Antioxidants levels of experimental group G1P2 and G2P2: The results in the present study, as shown in Figure 4, showed a high significantly differences (P≤0.01) between the experimental group with HbA1C less than 8 (G1P2) and more than 8 (G2P2) during last 6-10 years. The duration of P2 injury for groups G1 and G2 was between (6-10) years compared with the control group in terms of MDA, CAT, SOD, GPx and GSH.

The average concentration of MDA in the group G1P2 and G2P2 were 12.68±0.69 and 14.08±0.68, respectively, a compared to control group was 11.105±1.9. The mean CAT concentration in G1P2 and G2P2 were 1.12630±0.017 and 0.056±0.015, respectively. While, the CAT concentration in the control group 1.12±0.02. The SOD in the G1P2 and G2P2 are 6.89±0.6 and 1.051±0.01, respectively, as compared to the control group (7.51±0.53). The GPx in the G1P2 and G2P2 groups were 0.34±0.22 and 3.75±0.9, respectively, as compared to control group (0.60±0.4). The GSH levels in G1P2 and G2P2, 0.069±0.01 and 0.33±0.1, respectively, while, in control group was 0.08±0.02.

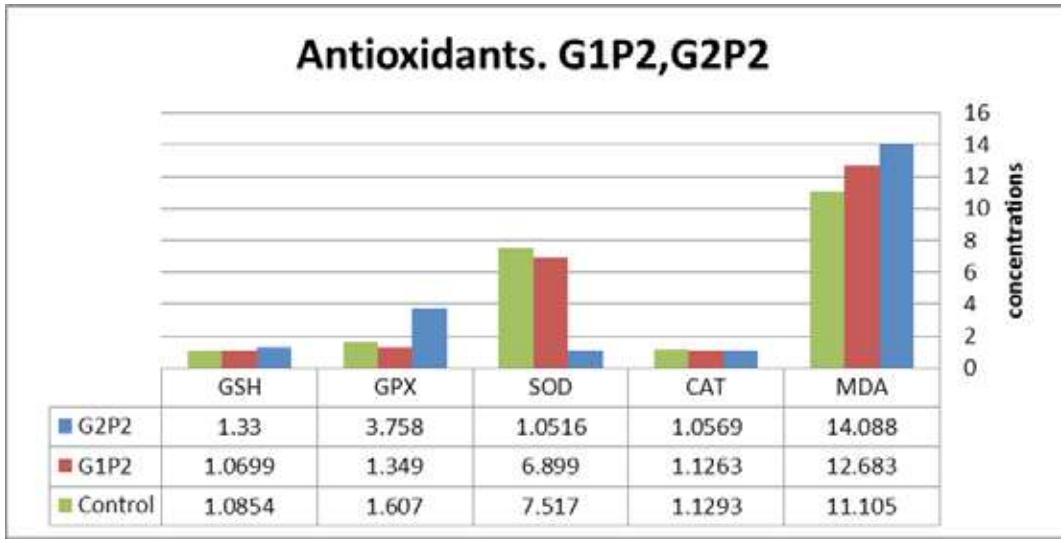

Fig. 4: Levels of antioxidants in experimental group G1P2 and G2P2.

Antioxidants levels of experimental group G1P3,G2P3: Figure 5 showed significant differences ($P \leq 0.01$) between the experimental group with HbA1C level less 8(G1P3) and more than 8(G2P3) and the injury period P3 for G1 and G2 groups 11 years and above compared with the control. The average MDA concentration in the group G1P3 and G2P3 15.736±0.9 and 15.61±1.3, respectively. While, the average of mean concentration of CAT in control group was 11.10±1.9. The CAT levels of G1P3 and G2P3 were 1.11±0.01 and 0.02±0.009, respectively. While, the average concentration of CAT in the control group 1.12±0.02. The SOD concentration in G1P3 and G2P3 respectively were 4.62±0.01 and 1.03±0.01, respectively. While, the mean SOD concentration in the control group was 7.51±0.53. The GPx concentration in G1P3 and G2P3 0.30±0.18 and 2.95±0.7, respectively. The GPx in the control group 0.607±0.4. The GSH in G1P3 and G2P3 groups 0.03±0.01 and 0.21± 0.08, respectively. While, the mean concentration of GSH in the control group was 0.08±0.02.

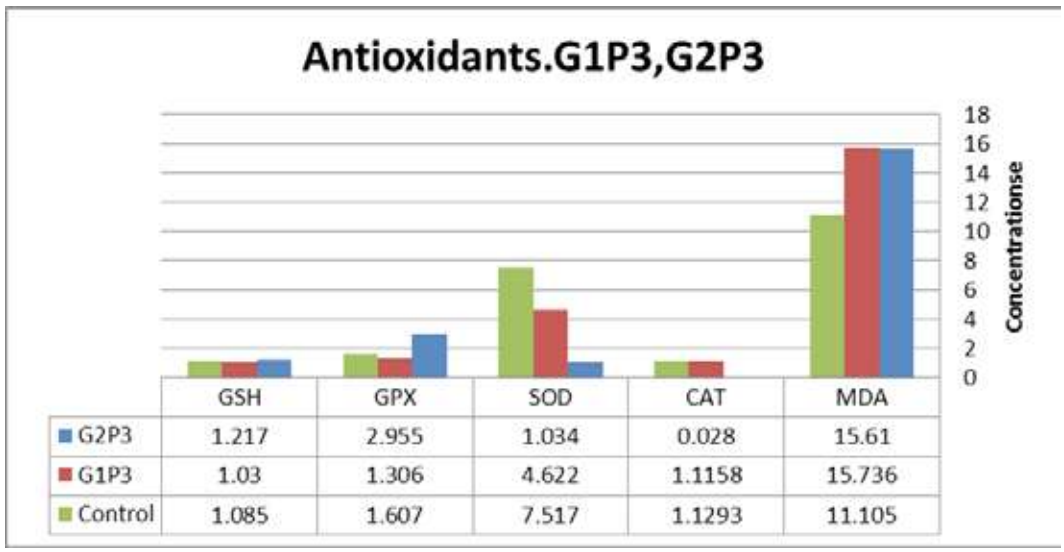

Fig. 5: Levels of antioxidants in experimental group G1P3, G2P3

Discussion

Diabetes Mellitus is a chronic and inflammatory disease, characterized by chronic hyperglycemia associated with ROS generation, oxidative stress and lipid peroxidation, and subsequent macro and microvascular complications[21]. The metabolic disorders such as hyperglycemia, altered lipid profile, carbohydrates and protein metabolisms and increased risk of cardiovascular disease complications are associated with diabetes mellitus. Our result in the present study showing high significant differences in the antioxidants values compared with control, value of HbA1c and duration of infection. We report the effects of the high value of HbA1c oxidative damage and its role in the significant changes in antioxidants enzymes activity in blood and liver or other organs such as muscle tissues and kidney[22,23].

The present study was aimed to investigate whether oxidative stress have any difference exists between diabetic male with HbA1c up of 8, and less than 8. Experimental studies suggest that oxidative stress plays a major role in the pathogenesis of type 2 diabetes mellitus. Free radicals are formed excessively in diabetes due to glucose oxidation and non- enzymatic protein glycation[7].

Elevated free radicals levels and the decreased of antioxidants protective mechanism lead to increase the lipid peroxidation products in diabetic patients which have special interest because of their hyperlipidemia is considered to be significant risk factor for the development of vascular complications[22].

MDA is an end marker of lipid oxidation processes[24]. We found that MDA levels, which are the most important marker of oxidative stress were increased significantly in all patients with diabetes mellitus. Oxidative stress occurs in patients with diabetes mellitus due to the alteranation of redox status, ROS overproduction, and dysfunction of main antioxidant enzymes. The first ROS generated is a superoxide anion which involves SOD to produce the hydrogen peroxide (H_2O_2), which in turn can act as an activator of the next antioxidant defense system CAT[25,26]. Endogenous enzymatic antioxidants CAT and SOD act as reducing agents and detoxified highly reactive oxygen and nitrogen species, we found decreased in the activity and this result was agreed with Alghazeer et al (2018)[27]. SOD catalyzes the superoxide to oxygen and hydrogen peroxide by reduction. Also SOD can be used to prevent the destruction consequences of hyperglycemia –induced ROS production in patients of diabetes mellitus[23]. CAT play important role in conversion of hydrogen peroxide to water and oxygen, therefore protect the cells from damage. Both of SOD and CAT decreased significantly in our study and this result was corresponding with many studies[6,21]. GPX is the first antioxidant enzyme involved with preventing the aggregation of hydrogen peroxide in the cells, and play a role in converts hydrogen peroxide to water. GSH is oxidized by lipid peroxidase under the influence of GPX. GSH may serve a purpose in detoxifying lipid peroxides[5]. Diabetes induces alternation in activity of both enzymes GPX and GSH as we reports in our results which were parallel with[6,8].

HbA1c is the indicator of type2 diabetes mellitus and the main proved predictor of complications. The high glucose levels impair the free radicals metabolism and this confirms our result of the significant differences of antioxidant enzymes activity[8].

Conclusion

The Diabetes mellitus change the oxidative status and it is clearly affected the endogenous antioxidant status in patients with T2DM. T2DM patients have a high risk of experiencing micro and macrovascular complications. In addition to the combination of diet, exercise and medication can improve the level of HbA1c for the patients with type2 DM.. Further studies should be conducted to strengthen this evidence.

Abstract

Background: Chronic myeloid leukemia (CML) is a hematopoietic stem cell cancer driven by the BCR-ABL fusion protein that arises from the translocation of chromosomes 9 and 22. Since the found of the Tyrosine Kinase Inhibitor (TKI) as a targeted therapy, the relative survival rate of 5 years has significantly increased compared to the era of the use of previous agents. As a successful leukemia treatment, it can be seen based on the survival rate. Several factors have been known to influence the survival and prognosis of CML patients, including the age of the patient at diagnosis, gender, and response to therapy and treatment. This study aims to determine how many a three-year survival rates for CML patients with targeted therapy in Makassar and the factors that affect survival.

Method: This study used a retrospective cohort using secondary data (medical records) of CML subjects who had been outpatient or inpatient followed in the same time period. The study was conducted in January 2015 to December 2017 at Dr. Wahidin Sudirohusodo Hospital, Makassar. The samples consisted of 108 subjects who met the inclusion criteria. Gender, age, BCR-ABL transcript, targeted therapy and status were taken from medical records. Data were analyzed with SPSS 22.0 version and survival analysis, Meier Kapplan curves, survival median, log-rank and test statistic

Results: There were 108 subjects of CML patients who received targeted therapy, 58 male (53.7%), 30-39 years old 32 subjects (29.6%), b3a2 transcript 67 subjects (73.6%), Imanitib 62 subjects (57.4%) and status for 36 months was followed during the targeted treatment of dead 19 subjects (17.6%) and alive 89 (82.4%). The survival rate of a three years CML subjects who received targeted therapy of 51%, found no significant relationship between gender, age, and targeted therapy

Conclusion: The survival rate of three years of CML patients at Wahidin Sudirohusodo Makassar Hospital is 51% and factors related to age, gender, and targeted therapy tend to influence even though statistically not significant

Keywords: *Three-year survival, CML, targeted therapy.*

Background

Chronic myeloid leukemia (CML) is a hematopoietic stem cell cancer driven by the BCR-ABL fusion protein that arises from the translocation of chromosomes 9 and 22. (1) The conjugation of the breakpoint cluster region (Bcr) gene on chromosome 22 and the Abelson kinase (Abl) gene on chromosome 9 creates the Bcr-Abl oncogene, which encodes the deregulation of tyrosine

kinase. Bcr-Abl activity will create uncontrolled cell proliferation and reduce apoptosis, thereby it will increase malignant expansion of pluripotent stem cells in the bone marrow.[2,3]

Data on CML in Indonesia in 2018 obtained as many as 2,374 patients, most in Surabaya as many as 516, while at least, in Banda Aceh as many as 40, and in Makassar as many as 110. The median age for CML event is 45-55 years old and the event will increase with age.[4]

By recognizing the molecular basis of CML, a highly effective targeted therapy has been developed. This therapeutic agent will block the activity of the tyrosine kinase inhibitor (TKI) of Bcr-Abl in which will inhibit the course of the CML molecular process. Since the found of the Tyrosine Kinase Inhibitor (TKI), the relative survival rate of 5 years is much increased compared to the era of the use of the previous agent. The first generation of Tyrosine Kinase Inhibitor, Imatinib Mesylate was proven to provide excellent clinical outcomes. In Indonesia, the use of TKI has been applied to CML patients and has reached the use of the second generation namely Nilotinib (Tasigna). The comparison of the survival of the two target therapy was reported in the ENESTnd study (Evaluating Nilotinib Efficacy and Safety in Clinical Trial-Newly Diagnosed Patients) where from the 5-year follow-up of patients with nilotinib 300 mg of 93.7%; nilotinib 400 mg by 96.2% and Imatinib 400 mg by 91.7% did not show a significant difference between the two. However there were differences in death due to progression from CML, namely 16 Imatinib death 93.8% while 6 Nilotinib death 97.7% .[5] The survival of CML patients with imatinib in 2006 reported by Drukker, et al. stated an overall survival of 89% after five years. [6]

As a successful leukemia treatment, it can be seen based on the survival rate.. In leukemia patients, using a five year survival rate. This was study carried out for three years as in the second or third year the patient level of compliance sometimes begins to decrease because they felt healed. Several factors that have been known to affect the survival and prognosis of CML patients include the patient's age at diagnosis, gender, and response to therapy and treatment. Nowdays there is no data of survival rates of CML with targeted therapy in Makassar, therefore we are conducting this research.

Method

This study used a retrospective cohort using secondary data (medical records) of CML subjects who had been outpatient or inpatient followed in the same time period. The study was conducted in January 2015 to December 2017 at Dr. Wahidin Sudirohusodo Hospital in Makassar. Samples were CML patients who met the inclusion criteria included (1) CML patients based on BMP (2) positive BCR-Abl (3) age ≥ 18 years (4) willing to join the study. Exclusion criteria (1) Patient cannot be contacted either by telephone (2) Incomplete data. The minimum number needed is 61 research subjects. Sampling was carried out consecutively during the study period until the desired number of samples was reached. Furthermore, Data were analyzed with SPSS 22.0 version and survival analysis, Meier Kapplan curves, survival median, log-rank and test statistic.

Results

From this research, subject studied was 108 CML patients with target therapy, consisted of 58 male (53.7%) and 50 female (46.3%). Age of the subjects were 30-39 years is 32 (29.6%). Bcr-abl transcripts of the subjects is b3a2 with 67 subjects (73.6%), 22 subjects (24.2%) b2a2, and 1 subject (1.1%) c3a2 and e1a3 respectively. Subjects receiving targeted therapy were imatinib 62 subjects (57.4%) and nilotinib 46 subjects (42.6%). The last status during the administration of target therapy is dead 19 subjects (17.6%) and alive 89 (82.4%). It can be seen in table 1.

Table 1: Distribution of Sample Characteristic (n=108)

Variable		n	%
Gender	Male	58	53,7
	Female	50	46,3
Age	<30 years	24	22,2
	30-39 years	32	29,6
	40-49 years	26	24,1
	50-59 years	16	14,8
	>=60 years	10	9,3
BCR-ABL Transcript	b2a2	22	24,2
	b3a2	67	73,6
	c3a2	1	1,1
	e1a3	1	1,1
Targeted therapy	Imatinib	62	57,4
	Nilotinib	46	42,6
Status	Dead	19	17,6
	Alive	89	82,4

Three-year survival rate for CML patients with targeted therapy, an analysis using the life table-Wilcoxon (Gehan) method was obtained, and a one-year survival rate (99%), a two-year survival rate (93%) and a three-year survival rate (51%) (table 2).

Table 2: A Three-Year Survival Analysis of CML Patients

Time Interval (Month)	n	Survival (%)
0	108	100
3	108	100
6	106	99
9	98	99
12	91	99
15	89	98
18	88	97
21	81	97
24	77	93
27	67	91
30	61	85
33	42	85
36	32	51

Figure 1 shows the probability of survival at each 3-month interval in the Kaplan-Meier curve. The duration of follow-up of all patients is from 5 to 102 months with a mean of 30.4±16.3 months.

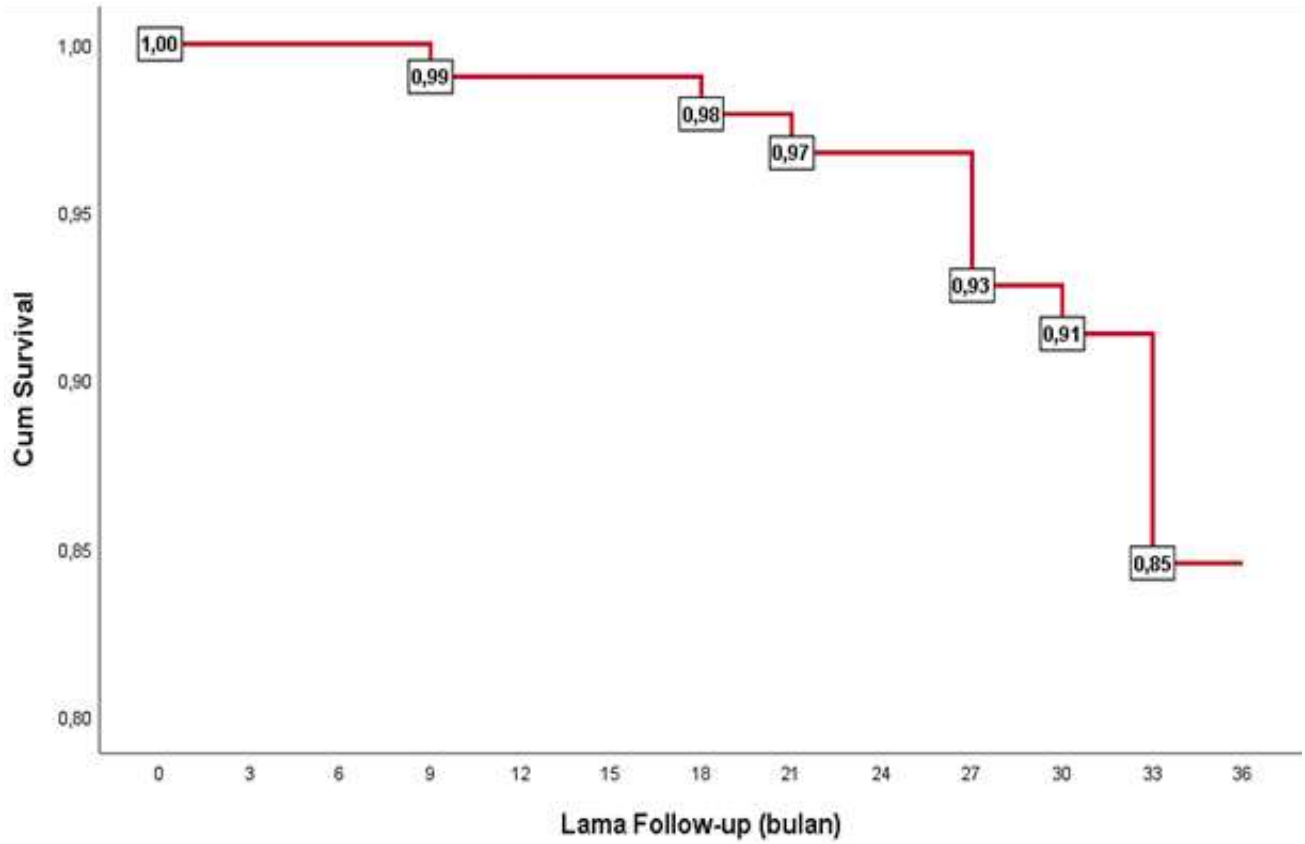

Figure 1: Kaplan-meier Curves of Three-year Survival Probability

Table 3. Three Years Survival of CML Patients by gender

Gender	n	Survival Estimation		p
		Mean (Month)	%	
Male	58	34,6	43	0,856
Female	50	34,2	57	

Table 3 shows that survival in female is higher than in male, which is 57% and 43% (34.2-34.6 month), but statistically not significant (p> 0.05).

Table 4. Three Years Survival of CML Patients by Age

Age (Years old)	n	Survival Estimation		p
		Mean (month)	%	
<30	24	34,5	73	
30-39	32	34,9	64	
40-49	26	34,4	54	0,631
50-59	16	34,1	37	
>=60	10	33,8	29	

Table 4 also shows a decrease with increasing age, but not statistically significant (p> 0.05). The highest survival occurred at age <30 years (73%) and the lowest was at age > = 60 years (29%).

In general, survival in the two treatment targets was not found to be statistically significant difference (p> 0.05) (table 5).

Table 5: Three Years Survival of CML Patients by Targeted Therapy

Targeted therapy	n	Survival Estimation		p
		Mean (Month)	%	
Imatinib	62	34,3	52	0,849
Nilotinib	46	34,7	47	

Table 5 also show imatinib gives the highest survival rate (52%) compared to nilotinib (47%). The mean survival rate is also not much different, namely 34.3-34.7 months.

Discussion

This study found that the subjects studied was 108 CML subjects. Most of the subjects were male: 58 (53.7%) and 50 female (46.3%). This result is in line with research conducted by Reksodiputro et. al. in 2011 in Jakarta, where 19 reported samples were studied, slightly dominant in males than females at 63.2%.[7] Several overseas studies conducted by Hofmann in 2015 reported that CML patients were more frequent in male than female.[8] Research was also supported by SEER (Surveillance, Epidemiology, and End Results) USA which stated that of all race, the ratio of male and female from CML is 2.2:1.3.[9]

Age range between 18-72 years old with an average of 39.8±13.1 years old. Research conducted by Reksodiputro et. al. in 2011 where the age of CML patients was in the age range of 13-62 years.[7] It is different from American Cancer Society data that CML cases in the United States in 2019, the average age at diagnosis of CML is around 64 years. Nearly half of the cases are diagnosed in people aged 65 and older.[10]

The duration of follow-up of all patients is from 5 to 102 months with a mean of 30.4±16.3 months. In this study, a one-year survival rate of 99%, a two-year survival rate of 93% and a three-year survival rate of 51% (table 2 and figure 1). This study carried out for three years because, in the second and third years, the patient level of adherence in treatment slowly decreased, where patients sometimes seemed to have felt healed with the disease they experienced. In a study conducted

by Di Felice et. al. in 2018 in Italy, 357 subjects reported having CML after being given TKI, survivability for one year (from 83.3, 95% CI 76.2-88.5% to 91%, 95% CI 86.5-94.4%) and survival for three years (from 60.4, 95% CI 51.7- 68% to 84.5%, 95% CI 79-89%).[11]

Survival rate for female was higher at 57% and for male 43%, with a mean survival rate at 34.2-34.6 months. But it did statistically not significant (p> 0.05) (table 3). Research by Berger et. al. in 2005 in Germany reported 856 subjects with Ph/BCR-ABL-positive CML in a randomized CML study, where the survival rate was average longer in female sufferers than in male with an average of 59-49 months and this also not significance.[12]

It is well known that age is a very important prognostic marker, and old age has several times been associated with poor survival. In this study, survival analysis according to age was found to be highest at age <30 years old (73%) and lowest at age> = 60 years old (29%).The decrease occurred with increasing age, but it was not statistically significant (p> 0.05) (table 4). Research by Castagnetti F et. al. in 2017 in Italy reported 337 CML patients, obtained OS was not affected by age in the interval between 18-69 years old (OS 5 years 92%, average from 89% to 95% in different decades), but the probability of OS 5 years for old age (≥ 80 years) was significantly lower (34%, P <0.0001).[13] Research by Di Felice et. al. in 2018 in Italy, reported survival by age was relatively decreased, age <65 years old (from 69%, 95% CI 55.3-79.5% to 94%, 95% CI 88.4-97.4%), age 65-74 years old (from 46%, 95% CI 30.8 -61.2% to 69%, 95% CI 52.5-80.4%) and age> 74 years old (from 8.05%, 95% CI 0.8-26.7% to 51, 2%, 95% CI 32.4-67.1%).[11] It can be assumed that relatively older ages have poor survival.

In general, the survival the Imatinib and Nilotinib, was not found to be statistically significant (p> 0.05). Imatinib highest survival rate (52%) compared to nilotinib (47%) with the mean survival rate also not much different, ie 34.3-34.7 months (table 5). The Food and Drug Administration (FDA) approved imatinib as the first-line treatment for newly diagnosed CML in December 2002 after the International Randomized Study (IRIS), which began in June 2000, the results of this study show the effectiveness of imatinib and its remarkable superiority with respect to complete haematological response rates (CHR), molekuler and complete cytogenetic responses (MCyR, CCyR) with an overall survival rate (OS) of 85% for patients receiving imatinib.[13] This is different from the ENESTnd study by Larson et. al. (2012) in the United States, which examined 868 subjects comparing nilotinib (300 mg and 400 mg doses respectively) with imatinib, estimated that the three-year survival rate was higher in nilotinib with imatinib is nilotinib 300 mg 95.1%, nilotinib 400 mg 97.0% and 94.0% for imatinib.[14] While another study by Sanglio et. al. (2010) in Australia also found that nilotinib at a dose of 300 mg or 400 mg twice daily was better than imatinib in CML patients with newly diagnosed positive Philadelphia chromosomes.[15] According to Au WY et. al. (2009), In general, Asian patients, the use of imatinib is still used as the first choice therapy for treating CML patients. Either from Asia, Europe or the United States for giving imatinib is generally giving a good response. Most health practitioners in Asia follow the guidelines found on ELN (European Leukemia Net) or NCCN (National Comprehensive Cancer Network). Based on the results of studies that have been collected regarding the response of CML patients to imatinib, in Europe and the United States shows a complete hematological response of more than 95%, while in Thailand, Philippines, India, China, Hong Kong and South Korea by 90-100%.[16]

This study carried out no dose distribution of nilotinib or imatinib and no further examination of the molecular response achieved which should be examined every year after administration of target therapy so that the results found were inadequate. Besides, various factors influencing the survival of the comparison between the two target therapy are not evaluated precisely such as adherence to take medication or how to take medication, cause of death and the presence or absence of a previous comorbid patient history.

Conclusion

Survival rate of three years of CML patients at Wahidin Sudirohusodo Hospital in Makassar was 51% and factors related to age, gender, and target therapy tended to influence even though it was not statistically significant.

Gene Polymorphism of CSN1S1 and CSN3 Gene Associated with Casein Production Milk Trait in Iraqi Buffaloes (Bubalusbubalis)

Rasha M. Othman[1], Nada S. Hadi[2], Basil A. Abbas[3], Moaed H. Sayhood[4], Firas M. Al-Mubarek[5]

[1]Assistant Professor, [2]Professor Lecturer, [3]Professor, [4]Lecturer, Department of Microbiology and Parasitology, Department of Public Health, [5] Assistant Professor, [5]Department of Microbiology and Parasitology, College of Veterinary Medicine, University of Basrah

Abstract

Twenty-four blood samples of lactating Iraqi buffaloes were analyzed for the presence of CSN1S1 and CSN3 genes using two pair primers to amplify 314bpand 453bp DNA fragment, respectively. Most investigated samples showed the presence of the CSN1S1 gene. In contrast, all samples showed the presence of CSN3 gene. Sequence analysis of both CSN1S1 and CSN3 genes were analyze using Blast algorithmic tool. The results showed that most of the investigated animals resemble those of the Middle East and Asian buffaloes at a percentage of 100% .Moreover, some of investigated genes showed little differences than animals of the other countries by having polymorphism genes posing DNA mutations. Most mutations were either insertion or transition mutation and located between 10936-10938 region. In conclusion, the mutations occur in these genes, which play a role in milk productivity may face unflavored climate condition in the summer in the south of Iraq.

Keywords: *Polymorphism, CSN1S1, CSN3, casein, milk, buffaloes.*

Introduction

Domestic water buffalo (Bubalusbubalis) is an important milk source in many worldwide countries. About 185 million animals were found around the world(1). Buffalo is of great importance and superiority to domesticate cattle due to its high capacity for climate changes, good nutritional benefits and disease resistance. Buffalo milk contains 7% fat, 16%solid not fat (lower phospholipids and cholesterol levels, and a higher saturated fatty acid ratio (2). For best animal production, genotype selection of the animals must be used according to their productivity(3).Animals have a high ability for genetic improvement in the production of milk and meat (4). As in other bovines, buffalo milk is having four types of casein, αS1, αS2, β and π casein. They are under control of CSN1S1, CSN2, CSN1S2, and CSN3 genes. The most dominant one is β (53.45%), followed by αS1, αS2 and π at 20.61%, 14.28% and 11.66%, respectively (5). Casein proteins are high in an essential amino acid such as lysine which is not found in many plant sources (6). They also have a high concentration of phosphate that compound which allows high amounts of calciumto bind tocasein(7). The purpose of this work was to characterize the genetic polymorphism of the CSN1S1and CSN3 gene in the Iraqi buffaloes.

Materials and Method

Animals and sample collection: A total of 24 blood samples were collected from healthy lactating Iraqi buffaloes (Bubalusbubalis) from different farms of Basrah governorate.

DNA Extraction and Primers: Whole blood of buffalo was used for DNA extraction by ReliaPrep™ Blood gDNAMiniprep System. The primers used for CSN1S1 amplification were previously used (Chessaet al.,2007), with a fragment length of 314bp.

F: TGGATGCCTATCCATCTGG

R: CACTGCTCCACATGTTCCTG.

The primers used for CSN3 amplification with 453bp fragment were described by (8) and have been

used by [9]. The 453bp fragment of CSN3 covers most of the exon IV coding region [10]. They have the following nucleotide sequences:

F: 5'-3'TGTGCTGAGTAGGTATCCTAGTTATGG;

R: 5'-3'GCGTTGTCTTCTTTGATGTCTCCTT

Polymerase Chain Reaction: The PCR reaction contained (25µl) including 5 µl of DNA. The following conditions were used for CSN1S1 gene: initial denaturation for 5 min. at 94 ◦C; 35 cycles of denaturation for1 min at 94 ◦C; annealing for 45 s at 60 ◦C; elongation for 80 s at 68–72 ◦C and a final extension for 7 min. at 72 ◦C. While the following cycling conditions were used for CSN3 gene: initial denaturation for 3 min. at 94 ◦C; 35 cycles of denaturationfor 1 min at 94 ◦C; annealing for 45 s at 60 ◦C; elongation for 80 s at 72 ◦C and a final extension for 10 min at 72 ◦C.

The PCR reaction products were electrophoresed on 1.5% agarose gel stained with ethidium bromide to test the amplification success.Agarose gel was run at 75 V for 4 hrs. Gels were examined and photographedunder UV illumination (E - graph – ATTO -Japan). Fragment size of approximately 314bp and 453bpwas verified as positive for CSN1S1and CSN3 genes, respectively. A 100bp DNA ladder (Bioneer, Korea) was used as a molecular size standard.

DNA Sequencing:Purification of PCR products were done by using GeneJET™PCR Purification Kit (Fermentas #K0701). The product thensequenced by Bioneer ABI 3730XL DNA analyzer. Blast analysis wasdone using Blast directory of the NCBI at (https://blast.ncbi.nlm.nih.gov/Blast.cgi).

Results

Twenty-four lactating Iraqi buffaloes were analyzed for the presence of CSN1S1 and CSN3 genes using two pairs of primers for the amplification of 314bpand 453bp DNA fragment, respectively.

PCR results of CSN1S1 gene: The fragment size of approximately ~314bp was verified as positive for CSN1S1 gene. Most investigated samples showed the presence of this gene (Fig. 1).

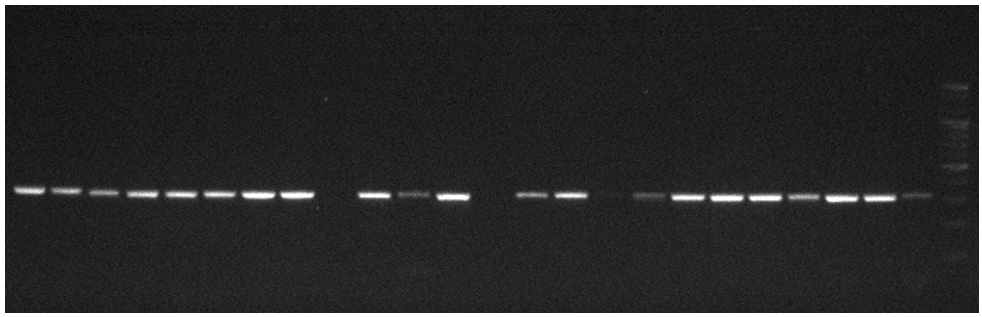

Figure 1: Agarose gel electrophoresis showing the presence of 314bp CSN1S1 gene in blood samples of Bubalusbubalis.

PCR results of CSN3 gene: Fragment size of approximately 453bpwas verified as positive for CSN3 genes. All investigated samples showed the presence of this gene (Fig 2).

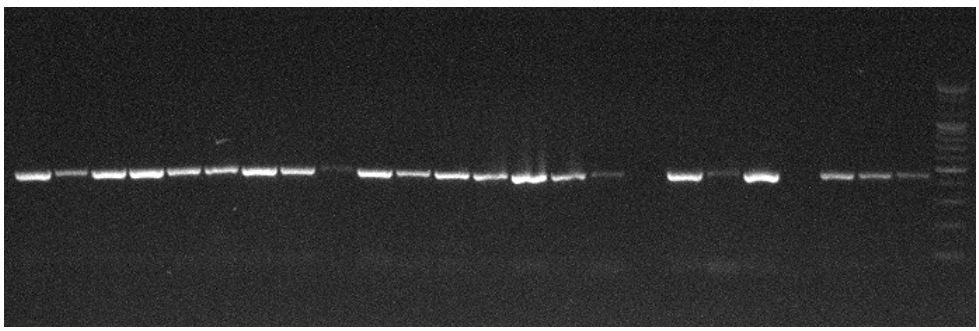

Figure 2: Agarose gel electrophoresis showing the presence of 453bp CSN3 gene in blood samples of Bubalusbubalis.

Sequencing Results: Sequence analysis of both CSN1S1 and CSN3 genes were analyze using Blast algorithmic tool. The results showed that most of the investigated animals resembled those of the Middle East and Asian buffaloes at a percentage of 100%. Moreover, some of investigated genes showed little differences than animals from other countries by having polymorphism genes posing DNA mutations.

Sequencing results of CSN1S1 gene: Results of sequencing of this gene showed 100% identity with Egyptian animal with accession numbers KC577235.1 and JQ670674.1. Only two strains showed insertion mutation at location 67 (Table 1).

Table 1: Results of sequencing of CSN1S1 gene

Source	Identities	GenBank	Nucleotide	Location	Mutation	Sample No.
B.bubalis Egypt	100%	KC577235.1	-	--	-	S2, S3, S6,S13, S15,S17-S23
B.bubalis Egypt	99%	JQ670674.1	- >G	67	Insertion	S4
B.bubalis Egypt	100%	JQ670674.1	-	-	-	S5
B. bubalis Egypt	99%	KC577235.1	- >C	67	Insertion	S7

Sequencing results of CSN3 gene: The results of sequencing of this gene were listed in table 2. The comparison was done with the most resembled Indonesian animals of Bubalusbubalis with accession number MF679163.1. Most investigated samples showed 100% identity whereas five samples showed variable sequence having one or more mutations. Most mutations were either insertionor transition mutation and located between 10936-10938 regions.

Table 2: Results of sequencing of CSN3 gene

Source	Identities	GenBank	Nucleotide	Location	Type of mutation	No. of sample
B.bubalis Indonesia	100%	MF679163.1	-	--	-	N3,N5, N7,N10, N11,N14
B.bubalis Indonesia	99%	MF679163.1	T>C	11131	Transition	N12
B.bubalis Indonesia	99%	MF679163.1	- >C G>A	10936 10937	Insertion Transition	N13
B.bubalis Indonesia	99%	MF679163.1	- >A	10894	Insertion	N15
B. bubalis Indonesia	99%	MF679163.1	- >A - >A	10894 10938	Insertion Insertion	N17
B.bubalis Indonesia	100%	MF679163.1	-	--	-	N18,N20, N21,N22
B.bubalis Indonesia	99%	MF679163.1	- >C G>A	10937 10938	Insertion Transition	N19

Phylogenic tree of the sequenced results showed that both genes (CSN3 andCSN1S1)of local animal are closely related to those previously registered in GenBank from Egypt, Brazil, India, China and Indonesia (Figure 3, A & B).

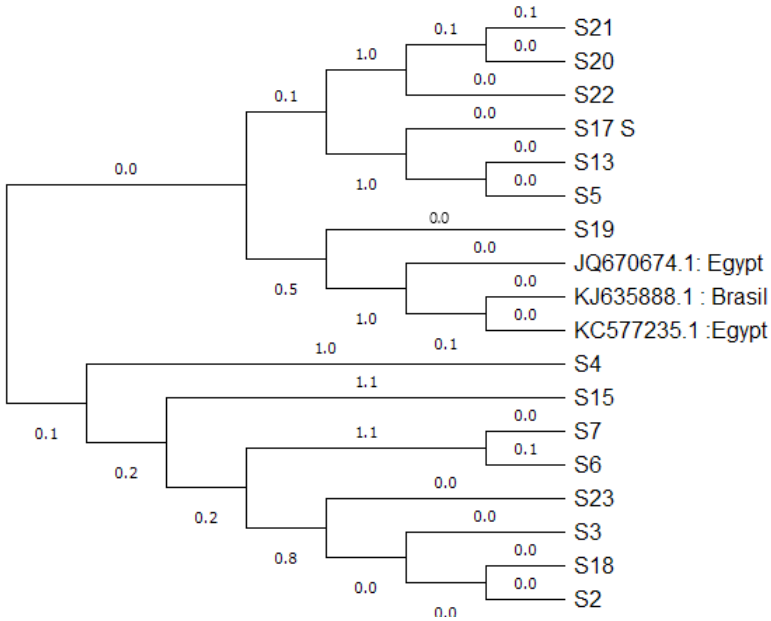

Figure 3: The neighboring phylogenic tree of A= CSN3; B= CSN1S1 genes of local animal compared with that previously registered at GenBankfrom different countries.

Discussion

In order to select more efficient breeding of farm animals there is aninterest in applying genetics technology of specific gene markers associated with productivity characteristics (Spelman et al., 1998). In order to improve animal characteristics and productivity, animals should be selected periodically based on the genotype that reflects their productivity and national economy[11]. CSN1S1 Polymorphism and CSN3 exon IV have not been previously investigated in Iraqi buffaloes. In this study, for the first time we report here, sequence analysis in 24 unrelated Iraqi buffaloes lactating has characterized CSN1S1 Polymorphism and CSN3 exon IV.

Several genes, including casein genes, control the milk trait. CSN1S1, CSN1S2, CSN2, and CSN3 are closely linked to four casein genes. They code a(S1) and a(S2), b, and K casein, respectively. Approximately 80% of the total milk protein is kappa casein [12] CSN1S1 gene sequencing results showed 100% identity with Egyptian animals. [13] confirmed the monomorphism at 178Ser by analyzing Indian buffalo's full CSN1S1 mRNA (accession number: DQ111783). However, a different variant was detected at 192Glu (GAA) versus 192Gly (GGA). Variation of Glu/Gly was detected in bovine animals as investigated by [14]. The Mediterranean type belongs to the Egyptian and Italian buffalo. Mediterranean buffalo appeared as descendant of Indian Murrah buffalo. The long isolation lead to development of some unique characteristics [15].In this study, location 67 strains showed only two additional mutations. It was noted that there were two variants of CSN1S1 in buffalo from Egypt. The variation occurred in the CSN1S1 (178Ser (TCA)/178Leu (TTA) 178 mature protein codon and have been reported in Italian buffalo and referred to HE573920 and HE573919 by [16]. CSN3 gene sequencing results have been analyzed and most of the samples showed 100% identity with Bubalusbubalis Indonesian animals. Between the locations 10936-10938, there was a change in insertion or transition. Exon IV was involved in most of the CSN3 polymorphism. Exon IV mutations are responsible for gene expression differences[17]. The samples of animal blood were collected from buffaloes known for their high production of milk and meat. High temperatures, drought and high water salinity, unflavored climate conditions duringthe summer in the south of Iraq may result in increasing the prevalence of mutations in genes coding for high productivity and higher resistance of animals. Using nucleotide sequence analysis, CSN3 polymorphism has been investigated in buffalo over the past decade. Two variants of nucleotides in codons 135 Thr (ACC)/Ile(ATC) and 136Thr (ACC/ACT) (silent mutation) were reported in Italian [18], Bulgarian[19], and genomic library of water buffalo [20]. Buffalo

polymorphism was investigated using the method of PCR–RFLP. BB monomorphic were mentioned in Egyptian buffalo [21], in Pakistani buffalo[22],and in [23].

In Vitro Evaluation of Antibacterial Effect of a New Bioactive Restorative Material (Activa)

Rasha Saad Zaghlool[1], Rehab Mahmoud Abd El-Baky[2], Mohamed Mohamed Mostafa Abdelmoaty[3], Mona Ismail Riad[4]

[1]Assistant Lecturer of Operative, [2]Professor of Microbiology Department, [3]Associate Professor of Operative, Faculty of Dentistry, Minia University, [4]Professor of Conservative Dentistry, Faculty of Dentistry, Cairo University, Egypt

Abstract

Aim: Evaluation in vitro the antibacterial effect of new bioactive composite restorative material (Activa) in comparison to two different bioactive materials on *Streptococcus mutans*, and *lactobacillus acidophilus*.

Materials and Method: Three types of bioactive restorative materials were used. The materials used in this study were Bioactive composite Activabioactive composite **(A1),** FUJI II LCCapsules **(A2)** and Fuji IX Extra Capsules **(A3).** Each restorative materialwere manipulated in accordance with manufacturer's guidelines and embedded in wells made-up inplates of trypticase soy agar seeded with *Streptococcus mutans* **(B1**) and Lactobacillus MRS agar seeded with *Lactobacillusacidophilus* ***(B2)*.** The antibacterial activity was evaluated by using a caliper to measure the diameter of growth inhibitionzones after 1 day, 1 week, 2weeks and3weeks.

Results: The results of the tested materials were collected, statistically analyzed using the ANOVA test to determine the difference between the mean diameters of the inhibition zone produced. The results indicate that Fuji IX hadhigher antibacterial effects in comparison with the other Activa Bioactive materials and FujiII LC.

Conclusion: All three different bioactive materials promoted growth inhibition of the cariogenic bacteria assayed. Fuji IX glass-ionomer showed the highest efficacy and durability against the tested strains.

Introduction

Dental caries is one of the most common diseases and public health problems that affect human beings negatively which started with infection by cariogenic bacteria, leading to acid production as a result of the bacterial carbohydrates metabolism within the oral biofilm. *Streptococcus mutans* is a Gram-positive bacterium that is the primary causative agent in the formation of dental cavities in humans and animals. Lactobacillus acidophilus is the principal bacteria related to caries progression and is responsible for the formation of secondary caries. [1]

The treatment of dental cavities does not always eliminate all microorganisms from the caries focus by therapeutic procedures. The presence of bacteria in dental tissue left behind or bacterial invasion through a micro-leakage between the tooth and the filling lead to secondary caries. It is the most frequent indication for replacement of all types of restoration and the limited durability of dental restorations.

One of the ways of controlling cariogenic activity was to reduce the number of such microorganisms in

e-mail: rsaadz@yahoo.com

dental biofilm through the use of antimicrobial agents that can alter its composition and to be resistant to secondary caries and to micro-leakage at the edges, properties they possess on account of their ability to release fluoride and to be bonded to the prepared tooth surface. [2.3]

Modern approach to control dental caries requires dental materials that possess both restorative and anticariogenic characteristics. Fluoride is well documented as an anticariogenic agent. Its role includes reduction of demineralization, enhancement of remineralization, interference of pellicle and plaque formation and inhibition of microbial growth and metabolism.

Glass-ionomers (GIC) are considered to be the conventional restorative materials that are bioactive with heaps of uses in all restorative techniques. But their sensitivity to moistness is one of their main drawbacks. Changes in their structures have been made to overcome this defect.The resin modified glass ionomer (RMGI) materials appear to have considerable benefits, keeping the benefits of fluoride release and adhesion. [4]

Bioactive product is the first dental resins with a bioactive ionic resin matrix, shock-absorbing rubberized resin component, and reactive ionomer glass fillers that mimic the physical and chemical properties of natural teeth. These bioactive materials actively participate in the cycles of ionic exchange that regulate the natural chemistry of teeth and saliva and contribute to the maintenance of tooth structure and oral health.

Activabioactive (Pulpdent MA, USA) restorative materials are ionic composite resins which combine the biocompatibility, chemical bond and the ability to release fluoride of GIC with the mechanical properties, aesthetic and durability of resin based composite. [1]

This study was conducted to evaluate the antibacterial effect of bioactive composite against *Streptococcusmutans* and *lacto-bacilli* in comparison to two different bioactive materials.

Aim of the study: The purpose of this study was to evaluatethe antibacterial effect of active bioactive composite in comparison to two bioactive restorative materials; conventional glass-ionomer and resin-modified glass-ionomer after 1 day, 1week, 2weeks and 3weeks.

Subject and method: Three types of bioactive restorative materials were used. The materials used in this study were Bioactive composite (ACTIVA BioACTIVE restorative)(Pulpdent Corporation, Watertown, MA, USA) (**A1)**, a restorative Resin modified glass- ionomer (FUJI II LC)(GC corporation, Tokyo,Japan) Capsules **(A2)** and Conventional glass- ionomer (Fuji IX Extra) GC corporation,Tokyo,Japan)Capsules **(A3).**

Thirty discs from each of restorative materials were made. Each group was further sub divided into to 2 sub group; 15discs for streptococcus-mutans **(B1)** and 15 discs for lactobacillus **(B2).** Capsules (**A2, A3**) were activated and mixed mechanically for 10 seconds using a Silamat device (Vivadent, Schaan, Liechtenstein).

The material was then injected in a mold. Each specimen was prepared by packing each mix into a split Teflon ring with a central hole having dimensions (10mm in diameter X 2mm in thickness)to standardize the dimensions of each tested specimen. The split Teflon mold was encircled with a copper ring to stabilize the mold during specimen preparation**.**

Each mold was placed on the top of a microscope glass slide and a Mylar strip. Each mold was then filled with the each tested material and second Mylar strip was used to cover the top side of the mold and another microscope glass slide was applied over it. Hand pressure was applied to insure no air was trapped and an excess material was removed**.**

The self-cured glass- ionomers Fuji IX **(A3)**was allowed to set before their removal from the mold. While in the mold, the light-cured material; Fuji II LC **(A2)** was cured with a 40-second exposure of each flat surface to a visible light source by using a light-emitting diode (LED) light cure unit (Demi, Kerr).

Activa Bioactive Restorative **(A1)** samples were made by light-curing 2 mm thickness of the material for 20 seconds from both sides was as the manufacturer instructed. Specimens were removed from their molds and then rechecked for their diameter and thickness using a digital caliper. [9.10]

Agar Diffusion Testing: The antibacterial activity was evaluated against *Streptococcus mutans* ATCC® 25175™ and *Lactobacillusacidophilus* ATCC® 314™ (Microbiologics®, Lyophilized microorganisms, USA) using the agar diffusion test.

Each bacterial strain from stock cultures were cultivated overnight in specific culture media: Trypticase-soy agar for *Strep. mutans* (Becton Dickinson

Microbiology systems, Cockeysville, MD21030, USA) and Lactobacillus MRS agar for *L.acidophilus* (Himedia laboratories PV, 23 Vadhani India, Est., LBS Marg., Mumbai, India) after incubation for 24h for *Strep. mutans* and 48h for *L. acidophilus* in incubator (Gallenkamp cooled incubator, IR211GAmodel, Pinal way, Loughborough, England) at 37°c ± 1°c, Two or three discrete representative overnight colonies of each tested strain were inoculated into 2 ml sterile saline and diluted to obtain a turbidity equal to 107 CFU/ml equivalent to 0.5 McFarland turbidity standard solution (About 9.95 ml of solution A (1% (V/V) of sulfuric acid) was mixed with 0.05 ml of solution B (1.175% (W/V) aqueous solution of barium chloride dehydrate) slowly and with constant agitation in a clear glass test tube.

The tube was sealed and stored in the dark at room temperature)] Petri dishes (15 cm diameter) containing 30 ml agar to a thickness of 2 mm were seeded by 0.5 ml of microbial suspension using Automatic micropipette (Huawei Adjustable micropipette (H) series, Zhejiang, China Mainland). For each Petri dish, nine standardized wells with a diameter of 10mm were punched into the agar with the blunted end of a sterile Pasteur pipette. For each Petri dish 9 specimens (10mm in diameter x 2mm in thickness) were inserted in the wells onto agar withsterile forceps.

For monitoring the immediate antibacterial effect ofthe tested groups (day 0), the plates were incubated inincubator at 37°c ± 1°c for 48h. Then the diameters ofthe circular inhibition zones produced around thespecimens (specimens + inhibition zones) weremeasured in millimeters with a digital caliper (Owner'smanual, IOS-USA) at three different points, and themean was recorded as the (day 0) value.

The specimens were then left in the same plates for five more days in the incubator (total of 7 days) and transferred to freshly inoculated plates and incubated at 37°C for 24h for *Strep. mutans* and for 48h for *L.acidophilus* to obtain the inhibition zones for day 7. On that day, the respective culture media with fresh agar for the microorganisms were placed in new Petri dishesand microorganisms' suspensions were added and 9 wells were punched into the agar.

The glass ionomer specimens were taken out of their previous Petri dishes and placed in the new wells. The plates were then incubated with active microorganisms at 37°c ± 1°c for 24h for *Strep. mutans* and for 48h for *L. acidophilus*, and the inhibition zones around the specimens were measured in millimeters with a digital caliber the day after.The same procedure was repeated every 7 day for 21 days (measurement at 7, 14 and 21 days).[6,7,8]

Statistical Analysis: Statistical analysis was carried out using SPSS program, One way analysis of variance (SPSS, analysis, compare means, one way ANOVA) was used to test the effect ofmaterial on free bacterial area within each time. Duncan Post-Hoc Multiple comparisons at $p \leq 0.05$ was used for means comparison (SPSS Inc., Chicago, IL)

Results

I. Inhibitory zone (S. mutans):

A. Effect of tested materials: Figures (**1**) revealed significant difference among Streptococcus mutans inhibition zones of the three bioactive restorative materials at day 1, 1week, 2weeks and 3 weeks as Fuji IX **A3B1** showed the highest inhibition zone followed by FujiII LC**A2B1** and Activa **A1B1**.

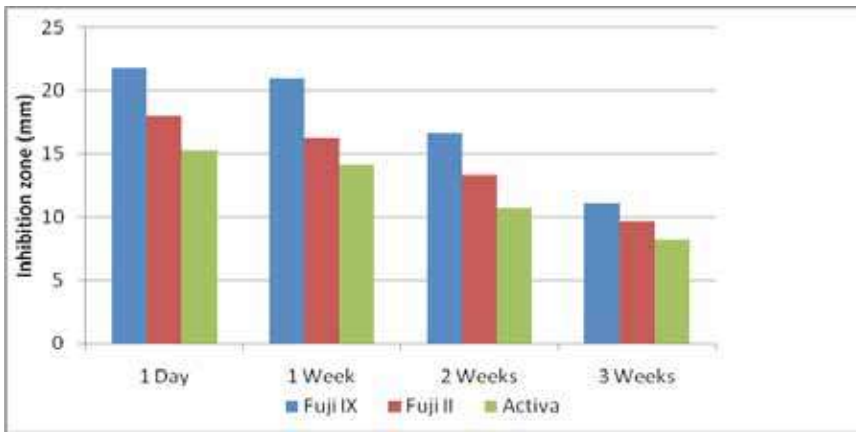

Figure 1: Bar chart showing mean Inhibitory zone (S. mutans).

B. Effect of time: Figure (2) revealed the effect of time one the Inhibitory zone (S. mutans) of each tested materials. There was a statistical significant difference $p < 0.001$ between the inhibition zones of 1 day,1 week, 2 weeks and 3 weeks groups for Fuji IX, FujiII LC and Activa.

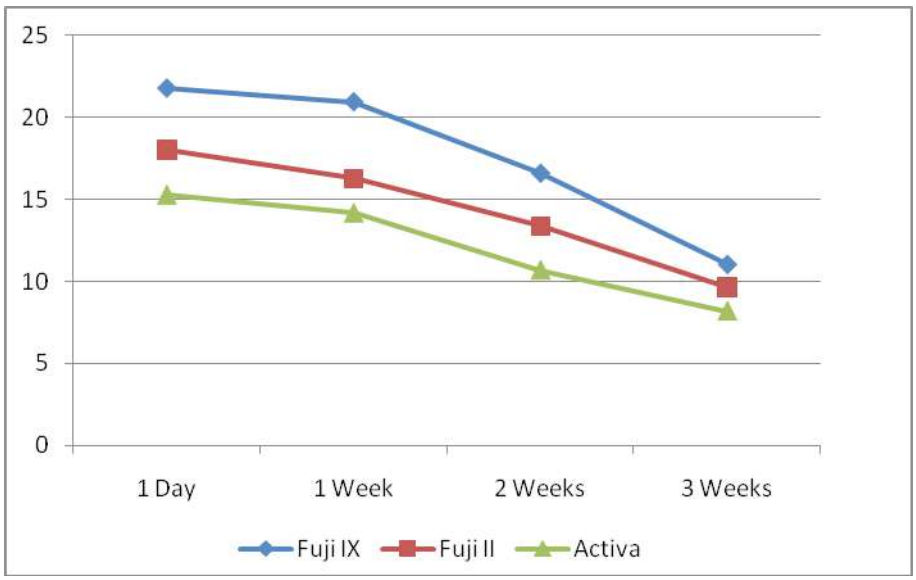

Figure (2): Line chart showing mean Inhibitory zone (S. mutans).

II. Inhibitory zone (Lactobacillus):

A. Effect of tested materials: Figure (3)revealed that; at day **1**There was a statistically significant difference $p<0.001$ between the inhibition zone of the Fuji IX and the inhibition zones of Fuji II and Activa groups. At 1 week There was a statistical significant difference $p<0.001$ between the inhibition zone of the Fuji IX, Fuji and Activa groups. At 2 weeks and 3 weeks There was no statistical significant difference $p=0.164$ between the inhibition zone of the three tested material Fuji IX**,** Fuji II andActiva groups.

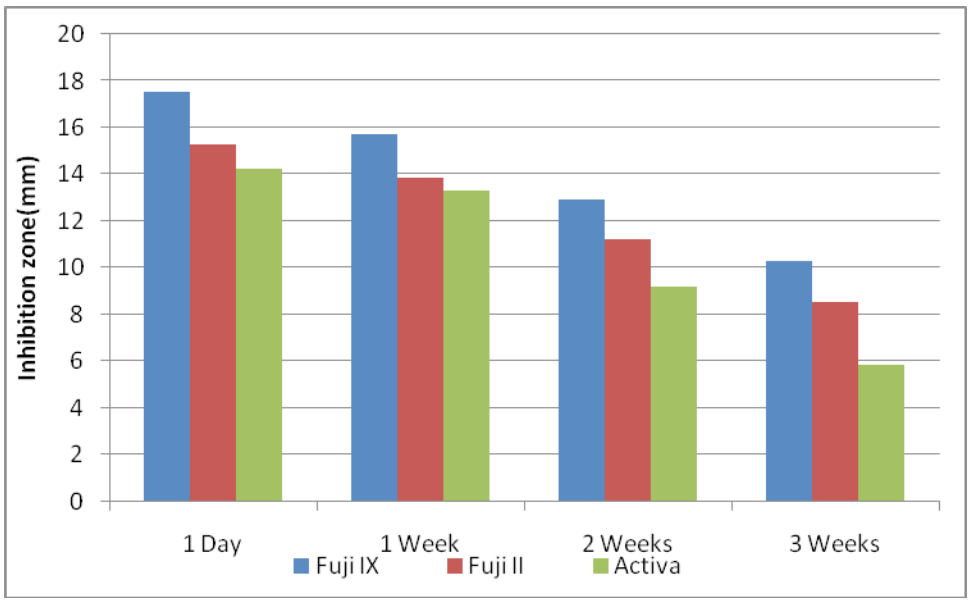

Figure (3): Line chart showing mean Inhibitory zone (lactobacillus).

B. Effect of time: Figure(4) revealed that There was a statistical significant difference $p<0.001$ between the inhibition zone of the 1day**,** 1week**,** 2weeks **and** 3 weeks **of** Fuji IX,FujiII LC andActiva

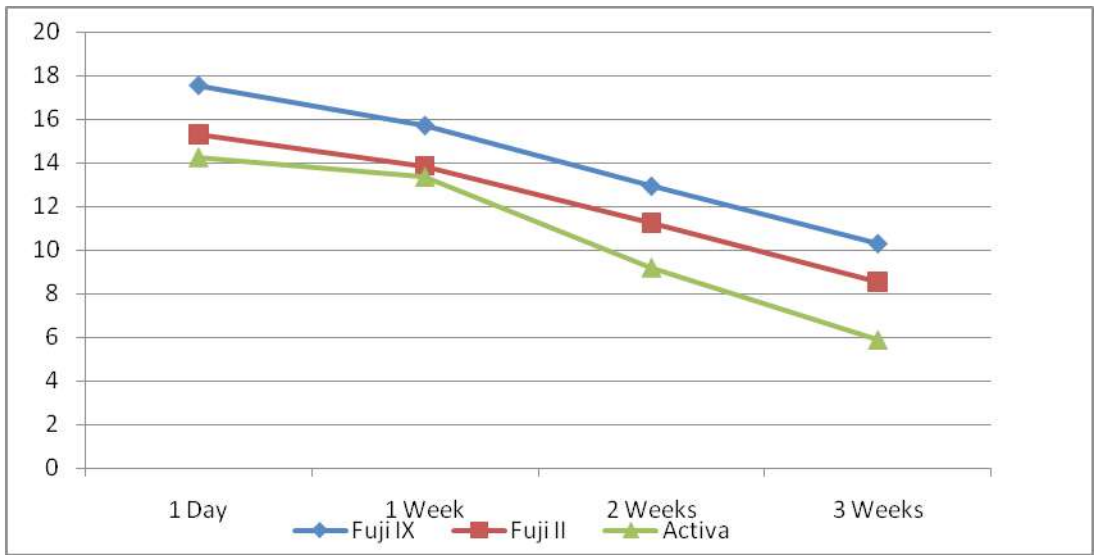

Figure (4): Line chart showing mean Inhibitory zone (Lactobacillus).

Discussion

Dental caries constitutes one of the most common infectious diseases. It is amulti-factorial disease related to the presence of cariogenic bacteria embedded in the dental plaque.

In this study Streptococcus mutans microorganisms were chosen because they are considered to be the most important group of bacteria initiating caries lesions .It was reported that the number of salivary S.M in the oral cavity is correlated to the formation of new caries lesions, and it is generally accepted that reducing the number of S.M also reduces caries activity. They are considered as the main bacteria responsible for caries formation. Also Lactobacillus acidophilus were chosen in the study because it considered as the principle bacteria related to caries progression[2,3]several experiments have been conducted to incorporate antibacterial agents into dental filling materials as resin composites and glass-ionomers, in order to inhibit bacterial attachment and thus plaque accumulation. However, the antibacterial activity is considered to depend upon release of the antibacterial agent [1,2].

In this study, the antibacterial properties of three bioactive dental restorative materials were investigated using the agar diffusion test. The agar diffusion test was used to evaluate the antibacterial activity for each type of tested material against the tested microorganisms. This method was chosen for this study because it is relatively inexpensive and can be performed rabidly and easily with a large numbers of specimens; also it had been widely accepted as a simple screening assay to assess the antibacterial properties or restorative materials. However there are limitations associated with the agar diffusion test. One of the main limitations is the inability to distinguish between bacteriostatic and bactericidal effects, so the test does not provide any information about the viability of the test microorganisms within the inhibition zones and also this assay does not reflect the actual status in the oral cavity where the bacteria exist as a biofilm which exhibits an increased resistance to antibacterial agents [1,2,3]

In contrast to other testing method,direct contact test offers an advantage, in which the bacteria come incontact directly with the tested materials.In the present study, monitoring of the antibacterial effect of the tested groups carried after day1,7day,1 week,2 weeks and 3weeks. Digital caliper was used for measurement of the inhibition zones around the specimens [7].

The results of this research suggest that Fuji IX extra had the highest antibacterial effect in comparison to Fuji II LC an active bioactive composite. The glass-ionomers results are in agreement with a study conducted by Klai

et al. where it was concludedthat various products of GIC exhibited some degree of antimicrobial effect by reducing thenumber of colony forming unit of *S. mutans* and lactobacillus indicating limited bacteriostatic properties butnot bactericidal properties.

The investigators suggested that the inhibitory effects wererelated to the ability of the material to release fluoride as has been indicated extensively Fluoride has been reported to reduce the acidogencity of *S. mutans* by influencing their metabolism and lactic acid production[11,12]. The weak-to-moderate inhibitory effects of GIC in this study are in contrast to multiple studies which indicated that GIC had potent antibacterial effects against *S. mutans*[13].

The bioactive materials Activa in this study also showed weak antibacterial activity As it contain monomers such as urethane dimethacrylate (UDMA) in comparison to Fuji IX extra and FUJI II LC Moreover, resin-based fluoridereleasing materials were reported to release a smaller quantity of fluoride in comparison with GIC.So the less fluoride release may contribute to less antibacterial effect. We believed that these variable results could be related to variations inmaking the dental samples such as polymerization of the materialsfor example, the exacttime of light-curing and how far the light-cure unit from the materials.

Conclusion

The highest antibacterial effect among the materials tested was obtained with Fuji IX. This could be related to the material ability to release fluoride as was reported in [10,11].The bioactive material Activa Bioactive Restorative showed weak antibacterial properties. Such a weak inhibition would not be effective in preventing secondary caries formation.

Recommendation: We suggest that future studies should investigate the antibacterial effect of the dental materials in vivo in order to evaluate the interaction between the bioactive dental restorative materials.

Ethical Clearance: Was taken from Faculty of Dentistry, Minia University.

A Cross-secsional Study: Analysis Risk Factors Against Hypertension in Indonesia 2014

Ria Arihta Ujung[1], Nasrin Kodim[2]

[1]Master of Epidemiology, [2]Departement of Epidemiology, School of Public Health, University of Indonesia

Abstract

Background: Hypertension is one of the issues of global health problems. This is because hypertension can contribute greatly to the incidence of cardiovaskular disease, stroke, kidney failure and early death. Moreover hypertension rarely causes symptoms at an early stage, so many cases are undiagnosed. The prevalence of hypertension based on measurements in Indonesia through Riset Kesehatan Dasar in 2007 was around 31.7%, this figure declined in 2013 to around 25.8%, and increased in 2018 to around 34.1%, which was the largest prevalence in last ten years. This study aimed to look at risk factors that can affect the incidence of hypertension in Indonesia.

Method: This study was a quantitative study with a cross-sectional design using Indonesian Family Life Survey-5 (IFLS-5) datain 2014. The sample of this study amounted to 36,405.

Results: The results of this study obtained the prevalence of hypertension by 21.8%. Some risk factors that are proven statistically and substantially can affect the occurrence of hypertension, including age> 57 years (PR= 1.18; 95% CI 1.12-1.24), <=junior high school education level (PR=1.52: 95% CI 1.46-1.58), with mariage status (PR = 1.36; 95% CI 1.30-1.18), have a diabetes mellitus history (PR= 2.28; 95% CI 2.11-2.46), have a high cholesterol history (PR= 2.16; 95% CI 2.03-2.29), and have a sleep disorders (PR= 1.08; 95% CI 1.03-1.13).

Suggestion: The results of the study suggest people especially those aged 15 years and over who have risk factors for hypertension in order to routinely maintain a healthy lifestyle; became input to the Ministry of Health of the Republic of Indonesia to improve the quality of the implementation of Posbindu PTM such as providing blood pressure measuring devices and equipping cadres' understanding of risk factors for hypertension.

Keywords: *Hypertension, Risk Factors, Indonesia.*

Introduction

Hypertension is one of the issues of global health problems because hypertension can contribute greatly to the incidence of heart disease, stroke, kidney failure and early death. Hypertension rarely shows symptoms at an early stage, so many cases are not diagnosed so patients with early hypertension rarely get treatment. In connection with this, hypertension is also called Silent Killer disease.(1)

The incidence of hypertension continues to grow along with the development of the epidemiological transition. Based on data from the World Health Organization (WHO) in 2008, there were around 1 billion people in the world who had been affected by hypertension. In 2015, that number increased to around 1.13 billion cases of hypertension. This shows that one in three people worldwide experiences hypertension. The prevalence of hypertension in the Southeast Asian region is around 36%, this figure is higher than the

Corresponding Author:

Master of Epidemiology, School of Public Health, University of Indonesia
e-mail: riaujung@gmail.com

American region. This is due to the risk of hypertension in countries with low or moderate income which is about 40% greater than those with high income[1].

In the Southeast Asian region it is estimated that around 1.5 million people with hypertension each year In Southeast Asia, Indonesia ranks the second highest with the highest incidence of hypertension after Myanmar[1]. In Indonesia, the prevalence of hypertension based on measurements in Indonesia through Basic Health Research in 2007 was around 31.7%[2], this figure declined in 2013 to around 25.8%[3], and again increased in 2018 to around 34.1%[4] which was the largest prevalence in last ten years. This is different from the hypertension survey rate based on doctor's diagnosis, in 2013, the prevalence of hypertension was based on doctor's diagnosis of 9.4% and in 2018, it dropped by around 8.4% .

Hypertension can occur due to several accompanying risk factors. These risk factors such as family history, unhealthy lifestyle, wrong dietary patterns, and poor sleep duration or quality [5] According to the Ministry of Health of the Republic of Indonesia, the risk factors for hypertension are divided into 2 groups, namely: irreversible risk factors, namely risk factors inherent in hypertensive patients and cannot be changed, including: age, sex, and genetics. Risk factors that can be changed are risk factors caused by unhealthy behavior of people with hypertension including smoking, low fiber diet, excessive salt consumption, lack of physical activity, excessive body weight/obesity, alcohol consumption and stress.

This study aims to see an overview of hypertensive patients based on risk factors in the form of age, education level, mariage status, diabetes mellitus history, high cholesterol history, and sleep quality.

Materials and Method

Study Design and participants: The type of research used is descriptive research, namely research conducted on a set of objects that aims to see a picture of phenomena (including health) that occur in a particular population and see some relationships between variables.[6] This study used a Cross Sectional design. The data source comes from secondary data from the Indonesian Family Life Survey-5 (IFLS-5) survey in 2014/2015. The target population and study population in this study were all respondents of Indonesian Family Life Survey -5 in 2014-2015 totaling 50,148 respondents. There are 36,405 respondents whose data can be connected to all the variables studied.

This study used secondary data derived from the 2014/2015 Household Life Survey 5 (IFLS-5) in Indonesia 2014/2015. This survey provides extensive information on the socio-economic, health and other aspects of both the household and individual level. IFLS is considered as the most comprehensive survey ever conducted in Indonesia [7]. The IFLS-5 is a continuous health survey that began in 1993 with four subsequent rounds of data collection where the sample represented 83% of Indonesia's population (1997/1998; 2000; 2007/2008; 2014/2105) [8]. This survey activity was conducted in collaboration with the RAND Corp research organization (Santa Monica, California, USA) with the Population and Policy Center (Gajah Mada University and Survey METER research institute).

Measures: This study uses IFLS-5 data for 2014-2015, where before conducting research, researchers study the questionnaire first to find out the available variables that will be used in accordance with the research objectives. IFLS-5 has used the Computer-Assisted Personal Interview (CAPI) system so that it no longer uses paper questionnaires and there is no repeat data entry process. This CAPI system has been tested first. The variables assessed in this study were analyzed derived from several questionnaires.

Results

Proportion of Risk Factors against Hypertension: The description of each risk factors variable from the the study: age, education level, mariage status, diabetes mellitus history, high cholesterol history, and sleep quality. The prevalence of hypertension in Indonesia was 21.8%.

Table 1: Frequency of Hypertension According to Individual Characteristics

Characteristics	Hypertension		Non Hypertension		Total
	n	%	n	%	
Age Category (Years)					
15-27	677	6.7	9456	93.3	10133
28-37	1168	12.2	8443	87.8	9611
38-47	1646	23.0	5510	77.0	7156
48-57	1859	39.6	2830	60.4	4689
>57	2598	53.9	2218	46.1	4816
Education Level					
<=Junior high school	4532	26.7	12419	73.3	16951
> Junior high school	3416	17.6	16038	82.4	19454
Mariage Status					
SIngle	654	9.2	6434	90.8	7088
Mariage	5772	22.2	20230	77.8	26002
Divorce	1522	45.9	1793	54.1	3315
Diabetes Mellitus History					
Exist	377	48.4	402	51.6	779
Not exist	7571	21.3	28055	78.7	35626
High Cholesterol History

Not exist	7319	20.9	27693	79.1	35012
Sleep Quality					
Sleep disorders	5729	22.3	19947	77.7	25676
Non sleep disorders	2219	20.7	8510	79.3	10729

Based on age category, the highest proportion of hypertension was ≥ 57 years group (53.9%) and the highest proportion of non hypertension was 15-27 years group (99.3%). The proportion of hypertension in education level <=Junior high school was 26.7% higher than > Junior high school 17.6% but non hypertension in education level <=Junior high school was 73.3%, and >Junior high school 82.4%. Based on mariage status, divorce status has the highest proportion of hypertension which is equal to 45.9%, at mariage was 22.2%, and single status was 9.2%.Respondents had diabetes mellitus history and suffered hypertension 48.4% but non hypertension 51.6%. Respondents had high choleterol history and suffered hypertension 45.2% but non hypertension 54.8%. Based on sleep quality category, the highest proportion of hypertension was respondents who had sleep disorder group 22.3% and the highest proportion of non hypertension was non sleep disorder group 79.3%.

Table 2. Crude Assosiation of risk factors against Hypertension

Characteristics	Hypertension	Non Hypertension	PR Crude
	n = 7.948	n = 28.457	95% CI
Age Category (Years)			
15-27	677	9456	1
28-37	1168	8443	1.25 (1.12-1.39)
38-47	1646	5510	1.45 (1.33-1.58)
48-57	1859	2830	1.25 (1.16-1.34)
>57	2598	2218	1.18 (1.12-1.24)

Characteristics	Hypertension	Non Hypertension	PR Crude
	n = 7.948	n = 28.457	95% CI
Education Level			
<=Junior high school	4532	12419	1.52 (1.46-1.58)
> Junior high school	3416	16038	1
Mariage Status			
SIngle	654	6434	1
Mariage	5772	20230	1.36 (1.30-1.42)
Divorce	1522	1793	1.18 (1.09-1.27)
Diabetes Mellitus History			
Exist	377	402	2.28 (2.11-2.46)
Not exist	7571	28055	1
High Cholesterol History			
Exist	629	764	2.16 (2.03-2.29)
Not exist	7319	27693	1
Sleep Quality			
Sleep disorders	5729	19947	1.08 (1.03-1.13)
Non sleep disorders	2219	8510	1

In table 2 could be seen, the risk of hypertension were 1.25 among 28-37 years category, 1.45 among 38-47 years category, 1.25 among 48-57 years category, and 1.18 among ≥ 57 years category. Education level especially <=Junior high school has a significant risk of hypertension (PR=1.52: 95% CI 1.46-1.58. The size of the association based on Crude Prevalens Ratio (PR) found that the group with mariage marital status compared to the unmarried group made as referrals obtained 1.36 (95% CI 1.30-1.18) meaning mariage in the marital status category had 1.36 times the risk of the incidence of hypertension compared to single groups.

The proportion of groups with a history of diabetes mellitus (DM) in the incidence of hypertension was 48.4%, greater than the category that did not have DM history of 21.3%. PR was obtained at 2.28 (95% CI 2.11-2.46) meaning that the group with a DM history had a 2.3 times risk of the incidence of hypertension compared with those who did not have a DM history. The proportion of groups with a high cholesterol history in the incidence of hypertension was 45.2%, greater than the category that did not have high cholesterol history of 20.9%. PR was obtained at 2.16 (95% CI 2.03-2.29) meaning that the group with high cholesterol history had a 2.16 times risk of the incidence of hypertension compared with those who did not have high cholesterol history. The proportion of groups with a sleep disorders in the incidence of hypertension was 22.3%, greater than the category that did not have sleep disorders of 20.7%. PR was obtained at 1.08 (95% CI 1.03-1.13) meaning that the group with sleep disorders had a 1.08 times risk of the incidence of hypertension compared with those who did not have sleep disorders.

Discussion

Based on the results of data analysis that has been done, it shows that most hypertensive patients in the age group> 57 years. Age is often associated with the incidence of hypertension. This is because with age, the elasticity of arterial blood will decrease. This is affected by the accumulation of collagen and hypertrophy of very thin, fragmented smooth muscle cells and fractures of elastin fibers. Hypertension Risk in Indonesia continues to increase as much as 11.5 times when a person is over 75 years old [(9)]. This is reinforced based on the results of Riskesdas (2013) that most of the elderly tend to experience hypertension, which is equal to 57.6%.

Based on research by Okpechi et all (2013) [(10)]that there is a relationship between the level of education with hypertension. The relationship between education and the incidence of hypertension can be attributed to indirect relationships. Based on research conducted in Thailand, it was proved that respondents who received formal education 6.5 times were more aware of hypertension than those who had never received formal education[(11)]. However, even a sufficient level of

knowledge does not necessarily guarantee that someone has the behavior to prevent hypertension. Information received outside the educational environment can also contribute to increasing one's knowledge[12]. Therefore the extension method needs to be considered in order to attract interest from the community.

Research by Tambunan[13] found that people with not/unmarried status reduced the risk of hypertension, while widows/widowers were twice as likely to develop hypertension. This is caused by the stress of life because of the loss of loved ones and can be accompanied by the possibility of disease and death. Nevertheless the response of each individual is different, but losing someone who is loved decreases the body's immune system by about 50% [14].

Diabetes mellitus is also one of the risk factors for hypertension. This is because people with diabetes can suffer from insulin resistance. This insulin resistance will increase blood pressure due to loss of normal vasolidator activity from insulin or long-term effects[15]. Some studies suggest that there is a relationship between the history of diabetes and the incidence of hypertension. In Brazil a history of diabetes increases the risk of hypertension by 4.43 times in urban areas and 4.61 in rural areas[16].

Cholesterol is one of the risk factors that can be changed from hypertension. The higher the total cholesterol level, the higher the possibility of hypertension [17]. Increased blood cholesterol levels are experienced by many people with hypertension, this statement is reinforced by various supporting studies. In America, Framingham's heart research states there is a relationship between cholesterol levels and blood pressure.

In Javaheri's research, S et al [18]showed that there was a relationship between poor sleep quality and the incidence of hypertension in adolescents. This proves that sleep disturbances continuously will affect the physiological changes of the body that interfere with the balance between the regulation of the sympathetic and parasympathetic nervous system. Sympathetic nerves play a role in increasing blood pressure while the parasympathetic nerves play a role in decreasing blood pressure.

Conclusion

Based on the results of the 2014/2015 IFLS-5 data analysis, the prevalence of hypertension was 21.8%. Some risk factors that are proven statistically and substantially can affect the occurrence of hypertension, including age> 57 years, <=junior high school education level, with mariage status, have a diabetes mellitus history, have a high cholesterol history, and have sleep disorders.

Hypertension is a very dangerous disease. To control it, the government implemented a Healthy Indonesia Program with a Family Approach (PIS-PK) and the Healthy Living Society Movement (Germas). The hope is that all components of the nation consciously want to cultivate healthy living behaviors starting from the family (Ministry of Health, 2018). Communities, especially those aged 15 years and over, especially those who have risk factors related to hypertension, should routinely maintain a healthy lifestyle such as eating nutritious and balanced foods, maintaining sleep patterns and doing enough physical activity.

Ethical Considerations: The data used in this study collected from interviews directly with respondents using questionnaires and direct health measurements. IFLS data is data that is open to the public and its use has been approved by Institutional Review Boards (IRBs) in the United States (RAND) and Gajah Mada University in Indonesia. All IFLS-5 respondents before being interviewed and examined were asked to fill out the Informed Consent sheet. The confidentiality of the respondent's identity is very much considered and is only used for research purposes.

Conflict of Interest: Both author declared that no competing interest exist.

Funding: This study uses personal funds from researchers.

Acknowledgements: We thank to RAND Corporation for providing data in this study.

Limitations: This study uses a cross sectional design, where the exposure and outcome are measured at the same time. The use of this design in this study has a weakness because of the temporal ambiguity, so that between the incidence of hypertension and the exposure variable can overtake each other which results in unclear aspects of causality.

Abstract

Background: Obesity is a condition of chronic accumulation of body fat and a factor for the onset of serious diseases such as dyslipidemia. Obesity and dyslipidemia are emerging as significant public health challenges in South Asian countries

Aim: This study aimed to assess the association of obesity with dyslipidemia by measuring LDL and HDL in adolescents

Method: This study is an observational analytic study with a cross-sectional design. Sixty-two adolescents aged 17 – 19 years were randomly using systematic random sampling. LDL and HDL, anthropometric (weight, height, and BMI). Analysis data was performed using an independent t-test, chi-square test, and Fisher test

Results: The results showed that the samples with a high risk for the measurement of LDL and HDL.

Conclusions: It was concluded that obese adolescents have close links with dyslipidemia and have low HDL level. Obesity in adolescents is essential as early as possible so that it does become a significant health problem.

Keywords: *Obesity, Dyslipidemia, LDL, and HDL.*

Introductions

Obesity is a chronic disease that can cause various other degenerative diseases. The development of the problem of obesity has been widespread throughout the country, and its occurrence has increased every year for the past 40 years. The increase in the incidence of obesity also increases the increase in the incidence of degenerative diseases. Such as dyslipidemia which even increased in adolescence.

The Problem of Body Weight Proportion has experienced a very remarkable development, from 1975 to 2014, with changes in the average value of BMI of the world's population, ranging from 21.7 kg/m^2 in 1975 to 24.2 kg/m^2 in 2014, where in males from 22.1 kg/m^2 in 1975 to 24.4 kg/m^2 in 2014. These data indicate that an increase in BMI of the world population supports a positive shift towards obesity BMI. And finally in 2014 the face of the world changes increasingly concentrated due to obesity problems with the prevalence of morbidity due to obesity globally of 0, 64% of male sex and 1.4% of women[1]. Thus, the change in BMI of the world's population for four decades supports the spread of obesity to high mortality rates.

Likewise, the development of the problem of obesity in Indonesia is clearly illustrated in the 2007 Riskesdas data with the national prevalence of obesity in people aged> 18 years by 13.9% and becoming 19.7% in 2013 [2]. The picture of the population above the age of 18 shows that for the Indonesian population the coverage of adults and the elderly has a problem of obesity which is quite alarming and requires special attention in their snacks.

The incidence of obesity for South Sulawesi has experienced a very large increase. The prevalence of obesity in the Selayar Archipelago District is 32.49% greater than the prevalence of obesity at the provincial level in South Sulawesi which amounted to 23.67% in 2016.

Where in adolescence, obesity, drugs cannot be done because they are still in growth period. While on the other hand the condition of obesity experienced by adolescents raises new problems namely dyslipidemia.

LDL and HDL changes that occur in adolescents can cause dyslipidemia problems more quickly at a younger age. This change is a very big dynamic from very high LDL and very lace HDL in adolescents. Or a standard LDL level but a very low HDL level.

This study aimed to assess the association of obesity with dyslipidemia by measuring LDL and HDL in adolescents. The purpose of this study is to prove that there are changes in LDL and HDL in adolescents due to their obesity. This is important to be the reason for the importance of promoting obesity treatment in adolescents. To prevent dyslipidemia.

Method

In our respondents we measured LDL, HDL, and anthropometric measurements including abdominal circumference using measuring tape, body weight with weight scales, height with microtoa, and BMI (Body Mass Index).

BMI measurement by calculating body weight in Kg divided by height in meters squared. Like the following formula:

$$BMI = \frac{weight(Kg)}{(height\ (m))^2}$$

Measurements of LDL and HDL were carried out as a result of venous blood tests taken from adolescents and measured in Lab. Prodia Makassar, Indonesia.

The data of this study were analyzed by independent t-test, chi-square test, and Fisher test to see the relationship of several measured variables.

Results

The results of this study:

Table 1: Characteristics of Adolescent Respondents

Variabel	N	%
Gender		
Men	27	43.5
Women	35	56.5
Age		
17	5	8.1
18	45	72.6
19	12	19.4
Central Obesity		
Normal	21	33.8
Obesity	41	66.2
BMI		
Normal	22	35.5
Obesity	40	64.5

Based on table 1 above shows the majority of respondents are female adolescents with a percentage of 56.5%. and dominated by 18 years old with 72.6%. Respondents who had central obesity based on measurements of abdominal circumference were 66.2%, and for respondents who were obese based on the results of BMI measurements were 64.5%.

Table 2: Lipid Profile and Obesity According to Central Obesity of Adolescent

	Central Obesity		
Variable	**Normal Mean ± SD (n=21)**	**Obesity Mean ± SD (n=41)**	**P**
HDL	51.9 ± 10	43.9 ± 7	0.001
LDL	98 ± 18	115 ± 33	0.01
LDL/HDL	2.2 ± 0.58	2.6 ± 1	0.063

From table 2 above shows that HDL levels in adolescents with central obesity conditions are much lower than in adolescents with normal abdominal circumference which is a mean of 43.9 ± 7 with a value of P <0.005.

Table 3: Lipid Profile and Obesity According to Body Mass Index of Adolescent

Body Mass Indeks			
Variable	**Normal Mean ± SD (n=22)**	**Obesity Mean ± SD (n=40)**	**P**
HDL	51.4 ± 10.4	44 ± 7.6	0.002
LDL	98.2 ± 17	116.3 ± 32.8	0.007
LDL/HDL	2.2 ± 0.6	2.6 ± 1.05	0.057

In table 3 above shows that adolescents with obese conditions have very low HDL levels compared to normal adolescents. This obesity measurement was based on the Adolescent Body Mass Index adjusted for BMI chart percentile tables for children and adolescents based on CDC 2000.

Table 4. Obesity Based by Waist Circumferences According to Lipid Profile of Adolescent

Variabel		LDL					HDL					LDL/HDL				
		Hight Risk		Low Risk		P	Low Risk		Hight Risk		P	Low Risk		Hight Risk		P
		N	%	N	%		N	%	N	%		N	%	N	%	
Central Obesity	Obesity	29	70.7	12	29.3	0.153 *	14	34.1	27	65.9	0.036*	11	26.8	30	73.2	0.046**
	Normal	11	52.4	10	47.6		2	9.5	19	90.5		1	4.8	20	95.2	

*Chi-square test, **Fisher test

Based on table 4 above shows that central obesity has a close relationship with HDL levels and LDL/HDL ratio which shows a close relationship with the risk of heart disease. This is seen as a significant value from the Chi-squer and Fisher test analysis results as attached in table 4 above.

Table 5: Obesity Based by Body Mass Index According to Lipid Profile of Adolescent

Variabel		LDL					HDL					LDL/HDL				
		Hight Risk		Low Risk		P	Low Risk		Hight Risk		P	Low Risk		Hight Risk		P
		N	%	N	%		n	%	N	%		N	%	N	%	
Obesity by BMI	Obesity	29	72.5	11	27.5	0.076*	13	32.5	27	67.5	0.104*	11	27.5	29	72.5	0.042**
	Normal	11	50	11	50		3	13.6	19	86.4		1	4.5	21	95.5	

*Chi-square test, **Fisher test

Based on table 5, the relationship of obesity based on BMI in adolescents shows a very close relationship with the LDL/HDL ratio for those who are at high risk of heart disease.

Discussion

This study provides an overview of the relationship of Obesity in adolescents both based on BMI and Abdominal Circumference have very low HDL levels and this poses a severe risk for heart disease in the future. This research provides evidence of the obesity conditions experienced by adolescents putting the burden of other health problems. And giving the weight of obesity management treatments is important given to adolescents to prevent the occurrence of diseases due to weight gain.

The high prevalence of dyslipidemia problems in children is higher in the community of children with obesity so that the examination of lipid profiles in children with obesity is needed for prevention[3]. Conditions like this have a bad impact on their health status in adulthood[4].

One important determinant that can cause early atherosclerosis problems at a younger age is adiponectin[5]. Low adiponectin is associated with atherogenic lipid profiles[6]. Likewise, the problem of cardio vascular disease in adulthood is suspected of having begun since childhood[7]. This is the main key to the importance of examining the lipid profile in the condition of observation both in children and adolescents.

Because further research is still needed to answer and provide a big picture of this in younger age groups and the involvement of more respondents.

Conclusions

Based on the results of this study it can be concluded that obesity experienced by adolescents can reduce HDL levels in lipid metabolism in adolescents' bodies and has a high risk of the appearance of heart disease.

Conflict of Interest: None.

Abstract

In recent years, the increasing incidence of chronic suppurative otitis media (CSOM) diseases worldwide is often associated with the role of TLR4 as a component of innate immunity. This study aimed to analyze the TLR4 levels in patients with chronic suppurative otitis media with and without cholesteatoma. This study was conducted using the cross-sectional technique on 30 patients divided into two groups. The first group is CSOM with cholesteatoma that consisted of 10 patients and the second group isCSOM without cholesteatoma that consisted of 20 patients. Each sample was examined for TLR4 levels and bacterial identification cultures in secretions and several samples were also examined for TLR4 levels in the middle ear mucosa. TLR4 levels were examined by the ELISA method.

The results showed that TLR4 levels in middle ear secretions and mucosa of CSOM patients with cholesteatoma were higher than chronic suppurative otitis media without cholesteatoma but there were no significant differences. TLR4 levels in mucosal samples are higher than secret samples but there are no significant differences.There were no significant differences in TLR4 levels in both secret and mucosal samples between groups of CSOM with cholesteatoma and CSOM without cholesteatoma. There were no significant differencesin TLR4 levels betweenthe secret and mucosal sample in both CSOM with and without cholesteatoma.

Keywords: *Chronic Suppurative Otitis Media, Cholesteatoma, TLR4, Innate Immunity.*

Introduction

Otitis media (OM) is a middle ear infection associated with inflammation. This disease frequently afflicts humans and is the major cause of hearing loss worldwide. Substantial morbidity associated with OM is further exacerbated by the high frequency of recurrent infections leading to chronic suppurative otitis media (CSOM).[1] Chronic suppurative otitis media (CSOM) is a serious health care concern worldwide due to its substantial financial and non-financial burden.[2] Otitis media is the most common disease in children in the United States, with about 5 billion spent each year in direct and indirect costs.[3] The World Health Organization (WHO) estimates that about 65-330 million people suffer from CSOM and that as many as 50% of these have some form of significant associated hearing loss and this disease results in reduced quality of life for patients.[1,4]

Chronic suppurative otitis media is divided intochronic suppurative otitis media without cholesteatoma and withcholesteatoma. Both are distinguished by looking at the inflammatory process, the presence or absence of cholesteatoma and the location of the tympanic membrane perforation, and different

management.[5] The pathogenesis of otitis media is considered multifactorial, however, a bacterial infection is a major cause of acute and chronic otitis media.[6,7] In a study conducted by Pancawati in 2016 in Makassar, it was found that the overall pattern of the pathogen that caused CSOM was gram-negative aerobic bacteria.[8] The body's immune response to microorganisms, including bacteria, consists of innate immunity and adaptive immunity. The innate immunity response acts as a non-specific first-line barrier to defense.[4,9]

Toll-like receptor (TLR) is a homologous protein in the cell membrane Antigen Presenting Cell (APC) that functions as a functional receptor that activates leukocytes to trigger innate immune responses or inflammatory responses to fight pathogens.[10] TLR is an important mediator and the best innate immune receptor of the innate immune response.[6,11,12] There are 11 types of TLRs have been identified from mammals and each response to a different class of pathogenic infections and is named TLR1-11.[10] TLR4 mainly recognizes a large number of pathogens associated with PAMP that are specific to LPS (lipopolysaccharide) in gram-negative bacteria.[13,14]

Studies in humans have been carried out regarding the role of TLR in CSOM.[15,16,17,18,19] Studies in animals have added in vivo evidence regarding the importance of TLR as innate immunity in OM resistance.[16,18]The involvement of the innate immune system and TLRs in OM, as well on their relevance for new vaccination strategies and immunotherapies.[20]

Materials and Method

Patient Selection: The research subjects were selected from two patient groups of CSOM: Group Iconsist of 10 patients CSOM with cholesteatoma and Group II consist of 20 patients CSOM without cholesteatoma. Each sample was examined for TLR4 levels and bacterial identification cultures in secretions. 5 of 10 patients from Group I and 10 of 20 patients from Group II was examined for TLR4 levels in middle ear mucosa. All patientsare diagnosed based on history, physical examination and CT-Scan of temporal bone examination. Patients with acute suppurative otitis media, inactive chronic suppurative otitis media, congenital and primary acquired cholesteatoma, and patients with a history of other acute and chronic infectious diseases were not included as subjects in this study.

Middle Ear Secretion Swab Culture: Middle-ear swab culture was performed for both sample groups. The external auditory canal was cleaned, and the middleear discharge was collected using sterile cotton swabs than placed in a sterile tube and subjected to bacteriological examination.

Middle Ear Secretion Collection: The external auditory canal was cleaned, and the middle ear discharge was collected using sterile cotton swabs than placed in an Eppendorf tube contains 1 ml phosphate buffer saline (PBS).The samples were stored in a freezer with a temperature of -20°C for further use in ELISA.

Middle Ear Mucosa Collection: During each operation, the middleear mucosa was exposed via tympanostomy anterior or posterior. The mucosae were collected using a microcurette and forceps than placed in an Eppendorf tube contains 1 ml phosphate buffer saline (PBS) than stored in a freezer with a temperature of -20°C for further use in ELISA.

Elisa: TLR4 protein levels were selectively tested by ELISA kits. The standard curve range of the ELISA kit is 0,05 ng/ml – 15 ng/mland sensitivity are 0,027ng/ml. Middle ear secretion and mucosae from the two groups were recollected. Middle ear secretion and mucosae homogenized in 0.5 ml of PBS. All samples were centrifuged for 5min at 13,000 g and the supernatant was tested in duplicate for TLR4 according to the manufacturer's instruction.

Statistical Analysis: Data were analyzed using SPSS (Statistical Package for Social Sciences)version 24.0 for Windows. Samples were analyzed usingin dependent T-test.

Results

Types and proportions of cultured pathogens: All of the samples were positive for bacteria. The most pathogen in CSOM without cholesteatoma are gram-negative bacteria, species *Pseudomonas aeruginosa* with 8 samples (40%), followed by gram-positive species *Staphylococcus haemolyticus* with 3 samples (15%). The most pathogen in CSOM with cholesteatoma are gram-negative bacteria, species *Pseudomonas aeruginosa* (Table 1).

Table 1: Organisms are cultured from middle ear swabs.

No	Bacteria	Gram (+)/(-)	Cholesteatoma (-)		Cholesteatoma (+)	
			n	%	n	%
1	Pseudomonas aeruginosa	Gram (-)	8	40	2	20
2	Acinetobacter baumanii	Gram (-)	1	5	1	10
3	Serratia marcescens	Gram (-)	1	5	0	0.0
4	Serratiarubidaea	Gram (-)	1	5	0	0.0
5	Enterobacter cloacae	Gram (-)	0	0.0	1	10

	Total		**20**	**100.0**	**10**	**100.0**

TLR4 Levels: In the secret samples with the independent T-test obtained p-value 0.460 ($p > 0.05$) that showed no significant difference. In the mucosal samples with the independent T-test obtained p value 0.114 ($p > 0.05$) that showed no significant difference (Table 2).

Table 2: TLR4 levels between groups of CSOM with cholesteatoma and CSOM without cholesteatoma based on secretions and mucosal samples.

CSOM		N	Mean	Std. Deviation	p-Value
Secret	With Cholesteatoma	10	3.7244	0.583	0.460
	Without Cholesteatoma	20	3.4615	1.024	
Mucosa	With Cholesteatoma	5	4.1660	0.610	0.114
	Without Cholesteatoma	10	3.7595	0.332	

*Independent T-Test

TLR4 levels were also examined to compare TLR4 levels in secretions with TLR4 levels in the mucosa in each study group. In the group ofCSOM with cholesteatoma with the independent T-test obtained p-value 0.196 ($p > 0.05$)that showed no significant difference. In the group of CSOM without cholesteatoma with the independent T-test obtaine dp-value 0.381 ($p > 0.05$) that showed no significant difference (Table 3).

Table 3: TLR4 levels between secret samples with mucosal samples in CSOM with cholesteatoma and CSOM without cholesteatoma

Sample		n	Mean	Std. Deviation	p-Value
With Cholesteatoma	Secret	10	3.7244	.58336	0.196
	Mucosa	5	4.1666	.60976	
Without Cholesteatoma	Secret	20	3.4615	1.02485	0.381
	Mucosa	10	3.7595	.33240	

* Independent T-Test

Discussion

In this study, the most pathogen in CSOM with and without cholesteatoma are gram-negative bacteria, species *Pseudomonas aeruginosa*. Pancawati[8] in Makassar also received the most pathogen in CSOM without cholesteatoma are gram-negative bacteriabut species *Proteus mirabilis* inCSOM withcholesteatoma. Harshika[21] in India also obtained the dominant microbiological pathogen in CSOM is *Pseudomonas aeruginosa.*

P. aeruginosa is the main cause of CSOM disease in the tropics.[22] *Pseudomonas* is more able to survive than other pathogens because it only requires minimal food and produces pyocyanin and bacteriocin which is its ability to carry out local infections in the form of necrotic activity by extracellular enzymes, which have characteristics such as epithelium damage, circulatory breakdown, and loss of tissue protection devitalizing organisms from normal defense mechanisms.[23]

Toll-like Receptors (TLR) 1-10 plays a very crucial role in inducing and activating the natural immune system during an infection. Recent data have shown an important role for TLR in the inflammatory response to bacteria in the ear, and these receptors are particularly important during recovery from otitis media in mice.[24,25]

Si (2014) on examining TLR4 levels using Real-Time - PCR and Western blot found low TLR4 mRNA levels and TLR4 protein levels in the middle ear mucosa of CSOM compared to normal middle ear mucosa. This is one proof of the involvement of TLR4 in the pathogenesis and recovery of CSOM.[25]

Usually, TLR is expressed in immune cells, epithelial cells, and endothelium. The ligand is called Pathogen Associated Molecular Patterns (PAMP). The TLR bond and its ligand will cause signal transduction to release proinflammatory cytokines such as IL-1 and TNF-α. The most important histopathological features of cholesteatoma are the cholesteatoma matrix, immune cells, and stroma (stroma).The pathogenesis of cholesteatoma is still controversial. Excessive production of several cytokines such as IL-1α and IL-1ß is found in the cholesteatoma epithelium and stroma. IL-6 is found in the stroma and intestines of cholesteatoma. These cytokines affect epithelial proliferation and bone resorption that occur in cholesteatoma. The discovery of these inflammatory mediators and the intercellular connecting molecule explain the immunologic aspects of the growth of cholesteatoma.[24]

The results of this study generally obtained levels of TLR4 secret samples and mucosal samples in the CSOM group with cholesteatoma higher than TLR4 levels in CSOM without cholesteatoma but did not show a significant difference. Jesic et al.[17] also found no significant difference in TLR4 expression between the granulation tissue of CSOM with cholesteatoma and CSOM patients without cholesteatoma on TLR4 examination with histopathological and immunohistochemical examination techniques. Whereas Hirai et al.[26] found higher TLR4 expression in middle ear mucosa CSOM with cholesteatoma than middle ear mucosa CSOM without cholesteatoma by immunohistochemical examination.

Higher TLR4 levels in CSOM with cholesteatoma caused by an infection process that occurs in CSOM with cholesteatoma is more severe than in CSOM without cholesteatoma. Cholesteatoma is a good medium for bacterial growth so that infection occurs. Infection can trigger a local immune response which results in the production of various inflammatory mediators and various cytokines. Inflammatory mediators and cytokines can stimulate keratinocytes of the cholesteatoma matrix to be hyperproliferative, destructive.[27] In this study, TLR4 levels did not show a significant difference probably due to the lack of samples in this study.

The results of this study generally obtained levels of TLR4 in mucosal samples higher than TLR4 levels in meddling ear secret samples both ongroup CSOM with cholesteatoma and CSOM without cholesteatoma but did not show a significant difference. TLR4 levels in the secretions and mucosa which are almost the same and statistically do not show a significant difference in each sample group show that TLR4 levels can be measured using secret samples and mucosal samples.

Bacterial infections are the dominant factor in most cases of otitis media. The natural immune system of the mucosa (epithelial cells and other mucous cells) functions as a barrier and anti-infection. The natural immune system of the mucosa plays an anti-infectious role by recognizing Pathogen Associated Molecular Patterns (PAMP) through Pattern Recognition Receptors (PRR), such as Toll-like receptors (TLR). TLR activation mobilizes the innate immune response, including infiltration of inflammatory cells, production of inflammatory cytokines, and defense against bacterial infections.[25]

Conclusion

TLR4 levels in secret and mucosal samples are higher in CSOM with cholesteatoma than in CSOM without cholesteatoma but there were no significant differences. TLR4 levels in mucosal samples are higher than secret samples but there ware no significant differences in both group CSOM with and without cholesteatoma.

Conflicts of Interest: The authors have no conflicts of interest to declare.

Acknowledgments: The authors very gratefully thank all chronic suppurative otitis media patients who were willing to be a respondent in this study.

Ethical Clearance: Taken from Biomedical Research Ethics Committee on Human Faculty of Medicine Hasanuddin University Makassar Indonesia (Register number :1122/H4.8.4.5.31/PP36-KOMETIK/2018).

Effect of Different Levels of Coriandrum Sativum and Piper Nigrum and their Interaction on Production, Biochemical Parameter, Liver Enzymes, TSH and Growth Hormone for Broiler Chickens

S.G. Hussein[1], H.Q. Baker[2]

[1]Assistant Professor, [2]Assistant Lecturer, College of Agriculture,University of Sumer, ThiQar-64001, Iraq

Abstract

This study was conducted in Agri. Faculty field, University of Sumer De-Qar province for period from 10th of April 2019 to 14th of May 2019, they had fed 35 days. The objective of this study was to evaluate the effective of watery extraction of Coriander and Black pepper to (80) chickens, one day old, Strain Rose 308, unsexed birds and breed in four cages of batteries. This experiment was divided into four groups, three treatments with different levels and the fourth as a control. The results showed a significant increase of weekly body weight (BW), as well the treatments were improving feed consumption $P < 0.05$, furthermore there is increase in feed conversion ratio with significant result $P<0.05$. The study reported about biochemical parameters, It showed that a significant decrease in cholesterol and triglyceride (T.G.) $P<0.05$ incompared with the control and no significant difference with total protein. Liver enzymes activity after use medicinal herbs and spice for broiler chicks were recorded a significant reduction in GOT and GPT and no Significant effect on ALP, $P<0.05$. As well as the herbs and spice gave increase in growth hormone maybe that herbs contain mineral and vitamins which increased growth hormones $P<0.05$ the efficient of growth hormone (somatotrophin) was increase protein retention and glycogen deposited in the muscles, as well increase in TSH hormone that gave significant result $P<0.05$. Increased of TSH hormone secrete from pituitary gland and causes elevated in T_3, T_4 and increased the metabolism. The result indicated that there is significant differences between treatments for Immunological test of N.D. $P<0.05$ when compared with a control and no significant differences for I.B. test. It is concluded the extraction enhanced the performance and health situation with improvement antibody titer against N.D. but the medicinal herbs did not effect on infection bronchitis (IB) disease as well all the chickens were vaccinated with N.D. and No vaccine with IB.

Keywords: *Coriander seed, spices, Liver enzymes, Growth hormone and chickens Rose 308.*

Introduction

Coriander is an annual, short, fast – growing and prefer dry climates and thrives in well-drained soils [8].The plant grow up to 1-3 Feet high, the leaves are light green in color. The flowers are white or pink, the stem is green, erect Sympodial, which grow up to the height of 75cm, the plant blooms during late Summer. The plant yield a seed as a fruit. The brownish seed are round ¼ inch long and 6mm as a diameter. The seed possess sweet and orange flavor .Herbs and spices have recently emerged as alternatives to antibiotics in animal production. They are known to exert antimicrobial actions in vitro against important Pathogens including fungi [6]. It has also been reported that plant extracts and spices as single compound or as mixed preparations can play a role in supporting both performance and health status of the animal[17]. About 20 gram of Coriander leaves contains 5 calories 0.73 gram of carbohydrate, 0.19. of Fat, 0.43g of protein, 3%daily value of Vit. B_9 and daily value of Vit. C. It possesses antioxidants such as selenium, Ascorbic acid, Vit. A., Beta-Carotene and Vit. E [8].

Functions of Coriandrum Sativum:

1. Reduce cholesterol. Its possesses oleic acid, Linoleic acid, Stearic acid and ascorbic acid which lower the level of cholesterol and bad cholesterol in the inner walls of veins and arteries.

2. Prevents anemia: Coriander contains good amount of iron which is helpful for the anemia patients.
3. Anti-allergic activity: Anti-histamine properties in coriander helps to lower the uncomfortable condition caused by hay fever and seasonal allergies.

Black Pepper: Piper Nigrum is a flowering vine extracted from the core of a pepper plant and belongs to the family Piperaceae, genus Piper and spices Piper Nigrum. Black Pepper has been shown to be rich in glutathione peroxidase and glucose-6-phosphate dehydrogenase[13].

The antioxidant and radical scavenging properties of black pepper Seed have been well documented[9].

[12]: Showed that piperine Can increase the absorption of Selenium, Vit B Complex, beta Carotene and Curcumin as well.

The pepper is a Creeper and normally grown on tall trees and grows up to 4 meter. The pepper we use at home is the dried pepper Fruit, when ripe the pepper fruit is red in color and when dried it becomes black.A tea spoon of pepper which makes about four grams gives as low as (10) Calories and contributes to daily value requirement of about 10% Mn, 5.4% Vit.k, 14.4% Iron 4.9% copper and about 2.8% of dietary fiber, its Promotes production of hydrochloric acid in stomach and improves digestion. Black pepper antioxidant benefits as well established and known to promote good intestinal health. It is help food to stay no longer than required there by reducing stomach gas and irritations. The pipperine seems to increase metabolic reactions to keep the fat levels under control. Black pepper also a good antiseptic, it prevents or reduce temperatures during fever.

Chickens Rose 308: is recognized globally as a broiler that will give consistent performance in broiler house.

Integrated and independent producers value the growth rate, Feed efficiency and robust performance.

Rose 308 is a robust, fast growing, Feed efficient broiler with good meat yield.

It is designed to satisfy the demands of customers who require consistency of performance and the versatility to meat a broad range of end product requirements.

Features of Broilers Rose 308:

1. Rapid growth, the possibility of early Slaughtering.
2. More muscle mass.
3. Bright skin.
4. High performance

Advantages of cross broiler Rose 308:

1. Excellent Live weight gain.
2. Large and long legs.
3. Excellent Feed Conversion.
4. White and large breasts.

Materials and Method

The experiment started from 10th of April 2019 to 14th of May 2019 the chickens Fed ad-libitum for 35 days. Its was done in Agri. Faculty Field, Univ. of Sumer, De- Qar/Raifae.

The project divided into four groups, three treatments with different levels and the fourth as a control.

The chickens Rose (308) were distributed randomly for (3) treatments and the fourth as control.

T_1 = Control : just water drank.

T_2 = Coriandrumsativum only 4 mL Ext.COR./Lit. Water.

T_3 = Coriander + Black Pepper 3 mL Ext. COR. + l ml Ext. B.P./Lit. water.

T_4 = Coriander + Black Pepper 2.5 mL Ext. COR. + l.5 ml Ext. B.P./Lit. water.

The procedure of extraction: The medicinal herbsplant was brought from popular Market and Mill the seeds by electrical Machine to get Powder, after that it was dissolved with distilled water and left for 24 hours.

The percentage recorded 1g. Powder dissolved with 2ml of distilled water then the solution was kept in water bath on 60°C until boiling then left it to cool and filtered by sterile gauze after that the solution was ready for use.

Statistical analysis: The statistical computations were done by using SAS Software program (SAS, 2012). Duncan's multiple range test (1955) to comparison between means. (21 and 22).

Results

The study deal with different treatments of herbs on many differ Biological Parameters. It contain (6) tables.

Table 1: Effect of Extraction for medicinal herbs and spices on feed consumption of broiler chickens

C.F.C.	Weekly age					Treat
	5	4	3	2	1	
18.28±3247.40 d	12.35±1560.47 c	5.66±813.33 b	3.49±534.57c	1.67±217.95	1.13±121.08	T1
16.11±3369.93 c	10.29±1655.58b	6.14±817.05 b	2.95±553.26 b	1.33±223.20	0.96±120.84	T2
17.83±3460.83 a	11.33±1709.72 a	6.11±838.47 ab	2.77±569.73 ab	1.58±223.79	1.11±119.12	T3
18.83±3501.07 a	1.33±1717.30a	5.83±855.71 a	3.18±582.96a	1.38±223.94	1.11±121.16	T4
*	*	*	*	*	N.S	L.s.ig

There is significant decrease in cumulative feed consumption P<0.05 and as well between the treatments,started from third week of the experiment.

Table 2: Effect of extraction for medicinal herbs and spice on feed conversion ratio to broiler chickens.

F.C.R.	Weekly age					Treat
	5	4	3	2	1	
0.012±1.77c	0.022±1.94c	0.016±1.75c	0.013±1.64c	0.011±1.49b	0.008±1.12	T1
0.011±1.68b	0.017±1.86b	0.014±1.66b	0.011±1.57b	0.010±1.44ab	0.010±1.13	T2
0.010±1.66ab	0.019±1.84ab	0.017±1.63ab	0.015±1.54ab	0.010±1.43a	0.006±1.12	T3
0.012±1.63a	0.017±1.80a	0.016±1.61a	0.013±1.50a	0.009±1.40a	0.008±1.13	T4
*	*	*	*	*	N.S	L.s.ig

This results indicated there is significant P<0.05 on feed conversion ration started from third week of treatments.

Table 3: Shows the comparison between different treatments in Biochemistry.

Treatment	Mean ± SE		
	Cholesterol (mg/dl)	Triglyceride (mg/dl)	Total protein (g/dl)
T1:Control	140.00±8.31 a	55.00±2.58 b	3.30±0.09 a
T2:4 ml/L Coriander	90.00±4.58 b	56.00±2.75 b	3.00±0.06 a
T3: 3ml/L Coriander + 1 ml/L Black pepper	120.00±7.08 a	62.00±3.23 ab	3.20 ±0.11 a
T4: 2.5ml/L Coriander + 1.5 ml/L Black pepper	135.00±7.43 a	75.00±5.07 a	3.40 ±0.15 a
Level of sig.	*	*	NS

There is significant reduction p<0.05 for cholesterol and P 0.05 >for T.G and No. Sig. for total protein.

Table 4: Effect of medicinal herbs and spice on Liver enzymes.

Treatment	Mean ± SE		
	GOT	GPT	ALP
T1:Control	52.00±2.51 a	14.00±0.55 a	690.00±24.53 a
T2:4 ml/L Coriander	40.00±1.63 b	10.00±0.37 b	695.00±27.74 a
T3: 3ml/L Coriander + 1 ml/L Black pepper	47.0±2.06 a	9.00±0.41 b	680.00±19.47 a
T4: 2.5ml/L Coriander + 1.5 ml/L Black pepper	49.00±2.37 a	12.00±0.68 ab	680.00±25.04 a
Level of sig.	*	*	NS

The Results showed a significant p<0.05 decreasein GOT and GPT but there is no significant in ALP.

Table 5: Effect of coriander and black pepper on growth and TSH hormones in broiler chickens.

Treatment	Mean ± SE	
	GH-Growth hormone	TSH
T1:Control	0.10±0.02b	0.20±0.03 a
T2:4 ml/L Coriander	0.10±0.02 b	0.21±0.05 a
T3: 3ml/L Coriander + 1 ml/L Black pepper	0.14±0.05 a	0.11±0.01 b
T4: 2.5ml/L Coriander + 1.5 ml/L Black pepper	0.12±0.02 ab	0.23±0.05 a
Level of sig.	*	*

The result showed a significant increase $p<0.05$ for growth and TSH hormones.

Table 6: Effect of herbs and spice for Immunity in Broiler chickens.

Treatment	Mean ± SE	
	N.D.	I.B.
T1:Control	1504.00±62.48 b	0.00±0.00 a
T2:4 ml/L Coriander	2281.00±94.53 b	0.00±0.00 a
T3: 3ml/L Coriander + 1 ml/L Black pepper	5825.00±135.09 a	0.00±0.00 a
T4: 2.5ml/L Coriander + 1.5 ml/L Black pepper	6715.00±164.74 a	0.00±0.00 a
Level of sig.	*	NS

There is significant $p<0.05$ for N.D. with different treatments compare with control and No. Sig. with infection bronchitis (IB).
Note: All broiler chickens vaccinated against N.D. only .

Discussion

The study was conducted to assessment the effect of watery extraction of medicinal herbs and spices on weekly Body weight gain (B.W.G.), Feed Consumption (FC.) and Feed conversion ratio (FCR).

Body weight gain (B.W.G.), Feed Consumption (FC.) and Feed conversion ratio (FCR). All treatments significant differences $p<0.05$ compared with control, that study Carried out through Table [1 and 2] These results agreed with author[20] who observed that COR. Supplementation improved BW., BWG, and FCR. As well author[10] who started that COR. Supplementation at a level of 2% improved B.W. and FCR in Japanese quails.

Author[4] observed that BWG, of male broiler during different weeks was no influenced by (BP) Black Pepper (TUR) Turmeric or their Combination.

From this study we observed improved with Biochemical parameters, the result showed a reduction in cholesterol $P<0.05$ and increase with T.G. $P> 0.05$ but no significant with total protein, maybe due to active Fatty acid such as oleic acid palmitic acid and essential oils such as Linalool that Lowered cholesterol by hepatocytes. Table 3.

The study showed that a significant reduction for two enzymes of the liver GOT and GPT $P<0.05$ Compare with the control and no significant with ALP enzyme. Table 4. that medicinal herbs and spice maybe contribute to decrease liver damage.

The result unagreed with author[18] who observed that TUR supplementation alone was not significant with total cholesterol.

Present study indicated that growth and TSH hormones had significant increased $p<0.05$ compare with the control.

Growth hormone are protein and contribute to grow the bird to quickly. It is responsible for growth of the body including bones and help for increase metabolic process, as well as TSH hormone are principal hormone responsible for attainment the growth. Table 5.

Result of Table 6 deal with immunity test for chickens treated with different medicinal herbs and spice, and all chickens were vaccinated with N.D. only, and we found

a significant differences and increased antibody value against N.D. compare with the control, P<0.05 and no significant antibody against IB. Author [15] observed the chickens immunized with Eimeriaprofilin protein and fed diets supplemented with carvacrolcinamaldehyde and capsicum oleoresin or turmeric oleoresin and capsicum oleoresin had increased body weights and antibody levels compared with unimmunized and infected chickens Feda non Supplemented diet.

Conclusions

From this project, it is concluded that supplementation of medicinal herbs and spice as watery extraction for Broiler chicken improving Body weight, Body weight gain, Feed Consumption, Feed Conversion ratio and reduction of Biochemical such as cholesterol and as well reduction ofliver enzymes with enhanced the immunity of the birds.

Recommendation: Added medicinal herbs and spice for Broiler chickens enhanced flavor of the Feed and stimulate the digestive enzymes activity that improved B.W., B.W.G., F.C., F.C.R. and reduction the cholesterol, enzymes GOT, GPT.

The Author suggested that used the medicinal herbs and spices contribute for enhance daily body weight gain, gave reduction for liver enzymes and cholesterol as well Author suggest that herbs improving growth and TSH hormones to boost the metabolism and enhance the immunity of the birds .

Conflict of Interest: None of the authors have any conflicts of interest to declare.

Source of Funding: The research was performed independently, there is no funding, influence over study design, analyses, manuscript preparation, or scientific publication.

Ethical Clearance: The project was approved by the local ethical committee (College of Agriculture,University of Sumer).

Diagnostic Study and Some Pathological Aspects of Parasites Associated with Appendicitis in Al-Najaf Al-Ashraf Governorate

Sahira Ayed A. Al-Musawi

Medical Lab. Analysis Department, Kufa Technical Institute, Al-Furat Al-Awsat Technical University, Iraq

Abstract

The study is intended to investigate the parasites that existenec and accompany appendicitis after its removal in the surgical department at al-Sadr Educational hospital and Al-Hakim General Hospital in Al- Najaf Al-Ashraf Governorate for the period from October 2017 to April 2018. The results of the current study of the appendectomy samples showed that 45 parasite samples were infected with 128 parasites (35.15%), the highest percentage of enterobius vermicularis (28.8%), and Ascaris lumbricoidis (22.2%). Entamoeba histolytica (17.7%), Entamoeba coli (13.5%), Giardia lamblia (11.3%), Cryptosporidium (6.5%), and male infection The parasite appendicitis was 55.6%, while the female infection rate was 44.4% 6 years had the highest incidence of parasitic appendicitis (33.3%), and the lowest rate of infection was in the 65-56 age group (4.4%).

