysis therapy, restrictions on physical activity, changes in body image, sexual dysfunction, as well as fluid and food restrictions [(3)].

Mollahadi, Tayyebi and Daneshmandi[(4)] said psychological problems that often occur in hemodialysis patients, namely anxiety, depression, and stress. This study is in line with research conducted by Wang and Che[(5)] stated that hemodialysis is a therapy that can affect a patient's psychological status. Psychological problems are a major factor contributing to sleep disorders in patients undergoing hemodialysis [(6)].

Sleep disturbance is the most frequently reported complication among hemodialysis patients with a prevalence of 80%[(7)]. Sleep disturbance is an abnormality in the normal sleep-wake cycle, causing distorted and fragmented sleep patterns [(8)].

Sleep disorders during long periods refer to poor sleep quality can result in physical and psychological complications in patients undergoing hemodialysis[(9)].

Physical complications related to sleep disorders such as daytime drowsiness, lack of energy, psychomotor dysfunction, and can lead to decreased patient appearance such as cognitive and memory dysfunction [10]. Sleep disorders can also result in impaired immune function, obesity, diabetes, hypertension, stroke and heart disease[11].

Non-pharmacological management that can be used to improve the sleep quality of hemodialysis patients is progressive muscle relaxation and benson relaxation. Progressive muscle relaxation is a therapy that aims to provide emotional balance and peace of mind by focusing on muscle activity by identifying tense muscles and then reducing tension by using relaxation techniques to achieve a relaxation response (relax) [12].

The study by Rambod, Pourali-Mohammadi, Pasyar, Rafii and Sharifstated that Benson's relaxation has a significant effect on daytime sleep disorders in hemodialysis patients [13]. Supporting related study by Masry, Aldoushy and Abd showed that Benson's relaxation techniques have a positive effect in reducing postoperative pain and improving sleep quality among adults and elderly patients undergoing joint replacement surgery [14].

Based on the description above, researchers are interested in conducting research on "The Effectiveness of Progressive Muscle Relaxation with Benson Relaxation on the Sleep Quality of Hemodialysis Patients in H. Adam Malik General Hospital Medan".

Method

This research was a quasi-experimental research with a comparative approach. This research was carried out in the hemodialysis unit in July-September 2018. Sampling using consecutive sampling. The sample size in this study was determined using the Power Analysis table with power (1-β)=.90, effect size (γ)=.73 and α=.05. Anticipating the possibility of selected subjects or samples dropping out, it is necessary to increase the number of samples by 10% so that the sample size remains fulfilled so that the sample in each intervention becomes 48 people.

This research used The Pittsburgh Sleep Quality Index (PSQI) instrument. PSQI is the gold standard for the assessment of subjective sleep quality[15]. PSQI is a questionnaire that assesses sleep quality during a month interval. This instrument is to identify "good" and "bad" sleep quality by measuring sleep based on 7 sleep components including sleep duration, sleep disturbance, sleep latency, sleep dysfunction during the day, sleep efficiency, sleep quality, and use of sleeping pills. The score on the subjective sleep quality assessment is divided into 4 criteria: very good, good, bad, and very bad. The assessment is done by giving a score of 0-3 with a range of scores of 0 for very good and a score of 3 for very bad. Then the total score for the seventh. This component produces a global score which has a range of scores from 0 to 21. The overall PSQI score which shows ≤5 means that the respondent has good sleep quality and if it shows a number> 5 means poor sleep quality [16].

The bivariate analysis used in this study was the Wilcoxon signed ranks test. This test was to see differences in sleep quality before and after relaxation interventions in each intervention group, while the Mann-Withney U test is used to see differences in sleep quality between progressive muscle relaxation groups and Benson relaxation.

Results

Table 1: Frequency distribution of demographic characteristics of hemodialysis patients

Variable	Progressive Muscle Relaxation (n=48)		Benson Relaxation(n=48)	
	f	%	F	%
Age				
18-34 years	18	37.50	14	29.20
35-54 years	23	47.90	32	66.70
≥55 years	7	14.60	2	4.20
Gender				
Male	37	77.10	31	64.60
Female	11	22.90	17	35.40

Variable	Progressive Muscle Relaxation (n=48)		Benson Relaxation(n=48)	
	f	%	F	%
Long of Hemodialysis				
< 1 year	20	41.70	18	37.50
1-2 years	18	37.50	19	39.60
> 2 years	10	20.80	11	22.90
Hemodialysis Session				
Morning	32	66.70	30	62.50
Afternoon	16	33.30	18	37.50

Based on table 1, respondents in both intervention groups were more male, age 35-54 years old, long of hemodialysis is in the range <1 year to 1-2 years and morning hemodialysis session schedule.

Table 2: Mean rank difference in sleep quality of hemodialysis patients before and after progressive muscle relaxation and benson relaxation (n = 48).

Variable	Mean rank		Z	p-value
	Pre-test	Post-test		
Progressive Muscle Relaxation Group				
Sleep quality	21.00	,00	-5.59	,00
Benson Relaxation Group				
Sleep quality	22.50	,00	-5.78	,00

Based on table 2, the results of data processing using the Wilcoxon Signed Rank Test showed that there were differences in the sleep quality of hemodialysis patients before and after the intervention of progressive muscle relaxation and benson relaxation as measured by PSQI.

Table 3: Differences in the quality of sleep of hemodialysis patients after the intervention between progressive muscle relaxation and benson relaxation groups (n = 48)

Variable	Median (Minimum-Maximum)	z	p-value
Progressive Muscle Relaxation Group			
Sleep quality	4.00 (3-14)	-1.85	.06
Benson Relaxation			
Sleep quality	4.00 (2-14)		

Based on table 3. the results of statistical tests using the Mann-Whitney U Test, obtained p=0.06 (p> 0.05), showed that there was no difference in the quality of sleep of hemodialysis patients after the intervention of progressive muscle relaxation and benson relaxation as measured by PSQI.

Discussions

The results of this study indicate that there was a significant difference between sleep quality before and after progressive muscle relaxation interventions (p=0.00). According to Seyedi Chegeni, Gholami, Azargoon, Hossein, Birjandi and Norollahi progressive muscle relaxation can improve sleep quality in hemodialysis patients, where by contracting and relaxing muscles it can reduce the input and output of motor neurons, i.e. pre-synapse it will reduce proprioceptive reflex control and post-synapse will reduce the control of the ecstrospective reflexes [17]. Proprioceptive and ecsteroseptive reduction will result in decreased motor evoked potential (MEP) which will further reduce the activity of the skeletal-motor system, autonomic nervous system (sympathetic and parasympathetic) and cortical pathways [18].

Activation of the parasympathetic nervous system, also called trophotropic, will manipulate the hypothalamus by causing a feeling of relaxation and being more physiologically and emotionally comfortable,

and can cause feelings of wanting to rest, and physical repair of the body, whereas a decrease in the cortical and hypothalamus can cause a relaxed sensation and calm psychological[19].This relaxed feeling will be transmitted to the hypothalamus so that the hypothalamus produces Corticotropin Releasing Factor (CRF). CRF will stimulate the pituitary gland so that the production of several hormones will increase, such as β-endorphin, encephaline and serotonin. Physiologically, the need for sleep will be fulfilled because of the decreased activity of the Reticular Activating System (RAS) and noreepineprine as a result of decreased activity of the brain stem system. The relaxation response will occur because of the activity of the nuclear nucleus parasympathetic autonomic nervous system [20].

The results of this study indicate that there was a significant difference between sleep quality before and after the benson relaxation intervention (p=0.00). Improving sleep quality can be done by using Benson relaxation. This technique is a combination of deep breath relaxation by involving the beliefs held, where by saying a word or sentence can be the name of God or a series of prayers repeatedly according to each religious beliefs accompanied by an attitude of resignation can produce an optimal relaxation response that is the condition of relaxation is not only physical but also mind. This relaxation response is needed to enter the alpha wave, which is a condition that someone needs to enter the initial sleep phase. The basis of this theory is that in the human nervous system there is a central and autonomic nervous system[13]. The function of the central nervous system is to control the desired movements, while the autonomic nervous system has two opposing functions, namely the sympathetic nerve function which stimulates the work of organs and the parasympathetic nervous system which dampens the work of organs. When humans are in tension or stress, the sympathetic nerves are stimulated so that the workings of the body's organs will increase, whereas when humans do benson relaxation will produce a relaxation response, where the resulting relaxation response will cut off the activation pathway of the sympathetic nervous system and replace it by activating the parasympathetic nerve response resulting in a decrease in the workings of body organs. This condition will accelerate someone entering the alpha wave which is a condition needed by someone to enter the early sleep phase [21].Physiologically when humans enter the relaxation phase, then they enter the alpha wave (7-14 Hz). When the brain enters this wave, the brain will produce endorphin hormones which produce a sense of comfort and calm [22].

Mann-Whitney test results, obtained p=0.06 (p>0.05), so it can be concluded that there is no difference in sleep quality between the progressive muscle relaxation and Benson relaxation groups. This can be understood because based on the theory of both progressive muscle relaxation and benson relaxation can produce trophotropic relaxation responses, where the resulting relaxation response will cut off the activation pathway of the sympathetic nervous system and replace it by activating the parasympathetic nerve response. Activation of the parasympathetic nervous system will manipulate the hypothalamus by causing feelings of wanting to rest and physical repair of the body [19].

Conclusion

Based on the results of this study, it can be concluded that progressive muscle relaxation exercises and Benson relaxation performed twice a day for 4 weeks have the same effectiveness in improving the sleep quality of hemodialysis patients. Progressive muscle relaxation and Benson relaxation can be complementary therapies in hemodialysis patients who experience sleep disturbance problems.

Analysis of Factors Relating to Loyalty of Patients in Pertamina Bintang Amin Hospital Lampung in 2019

Wayan Aryawati[1], Bagus Nur Eko Prasetio[2], Vera Yulyani[1]

[1]Lecturer, [2]Student of Public Health Graduate Program, Faculty of Public Health, University of Malahayati

Abstract

Background: Presentation of inpatient satisfaction of Pertamina Bintang Amin Hospital only reached 75%. The purpose of this study is to determine the factors associated with inpatient loyalty at Pertamina Bintang Amin Hospital Lampung in 2019.

Method: This is a quantitative study with a cross sectional approach. The population in this study were all patients who used inpatient services in 2019. Sampling using accidental sampling technique with a sample of 196 respondents. Univariate, bivariate, and multivariate data analysis used multiple logistic regression tests.

Results: Factors related to patient loyalty are gender, cost bearer, empathy, reliability, and hospital image with p-value (0.015; 0.000; 0.014; 0.007; 0.000). Factors not related to loyalty are age, job, and income. Reliability is the most dominant factor affecting the patients loyalty with OR 5.732.

Conclusions: Reliability is the most dominant factor influencing patient loyalty. It is recommended to the hospital for training to improve human resources through increasing knowledge, skills and abilities.

Keywords: *Patients loyalty, inpatients, hospital.*

Introduction

Hospitals are the spearhead of public health services. The number of hospitals in Indonesia encourage hospitals to compete to provide the best service in order to get patient loyalty.[1-3]

In Indonesia, the number of hospitals from 2014-2018 increased by 16.92%. In 2014 the number of hospitals was 2,406, becoming 2,813 in 2018. The existence of hospitals in the city of Bandar Lampung had grown. The number of hospitals in Bandar Lampung City is 17 hospitals.[4]

There are 2 basic approaches to creating patient loyalty, namely the attitudes and behavior of health workers. The loyalty approach based on attitude is empathy. While the loyalty approach based on behavior is reliability. A number of other factors turned out to play a role in customer loyalty issues in addition to service quality factors, namely customer characteristics.[5-9]

Pertamina Bintang Amin Hospital (PBAH) Lampung is a hospital that has been Paripurna accredited by the Hospital Accreditation Committee (KARS) in 2012. Based on the data obtained from the PBAH service section, it was found that the presentation of PBAH inpatient satisfaction was assessed to have reached 75% internally. This value is still below the standard inpatient service indicator (90%).

According to the initial survey conducted by researchers, data obtained in 2016 the number of inpatients 36.6% (13,323 patients), fell to 33.6% (12,258 patients) in 2017, and fell again to 29.6% (10,804) patient) in 2018. The data showed that there was still a lack of patient loyalty which is marked by a decrease in the number of inpatient visits for 3 years in a row. This study aimed to determine the factors associated with inpatient loyalty in PBAH Lampung in 2019.

Method

This is a quantitative study with cross-sectional design. The study was conducted at PBAH Lampung October-November 2019. The population in this study

were all inpatients. In this study the number of samples was 196 respondents obtained using lameshow formula. With inclusion criteria namely inpatients, aged ≥17 years, patients in a conscious condition and able to communicate well, patients are willing to be interviewed. The exclusion criteria are patients <17 years, patients or families of patients who work in PBAH Lampung. The sampling technique in this study was accidental sampling. Primary data collection was carried out in the inpatient room using a questionnaire through interviews. Before being distributed, the questionnaire was tried out first in PBAH to respondents who were different from the research respondents. From the test of the validity and reliability of the questionnaire before the study, it was found that the questionnaire was valid and reliable with a significance of 5%, all regression coefficients r counted> r table (0.361) and Cronbach alpha> 0.60. Secondary data were obtained from literature studies, literature books, and other important documents such as annual reports, profiles and PBAH Lampung Medical Records. Data analysis used univariate to determine the frequency distribution, bivariate chi-square test and then multivariate test using multiple logistic regression tests. This research was compiled from the Loyal Customer Behavior theory[10]; Individual Characteristics[11]; Customer Satisfaction[10,11]; Services Quality[12]; Company Images[13].

Results

The results showed that of the 196 respondents most of them had good loyalty 105 respondents (53.6%). The Bandar Lampung community acknowledges that PBAH has complete facilities and adequate doctors so that many patients return to PBAH. Most respondents were adults (84.2%), didn't work (65.8%), low income (70.4%), had good empathy (93.9%), and had good reliability (93.4%) (Table 1).