Keywords: *Parasites, inflammation, appendicitis, Al-Najaf Al-Ashraf, worms.*

Introduction

Acute appendicitis is one of the most common cases of invasive surgical surgeries worldwide[1] . The appendix is known It is a tubular structure or a small, irregular cavity. There is a lot of lymph nodes in the wall, which is like a large intestine. Of four primary serological layers (serosa) Outside and then the muscle layer (muscularis) And under mucous (submucosa) And to the mucous layer inside (mucosa), The Appendix differs from the large intestine by containing fewer and fewer glands and the hollow walls of the coliform strips, as well as the internal tissue content of the appendix is not as new as the other histological content of the digestive tract . In addition to being a closed cavity, it is a suitable place for the growth and multiplication of different types of pathogens Including parasites, and for these and other reasons they are often susceptible to inflammation that may develop to a degree leading to inflammation of the abdominal cavity [23]Considered a protozoa And worms are a cause of many symptoms and disorders such as vomiting, abdominal pain, diarrhea, intestinal obstruction, rectal rectal inflammation, appendicitis and intestinal ulcers [45]**.** the presence of intestinal parasites in the appendicitis cavity and subsequent activity may cause in some cases symptoms of appendicitis without infection by[6], I pointed out a lot of Studies have shown a close relationship between appendicitis and the presence of types of parasites in them such as ***Ascaris lambricoides*** and ***Enterobius vermicularis*** **and Schistosoma spp and Taenia spp**[7]

Materials and Method

Collection of Samples: Was collected 128 Of appendicotomy samples after resection in the surgical section of Al Sadr Teaching Hospital and Al Hakim General Hospital In the province of Al-Najaf Al-Ashraf Governorate for the period of October 2017 Until April 2018, And the samples were placed in special containers containing NaCl 0.9% Until diagnosis.

Examination of Samples: The appendectomy was performed longitudinal and was visually examined

using a magnifying hand lens to diagnose and observe mature worms in the appendage cavity. The samples were then examined in several ways to identify the types of parasites present and their stages. precipitation And Direct smear method And the method of Floatation According to **[9,10]** Data on the sex and age of patients were recorded .

Results

Numbers and percentage of parasites that cause appendicitis: The results of the current study of the appendectomy samples showed that 45 parasite samples of 128 samples were infected with 35.15%. The highest incidence of *Ebterobius vermicularis* was 28.8%, while *Ascaris lumbricoidis* was 22.2%, *Entamoeba histolytica* was 17.7%, *Entamoeba coli* was 13.5%, *Giardia lamblia* was 11.3*%, Cryptosporidium* was 6.5%, as shown in Table (1).

Table No (1): Numbers and proportions of parasites that cause appendicitis.

Type of parasite	Number of injured	Percentage
Enterobius vermicularis	13	28.8
Ascaris l umbricoidis	10	22.2
Entamoeba histolytica	8	17.7
Entamoeba coli	6	13.5
Giardia lamblia	5	11.3
Cryptosporidium	3	6.5
Total	**45**	**100%**

Relationship of appendicitis with parasites by age and sex: The results of the current study showed that the incidence of male appendicitis was parasitic 55.6%, While the percentage of infection in females 44.4%, And recorded age group 45-36 The highest incidence of parasitic appendicitis was 33.3% The lowest incidence was in the age group 65-56 year it was 4.4%, as shown in table (2).

Table (2): Relationship between parasitic appendicitis, age and sex .

Age Categories	Sex	Samples Infected		Total Infected Samples	Percentage
		The Number	%		
15-10	Female	1	2.2	4	8.8%
	Male	3	6.6		
25-16	Female	4	8.8	7	15.4%
	Male	3	6.6		
35-26	Female	5	11.1	10	**22.2**%
	Male	5	11.1		
45-36	Female	6	13.3	15	33.3%
	Male	9	20		
55-46	Female	4	8.8	7	15.4%
	Male	3	6.6		
65-56	Female	0	0	2	4.4%
	Male	2	4.4		
Total	**Female**	**20**	**44.4%**	**45**	**100%**
	Male	**25**	**55.5%**		

Discussion

Results of the current study showed that the ratio of 35.15% Of appendicitis is caused by a parasite, and this result is consistent with some studies, where he noted [8] That the percentage of renal parasites in cases of appendicitis reached 64%, As consistent with the results a study [9] Which showed rates of injury of 39.7% Samples of excised, recorded [10] Proportion of its approach to infection with parasites to study samples reaching 34.8%, While the results of the current study did not agree with other studies such as the study[11] As it recorded a lower percentage 16.2%, As well as record[12] Percentage of total injury hit 8%, While recording[13] The highest injury rate reached 79% .Although parasites are present in the

tapeworm tissue, this does not mean that the cause of the appendicitis is always due to the effect of parasites. It is common knowledge that people with appendicitis may show symptoms only after parasites enter the waste into the appendix.[14] However, to discharge the role of parasites in the incidence of infection, however, should be treated with parasites in excess of injuries appendicitis confirmed the parasite after surgery, in addition to a diagnosis of parasites of the family and those around the grave who are directly with him in contact, and should pay attention to personal hygiene and health care For people working in food factories and restaurants to reduce the spread of parasites as well as attention to water sanitation plants and the provision of safe drinking water, these factors help to reduce rates of appendicitis caused by parasites.[14] Poor economic and social conditions such as poverty, low drinking water supply, environmental and climatic conditions such as high temperatures and population density, as well as the biological and mechanical resistance to phylogenetic growth are all factors contributing to the transition and survival of protozoa And intestinal worms in the environment, and spread in different age groups and in both sexes[15] The record in the twentieth century atheist and high injury rates for appendicitis in industrialized countries in Asia, South America and the Middle East, compared with Western countries because of different environmental factors and exposure to injury [16] .

The current study showed that the incidence of the most common parasitic worm was *E.vermicularis* this result is in agreement with other studies.[17] Bowel injury *E.* The most common vermicularis in all parts of the world between the parasitic worms injuries[18], it should be noted that the eradication of APPENDICITIS does not necessarily mean appendicitis syndrome, because there is ambiguity and symptoms associated with some of the situations that could lead to an error in the diagnosis. Therefore, there must be increased vigilance in identifying possible cases of APPENDICITIS, especially the very young patients and adults because they have a high rate of complications which overlap with symptoms of APPENDICITIS[19].

It may be due to the difference in the rates of infection between males and females to the nature of community life where the presence of males outside the home and thus exposure to various types of microbes, including parasites, as well as eating fast food, which are often the cause of various types of injuries.

The results of the present study showed that the age group with the highest incidence is 36-45 Year where it reached 33.3% Of the total infection rate, while the age group 56-65 Year is the least injury where it reached 4.4%, And this result corresponds to its findings [2], In his clinical, clinical and pathological study of acute appendicitis cases in Babel governorate where the incidence rate was in the age group 40-31 Year 34.3% The highest rate of infection among the total infection rates for the other age groups, and is not consistent with the results of the study reached [14] Where the age group most affected in their studies are 20-35 Year.

Conclusion

It is concluded to Diagnosis of parasitic infections in appendix samples and their relationship with appendicitis surgically removed in Al-Najaf Al-Ashraf Governorate As well as to study of some pathological variables related to infection rates such as age and sex of the infected .

Chemical and Histological Study of Hexane Extract of Plant Capsella Bursa-pastori in Western Iraq

Saja Mahmoud Najem Al Rubaie[1], Nidhal Ibrahim Lateef[2], Ashwaqtalibhameed[2]

[1]Researcher, Anbar section,Ministry of Education, [2]Asistant Prof., College for women Education, University of Anbar, Iraq

Abstract

The study was carried out by extracting the aerial parts of the capsella bursa-pastoris plant and performing quantitative and qualitative detection of seven types of active compounds that exist in it because of its importance, its therapeutic ability and its effect as active antioxidants on the male reproductive system. The results of the qualitative and quantitative detection of hexane extract of the capsella bursa-pastoris plant showed the presence of polyphenols in high quantity (43.8) compared to other active compounds, soaps (11%), glycosides (0.55%), flavonoids (6%), tannins (0.88%) and alkaloids. (13.6%).The results of the analysis of hexane extract of the shepherd ki plant in mass chromatography gas mass - GC in that it contains many fatty acids where the highest percentage of fatty acid linolenic acid (31.38), while the lowest percentage of fatty acid palmitoleic acid (0.08) compared with other types of acids Fatty acids in the extract, and we arranged the fatty acids according to the retention period starting from the minimum duration of palmitoleic acid (14.36) to the highest duration of Eicosanoic acid (Arachidis acid) (22.41). The results of the study showed a significant increase of $p \leq 0.05$ for the second, third and fourth treatment compared with the control animals and the first treatment acetylcarnitin in the first and second duration of the testicular tubule diameters. The results indicated a significant increase of $p \leq 0.05$ height in the testicular epithelial lining epithelial cells. For the second, third and fourth treatment compared to the control and the first treatment for all durations, the results of the study showed a significant decrease p 0.0.05 for the first treatment acetylcarnitine compared to the rest of the treatments in all durations in the rate of elevation epithelial cells lining Testicular tubules.

Keywords: *Hexane, Capsella bursa-pastori, Western Iraq.*

Introduction

Medicinal plants are considered as alternative drugs in the manufacture of medicinal drugs because they have a wide range of effective chemical compounds as a treatment and have an effect on biological functions and metabolic processes without any adverse side effects compared to medicinal chemical treatments that have harmful side effects[(1)]; confirmed that there are numerous studies indicating the use of medicinal plants to cause certain physiological changes in different organs of the body. The chemical drugs manufactured to treat and strengthen fertility and reproductive performance in males have a lot of side effects [(2)], the use of plants as a drug to the early years of human development as medicinal plants and extracts work as therapeutic alternatives and a safer option and effective treatment alone or complementary Herbal medicine has attracted various social strata and has become a strong competitor for chemotherapy[(3)], Many medicinal plants require discovery to be used to treat cases of infertility, ED or infertility[(4)]. Capsella bursa-pastoris is a medicinal plant that uses the herb to lower the temperature, prevent bleeding and increase urination rate for Japan and China for many centuries. It is also used as a whole plant to treat nephritis resulting in kidney swelling. For eating fresh or after cooking in a section of countries and the whole vegetarian part is used as a tea in the narrowing of the vessels and stimulant and antidepressant and a major treatment against bleeding of all kinds for the uterus, lungs, stomach and kidneys as well as classified within the plants stimulating fertility [(5)] the continuous development in the extraction techniques of medicinal plants and

method of detection of their compounds according to the extraction method which was an incentive to conduct the study. Current use of hexane alcohol in the extraction of aerobic fractions of the capsella bursa-pastoris plant and investigation of its efficacy and quantitative and qualitative evaluation of hexane extract on histological changes of testis and cellular testicular activity by the production and composition of Tef and chemotherapy compared to male Swiss mice eggs.

Materials and Method

Plant collection, preparation and classification: The shepherd bag plant was obtained from the western part of Anbar and was classified in the grassland Desert Studies Center. University of Anbar Common name Shepherd Bag (capsule Pasteur) Capsella bursa- pastoris L.Medic.

The plant was dried by distributing it as a thin layer permeated by air in a strayed area without exposure to direct sunlight to protect the chemical properties by stirring twice daily.

Preparation of Capsella bursa-pastoris Plant Extract: The shepherd bag plant was obtained from the western part of Anbar and was classified in the grassland desert studies center. The common name is the shepherd bag (capsule Pasteur) Capsella bursa- pastoris L.Medic. The plant is exposed to direct sunlight to protect the chemical properties, stirring twice daily.

Preparation of Capsella bursa-pastoris Plant Extract. The extract of hexane alcohol was prepared according to the method [6]. The qualitative and quantitative detection of the active compounds of the capsella bursa-pastoris plant of Glycosides according to Evans (1999) and the extraction and estimation of Glycoside extractAlkaloids [7] and Alkaloids extract [8] and Tannins [9] and Tannins extract were carried out [10]. Flavonoids are also detected [11] Flavonoids were extracted and evaluated by [12] and saponin [13].[14]The detection, extraction and estimation of polyphenols[15,16].The quantitative and qualitative determination of fatty acids using GC-MS gas chromatography was done in a method [17].

Laboratory animals: In this study, Swiss egg mice brought from the National Center for Drug Control in Baghdad were placed in plastic cages for breeding of these laboratory animals and sawdust. The cages were cleaned and brush replaced twice a week. All crate.

The mice were subjected to suitable ventilation conditions at a temperature of 21-24 ° C and a light cycle of 14 hours of light and 10 hours of darkness.

Special dietary food consisting of (flour, wheat, corn, barley, bran, lime, salt, iodine, calvostonicmulti.v.) Was given to these mice and water was available continuously free to the mice throughout the experiment.

The animals were left for a week before the experiment began to cope with new conditions.

Preparing the required dosages for the shepherd's sachet: In this study, three different doses of shepherd's sachet were 0.02 mg/day, 0.04 mg/day and 0.06 mg/day based on the British Pharmacopoeia herbal dosage. A weight-sensitive scales weighing 0.2 mg, 0.4 mg and 0.6 mg in 10 ml of distilled water were used to dissolve these weights to reach the required concentrations of 0.02 mg/day, 0.04 mg/day and 0.06 mg/day. Oral dosage method.

Experiment design: This study was conducted on 150 Swiss white variants and the average weight (14-21) g at an average of 18 g and the age of (4-6) weeks. The study was divided into three test groups according to the duration of oral dosage two weeks - four weeks - six weeks.Oral dosage method was used using the rat dosage tool and each treatment contains 10 male mice. The ear loan method was used to teach the mice and then weights were measured before starting the dosage.Each test group consists of five parameters as follows

1. Mice orally dosed with distilled water
2. Acetyl-carnitine T1 10 mice with a concentration of 0.02% mg/day
3. T2 Capsella bursa-pastoris extract (10 mice) at a concentration of 0.02% mg/day
4. T3 Capsella bursa-pastoris extract (10 mice) at a concentration of 0.04% mg/day
5. T4 Capsella bursa-pastoris extract (10 mice) at 0.06% mg/day

Histological preparations Conducted by [18]

Results and Discussion

Capsella bursa-pastoris extract: The results of quantitative and qualitative detection of Capsella bursa-pastoris extract as shown showed the presence of polyphenols in high quantity (43.8%) compared to other active compounds, saponins (11%), glycosides (0.55%)

and flavonoids (6%). Tannins (0.88%) and alkaloids (13.6%).

Fatty acids in hexane extract geranium cyst germination: The results of the analysis of hexane extract of the shepherd ki plant in the gas chromatography device - GC in Table (1) and Figure (1) showed that it contains many fatty acids where the highest percentage of fatty acid was linolenic acid (31.38), while the lowest was for palmitoleic acid fatty acid (In comparison with the rest of the fatty acids found in the extract, we arranged the fatty acids according to the retention period starting from the lowest duration of palmitoleic acid (14.36) to the highest duration of Eicosanoic acid (Arachidis acid) (22.41) Table (2).

Dietary fat type and feeding period rather than fat level significantly affected testosterone production and testosterone absorption by male rats since a rapeseed diet rich in unsaturated fatty acids stimulated testicular function in mice [19].Dietary fats may affect testicular function as omega-3 fatty acids are positively associated with testicular function [20]. Nigellasative seeds contain nutrients such as carbohydrates, vitamins, minerals and proteins including eight essential amino acids as well as a lot of unsaturated fats such as linoleic acid and oleic acid.

Capsella bursa pastori sample by GC-MS:

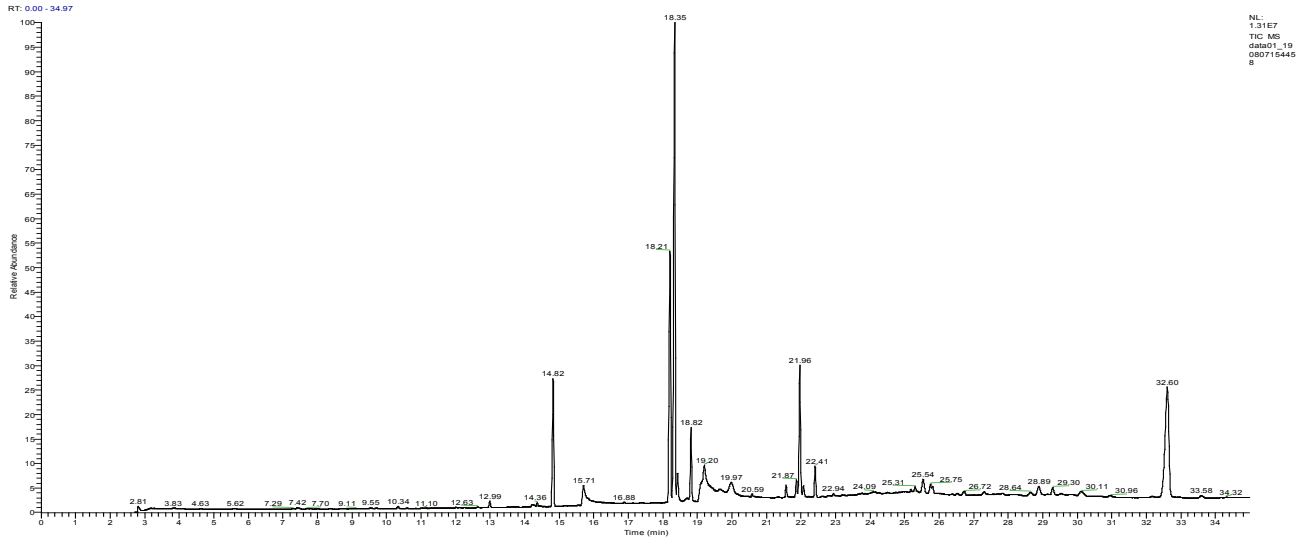

Figure 1: Illustrates the fatty acids present in the capsella bursa-pastoris extract by GC- (mass)

Table (1): Shows the fatty acids present in the capsella bursa-pastoris extract by GC- (mass)

Retention time	Compounds name	Content (%)
14.36	Palmitoleic acid	0.08
14.82	Palmitic acid	9.2
18.21	Linoleic acid	17.85
18.35	Linolenic acid	31.38
18.82	Oleic acid	4.07
19.2	Stearic acid	6.67
21.96	11-Eicosenoic acid	7.82
22.41	Eicosanoic acid (Arachidic acid)	1.56
	Other compounds	21.3

Testicle: The results of the study showed a significant increase of p≤0.05height for the second, third and fourth treatment compared to the control animals and the first treatment of acetylcarnitin in the first and second period of the testicular tubule diameters and the highest increase in the third treatment in the first period (38.0) and the second duration (37.4) (1).

The results indicated a significant increase in p ≤0.05height in the testicular tubule lining epithelial cells for the second, third and fourth treatment compared with the control and the first treatment for all durations, if the highest increase was recorded for the second treatment 11.8 and the third 12.40 and the fourth 15.9 for the three durations respectively.

The results showed a significant decrease ($p \leq 0.05$) reduction for the first treatment acetylcarnitine compared to the rest of the treatments in all periods was the highest decrease in the first period (7.43) and the second (8.03) and the third (12.2) in the rate of elevation of epithelial cells lining the testicular tubules, As for the germ cells lining the testicular tubule appeared in all types, especially the completed sperm, which contacted the upper apical part of the supporting cells as well as inside the middle cavity of the tubule of the sperm carrier pictures (1) for the first two weeks, The second period of four weeks showed that the germ cells that line the sperm transporting tubule in Sur [2] consist of layers that show various stages of the development of sperm sulfate and sperm cells of both primary and secondary types as well as spermatids. In the third six-week period, there was an increase in the diameter of the tubule transporting semen in the fourth treatment, where it exceeded the rest of the treatments and the control treatment $p \leq 0.05$. The Germ cells appeared in the form of layers showing all the stages of development and their numbers are many starting from sperm sulphate and primary and secondary sperm cells as well as vanguard sperm, while sperm appeared densely within the cavity of the spermatic tubule [3].It also agrees with [22] that containing sage powder is similar to the content of the shepherd's sachet of phenolic compounds, flavonoids, saponins and vitamins, which are antioxidants that help regulate cell metabolism and increase the effectiveness of enzymes and affect the secretion of testosterone, which has a role in The formation and transformation of sperm cells and also the hormone gonadotropin CSH, which stimulates the cells of your hand to secrete. It is also consistent with (23) that sesame seeds are rich in oils and protein and the most important fatty acid found is oleic acid, which is characterized by the highest percentage and linoleic acid, which used in diabetic mice to improve the thickness of the epithelium and tubular diameter of the seminal after six weeks treatment where It has been shown to have a protective effect against oxidative stress induced testicular function in diabetic mice.

Table (2): Effect of Capsella bursa-pastoris Extract in Different Concentrations on Sperm Diameter and Height of Epithelial Lining Cells ($P \leq 0.05$).

Picture (16) of the testicle of an animal with the extract of the capsella bursa-pastoris plant for a period of six weeks showing the heightSeminiferous tubules (S.T) show the complete maturation of the germ wall Height of epithelial ce The sperm carrier diameter (Ep.C.) and also the presence of mature sperm and sophisticated interstitial tissue (I.T) Haematoxyli dye and Eosin 1230.X.

Conclusions

The hexane extract of the capsella bursa-pastoris plant has an effective effect on raising reproductive efficiency by stimulating teticular development with less duration.

Formulation and Nutritional Appraisal of Renal Specific Formula

Sakphisutthikul C.[1], Sanchaisuriya P.[2]

Faculty of Public Health, Khon Kaen University, Khon Kaen-40002, Thailand

Abstract

Enteral diet formula has shown to be beneficial in hemodialysis patients, where otherwise the gut is efficacious in digestion and absorption of food but oral intake is not possible due to anorexia, and side effects of treatments. Long term enteral feeding programmed with extreme use of commercially available expensive enteral formula all pose a requirement of development of an low cost diet Formula. The objective of this study was to appraisal of formulation and analyze its nutritional composition in comparison to other commercial formula available in market. Material and Method: The renal specific formula was developed by undergoing to different procedures. Samples of two different enteral formula (one renal specific formula and one commercial) were collected from each hospital on three separate occasions and evaluated for nutritional value and cost. Results: The results were compared with the nutritional requirements proposed by the National Kidney Foundation's Kidney Disease Outcomes Quality Initiative (K/DOQI) and the European Society for Clinical Nutrition and Metabolism (ESPEN) to enteral renal specific formula. This study demonstrates that hospital prepared enteral renal specific formula render unpredictable levels of micronutrients and macronutrients and appear likely to deliver less than the desired amounts of nutrients. The analysis showed diets with a normal distribution of carbohydrates. The total amount of dietary fiber in the renal specific formula was between 12 g and 15 g. In commercial formula dietary fiber was 3.40 g. Concerning minerals, all formulations were appropriate in iron and most of them in calcium, phosphorus, and sodium. No formulation evaluated presented appropriate values of potassium and magnesium. Additionally, the viscosity of renal specific formulas may be unsuitable for infusion through feeding tubes. The cost of the enteral renal specific formulas ranges from 60 – 88 baht/feed Conclusion: Enteral renal specific formula offers an efficacious, nutrient dense alternative, with known specifications, to assist medical professionals optimize nutritional strategies and improve clinical outcomes within the complex etiology in renal disease patient.

Keywords: *Formulation, Nutritional appraisal, Renal, Specific formula.*

Introduction

Malnutrition is common in patients with chronic kidney disease (CKD), with prevalence ranging from 9% to 72% in dialysis patients.[1,2] Oral supplementation of malnourished patients undergoing hemodialysis [3-5] and peritoneal dialysis[6] may improve nutritional parameters. While the patient is being treated in the hospital, use of commercial formula makes it easier for the provision of energy, protein and all essential micronutrients. As many patients are from low socio-economic group, it may not be possible for all the patients to use ready to use, disease specific, and expensive nutrition products especially after obtaining discharge from the hospital.

Enteral tube feedings are commonly used in hospitals to provide nutritional support. While commercial, ready-to-use formulas have been available for over 20 years, many institutions prefer the use of Blenderized Tube Feedings (BTF). This preference may result from believing them to be more "natural" (physiologic) or more economical. BTFs typically contain common foodstuffs such as milk, eggs, meat, soft fruits, and vegetables that are pureed in a food blender or mixer. Other BTFs are made from a base of a commercial nutritional powder, which is reconstituted with water or other liquid. To this base, other foods may be added to modify the consistency or nutritional composition.

While BTFs appear to permit flexibility with regard to the selection of ingredients, and therefore nutritional content, problems with their use have been reported. Gallagher-Allred analyzed prepared BTFs for nutritional content, osmolality, and bacterial contamination[1]. An institutionally prepared "high calorie" formula expected to deliver 1.5 kcal/mL yielded only 1.0 kcal/mL on analysis. In addition, this "high calorie" formula did not meet the US Recommended Dietary Allowances (US RDA) for vitamin B_{12}, biotin, iron, and copper in 3,000 kcal. By contrast, commercial feedings designated to provide 1.0 kcal/mL and 1.5 kcal/mL met all nutrient standards and provided the expected caloric density.

The purpose of this study was to appraisal of formulation and analyze its nutritional composition in comparison to other commercial formula available in market.

Materials and Method

4 hospitals in Khon Kaen Province, Thailand were selected for participation in the study. The participating hospitals all used BTFs as a standard of practice for their enteral tube fed patients. Each hospital submitted two different enteral formula (one renal specific formula and one commercial). The providers of the recipes believed them to be nutritionally complete, providing all essential nutrients. Supplies used for the collection of the tube feeding samples (sterile containers, dry ice, cooler) were provided by Nutrition Division, Queen Sirikit Heart Center (QSHC) in the Northeast of Thailand (Khon Kaen Province) . Each hospital prepared at least one liter of BTF recipes. The recipes was analyzed using nutritional analysis software (Inmucal Version 2.0). Recipes for all feedings are shown in Table 1.

Cost Calculations: The cost of the feeds was calculated by using the market price of every ingredient in the feeds.

Table 1: Recipes for Renal Specific formulas

Hospital A	
Cooked rice	34.1 g.
Egg white	32.0 g.
Chicken Breast	32.0 g.
Gourd	162.0 g.
White cabbage	149.0 g.
Sugar cane	21.3 g.
Soybean oil	21.3 g.
Total 237 ml.	
1.8 kcal/1ml.	
Hospital B	
Mung bean noodle	72.52 g.
Egg white	127.98 g.
Chicken Breast	85.32 g.
Banana	106.65 g.
Pumpkin	127.98 g.
Sugar cane	29.86 g.
Rice bran oil	53.32 g.
Total 237 ml.	
1.8 kcal/1ml.	
Hospital C	
Maltodextrin	42.66 g.
Job's tear	106.65 g.
Egg white	85.32 g.
Nile Tilapia (Fish)	106.65 g.
White cabbage	100.25 g.
Rice bran oil	31.99 g.
Total 237 ml.	
1.8 kcal/1ml.	
Hospital D	
Maltodextrin	49.06 g.
Boiled rice	85.32 g.
Chicken Breast	127.98 g.
Egg white	170.64 g.
Apple	132.25 g.
White cabbage	127.98 g.
Sugar cane	10.67 g.
Soybean oil	29.86 g.
Total 237 ml.	
1.8 kcal/1ml.	

Results

The results were compared with the nutritional requirements proposed by the National Kidney Foundation's Kidney Disease Outcomes Quality Initiative (K/DOQI)[7], the European Society for Clinical Nutrition and Metabolism (ESPEN)[8], and the European Best Practice Guidelines (EBPG)[9] to enteral renal specific formula (Table 2 and Table 3) . This study demonstrates that hospital prepared enteral renal specific formula render unpredictable levels of micronutrients and macronutrients and appear likely to deliver less than the desired amounts of nutrients. The analysis showed diets with a normal distribution of carbohydrates. The total amount of dietary fiber in the renal specific formula was between 12 g and 15 g. In commercial formula dietary fiber was 3.40 g. Concerning minerals, all formulations were appropriate in iron and most of them

in calcium, phosphorus, and sodium. No formulation evaluated presented appropriate values of potassium and magnesium. Additionally, the viscosity of renal specific formulas may be unsuitable for infusion through feeding tubes. The cost of the enteral renal specific formulas ranges from 60 – 88 baht/feed

Table 2. Nutritional recommendations for Stage 5 CKD patients on dialysis

K/DOQI		ESPEN	EBPG
Energy	< 60 years: 35 kcal/kg/d ≥ 60 years: 30-35 kcal/kg/d	35 kcal/kg/d	30 - 40 kcal/kg/d
Protein	1.2 g/kg/d 50% high biological value	1.2 - 1.4 g/kg IBW/d	1.1 g/kg/d
Sodium	-	1.8 - 2.5 g/d	2,000 - 3,000 mg/d
Fluid	-	1,000 ml. + urine volume	-
Potassium	-	2,000 – 2,500 mg/d	1,950 – 2,730 mg/d
Phosphorous	800 – 1,000 mg/d or < 17 mg/kg IBW or SBW	800 – 1,000 mg/d	800 – 1,000 mg/d
Calcium	≤ 2,000 mg/d	-	2,000 mg/d

Table 3. Comparison of the costs and nutritional value of commercial formula with Renal specific formula.

	Commercial	Hospital A	Hospital B	Hospital C	Hospital D
Energy (kcal)	427	428.03	426.97	427.02	427.37
Energy Distribution					
Carbohydrate (%)	31.80	33.02	36.18	47.40	48.38
Protein (%)	18.00	16.29	19.21	18.71	18.57
Fat (%)	48.80	51.35	51.13	33.30	35.58
Fiber (g/100 ml.)	3.40	2.37	2.38	0.80	1.43
Modified mineral levels					
Calcium (mg./100 ml.)	106.00	26.50	17.89	64.18	55.12
Phosphorous (mg./100 ml.)	72.00	58.50	102.74	159.75	140.78
Iron (mg./100 ml.)	4.50	0.54	1.45	3.00	1.45
Sodium (mg./100 ml.)	70.00	80.40	144.27	124.49	258.01
Potassium (mg./100 ml.)	106.00	201.00	429.84	317.05	465.70
Magnesium (mg./100 ml.)	50.00	0.04	0.10	0.03	0.08
Zinc (mg./100 ml.)	6.40	0.20	0.51	0.23	0.50
Modified Vitamin levels					
Vitamin A (µg/100 ml.)	95.00	1.73	36.99	16.56	9.31
Vitamin C (µg/100 ml.)	25.00	15.70	10.80	19.07	15.70
Price/feed	120.00	60.00	65.00	88.00	85.00

The nutrient requirements for CKD patients are well known. Energy and protein requirements are well established, as are the requirements for phosphorus, potassium and sodium, although questions regarding quantities of other macronutrients and micronutrients have yet to be answered. Three major renal nutrition expert groups exist;. Each group has its own set of guidelines, however there is considerable agreement amongst them, which is a major advantage; Table 2 shows the recommendations for dialyzed CKD Stage 5, also known as End Stage Renal Disease (ESRD).

Because of the nutrient requirements and especially because of the mineral restrictions, the renal diet is infamous for its limitations on what foods can be consumed. Furthermore, dialysis patients (ESRD)

are recommended to restrict fluids (water, coffee, tea, etc.) which is intricately linked with salt/sodium restrictions[10]. Many CKD patients also have diabetes, and other comorbidities, so diet confusion is elevated as the renal diet can contradict diabetes dietary guidelines as well as general healthy diet guidelines. Therefore, the first criterion for a renal specific formula would be to adhere to expert guidelines.

Viscosity was uniformly much lower and more consistent for feedings prepared from powdered formulas and water (usually <10 cps) than for feedings prepared from blenderized whole food ingredients (19,090 – 38,175 cps).

Conclusion

Enteral renal specific formula offers an efficacious, nutrient dense alternative, with known specifications, to assist medical professionals optimize nutritional strategies and improve clinical outcomes within the complex etiology in renal disease patient.

Protein is possibly the single most important nutrient in relation to CKD. As noted by all three expert groups[7-9], at least 50% of the protein in a renal specific formula should be of high biological value. Using the latest protein scoring system recognized by the World Health Organization, the Protein Digestibility Corrected Amino Acid Score (PDCAAS), milk, soy and egg proteins are recognized as having the highest score[11]. In addition, there should be two protein level options/products for CKD patients; a higher level for dialysis patients and a lower level of protein for those not on dialysis. Furthermore, K/DOQI recommends a phosphorus to protein ratio for dialysis patients of < 10 mg/g[12]. This recommendation is difficult as many high biological value proteins are high in phosphorus. Phosphorus is essential for life; it is a component of genetic material, phospholipids in cell membranes, and breaking phosphorus bonds is how humans make energy. Phosphorus is also required for protein function and regulation, bone structure and blood acid-base balance. The importance of phosphorus is recognized by the expert groups[7-9], thus an intake of 800-1,000 mg/d is recommended. Casein, a milk protein contains 0.7-0.9% phosphorus[13], whey protein, another milk protein, contains 0.1-0.6% phosphorus[14], and soy contains approximately 0.8% phosphorus[15]. Currently no CKD specific guidelines for either the total lipid intake or the types of lipids exist; therefore, following current dietary guidelines for healthy people is the default option. Globally, healthy guidelines for lipid intake suggest saturated fat should be < 7% of total calories, unsaturated fat should substitute for saturated fat, increase n-3 (omega-3) fatty acid intake and aim for zero trans fatty acids [16,17]. Therefore, the criteria for the lipid blend used in renal specific formula should follow healthy guidelines and include the n-6 and n-3 essential fatty acids (linoleic acid and alpha-linolenic acid respectively), and have a lower n-6/n-3 ratio, contain monounsaturated fatty acids, be low in saturated fats and have zero trans fatty acids.

Choosing a renal specific product over a standard or other disease specific nutritional supplement is a better choice for the patient as it follows expert guidelines and opinion. The following table summarizes the key differences between a standard oral nutritional supplement (ONS) and a renal specific ONS. (Table 4).

Table 4. Key differences between a standard oral nutritional supplement (ONS) and a renal specific ONS for development of new product.

Component	Standard ONS	Renal Specific ONS
Protein	Not optimized for CKD stages	Higher protein for dialysis Lower protein for nondialyzed
Glycemic index	Higher	Lower for diabetes
Monounsaturated fatty acids	Lower	Higher
Phosphorous, Potassium, Sodium and Calcium	Higher	Lower
Fluid volume	Higher	Lower
Caloric density	Lower	Higher
Fiber	Lower	Higher

The Effect of Using Healthy Programmed Education on Learning the Basic Skills of Futsal in the Republic of Iraq

Salah Bresem Salih[1], Maytham Mohsin Habeeb Alhamdi[1], Mahmood Abd ALjaleel Abd[2]

[1]Lecturer, Ministry of Education, Missan Education Directorate. Missan, [2]Lecturer, Ministry of Industry and Minerals, Najaf, Iraq

Abstract

We have noticed in the recent years that there is a clear improvement in the practice level of football in general and Futsal in particular, Which consider the product of the scientific development of modern multi-purpose training method, which all world countries seek to prepare their trainers in a scientific way to aim of improving their athletes to reach the international levels,Scientific research is the best method which to check of the various scientific theories in the sports field and benefit from them to serve and develop sport.

In view of the development of science and knowledge in many sports fields, including football, the game has received a large share of the attention researchers, which reflected on the development of play styles, plans and laws that contributed to give aesthetic in the players performance and increase the enthusiasm of the public, and from among those method is Futsal, which is one of the game method being a basic pillar for its development, as well as its skills, plans, events and unexpected positions in the game works to excite everyone and excitement towards practice and viewing because of the ease of law and small stadium space, the small of players number and similar of the basic skills with the football skills (Soccer), which led to practice by a large number of players.

Keywords: *Healthy programs, basic skills, performance.*

Introduction

According to Taha Ismail(1), physical preparation has become one of the essential pillars of the annual training plan through its various stages and periods, It has been scientifically and practically emphasized the importance of the physical and technical skill side which cannot be separated at any stage of preparation as well as during the competitions.

In addition, we find that(2) explains that physical preparation is the most important element of the general preparation or one of the parts of the general preparation geared towards the development of fitness elements and raising the efficiency of the organs and the functional bodyorgans. Its generally goal is to acquire the physical and functional bases of the general and special type of sports activity to build high levels and achieve adaptation to the requirements of competitions through the exercises of quantity and quality that are fit with the player level and his age as well as the special activity type, and continue these exercises throughout the entire sports season (3).

Moreover, we can see that Mohammed(4)agrees that skill preparation is also one of the basic aspects of the training process in football. The proficiency level of skill performance is one of the indicators of the general skill ability (skill achievement) of the player, especially if similar this performance with the requirements of play positions during the matches, the skill performance of football represents a group of motor performance integrated with the ball and without a ball, which requires the implementation of the player's physical, cognitive and psychological capabilities integrated together to output this performance in the form and appropriate form of competitive position in the game, The skill performance is consider a crucial and important element with the availability of other preparation elements and constitutes an important basis for football players in controlling the playing during the match (5).

On the other hand, we notice that[6] ensure that it is necessary to upgrade some aspects of the player, such as physical side and development till upgrade many things and get the required technical level which performed from the player and there is always a difference in the players abilities, which makes one distinct from the other in the performance.

Also, we see that[7] explains that the skill performances in the football game means all the necessary and purposeful movements that lead to a specific purpose within the framework of the football law, whether those movements with ball or without the ball, and the player's proficiency is determined by the level of his handling of the ball and how to run and control The mastery of basic skills and the players ability to control and use the ball efficiently is the first basis to implement the plans, whether offensive or defensive, whenever the proficiency level of the player higher for the skill performance whenever high his value in the team, football is a collective educational sport requires that each player's performance complement the performance of the rest of his teammates, and this also applies on the basic skills till became each team fully diversified in the performance level of its players and thus become a good level of team[8].There is a clear and abbreviated division of the skill performances with the ball are:

1. Individual (single) performances
2. Composite performance (integrated)

The only skill performances: are performed individually and have a definite beginning and end, the effect and the introductory movement role in accomplishing the main duty of the skill are evident, These skills appear in the player's performance of the control skill on the ball (suck, mute, receipt), the side glide, throw ball out of bounds, passes, free kicks and corner and penalty. Composite skill performances: They represent models of different forms of a set of individual skill performances that merged with each other and overlap their end stages to form the beginning of the next skill performed by the player in a particular game position to achieve a specific goal according to his requirement. The motor activity of the football player is not only a single skill, but a set of individual skills that merged to become a multi-skill performance that is connected and interdependent among them, where the distinguished players direct to integrate process and melting individual skills inside the only integrate skill such as control the ball and running then pass where this includes integrated skills, i.e., abbreviated in terms of total time and the total area to perform thus become more connected performance [9].

There are some skill performances that depend mainly on the technique and technical style of performances and some other skills depend on the player's ability to respond to external stimulants related to others in actual competition situations and this is what happens in football as we note the emergence of some players are highly skilled in training but fail to show the same superior level during matches because they are unable to respond properly to different playing situations[10].

After conducting an analytical study to identify the most important of these composite skill performances (integrated) number of (10) composite skill performances are through direct pass from the movement (running). Receiving and passing (receiving and passing from movement). Receiving then run the ball and then pass. Receiving then dribbling and passing. Receiving with dribbling and passing. Receiving with dribbling then running the ball and passing. Receiving then running the ball then dribbling then passing. Receiving then dribbling then running the ball then passing. Receiving then running the ball then dribbling then run and pass. The same previous skill sentences but ending with the correction [11].

It is clear from the above that the physical preparation is an important pillar and an essential duty in Futsaland the modern football requires high capacity, where the players movementon the playground requires a great deal of physical abilities, in addition to the ability of accomplishing and control the ball throughout the periods of dealing with the ball, and to achieve the futsal's player the highest level of performance during the matches the player must be considered a completely physical preparation in the light of playing the game because the good preparation of physical players has a closely related to his mastery of the basic skills of the game and makes him perform competitions in a distinctive way because the skill and planning performance depends largely on the Physical competence of the player due to many factors, including the game nature, the game time, the size of the stadium space and the large duties lies on the player.

The studying process of any problem requires extensive knowledge and especial realization of the

problem type and basing on scientific grounds aimed at reaching the player to the highest levels, and in order to reach the player to high levels of sports in the performance of sports activities in general and futsal in particular, it requires a high level of skill performance and physical abilities, Through the researchers experience in the futsal training field have noticed that there is a very obvious weakness in physical and skills abilities of the players, and may be the reason is not to rely on scientific training programs to develop the physical qualities and skills and using the correct scientific evaluation for address these problems, therefore, the researchers see the need to develop effective training programs with using training means (Pleomorphic)and circular and cross training in order to develop some of the physical and skills abilities of futsal players for the deaf and mute.

The importance of the research is to identify the impact of the various training method (Pleomorphic, circular, cross) in the development of some physical abilities and integrated skills of futsal players, and through the reference research and access to Arabic and foreign studies within the researchers' knowledge limits, it was found that there are no studies have the various training method to develop some physical abilities and integrated skills of the players of the Paralympic Committee in Maysanprovince of futsal, this prompted the researchers to try to identify the impact of these method on the futsal players in Maysan and the relation of physical and developing the skill side of the players, which are clearly affecting the level of their performance while playing in the league.

The research aims to develop some of the physical abilities and skills performance of futsal players through; identify the impact of using the different training method to develop the physical abilities of the futsal players. In addition, though identify the impact of using the various training method to develop the skills performance of the futsal players.

Research Methodology: The researcher used the experimental method to design two experimental groups and the other controlled by using pre and post measurements to suit the type and nature of the research.

Research fields:

The human field:

1. **Research population:** The research population is represented by (44) players of the Paralympic Committee in Maysan governorate of futsal for the season 2017-2018
2. **Research sample:** The research sample was selected by deliberate random method from the players of the Paralympic Committee in the Maysanprovince of futsal for the season 2017-2018 and the number (30) were divided into two groups (control group, experimental group) The number of each group (15) players were taken into account in the selection of the sample in accordance with the following conditions.

Sample selection conditions:

1. Age between 15 and 17 years.
2. The player's height and weight shall be Proportional with the stage of the age under study.
3. Hearing degree should be 91 decibels (deep loss).
4. Free from diseases that effect of performance.
5. To be committed and continuing in training without interruption.
6. Paralympic Committee officials agree to conduct the experiment on the players.

Spatial field: The application of scientific transactions to calculate the validity and reliability of the test and the proposed program of the basic research sample on the stadium of the closed hall in the Technical Institute of Technology in Maysan

Time domain:

1. Scientific transactions were applied to calculate the validity and reliability of the test on Saturday, 4/11/2017
2. The test was repeated on Tuesday 14/11/2017
3. Pre- tests were applied on Thursday 23/11/2017
4. The basic study of the proposed program was conducted on Sunday 26/11/2017 until Wednesday 24/1/2018
5. The tests were conducted on Thursday 25/1/2018.

Discussion

There are statistically significant differences between the pre-measurement and post-measurement of the members of the experimental group in favor of post-measurement in the development of special physical abilities of the futsal players.

There are statistically significant differences between the pre - measurement and post-measurement of the members of the experimental group in favor of post-measurement in the development of the skill performance of the futsal players.

It is a training method through which a sudden lengthening (ie, decentralized contraction) which precedes the maximum central contraction where the muscle is lengthened and shortened and helps to develop and improve the explosive capacity, and this type depends on the muscle rubber to give them great kinetic energy, and plyometric exercises are divided into (exercises related to the limb) Lower body and upper limb) and may be performed by using or without tools and include (partridge, jump, leap) and other free exercises, which is a sudden lengthening of the muscle and then followed by shortening them.

It means doing different things for a lot of people. For some, it may mean the effect of training one side of the body on the other,for others it is an activity used to give active rest from an organized training program,for some, it means using things related to the main activity to avoid the negative results in organized training.

It is a regulation of physical effort to achieve a state of adaptation, where it operates through a predetermined path, with a group of activities and performances of the momentary stop at each training station to perform a specified number of repetitions of exercises, free activities, tools or weights according to a specific system.

It is the term used internationally for the game, which is derived from the Spanish and Portuguese language and is an abbreviation word of (football) which means football in Spanish and the word (sala) its internal meaning to be the term is football for the halls, and this term is an alternative to the previous term, which is called five-way football.

Abstract

The purpose of this study was to assess levels of anxiety among the Students of the High Healthy Vocations Institute, to find out relationship between students' anxiety levels and some socio-demographic characteristics such as (age, residency, marital status and department) of the Students of the High Healthy Vocations Institute. The period of the study was from April 2nd, 2019 to June 2nd, 2019). To meet the study objectives a questionnaire was constructed. This questionnaire consisted of two parts: the first part includes four demographic characteristics: age, residency, marital status, and department; the second part concerning with the test anxiety scale. The scale measures the most important symptoms that characterize the test anxiety. Data were analyzed by applying: descriptive statistical analysis: frequencies and percentages and distribution; and inferential analysis: Correlation Coefficient, Chi-squire. The findings of the study revealed that assessment of exam-related anxiety among the Students of the High Healthy Vocations Institute is moderately to severe level of anxiety. There was a significant relationship between severity of anxiety and age of the students. The present study recommends encouraging the students to learn some coping strategies and stress managements by attending training and relaxation sessions. Advice to regular recreational programs that include trips to reduce stress and to help them to prevent and lessen the stress associated with every-day life events stress.

Keywords: *Exam-Related Anxiety; High Healthy Students; Contributing Factors.*

Introduction

Anxiety is an unpleasant state characterized by feelings of tension and apprehension, worrisome thoughts and the activation of the autonomic nervous system when an individual faces evaluative achievement demanding situations[(1)]. Fear of exams and test situations is widespread and appears to become more prevalent and test anxiety has a negative detrimental effect on test performance[(2)]. If an examination particularly affects the person's carrier selection and future opportunities, it may be stressful. Exam anxiety prevalence has been reported as 10-41% in school aged children. Researchers have estimated test anxiety prevalence rates of between 15-20% for college students[(3)]. Exam anxiety is primarily a concern over negative evaluation, so defined as a subtype of social phobia in DSM diagnostic system. Many studies have reported an association between exam anxiety and anxiety disorders[(4-5)]. Psychological factors which contribute significantly to exam anxiety are negative and irrational thinking about exams, outcomes of exams and feelings of no control over exam situation (e.g., going blank during exam) are reported by many authors[(6)]. Higher anxiety levels in the student community are considered as important indicators for poor mental health[(7)]. The potential negative effects of emotional distress on students include impairment of functioning in classroom performance and clinical practice, stress-induced disorders and deteriorating performance[(8)]. Students in extreme stress need serious attention, otherwise inability to cope successfully with

the enormous stress of education may lead to a cascade of consequences at both personal and professional[9]. Moreover, studies suggest that test anxiety comprises of many negative effects such as low enthusiasm, poor performance, negative self-evaluation viewpoints and low concentration[10-11]. Researches on examination anxiety have the notion that examination anxiety prepares threats for higher institution students. Anxiety symptoms are distributed along a continuum and different symptom levels of anxiety and predict outcomes. Responses consisted of increase heart rate, stress hormone secretion, restlessness, vigilance and fear of potential dangerous environments. Anxiety prepares the body for physical, cognitive and behavioral instincts to detect and deal with threats to students examination survival and then result to students, beginning to be hyperventilate to allow more oxygen to enter into the blood-stream, divert blood to muscles and sweat to cool the skin[12]. Posited that the difference between generalized anxiety disorders and examination anxiety. He explained that general anxiety disorders are characterized by trait anxiety that results to students experiencing higher levels of stresses across a wide range of situations. Contrarily, students that are prone to examination anxiety have a state of anxiety that results to higher levels of nervousness that are specific to examinations. The symptoms of examination anxiety range from moderate to severe anxiety. Students who exhibit moderate symptoms are able to perform relatively well on examinations. On the other hand, students with severe anxiety experience panic[13]; the common physical symptoms include: headache, upset stomach, feeling of fear, feeling of dread, shortness of breath, sweating, pacing or fidgeting, crying, acing thoughts and blanking out. Lyness explained that during the state of excitement or stress, the body releases adrenaline[14]. Adrenaline is known to cause physical symptoms that accompany examination anxiety such as increased heart beat-rate, sweating and rapid-breathing. In many cases, adrenaline is good; it is helpful when dealing with stressful situations, ensuring alertness and preparation. But to some students, the symptoms are difficult or impossible to handle, making them impossible to focus on examinations. The topic of test anxiety has prospered, in part, due to the increasing personal importance of test situations for people inmodern society, making tests and their long-term consequences significant educational, social, and clinical problems formany. Since test results in most academic and occupational settings have important practical implications for a person's goals and future career, test anxiety is frequently reported to be a meaningful factor impacting upon test scores. This study aims to (1) assess levels of anxiety among the students of the High Healthy Vocations Institute; (2) find out relationship between students' anxiety levels and some sociodemographic characteristics such as (age, residency, marital status and department) of these students.

Method

A descriptive analytical design study is applied to assess the anxiety among the students of the high healthy vocation institute at Medical City. The period of the study was from April 2nd, 2019 to June 2nd, 2019. The study included a probability (Stratified random) sample of 70 students. To meet the study objectives a questionnaire was constructed. This questionnaire consisted of two parts: the first part includes the demographic characteristics of age, residency, marital status, and department; the second part concerning the Sarason test anxiety Scale [16] of 38 item self-report scale that assesses all symptoms of test anxiety. The scale encompasses four domains, each item of scale was rated (1= never, 2= rarely, 3= sometimes, 4= always). By applying the descriptive data analysis of Quartiles which determine the cut-off-points for the levels of anxiety which are Mild (38-103), moderate (104-115, (severe (116-148). Reliability of the questionnaire was determined through pilot study and validity determined through a panel of experts consists of (11) experts. Data were analyzed by applying descriptive statistical (frequencies, percentages) and inferential statistical (Correlation Coefficient and Chi-squire) through the SPSS (Statistical package for Social Sciences) version 21.0.

Results

Table 1: Participants' sociodemographic characteristics

Age		
Year	**Frequency**	**Percent**
≤ 9	19	12.2%
20-24	37	23.7%
25-29	7	4.5%
30-34	2	1.3%
35-39	2	1.3%
≥40	3	1.9%
Total	**70**	**100.0%**

Residency		
Residency		
Baghdad	60	38.5%
Outside Baghdad	10	6.4%
Total	**70**	**100.0%**
Marital Status		
Marital Status		
Unmarried	60	38.5%
Married	10	6.4%
Total	**70**	**100.0%**

Department		
Department		
Nursing	40	25.6%
Midwifery	15	9.6%
Anesthesiology	10	6.4%
Emergency	5	3.2%
Total	**70**	**100.0%**

Most of the study sample 23.7% are of age 20-24-years, the highest percentage (38.5%) live in Baghdad, more than half (38.5**%)**are single, and the highest percentage (25.6**%)** are from the nursing students.

Table 2. Participants' levels of anxiety

Total No.	**Levels of Anxiety**							
	Mild		**Moderate**		**Severe**		**Total**	
	F	**%**	**F**	**%**	**f**	**%**	**F**	**%**
	35	22.4%	16	10.3%	19	12.2%	70	100.0%

There is different severity of Anxiety the students inflicted with; 22.4% have mild level; 10.3% have moderate level and 12.2%with severe level of Anxiety.

Table 3. Distribution of the sample according to the levels of Anxiety

			Levels of Anxiety			**Total**
			Mild	**Moderate**	**Severe**	
Age	≤ 19	F	11	4	4	19
		%	15.7%	5.7%	5.7%	27.1%
	20-24	F	18	6	13	37
		%	25.7%	8.6%	18.6%	52.9%
	25-29	F	3	3	1	7
		%	4.3%	4.3%	1.4%	10.0%
	30-34	F	2	0	0	2
		%	2.9%	0.0%	0.0%	2.9%
	35-39	F	1	1	0	2
		%	1.4%	1.4%	0.0%	2.9%
	≥ 40	F	0	2	1	3
		%	0.0%	2.9%	1.4%	4.3%
Total		**F**	**35**	**16**	**19**	**70**
		%	**50.0%**	**22.9%**	**27.1%**	**100.0%**

Less than a fifth(18.6%) of the age group 20-24 have severe level of Anxiety while just 1.4% of age groups 35-39 have mild level of Anxiety.

Table 4. Levels of Anxiety according to residency of the students participated

			Levels of Anxiety			Total
			Mild	Moderate	Severe	
Residency	Baghdad	F	32	14	14	60
		%	45.7%	20.0%	20.0%	85.7%
	Out Baghdad	F	3	2	5	10
		%	4.3%	2.9%	7.1%	14.3%
Total		**F**	**35**	**16**	**19**	**70**
		%	**50.0%**	**22.9%**	**27.1%**	**100.0%**

A fifth(20.0%) of the students who live in Baghdad have severe level of Anxiety while just 4.3% of students are living outside Baghdad have mild level of Anxiety.

Table 5. Participants' levels of Anxiety according to the marital status

			Levels of Anxiety			Total
			Mild	Moderate	Severe	
Marital Status	Unmarried	F	32	14	14	60
		%	45.7%	20.0%	20.0%	85.7%
	Married	F	3	2	5	10
		%	4.3%	2.9%	7.1%	14.3%
Total		**F**	**35**	**16**	**19**	**70**
		%	**50.0%**	**22.9%**	**27.1%**	**100.0%**

A fifth(20.0%) of the students group unmarried has severe level of Anxiety while just 4.3% of the married students have mild level of Anxiety.

Discussion

The most important consequence of this study is that the results of table (2) show that the students have different levels of anxiety. This result is supported by Clark and her colleagues (2000) found that the majority of subjects had high levels of test anxiety, as can be inferred from the results of the present study, the high and moderate levels of anxiety are higher than those of studies cited above. This difference may be due to several factors that have an impact on anxiety, such as different course contents, educational environment, test conditions, types of test questions and other factors[17].

The results show that the students are young and being around eighteen years old and of mid- aged and being around forty years old and have different levels of anxiety table (3). In addition, the age groups of (20-24) have more levels of anxiety (52.9%). This result is supported by McDonald (2001); Showed that fear of failing a test increased with age in American and Australian students, in studies that use specific test anxiety scales, anxiety levels typically increase with age, found that test anxiety levels increase through in younger and middle-aged students[18].

The study indicates that the students living in the City of Baghdad have more levels of anxiety 85.7% than the students living in the outside Baghdad table (4). This might be due to the long way those students need to reach to the institute everyday, but the other students live in places around the institute.

Regarding the marital status, this study shows that 85.7% of unmarried female students have more levels of anxiety Table (5). This is supported by Amuda and colleaguesinvestigated the relationship between marital status and test anxiety, academic performance of undergraduate students in the USA, the result showed that the single students more anxiety than married students. This means that marital status influences students' academic achievement and those that are married tend to do better than the single students[19].

Conclusion

The results of present study indicated that most of the students jointed in the study are of age twentieth and twenty-four; about half of them live in Baghdad; more than half are unmarried; and most of them are of the nursing department students. The study indicates that high percentage of those students have anxiety in different levels; about a quarter of them are with mild level, less than the quarter are with moderate level, and a twelve of the sample have severe level of anxiety. The study describes statistically significant association between age and severity of anxiety.

Recommendations: The researchers recommend the following:

1. The teachers should acknowledge the existence of test anxiety on the part of students and should take initiatives for its effective reduction. They should identify individuals with signs of stress and anxiety and should apply appropriate strategies to help them counteract these feelings.
2. Teachers should initiate discussions in the class about the feelings of anxiety and should take measures to reduce the sense of competition among them.
3. There should be some specific teachers training courses on managing test anxiety in order to make teachers aware of this complex issue and, hence, alleviate it.
4. Students should seek counselling before doing tests so as to increase their confidence.
5. Building on 2 above, group counselling sessions may be more beneficial. Such sessions enable students to share their personal experiences and copes strategies with others so that they know that they are not alone.

Conflict of Interest: The researchers report no conflict of interest.

Funding: This study did not receive any funding from any agency.

Ethical Clearance: A permission to conduct this study was obtained from the ethical committee in the College of Nursing, University of Tikrit.

Botox Effect on Sex Hormones and Lipid Profile of Females Rats

Sameera Jameel Tarfa

Assistant lecturer, Restorative and Cosmetic Department, College of Density University of Thi-Qar, Iraq

Abstract

The present study aimed to investigate the effect of Botoxon sex hormones level which including follicle-stimulating hormone (FSH), luteinizing hormone(LH)and progesterone in female rats and measurement of serum lipid profile. Two doses 0.1/animal and 0.2 ml/animal from Botox were used and the animals were injected intramuscular of botulinum toxin for 1 day as two doses only. The results showed a significant decrease ($P<0.05$) in the level of FSH and LH, with a significant increase the level of progesterone of the female treated with 0.1 ml and 0.2 ml of Botox compared with the control group. The results showed a significant increase in the level of cholesterol, TG, HDL, LDL and VLDL of the female treated with Botoxat dose 0.2 ml when compared with the control group. While,the female treated with Botoxat dose 0.1 ml there was no a significant in level of cholesterol compared with control group. Also, there was a significant decrease of HDL of female rats treated with Botox compared with control group. Injections of female rats with botulinum toxin are generally well tolerated and side effects are few. A precise knowledge and understanding of the functional anatomy of the mimetic muscles is absolutely necessary to correctly use botulinum toxins in clinical practice.

Keywords: *BOTOX; FSH; LH; Progesterone; Lipid profile.*

Introduction

Botulinum is a neurotoxin produced by the bacterium *Clostridium botulinum*, an anaerobic, gram-positive, spore-forming rod commonly found on plants, in soil, water and the intestinal tracts of animals[1]. There are seven recognized serotype (BoNT/A to/G) with the recent addition of another serotype, BoNT/X[2;3].

All serotypes interfere with neural transmission by blocking the release of acetylcholine, the principal neurotransmitter at the neuromuscular junction, causing muscle paralysis[2].

BoNT-A is the most commonly used serotype for medical application and was the first to be licensed for medical use. There are several commercially available forms; Botox (Allergan Pharmaceuticals, Parsippany, NJ, USA) is the most widely used and has the most medical applications. Each formulation varies slightly in structure, efficacy, duration,and safety profile[4]. The effect of BoNT is site specific; it is administered by local injection (subcutaneous or intramuscular)into the targeted area. It can be administered using endoscopic procedure and by injection directly through the skin. Given the high affinity of BoNT to cholinergic neurons, its effects are consistent and, given at a low dose, have limited systemic adverse effects[5]. Botulinum toxin was first used clinically in the late 1970s in ophthalmology to treat strabismus[1] and over the last 20 years has gained widespread use in conditions requiring inhibition of excessive muscle spasm.

The broad range of medical indications for botulinum toxin include treatment of movement disorders (e.g. spasticity, cervical dystonia), urological disorders (e.g. overactive bladder), dermatological conditions (e.g. axillary hyperhidrosis), as well as cosmetic applications. Botulinum toxin A inhibits the release of substance P

Corresponding Author:

Assistant lecturer, Restorative and Cosmetic Department, College of Density,University of Thi-Qar, Iraq
e-mail: samirajameel64@gmail.com

from the dorsal root ganglia of the rat[6] and iris sphincter of the rabbit[7]. Substance P is believed to sensitize primary afferents and promote local release of histamine and bradykinin, both known to excite nociceptors[8]. **Also, BoNT-A was used in medicine in 1977 for the treatmentof strabismus in children. Since then, it has been widely used for different conditions and by different specialties. It is best known for its use in the cosmetic industries**[9]. In 2002, the FDA approved the use of Botox (Botulinum toxin-A) for the cosmetic purpose of temporarily reducing glabeller forehead frown lines. The present paper aimed to investigate the effect of local injection of botulinum toxin on the level of reproductive hormones and lipid profile of female'srat.

Materials and Method

Experimental design: The study was carried out on 24 mature female rats (*Rattusnorvegicus*), aged as 10-12 weeks and weighing between 180 - 200 gm were obtained from Department of Biology,College of Science, University of Thi-Qar, Iraq. The animals were housed in a well ventilated 12 hrs light and 12 hrs dark cycles. The animals were divided into three equal groups, each group consist of (8) rats:

1. The first group(control group) injected with 0.9% NaCl.
2. The second group was injected with (0.1ml/animal/ day) of BOTOX.
3. The third group was injected with (0.2ml/animal/ day) of BOTOX.

Blood collection: After 30 days of treatment, the animals were sacrificed. Blood samples were collected by cardiac puncture, 5mL of blood were drawn from each animal of experimental groups, and put in tubes without EDTA, centrifuged at 3000 rpm for 15 minutes, and then serum was separated and kept in the refrigerator at -20ºC until the time of assay.

Hormone assay: Serum samples were analyzed for FSH and LH level, through solid phase ELISA based on the principle of competitive binding, using commercial kits from VEDALAB (France), while for measurement of progesterone using kit from Bio Meraux (France).

Measurement of serum lipid profile: The used reagents were supplied by Biolabo (France), and serum total cholesterol was measured according to[10],and serum TG was measured according to[11]. While, serum HDL was measured according to[12] and measurement of LDL and VLDL according to[13], LDL and VLDL concentration was measured as follows:

LDL = total cholesterol – (HDL + VLDL):

VLDL = serum TG/5:

Statistical analysis: Standard analysis of the data of different studied groups was performed using the computerized statistical program: The SPSS program (Statistical Program for Social Sciences). The results were expressed as mean± S.E. Analysis of variance (ANOVA) was used to compare the results of different groups. The differences are considered to be significant at the level ($P \leq 0.05$)[14].

Results

The results showed a significant decrease ($p<0.05$) in the level of FSH and LH of the female treated with BOTOX at dose 0.1 and 0.2 ml when compared with the control group. While the results showed a significant increase ($p<0.05$) in the level of progesterone of the female treated with BOTOXat dose 0.1 and 0.2 ml when compared with the control group (table 1).The results showed a significant increase ($p<0.05$) in the level of TG,,LDL and VLDL of the female treated with Botox when compared with the control group,while, the female treated with Botoxat dose 0.1 ml there was no a significant in level of cholesterol compared with control group. Also, there was a significant decrease of HDL of female rats treated with Botox compared with control group. (Table 2).

Table 1: Effect of BOTOX on sex hormones levels of female rats

Progesterone (mg/dL)	LH(mg/dL)	FSH (mg/dL)	Animal Groups

Discussion

The present study indicated the effect of Botox on sex hormones female rats by decreasing level of FSH and LH and increasing level of progesterone level compared with the control group. The indications for Botox have evolved beyond cosmetic use to urinary incontinence and muscle spasms. With this popularity come more potential adverse effects, which are known to be short-lived and involve general or extremity weakness and pain. Researcher findings present the first reported case of a potential severe adverse side effect affecting the pituitary gland and persisting over a year after the injection.

These results are in line with the findings of other studies which found that(Botox), Botulinum toxin inhibits neurotransmitter release by cleaving SNAP-25 and SNARE proteins[15]. These proteins are necessary for vesicular exocytosis and have been implicated in the release of hormones from the anterior pituitary. Similarly, Botox could have caused inhibition of ACTH release resulting in central adrenal insufficiency for patient. Central adrenal insufficiency is a severe but treatable condition. Being aware of this potential adverse event and further researching its mechanism can help diagnose and treat affected patients promptly. This mechanism for GH and prolactin release has made Botox a targeted secretion inhibitor to treat prolactinomas and acromegaly. In our results showed a significant decrease in the level ofFSH and LH and a significant increase in the level of progesterone of the female treated with BOTOX when compared with control group, as this side effect was documented when used difference of doses .While the side effect profile of long-term botulinum toxin injections has been well documented, especially in individuals with dystonia and spasticity[16;17].

Although commercially available preparations of BoNT have an excellent safety profile, especially for cosmetic purposes. Also, in our result we showed higher significant in lipid profile in animals groups injection with Botox, but, no significant in level of cholesterol in rats treated with 0.1 ml of Botox compared with control group and there was a significant decrease of HDL of female rats treated with Botox compared with control group. This result accept with several studies have reported that following multiple and higher doses of BoNT injections,there is evidence of interamuscular lipid accumulation as a pathological response[18;19]. Although the mechanisms are not known, several factors such as activation of satellite cells or alteration of muscle ultrastructure could promote this lipid accumulationdysferlin[18;19], an important muscle membrane protein, is deficient in limb girdle muscular dystrophies which leads to intramuscular lipid accumulation[20;21]. Additionally, treatment with acetylcholinesterase inhibitors such as pyridostigmine can restore synaptic function and aid in muscle strength recovery. As discussed above, after BoNT injections muscles have the propensity to accumulate lipid which may lead to underestimation of atrophy in these muscles[22]. In present study the lipid accumulation leads to increased cholesterol and lipid profile in the blood,the reason back to Dysferlin, an important muscle membrane protein, is deficient in limb girdle muscular dystrophies which leads to intramuscular lipid accumulation[20;21], this side effect was not documented. Some animal studies have focused on the atrophy-inducing effects of BoNTs; however, in this study showed when injection with high doses from Botox induced side effect on level sex hormones and lipid profile.

Regional Health Care: Does Give Benefits for Poor Communities?

Siti Nuraini[1], Riski Isminar Ardianti[1], Deddy Kurniawansyah[1]

[1]Lecturer of Accountancy Department, Faculty of Economics and Business, Airlangga University, Jl. Airlangga 4-5 Surabaya, Indonesia

Abstract

This research to observe implementation of the regional health care program of Banyuwangi Regency, especially in the implementation of pro poor budgeting in poverty alleviation and the benefits received by the poor. The method used in this research is descriptive qualitative with respondents and the informants are beneficiaries of regional health care, health offices and technical support officers at the village/urban village office. The results of this study indicate that the implementation of public health care in Banyuwangi has been going well. The poor health care program in Banyuwangi is more commonly called the Declaration of Poor Letter (SPM). Problems rise from the implementation of the SPM are convenience for some people who have access to village officials, so that they can have SPM. In addition to the single parent, the difficult rule which states that only family members in a Family Card that can take care of SPM. We suggest for regional goverments to increase human resources at the village level in SPM services. Most of the respondents, 95 percent stated that the regional health care program provides considerable benefits for the community, especially the poor.

Keywords: *Regional health care, Declaration of Poor Letter (SPM), poor community.*

Introduction

Regional autonomy system expects full participation of the community and regional government to be able to realize regional welfare and independence in development. The main problem of development is that poverty and the main goal of the central government and regional governments to reduce it. Poverty is an integrated problem with various other sectors such as health, education, infrastructure and community income. Decresing poverty is expected to improve the quality of development, therefore regional government look for the potential regional to reduce poverty and improve the quality of human development.

Poverty are factor of lack of capital, productivity in poor households so that they reduce spending in the education and health. Low-income people have relatively low spending in the health sector, adequate access to education that informs about health, nutrition and disease prevention.[1,2]Some research states that the health sector has an impact on human resources that has an effect on economic growth and has a positive impact in developed countries. This shows that the role of government in developed countries is greater in the health sector than in developing countries [3–5].

Public expenditure is intended for management to public needs creating public welfare. Welfare is determined by the source of income or adequate income by having jobs according to ability and talent. Besides that, the services needed by the people of his country not only the availability of public needs (water, electricity, health, education, security) but also other public rights to be eligible for life [6].

Pro poor budgeting are (1) a budget that directs the importance of development policies of the poor, (2) the practice budgeting policies that are design aimed at making policies, programs and projects that are pro-poor community, (3) budget policies whose impact can

e-mail: sitinuraini@feb.unair.ac.id

improve welfare and basic needs of the poor people. Pro-poor budget requires support through pro-poor policies which commitment from the government to prioritize poverty alleviation. In general, pro poor policy is a political action carried out with the aim of providing the allocation of rights and resources to individuals, organizations and territories that are marginalized by the market and the state. This can be interpreted that the policies taken by the government must emphasize the improvement that affect the problem of poverty. The realization of the allocation and distribution is to provide basic services in the form of education, health, housing and others[7,8]. Health capital can increase the return on investment devoted to education, because health is an important factor so that someone can attend school for learning. Longer life expectancy can increase returns on investment in education, while better health will lead to lower levels of education depreciation [9].

The human development index in Indonesia is quite low. One of the provinces with low human development index is East Java. East Java from 2010 to 2015 experienced an increase in the human development index even though it only ranged from 0.5 to 0.8. This shows that the efforts of each city/regency are very strong to realize a better community life. As one of the regencys in East Java, Banyuwangi Regency is one thatcommitted to reducing poverty by improving the quality of human development. The commitment of the government can improve the quality of public health, especially the poor. Although indirectly the population's health will improve quickly but government intervention in providing health services or health subsidies will have a good impact both the access of the poor to health services [3,10–12].

Increasing human development index of Banyuwangi Regency shows the commitment of the local government to improve the quality of education, health and community income as three factors making up the human development index. One form of this commitment is an increase in local government expenditure in the education and health sector. One of the policies set out in Banyuwangi Regent Regulation No. 28 of 2016 concerning Guidelines for the Implementation of the Regional Health Care program and Health Services through a Poor Declaration Letter. The regulation stated that the Banyuwangi Regency Government provided the Regional Health Care program (Jamkesda) for participants who were not included as Contribution Beneficiaries (PBI) participants and the National Health Care Program (JKN). With the support of local government programs, it is expected that access to health for the community, especially the poor, will be easy, because the facilities provided are not only for outpatient but also inpatient facilities. It is hoped that the community, especially the poor who need it, will be able to receive benefits from this local government program. For this reason, this study will examine the benefits received by the community, especially people with incomes below the average decent income in utilizing the Regional Community Health Care program, especially in Banyuwangi Regency.

Based on the situation analysis presented, this study looks for the implementation of the Banyuwangi Regency Health Care and its impact on the poor. Several studies on health programs from the government have been carried out such as the results of Wagstaff's (2011) research using the Benefit Incidence Analysis (BIA) in Vietnamese society found that health social care in Vietnam is more enjoyed by the rich than the program's goal to reduce poverty. While the Afghanistan Ministry of Health's research (2013) shows that public spending on health is still concentrated in Afghanistan Central Hospital, so there is still a need for grouping for government programs related to health. In China, Zhao (2019) found that since the adoption of NCMS the rural poor did not delay treatment to the hospital, so that they could receive treatment in a timely manner [10,13,14].

Material and Method

This type of research used in this research is descriptive qualitative research, which is research that emphasizes the quality of the process rather than just the final result. The approach used in this research is a descriptive approach that emphasizes the individual in understanding and creating his daily life. A descriptive qualitative research approach is more likely to explore information from sources and respondents directly and written narrative so that it is easily understood by other communities. The focus of research in qualitative research is useful in providing direction during the research process, especially at the time of data collection, namely to distinguish data relevant to our research goals. The focus of this research is the community receiving health care for the poor in Banyuwangi Regency in 2016. The limitations of the study year are due to the existence of a data system in the Banyuwangi Regency Health Office.

This research was carried out in Banyuwangi Regency within a period of one year with a sample

selection in the form of Regencys resulting from random purposive sampling based on Regencys with the largest recipients of health care for the poor. Subjects and sources of information in this study are the Banyuwangi Regency Health Office, Sub-District Officers and Village Heads, Officers at the village/urban level who are in charge of taking care of the Poor Statement and Recipients of Regional Health Care using the method of observation (observation) and in-depth interviews. In 2016 Jamkesmin recipients in Banyuwangi were 506 people, so researchers took samples to conduct in-depth interviews as 84 beneficiary program.

Findings: The health care program for the poor is a national program that is integrated with the regions. There are three criteria for the Jamkesmin program in Banyuwangi Regency, namely financing from the Central Goverment, funding from the East Java Provincial Government and from the Banyuwangi Regional Government. The Health Care Program for the Poor has been legally through Banyuwangi Regent Regulation No. 8 of 2017 concerning Guidelines for Implementing Health Services for the Poor in Banyuwangi Regency. This regent's regulation states that the health of the poor who are not included in the Contribution Beneficiary Participants (PBI) of the National Health Care Program (JKN) will be provided by the Banyuwangi Regency Government. The *Jamkesmin* Program in Banyuwangi is also called the SPM Program. The SPM program (Declaration of Poor Letter) is a letter or identity given to the community outside JKN membership that meets the criteria of being poor. The first process of issuing this letter was a recommendation from a local Household Head (RT/RW) which was strengthened at the Village/ Urban Head and known to the Sub-district Head. The second process is the issuance of SPM by authorized officials in this case the Social Office which has been legalized by the Health Office.

The financing of this health program includes funding for outpatient and inpatient care at health service centers and hospitals in collaboration with the Banyuwangi Regency Government, including Health Center, Blambangan Regional Hospital, Genteng Regional Hospital and East Java Provincial Hospital. Financing of this SPM program is fully charged to the Regional Development Budget of Banyuwangi Regency on condition that there is no duplication from other sources. For people who get a Declaration of Poor Letter (SPM) can receive services free of charge valid for three months and when they have expired can be extended.

The SPM can be issued manually or electronically. SPM issuance is manually issued if the electronic publishing process cannot be carried out. The status of patient participation must be ensured from the beginning of entry to the Advanced Referral Health Facility (FKRTL) and given the opportunity to administer the SPM no later than 3 (three) working days after the patient is admitted to the hospital, if until the specified time the patient cannot show the SPM, the financing is stated as general patient. If the patient is in an emergency condition and has been hospitalized, the Health Center will issue a referral based on the Certificate of Hospitalization from the Hospital. This SPM is only valid for 3 (three) months from the date set. If the SPM is used when it expires, an extension must be made by carrying out all procedures from the beginning.The average time needed for the issuance of the SPM is around 1-2 days. This is in accordance with existing regulations that the opportunity to take care of SPM no later than 3(three) working days after the patient is hospitalized. However, based on the results of interviews with SPM user respondents, the SPM issuance process before 2017 is still done manually.

In accordance with the results of interviews with village officials, that the SPM submission by the applicant is required to bring a referral letter from the Health Center/Hospital after which the applicant completes administration and submits SPM requests to service officers at the village/urbanoffice. The village/ urban official will input data on the online SPM system so that the SPM can be issued.

Discussion

The problem that occurs when interviewing beneficiaries and health providers is that some people who submitted SPM have been treated at the regional hospital so that the village/urban is late in issuing SPM so that patients are not accommodated for financing health services. To anticipate this, some respondents stated that they made SPM without any health problems just in case. Another problem is the incomplete requirements submitted by the SPM applicant. The SPM can be issued even in the absence of a referral letter from the Health Center or Hospital due to the close relationship factor between the applicant and village officials. One of the reasons respondents use SPM as a precaution is because the person who can apply for SPM is the person concerned or family on a family card, it is quite difficult for respondents, especially single female parents and have children who are still not old enough. Although

according to the Health Department this method can reduce brokering practices but for single parents especially women it is quite difficult because besides they have to take care of sick family members, they also have to take care of SPM.

In addition, some respondents felt that not all SPM recipients were poor people. Some beneficiaries are believed to be capable communities, only because of the proximity to village officials, they have easy access to SPM. The lack of socialization in the community about the criteria of the poor and the criteria of SPM recipients also makes the community not fully understand the categories of the poor. On the other hand, the regional government through the Health Service seeks to provide health services to the poor evenly and on target, not to cause double funding in the community. In addition to the SPM beneficiary criteria that have not yet been socialized, one of the obstacles is the area of Banyuwangi Regency. From the 2016 SPM beneficiary data of 506 beneficiaries, 60 percent of beneficiaries are located in areas close to the city, with a radius between 30-40 km. this reinforces the statement from the public that there is a lack of socialization about SPM.

From the positive side of SPM, the implementation of comparisons between the handling of SPM manually and online is very different. Managing SPM online in accordance with the statement of the village head and the health office only requires a maximum of one day. Meanwhile, according to the results of interviews with respondents, online SPM maintenance can take up to three working days, faster than the time needed for manual handling because it takes approximately one week. The differences in SPM maintenance need to be minimized so that all people are able to reach them. Besides SPM service officers at the village level also need to be added so that the task runs optimally. Most of the respondents, 95 percent stated that the regional health care program provides considerable benefits for the community, especially the poor.

Conclusion

From the results of this research it can be concluded that the Poor Public Health Care Program in Banyuwangi Regency from the Local Government Budget is called the Declaration of Poor Letter (SPM). Namely the health care program for the poor with beneficiaries who do not receive health care from the central government and others source. The implementation of the SPM program in Banyuwangi has several constraints, namely the SPM recipients who are not on target because of the tendency of alignments of village/urban officials, lack of human resources in carrying out online issuance of SPM and targets who are able families.

The Effect of Olanzapine on the Improvement of the Clinical Symptom of Schizophrenia

Sonny T. Lisal[1], Saidah Syamsuddin[1], Balgis[1]

[1]*Department of Psychiatry, Faculty of Medicine, Hasanuddin University, Makassar 90245, Indonesia*

Abstract

Administration of atypical anti psychotics (risperidone, olanzapine and clozapine) can improve cognitive dysfunction which occurs in schizophrenia patients. This study was aimed at analyzing the effect of olanzapine on the improvement of clinical symptom (the positive and negative symptoms) in schizophrenia patients. The study was observational with analytic approach on inpatient and outpatient schizophrenia patients in Wahidin Sudirohusodo Hospital and its networking. Subjects comprised of 30 samples who were divided into two groups: the risperidone group which consisted of 15 subjects and the olanzapine group which consisted of 15 subjects. The positive and the negative Symptom Scale (PANSS) was used to evaluate the psychopathological symptoms. The results showed that improvement of clinical symptom based on the decrease of the positive symptom of the PANSS was significant ($p<0.05$) since the 2nd week in both groups. However, comparison of the changes of the positive symptom of the PANSS after medical treatment showed that the decrease of the positive symptom of the PANSS was greater in the risperidone group compared to the olanzapine group ($p<0,05$). As for negative symptom of the PANSS between the two treatment groups showed that the decrease of negative symptom of the PANSS was significant ($p < 0.05$) since the 2nd week.

Keywords: *Risperidone, olanzapine, clozapine, positive and negative symptoms, Schizophrenia.*

Introduction

The course of schizophrenia consists of three phases. The first phase is the acute phase, characterized by the emergence of positive and negative symptoms, then followed by a stabilization phase, characterized by the relief of a symptom, and then a stable phase, characterized by reduced symptom severity.[1] Schizophrenia is a chronic, severe, pervasive mental disorder, which is characterized by hallucinations, delusions, and impairments in reality assessment. This disorder has a profound and influential impact on many lives and ultimately affects the quality of life of patients.[5,2] Several studies have been conducted to compare the advantages of atypical antipsychotics, since atypical antipsychotics have a brood effect in reducing psychotic symptoms with lower extrapyramidal side effects, leading to a better quality of life than typical antipsychotics.[3] Until now, schizophrenia was known as chronic disease. At the beginning, the goal of therapy is to control positive and negative symptoms in schizophrenia. A data published in 2013 showed that the prevalence of severe mental disorders in Indonesia such as schizophrenia reached around 400,000 people or 1.7 per 1,000 population, overall there was 1% of the population in the world who suffered from schizophrenia.[7]

Oral atypical antipsychotics are considered as the first line treatment, especially for people with newly diagnosed schizophrenia.[9] Atypical antipsychotics are also referred to as second generation antipsychotic (SGA). Included in this class of drugs are risperidone, olanzapine, quetiapine, clozapine and ziprasidone. SGA can suppress positive symptoms, improve cognitive dysfunction, improvesymptom which are refractory to typical antipsychotic treatment by blocking more 5HT2A

Corresponding Author:

e-mail: raizahgis@gmail.com
Mobile: 082291224941

receptor than dopamine inmesocortical pathway. SGA also blocks D2 receptors, resulting in more dopamine being released in the mesocortical pathway and causing an improvement in negative symptoms of schizophrenia. However, the affinity of each drug varies with various types of neurotransmitter receptors which in turn give different therapeutic profiles.[10,11,12]

Risperidone can improve schizophrenia, improve mood in schizophrenia and bipolar disorder. Serotonin has an important role in influencing dopamine but has different effects on each dopamine pathway. Serotonin inhibition occurs in the mesocortex pathway resulting in the release of dopamine in the body cells and axon terminal at post-synapse. This is why risperidone could improve negative symptom.[10] Lately, the use of atypical antipsychotic drugs was more often, with minimal side effect and could improve the positive and negative symptoms of schizophrenia patients.

Previous research[6,8] compared the administration of risperidoneand olanzapine therapy in schizophrenic patients. The results showed improvement for clinical symptoms of schizophrenia patients, especially the negative symptoms of patients who received olanzapine therapy compared to those who received risperidone therapy, meanwhile the administration of risperidone showed improvement in positive symptoms of schizophrenia compare to those who received olanzapine therapy.Since it is importance to determine the right antipsychotic from the beginning of therapy to ensure a good response for the improvement of symptoms of schizophrenic patients, researchers were interested in comparing the effectiveness of the two types of atypical antipsychotics most commonly used in Makassar, which arerisperidone and olanzapine.So far, there had never been any research on the comparison of these two types of drugs based on the positive and negative symptoms of general psychopathology of schizophrenia.

Materials and Method

Location and Time of Research: The study was conducted at Wahidin Sudirohusodo Hospital and its network and from June to August 2018. This study was an analytic observational study. Subjects of the study were schizophrenia patients who were inpatient and outpatient whomet the inclusion and exclusion criterias.

Method of data collection: Every schizophrenia patientswho met the inclusion criteria was included in the study and data was taken including name, gender, age, last education, occupation,history of the objects previous diseases. The subjects were divided into two groups, risperidone group treatment (group A), and olanzapine group (treatment group B). Each objects from both groups were assessed for PANSS scores before being given therapy with olanzapine or risperidone. The positivesymptom of the PANSS and the negative symptom of the PANSS scores were assessed for both groups in the 4th and 8th week.

*All data wa*s processed and analyzed by statistic program

Results

Thirty subjectsjoined the study, consist of fifteen subjects who were given risperidoneand fifteen subjects who were given olanzapine. The risperidonegroup was given 2 mg each 12 hours orally and theolanzapine was given10 mg each 24 hours orally. Measurement of PANSS scores for each subject was carried out at baseline, on the 2ndweek,on the 4th week and on the8th week of therapy.

The change of the positive symptom of the PANSS score inrisperidone group (A) andolanzapine group (B) by the Independent T-test showed that the positive symptom of the PANSS was greater in group A than in group B significantly ($p < 0.05$), which was respectively 14.6% vs 8.5%on the 2nd week, 26.1% vs 19.1%.on the 4th week and 40.1 vs 31.0 on the 8th week. Result of the paired T-test for each group showed a significant decrease of the negative symptom of the PANSS ($p < 0.05$) since the 2nd week, in both groups. The longer the treatment, the greater the changes of the positive symptom of the PANSS which were 14.3% vs 11.5% on the 2nd week, 32.8% vs 24.3% on the 4th week and 48.1% vs 36.1% on the 8th week respectively.

Table 1: Comparison of Positive Symptom of The PANSS and Negative Symptom of The PANSS at Various Lengths of Treatment

Variable	Length of Treatment	Group		P*
		A	B	
		Mean (SD)% Changes	Mean (SD)% Changes	
Positive PANSS	the 2nd week	14.6(8.6)%	8.5(5.7)%	0.029
	the 4th week	26.1(8.4)%	19.1(9.1)%	0.036
	the 8th week	40.1(11.7)%	31.0(8.9)%	0.024
Negative PANSS	the 2ndweek	14.3(8.4)%	11.5(7.1)%	0.318
	the 4th week	32.8(9.3)%	24.3(5.6)%	0.008
	the 8th week	48.1(11.1)%	36.1(6.9)%	0.001

* Paired T-test. A: risperidone group, B: olanzapine group. Source: Primary Data, 2018.

Paired T test was used to see change of the positivesymptom of the PANSS in the two groups because the data was distributed normally. There was a significant decreased of the positivesymptom of the PANSS ($p < 0.05$) since the 2nd week in both groups. The longer the treatment, the greater the changes of the positivesymptom of the PANSS, which were 14.6% vs 8,5% on the 2nd week, 26.1% vs 19.1% on the 4th week and 40.1% vs 31.0% on the 8th week respectively.

Table 2. The Effects of Both Treatment Groups on Positive Symptom of the PANSS Changes in Various Lengths of Treatment

Group	Length of Treatment	Decreases of positive PANSS			P*
		PANSS Value	Changes	% Changes	
A	the 2nd week	24.33(8.36)	3.73(3.6)	14.6(8.6)%	0.001
		20.60(6.87)			
	the 4th week	24.33(8.36)	6.67(3.96)	26.1(8.4)%	<0.001
		17.67(5.51)			
	the 8th week	24.33(8.36)	10.07(4.71)	40.1(11.7)%	<0.001
		14.27(4.96)			
B	the 2nd week	21.20(7.89)	2.13(1.51)	8.5(5.7)%	<0.001
		20.87(6.42)

		18.53(6.19)			
	the 8th week	21.20(7.89)	7.27(2.99)	31.0(8.9)	<0.001

* Paired T-test. A: Risperidone group, B: Olanzapine group. Source: Primary Data, 2018.

Result of the paired T-test for each group showed a significant changes of the negative symptom of the PANSS ($p < 0.05$) since the 2nd week. In both groups the longer the study, the greater the change of the positivesymptom of the PANSS which were 14.3% vs 11.5% on the 2nd week, 32.8% vs 24.3% on the 4th week and 48.1% vs 36.1% on the 8th week respectively.

Table 3. Effects of Both Treatment Groups on NegativeSymptom of The PANSS Changes in Various Lengths of Treatment

Group	Observation	Decrease of Negative PANSS			P*
		Values	Changes	% Changes	
A	the 2nd week	20.27(6.27)	2.80(2.40)	14.3(8.4)%	<0.001
		17.47(5.95)			
	the 4th week	20.27(6.27)	6.53(2.80)	32.8(9.3)%	<0.001
		13.73(5.04)			
	the 8th week	20.27(6.27)	9.93(4.71)	48.1(11.1)%	<0.001
		10.33(3.58)			
B	the 2nd week	21.20(7.89)	2.40(1.40)	11.5(7.1)%	<0.001
		18.80(7.19)			
	the 4th week	21.20(7.89)	4.93(1.58)	24.3(5.6)%	<0.001
		16.27(6.64)			
	the 8th week	21.20(7.89)	7.60(3.02)	36.1(6.9)%	<0.001

* Paired T-test. A: Risperidone group, B: Olanzapine group. Source: Primary Data, 2018

The difference in total PANSS score between the two groups was consistent ($p<0.05$). Comparison of the changes in the total PANSS score in groups A and B by the Independent T-test showed a reduction of total PANSS in both groups($p > 0.05$).

Table 4. Effects of Both Treatment Groups on Total PANSS at Various Lengths of Treatment

Group	Observation	Decrease in Negative PANSS			P*

		45.8(14.4)			

Discussion

This study showed that risperidone and olanzapine were both effective for the positive symptoms and the negative symptoms, but risperidone was superior in dealing with both positive and negative symptoms. Olanzapine, a thienobenzodiazepine derivative is an atypical antipsychotic drug which shows affinity for D1-D5 receptors, serotonergic receptor (5HT2, 3, 6), muscarinic receptors (subtypes 1-5), adrenergic receptors (alpha 1-2), and histaminergicreceptor (H1). Structurally, this drug resembles clozapine but has little difference in terms of its affinity. This drug is weaker than clozapine as alpha 1 and alpha 2 adrenergic agonists, and is slightly different as D2, D4, or 5HT2A receptor antagonists.[4]

Paired T-test was used to see the changes in the positive PANSS for both groups, and each group showed a significant decrease in positive PANSS ($p <0.05$)on

the 2nd week of therapy in both groups. The longer the treatment, the greater the changes in the positive symptom of the PANSS score,which were 14.6% vs 8.5% on the 2nd week, 26.1% vs 19.1% on the 4th week and 40.1% vs 31.0% on the 8th week of study. Risperidone and olanzapine improved ofthe positive symptoms in both groups (risperidonegroup and olanzapine group) starting from the2ndweek tothe 8th week (p = 0.001).

When the Independent T-test was used to see the difference of the positivesymptom of the PANSS score between the group given risperidone and the group given olanzapine, different results were obtained. The decrease of the positive PANSS was greater in group A (given risperidone) than in group B (given olanzapine) significantly (p <0.05)which were 14.6% vs 8.5% on the 2nd week, 26.1% vs 19.1% onthe 4th week and 40.1% vs 31.0%.

The changes in the positivesymptom of the PANSS score was higher in therisperidone group sincethe 2nd week (p = 0.029) and there were more clinical changes in the positive symptoms in the risperidone group compared to the olanzapine group onthe 8th week. This finding was consistent with previous study,[5] where risperidone have a greater affinity for D2 than olanzapine.

The paired T-test results for each group along the study showed a significant decrease in the total PANSS scores (p <0.05), seen from the 2nd week for both groups. This suggests that risperidone and olanzapine were equally effective for the negative symptoms. It was seen that the longer the therapy was given, the greater the changes in the negative symptom of the PANSS, which were 14.3% vs 11.5% on the 2ndweek, 32.8% vs 24.3% on the 4th weeks and 48.1% vs 36.1% on the 8th weeks.

This finding was not in consistent with the publication results,[6]on which those who received olanzapine was better for the negative symptoms compared to risperidone since the first 3 months of treatment. This might becausedby different sampling method, different subtypes of schizophrenic, where in this study most of the subjects were paranoid schizophrenia with positive symptoms dominated over negative symptoms and simplex schizophrenia with negative symptoms dominated over the positive symptoms thus affecting the assessment results. Another thing that might affect this outcome was the sampling which combined inpatients and outpatients, in where hospitalized patients were more often in acute phase and predominated with positive symptoms compared to the outpatients. In addition, the outpatients had more family attention and support than those who were hospitalized, thus affecting the results of the assessment of the negative symptoms. Due to the limitations of the study, were the author's ability, time of study and costs. There were several weaknesses in this study,the PANSS score was not measured regularly every week due to clinical symptoms of schizophrenia, and this study did not examine the side effects of medication and drug effects that was used to minimize the side effects.

Conclusions and Recommendations

This study showed that risperidone and olanzapine were effective for both the positive and the negative symptoms, but risperidone was better for both positive and negative symptoms. Subject who received risperidone experienced more positive and negative symptoms improvement compared to olanzapine. The researchers suggested that further studies should be carried out with bigger samples sizeand longer observation times. It was necessary to differentiate the treatment status of patients taken as a subjects whether they were outpatients or inpatients.

Ethical Clearance: Taken from Wahidin Sudirohusodo Hospital and Hasanuddin University committee.

Study of Some Virulence Factors of Candida Albicans Causing Intestinal Infection

Sozan Khaled Kadhum

Department of Biology, College of Education for Pure Sciences,Thi - QarUniversity, Iraq

Abstract

The incidence of systemic candidiasis which is caused by *Candida albicans* has increased so the present study sheds light on detecting some virulence factors of *Candida albicans* like production of phospholipases and proteinases, besides the adherence on epithelial cells (from human mouth) and drug tolerance were concerned. Proteinase enzyme was produced by 20 *C.albicans* isolates (47.62%) out of 42 isolates. On the other hand, 18 out of 42 (42.86%) isolates of *C.albicans* could produce the phospholipase enzyme. The ability of the isolates for attachment onto the surface of epithelial cells was studied and found that 39 isolates of *C.albicans* could adherence epithelial cells and 20 isolates recorded percentage 95- 98%. As the resistance to antifungals concerned, we found that 32 isolates of *Candida* were resistant to nystatin. Amphotericin B was the most effective against all isolates of *Candida*. Microscopic examination results of histological section taken from rats' intestine tissues that artificially infected with *C.albicans* which included degeneration, necrosis, hemorrhage.

Keywords: *Virulence factors, Candida albicans, Intestinal infection.*

Introduction

The fungal infections caused by yeasts has increased over the past several decades. Among them, the imperfect yeast *Candida albicans* and several related *Candida* species are importance as opportunistic pathogens in immunocompromised hosts and may cause life-threatening infections. [(1)].The ability of *C. albicans* to infect host issupported by a wide range of virulence factors so that *C.albicans* shows various mechanisms that are suggestive of virulence such as ability to form hyphae (germ tube formation and pseudo hyphae), capacity to adhere to mucosal surfaces; produces hydrolytic enzymes; proteinases which hydrolyze peptides and phospholipases which hydrolyze phospholipids[(2)]. *C. albicans* is polyphonic. *C. albicans* grows as ovoid "yeast" cells,when cultured in standard yeast laboratory medium, however, mild environmental changes in temperature and pH can result in a morphological shift to pseudo hyphal growth. When *C. albicans* cells are grown in a medium that closed to the physiological environment of a human host, they grow as "true" hyphae. These structures are often observedin invadingtissue[(3-4)]. *C. albicans* can cause two types of infections in humans: superficial infections and life-threatening systemic infections [(5)]. Adherence of *C. albicans* to host epithelial cells is a first step in the infection process,it is essential for colonization and mucosal disease. Colonization of mucosal surfaces is lead to disseminated Candidiasis [(6)].

Materials and Method

One hundred anof stool samples were taken frompatient with intestinal infection during the period of first of June 2015 till the end of April 2016. All samples were inoculated on the suitable culture media including (SDA, MRS, CHROM) agar. All plates were incubated aerobically at 37˚ C for 24 hr.

Yeast Identification: Single colonies were isolated from primary positive cultures and identified according to the criteria of[(7)], that were included the following tests: Morphological tests, germ tube test, production of chlamydospore, Gram stain, biochemical test sugar fermentation and assimilation test Chromogenic agar culture, growth at 45°C, API Candida system Diagnostic kit of *Candida*

Virulence factors tests:

Detection of protease production: *Candida albicans* isolates were inoculated the medium Trypticase Soya agar, after then the medium was incubated at 37˚ C for (24-48) hr., positive result it was observed when clear zone around the colony was appeared [8].

Detection of Phospholipase production: Yeast suspension was inoculated the Egg- Yolk agar medium after then the medium was incubated at 37˚ C for (24-48)hr., positive result it was observed when clear zone around the colony was appeared (8).

Adhesion assay:

1. Preparation of yeast suspension

- Apart of yeast culture which growing on SDA in aged 24 hrs was the transferred to test tubes, the test tubes containing SDB and incubated at 30˚C for 24 hrs.
- The yeast culture centrifuged at 500 cycle/minute
- The precipitated cells were washed by PBS then centrifuged them and washing three times
- PBS solution was added to precipitate cells until the concentration of cells became 1×10^5 by using heamocytometer[9].

2. Preparation of epithelial cells suspension

- By using cotton swabs the epithelial cells which found in buccal cavity endothelial cells were obtained from healthy women after washing their mouth by using sterile normal saline three times, then cotton swabs infused in PBS for 10 minutes
- The solution contain epithelial cells centrifuged at 300 cycle/minute and then washed it with PBS three times
- The PBS was added to precipitate cells to preparation epithelial supernatant with concentration 1×10^4 by using heamocytometer.
- The 0.5ml of candida suspension and 0.5ml of epithelial cells suspension were mixed in test tube and incubated at 37˚C for 1h in Shaking incubator 40 rpm.
- The mixture was centrifuged and washing with PBS three times then PBS added to precipitate cells to prepared supernatant.
- The supernatant was centrifuged at 1000 cycle/ minute for 5 minutes, then PBS added to precipitate cells
- Drop of supernatant cells was taken and spread onto clean slid then let to dry and fixed by flame. The percentage of epithelial cells attached by yeast cells were calculated as flow: Adherence percentage = the number of epithelial cells attached by yeast cells /total epithelial cells × 100. (9).

Susceptibility to antifungal agent's tests: It was used for study yeast susceptibility toantifungal agentsDisk diffusion method thatby transferred part of colony of yeast were grown in SDA by loop to test tube that contained 5 ml of normal saline and count the fungal cells by using Haemocytometerto obtain concentration 1×10^5, and then transferring 0.1 ml of the yeast suspension has been spread on the surface of Emmons medium plate and left to dry. Antibiotic disks have been placed and incubated for 24 hr. at 37^0C, Then the zones of inhibition have been measured using a ruler and compared with the zones of inhibition determined by National Committee for Clinical Laboratory standards (NCCLS, 2003) or [10]

1. **Yeast suspension:** *Candida albicans* that contained most virulence factors. obtained from a culture on SDB medium and incubated for 24 hrs. at 37 ˚C, cells were precipitated by centrifuging and the sediment was suspended in normal saline to result 5x 10^5cell/ml [11].
2. **Intestine Candida inoculation:** Rats were given 5x 10^5cell/ml in drinking water from day 1 to day 15 induce intestine inflammation. Inoculated control rats were oral gavage inoculated with sterile PBS [11].After 24 hr of injection the rats were divided into four groups each group contain 10 rats, group 1,2 and 3 were prepared to study *Candida* infection and group 4 as control group, animal of each group were killed after (5, 10, and15)days.Then the rat scarified after 15 days and removed intestine tissue then fixed with 10% formalin.

Results and Dissection

Isolation and Identification of Candida spp: Out of 100 stool samples,95 isolates of Candida specieswereisolated from patient with fungal intestinal infection and diagnostic 8 isolates of candidaspp from 30 stool samples as control group. The types and numbers of these isolates, listed in (Table 1), were identified by using the CHROMagar, Biochemicaltests, API20.

The majority of *Candida* species amongst the Candida isolates were *Candida albicans* (44.4%)followed by *C. tropicalis*, *C. krusei*, *C. parapsilosis*and *C.glabrata.* The color used to identify the *Candida spp* figure (1). *C. albicans* isolates produced green smooth-type colonies after incubation for 24, 48 and 72 h. the present study found CA to be useful for the identification of non- *C. albicans* species. This agreed with [12] who found that the chromogenic agar medium can be identification of not only *Candida* species but also othere medically important non *Candida*yeast species, based on the development of coloured colonies. [13]Foundthat Chromogenic*Candida* Agar to be the most effective for distinguishing between different *Candida* species.The identification of clinically relevant yeasts by chromogenic medium is highly reliable and can be used as an accurate alternative to conventional identification method[12].

Table 1: Frequency of isolation of important Candida spp.

Types of Candida	Number of Isolates		
	Healthy (%)	FII	%

Detection of virulence factors for *Candida* species:

Adherence ability: The results showed that the ability of *Candida spp* for attachment onto the surface of epithelial cells andshowed that the highest percentage of adherence was for *C.albicans* 98% and fallowed by *C.tropicalis* 95% while the lowest percentage of adherence was for *C.glabrata* 72%. The results showed that 39 isolates of *C.albicans* could adherence on oral cavity epithelial cells and 20isolates recorded percentage 95- 98% (Table, 2), (Figure, 2).

90-94	8
85-89	11
Total	39

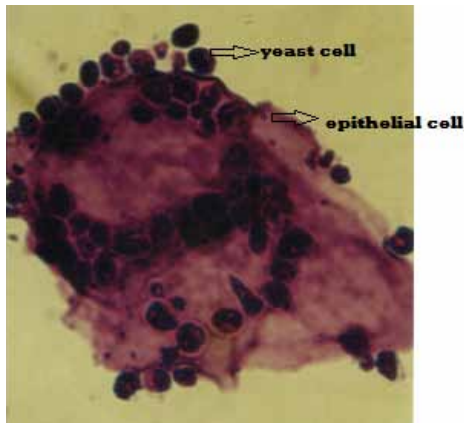

Figure 2: epithelial cells attached by Candida albicans yeast cells, slid staining by sfranine (Light microscope, 100x).

Resistance of C.albicans to antifungal agents: Sensitive test for all isolates of *C.albicans* was done against four antifungal agents (Amphotericine B, Miconazole, Econazole, Nystatine) by cell diffusion method and the results are compared with [10]. *C.albicans* showed the major resistance to Nystatine with percentage 76.19 followed by Econazole 71.43 Miconazole 66.7 and then Amphotericin B 42.86 (Figure,3). The result was close to the result of b[14] who showed that Nystatine had the highest percentage of resistance reached to 57.5% compared with other antifungal agents. The mechanism of resistance will be different depending on the mode of action of antifungal compounds. Cellular and molecular mechanisms supporting resistance against antifungal classes[15-16]. Resistance was probably due to a decrease or lack of ergo sterol content in cell membranes. Mitochondrial dysfunction was one of the possible mechanisms by which azole resistance can occur in *Candida glabrata*and C.*albicans*[17] (Table, 3 A)

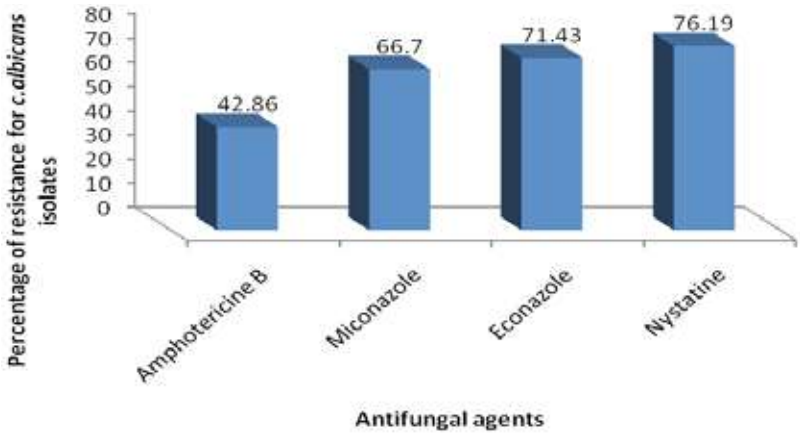

Figure 3: Percentage of antifungal resistance toC.albicans

Production of proteinase andphospholipase enzyme: The results revealed that proteinase enzyme was produced by 20 C.albicans isolates (47.62%) out of 42 isolates (Table 3 B). That is similar to the observation[18] who found that proteinase production was also seen in *C.albicans* (82.1%).proteinase activity was detected in *C. albicans, C. tropicalis*, and C. *parapsilosis*[19]. The non-*Candida albicans* produced more proteinase than *C. albicans*. *C. albicans* produced higher levels of phospholipase than non-*Candida albicans* in the study of[19]. The enzyme phospholipase was produced by 18 out of 42 (42.86%) isolates of *C.albicans*. The result is close to the result of [20] who detected Phospholipase activity in 75% (9 out of 12) of the *C. albicans* isolates. Several studies have shown that phospholipase activity is observed only in *C. albicans* strains[21]. However, otherresearchers described that other *Candida* species such as *C. glabrata*, *C. guilliermondii*, *C. tropicalis*, *C. famata*and *C. inconspicua* secreted smaller amounts of phospholipase[22]. Phospholipase enzyme digests the host cell membrane phospholipid causing cell lysis and changes in the surface features that enhance adherence and consequent infection and hence phospholipase production may be used as one of the parameters to distinguish virulent invasive strains from non-invasive colonies[22].

Table 3: A. Ability of candida albicans to produce proteinase and Phospholipase enzyme. B-Antifungal sensitivity of C.albicans.

A. Ability of *candida albicans* to produce proteinase andPhospholipase enzyme.								
Number	Amphote-ricin B	%	Miconazole	%	Econazole	%	Nystatine	%
R	18	42.86	28	66.7	30	71.43	32	76.19
S	24	57.14	14	33.3	12	28.57	10	23.81

B- Antifungal sensitivity of *C.albicans*.				
Types of enzyme	Positive	%	Negative	%
Proteinase	20	47.62	22	52.38
Phospholipase	18	42.86	24	57.14

Conclusion

As resistance to fungi involved, it was found that 32 isolates of *Candida* were resistant to nystatin. Amphotericin B was the most effective against all Candida isolates.

The Effectiveness of National Early Warning Score (News) as Predictor of Mortality in Heart Failure Patients in Emergency Department

Srikandi Puspa Amandaty[1], Siswanto[2], Asti Melani Astari[2]

[1]Nursing Master Program, [2]Lecturer, Faculty of Medicine, University of Brawijaya

Abstract

Introduction: Heart failure is one of the global health problems for society characterized by a high mortality rate, increased hospitalization and rehospitalization. National Early Warning Score (NEWS) is one who has the EWS development of physiological parameters include pulse rate, systolic blood pressure (SBP), respiratory rate, body temperature, level of consciousness (AVPU), oxygen saturation and the use of supplemental oxygen in the range of 0-3 on each parameter

Objective: This study aimed to analyze NEWS effectiveness as a predictor of mortality of heart failure patients in the Emergency Department (ED)of General Hospital of Dr. Slamet Martodirdjo Pamekasan.

Method: This study using observational analytic design with prospective cohort approach. The respondents in this study were 64 patients in *quota sampling*. The research instrument is observation sheet. ROC analysis and multivariate used multiple logistic regression test

Results: ROC test showed that NEWS has value of p=0.000 and AUC of 0.856 which describes NEWS can be a strong predictor related mortality in heart failure patients with CI of 95%, sensitivity value of 0.85 (85%) and specificity of 0.818 (81.8%). Logistic regression analysis explained the SBP became independent variables that most associated with mortality of heart failure patients with Exp(B) of 10.208 which describes the high score of SBP has greater risk 10.208 times to death compared with a normal score of SBP after controlled by SPO_2.

Conclusion: NEWS is an effective predictor of mortality of heart failure patients.

Keywords: *National Early Warning Score, heart failure, mortality, ED.*

Introduction

Heart failure is one of the global health problem for society characterized by a high mortality rate, increased hospitalization and rehospitalization[1]. Patients with heart failure who have the condition decompensation come with a return visit to the installation of emergency and have high rates of hospitalization, resulting in an increase in health care costs[2]. WHO (2016) recorded more than 17.5 million people in the world die of cardiovascular disease[3].

Based on data from basic medical research in 2013, the prevalence of heart failure are diagnosed by a doctor or symptoms by 0.3%, or about 530 068 people, with a prevalence of heart failure is based on the highest diagnosis in Yogyakarta (0.25%), followed by East Java (0.18%), while the prevalence of heart failure in North Sulawesi (0.14%), the prevalence of heart failure increases with age and the highest prevalence occurs at age 65-74 years (0.5%) and are more prevalent in urban areas[4].

The treatment of patients with heart failure remains a problem for doctors and nurses in the ED, in terms of setting priorities, monitoring and assessing on an ongoing basis on the condition of the patient, and provide support to patients and families in a limited time[5]. One of strategy for detecting deterioration of non-trauma patients in

the ER is the implementation of Early Warning Score (EWS). National Early Warning Score (NEWS) is one of the development of EWS by the Royal College of Physicians that have physiological parameters include pulse rate, systolic blood pressure, respiratory rate, body temperature, level of consciousness (AVPU), oxygen saturation and the use of supplemental oxygen in the range 0-3 on each parameter. NEWS recommended to assess patients in acute pain conditions[6]. Currently there are limited studies that address the application NEWS in heart failure patients in the ED. EWS research in the ED just focused on predicting mortality and referral to the ICU and the study was conducted retrospectively[78].

Based on preliminary studies, the number of visits a patient in the ED of General Hospital of Dr. Slamet Martodirdjo Pamekasan in 2017 as many as 15.689 patients, while in 2018 until September as many as 111.276 patients. Heart failure among the 10 major diseases in the ED in 2017 until 2018. Interviews with ED nurse that there are some patients with heart failure who suddenly experience worsening and nurses require early detection system to predict the deterioration of the patient so that they can be addressed early and prevent death. Therefore, this research needs to be carried out.

Methodology of Research: This study used observational analytic design with prospective cohort approach. The respondents in this study were 64 patientsin *quota sampling*. The research was conducted in the ED of General Hospital of Dr. Slamet Martodirdjo Pamekasan. The research instrument is observation sheet. ROC analysis and multivariate used logistic regression test.

Research Result:

Table 1: Characteristics of Respondents based on NEWS, Age, Systolic Blood Pressure, Heart Rate, Respiration, Temperature and Oxygen Saturation

Variables	N	Mean ± SD	Min-Max
News	64	6.83 ±2.815	0-13
Age	64	58.25 ±14.46	25-85
Systolic blood pressure	64	154.36 ±37.33	95-261
Heart rate	64	97.36 ±21.69	53-149
Respiration	64	27.02 ±4.981	16-40
Temperature	64	36.5 ±0.61	34.9-38.5
Oxygen saturation	64	94.08 ±4.25	77-100

Table 1 shows the highest NEWS is 13 and the lowest is 0 with the average value is 6.83. The oldest respondent is 85 years old and the youngest is 25 years old with an average of 58.25 years old. A maximum systolic blood pressure on patients is 261 mm Hg and the lowest is 95 mmHg with an average of 154.36 mmHg. The maximum heart rate of patient is 149 and lowest is 53 with an average of 97.36. The maximum respiration rate on patient is 40x/minute and the lowest is 16x/min with an average of 27.02x/min. The highest temperature of the patient is 38.5^0C and the lowest is 34.9^0C with an average of 36.5^0C. The maximum oxygen saturation of patient is 100% and the minimum is 77% with an average of 94.69%.

Table 2: Characteristics of Respondents based on Gender and Mortality

Variables	Category	f	%
Gender	Male	32	50
	Female	32	50
Mortality	Die	20	31.2
	Survive	44	68.8
Level of consciousness	Alert	58	90.6
	Verbal	2	3.1
	Pain	3	4.7
	Unresponsive	1	1.6
Oxygen	Use	61	95.3
	Do not use	3	4.7

Table 2 describes the gender of the respondents have an equal number of male and female with each number of 32 people. The survive respondents in this study were 44. The most respondents with alert awareness level were 58 people. The most respondent that use oxygen were 61 people.

Table 3: Description The Value of Area Under Curve (AUC) of NEWS

	AUC	Std. Error	p-value	CI 95%	
				LB	UB
News	0.856	0.059	0.000	0.741	0.971

Table 3 shows the NEWS has a value of p=0.000 and the AUC of 0.856 which describes NEWS can be a strong predictor related to mortality in patients with heart failure.

Table 4. Cut off Point, Sensitivity and Specificity NEWS

	Cut off Point	Sensitivity	Specificity
NEWS	6.5	0.85	0.818

Table 4 shows the cut off point of NEWS is at a point 6.5 which means that the detection of mortality of heart failure patients in the score of 6.5 with the sensitivity of 0.85 and specificity of 0.818. The sensitivity of 0.85 indicates the NEWS abilityclinically to generate positive value or their mortality of heart failure patients by 85%. The specificity of 0.818 showed NEWS abilityclinically to produce a negative value or the patient's life in case of heart failure by 81.8%.

Table 5. The results of multiple logistic regression test between the scores of systolic blood pressure (SBP), respiratory rate (RR), temperature, oxygen saturation (SPO_2), level of consciousness (AVPU) and use of oxygen to mortality in heart failure patients in the ED

Variables	Coefficient	The p-value	Exp (B)
Step 1			
Systolic blood pressure	2.109	0.017	8.237
Respiratory rate	0.775	0.239	2.171
Temperature	0.613	0.307	1.847
SPO_2	0.987	0.016	2.684
Level of consciousness (AVPU)	7.276	0.999	1.445E3
The use of O_2	8.624	0.999	5.565E3
Constants	-21.939	0.999	0.000
Step 2			
Systolic blood pressure	2.118	0.017	8.318
Respiratory rate	0.810	0.210	2.248
Temperature	0.629	0.297	1.876
SPO_2	0.999	0.015	2.717
Level of consciousness (AVPU)	7.277	0.999	1.447E3
Constants	-4.812	0.013	0.008
Step 3			
Systolic blood pressure	2.177	0.021	8.816
Respiratory rate	0.771	0.267	2.162
SPO_2	1.100	0.004	3.003
Level of consciousness (AVPU)	7.352	0.999	1.560E3
Constants	-4.478	0.022	0.011
Step 4			
Systolic blood pressure	2.323	0.013	10.208
SPO_2	1.060	0.003	2.886
Level of consciousness (AVPU)	7.462	0.999	1.741E3
Constants	-2.529	0.000	0.080

Table 5 shown the final results of the multiple logistic regression test indicate the calculated value Exp (B) systolic blood pressure is 10.208, the value of Exp(B) of SPO_2 is 2.886 and the value of Exp(B) of the level of consciousness (AVPU) is 1.741. Based on the results of this analysis, the variables SBP became independent variables that associated with mortality of heart failure patients with Exp(B) value of 10.208 which describes high score of SBP has greater risk of 10.208 times to the death compared with a normal score of systolic blood pressure (SBP) after being controlled by oxygen saturation (SPO_2).

Discussion

The results of this study indicate that the NEWS is effective in detecting the occurrence of mortality in heart failure patients in the ER. Based on Table 5.4 shows that NEWS has the Area Under the Curve (AUC) of 0.856 (0.741-0.971), which means NEWS can be a strong predictor related mortality. Furthermore, the cut off point values of NEWS obtained at a point 6.5 which means that the detection of mortality of heart failure patients in the score of 6.5 with the sensitivity of 0.85 and specificity of 0.818. Supported by the positive predictive value of 0.68 indicates clinically NEWS ability to generate positive value or their mortality of heart failure patients by 68%.

According to the study results Alam et al., 2015 with a prospective design, explained NEWS as a good predictor of death with AUC value 0.768 (0.618 to 0.919)[9]. Powered studies Smith et al., 2012 retrospectively say that NEWS is an effective predictor to detect unexpected death compared with 33 EWS others with mean AUC value of 0.894 were strong[10] (Smith et al., 2012). The study by Pimentel et al., (2018) retrospectively to detect mortality in patients in the ER told NEWS has a value of 0.862 which means strong AUC as a predictor of mortality[11]. The purpose of NEWS including the assessment of acute illness, clinical deterioration detection, and enable timely clinical response. NEWS should be used for a preliminary assessment of acute illness and for further monitoring of patients during hospital stay. By NEWS regularly noted, the clinical response of patients can be identified when there is a potential patient's clinical deterioration and the need to obtain clinical care. Likewise Scoring NEWS will provide guidance on patient recovery and re-stabilized, thereby reducing the frequency and intensity of clinical monitoring to discharge patients[6].

NEWS has seven physiological parameters include heart rate (HR), systolic blood pressure (SBP), respiratory rate (RR), body temperature, level of consciousness (AVPU), oxygen saturation and the use of supplemental oxygen in the range of 0-3 on each parameter[6]. On multivariate analysis, obtained the variable component of the NEWS of the most influential is the component of systolic blood pressure (SBP) with Exp (B) 10 208 which describes score SBP high 10 208 times greater risk of death compared with a score of SBP normal after being controlled by the oxygen saturation (SPO_2).