Table 1: Patient Characteristics in Inpatient Unit PBAH Lampung in 2019

Variable	Category	Total (n=196)	%
Patients Loyalty	Good	105	53.6
	Not Good	91	46.4
Age	Adult (17-60 tahun)	165	84.2
	Elderly (>60 tahun)	31	15.8
Sex	Male	94	48.0
	Female	102	52.0
Occupation	Working	67	34.2
	Not Working	129	65.8
Income	High (IDR ≥2,445,141)	58	29.6
	Low (IDR<2,445,141)	138	70.4
Cost Bearer	Independent	46	23.5
	Institution (Insurance)	150	76.5
Empathy	Good	184	93.9
	Not Good	12	6.1
Reability	Good	183	93.4
	Not Good	13	6.6
Hospital Images	Good	106	54,1
	Not Good	90	45,9

Relationship age with patient loyalty: The older a person needs their health services will increase.[14] The type of disease can affect patient loyalty because some diseases require health services in the hospital more often than other types of diseases.[1] Chi-square test results showed a p-value 0.696 (> 0.05), it can be concluded that there was no statistically significant relationship between age and patient loyalty (Table 2). This result is in line with the study of Ulfa (2012) which states there was no significant relationship between age and patient loyalty.[15] In research on the correlation between demographic factors and loyalty, the older a person is significantly more loyal than the younger age.[11,16,17]

Relationship sex with patient loyalty: Most respondents were female (102.0%). The results of the chi-square test relationship of sex with patient loyalty in the inpatient ward of PBAH obtained p-value 0.015 <0.050, it can be concluded that there was a significant relationship between sex and patient loyalty (Table 2). Sex differences between women and men, for example in differences in needs, desires and expectations. Women's group usually uses health services or products more than the male group. They also presented a national survey in the United States in 2006 which showed a conclusion that women have an important role as decision makers in health care, not only for themselves but also for their families.[18]

Relationship occupation with patient loyalty: The majority of respondents was not working 129 (65.8%). Chi-square test results of the relationship of occupation with patient loyalty obtained p-value 0.230> 0.05, it can be concluded that occupation has no relationship with patient loyalty. Occupation also affects consumption patterns, someone who had a certain job would buy the needs that were in accordance with his job. In this case if the majority of workers who had relatively high risk of health problems, thus affecting the patient's behavior in repurchasing because of his needs, which ultimately reflects his loyal behavior.[11]

Relationship income with patient loyalty: Most respondents had low income 138 (70.4%). Consumer perceptions about the economic resources they have affect their willingness to use money .[18] Chi-square test results obtained p-value 0.158> 0.05 which means there was no significant relationship between income and patient loyalty (Table 2). The results of this study were in line with other studies that show income has no relationship with patient loyalty and there was no difference between the level of patient income to patient loyalty.[15,19]

Relationship cost bearer with patient loyalty: Most respondents have agency expense insurers 150 (76.5%), where the dominant agency cost bearers with good loyalty are 92 (87%) and the dominant independent cost bearers with poor loyalty 33 (36.3%) (Table 2). Chi-square test results obtained p-value 0.007 <0.05, it can be concluded that there is a significant relationship between the cost insurer and patient loyalty. In addition, from the calculation, an OR 2.75 is obtained, which means that the independent cost insurer has a 2.75 times probability of generating good loyalty compared to the agency cost insurer. The results of this study are in line with previous research which states that cost bearers have a relationship with loyalty.[15]

Table 2: Factors Associated with Patient Loyalty in Inpatient Unit PBAH Lampung in 2019

Variable	Loyalty				Total		OR 95% CI	P-Value
	Good		Not Good					
	n=105	%	n=91	%	N	%		
Age								
Adult	87	52.7	78	42.3	165	100	0.80 (0.37-1.75)	0.696
Elderly	18	58.1	13	41.9	31	100		
Sex								
Male	59	62.8	35	37.2	94	100	2.05 (1.15-3.63)	0.015
Female	46	45.1	56	54.9	102	100		
Occupation								
Working	40	59.7	27	40.4	67	100	1.45 (0.80-2.85)	0.230
Not Working	65	50.4	64	49.6	129	100		
Income								
High (>IDR 2,445,141)	36	62.1	22	37.9	58	100	1.63 (0.87-3.06)	0.158
Low (<IDR 2,445,141)	69	50.0	69	50.0	138	100		
Cost Bearer								
Independent	13	28.3	33	71.3	46	100	2.75 (1.34-5.63)	0.007
Institution	92	61.4	58	38.6	150	100		

Variable	Loyalty				Total		OR 95% CI	P-Value
	Good		Not Good					
	n=105	%	n=91	%	N	%		
Empathy								
Good	103	56.0	81	44.0	184	100	6.35 (1.35-29.83)	0.014
Not Good	2	16.7	10	83.3	12	100		
Reliability								
Good	103	56.3	80	43.7	183	100	7.08 (1.52-32.85)	0.007
Not Good	2	15.4	11	84.6	13	100		
Hospital Images								
Good	76	71.7	30	28.3	106	100	5.32 (2.89-9.82)	<0.001
Not Good	29	32.2	61	67.8	90	100		

Relationship empathy with patient loyalty: Most respondents have good empathy 184 (93.9%). Chi-square test obtained p-value 0.014 <0.05, it can be concluded that there was a significant relationship between empathy and patient loyalty (Table 2). In addition, from the calculation, an OR 6.35 is obtained, which means that good empathy has a 6.35-fold chance of generating good loyalty compared to not good empathy. The results of this study were in line with Yasril's study (2019) which states that there was a relationship between the dimensions of empathy and patient loyalty.[20]

Empathy is the individual and personal care and attention given by service providers to customers by trying to understand the desires of consumers specifically.[12] Table 2 showed that out of 184 empathy both dominant loyalty was good as many as 103 (56.6%) and from 12 empathy was not good dominant loyalty was not good as many as 10(83.3%).

Relationship reliability with patient loyalty: Most respondents have good reliability 183 (93.4%). Chi-square test results obtained p-value 0.007 <0.05, it can be concluded that there was a significant relationship between the reliability of health personnel with patient loyalty, besides that the calculation obtained OR 7.08 which means that good reliability had a possibility of 7.08 times generate good loyalty compared to less good reliability. Reliability of services means the ability of health workers to provide services in accordance with what was promised accurately and reliably in the form of procedures for receiving patients served quickly, readiness to serve patients at any time, providing drugs according to the procedure.[21,22]

Relationship hospital image with patient loyalty: Most respondents have good hospital images 106 (54.1%). Chi-square test results obtained p-value 0,000 <0.05, it can be concluded that there was a significant relationship between the image of the hospital with patient loyalty, in addition to the calculation obtained OR 5.32, which means that a good hospital image has a 5.32 chance times generate good loyalty compared to not a good hospital image. Image is a set of beliefs, ideas, and messages that a person has towards an object. The image of the hospital is closely related to patient loyalty, there are still many people in this study choosing government hospitals as the first choice in the use of health services.[13,23]

The Most Dominant Factors Associated with Patient Loyalty: Based on the results of multiple logistic regression tests of 5 variables that have the highest OR value is the reliability (OR = 5,732), it can be assumed that the reliability is the variable that most influences on patient loyalty. Based on the results of the multivariate analysis as a whole, the logistic regression equation is obtained in part below:

Patient loyalty = -6,787+(1,300*handling costs)+(1,746*reliability)+(1,687*hospital image). With the equation model above, it can be estimated the possibility of patient loyalty. The equation shows that with a constant - 6,787 the possibility of patient loyalty will turn out to be good at 1,746 if reliability is good.

Table 3. The Most Dominant Factor in Patient Loyalty

Variable	B	SE	P Wald	P-Value	OR	95% CI
Cost Bearer	1.300	0.421	9.521	0.002	3.670	1.607-8.381
Reliability	1.746	0.815	4.588	0.032	5.732	1.160-28.329
Hospital Images	1.687	0.331	26.013	0.000	5.405	2.826-10.337
Constant	-6.787	1.337	25.783	0.000	0.001	-

The results of the analysis showed that the determinant coefficient (R2) showed a value of 0.284 meaning that the regression model obtained can explain 28.4% of the reliability variable is able to explain the incidence of patient loyalty and the remaining 71.6% is explained by other variables. Reliability is the ability to provide the promised service immediately, accurately and satisfactorily.[24] Reliability relates to the ability of hospital medical staff to provide or deliver services as expected.[3] The results of this study were in line with the Djohan study's (2015) which states that reliability has a positive and significant influence on the level of patient loyalty.[25]

Based on the theory and results of the study, researchers argue that when health workers and hospital staff provide timely service time, listen to patient complaints gently, treat patients and families, explain the patient's condition, how to treat, how to take medication, do not differentiate- differentiate services based on social levels, complete facilities and comfortable rooms, these things will foster a high sense of satisfaction, comfort and trust so that good empathy and reliability arises.

Conclusions

Loyalty of patients in the PBAH inpatient unit in 2019 shows good loyalty. Factors that influence patient loyalty to be good were sex, female is a determinant of increased patient loyalty, cost bearer, agency cost bearer is a factor that can affect patient loyalty in the future, empathy is one of the factors that can affect patient loyalty, physician reliability and health workers is very influential on patient loyalty and the image of the hospital can increase patient loyalty, of the five variables, the reliability factor is the most dominant factor on patient loyalty.

Risk Factors Associated with the Incidence of Cervical Cancer in Dr. H. Abdul Moeloek Hospital Bandar Lampung in 2019

Wayan Aryawati[1], Ni Made Arianingsih[2], Nurul Aryastuti[1]

[1]Lecturer of Faculty of Public Health Graduate Program, [2]Student of Faculty of Public Health Graduate Program Health Reproductive Concentraion, University of Malahayati, Kemiling Permai Village, Kemiling Sub-District, Bandar Lampung, Indonesia

Abstract

Cervical cancer is the most common cause of death in developing countries. The number of cervical cancers in Lampung was 385 cases in 2016. The prevalence of cancer morbidity in Lampung was 0.7 per 1000 population, many factors that cause cervical cancer were the age of first sexual intercourse, parity, multiple sexual partners, smoking, use of vaginal cleansers, use of hormonal contraception, history of sexually transmitted infections and family history. This is a quantitative study with a case control approach. The study population was all women who had cervical cancer and not cervical cancer, with a sample ratio of 1:2. Study respondents numbered 174, univariate data analysis, bivariate using chi-square and multivariate using multiple logistic regression. The results showed the most dominant factor associated with cervical cancer was a family history of p-value 0.009 OR 3.33 (95% CI 1.41-7.83). It is recommended that health workers can provide information about cervical cancer and prevent it by carrying out HPV immunization and pap smears regularly.

Keywords: *Risk factors, cervical cancer, family history.*

Introduction

Cervical cancer is one of the leading causes of death in women in developing countries. The main cause of cervical cancer is chronic infection by HPV (Human Papilloma Virus). The International Agency for Research on Cancer (IARC) notes that cervical cancer ranks first with an average incidence of 0.015% and a mortality rate of 7.8% per year of all female cancers in the world.[1] The number of cervical cancer sufferers in Lampung Province was 385 cases in 2015.[2]

Risk factors for cervical cancer include age> 35 years old, married age <20 years, having> 1 sexual partner, smoking, low personal hygiene, poverty, giving birth to children at a young age, use of hormonal contraceptives, number of parities> 3 and the presence of materials mutagens were thought to genetically alter cells in uterine tissue such as HPV types 16 and 18.[3-5]

Women who had sex for the first time at the age of less than 20 years had a risk 3 times greater than women who had sex once at age more than 20 years.[6-8] Sex partner changing habits was an important risk factor. Women who were married were 2-4 more likely to get cervical cancer than those who were not married..[9-11]

Having many children also triggers cervical cancer, when giving birth the fetus will pass through the cervix and cause injury to the cervix. If this happens repeatedly then the cervix will be more susceptible to infection and exposure to cervical cancer.[12,13] Using long-term birth control pills for more than 5 years can increase cervical cancer exposure by 1.53 times.[14,15]

Family history such as mother and sister also determine the high potential for cervical cancer. At least the risk increased 2-fold compared with those with no family history.[16] Moreover, washing the vagina with antiseptics that have a high PH can increase the risk of cervical cancer.[17]

Method

This is a quantitative study with case-control design by selecting cervical cancer patients as cases and not cervical cancer patients as controls. The approach used is a retrospective approach, this research will be conducted

at Dr. H. Abdul Moelok Hospital in March-April 2019. The study sample consisted of 58 respondents in the case group and 116 respondents in the control group with a comparison between case groups and control groups of 1:2. Sampling for the case is taken by using purposive sampling technique by accidental sampling, data collection by interview in questionnaire format as well as primary and secondary data.

Data processing consists of several processes namely editing, entry, coding, and tabulating. Data were analyzed by finding the Odds Ratio (OR) of each variable for cervical cancer and to see the difference in risk between the exposed and unexposed groups. OR is the ratio between the risk of disease in the exposed group and the risk of disease in the non-exposed group. If the value of the OR confidence interval includes a value of 1 then it means maybe OR = 1, so it cannot be concluded that the factor under study is a risk factor or protective factor.[18]

Results

Abdul Moeloek Hospital has the main task of carrying out the preparation and implementation of regional policies in the field of hospital services, the task of deconcentration and assistance tasks given by the government to the governor and other tasks in accordance with the policies set by the governor based on applicable laws and regulations.

Table 1: Characteristics of Respondents at Dr. H. Abdul Moeloek Hospital 2019

Characteristics	Group			
	Cases		Control	
	n=58	%	n=116	%
Umur (Years)				
<20	-	0	29	25
≥20	58	100	87	75
Education				
Low (Elementrary/Middle)	14	24	30	26
Moderate (High School)	32	55	51	44
College	12	21	35	30
Occupation				
Civil servant	11	19	30	29

Widow	20	17	35	30
Number of Children				
<2	31	53	81	70
≥2	27	47	35	30

Majority of respondents were ≥20 years old and in the case group were 58 people (100%). The majority of education in the case group was moderate (high school) as many as 32 people (55%). Occupation for the majority of case groups were 20 workers (34%). In the marital status of the majority of the case group married 48 people (83%). For the number of children, the majority of case group respondents had <2 children 31 people (53.4%) (Table 1).

Yes	15	25.9	11	9.5		

Noted: STI: Sexual Transmitted Infections; OR: Odds Ratio; CI: Confidence Interval

Based on table 2 shows that in the case group, the majority of respondents first had sexual intercourse <20 years as many as 35 people (60.3%). In the parity variable the majority of respondents had parity <3 children as many as 31 people (53.4%). In the variable sexual partner change the majority of respondents have the number of sexual partners 1 partner as many as 39 people (67.2%). Mayoritasrespondenmerokoksebanyak 46 orang (79,3%). The majority of respondents used vaginal cleansers as many as 34 people (67.2%). The majority of respondents not using hormonal contraception were at risk as many as 36 people (62.1%). The majority of respondents had a history of STIs of 37 people (63.8%). The majority of respondents did not have a family history of 43 people (74.1%).

Bivariate statistical test results showed a relationship between the age of first sexual intercourse (p=0.001; OR=3.004 95% CI 1.565-5.767), parity (p=0.050; OR=2.016 95% CI 1.052-3.864), alternating sexual partners (p=0.010; OR=2.837 95% CI 1.338-6.018), cleaning use (p=0.001; OR=3.025 95% CI 1.575-5.807), use of hormonal contraception (p=0.035; OR=2.224 95% CI 1.115-4.438), history of STI disease (p=0.001; OR=3.104 95% CI 1.611-5.981), family history (p=0.009; OR=3.330 95% CI 1.416-7.831) for cervical cancer. In addition there is no relationship between smoking and cervical cancer.

Table 3: Prediction Models of Risk Factors Affecting Cervical Cancer Occurrence in Dr. H. Abdul Moeloek Hospital Bandar Lampung in 2019

Variable	Sig	Exp(B)	95% C1 for Exp (B)	
			Lower	Upper
First Age Sex	0.011	2.716	1.261	5.853
Parity	0.020	2.540	1.160	5.560
Sexual Partner	0.027	2.540	1.120	6.479
Use of Vaginal Cleansers	0.034	2.348	1.067	5.168
Use of Hormonal Contraception	0.033	2.473	1.075	5.693
STI History	0.033	2.246	1.067	4.728
Family History	0.036	2.842	1.073	7.523

Based on the OR values of the variables in the model it can be seen that, family history (OR = 2,848) is the most dominant variable as a risk factor influencing the incidence of cervical cancer in Dr. H. Abdul Moeloek Hospital Bandar Lampung in 2019, probability/chance of cervical cancer occurrence in women with a family history, age of first sexual intercourse <20 years, multiple sexual partners> 1 sexual partner, parity ≥ 3 children, usage Hormonal contraception is risky, using female cleansers, and there is a history of STIs of 0.9720 (97.20%), as much as 3.80% is influenced by factors not examined.

Discussions

Before the age of 20, the female reproductive organs were immature.[19] This will get worse if pregnant women under the age of 20 years have a risk that is twice as big as cervical cancer later in life.[20] The results of this study were in line with the results of Rhina's study (2017) which showed that in the case group, the majority of respondents who had first had sexual intercourse <20 years were 36 people (62.1%).[21] The study conducted by Darmayanti (2015) also got the same results as the researchers did, namely there is a relationship between the first age of sexual intercourse with the incidence of cervical cancer (p=0.001).[22] According to researchers the age of first sexual intercourse is recommended at age> 20 years because mucosal cells are no longer too vulnerable and sensitive to changes. Judging from the first age of sexual intercourse a woman who is sexually active since a young age will increase the risk of cervical cancer.

Having many children can trigger cervical cancer, because during delivery the fetus will pass through the cervix and will cause trauma to the cervix. if this happens continuously the cervix will become infected and can cause cancer.[12] The results of this study were also compatible with research conducted by Aziyah (2017). Based on the results of statistical tests after the merger, the p-value of 0.000 <α 0.05 results shows that there is a relationship between parity status and cervical cancer in Dr. Kariadi Hospital Semarang in 2016.[23]

According to researchers, respondents who had parity ≥ 3 children were caused by respondents not suitable to use contraception and the lack of knowledge and information to choose suitable contraception, in addition this was worsened by husbands who did not want to participate in using contraception.

Women who frequently change sex partners, especially if the man does not use a condom, the greater the chance of suffering from cervical cancer. The injuries that arise will be a place for developing HPV viruses.[9]This study is in line with research conducted by Indiani (2010), that the number of sexual partners associated with the incidence of cervical cancer lesions. In the bivariate analysis p value was 0,000 with OR 3,805 (95% CI 1,791-8,084).[24]

In the opinion of researchers changing sexual partners is very risky to transmit sexual diseases, at the time of the study many women were found to have been married 2-3 times, but they did not know that getting married more than once was included in the category of changing partners.

In addition to active smokers, passive smokers were also at greater risk of cervical cancer attack three times more likely than active smokers.[17] The results of this study were in line with Melva note that the largest proportion of cervical cancer cases from the

Chi-square test value of 0.572 p> 0.005 means that there is no significant difference between smoking and cervical cancer. According to researchers at the time of conducting research in addition to the presence of respondents who smoke actively there are respondents who said that many family members who smoke, such as parents, children's husbands and work environment.

Diananda (2007) stated that washing the vagina with antiseptic or deodorant drugs will cause irritation to the cervix that stimulates cancer. The results of this study were in line with the results of Rhina's (2017) study, the most dominant risk factor for cervical cancer incidence is the use of vaginal cleaning OR 8,428 (95% CI 2,991-23,744). The use of antiseptics is a risk for cervical cancer. According to researchers, respondents argued that after using antiseptic soap there was a rough and clean effect, making women continue to use the soap especially during vaginal discharge and after sexual intercourse, in addition many respondents who performed vaginal care in the salon to get a rough and tight effect on the area womanhood. This is not good because it can kill good bacteria that should remain in the vagina to maintain the PH balance and prevent the entry of bad bacteria.

Conclusions

Most age of first sexual intercourse <20 years(60.3%), parity <3 children (53.4%), changing sexual partners> 1 partner (67.2%), smoking (79.3%), using female cleansers (58.6%), using risky hormonal contraception (62.1%), there is a history of STIs (63.8%) and there is a family history (74.1%).

There was a relationship between age at first sexual intercourse (OR = 2.716 (95% CI 1,261-5,853), parity (OR = 2,540 95% CI 1,160-5,560), changing sexual partners (OR = 2,254 95% CI 1,120-6,479), vaginal cleaners (OR = 2,348 95% CI 1,067-5,168), use of hormonal contraception (OR = 2,473 95% CI 1,075-4,728), history of STI disease (OR = 2,246 95% CI 1,067-4,728), family history (OR = 2,842 95% CI 1,073-7,523) with cervical cancer incidence. There is no relationship between smoking and cervical cancer incidence.Family history is the dominant variable on cervical cancer events.

Health workers are expected to improve promotive services by providing information about cervical cancer especially to women who have a family history of cervical cancer, providing HPV immunization and pap smears to prevent and detect cervical cancer.

Building Healthy Open-minded Measure for the Fourth Stage Students in the Faculties of Physical Education and Sports Sciences in Iraq

Yassar Sabah Jassim[1], Lahib Ahmed Shaker[2]

[1]Professor, [2]Student, University of Diyala College of Physical Education and Sport Science

Abstract

The psychology from the sciences which is concerned with the psychological aspects of the individual and has an active role in building the human civilization, positive psychology is a modern branch of psychology that seeks to improve the psychological life through caring to the personal life of the individual. The Open-mindedness is one of the positive psychological concepts that make the student has a happy life, whether academic, social or professional through his mental and physical abilities to achieve success and make him an effective productive member of the society. Hence the importance of the current research in scarcity of scientific studies about the concepts of open-mindedness in Iraq, especially for fourth stage students in the faculties of physical education and sports sciences as well as the importance of university education of students as being one of the most important corners of the educational process, the problem of the research that there is no standardized measurement tool enables researchers to identify the concepts of open-mindedness of the fourth stage students in the faculties of physical education and sports sciences, so the researchers decided to build a measure of open-mindedness for the fourth stage because it is the vanguard of the society youth and elite and basis of the society renaissance.

Keywords: *Physical education, open-minded measure.*

Research Objective

Building open-mindedness measure of the fourth stage students in the faculties of physical education and sports sciences in Iraq. The students sample of the Faculty of Physical Education and Sports Science, the fourth stage of the year 2018-2019.

Introduction and Importance of the Research

The psychology of the sciences which cares about the psychological aspects of the individual and has an active role in building human civilization, and the positive(1). Psychology is a modern branch of psychology branches, which seeks to improve the psychological life through caring of the individual personal(2). It is a science interested of study and analysis the self-experiences such as open-mindedness and the psychological life and satisfaction of the past, flow and happiness in the present, hope and optimism for the future, At the individual level(3). It is concerned with studying and analyzing the positive features such as the ability to work, social relations with others, open mindedness and looking forward to the future. At the community level, it revolves around the virtues that move the individual towards good citizenship, responsibility, dealing with others and caring them.

Research Problem: The social, economic and political changes witnessed of the present era and which have a change in some human values, and carried many psychological difficulties and stresses of different life, including pressures during the university study that led to a lot of unhappiness and negatively affected on the level of students' academic, athletic and professional ambition and appreciation Self, open-mindedness is a positive psychological characteristics that must students have to qualify them to perform their role in the future and accept the variables with innovative and creative abilities.

The Research Objectives: Building a measure of open mindedness for students of the fourth stage in the faculties of physical education and sports science in Iraq.

Research Fields Human field: Includes the

students of the fourth stage in the faculties of physical education and sports sciences for the preliminary study only morning, for the academic year 2018 - 2019.

The Time field: from 10/11/2018 to 7/2/2019

Spatial Field: Classrooms and playgrounds in the Faculties of Physical Education and Sports Science in Iraq.

Open-mindedness: It is a pattern of thinking characterized by a flexible, growing, developing and accepting change, where the individual interested in knowing the other ideas and thoughts and accept it, and has the ability to change his thoughts if proven that it is wrong[4].

The procedural definition of the open mindedness concept: the degree that the students obtained of the fourth stage in the faculties of physical education and sports science through their responses to the open mindedness measure [5].

Research Methodology: One of the most important steps that will lead to the success of the research. It is to choose the appropriate approach for researching the problem and achieve the object, therefore the researchers used the descriptive approach in the survey method because it is more appropriate to the nature of the research problem and its objectives in building a measure of open mindedness, as descriptive research "aims to determine the nature and the characteristics of some phenomena to identify or depict the current situation and analyze it to try to draw conclusions and make predictions or projections on the evolution of these phenomena(1).

Research population and sample: The current research population is determined by the students of the faculties of education, physical and sports sciences/the fourth stage in the Iraqi universities for the morning study only and the academic year (2018-2019) the number of (1591) student distributed to (14) faculties, Kirkuk University excluded because most of its students do not speak the correct Arabic language and the researchers were unable to translate a measure with Arabic and to preserve the true meaning of the measure. The sample of building and technique was selected randomly for the measure of open mindedness, the sample of building (statistical analysis sample) reached (400) students from the total population with 25.14%.

Research tools: The researchers used in collecting research data of the following means:

3-3-1 Means of data collection

Note

Personal interviews

Questionnaire

Previous psychological measures

3-3-2 Means of information collection

- Scientific sources and references
- Previous studies and research
- Internet

3-3-3 Means of Data Analysis

- Calculator manual (1) made in china.
- Statistical means
- (laptop) brand: TOSHIBA

3-3-4 Assistant means:

- Assistant Working Group (*).
- Pens.
- HUAWEI mobile phone for Photography and timing.

Field research procedures:

Research tools: The researchers used in the current research pen mindedness measure that was built, the researchers care of the scientific measurement conditions such as honesty, consistency and the distinguish ability, and the following steps taken by the researchers

Steps of Building the open mindedness Measure: To achieve the goal of the research, which is to build a measure of openmindedness, the researchers will follow the steps of[7] who determines he aim of the measure is building open mindedness measure, as the researchers did not find a local measure to measure the open mindedness of the fourth stage students in the faculties of physical education and sports sciences (as far as the researchers know) suits with the nature and objectives of the current research, and its sample to make the measure accessible to specialists and researchers of [8]determines the phenomenon to be measured for the measure.

After determining the objective of the measure, determine some basic considerations and theoretical

premises for building the measure before starting of preparation because it is important step and necessary to forms the basis which the measure depend on and derived its scientific components are summarized as follows.

(1) Determine the theoretical concept of the measure through informing the researchers on the literature, studies and theoretical frameworks that interested of this concept, and the researchers adopted [9] theory (2) in the formulation of paragraphs open minded measure.

(2) Adopt the method of self - report in answering the paragraphs of the measure as the student's emotional experience is able to express what it feels, as evidenced by the verbal behavior of the respondent about his psychological state (3), especially the current measure is relevant to that situation.

1. **Determine the measure Fields (open mindedness):** Open mindedness measure does not determine any field, and the researchers developed a procedural definition

2. **Develop the initial formula of (open mindedness measure)**

To develop the initial formula of measure, the researchers conducted several steps:

4. **Preparation of measure Paragraphs:** To prepare a special paragraph of the measure of open mindedness of students, the researchers followed two ways:

   - Review the theoretical framework and previous studies
   - Questionnaire exploratory

5. Determine the method and bases of formulating the measure paragraphs

After the researchers used the two method described to collect and prepare measure paragraphs, and obtained (53) paragraph,

Determine the validity of paragraphs and alternatives for answering the measure: After the collection and preparation of paragraphs in its initial formula of the measure and the identification of answering alternatives which contained (53) paragraph for the measure of open mindedness, the researchers presented the measure of the initial formula Annex (9), the experts and specialists in sports psychology, educational psychology, testing and measurement annex (4), to judge on its validity, as well as making adjustments, calendars, rephrasing, merging, deleting and adding on the paragraphs

Main Experiment of measure (open mindedness) (Statistical Analysis Sample): The main experiment through the application of the measure in its initial formula on the building sample of (400) students of the fourth stage students in the faculties of physical education and sports sciences to analyze their paragraphs statistically and choose the valid ones and exclude invalid ones based on the discriminatory strength and internal consistency as well as to extract the indicators of honesty and stability of the measure, which referred on Annex (11), on 18/10/2018 to 20/11/2018, and the measurement forms were distributed collectively and individually on students by the researchers and the assistant team.

Measure Correction: After collecting the answer forms of the sample, the total grades were extracted to them using the five-point correction key prepared for this purpose, In order to extract the total score of the measure, the grades obtained by each student in the answer on the measure paragraphs reached (30) paragraph as well as the highest score is (150) for being the highest score of the paragraph is (5 degrees and the lowest score is (30 degrees for being the lowest score for paragraph (1) degree, and the total grades of students ranged from (70-150) degree with an arithmetic mean of (33105)degree and standard deviation (6112) and the hypothetical mean of the measure in its initial formula reached (90), and (15) form was excluded for not fulfilling the general conditions,because some testers did not answer all the paragraphs, and some of them were answered some paragraphs, through this procedure the number of forms returned became (385) form, and also excluded some forms for not achieving the objective of the required answering.

Validity of the measure: Honesty is defined as "the degree which measured the test or measure something to be measured" [1], the concept of honesty is very important in the tests field and measurement as it is an indicator of whether the test measures the feature or phenomenon to be measured or not. The test is honest if it succeeds in measuring the achievement of the goals which set, In order to verify the validity of the measure; the researchers depend on the following:

First-the validity of the arbitrators (virtual honesty) of the measure: The researchers presented

the measure and its paragraphs on anexperts group in sports psychology, general psychology, education and measurement to determine its validity to measure the researched problem, and to evaluate the appropriateness of each paragraph, and thus accepted the paragraphs that got the experts approval and deleted the not agreed paragraphs, and thus check of the content validity. And "this honesty is calculated after presenting on a number of specialists and experts in the field which the test is conducted, if the experts recognize that this test measures the behavior which set to measure it, so the researcher can rely on the judgment of experts.

Second, the validity of the building of the measure: Usually the measure is applied on building sample as an experimental sample, in order to try to avoid the difficulties and obstacles encountered the application way during the main test of the research, and "Building validity is one of the most appropriate types to building the measures, because it is based on experimental verification of the matchingdegree of paragraphs with the property or concept to be measured [1].

The researchers have verified the building validity in the measure through the following:

1. **Method of the two terminal groups of the measure:** To reveal the discriminatory power of paragraphs of open mindedness, this method is used to identify the ability of paragraphs to distinguish between individuals with higher levels and individuals with lower levels of attribute measured by the paragraph and this is evidence of the building validity (2),as this method is one of the appropriate method to distinguish paragraphs, the researchers arranged the total degrees which obtained by students after the measure correction descending and then select the percentage (27%) for the top group from the total number of forms (380) and (27%) for the lower group to represent the two terminal groups. Accordingly, each group included (103) students.
2. **Internal uniform nesscoefficient of the measure:** "One of the most common measures of consistency, the idea of this method depends on how the paragraphs are related to each other within the measure and also how each paragraph is related to the measure as a whole. This method shows us how are homogeneous the paragraphs, There may be convergent paragraphs but it measure a different dimensions

In order to achieve this purpose it uses the coefficient of internal consistency, and many studies have used this method because it is characterized by the following:

1. Provides us a homogeneous measure in its paragraphs.
2. The discriminatory power of a paragraph is similar to the discriminatory measure power.
3. Ability to highlight the link of the measure paragraphs.

To find coefficient with the degrees of sample members on each paragraph and their degrees on measure (the degree of the paragraph and the total degree of the measure separately), the researchers used the correlation coefficient (Pearson),and therefore the correlation of the paragraph with the total degree of the measure means that the paragraph measures the same concept that it measures total degree (1).

The value of this indicator was extracted by using the Person correlation coefficient with the degree of each paragraph and the total degrees of the measure for all sample members of (380) students by Statistical Portfolio of Social Science s(SPSS).

- Correlation coefficient (Pearson) with measure paragraphs and the total degree of open mindedness measure

Conclusion

It is concluded that in the study the stability of the test means the test accuracy in the measurement and the consistency of its results when applied several times on the same individuals (2).

In order to verify the stability of the open mindednessmeasure, the researchers adopted the measure stability on their way:

1. Half reliability

2.- Alfa Kronbach coefficient.

First: Half reliability way of the measure:

Second: Alpha-Kronbach coefficient of the measure:

1. The relative importancelaw
2. Ca 2 Law
3. T test of independent samples
4. The simple coefficient of Pearson

5. The Fakronbach equation
6. Factor analysis
7. Arithmetic mean
8. Standard deviation

Value of Use Chest Ultrasound in Diagnosis of Pulmonary Embolism

Yosra Mohamed Ali[1], Ali Omar Abd El Aziz[2], Nadia Farouk El Ameen[3], Emad Allam Abd Naeem[4], Hala Abd El Hameed[5]

[1]Assistant Lecturer, [2]Associate Professor, Pulmonology Department, [3]Professor, Radiology Department, [4]Professor, Clinical Pathology Department, [5]Professor, Pulmonolgy Department, Faculty of Medicine Minia University-Egypt

Abstract

Background: Pulmonary embolism (PE) is a serious cardiovascular disease. Its symptoms are vague and resemble many other diseases. So diagnosis carries a great challenge.

Aim: Aim of this study is to assess value of chest ultrasound in diagnosis of pulmonary embolism using computed tomography pulmonary angiography (CTPA) as a gold standard.

Material and Method: In this study seventy three patients of suspected pulmonary embolism were evaluated in the period between June 2018 to October 2019 at the emergence department of chest, cardiology and internal medicine departments at Minia University Hospital. The patients were included according to inclusion criteria listed later. The patients were evaluated clinically and assess risk factors and probability scores (modified wells criteria). Then,Thoracic Ultrasonography (TUS) was done. Multi-slice computed tomography (MSCT) was the reference gold standard method in this study. MSCT scans were interpreted by a radiologist who was unaware of the TUS results. Predictive value of chest ultrasound in diagnosis of pulmonary embolism was evaluated by measuring sensitivity, specificity, positive predictive value (PPV), and negative predictive values (NPVs) of thoracic ultrasonography.

Results: In this study, sensitivity, specificity, PPV, NPV, and accuracy of chest ultrasound (CUS) for PE diagnosis were 81.25%, 95%, 98.3%, 77.3% and 87% respectively.

Conclusion: TUS is abedside, safe, easily available, noninvasive method for early diagnosis of PE in emergency department and in situations where CTPE couldn't be used.