Blood pressure is one of the hemodynamic parameters were simple and easy to do measurement[12]. According to Jones & Hall (2006), high blood pressure (hypertension) is an important risk factor for cardiovascular disease[13]. The results showed that patients with systolic blood pressure of 261 mmHg highest and the lowest was 95 mmHg with an average reach 154.36 mmHg. The study results Britton et al., (2009) says there is an increased risk of heart failure by 35% among subjects with systolic blood pressure of 130-139 mmHg compared to subjects with normal systolic blood pressure of 120 mmHg[14]. However, systolic blood pressure low (hypotension) an assessment of the worsening of the acute illness of the most significant because of hypotension may indicate compensation blood circulation due to a decrease in the volume of cardiac output, heart failure or heart rhythm disorders, and the effects of blood pressure lowering drugs[13], Low systolic blood pressure (<120 mmHg) at admission showed a worse prognosis. In the scoring system NEWS hypotension condition is given a higher assessment scores (a score of 1 and 2) than hypertension <200 mmHg given a low score (a score of 0). Described in severe hypertension (systolic blood pressure ≥200 mmHg), can occur as a result of the pain experienced by the patient but it is important to consider the impact of acute disease or be exacerbated by severe hypertension and selection of clinical measures[6].

Furthermore, oxygen saturation is a powerful tool for the assessment of pulmonary function and cardiac integrated[6]. Measurement of oxygen saturation is one of the non-invasive procedure using pulse oximetry are routinely be used in the clinical assessment of acute illness but are still rarely included in the EWS system. Because the measurements are considered practical, the oxygen saturation is considered as an important parameter in NEWS[6]. On the condition of heart failure with shortness of breath conditions can cause a decrease in oxygen saturation of the patient. In the

study Sittichanbuncha et al., 2015 says that the oxygen saturation including predictors of mortality. Oxygen saturation has a negative correlation with prehospital mortality[15]. In the results in Table 5.1 oxygen saturation values obtained for heart failure patients when entering the ED is 77-100%. There are still patients with heart failure had oxygen saturation below 94%. Studies have shown that the lower the patient's oxygen saturation owned by the increased risk of death in patients. Each 1% increase in oxygen saturation, it will be followed by a decrease in the risk of death by 8%[15]. By observing the oxygen saturation levels will be known needs oxygen delivery. Giving oxygen to patients would increase survival in patients so it will give good results. Oxygen saturation has a positive correlation with the amount of oxygen supplied which means higher oxygen levels given the higher levels of oxygen saturation[16].

Conclusion

NEWS is effective as a predictor of mortality of heart failure patients in the ED as well as systolic blood pressure (SBP) is the most closely related to NEWS parameters as predictors of mortality of heart failure patients in the ED.

Breast Cancer and Hormonal Level Changes

Suhad Kahdum Ali

Professor, Hammurabi Medical College, University of Babylon

Abstract

Purpose: Study of Surgical procedure used in treating Breast Cancers – Mastectomy, Bilateral Mastectomy and Adjuvant procedures and the rise in the blood hormonal levels of the breast cancer patients. The purpose of the study is to understand breast cancer and to delve into various factors that increase the risk of contracting breast cancer. It describes various surgical procedures like mastectomy, bilateral mastectomy and adjuvant procedures. It also describes the various serums that body secretes that can cause cancer. It sees the genetic factors and other risk factors that can cause cancer.

Method: It studied 30 breast cancer cases from private Clinicat Babylon. Only those patients who had undergone mastectomy or had tumors removed from breast were considered. These patients were in the age group of 25 to 65. Statistical data was arrived at by questionnaires and interviews with surgeons, nurses and patients. The paper also describes changes in the blood hormones of cancer patients. Complete blood tests were done on 30 patients that included the measurement of various serum and blood plasma cells such as Estrogen hormone, Progesterone hormone (Prog. H), Serum total cholesterol, Serum triglyceride, Serum HDL-cholesterol, the concentration of LDL cholesterol and other proteins in serum as IgG, IgM, and IgA.

Interpretations: Cancer if detected at a young age need not lead to mastectomy, but surgically removing tumors will suffice. As the age progresses the incidence of mastectomy and bilateral mastectomy also increases. The blood hormones of cancer patients showed abnormal readings and a conclusion can be drawn that BC can be detected from the abnormal levels of blood hormones.

Keywords: *Blood hormones, breast cancer, tumors.*

Introduction

According to Cancer.Net (2019)[2 & 3] Breast Cancer kills around 42000 women and at least 500 men every year. The number of women who are diagnosed for invasive breast cancer is approximately 268,600 in United States alone and 62000 women have in situ breast cancer. Though there have been many innovations in the medical science, women and to a lesser degree men continue to die or suffer because of this cancer.

According to Holst-Hansson, Idvall, Bolmsjö & Wennick, (2018)[12] say that cancer is gaining attention in Iraq as a significant health problem, this is because there is an increase in the cases of incidence as well mortality. Iraqi Cancer Board also echoes the same concerns. The reasons for the increase in cancer cases is attributed to many factors like improvement of case detection, early detection programs, rising awareness amongst the population and better registration of cases.

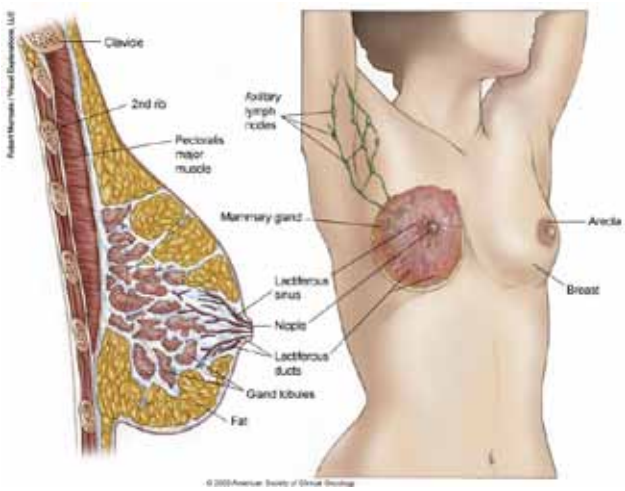

Fig. 1: American Society of Clinical Oncology.

Fisher et al (2014)[9] opine that breast cancer (BC) is kind of malignancy that appears in the tissues of the breast. It occurs in both pre-menopausal and post-

menopausal women. BC forms in those tissues of the breast that usually carry milk and milk producing glands called lobules. Females with a history of breast cancer are at a risk having breast cancer too. Fisher et al (2014)[9]

Malvia, Bagadi, Dubey & Saxena (2017)[8] opine that breast cancer (BC) starts with a development of tumor in the breast. There are 2 types' tumors benign and malignant.

Malignant tumors are aggressive and cancerous. In case malignancy is suspected the doctor will perform biopsy to understand the aggressiveness and severity of tumor. Coles et al (2017)[13]

Metastatic cancer happens when the cancerous cells of the malignant tumor spread to the other parts of the body via lymph system to form secondary tumors.

Anampa, Makower & Sparano (2015)[12] say that there is only one cure for advanced breast that is mastectomy, if cancer is detected earlier then only the tumor can be removed with some healthy tissue surrounding it called margin.

Cancer Detection: Hosseini, et al (2016)[13] says that detection of cancer is very difficult as normal hormones and chemicals that are useful to the healthy body go on to fuel cancer cells also. Some of them are listed below.

Estrogen: Estrogen which is essential for growth and normal development of breast and its tissues is known to cause cancer if there is a higher exposure of the hormone. 2 types of cancers can be formed when there is a high exposure to estrogen as genotoxin and mitogen. Samavat, & Kurzer, (2015)[11]

Lipids: It is believed that the changes in the lipid profile also causes cancer. Lipids have an important role in the maintenance of the cell integrity. It is hypothesized that when there are changes in the lipoprotein levels and plasma lipid there is malignant proliferation in the tissues of the breast. It has been further postulated that because of concentration in serum lipid in cancer patients can bring about increase production of tumor necrosis factor. Garg, et al (2016)[11]

HER_2:

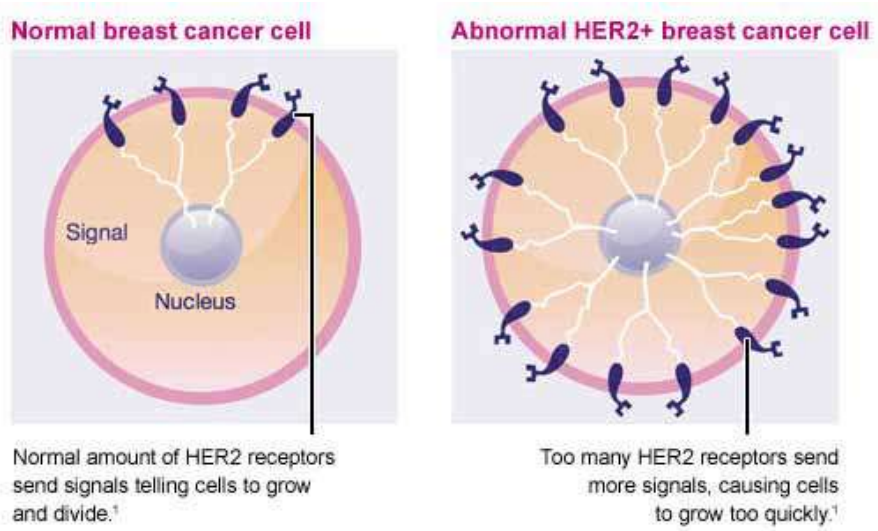

Fig 2. HER_2 (Source Cancer Research UK)

In fig 2. Shown HER_2/neu gene is a growth hormone. Healthy HER_2 receptors are proteins which are put in use when the breast cell grows, divides and in repairs. It was observed that in at least 25% of breast cancer patients this gene is not functioning properly. It makes excessive copies of itself in a process known as "HER_2 gene amplification." These extra cells then make the cells to make many HER_2 receptors. This is called "HER_2 protein overexpression." It is because of these processes that breast cells divide and grow in an uncontrollable fashion. Katayama et al (2019)[14]

The Lymph System:

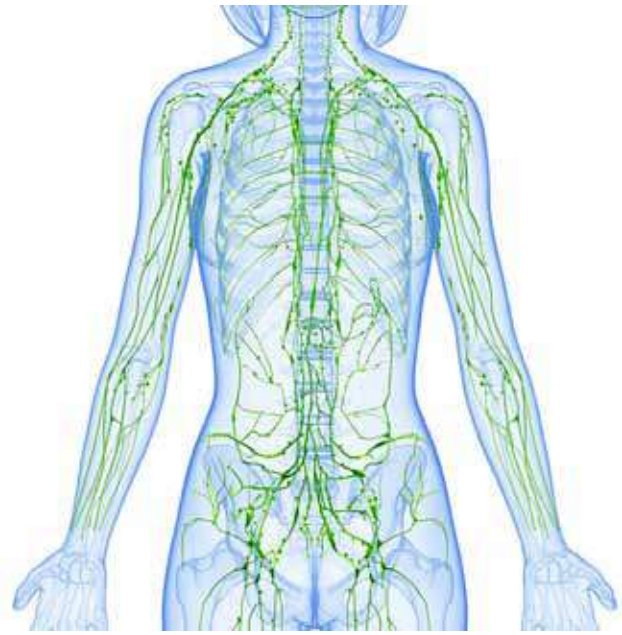

Fig 3. The Lymph Systems (Source cancer research UK.)

The network of lymph (fig. 3) nodes and lymph vessels run throughout the body and are part of the immune system. Just as the circulatory system of blood which distributes elements across the body. This system transports fluids and disease fighting cells.

Cancer cells typically grown in the ducts, lobules and the lobes within the lymph network. Katayama et al (2019)[14]

Genetic Factors: Lahart, Metsios, Nevill, & Carmichael, (2015)[15] say that the following genetic factors are associated with BC

- *Gender: Female*
- *Age:* 55.
- *Race:* Caucasian women are more vulnerable to BC than any other race.
- *Family History and Genetic Factors:* If there has been a case of cancer (either breast or ovarian) in the immediate family such mother, sister then the chances of having cancer increase. If the relative had cancer before 50 then the risk increases.
- *Personal Health History*: If the patient has been diagnosed with BC in one breast, then the chances of having BC in the other breast increases in the future. The risk also increases if abnormal breast cells have been found before (such as lobular carcinoma in situ (LCIS), atypical hyperplasia, or ductal carcinoma in situ (DCIS)).
- *Menstrual and Reproductive History:* Late menopause (after 55), Early menstruation (before age 12) having the first child at an older age, or if a women has never been pregnant also increases the risk for breast cancer.
- *Certain Genome Changes*: Mutations in some genes, like BRCA1 and BRCA2, can increase the risk of breast cancer. This is determined through a genetic test, which patients can consider taking if they have a family history of BC. Those who have these mutations may pass them to their children.
- *Dense Breast Tissue:* Dense breast tissue also increases risk for BC. It also makes the lumps harder to detect.
- Radiation therapy on the chest: If the woman has been given radiation therapy to the chest before the age of 30 then there is risk of contracting BC.
- Combined Hormone Replacement Therapy (HRT): Having combined hormone replacement therapy, as prescribed for menopause, increases the risk for BC and It also increases the risk that the cancer will be difficult to detect in the earlier stages.

Cancer treatment: Rheinbay et al (2017)[9]opines in case there is BC is found then the surgery is the only effective treatment. In case the cancer is detected in early stages then lumpectomy is done where only the tumour is removed and the rest of the breast is conserved.

Decision to perform mastectomy (removal of the breast) or lumpectomy (removal of the tumour) is done with through consultation and permission of the patient.

Nowadays there are better method to perform mastectomy which preserve the breast skin and allows for a natural breast appearance following the surgery.

When do doctors advise mastectomy?

- In case of multiple tumours in the breast
- There are widespread or malignant-appearing micro calcifications (calcium deposits) that have been identified as cancerous after biopsy.
- In case of recurrence of breast cancer after radiation therapy

- Even after undergoing lumpectomy; cancer is found on the edges of the operated area.
- The size of the tumour is large compared to the size of the breast
- In case of pregnancy where radiation will harm the fetus. Coles et al (2017)[13]

Material and Method

A cross-sectional of 30 female breast cancer patients both young and old from hospitals and daily clinics in Babylon province were studied. They were presented with questionnaires and the physicians and nurses were interviewed. Their ages varied from 25 to 65 as shown in the table and pie chart below.

Table 1 and pie chart about age of patients

Age	No. of patients
25-35	1
36-45	5
46-55	11
56-65	13
Gender	All females

Surgeries and Adjuvant procedures performed on the study group

Table 2.

Age	Mastectomy of single breast	Bilateral Mastectomy	Removal of tumor	Chemotherapy	Radiation Therapy
25- 35	0	0	1	1	0
36-45	4	0	1	1	1
46-55	7	3	1	11	11
56-65	8	5	0	13	13

Discussion on Surgical Procedures: The female aged 25-35 had tumour which was surgically removed, biopsy showed it was malignant in nature and so chemotherapy was prescribed to her. Hosseini et al (2016)[13]

Tumour also removed from 1 patient in the age group 36-45, but radiation was used before surgery to reduce the size of the tumour. Holst-Hansson Idvall, Bolmsjö, & Wennick, (2018) [12]

Tumour was also removed from the age group 46-55. All the patients had to undergo adjuvant procedures to prevent the disease from appearing again. Holst-Hansson Idvall, Bolmsjö, & Wennick, (2018) [12]

19 females had to undergo single mastectomy and also adjuvant therapy and 8 patients had to undergo bilateral mastectomy and adjuvant procedures to arrest the spread and re-occurrence of the disease.

Study of the blood samples for serum/hormonal imbalance

Blood contains different types of cells in definite proportions in normal human beings, however in case of diseases or infections these proportions change dramatically. The same holds true for cancer patients also. Therefore the hematological and bio-chemical parameters of these 30 women were also studied.

Findings:

Table 3 shows the results of hematological parameters received from 30 BC patients

TEST	Patient
ESR mm/hr	17.355 ±6.154*
WBC X103 /µL	4.509 ±0.8839*
RBC x106 /µL	4.372 ±0.7995*
Packed cell volume (%)	35.206 ±4.105*
Platelets X103 /µL	180.27 ±32.158*
Lymphocytes (%)	46.009 ±4.7399*

*Values expressed as Mean +/-SD P value <0.05 was considered as significant.

The mean red blood cell count, packed cell volume, platelets count, white blood cell count, and lymphocytes are lower than what is observed in healthy women. Whereas the mean ESR values of the breast cancer patients were considerably higher than normal healthy women.

Table 4: Biochemical parameters of 30 female BC patients

Test	Patients
Est. H (Pg/ml)	92.286 ±20.407
Prog. H. (ng/ml)	2.347 ±0.850
Cholesterol(mg/dl)	182.14 ±16.868
Triglyceride(mg/dl)	120.77 ±10.152
H.D.L. (mg/dL)	55.148 ±20.486
L.D.L. (mg/dl)	74.605 ±13.050
IgA (g/L)	3.550 ±0.411
IgM (g/L)	1.685 ±0.351
IgG (g/L)	18.478 ±1.834

*Values expressed as Mean +/-SD P value <0.05 was considered as significant.

Table 3 shows the biochemical profile (Mean ±SD) in women with breast cancer. The data indicated higher levels of estrogen and progesterone than normal healthy women. Also total cholesterol, triglycerides level HDL were at higher than normal healthy levels. LDL levels were lower than those found in healthy women. Immunoglobulin's IgG, IgA and IgM were also at higher than normal levels.

Discussion on blood tests: Physicians routinely use complete blood picture in diagnosing various diseases and infections like anemia, hemorrhagic states, cancers, allergic disorders and immunity disorders. Lahart, MetsiosNevill, & Carmichael (2015)[15] In this study the low hematocrit levels show that cancer patients are suffer from anemia. This observation is in sync with other studies of similar nature.

With regards to age BC patients above the age 40 have significant reduction in RBC count and hematocrit level than healthy individuals of the same age. Medicinal Chemistry[12] opine that this could be because these parameters tend to reduce after the 5th decade or it could be that because of cancer also causes immune suppression and bone marrow suppression. It is also found that BC tends to be more aggressive in the younger patients. The low blood counts can also be attributed to side effect of chemotherapies that patients had to undergo as post-operative procedure. Chemotherapy also reduces the lymphocyte and it is considered as an adverse effect of this procedure Anampa, Makower, & Sparano (2015)[12]

There is a significant increase serum estrogen in patients of breast cancer women than normal healthy women. These results are also in sync to those obtained by other investigators.

According to Rheinbay et al (2017)[9]It can be concluded that increased estrogen levels is a good marker in for increasing the risk factor of BC. Estrogen levels play an important role in the development of BC.

The results of table 3 show that there is noticeable increase in progesterone hormone in BC women compared to healthy women. Other investigators have also reported the same results. It is believed that increase in ovarian secretion of progesterone hormone could lead to BC. There is a marked increase in serum cholesterol in BC women than normal levels. However this may be because there is positive correlation between increased cholesterol levels and menopausal status. Rheinbay et al (2017)[9] There is an increase in serum Triglyceride in the BC patients, but this could be attributed to the intake of tamoxifen, which is prescribed for patients having BC Rheinbay et al (2017)[9]

Finally it was observed that there were marked differences in BC women and healthy women in serum immunoglobulin IgA, IgG. However the results also showed that there was marked difference in serum immunoglobulin IgM. Some investigations have reported that the advancing metastatic BC is associated with high serum immunoglobulin levels of IgG and IgA, other investigators believe that a defense reaction against increasing tumor load or the secretion of immunoglobulin by the tumor Garg, et al (2016)[11]

Conclusion

This study shows that all these women had contracted with breast cancer which was in different stages. All had undergone surgery as described above and also adjuvant procedures to arrest the spread of the disease.

Further blood samples were taken from the study group it was found that anemia; thrombocytopenia and leucopenia were usual basic features to be found in breast cancer patients.

This study also measured various biochemical factors like cholesterol, level of estrogen, progesterone hormones, lipoproteins (HDL, LDL), triglycerides and some immunoglobulin's (IgG, IgA and IgM). The results show that there was a huge increase in cholesterol, level of estrogen, progesterone hormones, lipoproteins (HDL, LDL), triglycerides and high levels were also recorded in immunoglobulin's (IgG, IgA and IgM).

Conflict of Interest: The author would like to state that there was no conflict of interest whatsoever.

Socio-demographic Characteristics and Caregiver's Quality of Life Associated with Suspected Developmental Delay among Early Childhood in Northeast of Thailand

Supattra Boonjeam[1], Rajda Chaichit[2], Benja Muktabhant[3], Suwit Udompanich[4]

[1]Student of Doctoral Program of Public Health, Faculty of Public Health, Khon Kaen University, [2]Department of Preventive Dentistry, Faculty of Dentistry, Khon Kaen University, [3]Deparment of Health Administration, Health Promotion, and Nutrition, Faculty of Public Health, Khon Kaen University, [4]Faculty of Dentistry, Phayao University, Thailand.

Abstract

The first 5 years was possibly the most critical and extremely important in child development. Development problem of Thai children are not improve to standard.

This research aimed to analyze about association between Socio-demographic Characteristics, Caregiver's quality of life and suspected developmental delay among early childhood. A Cross-sectional analytical study, there are 1,168 sampling groups; caregivers 584 persons, early childhood 584 persons, between April to May 2019. The multivariable analysis was used by multiple logistic regression.

Early childhood aged average 36.1 months, males are 53.1%, and with suspected developmental delay 48.1%. There are 4 factors which are associated with the suspected developmental delay; 1) monthly self-income of caregiver (AOR= 1.9; 95%CI: 1.24 to 2.87; p= 0.003) 2) gander (AOR= 1.9; 95%CI: 1.33 to 2.64; p<0.001) 3) age range (AOR= 2.5; 95%CI: 1.54 to 4.09; p<0.001) and 4) quality of life about social relationship (AOR= 1.6; 95%CI: 1.23 to 2.01; p= 0.020).

Prevalence of suspected developmental delay is quite high, Socio-demographic Characteristics and caregiver's quality of life has influenced to the early childhood development.

Keywords: *Early childhood, Developmental, Quality of life.*

Introduction

Children are important resource in society; therefore, the children should have efficient development so that they can grow up to be good children learn qualities that will help them become happy, and be able to create and do anything benefit to our society in the future. The children are significant to our county which we should invest them to get high number of returns around 6.7-17.6 times[1].

In the first five years of life, it's the most important time at any other time in their lives; their developments will go faster including their brain develop more and faster around 80% comparing to adults. Besides, it's also related to the foundation for children developments and their quality of life. Window of opportunity points us that if we evaluate or notice their delayed development in early before age of 6 years, that can stimulate their development and help them to be their normal developments[2].

A report from World Health Organization found out that the children all around the world 15-20%, their development are not appropriate[3]. In addition, department of health, ministry of public health 2017 has observed that children normal developments for

early children in Thailand are in their rate at 70%, the children in Northeast of Thailand is at only 50-60% [4]. Regarding to family structure, some parents move out from rural area to city and leave their children to stay with grandparents, this situation has occurred so much in Northeast region, the children do not live with their own parents are 30%[5], so family structure are members of grandparents and grandchildren which without parents.

After literature review, there are risk factors which effect to the children developments involve with biological and economic and social. Regarding to biological risk factor composes of health and mothers' nutrition status, complication during intra partum and postpartum periods including health and nutrition status of the children[6]. Relating to economic and social factors compose of age, occupation of mothers, including family income and the way how they raise the children, especially mothers' education level is quite so much affect to the children than fathers[7,8]. In the past, there are many studies related to risk factors which effects to the early children developments which still be problem. A part of this issue might cause of biological and economical and social risk factors. However, there is not any study about socio-demographic characteristics, caregiver's quality of life and early children developments in Northeast of Thailand.

Therefore, this study aimed to analyze about association between socio-demographic characteristics, caregiver's quality of life and suspected developmental delay among early childhood in Northeast of Thailand.

Material and Method

Study Design and Sampling: A cross-sectional analytical study and collect data from April through May 2019. The sample size was calculated following formula to specify sampling size by multiple logistic regression, Hsieh FY [9]. ρ of 0.70, VIF= 3.33. The sampling size of this study is 584 persons.

Using Multi Stages random sampling did in research for 20 provinces in Northeast region. Simple random sampling is used for 5 provinces at 25% out of all provinces in this region, next, for selected 2 districts out of each sampling province. Then, do random sampling group from name list of the early children (0-6 years) from public health department of sampling district (HosxP PCU program), according to proportional to size for 10 districts, get sampling group 58-60 persons each.

Inclusion criteria are Thai nationality children aged 0-6 years and been live in Northeast of Thailand. The caregivers are look after children at least 6 months up, their profiles can be given us completely and they must have the maternal and child health handbook. Regarding to exclusion criteria are disable children from birth which effect to their developments such as down syndromes, autism, cerebral palsy and children with seizure history, children with no cooperative to check development, children with no any age history and children who are not raised by their own blood relatives.

Material: Socio-demographic Characteristics which compose of age, gender, occupation, education level, self-income, family income, income sufficiency, number of children per family and living with their own parents.

Evaluation of Caregiver's quality of life by WHOQOL-BREF[10]: there are 4 domains; physical, psychological, social relationship and Environmental. Divide quality of life in each domain and overall for 3 levels which are poor, medium and good.

Suspected developmental delay test by Denver II is used to screen children's development. Four domains (gross motor, fine motor adaptive, language and personal-social). It consists of 125 items, testing time is around 10-20 minutes. The testing results are divided into 2 levels; Normal, develop a child without a delayed test and no more than one caution tests. Suspected has a test two or more cautions and one or more than one delay tests. This study uses Denver II in Thai[11] to do developmental tests. In addition, assessor has been passed children development training from the National Institute for Child and Family Mahidol University.

Data analysis: Relating to analysis of association between socio-demographic characteristics, caregiver's quality of life and suspected developmental delay, a simple logistic regression, was used for bivariate analysis to identify individual factors associated with suspected developmental delay. The factors that had p-value <0.25 were processed into the multivariable analysis using multiple logistic regression by backward elimination method which statistical significance is (p-value= 0.05), reported the adjusted odds ratio (AOR), 95% confidence interval (95% CI) and using Stata version 13.1 program (Stata Corp, College Station, TX)

Result

Socio-demographic Characteristics: The total 1,168 sampling; 584 caregivers and 584 childhood found most of caregivers are female 93.3%, average age is 40.4 years with a range of 16-74, their occupation is agriculturist 44.4%. Education level is primary school 46.4%, average monthly self-income 6,394.8 THB, average monthly family income 15,029.8 THB. Early childhood are males 53.1%; average age is 36.1 months with a range of 9-72 months, the children aged 36-76 months is 46.7%. The child living with their own parents is 51.4%. (Table 1).

Table 1: Socio-demographic characteristic

Factors	Number	(%)
1. Caregiver's age (Years)		
16 - 29	165	28.2
30 - 59	359	61.5
60 - 74	60	10.3
Mean: SD	40.4	13.8
Median (Min: Max)	39.0	16: 74
2. Occupation		
housewife	147	25.2
agriculturist	259	44.4
governmental officer	120	20.5
businessman, trader	58	9.9
3. Education level		
primary school	271	46.4
high school/vocational	213	36.5
bachelor's degree up	100	17.1
4. Monthly self-income (THB)		
< 10,000 (325 US dollars)	455	77.9
> 10,000	129	22.1
Mean: SD	6,394.8	7,922.9
Median (Min: Max)	4,000.0	0: 70,000
5. Monthly family income (THB)		
< 10,000	244	41.8
> 10,000	340	58.2
Mean: SD	15,029.8	15,706.5
Median (Min: Max)	10,000.0	1,000: 200,000
6. Income's sufficiency		
sufficient	299	51.2
insufficient	285	48.8
7. Gender of child		
male	310	53.1
female	274	46.9
8. Age range (months)		
0 - 12	105	18.0
13 - 35	206	35.3
36 - 72	273	46.7
Mean: SD	36.1	15.7
Median (Min: Max)	36	9:72
9. Number of children per family		
1	276	47.3
2	257	44.0
3 - 5	51	8.7
10. living with parent		
living with parents	300	51.4
not living with parents	284	48.6

Caregivers' quality of life: It found average score of their quality of life in good level 77.7%. When consider in each domain, their psychological domain is in good level 75.7%, next on down environmental domain is 71.7%, social relationship is 68.5% and physical is 66.3%. (Table 2).

Table 2: Caregiver's quality of life

Factors	Number	(%)
Quality of life in overall		
medium	130	22.3
good	454	77.7
Mean: SD	104.9	13.0
Median (Min: Max)	104.0	71: 130
Quality of life in each domain		
Physical		
medium	197	33.7
good	387	66.3
Psychological		
poor	2	0.3
medium	140	24.0
good	442	75.7
Social relationships		
poor	6	1.0
medium	178	30.5
good	400	68.5
Environmental		
poor	1	0.2
medium	164	28.1
good	419	71.7

Children development: The early childhood development in Northeast of Thailand found they are in suspected developmental delay 48.1%. If consider each domain development, language domain tends to be delayed the most 39.4%, next, it's fine motor adaptive 27.2%. (Table 3).

Table 3: Denver II Results

Denver II	Number	%
Normal	303	51.9
Suspect	281	48.1
Gross motor	79	13.5
Language	230	39.4
Fine motor adaptive	159	27.2
Personal-social	74	12.7

Factors associated with suspected developmental delay: Bivariate analysis: Bivariate analysis on the association between each independent variable and suspected developmental delay in early childhood was performed presenting the crude odds ratio (OR) with 95% CI, and p-value. All factors that had p-value <0.25 were proceeded to multivariable analysis by using multiple logistic regression. (Table 4)

Table 4: Factors associated with suspected developmental delay: Bivariate analysis

Factors	Number	% of Event	Crude OR	95%CI	P-value
1. Monthly self-income (THB)					**0.003**
> 10,000	129	36.4	1		
< 10,000	455	48.1	1.8	1.23-2.76	
2. Gender of child					**<0.001**
Female	274	39.8	1		
Male	310	55.5	1.9	1.36-2.62	
3. Age range (months)					**<0.001**
0 – 12	105	31.4	1		
13 – 35	206	46.6	1.9	1.16-3.12	
36-72	273	55.7	2.7	1.70-4.41	
4. living with parent					**0.011**
Living with parents	300	43.0	1		
Not living with parents	284	53.5	1.5	1.10-2.12	
5. Quality of life in physical domain					**0.049**
Good	387	45.2	1		
Medium	197	53.8	1.4	1.00-1.99	
6. Quality of life in social relationship domain					**0.016**
Good	400	44.7	1		
Medium and poor	184	55.4	1.5	1.18-2.18	

Factors associated with suspected developmental delay: Multiple logistic regression: Multiple logistic regression analysis by Backward elimination indicated that The children who are raised by the caregiver who has monthly self-income lesser than 10,000 THB, tend to be suspected developmental delay more than the ones who are taken cared by the caregiver with monthly self-income over than 10,000 THB for 1.9 times. (AOR= 1.9; 95% CI: 1.24 to 2.87). Boys tends to be suspected developmental delay more than girls for 1.9 times (AOR= 1.9; 95% CI: 1.33 to 2.64).

The child aged 13-35 months has a chance to suspected developmental delay more than the ones aged 0-12 months in double fold. (AOR= 2.0; 95% CI: 1.21 to 3.34). In addition to the children aged 36-72 months tends to be suspected developmental delay more than the children aged 0-12 months in 2.5 times (AOR= 2.5; 95% CI: 1.54 to 4.09)

The children who are raised by the caregiver with social relationship in medium and poor level, it has chance to reflect the children be suspected developmental delay more than the ones who are in good level for 1.6 times. (AOR= 1.6; 95%CI: 1.23 to 2.01). (Table 5).

Table 5: Factors associated with suspected developmental delay: Multivariate analysis

Factors	Number	% of event	Crude OR	Adjusted OR	95%CI	P -value

Discussion

This study revealed that the suspected developmental delay among early childhood in Northeast of Thailand were 48.1%. The associated factors with suspected developmental delay were found 4 factors including: monthly self-income, gender, age range and quality of life in social relationship domain.

The association between Monthly self-income of caregivers and suspected developmental delay was consistent with Ozkan et.al[12], they found that economic and social factor effected to the delayed development.

Girls who are in normal development greater than boys were concordant with a study of Bhattacharya and Brito et al[13,14]. They found that boys were suspected developmental delay greater than girls. Nevertheless, it was different from a study of Ozkan et.al[12] reported that there was not difference on gender with suspected developmental delay.

Age range of the early childhood with developmental delay the most was 35-72 months which this result was consistent with problem about developmental delay on language domain which tended to increase up. A part of problem is environmental circumstance was not propitious to support the children development; for example, eating food following advertisement, leaving kids to use electric media alone, so the kid aged 3-5 years were slightly risky greater than the kid aged 0-2 years which were consistent with a study of Brito et al. and Celikkiran et al[14,15]., they found that infant stage had normal developmental better than preschool age.

Regarding to the caregiver's quality of life in social relationship is related to children development which also conformed to a study of Yamada et al[16]., especially mother who was in poor quality of life which her might get lower social support, it also affected to another family members on development, personality and children behavior.

Conclusion

The risky factors affected to the children development issue, biological factor slightly was lowering significant, but the socio-demographic characteristics factor was more important. Therefore, we should closely pay more attention to the risk factors which were biological, social and environmental factors which cause of children development issues. As a result, we should monitor these risk factors which might affect to the children in first five year in order to solve the problem and did any activities to stimulate and do support their normal developmental and being main human resource to develop our country in the future.

Research Ethics approval for this study was obtained from the Khon Kaen University Ethics Committee for human Research (HE622051).

Lapin Stealth Citrobacter Urogenital Infection Model

Thewaini QNA[1], Shnawa IMS[2], ALshibeeb A.R.[3], Mosa M.[4]

[1,2]Professor, [3]Lecturer, Department of Biotechnology, College of Biotechnology, University of Qasim, Qasim,Babylon/IRAQ, [4]Assistant Professor, Babylon Board of Health, Central Public Health Laboratory, Babylon, IRAQ

Abstract

A lapin stealth C.freundii urogenital infection models were being developed. Three groups each of five rabbits were assigned as group I for stealth C.freundii, group II for intact C.freundii and group III for control. The infectious dose was rated to, 1x10 to 7 CFU/ml. The dosing program was through transurethral route. From the time zero day up to the day eight post infection the rabbits was watched for signs of disease. The changes in the whole animal beings were found as; rise up in body temperature, loss of appetite, loss of body weight and sluggishness .Postmortem gross urogenital organ/tissue matrix changes were congestion and haemorrhage. Tissue changes were noted as an acute to sub-acute urethritis,cystitis and testiculitis. To this end rabbits were proved to be suitable experimental models for evidence of stealth C.freundii pathogenicity. The developed models are being novel so far C.freundii is concerned.

Keywords: *Acute, body, Infection, model, transurethral, urogenital.*

Introduction

Citrobacter freundii in classical medical microbiology literature have been mentioned as commensal organism with an opportunistic pathogenic potentials[1,2]. Current published works have been assuring more than once clinical proves that C.freundii stands as an emerging human pathogens causing; enteritis,colitis, arthritis, urinary tract infections and meningitis[3].Though most of the workers hold the idea that it stands as an opportunistic human uropathogen[2,4]. The objective of the present work was to develop a lapin models for C.freundii urogenital pathogenicity.

Materials and Method

Pathogens: The infectious C.freundii was a confirmed urinary isolate from human being that was identified using classical and API20E system. It was used in two forms; stealth and intact whole infectious units per fixed volumes. In both of the cases the stock was revived onto fluid overnight broth culture then onto quadrate streak 24 hr. culture valid for more processing. For intact, five similar colony morpho-types onto selective enteric solid media were elected and tranfered to 25ml. flask culture containing brain heart infusion broth. The inoculated broth was incubated for 24 hr at 37C then centrifuged at 5000rpm for 10 mints. Pellet was washed twice with sterile normal saline the reconstituted to the rate of 1x10 to 7 CFU/ml.,[3,4,5].

Stealth Pathogen: The isolate was grown onto variant medium with 62.5 ug/ml. Impenim at 37C for;24,48,72,96 and 120 hrs.,with continual shake every now and then during incubation period .The transformation percentages to cell wall defective stealth form was checked at the aforementioned periods by direct microscopic exam of methylene blue stained films of inocula from the cultures. Reasonable high percentages were considered for preparing the infectious doses and rated to 1x10 to 7 CFU/ml.,[6].

Lapin Models: The experimental rabbits were checked for absence of common pathogens and their specific antibodies .Among the negatives,three groups each of five were adapted for the housing conditions for one week then assigned as group I for stealth, group II for the intact and group III for saline controls. The stealth C.freundii infectious doses were prepared as 10 days variant culture with 62.5 ug/ml. Impinim, checked and rated to 1x10 to 7 CFU/ml. Intact infectious C.feundii doses were made as in paragraph 1. The infection rout was through transurethral mini-catheters made as two

sided open polyethylene tubing of 0.5mm diameters fitted to needle-less disposable syringes inserted to urethra[6,7,8]. Tissue section preparations were performed as in [9].

Results

Stealth Infection Model: The whole animal being gross changes observed onto stealth infected rabbits were;rise up in body temperature,loss of appetite,loss of weight, sluggish-ness, polyuria as compared to the normal beings in saline control rabbits. The gross postmortem organ/tissue changes were;congested hyper-atrophized urinary bladder with marked vein congestion and pan patchy haemorrhage in bladder tissue matrix. The urethral tissue sections was shown an inflammatory cell infiltrate of mixed macrophages and lymphocytes with urethral epithelial tissue damage indicating sub-acute urethritis. The whole mark of urinary bladder tissue section diffuse patchs of haemorrhages, Figure 1. Renal tissue changes were as; thickening and damage of the mucosal layer of the renal tubules with an apparent derrangment of mucosal congestion, Figure 2. Testicle tissue changes were as marked derrangment in the mucosal layer of the semi-neferous tubules and inflammatory cell infiltrates, Figure 3.

Intact Infection Model: The intact infected rabbits model have expressed animal whole being changes as; rise up body temperature, loss of appetite, loss of weight,sluggishness, polyuria as compared to the normal being saline injected rabbits. The gross postmortem changes were congested hyper-atrophized urinary bladder with an apparent mild congestion in the urogenital tissue matrix. The urethral histologic tissue changes were infiltration of macrophages and lymphocytes in the tissue matrix with an evident urethral epithelial damage indicating sub-acute urethritis . Urinary bladder was showing dense inflammatory cell infiltrates together with translocation of bacterial populations into sub-mucosal tissue regions which is consistent with cystitis. Renal tissue sections were showing mild inflammatory cell responses in renal cortical area nearby the glomeruli with renal tubular damage. Testicular tissue sections have shown inflammatory cell infiltrates with epithelial damage in the seminefereous tubules.

Control Model: The control rabbits were showing normal animal beings of body temperature, body weight,appetite and mobility,normal tissue cellularity and tissue contours,Figures 4,5,6.

Comparative View: Both of the infection models have shown inflammatory responses in urethra,urinary bladder, kidneys and testicles. The pathologic entities of these inflammations were spanning between acute to sub-acute inflammations with an apparent mucosal epithelial layer of the tubular structures. Though the tense damage was evident stealth than in intact infection models, Table 1.

Table 1: Pathogenicity of Stealth and intact C.freundii in rabbits

Pathogenicity features	Stealth infection Model	Intact infection model	Saline controls
Morbidity			
Body Temperature	High	High	Normal
Loss of Appetite	Present	Present	Normal
Loss of Weight	Present	Present	Normal
Mobility	Sluggish	Sluggish	Normal
Urination frequency	Polyuria	Polyuria	Normal
Postmortem			
Urinary bladder	Hyperatrophized	Hyperatrophized	Normal
Urinary bladder main venous supply	Congested	Normal	Normal
Bladder wall	Marked haemorrhagic	Mild haemorrhagic	Normal
Histology			
Urethra	Sub-acute urethritis	Sub-acute urethritis	Normal
Bladder	Cystitis	Cystitis	Normal
Kidneys	Renitis	Renitis	Normal
Testicles	Testiculitis	Testiculitis	Normal

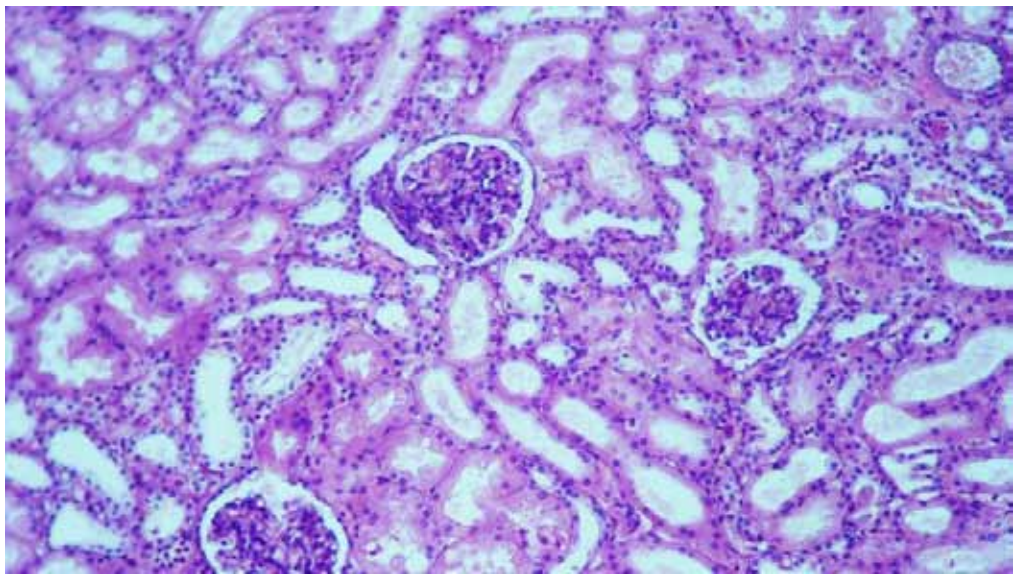

Figure 5: Kidney tissue section H & E 400X,from control rabbits showng normal cellularity and normal contour.

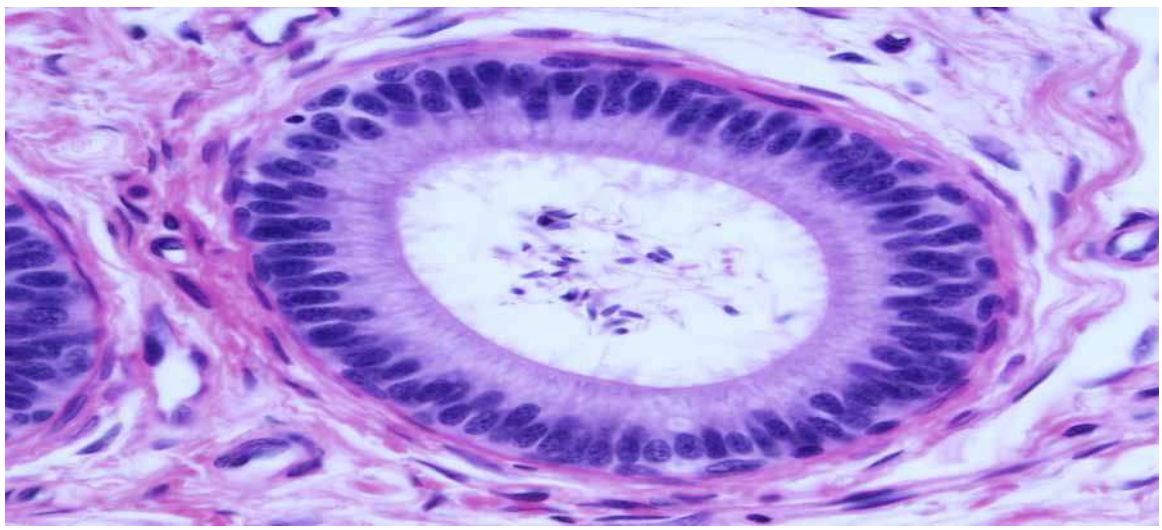

Figure 6: Testicle tissue section H & E 400X,from control rabbits,shwing normal cellularity and normal contour.

Discussion

The pathogenesis of urinary tract infection in mammals including man is starting through three main routes; the ascending urethral, the descending haemato-genous and lympho-genous[1]. The theme of the present work was via the ascending urethral rout. The presence of C.freundii populations in the lapin urogenital tract tissues can be an indications to their ability to penetrate, invade, adhere and populate in to urinary and genital tissues. When C.freundii grow up in populations may be in form of biofilms, producing quaroum sensing signals[10], attaching, effacing, and/or other pathogenicity factors[2] that may avoid local mucosal defense mechanisms as well as mechanical urine voiding mechanisms leading to initiation of an inflammatory processes which may be terminated by tissue damage and urogenital disease in urethra,urinary bladder, kidney and testicles and this was clear from the morbidity, postmortem and histological changes of the infected rabbits, Table 1 and figures 1-6. From this contribution it was evident that the intact C.freundii have tissue tropism towards lapin urogenital tract and its pathogenicity was more potentiated in case of losing their cell walls[13,14,15]. To this end one can theorize the host range of C.freundii pathogenicity covers mammalian vertebrates including lapin and human beings. From the practical point of view rabbit were proved to be of value as an experimental C.freundii urogenital infection models through transurethral infection routes[7,8]. The present models are novel since lapin models of C.freundii infection seemed to be rare[7,8,11,12,13,14,15].

Conclusion

Transurethral as ending infection rout for both of stealth C. fuendii and C. fruendii in a lapin model was proved to be valid for the urogenital pathogenicity study. Stealth C. fruendii appeared to be more potent urogenital pathogen than intact C. fruendii in a lapin model.

Conflict of Interest: Non

Source of Fund: Personal

Ethical Issue: The research project is registered in the Afilated Department Ethical. Rabbits were reared and kept under standard Add Libitum conditions during experimentation period. On handling of rabbits authors fallowed the international athecal guidelines for laboratory animals.

Dosing of Erythropoietin Stimulating Agents in Patients on Hemodialysis: A Single-Center Study

Thuraya Salim Abed[1], Jawad Ibrahim Rasheed[1], Hayder Adnan Fawzi[2]

[1]Lecturer, Baghdad Medical City Campus, Ministry of Health and Environment, [2]Asst. Prof., Department of Pharmacy, Al-Esraa University College, Baghdad, Iraq

Abstract

Objective: Study the relationship of dialysis adequacy with the effectiveness of erythropoietin for the management of anemia in hemodialysis patients.

Materials and Method: A retrospective cohort study, conducted in the Medical city complex from January 2019 to June 2019, the study involved 162 ESRD patients on regular hemodialysis sessions.

Results: Change in Hb (percentage and value), was significantly higher in patients receiving once-weekly erythropoietin compared to both twice and thrice and more dosing per week. Overall only 33 (21.2%) of the patients achieved target Hb (10 – 11 mg/dL) with 6 months of follow-up. There was an inverse significant correlation between percentage change after 6 months with baseline Hb, baseline ferritin, and baseline albumin. While with urea at baseline, number of weekly sessions, and Kt/V the relationship becomes direct and significant There is an increased risk (2 folds) of not achieving target Hb (10-11 mg/dL) in patients with DM compared to those without DM.

Conclusion: Once weekly regimen appeared to superior to other regimens (twice or more per week).

Keywords: *Erythropoietin, dialysis, hemoglobin, anemia, weekly dosing.*

Introduction

End-stage renal disease (ESRD) occurs when there is a progressive loss of kidney function over a period of months to years to the point where the kidneys can no longer maintain normal function [1]. Anemia is common among patients with chronic kidney disease (CKD). Anemia underlies many of the symptoms associated with reduced kidney function and is associated with increased mortality and hospitalizations[2]. The anemia of CKD is, in most patients, normocytic and normochromic and is due primarily to reduced production of erythropoietin by the kidney (a presumed reflection of the reduction in functioning renal mass) and to shortened red cell survival [3]. The primary therapeutic options for the anemia of CKD include iron, erythropoiesis-stimulating agents (ESAs), and, rarely, red blood cell (RBC) transfusions. The treatment depends on the severity of anemia and iron deficiency. ESAs are administered to most CKD patients who have hemoglobin (Hb) <10 g/dL, providing the transferrin saturation (TSAT) is >25 percent and ferritin >200 ng/mL[4]. The current work aimed to study the relationship of dialysis adequacy with the effectiveness of erythropoietin for the management of anemia in hemodialysis patients.

Method

Patients: A single-center study involved 162 ESRD patients on regular hemodialysis sessions

Data Collection: Demographic characteristics, cause of end-stage renal disease, time on dialysis, and

type (epoetin alpha) and the dose of erythropoietin (50 to 100 units/kg/dose 3 times weekly, SC), type and dose of iron preparation.

Two consecutive (every 6 months) laboratory records of the patients were collected by trained nurses and data were entered into a specifically designed datasheet.

Laboratory analysis: Laboratory data collected from patients' charts included hemoglobin level, serum ferritin, and single-pool Kt/V, serum albumin, blood urea, and serum creatinine.

Inclusion criteria:

1. Age above 18 years
2. Patients on regular hemodialysis
3. End-stage renal disease

Exclusion criteria:

1. Pregnant women
2. History of hematologic disorders such as thalassemia, sickle cell disease, and hematologic malignancies
3. Patients with active or past cancer

Statistical analysis: Discrete variables presented using their number and percentage, chi-square test used to analyze the discrete variable. One-way ANOVA used to analyze the differences between more than two groups after that in the results is significant post hoc Tukey test will be used. Linear regression analysis performed to assess the relationship between different variables, r (correlation coefficient or standardized beta is a representative of magnitude and direction of the relationship), negative sign indicates inverse relationship, but positive sign represents direct relationship. SPSS 22.0.0 (Chicago, IL), Minitab 17.1.0, software package used to make the statistical analysis, p-value considered when appropriate to be significant if less than 0.05

Results

The study included 162 patients, with mean age of 52.7 ± 15.9 years, 57.4% of them were males. There was no significant difference in the age of patients when divided by gender (50.6 ± 13.6 vs. 54.3 ± 17.3 years, female vs. male, p-value = 0.128), as illustrated in table 1.

Table 1: Baseline Characteristics and Demographic Data

Variables	Value
Number	162
Age (years), mean ± SD	52.7 ± 15.9
Gender, n (%)	
Female	69 (42.6%)
Male	93 (57.4%)
Medical diseases	
Hypertension, n (%)	147 (90.7%)
Dry weight (kg), mean ± SD	70.2 ± 14.7
Cause of end-stage renal disease, n (%)	
Diabetic nephropathy	66 (40.7%)
Glomerulonephritis	27 (16.7%)
Polycystic kidney disease	21 (13.0%)
Hypertensive nephropathy	36 (22.2%)
Obstructive uropathy	24 (14.8%)
Dialysis duration, n (%)	
<1 year	72 (44.4%)
≥ year	90 (55.6%)
Vascular access	
Temporary double-lumen	126 (77.8%)
Tunneled	12 (7.4%)
Fistula	24 (14.8%)
T/V	0.85 ± 0.31
Dialysis adequacy (Kt/V ≥1.2)	30 (18.5%)

After 6 months of therapy with EPO, 6 patients (3.7%) stop their EPO since they maintain Hb level above 10 mg/dL during this period, the rest of the patients (156, 96.3%) categorized according to dosing intervals, in which 27 (17.3%) used single weekly dose, 63 (40.4%) used twice weekly doing, and 66 (42.3%) used trice weekly dosing.

Change in Hb (percentage and value), was significantly higher in patients receiving once-weekly EPO compared to both twice and thrice dosing per week (see Figures 3 and 4). Overall only 33 (21.2%) of the patients achieved target Hb (10 – 11 mg/dL) with 6 months of follow-up, as illustrated in table 2, figures 1.

Table 2: assessment of the effect of EPO on Hb

	Once Weekly	Twice Weekly	Trice Weekly	p-value
Number	27	63	66	-
Baseline Hb	8.6 ±2.0	8.6 ±1.5	7.4 ±1.2	<0.001

Hb change	1.7 ±2.1	0.3 ±1.6	0.6 ±1.7	0.002
Patients achieved 10-11 mg/dL	15 (55.6%)	9 (14.3%)	9 (13.6%)	<0.001
Hypertension, n (%)	24 (88.9%)	57 (90.5%)	60 (90.9%)	0.956
DM, n (%)	6 (22.2%)	30 (47.6%)	33 (50.0%)	0.039

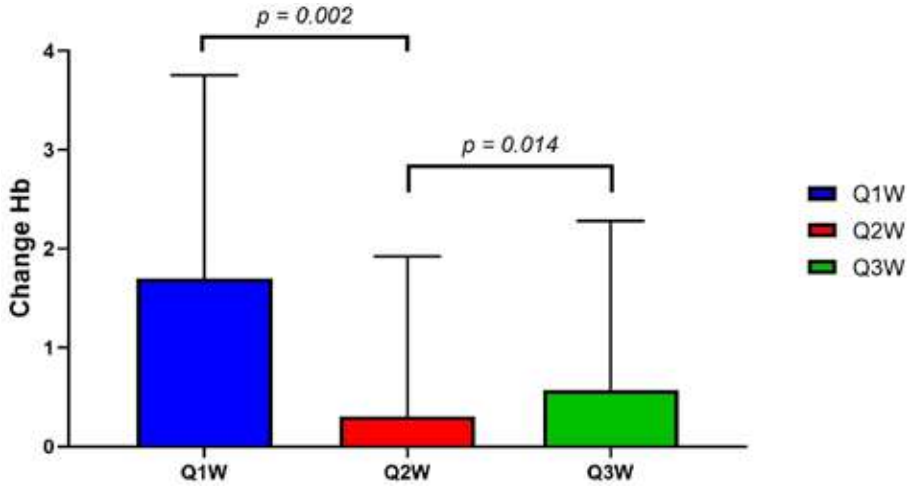

Figure 1: Assessment of the change in Hb from baseline to 6 months

There was a direct relationship between baseline urea, number of sessions per week, and Kt/V with percentage of Hb change.

There was an inverse relationship between baseline hemoglobin, baseline ferritin, and baseline albumin with percentage of Hb change, as illustrated in table 3.

Table 3: The relationship between change in Hb after 6 months and various variables

Variables	Percentage change in Hb	
	r	p-value
Age	0.084	0.288
Dry Weight	-0.088	0.266
Dosing Interval	-0.122	0.130
Hb at baseline	-0.629	<0.001 [S]
Ferritin at baseline	-0.194	0.013 [S]
Albumin at baseline	-0.284	<0.001 [S]
Urea at baseline	0.270	0.001 [S]
Creatinine at baseline	0.116	0.141
Ferritin after 6 months	-0.091	0.247
Albumin after 6 months	-0.110	0.162
Urea after 6 months	-0.060	0.448
Creatinine after 6 months	0.099	0.210
Session Per week	0.214	0.007 [S]
Kt/V	0.263	0.001 [S]

There an increased risk (1.943 folds) of not achieving target Hb (10-11 mg/dL) in patients with DM compared to those without DM, as illustrated in table 4.

Table 4: The relationship between DM and patients achieving target Hb

	Not DM	DM	OR	95% CI	p-value
Achieved target (%)	27 (29.0%)	12 (17.4%)	1.943	0.903 – 4.183	0.090
OR: odds ratio, CI: confidence interval					

Patients with higher Kt/V value had increased odd of achieving target Hb (1.5 folds), however, it did not reach statistical significance, as illustrated in table 5.

Table 5: The relationship between targets Hb with Kt/V

Variable	Target Hb		OR	95%CI	p-value
	Not achieved	Achieved			
Kt/V	0.84 ± 0.33	0.88 ± 0.24	1.548	0.498-4.809	0.450
OR: odds ratio, CI: confidence interval					

Discussion

In the current study, only 33 (21.2%) of the patients achieved target Hb (10 – 11 mg/dL) with 6 months of follow-up , with mean Hb after 6 months (8.8 ± 1.5 mg/dL), which lower than reported by international studies[5-9].

In the present study, there was a direct relationship between number of sessions with change in Hb (*r = 0.238, p-value = 0.001*), indicating that patients offered higher number of sessions had better anemic response. Although iron deficiency is probably the most important factor affecting the response to erythropoiesis-stimulating agents (ESA) in most patients, occult blood loss, infection, and inflammation also are important. Adequate dialysis can contribute to anemia correction by removing small and possibly medium/large molecules that may inhibit erythropoiesis [10].

Several metabolites have been implicated as potential EPO toxins, including various polyamines, such as spermine, spermidine, putrescine, and cadaverine, and parathyroid hormone. However, these substances have been found to be general bone marrow toxins and not specific suppressors of erythropoiesis. More recently, polymeric polyamine-protein conjugates have been shown to have a selective inhibitory effect on colony-forming units-erythroid proliferation without any appreciable effect on burst-forming units-erythroid[10].

In the present study we found that a once-weekly regimen is better than two or three times per week's regimens. This finding is unique since it is not reported in the literature.

In the present study patients with diabetes had two folds (OR = 1.94 3 , 95%CI: 0.903 – 4.183) increased risk of not achieving target Hb (10 – 11 mg/dL). Diabetes is known to be a risk factor for the severity of anemia in non-dialyzed patients with renal failure, as well as in patients who require maintenance dialysis. Few studies have evaluated the difference in response to erythropoietin therapy in diabetic and non-diabetic patients [11, 12].

Despite the similarity of the response offered by erythropoietin therapy on Hb among various regimen, the overall percentage of patients achieving target Hb (10 – 11 mg/dL) was low 33 (21.2%), with once-weekly regimen offered the highest proportion (55.6%) within target, while the rest of the regimens offered lower percentage (14.3%, and 13.6% for Q2W, and Q3W respectively). This was in disagreement with previous studies in which the percentage of achieving target was higher (80 – 90% in most studies)[6-8].

In the present study Dialysis adequacy (defined at Kt/V ≥1.2 according to KDOQI guideline [13]) achieved in 30 (18.5%) of the participants, which is lower than other reported studies like Nafar et al with 58% achieving dialysis adequacy [14], and once-weekly than Amini et al with 43.3% achieving dialysis adequacy[15].

Because anemia improves after the start of dialysis, adequate dialysis is of paramount importance

in correcting anemia by removing small, and possibly medium/large molecules that may inhibit erythropoiesis. Even if previously underestimated, the role of dialysis dose per se on anemia and response to ESA has progressively come to the scene. In a previous study a direct relationship between hematocrit level and urea reduction ratio (URR) after adjustment for other factors; at logistic regression analysis, an 11% increase in URR doubled the odds that a patient would have a hematocrit higher than 30%. Twenty consecutive patients receiving inadequate dialysis (baseline URR, 65%) received an increase in dialysis dose and were compared with another 20 End-stage patients receiving inadequate dialysis and in whom the dialysis schedule was not modified.19 After 6 weeks, in parallel with an increase of mean URR to 72%, the hematocrit level increased from 28.4% ± 0.78% to 32.3% ± 0.71% (P-value 0.002), whereas it remained unmodified in the control group, without any difference in ESA dose in the 2 groups explained [10].

Data on the possible role of dialysis dose on anemia correction also come from the dialysis center in Tassin, France. In this facility, patients are treated with long hemodialysis sessions lasting 8 hours. Fifty-nine of these patients were compared with 53 patients from Sweden receiving conventional hemodialysis lasting 3 to 5 hours.23 Even if the mean hematocrit level was similar in the 2 groups, the proportion of patients treated with rh-EPO was much higher and the mean Kt/V was significantly lower in the Swedish than in the Tassin group. The better control of anemia observed in the patients from Tassin mainly is owing to a higher depuration rate, but it also is possible to hypothesize an effect of dialysis time per se, independent from dialysis adequacy [10].

In the present study, there is direct correlation between dialysis adequacy with increase in Hb (r = 0.263, p-value =0.001), which is in agreement with other studies[16,17].

One of the major determinants of anemia severity and ESA responsiveness is dialysis adequacy [18]. Patients with an inadequate dialysis dose are resistant to ESA, and their target Hb is harder to reach[19]. In hemodialysis, there is an inverse relationship between the achieved Kt/V and ESA dose, while increasing the dialysis dose is associated with an increase in hematocrit level [20]. Uremic toxicity in general and/or retention of some direct inhibitors of erythropoiesis results in aggravated anemia and poor response to ESA treatment[17].

Conclusion

Once weekly regimen appeared to superior to other regimens (twice or more per week).

Analysis of Risk Factors Occurrence of Juvenile Delinquency Behavior

Tri Anjaswarni[1], Nursalam[2], Sri Widati[3], A. Yusuf[3]

[1]Doctoral Student of Health Science Program, Faculty of Public Health, Universitas Airlangga, [2]Professor, Faculty of Nursing Universitas Airlangga, [3]Lecturer, Faculty of Public Health Universitas Airlangga

Introduction

Now a days juvenile delinquency is increasing in terms of number and type. Delinquency and criminality among teenagers are generally categorized as deviant behavior in society and can be interpreted as a form of teenage resistance to normative rules and values that apply in society. Many risk factors are related to deviant behavior.

Objective: This study aimed to analyze the risk factors that influence the occurrence of juvenile delinquency.

Method: This study used a cross-sectional design and a simple random sampling technique. The calculation results involved 295 samples. The independent variables were individuals, families, school environments, peer groups, coping mechanisms, lifestyles, and technologies. The dependent variable was juvenile delinquency. The data was collected using a questionnaire. The analysis used a multiple linear regression test with a significance level of $\alpha \leq 0.05$.

Results: Of the seven variables, six of them significantly influence juvenile delinquency. Technology is the variable that has the greatest influence on the occurrence of teenager wear.

Conclusion: Technology is the most influential factor. These results indicate a significant shift in the causes of juvenile delinquency from family and peer factors to technological factors. This is quite reasonable because technology is a major need and is a trend for teenagers at this time.

Keywords: *Risk factors, delinquency, juvenile.*

Introduction

Juvenile delinquency has occurred since the early 19th century and has become a world problem, including in Indonesia. Juvenile delinquency is included in social disorders and now the incidence rate continues to increase[1]. Delinquency and crime among teenagers are generally categorized as deviant behavior in society. These behavioral deviations can be interpreted as a form of teenage resistance to normative rules and values that apply in society [2]. Juvenile delinquency is one form of mental health disorder in the community, which directly or indirectly can affect the degree of mental health of the community. Short-term impacts can be dangerous directly to safety teenagers and groups themselves. Fights, brawls, speeding will potentially lead to injury and possibly even death. Narcotics can threaten their lives and society, potential free sex behavior for sexually transmitted diseases, and other harmful effects. The long-term impact is the threat of future loss so that they cannot take part in the development of the nation and state. This is not in line with the expectation that teenagers are the spearhead of development and the next generation of the nation [3].

Adolescence is a period of transition from childhood to adulthood that is full of responsibility, where they are required to be able to adapt to these changes [4]. Adaptation failure will lead to problems and behavioral disturbances in the future. This is relevant to coping mechanisms owned by individuals because coping mechanisms are a measure of the ability of teenagers to solve problems.

Furthermore, the factors that play a role in juvenile

delinquency are actors who originate from their own teenagers or individual factors. Individual factors are internal factors that are related to the abilities and abilities of individuals in running their roles and social activities. Factors that also act as risk factors for juvenile delinquency are family. This family factors related to the attitudes and habits of parents in educating and caring for children, including how parents in facilitating the economic needs of the child, personal communication patterns and proximity (bonding)[4,5]. The next external factor is the school environment and peergroups. School factors that become a risk factor for juvenile delinquency, related to various things that exist in the school environment include child relationships with teachers and peergroup, the presence of children in school, and adherence to school rules. For peergroup factors which are risk factors for juvenile delinquency is the frequency of children seeing exposure to harmful substances, both directly seeing and seeing events in the mass media. Included also in peergroup factors are attitudes and relationship patterns[5].

Technology use today also play a role in the occurrence of delinquency. Incorrect use of technology can have the effect of deviating behavior including violence, theft, and so on. Research shows that playing violent video games correlates with the occurrence of aggression in juvenile delinquents imprisoned[6]. Another factor that contributes to juvenile delinquency is a lifestyle. Changes in lifestyle due to environmental differences in the past and present will affect psychological well-being. Individuals who are not able to adapt to these lifestyle changes will lead to welfare problems[7]. A bad lifestyle has the potential to trigger juvenile delinquency. Based on the background above, it is necessary to analyze various risk factors that play a role in juvenile delinquency. The purpose of the study was to analyze risk factors that influence juvenile delinquency.

Materials and Method

Design: This type of research was observational with a cross-sectional design[8].

Population and Samples: The population was all teenagers aged 12-19 years. The number of samples was 295 teenagers who attended schools in Malang City, East Java - Indonesia, and teenagers who were undergoing coaching in class I LPKA Blitar City.

Procedures: After getting permission, followed by retrieval of data that begins with providing explanations and informed consent to students as respondents with parents and or teachers representing parents, as well as to teenagers in LPKA with prison providers or parents. To provide explanations and request parental consent through telephone contact or direct interaction.

Instrument: Data collected using questionnaire that has been tested for validity and reliability. The instrument was developed referring to the Juvenile Counseling and Assessment Program Model (JCAP Model) as risk factors including the factors the individual, family, school, and peer group,coping mechanisms, lifestyle and technology [4,5,7,9–11]. Juvenile delinquency instruments were developed based on theory [3,12,13].

Respondents assessed the independent variable associated himself to be risk factors and its behavior as the dependent variable. Subject given a goal by circling number 1 (strongly disagree), 2 (disagree), 3 (agree) or 4 (strongly agree) regarding the measured independent variables. For instruments related to the dependent variable, respondents were asked to rate the degree of frequency associated with their behavior by circling the numbers 0 (never), 1 (sometimes), 2 (often) and 3 (always).

Data Analysis: Original data were inputted into an excel spreadsheet and checked by the researcher. All data were analyzed using the SPSS 20.00 software. The analysis is done in two ways, Bivariate analysis risk factors (independent variables) on juvenile delinquency (dependent variable) with Chi-square test analysis (X^2) after the data is converted into category data and then Analysis of the logistic regression test using the enter method to find out the magnitude of the influence (Odds Ratio) of each risk factor for the occurrence of juvenile delinquency .

Result

The following is described the results of the descriptive analysis of each variable and the results of the bivariate analysis of the effect of modern and dependent-independent variables.

Juvenile Delinquency (Juvenile Delinquency): The juvenile delinquency which is the indicator in this study contains the 6 most types of hate based on the results of previous studies. Description of juvenile delinquency based on the type as in table 1.

Table 1: Overview of Juvenile Delinquency Based Type Naughty Behavior

No.	Variable	There is No	Low-Moderate	Weight
1.	Violent Behavior	101 (34.2%)	126 (42.7%)	68 (23.1%)
2.	Theft/Deprivation	143 (48.5%)	103 (34.9%)	49 (16.6%)
3.	Use of substances/drugs	140 (47.5%)	84 (28.5%)	71 (24.1%)
4.	Destructive- an Property	80 (27.1%)	174 (59.0%)	41 (13.9%)
5.	Sexual Abuse/Harassment	120 (40.7%)	115 (39.0%)	60 (20.3%)
6	Murder	250(84.7%)	33(11.2%)	12(4.1%)

Based on table 8 it is known that the most juvenile behavior is substance use or included in narcotics, alcohol, psychotropic,and other addictive substances (NAPZA) groups, then violent and sexual abuse/abuse. Next, to find out the effect strength of the independent variable on the occurrence of juvenile delinquency, logistic regression tests were conducted with the enter method.

Logistic Regression Test Analysis Risk Factors for Juvenile Delinquency: Analysis results to determine the power of influence risk factor (independent variable) on ramen delinquency (dependent variable) can be identified based on the value of *Odds Ratio* (OR) such as table 2.

Table 2: Test Analysis Results in Logistic Regression Risk Factors for Teenager

Variable	B	P-value (sig)	Odds Ratio (Exp B)
Individual	-0.039	0.008	0.962
Coping Mechanism	-0.038	0.186	0.963
Family	-0.020	0.005	0.980
School Environment	-0.116	0.000	0.891
Peers	0.268	0.000	1.307
Lifestyle	-0.111	0.000	0.895
Technology	0.346	0.000	1.413

Based on table 2 it is known that of the seven risk factors, which have a significant effect on juvenile delinquency there are six, namely the variables of the individual, family, school environment, peers, lifestyle and technology. Coping mechanisms do not have a significant influence on the occurrence of juvenile delinquency. The results of the analysis also show that technology is the most influential factor in the occurrence of juvenile delinquency with an Odds Ratio (OR) of 1.413. This means that technological factors have an effect 1,413 times on juvenile delinquency. Based on the OR value it is known that after technological factors, the factors that influence juvenile delinquency are peers, family, individuals, lifestyle and school environment.

Discussion

The results of the analysis it is known that individual factors significantly influence juvenile delinquency. Individuals who do not have the ability, do not have confidence in their success in the future, do not have a good foundation of faith that has the potential to act according to their wishes. This is in accordance with the researcher's opinion, that life skills or individual competence affect juvenile delinquency[5]. This is in line with the opinion of Robles that life skills in the form of soft skills are interpersonal qualities and personal attributes that a person has[14]. Soft skills are personal and interpersonal behavior to develop and maximize human appearance or performance. Coping mechanism factors also significantly influence juvenile delinquency. Individual failure in solving problems will have the potential for behavioral disorders including juvenile delinquency. Coping mechanisms can be constructive or destructive[4]. The results of family factor analysis found no significant effect on juvenile delinquency. This is not in accordance with the opinion of experts that the family

is a risk factor that affects the occurrence of juvenile delinquency. families that influence juvenile delinquency are high levels of family dynamics, violence, poverty, family dysfunction, and poor family communication and relations[9]. This result is also not in accordance with the opinion of experts who stated that parenting and bonding effects on children's development. Poor parenting results in poor mother-child bonding (poor bonding) which can eventually lead to criminal behavior in children[15].

family factors are still a risk factor that has great potential for juvenile delinquency and should get serious attention. Families have a significant role in the success of children in the present and future. School environment factors significantly influence juvenile delinquency[5]. The incompatibility of school policies or rules, the pattern of teacher-student relations, has the potential for adolescents to rebellion or against existing rules. Peers have a significant effect on juvenile delinquency. This is also in line with the researcherthat juvenile delinquency is related to peer influence, antisocial behavior, and the quality and level of relationships in the group[16]. Further explained by other experts that bad friendships can result in problems in schools which can eventually lead to criminal behavior in children [15].

At the age of adolescence, children are more likely to gather with peers than with parents. Teenagers are comfortable if they gather with their peers because they have the same problems. Thus, if the peer group is bad, it will also have a negative impact on adolescents. Lifestyle factors significantly influence juvenile delinquency. This is in accordance with the theory that a good lifestyle will have a good impact on adolescents. Conversely, a bad lifestyle will have an adverse effect on adolescents. Associated with sleep rest patterns explained that sleep disorders or poor sleep patterns will interfere with emotional stability, individuals become irritable and irritable. Emotional disorders that occur due to disturbances or sleep patterns that are not good will have the potential for violence[17]. Likewise, the habit of exercise activities or recreation can reduce tension so as to make individual behavior adaptive. The inappropriate use of leisure time and recreational culture will have an impact on health [18].

Technological factors significantly influence juvenile delinquency [11]. This result is quite relevant because of the phenomena of life in today's technological era, making the internet and cellphones a necessity. Individuals are more pleased with cyberspace than the world of reality by using the internet and cell phone facilities they have. Related to the six indicators of juvenile delinquency behavior, it is known that the most juvenile behavior is the use of substances or included in narcotics, alcohol, psychotropic and other addictive substances (NAPZA), then violent behavior and sexual abuse. Furthermore, the results of the logistic regression test with the enter method are known that there are six risk factors that significantly influence juvenile delinquency, namely individual, family, school environment, peers, lifestyle and technology variables, while coping mechanisms do not have a significant influence.

The logistic regression test results are different from the bivariate test results with the chi-square test which shows that the coping mechanism has a significant effect, while the family does not significantly influence. In the opinion of researchers, these results indicate that the family is a factor that still must be considered and also determines the occurrence of juvenile delinquency. The family is the first place for individuals to learn and the golden age is formed early in the family. This is explained by Wiyani that the beginning of a child's life (early age) is a golden age ("Golden Age")[19]. Golden Age is a period of growth and development of children that occurs at the age of 0 to 6 years, where this time a child is in a family environment. Associated with coping mechanisms do not have a significant effect, in the opinion of researchers because these factors are not dominant in influencing adolescent attitudes and are internal. As is known that external factors are factors that are a more and more powerful influence on adolescents. So that the possibility of coping mechanisms will be maladaptive if the external push is too strong in adolescents. The results of the analysis also show that technology is the most influential factor in juvenile delinquency when compared to other factors. This is in accordance with the opinion which explains that the development of information and communication technology through the internet and cellphones (cellphones) is a phenomenon of modern society that can have an impact on society both positively and negatively[11].

Conclusions

Technology is a factor that has the most influence on juvenile delinquency. Inappropriate use of technology, for example, the wrong use of gadgets has the potential for juvenile delinquency. This shows that in this digital era there has been a significant shift in the causes of juvenile delinquency, from family and peer factors

to technological factors. This is reasonable because technology is now a major need for teenagers. Based on these results, further analysis is needed regarding the indicators of the factors that influence juvenile delinquency in order to develop new instruments in the early detection of juvenile delinquency behavior.

A Case Study of the Health Adaptation of Former Schizophrenics in Communicating with the Bugis Makassar Community in the South Sulawesi Province

Tuti Bahfiarti[1], Arianto[1], Muhammad Harun Achmad[2]

[1]Departement of Communication. Faculty Social and Political Science, [2]Department of Pedodontic, Hasanuddin University, Faculty of Dentistry, Hasanuddin University, Indonesia

Abstract

Objective: This study aims to identify and categorize the cases of health adaptation of former schizophrenic patients in the process of interaction and communication with the community after experiencing a healing phase.

Method: This research uses a qualitative method with the type of case study. The technique of determining informants using non probability sampling is purposive sampling intentionally characterizing former schizophrenics who have interacted and communicated directly with the internal and external environment. Field data collection techniques through primary data, such as participant observation and in-depth interviews with former schizophrenics. The informants selected and analyzed were nine cases of former sufferers who, on average, were aged 34 to 60 years.

Results: This study found a categorization of health adaptation cases of former schizophrenics who had been cured medically and had initial interactions with the internal and external environment. Based on the analysis of health adaptation cases, four phases are categorized, namely: the healing phase, the interaction phase, the acceptance phase, and the openness phase. After going through these four phases, it was found a pattern of health adaptation of former schizophrenic patients in interacting and communicating with the Bugis-Makassar community. First, the manifest pattern is the ability of former schizophrenics to deal with and overcome internal and external environmental problems. The manifest pattern is characterized by positive self concepts and self disclosure is increasingly open. Second, latent patterns indicate the inability of former schizophrenics to overcome problems in the external environment. This gives rise to negative self concepts and closed self disclosure to communicate with the Bugis-Makassar community.

Conclusions: Based on an analysis of nine cases of health adaptation of former schizophrenic patients in communicating with the Bugis-Makassar community, it was more dominant in the latent pattern than the manifest pattern. This is due to the higher openness in the internal environment compared to the external environment due to the shame of 'siri' in themselves and the nuclear family. As a result, fear arises when their families who are former schizophrenics suffer from lack or are not accepted in the Bugis-Makassar community.

Keywords: *Health Adaptation, former schizophrenics, Communication, Bugis Makassar.*

Introduction

Schizophrenia is a mental picture due to disharmony in the thought process, feelings and actions so that it affects social behavior. Schizophrenia is a schizophrenic reaction suffered by individuals and is regressive to avoid tension and anxiety in the self so as to cause delusions and hallucinations.[1] In the Bugis-Makassar community, the type of schizophrenia is still considered a psychiatric disease that although it has been declared medically cured from a doctor, people's perceptions of this disease still cause negative stigma. As a result, the nuclear family and community have a fear of schizophrenia.[1,2]

A very interesting factor is that South Sulawesi is in third place with a prevalence of 0.26% after Yogyakarta on Java and Aceh on Sumatra. Data of the South Sulawesi Special Region Hospital indicates that the data for schizophrenia patients tends to increase every year. This increase was shown by patients from the Toraja area. Medical record data of South Sulawesi Province Special Region Hospital in 2016 of 348 patients recovered with an initial diagnosis of a rage with 240 patients and anxious 108 patients.

Schizophrenia is an interesting phenomenon in South Sulawesi, where the majority of the population is ethnic Bugis-Makassar. Streotype factors and personal prejudice against schizophrenia cause the Bugis-Makassar community to tackle this type of disease through non-medical treatment, such as traditional healers and even 'inclusion'. The term shaman or 'sanro' in the Bugis-Makassar community, is a person who is an expert in treating diseases traditionally.[5,6,8]

The specification of the focus of this research is to find, categorize the process of interaction of health adaptation carried out by former Schizophrenic patients in communicating with the Bugis-Makassar community.

Method

Research Location: The health adaptation case study of a former schizophrenic sufferer in communicating with the Bugis-Makassar community is located in South Sulawesi, namely; Parepare City, Makassar City and Wajo District..

Types and Sources of Data: This type of research uses qualitative method referring to case studies. The aim is to reveal the health adaptation process of former Schizophrenia sufferers in communicating with the Bugis-Makassar community. The technique for determining informants through non probability sampling is purposive sampling based on the terms and objectives of the study. The informant's requirements are first, a former schizophrenic who has interacted directly with the community at least 3 months after being medically recovered from a doctor. Second, former schizophrenics who are willing to analyze their cases sequentially and in detail. Informant cases are based on research data sources, namely direct observation of social life. In depth interview techniques by collecting individual narratives of former schizophrenics based on medical records, recover, interact and communicate with their environment. This technique can explore deeply the lives of former schizophrenics before and after recovery.

Data Collection Techniques

In analyzing the identification and categorization data of health adaptation cases of former schizophrenic patients in the process of communication and interaction is done through the analysis of Miles.[12] The steps of Huberman's analysis in qualitative research are: data condensation steps (data condensation), presenting data (data display), and conclusion drawing and verification. Data condensation refers to the process of selecting, focusing, simplifying, abstracting, and transforming.

Results

Humans are social creatures who need direct interaction and communication with their environment. The need to communicate with other individuals, such as family, and peers is a basic need that must be met. Former schizophrenics are individuals who need a process of direct interaction and communication with the internal and external environment. Human psychological needs to communicate and need other people in social life.

Research informants are former schizophrenics who have been medically recovered from mental disorders due to physical, psychological and socio-cultural changes. Schizophrenics have a negative stigma in the views of some Bugis-Makassar people. Public perception assumes that Schizophrenia is a curse that must be avoided. As a result, people tend to keep their distance and direct contact with them. This is due to the myth of schizophrenia which is considered a "crazy" disease in which individuals experience hallucinations, illogical thoughts, cause aggressive behavior, and often scream hysterically. Even schizophrenics lose their ability to think, hallucinating causing them to be seen talking to certain objects that are not in front of them.

The results of tracing the case were carried out in three locations in South Sulawesi Province, namely Makassar City, Parepare City and Wajo Regency. In tracking down informants who were willing and open to be observed and interviewed on an ongoing basis found only nine people. This factor is caused by the closure of former schizophrenics when first interacting with the external environment. Shame or known as 'siri' in the Bugis-Makassar community is a barrier to the openness of the causes of the illness. The findings of informant characteristics based on the medical records of former schizophrenics can be seen in the following Table 1:

Table 1: Medical Records of Former Schizophrenics

Informant Number	Informant Former Schizophrenic Patient	Age (Years)	Gender	First Age Category Suffering from Schizophrenia (Years)	Age of Medical Treatment Period (Years)	Alternative Early Treatment
1.	Andi	60	Male	35	37	Shaman
2.	Lia	45	Female	37	37	Medical
3.	Baso	40	Male	30	31	Shaman
4.	Arlina	43	Female	22	22	Medical
5.	Adi	45	Male	21	26	Shaman
6.	Rafi	48	Male	33	33	Medical
7.	Elia	40	Female	35	35	Medical
8.	Ahmad	34	Male	22	29	Shaman
9.	Dani	50	Male	42	42	Medical

Source: Primary Data, 2019.

The data in Table 1, indicates that the informants of former schizophrenic patients had an average age of 40-45 years of age of 5 people. Age 46-60 years as many as 3 people and only 1 person aged 34 years. This condition is different from the results of Dindia's research (2000b: 24) which found women to be more open than men. Dindia found cases that women were more open about expressing themselves to women than men to women; or women are more open about expressing themselves to men than men to women. Then, an analysis of 205 studies assessed gender differences in self disclosure.) find women more open than men.[14] That when women told stories with their friends, they usually involved emotional feelings in expressing themselves.[15]

Analysis of the patient's medical record when first experiencing initial symptoms tends to choose the hospital or medical treatment as many as 5 cases. There were 4 cases that used medical treatment or traditional medicine for 1 to 4 years. Pure schizophrenia is a medical disease that has the potential to affect everyone.

Health Adaptation Phase Process of Former Schizophrenic Patients in Communicating with the Bugis-Makassar Society: The case of health adaptation of former schizophrenics starts with self-concept as a mirror for the individual in seeing himself. Individuals will react to the environment according to their own self-concept. The phase is the healing phase, the interaction phase, the acceptance phase, the openness phase. The characteristics and characteristics of the four phases can be seen in Table 2 below:

Table 2. Health Adaptation Phase Former Schizophrenic Patients

Early Phase of Healing	Interaction Phase	Acceptance Phase	Openness Phase
Passive ndividuals choose to remain silent and less interact and communicate with the external environment.	**Internal** Individuals tend to be open and interact with nuclear families.	**Reception** Individuals are personally accepted by the external environment.	**Closed** Individuals have gone through the process of healing, interaction, acceptance, but still closing themselves with the external environment.
Active Individuals are active and have their own initiative to open and interact, communicate with the external environment.	**External** Individuals tend to be closed or silent when interacting with the community in their environment	**Rejection** Individuals are personally denied the external environment.	**Open** Individuals have gone through the process of healing, interaction, acceptance, but still closing themselves with the external environment.

Source: Primary Data, 2019

Based on the findings and categorization of health adaptation cases of former schizophrenics in four phases: First, the healing phase. In this phase, former passive schizophrenics remain silent, lack of interaction and communication with the external environment. Passivity is caused by feelings of 'siri' shame in the self so that it affects the negative self concept that is owned. That one's self-concept is oriented towards positive self-concept and negative self concept.[16,17] Former schizophrenics in the passive phase are in the category of negative self-concept. The behavioral characteristics of former schizophrenics consider themselves helpless, diseased and afraid of being ostracized in society.

Second, the interaction phase. This phase is marked by the motivation of former schizophrenics to interact and communicate with the internal and external environment.

Third, the acceptance phase. This phase is marked by the feeling of being accepted or rejected by the Bugis-Makassar people who still believe the myths of the history of schizophrenia.

Fourth, the openness phase. This phase category is characterized after the individual goes through a process of healing, interaction, acceptance. Although, the internal and external environment has been open to receiving former schizophrenics, there are still some who remain closed, especially in the external environment.

Pattern of Health Adaptation Former Schizophrenic Patients in Communicating with the Bugis-Makassar Society: Health adaptation is a way for former schizophrenics to adapt themselves to the internal and external environment to communicate with the Bugis-Makassar community. Based on the analysis of nine cases found two patterns of health adaptation of former schizophrenics communicating with the Bugis-Makassar community, namely the manifest pattern and the latent pattern. The manifest pattern is openness and positive self acceptance..

Furthermore, the latent pattern is marked by the closure of former schizophrenics who do not interact with the Bugis-Makassar community. The reason is that former schizophrenics fear the risk of resistance from the surrounding community. Former schizophrenics prefer to stay at home or do homework activities. Factors of self confidence and embarrassment 'siri' cause them to choose to close themselves with the surrounding environment. Former schizophrenics perceive that mental illness suffered will never be completely healed and must continue to take medication for life. Medical control through drugs makes former schizophrenics feel that the illness can recur. Finally, they have a negative self concept that tends to live in fear and not trust others too much. Based on tracing the cases of former schizophrenics, there were two patterns of health adaptation of former schizophrenics in communicating with the Bugis-Makassar community, as shown in the following Table 3:

Table 3. Pattern of Health Adaptation Former Schizophrenic Patients

Informant	Pattern of Health Adaptation	Former Schizophrenic Patient
Former Schizophrenic Patient	Manifest Pattern	Latent Pattern

Lia		√
Baso		√
Arlina		√
Adi		√
Rafi	√	
Elia		√
Ahmad		√
Dani	√	√

Source: Primary Data, 2019

The results found that the pattern of health adaptation cases of former schizophrenics in communicating with the Bugis-Makassar community was more dominant than the latent pattern of manifest patterns. Latent patterns indicate an inability to overcome the problems of self concept and self disclosure in former schizophrenics. There are only three informants in the manifest pattern category who are able to face and overcome problems to interact and communicate with the internal and external environment. former schizophrenics who are in the manifest pattern have had positive concepts and increasingly open self disclosure, such as, Table 4 follows:

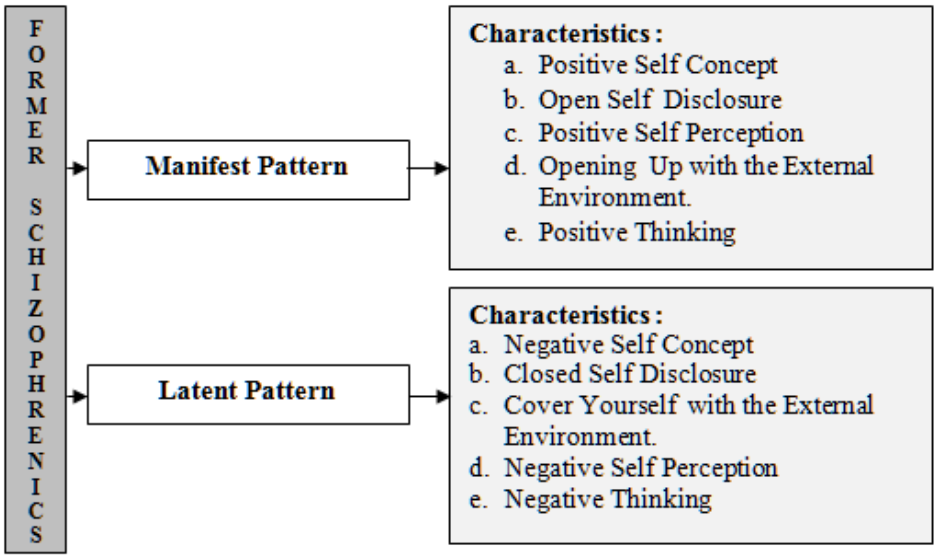

Figure 1. Characteristics of Health Adaptation Patterns of Former Schizophrenic Patients

In the case of former schizophrenics, community acceptance factors become a variable that can cause them to be in manifest or latent patterns. That is, the more positive acceptance of the internal and external environment of former schizophrenics, the more positive self concept and self disclosure they have. Positive self concept can lead to more effective individual interpersonal abilities, intellectual abilities and environmental mastery. The concept of self is not innate but rather through a process of learning and experience of interaction with others. Self concept is a life cycle that can change the mindset, positive outlook, culture, and socialization with the environment. For example, nuclear family, peers, and the community.

Conclusions

This study found the categorization of health adaptation cases of former schizophrenic patients in four phases, namely: the healing phase, the interaction phase, the acceptance phase, and the openness phase. The phase process of the former schizophrenic patient is a different health adaptation for each individual in interacting and communicating with the Bugis-Makassar community. The manifest pattern has the characteristics of a positive self concept and self disclosure is increasingly open. Latent patterns are characterized by negative self concepts and closed self disclosure to communicate with the Bugis-Makassar community. The results show that the health adaptation of former schizophrenics is more dominant in the latent pattern than the manifest pattern. The condition is caused by self concepts and self disclosure of former schizophrenics, nuclear family, and the perception of acceptance of the Bugis-Makassar community.

Acknowledgments: We would like to thank the collaborative research with students of the Communication Studies undergraduate program at Hasanuddin University for trust and funding in 2018-2019. Furthermore, the Bugis-Makassar community in the province of South Sulawesi, in particular, former schizophrenics who participated in the process research. Nurul as a team of enumerators who have contributed in the implementation of research.

Conflict of Interest: There is no conflict of interest in this study.

M.B.Ch.B, [4]Specialist Family Physician/ Al Zahraa Primary Health Care Center, Al Karkh Health Directory, Baghdad, Iraq, M.B.Ch.B. Fellow of Iraqi Board of Family Medicine

Abstract

Background: Anxiety at workplace is a learnt response to stress and it differs from generalized anxiety disorder as the symptoms are specifically related to the work environment. Excessive pressure from educational institutions, students and student parents, community attitude, work overload, students' poor behavior and role conflict make teachers always confused and this predispose to anxiety.

Aims of Study:

1. To estimate the prevalence of anxiety symptoms among an Iraqi sample teachers of primary and secondary schools.
2. To determine the socio demographic factors contributing to anxiety among teachers.

Subjects and Method: This is a cross-sectional study involving teachers from 16 primary and secondary schools in Baghdad, Iraq. Beck Anxiety Inventory (BAI) (Arabic Version) was used to measures anxiety symptoms and determine anxiety levels among school teachers. All teachers of both sexes in selected primary and secondary schools who agreed to participate in the study and responded with data required were included.

Results: Most of teachers showed levels of anxiety symptoms that are higher than normal cut off of anxiety according to BAI. There was significant higher average score for BAI among primary school teachers while no significant difference was found when comparing different categories of levels of anxiety symptoms between the two groups.

Conclusion: Teaching profession is associated with high levels of anxiety in Iraq . Further studies are needed to confirm whether this anxiety is general to all Iraqi population or it is unique to teaching profession.

Keywords: *Anxiety, symptoms, occupational, school, teachers.*

Introduction

Anxiety is normally occurring emotion that is observed throughout human cultures and several animal species.(1)Anxiety is a diffuse, unpleasant, vague sense of apprehension which is often a response to an imprecise or unknown threat.(2) Anxiety is a normal human physiological mechanism that helps body respond to threat. The autonomic changes occurring in anxiety are essential to avoid danger and moderate anxiety

improves performance. When anxiety is associated with autonomic arousal, erroneous cognitions, exaggerated threat perceptions and dysfunctional coping strategies, it results in distress and impairment in activities of daily living. For most modern individuals, running from larger animals and imminent danger is a less pressing concern. Anxieties now revolve around work, money, family life, health, and other issues that demand a person's attention without necessarily requiring the 'fight-or-flight' reaction which is a physiological reaction that occurs in response to perceived harmful event, or threat to survival.(3)

Some people experience more anxiety than others. They misinterpret events and linger on their misinterpretation, thinking them through over and over again.(4). Symptoms of anxiety include fear,uneasiness, insomnia, cold or sweaty hands and/or feet, shortness of breath, incapability to be steady and calm, dry mouth, numbness or tingling in the hands or feet, nausea, muscle tension and dizziness**.**(5).Anxiety disorders are the most prevalent mental disorders around the world and are associated with significant comorbidity. Prevalence of anxiety disorders is estimated to be around 7.3% (4.8% to 10.9%).(6)

Occupational anxiety is a learnt response to stress. It differs from generalized anxiety disorder as the symptoms are specifically related to the work environment. It may develop as generalized fears, phobias, hypochondriacal anxieties regarding working conditions, and fears of inadequacy or judgment. Common anxieties include fear of public speaking, working in groups, fear of not meeting deadlines, worrying that work may not meet expectations of others .(7)

Excessive pressure from educational institutions, students and student parents, community attitude, work overload, students' poor behavior and role conflict make teachers always confused and this predispose to anxiety.(8)

Aims of the Study:

1. To estimate levels of anxiety symptoms among teachers of primary and secondary schools at Al Karkh province of Baghdad city, Iraq
2. To determine contributing sociodemographic factors associated with anxiety symptoms.

Subjects and Method: This is a cross-sectional study arranged from January 2018 till end of April2018. Data were collected during two working days a week (Sunday and Thursday) from 9 am o'clock to1 pm o'clock.

Al Karkh 1 Directory of Education is one of three educational general directories responsible on administration of schools at Al Karkh province; Baghdad city,Iraq. A list of all primary and secondary schools within in Al Karkh 1 administration were taken from General Directory of Education/Baghdad/ Alkarkh_1 records. Primary schools include classes of 1st to 6th grades while secondary schools include classes of 6th to 12thgrades. 500 schools were eligible for the study. A cluster sample of 8areas within Al Karkh 1 administration is selected and from these areas 16 schools were selectedrandomly.

A total number of teachers present at time of visit were 320. Fifty six teachers refused to participate in the study and 47 teachers returned incomplete information, 217 teachers fully responded to required data for the study; 75 being from primary schools and142 from secondary schools,and were willing to participate in this study.

A self-administered questionnaire form is used. The first part of questionnaire included socio demographic characteristics;age,gender, marital status, years of work, educationaldegree, monthly income, number of classes per week.

The second part of questionnaire included the Beck Anxiety Inventory (BAI) (Arabic Version) which measures anxiety symptoms and determine anxiety levels(9). A preliminary pilot study was carried out on small group of 10 teachers (this group of teachers was excluded from the study sample).

Ethical Approval: This study was approved by the Scientific Committee Supervising Study of Fellowship of Arab Board of Family Medicine in Iraq. Official approval was obtained from General Directory of Education Baghdad/Alkarkh_1 to collect data needed for the study

All teachers were informed about the aim of the study, the way of answering the study instruments, and their right not to participate. Before sharing in the study, informed consent was obtained from all participants.

Statistical Analysis: Analysis of data was carried out using the available statistical package of SPSS-24.

Data were presented in simple measures of frequency, percentage, mean, standard deviation, and range (minimum-maximum values).

T test was used to test significance of differences for continuous data while chi square or Fisher exact were used for categories. Statistical significance was considered whenever the P value was equal or less than 0.05.

Results

A total of (217) teachers from both primary and secondary schools were included with mean age of the teachers of primary schools was (44.7±8.8), while mean age of teachers of secondary schools was (43.3±9.3). Female teachers were more than male teachers in both groups and the numbers of females were significantly higher in secondary schools (p value 0.0027). Most of teachers were married compared to single and divorced or widowed with significant difference favoring married status for the secondary school teachers (p value 0.002) .The means of number years of work were (19.1±9.4) and (15.6±8.0) for primary and secondary schools respectively and the difference was found to be significant (p value 0,012) . Most of primary school teachers were of institute qualification while secondary school teachers were mostly of bachelor qualification. The monthly income was significantly higher among primary school teachers (p value 0,027) and both groups showed comparable average number of classes per week.

Most of teachers (72.8%) showed levels of anxiety symptoms that are higher than normal cut off of 8 according to BAI in both groups and 27.2% of teachers only showed normal or minimal levels of anxiety (table 1). Although there was significant higher average score for BAI among primary school teachers (table 2) there was no significant difference when comparing different categories of levels of anxiety symptoms between the two groups (figure 1).

The levels of anxiety symptoms were significantly associated with female gender in both groups (p value 0,0001 for both groups) . There was significant relation between levels of anxiety symptoms and number of school years (p value 0.004), monthly income (p value 0.034) and number of classes per week(p value 0.0001) for primary school teachers but not secondary school teachers while other socio demographic characteristics showed no significant relation with levels of anxiety in both groups.

Table 1: Rates of anxiety among all participant school teachers.

BAI	No. of teachers	Prevalence
Normal-Minimal (0-9)	59	27.2%
Mild-Moderate (10-18)	63	29.9%
Moderate-Severe (19-29)	51	23.5%
Severe anxiety (30-36)	44	20.3%
Total	**217**	**100%**

Table 2: The difference of means and SD of BAI between primary and secondary school teachers.

Beck Anxiety Inventory (BAI)	Primary	Secondary
Mean±SD	22.0±12.4	18.0±12.1
Standard Error of Mean	1.43	1.02
P value	0.022*	

*Significant difference between two independent means using Students-t-test at 0.05 level.

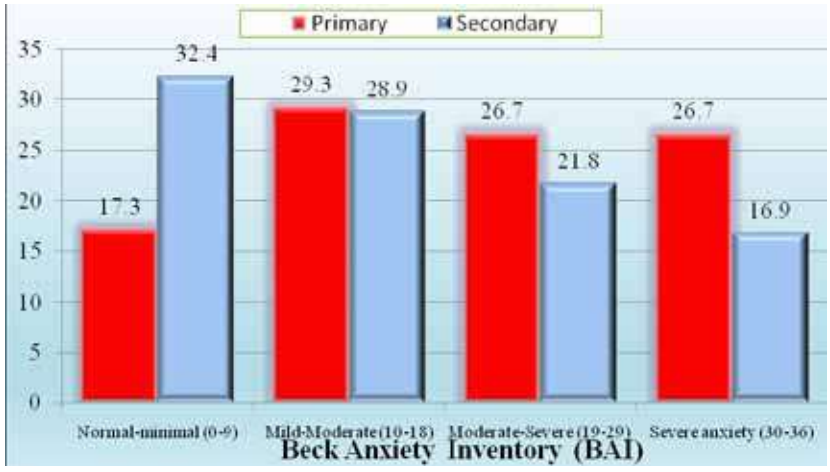

Figure 1: Comparison between rates of anxiety among primary and secondary school teachers. P value 0.05

Discussion

The overall rates of anxiety symptoms among this sample of school teachers are high. Such high rates are not unique to Iraqi population of teachers. Gonçalves GB et al (2015) in Brazil found comparably high anxiety rates .[10] Dalia D. and Hiba A. (2017) in Egypt found prevalence of anxiety among school teachers to be of about 67.5%[11] and Sharron SK Leung et al (2009) in Hong Kong noted that prevalence of anxiety was even higher and moderate to extremely severe levels of anxiety were found in 57.2% of school teachers [12] while Yousef A. Taher et al (2016) in Libya found that 61% of teachers had high rates of anxiety **[13]**.It is not known how much are the rates of anxiety symptoms among Iraqi population in general . In the Iraqi mental health survey arranged by world health organization at 2006-2007 it was found that 9.11% of Iraqi population had met the criteria of any anxiety disorder [14]. This survey examined the presence of disorders rather than symptoms and this can explain the much lower figure than one found in this study and the many other above mentioned studies. Further studies are needed to look for how much are the figures of prevalence of anxiety symptoms in the general Iraqi population and also in other profession to confirm how much anxiety is specifically related to school teaching in Iraq.

The number of female teachers in the current study is significantly high and there is significant association between gender and rates of anxiety. Inherently anxiety is more common amongwomen than men [15]. Females prefers teaching as a job as its relatively short working hours saves time for other household responsibilities, on the other hand such dual role of house wife and working woman can predispose to stress that ultimately results in anxiety . This is supported by fact that most teachers in this study are married although no significant relationship was found between marital status and levels of anxiety. Marriage by itself is protective for both physical and mental health [16] but it is possible that such dual role conflict between house and job duties of modern working woman that predispose to anxiety [17]

Further studies are needed to examine factors from home environment and school environment that contribute to such high figures of anxiety symptoms among school teachers, more over comparative studies are needed to be arranged with samples from otheroccupations to confirm this association between teaching career and anxiety.

Study limitations:

The limitations of this work include the use of a cross-sectional study where the causality and the direction of relationships couldn't be determined. Another limitation was the use of self-reported questionnaires where the responses to questionnaires could be affected by personal or social values leading to the probability of recall bias. A complete refusal of several teachers in many school lead to a reduction in sample size.

Acknowledgement: Authors would like to express their appreciation and thanks to all the teachers who agreed to participate in the study. The authors do appreciate help presented by official staff of Al Karkh 1 educational directorate; Baghdad, Iraq for their help they provided to authors while doing this research. Thanks and gratitude are owed to staff of schools included who helped make this work possible.

Conflict of Interest: The authors and planners have disclosed no potential conflicts of interest, financial or otherwise.

Funding: This work received no any funding and was arranged by authors for personal academic achievement.

Psychososial Experience of Diabetes Melitus Patients While Experiencing the Diabetes Feet Ulcer in Rumah Perawatan Luka Ubalan Pamotan Village Dampit Subdistrict Malang Regency

UlulAzmi Iswahyudi[1], Indah Winarni[2], Tony Suharsono[2], Heni Dwi Windarwati[2], Ikha Andriyani[3]

[1]Nursing Masters Study Program, Faculty of Medicine, Universitas Brawijaya, [2]Teaching Staff of the Faculty of Medicine, Universitas Brawijaya, [3]Owners of Rumah Perawatan Luka Ubalan

Abstract

Introduction: This study reveals the psychosocial experience of diabetic mellitus patients with diabetic foot ulcers while undergoing treatment at *Rumah Perawatan Luka Ubalan* (Ubalan Ulcer Nursing Home).

Objective: Exploring the meaning of psychosocial experiences of diabetes mellitus patients with diabetic foot ulcers during treatment.

Method: Qualitative research uses phenomenological interpretive approach and is analyzed using IPA (Interpretive Phenomenological Analysis).

Findings: This study found 3 major themes: fear of facing death, loss of opportunity to interact socially with others, feeling insecure about the physical appearance of the disease.

Conclusion: Perceptions and psychosocial responses in diabetic foot ulcer patients have an impact on the life of social interactions.

Keyword: *Meaning of life, foot ulcer, diabetes mellitus.*

Introduction

Diabetes mellitus is a metabolic disorder characterized by an increasing of blood sugar levels[(1)]. Diabetes mellitus to be considered as a serious public health problem, because it is one of the four dangerous non-spread diseases after cardiovascular disease, cancer, and chronic lung[(2)]. Diabetes mellitus which occurring lasts long may cause damage to organs such as heart problems, blood vessels, eyes, kidneys, and nerves [(3)].

The occurrences number of Diabetes mellitus has increased each year. Huang reported that in 2015 there were 415 million people and an increase of 451 million in 2017[(1)]. International Diabetes Federation found that Indonesia was ranked 7th in the world for the highest prevalence of patients with diabetes mellitus in the amount of 8.5 million, after China, India, America, Brazil, Russia and Mexico [(4)].

Data obtained from the Malang District Health Office in July 2018, stated that diabetes mellitus is a disease that is ranked eighth in the category of 15 most diseases with a total of 1023 people. In 2017, the Pamotan Public Health Service, DampitSubdistrict, Malang Regency ranked 9th from 10th health centers which had the most cases of diabetes mellitus with 785 people. The researchers did not find patients suffering from diabetes mellitus with diabetic foot ulcers based on data provided, but empirically researchers found that many patients had diabetic foot ulcers in the society. Frykberg stated that estimated 15% among all patients with diabetes mellitus are suffering diabetic ulcers[(5)].

Prolonged treatment processes in diabetic foot ulcer patients may affect physical, economic, emotional response, depression, unhappiness with social life and their quality of life resulting in psychosocial disorders[(6)].

King in his research entitled 'Psychological Factors and Delayed Healing in Chronic Wounds' stated that there is an effect of psychosocial stress factors on the healing process of foot ulcers in diabetes mellitus and recommend nurses as medical teams to always pay attention to psychosocial aspects as an important part in treating diabetes mellitus foot ulcers by providing comprehensive services[7].

Data obtained from preliminary studies conducted by researchers in October 2018 indicated that participants had diabetes for approximately 20 years, still undergoing ulcer treatment. Doctors recommend amputation of the left leg. The verdict of amputation given by the doctor made him feel scared and anxious because he would lose one of his legs. Participants feel inferior because cannot work any longer, worried about financing ulcer treatment even though it have been borne by their children, pitying their children and wife for their sacrifice in caring for him, disappointed with his closest friends who rarely communicate and stay away. He had stopped participating in society activities because of embarrassment with the condition of his leg ulcer. The only thing for his daily activities are watching TV and listening radio.

Mental care is essential for treating process for patients with psychosocial cases. Fulfillment of psychosocial needs is required to help patients return to their family and society to be able to continue their duties and functions in accordance with their roles. Providing health education to achieve life goals independently aimed at patients, families, and groups and communities by improving their abilities, attitudes and skill is the goal of mental nursing [8].

The purpose of this study is to explore the meaning of the patient's experience of perceptions and psychosocial responses while undergoing wound care in Rumah Perawatan Luka Ubalan, Pamotan Village, Dampit District.

Research Method

This research is a qualitative research with an interpretive phenomenology approach. Participants in this study were persons with diabetes mellitus with diabetic foot ulcers, in total 5 (five) persons. The participant selection procedure was carried out using a purposive sampling technique, in accordance with inclusion criteria, specifically undergoing diabetic foot ulcer treatment at Ubalan Ulcer Nursing Home regularly, level 4 diabetic foot ulcer classification, have married and aged between 40-65 years old.

Research Findings: This study found 3 main themes and the researcher described the overall themes formed from the results of the analysis based on the expressions of the participants.

Theme: Fear of facing death: Fear according to Indonesia Dictionary (KBBI) means "feeling afraid (horrified) to face something that is considered to bring disaster". The researcher interpreted this theme that participants felt afraid of death due to their illness. This theme is arranged on sub themes Fear of death. This sub theme describes the concerns of participants in the process of diabetes itself. This was conveyed by participants through the following quote:

"Worried about how the person with diabetes, I saw my friend who died (because of diabetes)..." (P4)

"Yes, I am afraid of death, fear of death, I am afraid ... but I am not ready ... not ready yet ..." (P5)

"I was dumbfounded ... scared if there was a relapse of the disease (diabetic foot ulcer), suddenly died" (P4)

Theme: Loss of opportunity to interact socially with other people: The loss according to KBBI is "no more; vanished; invisible". The researcher interpreted what was conveyed by the participants that participants expressed disappointment that they could not socialize with others because of their physical limitations. This theme is composed of two sub-themes described by the researcher as follows:

Feeling disappointed can't socialize: It describes a condition in which participants feel disappointed because they are unable to relate socially to other people around them. The condition of diabetic foot ulcers limits the movement of participants socialize with others. This has an impact on his mentality, participant feels regret because he has lost the opportunity to interact with others. The participant's statement is illustrated as follows:

"Yes ... if I can't come (to recitation), I feel regretful ..." (P4)

"Actually, it is unfortunate (regretting) that you cannot attend (recitation) ... gathering with people like our own family ... and being friends" (P3)

Feeling physical limitations prevents interaction with others: It was interpreted by researchers based on the participants' expressions that with their diabetic foot ulcer condition, participants felt they were not free in associating with friends and the community around their home. Participants reveal the condition of his body at this time causing physical disturbances that can interfere with the interaction of his life. The following is a quote from participants regarding the statement above:

"... when I want to get out I find it difficult to wear sandals, and actually there is also a desire to sunbathe under the sun" (P1)

"... Yeah no, I am sick ... I can't walk, so I can't go anywhere, just at home" (P2)

Theme: Feeling insecure about the physical appearance of the disease: It describes a situation which participants feel insecure about the condition of their foot ulcer. This condition may arise because diabetic foot ulcers have a characteristic that makes this disease shunned by people around him as the presence of a distinctive smell. This has an impact on the emergence of insecurity when interacting with others. Confident according to KBBI, is "absolutely sure or ensuring the ability or strength of someone or something". Lack of confidence means individuals who do not have confidence in their abilities or strengths. The theme of feeling insecure about the physical appearance of the disease is composed of two sub themes, namely:

Worried about gangrenous ulcer conditions, this sub-theme provides a picture of the feelings experienced by participants regarding the distinctive odor of the ulcer's leg. Participants express these feelings through the following quote:

"... The fear is, people said diabetes is a deadly disease that is difficult to heal ... it is difficult to recover, continue to wet (ulcer) ..." (P5)

"Yes, I feel worried (ulcer odor) ... I'm worried like this ..." (P1)

The second sub theme which was composed from the theme above was **feeling inferior because of their illness condition**, participants felt embarrassed when they gathered with other people because of the condition of the wound in the leg with bandage dressing. This was revealed from the participant's statement, as follows:

"Yes, my feeling when wearing there a bandage ... and when there are flies ... I feel more reluctant ... I'm ashamed of this" (P4)

"…… It means that I don't seem to have function anymore, it's my feelings ... but this is only my own feeling, because you say it's not like that, people think, it's just my feeling "(P1)

The other sub-theme is **fear of disability,** the meaning of this sub-theme is the participants are afraid of amputation if the condition of diabetic foot ulcer is getting bigger (and worse). The quote as follows:

"... What I can do sir. If going to be like this, it's hard for me ... later if getting bigger, shall go to see doctor. It will be amputated, my troubles "(P4)

Discussion

Theme: Fear of facing death: Contextually the fear of facing death reflects the feelings of participants who are afraid of death. This is due to diabetic foot ulcer conditions. Fear of the disease that began to be felt when the victim was convicted of suffering from an illness, this has an impact on worry and anxiety. Taylor revealed that feelings of anxiety or fear of chronic health problems (diabetes mellitus) caused by imagination of potential life changes and the possibility of death may worsen glucose control and symptoms of diabetes [(9)].

Other research reveals the same phenomenon, as conducted by Ismail through his research, found results that one third of people with diabetes mellitus experience depression which is directly related to death[(10)]. The results of the study also provide the same picture that participants were worried about the disease, because some of the participant's friends eventually died because of the same disease. Other feelings of fear of death are also felt by participants but psychologically, participants are not ready to face it. This condition is in line with the expression of Lehto, that many factors make an individual feel anxious about death. Amongst them they do not know what he is facing after death, a picture of the pain of death, worry about the family that will be left after and lack of understanding the meaning of life and death [(11)].

The condition of fear of death is physiologically described in patients with diabetes mellitus will cause failure in treatment such as fear of glucose monitoring, failure in self-control related to dietary habits, memory failure and perceived self-failure in controlling diabetes

can inhibit diabetes self-management behavior so that it interferes with the process daily treatment and care [12].

Theme: Loss of opportunity to interact socially with other people: This theme has a contextual meaning, that's participants have a dilemma towards the condition of diabetic foot ulcers which limits their social interaction with others. The results of a study conducted by Trisnawati revealed that foot ulcer patients diabetes will feel cautious in carrying out their activities because they are afraid they will cause more severe conditions[13]. This situation causes patients to be stressed and may interfere with their social interactions with others. In line with research, Astrada stated that social interaction is one of the risks that may occur in diabetic foot ulcer patients [14].

Participants expressed feelings of disappointment cannot interact because the condition of diabetic foot ulcers that cause odor, pain and cannot walk so they depends on the child and spouse for daily activities. According to Agustin, she revealed the results of her research, if diabetic patients suffer injuries, they will experience disruption of activity, emotions, and pain due to the smell of diabetic foot ulcers [15].

Physical limitations cause participants unavailable to socialize with the society. Participants revealed that his condition was still not healthy enough so he felt uncomfortable to interact socially with other people. Social interaction can be disrupted due to physical weakness, feeling bad and dirty wounds that affect the feeling of comfort both physically, psychologically and socially.

Other participants felt sad and sorry that they could not interact socially. Participants assume that by gathering together there will be many benefits, such as the existence of a sense of pleasure in being able to share and exchange ideas and remind each other in self-improvement. Another thing illustrated by this theme is the existence of desire but is limited by the physical conditions suffered by the participants, he is aware about his physical difference with others. Brown said patients with chronic diabetic foot ulcers did not seems to suffer a higher level of loneliness than their healthy counterparts, but with their present conditions they felt different from others [16].

Theme: Feeling insecure about the physical appearance of the disease: It has contextual meaning, namely participants with diabetic foot ulcer conditions feel inferior due to diabetic foot ulcer conditions that cause unpleasant odors, and this has an impact on the low self-esteem of a person. This low self-esteem may occur when a person has physical limitations or deficiencies and disrupts his life [8]. The results of this study illustrate that participants were afraid if their legs would be amputated if diabetic foot ulcers were not immediately treated. This makes participants feel shy and worried to interact socially with others.

The feeling of inferiority over the condition of diabetic foot ulcers has made participants uncomfortable, unsatisfied with their abilities, lacked self-confidence, and unable to express themselves in the social environment so they feel insecure even in their own environment and vice versa if the individual has self-esteem high, they will feel satisfied and comfortable and be able to get positive appreciation from the environment [15]. Diabetic foot ulcers can worsen the patient's psychosocial condition. This is in line with the report Ningsih about the psychosocial experience of diabetic patients who stated that complications of diabetic foot ulcers cause patients to feel scared, blame themselves, helpless, and feel insecure in socializing [17].

Conclusion

Psychosocial problems may occur in individuals who have a disease or suffer from a particular disease. This problem does not only have an individual impact, but in a broad sense, this problem will affect his social life. Diabetes ulcer sufferers have fears and anxieties for their illness, various limitations that have resulted in changes in the sufferer such as low self-esteem. These problems must be addressed immediately to prevent other health problems occurring. Various efforts need to be made by health workers to prevent this psychosocial problem to have a further impact on behavioral irregularities.

Is Osteopontine of Value in Diagnosis of Knee Osteoarthritis?

Walaa F. Mohammed[1], Faten Ismail Mohamed[2], Gihan M. Ahmd[3], Rasha A. Abdelmagied[3], Aliaa M. Mounir[4], Mustafa Abdel- Kader[5]

[1]Assistant Lecturer, [2]Professor, [3]Professor of Rheumatology and Rehabilitation, Faculty of Medicine, El-Minia University, Egypt

Abstract

Background: Osteoarthritis is a painful chronic joint disease characterized by structural changes to the whole joint, including loss of articular cartilage, development of osteophytes, synovial inflammation, subchondral bone changes, meniscal damage, muscle weakness, and ligamentous laxity.

Aim of the Work: To detect osteopontine (OPN) in knee osteoarthritis.

Method: 60 patients diagnosed as primary knee OA fulfilling Arthritis Rheum 1986 OA classification criteria, And 60 healthy control were included. All patients subjected to through history taking and full examination, body mass index, plain x ray knees PA view to assess severity according to Kellgren and Laurence grading, plasma and synovial fluid OPN levels, and plasma OPN for control. Assessment of pain for OA patients by patient pain visual analogue scale (VAS) and for functional status by Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC), ESR, CRP were done.

Results: there was significant difference between both groups regarding plasma osteopontine ($p<0.0001$), OPN levels in OA patients in plasma and synovial fluid was correlated with each other ($p <0.0001$), patient pain VAS, WOMAC score, K-L grading were correlated with plasma OPN levels with p value (0.001, <0.001, <0.001), and with synovial fluid OPN levels in primary OA patients with p value (0.008, <0.001, <0.001) respectively. ESR positively correlated with plasma OPN $p=0.004$.