Keywords: *Chest ultrasound, pulmonary embolism, CTPA.*

Introduction

Pulmonary embolism considered to be the third most frequent acute cardiovascular event after acute myocardial infarction and stroke. PE may cause about 300 000 deaths per year in the US.(1)

Pulmonary embolism (PE) has many risk factors predispose for its development. Major trauma, surgery, lower-limb fractures and joint replacements, and spinal cord injury are strong provoking factors for pulmonary embolism(2)

The most common sources of PE (up to 85% of cases) include DVT followed by thrombosis of iliac and renal veins, and the inferior vena cava. The upper limbs are not usually identified as a source of major PE. (3)

Cancer is a well-recognized predisposing factor for PE. The risk of PE varies with different types of cancer; pancreatic cancer, hematological malignancies, lung

cancer, gastric cancer, and brain cancer carry the highest risk. Moreover, cancer is a strong risk factor for all-cause mortality following an episode of VTE.[4]

Also, Pregnancy, perperium, estrogen containing oral contraceptives and cesarean section all are predisposing factors for development of PE.[5]

The use of transthoracic ultrasound (TUS) as a diagnostic tool was previously considered unjustifiable on the grounds of conventional knowledge that the lungs are filled with air and that the TUS beam cannot normally pass through air-filled structures [6].

TUS has become now an important diagnostic tool in modern chest medicine as it is a noninvasive, readily available, bedside imaging modality that can be used in association with physical examination and clinical evaluation [7].

So, this study tried to clarify role of chest ultrasound in diagnosis of pulmonary embolism and assess its accuracy, sensitivity, specificity and also its positive & negative predictive values.

Material and Method

This prospective, randomized clinical study was carried out after obtaining the local ethics committee of El-Minia university hospital approval and written informed consent was taken from the patients.

It had been done from June 2018 to October 2019 at the emergence department of chest, cardiology and internal medicine departments at Minia University Hospital.In this study73 patients aged between 21-90 years old were clinically suspected pulmonary embolism and enrolled in research according to inclusion and exclusion criteria.

Inclusion criteria:

a. The main inclusion criteria will be clinical suspicion of PE under consideration of the presence of:

   1. Any age group and both sex

   2. Risk factors of pulmonary embolism as malignancy, lower extremity fracture, COPD,obesity, postpartum period, and history of venous thromboembolism, operation, and PE.

   3. The presence of unexplained dyspnea, tachypnea, pleuritic pain.

Exclusion criteria:

(i) Other acute ischemic diseases newly diagnosed during the ED visit in question, as acute coronary syndrome, acute ischemic cerebrovascular disease, acute peripheral arterial occlusion, or acute mesenteric ischemia.

(ii) An abnormal serum albumin level making the determination of IMA levels impossible (normal level 3,5–5,5 mg/dl);

(iii) Advanced liver, kidney or heart failure;

(iv) Troponin-I and ECG testing was performed for evidence of asymptomatic coronary ischemia;

(v) Allergy to contrast material and

(vi) Refusal to participate in the study.

Included patients will be subjected to:

1. Complete history tacking
2. Clinical examination
3. Pretest clinical probability and simplified Wells score.
4. CXR.
5. Compression ultrasound (CUS) of both lower limb if needed.
6. Trans-thoracic ultrasonography (TUS)

There are number of criteria which can be applied in the diagnosis of PE. The most characteristic finding in PE is hypoechoic, pleural-based paranchymal alteration. Greater than 85% of these lesions are wedge-shaped. They may also have rounded or polygonal configuration. A single hyperechoic structure localized at the center of the lesion which indicates the presence of air-filled bronchiole may be detected in 20% of the patients. Pleural involvement in PE initially leads to localized fluid collection adjacent to the affected pulmonary region and may eventually develop into a basal pleura effusion. Exploration of lesions by color Doppler imaging may provide additional diagnostic information. In pulmonary infarction, pulmonary arterial flow cannot be detected by color Doppler ultrasound, referred to as “consolidation with little perfusion”. A congested thromboembolic vessel may be visible called “vascular sign”.These described TUS findings support the diagnosis of PE, but in the absence of them PE cannot be ruled out[8].

7. Electrocardiography (ECG)

8. Echocardiography
9. Laboratoryand Serological tests including:
    - CBP,ABGs
    - D-dimer
    - Ischemia Modified Albumin (IMA)
10. **Multislice Computed Tomography Pulmonary Angiography (CTPA)** was used as the reference method in diagnosis of PE.

Results

Table (1): Findings of Computed Tomography with PulmonaryAngiography in patients positive for pulmonary embolism

		N	(%)
CTPA thrombus location	Bilateral	27	(50.9%)
	Rt.	18	(34%)
	Lt.	8	(15.1%)
CTPA site of affected artery	Main pul. Art.	8	(17%)
	Lobar branch	6	(12.8%)
	Segmental	12	(25.5%)
	Subsegmental	20	(42.6%)
	All	1	(2.1%)

Table 1 showed location of thrombus in CTPA in PE positive patients. There were 27(50.9%) patients had bilateral PE and 26 patients with unilateral PE (18 patients “34%” at Right side and 8 patients “15.1%” at Left side. Also, the level of the occluded artery was mainly at subsegmental branches (42.6%) followed by segmental branches (25.5%) then lobar branches (12.8%),main pulmonary artery in (17%) and only one patients had occlusion at all levels (2.1%).

Table (2): Comparison of the lesions detected by chest ultrasonography in both PE positive and PE negative groups

TUS		All cases	-Ve	+Ve	P value
		N=73	N=20	N=53	
Number of lesions	Range	(0-2)	(0-1)	(0-2)	
	Mean ± SD	0.8±0.7	0.1±0.2	1.1±0.5	
	Median	1	0	1	
Shape	Normal	8(11%)	4(20%)	4(7.5%)	<0.001*
	Wedge shape	18(24.7%)	0(0%)	18(34%)	
	wedge with pleural effusion	19(26%)	0(0%)	19(35.8%)	
	Rounded or oval shaped lesion	6(8.2%)	0(0%)	6(11.3%)	
	Polygonal shaped lesion	6(8.2%)	1(5%)	5(9.4%)	
	Compressive atelectasis	0(0%)	0(0%)	0(0%)	
	Consolidation	15(20.5%)	14(70%)	1(1.9%)	
	Multiple B lines “suggestive pulmonary edema”	1(1.4%)	1(5%)	0(0%)	
Site	No	8(11%)	4(20%)	4(7.5%)	0.489
	Bilateral	11(15.1%)	3(15%)	8(15.1%)	
	Rt.	32(43.8%)	7(35%)	25(47.2%)	
	Lt.	22(30.1%)	6(30%)	16(30.2%)	

TUS		All cases	-Ve	+Ve	P value
		N=73	N=20	N=53	
Location	No	8(11%)	4(20%)	4(7.5%)	0.229
	Upper lobe	4(5.5%)	2(10%)	2(3.8%)	
	Middle lobe	8(11%)	1(5%)	7(13.2%)	
	Lower lobe	53(72.6%)	13(65%)	40(75.5%)	
Effusion loculation	No	43(58.9%)	12(60%)	31(58.5%)	0.907
	Free	30(41.1%)	8(40%)	22(41.5%)	
	Loculated	0(0%)	0(0%)	0(0%)	
Thinned or fragmented visceral pleural line		35(47.9%)	0(0%)	35(66%)	<0.001*

Table 2 describe characters of the lesions detected by chest ultrasound in both groups as regard number of lesions in PE positive group ranged from (0-2) lesion/ patient with Mean ± SD 1.1±0.5.

Wedge shape lesion was significantly common in PE +VE group either alone(34%) or with effusion(35.8%) followed by rounded shape (11.3%) and polygonal shape (9.4%).also table demonstrate distribution of lesions, affected lobes, condition of visceral pleural line that showed significant thinning and fragmentations among PE +VE patients.

Table (3): Demonstrate pattern of vascular flow signals and qualitative and quantitavecolour Doppler ultrasound in all patients

		All cases	-Ve	+Ve	P value
		N=73	N=20	N=53	
Qualitative CDU					
Normal perfusion	N (%)	23(31.5%)	18(90%)	5(9.4%)	<0.001*
Decrease perfusion		4(5.5%)	0(0%)	4(7.5%)	
No vascularity		46(63%)	2(10%)	44(83%)	
Pattern of flow					
No perfusion	N (%)	46(63%)	2(10%)	44(83%)	<0.001*
Monophasic		4(5.5%)	0(0%)	4(7.5%)	
Triphasic		23(31.5%)	18(90%)	5(9.4%)	
Quantitative CDU					
RI	Range	(0-2.7)	(0-2.7)	(0-1)	<0.001*
	Mean ± SD	0.4±0.5	0.9±0.6	0.2±0.3	
	Median	0	0.9	0	
PI	Range	(0-19.5)	(0-13.2)	(0-19.5)	<0.001*
	Mean ± SD	2.5±4.2	5.5±4.2	1.4±3.7	
	Median	0	4.5	0	
PSV	Range	(0-81.5)	(0-81.5)	(0-49.5)	<0.001*
	Mean ± SD	10.5±18	27.9±20.6	3.9±11.5	
	Median	0	22.7	0	
EDV	Range	(0-19)	(0-19)	(0-11)	<0.001*
	Mean ± SD	1.6±3.9	4.5±5.8	0.5±2	
	Median	0	1.1	0	

Table 3 show the use of color Doppler ultrasound (CDU) in qualitative & quantitative assessment of vascular flow in lesions detected by gray scale ultrasound. It showed significantlyabsent perfusion in lesions in PE +Ve cases 44(83%) associated with no flow signals. quantitative measurements of Resistive Index (RI), Pulsatile Index (PI), Peak Systolic Velocity (PSV) and End Diastolic Velocity (EDV) showed significant changes in different lesions between two patient groups.

Table (4): Show sensitivity, specificity, positive predictive value, negative predictive value and accuracy of chest ultrasound in diagnosis of pulmonary embolism:

	TUS
AUC	0.831
95% CI	0.743-0.899
P value	<0.001*
Sensitivity	81.25
Specificity	95
PPV	98.3
NPV	77.2
Accuracy	87

Table 4 show sensitivity, specificity, positive predictive value, negative predictive value and accuracy 81.25%,95%,98.3%,77.2% and 87% respectively.

Discussion

Pulmonary embolism (PE) is a major health problem. It may be life-threatening if not early diagnosed and treated[9].

Clinical picture of pulmonary embolism is vague and nonspecific, so there is a great need for protocol for early diagnosis & management of pulmonary embolism.

CTPA has brought a great improvement in the diagnostic approach to patients with suspected PE, allowing an adequate visualization of the pulmonary arteries and their level of obstruction up to at least the segmental level, and this make it the gold standard in diagnosis of pulmonary embolism [10].

In the current study we assessed role of noninvasive bedside chest ultrasonography in diagnosis of pulmonary embolism.

In the current study the age of patients insignificantly different between PE +Ve & PE +Ve groups. The mean age in PE positive group **(47.1±16.1)** was younger than negative group **(52.5±16)**. These results are in agreement with[11] and also in agreement with[12].

In contrast to **Stein et al.,**[13], who found that pulmonary embolism is associated with advancing age due to the cumulative effect of risk factors that patients acquire with aging such as immobility, hypertention, obesity, trauma, and surgery.

In this study, we noticed that female patient were more among PE positive group proved by CTPA (60.4%).But it was statistically insignificant finding.

This in disagreement with **Nataliia et al.,**[14] who noted that PE is more common among men than women and explained by the more exposure of men to smoking and trauma .

In this study, dyspnea was the most common symptom (95.9%) that was mainly grade IV (54.2%) followed by chest pain (63%) and lastly Hemoptysis (53.4%).

In this study the location of the lesions were detected mainly in the lowerlobe (40 lesions, 75.5%) followed by the middle lobe (7 lesions, 13.2%) and the upper lobe(2 lesions, 3.8%).

This is in agreement with **Comert SS et al.,**[15]

These results can be explained by that the lower lobes are easily viewed by chest ultrasound,while the upper lobes can only be inspected with difficulty because of masking by bones of chest wall.

In this study the majority of lesions were wedge-shaped. This finding was similar to that reported in **Pfeil A et al.,** [16].The anatomy of the lung could explain the finding. Wedge-shaped opacities are representative of pulmonary ischemia which characterized, as areas of lung filled with red blood cells, with or without tissue necrosis. [17]

The blood flow and perfusion in pulmonary infarction can be easily demonstrated. Color Doppler ultrasound is the only imaging modality capable of assessing the vessels in peripheral pulmonarylesions.[18]

In the present study, the majority of PE positive patients (83%) show a predominantlyno vascular flow. On the other hand, we noticed that a monophasic flow was foundonly in (7.5%) of cases in positive pulmonary embolism.the vascular sign with characteristic

circulation stop was found in any lesion which couldbe attributed to absence of blood flow in infarct area.

Also, in this study, quantitative CDS values revealed statistically significant differences in RI, PI, PSV and EDV values between PE positive and negative groups as the majority were absent flow.

This in contrast to**Yuan et al**. [19]and **Mathis et al.**[20] stated that, in very few cases, the investigator was able to visualize, on ColorDopplerultrasound, a circulation stop caused by embolism.

The current study reported the sensitivity, specificity, positive predictive value, negative predictive value and accuracy of chest ultrasound in the diagnosis of PE 81.25%,95%,98.3%,77.2% and 87% respectively.

This is in agreement with **Ghanem, M. K et al.,** [21], who reported the sensitivity, specificity, positive predictive value, negative predictivevalue and accuracy of TUS in clinically suspicious PE cases were presented as 82%, 90%,94%, 72% and 85% respectively.

Conclusion

Chest ultrasound is noninvasive, safe, inexpensive, available, bedside diagnostic alternative to CTPA at emergency sitting and in critically ill patient or when CTPA is contraindicated.

Assessment of the Knowledge Regarding HIV/AIDS among Nursing College Students in University of Basrah

Zainab Alag Hassan[1], Sajjad Salim Issa[2], Abdulameer Abdullah Al-Mussawi[3], Saja Kareem Jasim[4]

[1]Lecturer, [2]Assistant Professor, [3]Professor, [4]Assistant lecturer, College of Nursing, University of Basrah, Basrah, Iraq

Abstract

Background: AIDS is a common infectious disease worldwide, so every health staff have to have a knowledge about it, specially nursing staff .

Aim: To evaluate the knowledge of nursing college students about HIV/AIDS.

Method: The study was carried out on 150 nursing students at University of Basrah College of nursing during the 2018-2019**.** Structured questionnaire was used for data collection,which was consisted of twenty multiple choice questions to assess knowledge of students about HIV. Data was analyzed by using SPSS statistics version 23.

Results: The current results reveal that(76%) of nursing students have poor knowledge toward HIV/ AIDS,and there was a nostatistically significant difference between the stages.

Conclusion: The study concluded that nursing students need to increase their knowledge regarding HIV/ AIDS by for example developing the curriculum of nursing college.

Keywords: *Assessment, nursing, knowledge, HIV/AIDS.*

Introduction

World Health Organization (WHO) estimated that 75 million people have been infected with HIV while about 32 million people have died of it. Globally, 37.9 million people were living with HIV at the end of 2018[1].

In Iraq about 0.1% of the total population are living with HIV comparing to other parts of the world, it is considered low-prevalence HIV epidemic[2,3].

Nurses play an important role in prevention of HIV by providing care and treatment for people living with HIV/AIDS. Therefore, nurses should be competent in caring and solving health problems of them[4].

Nurses have to deal with collecting various body fluid samples of patient for investigation, giving medication as per instructions, taking care of patients, and giving injections[5].

Nurses and nursing students' attitude toward HIV/ AIDS patient is determined by their knowledge of the same. It is important to assess the knowledge of nurses regarding the HIV/AIDS to evaluate the prevailing conditions and gap so that policy measures can be taken to improve the knowledge,if there is a gap. Since health care professionals including nurses have the responsibility of educating people about the ways of HIV contamination, their knowledge regarding HIV/ AIDs patients play an important role in communicating with patients[6].

The purpose of this study is to assess the knowledge of nursing students regarding HIV/AIDS.

Amongst the health care professionals, nurses and nursing students are an important component of the

health care delivery system. Since they are the one who are responsible for the constant care of in-patients and thus, they come in close contact with blood and other body fluids of patients. Due to frequent and prolonged contact,they are being identified as a potential risk group for the HIV/AIDS spread. To reducethe transmission, adequate knowledge about the disease and practice of safetymeasures are of great importance. Generating awareness regarding HIV/AIDS in thisgroup is crucial for AIDS management and the prevention of HIV spread[7].

Methodology

Design of study: Descriptive cross-sectional study carried out to evaluate knowledge of students about HIV.