Conclusion: OPN is higher in OA patients more than control, and it is higher in synovial fluid than plasma in knee OA patients, OPN correlated with markers of systemic inflammation and has impact on functional status so it can be used as a diagnostic and prognostic factor in knee osteoarthritis.

Keywords: *Osteoarthritis–OPN, ESR, synovial.*

Introduction

Osteoarthritis is a painful chronic joint disease characterised by structural changes to the whole joint including: loss of articular cartilage, development of osteophytes, synovial inflammation, subchondral bone changes, meniscal damage, muscle weakness, and ligamentous laxity. It results from a complex interplay of genetic, metabolic, biomechanical, and biochemical factors. At the knee, osteoarthritis most commonly affects the medial tibiofemoral and patellofemoral joint compartments.(1). Biochemical markers can be used to detect the disease and determine its severity. Therefore the extracellular matrix proteins were crucial to the occurrence and development of osteoarthritis. some extracellular matrix proteins such as osteopontin (OPN) was found to play important roles in promoting the inflammatory occurrence of cartilage cells in knee osteoarthritis, As an important extracellular matrix protein, OPN can mediate cellular growth, survival, adhesion and migration in osteoarthritis(2).

Aim of the work: To detect osteopontine (OPN) in knee osteoarthritis.

Patients and Method

The study conducted in Minia university hospital, included 60 patients with primary knee osteoarthritis (group I) and 60 apparently healthy controls (group II), patients in group I was complaining of knee effusion candidate for aspiration for detection of synovial fluid OPN level, both groups also were tested for plasma OPN level. All patients fulfilled criteria for diagnosis of primary knee osteoarthritis[3] were included as (group I). Sixty apparently healthy volunteers were served as a control group (group II). Patients with other rheumatological diseases as rheumatoid arthritis, systemic lupus, gouty arthritis, Other forms of arthritis, cancer or other chronic inflammatory diseases, Secondary knee osteoarthritis, Diabetes mellitus were **excluded** from the study

Statistical analysis: Analysis of data was done by personal computer using SPSS (Statistical program for social science) version 16.The data of all software patients and controls were fed into an IBM personal computer. Data were expressed as mean ± SD for parametric variables and as number and percent for non-parametric variable. Comparison between groups for parametric data was done by independent samples t-test (unpaired t-test). The difference was considered significant if P <0.05. The Bivariate Correlations procedure computes Pearson's correlation coefficient with its significance levels. Pearson's correlation coefficient is a measure of linear association for parametric variables and Sperman-rho correlation coefficient for nonparametric variables.

Results

Characters of OA patients; demographic data, laboratory investigation, functional status and radiological KL grading in table 1

Table 1: Characters of OA patients

Parameters Mean±SD and/or n (%)		OA patient n = 60
Age (y)		46-72(56.3±7.95)
DD (y)		2-10 (5.8 ±2.33)
BMI	Over weight	4 (6.7%)
	Obese I	16 (26.7%)
	Obese II	24 (40%)
	Obese III	16 (26.7%)
VAS		5-10 (7.53±1.22)
WOMAC total score		45-96 (74.26±14.07)
KL grading	I	5%
	II	35%
	III	38.33%
	IV	21.67%
Plasma OPN		92-222 (136.67±35.1)
Synovial fluid OPN		162-298 (218.4±37.7)
ESR mm/1st hour		8-36 (23.97±7.4)
CRP		53 (88.3%)

Functional status and severity in group I (OA patients): Table 2 shows that patient pain VAS, WOMAC score, K-L grading were correlated with plasma OPN levels with p value (0.001, <0.001, <0.001), and with synovial fluid OPN levels in primary OA patients with p value (0.008, <0.001, <0.001) respectively. ESR positively correlated with plasma OPN p= 0.004.

Table 2: Correlation between plasma & synovial osteopontine with demographic data, disease functional and severity indices in OA patients:

Parameters r (p)	Plasma OPN	Synovial fluid OPN
Age	0.032 (0.730)	0.800 (<0.0001)
DD	0.155 (0.236)	0.390 (0.002)
BMI	0.629 (<0.0001)	0.074 (0.574)
Patient pain VAS	0.431(0.001)	0.338 (0.008)
WOMAC totoal score	0.342 (<0.001)	0.358 (<0.001)
KL grading	0.358 (<0.001)	0.680 (<0.001)
ESR	0.362 (0.004)	0.087 (0.510)
CRP	0.895)) 0.017	0.689 (0.455)

Discussion

Osteoarthritis (OA) is a low-grade inflammatory disease of synovial joints and the most common form of arthritis[4]. It is a leading cause of chronic pain and physical disability in older individuals. OA is one of the most costly and disabling forms of joint disease, being far more common than rheumatoid arthritis (RA) and other forms of joint disease [5].

The increased expression of OPN has been observed in the joints of patients that were reported to be correlated with the severity of joint lesion and inflammatory status in the OA patients [6].

In our study patient pain VAS, WOMAC score, KL grading was positively correlated with plasma and synovial OPN levels.

Plasma osteopontine show statistically significant difference between both groups (p**<0.001**), and synovial fluid OPN was significantly higher than paired plasma level in primary OA patients.

In agreement with[7] who found in a similar study on Plasma OPN (in patients and control) and in synovial fluid OPN (in patients) levels in knee OA patients, that patients had higher plasma OPN concentrations compared to healthy controls (P <0.0001). Also OPN levels in synovial fluid were significantly higher with respect to paired plasma samples (p <0.001).

In another study done by **Qin et al.,**[2], who examined the synovial fluid from 42 patients with knee OA and 40 cases of the normal control group had effusion due to traumatic causes as meniscus injury or lower extremity fracture surgery in the hospital at the same period for OPN level and demonstrated that the expression levels of OPN in OA group was significantly higher than those in the control (post traumatic) group, (P<0. 05)

In agreement with **Haider et al.,**[8] who found In their study about OPN in knee OA patients and control, that plasma OPN level significantly correlated with synovial OPN in OA patients (r =0.806, P < 0.001), a significant difference between patients and controls as regards the plasma OPN levels (t =8.534, P < 0.001), OPN in synovial fluid was higher with respect to paired plasma. Also, OPN level in bothplasma and synovial fluid was significantly correlated with severity of knee pain (r =0.878, r =0.795, p <0.001).

In Conclusion: This study suggests that OPN is an inflammatory marker that can be used as a diagnostic and prognostic marker in knee OA.

Acknowledgment: Many deep thanks and gratitude go to my supervisors, my colleagues, patients and every person who had helped me by any means throughout this work.

Coal Dust Exposure and Gingivial Lead Line in Coal Miners

Widodo[1*], Sahdhina Rismawati[1], Eko Suhartono[2], R. Darmawan Setijanto[3]

[1]Department of Dental Public Health, Faculty of Dentistry, Universitas Lambung Mangkurat, Banjarmasin, Kalimantan Selatan, Indonesia, [2]Department of Medical Chemistry/Biochemistry, Faculty of Medicine, Universitas Lambung Mangkurat, Banjarbaru, Kalimantan Selatan, Indonesia, [3]Department of Dental Public Health, Faculty of Dental Medicine, Universitas Airlangga, Surabaya, Indonesia

Abstract

Coal dust contains less than 1% lead (Pb). This dust can enter the body through breathing, mouth and skin. Lead contained in coal dust can react with Sulfur and form gingivial leadline. The study was an observational study with cross-sectional design. The research subjects were coal miners in Sambung Makmur Sub-District, Banjar District, amounting to 100 people. The number of samples was calculated by the Slovin formula and obtained 80 people as samples and determined by simple random sampling technique. The sample obtained then determined the value of the gingivial lead line score as done by Sudibyo. The degree of gingivial lead line is assessed based on the score as follows: 0 = no gingivial lead line; 1 = gingivial lead line found in 1-2 marginal gingival anterior teeth labial surface; 2 = gingivial lead line found at 3-4 marginal gingival anterior teeth labial surface; 3 = gingivial lead line at>4 marginal gingival anterior teeth labial surface. In addition, age, working period (tenure), and smoking habits are the variables measured in this study. The data obtained were analyzed using the chi-square test with α = 5%. The conclusion is the incidence of gingivial leadline of coal miners was related to age, tenure, and smoking habits.

Keywords: *Gingivial leadline, lead, coal dust, coal miners.*

Introduction

Kalimantan Selatan is one of the provinces in Indonesia which has the largest coal mining with locations spread throughout the region. One of the problems arising from mining is the issue of coal dust which can have an impact on health. This is due to the metal content found in coal dust, namely Fe 36.9%; Si 17.9%; Mo 15%; Al 10%; Ca 8.67%; S 4.7%; Ti 3.65%. Some heavy metal content of less than 1% includes K, V, Cr, Mn, Ni, Cu, and Pb.[1]

Coal dust containing metals can enter the body through breathing, mouth and skin. Furthermore, metals contained in coal dust, especially Lead and Sulfur will accumulate in gum tissue through systemic and local processes, namely direct absorption by the oral mucosa. Lead and Sulfur produce lead sulfate which is deposited in the basement membrane of gum.[2] These deposits provide a picture of the lead line in the gums. Various factors that are thought to influence the occurrence of gingivial lead line, such as working period, age, use of personal protective equipment (PPE), smoking habits, etc.[3]

The working period (tenure) affects the incidence of gingivial lead line, because the working period shows the length of time someone is exposed to coal dust. The longer the exposure time, the incidence of gingivial lead line will bemore severe . Likewise, increasing age causes the detoxification rate to slow down, resulting in a buildup of lead from coal dust. This incident gingivial lead line will be more severe.[4]

Previous research has revealed that the working period has a relationship with the incidence of gingivial lead line in traffic police.[4] Other studies have also

Corresponding Author:
Widodo
Department of Dental Public Health, Faculty of Dentistry, Universitas Lambung Mangkurat, Jl. Veteran No. 128B Banjarmasin - Indonesia
e-mail: dodowident@gmail.com

revealed that the workshop workershave a risk of gingiviallead line, because every day they are exposed to fumes that contain lead.[5] Coal miners are a group at risk of developing gingivial lead lines. This is due to his daily exposure to coal dust containing lead and sulfur. However, not many studies have revealed this. Therefore in this study we will examine the relationship of working period, age, and smoking habits to the incidence of gingivial lead line of coal miners.

Materials and Method

The study was an observational study with cross-sectional design. The research subjects were coal miners in Sambung Makmur Sub-District, Banjar District, amounting to 100 people. The number of samples was calculated by the Slovin formula and obtained 80 people as samples and determined by simple random sampling technique.

The sample obtained is then determined by the value of the gingivial lead line score as done by Sudibyo.[6] The degree of gingivial lead line is assessed based on the score as follows:

0 = no gingivial lead line

1 = gingivial lead line found in 1-2 marginal gingival anterior teeth labial surface

2 = gingivial lead line found in 3-4 marginal gingival anterior teeth labial surface

3 = gingivial lead line at>4 marginal gingival anterior teeth labial surface

In addition, age, working period, and smoking habits are the variables measured in this study.The data obtained were analyzed using the chi-square test with α = 5%.

Findings and Discussion

This study involve 80 male who were willing to be sample in the study. The lowest age is 19 years and the highest is 45 years. The existence of gingivial lead line can be seen in Figure 1.

(a) **(b)**

Figure 1. Normal gum looks reddish (a) and gingivial lead line (b)

Gingivial leadline, also called Burtons's Line, is a pigment in the form of gray-blue lines at the border between teeth and gums.[7,8] Leadline occurs due to a reaction between lead and sulfur ions released by the bacterial oral cavity, leading to lead sulfid at the tooth and gingivial surface.[8]

Relationship between age and gingival lead line: The relationship between age and the gingival lead line is presented in table 1. Gingivial lead line is found in>4 marginal gingival anterior teeth labial surfaces. It is found more at the age of 30-45 years.

Table 1. Relationship of Age with Gingivial Lead Line

Age (Years)	Gingivial Lead Line Score			
	0	1	2	3
15-30	15%	23.75%	7.5%	6.25%
30-45	7.5%	8.75%	15%	16.25%

Based on the results of the chi-square test obtained p = 0.005 (p <0.05), it was concluded that age was associated with the incidence of gingivial lead lines in coal miners. The relationship between age and

gingivial lead line caused by in the young age more sensitive to lead activity. It is closely related to organ development and function are not perfect. In the old age the sensitivity is higher, this is caused by the activity of the biotransformase enzyme decreases with increasing age and the resistance of certain organs decreases to the effects of coal dust containing lead. The older the person, the higher the amount of lead accumulated in the body tissues.

On the other hand, the activity metaloprotein (metal-binding protein) in the oral cavity will slowly decrease the activity. This causes lead contained in coal dust can not be transported optimally by metalloproteins. As a result, lead reacts with sulfur in the oral cavity and leadline is formed. The results of this study are in accordance with the study by Vera[9], which states that the age of street vendors in the city of Semarang affects the incidence of gingivial leadline.

Relationship between working period and gingiviallead line: Working period of more than 12 months caused 16% of the study subjects have gingivial lead line at>4 marginal gingival anterior teeth labial surface. The relationship between the working period and the gingivial lead line is presented in table 2.

Table 2: Relationship between Tenure and Gingivial Lead Line

Working period (month)	Gingivial Lead Line Score			
	0	1	2	3
<3	12.5%	3.75%	1.25%	1.25%
3-6	5%	7.5%	1.25%	1.25%
6-9	1.25%	6.0%	6.25%	1.25%
9-12	2.5%	2.5%	1.25%	2.5%
>12	1.25%	13.5%	12.5%	16.25%

Based on the results of the chi-square test obtained p = 0.000 (p <0.05), it was concluded that the working period of coal miners was related to the incidence of gingivial lead line. The working period shows the length of exposure to coal dust containing lead. Lead as the cause of many lead lines accumulates in gum tissue through systemic processes or local processes, namely direct absorption by the oral mucosa. This lead will only form a lead line after reacting with sulfur ions produced by anaerobic bacteria in the oral cavity.[10] The results of the reaction are lead sulfate compounds which are then deposited on the gum basement membrane. These deposits provide a picture of the lead line in the gums. Thus, it can be concluded that indirectly the Oral Hygiene Index (OHI) and Gingivitis Index (GI) are important factors that determine the quality of lead line formation because these two factors are closely related to the presence of bacteria in the oral cavity.[11]

Relationship between smoking habit and gingivial lead line: In table 3, the relationship between smoking habits and the incidence of gingivial lead line is presented.

Table 3: Relationship between Smoking Habit and Gingivial Lead Line

Smoking habit	Gingivial Lead Line Score			
	0	1	2	3
Not a smoker	7.5%	10.0%	7.5%	1.25%
Smoker	15.0%	22.5%	15.0%	21.25%

Based on the results of the chi-square test obtained p = 0.158 (p <0.05), it was concluded that the smoking habits of coal miners were not related to the incidence of gingivial lead lines. The standard of cigarettes taken from tobacco, in the handling process often uses pesticides which also contain basic ingredients of lead (Pb).[12] Thus, research subjects who had a smoking habit of Pb levels increased the amount of Pb exposure both from the contents of the cigarette and from coal dust were also sucked. This can worsen the incidence of gingivial leadline.

Conclusion

The results of this study concluded that the incidence of gingivial leadline in coal miners was significantly related with age, working, and smoking habits. Thus, a comprehensive effort is needed to improve dental and oral health.

Ethical Clearance: This research has gone ethical feasibility testing by the Ethical Research Commission of the Faculty of Dentistry, University of Lambung Mangkurat and declared as ethical: no. 28/KEPKG-FKGULM/EC/IX/2017.

Re-evaluation of Psoriatic Patients with Metabolic Syndrome: A Case Control Study Searching for the Highly Prevalent Criteria

Wisam Majeed Kattoof

Lecturer, Dermatology and Venerology, College of Medicine, AL-Mustansiriyah University, Iraq

Abstract

Psoriasis is a common chronic inflammatory skin disorder, presented as erythematous plaques with salmon pink color and silvery white scales. The association between psoriasis and metabolic syndrome have recently demonstrated by many studies, and this link suggested by the presence of systemic inflammatory status with the high level of cytokines. The study aimed to evaluate psoriatic patient who have metabolic syndrome with recording of the frequency of the criteria of this syndrome. Sixty two cases of psoriasis involved in this study with age and gender matched controls. Patient was diagnosed as having metabolic syndrome if he has three or more of the criteria depend upon IDF/NHBLI/AHA/World Heart Federation/International Atherosclerosis Society/International Association. Thisstudy revealed that metabolic syndrome occur in a higher frequency among psoriatic patients (58%) than the controls (16%). The highly prevalent criteria among psoriatic patients with positive metabolic syndrome was increase waist circumference at the top (100%) and hypertriglyceridemia came next (69%), with low HDL, hypertension, and raised fasting blood glucose came successively. The study reiterates the fact that Metabolic Syndrome and psoriasis do have a close association. Our study shows that central obesity and hypertriglyceridemia occur with high frequency among psoriatic patients with positive metabolic syndrome.

Keywords: *Psoriasis, metabolic syndrome.*

Introduction

Psoriasis is a common chronic inflammatory skin disorder, presented as well defined plaques with salmon pink color and silvery white centrally attached scales. Psoriasis is considered to be a polygenic disorder [1-3].Recently, many studies demonstrated the association of psoriasis with systemic disorders like metabolic syndrome, cardiovascular disease, osteoporosis,inflammatory bowel disease, cancer, and depression. Systemic inflammation and the presence of interleukin-6 and tumor necrosis factor-α in high levels suggested the link between psoriasis and associated systemic disorders[4].

With regards to the immunopathogenesis of psoriasis and metabolic syndrome [chronic inflammation mediated by pro-inflammatory cytokines], both may develop "interdependently". Additionally, "insulin-like growth factor 1" have implicated in psoriasis "as a shared mediator in the proliferation of keratinocyte " and the development of hyperlipidemia and diabetes [5-10] .

Chronicinflammation (Th-1 and Th-17) with cytokines dysregulation, in addition to promotion of hyperplasia of epidermis in psoriasis, may also antagonize insulin signaling leading to increase risk of obesity and insulin resistance. In addition, both psoriasis and metabolic syndrome sharing the genetic susceptibility by the existence of pleiotropic "PSORS2-4, CDKAL1, and ApoE4" genetic loci [11,12] .Significant clinical implications may be demonstrated in psoriatic patients with metabolic syndrome, especially those on chronic

systemic treatments "use them with caution"because the coexisting metabolic disorders may be adversely affected[13].

Aim of our study was to evaluate psoriatic patient who have metabolic syndrome with recording of the frequency of the criteria of this syndrome .

Patients and Method

This case control study was conducted over a period of nine months from October 2018 till march 2019. Sixty two cases of psoriasis involved in this study collected from Department of dermatology in AL-Yarmok teaching hospital in Baghdad province with age and gender matched controls. Psoriasis was diagnosed clinically and suspicious cases proved by histopathological study .***Inclusion criteria*** are those with plaque psoriasis of at least 3 months, more than 18 years old, and not received any systemic medication for psoriasis for at least three months while ***Exclusion criteria*** are pustular and erythrodermic psoriasis, those taking systemic drugsin the three months before enrolling, pregnant women and those complaining from other autoimmune diseases .

Questionnaire was designed to obtain the information age,gender, duration of psoriasis,family history, height, and weight . Waist circumference was measured by placing a tape measure around the abdomen at the level of uppermost part of the pelvic bone. Blood pressure was recorded by taking the average of two separated measurements. Body mass index was measured by dividing the weight in kilogram on the square of height in meter and psoriasis severity evaluated by using the psoriasis area and severity index (PASI). Venous blood samples were taken 12 hour fasting status in the morning to measure fasting blood sugar and serum triglyceride in our hospital laboratories .For diagnosis of metabolic syndrome I depend upon "IDF/NHBLI/AHA/World Heart Federation/International Atherosclerosis Society/ International Association for the Study of Obesity, 2009". Patient was diagnosed as having metabolic syndrome if he has three or more of the following :

- waist circumference [>94 cm in men and >80 cm in women].
- serum triglycerides [≥150 mg/dL] or lipid-lowering drugs.
- serum HDL [<40 mg/dL in male and <50 mg/dLin female].
- Blood pressure [≥130/85 mm Hg]or antihypertensive therapy.
- Fasting plasma glucose [≥100 mg/dL] or pharmacologic therapy.

To clarify the effect of difference factors in this study parameters, the "Statistical Analysis System 2012" program was used and Chi-square test applied to compare the significance .

Results

Sixty two psoriatic patients [34 male (55%) and 28 female (45%) with their matched control] enrolled in this study . Their age distribution : 46 (74.2%) between 21years and 50 years, 10 (16.1%) above fifty years, and only six (9.7%)between 18 years and 20 years. Metabolic syndrome discovered to be presented in a higher frequency in psoriasis patients [36 (58%)] in comparison with controls [10 (16%)], the result is highly significant and the *p*-value was .000001. The highly prevalent criteria among psoriatic patients with positive metabolic syndrome was increase waist circumference [36 (100%)] with same percent in controls with positive metabolic syndrome. Serum triglyceride in the second place (25 patients 69%) with a nearly equal value in control group (7 control 70%) .

There were 12 (33%) psoriatic patients with positive metabolic syndrome found to have low S.HDL while in control group only two (20%) appeared to have low value of S. HDL . Elevated blood pressure was noticed in 22 patient (61%), in control group 6(60%) persons have elevated blood pressure . Sixteen (44%) psoriatic patients had elevated fasting blood sugar, in contrast to control group in which there were only 2 persons.

Regarding PASI score among psoriatic patients with positive metabolic syndrome: 32 (89%) subjects with a score less than 8, while only 4 (11%) subjects above 10 body mass index measurement revealed that 16 (44%) patients were obese, 10 patients (28%) were overweight and the another 10 (28%) patients presented with normal weight.

Table 1: The frequency of metabolic syndrome criteria among psoriatic patients in comparison with controls

Metabolic Syndrome criteria	Psoriasis Group = (62)					Contrpl Group = (62)				
	+ Metabolic syndrome 36		Metabolic syndrome 26		Chi-square (χ^2)	+ Metabolic syndrome 10		- Metabolic syndrome 52		Chi-square (χ^2)
	No.	%	No.	%		No.	%	No.	%

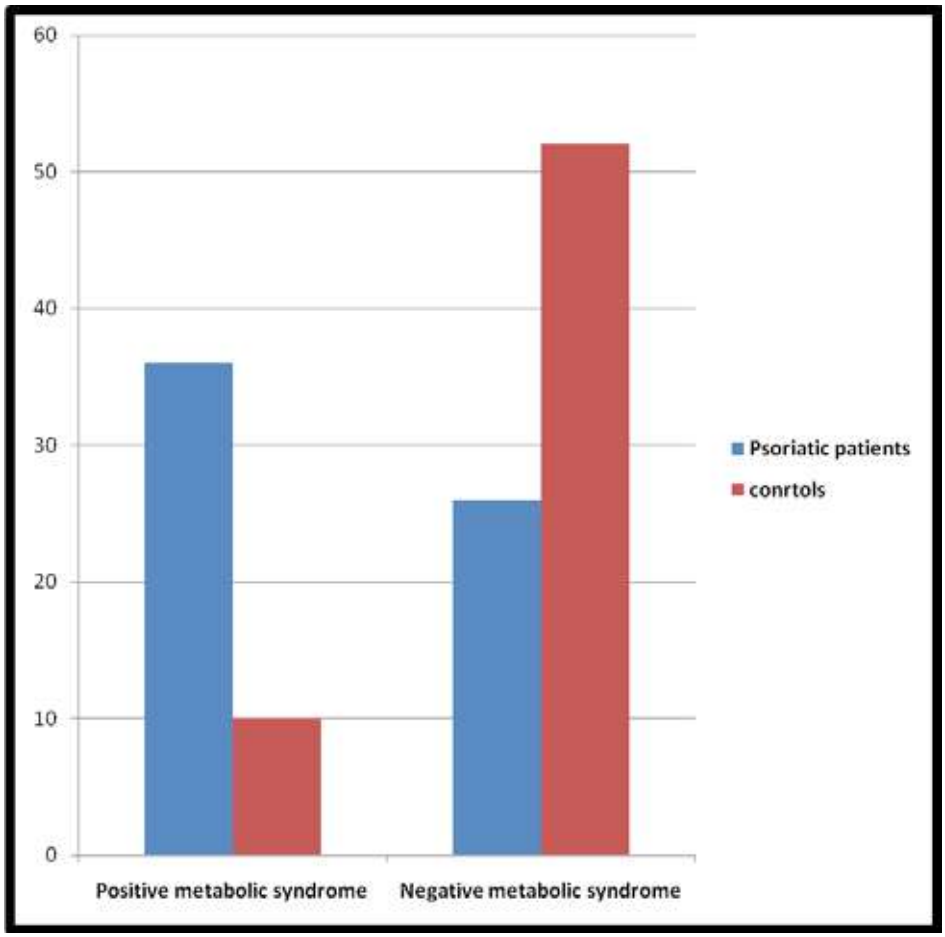

Fig. 1: Prevalence of metabolic syndrome among psoriatic patients in comparison with controls

Discussion

Recently, "the understanding of the role of inflammatory cells and mediators in the pathogenesis of psoriasis" have changed our look to psoriasis from being a cutaneous disease to that of a systemic disorder.[14] Psoriasis and metabolic syndrome are characterized by sharing inflammatory pathways display similar inflammatory profiles with Th1 and over expression of IL-6 and TNF-alpha[15]. Epidemiological link of psoriasis to metabolic syndrome and it's prevalence was suggested by several observational studies (15–25% in the general population)[16].

In this study psoriatic patients examined for the presence of metabolic syndrome in comparison with

controls, and data was analyzed to clarify the prevalence of criteria of such syndrome. Males were the predominant sex and maximum number of psoriatic cases (74.2%) was noted in the age group of between 21 years and 50 years. This study revealed that metabolic syndrome occur with a higher percentage inpsoriatic patients (58%) than controls (16%) this appear higher regarding recent case control study by Narendra Gangaiah, NS Aysha Roshin, et al (38% vs. 22%)[17]. Regarding the prevalence of metabolic syndrome criteriaamong patients :central obesity (Raised values of waist circumference) was at the top (100%) and hypertriglyceridemia came next (69%), with low HDL, hypertension, and raised fasting blood glucose came successively .

Visceral obesity and type 2 diabetes are the main components of metabolic syndrome. Adipose tissue pathologically has important effects as it infiltrated by macrophages that secrete cytokines in the systemic circulation resulting in a chronic inflammatory state which will lead to the development of numerous diseases associated with obesity [18]. In most international studies obesity appear to be more frequent among psoriatic patients than controls[19]. All psoriatic patients in the present study have increased Waist circumference and visceral obesity could be the possible mechanism that correlate psoriasis with metabolic syndrome and its comorbidities. It was also demonstrated that obesity is a risk factor[more than two times] for developing psoriasis[20]. Middle or older age men with mild obesity are more likely to develop psoriasis as suggested by Naito and Imafuku[21].

Significant elevation in serum triglyceride levels have shown in various studies done in Caucasians[22-24]. In the present study, psoriasis was strongly related with dyslipidaemia. Hypertriglyceridemia represent (69%) in psoriasis group with no difference among controls . Low value of S. HDL was found in 33% of psoriasis group, while it was found to be low in 20% of controls. Similar observations were documented in Lebanon study[25].

Hypertension was documented among 22 cases of psoriatic patients with positive metabolic syndrome, in comparison to controls with metabolic syndrome. Psoriasis patients in regards to the risk of developing hypertension showed modest increase in comparison with the general population[26,27].No known mechanism explain the relation that link psoriasis to hypertension. Multiple researchers proposed that the major source of angiotensinogen is the adipose tissue andthe derived angiotensin II [in addition to its function in salt retention by kidneys] may act asstimulator for T-cell proliferation. Perivascular fat which result from increased visceral adipose tissue “can serve as a reservoir for activated effector T cells” which in turn lead to the promotion of dysfunction in theblood pressure[28].

Regarding the relation between psoriasis and hyperglycemia, there is high risk to develop diabetes in addition to metabolic syndrome[29]. Elevated fasting blood sugar was present in 44% of Psoriatic patients and in 20% of controls. This finding is supported by a study conducted by Samer A Dhaher,and Alaa Abdul Hassen Naif[18,30].

Both hypertension and dyslipidemia cause increase the “systemic inflammatory burden”together with obesity, all of these adds to the comorbidities of psoriasis[31]. PASI score among psoriatic patients with positive metabolic syndrome was less than 8 in nearly 90% of cases, this gave usa negative impression about the relation between the severity of disease and metabolic syndrome. Nisa and Qazi study also found no significant correlation[32].

While studying of body mass index and its association with metabolic syndrome in both groups shows no significance. This comparable with Korean and Norwegian studies were they found a non-statistically significant association with increment in the weight[33,34].

Conclusion

The study reiterates the fact that Metabolic Syndrome and psoriasis do have a close association and showed that central obesity and hypertriglyceridemia occur with high frequency among psoriatic patients with positive metabolic syndrome

Analysis of Employee's Satisfaction in Efforts to Improve Service in Regional Public Hospital of Dok II Jayapura Papua

Yohana Yosevine Usmany1, Ernawaty2

[1]*Master Program of Health Policy Administration Interest in Health Care Management,*
[2]*Lecturer, Public Health Faculty, Airlangga University, Surabaya, Indonesia*

Abstract

Dissatisfied employees tend to experience a decline in performance, so they can't provide good health services. Patient satisfaction is influenced by the good and bad health services provided by employees, so there may be problems with human resource management. The purpose of this study was to describe employee job satisfaction in an effort to improve services in the Regional Public Hospital of DOK II Jayapura Papua. The type of research was descriptive (case study). The number of samples of 74 samples with the sampling technique was random sampling. Results obtained by employees who stated that they were not satisfied 51.3%, very dissatisfied 1.4% while those who expressed satisfaction were 47.3%. Most employees were not satisfied with efforts to improve service. One form of human resource development can be done through the creation of a strategic plan. The Strategic Plan itself must be based on a SWOT analysis where systematic identification of various factors will be carried out to formulate a strategy by maximizing strengths, opportunities, and simultaneously minimizing weaknesses and threats.

Keywords: *Patient satisfaction, Health Service, Hospital.*

Introduction

Health service organizations are an organization that consists of various kinds of health professions and other professions related to health service activities to the community. In carrying out its functions, this organization requires a management system that is comprehensive and sustainable. An effective human resource management can create a work environment that gives a sense of togetherness, equals, supports productivity, encourages its members to work towards organizational goals, and is able to meet the needs of its members to actualize themselves and fulfill their individual expectations through appreciation, development and recognition of their identity[1]. The variety of health professions incorporated in an organization will be a challenge for human resource management. Different health education backgrounds will produce individual health practitioners with different egos and ideals. Health services are basically a complex and interrelated process between health practitioners. For this reason, collaboration between individuals or health professions is needed in an effort to provide maximum health services to the community[2].

A well functioning human resource management will have policies, rules, and programs in the activities of employee selection and recruitment (members), formulation of members' rights and obligations, training and organizational development, member safety guarantees, and succession systems in organizations. Strategic planning is the process of developing organizational goals, strategies and tactics to achieve the organization's mission and vision. An organization needs to determine short-term goals and long-term goals by using the organization's mission statement as a guide. The purpose of an organization can include

Corresponding Author:
Yohana Yosevine Usmany
Master Program of Health Policy Administration Interest in Health Care Management, Faculty of Public Health, Airlangga University, Surabaya, Indonesia
e-mail: yohana.yosevine.usmany-2017@fkm.unair.ac.id

sales targets, company profits, customer satisfaction, and increase organizational value (image branding). A health service organization must also have a plan to carry out its functions as an organization. The thing that must be considered in determining the health service organization policy is its function as a health service facility for the community[3].

Efforts are needed to fulfill greater comfort so that patients are satisfied. Satisfaction and comfort causes the concerned to become a subscription. It is hoped that not only those concerned, but also their families and relatives may be interested[4]. The good and bad health services are influenced by the level of job satisfaction of hospital employees. Dissatisfied employees tend to experience a decrease in performance, so they can't provide good health services[5].

Successful organizations are organizations that are capable of human resource management to become a force that can unite, have commitment and high work motivation through human resource management. It is a process of dealing with various problems for employees, managers and other workers to be able to support the activities of the organization in order to achieve the intended goals. One of the problems in managing human resource is the problem of job satisfaction. Job satisfaction is a positive attitude that involves healthy adjustments of employees to work conditions and situations, including salary issues, social, physical and psychological conditions. Job satisfaction is also defined as a pleasant emotional state or a general attitude towards differences in rewards that are accepted and should be accepted as well as for work factors, adjustment and social relations outside of work[6].

Method

This study used descriptive survey design. This research was a case study in the Regional Public Hospital of DOK II Jayapura Papua. This research was conducted from April to May 2018. Total sample was 74 samples with using random sampling technique. Primary data was collected through filling out questionnaires submitted to employees to identify employee job satisfaction. The results of the data obtained from the questionnaire were analyzed to determine efforts to improve human resource management in health services.

Results

In this study, job satisfaction will be measured by a structured questionnaire compiled by adopting and adapting the standardized translation questionnaire measuring tool, Minnesota Satisfactionare (MSQ). The following are the results of the job satisfaction questionnaire:

Table 1: Distribution of Frequency of Employee Job Satisfaction in the Regional Public Hospital of DOK II Jayapura Papua

No.	Job Satisfaction	Frequency	Percentage
1	Satisfied	35	47.3
2	Dissatisfied	38	51.3
3	Very Dissatisfied	1	1.4
Total		**74**	**100**

Based on Table 1, Employees who stated that they were not satisfied were 51.3%, very dissatisfied 1.4% while those who expressed satisfaction were 47.3%. Good or bad health services are influenced by the level of job satisfaction of hospital employees[7]. According Soeroso (2003) that dissatisfied employees tend to experience a decrease in performance, so they can't provide good health services. It is known that patient satisfaction is influenced by the good and bad health services provided by employees, so there may be problems with human resource management.

Discussion

In managing human resource management must pay attention to the organization's demands, goals, vision, mission, organizational plan and human resource division as well as the supply of health workers in the community and prospective producer institutions. Soeroso (2003) said that There are two human resource planning, namely quantitative, namely the planning of the number of each health worker needed, and qualitative, namely the special aspects of each element of the human resources management cycle from planning to recruitment, selection, placement, utilization and development, career, supervision and control and evaluation performance.

Human resources management is increasingly important in the future, due to internal factors, namely the need for hospitals to get suitable employees, increasing human resource costs (compensation: salaries, incentives, facilities etc.), demands of managers and employees and the development and expansion of hospitals. Whereas because of external factors, namely government/stakeholder policies, the development

of Socio-Economic and Science and Technology, competition with competitors and market development and the impact of globalization.

According Soedarmo, *et.al* (1997) The success of the use and development of human resources is largely determined by various aspects of the organization such as; career management aspects, leadership, work relations, work motivation and job satisfaction, achievement and work productivity, compensation, transfer and promotion, education and training, rewards and punishments, employment and union regulations, supervision and control, work evaluation and evaluation. There is no standard and appropriate or appropriate human resources development and development pattern for all organizations. The most appropriate form is the use and development of human resources that must be sought, processed and can change from time to time or be dynamic.

Management is a function that deals with realizing certain results through the activities of people. This means that human resources play an important and dominant role in management. human resource management organizes and establishes a staffing program that covers the following issues: establish effective amount, quality, and work placement according to company needs based on job description, job specification, job requirements, and job evaluation, establish employee withdrawal, selection and placement based on the right man in the right place and the right man in the right job, establish a welfare program, development, promotion and dismissal, predicting the supply and demand of human resources in the future, estimating the state of the economy in general and the development of the company in particular, carefully monitor labor laws and policies for granting remuneration of similar companies, monitor technical progress and development of trade unions, carry out education, training, and employee performance appraisal, efforts to improve services in health service institutions are efforts to improve employee efficiency, efficiency of operational funds, fairness and ability of health services held in accordance with the development of the latest medical science and technology[8].

Conclusions

Most employees were not satisfied with efforts to improve service in the Regional Public Hospital of DOK II Jayapura Papua. One form of human resource development can be done through the creation of a strategic plan. The Strategic Plan itself must be based on a SWOT analysis where systematic identification of various factors will be carried out to formulate a strategy by maximizing strengths and opportunities, and simultaneously minimizing weaknesses and threats.

Identifying the Most Influential Variables in Breast Cancer Using Logistic Regression

Yousra Abdulaziz Mohammed

Lecturer at College of Medicine, University of Fallujah, Iraq

Abstract

Breast cancer has become recently the most common cancer and a major cause of death among women all over the world and especially in developing countries like Iraq. This study aims to identify the most important features that affect in deciding the type of breast cancer whether benign or malignant.

A predictive model was developed using binary logistic regression which is expected to be helpful for oncologists in diagnosing the type of breast cancer data set have been downloaded from UCI ml repository that consists of 9 attributes and 683 valid instances.

At first, some preprocessing was done to cleanse the data, then two models were built using two different LR method to find out which one will give the most suitable model and highest classification rate. The first one was the full model with all predictive variables, while the other called reduced model with only 5 predictive variables. Each model was validated with a different data set than that used for developing the two models. Both validated and trained models were evaluated using different performance metrics like ROC curves, AUC, sensitivity and specificity. The analysis of the results showed that the reduced model is the best classifier since it gives the higher classification rate.

Keyword: *UCI ML repository, Logistic Regression, classification, validation, Breast Cancer.*

Introduction

Breast cancer is one of the most common types of cancer in the world, especially in the developed countries and it has been the most common cancer in Iraq for the years (1986-2012). A study has shown that survival rate is 88% after 5 years of diagnosis and 80% after 10 years of diagnosis. Therefore it is necessary to detect breast cancer at earliest stage possible[1].

Machine learning has become more influent in diagnosing cancer, because It allows deductions or inference to be made that classical statistical procedures could not make[2].

In order to assist oncologists making the right diagnosis of biopsy in breast cancer, a classification model known as a classifier can be very helpful. The classification problem refers to predicting the target class of new observations, from a given set of predictive variables from the population data set.

Since the outcome of biopsy can confirm the existence/absence of the malignancy it is hence considered a binary outcome.

Logistic Regression LR have been applied increasingly in many fields particularly the medical fields, and is a perfect statistical algorithm for binary classification, that is evaluating the correlation between one or more categorical or continuous predictor variables and a dichotomous dependent variable[3]. Logistic regression technique has the ability of assigning distinct data sets to predefined classes, the distinction is done by setting up the discrimination rules, these rules are estimated through the training phase and can be used to assign the new observations into the classes defined formerly[4].

Method of variable selection differ according to the problem. It is essential to include all relevant variables in the model. Some researchers propose inclusion of

all clinical and other predictive variables in the model regardless of their significance toget a better model fit to the data. Yet, more variables will affect the coefficient in the model and lead to over-fitting model. Besides, amodel with many insignificant predictors will produce less classification accuracy and it would be hard to explain the results. Commonly, statistical model building techniques attempt to minimize the number variables to get a numerically stable and generalized model, but this can cause in a large standard errors. Variables selection can be done in two ways filter and statistical[5,6]. For filter method, the variables are reduced according to their importance as was done in similar research.

On the other hand, statistical method for variable selection can be done by either of the following method[11];

- "Enter: A procedure for variable selection in which all variables in a block are entered in a single step.
- Forward Selection (Conditional).
- Forward Selection (Likelihood Ratio).
- Forward Selection (Wald).
- Backward Elimination (Conditional).
- Backward Elimination (Likelihood Ratio).
- Backward Elimination (Wald)."

In forward selection, the significant effects once entered then could not be removed from the model. For backward elimination, removed effects from the model, cannot be entered again. While, for stepwise selection which are the method of focus in our study the variables already included in the model do not need to remain, they can be entered into or eliminated from the model in a certain manner that every step of forward selection could be followed by a backward elimination step or more. The stepwise selection procedure stops if no additional effect is added to the model[7].

In this study, two different variable selection procedures were implemented, namely Enter and Stepwise method to establish logistic regression models. This study aims to evaluate the performance of the two developed models in order to determine which of the used method is more powerful in identifying the most influential predicted variables in predicting breast cancer.

Materials and Method

The data set used in this study, is the breast-cancer-Wisconsin data file which was collected from UCI machine learning repository[8].

The data set consists of observations of 699 patients diagnosed with cancerous tumors. It is arranged in 11 columns each row represents observations belong to a patient that was obtained from medical analysis. The first column is an identification code associated with each patient; the following 9 columns are the features used to analyze each patient; tumor thickness, uniformity of cell sizes, uniformity of cell forms, marginal adhesion, size of the simple epithelial cell, Bare nuclei, smooth chromatin, nucleolus normality, and mitosis[9]. The last column is the dependant variable (cancer type; 4 for malign and 2 for benign tumors).

All the independent variables have numerical values ranging from 1 to 10, and these values were obtained through medical assessments or lab tests. The distribution of the dependant variable Class is; Benign: 458 (65.5%) and Malignant: 241 (34.5%).

The first step in this study was converting the data into Excel sheet to make it easier to build the statistical model which is generated and analyzed using SPSS, V19.0, SPSS Inc. using LR algorithm, then the data was imported to SPSS for processing.

The second step is data cleaning; missing values is a well known issue exists in datasets. There are several method to overcome missing values like list wise or case deletion, substituting the missing values with mean or mode of that variable and other method[10]. For our study the case deletion method was applied to remove 16 cases having missing values. This leads to that the dataset size becomes 683 observations with 444 benign tumors and 239 malignant. As it is not required in the design and analysis of our model, the (Id) column was removed.

In order to identify the variables that count in investigating the type of breast cancer two LR models were established. The first one, named full model was developed using the standard ENTER method with all 9 attributes. The second model, which is the reduced model was developed using the stepwise forward selection (Wald) method. Stepwise selection method tests the entry of variables according to the significance of the score statistic, while removal testing is done according to the probability of the Wald statistic[11],

the model was developed with only 5 attributes which are tumor thickness, uniformity of cell size, marginal adhesion, bare nuclei, and smooth chromatin since they were statistically significant at the level of 0.05 using Wald statistic.

Validation of the model is very important to measure the stability and robustness of the coefficients resulting from logistic regression and a crucial part of the process of model-building[14]. Many statistical tools for model performance validation in binary logistic regression are available like data splitting, repeated data-splitting, jackknife technique and bootstrapping[15]. For this purpose, the data-splitting technique was used in our study, where the data had been randomly divided into two groups; the first consisting of 80% of the data (550) sample was used for developing the LR model with 372 benign and 178 malignant, and the second group consisting of 20% of data (133) sample (72 benign, 61 malignant) was used for validating the two models.

The training data was used at first to fit both full and reduced models then we apply the validation data to the fitted models to evaluate the model's performance. The obtained posterior probability for malignant class was considered and its value was then classified into two categories;posterior probability in range of (0-0.5) = benign, and posterior probability in range of (0.5-1) = malignant. Results obtained are then evaluated in terms of measures such as ACC, Specificity, Sensitivity, and ROC curve area.

Logistic Regression Model: The conditional probability for dependent variable to occur is given by the logistic function[16],

$$\text{Probability(dependant variable(Y) =1)} = \frac{e^{-z}}{1+e^{-z}}$$

Where probability estimates are between 0 and 1 because of the logistic transformation.

z is also called logit. The logit is a linear multiple regression model of the independent variables

$$z = \acute{\beta}\acute{X} = \beta_0 + \beta_1 * X_1 + \beta_2 * X_2 + \cdots \beta_n * X_n$$

where $\beta_0 \ldots \beta_n$ are coefficients of the independent variables calculated by estimation of the maximum likelihood, $X_1 \ldots X_n$ are independent variables and n is the number of explanatory variables.

while reference probability is defined as

$$p(y = 0) = 1/(1 + e^{-z})$$

the log(odds), or log-odds ratio, is defined by

$$\log(\text{odds}) = \ln\left[\frac{p}{1-p}\right] = z$$

and expresses the natural logarithm of the ratio between the probability that an event will occur, p(Y=1), to the probability that it will not occur p(Y=0), it is found by calculating the probability of each event. Odds ratio measure the incidence when the independent variable increases by one unit. The odds ratio is defined as

$$\frac{p}{(1-p)} = e^{\acute{\beta}\acute{x}}$$

This study aims to identify the most important predictive variables in classification of patterns into benign or malignance classes, and to compare the performance of the full model and the reduced model using different performance metrics, finally to validate the capability of each model to recognize new cases.

Performance Metrics: Accuracy which is the percentage of correct predictions is the most used measure in classification task. Sensitivity and specificity have to be calculated because the first indicates the performance of classification for minority class, while the second indicates the proportion of majority samples that are correctly identified. Also the area under a ROC curve (AUC) was used to evaluate the performance of the feature selection method[17]. For our work, the two models were evaluated using these metrics (Equations 1-4) based on the confusion matrix shown in Table 1.

Table 1. Confusion Matrix

Actual Class \ Predicted Class	Benign (0)	Malignant (1)
Benign (0)	TN	FP
Malignant (1)	FN	TP

$$\text{CCA}=(TP+TN)/(TP+FP+TN+TP) \quad \ldots(1)$$

$$\text{Sensitivity}= TP/(TP+FN) \quad \ldots(2)$$

$$\text{Specificity}= TN/(TN+FP) \quad \ldots(3)$$

$$AUC = \frac{1+TP_{rate}-FP_{rate}}{2} \quad \ldots(4)$$

where, TP_{rate} is sensitivity and

$$FP_{rate} = \frac{FP}{FP+TN}$$

Results

The results of training full model using the training sample is shown in Table 2 where the values of logistic regression parameters, standard errors, Wald statistic and p-values of the logistic regression model are computed. Considering all available variables, the logit of the full model is given by,

Logit 1 = -9.614+0.486* clump thickness +0.23* uniformity of cell size +0.166* uniformity of cell shape +0.271* marginal adhesion +0.019* single epithelial cell size +0.435* bare nuclei +0.401* bland chromatin+0.127* normal nucleoli +0.374* mitosis

Table 2: Parameter Estimations of the Full logistic regression model fitted to the training sample.

Variable	Coefficient estimate	Standard error	Wald	Sig.
clump_thickness	.486	.175	7.728	.005*
uniformity_of_cell_size	.230	.252	.832	.362
uniformity_of_cell_shape	.166	.278	.358	.550
marginal_adhesion	.271	.129	4.381	.036*
single_epithilial_cell_size	.019	.237	.006	.938
bare_nuclei	.435	.112	14.925	.000*
bland_chromatin	.401	.211	3.625	.057
normal_nucleoli	.127	.142	.800	.371
metosis	.374	.501	.556	.456
Constant	-9.614	1.415	46.143	.000

*significant at level of 0.05

From Table 2, we find that small p-values of clump thickness**,** marginal adhesion, and bare nuclei indicate that they are most significant predictor of malignancy in the model at level of 0.05. Also, the p-value obtained for bland chromatin was noticeable (p=0.057) though it is not statistically significant. Hence, a reduced model can be derived by removing from the full model the variables that have the largest Wald test p-value[18]. Using the mentioned significant variables along with bland chromatin, the logit of the full model can be modified into a reduced form as follows,

Logit 2 = -9.614+0.486* clump thickness+0.271* marginal adhesion +0.435*bare nuclei +0.401* bland chromatin

The evaluation of LR full model and modified model was done using logit 1 and logit 2.

The coefficients of the reduced model were computed from training the model by the stepwise method using the training sample is shown in Table 3. from which the logit of the reduced model is given by,

Logit (stepwise) = -9.413+0.546* clump thickness +0.435* uniformity of cell size +0.266* marginal adhesion +0.436* bare nuclei +0.506* bland chromatin

Table 3: Parameter Estimations of the reduced logistic regression model (stepwise) fitted to the training sample

Variable	Coefficient estimate	Standard error	Wald	Sig.
clump_thickness	.546	.167	10.617	.001*
uniformity_of_cell_size	.435	.162	7.237	.007*
marginal_adhesion	.266	.125	4.539	.033*
bare_nuclei	.436	.105	17.106	.000*
bland_chromatin	.506	.198	6.524	.011*
Constant	-9.413	1.230	58.603	.000*

*significant at level of 0.05

Table 4 and Fig. 1 show a comparison of performance of the logistic regression models on testing sample (n=133).

Table 4: Comparative performance of the full, modified and reduced modes l on validation sample (n=133)

Model	Full model	Model modified from full	Reduced model
Sensitivity	0.902	0.459	0.836
Specificity	0.972	1.000	0.972
CCA	0.908	0.752	0.940
AUC	0.904	0.730	0.937

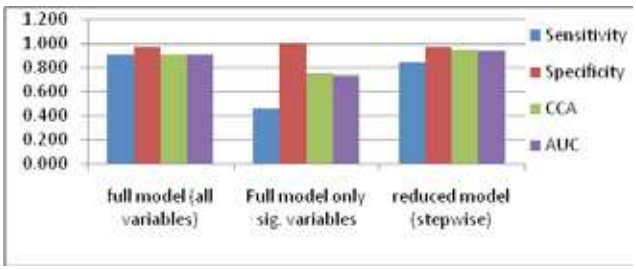

Figure 1: Comparative histogram of the average sensitivity, specificity and accuracy obtained for the full, modified and reduced models.

Discussion

In this work, the first model set was full model included all the nine covariates and the second was a reduced model. Based on guidelines for variables selection from the previous research, we removed the variables with the largest wald test p-value from the full model which were; uniformity of cell size, uniformity of cell shape, single epithelial cell size, metosis, and normal nucleoli, retaining the coefficients of the significant covariates as in the full model, but the output of the resulting model did not show any improvement in any of the metrics used except for specificity as shown in Table 4. & Fig. 1. The reduced model was established by the stepwise method resulting in a model with 5 predictive variables which were the same four in the modified model in addition to uniformity of cell size factor.

The results of the reduced model showed improvement (94%) in the correct classification rate in comparison with one obtained from the full regression model (90%); as for the specificity, it was about 97% for both. However, reduced model showed less sensitivity (84%) than the full model (90%) but it could still be considered as highly sensitive. These results showed that if we use the most significant features in logistic regression model, its performance would be improved in comparison with a full model.

Limitations and Future Work: The size of the dataset affects the performance of the models so increasing the number of samples could lead to an improvement in performance. In order to have more than 2 classes a multinomial logistic regression could be implemented. Also other machine learning techniques such as different types of ANN could be tested.

Lived Body Principle Police of the Regional Traffic Management Center (RTMC) of the East Java Regional Police to Their Families

Yunus Adi Wijaya[1], Tita Hariyanti[2], Tina Handayani Nasution[2]

[1]Student, [2]Lecturer, Nursing Master Program, Faculty of Medicine Universitas Brawijaya

Abstract

Introduction: Guilts is the first and foremost in the form of emotional outbursts. Guilts is not a very good motivator. It is more accurate to regard guilt as an internal condition and a negative feeling. Happiness is a feeling of satisfaction, that life is as it should be and all needs have fulfilled.

Objective: It is to explore the meaning of feeling guilt and happiness experiences (Lived Body) police of the Regional Traffic Management Center (RTMC) to their families.

Method: The method are qualitative by using phenomenology interpretative approach and Interpretative Phenomenological Analysis (IPA).

Results: The emerging themes based on relationship principle are two: feeling guilty to the family and feeling happy with family.

Conclusion: The findings obtained were that members of the police at RTMC could be free from stress while working and were able to return and get support from the family. Being able to live happily, both happy at work and happy with the family that will reflect in the calmness in their life.

Keyword: *Police; Regional Traffic Management Center (RTMC); Lived Body; Family; Phenomenology.*

Introduction

More than 400 pairs of police officers were surveyed with a questionnaire to assess the impact of police work on the feelings and functions of their partners and families. The results of the study show that police work has an adverse effect, especially in terms of the social life of the couple. The leading causes are long working hours, work schedules, and canceled leave[1]. Positive emotions such as excitement, interest, love, and receiving love contribute to human growth[2]. About 50% of happiness is determined genetically[3], so each of us has a different level of joy, but it remains a regulatory point where our daily happiness experiences fluctuate. Thus, the development of positive emotions helps a person to return to a genetically determined position of happiness regulation[4], after suffering from stress and trauma[5]. Positive emotions also indirectly help accumulate personal resources in four dimensions: physical, intellectual, social, and psychological, to enable one to overcome stress[6]. The development of positive emotions is obtained and collected through the functions of various emotions, so that feeling of fear, anger, and sadness are associated with danger, transgression, and despair, respectively, and this feeling triggers danger avoidance or flying behavior, while positive emotions are associated with expectations, and therefore, people build resources for long-term survival[6].

A preliminary study conducted on seven police officers who were on duty at that time found that

Corresponding Author:

Student of Nursing Master Program, Faculty of Medicine Universitas Brawijaya
e-mail: yunus.adi.wijaya.2305@gmail.com

members of the police experienced a change of feelings to their families. The police caused the shift in feelings they experience as law enforcers who are required to disciplined in carrying out their duties. Besides that, he or she was worried about safety at work, and feel work hours exceed time.

Police work and how it affects the family is very complicated. There was a feeling of guilt and a sense of happiness to his family caused by the impact of work as a police officer. This feeling will mainly create by work stress. When examining this paper, it founded that there was no special education for officers to guide them in handling their beliefs, especially feelings of guilt to the family. There is also no education offered after assuming their professional role as police officers about effective techniques for using wisdom or dealing with stress. The pressure experienced by officers in his or her profession can be transferred to or shared by his or her family appropriately[7]. Aim of the study is to explore the meaning of feeling guilt and happiness experiences (Lived Body) police of the Regional Traffic Management Center (RTMC) to their families.

Method

This study used a qualitative research design with an interpretive phenomenology approach to explore the meaning in the experience of feeling guilt and happiness police of the Regional Traffic Management Center (RTMC) to their families. Participants involved in the five members of the police at RTMC were by the inclusion criteria determined through purposive sampling. Data collection by in-depth interviews using a semi-structured interview guide. During the meeting, the researcher used field notes. After the data collected, the researchers used Interpretive Phenomenological Analysis (IPA) to analyze the data.

Findings: Thematic aspects, such as the meaning of mental or psychological experience, can be found apart from the description of participant experience: A comprehensive approach, allowing researchers to read and analyze each sentence carefully to find the essence or meaning of the participants' experience. The holistic approach allows researchers to look at the whole text and try to find meaning from the text. The emotional experience of police officers at RTMC to their family gets these two themes:

Theme 1: Feelings of guilt in the family: Most participants expressed a sense of sin in the family. Guilty according to Indonesia Dictionary is doing wrong; make mistakes (mistakes); has an error[8]. The theme was derived from several sub-themes as follows:

Sub-theme: feeling guilty for children because rarely at home, participants said feeling liable to children because they are seldom at home because of their work. The following are excerpts from the interview:

Sometimes I feel guilty about my child, and I am rarely at home because of my job. (P1)

Sub-theme: bestow resentment on family members, the first participant reveals present bitterness or anger at family members when emotional stress is increasing due to pressure. The following are excerpts from the interview:

Even though sometimes my husband was my target if I went berserk because of fear in the office. (*): teary eyes (P1)

Sub-theme: opposed by children because they rarely deliver school, the second participant said that he felt challenged or protested by children because he rarely drove to school. Protests according are statements that do not approve, oppose, deny, etc[8]. The following are excerpts from the interview:

But sometimes I was also protested by my child because I rarely drove to school. (*): smiled while lowering head (P2)

Sub-theme: feeling sorry for children because they rarely go home, feeling sorry is compassion(8). The fourth participant's expression about this is as follows:

I'm sorry for that too. Usually, the first child, because I also rarely go home on time. (P4)

Sub-theme: feeling bad in the eyes of the family, the third participant said that they felt terrible in the eyes of the family. Feeling useless, not doing (behaving) is not good too; properly treating is the meaning of feeling bad(8). The third participant's phrase about this is as follows:

Sometimes I think that I am not useful in my family's, especially my children. (*): head down. (P3)

Sub-theme: unable to make children happy, participants revealed that they thought they were not able to make children happy. Happy is satisfied and

relieved, without feeling awkward and disappointed, and so on(8). Quotation of the fourth participant interview as follows:

Sometimes I thought that I couldn't make my child happy (P4).

Theme 2. Feeling happy with the family: All participants revealed that there was a feeling of happiness when with family. Participants assume that family is one of the greatest gifts in his life. Together with the family, a sense of joy, a happy heart, peace of mind, there is a feeling of a miss, a family of removers and a stressed therapist, and can be various stories. Happiness means the situation or feeling happy and serene (free from all that is troublesome) [8]. The theme was obtained from several sub-themes as follows:

Sub-theme: feeling great happiness with my husband, the first participant said that he thought great satisfaction with her husband, especially the husband and police member who knew the workload. This sense of joy means circumstances or feelings of pleasure and serenity (free from all that is troublesome) [8]. The following are excerpts from the interview:

Indeed happy with my husband, mainly my husband also works as a member of the national police. (*): laugh out loud. (P1)

Sub-theme: feeling great happiness and lingering with the family, the third participant said that feeling happy was extraordinary and wanted to stay with the family. The following are excerpts from the interview:

The point is that my family always makes me want to linger at home. Happy extraordinary (*): smile. (P3)

Sub-theme: feeling great and pleased with the family, the second participant said that feeling comfortable and pleasant was exceptional with the family, but because of the demands of work it was obligatory to go home late. Excerpt of the interview as follows:

Wahh, if it's not asked, it's clear that the family is happy and extraordinarily happy. (P4)

Sub-theme: feeling great happiness with my husband and children; the second participant explained that he felt great pleasure with her husband and children. Feelings of desire define happy things; satisfaction; conveniences; happiness; relief (8). Excerpt of the interview as follows:

It's beautiful, especially if it's complete at home. There is a husband, and there are children. That's what makes me always excited about working. (*): points to several angles with the right index finger (P2)

Sub-theme: feel happy to be noticed and given advice by the wife, the fourth participant said that handle happy to be seen and offer information by the wife about health. Excerpt of the interview as follows:

I am so glad because my wife is always attentive and always gives advice to me. (P4)

Sub-theme: feel happy to meet parents and family; the fifth participant said that they felt comfortable to meet their parents and family at home. Excerpt of the interview as follows:

Indeed, I am delighted, mainly I also rarely meet my parents and family at home because of work that cannot be left behind. (P5)

Sub-theme: feeling happy and peaceful to reach children, the second participant said that feeling heart becomes comfortable and calm when meeting children at home. Excerpt of the interview as follows:

So, when I have met my children, my heart is peaceful and serene. (*): smile. (P2)

Sub-theme: feeling nostalgic for mother, the fifth participant explained that felt miss mother. Miss is eager to meet, miss. Excerpt of the interview as follows:

If there is my mother here, I will hug tightly, and I miss her. (P5).

Sub-theme: feel the medication is stressed and tired is family, the second participant said that the family is a stress medication and tiredness reliever. Healers mean something that is used to treat; people who treat; heart entertainers[8]. Excerpt of the interview as follows:

Whose name is tired, stress is whatever the title must go. The family is a stressed medication. (P2)

Sub-theme: feeling calm to be happy and tired when meeting family, participants said that when they met with their families, they felt relaxed, comfortable and bored. Excerpt of the interview as follows:

Anyway if I have reached my family, I am pleased and calm, like my tiredness is gone, even though I am exhausted. (P3)

Sub-theme: feeling forgetful with stress and stress at the office when with family, the fourth participant said that when with a family feeling tired and stressed at the office will forget. Excerpt of the interview as follows:

Yes, if you are with your family, tired and confirmed, the office has ignored. (P4)

Discussion

Feelings of Guilt in the Family: Guilt is a common emotion that everyone must experience. Guilt does contain not only positive values but also negative values if those who feel are too excessive[9]. These guilt feelings play an indispensable role in maintaining human behavior standards and maintaining personal, family, and community relationships[10]. Guilt Survivor is very complicated. They do not know what to do to make up for their misconduct.

Most participants have feelings of guilt in their families. The members of this police feel themselves guilty of his child, feeling challenged by his child, feeling bad in the eyes of his family, feeling unable to make his child happy, even from feeling guilty arose pity for his family members and also bestowed his frustration on the family. Evidence in psychology research suggests that even if there is a slight change in the condition of one's affection, it can affect cognitive processes and individual social behavior[11].

The guilt faced by police officers is not a mental disorder. But guilt is one of cause mental disorders. Excessive guilt causes neurotic problems such as obsessive-anxiety disorders, depression, and anxiety, and finally disturb their lives[12]. People with extreme guilt are identical to people with disabilities; limited in self-actualization[13]. Proper identification will help the handling guilt appropriately. If his guilt is objective, the way out to experience a soul recovery is to apologize to someone where we have been guilty of him. If subjective, it is necessary to look at the problem in a more objective and intact perspective. After identifying guilt and resolving it, it is essential to release guilt and negative thoughts that have been suppressing the soul. Mistakes and failures that cause guilt are part of the life process to be wiser.

Feelings Happy with Family: Participants assume that with family they get a sense of happiness, a happy heart, peace, a feeling of nostalgia, a family of relievers and stressors, and can be various stories. According to Compton[14], individuals have different ways of finding happiness according to their culture. Javanese society is part of the Indonesian community that is fertile for the repertoire of the philosophy of life. In the Javanese cultural environment, the togetherness of all family members is one of the forms of happiness that exists in a family and means to have the same meaning as a collectivist culture.

Participant revealed that there was a feeling of happiness when with family. Participants assume that family is one of the greatest gifts in his life. Together with the family, the police officer will feel happy, calm, and nostalgic. Hurlock[15], says that happiness is a combination of acceptance, affection, and achievement. The attitude of accepting others controlled by self-acceptance in social adjustment. Cultural adaptation requires physical attraction that can generate love and acceptance from others, while love is the result of the attitude of acceptance of others into the environment.

Mental health is a state of prosperity associated with happiness, excitement, satisfaction, achievement, optimism, or hope. This term is difficult to define, and meaning can change if it is associated with people and certain life situations[12]. Assessment of stressors involves determining the meaning and understanding of the impact of a job that is stressful to the individual. An estimate is an evaluation of the significance of an event related to one's well-being. Stressors contain meaning, intensity, and importance with unique and meaningful interpretations given by a person who is at risk of illness[12].

Conclusions

The participants' feelings originate from within internal factor, which distinguishes them from fear and related to external factors such as job risk and regulations. Feeling happy and guilty resulting from workloads have an impact on the quality and effectiveness of their work.

Infertility Causing Factors & the Success Rate of in Vitro Fertilization (IVF) in One of Fertility Center of Surabaya City, Indonesia

Yuriske Agnovianto[1], Linda Dewanti[2], Sri Ratna Dwiningsih[3]

[1]Faculty of Medicine Airlangga University, [2]Department of Public Health, Faculty of Medicine Airlangga University, [3]Department of Obstetrics and Gynecology Dr. Soetomo Hospital, Surabaya, Indonesia

Abstract

The success rate of in Vitro Fertilization (IVF) with ICSI depends on married couples factors such as maternal age, causes of infertility from the married couples, embryo status, reproductive history, lifestyle, ethnicity, and type of medical examination of infertility. The success rate of IVF was different among countries, rating from 21.4% to 51.7% meaning that the couples succeeded having a child, while in Indonesia the rate was unknown.

Objective: To analyze infertility causing factors in married couples who underwent IVF and the success rate of IVF in one fertility center in Surabaya, Indonesia. Method: This observational study was conducting during January to December 2017. All couples who visited the fertility center,the female ≤ 39 years old, and the couples finished medical examination in the study place were asked to participate this study. Their characteristics (female age and duration of marriage), type infertility causing factors as well as the success rate.

Results: Among 154 married couples, 64.3% of the female and 44.8% of the male had one or more abnormality in their reproductive status, while 26.6% of both (the couples) had the abnormalities, and 17.5% of both (the couples) had no abnormality (unexplained infertility). The success rate of IVF, meaning the female got pregnancy, was 37.7%.There was no significant association between male factors, female factors, more over the number of abnormalities were not associate to success rate. When correspondents divided in to 2 groups, having one or more abnormalities group vs. no abnormalities group (unexplained abnormality), we found that the success rate did not differ significantly between the two groups; suggesting additional examination were needed to predict the other factors for increasing the success rate in this study place.

Keyword: *Infertility, Success RateIn Vitro Fertilization (IVF), Indonesia.*

Introduction

Infertility is a problem in the reproductive system that is described by the failure to get a pregnancy after 12 months or more in which the couples have sexual intercourse at least 2-3 times per week regularly without using contraception.[1] Infertility occurs in 10-15% of couples[2], while in Indonesia was 12.5%. Infertility causing factorsin married coupleswere 35% male factors, 35-50% female factors, 5% unusual problems, 10% unexplained infertility.[2] In Vitro Fertilization (IVF) is one of Assisted reproductive technologies (ART) that commonly used in infertility therapy. ART is used if other medicines failed to treat caused of infertility.[3] Unfortunately, IVF is not always succesful[4], it depends on variability factors such as maternal age, caused of

infertility, embryo status, reproductive history, lifestyle, ethnicity, and type of medical examination.[5,6,7] The IVF outcome based on live birth rates in the South-East Asian, African-Caribbean, and Middle-Eastern were 38%, 23.3%, 21.4%, respectively in contrast to the live birth rates in white European population 43.8% and America was 51.7%.[6] However, in Korea, the pregnancy rate of IVF with ICSI was 34.1%.[8]The success rate of IVF in developed and developing countries can be comparable, although each country had different factors that influence the success rate of IVF. So, this study was important to analyzed the different causes of infertility that can influence the success rate of IVF in developed and developing countries.

Material and Method

Data collection from participants were gotten after they signed the informed consent. The protocol of this study was approved by the Health Research Ethic Committee Fertility Center in Surabaya, Indonesia.

The fertility center in Surabaya, Indonesiais a private hospital. Patients who visited this hospital come from many region of Indonesia, such as Surabaya, East Java, Kalimantan, Sulawesi and many east regions of Indonesia. Theirbackground of Fertility center patients were middle-high socio-economic background. This observational study was conducting during January to December 2017. All couples who visited the fertility center and fulfilled inclusion criteria were asked to participate this study. The inclusion criteria were married couples who recorded in medical record; married couples had complete medical examination of sperm, ovarian, tuba, and uterus factors; married couples who underwent IVF; and female age ≤ 39 years old. Their characteristics (female age and duration of marriage), type of medical examination, infertility causing factors, and the success rate were recorded and analyzed.

This study used an observational analytic research. The data were collected from medical record of married couples who underwent IVF therapy at the fertility center in Surabaya Indonesia, in the period of January 2017 to December 2017. Samples were taken from population using total sampling method. The total of samples was 154 married couples who underwent IVF according to the inclusion criteria. Medical records were compiled based on the inclusion and exclusion criteria.

Variablesin this study were infertility causing factors of male, infertility causing factorsof female, and in vitro fertilization (IVF).Infertility causing factors of male infertility was defined from normal and abnormal sperm analysis.Infertility causing factorsof female infertility was defined from normal and abnormal ovarian, tuba, uterus, and endometriosis medical examination. In vitro fertilization (IVF) was defined based on pregnancy rate,success if the titer of β-hCG is ≥ 25 mIU/mland failedif the titer of β-hCG is < 25 mIU/ml.The data analysis was tested by Chi-square test to analyze relation between infertility causing factorsin married couples with the success rate of IVF.

Findings: Total of 213 medical records obtained, 154 medical records met fulfilled inclusion criteria. In samples that were used to analyze infertility causing factors in married couples with the success of IVF, the most frequent female age were 30-39 year and female factors were the most frequent cause of the infertility [Table 1]. Fallopian tube disorders were the most frequent infertility disorder followed by uterus disorders and endometriosis [Table 3]. Meanwhile in male factors, oligoasthenoteratozoospermia (OAT) were the most frequent cause of the infertility [Table 3].The success rate of IVF based on pregnancy rate was 37.7% [Table 4]. Infertility causing factors in married couples were 17.5% unexplained infertility, 18.2% male factors, 37.7% female factors, 26.6% both factors [Table 5]. Analysis showed that there was no significant relation between infertility causing factors in married couples with the success of IVF (p = 0.586) [Table 5].When correspondents divided in to 2 groups, having one or more vs. no abnormalities (unexplained abnormality), we found that the success rate did not differ significantly (p = 0.216) [Table 6].There was no differ significant between female age and number of abnormalities in the success rate of IVF [Table 7, Table 8].

The research from Monash University, Australia which states that motility is one of the most important parameters in determining fertility levels. Sperm concentration does not significantly influence fertility levels when the motility and morphology of abnormal sperm can be controlled.[9]Another study, at hospital in Bandung also stated that there was a significant relation between sperm motility and the success of IVF. However, there was no significant relation between sperm morphology and the success of IVF. Motility have role in the success of IVF, while morphology has no role in the success of IVF.[10]In this hospital, azoospermia that diagnosed was caused by obstruction. In this study, the percentage of IVF success in the male factors who had sperm abnormalities, it was found that azoospermia had the biggest percentage of IVF success (3.9%) if compared to other sperm abnormalities. In this hospital, azoospermia that diagnosed was caused by obstruction. This can occur because the therapy for male infertility in the Fertility Centerwas done by intracytoplasmic sperm injection (ICSI), but might different in other studies that using conventional IVF techniques. ICSI is processof selecting the most qualified sperm for fertilization with oocytes. So, we can found the best quality of sperm from the azoospermia that caused by obstruction.

In this study, the success of IVF in women 20-29 years (5.9%) and 30-39 years (31.8%). This study was different from research in the UK in 2010, the success of IVF in women under 35 years of age (32.2%), ages 35-37 (27.7%), ages 38-39 (20.8%), above the age of 40-42 years (13.6%), while the age of more than 43 years (<5%).[8]In contrast to previous studies, in this study using the age range of 20-29 years and 30-39 years, this was because infertile patients who underwent IVF the most frequent were more than 30 years of age. In this study also excluded the age of more than 39 years so that the study sample was reduced. A phenomenon that exists in Indonesia, in infertile couples who underwent IVF, the female age is mostly over 30 years old. It should be on screening or early detection, if for one year have been related to a husband and wife regularly and do not use any contraception but have not been pregnant, then it should be immediately consulted with an obstetrician. However, in fact, most married couples check up their fertility for more than 30 years because they are waiting for probability to get pregnant at less than 30 years of age by adhering to the socio-cultural conditions in eachregion.

Based on the results of the statistical test with chi-square, it was found that there was no significant relation between infertility causing factorsand the success of IVF.Infertility in married couples can be caused by 35% male factors, 35-50%female factors, 5% unusual problems, and 10% unexplained infertility.[2]Medical examinationof the causes of infertility in thisFertility Center includes sperm analysis, laparoscopy, HSG, ultrasound, and menstrual disorder history. Medical examinationof causes of infertility in abroad is almost the same as in Indonesia, however, there are additional of medical examination, post coitus cervical mucus tests, the aim of which is to determine the ability of sperm to reach the uterine cavity and the ability to survive cervical mucus.[2]In the other research explained that the post coital test (PCT) was a valuable test in daily practice, as a negative outcome is associated with a lower ongoing pregnancy rates (OPR) and higher need in IUI and ART (IVF). Moreover, the PCT was particularly useful in couples with male factors infertility.[7]

In vitro fertilization (IVF) is a technology that is still developing to continue to deal with infertility. Depending on the type of calculation used, the results may represent the number of confirmed pregnancies, called the pregnancy rate, or the number of live births, called the delivery rate. The success rate of IVF depends on various variable factors such as maternal age, causes of infertility, embryo status, reproductive history, and lifestyle factors.[5]However, in the other research found that ethnicity, GDP, utilization, and type of medical examination could be influence of IVF success rate.[5,6,7]

The success of IVF in this study was 37.7% at Fertility Center in 2017. In other research, the IVF outcome based on the ethnicity, live birth rates in the South-East Asian, African-Caribbean, Middle-Eastern and white European population were 38%, 23.3%, 21.4%, 43.8%.[6] This study is comparable with research in Taipei, which shows a pregnancy rate of 47.7% and a delivery rate was 33.6%,[12] and in Korea, the pregnancy rate of IVF with ICSI was 34.1%.[8] However, it was contrast with the research in USA shows a pregnancy rate was51.7%.[13] The relation between the causes of infertility in couples with the success rate ofIVF in this study or research from abroad still not be explained yet. If there are no abnormalities found in male and female, infertility is categorized as unexplained infertility.[14] However, the success of IVF in unexplained infertility is still not explained yet, too. Based a psychological perspective, research in New York shows that psychological stress affects the success of IVF. Much stress level of couples who underwentIVF

can affect success of IVF.[15]Many factors can influence the success of IVF, could be related caused by ethnicity or other factors.However, the analysis of the causes of infertility in the success of IVF still not be explained yet.

This study had a number of limitations. The total number of samples collected was still low if compared with the other study. It recommended to use a large sample size and investigate otherfactorsthat influencethe success rate of IVF or external factors of infertility in further study.

Conclusion

The conclusion of this study is that infertility causing factorsinfluences the success rate of IVF. However, this study has not yet established relation between infertility causing factorsin married couples with the success rate of IVF at theone of fertility center in Surabaya, Indonesia in 2017 with the success rate of IVF. The success rate of IVF depends on various variable factors such as maternal age, causes of infertility, embryo status, reproductive history, and lifestyle ethnicity, and type of medical examination.

The Prevalence of Entamoeba Gingivalis and Trichomonas Tenax in Children Treated with Orthodontic Appliances in AL Muthanna Province, Iraq

Zahraa Abd Alhammza Abbass[1], Shayma Abdullah Hanoon[2], Taisir Abdulelah Kadhim[3]

[1]Researcher, College of Medicine, [2]Researcher, College of Dentistry, [3]Researcher, College of Nursing, Al Muthanna University, Al-Muthanna, Iraq

Abstract

The present study was aimed to determine the prevalence of *Entamoeba gingivalis* and *Trichomonas tenax* in children treated with Orthodontic appliances and their correlation with oral health. The study conducted on 95 children in age (9-12), treated by using orthodontic appliances (fixed or removable) in the pediatric oral center in dentistry faculty at AL Muthanna University, Iraq. Both microscopical method and PCR technique have been used in determining the presence of *Entamoeba gingivalis* and *Trichomonas tenax. T. tenax* hasn't detected by both diagnostic method the presence of *E. gingivalis*was in 9(9.47%) samples and 15(15.78%) samplesby the microscopical method and PCR technique respectively. The higher percentage was in the age(9-10) by both method. The statistical analysis showed a significant correlation between the infection and age at $p \leq 0.05$. Furthermore, depending on oral health, the highest percentage was in the mild gingivitis by both method, statistically no significant correlation between oral health and the presence of the *E. gingivalis* at $p \leq 0.05$. The percentage of the parasite depends on the orthodontic appliance treatment was similar (9.58%) in the fixed and (9.09%) in the removable by microscopical method, while by PCR technique was **(**12.32%) in the fixed and (27.27%) in the removable table, statistically no correlation between the infection with the parasite and orthodontic appliances type at $p \leq 0.05$.

Keywords: *Entamoeba gingivalis, Orthodontic appliances, Gingivitis.*

Introduction

Human oral cavity is colonized by specific bacteria, fungi, and protozoa[1,2]. Among these microorganisms *Entamoeba gingivalis* and *Trichomonas tenax*. *E. gingivalis* is a cosmopolitan and may be found on the teeth surface and gingival, in interdental spaces, carious lesions, gingival pockets and in dental plaque. Additionally can inhabit the tonsillar crypts and the bronchial mucus. Trophozoites are the infective forms[3]. The incidence of *E. gingivalis* in patients with periodontal disease was assumed that it mayparticipate in the etiology and development of this disease. Furthermore, the pathogenic perspective of *E._gingivalis* has been proven experimentally by the development of lesionsin immunosuppressed animals[4]. Another protozoan of oral cavity *T. tenax* found in the oral cavity and patients with poor oral hygiene and periodontal disease. *T. tenax* is less often found in patients with the poor oral condition. However, it has been involved in different infections outside the oral cavity[5,6]. Treatment with Orthodontic appliances which represent a new component in the oral cavity requiresa high degree of oral hygiene. Moreover, the orthodontic appliance creates a surface for the accumulation of the microorganisms. Many signs of gingivitis may appear in patients with fixed orthodontic appliances[7]. Fixed and removable orthodontic appliances constitute an obstacle which prevents the maintenance of oral hygiene resulting in aggregation of plaque[8].

Material and Method

The samples were obtained from 95 children aged (9-12)year who treated with orthodontic appliances(fixed and removable) in the pediatric dental clinic in the Department of Pedodontics, Orthodontics and Preventive Dentistry (POP) of Dentistry faculty, University of AL Muthanna. From the first of October 2018 till March 2019. All the subjects were healthy with no antibiotic consumption for the last six months. For each patient, plaque and saliva sampleswere taken from the deepest sites of one front tooth and one molarby using two sterile cotton swabs, sterile curette, and scaler. Then examined by the wet mount direct smear and PCR technique. Questionnaires were done for age, gender, oral health, and orthodontic appliances type. The samples were collected from all patients in the morning, before any oral hygiene.

Microscopic Examination: The swabs were washed in 0.9% NaCl solution. A droplet of the samples was put on microscope slides, which were then examined under 100x, 200x and 400x magnification.

DNA Extraction: The DNA of the parasites was extracted from the samples, according to the manufacturer's instructions. (gSYNC^{TM} DNA Mini Kit Blood/cultured cell/Protocol/Geneaid/Korea) was used. The DNA extracts were stored at -20°C till PCR executed.

PCR Amplification: The DNA extracts served as a template for the PCR amplification using the methodformerly described by[9,10,11]. In order to the detection of *E. gingivalis* and *T. tenax* the target DNA regions of the SSU rDNA gene and 18S rRNA gene respectively, were amplified using specific primers (mentionedin Table1).The amplification products were visualized and photographed under UV light after 1 h of ethidium bromide staining. Typical bands of the *E. gingivalis*, is manifested in Fig. 1.

Ethics Statement: The approval has been taken from all the parents of children, informing them that the samples would be for the study purpose only and no more samples will be needed.

Statistical analysis: Data were analyzed by using SPSS version 22 software Fisher's exact and Chi-square with a significant $P<0.05$.

Table (1): The primer sequences and PCR conditions with their amplicon size (Base pair (BP)).

Parasite (Gene's Name)	Primer Sequence (5′- 3′)	Size (BP)	Conditions	Reference
SSU rDNA gene of *E. gingivalis*	F: 5'-AGGAATGAACGGAACGTACA-3' R:5′-CCATTTCCTTCTTCTATTGTTTCAC-3′	203	initial denaturation at 94°C for 3.5min	(3)
			40 cycles of denaturation at 94 °C, 1min, annealing at 60 °C for 1min; and extension at 72°C for 1min)	
			final extension at 72°C for 1min and holding (4°C).	
18S rRNA gene of *T. tenax*	TGBK-F 5′-AGCAGCTGCGGTAATTCCAG-3′ TGBK-R 5′-CTTGTTACCACTTCTCCTTCC-3′	1000	*Taq* activation at 94°C for 5 min	(11)
			30cycles of denaturation at 93°C for 30 s, annealing at 55 °C for 30 s, and extension at 72°C for 2 min	
			final extension at 72 °C for 5 min

Results

Out of 95 samples(49 girls and 46 boys) were examined to evaluate the prevalence of *E. gingivalis* and *T. tenax* in children aged (9-12) years treated with orthodontic appliances. *T. tenax* parasite wasn't detected by PCR and microscopical examination in this study while *E. gingivalis* has been detected by both method. For *E. gingivalis* by Microscopical method showed only 9(9.47%) samples were positive, while by PCR technique the percentage of the *E. gingivalis*, was 15(15.78%). Depend on the agethe higher percentage was (23.52%) in the age(9-10) by microscopical method table(2,A), and 6 (35.29%) in the same age group by PCR technique table(2,B). The statistical analysis showed a significant correlation between the infection and age at $p \leq 0.05$. Depend on oral health the highest percentage was in the mild gingivitis (20%) by microscopical method table(3) and by PCR the highest percentage of the infection was (26.66%) in mild gingivitis as well table(5). The statistical analysis showed no correlation between oral health and the presence of the *E. gingivalis* at $p \leq 0.05$. The percentage of the parasite depends on the orthodontic appliance treatment was similar (9.58%) in the fixed and (9.09%) in the removable by microscopical method (table 4, A) while by PCR technique was(12.32%) in the fixed and (27.27%) in the removable table(4, B), statistically no significant correlation between the infection with the parasite and orthodontic appliances typeat $p \leq 0.05$.

Discussion

Oral protozoa have been detected in 95% of the population with poor oral hygiene. The present study was aimed to evaluate the presence of E. gingivalis and T. tenax in children aged 9-12 years treated by using orthodontic appliances, and their correlation with oral health. The study showed no prevalence for T. tenax in all examined samples by both Microscopical examination and PCR technique. On the contrary to many studies which were detected highly variable levels for the prevalence[11,12].

Out of 95 samples were examined only 9(9.47%) samples were positive by the microscopical method and 15(15.78%) positive samples by PCR technique. This percentage was compatible with many previous studies. [12]found the average number of E. gingivalis in urban children was 12.84 unity and a lower number was found in rural children (10.74 unity) in Lublin, Poland. In Egypt, the study showed the infection percentage 23 (28.75%) conducted on 80 cases with gingivitis. While in the control group, E. gingivalis was 9 (11.25%)[13].

Depend on the age the higher percentage was (23.52%) by microscopical method, and 6 (35.29%) in the same age group by PCR technique, statistically there is a significant correlation between the infection and age. The study of [3] indicated that E. gingivalis occurs in the oral cavity of children. Our present study found the highest percentage of the infection with E. gingivalis was in the mild gingivitis but the statistical analysis showed no correlation between oral health and the presence of the E. gingivalis at $p \leq 0.05$. In fact, E. gingivalis live in the oral cavity as commensals and flourish in poor oral hygiene. According to some authors, this commensal has the potential to become opportunistic pathogens[14]. The study of [12] found no significant correlation between the presence of E. gingivalis and dental caries. The study in Lublin, Poland found the presence of E. gingivalis (81,4%) in patients with some periodontal disease, and (62,5%) in people without oral diseases[10]. Another study in south India showed the presence of E. gingivalis was (88%) in patients with gingivitis, (76%) in patients with periodontitis and only 4% in healthy subjects[16].

The percentage of the parasite depends on the orthodontic appliance treatment was similar (9.58%) in the fixed and (9.09%) in the removable by microscopical method while by PCR technique was (12.32%) in the fixed and (27.27%) in the removable, the statistical

analysis found no significant correlation between the infection and the orthodontic appliances type. Both fixed and removable orthodontic appliances are likely plaque retentive instruments and may have a risk for periodontal diseases. That may provide a good environment to flourish the parasite. It should be kept in mind the intimate contact of the orthodontic appliances with teeth and gingival tissues has a harmful effect on oral hygiene[17,18].

Conclusion

The result of the present study suggested the presence of *Entamoeba gingivalis* in the oral cavity with poor hygiene, which may provide by using orthodontic appliances. It's important for everyone have the orthodontic appliance to maintaining perfect oral hygiene.

Abstract

The aim of this study is to assess the prevalence of overweight and obesity in retired athletes in Saudi Arabia. Seventy former athletes, aged from 20-60 years old, who had played in international and national competitions – and had since stopped competitive sport – were recruited for this study. Sports history, age, height, and weight were collected using an online questionnaire. The study results showed that 47.14% of the participants are overweight and 22.86% are obese. The results of this study indicated that many former athletes had high BMI after ceasing participation in competitive sport. Also, the results indicated that there is a significant difference between BMI before and after retirement.

Keywords: *Former athletes; obesity; overweight; physical activity; body mass index.*

Introduction

Being overweight and obese are increasingly recognised as a serious public health issue worldwide [(1–3)]. Results from several studies have reported that overweight and obesity lead to a wide variety of health issues, such as type 2 diabetes, high blood pressure, and coronary heart disease, and that they shorten the life span [(1–6)]. The relationship between high body mass index (BMI) and all-cause mortality and cardiovascular disease (CVD) mortality follows a U-shaped curve [(7)].

It is commonly acknowledged that engaging in regular physical activity (PA) and exercise in the early stage of life has a significant role in later life [(8–10)]. This means that those who do so decrease the risk of high body fat and contribute to sustaining an ideal body weight. The high accumulation body fat could cause several diseases, such as type 2 diabetes, high blood pressure, and coronary heart disease [(8,11,12)].

Participating in sports in early life, as exemplified by top athletes, can lower the prevalence of several non-communicable diseases, such as type 2 diabetes and high blood pressure, as well as helping them maintain psychological wellbeing in late adulthood[(8,13–16)]. According to Batista and Soares (2014), being an athlete at a high level is often associated with the possibility of decline for the occurrence of several non-communicable diseases. Batista and Soares (2013) have shown that former athletes may maintain appropriate levels of physical fitness (PF) in comparison with the general population, regardless of their participation in competitions or the level of PA.

However, a growing body of literature has emerged showing that the prevalence of obesity, which has experienced a remarkable increase among athletes after retiring from competition [(11,17,18)]. It has been reported that many former athletes engage in sedentary behaviours after ceasing to participate in sport, which can cause a risk to their health [(8,11)]. Functional capabilities in later life might be put at risk because of the negative consequences of injuries during exercises and competitions. The high demands of athleticism during adulthood probably make athletes unable to be as active as they become older, which could affect on their health [(19)]. Top athletes normally exercise for many

years or even several decades to reach their professional level, and when there is no longer any vigorous training motivation, they usually become affected both physically and mentally [20]. However, less is known about the impact of regular training on obesity risk in former athletes. In this context, the aim of this study to assess the prevalence of overweight and obesity in retired athletes.

Method

An online questionnaire was administered to participants. The link to the questionnaire was sent to the Saudi Athletics Federation, asking them to send a request to former athletes to participate in this research. This study was approved by a panel of experts who were considered to be an ethical committee for the school of education at the University Technology Malaysia (UTM). All participants provided informed consent electronically before participation in this study. Subsequently, 70 individuals agreed to participate. The research participants were former male athletes who had played in international and national competitions and had ceased playing competitive sport. The inclusion criteria was that the participant be aged 20 years or older. The online, self-administered questionnaire collected data on sports history, age, height, and weight. BMI was defined as weight (in kilograms) divided by the square of the height (in meters). For the comparisons between our groups and data from the World Health Organization (WHO), overweight was defined as a BMI of 25-29.9, and obesity was defined as a BMI ≥ 30 kg/m^2.

Statistical Analysis: The Data are reported as mean, standard deviations, or number (percentage,%). A paired samples t-test was performed to compare the means of BMI in athletes before and after retirement. Statistical analysis was performed using software SPSS version 23. P-values of <0.05 were considered to be statistically significant.

Results

The results are derived from the data obtained from the online self-reported questionnaire. The total number of participants in this study was 70, all of whom were former athletes from Saudi Arabia. Table 1 presents the demographic variables, and Figure 1 shows the prevalence of obesity classifications. As shown Table 1, the mean height and weight of the participants were 174.61 cm (SD = 7.605) and 83.99 kg (SD = 14.568), respectively. The mean age of the participants was 39.73 years old (SD = 7.75) and ranged from 24 to 59 years old. The majority of the participants were track & field players (34.3%), footballers (24.3%), and Karate practitioners (20.0%).

The findings, as shown in Figure 1, demonstrate that the majority of the former athletes were classified as overweight (47.14%), whereas, the prevalence of normal weight and obesity was 28.57% and 22.86%, respectively. In addition, the study results shown in Figure 3 reveal that there is a difference between the mean BMI before and after their retirement.

Table 1. Physical Variables

Demographic Variable	Mean +- SD
Age (years)	39.73+- 7.75 (24; 59)
Height (cm)	174.61 +- 7.605 (157; 194)
Weight (kg)	83.99 +- 14.568 (62; 130)
BMI (kg/m^2)	27.6244 +- .58630 (17.17; 43.94)

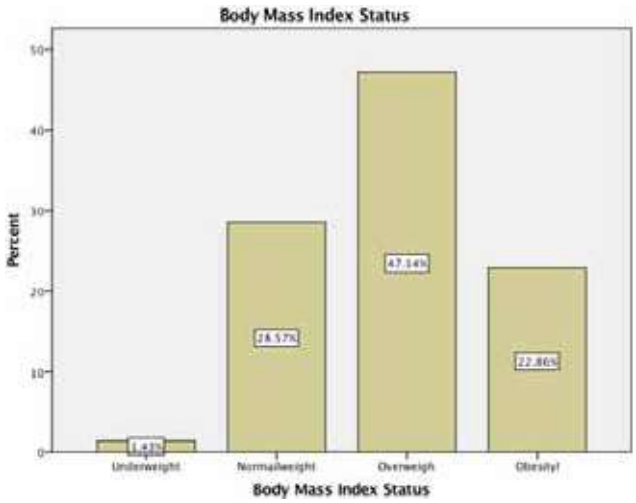

Fig. 1: Participant's BMI as percentages of the overall sample

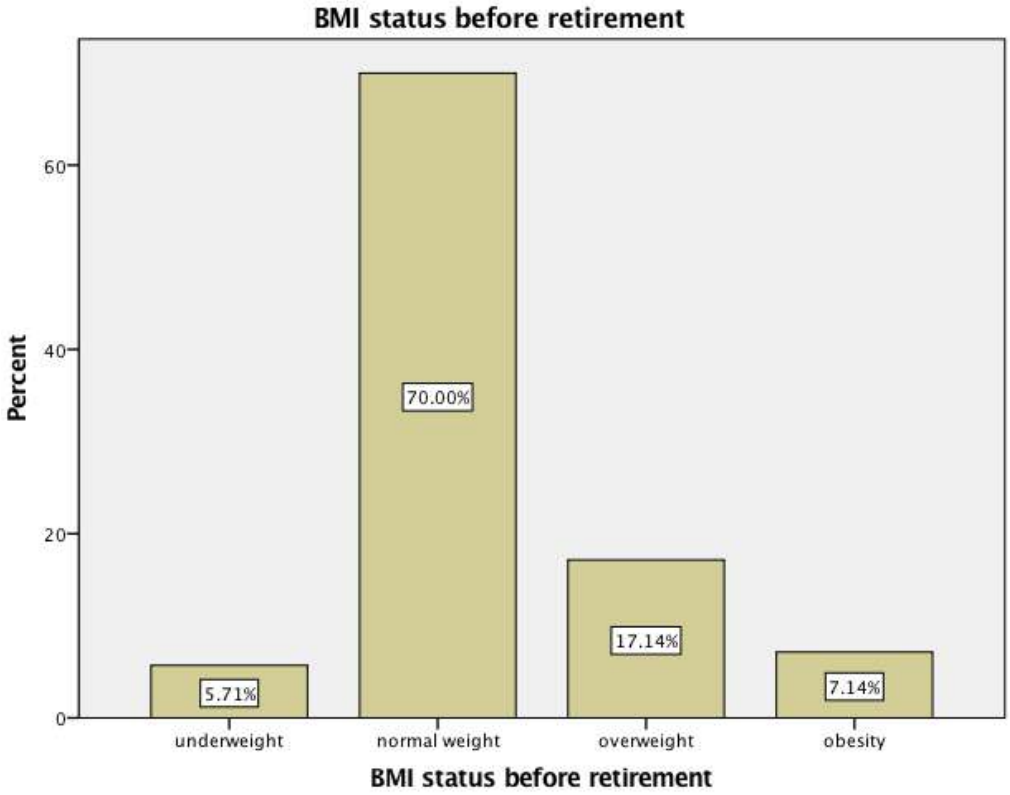

Fig. 2 Participant's BMI as percentages of the overall samplebefore retirement

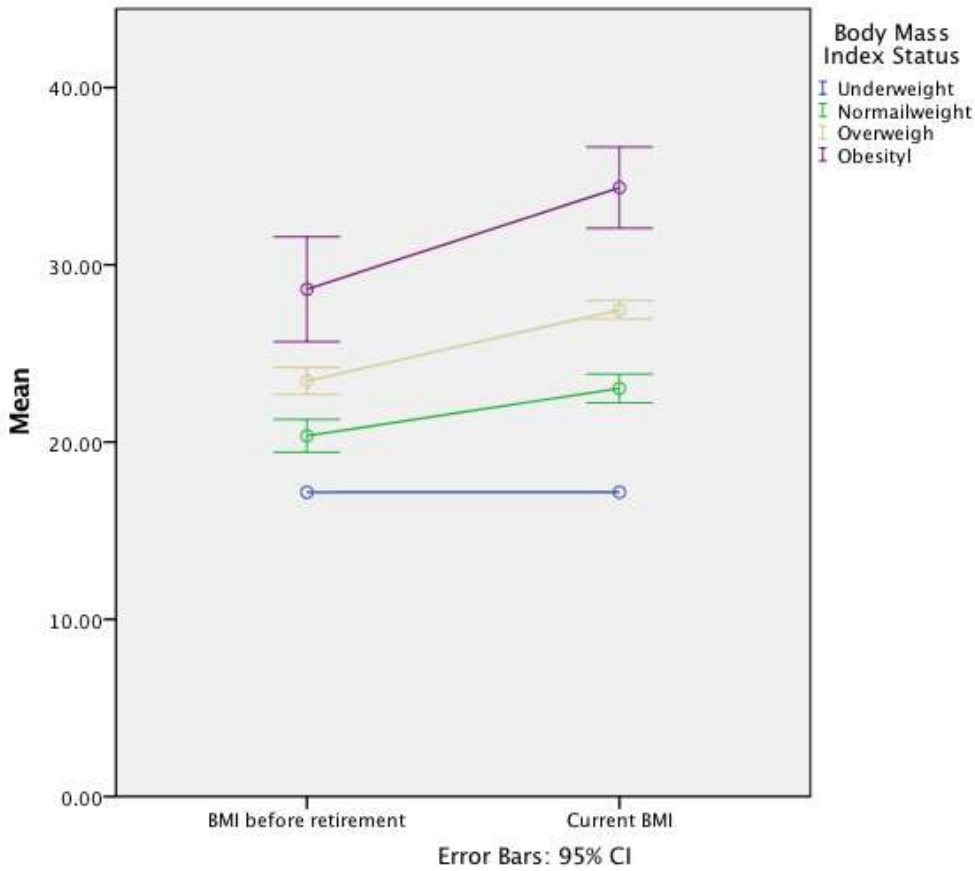

Fig. 3: The mean of BMI before and after retirement

Discussion

It is accepted that engagement in regular PA can lead a better health and a long life [12,19,21,22]. For example, when the level of PA is increased, the risk of mortality might reduce by 20-35%. Moreover, the risk of mortality by CVD can reduce by half if the person is active or fit [19,23]. However, several studies have reported that the risk of long-term diseases increase when the athletes adopted a sedentary lifestyle after ceasing to participate in competitive sport [9,11].

Regular exercise stimulates several physiological, biochemical and morphological adaptations in athletes [21,24]. Athletes have to develop several physical fitness components, such as cardiorespiratory endurance and strength, to meet the demands of the sport. As a result of regular exercise, athletes develop versatile adaptations in their musculoskeletal and cardiovascular systems. For instance, Melekoğlu and colleagues indicated that footballers have greater muscle tissue than non-athletes and typical people. Regardless of the type of sports in which the athletes participated, various adaptations occur in their bodies. Therefore, in order to retain these bodily modifications, they have to remain active and fit even after retirement [19].

It has been reported that former athletes generally keep active and live a healthier lifestyle when they get older[8,9,12,22]. However, several studies have indicated that a significant number of former athletes reduce their level of PA and or engage in sedentary behaviours after ceasing to participate in competitive sport [9,19]. It has been reported that there are several reasons why former athletes do not participate in physical activities: for example, long-term injuries might prevent former athletes from carrying out physical activity[19]. Furthermore, the process of ageing may play a significant role in increasing the body composition and reducing the cardiorespiratory functions [21,24,25].

Although many studies have focused on the current health of former athletes [8,10,11], there is a lack of research associated with athletes who had engaged in regular exercise before they had retired. The findings, which used a group of 70 former athletes that included men from 13 different sports, found that the percentages of overweight and obese individuals in the study sample were high, similar to those of the general Saudi population [1,3,26–29].

According to the study findings, a significant number of former athletes are now overweight or obese in spite of gaining a normal BMI before retirement (Figure 2). Such gain weight is of concern given the associated boosted risk of CVD [11,19,30]. Although having a high BMI may occur with age amongst the general population, athletes who had been retired from sports may reduce their physical activity, yet sustain their eating habits [31]. Interventions towards the end of the athlete's career might assist former athletes to independently manage their levels of physical activity and nutritional requirements upon they leaving the sport[31].

The study findings are consistent with previous results [11,17,19], which show that athletes' body weight and BMI increase after retirement. According to Arliani and colleagues, 80% of former footballers were overweight. A recent results also stated that former professional footballers had higher body weight and BMI scores[19]. It is accepted that obesity is a risk factor for several long-term disease, such as T2D, high blood pressure, CVD, and some cancers [11,25].Based on the study results, it seems that non-participation in sport and regular exercise results in higher BMI, and subsequently, this increases their risk for several chronic diseases. It has been reported that high BMI often occurs as a result of a lack of physical activity or high intake of foods [19].

Although this is a pilot study, it is in fact the first study to determine the prevalence of being overweight and obese in former athletes in Saudi Arabia. In addition, this is the first study to assess BMI before and after athletes retire, and therefore the outcomes are of great importance, in spite of the small number of participants.

Limitations: Some limitations need to be considered in this study. Firstly, the data on height and weight were reported by participants. Nonetheless, in spite of the problem with assessing this, the study reply rate offers useful data on former athletes, and the biases are unlikely to impact the study outcomes. Secondly, the absence of a control group for comparison represent another limitation for this study. Furthermore, the study did not take into account the participants' dietary habits. Although BMI is widely used to determine the prevalence of overweight and obesity in epidemiological research, this study is not a direct measure of fatness and can overestimate the prevalence of overweight and obesity in certain populations[32]. Therefore, using a waist circumference measure may provide a more accurate assessment of obesity than BMI amongst former athletes.

Conclusion

The results of this study of former athletes in Saudi Arabia indicated that these people had a high weight increase after retirement from sport, as well as a high prevalence of overweight and obesity. In addition, this study indicated that there are significant differences in BMI before and after retirement.

Abstract

Background: Indonesian Expanded Program of Immunization has implemented Japanese Emcephalitis vaccination in endemic area in Indonesia such as Bali Province, was initiated by catch up campaign program in children 9 months to 15 years of age.

Objectives: The objectives of this study are to assess the immediate serious systemic reactions within 30 minutes after immunization and also local reactions, systemic events and any serious adverse event, until 28 days following immunization.

Method: An observational study was conducted in 1000 subjects. Local reactions and systemic events within 28 days following immunization, were recorded into daily cards and will be confirmed by trained primary health center staffs.

Result: Totally, 1000 children and adolescents completed the study and can be analyzed. The most common local reaction was pain, occured in 21.1% subjects and mild swelling in 14.1% subjects within 30 minutes after vaccination. Redness occurred more frequent in 15.8% subjects at 24 hours following immunization. Fever, occured only in 0.8%, no serious adverse event reported during the observation.

Conclusion: This JE live vaccine was safe and well tolerated in children and adolescents.

Keywords: *JE, local reactions, systemic reactions, vaccines.*

Introduction

Japanese encephalitis (JE), a masquito-born flaviviral infection, is the leading recognized cause of childhood encephalitis in Asia. After yellow fever (YF), JE is the second flavivirus that is vaccine preventable. JE is transmitted throughout Asia, in a region supporting 3.4 million people, 50% of the world population. [1] Even though on a global scale the incidence of JE may decline as a result of large-scale vaccination programs implemented in India and China, however, transmission of JE is likely to increase in several countries in Asia, such as, Indonesia, Laos, Myanmar, North Korea,Bangladesh, Cambodia and Pakistan because of population growth, yield increase in rice farming, pig rising and breeding, and the lack of immunization programs and surveillance.[2]

JE virus usually transmitted by Culex mosquitoes bite, and circulates in an enzootic cycle in pigs and birds as a breeding hosts. Culex tritaeniorhyn-chus, usually

Corresponding Author:

e-mail: novilia@biofarma.co.id
Telp: 022-2033755 ext. 14101

bites at night and plays the most important role as a vector, breeds in ponds and wetrice fields. JE virus has the reservoir for breeding and cannot be eliminated but disease can still be controlled by extensive immunization in endemic areas.[3]

The estimation of severe symptoms are estimated to occur 1 out of 250 infections by the JE virus.[1] More than three-quarters of pediatric patients will experience seizures, but will be less in adults. In pediatric patients, the most common symptom is abdominal pain accompanied by vomiting.[4] Although the use of vaccines has begun to spread, it is estimated that around 67,900 cases occur each year, of which one quarter is a fatal case with an incidence of 1.8/100,000 in 24 countries at risk of disease due to JE infection..[5]

A study was conducted in 2001-2003 from 559,120 children under 12 years of age, 86 confirmed and 4 probable JE cases were identified. For children less than 10 years of age, the incidence rate of JE was 7.1 and adjusted to 8.2 per 100,000 over the 2.5 consecutive years of study. Among 96,920 children 10–11 years old (0.4per 100,000) only one JE case was found. The outcome of the patients were nine children (10%) died and 33 (37%) of the survivors had neurological sequele. Most of the cases (70%) were occurred in the rainy season, even though JE virus was transmitted in Bali year-round.[6] A study was conducted in 15 districts from 12 provinces in Indonesia among the pig rearing location. All provinces found JE infections with the highest number from Central Sulawesi. Unfortunately Bali was not included in this study.[7]

At 2006 WHO recommended to gradually replaced the first generation vaccine by a new generation JE vaccines, with fewer side effects. This article describes this new generation of JE vaccine in depth.[8] Indonesian government has decided to introduce JE vaccination in Bali province 2017-2018.[9] The immunization program will be started with catch up campaign from 9 months to 15 years of age.

Method

We conducted an observational study design as an active vaccine safety surveillance, involving 1000 children between 9 months to 15 years of age. The study was conducted in period March – July 2018. This study was conducted in 2 primary health centers in Denpasar City (Denpasar Barat 1 and Denpasar Utara 3) and 2 primary health centers in Badung District (Mengwi 1 and Mengwi 3).

The sample size was calculated using formula for Post Marketing Surveillance/Phase IV study, from known adverse event; fever, 0.014 require 883 subjects, with drop out estimation 20%, this study require 1000 subjects.

Procedures: The study protocol has been reviewed and approved by the Health Research Ethics Committee of Faculty of Medicine of University of Indonesia (Reference number:03540/UN2.FI/ETIK/2018) prior the study.

After informed consent has been signed, the subjects who met inclusion criteria were allocated to an inclusion number from 001 to 1000. The subjects received Japanese Encephalitis Vaccine, Live ®(Chengdu Institute of Biological Products (CDIBP), Chengdu, China) and vaccination based on campaign base Immunization Program. All subjects/teachers/ parents provided with diary card to assess and record information for local and systemic reactions within 28 days following immunization, with special attention in the first three days. Local reactions are reactions that arise at the injection site and systemic reactions are reactions that are experienced systemically outside the injection site. Safety assesments were confirmed by trained health care provider within 30 minutes after injection. Subjects received thermometers, plastic bangle and diary cards, to record the occurence of local and systemic reactions. The intensity (recorded as 1=mild, 2=moderate or 3=severe) of local (pain, redness, swelling and induration at injection site), and systemic reactions (fever ≥38ºC, irritability and others) recorded from day 0 through 28 days after immunization.[10-12]

Results

We enrolled a total of 1000 children and adolescent aged 9 months to 15 years of aged, 424 female and 576 male, and all subjects completed the study and can be analyzed.

No serious adverse event observed during the study. Fever was observed, 0.25% – 0.8% according to the time of onset. Most of the fever were mild, one fever classified as moderate, and none of them was classified as severe. Irritability was observed in 0.6% subjects 30 minutes following immunization and was decreased to 0.3% at the following day with the intensity were mild. For local reaction, pain was the most commonly

reported reaction following JE immunization. Onset of pain occured within 30 minutes in 211 subjects (21.1%), and most of the pain was mild to moderate intensity, and 0.7% was severe. Pain decreased within 24 hours after vaccination, and observed in 189 subjects (18.9%), the intensity was mostly mild to moderate and 0.4% was severe. At 30 minutes following immunization, 157 subjects experienced redness at the injection site, and increased 24 hours after immunization to 158 subjects (15.8%), mostly were mild in intensity, and decreased at the following day. Four subjects had severe redness. Mild swelling reported in 141 subjects (14.1%) within 30 minutes after immunization and were increased to 14.3% where 4 of them were severe in intensity. Swelling were decreased at the following day to 0.7% with the intensity mild.

If the adverse events were categorized based on the age group, the most frequent fever was in the 1< 7 years age group, but for the local reactions, all of the local reactions were most frequent in 7 <12 years of age, even though the highest number of participants were from 1< 7 years age group.

Table 1. Age distribution of the study participants

No	Age (Years)	n	%
1	≤ 1	37	3.7
2	1 < 7	516	51.6
3	7 < 12	330	33.0
4	>= 12	117	11.7
	Total	1000	100

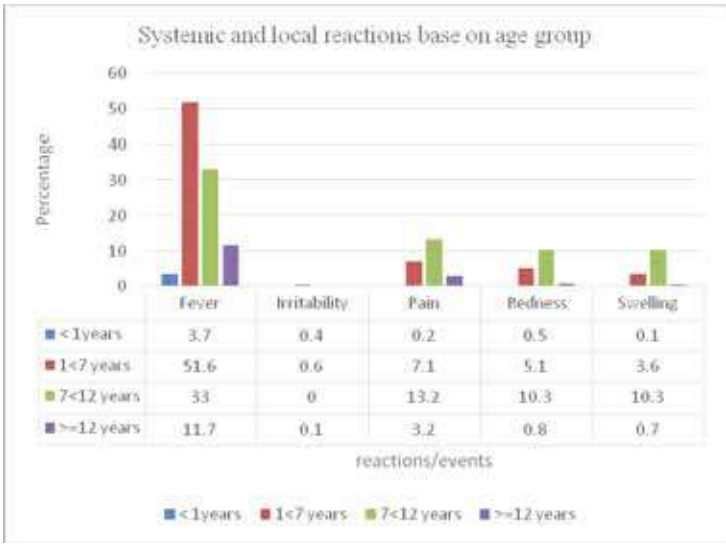

Figure 1. Systemic and local reactions based on age group

Discussion

Our study monitored the catch up campaign of live JE vaccine in 1000 subjects aged between 9 months to 15 years, in Bali. From 1000 subjects, all subjects completed the study visit.No serious adverse even occurred during the study. As the primary objective of this study, no immediate serious adverse event observed in this study.

The most common systemic event was fever. Fever was observed, 0.25% – 0.8% according to the time of onset. Most of the fever were mild, one fever classified as moderate, and none of them was classified as severe. Irritability was observed in 0.6% subjects 30 minutes following immunization and was decreased to 0.3% at the following day with the intensity were mild. For local reaction, pain was the most commonly reported reaction following JE immunization. Onset of pain occured within 30 minutes in 211 subjects (21.1%), and most of the pain was mild to moderate intensity, and 0.7% was severe. Redness occurred more frequent in 15.8% subjects at 24 hours following immunization and swelling 14.3% at the same visit.

A study conducted in China to evaluate JE live and measles vaccine in 545 subjects, at 8 months of age infants received measles and JE live vaccination. The most common local reactions was redness 2%, and the other local reactions were <1%. The most common systemic event was fever 19%, followed by cough 5%, diarrhea, upper respiratory tract infections and others 3% for each event.[13] Publication about safety review of JE vaccine was published in 2017. The frequency of erythema (0.2%–1.1%), swelling (0.4%–1.54%), pain (0.9–17%) as the local reactions and signs and/ or symptoms at the injection site were reported approximately 3% across studies that administered only one JE live vaccine dose.[14-17] A prospective cohort study among South Korean children, showed different profile, in which no local and systemic reactions were reported.[14,18] Induration was reported in 12 from 2878 infants within 14 days follow-up period from a study in Srilanka.[19] One dose administration of JE live vaccine

reported only mild and time-limited systemic reactions following immunization regardless of follow-uptime in majority of the studies.[13-16] Fever (>37.8°C) was found among 133 infants vaccinated with one dose of JE live vaccine, of whom 39% and 44%reported recovering within one day and 2 days, respectively which was conducted in Srilanka.[19] According to WHO information sheet for JE live attenuated SA 14-14-2 vaccine redness and swelling at the site of injection was reported in <1% vaccinees. For systemic event, the incidence is very low, fever 5/10,000, skin rash 1/10,000 nausea and dizziness 3/1,000,000). In the same literature, but from different study found fever 5% and irritability 4%.[20]

Compared to our study, all the systemic and local reactions observed in our study were mostly bellow or at least equal to that found in other studies above.

In conclusion, this JE live vaccine was safe and well tolerated in children and adolescents.

Conflict of Interests: Irawan Mangunatmadja, Julitasari Sundoro, I Made GDL Utama, Syafriyal, Hindra I. Satari, Sri R. Hadinegoro received grant support through their institutions. Rini M. Sari and Novilia S. Bachtiar were employees of PT Bio Farma at the time of the conduct of this study and manuscript preparation.

Heavy Metals Concentration and Biochemical Parameters in the Blood and Nails of Industrial Workers

Kameran Sh. Husien[1], Mohsin O. Mohammed[2], Tamara N. Ahmed[2]

[1]Professor, College of Nursing, [2]Assistant Professor, College of Science, Kirkuk University-Kirkuk, Iraq

Abstract

This study amied to measure the concentration of heavy metals (Pb, Cd) and certain biochemical variables in blood and nails of (50) samples(male and female) of workers (who were in risk of exposition to these heavy metals) from Northern Gas Company in Kirkuk city/Iraq. Flame atomic absorption spectrometer was used for measuring these elements. The results showed significant differences ($P < 0.01$) in the concentration of lead and cadmium in the studied samples (whole blood and nails) of workers compared to the control group. The concentration of lead and cadmium were higher in blood and Nails. As of the biochemical variables, significant differences ($P < 0.05$) showed in the concentration of antioxidant enzyme (SOD) in serum. As of oxidative stress (MDA), results showed significant differences ($P < 0.05$) in serum, the highest value of (MDA) was recorded in serum samples.

Keywords: *Heavy metals, Antioxidant, Oxidative stress.*

Introduction

Heavy metals have found as natural constituents of the Earth's crust and are non-degradable in nature and tend to form pollutants of living organisms in the environment,[1] and living organisms inhabiting contaminated sites may be exposed to very high amounts of heavy metals as they are toxic and may cause adverse effects, even if in small concentrations.[2-3]

Different sources of heavy metals were found in the environment (natural and industrial). Natural sources such as weathering and volcanic eruption contribute significantly to the pollution of heavy metals,[4-6] and industrial sources such as; mineral processing in refineries, power plants, coal combustion, oil combustion, nuclear power plants, chemical and metal industries, in addition to the plants of wood preservation, and paper processing.[7,8]

Malondialdehyde (MDA), one type of oxidant, is the final product for the oxidation of polyunsaturated fatty acids, which is an indicator for estimating oxidative stress.[9] Antioxidants are of great importance as they are the first line of defence against free radicals, and the need for antioxidants becomes more critical with increasing exposure to free radicals.[10] The human antioxidant defence system consists of enzymatic and non – enzymatic systems. Many enzymatic systems are stimulatingreactions to neutralise free radicals. These enzymes include Superoxide Dismutases (SOD), Catalases (CAT), Glutathione Peroxidases (GPX), Glutathione Reductases (GRX), and these mechanisms form the internal defence mechanisms of the body to help protect against cell damage caused by free radicals.[11] These enzymes also require co-factors such as copper, zinc, and selenium as a stimulant to activate enzymes to maintain functions and prevent oxidation in human cells, and the need for antioxidants has become very important with increased exposure to free radicals.

Materials and Method

The samples of blood and nails were collected from 50 employees (males and females) aged between 20-65 years of the Northern Gas Company in Kirkuk

governorate, while the duration of exposure or years of work ranged between (1-30) years. The control group was selected from 20 people outside the North Gas Company, which did not work in the industrial sector. The samples were collected in January 2019. The elements were estimated in all studied samples by an atomic absorption device (ASS), where the lead element was measured by the flame atomic absorption device (FAAS), while the Cd element by non-flammable atomic absorption device (GFAAS).[12]

Preparation and Sating Samples:

1. **Blood:** 10 ml of blood was collected from each person; blood samples were divided into two parts; in the first part, (5 ml) was placed in an anticoagulant tube and kept at room temperature to measure lead and cadmium. In the second part, (5 ml) was placed in plastic tubes with tight lids and free from any anticoagulant (Plain tube), and was left at room temperature (25 C) until coagulated, and then placed in the centrifuge for 10 minutes at a speed of 3000 rpm, afterword serum was collected by micropipette to measure biochemical tests. It was then transferred to dry plastic tubes and kept at 10 ° C using Deep Freezer [13] until tests were carried out. The concentration of lead and cadmium in the blood of the workers was estimated by Haswell method.[13]
2. **Nails:** Each person's nails were trimmed with clean, sterile scissors, and then placed in sealed plastic bags. Nails were then washed with non-ionic cleaners. After a standard wash, the nail samples were soaked in acetone. Finally, the samples are rinsed five times with deionised water and then dried in the oven at 110 ̊c and stored in the desiccant pending analysis. The samples were divided into two parts, the first part for measuring the heavy elements and the second part for measuring the biochemical variables. The heavy elements in the nail samples were estimated, according to Abdul-Rahman et al.[14] method.

Statistical Analysis: Results were statistically analysed using ANOVA test and the results obtained were described in the tables as (mean and standard deviation) and with a probability level (P <0.05) and P <0.01).

Results and Discussion

1. Heavy metals:

Estimation of heavy metals in whole blood:

Table (1): Concentration of heavy metals (Pb $_{\mu g/dl}$, Cd $_{\mu g/dl}$) inworkers'whole blood and control group.

Elements	Groups	Mean±SD	P-Value
Pb	Workers	25.40±4.20	P<0.01
	Control	13.91±2.02	
Cd	Workers	1.0904±0.0416	P<0.01
	Control	0.2782±0.0291	

Lead-(Pb): The results of table (1) showed different concentrations of the lead element; the concentration of the lead in whole blood of workers during the study period was (25.40 ± 4.20) and control (13.91 ± 2.02), respectively (Figure 1). Statistically significant differences were found (P<0.01) between the concentration of the lead in the whole blood of workers and the control group, that it was found to be higher than the control group. The reason for the high concentration of lead in the workers could be attributed to the tetraethyl lead, chemicals that emitted from North Gas Company. Furthermore, a study has shown that high concentrations of lead in industrial atmospheres are humanmade, as it is almost 100 times higher in industrial atmospheres compared to natural atmospheres [15]. Increasing the concentration of lead in the whole blood leads to many adverse consequences such as hypertension, renal failure, and brain damage.[16] These findings are consistent with those reported by others [17, 18].

Cadmium-(Cd): The results of table (1) showed different concentrations of the Cadmium; the concentration of the Cadmium in whole blood of workers during the study period was (1.0904±0.0416) and control group (0.2782±0.0291), respectively (Figure 1). Statistically significant differences were found (P<0.01) between the concentration of the lead in the whole blood of workers and the control group, that it was found to be higher than the control group. The high concentration of cadmium in workers was attributed to industrial emissions, especially the mining and mineral refining industry. Also, cadmium occurs naturally with zinc and lead in sulfide ores. Cadmium has a direct relationship with some chronic diseases, such as hypertension, which

is an excellent indicator of exposure to cadmium in occupationally exposed individuals. Cadmium leads to an increase in systolic and diastolic blood pressure, and thus an increase in high blood pressure.[19]

The results obtained were mostly consistent with studies conducted on gas station workers in Babil[17] and Basrah[18] governorates, where there was a decrease in the concentration of (Cu, Zn, Mg) and an increase in the concentration of (Cd, Pb) in the blood of gas station workers compared to the control group.

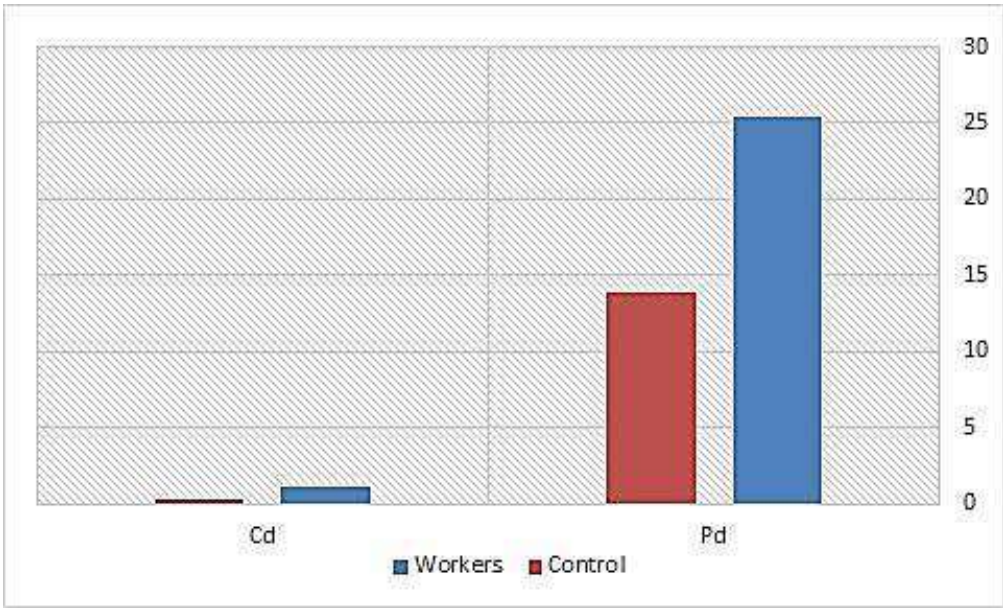

Figure 1: Concentration of Heavy Metals (Pb $_{\mu g/dl}$, Cd $_{\mu g/dl}$) in workers' Whole Blood and control group

Estimation of heavy metals in workers' hair compared to the control group:

Table (2): Concentration of heavy metals (Pb $_{\mu g/dl}$, Cd $_{\mu g/dl}$) in workers' hair and control group.

Elements	Groups	Mean±SD	P-Value
Pb	Workers Control	15.70±2.18 7.75±1.29	P<0.01
Cd	Workers Control	0.1330±0.0264 0.0820±0.0194	P<0.01

Lead-(Pb): The lead element poses a real concern among heavy metals because of its toxicity, and there is no primary function in the human body, the damage can occur only after its absorption from air or water [20].

The results of table (2) showed different concentrations of the lead element; the concentration of the lead in whole blood of workers during the study period was (15.70±2.18) and control (7.75±1.29), respectively (Figure 2).

Estimation of heavy metals in workers' nail compared to the control group:

Table (3): Concentration of heavy metals (Pb $_{\mu g/dl}$, Cd $_{\mu g/dl}$) in workers' nail and control group.

Elements	Groups	Mean±SD	P-Value
Pb	Workers Control	14.57±2.50 9.11±1.60	P<0.01
Cd	Workers Control	0.1362±0.0217 0.0925±0.0189	P<0.01

Lead-(Pb): The results obtained, shown in Table (3), indicate the concentration of the lead element in workers' nails compared to the control group, where the concentration of lead in workers' nails was 14.57 ± 2.50), and in the control group (9.11 ± 1.60), (Figure 3). Statistically, there were significant differences (P <0.01) for the average concentration of lead in workers' nails compared to the control group.This is due to occupational exposure, which contributes to the absorption of minerals, and these results are like those reported by others.[21, 22]

Cadmium-(Cd): The results obtained, shown in Table (3), showed the concentration of cadmium in workers 'nails compared with the control group, where the concentration of cadmium in workers' nails was 0.1362 ± 0.0217), and in the control group (0.0925 ± 0.0189), (Figure 2).Statistically, there were significant differences (P <0.01) on the average concentration of cadmium in workers' nails compared to the control group. The reason for the high concentration of cadmium is due to the complex occupational exposure of the elements, and the results obtained are consistent with the findings.[21, 22]

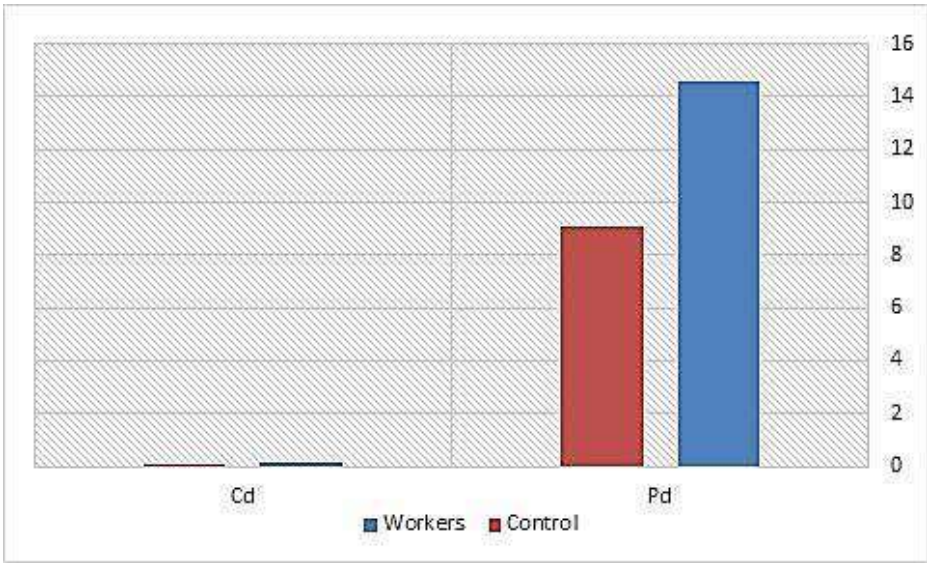

Figure 2. The concentration of heavy metals (Pb $_{\mu g/dl}$, Cd $_{\mu g/dl}$) in workers' nail and control group.

Biochemical variables:

Estimation of oxidative and antioxidant concentrations in blood serum

Table (4): Concentration of Enzymes (SOD $_{U/ML}$, MDA $_{\mu mol/L}$) in the blood serum of workers and control group

Variables	Groups	Mean±SD	P-Value
SOD	Workers Control	30.7±3.1 49.3±10.5	P<0.05
MDA	Workers Control	123.6±16.9 70.0±13.7	P<0.05

The concentration of Superoxide dismutase (SOD) enzyme: The results of table (4) show the concentration of enzyme (SOD) in the serum of workers and the control group, where the concentration of enzyme in the serum of workers was (30.7 ± 3.1) which was lower than the control group was (49.3 ± 10.5),(Figure 4).Statistically, there were significant differences between the workers and the control group (p <0.05). The reason for the decrease in the concentration of the enzyme SOD is that it is common in contaminated environments because this enzyme is necessary to protect the body's cells from free radicals and excessive oxygen that promote ageing or cell death.[23] Moreover, trace elements (Zn, Cu, Mg) are SOD components and are associated with antioxidant functions, so their deficiency may lead to poor control of free radicals, and all these elements are replaced by lead, which reduces the activity of (SOD).[24] The results obtained were in contrast with that reported in another study [25] and coincide with the others.[17, 18, 26, 27]

Concentration Serum lipid peroxidation (MDA): The results are shown in Table (4) indicate that the concentration of MDA in the serum of the workers (123.6 ± 16.9) was high in comparison to the control group (70.0 ± 13.7),(Figure 4). Statistically, there were significant differences between the workers and the control group (p<0.05). The reason for this is that the rise in the level of heavy metals leads to the destruction of oxidative stress by increasing the production of free radicals (ROS), which reduces the system of antioxidant defence in cells and increase the concentration MDA.[28,29] These results are consistent with other findings.[17,18,26,30]

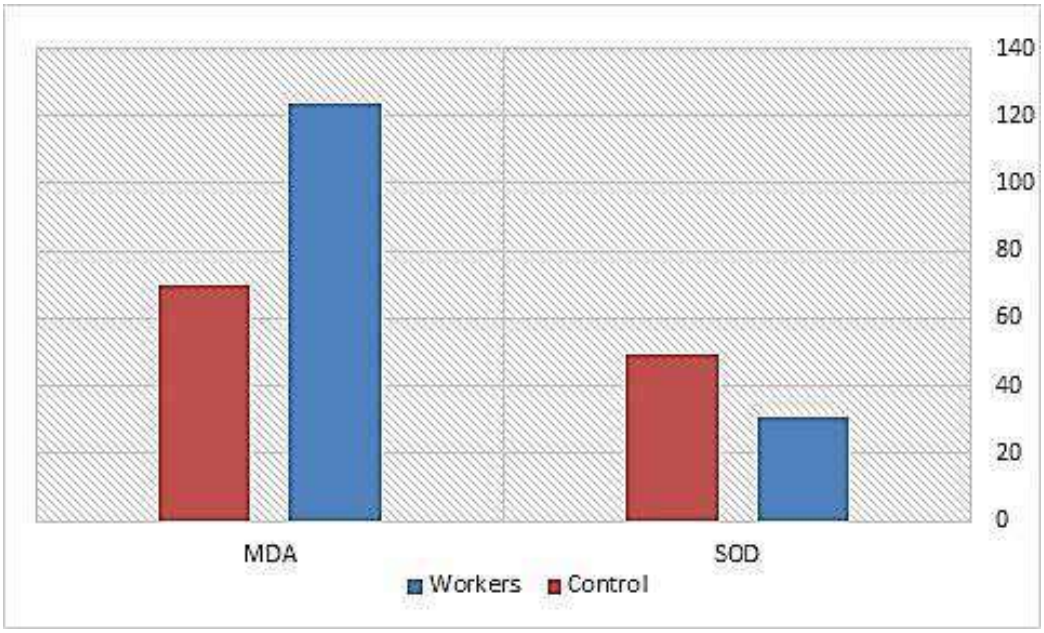

Figure 4. The concentration of Enzymes (SOD $_{U/ML}$, MDA $_{\mu mol/L}$) in the blood serum of workers and control group.

Conclusion

The results of this study concluded that the concentration of heavy metals (Pb, Cd) was high in the whole blood and nails of the workers in the North Gas Company. Moreover, the concentration of SOD enzyme in the blood and samples was low;the MDA was high in all samples of studied workers.

Conflict of Interest: None of the authors have any conflicts of interest to declare.

Source of Funding: The research was performed independently, there is no funding

Ethical Clearance: The project was approved by the local ethical committee in University of Kirkuk.

Dominant Factor Analysis of Medical Equipment and Device Affect Against Customers' Repeat Purchase Decision

Albern Liyanto[1], Christopher Alexander Wijaya[1], Karina Leonita[1]

[1]Bina Nusantara University, Jakarta, Indonesia

Abstract

This study is an attempt to identify what factors will affect customer to buy or do a repeat order of health equipment from them. Factors that define customer satisfaction are price, distribution channel, product quality, and service quality that will affect repeat purchase decision. Data were collected using observation and questionnaire method. A questionnaire sampling method was applied to 100 respondents. Data that has been collected was tested and processed with multiple regression analysis and sobel test method. This study has found that price and service quality affect customer satisfaction and customer satisfaction affect repurchase decision.

Keywords: *Price, distribution channel, product quality, service quality, repurchase decision.*

Introduction

Based on information taken from export.gov (2016), the market for medical equipment is very competitive market in Indonesia, one of the leading suppliers with shares above 10% in 2016[1]. Other countries competing for market share of medical devices and equipment in Indonesia included are China, Germany, Japan, Korea and the Netherlands. Medical equipment products from China and Korea have the biggest markets in Indonesia. Unlike other ASEAN regulatory systems, before entering the Indonesian health market foreign markets must establish investment companies that cooperate in the form of PT or appoint local agents and distributors who can be trusted to serve the Indonesian market. Because only through local agents and distributors who can handle product registration and play an important role in developing the market in Indonesia[2].

With the development of health services in Indonesia, the need for health equipment facilities in Indonesia is rapidly increasing. Health institutions continue to demand medical equipment to complete their facilities, so that a supply of medical devices is needed to meet the demand of a variety of health institution[3]. The demand of medical devices in Indonesia is one of the businesses that is prestigious and will certainly lead to competition between companies in the same field. The company needs to be certain what are their customer need and pitch their products to win the competition[4].

Based on the facts above, we tried to conduct a research to find out and identifies what are the driving factors that influence the customers repeat purchase decision? and what is the most influential factors that affect customers re-purchase decisions?

Hypothesis

H1 Ho: There is no significant effect between the price variable (X1) on Customer Satisfaction (Y1).

Ha: There is a significant effect between the price variable (X1) on Customer Satisfaction (Y1).

H2 Ho: There is no significant effect between the Distribution Channel variable (X2) on Customer Satisfaction (Y1).

Ha: There is a significant effect between the Distribution Channel variable (X2) on Customer Satisfaction (Y1).

H3 Ho: There is no significant influence between the Product Quality variable (X3) on Customer Satisfaction (Y1).

Ha: There is a significant influence between the Product Quality variable (X3) on Customer Satisfaction (Y1).

H4 Ho: There is a significant difference between service quality (X4) against Customer Satisfaction (Y1).

Ha: There is a significant influence between service quality (X4) against Customer Satisfaction (Y1).

H5 Ho: There is no significant effect between the Customer Satisfaction variable (Y1) on Repurchase Interest (Y2).

Ha: There is a significant effect between the Customer Satisfaction variable (Y1) on Repurchase Interest (Y2).

Method

Survey and observation are utilized on this research. The study setting used is realtime situation, hence author is not altering any environment in the research and the result are purely from natural activities (non-contrived) [5,7,8]. This research was conducted only in one occasion, within a period of time selected (one shot). While the data was collected by 2 method, the first is observation to know the past transaction that occurred before and see the pattern to be analyzed as a base foundation of hypothesis. To get the primary data, researchers require the do a survey while the secondary data can be obtained by visiting the library, study centers, archives or read many books related to the research. The second method is questionnaire. The measurement of all factors has been conducting using a 4-point Likert scale (1 = strongly disagree to 4= strongly agree). The final questionnaire was addressed to the selected past customer that we have done transaction with the company before. The size of the sample was 100 customers in Jakarta. The questionnaire contains 23 questions.

Result

Validity, Reliabilty, Normality: Based on the analysis using *Pearson product moment* obtained the results of validity for all instruments in this study $r^{count}>$ table, that can be concluded that the instrument in this study is valid. Based on the reliability test analysis on each of the independent and dependent variables, the results show that each variable gives a Cronbach alpha value > 0.60, it can be concluded that the instrument in this study is reliable. Unstandardized Residual (Y1) dan Unstandardized Residual (Y2) data with Kolmogorov-Smirnov (Sig) > 0.05 so it can be concluded that the data is normally distributed.

a. Model 1:

Table 1. Result of F Test Model

ANOVA[a]					
Model	**Sum of Squares**	**df**	**Mean Square**	**F**	**Sig.**
Regression	4,207	4	1,052	89,187	,000[b]
Residual	1,120	95	,012		
Total	5,328	99			

a. Dependent Variable: Customer Satisfaction, b. Predictors: (Constant), Service Quality, Distribution Chanel, Price, and Product Quality

Hypothesis:

Ho: There is no significant effect simultaneously between price (X1), Distribution Channels (X2), Product Quality (X3) and Service Quality (X4) on Customer Satisfaction (Y1).

Ha: There is significant effect simultaneously between price (X1), Distribution Channels (X2), Product Quality (X3) and Service Quality (X4) on Customer Satisfaction (Y1).

Conclusion

F-count 89,187 > F-table 2,47 → Ho rejected

b. Model 2:

Table 2. Result of F Test Model 2

ANOVA[a]					
Model	**Sum of Squares**	**df**	**Mean Square**	**F**	**Sig.**
Regression	301,296	1	301,296	465,260	,000[b]
Residual	63,464	98	,648		
Total	364,760	99			

a. Dependent Variable: Re-purchase interest, b. Predictors: (Constant), Customer satisfaction

Hypothesis:

Ho: There is no simultaneous significant effect between the Customer Satisfaction (Y1) on Repurchase Interest (Y2).

Ha: There is simultaneous significant effect between the Customer Satisfaction (Y1) on Repurchase Interest (Y2).

Conclusion

F-count 465,260 > F-table 3,94 → Ho rejected

There is simultaneous significant effect between the Customer Satisfaction (Y1) on Repurchase Interest (Y2)[21].

2. Multiple Regression Test

a. Model 1:

Table 3. Multiple Regression Test Model 1

Coefficients[a]					
Model	**Unstandardized Coefficients**		**Standardized Coefficients**	**T**	**Sig.**
	B	**Std. Error**	**Beta**		
(Constant)	,996	,093		10,705	,000
Price	,095	,006	,820	15,485	,000
Distribution Chanel	,002	,006	,020	,391	,697
Product Quality	,002	,004	,030	,550	,584
Service Quality	,017	,004	,191	3,971	,000

a. Dependent Variable: Customer Satisfaction

Multiple Regression Test Model 1:

$$Y_1 = 0{,}996 + 0{,}095X_1 + 0{,}002X_2 + 0{,}002X_3 + 0{,}017X_4$$

From the regression equation model 1 above it can be concluded that:

1. The constant coefficient 0 of 0.996 states that without the Price (X1), Distribution Channels (X2), Product Quality (X3) and Service Quality (X4) variables, the Customer Satisfaction value (Y1) is 0.996.
2. The coefficient of constant 1 worth + 0.095 states that the influence between Price (X1) and Customer Satisfaction (Y1) is positive.
3. The coefficient of constant 2 is + 0.002 stating that the influence between Distribution Channels (X2) and Customer Satisfaction (Y1) is positive.

4. The coefficient of constant 3 value + 0.095 states that the influence between Product Quality (X3) and Customer Satisfaction (Y1) is positive.
5. The constant coefficient 4 is + 0.017 stating that the influence between Service Quality (X4) and Customer Satisfaction (Y1) is positive.

Hypothesis:

H1: Effect of Price (X1) on Customer Satisfaction (Y1)

Hypothesis:

Ho: There is no significant effect between the price variable (X1) on Customer Satisfaction (Y1).

Ha: There is a significant effect between the price variable (X1) on Customer Satisfaction (Y1).

Sig = 0,000 < 0,05 and t count 15,485 > t table 1,66 → Ho rejected

H2: Effect of Distribution Channels (X2) on Customer Satisfaction (Y1)

Hypothesis

Ho: There is no significant effect between the Distribution Channel variable (X2) on Customer Satisfaction (Y1).

Ha: There is a significant effect between the Distribution Channel variable (X2) on Customer Satisfaction (Y1).

Sig = 0,0697 > 0,05 and t count 0,391 < t table 1,66 → Ho accepted

H3: Effect of Product Quality (X3) on Customer Satisfaction (Y1)

Hypothesis

Ho: There is no significant influence between the Product Quality variable (X3) on Customer Satisfaction (Y1).

Ha: There is a significant influence between the Product Quality variable (X3) on Customer Satisfaction (Y1).

Sig = 0,584 > 0,05 and t count 0,550 < 1,66 → Ho accepted

H4: Effect of Service Quality (X4) on Customer Satisfaction (Y1)

Hypothesis

Ho: There is no significant influence between Service Quality variables (X4) on Customer Satisfaction (Y1).

Ha: There is a significant influence between Service Quality variables (X4) on Customer Satisfaction (Y1).

Sig = 0,000 < 0,05 and t count 3,971 > t table 1,66 → Ho rejected

b. Model 2

Table 4. Multiple Regression Test Model 2

Coefficients[a]					
Model	**Unstandardized Coefficients**		**Standardized Coefficients**	**t**	**Sig.**
	B	**Std. Error**	**Beta**		
(Constant)	-7,414	,757		-9,795	,000
Customer Satisfaction	7,520	,349	,909	21,570	,000

a. Dependent Variable: Repurchase Interest

Multiple Regression Test Model 2:

Y_2= -7,414 + 7,520Y_1: The constant coefficient is negative -7.414 stating that by assuming the absence of the variable customer satisfaction (Y1), the interest in repurchasing tends to decrease by 7,414 units.

Hypothesis:

H5: Effect of Customer Satisfaction (Y1) on Repurchase Interests (Y1)

Hypothesis:

Ho: There is no significant effect between the Customer Satisfaction variable (Y1) on Repurchase Interest (Y2).

Ha: There is a significant effect between the Customer Satisfaction variable (Y1) on Repurchase Interest (Y2).

Sig = 0,001 < 0,05 and t-count 21,570 > t-table 1,66 → Ho rejected

3. Coefficient of Determination (R2)

Table 5. Coefficient of Determination Test

Model	R	R-sq	Adj R-sq	SE estimates
Model 1	,889[a]	,790	,781	,10860
Model 2	,909[a]	,826	,824	,805

The Adjusted R Square value in model 1 is 0.781. It means that 78.1% that the independent variables such as price, Distribution Channels, product quality and service quality are able to explain the variables that occur in the variable customer satisfaction. While the remaining 21.9% is explained by factors outside the research variable. Likewise, the Adjusted R Square value in model 2 is 0.824, which means that 82.4% that the independent variable which is customer satisfaction can explain the dependent variable, namely the interest in repurchasing. While the remaining 17.6% is explained by factors outside the research variable.

4. Sobel Test (Mediation Test): In this study, the authors conducted a sobel test by using the Online Sobel Test Calculator[22] for the Significance of Mediation from Daniel Soper at www.danielsoper.com to assess whether the tested variables were intervening variables that could mediate *P-value*< 0,05 or sobel test statistic> t-table 1,66

Table 6. Result of Sobel Test

Indirect Influence	Sobel test statistic	P-Value
Price → Customer Satisfaction → Repurchase Interesr	12,759	0,000
Distribution Channel → Customer Satisfaction → Repurchase Interesr	0,333	0,369
Product Quality → Customer Satisfaction → Repurchase Interesr	0,499	0,308
Service Quality → Customer Satisfaction → Repurchase Interesr	4,169	0,000

From the description of the sobel test above, it can be concluded that customer satisfaction can mediate the effect of variable prices and service quality on the repurchase interest.

Discussion

Price (X1) affects customer satisfaction (Y1): Based on the results of partial regression test, obtained a value of t-count (15.485) is greater than t-table (1.66) with sig 0.000, where the value of sig ≤ 0.05. Then, it can be stated that Ha is accepted which means that prices have a positive and significant effect on customer satisfaction.

Distribution Channels (X2) affect customer satisfaction (Y1): Based on partial regression test, obtained t-count is 0.391 (< t-table 1.66) with sig 0.697 (> 0.05). It means that Distribution Channels do not have a positive and significant effect on customer satisfaction. This is contrary to previous research conducted, Tonny Sopan, et al. (2014: 10), that there is a significant effect of Distribution Channels on Customer Satisfaction.

Product Quality (X3) affects customer satisfaction (Y1): Based on partial regression test, obtained t-count is 0.550 (< t-table 1.66) with sig 0.584 (> 0.05). It means that product quality does not have a positive and significant effect on customer satisfaction. This is contrary to previous research conducted by Tristiana (2016: 21) that product quality has a positive and significant effect on customer satisfaction and research conducted by Putri and Astuti (2017: 8) that product quality has a positive and significant effect on customer satisfaction.

Service Quality (X4) has an effect on Customer Satisfaction (Y1): Based on partial regression test, obtained t-count is 3.971 (> t-table 1.66) with sig 0,000 (< 0.05). It defines that service quality has a positive

and significant effect on customer satisfaction. This is confirmed by previous research conducted by Putri and Astuti (2017: 8) that there is a service quality that has a positive and significant effect on customer satisfaction.

Customer Satisfaction (Y1) has an effect on Repurchase Interest (Y2): Based on partial regression test, obtained t-count is 21.590 (> t-table 1.66) with sig 0.000 (< 0.05). It defines that Customer Satisfaction has a positive and significant effect on Repurchase Interest. This is reinforced by previous research conducted by Putri and Astuti (2017: 8) that customer satisfaction has a significant and positive effect on interest in repurchase.

Conclusions

Based on the data that has been collected and through the testing process with multiple regression analysis and sobel test method, we can know that distribution channels and product quality do not have a significant effect on customer satisfaction while price and service quality have a positive effect on customer satisfaction that influence customer to make repurchase decision[23].

Conflict of Interest: The authors declare that there is no conflict of interest.

Source of Funding: This research is financed by independent financial from the researchers.

Multimodal Hyperspectroscopy for Detection of Cervical Neoplasia

Mamdouh Tawfeek[1], Mohammed Tawfeek[1], Ahmed Sanad[1] , Mahmoud Hussney[1], Suad Attallah[2]

[1]Professor, [2]Assistant Lecturer, OB/GYN Dept., Faculty of Medicine, Minia, Egypt

Abstract

Objective: To provide a prospective evaluation of the sensitivity and specificity of MHS as a new test for detection of high grade cervical dysplasia.

Method: 203 women previously screened with liquid based cytology were evaluated with multimodal hyperspectroscopy (MHS), colposcopy and biopsy samples taken for histopathology.

Results: Sensitivity of MHS cervical scan for high grade intraepithelial neoplasia (CIN) 2+ was 86.6% and Specificity was 57.9%

Conclusions: MHS cervical scan is a noninvasive modality for detection of high grade cervical neoplasia with good efficacy.

Keywords: *CIN, cervical cancer screening, multimodal hyperspectroscopy.*

Introduction

Cervical cancer is the fourth most common female cancer worldwide.[1] Pap smear and colposcopy are widely-used method for the detection of cervical cancer. 80% of all cervical cancer deaths are reported in developing countries, where these tests are not routinely practiced. [2] This emphasizes the importance of effective screening and early detection techniques. However, the existing screening techniques have been shown to suffer from high false results, which could be attributed to the subjective interpretations and may lead to more unnecessary referrals[3].

One of these approaches is light spectroscopy.[4] Spectral imaging appears to be a powerful approach which is starting to become applied to medicine [5] after it has been largely exploited in other areas, such as mineralogy, remote sensing, drugs screening and food qualification [6]. In fact, spectral imaging appears to be successful in distinguishing between tumor and normal tissues [7], and has been used to study skin lesions.[8] and breast cancer [9].

While cytology testing relies on morphological and staining patterns, biospectroscopy records the spectral information from tissues reflecting its biochemical composition at molecular levels, which occur before the changes in morphology are seen under the light microscope[10].

Reflectance spectroscopy allows determination of the scattering and absorption properties of a turbid medium such as tissue. It indicates the presence of structural changes within tissue (cell size,arrangement and organelle density, Neoangiogenesis).[11]

The fluorescence spectroscopy identifies metabolic changes associated with neoplasia. Intrinsic fluorophores can absorb light at different wavelengths and re-emit it, the most common fluorophores include collagen, elastin, tyrosine, nicotinamide Adenine Dinucleotide (NADH) and Flavin Adenine Dinucleotide (FAD).[12] combining optical imaging techniques, referred to as

multimodal imaging, allows for an improved diagnostic reliability due to the complementary nature of retrieved information [5].

Multimodal spectroscopy was implemented in a cost effective new device LuViva® that can be easily operated by trained medical personnel. It is supposed to have The advantage of earlydetection of cervical neoplasia[13].

Aim of the work: To provide a prospective evaluation of the performance of MHS for detection of high grade cervical dysplasia

Methodology: This study included 203 women screened using liquid based cytology. a participant considered eligible for the study if they were 21 years old or above, and willing to undergo MHS cervical scan, colposcopy and biopsy. Patients were excluded if they had any pregnancy, menstruating,prior hysterectomy, congenitally abnormal cervix, orexcessive blood or mucus in the examination filed that cannot be removed.

Each participant had full history and clinical examination had been undertaken.

Cervical spectroscopy was performed using a noninvasive device (LuViva, Guided Therapeutics, Inc. Norcross, GA, USA). The system consisted of : base unit (light source, computer and monitor), handheld unit (optical systems), and the sight tube, (a hollow tube that is inserted into the vagina through a speculum).

The device collects and analyses fluorescence and reflectance spectra from the cervix without contrast agents. Light from the arc lamp is band passed, filtered to limit exposure of the cervix to three distinct color regions at wavelengths of 340 nm, 400nm and 460 nm, which excites fluorophores associated with neoplastic processes.

The resultant spectral output is imaged onto a charge coupled camera and stored for processing and analysis. In addition, the device contained a separate colposcopy quality imaging channel.

While patient in lithotomy position, speculum inserted, mucus or bloodwas removed by suction. the sight tube attached to the device to set the distance between the cervix and device while blocking ambient light. After calibrating the device, the tube was inserted into the vagina. This process was viewed on a monitor screen to ensure proper positioning and focus. Scan was performed in a 1minute procedure.

The output results were color coded : - Green (Low risk): negative, further evaluation is not necessary - Orange (Moderate risk): other medical factors should be considered before further evaluation - Red (High risk): positive,further evaluation is necessary.

Then, a conventional colposcopy with 5% acetic acid was performed. endocervical curettage was performed for subjects that had LSIL or HSIL cytology. Then , biopsy from the ectocervix from abnormal areas or from the quadrants if no obvious abnormality was observed. Biopsy specimens were sent to histopathology.

Results

Study included 203 cases with mean age of 42.80 ±8.5 years and parity of 3.2±1.5. participants were subjected to MHS cervical scan based on different indications, 88 case (43.3%) were referred following result of abnormal cytology, 22 cases (10.84%) had history of contact bleeding, 26 cases (12.8%) were referred due tosuspicious cervix, 3cases were presented for follow up after LEEP biopsy for CIN 1, another 2 with mastectomy, one case known as HIV patient. And 61 cases (30%) were referred for routine screening.11 cases had history of HPV infection, none of the included cases had history of HPV vaccination.

Cytology was normal in 46.7%, ASCUS was the most prevalent abnormality found in 22.6% , followed by ASCUH (8.9%) then LISL and HSIL (10.8% and 6.4%). and one case with AGC.

Colposcopy was negative in 60.1% of cases, 24 cases (11.82%) showed signs of chronic infection while CIN was detected in 32 cases (15.76%). Unsatisfactory colposcopy in 4 cases (1.97%), Acetowhite areas and abnormal vascularity were seen in 15 and 6 cases respectively.

For MHS: 108cases were low risk (53.2%), 27 cases were with moderate risk (13.3%), and 65 cases were with high risk for cervical neoplasia (32%).

Test failed in 3 cases (1.48%) due to failed visualization of the cervix. 2 of them due to excessive blood, the device reported “poor contact”, the 3rd case failed due to abnormal light reflection from the threads of IUCD, the device reported “excessive light” . although, the test was performed in many cases with IUCD with no errors.

Normal histopathology was reported in 45.81% of cases, benign conditions included: inflammatory changes (17.73%), polyps (3.45%), and metaplastic changes (11.33%). CIN 1 in 29 case (14.29%), and CIN2+in 15 cases (7.39%).

MHS was "high" in 46% of cases with abnormal cytology, while it was 'low' in 67.9% of cases with normal cytology.

Table 1: MHS correlated to cytology

MHS	Cytology						Total
	Negative	ASC-US	ASC-H	LSIL	HISIL	AGC	
Low	70	17	5	11	4	1	108
Moderate	12	8	2	2	3	0	27
High	19	21	10	9	6	0	65
Failed	2	0	1	0	0	0	3
Total	103	46	18	22	13	1	203

MHS reported high risk in 72.72% of abnormal colposcopic findings, it showed low risk in 70.83% of cases with normal colposcopy.

Table 2: MHS correlated to colposcopy

MHS	Colposcopy			Total
	Normal	Abnormal	Unsatisfactory	
Low	102	6	0	108
Moderate	17	8	2	27
High	23	40	2	65
Failed	2	1	0	3
Total	**144**	**55**	**4**	**203**

MHS was found 'high' in 30 cases out of 44 cases of dysplasia (75%). Adding the moderate risk MHS as a positive screening result, so 39 case were considered as positive out of 44 (88.6%).

In cases with severe dysplasia (CIN2+) MHS was positive in 13 case out of 15 (86.6)

Table 3: MHS correlated to histopathology

MHS	Histopathology				Total
	Benign	AGC	CIN1	CIN2+	
Low	104	1	2	1	108
Moderate	18	0	6	3	27
High	35	0	20	10	65
Failed	2	0	0	1	3
Total	**159**	**1**	**28**	**15**	**203**

Sensitivity of MHS for detection of 'any' dysplasia was 88.63%, and it had a specificity of 67.94%, with PP and NP values of 42.39% and 95.49% respectively

For high grade lesions (CIN 2+) MHS had a 86.66% Sensitivity, 57.97% specificity, 14.13% PPV and 98.19% NPV. Excluding the failed cases increased the sensitivity to 92.85%, with 58.6% specificity, 14.44% PPV, and 99% NPV

Combining cytology and MHS results, The sensitivity raised to 100% for high grade lesions.

One case was examined post LEEP biopsy, reported as high risk with MHS despite being negative histopathology.

Using the kappa test, cervical spectroscopy showed56.3% agreement with liquid-based cytology, and 74.5%with colposcopy, with high significance (p=0.001).

Discussion

This study included 203 women presented to the outpatient clinic either for primary (routine) screening or secondary screening or to be followed after treatment of cervical neoplasia.

We included this category of patients to our study for research reasons, as colposcopy and biopsy are parts of our evaluation.

In this study, The Sensitivity of MHS for detection of any degree of dysplasia was 88.63%, and its specificity was 67.94%. While, For high grade lesions MHS cervical scan had a little lower Sensitivity (86.66%), but much lower specificity (57.97%).

Several previous studies examined the performance of cervical spectroscopy using histopathology as a gold standard endpoint

The early pre-clinical trials, the largest was carried on 572 patients, The sensitivity was 95.1% for CIN2+ with a corresponding 55.2% specificity for benign lesions.[14]

A study of 113 women, compared results of cervical spectroscopy and HPV testing,concluded that Spectroscopic scanning of the cervix is equally sensitive (95%), and 2-fold more specific than HPV testing (66% , 27% respectively).Thus the use of cervical spectroscopy may reduce the number of false positive HPV test results.[15]

The largest phase 3 study was carried on 1850 women either presented for regular screening or referred for colposcopy, the sensitivity of MHS was 100% for detection of high grade lesions, 71% specificity. The device performance was best in the diagnostic rather than screening population[16]

A multi-centre study of 1,607 women with positive cervical screening test; compared the results of HPV testing, colposcopy and biopsy, with MHS. The Sensitivity of MHS for CIN2+ was 91.3%, the potential reduction in referrals to colposcopy and biopsy was 38.9% for women with benign histology and 30.3% for women with CIN1[17]. In a complimentary study by the same authors, 802 women were followed up for two years. MHS identified 89.6% of CIN2 + prior to their discovery during the follow-up period. They concluded that MHS as a triage would have reduced the need for further testing.

In our results MHS showed better performance in low grade lesions than with high grade lesions, This is in contrast to the results reported by ***Twiggs et al*** who found higher performance of MHS in higher grade lesions[17]. But in our study there was one case of CIN 2 which was missed due to test failure, which considered as false negative and it affected the test performance.

Combining cytology and MHS results for detection of high grade cervical lesions, The sensitivity raised to 100%. this is in agreement with results from the study by ***Werner et al.***[15]however, ***Twiggs et al.*** combined both test results and found no increase in the sensitivity but the specificity increased by 30% in detection of neoplasia[17].

Also, ***Louwers et al.*** studied the colposcopic dynamic spectral imaging in 275 women, they reported sensitivity of 79% in detection of high grade lesions, and 77% specificity, while sensitivity of conventional colposcopy was only 55%, combining both test results gave higher sensitivity 88% but lower specificity 69% [18]

post launch trials reported variable results.in a pilot study by ***Adewole et al.***[19] the sensitivity of MHS was 92.3%.MHS reduced the percentage of unnecessary colposcopy and biopsy by 37.5%.

Another report indicated that LuViva performed with a specificity of87% in a screening population and

it had potential as primary screening tool, especially inareas with no infrastructure for cervicalcancer screening[20]. however , ***Cantor et al.*** reported that the device performed best in diagnostic population.[21]

In the current work, findings of MHS showed better agreement with those of colposcopy (74.5%) than with liquid-based cytology (56.3%).

In a recent study with similar methodology, good correlation between spectroscopy and both cytology and colposcopy was noticed (79.3% , 47.9% respectively)[13].

In our study, 3 cases were examined for follow up after LEEP cervical biopsy, one of them had false positive result by MHS. It was noticed that this case were scanned no more than 6 month after the procedure. This may be attributed to the distorted anatomy in the early post-operative period.

In the current work one case with AGC by cytology underwent fractional endometrial curettage and cervical cone biopsy, histopathology reported CGIN. while it was reported as low risk by MHS. It buts a question on the ability of the device to detect endocervical lesions. However, other reports recorded high sensitivity for intracervical lesions up to 100%. As that by ***Wade et al.*** theyreported that the emerging light can penetrate and detect the deep epithelial, supepithelial or endocervical lesions in contrast to cytology which only smears the superficial layers of cells. [22]

Conclusions

MHS cervical scan had good efficacy in detection of high grade cervical neoplasia. It may be used as a triage for women who has low grade cervical cytology. And it can be used as screening tool for routine screening.

Abstract

Objective: To test and compare the sensitivity and accuracy of diffusion weighted imaging (DWI) and MR perfusion in women having ovarian tumors.

Patients and Method: Fifty women with ovarian masses were collected after meeting the inclusion criteria depending on gray scale sonographic findings which suggested the presence of ovarian masses. Conventional MRI, Diffusion weighted imaging (DWI) and MR perfusion (MRP) were done for all patient cohort after the approval of ethical committee of our institution. The sensitivity and accuracy of the techniques were compared.

Results: The surgical and pathological reports of our patients proved non tumorous lesion in three patients. They proved benign ovarian tumors in 18/47 (38.3%) patients, borderline tumors in 4/47 (8.5%) patients and malignant ovarian tumors in 25/47 (53.2%) patients. According to conventional MRI ovarian tumors could be diagnosed with sensitivity 92%, specificity 61.11%, PPV 76.7%, NPV 84.6% and accuracy 79.1%. DWI and MR perfusion showed the same results where they showed sensitivity 98%, specificity 83%, PPV 90%, NPV 98% and accuracy 93% with ADC cut off value $1x10^{-3}$ mm^2/sec.

Conclusion: Diffusion weighted imaging and MR perfusion are useful in diagnosis of ovarian tumors with approximately the same sensitivity and positive impact on the operative management.

Keywords: *MRI ovarian cancer, MR diffusion, MR perfusion, ovarian tumors characterization.*

Introduction

Ovarian tumors are the fifth commonest tumor in women and the leading indication for gynecologic surgery. The therapeutic strategy depends on whether the tumor is benign, borderline or malignant.[1, 2, 3]

Late diagnosis of ovarian cancer is due to lack of specific symptoms. [4, 5]

MRI diffusion weighted imaging (DWI) and MRI perfusion (MRP) increased the technical capabilities for preoperative characterization of ovarian masses.[6.7]

The fast "wash-in" of contrast coupled with the rapid "wash-out" through tumors more than normal tissue allows a functional analysis of the tumor microcirculation. [3, 8]

Multi-parametric calculations of permeability and perfusion are used to characterize the tumor vasculature within a tumor "microenvironment". The malignant

lesions enhance in contrast quickly and have more intense signals, compared to benign lesions.[9, 10, 11]

DWI is a non-invasive imaging modality depends on the Brownian motion of water molecules in tissues. Diffusion-weighted imaging provides qualitative and quantitative information about tissue cellularity. [12]

Aim of the Work: The aim of this study is to evaluate the benefit of application of diffusion weighted imaging (DWI) and MR perfusion (MRP) in characterization of ovarian tumors.

Patients and Method

Study design and population: This study was a prospective study. The study population comprised 50 consecutive women who were suspected to have ovarian neoplastic mass. Patients were collected between January 2018 and December 2018. They underwent MRI imaging after meeting the inclusion criteria. All patients signed a written informed consent before MRI examination.

Inclusion and exclusion criteria: All patients included in this study had previous trans-abdominal or trans-vaginal real time ultrasonography with diagnosis of complex ovarian lesions, cystic lesion with solid vegetation or thick septa or soft tissue component (figure 2), solid ovarian lesions (figure 3) or suspicious adnexal lesions.Patients with simple cystic ovarian lesions, ovarian lesions with pure fatty component, impaired renal functions or general contraindications to MRI as the presence of any paramagnetic substances such as pacemakers, metallic clips or claustrophobic patients were excluded from the study.

Method

MRI technique: MR imaging was performed using 1.5 Tesla MR Scanner (Ingenia, Philips Healthcare, Netherlands). All patients were imaged in the supine position using pelvic phased array coil. The MRI examination was conducted on the female pelvis including conventional MRI sequences; Axial, sagittal and coronal T2WIs using the following parameters (TR 5000/TE 110 ms, echo train length 13–15, slice thickness 5–7 mm, gap 1–2 mm, Field of view 24–38 cm, excitations (NSA) 3 and matrix 304 • 512). Followed by axial T1WI spin echo MR images (TR 162, TE 10–14 ms, slice thickness 5–7 mm, gap 1–2 mm, field of view 24–38 cm, flip angle of 90_, excitations (NSA) 1–2 and matrix 256 • 256).

Diffusion weighted imaging was acquired in the axial plane prior to administration of contrast medium by using a single shot echo-planar imaging sequence with b values (0, 800, 1000) (TR/TE 2871/78, Slice thickness 5 mm, Gap 1 mm), FOV 375 x 312 x 161 mm and matrix 124x105).

MRI perfusion was done for all patients using Gadolinium chelate (Dimegluminegadopentate) that was given at a dose of 0.2 ml per kilogram of body weight by using a power injector (Medrad, spectrissolaris R) at a rate of 2ml/sec, followed by 20 ml of normal saline to flush the tubing. Images were obtained sequentially every 14 seconds beginning 14 seconds (first phase) before the bolus injection. 40 sequential slices were taken with slice thickness 2 mm. Rapid acquisition (every 14 seconds) was performed for 30 consecutive phases with the whole time of the sequence 7 minutes. The images stack should include part of the soft tissue inside the ovarian lesionand the adjacent external myometrium in optimal plane.

Data processing and image interpretation: The images were transformed to Philips 881030 Intelli-Space IX/LX Workstation.Each MR sequence findings were evaluated as following:

(A) Analysis of conventional sequences: Conventional MRI sequences were evaluated for the morphologic features of the lesion including the lesion laterality, size, shape, and complexity of the tumor, T2 signal intensity of the solid part inside the mass and the presence of ascites and peritoneal deposits.

(B) Analysis of MRI perfusion: For ovarian tumor characterization, two regions of interest (ROI) were placed. One on external myometrium and one on the most enhancing part of solid tissue of the ovarian mass. The most enhanced solid part was determined by the use of maximum enhancement colored generated map by the workstation. The enhancement of the solid tissue was classified by using a time-signal intensity curve classification (figure 1):

1. A gradual increase in the signal intensity of the solid tissue, without a well-defined shoulder was defined as type 1 curve.
2. A moderate initial increase in the signal intensity of the solid tissue relative to that of myometrium followed by a plateau was defined as type 2 curve.

3. An initial increase in the signal intensity of the solid tissue that was steeper than that of the myometrium was defined as type 3 curve.

Enhancement measures:

Maximum enhancement (SI max): Difference between peak intensity S1 and S0.

Maximum relative enhancement: (MRE) Maximum of all relative enhancements

Wash in rate (WIR): Maximum slope between T0 and the time of peak intensity.

Wash out rate (WOR): Maximum slope between the time of peak intensity T1 and the end of measurement.

Histopathological evaluation: All of the patients underwent surgical management. Twenty seven patients underwent radical hysterectomy with bilateral salpingo-oophorectomy, 5 cases underwent simple oophorectomy, 10 cases underwent ovarian cystectomy and 8 cases underwent simple oophorectomy. All results were correlated to final post- operative histopathological data.

Statistical analysis: Statistical analysis was performed using the SPSS software for Windows v. 20 (SPSS Inc., Chicago, IL). For comparing quantitative data, Kruskal Wallis test and Mann Whitney tests were performed. For comparing qualitative data, Fisher exact test was performed. Accuracy of the studied diagnostic test in predicting malignancy was represented using the terms sensitivity, specificity, overall accuracy, negative and positive predictive values. A probability value (p=0.05) was considered statistically significant. Receiver operating curve ROC curve was used to determine the cutoff values of the semi- quantitative parameters.

Results

Our study included 50 female patients, three of them found to have non-ovarian tumors on histo-pathological evaluation, two of them were tubo-ovarian abscesses and one was cyst with hemorrhagic infarction. Those three cases were excluded from the study to avoid bias.

Diffusion weighted magnetic resonance imaging was done for all patients before contrast injection. Among our patients 37/47 cases (78.7%) showed diffusion restriction and 10/47 cases (21.3%) showed facilitated diffusion. The cut off value of ADC value below which malignancy is expected is less than $1x10^{-3}$ mm^2/sec. There was statistical significance between ADC value and pathological diagnosis (P value *<0.001)*.

Regarding MRP,SImax, MRE% , WIR and WOR were evaluated and correlated to the final histopathological results. There was statistical significance between SI max, WIR & WOR and pathological diagnosis with higher sensitivity specificity and accuracy in relation to WOR.There was no statistical significant difference between MRE% and pathological diagnosis. (Table I).

Regarding the time signal intensity curves of MRP; we found that Curves type 2 and 3 carry malignant probability with accuracy 95%, sensitivity 88% and specificity 92%. NPV 100%

ROC curve analysis was used for prediction of malignancy depending on conventional based diagnosis, DWI diagnosis, MRP and combined conventional MRI with DWI and with MRP.

There was statistical significant difference between the three method of diagnosis and the pathological diagnosis. However; the AUC, sensitivity, specificity and accuracy were higher on DWI and MRP- based diagnosis than those on conventional based diagnosis. Statistical correlation between results of conventional MRI, DWI and MRP to evaluate, the sensitivity, specificity, PPV, NPP and accuracy. (Table II)

Final pathological diagnosis after surgery revealed that 24/47 cases showed epithelial tumors (6 benign cases, 4 borderline cases and 14 malignant cases), 8/47 cases showed sex cord stromal tumors (5 benign cases and 3 malignant cases) and 15/47 cases showed germ cell tumors (7 benign cases and 8 malignant cases).

Table I: ROC curve analysis for prediction of malignancy according to MR perfusion measurements in correlation with histopathological diagnosis:

	SI max	WIR	WOR
Sensitivity	100	92	100
Specificity	94.44	94.44	100
PPV	96.2	95.8	100
NPV	100	89.5	100
Accuracy	97.67	93.02	100

Table II: ROC curve analysis for prediction of malignancy among various MRI techniques in correlation to the final histopathological diagnosis

	Conventional MRI	DWI	MRP	Combined conventional+ DWI OR Conventional+ MRI perfusion
Sensitivity	92%	98%	98%	97%
Specificity	61.11%	83%	83%	92%
PPV	76.7%	90%	90%	90%
NPV	84.6%	98%	98%	98%
Accuracy	79.1%	93%	93%	93%

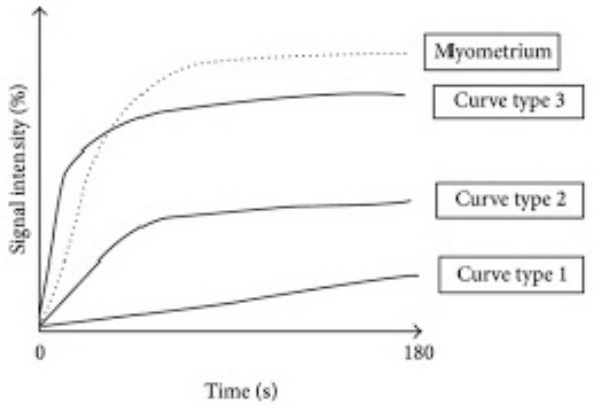

Figure 1:Time intensity curves

Figure 2: Axial T1WI shows cystic lesion with enhanced septae and enhanced posterior mural nodule. Diagnosis is strumaovarii.

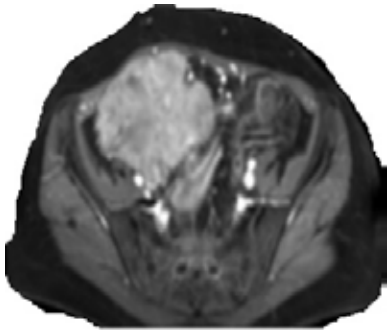

Figure 3: Axial T1WI fat sat. shows moderate enhancement of the right sided ovarian lesion. Diagnosis is ovarian clear cell carcinoma.

Discussion

Adnexal masses are challenging diagnostic problem because of the overlapping imaging features between benign and malignant tumors. [13, 14]

In our study, DWI based diagnosis showed 100% sensitivity while specificity remains low 88%. Such low specificity elicited in our study can be explained by the presence of eight benign masses that mimicked malignancy. These masses included mature cystic teratomas, strumaovarii and benign sclerosing tumor. They all showed restricted diffusion and mean ADC values 0.8 x 10^{-3} mm^2/s, $1x10^{-3}$ mm^2/s and $0.9x10^{-3}$ mm^2/s respectively presenting false positive cases due to mixed cellularity of the lesions. The mean ADC values for benign lesions were $1.7\pm0.6 \times 10^{-3}$ mm^2/s and for borderline and malignant lesions were $0.9\pm0.2x10^{-3}$ mm^2/s and 0.8±0.1 respectively. Cutoff value for ADC in malignancy is $\leq 1x10^{-3}$ mm^2/sec. This agreed with Thomassin-Naggara et al., where they attributed the presence of low mean ADC values elicited by benign fibrous tumors as fibromas, Brenner tumors, and cystadeno-fibromas are due to dense network of collagen fibers within the extracellular matrix. [15]

In a study done by Zhang P et al., they show higher sensitivity and specificity of DWI than our study because they excluded endometriomas, mature cystic teratomas and pure cystic adenomas from their study. [16]

In our study, Curve type I was found to be specific for benign ovarian tumors with 100% specificity. Curves type II and III were more in favor of borderline/ malignant tumors. From all cases with curve type III, only one case was benign which was pathologically diagnosed as benign sclerosing tumor of the ovary. The explanation for such result is the high vascularity of sclerosing stromal tumors.

In our study, the perfusion parameters that showed highest accuracy were WOR (100%) followed by SImax (97%) then WIR (93%).The cut off value for WOR in our study was >6 (lesions with WOR more than 6 is likely to be malignant). The PPV and NPV were 100%.

In our study, the cut off value of SI max was >1285 (tumors with SImax more than that number is considered malignant). The sensitivity was 100% and specificity was 94%. Those measurements do not agree with Dilks et al. that suggested a threshold value of >250 for prediction of malignancy with a sensitivity and specificity 100%. This difference can be explained by the unequal distribution of cases in our study. WIR showed less sensitivity, specificity, NPV, PPV and accuracy (92%, 94%, 89.5%, 95.8% and 93% respectively) than WOR and SImax. Bernardin et al. applied a cut off value > 9.5 for WIR where lesions with WIR mare than 9. 5 are considered malignant. In our study, the cut off value was higher than that value (>17.9) and this also can be explained by the unequal distribution of cases with increased number of cases with hypervascular nature.[13, 17]

Our study had several limitations. The unequal distribution of pathology included in the study. Some relatively common pathological entities were not included in the study as ovarian metastasis. Also there is small number of cases of ovarian epithelial borderline tumors included in the study. Also, the method of the ROI drawing that may be subject to human error, which may affect the performance.

Conclusion

The application of MR diffusion and MR perfusion are proved accurate in characterization of malignant and benign ovarian tumors. Improvements in evaluation of SI max and WI and WO lead to more accurate evaluation of ovarian tumors with high sensitivity and specificity and reduce false positive results.

Ethical Clearance: Taken from ethical committee in El-Minia university hospital.

Abstract

Introduction: Duchennemuscular dystrophy (DMD) is an uncommon X-linked disease affecting in average 1 in 3600 live male births. Cardiac disease is the major cause of mortality in affected patients. Several Echocardiographic parameters are available for evaluation of systolic and diastolic function among Duchenne patients. The aim of this paper is to determine which of those parameters has the highest accuracy in detection subtle myocardial affection in asymptomatic Duchenne patients. Method:28 asymptomatic Duchenne patients as well as 28 age and sex matched healthy controls have been screened with Echocardiography including Motion mode, conventional and Tissue Doppler, 2 Dimensional (2D) and 3 Dimensional (3D) speckle tracking Echocardiography. Results: Conventional Echocardiographic parameters failed to differentiate cases from controls while Tissue Doppler derived parameter such as the ratio between Transmitral flow velocity in early diastole and Left Ventricular averaged basal septal and lateral tissue velocity (LV E/E') as well as global longitudinal (GLS) and Global Circumferential strain (GCS) (2D and 3D) proved to be useful in differentiation between them. 3D derived ejection fraction also showed statistically significant difference between cases and controls (54.2±4.5 vs. 70.2±6.1, P Value<0.001) respectively, 3D derived parameters showed the highest sensitivities and specificities among relevant parameters (100%) for detection of subtle myocardial affection in Duchenne patients. Conclusion: This paper concludes that 3 D derived EF, GCS and GLS can be reliably used in detection of subtle myocardial affection in Duchenne patients.

Introduction

Duchenne muscular dystrophy (DMD) is an X-linked disease that affects 1 in 3600–6000 live male births.(1) The majority of DMD patients after their third decade of age have established cardiomyopathy. Although clinically overt heart failure may be delayed or absent (due to relative physical inactivity),cardiac disease is a major cause of death in patients with muscular dystrophies.(2) In young patients (aged <12 years) with DMD, cardiac systolic function is generally at normal range. Recent studies have suggested the presence of subclinical dysfunction in those young patients. Detecting latent myocardial involvement is essential in this disease because early use of drugs like angiotensin - converting enzyme inhibitors may delay the progression of heart disease.(3)

Several echocardiographic tools have been used for early detection of subtle myocardial dysfunction in patients with DMD. Traditionally, assessment of global

cardiac function has been evaluated via transthoracic echocardiography (TTE). However, the use of LVEF (Left ventricular Ejection Fraction) as a standalone method to predict myocardial affection in patients with DMD cannot be relied upon since affection of LVEF by M-Mode (Motion Mode) Echocardiography and cannot predict the earliest forms of affection.(4) Hence the need for newer techniques that can unleash myocardial affection the earliest the possible to initiate anti-failure treatment and other forms of therapy that can slow down the progression of myocardial affection.

Promising results of earlier detection have been offered by Tissue Doppler imaging and 2D (2 dimensional) strain. In early stages, subclinical diastolic function has been reported in DMD pediatric population, preceding the LV systolic dysfunction. However, thorax deformities and difficulties to have optimal images in wheelchair- bound patients technically limit Doppler echocardiography.(5) The use of 2D strain derived Global longitudinal and circumferential strain (GLS and GCS respectively) has also proved useful in early detection of systolic dysfunction before affection of conventional echocardiographic parameters. (6)To our knowledge no study has explored the role of 3D (3 dimensional) derived strain role in detection of early myocardial affection in patients with DMD.

The aim of the current study is to compare the statistical power of different echocardiographic markers derived from M-Mode Echocardiography, Tissue Doppler, 2D and 3D strain in early detection of myocardial affection in DMD patients.

Method

Study Population: This study was designed as a case-control, cross-sectional study on pediatric asymptomatic patients with DMD and was performed between February 2016 and October 2017. The patients were recruited from neurometabolic Clinic of Cairo University Children Hospital, Egypt(a tertiary care center)

Study Method:

Echocardiographic assessment: Transthoracic echocardiography was performed using General Electric (Vivid-7/9, Horten, Norway) machine with a 3 and 5MHZ (megahertz) transducers according to the age of the patient and having tissue velocity imaging capabilities. ***Conventional echocardiography*** included M-mode, 2D and Doppler echocardiographic parameters were averaged over 3 cardiac cycles and all measurements were performed according to the guidelines for performance of echocardiogram by American Society of Echocardiography.(7)Left ventricular fraction shortening (FS%) and ejection fraction (EF%) were calculated by M-mode echocardiography according to Teicholtz method.(8)Pulsed Doppler method was used for blood flow measurements from mitral valve: flow velocity during early filling (E), flow velocity during atrial contraction (A) and then E/A was calculated. The global myocardial performance index (MPI or Tei index) was calculated by conventional pulsed wave Doppler as the following: Tei index=$a-b/b$ where *a is* the sum of IVCT (isovolumic contraction time) and IVRT (isovolumic relaxation time) and *b* is ET (ejection time). ***Pulsed tissue*** velocity imaging measures systolic myocardial velocities at the basal segments of the lateral LV wall for calculation of the E/E′ ratio (the ratio between Transmitral flow velocity in early diastole and Left Ventricular averaged basal septal and lateral tissue velocity).

2D speckle Tracking was performed as follows: based on echocardiographic speckle tracking algorithm, apical four-chamber, two-chamber and threechamber views were analyzed in each subject. In each cardiac apical view, three points at the endocardial border were placed including two annular points at the base and one point at the apex. After that, the system calculates global longitudinal strain (GLS). To assess GCS, the endocardial border was traced automatically in end diastole in each short-axis view, with entire myocardium inside the region of interest for optimal tracking. Mid- and basal-short-axis views were divided in 6 segments while apical short-axis view was divided to 4 segments. After approving of border tracing, the system calculates global circumferential strain.

3D Echocardiography: full-volume acquisition of the LV was obtained by harmonic imaging from the apical approach. Six ECG-gated consecutive beats were acquired during end-expiratory breath-hold to LV full volume. All data sets were analyzed off-line using a commercially available software (4D Auto LVQ, GE-Vingmed, Horten, Norway). Papillary muscles were included within the LV chamber. After the adjustments software provided the LV volumes, EF. Subsequently, an automatic trace of the epicardial border was displayed to set the region of interest required for LV mass and 3D myocardial deformation parameters. The 3D GLS and

GCS from the 17 myocardial segments at end-systole was calculated.

Statistical Analysis: Data were statistically described in terms of mean ± standard deviation (± SD), median and range, or frequencies (number of cases) and percentages when appropriate. Comparison of numerical variables between the study groups was done using Student *t* test for independent samples in comparing 2 groups when normally distributed and Mann Whitney *U* test for independent samples when not normally distributed. Comparison of numerical variables between more than two groups was done using one-way analysis of variance (ANOVA) test with posthoc multiple 2-group comparisons. For comparing categorical data, Chi square ($\chi 2$) test was performed. Exact test was used instead when the expected frequency is less than 5. Correlation between various variables was done using Pearson moment correlation equation. P values less than 0.05 was considered statistically significant. The Receiver Operating Characteristic (ROC) curve analysis was performed to determine the best Echocardiographic predictor of subtle myocardial affection in Duchenne Muscular Dystrophy. All statistical calculations were done using computer programs SPSS (Statistical Package for the Social Science; SPSS Inc., Chicago, IL, USA) version 15 for Microsoft Windows.

Results

This current study included 28 asymptomatic patients with DMD as well as 28 age and sex matched healthy controls. Their age ranged from 9 to 16 years and they were allmales among DMD patients. They were all free of cardiac symptoms.

Demographic and conventional echocardiographic data of the studied population: No significant difference between the DMD patients and the controls as regards the demographic data [table 1].

By comparison of the conventional echocardiographic measurements and Doppler and tissue Doppler derived parameters, there was no significant statistical difference between the controls and DMD group in all parameters apart from LV E/E' ratio which was significantly higher in cases than controls [table 2].

2D and 3D derived speckle tracking (strain data) showed significant different between cases and controls as shown in table 3 as well as 3D derived EF which was significantly lower in DMD patients. [table 3]

Table 4 represents a **ROC curve analysis of the echocardiographic parameters** that proved statistically significant between cases and controls, it shows that the 3 D derived parameters have recorded the highest sensitivities and specificities in distinctions between DMD patients and controls (100%).

Discussion

Cardiac disease is a major cause of death in patients with muscular dystrophies accounting for a total of 40% of all DMD deaths. In view of this high percentage developing tool for early detection of myocardial affection in DMD patients is crucial as myocardial damage after the symptom onset with overt LV dysfunction may be irreversible and progressive, ending in death.

In our study, the examined DMD patients, who were free of cardiac symptoms, had normal EF and FS as compared to normal controls. Similary, Mertens et al., described normal systolic function (EF and FS) in young patients (aged <12 years) with DMD. [9]

Diastole is an active myocardial process that is influenced by alterations in cytosolic calcium concentration and flux. The lack of dystrophin in patients with DMD disrupts the sarcolemma membrane integrity resulting in altered intracellular calcium haemostasis and impaired ventricular relaxation. Diastolic dysfunction is often present in the absence of significant symptoms of identifiable systolic abnormalities.[10]

Left ventricular E/E' ratio is the ratio between Transmitral flow velocity in early diastole and Left Ventricular averaged basal septal and lateral tissue velocity. In diastolic dysfunction tissue velocity is reduced before flow velocity is affected, this makes the ratio higher in patients with diastolic dysfunction.[11]

In our study,the E/E' ratio was significantly increased in cases compared to controls denoting subtle diastolic dysfunction in DMD patients. This is in concordance with Markham et al., who found abnormal diastolic indices in DMD patients with normal systolic function compared with controls.[5]

Similar studies concluded that echocardiographic evidence of diastolic dysfunction precedes the development of dilated cardiomyopathy and applies to other dystrophinopathies and female carriers.[12]

Compared to normal controls, our patients had a statistically significant reduction of LV (GLS) with p-value <0.001 and LV (GCS) with p-value <0.001 by 2D STE. This is in concordance with a recent study done by Spurney et al., in 2015 where Speckle-tracking echocardiography demonstrated subclinical myocardial dysfunction with decreased average circumferential and longitudinal strain in DMD patients with normal EF. (13)

Hor et al. evaluated the natural history of occult cardiac dysfunction in DMD and found that DMD patients with normal EF had reduced LV GCS at an early age (<10 years) compared with control subjects. The DMD patients age >10 years with normal EF had further decline in left ventricular myocardial peak circumferential strain compared with younger DMD patients. They concluded that myocardial strain abnormalities are prevalent in young DMD patients despite normal EF, and these strain values continue to decline with advancing age. (4)

According to Kalam et al., the advantage of GLS is its superior ability to predict major adverse cardiac events, including hospital readmission and mortality, particularly when the ejection fraction is normal or near normal. (14)

To our knowledge this study is the first to involve the use of 3D derived strain in assessment of systolic functions of DMD patients. 3D derived GLS and GCS were significantly lower in DMD patients than in controls. Also 3D derived EF was significantly lower in cases compared to controls which may render 3D echocardiography a promising tool in substituting CMR in patients with DMD for accurate assessment of EF in DMD patients as it provides real volumetric assessment of left ventricle compared to the Teicholtz derived assessment in M-Motion Echocardiography. (15)

To our knowledge, there were not relevant studies that discussed the sensitivity and specificity of different echocardiographic parameters in detecting subtle myocardial affection in DMD patients.

Through analysis of the (ROC) curve, the parameters with the highest sensitivity and specificity to detect preclinical cardiomyopathy in asymptomatic Duchenne patients, in our study, were in order: 3D derived EF, GLS, GCS (sensitivity and specificity of 100%) followed by 2D derived GLC and GCS with sensitivity 96.4% and specificity 100%.

This may prompt the use of 3D echocardiography as a promising bedside method for patients with DMD

Conclusion

Young patients with DMD may suffer from asymptomatic cardiomyopathy that may not manifest until very late, when treatment would be less effective in combating the remodelling that occurred in cardiac muscle. In this aspect conventional Echocardiography is delayed in diagnosis and cannot be relied upon for early detection. The combination of conventional pulsed Doppler and tissue Doppler showed early diastolic affection in asymptomatic DMD patients. 2D derived GCS and GLS have showed great accuracy in detection of early systolic dysfunction. However, 3D derived parameters revealed superior to all the above mentioned parameters in early detection of subtle myocardial affection, offering a good substitute to CMR in DMD patients.

Conflict of Interest: No

Financial Support: No

Ethical Clearance: The aim and nature of the study was explained for each parent before inclusion. An informed consent was obtained from parents/surrogates before enrolment. The study design was confirmed to the requirements of Revised Helsinki Declara on of Bioethics (2008). The study protocol was presented to and approved by the scientific ethical committee of Paediatric Department, faculty of medicine, Cairo University.

The Association of Glutathion Peroxydase-1 Serum and Sensorineural Hearing Lossin MDR TB Patients with Kanamycin Therapy

Ratna Anggraeni[1], Arif Dermawan[1], Febri Wisudawan F.[1]

[1]*Department of Otorhinolaryngology-Head and Neck, Faculty of Medicine, Universitas Padjajaran*

Abstract

Introduction: Kanamycin therapy in Multi-Drug Resistance Tuberculosis (MDR-TB) patients increases the possibility of sensorineural hearing loss through increasing the level of Reactive Oxygen Species (ROS) production in cochlea, particularly in hair cells. In normal state, ROS is detoxicated by numerous antioxidant enzymes, including glutathione peroksidase-1 (GPx-1). Imbalance of antioxidant enzymes and ROS production leads to death of hair cells and eventually sensorineural hearing loss. **Objective:** This study aimed to observe the association of GPx-1 level and sensorineural hearing loss in MDR-TB patients with Kanamycin therapy.

Method: This study was a prospective observational study conducted at Dr. Hasan Sadikin General Hospital, Bandung, Indonesia, between February to April 2017. 17 patients were included into the study with pre- and post-kanamycin therapy examination within 3 weeks duration using pure tone audiometry and serum level of GPx-1. Statistic analysis was done using Mann Whitney test with significant level of $p < 0.05$.

Result: A significant reduction of GPx-1 level in 3 weeks period after the initial Kanamycin administration was found in the study; $p < 0.001$. Furthermore, there was a significant alteration in the hearing threshold on frequency of 500-800 Hz after Kanamycin administration; $p < 0.05$. There was a significant association between GPx-1 level and sensorineural hearing loss in Kanamycin therapy; $p < 0.05$.

Conclusion: Sensorineural hearing loss in patient with history of Kanamycin therapy was associated with level of GPx-1 degradation.

Keywords: *GPx-1, Kanamycin, MDR TB, Sensorineural hearing loss.*

Introduction

Tuberculosis (TB) remains a concern among global health problem with a high mortality and morbidity rate.[1] WHO also stated that Indonesia had approximately 6,800 new Multi Drug Resistance TB (MDR TB) annually with approximately 2% of new cases and 12% of re-treatment TB were MDR TB.[2,3,4] Among all injection drugs for MDR TB, Kanamycin is widely used as stated in WHO's recent MDR TB guideline due to its wide distribution area and affordable price.[5,6,7,8]

In general, three types of antioxidant present in human body.[14] Among all GPx, Glutathione peroxide-1 (GPx-1) is the main glutathione peroxide enzyme family; mainly found in erythrocyte, liver, lungs, kidney, and almost in all cells' organ (cytosol, mitochondria, and peroxisome).[15,16] Furthermore, in cochlea, GPx-1 has a higher enzymatic activity in organ of corti, spiral ganglion, stria vascularis, spiral ligament, and another supporting cell.[17,18,19] Higher activity of SOD and CAT are also found in stria vascularis and organ of corti. GSH and GPx are the main antioxidants in those areas.[14]

Study conducted by Alli, et al. in 2014 on 83 MDR TB patients showed that there was a significant degradation of antioxidant enzyme activity, including glutathione transferase and glutathione peroxide.[20] It was strengthened by Madebo et al who also showed a significant decrease in glutathione peroxide level in TB MDR patients.[20,22]

Rakhmawati in her study found sensorineural hearing loss, particularly in high frequencies, 4000-8000 Hz, in MDR TB patient treated using Kanamycin within the 19th to 22nd day of therapy, affecting high frequency hearing ability to lower frequency.[5] Study conducted by Jiang et al in 2006 found that there was a shift in auditory brain stem response (ABR) by 45-50 dB in the 14th day that was remained for 5 weeks also showed that the death of hair cells happened in the 11th day and 30% of the superficial hair cells died after 14 days.[24] It is proposed that hearing loss due to Kanamycin's toxicity mostly started on higher frequency tone as it is located on the basal of cochlea; this progressivity happens due to difference of survival ability among the hair cells on basal and apex cochlea; as explained by the lower level of GPx-1 in basal hair cell in comparison with apex of cochlea.[25]

This study aims to observe the association between GPx-1 level and SNHL in MDR TB patients treated using Kanamycin.

Material and Method

This study was an analytic prospective observational study with pre- and post- intervention examination for association between variables, which had been ethically legalized before. Participants. Patients with MDR TB at MDR TB Policlinic of Internal Medicine Department of Dr. Hasan Sadikin General Hospital, Bandung between February to April 2017. The inclusion criteria for the study were patients with MDR TB with plan for Kanamycin therapy, aged 20-50 years old, had intact tympanic membrane in both ears, had type A result on tympanometry examination, normal hearing threshold on DPOAE examination and audiometry. Exclusion criteria for the study were patient with history of treatment using ototoxic drugs except TB-MDR treatment, had a history of another diseases, including renal failure, diabetes mellitus, liver diseases, systemic lupus erythematosus (SLE), and cardiovascular diseases. Intervention. Data was collected from physical examination and laboratories data of already diagnosed MDR TB patients and planned for kanamycin therapy. Data before and 3 weeks after treatment consist of personal data collection, physical exam of ENT, tympanometry, pure tone audiometry, DPOAE, and blood sample collection for glutation peroksidase-1 (GPx-1) serum. Outcome.The data then analyzed for comparison of subject group characteristic using paired t-test if the data is normally distribute, and using Wilcoxon if the data is abnormally distribute. The data is also analyzed for GPx-1 level correlation with SNHL using Mann-Whitney test. The result is statistically significant if p≤0,05.

Findings: This study was held from February 2017 to April 2017, using 17 subject that fulfill the inclusion criteria. All subject received same test for pre and post Kanamycin therapy, which includes tympanometry, pure tone audiometry, DPOAE, and GPx-1 level.

Table 1: Subject Characteristic

Characteristics	**n=17**
Gender, n (%)	
Male	7 (41,2)
Female	10 (58,8)
Age (years)	
Mean ± SD	36 ± 8
Range	23 – 46

Table 2: GPx-1 Level Before and After Kanamycin Therapy

	Measurement		**Decendants (%)**	**p-value**
	Before therapy (u/l)	**After 3 weeks therapy (u/l)**		
GPx-1				
Mean ± SD	4,49 ± 3,12	1,2 ± 1,0	70.42 ± 20,94	<0,001*
Range	1,01 – 14,01	0,07 – 5,15	18.81 – 98,54	

Analysis using paired-t test. *significant if p≤0.05

Based on these table GPx-1 level before therapy with range 1,01-14,01 (4,49 ± 3,12) and GPx-1 level after therapy (1,2 ± 1,0) with range 0,07 – 5,15.

Table 3: Correlation between GPx-1 level and DPOAE value

	DPOAE test (Dp-NF)		p-value
	Pass n=4 (23,5%)	Refer n=13 (76,5%)	
GPx-1			
Mean ± SD	66,60 ± 21,02	84,59 ± 14,86	0,062*
Range	18,81 – 92,36	64,40 – 98,54	

Analysis using paired-t test. *significant if p≤0.05

From the analysis above, GPx-1 median value at ear that having DPOAE test a "refer" value is higher (84,59 ± 14,86) compared to those who have DPOAE test a "pass" value (66,60 ±21,02), but it's not significant statistically (p=0,062).

Table 4: Audiometry examination before and after Kanamycin therapy

Frequency	Ear	Threshold (dB)		p-value
		Before Therapy Mean ± SD	After Therapy Mean ± SD	
500 Hz	AD	20,6 ± 5,6	23,7 ± 5,3	0,002
	AS	21,2 ± 4,5	24,7 ± 4,1	0,020
1.000 Hz	AD	18,8 ± 3,3	19,4 ± 5,0	0,041
	AS	18,2 ± 5,0	21,8 ± 3,5	0,048
2.000 Hz	AD	14,4 ± 3,6	17,7 ± 3,3	0,045
	AS	14,4 ± 3,9	18,5 ± 5,8	0,016
4.000 Hz	AD	16,8 ± 5,6	20,9 ± 4,4	0,050
	AS	15,3 ± 6,0	21,8 ± 6,4	0,020
8.000 Hz	AD	19,1 ± 7,3	24,4 ± 6,6	0,003
	AS	18,0 ± 7,7	25,9 ± 10,3	0,004

Analysis using paired-t test. *significant if p≤0.05

There's a significant increase in hearing threshold on both ear from pre to post Kanamycin therapy using audiometry each frequency.

Table 5: Correlation between GPx-1 Level and Sensorineural Hearing Loss

	SNHL		P value
	Yes n=13 (76,5%)	No n=4 (23,5%)	
GPx-1 Pre Therapy			
Mean ± SD	3,68 ± 1,99	7,13 ± 4,88	
Median	3,73	5,88	0,049
Range	1,01 – 6,32	2,75 – 14,01	
GPx-1 Post Therapy			
Mean ± SD	0,95 ± 0,71	1,99 ± 2,17	
Median	0,82	1,30	0,013
Range	0,07 – 2,59	0,21 – 5,15	

Analysis using Mann-Whitney test. *significant if p≤0.05

There's a significant correlation between GPx-1 level and SNHL condition.

Discussions

This study conclude MDR TB is mostly suffered by female (58.2%) compared with male (41,8%). Liu et.al hypothesized that female mostly spend their day taking care of their family who has MDR TB, compared to male, so the risk of bacterial infection transmission is higher in female.[28] This result also found in Pelaquin et.al study and WHO data survey on 2015.[2,29] Pelaquin study stated that gender does not affect the ototoxic effect of Kanamycin in MDR TB therapy and there is no direct correlation between MDR TB incidence and gender.[29]

Based on age group, this study conclude that MDR TB cases occur mostly on productive age (23 – 46 years old). This result was supported by Rakhmawati and Reviono et.al study that also found that MDR TB cases most likely occur on age 20 – 50 years.[5,8] Medical record data at Dr. Hasan Sadikin General Hospital, Bandung, Indonesia on 2016 stated that MDR TB mostly happen in age group 25-54 years.[4] Productive age have higher working time than other age group, which may affect the obedience for taking medicine, which then lead to drug resistance. Productive age also has more contact to different people in work, school, or other activity, so the risk of bacterial transmission is higher and could influence the incidence of MDR TB.[28]

Kanamycin is known for its side effect damaging outer hair cell of cochlea. This study used DPOAE on frequency ranged 1,500 Hz to 8,000 Hz which was tested prior and 3 weeks after the therapy begin. The result was most of the study subject exhibit "refer" value, which indicates damage at cochlear cell hair. Other study by Mustikaningtyas also exhibit the same result.[25,29] DPOAE test could provide initial data of hearing condition and early detection of ototoxicity. Reavis et.al stated that DPOAE could detect around 78% of hearing problem cases, which then confirmed using HFA. Other study also stated that DPOAE test is sensitive in monitoring of ototoxicity caused by drugs.[28]

MDR TB infection is a chronic infection, marked by a decrease in one of antioxidant enzyme. Study of Alli et.al and Madebo stated that the antioxidant enzyme known to be decreased by chronic infection is GPx-1.[16,17] This study found that GPx-1 level is significantly decrease after 3 weeks therapy of Kanamycin. ROS production happens continuously inside the cell, together with a decrease in antioxidant production, which results an imbalance level of antioxidant and ROS. This imbalance leads to DNA, cell membrane, cell protein and kinase protein damage. DNA damage can be repaired by Base Excision Repair (BER) mechanism, but if the damage exceeded BER capability, the cell will activate protein P53 and result in apoptosis.[27] GPx-1 level is determined by many factor, such as inflammation process, inadequate nutritional intake, and low social economy condition.[20]

Pure tone audiometry testing is used to monitor the change of hearing threshold due to Kanamycin therapy. A study conducted by Rakhmawati also shows a decrease on sensorineural hearing function from frequency 4.000 Hz to 8.000 Hz.[5] Other study conducted by Mustikaningtyas shows that SNHL after Kanamycin therapy happens in several level (48% mild, 24% moderate, 4% moderate-severe, 1% severe and 15% very severe).[29]

Baseline data, consist of HFA, tympanometry, speech audiometry, and OAE, should be recorded before administration of ototoxic therapy to determine the hearing threshold. Pure tone audiometry is the only exam that still used before administering ototoxic therapy.[26]

Early stage of Kanamycin therapy does not exhibit hearing problem on speech frequency (500 – 4.000 Hz), so not many patient realized that hearing problem is already happened. HFA exam can be useful for early detection of hearing problem, so further and more severe condition can be prevented.[14]

Table 3 showed a tendency of diminishing level of GPx-1 level after Kanamycin therapy, although it is not statistically significant. This may result from a minimal number of samples. On this study, decreasing level of GPx-1 level is more likely to be lower on "refer" value ear compared to "pass" value ear after therapy, whereas GPx-1 level is higher on "refer" value ear compared to "pass" value ear before therapy. This may result from higher exposure of ROS on "refer" value ear cochlea as an effect of intracellular defense, which then lead to an increase in GPx-1 level at the beginning to balance ROS level. This mechanism will end at some point due to maximal compensatory effect of GPx-1 enzyme, so the imbalance of ROS and antioxidant enzyme is no more tolerable, which lead to the damage of cochlear hair cell.[14,23]

Table 5 shows that GPx-1 level is significantly related to SNHL. Low GPx-1 level decreasing the capability of this enzyme to eliminate ROS, especially in basal area of cochlea.[31] This phenomenon is because GPx-1 level in basal area of cochlea is lower than in

apex area, causing basal area to be more vulnerable.[15] Study conducted by Sharma et.al showed that 18 MDR TB patient that is given Kanamycin therapy for 6 weeks, develop sensorineural hearing problem, 2% on the first week and 12% after 6th week. Mostly having bilateral hearing problem.[25]

The limitations of this study were the fact that GPx-1 examination performed with ELISA which only saw serum levels or amount of the enzyme, but not the activity of the enzyme.

Conclusion

There is a significant correlation between GPx-1 level and SNHL condition proceeding Kanamycin therapy on MDR TB patient, characterized by a decrease in GPx-1 level and an increase in hearing threshold on subjects after administration of Kanamycin therapy.

Risk Factors of Osteoporosis in Postmenopausal Women in Karbala Governorate–Iraq 2019

Ruaa Mahmood AL-Rukabi[1], Shahrazad Shamki AL Jobori[2], Asaad Abdulmahdi Al abayechi[3]

[1]Student in High Diploma of Family Medicine, [2]Tutor in Department of family and Community Medicine, College of Medicine, University of Kerbala, [3]Lecturer in Department of Rhematologistin Al-Imam Hussain Medical City in Karbala, Karbala, Iraq

Abstract

Background: Osteoporosis is a major public health problem because it leads to weakness of skeleton, increase risk of fractures particularly of the spine and hip, increases morbidity and mortality which are a huge burden on the health system.

Objectives:

1. To evaluate bone mineral density (BMD) of postmenopausal women by dual energy x-ray absorptiometry.
2. To explore the association between bone density at lumber spine and investigated risk factors for osteoporosis.

Method: A cross sectional study was carried out from February till the end of June 2019. A purposive sample of (350) women who were referred to DEXA unit in Al-Imam Hussain Medical City in Karbala Province/ Iraq. Data were gathered by direct interview with the patients using a special questionnaire prepared for the purpose of the study.

Results: The overall prevalence of osteoporosis and osteopenia was (48.9% and 27.7%) respectively. The factors such as age, residence, educational level, BMI, history of diabetes, physical activity, sun exposure, age at menarche, duration of menopause, parity and duration of breast feeding showed significant association with bone density. Occupational status, history of hypertension, smoking, menopausal age, personal and family history of minimal trauma fracture showing no significant association with bone density.

Conclusion: The prevalence of osteoporosis in this study was high. Appropriate educational programs and interventions could help to increase the women's peak bone mass therefore reducing their risk of developing osteoporosis.

Keywords: *Osteoporosis, Bone mineral density, Dual energy x-ray absorptiometry.*

Introduction

Osteoporosis (OP) is known as a "silent global problem", which is characterized by a decline in the bone mass and structural deterioration of bone tissue that leads to decrease skeletal strength with increase in bone fragility and vulnerability to fracture(1).

According to World health organization (WHO), osteoporosis is defined by bone mineral density at the hip or lumbar spine that is less than or equal to 2.5 standard deviations(SD) below the mean BMD of a young-adult reference population (2).

Nearly 10% of the world's population and 30%

of post-menopausal women are suffering from the disease[3].

Osteoporosis can be categorized as either primary or secondary. Bone loss associated with primary osteoporosis is a normal part of the aging process, especially following menopause, while secondary osteoporosis is a result of certain medications or medical conditions [4].

Various risk factors are related with the occurrence of osteoporosis. There are some modifiable risk factors such as sex hormone, dietary intake of calcium and vitamin D, long duration consumption of some medications like steroids and antacids, sedentary life style, smoking and excessive intake of alcohol and caffeine. On the other side gender, age, body size, race and family history are non-modifiable risk factors [5].

Methodology: Study design, setting and time: A cross sectional study was carried out at DEXA scan unit in Al-Imam Hussain Medical City in Kerbela province/ Iraq from January to the end of June 2019.

Sampling method: A non-probability (purposive) sample included (350) females referred to DEXA unit from consultation clinics of Al-Imam Hussain Medical City and other private hospitals in the governorate. All women aged ≥ 40 years with menopausal duration more than one year were eligible to be included in the study. Patients with dementia, malignant tumors, body weight >120 kg, conditions affecting bone metabolism as diseases of the kidney, liver, hyperthyroidism, rheumatoid arthritis, cerebral infarction and patients taking medications affecting bone metabolism such as glucocorticoids, thyroid hormones, thiazide diuretic, anti-seizure, proton pump inhibitors, warfarin, heparin and cancer chemotherapy where excluded.

- Verbal consent was obtained from each participant and ethical approval of Karbala Health Directorate and Al-Imam Hussain Medical City also had taken.
- Data collection method and tools: information's were collected by direct interview with the participants using structured questionnaire consist of sociodemographic data such as: age, residence, occupation, educational level, history of hypertension or diabetes mellitus. Weights and heights were measured without shoes in light clothing by the use of well calibrated digital weight and height scale measuring device. Body mass index (BMI) was calculated by dividing weight in kilograms by the square of the height in meters as in the equation:

Weight (kilograms) / height (meters)^2[6]: Behavioral risk factors include: smoking habit, sun exposure, level of physical activity.

Patients were also asked about personal and family history of minimal trauma fracture and about reproductive risk factors as: age at menarche, age at menopause, menopausal duration, parity and duration of breast feeding.

Bone mineral density was measured at the lumbar spine L1–L4 by using DEXA machine type (STRATOS, DMS, made in France). The results of measurement categorized according to WHO definition guidelines Normal: T-score (≥ –1.0); Osteopenia: T-score between (–1.0 and – 2.5); Osteoporosis: T-score (≤ –2.5) [2].

Statistical Analysis: Data analysis was done using SPSS version 24 (statistical package for social sciences). Chi square/Fisher exact test was used to show the association between two categorical variables. P value of ≤ 0.05 was considered as statistically significant.

Results

The mean age of participant was 62.33 (mean ± SD, 62.33±8.28).The prevalence of osteoporosis and osteopenia was (48.9% and 27.7%) respectively as shown in (figure 1).

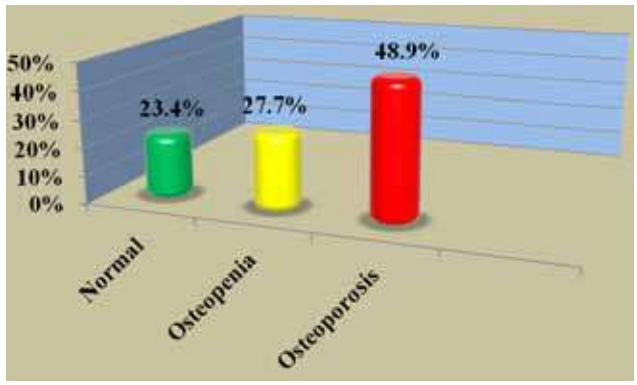

Figure 1: Distribution of women according to the result of DEXA scan

The sociodemographic and behavioral characteristics of the study sample are shown in (Table 1). The majority of women (41.4%) were in the age group (60-69), more than three quarters of them (82.6%) live in urban settings, (53.1%) are illiterate and (85.1%) are housewives. Other characteristics are shown in the following table.

Table 1: Distribution of women according to socio demographic and behavioral variables

Variables	Number (n=350)	Percent %
Current Age		
40-49	17	4.9%
50-59	111	31.7%
60-69	145	41.4%
≥70	77	22%
Residence		
Urban	289	82.6%
Rural	61	17.4%
Educational Level		
Illiterate	186	53.1%
Primary	72	20.6%
Secondary	72	20.6%
University	18	5.1%
Higher education	2	0.6%
Body Mass Index		
Under weight (<18.5)	1	0.3%
Normal (18.5-24.9)	65	18.6%
Over weight (25-29.9)	93	26.5%
Obese (≥ 30)	191	54.6%
Smoking		
Non smoker	300	85.7%
Current smoker	21	6.0%
Past smoker	29	8.3%
Exposure to Sun Light		
Never	221	63.1%
< 15 minutes/day	45	12.9%
≥ 15 minutes/day	84	24.0%
Physical Activity		
Sedentary	98	28.0%
Mild intensity	133	38.0%
Moderate intensity	112	32.0%
Vigorous intensity	7	2.0%

Table 2 and table 3 showed that older age group, rural residency, illiterate, low BMI, history of diabetes, physical activity and sun light exposure were significantly associated with osteoporosis. No significant association was found between osteoporosis and each of employment, history of hypertension, smoking, past history and family history of fracture due to minor trauma.

Table 2: Association between result of DEXA scan measurement and women's socio demographic variables

Socio Demographic Variables	Result of DEXA Scan				P-value

Discussion

The prevalence of osteoporosis among participants was (48.9%). This prevalence was higher than a study done in AL- Sulaimani Province 39%[7], Jordon 37.5% [8] and 18% in Saudi Arabia[9], but lower than 50.7% in Iran [10]. This inconsistency in the findings is perhaps related to the differences in diagnostic technique used, bone scan site chosen and selection of the patients.

In this study significant association was found between advanced age and the prevalence of osteoporosis. As the age increases, osteoporotic cases increase. This result was similar to other studies done in India and Iran[11,12]. The probable explanation is the alteration of the balance of the cellular activity with ageing process, with a reduced osteoblast response to continued bone resorption, so the resorption cavities are incompletely filled by a new bone formation during the remodeling cycle[13].

The prevalence of osteoporosis in rural areas was higher than that in urban areas. A recent study reported similar association [14]. This might be explained by the rural community had less availability of health services and treatment which leads to lack of early detection of the disease.

Osteoporosis was more prevalent among illiterate women which is in line with other studies[15,16].

High prevalence of osteoporosis in those with normal BMI in comparison with obese patients.

This difference was supported by other studies[17,18]. High BMI is responsible for the ability to endure larger mechanical loads thereby reducing bone resorption and stimulating bone formation. Besides, large body weight and BMI reflect the nutritional status, and malnutrition directly affects bone remodeling[19].

No significant association was found between history of hypertension and the risk of osteoporosis. These results disagreed with the other studies[20,21]. This difference can be explained by many hypertensive patients were not enrolled in the study because of exclusion criteria.

The study showed that osteoporosis was more prevalent among non-diabetic women in comparison with type 2 diabetic patient. This finding was agree with the findings of one study[22] but disagree with other[23].

Osteoporosis is more prevalent among women who not exposed to sun compared to women who exposed for ≥ 15 minutes. Similar study done in India stated that poor sunlight exposure is one of the factors contributing to bone loss in women above 40 years of age[24].

The current study failed to demonstrate a significant association between family history of fracture and risk of developing osteoporosis. This was inconsistent with Buttros et al., who reported that maternal history of fracture was clinical indicator of risk for osteoporosis[25]. This could possibly be explained by recall bias of family history of prior fracture.

Our study showed an association between the increase in age at menarche and risk of developing osteoporosis. Early menarche may have a protective effect on the development of osteoporosis since it is associated with higher circulating estrogen during and after menarche. This result agrees with the results of other study that reported associations between earlier menarche and increased BMD [(26)].

The results showed that the risk of osteoporosis increase with the increase in duration of menopause. This was in concordance with research literatures [(12, 27).]

Results of the current study demonstrated that parity and duration of lactation were significantly higher in the osteoporosis group than in the normal group. An association between parity and bone loss was reported by other study.[(28)]

Conclusion

Osteoporosis in this study appear to be associated with several risk factors include (older age, rural residence, low BMI, illiteracy, sedentary life, no sun exposure, age at menarche, menopausal duration, parity and duration of lactation).

Identification of Some Dermatophytes Isolated by PCR Technique in Misan Province/Iraq

Muhanad M. Mohammed[1], Ali A. Kasim[2]

[1]Student, [2]Professor, All at Department of Biology, College of Science, University of Misan, Maysan, Iraq

Abstract

Dermatophytes are a complex group of fungi, which include three genera *Trichophyton*, *Epidermophyton* and *Microsporum*. These fungi have the ability to degrade the keratin layer resulting in dermatophytosis, also known as Tinea or Ringworm. Because conventional method used to diagnose dermatophytes are slow and unspecialized, there is a need to use improved diagnostic method. Specialized primers were used OPAA11, OPD18, OPAA17 and OPU15 and the DNA sequence of the nuclear ribosome regions ITS1 and ITS4 were used. DNA was extracted for 14 isolates from dermatophytes (were isolated from patients in Misan province/southern Iraq Misan province/southern Iraq)and amplified by PCR for identify at species level by sequencing from the ribosomes using the MEGA program of mapping of the studied fungi to know the evolutionary relationships where the results of the genetic tree showed the existence of complex relationships between dermatophytes. The aim of this study was to identify different types of skin fungi as quickly and accurately as possible.

Keywords: *Dermatophytes, dermatophytosis, Tinea, Trichophyton, AP-PCR.*

Introduction

The fungal infections caused by skin fungi Dermatophytes, also known as ringworm, dermatophytosis, ringworm. Dermatophytosis or Tinea, a highly infectious skin disease of humans and animals[1]. Dermatophytosis is one of the most common infections worldwide and is estimated at 20-25%[2]. Dermatophytes are divided according to the environment Prefer into three types: Zoophilic, Geophilic and Anthrophilic[3]. These include three species: *Microsporum*, *Trichophyton*, and *Epidermophyton*. Infection by these fungi occur in the skin and accessories such as hair and nails[4]. The annual cost of treating injuries is estimated at around 500$ million globally, and these diseases are second only to skin diseases[5].

Filamentous dermatophytes secrete many metabolic substances that contribute to infection, including enzymes[6]. The enzymes secreted by dermatophytes can underlie the survival of the fungus on the host and develop[7,8]. Depending on the efficacy of these enzymes, the fungi races vary in their preference for the type of keratinous tissue, as the genus *Epidermophyton* prefers the tissues of the nails and skin, while the genus *Microsporum* prefers the tissues of the skin and hair, and with respect to the genus *Trichophyton* attacks all keratinized tissues, whether skin, hair or nails[9].

It is known that the diagnosis of dermatophytes requires a microscopic examination method has been found this method is sometimes inaccurate because it may give false results, especially if the species are close[9].In some slow-growing species, such as *T.verriucosum*, a transplant may take several weeks after which several diagnostic tests are required, which usually require different transplant media[10].and the phenotypic properties of dermatophytes are altered by many environmental, nutritional and chemical factors, which is why researchers prefer molecular method and genetic characteristics to identify dermatophytes, also thatmolecular method are fast and more specific[11].

Materials and Method

Collection of Samples: Clinical samples were collected of infected patients from the dermatological consultant at Al-Sadar General Teaching Hospital and some private clinics in Misan province / Iraq and for the period between December 2018 and June 2019. The study included the collection of samples from the affected areas of the skin, hairand nails for all ages and for both sexes. Part of the clinical specimens were then taken using sterile forceps and cultured on sabouraud dextrose agar (SDA)medium. cycloheximide (2.5 g/ml) and chloramphenicol (250 µg/ml)were added to prepare a selective media. The plates were incubated at 28 °C for 2–4 weeks. Dishes were examined for the appearance of any fungal growth[12].

Extraction of Fungal DNA: DNA extraction of colonies of dermatophytes isolated at the age of 8-10 days after activation on SDA medium containing cycloheximide and chloramphenicol using the Genomic DNA Mini Kit (Plant) supplied by the Taiwanese company Geneaid with a little modification.

Primers and PCR Analysis: Follow the method described by.[10] To conduct the test, mixing the components of the master mix in 0.2 ml tubes, especially after testing the PCR (Accuoower® PCR premix) containing the remaining reactants.Six types of primers used areITS1 (5′-TCCGTAGGTGAACCTGCGG-3′),ITS4 (5′-TCCTCCGCTTATTGATATGC-3′), OPAA11(5′-ACCCGACCTG-3′), OPAA17(5′-GAGCCCGACT -3′), OPD18(5′-GAGAGCCAAC -3′) and OPU15(5′-ACGGGCCAGT -3′)[13], were diluted with 0.5 ml TE in accordance with the company's instructions. The tube components were thoroughly mixed with vortex and all samples were placed in The PCR thermocycler is operated according to the programs shown in tables 1. After the PCR program was completed, 4µl of DNA Ladder (1000-100 bp) was placed in the first hole of the agarose gel and 5µl of the PCR product in the second hole. The agarose was dissolved in 100 ml of TBE buffer and at a concentration of 1x3µl of ethidium bromide dye was added and the current was fixed at 70 volts for 75 minutes.

Results and Discussion

ITs- PCR: The results obtained using PCR technique showed that the primers ITs1 andITs4 amplified the genotype of the fungi under study, where the amplified beams ranged from (550 - 750 bp) as shown in Figure 1.

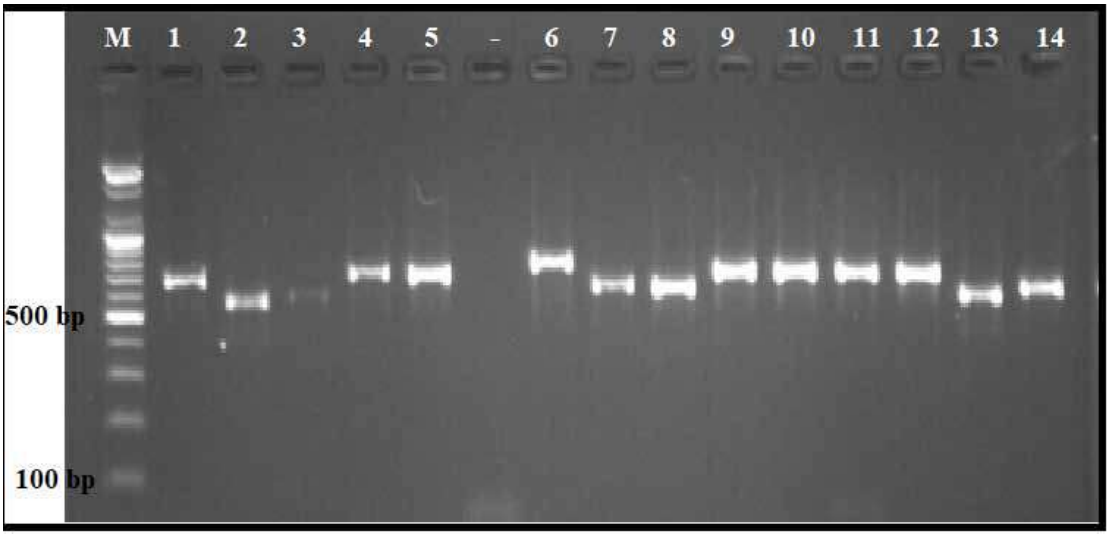

Figure 1: PCR polymers of DNA sequence on the acarose gel using prefixes (ITs1, ITs 4). M:Markar,1: T.equium, 2: T.interdigitale, 3: E.floccosum, 4: T.mentagrophytes, 5: M.persicolor, 7: M.audouinii, 7: M.canisver.distortum, 8T.erinace, 9: M.canisver.equinum, 10: M.nanum, 11: T.interdigitale, 12: T.ajello, 13: T.mentagrophytes, 14: T.rubrum.

RAPD–PCR: The study showed that all the RAPD primers used OPAA11, OPU15, OPAA17, and OPD18 amplified the DNA of the fungi under study (Figure 2). The total number of amplified packages was 628 The primer OPAA17 showed 94 bundle and higher Polymorphism 20.2 % While primer showed200 bundles with less Polymorphism 12% (Table 2).

Sequencing: The purified PCR products were sent to Macrogen Lab (Seoul, South Korea). DNA sequences obtained from forward and reverse primercycle sequences were analyzed by Blast analysis to shrink sequences and align them with previously published sequence data in GenBank.

Genetic tree of studied dermatophytes: The results showed the genetic tree obtained from the application of the MEGA program

It is composed of two main clan groups that included the first clan group *Microsporumaudouinii*, the second clan group *Epidermophyton floccosum*, *Trichophyton erinace*, *Trichophyton rubrum*, *Trichophyton mentagrophytes*, *Trichophyton interdigitale*, *Microsporumcanis*ver .distortum, *Microsporumaudouinii*, *Trichophyton mentagrophytes*, *Trichophytonequinum, Microsporumpersicolor*, *Microsporumcanis*ver. equinum, *Trichophyton ajello* and *Microsporumnanum* (Figure3).

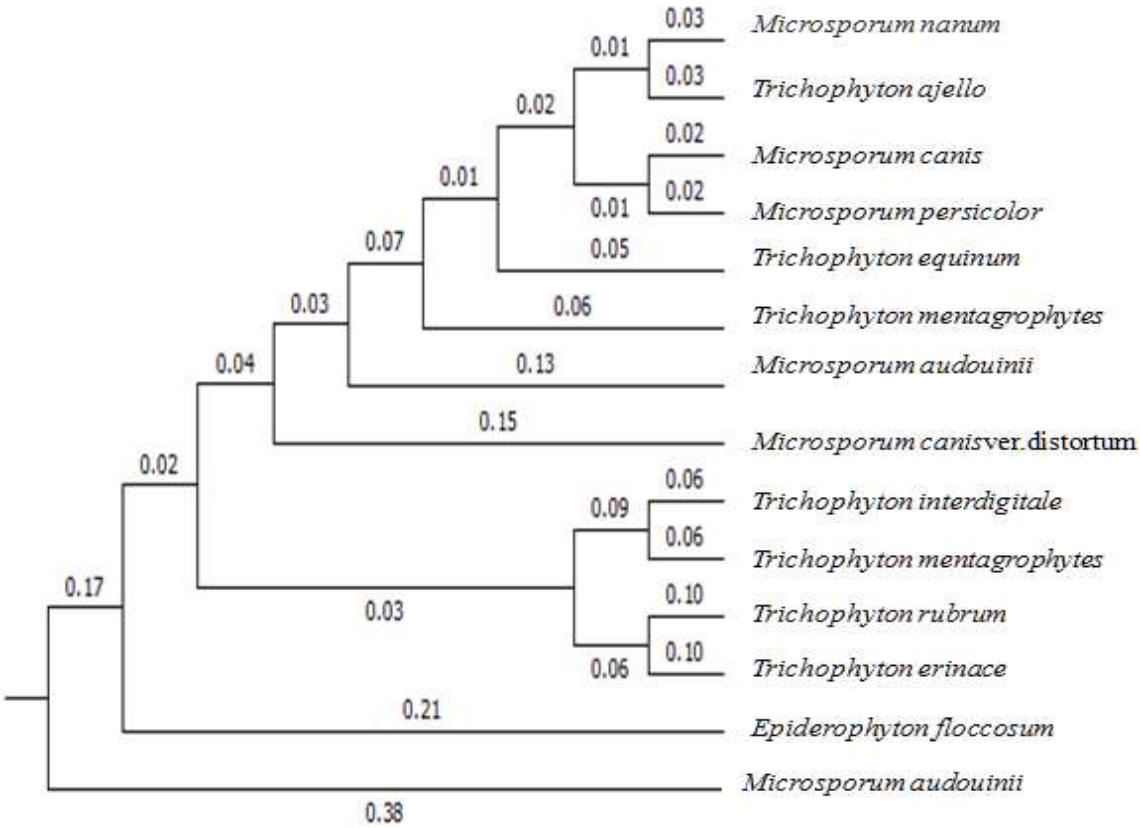

Figure 3: Genetic tree of the studied skin fungi species

PCR technology has become common and indispensable in biological and medical research laboratories for various applications[14].The molecular diagnosis of dermatophytes has been able to solve the epidemiology of dermatophytes, such as detecting common sources of infection, infectious method and spreading areas, as well as determining whether re-infection is the original isolation or new strains[15]. Molecular techniques aim to develop taxonomy, especially for genus, species or strain, and to study the evolutionary correlation between the new taxonomic orders. These and other studies have distinguished between physiologically similar species, morphologically and also between strains of the same species[16].In recent years, specialized region primers have been used for direct detection of fungi in skin and nail samples[17].

Molecular method provide an appropriate solution to the problems we face in the classification of dermatophytes compared to phenotypic diagnostic method .[18]It was found that the use of conventional method to identify species takes a long time can not be

sufficiently reliable and in some cases the diagnosis is wrong so molecular method are more rapid, accurate and sensitive than phenotypic method to identify the types of dermatophytes and we can get a result within 24 hours from the samples directly from the extraction DNA. [19]The use of molecular method has also facilitated significant progress in identifying and analyzing the results of the genetic tree of dermatophytes[20].

Traditional and molecular classification method have pros and cons, but traditional method have some advantages over molecular method in estimating differences between fungi. Therefore, we should rely solely on data obtained from molecular method in isolation from other data such as phenotypic traits, as this may lead researchers to Inferring misconceptions from the results of genetic tree analysis[21,22].

The use of PCR in the diagnosis of dermatophytes, where Zarrin*et al*. [18]identification ten species of fungi are *M.gypseum, M. canis, M. ferrugineum, T. rubrum, T. mentagrophytes, T. tonsurans, T. verrucosum, T. violaceum, T. schoenleinii, E. floccosum* while found Wiegand *et al*[23]. *T. violaceum*, the main causative agent of tinea capitis in children, followed by *T. rubrum* ,While in Egypt, five types of dermatophytes are identified*T. rubrum, T. mentagrophytes, T. violaceum, E. floccosum*, and *M. canis*[24].

The results of the present study showed that the primers used OPAA11, OPAA17, OPU15 (OPD18) are highly efficient in the diagnosis of dermatophytes by obtaining DNA bundles that appeared visible under ultraviolet radiation and this result is consistent with the findings Liu *et al*[25]. they showed that there is a possibility to diagnose about 25-20 species of dermatophytes using one of these primers. This method is quick and highly efficient for the diagnosis of dermatophytes since the diagnosis based on genetic characteristics is more accurate than depending on phenotypic characteristics[13].have used a number ofResearchers used this technique in the diagnosis of pathogenic fungi, including dermatophytes[26].The number of bundles of dermatophytes studied varied when using these primers Figure (4 a). This may be due to genetic mutations and new traits or may be due to differences in time periods obtained which can lead to genetic variation between isolates[27]. Obtained in this study as in Figure 4b.

Figure 4 A: The number of packets configured for each primer using PCR-RAPD technology. B. Single and multiple genotypes

Conclusions

PCR technology provides a solution to the problems we face in diagnosing skin fungi by conventional method. In addition, PCR technology is quick, easy and high accuracy.

Acknowledgments: The authors are grateful to Al-Sadar Teaching Hospital / Maysan / Iraq for their assistance in the collection of samples, which was necessary to complete the study.

Conflict of Interest: There are no conflict of interest.

Studying the Influence of Nano ZnO and Nano ZrO_2 Additives on Properties of PMMA Denture Base

Suroor Abd Alwahab[1], Jaafar M. Moosa[2], Sadeer Muafaq[3]

[1]M.Sc. Student, Department of Applied Sciences, Materials Science Branch, University of Technology, [2]Asst. Professor Dr. College of Dentistry, Department of Basic Sciences, Baghdad University, [3]Ph.D. Department of Applied Sciences, Materials Science branch, University of Technology, Baghdad, Iraq

Abstract

The aim of this study was to prepare materials that use to manufacture a denture by using a composite material, also studying their properties. Poly methyl methacrylate (PMMA) resin is widely utilized in dental applications. Two types of additives (Nano zinc oxide and Nano zirconium oxide) with different weight percentages (1%, 2%, 3%, 4% and 5%) were added to PMMA resin to improve its properties. The mixture was chosen experimentally to obtain the optimum properties also to avoid cracks formation. The ratio of PMMA and dichloromethane were (20% wt) and (80% wt) respectively for pure specimens. The result showed that there was an increasing in thermal conductivity, completion strength and a decreasing in roughness.

Keywords: *PMMA, biomaterial Dental Materials, Prosthetic dentistry.*

Introduction

Biomaterials are defined as natural or synthetic origin materials that are used as treatment, supplement or replacing any part of a living tissues or to do function in close contact with living tissue. Therefore two important criteria which biomaterial must fulfill are biocompatibility and bio-functionality(1). The developments in artificial bone and tooth field seem to solve most of the hard tissue problems. On the other hand artificial bone and tooth may cause an improvement in their properties(2).

Dental Materials, it is the science which deals with the materials used in the dentistry, their physical, chemical, mechanical properties and with their manipulation as such properties are related to the proper selection and use by the dentist. The study of dental material enables the dentist to understand the behavior of these materials, proper selection for appliance in patient and how to use them to their best advantage(3). Prosthetic dentistry is the replacement of missing teeth, which may have been lost for a variety of reasons, with either fixed or removable dentures, that using depending upon a many factors of these replacements.

Figure (1-1): Images of Prosthetic Denture(4)

Denture base material represents one type of biomaterial that must be have good properties, compatibility, performance, color stability and dimensional stability, in addition to esthetical pleasing and use in the oral cavity the part of denture that rests on the basis tissue and to which teeth are tied. Acrylic prosthetic resins are utilized in a number of kinds of dental prostheses, including removable partial or complete dentures, implant-supported prostheses and transitional prostheses. Poly methyl methacrylate (PMMA) material has been widely utilized as a denture based material because of its desirable characteristics

Poly (methyl methacrylate), more often called PMMA, is a commonly used low cost thermoplastic

polymer with boundless applications to everyday life. PMMA is the most commercially important acrylic polymer and is sold under several trade names including Plexiglas and Acrylate. High transparency makes PMMA an ideal replacement for glass where impact or weight is a serious concern. PMMA is compatible with human tissue making it an important material for transplants and prosthetics, especially in the field of ophthalmology because of its transparent properties [(5)].

PMMA has high mechanical strength, high Young's modulus and low elongation at break. It does not shatter on rupture. It is one of the hardest thermoplastics and is also highly scratch resistant. It exhibits low moisture and water absorbing capacity, due to which products made have good dimensional stability. Both of these characteristics increase as the temperature rises [(6)].

Many researchers study denture base, in 2013 Shyang and his coworkers [(7)], studied the effect of the incorporation of hydroxyapatite (HA) particles on the flexural properties of denture based. The results showed that the addition of (HA) particles increases the flexural modulus of PMMA denture base. Furthermore, flexural strain and flexural strength of PMMA/HA composite materials were decreased with the addition of (HA) particles [(7)]. In 2014 Mohamed and his coworkers [(8)], A. A., et al., (201**4),** studied the effect of the addition of zirconium oxide (ZrO_2) Nano fillers powder with different weight fraction. The results showed that the addition of zirconium oxide (ZrO_2) Nano fillers powder into heat-cured acrylic resin (PMMA) significantly increases the fracture toughness, hardness and flexural strength of heat-polymerized acrylic resin [(8)]. In 2015 Sama and her coworkers [(9)], study the effect of the addition titanium oxide Nano filler (TiO_2) on some mechanical and physical characteristics of denture base material The results showed that titanium oxide Nano filler (TiO_2) into heat cured acrylic denture base material will highly increase the impact strength and transverse strength, and a significant increase in surface Prosthetic dentistry hardness sand surface roughness. Also, the water sorption and decrease when compared with the control group (pure) [(9)]. In 2016 Eman and her coworkers [(10)], investigated the effect of the addition of zirconium oxide Nano particles (ZrO_2) on the fracture resistance of mandibular implant retain over denture base material and transmitted of stresses to the implants [(10)].

In this study, the results showed that the addition of zirconium oxide Nano particles significantly increase the fracture resistance of mandibular implant retain over denture base material and decrease the problem of repeated fracture of denture base material.

Experimental Work:

Used Materials:

1. Poly (methyl methacrylate) (PMMA).
2. Chloride methylene (CH_2Cl_2).
3. Nano- zinc oxide (ZnO).
4. Nano- zirconium oxide (ZrO_2).

Mould Preparation: The mould which used in this study was made from plastic has a circular shape with height (2.5cm) and diameter (4 cm).

Proportioning and Mixing of PMMA: The mixture was chosen experimentally to obtain the optimum properties also to avoid cracks formation. The ratio of PMMA and dichloromethane were (20%) and (80%) respectively for pure specimens. The ratios of Nano ZrO_2 and ZnO were (0.02%, 0.04%, 0.06%, 0.08% and 1%) from the percentage of the PMMA ratio.

The liquid dichloromethane was poured in a dry and clean beaker then the PMMA particles slowly added to the liquid. A magnetic stirrer was used to homogenize the mixture. The beaker must seal very well to prevent the formation of any bubbles and placed in an electric stirrer for 90 minutes until the solution is totally homogenized. After that the homogenized solution was poured into the mould and left for two days at room temperature to be casted. The mold was previously lubricated with paraffin to prevent adhesion and to easily extracting of the specimens from the mold.

1. **Thermal Conductivity:** Thermal conductivity (K) is the intrinsic property of a material which relates its ability to conduct heat. Thermal conductivity coefficient can be calculated according to (Fourier's Law).

The thermal conductivity depends on the many factors include (degree of crystallization, molecular weight, porosity). All polymer material have low thermal conductivity between (0.17-0.25 W/m.K), therefore most of polymer using as insulated material for this reason .This property represented the disadvantage of poly methyl methacrylate when used as denture base

materials; because of the high thermal conductivity of denture bases lead to [11]:

1. Improved tissue.
2. Better appreciation of taste.
3. Reduces feeling of dentures to the foreign body.

2. **Compression Test:** Compression test (Brazilian) was determined according to ASTM (D664) by using cylindrical specimens. The specimens were placed with its horizontal axis between platens of the testing machine. Diametrical strength was calculated by

$$Compression\ (\sigma) = \frac{2F}{\pi DL} \ldots\ldots\ldots (1)$$

Where (σ) compression (MPa), (F) Maximum applied load (N). (D) Diameter of

Specimens (mm), and (L) length of the specimens (mm).

3. **Roughness:** The surface roughness of product is very important surface properties and surface finish design requirements for many reasons and consideration which include Corrosion resistance. Such as, Cost consideration, Electrical and thermal contact resistance, Fatigue and notch sensitivity, and subsequent processing such as painting and coating appearance. Frictional wear, and lubrication consideration.

Results and Discussion

1. **Thermal conductivity Test:** The values of thermal conductivity for pure PMMA, for all specimens that were prepared in the current work are illustrated in the figure (1). The effect of the addition of various types of nanoparticles (zinc oxide (ZnO) and zirconium oxide (ZrO^2) showed an increasing in the thermal conductivity values because of the ceramic nanoparticles which serve as physical cross-linking centers between the PMMA molecules for the phonon conduction, have thermal conductivity insulating PMMA polymer [12].