Setting of study: The study was conducted at university of Basrah college of nursing 2018-2019

Sample of study: Sample [150] from first, second, third and fourth stage of the college of nursing. Number of male [59] and female [91].

Study instruments: structured questionnaire was used for data collection, consisted of two part:

Partone: Included demographic data [age, sex, type of study(morning or evening), residency (rural or urban), marital status, stage, to identify effect of demographic variables on students' knowledge.

Part two: Questionnaire was consisted of twenty multiple choice questions to evaluate knowledge of students about HIV. Right answer given 5 score and false answer given zero score. Data was analyzed by using SPSS statistics version 23.

Results

Table 1: Demographic characteristics of the study sample

Variables		Frequency	%
Sex	Male	59	39.3%
	Female	91	60.7%
Stage	First Stage	40	26.7%
	Second Stage	33	22%
	Third Stage	38	25.3%
	Fourth Stage	39	26%
Marital status	Single	140	93.3%
	Married	10	6.7%
Study type	Morning Study	91	60.7%
	Evening Study	59	39.3%
Residency	Urban	70	46.7%
	Rural	80	53.3%

The table (1) showed that the number of females were more than males (60.7%, 39.3% respectively). Majority of the samples was single (93.3%).Students from morning study were relatively more than students from evening study (60.7%, 39.3% respectively), rural and urban areas had a slight difference in number of students (53.3%, 46.7%). Only (24%) of students had good knowledge regarding AIDS (table 2).

Table (2): Students' knowledge regarding AIDS

Variable	F	%	Mean of score	Std. Deviation	p-value	Result
Good knowledge	36	24%	37.64	10.035	0.000	significant
Poor knowledge	114	76%	60.92	8.611		
Total sample = 150		**Mean of score = 55.33**		**Std. Deviation = 13.395**		

Table (3): Relation between variables and students' knowledge regarding AIDS

Variables		Mean of score	Std. Deviation	p-value	Result
Sex	Male	55.93	13.566	0.661	Insignificant
	Female	54.95	13.344		
Stage	First Stage	53.88	13.936	0.149	Insignificant
	Second Stage	54.55	13.132		
	Third Stage	59.61	13.968		
	Fourth Stage	53.33	11.994		

Variables		Mean of score	Std. Deviation	p-value	Result
Marital status	Single	55.39	13.345	0.839	Insignificant
	Married	54.50	14.804		
Study type	Morning Study	54.12	13.976	0.169	Insignificant
	Evening Study	57.20	12.327		
occupation	Urban	59.21	10.654	0.001	Significant
	Rural	51.94	14.637		

When comparing the variables under study with knowledge, the result showed that there was no statistical significant difference between sex, stage, marital status and type of study but there was a significant difference between students residency and knowledge (table 3). This difference may reflect the development in urban areas in terms of social and cultural communication, the Internet, the large number of schools, health centers, hospitals, and the multiplicity of occupations and businesses, as opposed to those in rural areas.

Table (4): Source of information regarding AIDS

Source of information	Frequency	Percent
Books and social media	83	55.3%
Schools & colleges	71	47.3%
Friends & family	42	28%
Heath care provider	20	13.3%

Books and social media were the major source of information for students about AIDS(55.3%)which can be used as a way to educate students about various diseases, where health care provider (13.3%) could not be consider as a good source of information for students (table 4).

Table (5): Students' answers regarding HIV

True and False Questions	Right Answer	Wrong answer
AIDS is considered viral diseases	143	7
AIDS Attacks Immune system	142	8
AIDS is transmitted by Sex with the infected person	132	18
HIV infection leads to joint pain	17	133
HIV infection leads to Swelling of the lymph nodes	18	132
HIV infection leads to Diarrhea	29	121

Table (5) showed that Most students knew that HIV/AIDS was viral, attacked the immune system and sexually transmitted.On another hand most of them did not know the signs and symptoms of the patient, especially: pain joints, swollen lymph nodes, and diarrhea .

Discussion

This study was done to assess the knowledge regardingHIV/AIDS among students of nursing college at Basrah University. In this study, it was found that main source of informationamong nursing students was Books and social media,followed bySchools and colleges. They got very lessinformation from Heath care provider. This result reflects the weak role of health care centers in educating the community about the seriousness of the disease and its transmission.

Large proportion of studentshad misconception regarding symptoms and complications of the disease. In Iraq there is a kind of silence on the cases of AIDS for religious and social reasons, because of the disease is association withforbiddensexual relations which makes people believe that there are no cases.

Iraq is considered a country with a low level epidemic of HIV/AIDS. The prevalence of HIV in Iraq is currently less than 0.1% of population, but associated risk factors may increase because of liberalized trade relations and increased drug use.As of December 2014, less than 100 people living with HIV were reported. They were nationals and foreigners. 57% were infected by blood transfusion and blood products (WHO). Iraq faces greater HIV risks as a result of poverty,low literacy and inadequate knowledge of modes of transmission[2].

Nursing students should have adequate information about the disease because in future they will play important role in educating peoples and saving the life of patientsand save themselves from infection.

Low knowledge regarding HIV/AIDS among nursing college students need national awareness programs.

Ethical Clearance: Approval to conduct the study was obtained from the dean of college of Nursing, University of Basrah.

Levels and Differences of Leadership Practices by Eminent Coaches Amongst the Team Athlete's at Universiti Pendidikan Sultan Idris (UPSI)

Zulakbal Abd Karim[1], Ramesh Ram Ramalu[1], Mohamad Zahurin Mohd Rusof[1]

[1]Faculty of Sports Science and Coaching, Universiti Pendidikan Sultan Idris, Tanjong Malim, Perak, Malaysia

Abstract

This research is conducted to identify the level and differences of leadership practices between the popular coachesamong team athletes at Universiti Pendidikan Sultan Idris (UPSI). A total of 50 respondents comprising 30 male athletes and 20 female athletes were selected from the team athletes at Universiti Pendidikan Sultan Idris (UPSI). The research instrument used is Leadership Scale for Sports (LSS) Questionnaire which was developed by Chelladurai and Saleh (1978; 1980) and has been translated into Malay language. This questionnaire has 5 dimensions of coaching style, ie a) Training and Instruction Dimension, b) Democratic Dimension, c) Autocratic Dimension, d) Social Support Dimension, e) Positive Feedback Dimension. An independent t-test inferential statistical analysis is used to analyze data. The findings show that there is no significant difference between male team athlete and female team athletes in all the favourite dimensions of coaching style amongst the athlete's team. The findings also showed that the dimension of leadership style using Training and Instruction is the most favourable among the athlete team at Universiti Pendidikan Sultan Idris (UPSI).

Keywords: *Leadership style, Trainer's Behavior, Performance, Leadership.*

Introduction

Leadership is a complex and dynamic behavioral process among group members, interpersonal communication and moving towards a defined goal[1,2]. Leadership of coaches are important as it affects the attainment of athletes and the team's performance[3]. The effectiveness of a coach is influenced by several factors which are adeqauely important to ensure the athlete is in excellent guidance. Among the most important factors are coach leadership style, coach behavior, athlete character and situation[4].

According to Chelladurai[5], the coach's leadership style covers the dimensions of training and instruction, democratic, positive feedback or rewards, social and autocratic support. The style of coaching is important to form outstanding athletes or team athletes to optimum performance level.

Coaching is classified as a leader who has been given authority and responsibility for forming followers in a team under his guidance in acquiring skills and confidence also competitiveness when competing[9].

Literature Review: The coach should respect the uniqueness of each different athlete to ensure proper coaching style to improve the athlete's performance. According to Chelladurai and Saleh[11], the style of coaching is divided into three components namely the behavior of real leaders, the behavior of leaders chosen by the athlete and the expexted behavioural from the leader. All components of this coaching style depend on the suitability of athletes to determine the satisfaction and improvement of the athlete's performance. In line with Ramalu[7] research finding that coaches that design motivation program into their coaching lesson will enhance their performance in the actual game meet. The

e-mail: zulakbal@fsskj.upsi.edu.my

most important factor for a coach is to help improve the performance of athletes in terms of sports development and the more specialized basic and psychological skills. Chelladurai et al.[13]states that the coach coaching style of leadership is effective in certain contexts due to changes in athletic characteristics and situations. The context of the sports situation and the behavior of the athlete itself determine the appropriate leadership style to achieve improved performance and control athlete discipline[15].

Problem Statement: The purpose of this study was to provide information to the coaches at UPSI in relation to the leadership of the team athlete. Coaches can also identify the level and style of leadership that is the choice of team athletes. In addition, the difference between gender and leadership style of team athletes at UPSI will be answered through this study.

As the study relates to the style of coach leadership that is still limited and under-reported at UPSI level, the previous study focuses only on school athletes. A study at UPSI should be carried out to identify the coaching leadership that the athlete is interested in.

Research Objectives: Based on the current study, among the objectives of the study to find out different levels of coach leadership practices at UPSI are:

a) Examining gender differences in leadership style dimensions of team athlete's at UPSI.
b) Identifying the level of the leadership style dimension which is the choice of team athletes at UPSI based on the level of leadership style difference.
c) Identify the effectiveness of leadership-style practices on athlete's current performance.

Research Methodology: This chapter contains the procedures and method used to obtain and analyze data and information on the level and differences in the practice of coach leadership amongst athletes in the UPSI. The results of the questionnaire were obtained and identified after the questionnaires were distributed to team athletes at UPSI.

Data Collection/Analysis: The data of this study was analyzed using the Statistical Packages for the Social Sciences (SPSS) version 23.0. The data analysis used in this study was an independent t-test analysis to find the mean, standard deviation and significance to analyze the dimensions and differences of leadership styles diminished by team athletes at UPSI. While the t-test is independent, it is used to examine the differences in the aspects of gender in the dimensions of leadership style of coach that interested by team athletes at UPSI.

Procedure: The design of this study is quantitative and uses the survey method. This survey method is suitable because the questionnaire can be given to the respondents ie team athlete at UPSI.

Study Participants: Participants for this study consist of 50 athletes that selected through a purposive sampling technique at UPSI, 30 are male team athletes and 20 are female team athletes. The selection of participants was chosen based on the participation of participants representing UPSI in team sports such as martial arts, football, netball, volleyball, tennis, badminton, table tennis, hockey, softball and sepak takraw. Selected candidates are from 19 to 25 years old and involved in university team sports.

Research Findings:

Table 1: Raw Data of The Leadership Style which is favoured by Team Athletes at Sultan Idris Education University (UPSI) By Gender

Variable Leadership Dimension						
Gender		**Training and Instruction**	**Democratic**	**Authocratic**	**Social Support**	**Positive Feedback**
Male	Min	2.58	2.376	2.052	2.388	2.364
	SP	0.368	0.419	0.570	0.507	0.444
	N	30	30	30	30	30
Female	Min	1.72	1.584	1.368	1.592	1.576
	SP	0.246	0.280	0.380	0.338	0.296
	N	20	20	20	20	20
Total	Min	4.3	3.96	3.42	3.98	3.94
	SP	0.614	0.699	0.950	0.845	0.740
	N	50	50	50	50	50

The findings in demographic aspects are as in Table 1, overall, team athletes at UPSI are more interested in training and instruction dimensions (min = 4.3, SD = 0.614) and the leadership style most disliked by male and female athletes and not suitable for the team athlete leadership dimension is an autocratic dimension (min = 3.42, SD = 0.950).

The objectives of the study in table 1 are to identify the levels and dimensions of leadership style which are the preferences of team athletes at UPSI based on gender differences.

Table 2: Descriptive Analysis Based on Gender Differences and Based on Preferred Leadership Positions In The Dimensional Coaches Leadership Style

Leadership Style Dimension Gender						
	Male (N=30)			Female (N=20)		
	Min	SD	Position	Min	SD	Position
Training and Instruction	2.58	0.368	1	1.72	0.246	1
Social Support	2.388	0.507	2	1.592	0.338	2
Democratic2.376	0.419	3	1.584	0.280	3	
Positive Feedback	2.364	0.444	4	1.576	0.296	4
Autocratic	2.052	0.570	5	1.368	0.380	5

The findings of the descriptive statistics in Table 2 show the t-test on the gender differences in UPSI. The findings show that there is no significant difference between male athlete and female athletes of team athletes in all the preferred dimensions of coaching style amongst the athletes at UPSI. From the finding, that leadership style dimensions of instruction and training is in the first place of the male and female athletes and the least liked by team athletes for both gender is an autocratic dimension.

The objective of this study is to examine the differences in gender aspects in leadership style dimension of team athlete at UPSI.

Table 3: Raw Data of Preferred Leadership Style by Team Athelete of Universiti Pendidikan Sultan Idris (UPSI) By Age

Age (Year)		Training and Instruction	Democratic	Authocratic	Social Support	Positive Feedback
19	Min	0.258	0.238	0.205	0.239	0.236
	SD	0.037	0.042	0.057	0.051	0.44
	N	3	3	3	3	3
20	Min	0.43	0.396	0.342	0.398	0.394
	SD	0.061	0.07	0.095	0.085	0.074
	N	5	5	5	5	5
21	Min	0.258	0.238	0.205	0.239	0.236
	SD	0.037	0.042	0.057	0.051	0.044
	N	3	3	3	3	3
22	Min	0.774	0.713	0.616	0.716	0.709
	SD	0.111	0.126	0.171	0.152	0.133
23	Min	1.29	1.188	1.026	1.194	1.182
	SD	0.184	0.21	0.285	0.254	0.222
	N	15	15	15	15	15
24	Min	0.946	0.871	0.752	0.876	0.867

Age (Year)		Training and Instruction	Democratic	Authocratic	Social Support	Positive Feedback
	SD	0.135	0.154	0.209	0.186	0.163
	N	11	11	11	11	11
25	Min	0.344	0.317	0.274	0.318	0.315
	SD	0.049	0.056	0.076	0.068	0.059
	N	4	4	4	4	4
Total	Min	4.3	3.961	3.42	3.98	3.939
	SD	1.277	0.7	0.95	0.847	0.739
	N	50	50	50	50	50

The findings based on descriptive analysis as in Table 3 show leadership styles of team athletes in UPSI according to age and this study is divided into 7 age distribution starting from the age of 19 to 25 who are the team sports athlete. Based on the descriptive analysis the min and standard deviation from all the age distribution shows that autocratic dimension is the least favoured dimension that preferred by athletes at UPSI).

Discussion

Based on the findings of the analysis table 1, the level and the difference in practice of coach leadership amongst the team athletes at UPSI as a whole shows that the percentage and the difference in leadership practices reveal no significant difference in terms of the level and differences in popular leadership practices. Overall, team athletes at UPSI would go for the leadership-style dimension of training and instruction and would not favour the authocratic dimension.

The athlete age factor is very much influential on the results of the analysis that has been conducted as older athletes love the training and instruction dimensions because these dimensions are intended to improve behavior or to develop the right skills by emphasizing on some of the essential and earnest training elements[16]. In addition, training and instruction dimension focuses on game techniques and tactics as well as coordinate activities for athletes resulting in instructional and training dimensions that are well-liked amongst the team athletes at UPSI. Furthermore, the autocratic dimension of leadership style is very unpopular with team athletes at the UPSI because of coaching style that does not help to improve performance or conduct of free coaching skills and behaviors and to emphasize personal power without taking care of the athlete's welfare and not giving athlete the opportunity to make a decision and do something to improve their performance or skills[10].

If referring to table 2 the findings show that there is no difference in terms of leadership dimensions of male and female athletes. Men and women's team athletes have similarities in choosing the most disadvantaged dimensions, which is the autocratic dimensions and this dimension should not be applied in the leadership style of team athlete at UPSI. The objective of this study is to examine the differences in gender aspects in leadership style dimension of team athlete at UPSI. Gender factors is seen to have strongly influence the style of coaching but being men and women have no significant difference in aspects of the dimension of the coaching style by interest[10,16].

In addition, based on the independent t-test analysis, there was no significant difference between male team athletes and female team athletes in all the favoured dimensions of coaching style the team athletes at UPSI.

The results of the study have shown similarities with the study conducted by Chelladurai et al.[11] and Serpa and Antunes[17] who chose the leadership style of training and instruction as the researchers assumed that most of the chosen athlete which have represented state or country that causes athletes to prefer training and instruction dimensions. This is because it facilitates trainer's to train athletes and manage teams under their control besides being able to train effectively to improve performance and correct mistakes made by athletes immediately[11,17].