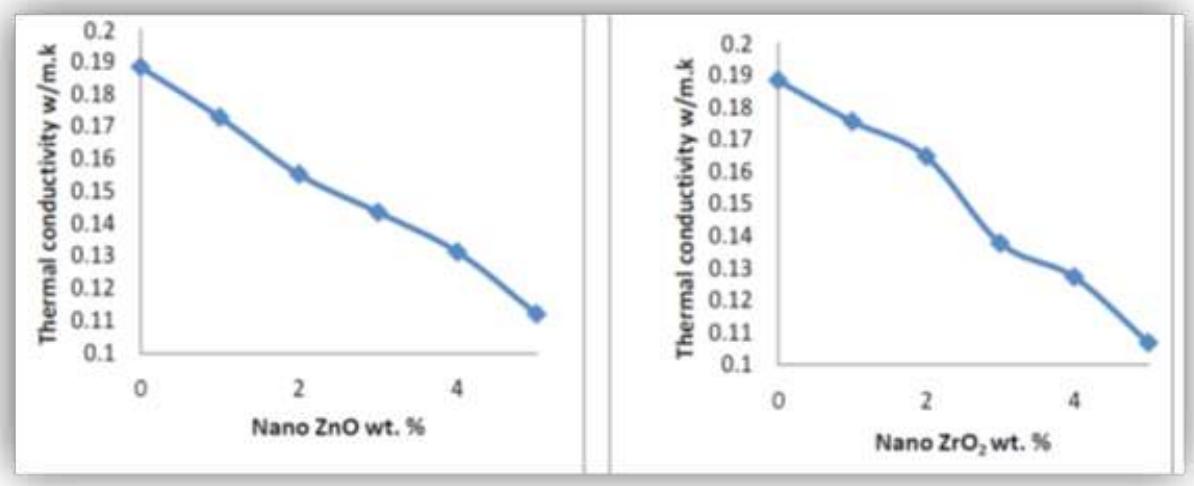

Figure 1: Thermal conductivity for Nano ZnO and ZrO_2 reinforced Specimen and Pure PMMA specimen

2. **Compression Test:** The values of compression for pure PMMA, for all specimens that were prepared in the current work are illustrated in the figure (2). The effect of the addition of various types of nanoparticles (zinc oxide (ZnO) and zirconium oxide (ZrO_2) showed an increasing in the compression values because of the formation of strong physical cross-links (supra molecular) bonding which covers (shield) the nanoparticles, and this in turn leads to prevent the cracks propagation within the PMMA material, as well as, the good bonding between the nanoparticles and PMMA matrix leads to change the propagation of cracks [13, 14].

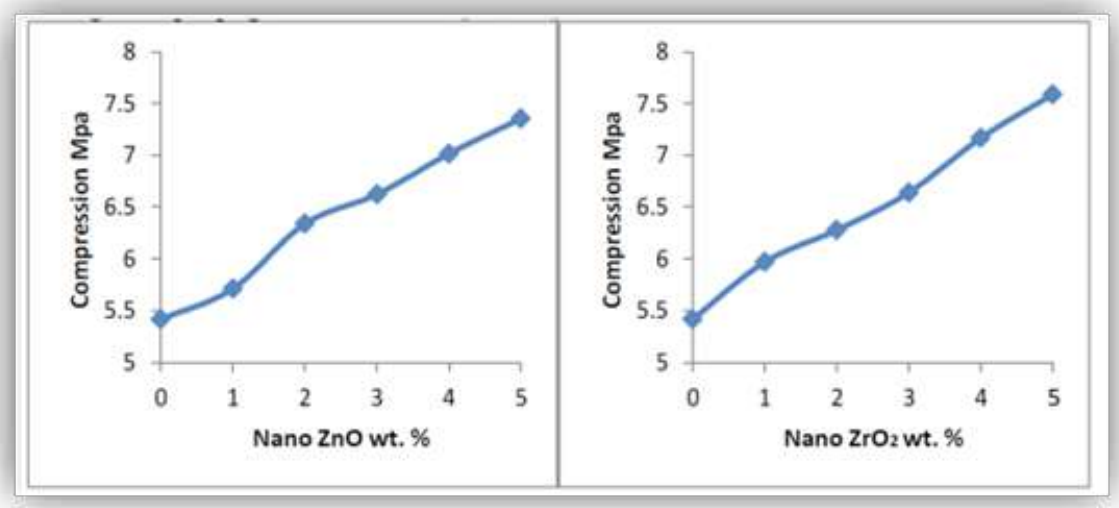

Figure 2: Compression strength for nano ZnO & ZrO_2 reinforced specimen and pure PMMA specimen

3. **Roughness Test:** The values of Roughness for pure PMMA, for all specimens that were prepared in the current work are illustrated in the figure (3). The effect of the addition of various types of nanoparticles zinc oxide (ZnO) and zirconium oxide (ZrO2) It can be noticed that the values of surface roughness decreased with increasing of the volume fraction of all types of particles for all groups. This is related to the surface roughness test is concerned with outer surface and not with inner surface of composite specimens. Furthermore, the number of particles that will be involved with in surface of the composite specimens increased when increasing the volume fraction of these particles in PMMA composite [15].

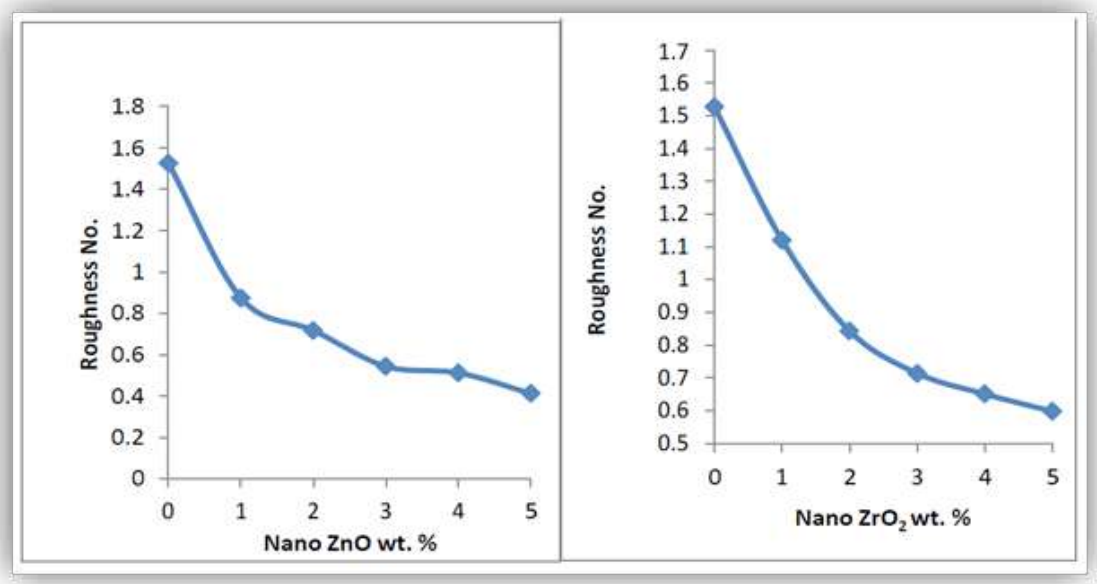

Figure 3: Roughness for nano ZnO & ZrO_2 reinforced specimen and pure PMMA specimen

Association of Osteoarthritis and Periodontitis in Sample of Iraqi Patients with Knee Osteoarthritis

Ali Hamdi Ghani[1] , Sami S. Shihab[2]

[1]MBChB, Resident doctor, Rheumatology and Medical Rehabilitation, Iraqi Board for Medical Specialization, Baghdad teaching hospital , Iraq. [2]FRCP, MRCP, DMR, CES, MBChB, Professor of Medicine & Rheumatology, Medical College / University of Baghdad, Iraq

Abstract

Background : Osteoarthritis **(**OA and Periodontitis (PD) share physiopathological characteristics ,and many previous studies show association of PD with other chronic musculoskeletal and bone diseases such as rheumatoid arthritis and Osteoporosis.

Objectives: To investigate the association between OA and PD in a sample of Iraqi patientswith knee OA.

Patients and Method: Acase-control study included 150 patients with OA and 150 healthy controls. The WHO community periodontal index was used to assess periodontitis, Periodontitis was defined as a CPI greater than or equal to ''code 3''. Binary regression analysis used to assess the predictors of periodontitis among OA patients

Results: OA patients were about 2.3 folds more likely to have Periodontitis, (odds ratio = 2.29, P. value < 0.05). In OA group only smoking showed a significant correlation with Periodontitis; where out of the 38 cases with periodontitis 7 (18.4%) were smokers compared to only 6 (5.4%) of 112 with no Periodontitis, (P. value = 0.013), Other variables showed no significant correlations, (P. value > 0.05).No statistically significant correlation had been found between prevalence of Periodontitis and severity of OA represented by KL score, (P. value > 0.05).

Conclusions: Patients with knee OA were about 2.3 folds more likely to have Periodontitis compared to healthy controls. Presence of Periodontitis was not affected by age, gender, Occupation, Alcohol consumption, BMI or severity of disease in knee OA patients.

Keywords: *Osteoarthritis , Periodontitis, physiopathological characteristics*

Introduction

Osteoarthritis is a degenerative joint disease, occurring primarily in older people and characterized by erosion of the articular cartilage, hypertrophy of bone at the margins (i.e., osteophytes), subchondral sclerosis, and a range of biochemical and morphologic alterations of the synovial membrane and joint capsule[1] OA is the most prevalent form of arthritis and a major cause of pain and disability . The exact pathophysiology of the condition has not been well understood yet [2,3]. Periodontal disease is broadly classified as either gingivitis or periodontitis; these conditions are distinguished by the presence of alveolar bone involvement that occurs with periodontitis and not with gingivitis [4-6]

Both Osteoarthritis and Periodontitis are common chronic diseases that have major impact on public health and quality of life. Periodontitis is an inflammatory

disease that its most important consequence is the loss of bone supporting the teeth. OA patients also suffer from an important inflammatory component in the soft tissue and bone structural modifications , so that OA and PD sharephysiopathological characteristics. [7]Many previous studies show association of PD with RA ,of which animportant local Iraqi study [8]. Also the association between PD and bone diseases with other systemic diseases also had been found[9,10]. However, the relationship between OA and PD remains unclear.

Patients and Method:

This wasa case-control study conducted at the Rheumatology Unit of Baghdad Teaching Hospital in Medical Cityand Al-Furat Al-Awsat hospital (Najaf) from October 2017 till July 2018. A total of 150 patients with knee OA were included in the study and 150 age and sex matched healthy controls were included. Patients with rheumatoid or other inflammatory arthritis , Chronic disease , Malignancy, users of some medications (bisphosphonates, CCB, phenytoin ,cyclosporine) and pregnant women were excluded. Radiographic severity of OA calculated using Kellgren and Lawrence system. The oral examination and diagnosis of periodontitis were performed by specialized dentists at Rheumatology unit in Baghdad teaching hospital and Dental Clinic in Al-Furat Al-Awsat hospital (Najaf). The oral examination was explained to each participant beforehand. The WHO community periodontal index (CPI) was used to assess periodontitis (table 1)[11] , and the mouth was divided into sextants, the index tooth numbers were 11, 16, 17, 26, 27, 31, 36, 37, 46, and 47. An approximately 20 g probing force was applied to each tooth by a specially designed, lightweight CPI metallic probe with a 0.5-mm ball tip , with a black band between 3.5 and 5.5 mm (figure 1), and the highest CPI code for each subject was recorded .. Periodontitis was defined as a CPI greater than or equal to ‘‘code 3’’, [12-14]

The WHO community periodontal index (CPI) was used to assess periodontitis[11]. Statistical analysis was performed using the statistical package for social sciences version 25, and appropriate statistical tests and procedures were applied accordingly with a level of significance of < 0.05.

Results

No statistically significant differences had been found between both groups in their baseline characteristics (P. value > 0.05). Periodontitis was reported in 38 (25.3%) OA patients and 18 (12%) controls. The OA patients were about 2.3 folds more likely to have Periodontitis, (odds ratio = 2.29, P. value < 0.05). (Table 1).Out of the 150 OA patients 46 (30.7%) had KL score of 2, 63(42%) had a score of 3 and 41 (27.3%), had KL score of 4, (Figure 1).Among the demographic variables of the OA group only smoking showed a significant correlation with Periodontitis; where out of the 38 cases with periodontitis, 7 (18.4%) were smokers compared to only 6 (5.4%) of 112 with no Periodontitis, (P. value = 0.013), Other demographic variables, BMI and KL score showed no significant correlations with the prevalence of Periodontitis, (P. value > 0.05), (Table 2).Binary regression analysis revealed that smoking still significantly associated with Periodontitis in OA group after adjustment for other variables with an odds ratio of 4.83 indicated that smoker OA patients were about 4.8 folds more likely to have Periodontitis than nonsmokers, (P.value = 0.04), (Table 3) .

K.L. Score	0.06	0.94	0.56 – 1.60	0.82

Discussion

The current study found that PD were more frequent in OA group than controls, where OA patients were about 2.3 folds more likely to have Periodontitis,

Chronic inflammation is thought to play a role in the pathogenesis of both (PD) and (OA), and increased blood levels of pro-inflammatory mediators such as IL-6, TNF alpha, and C-reactive protein have been documented in adults with OA and PD.[15]Mobility limitation resulting from osteoarthritis, particularly in the lower extremities, makes it difficult for those affected to visit dental offices for both routine hygiene and treatment. A large national survey in Australia found that persons who had osteoarthritis were less likely to have visited a dental professional within the past 2 years.[16] Also certain medications used to treat osteoarthritis, including corticosteroids and non-steroidal anti-inflammatory drugs, may suppress the immune system, thus potentially affecting the tissues of the oral cavity by increasing the risk of delayed wound healing, prolonged bleeding time, and fungal infections.[17]Finally , many patients with KOA also may have hand OA and the severity of osteoarthritis in the hands is correlated with impaired functional ability.[18]Hence, many people with osteoarthritis in their hands are unable to maintain proper oral hygiene, resulting in accumulation of plaque and calculus, which increases the likelihood of dental caries and periodontal disease.[19]However ,this finding disagree with Chung et al. which provided that OA and PD showed no significant association in overall analysis.[20]Also this finding is inconsistent with Kandati et al. which reported that OA was not significantly associated with any PD category (P-value =0.28).[15]

The current study revealed No statistically significant correlation between prevalence of PD and the severity of OA and this finding is inconsistent with Chung et al. that reported that patients with severe

OA were more likely to have PD (P=0.0316)[20]. In the present study no statistically significant relationship was found between PD and demographic variables except for smoking , where OA smokers were more likely to have PD compared to non-smokers on univariant analysis. Furthermore binary regression analysis revealed that smoking still significant after adjustments for other variables and that smoker OA patients were about 4.8 folds more likely to have Periodontitis than nonsmokers, (P.value = 0.04) .These results are similar to those reported by Dina Al- Tayeb[19] ,Gautam DK et al.[21] and Haffajee.[22] All of these studies have shown that compared to non-smokers, adult smokers have a higher prevalence and severity of periodontitis. However, in the present study smoking is a risk factor to get PD and have a synergistic effect with OA.[22]

It is well known that tobacco smoke contains many cytotoxic substances such as nicotine, which can penetrate the soft tissue of oral cavity, adhere to the tooth surface or enter to the blood stream. Potential molecular and cellular mechanisms in the pathogenesis of smoking associated periodontal diseases has been reported and these include, immuno-suppression, exaggerated inflammatory cell responses, and impaired stromal cell functions of oral tissues[19,21,22].

A potential importance of this study is that it is the first study performed in Iraq, Middle East and Arabic region that studied this concept , so it may be useful for other researchers as a baseline for subsequent future studies.

Conclusions

Periodontitis was more frequent in patients with knee OA compared to healthy controls Smoking was independent risk factor of Periodontitis

Ethical Clearance: Ethical approval was taken from Medical department, College of Medicine, University of Baghdad. Verbal consent was obtained from all participants

The Effectiveness of Special Exercises with the Black Bean in Improving the Lactic Endurance and the Digital Achievement of Runners 800 m Youth

Mahdi Lafta Rahi[1], Haider Abdul-Hassan Sajit[2], Hussein Manati Sajit[3]

[1]College of Physical Education & Sport Science, Wasit University, [2]M.A., Ministry of Education, Directorate of Education, Babil Governorate, [3]Assist. Prof., College of Physical Education & Sport Science, Karbala University

Abstract

The aim of this study was to prepare exercises using the black bean and in the form of doses based on studied scientific basis. The sample of the research was for Karbala players in 800 m activity for the youth group of 7 players. The experimental method was used for one group by tribal and remote testing. The black bean was given in capsules the results of the study showed that there was a significant effect of the black pill dose and the sports training, which was demonstrated by the emergence of significant differences in the post-test in running 800 meters for the benefit of Dimensional test.

Keywords: *Improving, Lactic, Endurance.*

Introduction

Human societies at this stage witness a scientific renaissance in a wide range and in various fields and it is based on the foundations of scientific research and the objective study. Physical education is one of these areas that have been progressed. Arena is one of the games that have developed as they occupy a good place among games and events Sports as a result of the high potential of players and the pursuit of serious and continuous in the teaching process[1], which led to the high level and the breadth of popularity in all countries of the world. In order to keep pace with the progress of the game, many researchers have tried to find ways to help improve the player's physical and functional efficiency. Some of these medicinal plants [2] have been used and given the global trend of expanding the use of plant raw materials in the manufacture of pharmaceuticals instead of chemicals [3] with harmful side effects (7: 7) and the importance of the black bean increased after the mention of the Prophet Muhammad (peace and blessings of God be upon him), which God Almighty said, the importance of research lies in the recognition of the effect of anaerobic exercises in the development of lactic endurance and the achievement of a hostile 800 meters youth. The problem of research is that[4] most players of effective 800 meters for the youth class are characterized by a clear drop, especially in the final distance of the race, which is a critical distance and concentrated fatigue in the athlete and through the directions of researchers in the field of sports training physiology and by the knowledge of many references of medicinal plants and found that black seed plant has a great benefit, especially for athletes working under the Lactic energy system[5] and through our observations on the[6,7] level of players and physical ability, we try to contribute to the development of players physically and functionally, using some plant Black pill so as to raise the efficiency of the players less expensive and without collateral damage. Research's Goals: Preparation of exercises with anaerobic effort to take the black bean in the development of the tactical endurance and achievement of runners 800 meters youth. Identifying the effect of exercise with the treatment of the black bean in the development of lactic resistance and achievement of runners 800 meters young.

Research Hypotheses: There is a positive effect of the exercise in the treatment of black bean in the development of Lactic endurance for young runners of 800 meters.

Research's Areas:

1. **Human area:** Players of Karbala province clubs athletics 800 meters youth for the training season 2018-2019.
2. **Time:** for the period from 5/9/2018 to 5/11/2018.
3. **Place:** Karbala International Stadium

Methodology: The researchers used the experimental method of a one-group method of pre and post measurement that suit to problem type.

Sample of the Study: The sample of the study was 7 players of Karbala province clubs for the activity 800 meters youth for the training season 2018 -2019.

Homogeneity of the sample: The researchers conducted homogeneity between the sample members in order to start with a single line of origin. This was done by finding homogeneity of the dependent variables as well as the anthropometric measurements as shown in Table (1):

Table (1). Homogeneity of the dependent variables as well as the anthropometric measurements

No.	Variable	Measuring unit	Test value (Leven)		Indication level	
			Calculated	Standard error		
1	Age	Year	1,246	0,322	Not significant	matching
2	Training age	Year	0,372	0,429	Not significant	matching
3	mass	Kg	0,088	0,871	Not significant	matching
4	Length	Cm	1,270	0,320	Not significant	matching
5	Lactic endurance	Minute	2,347	0,228	Not significant	matching
6	The completion time is 800 meters	Degree	1.873	0.231	Not significant	matching

Collecting information means:

1. Observation.
2. Tests and measurements.
3. Registration and unloading form of test's results.

Instruments and tools used in research:

1. Height and weight measuring device.
2. Athletics track
3. Leather measuring machine 20 meters.
4. Boundary (7)
5. Three electronic timer (Caslo)
6. Treadmill

Lactic Endurance Test (Abu El-Ula Ahmad, 1997, 3):

- The purpose of the test: Measurement of tactical endurance
- Machine speed: 14 km/h
- Inclination angle: 11 Degree, 20%
- Test time: till the player is tired
- The Procedure: after the player finishes warm up for 5-10 minutes The player is start playing on Treadmill as shown in Figure (4) The machine starts at the specified speed (14 km/h) The device starts to increase the speed gradually up to the prescribed speed This gives the experimenter Sufficient opportunity to work on the device in a suitable and consistent manner and after reaching the prescribed speed, two electronic timers will begin switch on by the arbitrators The player has to work on the treadmill until he reaches the extreme fatigue so that he cannot run on the treadmill then the two timers are stopped.
- Registration: the experimenter's time is recorded from the beginning of the test the arrival of the device to a speed of (14 km/h) until the end of work (fatigue).
- Measuring the digital completion time of 800 meters: The digital achievement of the s of the research sample is based on the results obtained in the Iraqi clubs championship which is held annually in Baghdad.
- The exploratory experiment: The researchers conducted an exploratory experiment on a sample of (5) players on Tuesday 5/9/2018 at 3:00 pm at

the Karbala International Stadium. The exploratory experiment helped the researchers in identifying: the validity of the equipment and tools used in the research.

- Pre-tests: The researchers conducted pre-tests on Sunday, 10/9/2018 at 3 pm and in Karbala International Stadium.

Specific Exercises: The proposed exercises started on 15/9/2018. The training period is set at 8 weeks. The total number of training units is 24 training units. Number of weekly training units: (3) units. Weekly training days: (Sunday - Tuesday - Thursday). Total module time: (90) minutes. The main section of the module is: (30-45) minutes. Training method used: high intensity training and repetitive training. Training intensity used: (85 - 95%) of the extreme intensity of the player's performance.

- **Procedures of using the black bean:** The researchers used scientific sources to know how to give the prescribed doses and discover that (1 g/day) capsules before and after exercise in two hours is the best dose to give good results (4: 13).
- Post-tests: on 13/11/2019 at 3:00 pm at Karbala International Stadium the post-test are made.
- **Statistical method used in the research:** The researchers used the statistical bag (SPSS) to find the appropriate statistical processes.
- **Presenting, analyze, and discuss results:** Presenting the results' differences between pre-test and post-tests of the research sample of research's variables and their analysis. Table (2) show The difference in the computation and its standard deviation and the value of (t) and the significance of the differences between the results of the pre-test and the post- tests of the research sample in the variables .

Table (2). The difference in the computation and its standard deviation and the value of (t).

Assessments		Pre-test		Post-test		(t) value	Standard error	Differences indications
Lactic endurance	Minute	1.510	0.101	2.81	0.29	4.698	0.003	Significant
Digital achievement	Second	1.590	0.231	1.539	0.211	8.543	0.000	Significant

*Significant at the level of significance (0.05) if the error level is less than (0.05)

Results Discussion

The results showed a significant difference between pre-tests and post- tests of the research sample to test the digital achievement and the non-tactical endurance test and for the post-test. The researchers attribute this difference to the effectiveness of the anaerobic exercise, especially if it is built on a systematic scientific basis through the use of appropriate and gradual stress and taking into consideration individual differences. Individual's physical ability is reflected in the results of the variables of study. This is what Essam Abdul Khaliqsaid: "Skill performance is related to physical and motor abilities of the individual" . Practitioners can attribute this result to the effectiveness of anaerobic exercise, which lasted (12) weeks with (3) weekly training modules and in the form of high-intensity infant training are important method that also aim to improve the overall endurance, The training method is one of the method used in the training of mid-range sprinters, including an enemy of 800 meters, through which the development of the aerodynamics needed by the athlete in the distance The researchers explained that the reason for the development of the non-tactical endurance is the result of a number of things, foremost of which is the type of exercise offered to the players during 24 doses Which resulted in the ability to resist the fatigue caused by the accumulation of lactic acid as a result of the exercises performed, as well as the insufficient rest to remove the accumulated acid. This means that the players repeat work with the presence of quantities of lactic acid as well as low blood pH, As This has positively affected the work of the internal organs of the body, especially in the work of the vital organizations that delay the decline of PH blood quickly by reducing the acidity caused by acid

lactic acid and converted from strong acid to weak acid, which contributed to delay the decline of blood pH And then increase physical effort. Jabbar Rahimah, asserts that the improvement of the capacity of the production of energy in lactic acid system requires the guidance of the training load, which makes the rate of accumulation of lactic acid in the muscles and blood is greater than the rate of disposal to ensure that the threshold exceeded the laconic difference.

Conclusion

There is significant effect of the black bean in the improvement of lactic stress and time of digital achievement. There is a significant effect of the dose of black bean and proposed exercises to improve the search variables and for the benefit of the post-test.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the College of physical education & sport science/Wasit University, Iraq and all experiments were carried out in accordance with approved guidelines.

Urinary Tract Infection in Spontaneous Urticaria among Thi-Qar Patients

Kadhim Ahmed Kadhim[1], Hadaf A. Al Junaiyeh[1], Alaa Naif[1], Yahya Ali[2]

[1]College of Medicine, University of Thi-Qar, [2]Al-Hussain Teaching Hospital, Thi-Qar Province, Iraq

Abstract

Urticaria is a common worldwide disease characterized by local transient skin or mucosal edema (wheal), deeper tissues involvement (angioedema), or both. It is classified into acute (initially) and chronic (after 6 weeks' duration); and into spontaneous (symptoms occur spontaneously) or inducible (in response to specific stimuli). Occasionally, infections are blamed as an underlying cause; of them are urinary tract infections (UTIs). An equal number (465) of urticaria patients and their age-sex matched controls were evaluated for presence of UTIs in a case-control observational study. Pyuria was found in (19.8%) of urticaria patients and (7.7%) of controls; while urine culture was positive in (8.2%) of urticaria patients and (2.4%) of controls. Association of urticaria with both pyuria and positive culture results were highly significant (p value < 0.001).

Keywords: *spontaneous urticaria, urinary tract infections, urinalysis, pyuria, case-control study.*

Introduction

Urticaria is characterized by local transient skin or mucosal edema (wheal), deeper tissues involvement (angioedema) or both[(1,2)].

It is a common worldwide disease with lifetime prevalence ranging from around 8% to 22%[(1,3,4)], with detrimental effect on quality of life measures (both objective functioning and subjective well-being).[2]

Different classification schemes of urticaria exist.

According to duration, urticaria is classified into acute and chronic[(2,4)]. Acute urticaria last less than 6 weeks while episodes of daily or almost daily wheals or angioedema lasting for 6 weeks or more are designated as chronic urticarial[(2-4)]. There is no qualitative difference between acute and chronic spontaneous urticaria, but acute forms tend to be more severe[1]. However, we should notice that all urticarias are acute initially with some (about 20% to 45%) become chronic after a period of time (i.e. 6 weeks)[3]. According to clinical behavior, urticaria can be classified into spontaneous (symptoms occur spontaneously) or inducible (in response to specific stimuli such as physical stimuli)[(1,3-5)].This classification (rather than etiology based) is regarded the most practical when defining groups of patients, since etiology of urticaria at time of first consultation is often unknown[(2,3)].Spontaneous urticaria (ordinary urticaria) include acute, intermittent (episodic), and chronic (idiopathic) subtypes, while inducible urticaria encompass physical and contact urticarias[(3,5)]. Urinary tract infections (UTIs) refer to growth of microorganisms (mostly bacteria) within the urinary tract. They are considered the commonest bacterial infection, though incidence is difficult to be accurately assessed since they are not reportable diseases[6]. The gold standard for the diagnosis of a UTI is the detection of the pathogen, in the presence of clinical symptoms, by urine culture (using midstream urine)[7]. Pyuria is the presence of an increased number of polymorphonuclear leukocytes in the urine (generally >10 WBC/HPF)[(8,9)]. It is evidence for genitourinary tract inflammation, not necessarily UTI, and being just present is not an indication for

treatment. Lack of pyuria, however, is strong evidence UTI is absent[8,9,14].

Methodology

Patients and Method: An age and sex-matched case-control observational analytic study arranged over a period of 2 years (since January 2017 till March 2019) to evaluate the association between urticaria and urinary tract infections.

Patients with clinical diagnosis of spontaneous urticaria was recruited from those with various types of urticaria attended specialist day clinics in 2 general hospitals and 4 specialist private dermatology clinics at Thi-Qar province in south of Iraq.

Each patient was evaluated by dermatologist to exclude patients with inducible urticaria, urticariavasculitis, and known urticarial drug reactions. All patients diagnosed as spontaneous "ordinary" urticaria, who agreed to be involved in study, were included. Repeated cases taken once.

Control group was selected randomly from patient attending these clinics who were not complaining from urticaria nor presented primarily for genitourinary complaints. Care was performed in this selection to match, whenever possible, proportions of study group regarding age, sex, and known influential factors such as pregnancy and diabetes mellitus.

Verbal consent was taken from each in both groups and extra cost was added on regarding investigation.

Data regarding age, sex, marital status, pregnancy, diabetes mellitus, were recorded and, whenever applicable, every patient was interrogated about symptoms of urinary tract infection i.e. urinary frequency, urgency, dysuria, new onset hematuria, suprapubic pain). They were examined for suprapubic and/or costovertebral tenderness, and for fever.

After carefully instructing patient regarding washing the area with soap and water and passing first part of voided urine, a clean mid-stream urine sample was collected using the commercially available sterile wide mouth leak proof 5 ml container and submitted directly (as early as possible) to the laboratory for analysis.

Initial rapid urine leucocyte esterase test was done using a test strip (Dipstick), and pyuria was regarded positive when leucocyte esterase test was positive.

Ten ml of urine sample was centrifuged for 5 minutes at 1500 rpm, 9.5 ml of supernatant was decanted, deposit was suspended and examined microscopically for presence of RBC, WBC, epithelial cells, cast, crystals, and bacteria.

White blood cell was expressed as cells per high power field (WBC/HPF), and pyuria was considered positive when number exceeds 10 (WBC/HPF).

Urine samples revealing high count of squamous epithelial cells (> 20/HPF) were regarded contaminated and urine sampling repeated with extra carful instructions regarding methodology.

Urine specimens with pyuria were inoculated on blood agar and MaConckey agar plates and incubated at 37C° for 24hours. The single pure isolated colony, when present, was transferred to nutrient agar medium for preservation and to carry out other tests. Positive cultures were recorded.

All data were tabulated, cleaned, edited and entered "IBM SPSS Statistics" program version 25 for analysis. Pearson Chi-Square Independence test (χ^2) was employed to assess the association. *P* value <0.01 were considered statistically significant.

Results

A total of 465 patients with clinical diagnosis of urticaria, which was regarded as non-inducible (i.e. spontaneous), was recruited for study.

Their age ranged from 3 to 77 years with a mean age of 35.74 (±SD 17.450) years. Regarding the control group (No.=465) their age ranged from 3 to 75 years with a mean age of 35.21 (±SD 17.234) years. Distributions, regarding the age group, were comparable. (Table 1).

Table 1: Distribution of both urticaria and control groups according to age.

Age (Year)	Urticaria Group		Control Group	
	No.	Percent	No.	Percent
1-10	57	12.3	59	12.7
11-20	29	6.2	30	6.5
21-30	70	15.1	70	15.1
31-40	117	25.2	116	24.9
41-50	98	21.1	101	21.7
51-60	52	11.2	50	10.8
61-70	33	7.1	32	6.9
71-	9	1.9	7	1.5
Total	**465**	**100.0**	**465**	**100.0**

Females constituted majority with 322 (69.2%) patients in the study group leaving males with 143 (30.8%) patients. Comparable figures are found in control group: 324 (69.7%) patients and 141 (30.3) patients for females and males respectively.

Pyuria was regarded positive in 92 (19.8%) patients of the urticaria group, while it was found only in 36 (7.7%) of the control group. (Figure 1).

A highly significant association between urticaria and pyuria was observed, ($\chi 2(1) = 28.410$, $p < 0.001$). (Table 2).

Regarding symptoms attributed to urinary tract infections: out of 92 urticaria patients with pyuria, 30 (32.6%) patients denied any such symptom. Out of 38 patients with positive urine culture, 11 (28.9%) revealed same negative symptomatic history.

Pregnant females constituted 12 from those 30 asymptomatic pyuria, and 5 of the 11 asymptomatic positive urine culture subgroups.

Regarding the isolated pathogens in positive culture results, these were dominated, in the urticaria group, by *Escherichia coli* which found in 20 (52.6%), followed by *Staphylococcus aureus* In 9 (23.6%), *Pseudomonas Spp.* In 5 (13.1%), *Klebsiella Spp.* In 3 (7.8%), then *Proteus* in 1(2.6%). In the control group, *Escherichia coli* was found in 7 (63.6%), followed by *Staphylococcus aureus* In 4 (36.6%), and *Pseudomonas Spp.* In 2 (18.1%).

Discussion

Association between infections (bacterial, viral, parasitic, or fungal) and ordinary (spontaneous) urticaria (acute or chronic) has been noted long before, as early as in the 1920ies[3,10,11].Their role had been discussed and included in most reviews[11], Never the less, proving a cause and effect relationship is often difficult, and inappropriate "blaming" a condition for causing urticaria may occur[3].

Nearly all of the numerous studies reporting evidence for infectious agents triggering urticaria are case reports or retrospective observational studies without appropriate controls.[12] The relevance and frequency of infectious diseases varies between different patient groups and different geographical regions[1,4,6]. Urinary tract infection has been reported in number of publications as a cause in both acute and in chronic spontaneous (less in inducible) urticaria and angioedema[10]. As far as there is no possibility to challenge the patient with the suspected pathogen, thus making definitive recommendations regarding the role of infection in urticaria needs more research[2,10].

Urinary tract infection, remarked initially by pyuria

and positive leukocyte esterase test was frequently noted to be found in cases of urticariaattending our clinics. The current study was arranged to test the substantial role and the "weight" of this association which, as we thought, did not receive the deserved attention in available studies.

Over period of 2 years we were able to collect a cohort of 465 patients with acute and chronic urticaria, which could be regarded as a reasonable sample of patient that get over many epidemiologic studies[2,6,10,12] and enable studying the demographic characters of urticaria among our community.

Females (322 patients) outnumber males (143 patients) with a ratio of 2.2:1. Most epidemiologic studies reported similar predominance of females with variable ratios[1-6], though some excludes acute urticaria and extremes of age from this female predominance[3].

Age groups affected were dominated by third to fifth decade, this may in part be due to more tendency to consult earlier in those age groups. So that many cases of urticaria that develop on just a single or a few occasions diminish within a week may be overlooked and not included. Most studies reported such peak age between 20 and 40 in chronic spontaneous urticarial[1,6]. When all types of urticaria were surveyed, a bimodal age distribution in patients aged birth to 9 years and 30 to 40 years was revealed [1,3]. acute spontaneous urticaria (along with urticarial reactions) may represent the first peak[1].

The term pyuria literally means "pus in the urine" but, in common usage, the focus is not on the presence of pus but on the number of white blood cells (WBCs) or amount of leukocyte esterase (LE) that exceeds a threshold and suggests a urinary tract infection (UTI) [8,9].

Pyuria was detected (both by urine microscopy and by leukocyte esterase test) in 92 (19.8%) patients of the urticaria group, while it was found only in 36 (7.7%) of the control group. Statistical analysis of the two rate values revealed a highly significant association (with a *p* value < 0.001) between urticaria and pyuria.

Using evidence of inflammation (pyuria) in the urine to screen for who needs a culture seems justified on the basis of practicality at point of care and likelihood of UTI[9,13]. The absence of pyuria is a strong indicator that a UTI is not present and is useful in ruling out a UTI[8,9,14].

Also If there are, in fact, some true UTIs without evidence of inflammation from the urinalysis, are they as harmful as those with "pyuria"? Animal data demonstrate it is the inflammatory response, not the presence of organisms, that causes the harmful effects and renal damage[9].

Adding to that asymptomatic bacteriuria (positive urine cultures, with or without pyuria, without accompanying genitourinary symptoms attributable to infection) is regarded as harmless and is not an indication for treatment[8,14].

Available data about prevalence of pyuria in general community is scare, but in our study it was found in (7.7%) of the randomly selected control group (465 patients) who were seeking medical advice for conditions not related to genitourinary complaints.

Culture: Despite availability of molecular diagnostic approaches for diagnosis of many infections, UTI are still generally diagnosed, as they have been for decades, by urine culture results[7-9]. However, urine culture may not be necessary as part of the evaluation of outpatients with uncomplicated UTIs[13,14].

Positive urine culture results were obtained from 38 (8.2%) patient in the urticaria group, while such results were found in 11 (2.4%) urine samples from the control group. When these figures were statistically tested, the association between urticaria and positive urine culture was found to be a highly significant association, (with a p value < 0.001).

Comparison of these results with data obtained from other studies is impeded by variable differences between study designs [15].

Prevalence of community-associated UTI was reported to be 0.7%, However frequency of UTIs vary according to geographical setting and location, and providing exact figures is challenging[6,16]. Positive culture results were found in 11 (2.4%) urine samples from the control group, those were assumed to be asymptomatic since they were attending clinics for complaints not primarily related to genitourinary complaints. However, when those with positive culture results were carefully questioned about symptoms related to UTIs, positive and negative replies were obtained and thus constituting a hybrid between UTIs and asymptomatic bacteriuria.

Pyuria has multiple causes[17,] and we concentrate in current study on UTIs but others should be considered in cases where culture is Negative

The exact mechanism of how infectious agents cause urticaria is not known[10,11]. It is accepted that hives are caused by "friendly fire" from the human body's own defenses rather than caused directly by the infectious agents. It has been postulated that these agents trigger release of histamine and leukotrienes from the mast cells and basophils by IgE antigen complex; or through anaphylotoxin C3a, C4a generated through activation of complement system or through the kinins, e.g., bradykinin[11,18].

Conclusion

Though establishing a causal relationship through experimental study is difficult, this study showed a highly significant association between bacterial UTI and spontaneous urticaria.

Further prospective studies to elucidate effect of eradicating UTIs on course of urticaria is advisable.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the College of Medicine, University of Thi-Qar, Iraq and all experiments were carried out in accordance with approved guidelines.

Antimicrobial Peptides AMPs Produced by Bacillus spp.

Amel H. Mussa

Department of Microbiology, College of Science, Al-Mustansiriyah University, Iraq

Abstract

Bacillus species are one of the most interesting Gram-positive bacteria, forming endospore which are usually capable to produce variety of secondary metabolite compound such as antibiotic, enzymes which playing important roles In pharmaceutical industry, subtilin, bacilysin, gramicidin, tyrocidine, bacitracine, polymyxin, etc. The Bacillus species have a wide range of antimicrobial activisms since they are used as antibacterial, antifungal, antiviral, antimycoplasma and anti ameobocytic agents .The production of this active compounds involve orangutans peptides, that divieded into two class firest class ribosomally generated and post-translationally altered which include (lantibiotics and lantibiotic-like peptides),second class non-ribosomally procreated, besides a various number of non-peptidicsubestansis like polyketides, an amino - sugar, and a phospholipid. In this review abridge the structures of antimicrobial peptide produced from *Bacillus,* the genetics encoded and analysis their generative and the current finding of antimicrobial activity for each peptide.

Keywords: *Antimicrobial, Peptides, AMPs, Bacillus spp.*

Introduction

The excessive uses of antibiotics have led to the appearance of highly reactance species of athogenic bacteria as well as, these strains could Easley rapidly gained extra resistance to the newcomer synthetic antibiotics[1]. The distinguished of new active compound is the most obvious curriculum to fighter this excesses antibiotics resistance[2,3] the Rhizosphere region of plant root is the source of Most important of microorganisms found, it had determined significant consideration due to the ability to produced secondary metabolites like antibiotics and enzymes which played important role in plant and human life[4] the important of the bacillus as genus is attribioted to forming spores and to the great part playing in agricultural, indesterialand pharmacy aspect. Bacillus spp. consider one of the most complicated bacteria at the diversity in genetics, structural, activity, sorting, and environmental level, allowing them to be very consequential in various habitat, notably in soil (5).antibiotics such as subtilin, bacilysin, gramicidin, tyrocidine, bacitracine, polymyxin, could produced by Bacillus species and exhibition antibacterial, antifungal, antihelmenthic and phytotoxic activity. [6]sequence of genomic have expressed that *Bacillus spp* have highly numerous of genes associated in the accumulative of different metabolites such as antibiotic [7,8]. According to their structural form and biosynthetic mechanism, this compound could be classified include dominantly ribosomally producing peptide involving bacteriocins,or non-ribosomally synthesized comprises small microbial peptides synthesized enzymatically, besides numerous of non peptdes compounds for example polyketides, an amino sugar, and a phospholipid [9]. The aims of this review is to describe the synthesis and chemical structural of various antimicrobial peptides produced from different species of *Bacillus* . Peptide antibiotics exampled the prevailing class. They showed highly rigid, hydrophobic and cyclic structures with extraordinary constituents such as D-amino acids and are commonly resistant to hydrolysis by enzymes like peptidases and proteases (10). Moreover, amino acid cysteine residues could oxidized to disulphides or could be amended to property intermolecular C–S (thioether) bonds, and consequently the peptide compound non-sensitive to oxidation. Basically, two varied pathways for synthesis allows the founding of an extraordinary substances 1- the ribosomal synthesis of linear precursor peptides that are subjected to post-translational modification and

proteolytic processing . 2- the non-ribosomal synthesis of peptides by large megaenzymes, the non-ribosomal peptide synthetases (NRPSs) .[7]

Ribosomal Peptide Antibiotics: Ribosomally synthesized peptide antibiotics are extensively circulation in natures, include among 12 and 50 amino acid residues. They are customarily cationic and displayed great structural variety [11]. Bacteriocins are ribosomally synthesized AMPs that are produced by bacteria and are usually active against strains of bacteria that are closely related to the producer strains [12,13].

Bacteriocins had specific characteristic made it suitable alternate to antibiotics and prevent the growth of bacteria, even against certain multidrug resistant bacteria in the same related species or wide spectrum of effectiveness . They are usually heat-stable, small peptides made of short chains almost about 20-60 amino acid residues; as well as long chains can also be found. Most bacteriocins are products from Gram-positive bacteria, whoever, Some bacteriocins could produced from Gram-negative bacteria.[14,15]. There is no effect of bacteriocins on mankind due this cells do not have a receptor recognized it [16,17]. Thates make bacillus be ideal and perfect as stotred for new and effectively bacteriocins. Based on discriminated structural and functional particularity,Bacteriocinsare categorize into two category, category 1 and 2 [16]. Mostly of the bacteriocins generative from *Bacillus* spp resources to the category 1,dubbed lantibiotics[18]Lantibiotics are peptide-derived antimicrobial agents that are ribosomally synthesized and post translationally modified to biological form of activity . Lantibiotics was abbreviator of lanthionine-containing antibiotic peptides.[1]Lanthionines consist of two alanine residues of amino acid that are linked at the β-carbons by a thioether bon . [19] (Figure 1) .production of bacteriocins controlled by regulatory system consisting of a histidineprotein kinase (HPK) and a response regulator (RR) in the presence of the specific autoinducer peptide (AIP).

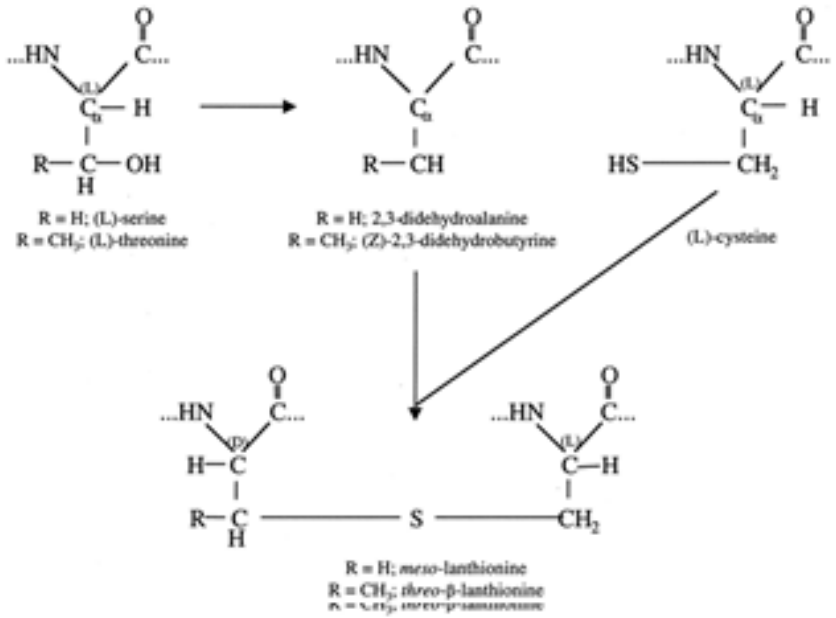

Figure 1: Chemicalstracture of lantibiotics

The class II bacteriocins could be further divided into four subclasses, class a : (active against *Listeria* and pediocin-like),class b consist of two peptide, class c (cyclic), and class d (nonpediocin single linear). [16].lantibiotics can be additionally divided in to two sub division A and B for their commonality structure, molecular weighing and biologic activism . sub division A lantibiotic (molecular weight 2100 – 3500 Dalton; almost 20 – 37 a.a residue) exhibit a more linearity the secondary structure with net charge be positive compare with sub division B includes globular broadly uncharged lantibiotics[20].

Subtilin: Subtilin is synthesized by B.*subtilis* ATTC 6633,considered very important advertency and focoucing antibiotics.Subtilin is a small peptide antibiotic (figure 2),It chemical structure consists of 32 amino acid of pentacyclic[23] . Subtilin is settled to acid and temperature manipulating above to 121ºC for one houre, and showed activity against various number of Gram positive bacteria consisting bacillus spp. . The mechanism of subtilin action appeared very complex, including the associating to a appointed target cell as well as lipid II which is targeted by vancomycinantibiotic,which is stracture belongs to kind glycopeptide[21] numerous genetic studies reveal that clump of ten genes *spa* BTCSIFEGRK controlled Subtilingeneration and its locus the chromosome, transcription occurs with 2 promoters. Subtilin regulates/activates its own biosynthesis via a two component regulatory system. The aggregation of the genes domination the production of various proteins developable in the processes of maturation as well as production of such compound [24-27],

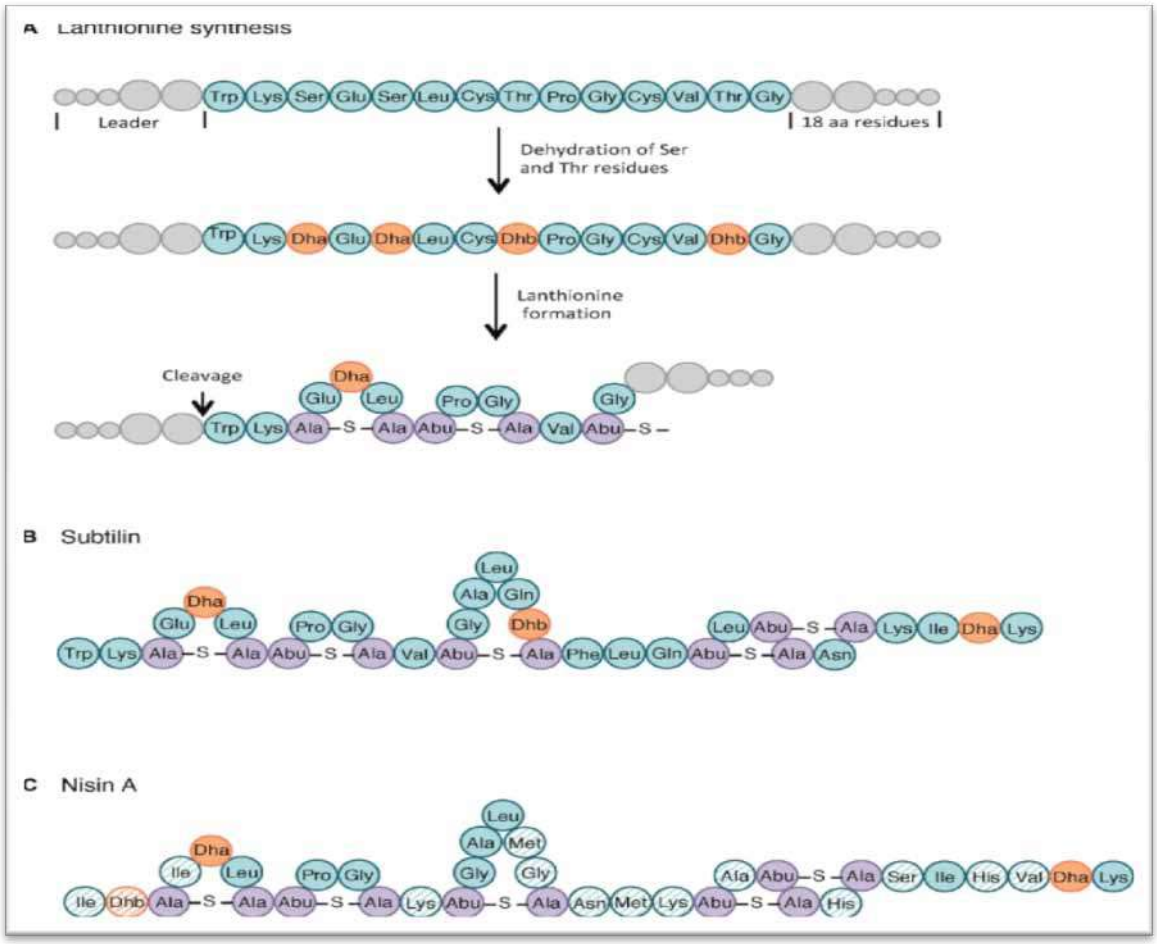

Fig 2 :generated of Lanthionine. (A) Commonality pathway of the lanthionine production. (B) the chemical structure of subtilin (C) the chemical stracture of nisin A . Adopted from [27,28].

Ericin: Ericin S and ericin A are two lantibiotic belong to type A its synthesized by Strain of *B. subtilis* A 1/3 with sturdy resembles to subtilin . The genetic studies reveals that the gens encoded ericin gene is clump consist of two structural gene *eri* S and *eri* A (29). Purified ericin (mainly ericin S) have antimicrobial activity athwart a different species of bacteria, particularity against athwart *Clavibactermichiganesis*, the causative assignee of tomato bacterial sore [30].

Mersacidin: Mersacidin is a tetracyclic peptide,output by *Bacillus* sp. strain HIL Y-85,54728

this lamtibioticis the one of the most smaller of lantibiotic known so far,the M.W is (1825 Dalton). It is an uncharged molecule of twenty amino acids constituting four intra molecular thioether bridges, which impart a globular structure to the molecule [31]

It enumerator to the lantibiotics family group of peptides containing lanthionine- with antimicrobial activisms [32]Group type B lantibioticsinclodeMersacidin, actagardine, and the cinnamycin., which consist of flintier globular peptides without net charge or a net negatively charge. In contrast, type A lantibiotics areflexile, elongated peptides that act by constitute pores in the bacterial membrane. As well as,lanthioninelantibiotics encompasses a numeral of uncommon amino acids, such as didehydroalanine, didehydrobutyrine, methyllanthionine, *S*-aminovinylcysteine, etc[33,34]. The meracidin gene cluster involved of the structural gene *mrs* A (figure 3), besides genes implicated in beyond translational alteration (*mrs* D with *mrs* M), regulation (*mrs* R1, *mrs* R2, *mrs* K2), transport (*mrs* T) and immunity (*mrs* FEG) [35] . Mersacidinproduced its activism on bacterial cell through prevention the synthesized of cell wall; meracidin could configure the compiler with lipid II as previously shown for subtilin. numerous studies declared the important of meracidin in prevention the growth of Gram positive bacteria ones enterococci expressing the V and A vancomycin resistance phenotype, besides MRSA, strain of Staphylococcus aureus which resistant to methicillin.

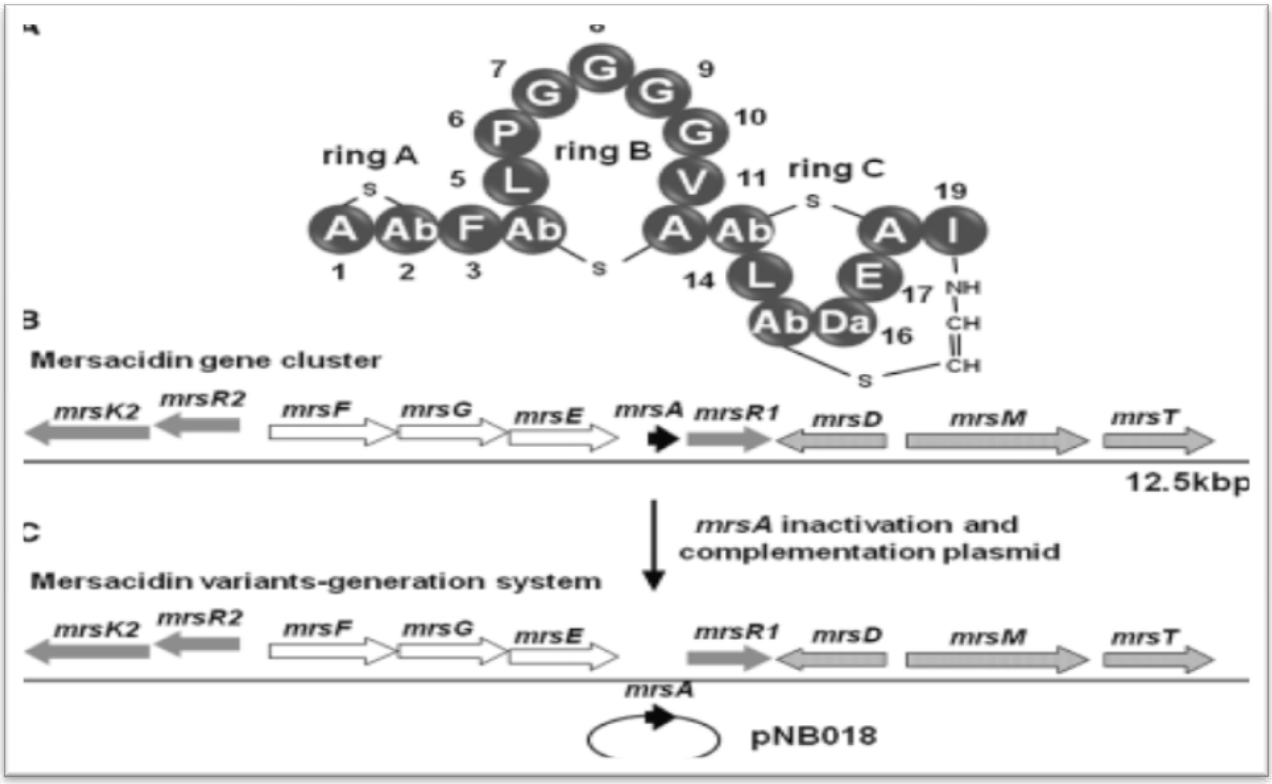

Figure 3. The Structure of Mersacidin and the Gene Cluster:(A) Primary structure of mersacidin (B) Organization of the mersacidin biosynthetic gene clump.(C) Engineered system for generating mersacidin mutants. Da, dehydroalanine; Ab, 2-aminobutyrate

Subtilosin A: Subtilosin A is unusual lantibiotics composed of number of amino acid almost 35 inherently produced from Bacillus subtilis and from Bacillus atrophaeus and isolated from Bacillus amyloliquefaciens. Stracture of Subtilosin A is peptide contain macrocyclic, and there is no found lanthionine and methyllanthionine residues, Subtilosin A is configurative from its precursor by proteolytic splitting of the N-terminal leader peptide and cyclization through covalently bond between the N-terminal asparagine and the C-terminal glycine.

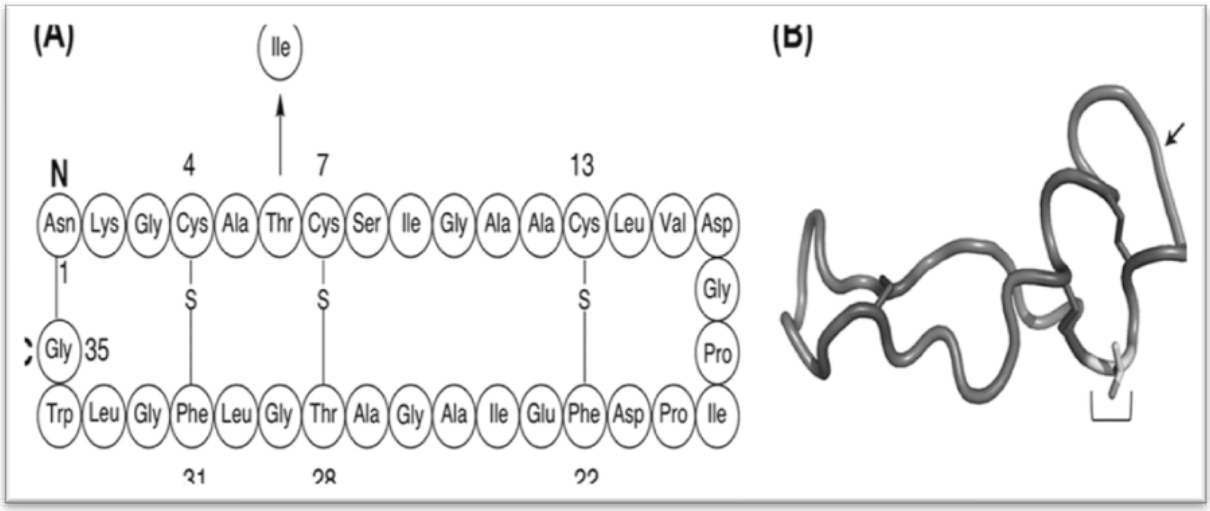

Figure 4: Structures of subtilosin A. (A) Amino acid concatenation ofsubtilosin A. The backbone cyclization of the peptide via an amide bond betwxit the N and C limit. (B) Backbone involuted hulk of subtilosinA .

Sublancin 168: Sublancin 168 it is unusual lantibiotics secreted by the strain *B. subtilis* 168, incorporates singular lanthionine bond and two extraordinary disulfide pont. Sublancin 168 is a novel and distinctively S-linked bacteriocinglycopeptide comprises of 37 amino acids(45). using N M R declared that Sublancin 168 comprises of two α-helices and ring well-defined inter helices . The two helices span residues 5−16 and 24−34, and the ring region comprises residues 17−25 amino acid . The 9 amino-acid loop region comprise a β-S-linked glucose moiety attached to Cys22. The three-dimensional structure provides unusual high stability of sublancin 168. .this lantibiotic had good antimicrobial activity against some species of Gram positive bacteria, involving B. megaterium, B. subtilis 6633, and *S. pyogenes,* and *S. aureus*, this activity of this compound would be very important in different applications, in agronomic and industrial field.

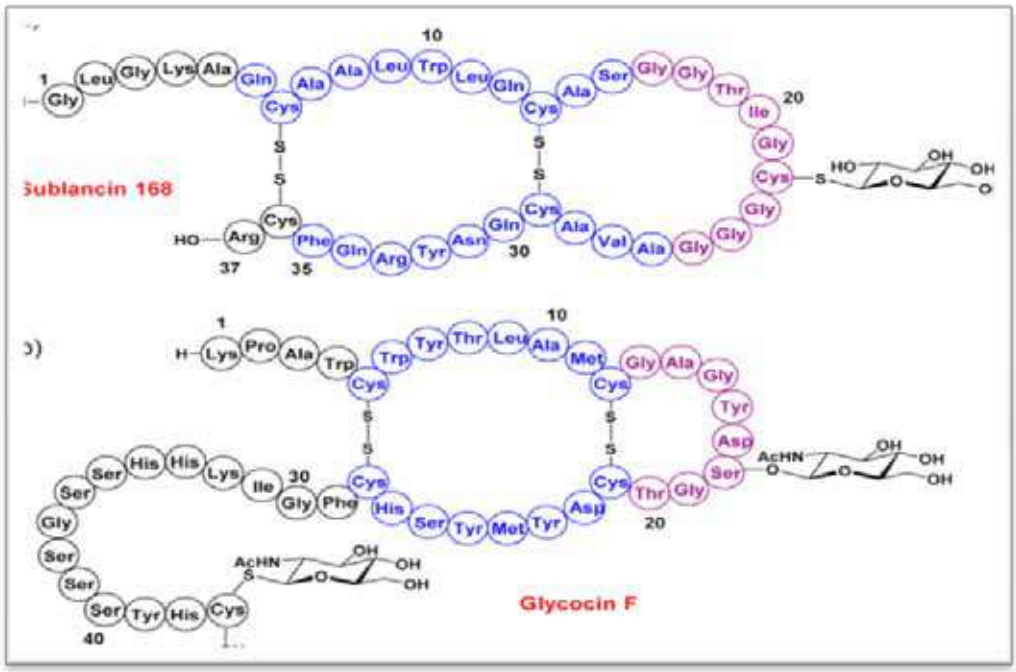

Figure 4: Chemical structures of Glycocin. (a) Sublancin 168. (b) GlycocinF.

Some species of bacillus could produced proteins with antimicrobial activity,it is characterized and identified insufficiently,its known as bacteriocin – like inhibitory compound (BLIS). One of this substances is from *B. cereus is* able to produce BLIS which have interested ascrible to the probable implementation as ordinary food preservatives,. *B. licheniformis*, also produced BLIS this bacteria dissociated from water buffalo rumen, lichenin synthesis by this bacteria under anaerobically requirement, the activism of this peptide athwart wide variety of microbes found in buffalo rumen attributed to the ability to tolerant abroad range of pH and high temperature.Gene sequences of *B. thuringiensis is* identical to *B. cereus*,tochicin and thuricins family include H, S nd 17, is BLIS generated from *B. thuringiensis* with abroad inhibitory spectrum . theeffectiffines of Thuricin H on variety species belong to Gram positive bacteria include *Staph . aureus* and *Listeria spp*. Thuricin S is heat stable, prevent the accreation of bacteria belong to gram positive,involving *Salmonella enterica*, *Listeria . monocytogenes* and *Pseudomonas aeruginosa*; while thuricin 17 it's activity athwart other species of *Bacillus*.

Non – Ribosomal Peptide Antibiotics: Nonribosomal peptides (NRP) are a class of peptide, ordinary synthesized by bacteria and fungi. Non ribosomal peptide synthetizes (NRPSs) are involved in the biosynthesis of numerous peptide and peptide-like natural products that have been utilized in medicine, agriculture, and biotechnology, besides other fields.

Numerous Strains of *Bacillus*spp generative NRP thru serial steps mechanism consisting the choosing the amino acid and adsorption of residues such as macrolactones (surfactins and fengycins) and cyclic lipopeptidides (iturin group).

Cycliclipopeptides (CLPs): Cyclic lipopeptides (CLPs) are one of the significant type of biosurfactants which possess special surface-active as well as activity against fungal. CLPs are produced through non-ribosomal peptide synthetases (NRPs), and produced particular variety of CLP products differentiated according to the sequences of amino acid, length ramified chain of fatty acids and the kind of bonds which bind the amino acids.

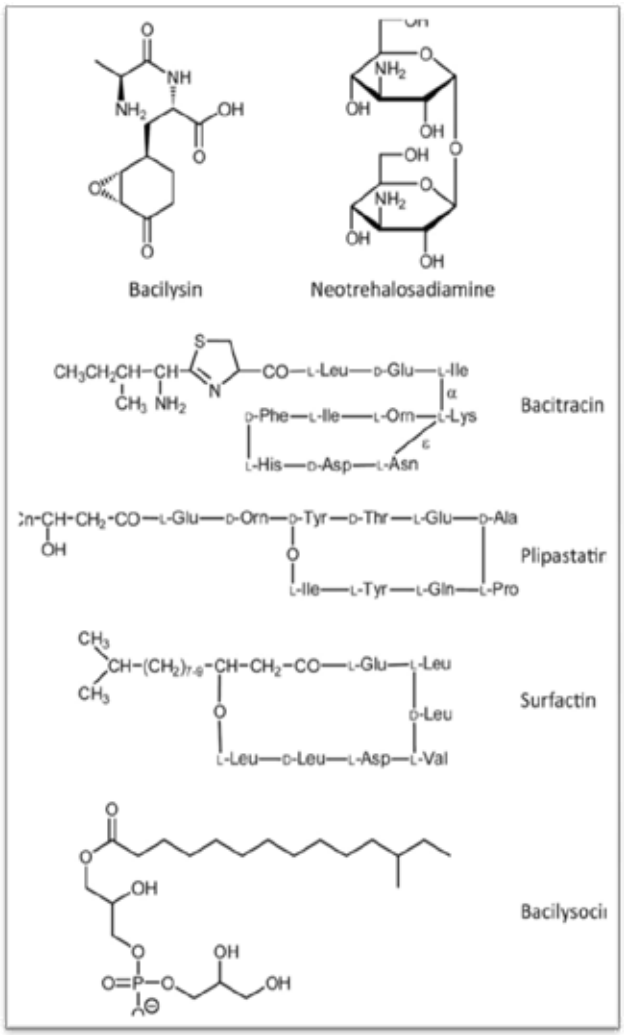

Figure 5. chemical Structures of some non-ribosomal peptides synthesis by variable strains of B. subtilis . adopted from(86)

Conclusion

The Bacillus species have a wide range of antimicrobial activisms since they are used as antibacterial, antifungal, antiviral, antimycoplasma and anti ameobocytic agents .The production of this active compounds involve orangutans peptides, that divieded into two class .firest class ribosomally generated and post-translationally altered which include (lantibiotics and lantibiotic-like peptides),second class non-ribosomally procreated, besides a various number of non-peptidicsubestansis like polyketides, an amino - sugar, and a phospholipid. In this review abridge the structures of antimicrobial peptide produced from *Bacillus,* the genetics encoded and analysis their generative and the current finding of antimicrobial activity for each peptide.

Effect of Infliximab and Methotrexate on Bone Mineral Density in Rheumatoid Arthritis Patients

Israa Mohammed Redia[1], Mayyadah Jebur Abed Al-Zubaidi[2], Mohammed H. Al Osami[3]

[1]Mirjan Medical City, [2]Al Karama Teaching Hospital, [3]Baghdad Medical College, Iraq

Abstract

Background: Osteoporosis is an extra-articular complication of rheumatoid arthritis that results in increased risk of fractures and associated morbidity, mortality, and healthcare costs. The study aims at evaluation of changes in bone mineral density in a Rheumatoid arthritis patients on inflixmab and methotrexate.

Patients and Method: A cross sectional study enrolled 60 RApatients diagnosed according to the ACR 1987/2010 revised criteria for the classification of RA. Thirty patient were on infliximab and other (30 patient) on methotrexate. Dermatographic and clinical data were collected (disease duration, disease activity score index of 28 joints (DAS 28) and (CDI), functional class, body mass index and treatment history. Patients with histories of chronic disease and smokers were excluded. Complete blood count, erythrocyte sedimentation rate serum calcium, phosphorous, alkaline phosphatate, vitamin D level were measured in both groups. Bone mineral density was measured by dual energy x-ray absorptiometry of hip and lumber spines for patients. Tor Z–score equal or less than (-2.5 standard deviation) of healthy young adults was taken as osteoporotic, and scores between (-1 to -2.5 standard deviation) was taken as osteopenic. Informed consent was obtained from individuals.

Results: The analysis of Dual energy x-ray absorptiometry of hips and lumber spines revealed that the number of RA patients on Inflixmab having osteoporosis was 1 (3%) and 12 (40%) were osteopenic, compared to patients on MTX osteoporosis was present in 8 (26%) and osteopenia in 13 (43%), which is a significant difference, p-value (0.019). Vitamin D level in patient on Inflixmab was low in 24 (80%) and normal in 6 (20%) patients. While in MTX it was low in 13 (43.3%) and normal in 17 (56.7%) of patients, p-value (0.003).

Conclusions: There was significant decrease in bone mineral density in RA patients on MTX while inflixmab had a role in arrest in bone loss.

Keywords: *RA, MTX, Infliximab, Methotrexate.*

Introduction

Rheumatoid arthritis (RA) is a symmetric chronic autoimmune inflammatory poly arthritis of unknown etiology primarily affecting the small joints of hands and feet. Larger joints can be involved such as the ankles, shoulder, and knees. It is progressive disease that can lead to joint destruction, deformity, and disability, with heterogeneous manifestations[1,2]. In Iraqi patients, the prevalence is 1%.[3] The exact cause remains unknown, but the genetic, environmental and immunological factors that play a role.[4] The American Rheumatism Association 1987 revised criteria for the diagnosis of RA.[5] American college of rheumatology/European league against rheumatism collaborative initiative classification criteria (2010 ACR/EULAR) and Score for RA.[6] Two of commonly used drugs for treatment are the followings; 1st; Methotrexate-A dihydrofolatereductase

inhibitor originally used for its anti-proliferative effects in the treatment of cancer, methotrexate is now an anchor drug among DMARDs and a gold standard against which all emerging therapies are compared.

An oral drug administered on a weekly basis, its anti-inflammatory mechanisms of action and are largely related to its induction of adenosine release to the inflammatory. The 2nd drug is (Infliximab) is a chimeric monoclonal antibody, infliximab is also cytotoxic for TNF-expressing cells. Infliximab is administered as an intravenous infusion every 8 weeks (after an initial loading regimen). Infliximab standard dose (3mg/kg), can be titrated up to 10 mg/kg, if needed and/or the dosing interval can be decreased (to every 6 or every 4 weeks). Infliximab is recommended to be administered concurrently with methotrexate (at least 7.5 mg/week) to prevent neutralizing antibodies development.[7] Osteoporosis (OP) is a common complication of RA. OP mechanisms in RA are not fully understood, but it is thought that osteoclast dysfunction with cytokines that mediated them are the principal pathogenesis factors of this bone disease. [8] RA bone loss is of multifactorial nature, but the inflammation has a major role in its development. Bone loss progression in RA patients is more severe, & are associated with greater risk of bone loss. So, the presence of initial radiographic damage, antibodies to cyclic citrullinated peptide (anti-CCP), C-reactive protein (CRP) levels, and other inflammatory markers are used to identify patients at greatest risk for developing progressive joint damage.[9,10]

Heidari B et al & Dolan L et al found that [10,11] treatment of RA patients with DMARDs for two years will decreased the levels of bone resorption markers like deoxypyridinoidine (D-PYR) significantly. However, decreasing disease activity by suppression of inflammatory process in RA is expected to preserve further bone mass. TNF has profound effects on bone. TNF Over-expression cause local & generalized bone erosion. Therefore, TNF is an important link between chronic inflammation and bone loss. TNF is also act as central inflammatory mediator of RA and its therapeutic inhibition leads to dramatic improvement in RA signs and symptoms.[12,13] OP is an early and common feature in RA and occurs in two forms during the course of the disease:[14] 1st; Periarticular osteopenia [15], 2nd Generalized OP: is an extra-articular RA complication which affects the axial and appendicular bones that cause an increased risk of fractures and related morbidity, mortality, and healthcare costs .[16].

Patients and Method: A cross sectional study was conducted on 60 RA patients at rheumatology outpatients clinic, in Baghdad Teaching Hospital from July 2013-July 2014. Thirty RA patient were treated by biological agent (inflixmab) and 30 patient on non biological DMARD (methotrexate). RA patients diagnosed according to American College of Rheumatology 1987, 2010(5,6) criteria. All female patients were of 50-years-old (premenopausal) and male of under 55. All RA patients were subjected to the following: detailed history and clinical examination, calculation of body mass index, bone mineral density measurement of lumbar spine (L1-4) (L2-4) and right proximal femur (femoral neck,greater trochanter and total). Osteoporosis was diagnosed according to WHO guidelines criteria for osteoporosis diagnosis (17), and DEXA machine (Dexxum) 3, Korean company (osteosys) was used.

Laboratory investigation: the following investigation done for all patients; 1. complete blood count (CBC), 2. Erythrocyte sedimentation rate (ESR), 3. Total serum calcium (N=8.4-10.2 mg/dl), 4. Total serum phosphorus (N=2.3-4.7mg/dl), 5.Total serum alkaline phosphatase (N=40-150 IU/L), 6.Total serum 25-hydroxyvitamin D was measured by ELIZA The kit was derived from Euroimmun Medizinische Labordiagnostika AG (Germany), Serum vitamin D level (N=22-42 ng/ml) while level of less than 22 ng/ml consider low. Statistical analysis was carried out using SPSS version 20. A *p*-value of ≤ 0.05 was considered as significant

Results

Table 1 shows the distribution of RA patients by vitamin D, Calcium, phosphorous as well as alkaline phosphatase. Vitamin D mean was (20.92±3.95) mg/dl and (61.7%) of patients had low vitamin D. Serum calcium mean was (8.25±1.12) mg/dl and (58.3%) of patients had normal serum calcium. Serum phosphorous mean was (3.54±0.78) mg/dl and (96.7%) of patients had normal phosphorous. ALP mean was (78.57±31.82) mg/dl and (88.3%) of patients had normal ALP.

Table 1: RA Patients distribution by Vitamin D, Calcium, Phosphorous and Alkaline Phosphatase

Variable	Mean±SD	Frequency (%)

Discussion

This study showed that patients with rheumatoid arthritis on biological agents (anti TNF alpha) had arrest bone loss while in non biological (DMARD) showed decrease in bone mineral density. In this study the mean age of RA patients was (40.70+9.09)years. and female: male ratio was 3:1 similar to O.Dell'sT.R,etal that show RA is more common in women (female:male ratio was 3:1) and RA occurs at any age but typically late child bearing years .[18] The bone mineral density was significantly associated with types of therapy,which showed non significant decrease in bone loss in RA patients on biological agents (anti TNF alpha) .this finding is in agreement with that of Wijbrandts CA etal who found TNF blockade may result in an arrest of general bone loss in patients used infliximab in combination with methotrexate, lumbar spine and femoral BMD remained unchanged.[19] Also Large UJ et al showed significant BMD increase in femoral neck and on ameliorating trend in the spine in patients with rheumatoid arthritis on infliximab.[20] Hougeberg G,et al found strong evidence of causal link between inflammation and bone loss in

RA patients,anti inflammatory effects of infliximab was potent enough to arrest inflammatory bone loss at hip but not at the spine and hand .[21] The current study found significant association between RA patients on DMARDS (MTX) and decrease in BMD, this finding agree with Cranney AB et al who found that BMD of femoral neck did not differ significantly between MTX treated group and RA patients without treatment.[22]

Morgan SL et al found in their study that BMD significantly higher in RA patient who did not receive MTX versus those who received MTX. [23] The current study showed that body mass index showed non statistically significant difference with types of therapy used and 46% of patients with biological and non biological DMARD were obese this finding is consistent with the recent finding of Senturk T et al that anti TNF alpha treatment may have indirect positive effect on lean mass, throughout the general health improvement of patients leading to increase appetite .[24] and Briot K et al who found that Anti TNF agents in inflammatory rheumatic diseases are associated with increase in BMI which result from decrease bone resorption and increase in body weight and lean mass which is observed in parallel with increase in IGF-1.[25] and also found high BMI in MTX treated group attributed to reduction of disease activity.[26] The current study found significant association between anti TNF alpha and decrease vitamin D level, this result disagree with Vacca A et al who found that in inflammatory rheumatic disease anti TNF alpha agents seem to improve vitamin D level as well as disease activity but it remain controversial.[27]

Low vitamin D in patient with anti TNF alpha in the current study may be due to decrease sun exposure (majority of the females patients are veiled) and may be part of disease activity and long duration RA which leads to deformity and immobility. Other explanation was most of patients used NSAIDS that influenced liver metabolism of vitamin D.[28] and recent study show absence of overall decrease in bone mineral density associated with low vitamin D level. [29] This study results revealed statistically non-significant decrease in vitamin D level in RA patients on non biological (DMARD), which is agree with Raczkiewics A et al who found adequate DMARD therapy (without steroid) seem to have beneficial effect on vitamin D level .[30] In this study there is non-significant changes in calcium, phosphorous, and alkaline phosphatase level in RA patients on biological and non biological agent, which is similar to Lange U et al findings. [20]

Conclusion

There was significant decrease in bone mineral density in RA patients on MTX while inflixmab had a role in arrest in bone loss.

Effects of Infliximab on Rheumatoid Factor & Anti-cyclic Citrullinated Peptide Antibodies in Patients with Rheumatoid Arthritis

Mayyadah Jebur Abed AL-Zubaidi [1],Israa Mohammed Redia[2], Sami Salman[3]

[1]Al Karama Teaching Hospital, [2]Mirjan Medical City, [3]Baghdad Medical College, Iraq

Abstract

Background: Anti-cyclic citrullinated peptide antibodies (ACPA) and rheumatoid factor (RF) are two important investigations that help in confirming the diagnosis and may help deciding strategies for the treatment. This study's aim is to investigate the effect of infliximab, a tumor necrosis factor inhibitor on ACPA and RF in patients with rheumatoid arthritis.

Patients and Method: Thirty five Iraqi patients with established RA, enrolled in this study during September 2013-May 2014. They received 3 mg/kg infliximab intravenously at weeks 0, 2, 6, and every 8 weeks thereafter in combination with methotrexate (15-20) mg. At baseline, week 24, CRP and ESR were determined and the disease activity score (DAS28) was calculated. Serum samples collected at the same time points were used to measure ACPA, and IgM-RF (ELISA).

Results: RF mean at the first visit was (106.1±25.2) IU/ml and at the second visit it reduced to (60.1±14.6) IU/ml and the difference was statistically significant, (P=0.038). ACPA mean was (466.5±61.4) U/ml at the first visit reduced significantly to reach (241.9±36.6) U/ml at the second visit (P<0.001). A dramatic and significant change had been found in the disease activity; (P<0.001) mean DAS 28 was (5.7±1.1) at the first visit with a range of (2.7– 8.6), at the second visit the mean was (4.5±1) and the range was (2.04–6.4).

Conclusions: Anti-TNF a treatment in RA cause decrease in serum titers of RF and ACPA in patients with clinical improvement.

Keywords: *Anti-TNF a treatment, RF, ACPA.*

Introduction

Today, a much more aggressive treatment approach is advocated for people with rheumatoid arthritis (RA), with prescription of non-biologic DMARDs within three months of diagnosis to reduce disease activity and prevent joint deformity[1]. The 2012 revision updated the 2008 ACR recommendations, the 2012 update addressed use of DMARDs and biologic agents, switching between therapies, the use of biologic agents in high-risk patients, TB screening with the use of biologic agents, and vaccination in patients with RA receiving DMARDs or biologic agents[2].

Infliximab: is a chimeric monoclonal antibody, specifically binds to both soluble and membrane-bound TNFα with high affinity forming stable non disassociating immune complexes. Infliximab was approved by the U.S. Food and Drug Administration for the treatment of (RA). Treatment regime consists of intravenous infusions at 0, 2 and 6 weeks. Subsequent infusions are given 6 or 8 weeks thereafter, depending on clinical response. Infliximab dose is usually 3mg/kg iv (dose range 3-10mg/kg)[3].

RF: In established (RA), RF has sensitivity on the order of 70%. A positive RF assay, far from specific for RA, can be found in many other autoimmune diseases, and a small percentage of healthy people. IgA isotype has been linked to erosive disease and to rheumatoid vasculitis, but its precise clinical utility remains unclear. Higher titers of RF are associated with more severe disease, but as a longitudinal measure of disease activity RF fares poorly [4]. Anti-citrullinated protein antibodies (ACPA) are autoantibodies that are present in the majority of patients with RA. Clinically, cyclic citrullinated peptides (CCP) are frequently used to detect these antibodies with high sensitivity in patient serum or plasma. [5]. Effect of therapy on ACPA & RF status; TNF-α-inhibiting agents like infliximab can reduce disease activity and delay radiographic progression of RA [6]. Determination of ACPA, RF levels during treatment course may give clues regarding effectiveness of treatment and role of these antibodies in disease process. Several papers have reported effects on ACPA, in patients treated with [DMARDs mainly methotrexate MTX] with [7-11] or without [12, 13] infliximab. The DAS28 score is widely used to assess disease activity, the response to treatment and the need for biological therapy. The higher the value, the more active the disease. Interpretation: DAS28 provides the physician with a number on a scale from 0-10 indicating current RA disease activity.

- Remission: DAS28 ≤ 2.6
- Low Disease activity: DAS28 (2.6 -3.2)
- Moderate Disease Activity: DAS28 (3.2-5.1)
- High Disease Activity: DAS28 >5 [14].

Patients and Method

The trial was conducted at rheumatic diseases center in Baghdad Teaching Hospital, Iraq. Thirty five Iraqi patients, with refractory RA who diagnosed according to the American College of Rheumatology Revised 1987ACR criteria +2010 ACR/EULAR, were enrolled in this study between September 2013-May 2014. All candidates: 1st had failed treatment with methotrexate and another DMARD course. 2nd No biological agents had been used previously in these patients. They received 3 mg/kg infliximab intravenously at weeks 0, 2, 6, and every 8 weeks thereafter in combination with methotrexate (15-20) mg/wk. Serum samples were collected before infusion at baseline and at week 24, and stored At -20^0C until further analysis. Theses variables were recorded at baseline and after 24 weeks of infliximab therapy: tender and swollen joint counts, patient assessments of general health on visual analogue scale, erythrocyte sedimentation rate (ESR), serum CRP level and DAS28 score. ESR normal value for men (15-20mm/hr) and for women (20-30mm/hr), CRP normal value less than 10mg/L. DAS28 parameter was used to evaluate clinical activity & response to treatment. Functional class using was assessed at baseline & after 24 wks of infliximab therapy. ACPA was measured by ELISA and titers greater ‘than 25 IU/ml were considered positive.

Results

There were 35 patients enrolled in this study, with a mean age of (48.9±11.7) years (range: 27–77) age. Interval distribution of the studied group revealed that 8 patients (22.9%) aged 39 years or less, 11 patients (31.4%) aged40-49 years, 11 patients (31.4%) aged 50 –59years and 5 patients (14.3%) aged more than 60 years and above. Females were the dominant; they were 27 represented (77.1%) of the studied group compared to only 8 males (22.9%). The female to male ratio was (3.4:1). The disease duration of the patients ranged (2 – 20) years with a mean of (7.2±4.5) years, 9 patients (25.7%) had a disease duration of less than 5 years, 18 patients (51.4%) had their disease for 5–9 years and 8 patients (22.9%) had the disease for 10 years or more as in (Table 1).

All patients received infliximab in a dose of (3 mg/kg infliximab intravenously at weeks 0, 2, 6, and every 8 weeks), Methotrexate (MTX) was received by 20 patients (57.1%), 15 patients received combination of 2 or more treatment; 11 patients (31.4%) received MTX + Prednisolone (PDN), 4 patients (10.5%) received other Disease Modifying Drug (HCQ 400 mg, azathioprine and sulfasalazine) in addition to MTX and PND. Non-steroidal anti-inflammatory drugs (NSAIDs) received by all patients; Diclofenac (100 mg) received by 20 patients (57.1%) and Ibuprofen by 15 (42.9%). On the other hand, none of the patients received biological treatment prior to the study and use of PND was stopped in 4 patients (10.5%) as in (Table 2).

Table 1: Demographic characteristics of the studied group (N=35).

Characteristics	No. of patients	%
Age (years)		
≤ 40	8	22.9
41 – 50	11	31.4
51 – 60	11	31.4
> 60	5	14.3
Mean±SD*	48.9±11.7	-
Range	27 – 77	-
Sex		
Male	8	22.9
Female	27	77.1
Disease duration (years)		
< 5	9	25.7
5 – 9	18	51.4
≥ 10	8	22.9
Mean±SD	7.2±4.5	-
Range	2 – 20	-

*SD: standard deviation

Table 2. Distribution of types of treatment received by the patients (N=35)

Treatment type	No. of patients	%
MTX*	20	57.1
MTX + PND	11	31.4
MTX + PND + other DMARD**	4	10.5
NSAIDs		
Diclofenac 100 mg	20	57.1
Ibuprofen 800 mg	15	42.9

* MTX median dose was 15 mg, median dose of PND was 5 mg/day** Other DMARDs include (HCQ 400 mg, azathioprine, and salfasalazine).

Out of the 35 patients enrolled in this study, 7 patients were missed at the second visit, so they were excluded from the following comparison. As it shown in table 3, the mean RF at the first visit was (106.1±25.2) and at the second visit it was reduced to (60.1±14.6) and the difference was statistically significant, (P=0.038). Regarding the ACPA, the mean was (466.5±61.4) at the first visit reduced significantly to reach (241.9±36.6) at the second visit (P<0.001). A dramatic and significant change had been found in the disease activity; the mean DAS28 was (5.7±1.1) at the first visit with a range of (2.7-8.6), at the second visit the mean was (4.5±1) and the range was (2.04-6.4). Furthermore, according to DAS28 values, at the first visit only one patient (3.6%) had low disease activity, 5 patients (17.9%) had moderate, and 22 (78.6%) had high disease activity. At the second visit these figures were significantly changed; 3 patients (10.7%) had remission, only one patient (3.6%) had low disease activity without remission, 16 patients (57.1%) had moderate disease activity and only 8 patients (28.6%) still had high disease activity these findings indicated a trend of change in disease activity from high toward the moderate and low disease activity, table 3, 4. Regarding the other parameters, it had been significantly found that the mean number of tender joints of the patients reduced from 14.1±1.4 at the first visit to 9.3±1.2, (P=0.005), similarly, the mean number of swollen joints reduced from 7.9±0.8 Dropped to 5.5±0.7 at the second visit (P=0.021). The mean values of Visual Analogue Scale (VAS) by doctor and by Patient were slightly reduced and the mean difference between the mean values at the first and second visits was only 0.5 and 0.4 respectively which did not reach the statistical significance, (P>0.05). Also, at the second visit, a statistically significant reductions in mean values of ESR (P<0.001), CRP (P<0.001), table 3.

Table 3. Comparison of mean clinical and laboratory values of in 28 patients completed the study at first and second visit. (7 patients were missed at the 2nd visit)

Finding	First visit	Second visit	Difference	P.value
	Mean±SE*	Mean±SE*	Mean±SE*	
RF	106.1±25.2	60.1±14.6	46.0±21.1	0.038 sig

DAS28	5.7±1.1	4.6±1.0	1.1±0.27	< 0.001 sig
No. of tender joints	14.1±1.4	9.3±1.2	4.8±1.6	0.005 sig
No. of swelling joints	7.9±0.8	5.5±0.7	2.4±0.9	0.021 sig
VAS by doctor	5.8±0.3	5.3±0.4	0.5±0.4	0.27 *NS*
VAS by patient	5.7±0.3	5.3±0.3	0.40±0.2	0.33 *NS*
ESR	67.2±4.7	42.1±4.4	25.1±5.6	< 0.001 sig
CRP	31.7±3.4	14.6±2.5	17.1±3.8	< 0.001 sig

Sig: Significant, NS: Not Significant and SE: Standard Error of mean

Table 4. Changes in disease activity according to DAS28 categories of the 28 patients completed the second visit.

DAS28 category	Disease activity			
	1st visit		2nd visit	
	No.	%	No.	%
Remission	0	0.0	3	10.7
Low	1	3.6	1	3.6
Moderate	5	17.9	16	57.1
High	22	78.6	8	28.6
Total	28	100.0	28	100.0

Chi square = 15.3, P. value = 0.0016 (sig)

The distribution of the functional classes reported at the first visit showed that 3 patients (10.7%) had class I, 13 (46.4%) had class II, 7 (25%) had class III and 5 patients (17.9%) had class IV, at the second visit there was an increase in the number of patients who had the first three classes and a decrease in the number of patients with class IV; 5 patients (17.9%) had class I, 14 patients (50%) had class II, 8 patients (28.6%) had class III and only one patients remain with class IV, this indicated an improvement in the patients function, however, these differences in the functional classes didn't reach the statistically significance despite the clinical significant, (P>0.05), Table 5.

Table 5. Comparison of functional class at first and second visit (N=28)

Functional class	No. of patients	%	No. of patients	%
I	3	10.7	5	17.9
II	13	46.4	14	50.0
III	7	25.0	8	28.6
IV	5	17.9	1	3.6
Total	28	100.0	28	100.0

Chi square = 3.27, P. value =0.38 *NS*

Discussion

Although none of the patients who were positive for RF and ACPA at baseline became negative during follow up, a significant RF and ACPA decrease in patients treated with infliximab after 24 wks. A significant decrease in ACPA levels found at week 24 of treatment (p<0,001) & significant decrease in RF level (P=0.038) at week 24 of treatment.

Regarding clinical measures of disease activity there was significant change in DAS28 (P<0.001), but the functional assessment failed to reach the significant value (p>0.05). Other laboratory parameters showed significant reduction in the ESR (P<0.001) and CRP (P<0.001). *Alessandri et al.* showed that a small but significant decrease in ACPA levels at week 24 of treatment in the patients with clinical improvement. This effect, also observed for RF, was dependent on infliximab, since reductions in ACPA levels were not observed after treatment with MTX alone[9] .Nevertheless, DMARD-only therapy can result in a significant (>25%) reduction in both ACPA and RF in about 50% of patients [11].Rönnelid et al. showed that treatment with sulphasalazine, but not other DMARDs, resulted in a drop in ACPA levels, but this decrease occurred only in the first year of follow-up and did not correlate with clinical indicators [13].*Nissinen et al*. showed that ACPA (measured by CCP1assay) did not change during 6 weeks of follow-up, though 60% of the patients had a significant clinical response. IgM-RF levels were somewhat decreased in the first weeks of therapy [8]. *Bobbio-Pallavicini* et al .studied autoantibody profiles during long-term (78weeks), combination treatment with infliximab and MTX. Though treatment resulted in a significant decrease in disease activity scores, no changes in the percentages of patients who were positive for ACPA or IgM-RF were observed. Titers of RF, on the other hand, were significantly reduced, unlike those of ACPA [7]*Caramaschi et al*. showed that RF levels decrease but ACPA remain stable in RA patients treated with infliximab for 22, wks[11].*De Rycke et al*. showed that RF levels but not ACPA is modulated by infliximab treatment in rheumatoid arthritis, with follow-up period of 30 weeks [10]. An explanation of the discrepancies could be that the end-point may be different in the different series (from 14 weeks to 12 months or 18 months), At these later time points, clinical parameters may not reflect primary response to treatment but also secondary loss of response, which can be influenced by development of antibodies to infliximab [15].And the ELISA test differed from one study to another. Our results showed significant reduction in both auto antibodies after 24weeks of infliximab treatment in association of clinical improvement, these results were supported by the previous result of Alessandri et al [9].

Study the Influence of Aqueous and Organic Extracts of Conocarpuserectus on the Growth of Some Pathogenic Bacteria

Nibras Y. Abdulla[1], Baydaa A. Hassan[1], Suzan Nazar Rasool[2]

[1]Department of Biology, Faculty of Science, Kufa University, [2]Ministry of Health, Iraq

Abstract

The aim of this study was to detect the effect of active compound in fruit, leave and stem of*Conocarpus* (which extracted by cold and hot water, and by methanol and ethanol alcohol) on the growth of *Staphylococcus aureus, Streptococcus agalactiae, E.coli, Klebsiellapneumonia, Enterobacter, Proteus mirabilis, Salmonellatyphi* and *Pseudomonas aeruginosa.* Also, this study aimed to determine the MIC value of methanol and hot aqueous extracts.The present study detected the methanol extract was the higher effect on bacterial growth and the inhibition zone diameter was 19mm, while the hot aqueous extract, ethanol extract and cold extract were 15, 12 and 7.8 mm respectively.The present study detected the least value of MIC for methanol and hot aqueous extracts were 6.25 mg/ml against *Staphylococcus aureus* and *Streptococcus aglatial* .

Keywords: *Conocarpus, antibacterial, MIC, extract, bacteria.*

Introduction

Antimicrobial resistant is the resistance of a microorganism to an antimicrobial drug that originally effective for the treatment of infection caused by it[1] Resistant microbes are increasingly difficult to treat, requiring alternative medications or higher doses—which may be more costly or more toxic. Microbes resistant to multiple antimicrobials are called multidrug-resistant (MDR); or sometimes superbugs[2]. A few infections are now completely untreatable due to resistance[3]. For this reason, we most begin to research on a new source for antibiotic or research on source produce new antibiotic, medical plants good source for production antimicrobial agent. natural products are considered a valuable source of drugs development against various diseases[4]. According to the World Health Organization (WHO) medicinal plants would be the best source to obtain a variety of drugs. About 80% of individuals from developed countries use traditional medicines which have compounds derived from the medicinal plants [5].*Conocarpus erectus* one of medicinal plants is a low branching evergreen shrub or tree with a typical height of up to 40 feet. It contains phenols such as flavonoids and tannins as major constituents, these phenolic compounds have antimicrobial activity against different types of bacteria,thus consider a good alternative in treated multidrug-resistant bacteria [6].

Different parts of *Conocarpus erectus* as leaves, stem and fruits have antioxidant, anticancer and antimicrobial properties, In folk medicine, it was reported to astringent, styptic and tonic preventing anemia,catarrh, conjunctivitis, diabetes, diarrhea, fever,gonorrhea, headache, hemorrhage, orchitis, prickly heat, swellings and syphilis[7].

Material and Method

Samples Collection: The Leaves,stem and fruit of *Conocarpus* collected during November and December from the garden of the college of sciences, University of Kufa . Washing with tap water and once with sterile water and dried at room temperature and pulverized into powder with an electric blender.

Preparation of extracts:

1. **Hot aqueous extract:** The hot aqueous extract was prepared by mixing of 30 gm of plant powder with 300 ml of distilled water and putting in the water path for 30 min. Then, the mixed filtered and dried

at laboratory temperature. The crude extract was collected and kept in a laboratory until uses[8].

2. **Cool aqueous extract:** The cool aqueous extract was prepared by mixing of 30 gm of plant powder with 300 ml of distilled water for 48 h. with shaking. Then, the mixed filtered and dried at laboratory temperature. The crude extract was collected and kept in a laboratory until uses [8].

Preparation of Methanol and ethanol Extracts: The plant powder (30 g) of each part was steeped in 150 ml methanol for 7 days at room temperature with vibrating day by day followed by filtration. Each extraction concentration at 40 C to remove the organic solvent affording the known weight of each crude methanol and ethanol extract. The defatted crude extracts were ready for bioassay[9].

Study the influence of aqueous and organic extracts of Conocarpus on the growth of bacteria: Used the method of agar diffusion by well [10]in susceptibility test for the active components of plant by make four equal well in Muller Hinton with diameter 6mm by cork borer and added 0.1ml from each extraction, before this stapes spreading o.1 ml from bacterial suspension on surface of media,after then incubation the plate over night in 37 C and then measured the diameter of inhibition zone to detect the effect of test plant on growth of bacteria .

Determining the MIC: Used the broth dilution method to determine the MIC value by used nine sterile tube and added 0.5ml of sterile broth for each tube,added 0.5ml from active compound for the first tube,mix the active compound and broth thoroughly and transfer 0.5ml from this tube into the second tube,repeated this step to seventh tube and discard 0.5ml of broth from final tube . the eighth and ninth tube remain without antibiotic, inoculation the tubes from first to eighth tube with 0.1ml from bacterial suspension (which comparison with MacFarland tube 0.5) and the ninth tube content on broth only without bacteria after then incubation all tube at 37C for 24h, after then examine each tube if it was clear or turbid to determine the MIC [11].

Antibiotic sensitivity test: Tested the sensitivity of bacteria to some of the antibiotic by cultured each genus of bacteria on Muller Hinton agar by spreading 0.1ml from bacterial suspension(which comparison with MacFrland tube 0.5) on agar surface and put the antibiotic disc in each plate after then incubator all plate at 37 C for 24 h. and measured the inhibition zone [12].

Result and Discussion

This study showed the methanol extract was higher effect on bacterial growth and the inhibition zone diameter was 19mm and this agree with [13],while the hot aqueous extract,ethanol extract and cold extract were 14.5,12 and 7.8 mm respectively (fig. 1), the antibacterial activity of Conocarpus attributed to phenols such as flavonoids and tannins as major constituents,this phenolic compounds have antimicrobial activity against different types of bacteria[6].

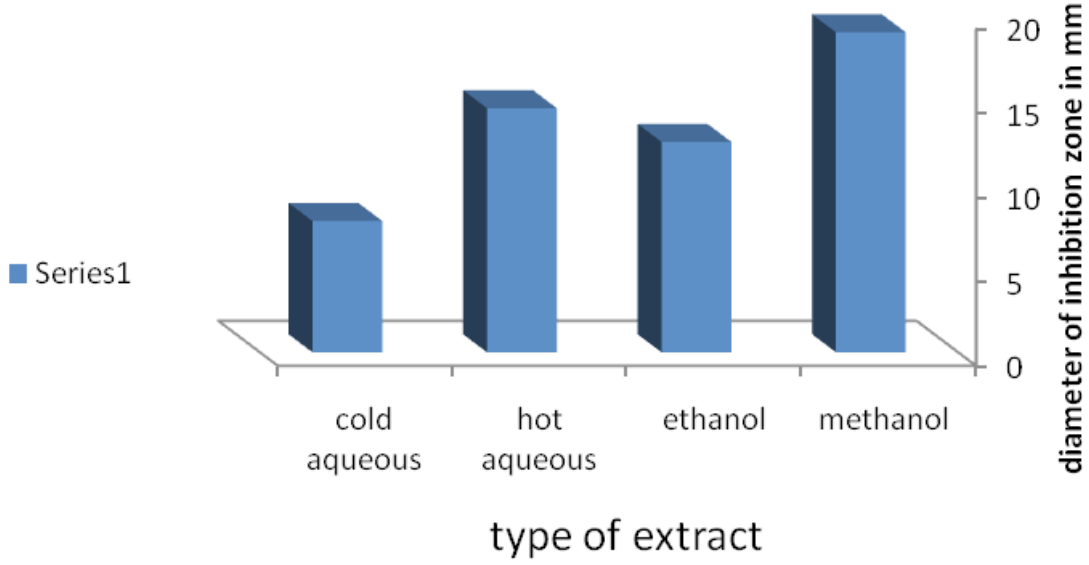

Fig. 1: Effect the active compound of methanol extract on bacterial growth

This study showed the methanol extract of leaves gave higher effect against *Streptococcus* and the inhibition zone diameter was 27mm and the least effect against *Enterobacter* and *Salmonella* the inhibition zone diameter was 17 mm the antibacterial activity of methanol extract for leave attributed to high containing from phenolic compounds[14],for the methanol extract of fruit gave higher effect against *Streptococcus* and the inhibition zone diameter was25mm and the least effect against *Enterobacter* and *Proteus* the inhibition zone diameter was 12 mm,while the methanol extract of stem gave higher effect against *Streptococcus* and the inhibition zone diameter was 23 mm and the least effect against *Salmonella* and the inhibition zone diameter was 8 mm (table 1).

Table 1: Effect the active compound of methanol extract on bacterial growth

Extract / Bacteria	Leave	Fruit	Stem
Staph. aureus	24 mm	21mm	16mm
Streptococcus	27mm	25mm	23mm
E.coli	20mm	14mm	12mm
Klebsiella	20mm	18mm	16mm
Proteus	22mm	12mm	14mm
Enterobacter	17mm	12mm	11mm
Salmonella	17mm	16mm	8mm
Pseudomonas	19mm	15mm	11mm

This study showed the ethanol extract of leaves gave higher effect against *Streptococcus* and the inhibition zone diameter was 24 mm and the least effect against *Salmonella* and*Enterobacter* the inhibition zone diameter was 8 mm and this result was near to [15],for the ethanol extract of fruit gave higher effect against *Streptococcus* and the inhibition zone diameter was 23 mm and the least effect against *Pseudomonas* which was resistance to it,while the ethanol extract of stem gave higher effect against *Streptococcus* and the inhibition zone diameter was 22 mm and the least effect against *Enterobacter, Salmonella* and *Pseudomonas* which were resistance to it (table 2).

Table 2: Effect the active compound of ethanol extract on bacterial growth

Extract / Bacteria	Leave	Fruit	Stem
Staph. aureus	17mm	15mm	13mm
Streptococcus	24mm	23mm	22mm
E.coli	13mm	10mm	9mm
Klebsiella	13mm	13mm	9mm
Proteus	12mm	11mm	8
Enterobacter	8mm	8mm	0
Salmonella	8mm	8mm	0
Pseudomonas	9mm	0	0

This study showed the hot aqueous extract of leaves gave higher effect against *Staph. aureus* and the inhibition zone diameter was 22 mm and the least effect against *Salmonella* and the inhibition zone diameter was to 10 mm,for the hot aqueous extract of fruit gave higher effect against *Staph.aureus* and the inhibition zone diameter was 20 mm and the least effect against *Klebsiella*, *Proteus* and *Enterobacter* the inhibition zone diameter was 9 mm, while the hot aqueous extract of stem gave higher effect against *Staph. aureus* and the inhibition zone diameter was 18 mm and the least effect against *Salmonella* which was resistance to it (table 3).

Table 3: effect the active compound of hot aqueous extract on bacterial growth

Extract / Bacteria	Leave	Fruit	Stem
Staph. aureus	22mm	20mm	18mm
Streptococcus	20mm	18mm	15mm
E.coli	13mm	10mm	8mm
Klebsiella	13mm	9mm	8mm
Proteus	14mm	9mm	11mm
Enterobacter	11mm	9mm	9mm
Salmonella	10mm	11mm	0
Pseudomonas	14mm	13mm	8mm

This study showed the cold aqueous extract of leaves gave higher effect against *Staphylococcus* and the inhibition zone diameter was 24 mm and the least effect against *E.coli* which was resistance for it, for the cold aqueous extract of fruit gave higher effect against *Klebsiella, Enterobacter*and *Pseudomonas* the inhibition zone diameter was 9mm and the least effect against *E.coli*, *Proteus* and *Salmonella* which were resistance for it,while the hot aqueous extract of stem doesn't have any effect against all bacteria (table 4).

Table 4: Effect the active compound of cold aqueous extract on bacterial growth

Extract / Bacteria	Leave	Fruit	Stem
Staph. aureus	24mm	8mm	0
Streptococcus	20mm	8mm	0
E.coli	0	0	0
Klebsiella	10mm	9mm	0
Proteus	16mm	0	0
Enterobacter	13mm	9mm	0
Salmonella	13mm	0	0
Pseudomonas	16mm	9mm	0

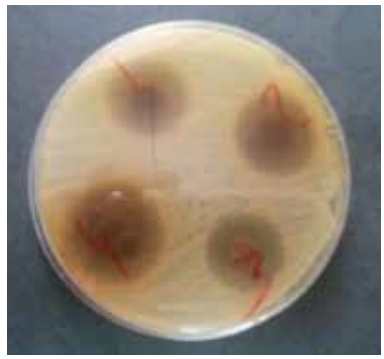

Fig. 2: Effect the aqueous and organic extract on Streptococcusaglatial 1: cold aqueous extract 2: ethanol extract 3: hot aqueous extract 4: methanol extract

This study showed some isolated bacteria were multi-resistance for most antibiotic (table 5).

This study showed the largest MIC value for methanol extract of leaves was 25 mg/ml for *E.coli* and *Salmonella*, and least MIC value was 6.25 mg/ml for *Staph.aureus* and *Streptococcus*. Also, this study showed the largest MIC value for methanol extract of fruit was 50 mg/ml for *Salmonella* and *Pseudomonas*, and least MIC value was 6.25 mg/ml for *Staph.aureus* and *Streptococcus* . Also, this study showed the largest MIC

value for methanol extract of the stem was 50 mg/ml for *Salmonella, Proteus*, and *Pseudomonas*, and least MIC value was 12.5mg/ml for *Staph.aureus*,*Streptococcus* and *Klebsiella* (table6) .

Table 6: MIC values for methanol extraction

Extract / Bacteria	Leave (mg/ml)	Fruit (mg/ml)	Stem (mg/ml)
Staph. aureus	6.25	6.25	12.5
Streptococcus	6.25	6.25	12.5
E.coli	25	25	25
Klebsiella	12.5	12.5	12.5
Proteus	12.5	25	50
Enterobacter	12.5	12.5	25
Salmonella	25	50	50
Pseudomonas	12.5	50	50

This study showed the largest MIC value for hot aqueous extract of fruit was 100 mg/ml for *Enterobacter*, and least MIC value was 12.5 mg/ml for *Staph.aureus*.Also,this study showed the largest MIC value for hot aqueous extract of leaves was 25 mg/ml for *Salmonella, Pseudomonas, Proteus,Enterobacter,E. coli* and *Klebsiella*, and least MIC value was 6.25 mg/ml for *Staph.aureus* and *Streptococcus* . Also, this study showed the largest MIC value for hot aqueous extract of the stem was 100 mg/ml for *Salmonella*,*Proteus*, and *Pseudomonas*, and least MIC value was 12.5mg/ml for *Staph.aureus* and *Streptococcus* (table 7).

Table 7: MIC values for hot aqueous extract

Extract / Bacteria	Leave (mg/ml)	Fruit (mg/ml)	Stem (mg/ml)
Staph. aureus	6.25	12.5	12.5
Streptococcus	6.25	25	12.5
E.coli	25	25	25
Klebsiella	25	50	25
Proteus	25	50	100
Enterobacter	25	100	50
Salmonella	25	50	100
Pseudomonas	25	25	100

Conclusion

The active compounds which extracted by methanol were the higher effect on bacterial growth. the least value of MIC for methanol and hot aqueous extracts were 6.25 mg/ml and were against *Staphylococcus aureus* and *Streptococcus agalactiae*

Antibacterial and Antibiofilm Activity of Aqueous Extract and Essential Oil of Origanummajorana and their Activity on Some Physiological Parameters of Blood in the Male of White Rats

Nibras Y. Abdulla[1], Baydaa A. Hassan[1]

[1]*Department of Biology, Faculty of Science, Kufa University, Iraq*

Abstract

The aim of this study was to detect the influence (aqueous extract and essential oil) of *Origanummajorana* on the growth of *Staphylococcus aureus, Enterococcus, E.coli, Klebsiella pneumonia, Proteus mirabilis, Salmonellatyphi*, *Enterobacter*, *Acinetobacterbaumannii* and *Pseudomonas aeruginosa*. Also, this study aimed to detection the influence of essential oil of *Origanummajorana* (which gave a higher influence on bacterial growth) on biofilm information. Also this study aimed to detection the influence of essential oil of *Origanummajorana* on some physiological parameters of blood in a male of white rats.

This study showed the essential oil *Origanummajorana* was a higher effect than aqueous extract. This study showed the ability of bacteria to formation of biofilm and biofilm inhibitors by essential oil of *Origanummajorana* . The results of the antibiotic sensitivity test showed some of the *bacteria* isolates were highly resistant to the antibiotic; therefore,it is considered multidrug-resistance (MDR). The results of the effect essential oil of *Origanummajorana* in vivo showed variation in values in some physiological parameters of blood in the male of rats

Keywords: *Origanummajorana, essential oil, antibacterial, antibiofilm, bacteria, physiological parameters of blood.*

Introduction

Discover the antibiotic in the last century contributed in treated many infection diseases which causes by many microorganism,used this antibiotic continue for a long time in treated diseases but in the last years some of the bacteria became resistance to many antibiotic and this antibiotic became unable to treated diseases,resistance bacteria to antibiotic begin increasing day after day and the bacteria which sensitive to antibiotic today may become resistance tomorrow so that we most begin to search for alternatives or new source to antibiotic .medical plant consider good source for antibiotic, Sweet marjoram (*Origanummajorana*) one of this plants has been used for centuries both as a culinary and medicinal herb. It has been evidenced in a number of studies that essential oil from sweet marjoram contains mainly terpinene-4-ol, α- and γ-terpinenes, linalool and carvacrol, which are the basis for their antimicrobial properties [1,2]. For centuries, marjoram oil has been used for curing various diseases [3]. Marjoram oil is also used in perfumes, soaps, and detergents for its spicy herbaceous notes [4]. Marjoram is considered among the main crops for increasing Egypt income from foreign currency [5]. The fresh or dried marjoram leaves and their essential oil are widely used in the food industry as a food ingredient, a herbal tea, flavoring, coloring, nutritional and natural preservatives [6].

Marjoram Essential oil from sweet marjoram reduced the growth rate of *Photobacteriumphosphoreum* which is the specific organism responsible for spoilage of modified atmosphere packaged fillets of cod [7].Whereas other isolates were used rarely in microbiological studies, it has been shown that aqueous and methanolic extracts from sweet marjoram contain multiple compounds with considerable antimicrobial action, e.g. phenolic derivatives (phenolic acids, flavonoids as apigenin, luteolin, quercitin and their glycosides as rutin or isovitexin) [8,9].The antiviral, bactericidal, antiseptic

and antifungal effects of marjoram also attributed to ursolic acid and essential oil and in particular to thymol and carvacrol[10,11]. Ursolic acid isolated from *O. majorana*appears to be a potent acetylcholinesterase inhibitor in Alzheimer's disease[12].

Material and Method

The plant used in experiment: In this study we used leaves and essential oil of *Origanummajorana*

Which obtain from market the leaves pulverized into powder with an electric blender.

Animals used in the experiment: In this study we used12 rats (male) their weight between150-200 g.

Preparation Hot aqueous extract: The hot aqueous extract was prepared by mixing of 30 gm. of plant powder with 300 ml of distilled water and putting in the water path for 30 min. Then, the mixed filtered and dried at laboratory temperature. The crude extract was collected and kept in a laboratory until uses [13].

Study the effect of the active compound of Origanummajorana on the growth of bacteria in vitro: Used the method of agar diffusion by well [14]in susceptibility test for the extraction and essential oil by make tow equal well in Muller Hinton with diameter 6mm by cork borer and added 0.1ml from each extraction and essential oil, before this stapes spreading o.1 ml from bacterial suspension on surface of media,after then incubation the plate over night in 37 C and then measured the diameter of inhibition zone to detect the activity of test plant on growth of bacteria .

Antibiotic sensitivity test: Tested the sensitivity of bacteria to some of the antibiotic by cultured each genus of bacteria on Muller Hinton agar by spreading 0.1ml from bacterial suspension(which comparison with MacFrland tube 0.5) on agar surface and put the antibiotic disc in each plate after then incubator all plate at 37 C for 24 h. and measured the inhibition zone.

Biofilm formation: Tissue culture plate method (TCP) assay (biofilm assay) described by [15] was most widely used and was considered as a standard test for detection of biofilm formation as follow:

1. Isolates from fresh culture were inoculated in TSB containing 1% glucose and incubated for 72 hours at 37C° and then diluted 1:100 with fresh TSB) [16].
2. Added 150µl aliquots of the diluted cultures for each bacterial isolated into Individual wells and only broth served as a control to check non-specific binding of media. Each isolate was inoculated in triplicate.
3. The plate was incubated for 24 hours at 37°C. After incubation content of each well was gently removed by tapping the plate. wells were washed 4 times with phosphate buffer saline (PBS pH 7.2) to remove free-floating 'planktonic' bacteria.
4. Biofilms formed by bacteria in plate was fixed by putting the plate in the oven at 37C° for 30min.
5. All wells stained with crystal violet (0.1% w/v). Excess stain was removed by thorough washing with deionized water and plates were kept for drying.
6. Added (150 µl) of sodium acetate (20:80, v/v) to dissolve bounded crystal violet. The optical density (O.D.) at 630nm was recorded.

Effect of antibacterial agents on Biofilm formation: The same procedure described in (tissue culture plate method for detection biofilm formation) was done with essential oil,15µl from essential oil add to each bacterial isolated in wells of tissue culture plate, The plate was incubated for 24 hours at 37°C,after fixing with sodium acetate for an hour and all steps done as the same steps that described previously [17].

Study the effect of essential *Origanummajorana* on the growth of bacteria in vivo

In this experiment used 12 rats divided into 4 groups include:

1. Three rats treated with normal slain for a week.
2. Three rats treated with 0.1 bacterial suspension.
3. Three rats treated with 0.1ml bacteria and after 24h. treated with essential oil of *O.majorana* 0.16ml⁄kg which consider safety dose[18] for a week.
4. Three rats treated with essential oil of *O.majorana* 0.16ml/kg which consider safety dose [18] for a week .

Result and Discussion

Effect the O. majorana on bacterial growth: This study showed the essential oil was higher effect than aqueous extract and gave antibacterial activity against all isolated bacteria and this result agree with[19] Thymol and carvacrol, which have been known as major compounds

of these essential oils [20,21], are able to increase the microbial cytoplasm membrane permeability, probably because their capability of dissolving into the phospholipid bilayer aligning between the fatty acid chains and causing a distortion of the membrane physical structure [22,23],while the aqueous extract was lest effect and must bacteria were resistance to it. (table 1).

Pseudomonas	0.448	0.190
Acinetobacter	0.669	0.236
Proteus	0.485	0.224

Effect the essential oil in vivo:

Physiological Assay: This study showed present variation in totalcount and differential count of WBCs in different treatment comparison with control group, the total count of WBCs for group which treated with bacterial suspension reach to 17 (10^3/µL) while the control group was 6(10^3/µL) this result attributed to present bacterial infection which led to increasing in WBCs count [24], also showed present little increasing in total count of WBCs in group treated with bacteria and oil,only oil which were7.5 and 7.8 (10^3/µL) respectively (table 6),in differential count of WBCs the lymphocyte for group which treated with bacterial suspension reach to 10.3 (10^3/µL) while the control group was 3.5(10^3/µL), also showed present little increasing in differential count in group treated with bacteria and oil and only oil comparison with group treated with bacteria which were 6 and 7 (10^3/µL) respectively (table 6).

Table 6: Effect the different treatment on total and differential count of WBCs

Parameter / Treatment	Total count of WBCs (10^3/µL)	Lymphocyte (10^3/µL)	Monocyte (10^3/µL)
Control group	6	3.5	0.8
Treated with bacteria	17	10.3	0.8
Treated with bacteria +oil	7.5	6	0.6
Treated with oil	7.8	7	0.5

This study showed little variation in RBC count and other parameters associated with it (HGB, MCV, HCT,PLT) in different parameter comparison with the control group except group treated with bacteria showed decreased in platelet count which were 700 (10^3/µL) comparison with the control group which was 1000 (10^3/µL) (table 7).

Table 7: Effect different treatment in RBC count and other parameters associated with it (HGB, MCV, HCT, PLT)

Parameter / Treatment	RBC (10^6/µL)	HGB (g/dl)	HCT (%)	MCV (fL)	PLT (10^3/µL)
Control group	7	11	36.8	53	1000
Treated with bacteria	6.5	10.6	35	54	700
Treated with bacteria +oil	7.3	10.8	35	50	1100
Treated with oil	6.5	10	33	53	930

Conclusion

The essential oil of *O.majorana* higher effect on bacterial growth from the aqueous extract. *O.majorana* have antibacterial activity in vivo.

Psychological Stress among Woman's and it's Health Seeking Behavior towards Breast Examination at Early Detection Centers for Breast Cancer in Hilla Teaching Hospital

Ghfran Qasim Raheem[1], Abdulmahdi A. Hasan[2]

[1]Psychiatric Health Nursing, Diwaniya Health Directorate-Iraq, [2]Ph.D. in Pediatric & Psychiatric Mental Health Nursing, Collage of Nursing, Babylon University-Iraq

Abstract

Background: Psychological stress as any stimulus, such as fear or pain, which interferes with the natural physiological balance of man, we all experience stress and stress in our daily lives for various reasons, whether due to family life or financial pressures or personal relationships. The study aims to identify the psychological stress among women's and its health seeking behaviors who attending to Early Detection Centers for Breast Cancer. As well as, investigate the relationship between women's their psychological stress and their health seeking behavior.

Methodology: A descriptive study is conducted by a non probability "convenience" sample of (100) woman's who vesting the early detection centers for breast cancer in Hilla City. The questionnaire which are included (40) items. These items are divided into (2) sections which include psychological stress domains which is composed of (23) items; and health seeking behaviors domains which is composed of (17) items. Data are collected through the use of an interview technique by the questionnaire as means for data collection. Data are analyzed through the application of descriptive statistical data analysis approach that includes, frequencies, percentages, mean of scores, standard deviation; and inferential statistical data analysis approach includes, Chi-squared test.

Results: The study results indicate that majority of (65%) of woman's were suffers partial psychological stress, and (54%) of them were never seek health behaviors towards breast examination for detection breast cancer. As well as, there was insignificant association between woman's their psychological stress towards early detection of breast cancer and their health seeking behaviors at p-value >0.05.

Conclusion: Overall woman's with partial psychological stress are never seeks of health and their psychological stress has been not affected their health seeking. Health directorate decision makers need to be employed based on a quality guidelines in order to improve the early detection center for breast cancer. Also, further studies could be undertaken to involve the national level of evaluation woman's knowledge regarding early detection of breast cancer and their health seeking behaviors.

Keywords: *Psychological Stress, Woman's, Health Seeking Behaviors.*

Introduction

Breast cancer is the leading cause of cancer death among women. It can be attributed only about 50% of breast cancer risk to a physiological or behavioral or genetic factor [1]. An increase in the incidence of breast cancer among grief compared with women who suffer from headaches. The relationship between "psycho" and cancer is still mostly short stories until the end of the nineteenth century [2]. Many reports indicate that 156 of the 200 women with breast cancer have suffered a painful life accident, including psychological aspects and a troubled life, usually like the loss of a loved one[3]. Accumulated knowledge resulted in the twentieth century with regard to tension and its mechanism of

action as well as enthusiasm with regard to the effect of stress hormones in the development of cancer to many research studies. Strong hypotheses have emerged, but experimental cancers maintain stress. But the results of epidemiological studies have been conflicting, ranging from the lack of a relationship between stress and breast cancer [4]. Breast cancer is the most common type of cancer among females worldwide; in the United States alone, it was expected to account for 29% of female cancers [5]. Depression and anxiety are the most common that can be found in patients with breast cancer through their illness starting from diagnosis until the end of the disease disorders [6]. Anxiety ranges between 10% and 30%. Patients suffered from symptoms of anxiety as a result of expected negative results, and a sense of bewilderment about the future, worry about repetition, and the discomfort of the health seeking and consequences of treatment [7]. Regardless of the high frequency of major depressive disorders among cancer patients; often remains detectable; this may result from the fact that the feeling of depression involved in the same physiological effect of cancer [8]. Early detection plays a key role in reducing morbidity and mortality of breast cancer. The American Cancer Society and the Union of Michigan Cancer of the American Medical Association advises that women aged 40 years or older Egern X-ray examination annually. Despite the effectiveness of early detection in reducing breast cancer mortality, these preventive health practices, rates are still low among many minority women [9].

Methodology

Study design: A descriptive study is conducted in order to identify the psychological stress among women's and its health seeking behaviors who attending to Early Detection Centers for Breast Cancer. As well as, investigate the relationship between women's their psychological stress and their health seeking behavior.

Study Sample: A non-probability "convenience" of (100) woman's who vesting the early detection centers for breast cancer in Hilla City.

Study Instrument: A questionnaire which includes which are included in the questionnaire, are (40) items. These items are divided into (2) sections which include psychological stress domains which is composed of (23) items; and health seeking behaviors domains which is composed of (17) items.

Data Collection the Method: Data are collected through the use of an interview technique by the questionnaire as means for data collection. Data are analyzed through the application of descriptive statistical data analysis approach that includes, frequencies, percentages, mean of scores, standard deviation; and inferential statistical data analysis approach includes, Chi-squared test.

Results

Table (1): Woman's their Demographic Characteristics

	Rating	No.	%
Age	19-29 years	47	47.0
	30-40 years	29	29.0
	41-51 years	18	18.0
	52+ years	6	6.0
Marital Status	Married	68	68.0
	Unmarried	26	26.0
	Divorced	4	4.0
	Widowed	2	2.0

	Rural	13	13.0
No. Children	Not found	66	66.0
	1-2 Childs	25	25.0
	3-4 Childs	8	8.0
	5+ Childs	1	1.0

Out of (100) subject who participated in this study their age ranged from (19-29) years old and constituted (47%) of the study sample. Only (6%) of them their age was over the (52) years and above. It's obvious among the findings that the highest percent of the study participants were married and constituted (68%) out total number. A thirty five of participants were diploma and above

graduated and works housewife, it constituted (35% and 62%) respectively. The highest proportion of the findings were making sufficiently income, it constituted (42%). Only small percent (9%) were sufficient and increased income. Most of the study sample residents at urban areas and without children, it composed (87% and 66%) respectively out total number of (100) sample.

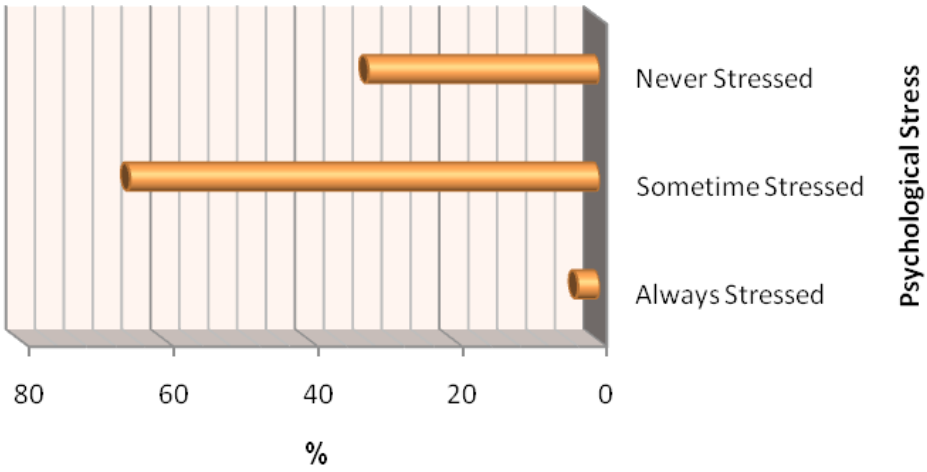

Figure (1): Overall Woman's Psychological Stress

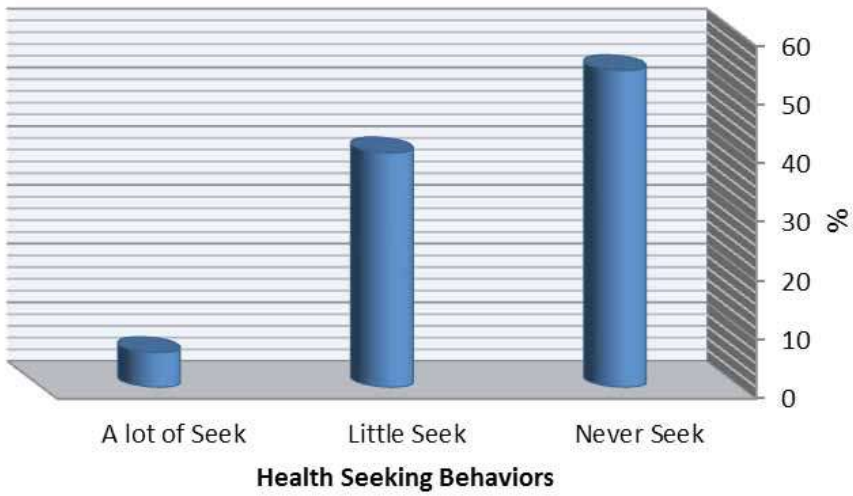

Figure (2): Overall Woman's Health Seeking Behaviors

Table (2): Statistical Relationship between the Woman's their Psychological Stress and their Health Seeking Behaviors

	Scale	Health Seeking Behaviors			Total	d. f	Sig.	
		Never	Little	A lot of				
Psychological Stress	Always	2	0	1	3	4	χ^2 obs.= 6.132 χ^2 crit.= 9.488 P-value=0.190	NS
	Sometime	33	29	3	65			
	Never	19	11	2	32			
	Total	54	40	6	100			

$\chi^2 obs.=$ Chi-square observer, $\chi^2 crit.$ Chi-square critical, Df= Degree of freedom, P-value= Probability value, NS= non significant.

This table depicts there was insignificant association between woman's their psychological stress towards early detection of breast cancer and their health seeking behaviors at *p-value >0.05*.

Discussions

People with cancer may find physical, emotional and social effects of the disease pressure. Those who are trying to control their stress risky behaviors such as smoking or drinking alcohol or who become more stable may suffer from the poor quality of life after cancer treatment. In contrast, it shows that people who are able to use effective strategies to deal with stress, such as relaxation techniques and stress management, they have low levels of depression, anxiety and symptoms associated with cancer and its treatment. However, there is no evidence that the successful management of psychological stress improves the survival of cancer, it must be health seeking in order to get rid of the psychological and physical negatives. Our findings their age ranged from (19-29) years old and constituted (47%) of the study sample. Only (6%) of them their age was over the (52) years and above. These results come because this age group is the most interested in itself. Results come with study has been measured the quality of breast cancer screening programs. Their results confirmed stress about breast cancer screening can occur especially in women who aged young to adults age groups [20]. It's obvious among the findings that the highest percent of the study participants were married and constituted (68%) out total number. This results come because most of the study participants in our society is considered the age of marriage. Expectations and experience in breast imaging study find that the most of those woman's were married[21]. Also, when assessed the transferred women's their knowledge and practices about breast cancer affiliated to Ahvaz' University. The results showed that the majority of the patients were married[22]. A thirty five of participants were diploma and above graduated and works housewife, it constituted (35% and 62%) respectively. While in a descriptive study has been assessed the depression and anxiety among women with breast cancer in Sohag University. Find that the most woman's works at homes and with low level of education [23].The highest proportion of the findings were making sufficiently income, it constituted (42%). Only small percent (9%) were sufficient and increased income. As is common, women depend on their husbands for their monthly income.Most of the study sample residents at urban areas and without children, it composed (87% and 66%) respectively out total number of (100) sample. Because the population density is one of the residents of the urban and this is what confirmed our results.Our findings represented the majority of (65%) of woman's were suffers partial psychological stress when reviews the early detection of breast cancer center in Hilla City. This results come as being the many reviews of the center has become so is normal with a partial stress. The our results come with a systematic review cross-sectional study was conducted in Iran, deals with psychological side in women with breast cancer. Their findings reveals that mild levels of depression for women with breast cancer were present to serious levels. There is an increase in the risk of depression in women with breast cancer. Therefore, it seems necessary to plan preventive and therapeutic measures in order to improve mental health and quality of life of patients [24].Cancer is the first cause of death among American women and Asian American women have the lowest for Asian detection of cancer among all ethnic groups in the United States rates. The American Cancer Society reported that the incidence of breast cancer rate was 81.6/100,000 and the mortality rate of 12.5% among American women Asian. Breast cancer is the leading cancer among Chinese women, Korean and Vietnamese women and Cambodian. Epidemiological studies have indicated an increase in the risk of breast cancer among Asian women and their descendants after emigrating to the United States [25].Our findings demonstrated the majority of (54%) of woman's were never seek health behaviors during towards breast examination for detection breast cancer in Hilla City. In our society the lack of follow-up health awareness through publications and mast media as well as, the attend health seminars that was shot by those non-existent women only after they are sick and be forced to correct the illness. In early detection for cues to expanded control and care for breast cancer among women from Western Kenya. Its confirmed that it's need to be creating breast cancer awareness alongside clear guidelines on accessing screening and treatment because of the lack of follow-up health awareness about the early detection of breast cancer.

Conclusions

Woman's with partial psychological stress are never seeks of health and their psychological stress has been not affected their health seeking. Health directorate decision makers need to be employed based on a quality guidelines in order to improve the early detection center for breast cancer. Also, further studies could be undertaken to involve the national level of evaluation woman's knowledge regarding early detection of breast cancer and their health seeking behaviors.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the Collage of Nursing/Babylon University, Iraq and all experiments were carried out in accordance with approved guidelines.

The Effect of Bacterial Infections on the Immune States in Eczematic Patients

Abeer Fauzi Al–Rubaye[1], Samah Ahmed Kadhum[2], Worood Alwan[3]

[1]Assistant. Prof., Ph.D.Microbiology, College of Science for Women, Department of Biology, University of Babylon, Iraq, [2]Assistant. Prof., Ph.D. Medical Microbiology, Head of Department of Clinical Laboratory Sciences, College of Pharmacy, University of Babylon, Iraq, [3]College of Science for Women, Department of Biology, University of Babylon, Iraq

Abstract

Background: Eczema is one of most important global diseases that affects both genders at all age groups, the relationship between bacteria and allergy in Eczematic patients is still as a great need of studies to show more of the microbial role in eczema.

Objective: This study has been investigating the main commonbacterial secondary infections associated with Eczema lesionand estimation the serum levels of immunoglobulin types and cytokines in both patients and control groups.

Material and Method: Swabs samples were taken from infected eczema lesions in patients consulting in Dermatology Consultation Unit in Medical Marjan City in Al-Hilla Province. Microbiology investigation for swabs were done with antibiotic sensitivity test. Blood was collected for measuring the concentrations of serum IgG, IgA, IgM by single radial immunodiffusion assay, IgE, IL-1β, IL-4, and IL-10 were measured using ELISA kits.

Results: The noted profile of bacteria associated with cases of pyogenic eczema were Staphylococcus aureus (81.08%), Streptococcus pyogenes (5.1%) and Pseudomonas aeruginosa (8.1%). Several skin areas were affected, such as Hands (35.13%), Thighs (18.9%) and Feet (18.9%). The relation between pyogenic Eczema lesions and Occupation, Season and Geography were studied.At the immunological level, we found a significant increased ($p \leq 0.05$) in the concentrations of IgM, IgG, IgA and IgE compared with control groups with a significantly increased ($p \leq 0.05$) in the concentrations of cytokines (IL-1β, Il-4, and IL-10) that stimulated the Th2 antibody production.

Conclusion: We concluded that the bacterial infections played an important role in systemic humoral and cellular immunity in eczematic patients.

Keywords: *Bacterial infections; immunoglobulin; cytokine & Eczematic patients.*

Introduction

Eczema (atopic dermatitis) is a type of skin inflammation andcommon skin diseases that can cause a variety of symptoms, from an itchy red rash to patchy sores. ... However, are not all people with eczema will experience infections[31,25] The infections of the skin and soft tissues of most Common infections, may lead to local and dangerous Systemic complications. These infections can be Potentially life-threatening has been progressing rapidly; Therefore, early recognition and appropriate medical[22]. Eczema is a specific inflammatory reaction of the skin which includes a range of highly etiologically heterogeneous clinical conditions[9]

Surgical management task Staphylococcus aureus and Streptococcus pyogenes plays an important role in skin and soft tissue infections and contributes of most complex skin disorders such as atopic dermatitis and other skin lesions[24]. (S. aureus) colonization/

infection is a very common and important factor in the pathophysiology of a topic dermatitis[7].

Bacterial resistance against commonly used antibiotics has increased considerably in the last decades The most common causes of secondary bacterial infections of the skin are staphylococci and. Secondary infections to skin lesions can be potentially life threatening and may progress rapidly[20,23].

Systemic immune response had been altered when foreign bacterial antigen enter the body through skin with suppression it's immunological barrier, Related pathological changes Includes intracellular edema of the skin and skin Inflammatory infiltration of predominantly lymphocytes

Macrophages[26] Eczema is associated with an increased in the serum immunoglobulins (IgG, IgM, IgA and IgE)levels withinduction of Th2 cytokine rather than Th1 cytokine throughcounter balanced between them [5].Furthermore, the induction of different immunological levels were considered to be antigen-specific mechanisms [1,10]. pro-inflammatory cytokines an increased the migration of inflammatory immune cells into the skin with elevated the IgE levels through down-regulated expression of the anti-microbial peptides necessary for host defense mechanisms[8,13]. The activation of Th2 increased the eosinophilia activity with different types of cytokines (IL-4, IL-5, IL-6, IL-9, and IL-13) that created a microenvironment suitable for Th2 cell differentiation[4].

The current work aims at isolation and identification of bacteria causing secondary infection of Eczema, with measurement of serum levels of immunoglobulin types and cytokines at both patients and control groups.

Material and Method

1. **Bacteriological Study:** Swabs samples were taken from the superlative exudates of infected Eczema lesions in patients consulting in Dermatology Consultation Unit in Medical Marjan City in Al-Hilla Province. was taken by means of sterile disposable swab and inoculated into peptone water as transport medium for aerobic bacteria between the clinic and the bacteriological laboratory

   Microbiology investigation for swabs were done according to Cowan and Steel (1985).Gram stain were done and biochemical test according to Collee et al.,1996; Forbes et al.,2010; Leboffe and Pierce,2011), antibiotic sensitivity test were done as in Brown(2007).

2. **Immunological Study:** Blood was collected for measuring the concentrations of serum IgG, IgA, IgM by single radial immunodiffusion assay, IgE, IL-1β, IL-4, and IL-10 were measured using ELISA kits. (provided from Ray Bio, USA, Company).

Results and Discussion

Table (1): culture and physiological characters of bacteria isolates from the pyogenic eczema lesion

Characters	S. aureus	S. pyogenes	P. aeruginosa
Gram stain	+	+	–

Patients Profile: The patients were distributed according to the bacterial isolates infections that caused Eczema into 4 groups with one group considered to be control (G5) as in table (2). Bacterial infection was found in some patients, The bacterial infection rates in each type of eczema and dermatitis are summarized in table (2). Staphylococcus aureus is the bacterium that is most commonly responsible for secondary infection of eczema. 55.56%.S. aureus is the predominant bacteria on the uninvolved palms of patients with atopic dermatitis [28]. in study done by [23] S. aureus was present in eight (35%) of lesions infections and was isolated from all areas. and S. aureus was mixed with group A haemolytic streptococci in one case. Group A haemolytic streptococci were isolated mainly from the extremities. Gram-negative aerobes (P. aeruginosa and E. coli) were isolated from areas on the leg and trunk.

In Singapore mentioned that S.aureus was the commonest organism causing secondary infection of skin lesions and represented 67%, 43.5% and 45% of all positive cultures respectively[30].

Staphylococcus aureus is the bacterium that is most commonly responsible for secondary infection of eczema It is often associated with hair follicle infections (folliculitis), boils and abscesses. [19,] Marwa et al. (2007) record that the bacteria S.aureus was the most commonly isolated organism (92.9%), followed by Enterobactericeae (35.7%) and Pseudomonas (14.3%) in eczema lesions, S. aureus isolates were obtained from14 (34%) patients with eczema lesions [23]

The S. aureus colonization rate was higher in atopic dermatites patients, which might be due to the skin barrier defects and imbalance of immune function[16]. The result of present study agree with Marwa et al. (2007) showed that Gram-negative bacilli were the second common pathogens causing secondary infection of skin lesions and were found in (21.7%) of all cases. And agree with [20]who found that enteric Gram-negative bacilli together with Strept. pyogenes were the second most common causes of secondary infection where each of them represented (23%) the distribution of infections showed in the table (3) the thight and the hand was the most infected part from the body[20] recorded that the most infected part of the body were the finger, scalp, face and neck.

Table (2) Profile of patients according to the bacterial isolates

Groups	Bacterial Isolates	Numbers	(%)
G 1	S. aureus	50	55.56
G 2	S. pyogenes	20	22.22
G 3	P. aeruginosa	12	13.33
G4	S. aureus+ S. pyogenes	8	8.88
G5	Control	20	-

Table (3) Distribution of secondary bacterial infection according to the anatomical site of

Location	No	%
Thighs	13	35.13
Hands	13	35.13
Feet	7	18.7
Ears	3	8.1
Scalp	1	2.7
Total	37	

Testing for the antibiotic sensitivity of staphylococci,Streptococci and Pseudomonas are done the three isolates were resistance for most of antibiotic use as showed in the figures (1, 2 and 3)

S. aureus isolates had good sensitivity to clindamycin, chloramphenicol, and Methicillin while they were resistant to penicillin, ampicillin, tetracycline and cefotaxime.

Streptococcus pyogenes isolates had good sensitivity to clindamycin, chloramphenicol, and Methicillin while they were resistant to penicillin, ampicillin, tetracycline and cefotaxime. While Pseudomonas aeruginosa isolates were for chloramphenicol and Methicillin

High resistance of S. aureus to ampicillin and penicillin may be indicate with the high incidence of β-lactamase production by staphylococci in the current study, Fusidic acid resistance may be due to the extensive use of topical fusidic acid by patients suffering from secondary skin infections. in the UK the S.aureus isolated from dermatology were high resistance to fusidic acid 50%[27].

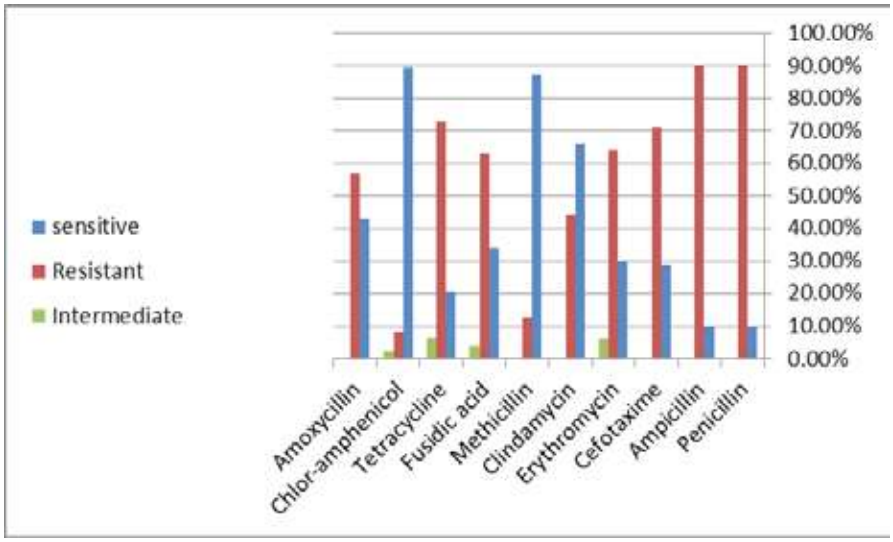

Fig (1) antibiotic sensitivity test of S.aureus

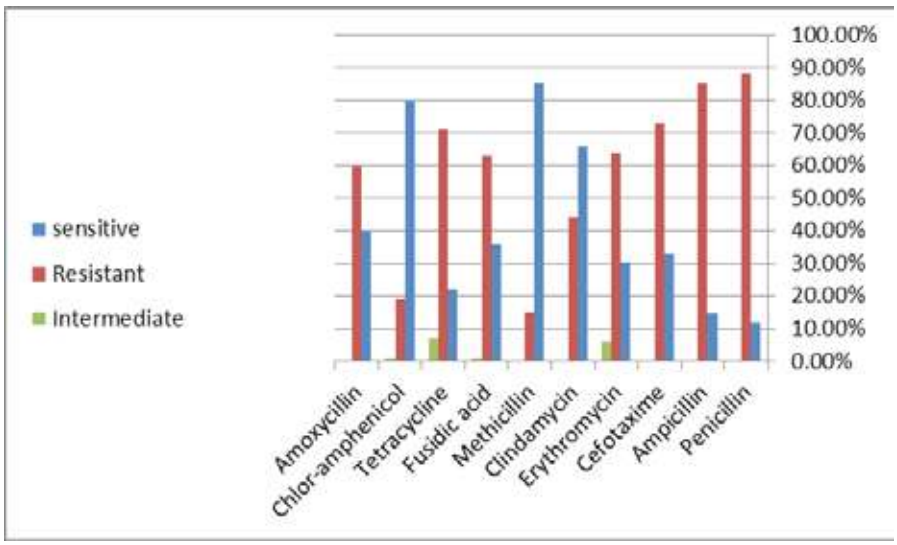

Fig (2) antibiotic sensitivity test of Streptococcus pyogenes

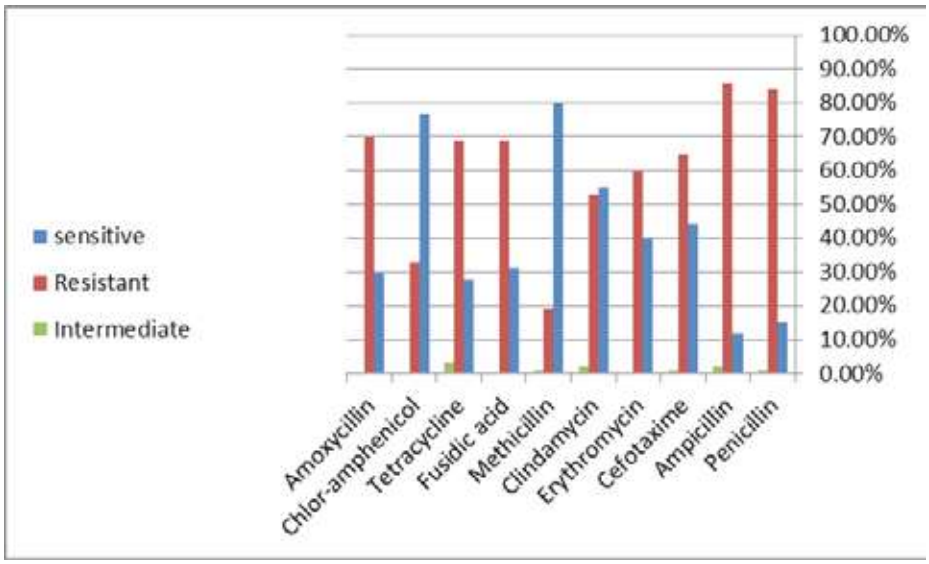

Fig (3) antibiotic sensitivity test of Pseudomonas

At immunological level we found a significant increased (($p \leq 0.05$) in the concentrations of IgM, IgG, IgA and IgE (mg/dl) compared with control groups as in table (3), thus the immunity of Eczematic disease involved mainly humoral immune response associated with a cell-mediated immunity towered many types of exogenous and endogenous factors, or anon specific reaction [1,14]. Increased in IgE concentrations facilitated the release of different types of inflammatory mediators from mast cells, basophils and immune

Cells involved with Eczema pathogenesis with chemotactic for eosinophils to the site of infections[12]. Others studies suggested that the elevated levels of serum antibodies in Eczematic patients may be associated with other pathogens through secondary infections (Roberts).

*Control groups

Table (4) showed a significant increased ($p \leq 0.05$) in the concentrations of cytokines that used in this study and this agree with many previous studies had been explained that skin microbial infections inducted the cytokines when penetrated the skin of patients and suppression the skin barrier then bind with IgE on Langerhans' cells, that stimulated TH2CD4to produce IL-4, which stimulated the IgE production by B lymphocytes[3,15].IL- 10 had a regulatory role in an inflammatory response and we foundthe IL-10 polymorphism associated with the elevated the level of IgE in Eczematic and alleregic diseases with inhibited the production of pro- inflammatory cytokines[6].IL-1β is a pro- inflammatory cytokines played an important role in the pathogenesis of Eczemathat produced from the inflammation of skin and activate Th1CD4 cells proliferation and differention [2].So the bacterial infections affected the systemic immune responses at both humoral and cellular levels that had been seen when the alleregic reactions elevated the IgE antibody with increased in numbers of eosinophil because the receptors of this antibody found on the surface of eosinophil and mast cell[11].

Table (4): Concentrations of cytokines in Eczematic patients

Patients group	Mean Concentrations (pg/ml)					
	IL-1β M±S.D.	P- value	IL-4 M±S.D.	P- value	IL-10 M±S.D.	P- value

*Control groups

Conclusion

From all of the above, we concluded that the bacterial infections played an important role in systemic humoral and cellular immunity in Eczematic patients and both of them produced chronic inflammatory response through stimulated antibody production and secreted of cytokines. E czema lesion are commonly seen in hand and feet. And lesions were associated with S. aureus, P. aeruginosa and S. pyogenes From all of the above, we concluded that the bacterial infections played an important role in systemic humoral and cellular immunity in Eczematic patients and both of them produced chronic inflammatory response through stimulated antibody production and secreted of cytokines.

Poultry Resources Multidrug Resistance Bacteria to Human

Fouad Hussein Kamel[1], Sara Ibrahim Othman[2]

[1]Erbil Medical Technical Institute, [2]Howler Health Technical College, Erbil Polytechnic University-Erbil-Iraq

Abstract

Chicken was found to be the most reservoirs of resistant *Escherichia. coli* bacteria. Moreover, the high dependence of antibiotics in animal farming is considered the most important factor of the selection and dissemination of antimicrobial resistant microorganisms. Therefore, the current paper aims to search antimicrobial resistance in isolated *E. coli* from chicken feces. The antibiotic disc diffusion technique was used in order to conclude the response of isolated *E.coli* against to antibiotics in sixty isolates collected from chicken's feces.

The isolates *E.coli* were more frequently resistant to Nalidixic acid, Tetracycline, Ampicillin, Sulfamethoxazole, Neomycin and Trimethoprim-sulfamethoxazole respectively. While, Ceftriaxine was recorded lesser resistant in isolated *E. coli* from chicken feces. Both Amoxicillin and Gentamycin have been examined and happen to be similar result of both resistant and sensitivity test.

From this work, we concluded that isolated *E. coli* from locally chicken's intestines are generally resistant to multiple antibiotics thus, should watchful to the public health and veterinary authorities to limit and decrease antimicrobial.

Keyword: *Bacteria, multidrug-resistant, chicken, Antibiotic.*

Introduction

There is a great deal of research and published about the antibiotic-resistant, and the antibiotic did not kill the bacteria as they did. That's for high exposure to antibiotics, food contamination with resistant bacteria or antibiotics presences in addition to its developed immunity against antibiotics.

Previous studies have shown that poultry is one of the significant reservoirs of pathogenic *E.coli*. Antibiotic usage randomly is consider the greatest factor promote the selection, emergence, and dissemination of antimicrobial-resistant bacteria [1].

E.coli is a general organism in the intestines of people and animals with certain strains that cause cases of gastroenteritis and other systematic diseases as well as blood poisoning[2]. It is also recognized as indicators of antibiotic resistance, because they are part of the natural bacteria of humans, animals also exist in the environment.

The misuse and overuse of these antibiotics lead to accumulation of violative levels of unfit for human consumption poultry tissues and organs, particularly with the lack of knowledge between poultry producers about withdrawal periods of antibiotics, and the occurrence of antibiotic residues in food of animal origin above the maximum residue limits (MRLs) is documented worldwide by numerous public health authorities as being unlawful[3,4]

The use and misuse of antibiotics have led to the development of resistant or long effective against infections for the treatment and prevention of pathogenic bacterial infections[5]. What happens here may be one of the most severe disasters of our time, and the antibiotics will no longer be useful.

In this study, *E. coli* strains isolated from locally chicken's intestines were collected from Erbil bazaar and analyzed to determine their susceptibilities to antimicrobial as a source of human contamination.

Material and Method

1. Sixty poultry intestines samples from locally chicken's field were collected after slaughtered in shops within residential units. The intestine placed in a sterile container transferred directly to the diagnostic laboratory. Feces samples were taken out from the gut in a sterile container.
2. The stool samples were supplemented in Tryptone soya broths for pre-enrichment at 37°C for 2 hrs. Then mixed to homogenize and inoculated on Tryptone soya agar, MacConkey agar and incubates at 37° C for 24 hours.
3. All *E.coli* colonies appeared on different media were further identified done by both morphological and by biochemical reactions [6].
4. All isolated *E. coli* were examined for sensitivity against thirteen antibiotics depended by antibiotic disk agar diffusion technique according to the clinical laboratory standard[7,8]. The used antibiotics included Ampicillin (10µg), Neomycin (30µg), Amoxicillin (30µg), sulfamethoxazole (300µg), Trimethoprim/sulfamethoxazole (1.25/23.75µg), Ceftriaxine (30µg), Streptomycin (10µg), Gentamycin (10µg), Amikacin (30µg), Tetracycline (30µg), Nalidixic acid (30µg), Chloramphenicol (30µg) and Nitrofurantin (300µg).

After incubation at 37° C for 24 hours, the inhibition zone investigated as a response of bacteria to antibiotics. The multidrug-resistant (MDR) strain was identifying as consider resistant of microorganism to three or more different classes of antibiotics[9].

Results and Discussion

According to table (1) and figure, investigation the prevalence of antibiotic resistance in isolated pathogenic *E. coli* from chicken's fecesof. The study concluded the different resistance patterns to several antibiotics that have been commonly used in animal's treatment [10].

The higher resistance rates were found in Nalidixic acid (90%), Tetracycline (88.33%), Ampicillin (80%), Sulfamethoxazole (75%), Neomycin (70%) and Trimethoprim-sulfamethoxazole (70%) respectively. While Ceftriaxine (66.6%) recorded lower resistant in isolates *E. coli* from chicken feces. Both Amoxicillin and Gentamycin comes out with the similar results of resistant and sensitivity test (50%).

Table (1): Percentage of antimicrobial resistance and sensitivity among isolates E.coli

No.	Antibiotics	Bacterial response to antibiotics	
		Sensitivity	Resistance
1.	Amoxicillin	30 (50%)	30(50%)
2.	Ampicillin	12 (20%)	48 (80%)
3.	Neomycin	18 (30%)	42 (70%)
4.	Gentamycin	30(50%)	30(50%)
5.	Trimethoprim-sulfamethoxazole	18 (30%)	42 (70%)
6.	Nalidixic acid	6 (10%)	54 (90%)
7.	Streptomycin	48(80%)	12 (20%)
8.	Sulfamethoxazole	15 (25%)	45 (75%)
9.	Ceftriaxine	20 (33.3%)	40 (66.66%)
10.	Nitrofurantin	26(43.3%)	34(56.66%)
11.	Amikacin	48(80%)	12 (20%)
12.	Tetracycline	7(11.66)	53(88.33%)
13.	Chloramphenicol	32(53.33%)	28(46.66%)

The exceeded levels of antibiotic resistance along with the *E. coli* in this study is generally consistent with those reported has previously been taken in the closed area of this topic in countries like China and Switzerland[11-14]. That was because Poultry fields where the drug is a widely higher dose of treatment used in treating bacterial disease and promoting feed conversion efficiency [12,15].

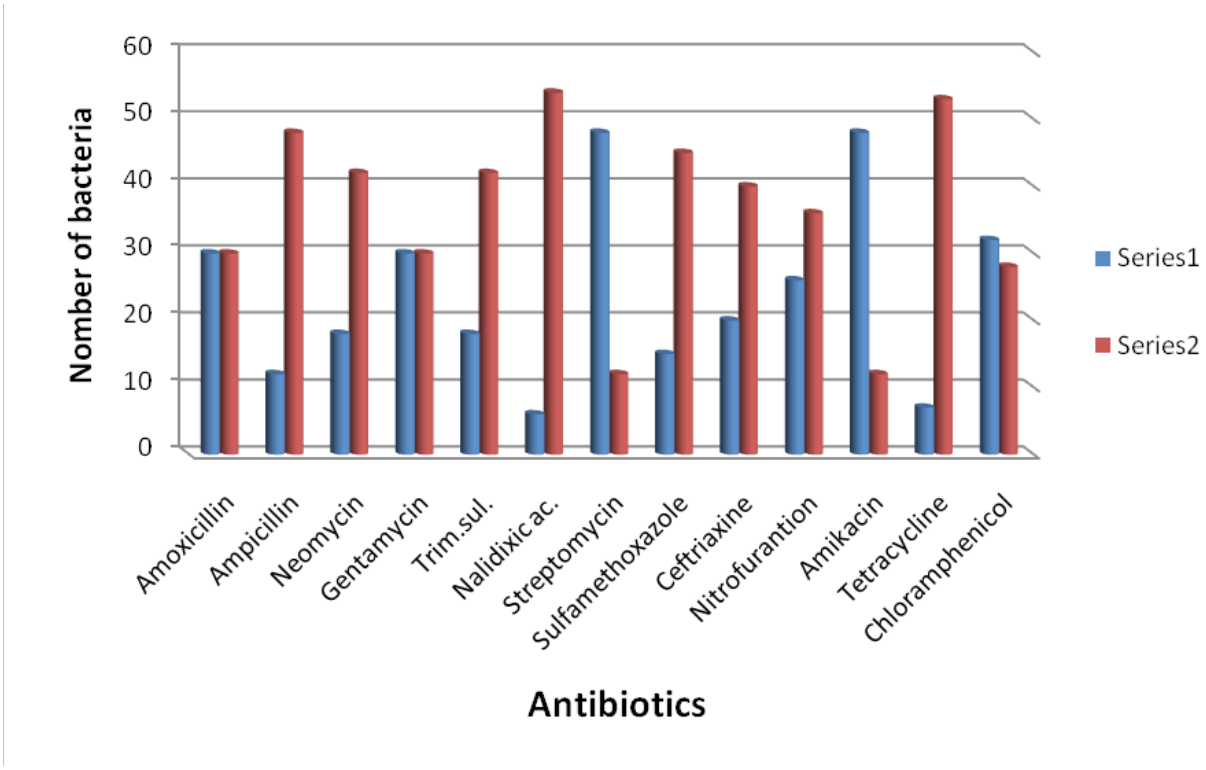

Figure (1): Microbial response to antibiotics

Other factors include incorrect medical diagnosis, prescription of unnecessary medications and the use of antibiotics as additional food for livestock to encourage their growth. In addition, translates into the loss of the economic cost of the cost of medicine.

Paper study results investigated that E.coli being a multidrug-resistant because the strain was defined as one which was resistant to at least three different classes of antimicrobials [16].

In conclusion, there is growing indication that pathogenic *microbial* infections of individuals are always more becomes hard to treatment and regulations are urgently needed to reduction uses of antimicrobial.

Returnee's Suicide Epidemiology among Internally Displaced Secondary School Students in Tikrit-Iraq

Zeena N. Abdulrahman[1], Ahmed Mahmood Younus[2], Islam A.R. Zardawy[1]

[1]Tikrit Medical College, Iraq, [2]Tikrit Nursing College, Iraq

Abstract

Introduction: One of the severe public health problems among adolescents and adults is suicide and suicidal behaviors. Suicide represent the 3rd leading cause death among adolescents and young adults between the ages of 10-24, accounting for 12% of all reported adolescents deaths in this age. Depression and suicide in a adolescents are not studied well, in spite of its prevalence in Iraqi community. This research aims at studying Returnee's Suicide Epidemiology Among Secondary School Students after Internal displacement in Tikrit-Iraq.

Subjects and Method: A cross sectional, descriptive study with analytic component was carried out on secondary schools students in Tikrit district. Questionnaire were presented to all students in the schools that day, in the classroom, depending on the help and cooperation of the school's administration and teachers during spare time. A screening tool used was the Columbia Depression Scale (CDS), a paper-and-pencil yes/no questionnaire. The DISC can be presented to the adolescents and youths (Ages 11 and over). It consists of a 22 items that are rated as Yes and No scored as (1) & (0) respectively. The total score is calculated as together the score of each of the 22 items. If the result of calculation is 0-6, 7-11, 12-15, 16 and above that mean the chance of depression was very unlikely, moderately likely, likely and highly likely respectively (Appendix -2-A, B)(60). Group (I) include unlikely and moderately likely considered as low risk for depression and Group (II) include likely and highly likely which considered as high risk for depression. A total of 269 students of returnees after internal displacement were selected randomly from secondary school students.

Results: High depression scores found in 26 (9.7%) while moderate scores found in 64 (23.8%) of Non IDPs of the study sample, which means that 33.5% of students were liable to have depression. High depression scores found in 6 (13.6%) of male Non IDPS students in comparison to 20 (8.9%) of females, while moderate scores found in 4 (9.1%) of males Non IDPs in comparison to 60 (26.7%) of females.

Conclusion: This study results found that 33.5% of students were more likely to have depression. Females more affected by depression and suicide.

Keywords: *Returnee's Suicide Among School Students, Suicide in Returnee's after Internal displacement in Iraq.*

Introduction

One of the common psychiatric disorder is depression, composed of features of the followings; loss of interest in usual activities, inability to experience pleasure, & persistent decreasing of mood[1]. Depression is usually a disabling disorder which influence affects a individual's job, his study, eating habits & sleeping, wellbeing and feeling of life enjoyment[2]. Depressed patients suffer from sadness, anxiousness, emptiness, worried, hopeless, guilty, helpless, worthless, restless, irritable, hurt. The following are presenting features of depression; lose interest's loss in previously pleasurable

Corresponding Author:

Tikrit Medical College, Iraq
e-mail: walledm251@gmail.com

activities, overeating or appetite loss, problems in concentration, remembering details, or decisions making, and there may be suicide contemplate or attempt. Fatigue, loss of energy, insomnia, excessive sleeping, generalized pain or aches, persistent digestive problems[3]. Depression influence around 7–18% of the people on at least single time in their lives, before the age of forty.[4] IDPs according to (UNHCR): "persons who are obliged to flee for different reasons (violence, armed conflicts, violation of human rights) without crossing international borders. IDPs legally remain under the protection of their own government-even though that government might be the cause of their flight. As citizens, they retain all of their rights and protection under both human rights and international humanitarian law [5]. The psychosocial factors that might be influenced by migration, and thereby pose a negative effect on mental health, are social support, social participation and feeling of powerlessness [6]. This might be the reason that studies dealing with acculturation have reported higher distress and depressive symptoms for those immigrants who migrate to culturally and socially distinct societies and try to adapt to the new social circumstances after migration [7]. IDPS are of special vulnerability to psychological distress. Researches on displacement and migration state that because displacement include obligatory movement between different societies and cultures put these people at great risk for mental diseases and psychological difficulty in any situations and persons. IDPS usually are held between a miserable present, horrible past and a vague future [8]. One of the commonest psychological reactions found in IDPS is depression [(9,10)].

Subjects and Method: Formal administrative approval sheet was taken to conduct the study from the ministry of education, department of education in Tikrit Education Directorate. The study was carried out in the secondary schools in Tikrit. This a descriptive study with analytic component carried out on secondary schools students in Tikrit district. Questionnaire were presented to all students in the schools that day, in the classroom, depending on the help and cooperation of the school's administration and teachers during spare time. The students filled out the questionnaires after explanation of each item by the researcher in about 35 minutes and returned them to researcher at the end of the session. A total of 269 students of returnees after internal displacement were selected randomly from secondary school students. A screening tool used was the ColumbiaDepression Scale (CDS), a paper-and-pencil yes/no questionnaire. The DISC can be presented to the adolescents and youths (Ages 11 and over). It consists of a 22 items that are rated as Yes and No scored as (1) & (0) respectively.The total score is calculated as together the score of each of the 22 items. If the result of calculation is 0-6, 7-11, 12-15, 16 and above that mean the chance of depression was very unlikely, moderately likely, likely and highly likely respectively (Appendix -2-A, B) [11]. Group (I) include unlikely and moderately likely considered as low risk for depression and Group (II) include likely and highly likely which considered as high risk for depression.

Results

High depression scores found in 26 (9.7%) while moderate scores found in 64 (23.8%) of Non IDPs of the study sample, which means that 33.5% of students were liable to have depression Table 1.

Table 1: Depression Scores in Returnees After Internal Displacement of the sample

Depression score	Non IDPs No. (%)
Weak	86 (32%)
Mild	93 (34.6%)
Moderate	64 (23.8%)
High	26 (9.7%)
Total	269 (100%)

High depression scores found in 6 (13.6%) of male Non IDPS students in comparison to 20 (8.9%) of females, while moderate scores found in 4 (9.1%) of males Non IDPs in comparison to 60 (26.7%) of females Table 2.

Table 2: Depression Scores in Returnees After Internal Displacement against gender

Depression Score	Non IDPs Males No (%)	Non IDPs females No (%)
Weak	27 (61.4%)	59 (26.2%)
Mild	7 (15.9%)	86 (38.2%
Moderate	4 (9.1%)	60 (26.7%)
High	6 (13.6%)	20 (8.9%)
Total	44 (100%)	225 (100%)

Suicidal attempts found in 142 (52.8%) of returnees after Internal Displacement, while suicidal thoughts found in 34 (12.6%) of returnees after Internal Displacement Table 3.

Table 3: Suicidal thoughts, Suicidal attempts in Non IDPs

Suicide	Non IDPs
Suicidal thoughts	34 (12.6%)
Suicidal attempt	142 (52.8%)
No suicidal factor	93 (34.6%)
Total	269 (100%)

Suicidal attempts found in 135 (60%) of females against 7 (16%) of males of returnees after Internal Displacement. Suicidal thoughts found in 8 (18.2%) of females against 26 (11.6%) of males of returnees after Internal Displacement Table 4.

Table 4: Suicidal thoughts, Suicidal attempts in Non IDPS according to the gender

Suicide	Males Non IDPs No (%)		Female Non IDPs No (%)	
Suicidal thoughts	8	18.2	26	11.6
Suicidal attempt	7	15.9	135	60.0
No suicidal factor	29	65.9	64	28.4
Total	44	100.0	225	100.0

Discussion

Very little information is available concerning suicide epidemiology in Iraqi society. An Iraqi Suicide National Study covered 13 Iraqi (out of 18) governorates, and revealed that 647 cases of suicide were present . Suicide crude rate per 100 000 population in 2015 was 1.09 (1.21 for males, 0.97 for females) & in 2016 1.31 (1.54 for males and 1.07 for females). [12]

This study results (that 33.5% of students were liable to have depression) is supported by Alkhafaji AM et al who found a statistically significant relation in the rate depression rate in IDPS was 34.5% in comparison to 16.4% in their matched group of control [13]. This high figures can be explained by the fact that Psychological disorders frequently take place progressively after multiple causes like: persistent stresses, violence, environmental factors and internal psychogenic factors which include Internalizing Items (fear of new situations, sadness, self underestimation, hopeless, unhappy, worries a lot, seems to have less fun); and Externalizing factors (unnecessary risky behaviors, ignoring rules, misunderstand feelings of others, fights with other children, teases others, blames others for troubles, refuses to share) [14]. This high figures is very serious problem because of severe deficiencies in mental & psychological health care services [15].

For more than 2 decades, Iraqi exposed to sanctions, wars, & displacement which affect all life, & health aspects of women, children, & adolescents. The situation complicated in 2014 by invasion and occupation of a terrorist organization to Iraqi governorates [(16-17).] In this study, the sample was from returnees secondary school students after internal displacement who their age (12-18 years), this supported by Noori and Janet who found that higher than 1/3 of their sample were aged (18-27 years) and stated that immigrants were young ages (15-24 years old) [18]. Also Joseph and Cristina found that (24%) of their study group of immigrants aged between (16-25) years and (33%) were (26-35) years [19]. The majority of cases (67.9%) were aged 29 years or below. Rate of suicide in Iraq is below suicide global rate. Young people more commonly affected by suicide, but almost equal gender distribution. Many cultural and social factors have major role in this epidemiology [20].

Being a young person, IDP secondary school students are put this group under risk of depression which is supported by Alkhafaji AM et al who found that majority of depressive patients were of high educational level 47% 13. This was explained by Beiser M who found that young and educated persons was target for violence, terror and experiencing more losing events [21]. High and moderate depression scores were found higher in females 20 (8.9%), 60 (26.7%) respectively than in males 6 (13.6%), & 4 (9.1%) respectively of returnees students from internal displacement. This means that 36.6% of returnees females may affected by depression, in comparison to 22.7% of returnees males. These figures are lower than the prevalence of depression was higher in IDP females (57.9%) than males (42.1%) 13. This may be explained by the end of internal displacement period will provide a rest and relief after stress of displacement and its related co-morbidities. But predominance of females may explained by the fact the females are more likely than males to 'internalize' stress, which put them at higher risk for getting depression. Johnson H found that females are at double risk to develop depression males and the psychological distress level was significantly higher for women than for men[22]. Piccinelli M suggested that females may be at greater risk of mental distress because of the psychological sequelae of rape, the violent loss of partner and children, and of becoming a single parent or widow[23]. This situation complicated by unique Iraqi society, cultural attitudes toward females specially young and unmarried[24.]

Clinic-Pathological Characteristics of Breast Cancer among Iraqi Women

Sarab K. Abedalrahman[1], Ali S. Al-Hashimi[1], Najim Abid Issa Al-Khalidy[1], Jawad K. Al-Diwan[2]

[1]Al-Alwiyaa Maternity Teaching Hospital, Women Health Center, [2]Dept. of Family and Community Medicine, College of Medicine, Baghdad University

Abstract

Background: Breast cancer is the commonest cancer globally and is the 1st cancer in Iraq among females. Its sequelae and prognosis depend on early diagnosis, this study aimed to identify the clinicopathological characteristics of breast cancer.

Method: Retrospective descriptive study, on 102 breast cancer women, attending the women health center in Al-Elwyiaa Maternity Teaching Hospital department in 2018.

Results: Invasive ductal carcinoma (IDC) was found among 82 (80.4%) of malignant cases, ILC was 14 (13.7%),most of cases diagnosed at stage II 54 (52.9%), followed by stage III 27 (26.5%), and most of lesions detected by the patient 51 (50%). Peak age was 45-54 year 39 (38.2%), followed by 55-64 years in 24 (23.5%), and 10 (9.8%) of breast cancer cases found among of patients aged 25-34 year. Most of the lesions were on the right breast 54(52.9%).

Conclusion: Iraqi women still diagnosed at late stage, and when become symptomatic, this will affect the management, outcome and 5 year survival rate.

Keywords: *Breast cancer, clinical characteristics, pathological characteristics. Breast cancer stage.*

Introduction

In Iraq, breast cancer is the 1st cancer among females, and the second cause of cancer related deaths.[1] Breast cancer is presented among younger age, late stage, and in aggressive form.[2,3] Breast cancer management and prognosis depend on early diagnosis, and staging. The aim of cancer staging is to identify the prevalence of the disease, to develop the treatment plan, to provide prognosis information,[4]and is a good indicator of early detection quality.[5] In previous study,[6] the majority of affected women presented in late stages. Bad prognosis always hand by hand with advanced stages.[7]In Iraq, usually tumor size at presentation >20 mm.[8] There is an early detection clinics only and no screening program was applied.[6,9] This study was aimed to study the changes in presentation of breast cancer within the last 2 decades.

Materials and Method: A total of 102 breast cancer female patients was included in the study. They were recruited from registered patients in the Women Health Centre in Al-Elwyiaa Maternity Teaching Hospital for the period Jan. 2017-Nov. 2017. Information requested was lesion characteristics (histopathology and clinical notes), anatomical staging done according to TNM classification.[10] All patients with full information, histological and radiological reports were included. All information, regarding histopathology was extracted from file records.

Result: The age distribution of the cases showed that peak age was 45-54 year 39 (38.2%), followed by 55-64 years in 24 (23.5%), and 10 (9.8%) of breast cancer cases found among of patients aged 25-34 year. Half of the cases diagnosed at clinical stage II 54 (52.9%), followed by stage III 27 (26.5%), two cases (1.96%) was at stage zero. The lesion was detected by breast self-examination in 51 (50%), and by clinical breast examination 51 (50%) of breast cancer cases. Lesions were found on the right breast in 54(52.9%), and on the left breast in 47 (46.1%), these findings are shown in table 1.

Table 1. The general and clinical characteristics of breast cancer cases

Patient Characteristics	Frequency	Percent
Age		
25-34 years	10	9.8
35-44 year	16	15.7
45-54 year	39	38.2
55-64 year	24	23.5
65-74 year	7	6.9
> 75 year	6	5.9
Stage		
0	2	1.96
I	18	17.6
II	54	52.9
III	27	26.5
IV	1	0.9
Lesion detected by		
Breast clinical examination	51	50
Breast self-examination	51	50
Site of lesion		
Right	54	52.9
Left	47	46.1
Bilateral	1	0.9
Total	**102**	**100**

Table 2. The histological types of diagnosed beast diseases

Histological type	Frequency	Percent
Invasive ductal carcinoma (IDC)	82	80.4
Invasive lobular carcinoma (ILC)	14	13.7
Ductal carcinoma in situ (DCIS)	2	2.0
Others	4	4.0
Total	102	100

Invasive ductal carcinoma (IDC) was found among 82 (80.4%) of malignant cases, Invasive lobular carcinoma (ILC) was 14(13.7%), and Ductal carcinoma in situ (DCIS) found among 2 (2%) (Table 2).

Discussion

The age distribution of cases in this study showed pattern of progressive increased cancer incidence with age, as documented in 2014 Egyptian and Chinese literature.[11] The sharp peak of breast cancer cases was at 45-55 years. This finding goes with that reported in Iraq previously (40-49 years),[12] and (35-49 years). [13]during 1976-1986, the peak was 40-50 year [14] and during 1986-1988 was 45-50 years.[15] The observed peak (40-50 year) is lower than reported in China (55-59 year) and Egypt (60-64 year) [11] and in UK (> 65 year).[13]

This difference might be explained by the difference in life expectancy [16]. Most of breast cancer women diagnosed at more advanced stages stage II (80.4%). This figure consistent with what reported previously in Iraq (88%).[13] It is higher than that in UK (39.2%),[13] and in Turkey (68.6%).[17]This difference might be attributed to the fact that no screening program was implemented in Iraq to detect breast cancer earlier. Early detection clinics were established in 2001. The observed figure (80.4%) is lower than that reported in 2010 (92.4%).[12]

In this study, 50% of the lesions were detected by patient herself (breast self-examination), which is lower than that reported previously in Iraq (90.6%).[12] The finding of decreased percentage of advanced stage at diagnosis about (12%) during the last 12 years, and the decrease in diagnosis by patient herself by (40.6%) than reported in 2010, may be explained by improvement in health services demonstrated by participation of clinical examination, the effectivity of early detection clinics and awareness to breast cancer among the population. Breast clinical examination shared in detection of breast cancer by (50%). The finding reflects the participation of primary health care centers in detection of breast cancer.

Most of breast cancer cases involved the right breast, this was supported by some previous study (55.6%),[18] and another study found that only women born in Asia and middle east countries had higher right sided breast cancer ratio. [19]This finding is opposed by many previous studies which found that breast cancers cases affected left breast more than right side.[20-22]Some studies found that patients with right breast tumors are more likely to have familial relative affected with breast cancer [22], tend to have more aggressive, and presented at younger age group than those with the left breast tumors. [21] This study results found that invasive ductal carcinoma found among (80.4%), invasive lobular carcinoma ILC among (13.7%). This figure consistent with previous

findings in Iraq (86.5%), and (8.8%) for IDC and LDC respectively, and in UK (81.5%), (10%), for IDC and LDC respectively.[13] Here ductal carcinoma in situ was found among (2%) of patients, & this is lower than found in Korea (10.6%) among never screened and (14.1%) among screened women. [23] The high figure among both groups in Korea may be explained by increased awareness among both, population and health staff about breast cancer due to screening program. Screening programs using mammography is widely conducted in many western countries, while is not common in many Asian countries.[24] Breast cancer is amenable to preventive strategies by primary and/or secondary prevention, hence a need for effective interventions tackling lifestyle risk factors, break the stigmas and improve awareness about this cancer.[25]

Conclusion

In Iraq, breast cancer diagnosed in earlier age than western countries, and even other neighboring countries, with high grade stage at diagnosis. There is a need for urgent implementation of screening program.

Quality of Life among Adolescents Patients with Irritable Bowel Syndrome

Zaid W. Ajil[1], Adraa H. Shawq[1]

[1]*Instructor, Pediatric Nursing Department, College of Nursing, University of Baghdad*

Abstract

Objective(s): The study aims to assess the quality of life for adolescent patients with irritable bowel syndrome in the city of Baghdad and determine the relationship between adolescents` quality of life level and their demographic characteristics.

Methodology: A descriptive study,using the assessment approach was conducted on a purposive "non-probability" sample of (100) patients from both gender aged (12-18) years, attending liver and digestive system diseases teaching hospital in Baghdad city. The instrument of the study was adapted from the World Health Organization quality of life questionnaire(1998) to achieve the purpose of the study, in addition to the participants' demographic characteristics and the some related medical data. The data were collected through direct interview,during the period of the 1st of July to the 16th of August 2018. SPSS program was used in data analysis.

Results: The findings of the study indicated that adolescents` social domain was affected, the finding also showed significant relationships among adolescents` age, gender, marital status, employment status and their quality of life.

Conclusion: Irritable bowel syndrome IBS affected on adolescents quality of life negatively, especially social, psychological, and environmental domains..

Recommendations: The study recommended the need to avoid disease risk factors and additional studies are required to interpret the results of the difference in the quality of life of adolescent patients with irritable bowel syndrome.

Keywords: *Quality of Life, Adolescents, Irritable Bowel Syndrome*

Introduction

Irritable bowel syndrome (IBS) is one of the common digestive system disorder, characterized by chronic abdominal pain, discomfort, bloating, and alteration in the habits of the bowel [1], IBS can occur at any age, but it start in the early adolescents, the incidence of females more than males [2,3].

Corresponding Author:
Zaid W. Ajil
College of Nursing, University of Baghdad
e-mail: zaidahjil@gmail.com

There's no cure for IBS, but the symptoms can be relieved by changing diet and lifestyle[4,5].IBS can affects on patients' quality of life due to chronic pain, fatigue, sleep and mood disturbance, and work activities[6,7]. Living with IBS presents daily challenges; IBS may be painful or embarrassing and can seriously affect the quality of life [5].

As documented in the previous studies that the impact of IBS on patients` quality of life is serious and similar to other chronic diseases such heart and kidney diseases, IBS has impact on patients' physical, emotional, social and psychological functions[7, 8, 9].

Nurses have important role in caring of patients`

with IBS, Iraqi patients with such syndrome need a help for adopted with their health problems, especially the adolescents for their lack of health knowledge [10]. Therefore the researchers bring highlighted on this health problems among adolescents.

Method and Materials

Objective of the study: The study aims to assess the quality of life for adolescent patients with irritable bowel syndrome and to determine the relationship between patients' quality of life and their demographic characteristics.

Design of the study: A descriptive approach is carried out to achieve the purpose of the study.

Setting of the study: The study was conducted at liver and digestive system diseases teaching hospital in Baghdad city. Data was collected from the period of the 1st of July to the 16th of August 2018.

Sample of the study: a purposive "non-probability" sample of (100) patients from both gender, aged from (11-18) years, with no others chronic diseases.

Instrument of the study and procedure: The data were collected by direct interview; the World Health Organization quality of life questionnaire (1998) was adopted to achieve the goal of the study, this scale consists of 6 domains: physical health, psychological, level of independence, social relationships, environment, and spirituality/religion/personal beliefs. Participants` sociodemographic characteristics such as (age, sex, marital status, educational level and employment status), and medical information related to IBS also included. The questionnaire was measured on 3 Likert type scale (always, sometimes and never).

Statistical data analysis: Data was analyzed by using the Statistical Package for Social Science (SPSS) version 23. Descriptive and inferential statistics had been used.

Results

This table shows that the majority of sample's ages (67%) were between 14 and 18years old, more than half (52%) were male. (48%) of them were single and (47%) were married. (50%) of has intermediate school graduates. (50%) of adolescent patients wereEmployee and (68%) of themhaveinsufficient income. (75%) of sample weresmoke, and most of them (77%) with negative family history with IBS.

Table (1): Distribution of samples`sociodemographi ccharacteristics

F. = Frequency,%=Percent, IBS = irritable bowel syndrome

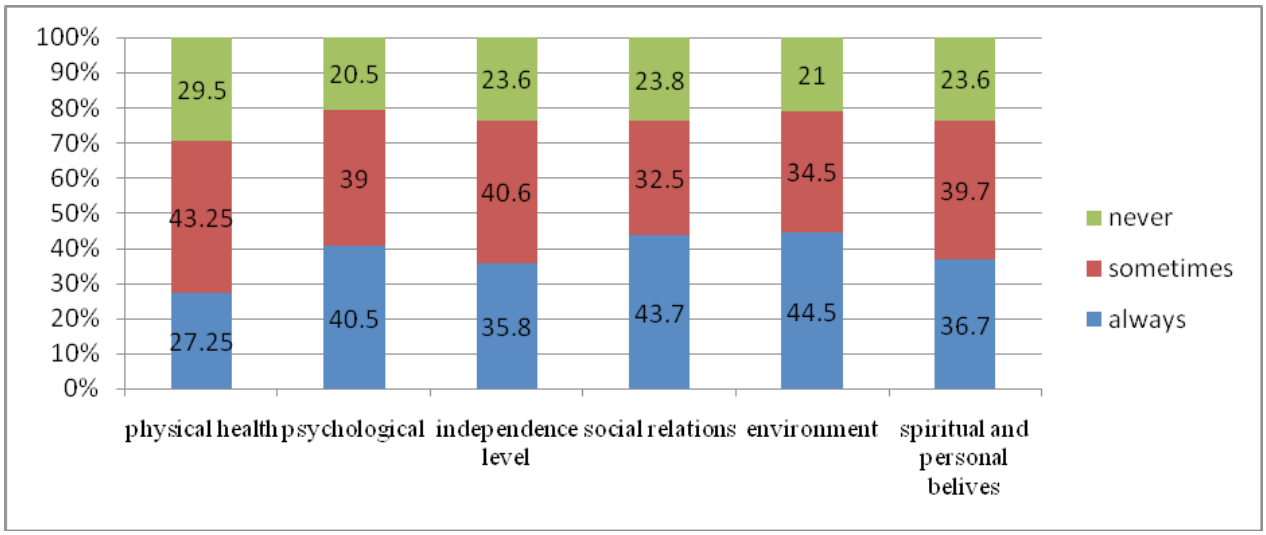

Figure (1): Adolescents' quality of life subdomains percentages

This figure shows that high percentages of adolescent with IBS have sometimes and always score for all subdomains of their quality of life. (43.25%) have sometimes physical health dysfunction, (40.5%) have always psychological dysfunction, (40.6%) have sometimes independence level, (43.7%) have always social relations dysfunction, (44.5%) have always environmental dysfunction, and (39.7%) have sometimes spiritual and personal dysfunction.

This figure reveals that the higher percentage (47%) of adolescent patients with IBShave bad quality of life.

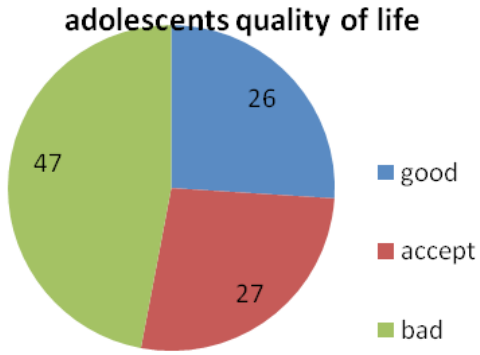

Figure (2): Levels of quality of life for adolescent patients with irritable bowel syndrome

Table (2): Relationship between quality of life level for adolescent with irritable bowel syndrome and their demographic characteristics

Quality of Life / Gender	Good	Accept	Bad	Total	χ^2 obs.	Sig.
	F	F	F	F

df = degree of freedom; f = frequency; P = level of probability; χ2 crit = critical chi square; χ2 obs = observed chi square,; sig. = significance; NS = Non significance; HS = High significance

This table shows that there is significant relationship between quality of life level for adolescents with IBS and their gender, marital status, level of education, and employment status.

Discussion

The findings of the present study showed that the majority of sample's ages were between (14- 18) years old who were accounted for (67%). As documented in previous studies irritable bowel syndrome IBS can occur at any age, but mostly at middle adolescents' life, this result supported by similar study about irritable bowel syndrome in the incidence at this age group 11. Relative to their gender, more than half of them were males (52%).According to our society attribute female patients may suffer from health care neglects by their families due to many causes such home duties and health awareness for their families. This result disagreed with a study medication used for patient with IBS that, the incidence more common in female than male 2:112.(48%) of adolescent patients were not married while (47%) of them were married. In Iraqi society some families encouraged the early aged marriage especially in young females due to religious causes and their poor socioeconomic status. This result supported by similar study which showed that the single person more likely to have IBS 13. (50%) of adolescent patients with intermediate school graduates, which indicated low level of education. Their health disorder or income may affect negatively on their school attendance and may cause school dropout. This result disagreed with another study about patients with IBS that, those patients showed a higher level of education 14. Concerning their employment status, (50%) of adolescent patients was employee. Because their early dropout from school and insufficient income and early marriage affects on demands and encouraged them to have a work in their early life. This result disagreed with a similar study about IBS patients that most of the patients were unemployed due to their health status14. (68%) of adolescent patients have insufficient monthly incomes. This may due to the financial burden of their health disorder and early marriage status. The proportion is similar in a study done by Noorbala, et al.14. (75%) of sample were smoked. Smoking consider as one of the most factors that can trigger IBS, especially early age smoking. This result supported by study done by Greg that indicates that the tobacco is one of the worst factors for digestive system disorders including IBS[15]. Most of them (77%) have negative family history for IBS. Most Iraqi families may have negative history or most of such disorder may be not diagnosed in some families so those adolescent did not know about other relatives with such disorder. This result disagreed with a study about patient with IBS that people with first relative degree diagnosed with IBS were at potential risk for such health disorder [17]. Other studies have no serious result that whether genes or the family history is responsible for IBS[18].

Figure (2) indicates that (47%) of adolescents with IBS has bad level quality of life related to their health disorder, while (27%) has accepted level. Unfortunately, this result is indicating low health care services and maladjustment with symptoms of IBS. This result agreed with a study about patients with IBS that those patients showed negative impact of IBS on their health and quality of life[8].

For more details regarding adolescents quality of life, figure (1) shows the highest percentages of them affected by psychological, social, and environmental domains (40.5%, 43.7%, and 44.5%) respectively, followed by independence level, physical health, and spiritual and personal believes (40.6%, 43.25, and 39.7%). The recurrent pain and alteration in bowel habits affects on their health status and body built and the body mass index negatively, which can cause body image dissatisfaction and isolation from others. IBS symptoms also can cause anxiety and frequent followed up to reduce the uncomfortable symptoms. Many studies showed the adverse effects of IBS on patients' social and psychological status [8].

The study shows a significant relationship between adolescents` quality of life level and their gender, marital status, education level and employment status. High percentages of males were married and have family responsibilities especially they were less than 18 years, that a burden on their life. Adolescents males when drop out from school they tend to have own work earlier to cover their financial demands in spite of their health status so it can cause adverse outcomes on their quality of life. This result disagreed with a study which showed that patient age, level of education, and employment status haveno relationship with their quality of life level [(11,14).] While a study about patients with IBS showed a significant association with their marital status [13].

Conclusion

The study showed psychological, social and environmental domains more affected on adolescents` quality of lifewho diagnosed with ISB.

Abstract

The present study aims to achieve the following objectives to assessment rheumatic arthritis patients in Maysan Governorate, an influence of the gender and age on the rheumatic arthritis and an effectiveness of the geographical areas (urban,rural) on the incidence of rheumatic. The data were collected between the (January to August 2016)Al-Sadder Teaching hospital in Maysan province and the total number of serum samples were (314).The study's data were analyzed through the use of Statistical processing, with program SPSS 20.0, Sigma Stat 2.03, Sigma Plot 2000, Med Calc and Excel 2010 and the blood samples were collected from patients aged (13–61years) (for both genders) and also from different areas in Maysan governorate, all blood samples were collected from people suspected having arthritis due to they had symptoms of diseases with pain,the rheumatic factor and C–reactive protein (CRP)were evaluated by latex agglutination test. The data analysis revealed that the majority of the patients about 27.4% in the study samples at age group (31-40 year. The chi-squared distribution is applied in hypothesis testing and to a minimum range for confidence intervals for population difference when the underlying distribution is normal.

Keywords: *C-reactive protein (CRP), Rheumatoid factors (RF) and chi-squared distribution.*

Introduction

Rheumatoid arthritis (RA) is an autoimmune disease in which the immune system of body which generally protects its health by attacking bacteria and viruses and others as foreign substances, attacks the joints viamistakenly . This creates inflammation that causes the tissue that lines theinto of joints (the synovium) to be thicken, resulting in pain and swelling around the joints. The lubrication joints and helping them move smoothly by synovium makes a fluid[2,4,1]. The elastic tissue that covers the ends of bones in a joint, as well as the bones themselves have damage when the inflammation goes unchecked. Moreover,there is loss of cartilage and the joint spacing among bones may become smaller, joints can become painful, stable and lose their ability to move Joint distortion also can occur,the damage of the joint none reversed, doctors recommend early diagnosis and aggressive treatment to control RA because it can occur early[3,8]. Clinical aspects of Rheumatoid arthritis differ, ordinarily reflecting the severity and stage of the disease. Joint pain,erythema,warmth, swelling, and lack of function are classic[9]. Palpation of the joints appears spongy or boggy tissue. Often fluid can be aspirated from the inflamed joint[2]. Peculiarly, the pattern of joint participation initiate with the small joints in the hands, wrists, and feet. The Rheumatoid arthritis can influence the body beyond the joint, such as blood anemia, blood vessels,eyes, skin, and lungs,the outer lining of the heart muscle (myocardium) and the heart (pericardium), also People with RA are more proneto risk of myocardial infraction (heart attack), atherosclerosis and stroke is markedly increased[5]. The risk factors for RA are inclusive genetic agents which (donate 50% to 60% of the risk of progressing rheumatoid arthritis[10]. Age and gender, the rheumatoid arthritis is far more prevalent in women than in men, the female-to-male ratio being (3:1)[4]. Nevertheless, the mechanism by which gender effects the vulnerability to rheumatoid arthritis remains

unclear, infections; several microorganisms have been involved in the expansion of RA based higher titers of the related antibodies in patients with rheumatoid arthritis. One prospect is that these microorganisms excite the expansion of rheumatoid arthritis in persons who carry genetic vulnerability agents to the disease[5], lifestyle, environmental agents, health and social outcomes[4, 5]. Rheumatoid factor (RF) is the autoantibody that was first set up in rheumatoid arthritis(RA). It is clarifying as an antibody opposed to the Fc portion of IgG and different rheumatoid factors can recognize various portions of the IgG-Fc. RF and IgG join to shape immune complexes that donate to the disease process[6].Rheumatoid factor can be either monoclonal IgM to polyclonal IgG (type 2) or polyclonal IgM to polyclonal IgG (type 3) .Although essentially encountered as IgM, rheumatoid factor (RF) may form of any isotype of immunoglobulins [7, 6].Rheumatoid factor (RF) isfrequently estimated in individual suspected of having any shape of arthritis even though positive outcomes can be due to other reasons, and negative outcomes do not cancel disease. But, in integration with signs and symptoms, it can play a function in both diagnosis and disease prognosis [4].It is part of the usual disease gauge of rheumatoid arthritis (RF). The presence of (RF) in serum can also mark the appearance of doubtful autoimmune activity detached to rheumatoid arthritis, such as that related with tissue or organ refusal [7] .In such cases, RF can avail as one of diverse serological signs for autoimmunity[11]. RFs may also be a marker of other autoimmune diseases, such as, definite infections, juvenile arthritis and some types of cancer[1]. RF also take place in other deficiency. As a representation, some connective tissue diseases, such as primary Sjögren's syndrome and systemic lupus erythematous (SLE), may be related with the existence of RF. In addition, RF levels may be raised in individuals with specific infections, such as rubella, malaria and hepatitis C[8]. The grades of RFraise with age, and positive reactions can be found in aged in women[9,8]. Rheumatoid factorsare proteins created by the immune system. Typically, the immune system assault disease-causing substances like bacteria and viruses. Rheumatoid factors assault glands, healthy joints or other normal cells by fault . The susceptibility of RF for determined RA is only 60-70% with a specificity of 79% [11]C-reactive protein (CRP) is an acute-phase protein that avail as an early sign of infection or inflammation. The c-reactive protein is synthesized in the organ of liver and is typically establish at concentrations of less than 10 mg/L in the blood. In the course of inflammatory disease states, CRP levels increase quickly within the first 6 to 8 hours and top at levels of up to 345–400 mg/L after 48 hours. A rise or growing levels of CRP submits have an acute infection (inflammation) in the patient[18]. The CRP test is not definite sufficient to detect a particular type of arthritis[5,13].

Materials and Method

The data were collected between the (January to August 2016) and the blood samples were collected from (314) patients age (13 – 61years) (for both gender) from the serological unite in Al-Sadder teaching hospital. also from different areas in Maysan governorate like AL- Hussein Q, AL- Majddia Q, AL-Ascarry Q, AL-Qadisea Q, Abo Romana Q, Al-Risala Q . RF and CRP were estimated by latex agglutination test, rely on indirect agglutination of latex particles covered with monoclonal anti-CRP antibody and human IgG, respectively. The analysis results were used to detect the findings according to CRP and RF as the follow

C-Reactive Protein: The slide agglutination test (CRP-latex) for the semi- quantitative and qualitative discovery of C - reactive proteinin human serum. Particles with goat lgG anti-human are when blended with samples including C - reactive protein; the CRP concentration can increase up to 350 in 12-24 hours. Through tissue necrosis and inflammation arise from microbial infections

Rheumatoid Factor (RF): The slide agglutination test (RF-latex) for thesemi quantitative and qualitative discovery of rheumatoid factor(RF) in patient serum. Latex particles covered with human gamma globulin are agglutinated when blended with samples including rheumatoid factor (RF).

Statistical Data Analysis: The study's facts were resolved through the statistical working has been drove out with program SPSS 20.0, MedCalc, Sigma Plot 2000, Sigma Stat 2.03 and Excel 2010. Statistical treatment has assisted us in interpretative analysis, whereas statistical parameters have assisted us to define the range index, standard error, arithmetic median, standard deviation, and confidence interval with precision 95% (95% CI).

Results

Table (1): Association between the C – Reaction Protein tests of individuals.

		%	74.8%	9.2%	15.9%	100.0%	

Table (2) indicates there was a significant relationship between rheumatoid factors of the patients with their age at confidence interval ($P < 0.05$), while show there are no significant relationship between rheumatoid factors tests with gender and residency at confidence interval ($P > 0.05$) when analyzed data by chi-square test.

Discussion

This study has been done to summarize and evaluate of rheumatoid arthritis and its distribution according to socio- demographic data with estimate the association between the C–RPtests and RFtests of patients with their demographic information. The level of education of individuals didn't play function in the happening of rheumatoid arthritis. The data analysis revealed the majority of RA patients are 27.4% at age group (31-40 years), this result agrees with a study conducted by[18, 16].Also due to the peak age of infected in the universal is between (35 to 45 years) with geographic variances, this agree with study .Most of infected are from females about(67%) more than males which agree with study by [13],the residence have high effects due to the majority of the patients about 96.5% are from urban regions reverse the rural regions which have agree with study by [15] he have been showed a prevalence of RA among urban Europeans, while rural groups showed much lower prevalence,in our research have dominated patients from urban areas. The study has been showed the majority of patients have C-reaction protein tests presented negative results (62.1%), as well as negative results (74.8%) of

rheumatoid factorwhich have agree with study by[16, 17] and the date of incidence distribution of RA diseases annually most occur in June month (27.4%)of the study sample.Table 1present that the majority of CRP test positive reaction increased in aged (41-50years) via (6.7%), Also this table indicates there was a high significant correlation between c- reactive protein in the gender with their age at ($P < 0.05$) and the reverse significant correlation between c- reactive protein in the gender with residency ($P > 0.05$) when analyzed by chi-square test.These data have agreement with study by [12, 13, 18]. According to the results in (table 2),which have been revealed the majority of the patients with age (41-50 years) via (3.2%) as positive reaction, this indicates there are a substantial links between rheumatoid factors test in the patients with their age at ($P < 0.05$) but there are no significant relationship between rheumatoid factors test with their gender and residency by ($P > 0.05$), when analyzed by chi-square test. This study is agreement with study by [14, 11].

Conclusion:

According to the results in tables, the recent studyconcluded the followings: Most of patient with rheumatoid arthritis (RA) at ages were ranging (31-40) years old with (27.4%), the females are more susceptible for infecting with rheumatoid arthritis (RA) than males by (67.5%). The majority of patients (96.5%) of the study samples were living in urban and therefore they have positive reaction of (CRP) and (RF),also both of reaction have increase with age.

The Value of Surfactant Therapy in Preterm Neonates with Respiratory Distress Syndrome

Moayed Mahdi Hussain

M.B.Ch.B.D.CH.C.A.B.P, Pediatrician, Al-Diwaniyah Maternity and Children Teaching Hospital, Al-Diwaniyah Province, Iraq

Abstract

The currents study was planned and conducted to evaluate the use of surfactant therapy in preterm neonates with respiratory distress in Al-Diwaniyah Maternity and Children Teaching Hospital. The present cohort study included 186 preterm neonates who were randomly selected from the pool of neonates admitted to Al-Diwaniyah Maternity and children teaching hospital, Al-Diwaniyah province, Iraq. There was no significant association between frequency of other complications and treatment method whether prophylactic, early rescue and late rescue ($P > 0.05$). Morality was significantly higher in prophylactic method in comparison to early rescue method ($P = 0.002$); and also it was higher than that seen in association with late rescue method with a borderline significant level ($P = 0.073$). Mortality was also significantly associated with less gestational age ($P < 0.001$). The rate of complications was significantly less in continuous positive air pressure (CPAP) ventilation method in comparison with mask method ($P = 0.006$). Sepsis and BPD were significantly less frequent in CPAP method ($P < 0.05$); whereas, nasal trauma, and air leaks were significantly less in mask method ($P < 0.05$).

Keywords: *Surfactant therapy, preterm neonates, RDS.*

Introduction

In modern obstetric practice, full term newborn is considered when delivery happens after the fetus has completed 37 weeks of gestation. However, a significant number of pregnancies end before this point of gestational period and the condition is going to be labeled as preterm labor [1-4]. Several predisposing factors are frequently associated with preterm labor, such as infection, placenta previa, substance use, placental abruption, inadequate prenatal care, stress, smoking, maternal age <18 or >40, low body mass index, polyhydramnios, oligohydramnios, fetal growth restriction, fetal anomaly, poor nutrition, premature preterm rupture of membranes (PPROM) and other factors [5-12]. Preterm birth is certainly to be accompanied by the problem of prematurity and respiratory distress (1-5). Other less common complications associated with preterm labor include intraventricular hemorrhage, sepsis and necrotizing enterocolitis [13, 14]. The presence of PPROM may be, in particular, associated with intrauterine inflammation and subsequent neurological insults [15, 16], besides, increased risk of accidents due to umbilical cord[17]. The principal cause of respiratory failure in preterm infants is respiratory distress syndrome (RDS) which was previously called "hyaline membrane disease"; however, because of its clear association with surfactant deficiency, its new name "RDS" becomes widely accepted in clinical practices[18]. The list of causes that are accompanied by respiratory distress in newborn is relatively long, but pulmonary causes, in particular, are often due to some underdevelopment of respiratory system which is a common manifestation of preterm labor (1-4). Indeed, from embryologic perspective, lung passes through five stages of development and preterm labor is often associated with underdevelopment of later stages [19].

The incidence and the associated complications accompanying respiratory distress syndrome have been greatly reduced with the use of antenatal corticosteroids and postnatal surfactant therapy. Lung compliance and oxygenation have been shown to be greatly enhanced following exogenous surfactant administration which

has led to marked reduction in the incidence of pneumothorax and mortality associating RDS [20, 21]. Nevertheless, a clear consensus about the magnitude of benefit of postnatal surfactant use in premature infants is lacking in available published articles. In addition, the rarity of Iraqi literatures disclosing this benefit has justified the conductance of the current study. For those reasons, the currents study was planned and conducted to evaluate the use of surfactant therapy in preterm neonates with respiratory distress in Al-Diwaniyah Maternity and Children Teaching Hospital.

Patients and Method

The present cohort study included 186 preterm neonates who were randomly selected from the pool of neonates admitted to Al-Diwaniyah Maternity and children teaching hospital, Al-Diwaniyah province, Iraq. The study started on January 2018 and ended on June 2019. The main variables included in the study were gestational age, gender, mode of delivery, number of births, time of taking surfactant, neonatal complications and mortality.

Medical intervention was in the form of surfactant administration using prophylactic, early rescue and late rescue method. Verbal consent was obtained from parents and the study was approved by institutional ethical approval committee.

Obtained data were transformed into SPSS (version 23) spread sheet. Categorical data were expressed as number and percentage. Chi-square test and Yates correction were used to study association between categorical variables. The level of significance was considered at $P \leq 0.05$.

Results

The general characteristics of neonates enrolled in the current study are shown in table 1. Complications that have been encountered are demonstrated in table 2. The most common complication was sepsis, followed by nasal trauma, air leak, pulmonary hemorrhage, patent ductus arteriosus and bronchopulmonary dysplasia.

Sepsis was significantly more in prophylactic mode in comparison to early rescue ($P = 0.024$) and to late rescue ($P = 0.005$); however, there was no significant difference in the frequency of sepsis between early and late rescue method ($P = 0.294$), as shown in table 3. There was no significant association between frequency of other complications, namely nasal trauma, air leak, pulmonary hemorrhage and patent ductus arteriosus, and treatment method whether prophylactic, early rescue and late rescue ($P > 0.05$), as shown in table 3.

Morality was significantly higher in prophylactic method in comparison to early rescue method ($P = 0.002$); and also it was higher than that seen in association with late rescue method with a borderline significant level ($P = 0.073$); however, there was no significant difference in mortality rate between early and late rescue method ($P = 0.575$), as shown in table 4. Mortality was also significantly associated with less gestational age ($P < 0.001$), as shown in table 5.

In general the rate of complications was significantly less in continuous positive air pressure (CPAP) ventilation method in comparison with mask method ($P = 0.006$). In particular, sepsis and BPD were significantly less frequent in CPAP method ($P < 0.05$); whereas, nasal trauma, and air leaks were significantly less in mask method ($P < 0.05$), as shown in table 6.

Discussion

The current study was conducted to evaluate the role of surfactant in reducing both mortality and morbidity rates in association with preterm infants and RDS. In particular, the main goals were to find which method of surfactant administration is associated with less morbidity and mortality.

We were able to demonstrate that mortality rate was significantly less in association with both early and late rescue method than with prophylactic method. Sepsis was also significantly less frequent in association with both early and late rescue method than with prophylactic method. It has been claimed that the use of prophylactic surfactant may reduce mortality rate in preterm infants; however, the introduction of antenatal steroid strategy and early positive air pressure has changed this claim because of the significant reduction in mortality rate with later two measures [22]. In one study, it has been found that both prophylactic surfactant and early rescue are equi-effective in reducing morality and morbidly with no significant variation between both method [22]. However, we found, on the contrary, that early rescue is even better than prophylactic surfactant. It is worth to mention that "prophylactic surfactant administration has a disadvantage in that it requires intubation and can lead to over-treatment of preterm infants who may not be prone to developing RDS" [22]. Moreover, a meta-analysis has shown that prophylactic surfactant is no more superior to early or late rescue method [23], in support for our findings.

In the current study, we found that early rescue is not superior to late rescue method, a findings that is in contrary to the findings of other authors [24]. Besides, our findings are dissimilar to that of Bahadue and Soll who found that the rate of complications is significantly lower in case of early rescue treatment method [25].

The currents study also showed that CPAP is preferred to mask method ventilation. In conclusion, late and early rescue method are better than prophylactic method in terms of morbidity and mortality and the use of continuous positive air pressure is preferred to mask method with respect to surfactant administration in preterm infants.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the Al-Diwaniyah Maternity and Children Teaching Hospital/Al-Diwaniyah Province, Iraq and all experiments were carried out in accordance with approved guidelines.

The Role of Faith Healer Visits in the Management and Prognosis of Mental Illness in Iraq

Waleed Azeez Mahdi Al Ameedee[1], Maythem Muhsin Alyasiry[2]

[1]Assistant Professor, Psychiatry, [2]Consultant Doctor, College of Medicine,Babylon University

Abstract

Background: Mental illnesses denote to disorders generally characterized by abnormalities of mood, thought, and/or behavior. Different attitudes toward mentally ill individuals were found among families, ethnicities and countries, the cultural and religious beliefs often affect the opinions about the nature and the origin of mental illness and even influence the attitude toward those who have mental illness.

Objectives: To investigate and document the rate of mentally ill patients who are visiting the faith healers and the effect of that visit on the management of their condition.

Method: This is a cross sectional study was done in Merjan Teaching Hospital during the period from November 2017 till February 2018 . The sample composed of 187 mentally ill patients (80 males and 107 females). A semi-structured questionnaire was used for information into socio-demographic data and questions about the visit to faith healers (time of the visit, the effect of the visit on the management, source of referral to the faith healer and if the money given or not). Diagnosis of mental illness was made according to DSM-V.

Results: 57.2% of the patients in the present study were females, 61% of the patients were married. 41.2% of our sample completed secondary school and 52.9% of them were unemployed. (74.3%) of patients had history of visit to faith healer. 25.1%, 22.5% and 19.4% were diagnosed as schizophrenia spectrum and other psychotic disorders, anxiety disorders and depressive disorders respectively. The visit to the faith healers was adversely affecting the compliance of mentally ill patients to their medications in about 76.3% of our sample. There was no significant association between history of visit to faith healers and type of psychiatric disease.

Keywords: *Mental illness, faith healers, management.*

Introduction

Mental illnesses denote to disorders generally characterized by abnormalities of mood, thought, and/or behavior, as recognized by the Diagnostic and Statistical Manual, 4th edition, of the American Psychiatric Association (DSM-IV). Mental illness is usually not culturally appropriate. It is associated with disability or distress and not merely a conflict between the individual and culture. Many people have a fear from mental illness and they stigmatize those who are affected by it. The reasons for that view originating from the idea that mentally ill patients cannot control their own behavior and that they may act in strange and possibly aggressive ways [1]. Stigma can affect the compliance of mentally ill individuals, it prevents him from seeking treatment, finding a job, and living successfully in his culture. To improve the state of mental health around the world, the World Health Organization (WHO) cited advocacy against stigma and discrimination, as it is one of the major barrier to overcome in the community [2]. Different attitudes toward mentally ill individuals were found among families, ethnicities and countries, the cultural and religious beliefs often affect the opinions about the nature and the origin of mental illness and even influence the attitude toward those who have mental illness, so it is mandatory to understand the cultural beliefs about

mental illness in order to offer effective mental health services[3] Many cultures widely believed that mental illness was attributed to the magical forces, Gods anger or the result of supernatural phenomena such as spiritual or evil possession. Treatment of mental illness date back to ancient cultures and was focusing on the method by which they can use to defeat these evil forces or remove the curse. A crude stone instruments was used to made a hole through the skull. It was believed that through this opening the evil spirits thought to be inhabiting patient's head and causing their psychopathology will leave and the individual would be cured [4]. In ancient Greece, the mental illness was viewed as a sign of guilt and a punishment from the God for both minor and major crimes, and the mentally ill individuals were often abstain by their society and some were even put to death [5]. During this period, the priests were the main therapists, they used the prayers to the God to achieve cure of the patients. Later on, the supernatural or the mystical agents could no longer accepted as the underlying cause of mental diseases. Hippocrates and Aristotle were among the most important and influential figures during this time period [6].

Patients and Method

This is a cross sectional study was done in Merjan Teaching Hospital during the period from November 2017 till February 2018 . The sample composed of 187 mentally ill patients (80 males and 107 females). Informed consent was obtained from the each patient before data was collected. Patients who did not give the consent were excluded from the study. In case of psychotic patients, the information were obtained from nearby relatives. A semi-structured questionnaire was used for information into socio-demographic data and questions about the visit to faith healers (time of the visit, the effect of the visit on the management, source of referral to the faith healer and if the money given or not). Diagnosis of mental illness was made according to DSM-V.Statistical analysis was carried out using SPSS version 17. Categorical variables were presented as frequencies and percentages. Pearson's chi square (X^2) test and fisher exact test were used to find the association between the categorical variables. A p-value of ≤ 0.05 was considered as significant.

Result

Figure 1 shows the distribution of patients according to visit to faith healer. Majority (74.3%) of patients had history of visit to faith healer.

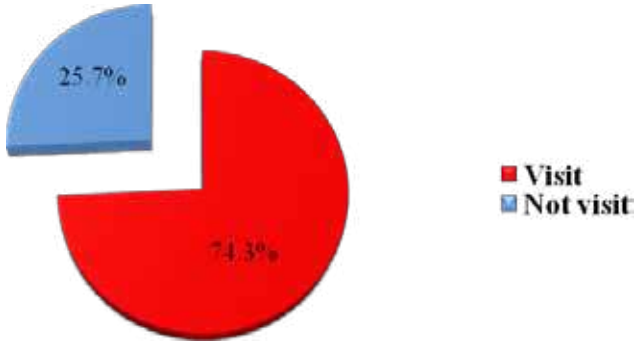

Figure 1: Distribution of patients according to visit to faith healer

Table 1 shows distribution of patients who visit faith healers according to study variables including (time of visit, source of referral to faith healer, money given to faith healer and effect of faith healer on patient compliance with medication). 69.8% of the patients in our study have a visit to faith healers before psychiatric consultation and 67.6% of the patients went to the faith healers with their family members. In most cases (88.5%) money was given to the faith healer. The visit to the faith healers was adversely affecting the compliance of mentally ill patients to their medications in about 76.3% of our sample.

Table 1. Distribution of visitors to faith healer according to study variables

Study Variables	N	%
Time of visit to faith healer		
Before psychiatric consultation	97	69.8%
After psychiatric consultation	31	22.3%
Before and after	11	7.9%
Total	139	100.0%
Source of referral to faith healer		
Himself	45	32.4%
Other	94	67.6%
Total	139	100.0%
Money given to faith healer		
Yes	123	88.5%
No	16	11.5%
Total	139	100.0%
Effect of faith healer on patient compliance with treatment		
Yes	106	76.3%
No	33	23.7%
Total	139	100.0%

Table 2 Shows mean differences of age by history of visit to faith healers. There were no significant differences between means of age by study variable.

Table 2: The mean differences of age by history of visit to faith healers

Variable	History of visit to faith healers	Number	Mean±SD	t-test	P value
Age (Years)	Yes	139	33.92±13.91	0.058	0.954
	No	48	34.06±13.5		

*p value ≤ 0.05 was significant.

Table 3 shows the association between history of visit to faith healers and type of psychiatric disease including (schizophrenia spectrum and other psychotic disorders, depressive disorders, anxiety disorder and other psychiatric disorders). There was no significant association between history of visit to faith healers and type of psychiatric disease.

Table 3 Association between history of visit to faith healers and type of psychiatric disease

Study Variable	Visit to Faith Healer		X^2	P-value
	Yes (%)	No (%)		
Type of psychiatric disease				
Schizophrenia spectrum	36 (25.9)	11 (22.9)	0.466	0.926
Depressive disorders	26 (18.7)	10 (20.8)		
Anxiety disorders	30 (21.6)	12 (25.0)		
Others	47 (33.8)	15 (31.3)		
Total	139 (100.0)	48 (100.0)		

*p value ≤ 0.05 was significant.

The stigma attached to mental illness and the beliefs that psychiatric disorders was attributed to supernatural forces, had made a significant number of patients in our country to visit the traditional faith healers as shown in the present study which revealed that 74.3% of patients had a visit to faith healer during the course of their disorder. The high number of faith healer visits may also reflects the level of belief & trust in faith healer to manage their illness. The result of this study was higher than the earlier research done in Nepal [16] and this can be explained by many reasons such as the faith healers are easily approachable by the patients in our country. In addition, in the last few years a greater number of such healers appeared in rural areas and even in the urban areas and most of them are using such ways of healing as a job to earn a lot of money from patients and their relatives and to our knowledge there are no legal restrictions to prevent this abusing way of healing. When compared to our results, a minority of patients with mental health problems are choosing the traditional faith healers in India[17] . 69.8% of patients in the present study are choosing the faith healers as the first service contact before psychiatric consultation and 67.6% of the visitors were following the recommendations of relatives and friends to seek help from such persons instead of psychiatrists and most of them gave money to get help from the faith healers. A widely spread wrong ideas about the medical treatment of psychiatric disorders in our culture and most of mentally ill patients and their relatives have a belief that all psychotropic medications are causing addiction and make the mental health more worse, so it is better and more safe at the first time to seek management from the faith healers who are using the Holey Quran and some herbals to treat the mental illness. The effects of mental illness on patient`s ability to take decision about psychiatric consultation along with the effects of other persons (relatives and friends) are the main reasons of the referral to the traditional faith healers not by the patient himself. In most of the cases in our study, the services provided by such healers are no free and money should be given before and sometime after the interview, and this of course has additional burden on the patient and his family. The present study shows that more females approached the traditional healers than males, and this result is nearly similar to other study done in India [19]. In our society the cultural

attitudes and limitations that are compelling the mentally ill females to comply and follow the orders of her family and her husband may greatly decreasing the referral rate to psychiatrist. The location of Merjan Teaching Hospital in the center of Hilla city makes most of its attenders from the urban area, thus only 80 patients in our study were from rural area and this may explain the slight increased rate (52.5%) of visitors to the faith healers were from the urban area. It is not easy (in our society) for the mentally ill married patients to visit psychiatrist and administer psychotropic medications because of their belief that psychiatric disorder and its therapeutic measures makes the family life more worse regarding their reputation among relatives and friends, in addition to the economic burden. This may explain why the high rate (64.7%) of the faith healer`s clients were married. The level of education among our patients may affect their choice to consult psychiatrist, as 87.8% of visitors to faith healers were of low education level. The higher educated persons have the knowledge about the likely outcome of delay in seeking psychiatric care and they are also more aware of using unhealthy remedies.The inverse relationship between faith healer`s visit and level of education is also found in previous studies[18]. There was no significant association between history of visit to faith healers and type of psychiatric disease. The present study is of benefit in showing the rate of mentally ill patients who have previous history of faith healers visit and the adverse consequences of following the advice of that healers. The possible factors that contribute to delay in seeking psychiatric care to our patients should be identified and managed in proper way. The active role of media and educational institutions should be directed toward providing adequate information about the common psychiatric symptoms and public education about reducing psychiatric stigma.

Nurse's of Knowledge toward Newborn Injuries in the Delivery Rooms at AL- Amara City Hospitals

Mustafa Salim Abdul Alridh[1], Ghazwan Abdulhussein Al-Abedi[2], Aqeel Azeez Arrar[3]

[1]MSc. Assistant Lecturer, Pediatric Nursing Department, [2]MSc. Assistant Lecturer, Community Health Nursing Department, [3]MSc. Assistant Lecturer, Adult Nursing Department, College of Nursing, University of Misan

Abstract

Childbirth wounds are damage to a child before, during or shortly after birth. Childbirth injuries, also known as birth trauma, are known in various forms of severity, but most are mild and these minor injuries become common over time at birth. They are more serious injuries that cause permanent damage. It damages many parts of the body, such as brain damage, nerve damage, bone and muscle damage and, in the worst case, death. Objectives: (i) Assessment knowledge of nurse about Birth injuries. (ii) To identify the relationship between demographic data and knowledge. A survey was conducted in 80 convenient samples with a pre-validated questionnaire . the total period of study are five month 2018/11/20 and ended 2019/6/23 populations of study were the staff in the delivery rooms at AL- Amara city hospitals. The knowledge level is mean in staff nurses who has experience from (5-10) and show the age (20-24) years and have nursing secondary graduate level of education have high level of knowledge and take (1-5) training courses have higher level of knowledge .On comparing these. There is mean nurses knowledge, The study found that there is a relationship between nurses' knowledge and demographic information (training courses).

Keywords: *Nurse, Knowledge, Birth injuries.*

Introduction

Newborn injury is the damage to the baby during the birth process usually when the child crosses the birth canal[1]. It was suggested that trauma associated with childbirth may be caused by difficulty in vaginal delivery especially with childbirth, blood proliferation and shoulder dystocia, and may use sharp tools such as forceps or vacuum during childbirth. The incidence of neonatal injuries ranged from 6-8 cases per 1,000 live births[2]. Neonatal injuries in a child can range from minor injuries to soft tissues at birth, bleeding (pituitary tumor, subchondral bleeding, intracranial bleeding), long bone fractures and bone Broken collarbone, peripheral nerve injuries. On this basis, this study was conducted to determine the incidence, risk factors and outcomes of childbirth injuries. This study aims to provide a comprehensive review of the literature search direction major injuries to newborns[3]. Twenty of these infections are often categorized according to the etiology, transmission and subsequent outcomes. Whereas, this classification is a strategic first step towards the development and future progress to know the injury of infants and classify them accurately and correctly. It gives obstetric caregivers a valuable tool to help predict, prevent, or alleviate the severity of childbirth injuries, so we will have long-term results that in turn serve us in the future. Factors responsible for mechanical injury can coexist with the fetus[4]. In 2016, Canker and Carter defined neonatal injury as structural destruction or neonatal dysfunction as a result of a traumatic event at birth. Some of these injuries can be avoided and grandfather ones when appropriate health care is available while others are part of the birth process that can occurs even when health personnel exercise extreme caution. There are also some causes that lead to prenatal injuries such as amniocentesis and intrauterine blood transfusion. However[5], injuries from fetal scalp electrodes and monitoring of heart rate during childbirth are considered injuries at birth. Over the past 20 years, the number of deaths from childbirth injuries has fallen so that they are no longer included in the 10 most common causes of death in the postpartum period.Birth processes, whether automatic or assisted

another, inherently shocking for newborns. Mechanical events and oxygen ischemia are the causes of birth-related injuries. This review was focused mostly on the mechanical shocks he suffered the newborn due to labor and birth forces experienced by the pregnant mother[7]. To summarize this review, birth-related hypoxia will not be taken separately. Birth-related trauma may affect many neonatal organs (ESM). The incidence of mechanical shock at birth may be somewhat reduced to some extent. The infection rate is 0.82%, and the rate of prevalence of 9.5 per 1,000 live births. Statistics show less than 2% of newborn deaths due to traumatic birth. Birth trauma or perinatal trauma indicates to injuries caused in newborns during childbirth at any stage during the entire birth process. Of course, the incidence of childbirth shocks is high in Western statistics and in reports from developing countries. This increase may coincide with both mortality and morbidity[6]. The total number of maternal injuries was reduced with improvement in obstetric care and prenatal diagnosis. Neonatal trauma in neonatal FD includes minor soft tissue injuries, long or bone clavicle fractures, renal tumor, and peripheral nerve injuries. In the literature, the focus has been highlighted on various risk factors such as infants, active neonates, poor presentations, and labor complications. The study of trauma at birth from an Indian perspective is rare. Thus, this study carefully planned to document the incidence and risk of childbirth trauma with the broader goal of generating income towards reducing neonatal mortality and morbidity[7]. As well as structural or functional deterioration of the newborn in high school known as the birth of the birth of this injury is a tragic event that occurred during the period of labor and delivery, or both. Is not taken into consideration that amniocentesis and move inside the uterus can cause injuries before birth and birth injuries. Injuries under neonatal resuscitation procedures cannot be classified as injuries at birth. When using fetal scalp electrodes and birth within a heart rate monitor, injuries can be described as birth injuries. Where the proportion of newborn injuries previously mentioned and compared with the mortality rate of children, which may occur during the second stage of labor, which occurs during the descent of the fetus through the birth canal [8-12]. The increase in morbidity and mortality of newborn infants occurs as a result of injuries during childbirth. Therefore, there are some measures and guidelines that avoid specific negative results. Acoustic and CT scans and magnetic resonance imaging, where these tests are possible to more accurately predict the abnormalities that put the fetus at high risk for large injury as this helps to reduce the severity of the injury but does not guarantee that these injuries do not occur. In addition to method that can be used for different conditions there are categories[9] of birth injuries. Official or professional research tools used in the literature to document or assess the degree of trauma resulting from birth injuries

Sample and sampling techniques Convenient sampling was done for this study; 80 samples collected representing staff nursing. The time it takes to collect the samples ware the month. The tools used in this study contains :First part of questionnaire :Demographic data. This theme addresses 5 modules, which include age, educational level, and years of work experience, training session and years of work in the hall of birth. Second part of questionnaire: specific information to sample research,that contains (15) items, which included question regarded injuries of newborn and question about the introduction, causes, signs and symptom, nursing care and treatment of new born injuries.The data collectionis formal permission obtained from the authorities for the collection of data. The data was collected from the misan hospital of delivery room. Explained the need and purpose of the study, the knowledge level assessed after obtaining permission from the staff nurses. In order to achieve the above objectives, the study data analysis through the use of the Statistical Package for Social Sciences (SPSS).

Results and Findings

The findings of systematic data analysis in the tables and these correspond to the objectives of the study as follows: The results in this table (1) indicate that the number of participants in the study sample are within the age group (20-24) years was (50%). Also with regard to the level of education topics, and the results showed that more than one level of them has high school graduates (N: 42) was (52.5%).Also in relation to subjects of years of work, the results showed that more than half of them in the age group of the study sample were within (5-10) years (70.0%). In addition, the Number of training courses of nurse involved in the study sample are within group (1-5) was (56.3%).Finally, in the table above, the results showed that the majority of participants more than half of years of experience are within group (5-10) years was (90.0).And table (2) shows that the majority of participants have a moderate level of knowledge (n = 69, 86.2%), and the results of data analysis, as presented in this table (3), Suggest that there is a statistically

significant relationship among nurses towards their knowledge of their birth injury will their experiment number (P <0.05), when analyzed by chi-square test.

Table (1): Participants' level of knowledge is distributed by mean of questions regarding knowledge nurses towards obstetric injuries.

Level of Knowledge	Frequency	Percent
Low	8	10.0%
Moderate	69	86.2%
High	3	3.8%
Total	80	100.0%

Table (2): Association between the nurses' toward their knowledge about the birth injuries and their no. experience

No. Experience		Knowledge			Total
		Low	Moderate	High	
5-10 yrs	F	8	62	2	72
	%	10.0%	77.5%	2.5%	90.0%

Discussion

More than the nurses age group for the study sample was within (20-24) years was (50.0%). This finding is consistent with a study conducted by Hubballi, 2015. This study aims to evaluate demographic characteristics such as (age, educational level of nursing and nurse`s experience in the intensive care unit), to assess the quality of nursing care and to reveal the relationship between the quality of nursing care with demographic characteristics. Such as (age, level of education and experience of nursing nurses in the ICU) in Belgaum, Karnataka that show the majority of samples age (20-25) in ratio (66.67%) from study sample.

Also in relation to the level of education subjects the result shows that almost half of them have a secondary nursing graduate (52.5%). this study agrees with study conducted by Rasheid and ali, (2010)[9],The objectives of this study were to assess nurses' knowledge, provide care for the newborn, meet the requirements of the newly delivered mother and fetus and monitor progress in their health after delivery.in Al Yarmook Teaching Hospital more sample are nursing secondary graduate in ratio (11%.(The result of this table show that the majority of nurses in years of experience group the study sample were within (5-10)was (90.0%), this agrees with study conducted by Rasheid and ali, (2010)[9], This study aims : To understanding quality of care have been updated to maintaining high quality of performance in the Al yarmook teaching hospital that show the majority of sample in years of experience. The result show that the majority of the nurses in the number of training courses to the study sample were within(1-5)was (56-3%), this result agrees with the study conducted Rasheid and ali, (2010)[9], this the study aims : To assess the knowledge of nurses and care of the newborn and meet the requirements of the newly delivered mother and her unborn child and to monitor progress in health after their birth. This table (1) reveals that the majority of participants have moderate level of Knowledge (n=80;

69.2%). This is result disagrees with a study conducted by (Hubballi, 2015), the revealed that test majority of nurses had average knowledge.

Conclusion

1. The study shows that the nurses in the age group (20-25) years they (50%) more knowledge about the Birth injuries.
2. The study show the nurses in Nursing institute graduate have more knowledge about the Birth injuries in ratio (52.5%).
3. The study show the nurses have (5-10) years of worker have more knowledge about the Birth injuries in ratio (75.0%).
4. The study show the nurses which have (1-5) training courses have more knowledge about the Birth injuries (56.2%).
5. The study show the nurses have moderate level of knowledge through the Mean of questions related to nurses knowledge toward the Birth injuries in average mean of scores (69.2).
6. The study shows that there is a relationship strong between the Demographic characteristics for nurses and knowledge about the Birth injuries.

Measurement Serum Level of Interleukin-34 in Patients with SLE and Healthy Control

Mohanad K. Mardan[1], Alaa S. Alattabi[2], Ali M. Al-kazaz[3]

[1]B.Sc. in Medical Technology, Department of Immunology, Alsader Hospital, Najaf City, [2]M.B.CH.B., FIMCS Path, Immunology Department of Microbiology, College of Medicine, University of Kerbala, [3]Rheumatology Department, Marjan Teaching Hospital, Rheumatologist

Abstract

Background: Systemic lupus erythematosus (SLE) is a chronic inflammatory autoimmune disease characterized by abnormal function of T-cells and B-cells involving production of autoantibodies and different type of interleukins including complement activation and multiple tissue damage accompanied with different clinical manifestation, all of this happened along with break tolerance. Many researches revealed a key role of interleukins and other biological molecules in SLE patients. Interleukin 34 responsible for increasing differentiation and surviving of autoimmune cells in SLE.

Objective: This study was aimed to estimate the concentration of IL-34 SLEpatients in compare with healthy people.

Materials and Method: This is a case-control study accomplished in the Advisory Clinic for Rheumatic Diseases Center in Al-Najaf city, for the period from December 2018 to August 2019. A total of 60 individuals were included in this study, 30 were diagnosed with SLEby specialist rheumatogy physician, and 30 were healthy controls. Blood sample were collected by venipuncture from 30 patients and 30 healthy controls under sterilized technique and putting in gel tube which then used in sandwich ELISA technique to detect serum level of IL-34.

All data that include age, gender, residence and history of autoimmune diseases were collected from all participants. The data were analyzed by using the statistical package social system (SPSS).

Results: This study show that level of IL-34were significantly higher in SLE patients (49.58±64.03) than in control (0.4±1.25). It is also found that the prevalence of SLE was higher in female in comparewith male26 (86.7%) to 4 (13.3%) respectively.

It also found that SLEwas more frequent in age interval from (31-50) years old.

Conclusion: Elevation of Il-34 concentration may play important role in pathogenesis of SLE, SLE most commonly affectfemales age groups (31-50 years old).

Keywords: *SLE, autoimmune disease, IL-34.*

Introduction

Systemic lupus erythematosus (SLE) is a chronic autoimmune and systemic disease recognized by production of antibodies against tissue components especially nucleoprotein and including complement activation and multiple tissue damage involving kidney, nervous system and blood cells[1].

Corresponding Author:
Mohanad K. Mardan
B.Sc. in Medical Technology, Department of Immunology, Alsader Hospital, Najaf City
e-mail: muhanedspeer89@gmail.com

Different type of cytokines are involved in pathogenesis of SLE and associate with activity of the disease[2]. The causes of SLE is not clearly understood but presence of genetic predisposition and other environmental factors (pregnancy, infections, toxin and Ultraviolet) canlead to exhibit clinical manifestations[3,4].

Interleukin 34 is a newly discovered interleukin which is not similar in amino acid sequence in compared to other cytokines. IL-34 share the receptor of colony stimulating factors (CSF-1), its responsible for proliferation and differentiation of white blood cells (Lymphocytes) which lead to increase inflammatory processes and autoimmune activity[5,6]. The Main tissue that produce IL34 are spleen, thymus, liver, testes, ovaries and brain[5]. Follicular dendritic cells inducing monocyte to proliferate and differentiate by the action of IL-34 producing by this type of dendritic cells[7].

Interleukin 34 have the ability to enhance production of many types of immune mediators such as interferon gamma, IL-6[8] and monocyte chemo attractive protein (MCP) [9].

The current study try to express role of interleukin 34 through measuring serum level of this biomarker in SLE and compared with healthy control.

Subjects and Method

Ethically, data collection and the design of the study groups were accomplished afterthe approval on theresearch proposal was done byResearch Ethics Committee of AL-Najaf Health Directorate to work in its hospitals.

A case-control study conducted during the period from December 2018 to August 2019 in Al-Najaf city. A total of sixty subjects were included. Thirty SLE patients including 4 male and 26 female, and the female to male ratio was 9:1, those patients were diagnosed byspecialist Rheumatology physician according to American college of Rheumatology criteria. However, thirty healthy individuals as control who were attended the Advisory Clinic for Rheumatic Diseases in Al-Najaf city.

Blood sample were collected by venipuncture from 30 patients and 30 healthy controls (five ml/cc of venous were drawing by disposable syringe under sterilized technique in colt activating vacuumed tube). The serum has been collected in Eppendorf tube then stored at -20C to be used for determining the concentration of IL-34 by ELISA technique.

Quantitative sandwich enzyme immunoassay technique was used, micro ELISA plate had been pre-coated with an antibody to measureIL-34 concentration. The color intensity produced was directly proportional to the amount of IL-34 bound in the initial step. The optical density (OD) was measured spectrophotometrically at a wave length of 450nm .The OD value was proportional to the concentration of IL-34 then, calculate the concentration of substances in the sample by comparing the OD of the samples to the standard curve.

All data that include: age, gender, history of other autoimmune diseases have been collected from all participants, and appropriate statistical and descriptive analysis were performed using IBM SPSS V21.

Results

A total of 60 individuals were included in this study, divided into 30 patients (4 males and 26 females), their ages ranged between (9-55) years,the male to female ratio was 1:9 and 30 as a control group (7 males and 23 females), their ages ranged from (9-55).

Concentration of IL-34 in SLE patients mean±SD (49.58±64.03) was significantly higher than control (0.4±1.25), P value greater than 0.001 Table (2).

frequency of SLE was higher in females than in males each male affected by SLE corresponding with about 7 of females affected by the SLE.

The number of SLE cases was more frequent in age interval (31-50) years old which comprises 16 patients (53.3%) from the total of SLE cases, the lowest number of cases was in the age interval (<=10) which is only 1 case (3.3%) and 3 cases consisted (10%) in age group (11-20) while in control group it include 15 individuals (50%) in (31-55 years) age group, and 8 (26.7%) in age group (11-20 years), while the age group (21-30 years) include 6 individuals (20%) and only 1 (3.3%) was under age of 10 years Table (1).

The mean of ages (mean±SD) for SLE patients were (33.4±12.01) and (31.5±12.59) for healthy control. Variable of age revealed no significant difference between studied group (P value=0.809).

The most affected SLE patients were females (86.7%), whereas male was revealed low percent (13.3%).

Table (1): Demographic information of controls and SLE Patients.

Variables		SLE patients		Healthy control		Statistics	p value
		No.	%	No.	%		
Age	<= 10	1	3.3	1	3.3	F= 0.212	0.809
	11 – 20	3	10.0	8	26.7		
	21 – 30	10	33.3	6	20.0		
	31 and more	16	53.3	15	50.0		
		Mean±SD 33.4±12.01		Mean±SD 31.83±11.56			
Gender	Male	4	13.3	7	23.3	$X^2 = 3.417$	0.181
	Female	26	86.7	23	76.7		
Total		30	100%	30	100%		

Table (2): Show difference in level of interleukin 34 between SLE patients and healthy control by using Chi-square statistical test.

Variable	SLE	Healthy Control	Statistics	p value	Post-hoc Analysis
	Mean±SD	Mean±SD			
IL-34	49.58±64.03	0.4±1.25	X2 = 56.785	<0.001	SLE> C

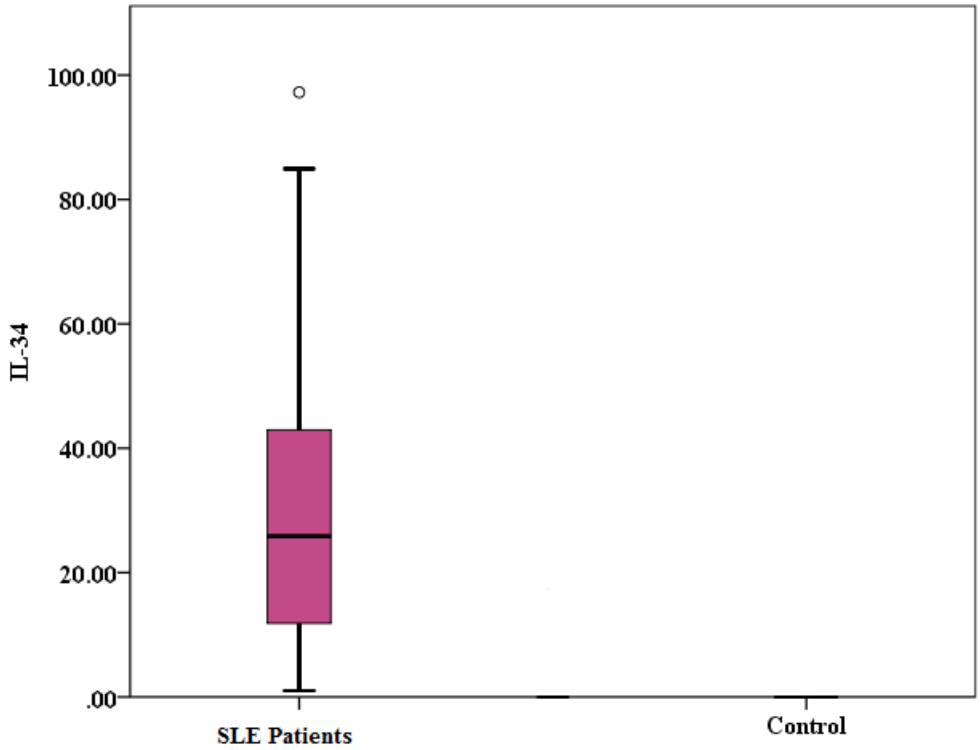

Figure (1): Boxplot of IL-34 levels between studied groups

Regarding to this Figure (1) level of interleukin 34 in SLE patients seems significantly higher than control with range from (1 pg/L) to (80 pg/L) and median fall in approximately (25 pg/L). whereas healthy control show a very low level of interleukin 34 maximally reach to 1pg/L (Mean±SD(0.4±1.25)).