Choosing the right leadership style is crucial in ensuring the effectiveness in controlling and managing the team effectively to give positive impact to athletes and teams. Appropriate leadership style is also important to influence athlete's behavior to ensure athlete's ability to exercise and not to be exercised[8]. It is clear here that the leadership style or coach should choose a leadership style that is compatible with the team or its athlete's guidance to ensure that planned goals are achieved and able to improve athlete's performance.

Conclusion

Based on the studies conducted and certain constraints we can conclude that there is no significant difference between the level and differences in the practice of coaching leadership amongst athletes in the UPSI. This can be demonstrated by the results of the study conducted on the participants who have chosen the training and instruction dimensions as the ultimate choice for the dimensions of the most popular leadership style. The dimension of leadership style of training and instruction is the most appropriate dimension and is most favored by male and female team athletes. This style of leadership is more pragmatic as it helps coaches in facilitating the team or athlete while being able to correct the mistakes of the athletes and at the same time emphasizing the strategy of a game[7].

Furthermore, there is no coaching style approach that can be determined by the appropriate suitability and effectiveness as each sport has a different coaching style approach. It is clear that the successful coach who practices a well-defined leadership style with the will of the player or team under his guidance[10,15]. All these aspects can be fulfilled if the coach recognizes the athlete under his control and understands the importance and suitability of the team and athlete. Hence, the success of an athlete and team can be determined if the coach uses an appropriate and effective approach to achieving a defined goal[6,14,15].

An effective coach is a coach who understands the wishes of his followers in planning and making good decisions. A good coach will pay attention to what this is and focus on what to share with athletes and teams. The coach who cares and focuses on what he or she wants to achieve will give the athlete a sense of appreciation and this will further bond with the team and the coach[5,11,12].

Study of Implementation of the Early Breastfeeding Initiation Program at the Lepo-lepo Public Health Center in Kendari City

Ruslan Majid

Faculty of Public Health Haluoleo University, Kendari, Southeast Sulawesi, Indonesia

Abstract

Early Initiation of Breastfeeding (EIB) apparently decreased infant mortality rate for 8.8% and increased exclusively breastfeeding success for 2 years. Less attention to EIB implementation and less counseling by health professional drove a low implementation of EIB. Objective of this study was to describe EIB implementation at Public Health Center of Lepo-Lepo Kendari in 2014. Type of the study was qualitative through phenomenological approach. Informants of the study were 5 within 1 key informant and the other 4 were common informants. The result of the study showed that midwives' knowledge regarding to EIB was good. Nevertheless, patient's knowledge about EIB was less. Patient didn't get information about EIB, either from birth assistance or socialization media. Attitude and support given by health professional was also less. EIB program was not realized and there was no socialization regarding to EIB given by midwives to the patient. Health resources were consisted of 14 midwives and none of those who ever received EIB training. There were no need special tools and infrastructures in implementing EIB. SOP of EIB announced on poster about it on the wall.

Keywords: *Implementation, Early Initiation of Breastfeeding.*

Introduction

The authorized capital for the formation of quality human resources starts from the baby in the womb and from an early age. One of the things that can be done in optimizing quality human resources is through breastfeeding, especially exclusive breastfeeding, namely breastfeeding for babies from birth to 6 months without other complementary foods[1].

World Health Organization in 2007 issued a new protocol about "***Asi Asap"*** which must be known to every health worker. The protocol is to make mother's skin contact with the baby's skin immediately after birth for at least one hour and help the mother recognize when the baby is ready to breastfeed. The statement was confirmed by the government with the issuance of Government Regulation of the Republic of Indonesia Number 33 of 2012 in Chapter III article 7 which states that every mother giving birth must give exclusive breastfeeding to the baby she was born in, and article 9 which contains the implementation of Early Breastfeeding Initiation (EIB) by health workers[2].

Early initiation of breastfeedingor the beginning of early breastfeeding is the baby starts breastfeeding himself immediately after birth. Early breastfeeding initiation is by placing a newborn baby on the mother's stomach or mother's chest, in almost an hour the baby will crawl looking for her mother's nipples and start breastfeeding herself. The way the baby initiates breastfeeding early is called the breast crawl or crawl looking for breasts [3].EBI will increase the success of exclusive breastfeeding for 6 months because early contact with the mother and baby will increase the duration of breastfeeding twice compared to slow contact. In Indonesia, early breastfeeding is 8 times more likely to give exclusive breastfeeding[4].Based on the results of the Basic Health Research in 2010, the percentage of breastfeeding started in children from 0 to 23 months in Indonesia in less than one hour (<1 hour) after the baby was born was 29.3%, for Southeast Sulawesi was 27.6% [5].

The success of the Early Breastfeeding Initiation program is also strongly influenced by the attitudes,

knowledge and motivation of the midwife/physician assisting childbirth itself. This is also supported by the statement of Siregar A, that the success of early breastfeeding is largely influenced by the attitudes and behavior of health workers (doctors, midwives, nurses) who first helped the mother during the birth process. In addition, the success of nursing mothers must also be supported by their husbands, families, health workers and the community[6]. The Lepo-lepo Health Center is one of the Health Centers in Kendari City that implements the EIB program. The number of mothers giving birth at the Lepo-lepo health center from 2011 to 2013 continues to increase. In 2011, the number of mothers giving birth was 127 people, in 2012 there were 148 people, and in 2013 there were 218 people. Of these 80% were assisted by midwives and the remaining 20% were assisted by doctors[7].

The implementation of EIB activities at the Lepo-lepo Health Center has not been fully implemented. This is due to medical indications in infants that make it impossible to do EIB, lack of awareness of the importance of EIB, and the lack of counseling by health workers. Based on the description of the problem, the researcher is interested in conducting research on ***"Study of Implementation of the Early Breastfeeding Initiation Program at the Lepo-lepo Health Center in Kendari City ".***

Method

This research is a qualitative research with a phenomenological approach, namely qualitative research conducted because researchers want to explore phenomena that cannot be quantified that are descriptive such as the process of a work step, notions of a diverse concept, characteristics of goods and services,etc.8. Then the data is used triangulate, through interviews, observation, and documentation.

Results

Knowledge Knowledge found Early Breastfeeding Initiation or EIB is the giving of newborn breast milk directly breastfed without waiting for an interval of, approximately 30 minutes. The where appropriate EIB management is done by means of the baby in his stomach or mother's stomach, with the baby's skin attached to the skin of the mother and left to look for her mother's nipples.

The benefits of early breastfeeding initiation for babies are to get exclusive breastfeeding as early as possible and increase the baby's immunity. While the benefits of EIB for mothers are to stimulate the mother's contractions and other benefits. In the provision of early breastfeeding initiation, there are several factors that hinder the implementation of EIB, among others, lack of maternal knowledge, factors of health workers, the condition of infants with problems such as Low Birth Weight or premature, and the condition of mothers who are still sick, the mother's nipples do not come out, and the absence breast milk from mother.

Attitude: The mother's attitude in the implementation of early breastfeeding initiation found that the implementation of the EIB program was very good to be carried out. Besides being very beneficial for babies, EIB is also beneficial for the mother. However, the results of observations made by researchers, there is no EIB implementation as proud of the health workers in the study location Puskesmas. Midwives immediately clean, measure, and weigh the baby, without doing an EIB first. The tthough it is expected to get as early as possible in order to get closer to the mother and baby, increase immunity to the wedge after getting the colossus from her mother's milk.

Furthermore, it was also found that health workers strongly supported the existence of the EIB program. They always recommend and teach patients to immediately do EIB. The however, different statements made by patients. They never get an explanation about the EIB from the delivery assistant midwife. Even though it is highly expected that the support of health workers on the importance of mothers breastfeeding early.

Health Resources: Health resources in understanding the initiation of early breastfeeding which is a motivator found the availability of 14 health workers (midwives) in the delivery room, which is always recommended to do EIB in patients being treated. Midwives who assist with childbirth are always encouraged to do EIB on their patients. Found with work shift scheduling used is a division of three shifts. Work shift scheduling with this model is very suitable to be used in the Lepo-lepo Health Center in carrying out its duties as a service provider, including EIB. Shift division of the job is suitable, division of three shifts.

Furthermore, it was found that there were no midwives or doctors who had participated in EIB training, other than just other training, because to do

EIB no special facilities and infrastructure were needed, as long as the mother and baby were in good condition, EIB could be carried out with special facilities that were important and her mother understands and feels that it is enough, and the media for socializing CDs, and flip charts is still a problem because there are no trained personnel.

Standard Operating Procedure (SOP): The availability of SOPs regarding EIB at the Lepo-lepoPuskesmas is included in the midwifery care SOP. In addition, SOP on EIB is only limited to posters about EIB that are posted on the wall. Whereas the stages of implementing EIB contained in the SOP in a nutshell are appropriate, for newborns to be thrown on their mother's chest to make skin contact and look for their own nipples.

Discussion

Knowledge: Knowledge related to EIB is what is known, understood and able to be remembered by health workers or mothers giving birth about EIB in the Lepo-lepo health center. Health workers involved in care during pregnancy until the baby is born are the primary in this study are midwives. But the lack of explanation about breastfeeding makes mothers less knowledge about EIB. Midwives and delivery mothers have not been able to explain EIB properly.

The results of this study are in line with the results of research conducted by Rati[9]. The Which shows that post-partum mothers have not been able to explain about EIB like their understanding of exclusive breastfeeding so that the EIB does not seem as popular as Exclusive breastfeeding. Even though post-partum mothers do not know anything about EIB, EIB will still be implemented because this is a program from the Puskesmas.

Inappropriate early initiation will reduce the success rate of early initiation of suckling. Inadequate early initiation is like pushing a baby's mouth into his mother's nipples for breastfeeding. Then this can result in a lack of success rate for early breastfeeding initiation. For this reason, health workers

EIB is very beneficial for babies, which is able to calm the baby, prevent hypothermia, and prevent the death of newborns through breastfeeding as early as possible at one hour of birth. In normal newborns that are separated directly from the mother to be bathed, weighed, measured, and cleaned resulting in 50% of babies unable to suckle on their own. EIB is also very beneficial for the mother, namely the presence of baby suction will stimulate the release of the hormone oxytocin which will stimulate uterine contractions so that bleeding does not occur, and will make the mother calm, relaxed and happy[10].

There are a number of things that can interfere with or hinder a baby's natural ability to find and discover his own breast or EIB Among these chemicals are given when the mother gives birth and may get to the fetus through the placenta, making it difficult for the baby to suckle the mother's breast. Births with actions and drugs such as surgery, vacuum, forceps, even feeling tired and aching in the area of skin cut during an episiotomy can also interfere with the implementation of EIB[11].

The results of Wahyuningsih's research[12] show that the implementation of IMD requires a long time, if bleeding is not carried out, the discharge of the placenta is difficult, less patient to do because it wants to be finished quickly, people who are not ready to do it because they feel dirty (disgust) get hit blood, born in a Private Hospital and lack of understanding of the implementation of the EIB program.

Attitude: Attitude is a reaction or response of someone who is still closed to a stimulus or object. Attitude is how people's opinions or assessments are related to health risk factors[13].The results of the study were also conducted, that EIB is very important because mothers feel its benefits directly. But there are also those who say that EIB is not so important in accordance with the experience that has been passed. This attitude is apparent from the results of the interview. So there should be an agreement from the mother to make a decision.

This is in line with the results of a study in Switzerland in 2005, which stated that babies born in hospitals with the support of high health workers were more likely to have EIB than those born in hospitals with the support of low health workers[14].

Health Resources: Midwives are health workers who have the most roles in implementing EIB, because midwives are tasked with helping and motivating mothers to do EIB. Midwives become one of the factors that influence the success of the EIB program, both in terms of quantity and quality. Whether or not early breastfeeding is successful at a maternity service in a hospital is highly dependent on health workers, namely

nurses, midwives or doctors, because they are the first to help the mother with her EIB. No matter how limited the time possessed by a midwife, is expected to still be able to take the time to motivate and help mothers after giving birth to implement EIB and exclusive breastfeeding.

The readiness of health workers including midwives in the EIB program is the key to success. The role of midwives in the success of exclusive EIB and ASI cannot be separated from the authority of midwives in providing services to mothers and children in improving the maintenance and use of breast milk. In addition, midwives also inform the importance of breastfeeding to every pregnant woman and help mothers start breastfeeding in the first hour after the baby is born.

Health workers, in this case midwives, can be a motivating factor, but they can also be a barrier to the success of the EIB program. Therefore, midwives need to get training on EIB. Training is a short-term process that uses systematic and organized procedures, in which non-managerial employees learn technical knowledge and skills for specific purposes. The training is intended as a planned effort to improve and enhance the knowledge and attitudes of midwives towards the EIB program[15].

Facilities and infrastructure in this study is the availability of everything needed to support the implementation of EIB program activities. The lack of socialization given about the EIB program was due to the lack of knowledge of the midwife itself because she had never attended EIB training. Therefore, efforts can be made to socialize the EIB program not only to mothers or patients, but also to midwives assisting childbirth.

Standard Operating Procedure: SOP or work procedure is a written statement that is compiled systematically and can be used as a guide by the implementers in decision making. SOP is a guide for employees to carry out a job with established standards [16].SOP as a document contains the processes and procedures of an activity that is effective and efficient based on a standard that has been standardized. EIB SOP becomes a need to be carried out and run systematically in accordance with applicable regulations.

Conclusion

Knowledge about EIB midwives is good enough, but implementation is not optimal, while patients are still lacking and they have never gotten information about EIB, either through midwifery delivery assistance or from socialization media. The EIB program is still lacking with program implementation and there is no attitude and support from midwives. Human resources, especially midwives, are adequate and have attended EIB training. Evidenced by work shift scheduling that is applied to the four shift group four model, and no special facilities and infrastructure are needed in implementing the EIB. The EIB Standard Operating Procedure includes a poster about the EIB attached to the wall and the stages of EIB implementation that are reflected in the SOP are briefly correct, newborn babies bend over their mother's breast to make skin contact and look for their own nipples.

Suggestions: It is expected to provide confirmation of the EIB implementation program and encourage midwives to socialize EIB to patients, support providing training to all midwives on EIB, and issue and determine EIB SOPs at the Lepo-lepoPuskesmas.

Ethical Clearance: The ethical clearance was taken from Faculty Committee and community agreement.

Psychosocial Factors to Increase Adherence Antiretroviral Treatment on New PLWH Infection

Widia Shofa Ilmiah[1,2], Stefanus Supriyanto[3], Purwati[4], Mochammad Bagus Qomaruddin[5]

[1]Student of Doctoral Program of Public Health, Faculty of Public Health, Universitas Airlangga, Mulyorejo Street, Surabaya, [2]Lecturere of Midwifery Program, Health Sience of Hafshawaty Islamic Boarding School Zainul Hasan, Probolinggo, [3,5]Lecturer of Faculty of Public Health, [4]Lecturer of Faculty of Medicine, Universitas Airlangga, Moestopo Street, Surabaya, Indonesia

Abstract

HIV become iceberg phenomenon. All HIV infected people have risk illness and die. Data of WHO 2018 were 37.9 million PLWH and 23.3 million on antiretroviral treatment. Every month about 8-15 new peoplegotnew HIV infection in Probolinggo district, Indonesia. HIV cummulative in Probolinggo at January 2018 were 1.140 people and only 60% ARV active and 15% lost to follow up. Many factors that influence adherence and many impact of it.. The aim to analysis psychosocial factors to increase adherence antiretroviral treatment on New PLWH infection.This method use observational study. The population were 61 PLWH on ARV treatment in Clini VCT Waluyojati General Hospital at January-May 2018, and sample were 54 people, sistematic random sampling, instrument quessionairres, observational sheet, medical record, independent variable were level of knowledge, age, sex, ethnics, level of education, employment, dependent variable was adherence to take ARV, analysis logistic regression with SPSS 16.0. α (0,05). The result that level of education (p=0.999; prevalence ratio (PR)=0.000), duration of ARV treatment (p=0.210; PR=2.988), level of knowledge (p=0.001; PR=4.450. It means only level of knowledge can increase 4.450 times of adherence to take ARV. The conclution wasrespondent that have good level of knowledge about antiretroviral schedule, risk, side effect, benefit, and outcomesinfluence adherence to take ARV than they have low level of knowledge. Health worker in Clinic VCT should conduct to increase counselling quality by giving about risk of ARV treatment, side effect, and all about ARV treatment and need social support to make them adhere to take ARV as doctors instruction.

Keywords: *Psychosocial, Adherence, Antiretroviral, PLWH.*

Introduction

HIV become iceberg phenomenon and pandemic in the world.[1]All HIV infected people have risk illness and die. Antiretroviral (ARV) is an HIV-proven drug that can inhibit HIV replication so decrease the level of viral load in the blood infecting immune cells or CD4 increases, so immunity begins to recover or increase.[1]

Data of World Health Organization (WHO) 2018 were 37.9 million People Living with HIV (PLWH) and 23.3 million on antiretroviral treatment (ART).[2]Since HIV AIDS was first discovered in Bali-Indonesia from 1987 to December 2016, about 80% of HIV AIDS has spread in 80.2% of regencies and cities.[3] Based on this data that only 70.5% was getting ARV treatment in Indonesia.[4] Every month about 8-15 new peoplegot new HIV infection in Probolinggo district, Indonesia. HIV cummulative in Probolinggo at January 2018 were 1.140 people and only 60% ARV active and 15% lost to follow up.From 60% that ARV active, they were on adherence I (<3 dose forget to take it on 30 days, CD4 increase), adherence II (3-12 dose forget to take it on 30 days, CD4 increase), adherence III (>12 dose forget to take it on 30 days, CD4 decrease).[5]

Many factorsthat caused non adherence to take ARV were lack of knowledge about ARV, perceived susceptibility, perceived severity about ARV.[5] According to other researchersthatbelief, self efficacy, self concept, barriers about side effect, disclosure of their status, stigma and motivation.[6,7,8] Whereas, according to Holstadthat adherence can influence by

self management, self efficacy, external motivation.[9]The impact of not adhere to take ARV as doctor instruction were resistance, failure treatment, and might make them drug poisoning.[10]

The aim of this study isto analysis psychosocial factors to increase adherence antiretroviral treatment on New PLWH infection.

Materials and Method

Our study was used observational design and conducted as long as 2.5 months start on 6 November 2018– 8 January 2019. The population this study were 61 all PLWH on ARV in VCT Clinic Waluyojati General Hospital and sample were 54 respondent. The inclution criteria, PLWH have age more than 15 years old, have low and midle economic status, stay on Probolinggo district, on treatment ARV between 2 weeks until 3 months, and willing to be respondent. The exclution criteria, PLWH with TB positive and on treatment TB < 2 weeks;They ARV treatment were stopped by their doctors because of the drug's side effects of systemic symptoms or organ dysfunction as well as hypersensitivity such as severe rash, impaired hepatic function. Data collection technique i.e respondentswho agreed to participate in our study signed a written informed consent after explaine the procedure and aim of this study.The instrument in this study were use quessionnaires to identify the characteristics of patient, observation sheets and medical records. Independent variable were age, sex, ethnics, level of education, employment, duration of ARV treatment (weeks), level of knowledge; dependent variable were adherence with indicators (schedule to follow up, dose and CD4 status). Data analysis was use logistic regression with SPSS 16.0 vertion.

Findings: Findings on this study conducted in the VCT Clinic of Waluyojati General HospitalProbolinggo District as long as for 2.5 months, and the result study can seeing on table 1-3. Base on the result study of the 54 samples that 79.6% respondents were age between 20-49 years old and mean 36 years old, 59.3% were female, 61.1% have ethnics madurese, 40.7% were level of education at junior high school and almost half of respondent were employment as house wife (33.3%), then most of respondent about duration of ARV medication between 2-8 weeks (64.9%), mean 6.61 weeks. Additionally, level of knowledge of respondent shows that 33.3% were good, mean 6.04. Base on CD4 status from 54 respondent that 9 respondent not check CD4 because they don't have Health Insurance and 45 respondent after checked CD4 status were 60% increase and 40% were decrease after drinking ARV (Table 1).

The increase in the number of CD4 patients can be caused by the initial CD4 count is not too low, so the respondent's body ability to improve the immune system is easier than those who have early CD4 therapy. In addition, low CD4 patients will easy to suffer of opportunistic infections that can greatly reduce the patient's condition. To start ARV treatment in patients who have health insurance based on CD4 values and in patients who have not checked CD4 because they do not have health insurance, initiation to start treatment ARV based on patient clinical stage and rapid test results obtained HIV positive results (Table2).

The result of logistic regressionshows that the education level has p 0.999 > α 0.05 and the value of Prevalence Ratio (PR) = 0.000, while the duration of treatment ARV obtained p 0.210 > α 0.05 and the value Prevalence Ratio (PR) = 2.988 as well as knowledge level obtained p 0.001 < α 0.05 and the value of Prevalence Ratio (PR) = 4.450 so that it can be concluded that the level of education and duration of treatment of ARV does not affect the adherence of ARV medication while the level of knowledge of ARV affects compliance. The better the level of knowledge about ARV will increase compliance by 4.450 times (Table 3).

Duration of ARV treatment	0,210	2,988
Level of knowledge	0,001	4,450

Discussion

The results of this study indicate the level of education and the duration of treatment of ARV has no effect on the adherence of ARV treatment, whereas the level of knowledge about ARV affects adherence to ARV treatment. The highest level of education in this study is junior high school, duration of ARV treatment averages 6 weeks, the respondent's level of knowledge was good about ARV and adherence about ARV in this study was measured through obedient dosages, schedule visits and the patient's CD4 status although there are some patients who do not check CD4 when they start ARV treatment due to health insurance theirs status. CD4 status was use to check that any correlation about adherence by dosage and schedule visit status and CD4 count in their body.

Adherence is the extent which the patient can follow the instructions of health workers.[3] Factors that affect the adherence of ARV treatment i.e. communication between patients with doctors, patient knowledge about an ARV treatment, health facilities and other factors including individual factors, beliefs, support social support and healthcare personnel support.[7]Individual factors include the modification factor of age, gender, ethnicity, level of education, personality, socio-economic, knowledge, belief and triger (cues to action).[11]The modification factor includes duraton of ARV treatment, religion, sex orientation, marital status.[12]and the supporting factors of compliance with ARV medications are internal factors including motivation, perception, level of knowledge, and external factors include service factors, social support factors of the family, support group or peer group, non-governmental organizations (NGOs), health worker and availability factors and the affordability of the drug.[13]

The level of respondents education and duration of ARV treatment does not necessarily affect of adherence. Whereas level of knowledge may affect of adherence to take ARV. Education in this study is a formal education pursued by individuals through a systematic process and gaining recognition from the government.[14]Although knowledge can be correlated with education, but not all knowledge is gained through formal education. The duration of ARV treatment is the length or number of days the individual follows the ARV treatment to the present.[12]Whereas level of knowledge is the result of know after a person does sensing against a particular thing or object. Knowledge can be a direct and indirect factor that can make their behavior.[15]

The result in this study, similar with other researcher, that levels of education have no effect on ARV treatment adherence. The results showed the level of education

of the majority respondent not at the college level and the greatest factor affecting the study was depression, conflict with spouse or patner as well as the maladaptive koping.[16] Additionally, education status does not affect the adherence of ARV treatment in both the intervention group and the control group. In their research socio economic or financial constraints were factors that affect adherence compared to the level of education. Financial constraints will cause respondents difficulty in accessing the transportation to go to the Clinic, so it impacts on the not adhere of respondents to take ARV.[17]

Duration of ARV treatment not affect of adherence. In this study, all respondent follow the ARV treatment between 2 weeks-3 months. At the beginning of ARV treatment between 2 weeks – 6 months, respondents tended to not be able to receive any side effects caused by ARV. Some types of ARV can cause side effects with different durations, such as the longer using the drug ARV of d4T (Stavudin), the more likely the effectiveness of the side effect.[18] Duration of ARV treatment with a range of 0-1 years, 2-6 years and 7-23 years proved to have no effect on adherence. It is a major influence on adherence of ARV treatment in their study i.e. anxiety and depression to initiate ARV treatment. Anxiety occurred due to lack of knowledge about ARV and depression occurred because of the still existence of stigma and discrimination against the PLWH.[12]

The level of knowledge in this study has an effect on adherence. The result of other study about "Difference between patients who do and do not adhere to antiretroviral therapy" shows that there were a difference level of knowledge in both groups between the care group and the ARV relapse group. The process of behavioral adaptation involves a person beginning with the conscious need of treatment because it has gained a particular knowledge of ARV treatment, a sense of interest in following treatment, the stage of evaluating interest on treatment and attempted and performed or behaved following the treatment of ARV. It means the better one's knowledge, the more positive it will be.[19]

Conclusions

In conclusions were level of education, duration of ARV treatment not influence toward adherence to take ARV, but level of knowledgeabout antiretroviral schedule, risk, side effect, benefit, and outcomes influence of adherence to take ARV than they have low level of knowledge. Health worker in Clinic VCT include doctors, midwife and case manager should conduct to increase counselling quality by giving about risk of ARV treatment, side effect, and all about ARV treatment and need social support to make them adhere to take ARV as doctors instruction.

Conflict of Interest: This study didn't have conflict of interest with General Hospital that become location of our study.

Reproductive Health Behavior of Street Youth Guided by Karya Putra Indonesia Mandiri Foundation in Central Jakarta Region

Prihayati[1], Hansrizka Raisna[2], Ridwan Amiruddin[3], Owildan Wisudawan B[4]

[1]Faculty of Health Sciences, University of Muhammadiyah Prof. Dr. HAMKA, Jakarta, [1]Doctoral Program Student, Faculty of Public Health Hasanuddin University, Makassar, [2]Magister Program of Public Health, University of Muhammadiyah Prof. Dr. HAMKA, Jakarta, [3]Department of Epidemiology, Faculty of Public Health Hasanuddin University, Makassar, [4]Faculty of Public Health Hasanuddin University, Makassar, Indonesia

Abstract

Background: Adolescents psychologically have a negative self-concept that is easily influenced and tends to behave freely. This study aims to determine whether there is a relationship between the role of parents and the role of friends with the reproductive health behavior of street adolescents. The problem with this research is the high rate of teenage pregnancy in Indonesia and adolescents account for 30% of unwanted pregnancies and unsafe abortions.

Material and Method: Cross sectional research design. The sample in this study was YPKIM fostered adolescents aged 15-19 years. Data processing and analysis using chi square test and multiple logistic regression.

Findings and Discussion: Poor reproductive health behaviors in YPKMI street adolescents by 33.3%. Based on the results of bivariate analysis found there is a relationship between the role of parents and the role of friends with reproductive health behavior. Multivariate analysis shows that knowledge is the most dominant risk factor associated with reproductive health behavior (OR = 6,610).

Conclusion: The results of this study prove the need to increase reproductive health knowledge in street adolescents to improve reproductive health behavior better by creating programs specifically for the coaching of adolescents, especially street adolescents.

Keywords: *Reproductive health, Sexual behavior, Street youth.*

Introduction

Adolescent relationships today tend to be free and experience a shift in values, where adolescence is a critical period where changes in emotions, thoughts, social environment and responsibilities are experienced[1]. Sexual Behavior is any behavior carried out because of sexual urges. In this concept no matter how and with whom or what that impulse is released. In adolescent sexual behavior, open communication with parents seems to be important.

Teenagers need sex education from older people to access contraception or refuse peer calls or partners to have sex before they are ready. In the US, public health activities to improve open communication between parents and adolescents to produce positive adolescent health. Not all sexual relations are voluntary, especially for girls, but also because of coercion among women aged 17 years, according to data from the National Survey of Children, there are 7% who are forced to have sexual relations[2].

Sexually transmitted infections (STIs) and unwanted pregnancies are very important public health problems, although in the long term they are needed to prevent them. Because there are a number of risk factors for STIs, prevention includes the delays in the emergence of sexual relations between teenagers who are actively engaging in sexual relations[3]. In 2012, an estimated 2.1 million adolescents were living with HIV. Despite effective interventions to prevent and treat HIV, adolescents face difficulties in accessing it. As a result the emergence of new infections among adolescents infected with HIV is common. Programs designed specifically for HIV-positive adolescents must focus more on interventions that have proven to be more effective in overcoming fundamental factors that drive incidents and the lack of effective care and care in this age group.

In adolescent sexual behavior, open communication with parents seems to be important[4], Because teenagers need sex education from older people to access contraception or refuse peer calls or partners to have sex before they are ready. In the US, public health activities to improve open communication between parents and adolescents to produce positive adolescent health. Not all sexual relations are voluntary, especially for girls, but also because of coercion among 17-year-old women in the National Survey of Children, 7% are forced to have sexual relations. Data from research from Katherine in 2003, parents who communicate with their daughters about sex will influence sexual behavior in a more positive direction. A family-based approach to improving communication can reduce the risk of risky sexual risk-related behaviors related to HIV[5].

The halfway house is a temporary informal camp, where street children meet to get information and initial guidance before being referred to further development processes. The purpose of establishing a halfway house is to re-socialize to reshape children's attitudes and behaviors that are in accordance with the values and norms prevailing in society and provide early education to meet the needs of children and prepare their future so that they become productive societies. Of the dozens of Shelter Houses that carry out street youth development in the DKI Jakarta area and in the Central Jakarta area there are five Shelter Houses Foundation, two of which are still active to date and one of them is shelter Yayasan Karya Putra Indonesia Mandiri (YKPMI). Based on observations made by researchers together with interviews with the Chairperson and Staff of the YKPMI Shelter Foundation, the 2014 data of the YKPMI Shelter Foundation has 215 street children assisted in 10 points in Central Jakarta and East Jakarta.

Material and Method

This type of research is a quantitative study using a cross-sectional approach, which is a study that studies the relationship between the role of parents and the role of friends on the reproductive health behaviors of YKPMI street adolescents by observation or data collection at the same time.

This research is a descriptive-analytic study using the quantitative cross-sectional method used to analyze the relationship between parental role variables and the role of friends on reproductive health behaviors in street children fostered by YKPIM in the Central Jakarta Region in 2015.

The sample in this study has the characteristics of inclusion, namely street children fostered by YKPMI in Central Jakarta and East Jakarta, aged 15-19 years and came to YKPMI at the time determined by the researcher. The exclusion characteristics in this study were adolescents aged <15 years and street adolescents who could not read and write.

Findings and Discussion

Univariate Analysis: Univariate analysis is used to look at quantitative data obtained from descriptive research, using tables, graphs and measures of central tendencies, such as the mean or average value of each variable.

The assessment results found that most of the street adolescents fostered by the Karya Putra Indonesia Mandiri foundation had good reproductive health behaviors as many as 40 people (66.7%) and only a small proportion were behaving less well, 20 people (33.3%).

Table 1: Frequency Distribution of Street Youth Assisted by Karya Putra Indonesia Mandiri Foundation according to Reproductive Health Behavior in Jakarta

Reproductive Health Behavior	Total (n)	Percentage (%)
Poorly	20	33,3
Well	40	66,7
Total	**60**	**100**

Based on the results of table 1 analysis, it is known that most of the street adolescents fostered by Karya Putra

Indonesia Mandiri Foundation have good reproductive health behaviors, as many as 40 people (66.7%) and only a small portion whose behavior is not good, namely 20 people (33.3%) . This study is consistent with Joseph's research findings that the lack of knowledge about reproductive health will affect health behaviors in adolescents[6].

Table 2: Frequency distribution of YKPIM-assisted street teenagers based on the role of parents and the role of friends in Jakarta

Variable	Total (n)	Percentage (%)
The role of parents		
Fewer roles	20	33,3
Most of the roles	40	66,7
The role of Friends		
Fewer roles	18	30,0
Most of the roles	42	70,0

Based on the results of table 2, it is known that the frequency distribution of the role of parents of YKPMI street teenagers is that most of the roles of parents are mostly 40 people (66.7%) and a small part has fewer roles, 20 people (33.3%). The distribution of the role of YKPMI street adolescent peers mostly played 42 people (70%) and a small part has fewer roles that 18 people (30%).

Bivariate Analysis: Bivariate analysis was performed to see the relationship between each independent variable with the dependent variable, namely reproductive health behavior using a statistical test, the Chi Square test. Bivariate analysis was used in this study as a method to see the relationship between the reproductive health predisposing variables of street children who are under the guidance of YKPIM Jakarta.

Table 3: Relationship between the role of parents and the role of friends with reproductive health behaviors

Variable	Reproductive Health Behavior				Total		OR (95% CI)	p-value
	poorly		Well					
	n	%	n	%	n	%		
The role of parents								
Fewer roles	12	60,0	8	40,0	20	100	6,000	0,005
Most of the roles	8	20,0	32	80,0	40	100	(1,837-19,594)	
The Role of Friends								
Fewer roles	12	66,7	6	33,3	18	100	8,500	0,001
Most of the roles	8	19,0	34	81,0	42	100	(2,444-29,562)	

Based on the results of the analysis in Table 3 shows that in YKPMI street adolescents, it is known that there are 60.0% of teenagers who lack the role of parents, the behavior is not good, while in the youth group who feel the role of parents there are only 20.0% of bad behavior. Statistical test results obtained p-value 0.005 meaning that there is a significant relationship between the role of parents with reproductive health behavior. The results of the analysis obtained OR 6,000 means that a group of adolescents who do not feel the role of parents has a 6 times greater chance to have bad behavior than adolescents who feel the role of parents.

The results of the analysis showed that in the street adolescents guided by YKPMI, it was found that in the group of teenagers who felt the lack of the role of friends there were 66.7% whose behavior was not good whereas in the group of adolescents who felt the role of friends there were only 19.0% whose behavior was not good. statistics obtained P value 0.001 means that there is a significant relationship between the role of friends with reproductive health behavior. The analysis results obtained OR 8,500 means that the group of adolescents who do not feel the role of friends has a 8.5 times greater chance to have bad behavior than adolescents who feel the role of friends.

The results of this study are consistent with the results of Jennifer's research that parent and teen communication about reproductive health has an important role in improving reproductive health in adolescents[7].

Multivariate Analysis: Multivariate analysis used is multiple logistic regression test, the steps being carried out are as follows: selection of predictive model candidates. Multivariate analysis in this study was conducted to see the most dominant independent variables related to the dependent variable simultaneously, because the independent variables are categorical and the dependent variables are dichotomous categories, so the analysis conducted is multiple logistic regression. Variables that have been analyzed bivariately and have a p value <0.25 are used as candidate variables to be included in the next analysis multivariately, to determine the best model. The results can be seen in table 4 below.

Table 4: Results of variable analysis as a candidate model

Variable	p-value	Explanation
The role of parents*	0,003	Following the Multivariate
The Role of Friends*	0,001	Following the Multivariate

The results of bivariate tests that have been done previously, it is known that of the eight variables, there are four variables that can be included in multivariate analysis, namely knowledge, attitudes, the role of parents and the role of friends (p-value <0.25). Other variables (age, gender, education and media access) have p-values >0.25 so they are not included in the multivariate analysis.

Conclusions

Communication that occurs between adolescents and parents is very lacking so that there is a failure of family function, this triggers adolescents to behave freely and even violate the norms, because they feel no one cares or prevents it. Lack of appropriate sources of information from the mass media, health workers, religious leaders, religious leaders and peers causes adolescents to obtain information and choose the wrong actions so that they regret after pregnancy after having premarital sex. Although premarital sexual behavior is at risk of being influenced by individuals and the environment, sometimes parents are met who do not regret the pregnancy that occurs in their children.

Conflict of Interest: There is no conflict of interest to be declared.

Source of Funding-self or Other Source: The source of funding for this research came from private funds.

Ethical Clearance: This research was approved by Karya Putra Indonesia Mandiri Foundation (518/B.04.02/2015) and Postgraduate University Prof. Dr. Hamka (No. 103/SK/Mp-Mhs/YKPIM/X/2015**).**

Acknowledgments: The author would like to thank all those who participated in this study, to the Chairperson and Staff of the Karya Putra Indonesia Mandiri Foundation and Postgraduate University Prof. Dr. Hamka.

Evaluation of the Antioxidant Levels and HbA1c of Type 2 Diabetes Patients

Qussay Noori Raddam[1], Ola Hassan Hadi[2]

Assistant Professor, Biology Department, Iraqi University, Iraq

Abstract

Type 2 Diabetes Mellitus is a chronic and inflammatory disease, characterized by chronic hyperglycemia associated with ROS generation, oxidative stress and lipid peroxidation.

A cross-sectional study was conducted with T2DM (n=60, male) aged over 40 years and nondiabetic control (n=30, male) with same age. All patients provided a written informed consent before the start of the study procedures. In the present study, we reported high differences ($p \leq 0.01$) in the antioxidants values (MDA, CAT, SOD, GPX and GSH) compared with control, value of HBA1c and duration of infection. High HbA1c is an indicator of high antioxidant enzymes activity. Serum MDA level was increased significantly in diabetes mellitus patients with a simultaneous decreased in SOD and CAT levels. Diabetes induces alteration in activity GPX and GSH. The hyperglycemia change the oxidative status which, in turn affects the endogenous antioxidant status in T2DM. They have high risk of experiencing micro and macrovascular complications. In addition to the combination of diet, exercise and medication can improve the level of HbA1c in T2DM. Further studies should be conducted to strengthen this evidence.

Keyword: *HbA1c, T2DM, MDA, SOD, GPX***.**

Introduction

Diabetes mellitus (DM) is regarded by hyperglycemia due to disruption in the metabolism of fats, carbohydrates, and proteins which resulting from faults in insulin action, insulin action, or both[1-3]. About 150 million diabetics, individuals were reported worldwide and the number is still increasing due to energy-rich diet consumption, sedentary lifestyle and obesity[3,4]. The diagnosed diabetes person may not showed any notable symptoms for years or decades. The symptoms may be subtle. Polyuria, polyphagia and polydipsia are three first and noticeable signs of diabetes. They are mild at first and gradually worsen over weeks or months[5]. Individuals may feel extremely fatigued, develop blurred vision, and may become dehydrated. However, early hypoglycemia was also reported in some cases[5,6]. Rarely, the blood glucose levels above 1,000 mg/dL was also observed due to some superimposed stress, such as an infection or drug use. Now days, individuals with type 2 diabetes are diagnosed by routine blood glucose test before they develop such severely high blood glucose levels[6].

The glycated haemoglobin can be diagnosed by the HbA1c (haemoglobin A1c or simply A1c) test. It develops when haemoglobin, the oxygen carrier protein within red blood cells, become glycated. An increase in the HbA1c levels is represented poorer glycemic control over a last period of weeks or months. The higher values of HbA1c, the risk of developing diabetes-related complications will be greater[7,8].

The free radicals such as O^-, SO_4^{2-}, PO_4^{2-}, Cl^- etc. are recognized as a reactive radicle species short-lived, very unstable, and extremely reactive[9]. They are formed excessively in diabetes due to glucose oxidation and nonenzymatic protein glycation. Abnormally elevated

free radical levels and the simultaneous decrease of antioxidant protective mechanisms can cause damage to cellular organelles and DNA, increased lipid peroxidation, and induction of insulin resistance[10]. Since, diabetes is considered as a consequence of increased in the radical formation, the autoimmune disorder is described during excessive and accumulation of free radicals, correlated with immune dysfunction and oxidative stress[11]. The leading antioxidant enzymes that are engaged in the neutralization of both reactive nitrogen species (RNS) and reactive oxygen species (ROS) are superoxide dismutase (SOD), catalase (CAT), glutathione peroxidase (GPx), and glutathione reductase (GRx)[12]. Studies have demonstrated that SOD can be used to prevent the destructive consequences of hyperglycemia-induced ROS production. In diabetes, a notable increase in CAT activity in lymphocytes was discovered in children with T2DM through all phases. Conversely, it has been reported that significant decreased CAT and significant increase in thiobarbituric acid reactive species concentration in T1DM patients with or without nephropathy compared with control[13]. Studies also indicated that the GPx activity was lower in children with diabetes compared with healthy children[14,15]. It has been implied that lowered antioxidative defenses from the excessive production of lipid hydroperoxide and NOx overproduction are present in juvenile patients with T1DM[16]. With this background, we aim to analyze the antioxidant levels and HbA1c in the T2DM patients of Iraq.

Material and Method

Study design: A cross-sectional study was conducted on T2DM individuals (n=60) aged over 40 years who attended the Diabetic Consult Center (DCC), in Al-Yarmook hospital Baghdad, Iraq. In addition, a control group (n=30) composed of nondiabetic individuals with the same age range as the diabetes patients who were not administered any medications. A detailed medical history was taken, and a physical examination was performed upon all participants. All patients provided a written informed consent before the start of the study procedures**.**

Blood samples: Blood samples (2ml) were collected into vacutainers after overnight fasting at the same standardized time to minimize any effect of diurnal variation for biochemical analysis. The serum, clear and nonhemolyzed supernatant, was separated by centrifugation and stored at −8°C for the analysis of lipid peroxidation (malondialdehyde) and antioxidant enzymes (GSH, GPx, SOD and CAT).

Oxidative stress parameters: Thiobarbituric acid-reacting substances content, a measure of lipid peroxidation was determined according to the method of Zhang et al[17]. The CAT activity was assayed based on the ability of hydrogen peroxide to form a stable stained complex with molybdenum salts[18]. GPx activity was determined according to the Hafeman et al[19] method. The estimation of SOD activity was performed using a SOD Assay kit-WST (Sigma Aldrich, USA) according to the manufacturer's protocol (Dojindo, Gaithersburg MD, USA). Xanthine oxidase system was used to generate a superoxide flux, and nitroblue tetrazolium was used as an indicator of superoxide production. Reduced GSH was determined using Ellman's reagent according to manufactures protocol[20].

Statistical analysis: Results were expressed as a mean±standard deviation. The statistical significance was assessed using the analysis of variance. $P<0.05$ was considered statistically significant.

Results

Antioxidants levels of control and T2DM patients: The levels of antioxidants in the serum are depicted in the Figure 1. The the present study, in diabetics group, serum MDA, CAT, SOD, GPx and GSH were increased ($P\leq0.01$) 0.149±0.186; 2.82±3.69; 2.82±3.69; 0.529±0.599 and 2.22±13.52 as compared to control group, 0.0274±0.0854; 0.429±0.607; 0.539±7.517; 0.0255±1.1293 and 1.92±11.11, respectively.

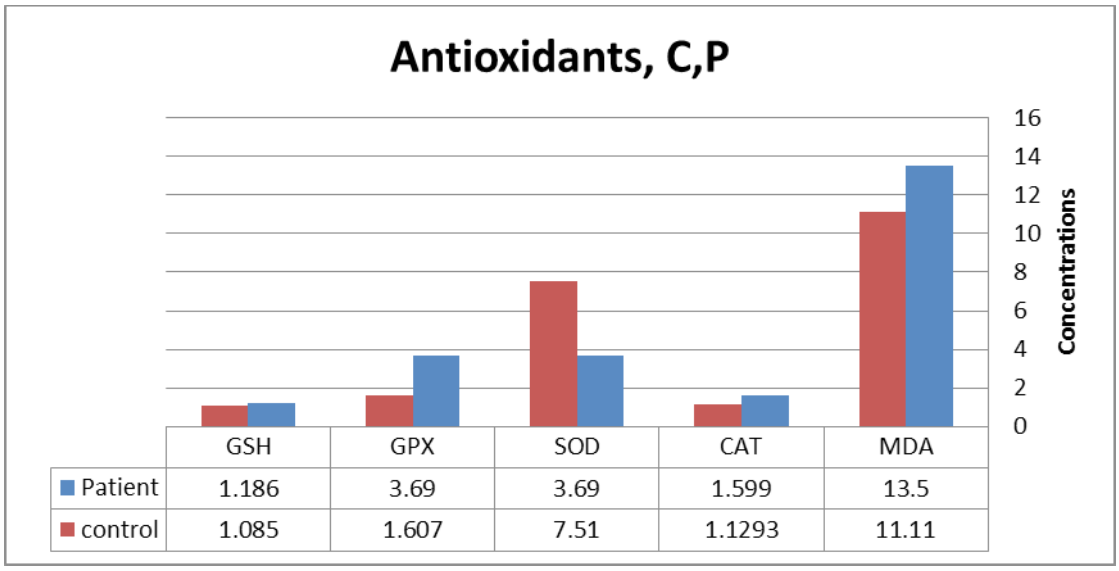

Fig. 1. Antioxidant levels of enrolled individual serum samples

Antioxidants levels of experimental group G1,G2: The results in the present study, as shown in Figure 2, showed high significantly differences (P≤0.01) between the experimental group with HbA1C less than 8(G1) and more than 8(G2) compared with the control group. The serum MDA concentration of G1 and G2 were 12.913±2.467 and 14.130±1.770 respectively as compared to the control group (11.105±1.922). Serum CAT levels for G1 and G2 were 1.122±0.02 and 0.076±0.051, respectively as compared to the control group (1.129±0.025). The serum SOD concentration for G1 and G2 were 6.325±1.361 and 1.064±0.042, respectively as comared to the control group (7.517±0.53).

The serum GPx for G1 and G2 were 0.341±0.17 and 3.932±1.3, respectively, as compared to the control group (0.607±0.42). The serum GSH in experimental group G1 and G2 were 0.0714±0.042 and 0.301±0.125, respectively, as compared to the control group (0.085±0.0274).

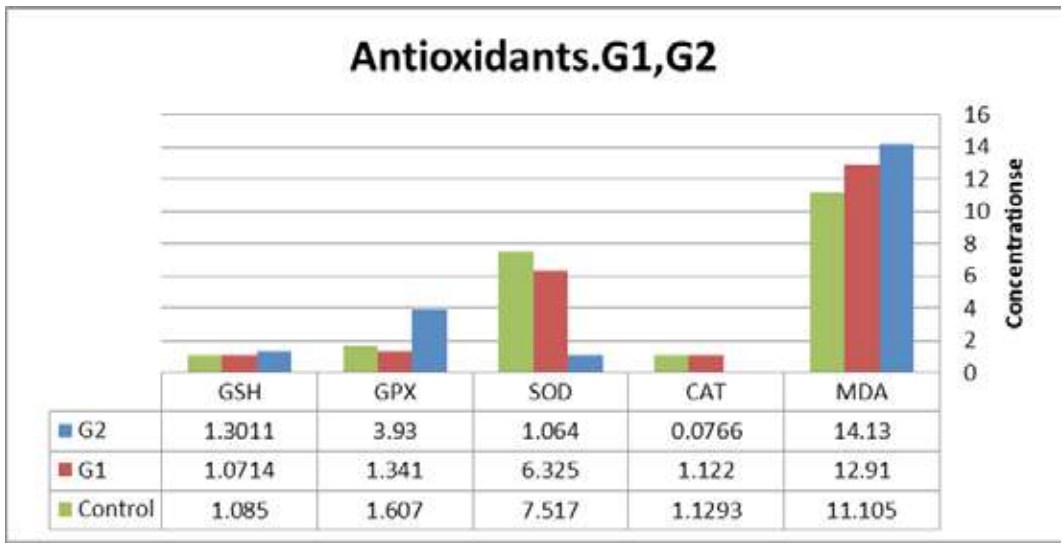

Fig. 2. Levels of antioxidants in experimental group G1 and G2

Antioxidants levels of experimental group G1P1,G2P1: The results in the present study, as shown in Figure 3 showed significant differences (P≤0.01) between the experimental group with HbA1C level less than 8(G1P1) and more than 8(G2P1) and the injury period P1 for groups G1 and G2(1-5) years compared to the control group of all antioxidants under study. The average concentration of MDA in the G1P1 and G2P1 groups was 10.32±1.36 and 12.68±1.734 respectively, compared to the control group which was MDA concentration 1.922±11.105.

The serum CAT levels for G1P1 and G2P1 groups were 1.123±0.023 and 0.144±0.017, respectively, as compared to the control group (1.1293±0.025). The SOD levels in G1P1 and G2P1 groups were 7.45±0.77 and 1.106±0.047, respectively, while the SOD concentration in control group was 7.517±0.53. The average GPX concentration in G1P1 and G2P1 groups were 0.36±0.10 and 5.08±1.4, respectively, while the average GPx concentration was in control group was 0.607±0.429. The GSH concentration in the G1P1 and G2P1 groups were 0.113±0.038 and 0.35±0.13, while the GSH concentration in the control group was 0.085±0.02.

	GSH	GPX	SOD	CAT	MDA
G2P1	1.3547	5.083	1.106	1.1442	12.68
G1P1	1.1139	1.364	7.45	1.123	10.32
Control	1.0854	1.607	7.517	1.1293	11.105