Discussion

Involvement of IL-34 have been shown in different important area such as infection, cancer, transplantation, and autoimmune diseases[10].In this study the concentration of IL-34 in serum of patients with SLE was higher in SLE, while in healthy control was very

low (0.4±1.25)pg/L. This finding is agreewith study done by Xie in 2018 [11] which found that the level of IL-34 was significantly higher in SLE in compare with healthy control and their level directly associate with CRP and anti-ds-DNA and inversely with C3 level, also its level successfully decrease after patients response to treatments. A study revealed that the increasing level of IL-34 led to increase osteoclastogensis and destroyed bone(erosion arthritis)[12]. Over expression of interleukin 34 strongly associate with chronic inflammation and other autoimmune disease such as Rheumatoid arthritis[13,14].

In this study, incidence of SLE in females are more than males (86.7% in SLE group were female while just 13.3% of them were males) with male to female ratio about 1:7, results which is almost found in autoimmune diseases reported that SLE is approximately nine times in females more than male[15]. Researchers reported that the ratio of females to males ranges from 10:1 to 15:1, and after menopause, the ratio is approximately 8:1[16]. Other study done in 1999 revealed the same ratio in 9:1[17].

A lot of factors can explain the different ratio between males and females which include

1. Types of sex hormones in males and females which is already different.
2. Some genes are sex-influenced and sex hormones provoke it to dysregulate immune response[18]
3. After all, there is a higher rate of autoimmune diseases among females[19].

Anti-Human leukocyte antigen (HLA) in parous females with SLE increase in compare with males and non-parous females.[20]

Conclusion

Highest level of Il-34 concentration may play important role in pathogenesis of SLE, SLE most commonly affect females more than males in age groups (31-50 years old).

Detection of Fungi Associated with Some Spices in Local Market in Hilla City (Babylon)

Nawras Abid Al-abas[1], Abeer Fauzi Al-Rubaye[2], Hawraa Wahab Aziz[2]

[1]MSc. Student, [2]Assist. Prof., Department of Biology, College of Science for women, University of Babylon, Iraq

Abstract

The present study included the isolation and diagnosis of contaminated fungi of some spices sold in the local markets in Hilla city in Babylon Governorate (Iraq) and includes, Black pepper, White pepper, turmeric, mixed spices for meet, Pizza Spices, Beef Shawarma, Pickled Spices, Rosemary ground and others. Results were recorded 346 fungus isolates belonging to 9 different fungal group. The most predominant fungal genera encountered were Aspergillus spp (40.17%), *Penicillium spp* (25.14%), *Cladosporium spp* (8.67%) *Alternaria spp,* and *Fusarium* spp. Yeasts were also frequently recovered, but not identified. All fungi were isolated on P.D.A. The study focus on *aspergillus spp* diagnosis by using molecular method to diagnosted it by using sequence'stechniques .The highest appearance of *Aspergillus flavus*(41.7%)was recorded fallowed by *Aspergillus niger*(25.9%), *Aspergillus parasiticus* (12.9%).

Keywords: *Spice, fungi, identification, P.D.A, Iraq.*

Introduction

Spices were described as a natural compound or a combination of natural compounds obtained from seeds, fruits, flowers or trunks (skins, roots, leaves) of several crops of native or exotic origin, aromatic or with a powerful flavor, used in minute amounts and added to food preparing and processing worldwide to provide color, taste, smell or flavor[3,11,16]. Spices are a prominent component of traditional cooking activities and are essential component of millions of people's daily diets around the globe and the majority come from tropical countries and is used to flavoring, coloring or preserving food and beverages[16].

Spices such as pepper, paprika, cumin, ginger, saffron and clove are widely used in the Middle East because they add excellent flavor to products and are used as medicines because of their preservative and antioxidant properties are extremely important, They are mainly aromatic agents used in tiny quantities if correctly stored and have positive effects as well as antimicrobial characteristics[4,5]. High temperature, moisture and precipitation rates are prevalent in tropical climate. These climate parameters are appropriate for intense microbial development, particularly with regard to fungi.Spices are contaminated in large quantities upon import.Most spices are traded commercially It is in an equipped form, and the drying process is the most important process is used,spices are likely to be exposed to a broad spectrum of microbial contaminants Contamination is likely to happen during the pre- and post-harvest phases during storage, delivery and sale [and/or use] [23,19].Although spices are present in tiny quantities in foods, they are acknowledged as significant carriers of microbial contamination primarily due to the circumstances under which they were cultivated, harvested and processed. Furthermore, due to possible negligence during sanitation or processing, foods containing spices are more likely to deteriorate and could also have damaging impacts with regard to health[19].

It was observed that most spices contain large

Nawras Abid Al-abas
MSc. Student, Department of Biology, College of Science for Women, University of Babylon, Iraq
e-mail: abeerbio15@gmail.com

numbers of molds and bacteria and small numbers of colon bacteriaand yeasts. Although spices are present in foods in relatively small amounts However, they are recognized as important carriers of microbial contaminants mainly due to different stages, The spice passes from planting and harvesting to processing, as well as due to possible neglect during discharge [Or sewage treatment][19] Food is contaminated with fungi and mycotoxins. and this very serious problems that threaten many developing countries, Especially those that lack the conditions of good food storage and are a source of great concern, which called on these countries to provide healthy food sources to achieve food security[21]. The Food and Agriculture Organization of the United Nations estimates that nearly 32% of the world's food and feed are at risk of contamination with mycotoxins [29].

Mycotoxins have significant public health effects It causes kidney poisoning, immunosuppression, fetal teratogenicity and congenital malformations. These toxins are capable of causing severe acute effects and chronic in human and animal ranging from disorder of the central nervous system, heart, blood vessels, pulmonary systems and death[(9,15)].Among the most important Toxins are aflatoxins, which are secondary carcinogenic metabolites produced mainly by *Aspergillus flavus* and *Aspergillus parasiticus*[(28)] Exposure to aflatoxins is known to produce Various diseases like carcinogenic, mutagenic, teratogenic, tremorgenic and hemorrhagic. It also cause damage in the central nervous system, liver or kidneys and effect of male reproductive toxic effects[2].

Material and Method

Sample Collection: A total of twenty two dried ground samples(Black pepper, White pepper, turmeric,cumin, mixed spices for chicken, mixed spices for meet, Pizza Spices, Rosemary ground, Pickled Spices, Biryani spices, Ginger Spices, cloves, dried Mint, dried Lime, saffron ground,Fenugreek, grill spices, cinnamon ground, Maggi beef, Maggi chicken, Maggi vegetables, Noodles spices) were bought from various locations of local markets Hilla city, depicting distinct kinds of spices. These spice products were selected based on their market accessibility and popular use. Spice samples were generally discovered outside, stored in or on the bare floor in metal or plastic containers, wooden boxes or gunny bags. For each spice 3 replicates were taken from three different placesEach sample (100 g) was put in a new paper bag and transferred immediately to the laboratory and stored in cool place at 4°C for fungal determination.

Culture of fungal isolate on Potato dextrose agar PDA: Prepare the food medium according to the manufacturer's instructions to dissolve 43 g of the medium in 1 liter of distilled water, then sterilize the sterilizer (autoclave) at 121° C for 15 minutes, then cool the medium and add the antibiotic chloramphenicol at a concentration of 1.2 mg. The fungal samples were cultured on potato dextrose agar (PDA) with three replications for each medium followed by incubated at 25 C° for 7 days,after this period the fungi were investigated[26]

Identification of the fungal genera:

The fungal isolates were transferred to sterilized plates for purification and identification. Identification of different fungi was done with help of slides prepared by direct mount from the culture. The examined under microscope and identified on the basis of their colony morphology and spore characteristics [(12,27)]

Recorded of Results: After incubation and identification percentages of isolated fungi, infection (contamination) in each sample were calculated according to the formula

$$\text{Percentage of appearance} = \frac{\text{Number of isolate that appeared in the same type}}{\text{Total number of samples}} \times 100$$

$$\text{Percentage of frequency} = \frac{\text{Number of isolates per species}}{\text{Total number of isolates of all species}} \times 100$$

Results and Discussion

Three hundred forty six isolates represent 22 species. The results of this study noticed that all samples of spices were infected with fungi Table (1),the fungi belong to 9 fungal genus, the *Aspergillus spp* was (40.17%) fallowed by *Penicillium spp*. (25.14%) and the *Cladosporiumspp*. (8.67%). The results of this study agree with [24] were isolated and identified 17 genera. *Aspergillus spp, Penicillium spp* and *Rhizopus spp* were the most common genera, *Alternaria* emerged in 40% of samples and *Eurotium spp, Fennellia spp* and *Fusarium spp* were detected as moderate contaminating agent where, they were isolated from 26.7% to 33.3% of samplesAs well as the results of the present study indicated to occurrence of yeast in some of spice samplesbut not identified and this result corresponds to what is reached by [31] When he studied contaminated

fungi for some dried and ground spice samples which indicated *Aspergillus spp*, *Penicillium spp*, *Rhizopus spp*, *Cladosporium spp* and *Trichoderma spp* were the most predominant fungal genera encountered were Yeasts were also frequently recovered,.When he studied contaminated fungi for some Relative occurrence values of taxa disclosed ranged between 36.4% for *A. flavus* and 0.6% for *A.parasiticus* and *Absidia spp* . [14]identified fungi in spices like *Acremonium spp*, *Alternaria spp, Aspergillus aculeatus, A. flavus, A. niger, A. fumigatus, A. terreus, Cheatomium spp, Choanephora spp, Cephalosporium spp, Drechslera spp, Colletotrichum spp, Curvularia spp, Fusarium spp, Penicillium spp, Phoma spp, Stemyphylium spp and Stachybotrys spp.*[17]. [10]show that the predominant mycoflora obtained was distributed in 10 genera. The genus *Aspergillus spp* was the most dominant genus recovered (179 isolates) followed by *Penicillium spp* (44 isolates).

The prevalence of fungi associated with some spices sample appered in table (2) *Aspergillus spp* was (70.20%)fallowed by *Penicillium spp.*(43.94%) and *Cladosporium spp.*(15.15%). In study done by [31] exhibit the genus *Aspergillus spp* is the most predominant genus encountered, with four species, followed by *Penicillium spp* with two species and all the remaining fungi with one species and the highest percentage relative density was shown by *A. flavus* (36.39), followed by *A. niger* (20.60) and *R. stolonifer* (14.58). The lowest density of occurrence was indicated by *A. parasiticus* and *Absidia corymbifera* (0.60).

[24] Record in their research that the *Aspergillus spp* was represented by 10 species and *Penicillium spp* was represented by 7 species, however, *Rhizopus spp* was represented by only 1 species. *A. niger* polluted 93.3% of spices samples and *A. flavus* polluted 60% of them,were the common *Penicillium spp* where, they isolated from 53.3% and 46.7%. of the samples, respectively and *R. stolonifer* contaminated 66.7% of spices.*Aspergillus spp*. and *Penicillium* genera were more frequently detected than other genera of fungi. *Aspergillus niger*. was found in all examined spices samples except Black pill, Caraway, sesame, Black pepper and Cumin while, *Penicillium spp*. were dominant in all samples except Coriander, Ginger, and Caraway[14.]

Table (3) showed that the dominant fungal species(percentages of appearance) were *Aspergillus spp Penicillium spp,*appeared in all samples of spicessuch as pepper, paprika, cumin, ginger, saffron and clove

Cladosporium spp.Alternaria spp, Fusarium spp, Mucor spp Rhizopus: [18] isolated 81 species belonging to 38 genera were from different 34 spices in Egypt Where was *the Aspergillus spp* the most prevalent (25) species.This difference in the numbers of isolated species and fungi may be due To the different numbers and types of spices studied in addition to that spices are likely to be vulnerable to the group a wide range of microbial contaminants during the pre- and post-harvest phase, as well as contamination is likely to occur during [Operations of storage, distribution, sale and/or use.[7] found the *Aspergillus* and *Penicillium spp*. the main components of cardamom, cinnamon, fennel, coriander, cumin, black cumin and white pepper.

The present study recorded the highest appearance of *A. flavus* and A. niger in all kinds of spices,And other species of *Aspergillus a*ppeared in different proportions *A.minisclerotigenes A. parvisclerotigenus A. oryzae A.parasiticus* (table 4) and fig (2).

[22] recorded that the most species isolated from different spices were *Aspergillus ruber, Aspergillus chevalieri, Aspergillus montevidensis, Aspergillus pseudoglaucus* and *Aspergillus penicillioides were the mostfrequent Aspergillus* as well, the mycotoxigenic species were *Aspergillus flavus* and *Aspergillus niger*. In other study, *Aspergillus alutaceus*, *Aspergillus fumigatus*, *Chaetomiumglobosum, A. montevidensis, A. chevalieri and P. chrysogenum* were isolated[1], [25] isolated 25 species of Aspergillus on anise and fennel fruits, of which *A. niger, A. flavus, A. ochraceus* and A. *flavus var. columnaris* were prevalent in both spices

Table (1): The number and frequency of fungal species isolated from spices

No.	Fungi	Percentage of Frequency	
1	Aspergillus spp	139	40.17
2	Penicillium spp.	87	25.14
3	Cladosporium spp.	30	8.67

Staff's Knowledge and Practices in Environmental Foundation Regarding Prevention from Mobile and Tower Health Risks in Erbil City, Iraq

Kareem Fattah Aziz

Assist. Prof.College of Nursing, Hawler Medical University, Erbil, Iraq

Abstract

Mobile phones,at the present time,are an essential part of contemporary communications in every single life. In a lot of countries, above half of the population uses mobile phones and the mobile phone market are rising speedily. Thus, mobile phones, towers and their risks are almost everywhere. This study originally designed to identify the knowledge and practices of 100 staff members in the environmental foundation in Erbil city in Iraq. Accordingly, the standard use of mobile, towers and health risks to identify an association between variables and their knowledge or practices took into consideration. This study was descriptive design began in 01-07-2018 to 01-07-2019. The utilized questionnaire, for data collection, contained three parts. It was viewed by a panel of experts in the nursing field for validity. The outcomes of this study specified that the majority of individuals have not satisfactory knowledge and practices about standard use of mobile phones, towers and health risks. There was a significant association between age, level of education, years of employment and their practical knowledge. Finally, this study recommended preparing a program for training to increase their knowledge, practices, and continue to conducting research regarding mobile phones and other communication facilities.

Keywords: *Health risk, mobile use, mobile towers, practical knowledge, radiation.*

Introduction

Nowadays mobile phones and towers are found every where[1]. As billions of human beingsutilize mobile phones internationally, a tinygrowth in the occurrence of argumentative impacts on health could possessmain public health insinuations on extended term foundation. Also the amount of cell phone calls per day, the length of each call and the amount of time people utilize cell phones are vitalaspects which improve the health associated danger [2]. Mobile phones, in general,radiate radiofrequency (RF) energy, an arrangement of nonionizing electromagnetic emission, which can be absorbedby tissues close to the phones. The amount of RF energy from mobile phone of the exposed user is depending on many factors. Among these factors; the fountainhead of the phone, the distance between the phone and the user, the extent of the mobile phone and the user's distance from cell phone towers[3]. Radio frequency emission is a form of electromagnetic radiation. X-rays, radon, and cosmic rays are ionized electromagnetic radiation, while radio frequency and extremely low frequency, or power frequency are among non-ionized electromagnetic radiation[4]. It can be stated that, the range frequency of RF radiation ranges from 30 kHz to 300 GHz. Thus, cell phones utilize this range for telecommunications. The human body absorbs energy from devices that emit RF[5]. Radio frequency electromagnetic radiation from these devices are risk for health. RF-EMF radio frequency and electro magnetize frequency may be risk for health but absorption of the waves by houses, trees, and other geographical barriers may reduce the exposure level of magnetizing waves. There is controversy about cancer incidence with magnetizing exposure so sometimes testing give negative results for this health problems, while in other in other findings agreed with health problems[6]. There are many studies about health risks as, the study by Meyer[7] who found no association between mobile phone base station exposure and cancer incidence. The studies done by Eger *et al.*[8] and Wolf [9] found a significant association between

mobile phone exposure and increased cancer incidence. Mobile and towers telecommunication systems have developed rapidly, to the point where then a sixth of the world's population use mobile phones more. By the end of 2004, more than a billion subscribers across more than 200 countries were estimated to be using mobile phones[10]. The development of mobile communications has increased rapidly. In the 1980s, first-generation mobile phones, using analog technology, allowed the transmission of sound only. The global system for mobile communication has begun in 1991 and includes such new developments as data and image transmission[11]. The new generation of mobile phones may have many other services in the markets. People have used the new technology for communication globally, but they do not know about potential health hazard from mobile phones. However, concerns the possible effects on health, as a result of the exposure microwave electromagnetic fields, have been expressed for the introduction of mobile phones[3]. Since the year 2000, several reports have reviewed relevant studies about health risks of a mobile phone to the common and accepted carcinogenic effects of RF and microwave energy[12]. Mobile phone use has developed and increased quickly at low prices. Industry sources expected that there will be more and more over billion users worldwide by 2025, far exceeding telephone use via fixed-lines [13]. Thus, even a small impact on health could have a major public health consequence. The aim of this investigation is to identify that the exposure to RF and microwave radiation from mobile phones and their base stations and tower microwaves might affect health and to identify the safety and standard use of these electronic devices. Concern continues about exposure to radiofrequency (RF) fields from sources used for mobile telecommunications, radars, towers, radio and television broadcast, medical and industrial applications. The objectives of this study is identifying staff's knowledge and practices in environmental foundation about health risks, standard mobile use and towers in Erbil City, Kurdistan Region, Iraq. Also, to identify the association between variables of sample study and their knowledge, practices about mobile use and towers.

Methodology

The design of this study is basically a cross-sectional, descriptive study. While, the sample of the study is a non-probability convenient purposive sampling which used to select 100 staff in the environmental foundation in Erbil City, Kurdistan Region, Iraq. The sample size was calculated by (application the sample size calculator),utilizing the following formula:

$$Sample\ size = \frac{\frac{z^2 \times p(1-p)}{e^2}}{1 + (\frac{z^2 \times p(1-P)}{e^2 N})}$$

Where N = population size, e = Margin of error (percentage in decimal form), z = z-score and p is the sample proportion. The z-score is the number of standard deviations an assumed amount is further than the mean[14]. As we stated the study/the study conducted in the environmental foundation in Erbil city. Time of the study/the study l began in 01-07-2018 to 01-07-2019. The tools of the study was based on the questionnaire that used for data collection, containing three parts (socio-demographic data included (age, address, sex, level of education, years of employment, family status, and type of family) part two included questions related to knowledge depending on the scoring system as followings (1 for I know, 2 for I do not know and 3 for I'm not certain). Part three was included questions about practices, depending on the scoring system as followings (1 for always do, 2 for sometimes do and 3 for never do). The validity of the questionnaire based on the viewingby the panel of experts in the nursing field and according to their comments a questionnaire was corrected and organized. Moreover the environmental foundation and the scientific committee accepted for conducting this study and approval from nursing college and ethical committee While, the inclusion criteria were all staff in the environmental foundation. Furthermore, the exclusion criteria were some staff who are in work with clients.It can be stated that, the data collection was done by interview technique with staff. However, the importance of the study was highlighted in its importance to identify the knowledge and practices of those staff for awareness and prevention. Finally, the data analysis done by using SPSS program version 23 for data analysis.

Results and Discussion

Table 1 below shows the socio-demographic characteristics of study sample as followings: the majority of them were between 22-31 years, most of them from urban, most of them were male, the majority of them were married, most of them graduated from the institute, while most of them had employed about 15-20 years.

Table 1: Socio-demographic characteristic:

Variables	Frequency	Percentage%
1-Age group:		
22-31	55	55%
32-41	27	27%
42-51	18	18%
Total	100	100%
2-Address:		
Urban	83	83%
Suburban	16	16%
others	1	1%
Total	100	100%
3-Sex : Female	40	40%
Male	60	60%
Total	100	100%
4-family status		
Single	28	28%
Married	64	64%
Widow	6	6%
Divorced	2	2%
Total	100	100%
5-tye of family		
Nuclear	38	38%
Extended	62	62%
Total	100	100%
6-Level of education		
Secondary	23	23%%
Institute	35	35%
College	34	34%
Others	8	8%
Total	100	100%
7-years of employment		
3-8 years	13	13%
9-14	21	21%
15-20	66	66%
Total	100	100%

Table 2 shows the practice levels of staff so 9% of them can practice mobile use and towers properly, while the majority of them couldn't do practices properly which represented 91% of them.

Table 2: Level of practices for Staff

Type of practice level	Frequency	Percentage %
Practice properly	9	9%
Non-practice properly	91	91%
Total	**100**	**100%**

The results of this study agreed with the study done by Meyer[7] who indicated that some young people practice bodily movements during talking with someone and they have unavailable habit. The outcomes of this investigation also agreed with the study of Savio *et al.*[15] who stated that it is necessary to utilize information system for mobile use in the organizations and another office to work standard and reduce the health risks of mobile and towers.

Table 3 shows the association between variables and practices of staff so there is a significant association between age, address, sex, educational level, years of employment and their practices about mobile and towers, while there was not the significant association between family status, type of family, and their practices. Other findings indicated that there was the significant association between age, address, sex, education level, years of employment and practices of staff regarding utilizing mobile and dealing with towers [16].

Table 3: Association between variables and practices

Variables	Degree of Freedom	P-Value
1-Age	15	0.000
2-Address	2	0.019
3-sex	1	0.041
4-family status	2	0.168
5-type of family	1	0.837
6-education level	3	0.049
7-years of employment	8	0.002

Table 4 shows levels of knowledge among staff regarding mobile and towers, so there are three levels of knowledge as followings (good 9%, fair 76% and bad 15%).

Table 4: Levels of knowledge among staff:

Level of knowledge	Frequency	Percentage %
Good	9	9%
Fair	76	76%
Bad	15	15%
Total	100	100%

Regarding their knowledge about using mobile and dealing with towers, the majority of the participants possess fair knowledge which represented by 76%, while a small number of them have good knowledge which represented by only 9%, and 15% of them have

bad information for that so according to this study there is lack of training course,workshop, symposium and other program in the environmental foundation and other office to increase their knowledge and practice regarding mobile,tower and other communication technology. Patrick et al.[17] in their investigation found similar conclusion to our study. The results found in this study also agreed with the study by Santini and coworkers [18] and Crilly et al. [19].

Table 5 shows the association between variables and level of knowledge of staff regarding mobile and towers, so there is significant association between age, sex, educational level, years of employment and their knowledge about mobile use and towers, while there was no a significant association between address, family status, type of family and their knowledge about mobile use and towers.

Table 5: Association between variables and level of knowledge

Variables	Degree of freedom	P-Value
1-Age	30	0.000
2-Sex	2	0.012
3-Address	4	0.421
4-Family status	4	0.143
5-Type of family	2	0.864
6-Level of education	6	0.000
7-Years of employment	16	0.010

These findings agreed with the study done by Kayyali *et al.*[11]. In their study they sates that in spite of the increasing number of "mHealth Apps" the level of consciousness and using of such APPS by patients, and pharmacologist was still somewhat small. Kayyali *et al.* also recommended that awareness and knowledge of these apps should increase both of public and for health professionals. It can be indicated that, the outcome of their study showed that there was lacking sufficient knowledge and practice among staff, clients, patients, and pharmacists in England. Thus, the results found in our investigation are highly agree with the results, perspectives and recommendations found by Kayyali *et al.*[11].

Conclusion

The findings of the study revealed that majority of them not practiced with mobile and towers properly and standard which represented nearly about 91%, while small number of staff were practiced properly which represented about 9% so according to my opinion the cause due to lack of training program for staff in environmental foundation in Erbil City, Kurdistan Region, Iraq, and lack of expert individuals in the office to train and educate other new staff. The other conclusion of this study was there is a significant association between age, address, sex, education level, years of employment and practices of staff regarding using mobile and dealing with towers. Among all these variables the education level and years of employment of staff may effect to increase their practices, knowledge, and experiences. The majority, *i.e.* 76%, of the participants possess bad knowledge with regard to their information about mobile and towers use. Which is a bad indicator and needs to improve by educational programs and workshops. A tiny amount, *i.e.* 9% of them they have good information about dealing with mobile phones and towers. This percentages can be increased by different channels such as; training course,workshop, symposium and other programs in addition to conducting research about mobile and other communication technology. The outcomes of the study, also, indicated that the majority of individuals have not sufficient knowledge and practices about standard use of mobile and towers. Finally, this study recommended that research about magnetic field, mobile, towers should be continued not only to increase the knowledge of the users and workers but also to decrease the hazardous of the mobile and towers radiation .

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the College of Nursing, Hawler Medical University, Erbil, Iraq and all experiments were carried out in accordance with approved guidelines.

Mycobiota and Enteric Viruses among Infants with Acute Diarrhea in Iraq

Hussein Alnasrawi

Assist. Prof., Medical Laboratory Technology Department-Amarah Technical Institute, Southern Technical University, Iraq

Abstract

Diarrhea is a disease responsible mortality and morbidity of children under five years of age .The present study revealed that from total of 104 collected stool samples taken from infants with acute diarrhea 55 case of diarrhea recorded in male infants and 49 in female. The finding of our study detected 29 infection with enteric viruses and 75 with non-viral agents. The study recorded 24 infant stool samples were infected with Rotavirus, 5 with Adinovirus and 29 samples with different Mycobiota (fungal community species): *Candida albicans* (24)*, C.tropicalis* (1)*, C.krusei* (1), *Saccharomyces cereviciae* (1)*, Aspergillus niger (1), Cladosporium cladosporoides* (1) *and Fusarium verticillioides* (1). Residents of rural community recorded higher rate of viral infection (54) compared with urban residents (15). Control Group revealed 18 infection with Mycobiota only. This study confirmed the interaction of Rotavirus and Mycobiota in the same samples .

Keywords: *Diarrhea, Infants, Enteric virus, Mycobiota.*

Introduction

Childhood diarrhea is a major public health concern globally, reported to be the second most important disease in the etiology of infant death[1,2]. Acute diarrhea is manifested by a sudden occurrence of three or more watery or loose stools per day lasting for seven to 10 days, 14 days at most, associated with higher mortality cases, correlated to young age, nutritional deficiencies, and inadequate food hygiene practices [3,4]. In developing countries, gastrointestinal disorders are directly associated with higher infant morbidity and mortality among children under five years of age due to different factors associated with occurrence of diarrhea among young children and these differ from place to place and only a few studies have attempted to compare diarrheal disease burden and its contributors in rural and urban communities[5,6,7].

The clinician encounters acute gastroenteritis in three settings. The first is sporadic gastroenteritis in infants, which is generally caused by Rotavirus. The second is epidemic gastroenteritis, which occurs either in semi-closed communities (e.g. families institutions, on ships, at vacation spots), and the third as a result of classic food-borne or water-borne pathogens[8,9,10]. Although there are many non-infective factors of diarrhea, the most common causative agents of diarrhea are biotic factors causing infective diarrhea originated from living microorganisms included viruses, bacteria and parasites[11,12].

The most clinic importance of enteric viruses among infants with acute diarrhea are Rotavirus, Norovirus, Adenovirus and Astrovirus [13,14]. Different groups of viruses have been showed to be causative agents of high incidence of acute viral diarrhea among children during their first years of life [15].

More studies focused on the role of microbiota (bacteria, viruses and parasites) on developing diarrheal cases specially among infants, but Mycobiota (fungal community) such as the causative agents of opportunistic mycoses, has received little attention. However, most studies to date have focused on bacterial colonization events and have left out fungi, a clinically important sub-population of the microbiota. A number of recent findings indicate the importance of host-associated fungi (the mycobiota) in adult and infant disease [16].

Candida is a yeast, part of normal flora in the gastrointestinal tract of healthy individuals can transmitted from oral cavity to the stomach and intestines leading to diarrheal case. Candida species are frequently isolated from stools of children with diarrhea but are not proven as the main causative agent of diarrhea. [17,18]. Although Candida species not confirmed to be the main causative agent of acute diarrhea among infants, many different species of fungi were isolated from stool samples of diarrheal cases in addition to *Candida* included *Trichosporon* and *Geotrichum* that have been reported to cause diarrhea [19].

The interactions between fungi and bacteria have been reported for a long time, particularly since the introduction of antibiotics in the mid-1900s, whereas the interaction of enteric viruses and mycobiota still unknown[20].

The aim of present study is to find the correlation between enteric viruses and` Mycobiota among infants with acute diarrhea .

Materials and Method

Sample Collection: Over a period of six months, from October 2018 to March 2019, 104 stool samples were received from infants with acute diarrhea patients admitted to Misan Maternal and Child Hospital in Iraq. Also 52 samples from control group without diarrhea matched for age and selected from patients admitted to the same ward. For processing and testing procedures,samples were transferred to the laboratories of Department of Medical Laboratory Technology at Amarah Technical Institute .

Test of Rotavirus and Adenovirus

Procedure: Test of Rotavirus and Adenovirus from stool was done by using Rota/Adeno kit.

A dropping cap (provided in the kit) was assembled on the sample collection tube. About 4-5 drops (about 100-125 µl) of the mixture from sample collection tube was added into the sample well of the test device. The results were interpreted within 10 minutes .

Negativeresult: Only one green band (control line) appears in the white central zone of the reaction test (control region).

Rotavirus positive result: In addition to the green control band, a distinguishable red band (Rotavirus result line) also appears in the white central zone of the reaction test (result region).

Adenovirus positive result: In addition to the green control band, a distinguishable blue band (Adenovirus result line) also appears in the white central zone of the reaction test (result region).

Rotavirus–Adenovirus positive result: All the lines above described (a green control band in the control region, a red band and a blue band in the result region) could appear at the same time during the test performance due to a simultaneous infection of Rotavirus and Adenovirus.

Isolation and identification of fungi:

A. Culture Method:

For Candida culture, diluting 0.2 g of feces in 1.8 ml of sterile saline solution. A 10 µl aliquot was then plated on Sabouraud's dextrose agar containing 300 µg/ml chloramphenicol and 10 µg/ml gentamicin . Plate cultures for yeasts were incubated in air at 35°C for 48 hours before counting and identified.

By using chrome agar for the identification of *Candida* species, and incubation period 24-48 hours at 35°C. The presumptive identification was made by color and morphology of the colonies; the isolates were further identified microscopically and morphologically.

B. Molecular Method:

For molecular classification of molds, 0.5g of fungal hyphae was carefully removed from petri dishes, transferred to bead tubes for DNA Extraction and Amplification, PCR screening technique. Genomic DNA was extracted from fungal isolates using a Mo-Bio Power DNA extractionkit (Carlsbad CA, USA). Fungal 18S rRNA genes were PCR amplified using NS1 [5'-GTA GTC ATA TGC TTG TCT-3'] and FR-1 [AICCAT TCA ATC GGT AIT] . Process of thermocyclingconditions was done .Amplicons were cleaned using a Mo-Bio UltraCleanPCR Cleanup Kit and sent for sequencing on an Applied Biosystems 3130xl Genetic Analyzer. The basic local alignmentsearch tool –BLAST was used to classification and identification fungal isolate.

Results

Table 1. Number of diarrheal cases according to age group.

Age (Months)	Diarrheal Cases in Female(%)	Diarrheal Cases in Male (%)	Total No. (%)
< 2	7(6.7)	10(9.6)	17(16.3)
2-6	28(26.9)	14(13.4)	42(40.3)
6-12	10(9.6)	25(24)	35(33.6)
12	4(3.8)	6(5.7)	10(9.6)
Total	49(47.1)	55(52.8)	104(100)

Table 2. Prevalence of entericpathogens among infants with acute diarrhea according to resident location

Enteric pathogen	No. of infected patients in Rural area	No. of infected patients in City center	Total no. of pathogens (%) n=104
Rotavirus	20	4	24 (23.07)
Adinovirus	3	2	5 (4.80)
Candida albicans	24	0	24 (23.07)
C.tropicalis	1	0	1(0.96)
C.krusei	0	1	1(0.96)
Aspergilus niger	1	0	1(0.96)
Cladosporium cladosporoides	1	0	1(0.96)
Fusarium verticillioides	1	0	1(0.96)

Table 3. Prevalence of enteric pathogens associated with Control Group according to resident location

Enteric pathogen	No. of patients in Rural area	No. of patients in City center	Total no. of pathogens (%) n=52
Rotavirus	0	0	0 (0%)
Adinovirus	0	0	0 (0%0
Candida albicans	4	1	5(9.61)
C.tropicalis	1	1	2 (3.84)
C.krusei	1	0	1(1.92)
Aspergilus niger	0	0	0 (0%)
Cladosporium cladosporoides	0	0	0 (0%)
Fusarium verticillioides	0	0	0 (0%)

Table 4. Single and mixed pathogens associated with stool samples of diarrheal patients

Single Infections	No. of samples infected (%)
Rotavirus	0(0.0)
Adinovirus	5(4.80)
Candida albicans	0(0.0)
C.tropicalis	1(0.96)
C.Krusei	1(0.96)
Aspergilus niger	1(0.96)
Cladosporium cladosporoides	1(0.96)
Fusarium verticillioides	1(0.96)
Total	10(9.61)

Single Infections	No. of samples infected (%)
Mixed Infections	
Rotavirus/Adinovirus	0(0.0)
Rotavirus/Candida albicans	24(23.07)
Total	**24(23.07)**

Discussion

As shown in table 1. The total of diarrheal cases among infants with acute diarrhea admitted at Misan Maternal and Child Hospital was 104 cases, distributed between male 55 and 49 female . The results of present study revealed that most enteric virus infections were recorded among infants originated from rural community

(Table 2.), which refers to poor hygiene practices, immune status, specially shortage of vaccination campaigns and nutritional deficiencies with an inadequate food hygiene practices [21]. Although the current finding of Rotavirus infection was high, (23.07%), our research recorded lower incidences in comparison with recent studies in neighbor cities in Iraq (Basrah 2018,32.5%, Basrah 2011, 40.5%,mid Iraq 2010,42.2%, Babylon city 2011, 45.7%, and Kurdistan 2005,37% [22].

Our results revealed infection of 29 infant with enteric viruses (Rotavirus 24 and Adinovirus 5) and mycobiota (fungal community) infection (Candida albicans 24, non Candida albicans 2, Aspergilus niger1, Cladosporium cladosporoides 1, and Fusarium verticillioides 1) as shown in table 2.Candida albicans among patients with acute diarrhea recorded recorded a high occurrence percentage than Candida albicans associated with control group (9.61%) as shown in table 3. Results revealed 24 mixed infections by two pathogenic microorganisms, Rotavirus and Candida albicans within the same samples(Table 4.).The high rate of Mycobiota infections followed Rotavirus infections may be due to replication process, which induce opportunistic infections such as Candida to be dramatically risk factor and increase the pathogenicity, leads to tissue penetration and inflammation of the mucosa[23]. Following the infection with Rotavirus, IgM and IgA responses occur in the small intestine, fecal, serum and salivary antibodies have all been suggested as surrogate markers [(24,25). .

Conclusion

Although Candida has clinical and medical importance as a normal resident flora of the gut, Rotavirus is the leading agent of acute diarrhea in infants . Nowadays, Mycobiota will be with an emerged risk factor as opportunistic pathogens, specially under the virulence of viral infection. The role of candida aloneor with viral pathogens play important clinical role in developing diarrheal cases among infants as a risk factors like bacteria and other causative agents responsible for mortality and morbidity cases among children under five year age .

Epidimilogical Study of Taxoplasmosis among Pregnant and non Pregnant in Baghdad City and its Relationship with Blood Groups

Farah Ali Hameed

Lecturer Dr. Middle Technical University, Institute of Medical Technology, Baghdad, Nursing Department, Iraq

Abstract

This study was conducted during the period from March 2018 to March 2019, and included using of direct hemagglutination method to determine the rate of infection with *Toxoplasma gondii*among women in Baghdad city. Detection of taxoplasmosis was carried out by collecting iso blood samples included 100 samples from pregnant women and 50 samples from non-pregnant women who had previous recurrent abortions due to probable toxoplasmosis at time of pregnancy. The infection rate with *toxoplasmagondii* was higher in non-pregnant women group Higher than the pregnant women group. Study of prevalence of toxoplasmosis among women's' age groups revealed that the highest infection rate was in the age group (26-30) years, while the lowest infection rate was in the age groups (15-20) and (>45) years of the pregnant women. The results of abortion frequency demonstrated that two times abortion was most frequent among pregnant women, and three times abortions was most frequent among non-pregnant women. Infection criteria for repeated abortions showed positive results for toxoplasmosis when serological examinations were used. Finally, our results found that the highest infection rate (98.3%) was among the pregnant women with A+ blood group, and (31.25%) among non-pregnant women with O+ blood group.

Keywords: *Taxoplasmosis, Pregnant, non-Pregnant.*

Introduction

Toxoplasmosis is a zoonotic disease with a broad range of vertebral hosts including types of mammals such as humans, however, the final hosts are domestic cats and other types of cats [1,2]. The causative agent of toxoplasmosis is a protozoan known as *Toxoplasma gondii*, which is an intestinal coccidia. The parasite was first described in a wild rodent (*Ctenodactylus gondii*) in North Africa in 1908, from which the name gondii was derived. Serological tests indicate that humans can be infected with toxoplasmosis at any part of the world, but most of these infections are benign in nature, or may be asymptomatic in adults and children after birth [3]. It is important to study this disease for humans in severe cases which show some symptoms, that in turn affect the infected person and limits or reduces his activity [4]. If the female is infected with toxoplasmosis, very important risk may occur due to fetal intra uterine damage in case of pregnancy, where this parasite causes damage of the fetus during its passage through the placenta and then causes abortion in most cases, especially in the first trimester of pregnancy or may lead to stillbirth if the infection occurred in the last trimester of pregnancy[5]. Toxoplasmosis caused by *Toxoplasma gondii* parasite is a worldwide spread infection because of the ability of the parasite to cause infection and multiply inside avian and mammal cells [6]. The infection occurs through foods and drinks contaminated with oocysts or ingestion of under cooked meat which contain tissue cysts. The ingestion of one mature oocyst is enough to cause human toxoplasmosis [7]. Blood transfusion is an important source of transmission of acute infection, and transplantation of infected organ and tissue to healthy individuals can also cause infection [8]. It was reported by [9] that prevalence of *Toxoplasma gondii* in France was due to the wide spread ingestion of undercooked meat. A study conducted by [10] showed that infection rate in Baghdad was (18%), while [11] found that the infection rate was (37%) in Basra city, whereas [12] stated that the infection rate in the Northern part of Iraq was (15.26%).

Materials and Method

1. **Collection of Samples:** This study was conducted in the Medical city/Private Nursing Home Hospital, Department of gynecology in Baghdad during the period from March 2018 to March 2019 and included collection iso blood samples from pregnant and non–pregnant women. Also aquestionnaire form was used for data collection including living standard, blood group, number of pregnancies, number of abortions, type of abortion as well as some clinical features which appeared on the infected women.

2. **Laboratory diagnosis of Taxxoplasmosisgondii:** Blood samples (5ml) were collected from 150 women (100 pregnant women) and (50 non-pregnant women) whose medical history indicates the possibility of being infected with previous toxoplasmaosis infection because they suffered from repeated abortions and giving birth to deformed children). The blood sampled were put in plain test tubes (without anticoagulant) and left in the water bath for 15-30 minutes to obtain serum, then latex agglutination test was performed by using a suspension of formal in fixed latex particles coated with toxoplasma antigen to detect toxoplasma antibodies in the sera of patients. The kit used is called (Toxoplasmosis kit) from the Spanish company (Biokit) which contained the following:

   A. **Toxoplasma latex:** Suspension of latex particles coated with *T.gondii* antigen and 0.1% Sodium azide as a preservative.

   B. **Positive control:** Human serum and 0.1% Sodium azide

   C. **Negative control:** Non-reactive human serum and 0.1% Sodium azide.

3. **Detection of blood group:** Bood group are detected (Maton et al .1997) was represented by the use of special solution

   1. Anti-A detection of blood A.
   2. Anti-B detection of blood B.
   3. Anti-D detection of reiss Rh.

The work method was summarized by adding three drops of for sampleon the slide and then adding adrop of Anti-A solution to the first drope, adrop of Anti-B solution to the second drope and adrope of Anti-D to the three drope then mixed by sticks to know the following:

1. In the case of coagulation of the first drope and non clotting the second,the blood type A.
2. In the case of non coagulation of the first drope and clotting the second,the blood type B.
3. In the case of coagulation first and second dropes,the blood type AB.
4. In the case of non coagulation first and second dropes,the blood type O.

As for Rh the occurrence coagulationin the third drope containing

An Anti-D solution indicates appositive test and the opposite is true.

Results and Discussion

The current study showed the importance of studying toxoplasmosis incidence in Baghdad city. Results in table (1) showed that the prevalence rate of toxoplasmosis was (61%) in pregnant women and (64%) in non-pregnant women. In comparing these results with the findings of other studies, it was found that [13] reported (12%) infection rate out of 100 pregnant women, while the study by [14] on 127 women who were suffering from repeated abortions reported (33.07%) infection rate by using the indirect hemagglutinin test and (40.15%) infection rate by using the complement fixation test.

Table (1): Infection rate with Toxoplasma gondii in Baghdad city

Women	Total Number	Positive (+ve)	%
Pregnant women	100	61	61
Non-pregnant women	50	32	64
Total	150	93	125

Table (2) shows the relationship between age and infection with toxoplasmosis. The highest infection number and rate 23 (77.66%) was found among pregnant women within the age group (26-30) years, while the lowest infection rate (25%) appeared among the two age range groups (15-20) years and (> 41) years. When comparing these results with those of non-pregnant women, it was found that the highest positive infection rate (77.8%) was found among non-pregnant women within the age group (36-40) years.

Table (2): Distribution of toxoplasmosis according to different age in the two groups of women

Age Group (Years)	Pregnant Women			Non-pregnant Women		
	Total Number	+ve	%	Total Number	+ve	%
15-20	4	1	25	5	3	60
21-25	19	10	52.63	10	6	60
26-30	30	23	76.66	5	3	60
31-35	31	21	67.74	8	4	50
36-40	12	5	41.66	18	14	77.8
> 40	4	1	25	4	2	50
Total	100	61	61	50	32	

Abortion period, times and types during infection with toxoplasma among both pregnant and non-pregnant women are shown in table (3). It is shown that the highest abortion rate (63.18%) occurred during the first trimester of pregnancy among pregnant women, while the highest abortion rate (63.37%) occurred during the first trimester of pregnancy among non-pregnant women, and these results agreed with[23] who recorded the highest incidence rate of toxoplasmosis during the first trimester of pregnancy in comparison with the second and third trimesters which is attributed to the period and time of infection. Moreover, our results agreed with the results of [24] who reported that the transmission rate of toxoplasmosis from the mother to her fetus during the first trimester of pregnancy was 70% and during the second trimester was 25%, therefore, abortion rate will be higher in the first trimester than the second trimester of pregnancy which depends upon the infection severity.

Table (3): Period and type of abortion during infection with Toxoplasma gondii among pregnant and non-pregnant women

Type of Abortion	Pregnant Women		Non-pregnant Women	
	Number	%	Number	%
Stillbirth	13	5.90	8	6.23
First trimester of pregnancy	139	63.18	17	63.37
Second trimester of pregnancy	53	24.04	12	25.78
Third trimester of pregnancy	15	6.81	6	5.12
Total	220	100	43	100
Total number of pregnancies	449	---------	72	----------
Total number of child loss	229	48.99	35	70

*The data is recorded by the questionnaire sheet.

Table (4) shows the effect of toxoplasmosis on abortion frequency in pregnant and non-pregnant women. It is observed that abortion for two times recorded the highest percentage of abortion among pregnant women (42.37%), while abortion for three times recorded the highest percentage of abortion among non-pregnant women (29.16%). However, these results were on the contrary of the findings of [26] who stated that seropositivity was the highest among women who had one abortion when compared with women with multiple abortions.

Table (4): Effect of toxoplasmosis and its relationship with abortion frequency among pregnant and non-pregnant women

Frequency of Abortion	Pregnant Women		Non-pregnant Women	
	Number	%	Number	%
One time abortion	10	16.94	8	11.11
Two time abortion	25	42.37	19	26.38
Three time abortion	9	15.25	21	29.16
Four time abortion	7	11.86	11	15.27
Five time abortion	4	6.77	7	9.72
Six time abortion	1	1.69	3	4.16
Seven time abortion	3	5.08	2	2.77
Eight time abortion	/	/	1	1.38
Total	59	100	72	100

*The data is recorded by the questionnaire sheet.

Releationship between toxoplasmosis and blood groups: Distribution of toxoplasmosis among pregnant and non-pregnant women with different blood groups showed that the highest infection rate was in the pregnant women with blood group A+ (98.3%) followed by the blood group O+ (27.8%)., the highest infection rate in the women with blood group A+ can be explained by the presence of A subgroups, which may help the parasite to be adapted with such groups, while for blood group O+, it is attributed to the presence of a negative allele similar to that found in the *plasmodium vivax* parasite, which was reported by [27,28]., and this can be explained by the presence of glycoproteins in the form of glycophorines in this blood group, which can be used as nutrient for the parasite[29,30]Regarding the infection rate among non-pregnant women, our study found that the highest infection rate was in the blood group O+ (31.25%) as seen in table (5).

Table (5): Distribution of toxoplasmosis according to the blood groups

Blood Group	Number	Positive	%	Number	Positive	%
B+	30	21	34.4	12	7	21.8
A-	/	/	/	2	1	3.125
A+	25	15	98.3	8	8	25
B-	/	/	/	2	1	3.125
AB+	15	8	13.11	8	4	12.5
AB-	/	/	/	/	/	/
O+	27	17	27.8	16	10	31.25
O-	3	/	/	2	1	3.125
Total	100	61	/	50	32	/

Conclusion

The results of laboratory diagnosis were showed that the infection rate with *toxoplasmagondii* was higher in non-pregnant women group Higher than the pregnant women group, Study of prevalence of toxoplasmosis among women's' age groups revealed that the highest infection rate was in the age group (26-30) years, while the lowest infection rate was in the age groups (15-20) and (>41) years of the pregnant women, The results of the current study also revealed a high number of abortions in both pregnant and non-pregnant women

groups during the first trimester of pregnancy (139 in the pregnant and 17 abortions in the non-pregnant women The results of abortion frequency demonstrated that two times abortion was most frequent among pregnant women, and three times abortions was most frequent among non-pregnant women., Finally, our results found that the highest infection rate (98.3%) was among the pregnant women with A+ blood group, and (31.25%) among non-pregnant women with O+ blood group.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the Middle Technical university, Institute of Medical Technology/Baghdad/Nursing Department, Iraqand all experiments were carried out in accordance with approved guidelines.

Assessment of Teachers' Knowledge about Child abuse at AL Nasiriya Primary Schools

Gossoon Juma Elywy[1], Adil Ali Hussein[2], Hussein Abdulmohsin Dabis[1]

[1]Assist Lect, College of Nursing, University of Thi-Qar, [2]Assist Lect, College of Nursing, University of Basrah

Abstract

Background: One of the most pressing issues concerning child health and well-being is child abuse; it remains to be particular and major risk to the emotional and social well-being of the children worldwide. As pupils spend long time in school, the teachers must be qualified to identify physical and behavioral fluctuations related to abuse to assuredly determine the reason and design interventions properly. The insufficient data and information result in a break in the vitalduty of teachers in determination and initial assistance in case of child abuse.

Objectives: The aims of the study were to evaluate the information of the primary school teachers on identifying and reporting of child abuse and to identify any link between the teachers' knowledge with designated sociodemographic variables.

Methodology: A descriptive design was applied during the study, which include 100 primary school teachers from 6 selected schools in Al-Nasiriyah city. The tool used for data collection were a designed questionnaire on signs and symptoms of child abuse.

Results: Mostof the school teachers (74%) had low knowledge on child abuse. Regarding association between knowledge and certain sociodemographic variables, no significant statistical association found except for Receive educational training courses in child abuse (p<.05).

Conclusion: Child abuse is an international concern, children experience abuse in several types, and additional awareness will assist in fighting this issues. Teachers' knowledge have to be improved by applying attentiveness programs on child abuse.

Keywords: *Assessment, knowledge, child abuse, primary school teachers.*

Introduction

Children all over the world must have the simple and basic human right to live safely, child abuse risk that right by engaging the child at danger of emotional and physical injuries and may be death. Child abuse and happen in all various groups all around the world despite ethnic, occupational, cultural, and socioeconomic differences[(1)].

Child maltreatment (child abuse) is generally defined by the World Health Organization (WHO) as "the abuse and neglect of people under 18 years of age. It includes all forms of physical and/or emotional ill-treatment, sexual abuse, neglect or negligent treatment or commercial or other exploitation, resulting in actual or potential harm to the child's health, survival, development or dignity in the context of a relationship of responsibility, trust or power"[(2)].

During 2016, around 4.1 million reports concerning 7.4 million child were reported to U.S. child protective service agencies[(3)]. Majority of these reports (65%) were by specialists who, while working, encountered the suspected child victim. With educational staffs,one of the major reporters of child abuse. In United States of America, educators introduce 16% of all reports[(4)].

Teachers are in direct contact on day-to-day basis with a large number of children for a longtime as the

child devotes a lengthier period in school. Therefore, teachers can detect behavioral abnormalities in the child and consequently are in a good place to perceive and report child abuse, but are not prepared or are not sufficiently informed[5]. Teachers' attitudes can effect the awareness and perception of abuse and subsequently reporting cases [6].

The teachers knowledge toward reporting of child abuse is a chief factor in dealing with the case. There are numerous components that may possibly be impacted by their attitude and recognition that may influence the quality of reporting and decision-creation of child abuse that teachers have to put in consideration [7].

Some of the recognized impacts affecting active teacher reporting child abuse emerge from the attributes of the child's condition, for example,the recurrence and seriousness of the child's behaviour and injuries [8]. Others identify with institutional elements, for example, a steady workplace. Still, many determinants related to the teacher, such as the teacher's consciousness of the presence of a lawful obligation to report alleged child abuse, their insight of the content of that obligation[9] and their disposition concerning the duty[10].

It is vital for teachers to own positive mentalities concerning the reporting obligation, knowledge regarding communal and educational background of child abuse, and 'lawful literacy' about the lawful and policy-based commitments to report. This professional advancement of teachers should happen not just in in-service settings, but also in pre-serviceones[11, 12].

The deficiency of researches (especially in Iraq) in teachers' knowledge and training in the subject of child abuse is alarming. Therefore, this study aims to assess teachers' knowledge concerning child abuse and set basis for future studies and solutions to this problem in Iraq.

Material and Method

Study Design: Descriptive survey is conducted in the period from 19th of April 2019 to 1st of October 2019.

Setting of the Study: The study was applied at 10 primary schools in Al-Nasiriyah city, Thi-qar, Iraq.

Study Sample: A probability (random) sample of (100) teachers, who were working in 10 primary schools in Al-Nasiriyah city.

The Study Instrument: The authors constructed a questionnaire for the purpose of the study

Part 1: Demographic Data: Socio-demographic data sheet composed of six points that included (Marital status, gender,education, passing of educational training courses, income).

Part 2: Part II. Clinical information regarding blood transfusion and its reactions: The questionnaire is consisted of (12) items separated into three domains.

First Domain: (4) items connected to signs and symptoms of physical violence.

Second domain: (4) items related to signs and symptoms of emotional violence.

Third domain: (6) items linked to signs and symptoms of sexual violence.

These items were rated according to the following scale; ["know"is given (1); "Don't know" is given (2)]

Data Collection: Data were gathered by application of the constructed questionnaire after estimation of the reliability and validity through direct interview with the sample.

Pilot Study: In order to estimate the study instrument (questionnaire) reliability, A (10) teachers sample were designated; pilot study was applied in the period from 1st of April to 15th of April 2019. The pilot study sample was excepted from the total study sample.

Validity: Study instruments validity were determined by agroup of (7) experts, that had more than five years of experience in the study field.

Reliability: Questionnaire reliability was estimated by the use of test re-test method on ten teachers. Outcomes displayed acceptable level of constancy and internal consistency of major items regarding responses' of the questionnaire, responses were calculated through applying the Alpha Cronbach parameter, which exhibit that the person correlation coefficient = (0.78).

Analysis of the Statistics: With the intention of analyze the study data, the statistical package of social sciences (SPSS) ver. (23) were used (Percentage, Frequency, Mean, Standard deviation, Mean of score, and Chi-square).

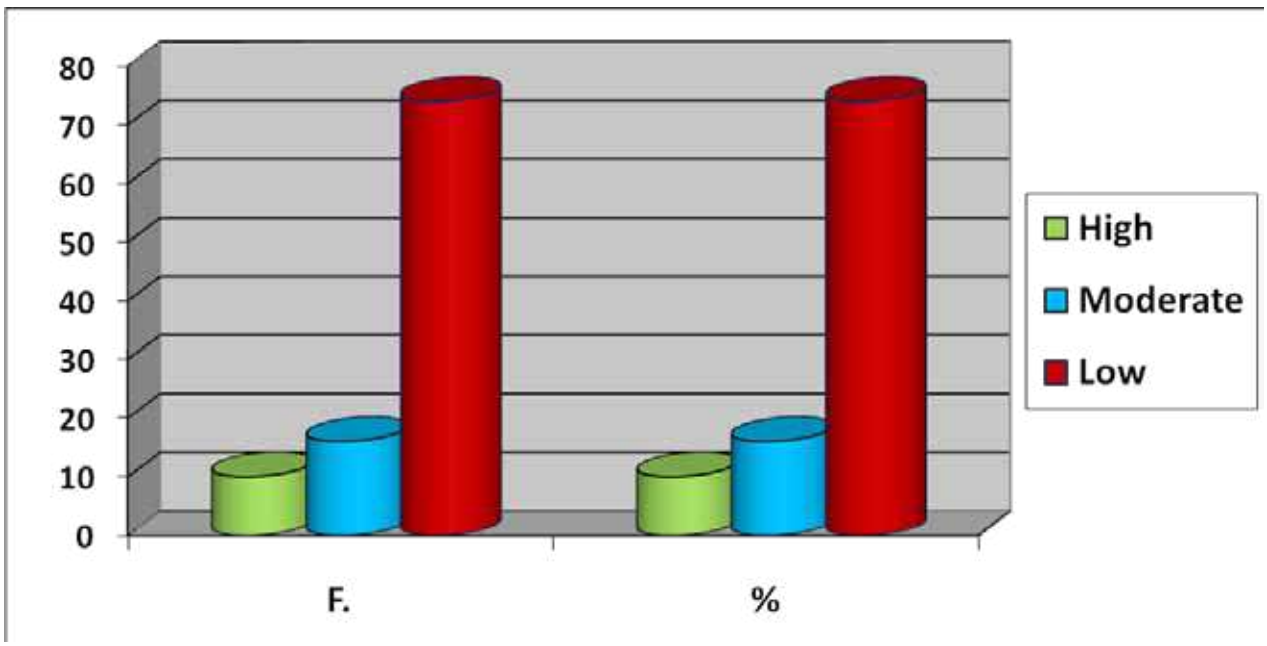
Results

Table 1: Frequency of Sociodemographic characteristics of Teachers (N=100)

SDVs	Group	Frequency (F)	Percent (%)
Marital Status	Single	33	29
	Married	57	61
	Divorced	6	6
	Widowed	4	4
Gender	Male	39	39
	Female	61	61
Education	Diploma or Associated Degree	78	78
	Bachelor's Degree or Higher	22	22
Receive educational training courses in child abuse	Yes	5	5
	No	95	95

SDVs = Sociodemographic variables, % = percentage, F = frequency, n = number of samples

Table (1) shows that the most of the study subjects were married (57%) Female (61%). The highest educational status of the participants was reported to be (78%) of diploma or Associated Degree. Majority of the study subjects (95%). Have not Receive educational training courses in child abuse.



n = number of samples, F = frequency, % = percentage

Figure (1): Total teacher's knowledge concerning child abuse

Figure (1) shows knowledge levels of teachers where most of them (74%) were have low level and (16%) were have moderate level, while only (10) were have a high knowledge level regarding blood transfusion reactions.

Table (3): Relationship between SDVs and nurses knowledge regarding main domains

Main Domains \ SDVs	Marital status		Gender		Education		Receive educational training courses in child maltreatment	
	X^2	Sig.	X^2	Sig.	X^2	Sig.	X^2	Sig.
Signs and symptoms of physical violence	19.177	.574	3.278	.858	20.261	.122	26.359	.023
Signs and symptoms of emotional violence	27.747	.271	19.704	.012	23.658	.097	36.634	.002
Signs and symptoms of sexual violence	30.908	.275	14.074	.120	17.212	.509	34.428	.011
Total	64.694	.796	23.291	.561	60.847	.140	71.069	.027

SDVs: Sociodemographic variables, X^2: Chi-square, Sig.: Significance.

Table (3) illustrates the relationship between SDVs and knowledge level concerning main domains and total level of knowledge.

Discussion

The issue of child abuse has substantial insinuations for pre-service teacher's preparation and proficient development. They have an instructive role in interacting with suspected children, and a lawful and professional obligation to report alleged case. Teachers need provision and training to improve the particular knowledge and confidence wanted to interact with this multifaceted context.

The results of the current study presented that most of the sample were married (57%) Females (61%) and the highest educational status of the participants was reported to be (78%) of diploma or Associated Degree.

The most important finding concerning sociodemographic variables is that (95%) of the study sample have not receive educational training courses in child abuse (either pre- or in-service) and that is an extremely alarming result that indicate poor administrations performance in providing knowledge and training programs for teachers. Many studies find low or no content at all concerning child protection in teachers training programs during pre-service period[12, 13]. Also, some studies suggest that reporting of the teachers is affected by the level and context of teachers' training programs in identifying abuse[14].

Concerning total knowledge of the teachers regarding child abuse, the study exhibits that majority (74%) have low levels of knowledge. From the researchers' viewpoint, that was expected because in Iraq (like in many of the developing countries) the governmental administrations have a "bigger" problems to deal with until child abuse has become an unimportant issue compared to other problems!

The results also illustrated that there was statistically significant relationship ($p< .05$) related to knowledge score with sociodemographic data (Receiving educational training courses in child abuse in specific). The relationship between these two items is undeniable as many studies shows [7, 14].

Conclusion

Child abuse is an international concern that need urgent and effective interventions in order to manage appropriately. In developing countries including Iraq, this problem takes a less attention from the specialized administrations and organizations that subsequently result in unnoticed escalation that primarily affect the children.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the College of Nursing, University of Thi_Qar, Iraq and all experiments were carried out in accordance with approved guidelines.

Pharmacological Activities and Chemical Constituents and of Bryonia Dioica L.: A Review

Thamer Mouhi Jasiem[1], Rasha Eldalawy[2], Zahraa Abdul Elah Alnaqqash[2]

[1]Lecturer, [1]Assist, Lecturer, Department of Pharmacognosy and Medicinal Plant, College of Pharmacy, Mustansiriyah University, Iraq

Abstract

Bryonia is one of the genera belong the Cucurbitaceae family (gourd family). *Bryonia dioica* distribute in Western Europe,this plant flowering in May as small, greenish and three or four flowers together in small cluster the stamens and pistils are found separated therefore consider a dioecious plant–growth as separate plant into (male and female).The phytochemical constituents of Leavesare Luteolin, flavonoids (kaempferol),. alkaloids, Glycosides, phenol steroids, Carbohydrates, anthraquinoine and terpenoids, while the part used of this plant (Roots)are Kempferol 3, 7-di-O-rhamnoside, polyphenols, sterols, triterpenes, alkaloids, heterosides-c, carbohydrates, saponins, terpenoids, flavonoids, tannins, alkaloids, quinones, reducing sugar and coumarin . The fruits containing triterpene, glucosides, calcium oxalate crystals and the flowers arePhenolic acid and flavonoids . The biological activity and pharmacological uses of all plant parts of *B.dioica* are antinociceptive effects, antimicrobial activities, antioxidant activity,hepatoprotective activity, Anticancer activity, hypercholesterolemia, diabetes and fertility disorders .

Keywords: *Bryonia dioica, phytochemical constituents, biological activity and pharmacological uses*

Introduction

Bryonia is one of the genera belong the Cucurbitaceae family (gourd family) which is flowering plant[1,2] The genus name Bryonia, came from the bryo word (Greek bryo), which means shoot, or appears of sprout according to the active growth of the plant stems[3]. The best-known common name is Bryony[4,5]. *B. dioica* distributed in Western Europe[6-8]. it has five-pointed leaves with different flowers like blue or white[9]. This plant flowering in May as small, greenish and three or four flowers together in small cluster the stamens and pistils are found separated therefore *B.dioica* consider a dioecious plant – growth as separate plant into (male and female) flowers with many petals (five greenish-white petals)[10]. Male flowers about 12 to 18 mm and having stalked bunches and loose. The stamens consist of one-celled and the anthers are yellow, while the female flowers about 10 to 12mm[11,12]. The fertile flowers, distinguish easily by the presence of an ovary beneath the calyx, in general without stalk (sessile) about two to five fertile flowers together when the stem and leaves are withered, The berries, hang about the bushes, about peas size when ripe,take pale scarlet color containing six seeds in large size and filly juice [13]. The stems of *B. dioica* plant containing a long tendrils, which use for climb and its springing from the stalks of leaves and the tendrils between the shrubs and trees extend for many yards during the summer season, and when the fruit is ripening the tendrils drying as vine shaped very rough with leaves and form like prick-hairs and its consider as general character for this plant[14-16] . The leaf blade is lobed, which is divided into five lobes and the middle one is longer than others, in general the leaves consider as curved stalked shape [17]. The part used of this plant is the root which collected in the autumn and used as fresh and dry state(18). the fresh root take a dirty yellow

e-mail: thamermouhi@uomustansiriyah.edu.iq

or yellowish-white, when cutting the root obtain milky juice as a bitter, and acrid taste. . The root is simple, like a carrot and some time forked into two parts[19-20]. The medicinal uses of *B. dioica* plant for Irritative, hydragogue and cathartic. But now don't recommended used as a purgative because its cause discomfort able and irritation[21-23]. It is useful in different diseases but in small doses used in cough, influenza, bronchitis, pneumonia, pleurisy and whooping-cough . Also used for cardiac disorders caused by rheumatism and gout, also in malarial and zymotic diseases[24] .

Vernacular Names: There are many common names for *B. dioica* plant like white bryony,mandrake, ladies' seal, Tetterbury, red bryony, Wild Vine, Wild Hops, Wild Nep. Tamus and in French Navet du diable[25-28].

Scientific Classification	
Kingdom	**Plantae**
Clade:	Angiosperms
Order:	Cucurbitales
Family:	Cucurbitaceae
Subfamily:	Cucurbitoideae
Genus:	Bryonia
Species	Bryonia dioica L.

Figure (1): Leaves and fruits of Bryonia dioica L. plant

Table (1): Phytochemistry Review

Plant Part	Constituent Reported
Leaves	Luteolin, flavonoids(kaempferol)(29-31). alkaloids, Glycosides, phenol steroids, Carbohydrates and, anthraquinoine and terpenoids(32-35).
Flowers	Phenolic acid, flavonoids(36).
Fruit	triterpene glucosides and calcium oxalate crystals(37).
Root	Kempferol3, 7-di-O-rhamnoside(38), polyphenols, sterols, triterpenes, alkaloids(39), heterosides-c, carbohydrates, saponins, terpenoids, flavonoids, tannins, alkaloids,quinones, reducing sugar, coumarin (40-43).

Pharmacological and Biological Activities:

1. **Antinociceptive Effects:** The antinociceptive activity of the leaves extract of Bryonia dioica plant confirm by hydroalcoholic extract of leaves by used standard test of tail flick and formalin which is one of the most common test used for measured the antinociceptive activity with acetic acid used as chemical stimulation the results were observed that dose of 300 mg/kg with $P < 0.01$[44]. and the compared between the leaves extract and indomethacin shown that no significant difference between them at dose of 300 mg/kg of leaves extract and the results determined the LD50 of the plant extract was 4200 mg/kg[45].
2. **Antimicrobial Activities:** The leaves extract of Bryonia dioica plant has a referred to antibacterial activity against many of pathogenic bacteria such as E.coli, K. pneumoniea, and P. valgaris. the results significant that activity against gram negative bacteria. The maximum inhibition zone (MIC)was 227.3mg ml-1 against *P. valgaris while* 186 mg ml-1 against *K.pneumoniea and then against E.coli was* 143.9 mg ml-1[46,47].

3. **Antioxidant Activity:** The phenols and flavonoids in the *B. dioica* plant act as antioxidant activities those active compounds found in different parts of this plant (leaves, stem and flower) and those active compounds act as radical scavenging capacity, the flowers of *B. dioica* consider an important part used rich in phytochemical compounds and act as antioxidant this study done by measured the scavenging activity by colorimetric assay DPPH and presented by IC50 value, the polar stem extract concentration at 28.75 µg/ml shown highest radical scavenging activity and in non polar extract at 31.27 µg/ml, while in leaves extract were 76.08 µg/ml in polar and 83.62 µg/ml in non polar and finally in flower extract were 98.35 µg/ml in polar and 91.54 µg/ml in non polar [48,49].

4. **Hepatoprotective Activity:** The hepatoprotective action of leaves extract of *B. dioica* plant was investigated by used oral dose about 250mg/kg plant leaves extract for week this study was used Rats model by histopathological effect in Rats liver which induce hepatotoxicity by used $CCl_4$and investigated the hepatoprotective activity of this extract in serum tested as the biochemical marker for hepatotoxicity AST and ALT . The leaves extract shown decrease the enzymes level by decrease the CCL_4 cause the plant extract have very important constituents like flavonoids, alkaloids, terpenoids, sterols[50].

5. **Anticancer Activity:** In Algerian study which proved the local population used the extract of *B. dioica* roots for treatment of breast cancer used this root extract only or by mixed this extract with honey and this study reported treat cancer 26% this study attributed to presence the major active compound: Kempferol 3, 7-di-O-rhamnoside which induced cell death in cancer cell line and also the same study reported the root extract treat hypercholesterolemia (22%), diabetes (18%), fertility disorders (14%)[51].

Conclusion

B.dioica one of the medicinal plant which widely used in traditional medicine and distribution in different countries specially in Western Europe and containing many active ingredients in all types of plant specially in root which consider as part used in this plant such as Kempferol 3, 7-di-O-rhamnoside and polyphenols which responsible for many biological activity and pharmacological uses such as antinociceptive effects, antioxidant activity, hepatoprotective activity, Anticancer activity, hypercholesterolemia, diabetes and fertility disorders .

Risk of Cesarean Delivery and Low Bishop Score after Induction of Labor in Nulliparous Women in Tikrit Ciry

Shaimaa Mohammed Sulaiman[1], Nabila Kamil Yaqoub[2]

[1]Higher Diploma Dr., Kirkuk Health Directorate, Kirkuk City,
[2]Assist. Prof. Flc.O.G. M. B. Ch. B. College of Medicine, Tikrit University, Iraq

Abstract

This prospective study was s carried out in Tikrit city in the period of 1st February to 1st of July 2019 on pregnant women admitted to the labor ward of Salahaddin general hospital to assess the risk factors of cesarean delivery associated with induction of labor in nulliparous women in relation to bishop score in unfavorable cervix. The study included 100 nulliparous pregnant women with singleton fetus in cephalic presentation who admitted for induction of labor for different indications. A total number of 100 pregnant women in whom spontaneous onset of labor was diagnosed at admission were assigned to the spontaneous onset group, which served as the control group. The cesarean delivery rate for women who were induced with an unfavorable cervix (Bishop score ≤ 4) was 27.14%; the rate for women who were induced with a favorable cervix was 10% (Figure 2). The induction of labor for women with an unfavorable cervix was associated with a significantly increased risk of cesarean delivery ($P < 0.002$). The study showed that Bishop score ≤ 4 was significant risk factor for C/S in addition to maternal age, gestational age and birth weight

Keyword: *Bishop Score, Induction of Labor; Cesarean Rate; Nulliparous Women.*

Introduction

Induction of labor is a common procedure in modern obstetrics. It is a relatively common procedure in modern obstetric practice; some of the obstetricians consider it to be quite simple, efficient, safe and psychologically well tolerated procedure and far superior to secondary interventions such as vacuum delivery or forceps delivery[1]. However, cesarean section (CS) rates vary worldwide, ranging from approximately 10% in Sweden to about 80% in private-sector hospitals in Brazil[2]. High rates are reported from regional, tertiary public and private hospitals. These high rates are probably due to large proportions of highrisk patients attending tertiary and regional[2]. Regarding our country, almost 26% of Iraqi women giving birth at public hospitals do so via CS according to the 2010 health report for the Iraqi Health Ministry [3;] and in 2016, the rate was further increased to 29.25%[1] . When a woman and her care provider decide that labor induction is desired, they must next choose a method of induction. In general, induction of labor is indicated when the risks of continuing the pregnancy outweigh the risks associated with delivery for the mother and the baby [5]. In 1955, Bishop devised a cervical scoring system for multigravida patients in which 0–3 points are given for each of five factors[6] . Bishop score is a pre-labor scoring system assisting in predicting whether induction of labor will be required[(7,8)]. It has also been used to assess the likelihood of spontaneous preterm delivery[1]. The Bishop scoring assign points for cervical effacement, dilatation, consistency, and position and for the depth of the fetal presenting part in the maternal pelvis[5]. He determined that the total score of at least 9 predicts the likelihood of vaginal delivery following labor induction and was similarly observed in patients with spontaneous onset of labor[8]. Thus Bishop's Score (BS) or the modified version is used universally to assess the favourability of the cervix with its characteristics of effacement and dilatation and the station of the presenting part and also used to predict the method and success of a medically indicated induction [(9,10)]. The aim of the study was to assess the risk factors of cesarean delivery associated with induction of labor in nulliparous women in relation to bishop score in unfavorable cervix.

Material and Method

This prospective study was s carried out in Tikrit city in the period of 1st February 2019 to 1st of July 2019 on pregnant women admitted to the labor ward of Salahaddin general hospital. The study included 100 nulliparous pregnant women with singleton fetus in cephalic presentation who admitted for induction of labor for different indications. Exclusion criteria include: Multiparous women., Multiple gestations, Fetal anomalies, Preterm deliveries (>37 weeks), Elective cesarean deliveries for medical or obstetric reasons and Patients with Failed inductions. A total number of 100 pregnant women in whom spontaneous onset of labor was diagnosed at admission were assigned to the spontaneous onset group, which served as the control group.

Method

At admission to the labour ward, specific data including maternal age, history of previous abortion, and the indication for induction was recorded. Depending on bishop score at admission we decided which method of induction should be used. The modified bishop score was calculated (cervical dilatation 0 - 3 point, effacement 0 - 3 point and fetal station 0 - 3 point). From the first vaginal exam before labour induction or any method of cervical ripping used. Induction was performed using either prostaglandin E2 vaginal gel alone, amniotomy alone, oxytocin in combination with or without amniotomy, or prostaglandin E2 vaginal gel followed by oxytocin, or amniotomy, or a combination of both. Based on the Bishop score at admission, the attending obstetrician decided which method of induction should be performed. In case of an unfavorable cervix, induction was usually started with prostaglandin E2 vaginal gel for ripening.

Statistical Analysis: Statistical analysis was performed using SPSS. Univariate analyses included the X^2 test followed by Scheffe´ test for differences between groups. Known prognostic variables were included in a multivariable logistic regression analysis. A final model of risk factors for cesarean delivery was created using the maximum likelihood estimation (P >0.5).

Findings: The mean maternal age of induced pregnant women was 25.82+4.11 years with range 37-40 years. The mean gestational age of induced women was 39.5+1.87 week. The mean Bishop score of theses pregnant women was as 3.2+0.23. However, body mass index (BMI) was significantly higher in both induction groups than in the spontaneous onset group. The gestational age in the spontaneous onset group was significantly lower than in the induced groups. Further differences between induced and spontaneous onset pregnant women were shown in Table 1.

The study demonstrated that the cesarean delivery rate for women in spontaneous labor was 10%; women who were admitted for induction of labor were found to have a cesarean delivery rate of 22% with a significant difference between the 2 groups (P: 0.033) (Figure 1). The cesarean delivery rate for women who were induced with an unfavorable cervix (Bishop score ≤ 4) was 27.14%; the rate for women who were induced with a favorable cervix was 10% (Figure 2). The induction of labor for women with an unfavorable cervix was associated with a significantly increased risk of cesarean delivery (P < 0.002).

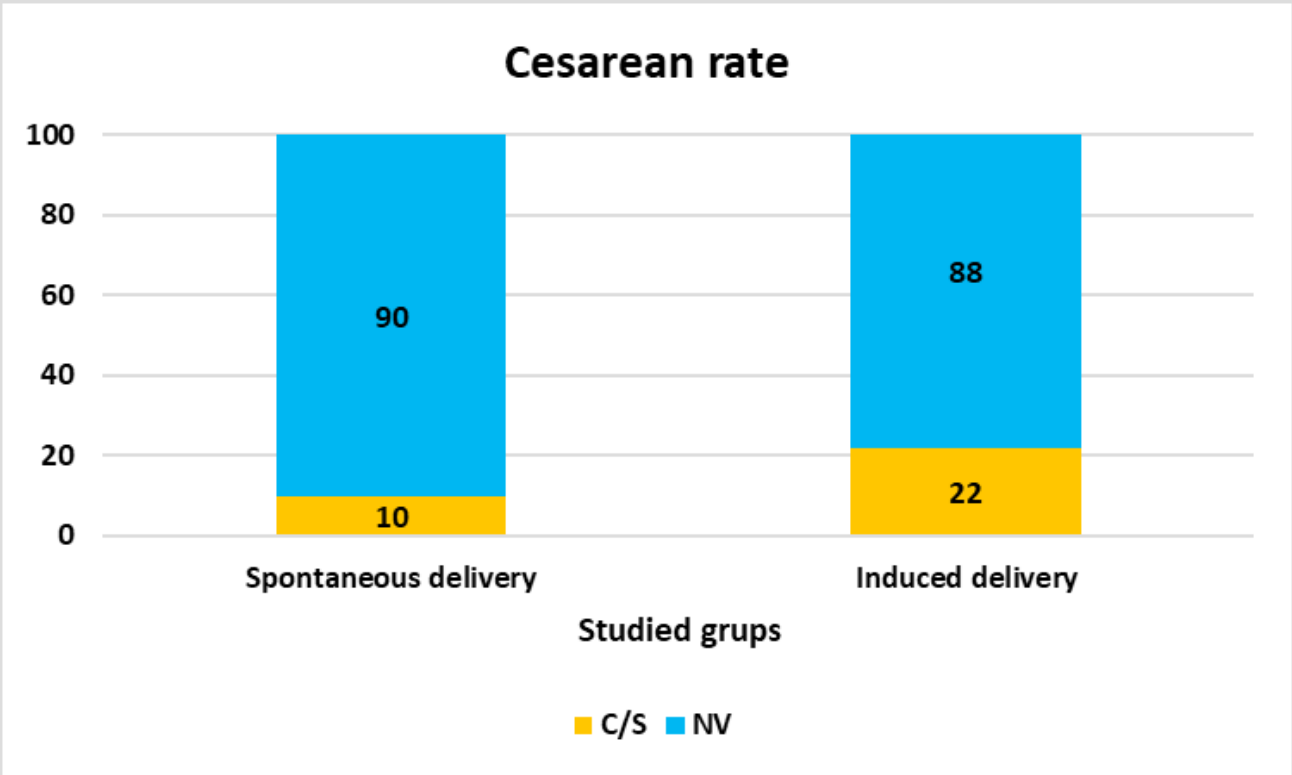

Figure 1: Cesarean delivery rate in induced and spontaneous delivery women

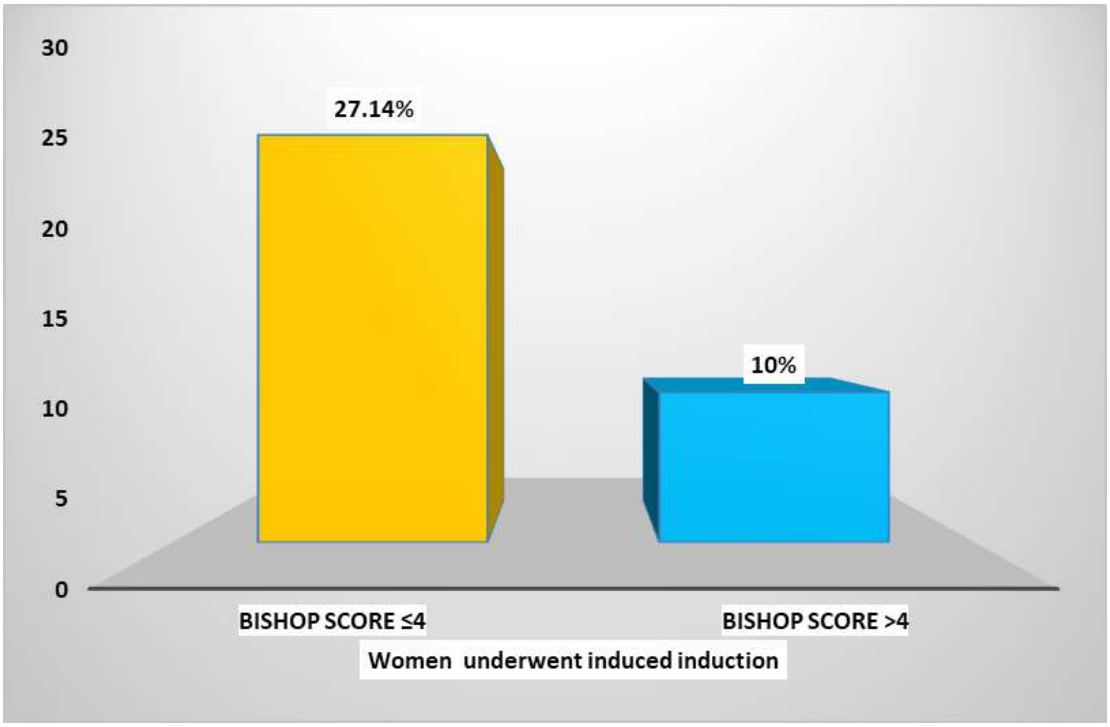

Figure 2: Cesarean delivery rate in women with favorable and unfavorable cervix

The four confounders in the logistic regression model were (1) maternal age of, (2) Bishop score, (3) birth weight and (4) baby's gestational age in weeks. We also examined possible interactions between the exposure variables and the confounders. The study showed that Bishop score ≤ 4 was significant risk factor for C/S in addition to maternal age, gestational age and birth weight (Table 2).

41-42	1.1

Discussion

In this study, when Bishop score included as an extra covariable in the multivariable regression model with gestational age, maternal age and birth weight, there was significant increase in cesarean delivery rate predominantly related to unfavorable bishop score at admission[11,12]. The degree of cervical dilatation and station of the presenting part, rather than cervical length can be a considered as a predictors for risk of cesarean delivery there for a bishop score at admission of 4 or lower and not the induction per se is associated with a more than double risk in cesarean delivery rate regardless of the causes of induction. In the 2 groups, the cesarean delivery rate was significantly related to the Bishop

score at admission; dilatation was the most important item, and failure to progress during the first stage was the most common indication for cesarean delivery. After including the Bishop score as an extra covariable in the multivariable logistic regression model, no significant differences in cesarean delivery rate between the 2 groups could be demonstrated. Therefore, a Bishop score at admission of 5 or lower, and not the induction per se, is associated with a more than double risk in cesarean delivery rate, regardless of whether the labor is induced for a medical or an elective reason. This is in agreement with t other studies that reported both labor induction and cervical ripeness as being of significance[2-4]. A possible limitation of this study was the absence of a prospectively determined method of induction in case of a certain Bishop score. Compared with the spontaneous onset group, women in both induction groups had a higher BMI. Body mass index was also an independent risk factor for cesarean delivery. Increased BMI was associated with an increase in the cesarean delivery rate, as demonstrated by others[5,6]. Because impending postterm pregnancy with its accompanying psychosocial problems was an indication for elective induction, and because postterm pregnancy was an indication for medical induction, it could have been expected that the lowest gestational age was found in the spontaneous onset group and the highest gestational age in the medical induction group [7,8]. Oxytocin stimulation during the first and second stages, and duration of the second stage were similar in the 3 groups. None of these factors had an independent relation to the cesarean delivery rate. As could be expected, more children with a birth weight below 2,500 g or 4,000 g or higher were born in the induction groups than in the spontaneous onset group. Birth weight was also an independent risk factor for cesarean delivery. Birth weight of 3,500 g or higher was associated with an increased cesarean delivery rate, again as mentioned by others[10-12]. The association between induction and increased risk for cesarean delivery has been documented in many studies especially when the focusing is placed specifically on nulliparous patients[13-15]. Studies that evaluated the induction of nulliparous patients consistently have shown an increased risk for cesarean delivery, although not always statistical significance has not always been reached. Seyb *et al* [11] prospectively studied 1561 nulliparous women at term in either spontaneous labor or awaiting induction. This included 437 women who labor was being induced both electively and for medical indications. The increased risk for cesarean delivery that was attributed to induction was found to be significant. They included the results of the initial cervical examination by dilation and separately for effacement, but not together, to determine cervical favorability. They did note that the spontaneous labor group generally had more advanced dilation and effacement. They also did not determine the cesarean rates on the basis of the initial cervical assessment. This is in contrast to studies done earlier showed that that induction of labour in 67 nulliparous women from a total of 210 when medically or obstetrically indicated is not associated with an increased risk of cesarean delivery, instrumental delivery and favorable out come for induction of labour both in low and high risk pregnancies [16,17]. This discrepancy may be explained by other method used for cervical ripening such as labour initiation by prostaglandins, improved fetal surveillance, and liberal use of analgesia along with more active approach to treatment of labour disorders which have been increasingly used during the last two decades. In the present study cesarean delivery rate was significantly related to maternal age, the higher the maternal age the higher the risk of cesarean delivery. In line with our observation several authors Maslow AS et al, Johnson DP et al, Heffner LJ et al, and Ecker JL et al. found that cesarean delivery risk increased with older maternal age and higher birth weight, induction without stated risk factors may not carry an increased risk of cesarean delivery[18-20].

Conclusions

The induction of labor for women with an unfavorable bishop score was associated with a significantly increased risk of cesarean delivery.

Abstract

Stachybotryschartarum in one of fungi that cause respiratory system infection to human and animals therefore this study it done to evaluation histological changes in some respiratory organs such as nose and lung induced by this fungus suspension . Detection of *Stachybotryschartarum* fungus confirmed by cultured samples which collected from baths floor on potato dextrose agar in room temperature for seven days. Then the suspension of positive samples of this fungus diluted by phosphate buffer saline and counted the spores by using hemocytometer before used experimentally in lab animals (Balb/C mice) to study histological changes in respiratory system . Twelve mice used in this study divided into two groups. first group consist of six mice induced with 0.5 ml from one positive sample of fungus suspension contain 2×10^4 spore/mm^3 (for month : one dose daily) according to count of hemocytometer to evaluate some histopathological changes in nose and lung .Second group induced with 0.5 ml from phosphate buffer saline only. The results revealed that the nose of mice injected with 0.5 ml contain 2×10^4 spore/mm^3 from *Stachybotryschartarum* fungus suspension causefocal superficial necrosis of the respiratory epithelial cells with acute inflammatory cells and infiltration of the mucosa while the lung of group mice treated with same concentration of fungus has interstitial pneumonia with thickening of inter alveolar space due to infiltration and chronic inflammatory cells especially mononuclear cell.

Keywords: *??.*

Introduction

Stachybotryschartarum is a fungus that has become notorious as a mycotoxin producer that can cause animal and human mycotoxicosis[1]

Schartarum called a black mold that produces its conidia in slime heads found in soil and grain, but the mold is most often detected in cellulose-rich building materials from damp or water-damaged buildings[2] It requires high moisture content in order to grow and is associated with wet gypsum material excessive humidity, water leaks, water infiltration, or flooding as in bathrooms[3].

[4,5]Fungal division from Deuteromycota and its single class Deuteromycetes and is a member of the order Moniliales and the family Dematiaceae[6]. *S. chartarum*is capable of producing mycotoxins that include both macrocyclic tricothecenes and nonmacrocylictricothecenes. There are very few reports that toxigenic molds found inside homes can cause health conditions such as pulmonary hemorrhage or memory loss. The (Institute of Medicine[7] found there was sufficient evidence to link indoor exposure to mold with upper respiratory tract symptoms, cough, and wheeze in otherwise healthy people, with asthma symptoms in people with asthma, and with hypersensitivity pneumonitis in individuals susceptible to that immune-mediated condition. Other recent studies[8] have suggested a potential link of early mold exposure to development of asthma in some children, particularly among children who may be genetically susceptible to asthma development, and that selected interventions that improve housing conditions can reduce morbidity from asthma and respiratory allergies. Previous experiments used exposures of rats and mice to *S. chartarum*

spores intranasally and intratracheally; lung tissue was examined for histological changes and bronchoalveolar lavage for evidence of injury and inflammation[9,10,11,12]. *Schartarum* has been consistently reported to cause pulmonary hemorrhage,extensive inflammation and chemokine levels in response to intratracheally instilled spores of *S. chartarum* a well as apoptosis, cytokine release, DNA damage, and changes in gene expression[13,14,15,16]

Schartarum is the only fungus that we know of to which BALB/c mice are more sensitive. [17]We have previously shown that BALB/c mice respond more to pulmonary exposure to S. chartarum spores than do other strain mice [12].

Health problems related to this mold have been documented in humans and animals since the 1930s. More recently, *S. chartarum* has been linked with so-called sick building syndrome[18,19], Blood tests confirmed the presence of a toxin produced by *S. chartarum*, and severe mold contamination was found in the home.[20].

The aim of the current study: Evaluation the histological changes induced by Stachybotryschartarum fungus suspension intranasally in mice (Balb/c).

Material and Method

1. **Samples collection and Lab tests:** *Stachybotryschartarum* fungus samples were collected from the baths ground and testing microbiological Laboratory that done by cultured on potato dextrose media and incubated at room temperature for 3-7 days in order to obtaining on *Schartarum* fungus. Dilution done by two –fold serial diluents in 8 tubes and harvesting of this fungus with normal saline.

One positive samples of this fungus was further used for the experimental study on laboratory animals (mice) after infected with 0.5 ml from fungus suspension contain 6×10 spore/mm^3 counted by using hemocytometer chamber (white blood cells count chamber) for evaluation the effects of *Stachybotryschartarum*on respiratory tissues sections taken from these mice.

2. **Experimental Study:** A total of 12 males mice species Balb/c have aged one month and weight 25-30 g divided into two groups, the first group consist of six mice infected intranasal with 0.5 ml from *Stachybotryschartarum* fungus suspension for one positive sample contain 6×10 spore/mm^3 (for month as one time daily) .The other as control group was received 0.5 ml of sterile phosphate buffer saline (PBS) according to method of [21]. After 7-14 days clinical signs were recorded in infected animals . then the Experimental mice were sacrificed after anesthetization by chloroform and open abdomen cavity by medical scissors. Nose and lung tissue sections were collected for the experimentally infected mice and placed in formalin 10% for histological changes examination in later. Histological sections and staining were prepared according to method described by [27].

The histological changes were read by Dr. Nemah . H. AL-jabori/college of medicine/university of Babylon under the magnification power 10X and 40 X of light microscope.

3. **Statistical Analyses:** Using statistical package for social science (SPSS) version 13.0, two-way analysis of variance was conducted to test the significance of effects of groups and periods post injection on the examined traits. The statistical differences among means of the different treatments were tested By Duncan's multiple range test.

Results

1. **Lab. Study Results:** Culture microbiological testing in laboratory observed *Stachybotryschartarum* fungus on potato dextrose agar . 0.5 ml contain 6×10^4 spore/mm^3 from this fungus suspension used with histological study in vivo (inside mice) to evaluation the histological changes in some organs of respiratory system (nose and lung) figure 1 and 2 shows these results the culture .

Figure (2): A culture of S. chartarumon PDA from bottom side (see the roots).

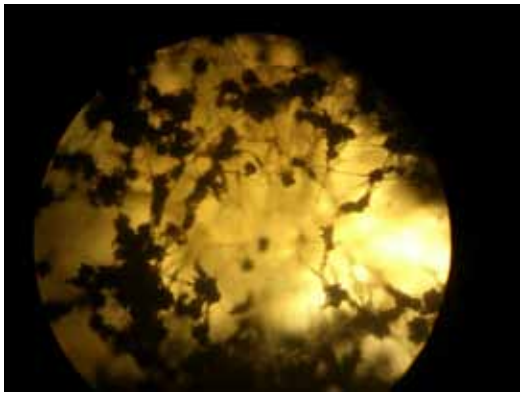

Figure (3): The mass of conidia of S. chartarum at the tip of the conidiophore networks. Under light microscopic magnification 4x.

2. **Histological changes:** Results of the current study revealed histological changes in nose and lung of mice infected with 0.5 ml contain 6×10^{4} spore/mm^3 from *Schartarum* fungus suspension, these changes shown in figure 4,6 while figures 5,7 represented control group of mice infected with 0.5ml phosphate buffer saline .

   In this results figure (4) the nose of mice infected with 0.5 ml contain 6×10^4 spore/mm^3 from *Schartarum* fungus suspension showsfocal superficial necrosis of the respiratory epithelial cells with acute inflammatory cells and infiltration of the mucosa.

   The results in figure (6) lungs of mice infected with 0.5 ml 6×10^4 spore/mm^3 from *Schartarum* fungus suspension indicated tointerstitial pneumonia with thickening of inter alveolar space due to infiltration and chronic inflammatory cells especially mononuclear cell.

While the figure (5,7) revealed to the nose and lungs of control mice infected with 0.5ml phosphate buffer saline. No histological changes observed in nose and lung control mice group.

The graph (8) shows the histological resulting column for compersation between injection and control groups after one month ago (one dose/ dailyfrom *Schartarum* fungus suspension).

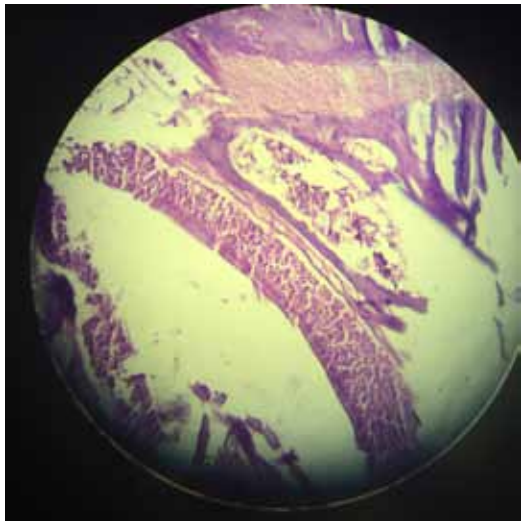

Figure (4): Nose of mice infected with0.5 ml contain 6×10^{4} spore/mm^3 from Stachybotryschartarum fungussuspension . This slide shows focal superficial necrosis of the respiratory epithelial cells with acute inflammatory cells and infiltration of the mucosa .E & H stain. Magnifications 20X.

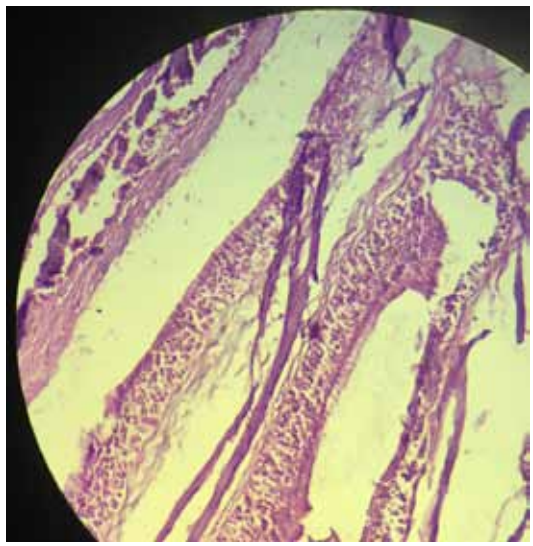

Figure (5): Control of Nose of mice infected with 0.5 ml phosphate buffer saline . There is normal appearance in respiratory epithelial cells of nose without any damage or destruction of epithelium cells. E & H stain. Magnification 20x.

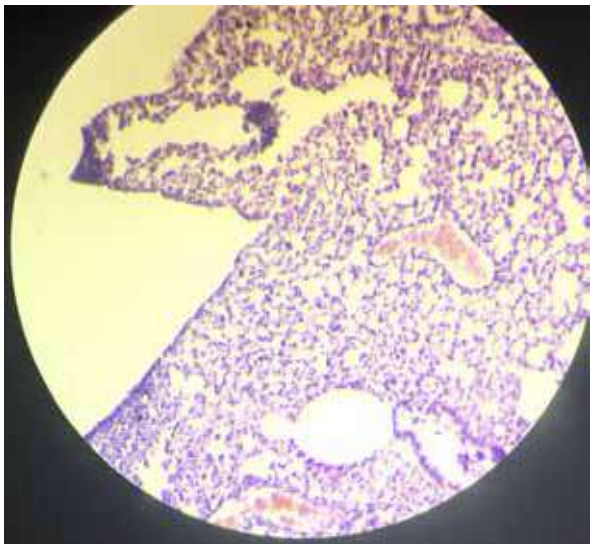

Figure (6): Lung of mice infected with 0.5 ml contain 6×10^4 spore/mm^3 from Stachybotryschartarum fungus. this slide shows interstitial pneumonia with thickening of inter alveolar space due to infiltration and chronic inflammatory cells especially mononuclear cells. E & H stain. Magnification 20x

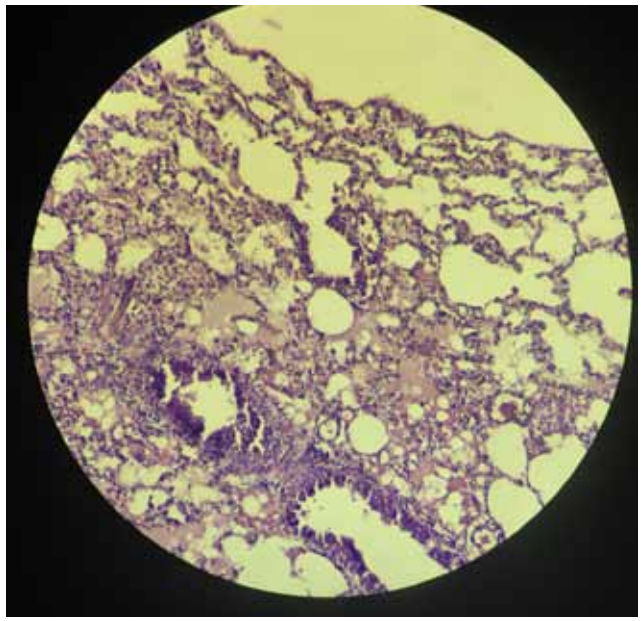

Figure (7): Control of lung of mice infected with 0.5 ml phosphate buffer saline. this slide shows normal inter alveolar space and normal cells of lung. (E & H 20X).

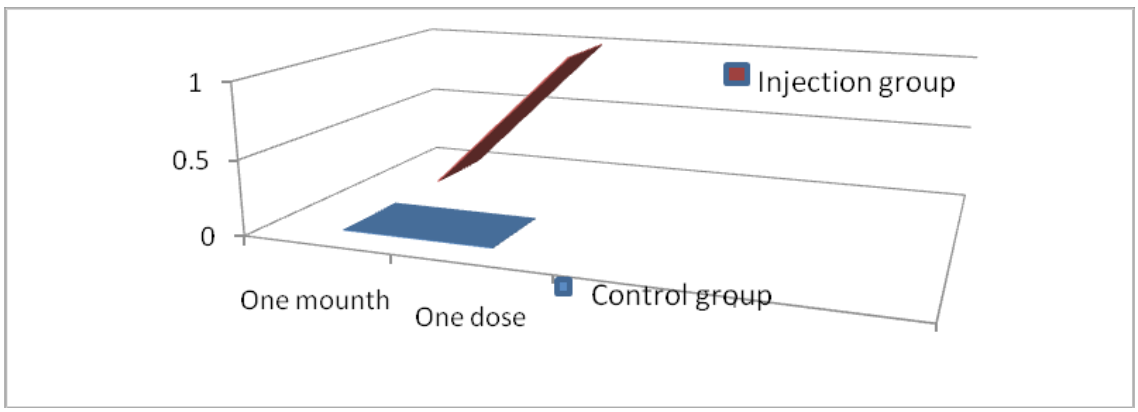

The graph (8) shows the histological results column for compered between injection and control groups.

Discussion

Stachybotryschartarum was reported to induce sensory irritation, inflammatory, and/or pulmonary responses in mice and rats exposed via intranasal instillation, intratracheal instillation and inhalation[21].

The results of present study about effects of *S. chartarum* suspension on nose and lung of mice which experimentally infected revealed to histological changes within nose and lung mice infected with 6×10^4 spore/mm^3 from this fungus suspension .These histological changes were observed in figure 3,5 figure (3) showed histological changes in nose represented in focal superficial necrosis of the respiratory epithelial cells with acute inflammatory cells and infiltration of the mucosa. Spores or spore components in the lungs of BALB/c mice persisted longer and thus may have elicited a greater response. This persistence might also explain how an extract of *S. chartarum* can also induce allergic asthma in BALB/c mice after repeated pulmonary exposures [22]. The first evidence that differences in spore clearance and macrophage susceptibility to spore-induced death may

contribute to strain differences in susceptibility to *S. chartarum* seen in vivo. [23,24]

This results similar to other studies mentioned that no inflammation or tissue damage was seen in the nasal cavity. [25]in spite of the interstitial inflammation with luminal hemorrhagic exudates were observed in nose of animals infected with this dose from fungus, as well as toxicity or mortality was seen[9].

The results of lung mice infected with same concentration of this fungus shows in figure (5) lungs of mice infected with 6×10^4 spore/mm^3 from *Schartarum* fungus suspension indicated tointerstitial pneumonia with thickening of inter alveolar space due to infiltration and chronic inflammatory cells especially mononuclear cell.

This results similar to other studies mentioned that*Schartarum* cause severe alveolar, bronchiola and the higher concentration caused a significant

increase in monocytes, neutrophils, and lymphocytes in the lung [26,10]. Genetic variability in human populations may account for some of the wide variation among individuals responding to mold exposure in contaminated occupational and domestic settings. In addition, other concomitant conditions, such as cigarette smoke exposure or bacterial infection, might further exacerbate poor spore clearance in susceptible populations. A Centers for Disease Control (CDC) report concluded that *S. chartarum* was responsible for acute idiopathic pulmonary hemorrhage in a cluster of infants[27,28,29].

Causes of histopathological changes in nose and lung of infected mice perhaps due to the toxin that produce by *Schartarum*effect on some organs of respiratory system including the nose and lung[30,31] .

Conclusion:the *Stachybotryschartarum* fungus suspension caused clear histological changes in nose and lung of mice (Balb/c) infected with 6×10^4 spore/mm^3 from fungus suspension .

Study the Activity of Lactate Dehydrogenase (LDH) and Some Biochemical Parameters in Atherosclerosis Patients

Jihan Jalil Mohammed[1], Sayran Sattar Saleh[1]

[1]M.Sc. Student, [2]Assist. Prof. Dr. Department of Chemistry, College of Science, Kirkuk University, Kirkuk, Iraq

Abstract

Atherosclerosis causes significant biochemical changes, serum biochemistry was studied to investigate the correlation of these factors to Atherosclerosis. Total of 100 subjects was studied, 40 healthy individuals and 60 Atherosclerosis patients. Blood samples were collected in gel tubes from Kirkuk, General Hospital. In this study,the high level of Lactate Dehydrogenase (LDH) activity (P≤0.01) were observed in Atherosclerosis patients. And a number of biochemical parameters were measured, a Significantly decreased at a level of probability (p≤ 0.01) in Antioxidant Superoxide Dismutase (SOD) Catalase (CAT) and increased at a level of probability (p≤ 0.01) in Antioxidant, Glutathione (GSH) and increased at level of probability (p≤ 0.01) in Lipids blood serum (TC) Total Cholesterol, (TG) Triglycerid for patients with Atherosclerosisas compared with the control group .

Keywords: *Atherosclerosis, Lactate Dehydrogenase activity, SOD, GSH, CAT, TC,TG, HDL, K.*

Introduction

Atherosclerosis is a pathogenic process that clinically affects all blood vessels, most notably cerebral, coronary and peripheral blood vessels [1.] Atherosclerosis is a complex process involving the deposition of plasma lipoproteins and the proliferation of cellular elements in the artery wall. This condition is accelerated especially under conditions that help plaque rupture and platelet formation [2]

Fat is deposited on the inner walls of blood vessels so that they can grow to obstruct blood flow in any part of the body's arteries, causing stroke, an aneurysm in the abdomen, and heart attacks [3]

The German histologist Felix Jacob Marchand first introduced the descriptive term "atherosclerosis" in 1904 to describe "porridge" as the accumulation of fatty substance within the hardened artery and suggested that atherosclerosis is responsible for blockage of the arteries[4.]

The enzyme (LDH EC 1.1.1.27) is an enzyme with a widespread in the tissues of the body where it stimulates the transformation of lactate to pyruvate as in the equation below, as the enzyme has five isomers, which is a homogeneous or heterogeneous quadromes, which consists of sub-proteins H, M They encode LDHB and LDHA genes and these isomers differ in chemical composition, properties and tissue distribution[5] The LDH enzyme is a multi-part enzyme Oligemeric and each of the sub-units of the enzyme LDH enzyme has the same function, the LDH enzyme four subunits Tetramers and has a molecular weight of about 140,000 Dalton, which means that the molecular weight of each of the subunits is about 35,000 Dalton. Subunits differ from each other in the composition of amino acids and are called the first type M-Form where there is a lot in the muscles that are linked to the skeleton and anaerobic tissues, where there is a lot in the heart muscles[6] H-Form The other type is

The LDH enzyme is a specialized enzyme whose concentration in the tissues of the organism is very high compared with its concentration in plasma [7] found in almost all cells and tissues of the body, especially in the heart, bones, smooth muscles and blood cells [8]

Materials and Method

Selection of Patients: This study was conducted in the Department of Biochemistry lab in Kirkuk University, Iraq. It included 60 patients diagnosed with

Atherosclerosis and 40 controls were also involved in the study.

Serological Technique: All were informed regarding the study and written consent was obtained. General information such as name, age, gender, acute illness, height, weight, and drugs usage etc was recorded in case of history performa. Blood samples were collected in a gel tubes from normal and Atherosclerosis infected patients. The biochemical test included each of LDH activity was measured using the standard kits from Biolabo While (SOD,GSH, and CAT) manually measured While Cholesterol, Triglycerides, and HDL was measured using the standard kits from Biolabo and K was performed by commercially available kit (Rocha).

Table (1): Method used to estimate the biochemical parameters.

Biochemical Parameters	The Method
LDH	BioLabo ready measurement kit9
SOD	Diagnostic Tool Kit supplied by Elabscience 10
GSH	Using the modified method (Sedlak and Lindsay) 11
CAT	The concentration or effectiveness of this enzyme depends on the consumption of hydrogen peroxide 12.
TC	Richmond13
T.G	Use of Biolabo Diagnostic Kit14
HDL	Richmond13
K	BioLabo15

Statistical Analysis: In this study, the results include mean±S.D and significant differences (P.Value) between groups that examined an available statical SPSS 17.0 significant differences were estimated as the p. value equal or less than 0.01

Results and Discussion

Lactate Dehydrogenase (LDH): Results are shown in Table (2) showed that the effectiveness of the enzyme lactate dehydrogenase increased significantly at the level of probability ($p \leq 0.001$) for all age groups in serum in people with atherosclerosis and for both sexes compared with the healthy group and the highest rate of increase was recorded in the age group (70-61). The enzyme may be caused by tissue injury and hypertension, which in turn causes hypoxia[16]. The enzyme is caused by kidney dysfunction, leading to damage to blood vessels. And lack of oxygen in humans[17] As a result of lack of oxygen will activate anaerobic decomposition which is a predominant feature of blood vessels LDH due to high blood pressure, which leads to increased activity of the enzyme and lactate production. Serum enzyme concentration.[18]

Table (2): Mean±S.D of LDH activity for patients Atherosclerosis and control group

Age	The activity of LDH (IU/L) (Mean±S.D)	
40-50	Control	(221.0±43.17)
	Patients	(**689.3±44.76)
51-60	Control	(222.8±69.5)
	Patients	(**716.1±40.72)
61-70	Control	(13.6±70.7)
	Patients	(**732.3±46.4)

Antioxidant levels in the blood serum of males with atherosclerosis and compared with females: The results shown in Table 3 showed a significant decrease at the probability level ($P \leq 0.001$) in the levels and effectiveness of antioxidants (CAT,SOD) in male patients with atherosclerosis and the results (0.0074 KU/L,0.8352 U/ml) respectively compared with the healthy group and the results(0.0190 KU/L,5.9316 U/ml) respectively. Significant decrease in female patients with atherosclerosis and the results were(0.0085 KU/L, 0.6788 U/ml) respectively compared to females for the control group, which reached (0.022 KU/L,4.9890 U/ml) respectively. to the oxidation component of the arteries. According to a study by colleagues and colleagues, increasing the levels of cholesterol in the arteries leads to an increase in the level of free radicals and weaken the role of antioxidants and low levels, causing endothelial damage to the arteries, leading to the development of atherosclerosis.[19]

The results of Sözmen, Bülent and his colleagues[20] showed a decrease in the activity of enzymatic antioxidant due to increased platelets of which leads to a decrease in the activity. This decrease can be explained by the effect of the increase of free radicals derived because the lower the activity concentration increases, CAT increases when peroxide concentrations are high. It also corresponded with studies Rande and colleagues[21] and McMurray colleagues.[22]

The serum level at the probability level ($P \leq 0.05$) of GSH male patients with atherosclerosis (12.552 µmol/L) compared to the control group (9.144 µmol/L), while the level increased at the same time.

Table 3: Shows the levels and effectiveness of antioxidants (SOD, CAT, GSH by age groups)

Age		SOD(U/ml)	CAT (KU/L)	GSH (µmol/L)
		(Mean±S.D)		
(40-50)	Control	(5.356±0.573)	(0.0183±0.0055)	8.945±0.678))
	Patients	(**0.807±0.099)	(**0.0084±0.0009)	(**12.870±0.546)
(51-60)	Control	(5.116±0.844)	(0.0246±0.0051)	(9.365±0.714)
	Patients	(**0.729±0.083)	(**0.0077±0.0009)	(**12.412±0.852)
(61-70)	Control	(6.150±0.363)	(0.0194±0.0085)	(9.220±0.425)
	Patients	(**0.689±0.076)	(**0.0080±0.0011)	(**12.795±0.985)

Lipid levels in serum males with atherosclerosis and compared with females–cholesterol, triglycerides,and high-density lipoproteins,) were measured in serum of females and males with atherosclerosis and compared with the control group.

The results shown in Table (4) show that the level of cholesterol increased significantly at the level of probability (P≤0.05) for all age groups in serum of people with atherosclerosis and for both sexes compared with the healthy group and that these results are consistent with the results of previous research that indicated a high level This increase in cholesterol level is due to the decrease in the level of high-density lipoproteins in the blood serum of patients as it helps to extract excess cholesterol deposited in the walls of blood vessels and provide it back to the liver for disposal Gastrointestinal tract and helps to keep blood vessels dilated and thus enhance the blood flow better and it carries cholesterol (old), which was rejected by the cells and return it to the liver for recycling or excretion [23]

High triglycerides and low high-density lipoproteins are characteristic of abdominal obesity, diabetes and insulin resistance[24]. High-density lipoproteins are inversely related and cholesterol is transported from high-density lipoproteins to triglycerides rich in very-low-density lipoproteins [25]

Table 4: Shows the lipid levels in serum males with atherosclerosis and compared with females

Age		TC (mg/dl)	T.G(mg/dl)	HDL(mg/dl)
		(Mean±S.D)		
(40-50)	Control	(95.44±6.37)	(94.16±8.02)	(40.65±3.93)
	Patients	(**229.6±27.91)	(**211.8±16.04)	(**21.69±3.21)
(51-60)	Control	(98.80±5.56)	(97.15±10.90)	(38.63±1.54)
	Patients	(**224.9±15.49)	(**199.3±13.91)	(**25.06±4.80)
(61-70)	Control	(79.46±4.91)	(99.56±15.77)	(3.56±40.95)
	Patients	(**228.2±21.81)	(**224.8±11.42)	(**21.88±4.34)

Potassium level in serum of males with atherosclerosis and compared with females The results indicated in table (5) showed that the level of potassium decreased significantly at the level of probability (P≤0.001) for all age groups in serum in people with atherosclerosis compared with the healthy group and that the reason for the low level of potassium in patients may be due to high blood pressure due to imbalance Potassium is transported through the smooth and vascular muscle cell membrane, which in turn regulates blood pressure[26]. It may also be caused by a decrease in nitric oxide release by endothelial cells, which leads to narrowing of blood vessels and increased platelet aggregation, which increases blood pressure. Control of blood pressure regulation which in turn leads to low serum potassium level.[27]

Table 5: Shows the Potassium level in serum

Age	K(U/L) (Mean±S.D)	
40-50	Control	(4.273±0.352)
	Patients	(**2.576±0.335)
51-60	Control	(4.083±0.277)
	Patients	(**2.676±0.310)
61-70	Control	(4.585±0.444)
	Patients	(**2.674±0.252)

Conclusion

An investigated of Atherosclerosis case was successfully performed, studying its effect on the Lactate Dehydrogenase activity. The main concluded points from this research were summarized as follow: the increase of Lactate Dehydrogenaseenzyme activity level; increasing the level of TC, TG, GSH, and decreasing the level of SOD,CAT,HDL, K.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the Department of Chemistry/ College of Science/Kirkuk University/Kirkuk, Iraq and all experiments were carried out in accordance with approved guidelines.

Electrocardiographic Changes and Cardiac Arrhythmias in Hemodialysis Patients with End-Stage Renal Disease, at AL-Hussein Teaching Hospital

Qasim Ali Khasal

Lecturer Dr. Adult Nursing Department, College of Nursing, University of Thiqar, Iraq

Abstract

Background: Cardiovascular disease is the leading cause of mortality among patients on dialysis. When considering all causes of death, about 30% are classified as cardiac arrest, death of unknown cause or cardiac arrhythmia. The increasing time of ventricular depolarization and repolarization, measured non-invasively by measuring the QT interval on the electrocardiogram at rest, has emerged as a predictor of complex ventricular arrhythmias, a major cause of sudden cardiac death.

Objective: To evaluate electrocardiographic abnormalities in patients with Chronic kidney disease on Maintenance Hemodialysis.

Method: This cross sectional observational study design was carried out through the present investigation from Jun 2nd January/2019 to2/July/2019 in order to achieve the objectives of the present study . A non-probability (purposive)sample of 120 patient which including (86) males and (34) females. Who were attending Hemodialysis Unit in AL- Hussein Teaching Hospital. The results according to the special criteria.

Results: Total number of patients included in the study was 124 Mean age of all patients was 49.9±13.8 years, 106 (84.8%) had hypertension, 84 (70%) had diabetes mellitus, and 35 (29.9%) had known cardiovascular disease. Mean serum creatinine was 7.±3.4mg/dl, mean eGFR was 10.6±9.2 ml/min/1.73m^2. Overall 78.4% of all CKD patients have one or more ECG abnormality. Left ventricular hypertrophy (40%), Q waves (27.2%), ST segment elevation or depression (23.4%), prolonged QRS duration (19.2%), tachycardia (17.6%) and left and right atrial enlargement (17.6%) were the most common abnormalities.

Conclusion: ECG abnormalities are common in hospitalized CKD patients in local population. All hospitalized CKD patients should undergo ECG to screen for cardiovascular disease.

Keywords: *Chronic Kidney Disease; ECG abnormalities; Cardiac Arrhythmias.*

Introduction:

Cardiovascular disease is a major cause of mortality and morbidity among subjects on hemodialysis. It is responsible for up to 50% of deaths among subjects on dialysis[1] Cardiac arrhythmias are frequent among the hemodialysis population, particularly during and immediately after a dialysis session.[2] These arrhythmias may be caused by the rapid changes in intracellular and extracellular electrolytes during the dialysis session.[3] Despite development of modern technologies electrocardiogram (ECG) remains an essential tool for evaluation of cardiovascular disease. ECG is important in detection of cardiac rhythm abnormalities, cardiac conduction defects and detection of myocardial ischemia.[4] Resting ECG abnormalities are common in patients with CKD and they independently predict future cardiovascular events.[5,6] However, there is wide variation in reported prevalence of various ECG abnormalities in different studies.8–15 Left ventricular hypertrophy (LVH) has been found in 27.6–83% percent of CKD population.10–14 Similarly prolonged corrected QT interval (QTc) was found in 16.9–66%.8,9, right bundle branch block (RBBB) in 2.2–12.8%, left bundle

branch block (LBBB) in 6.0–9.6%8,12 and left atrial enlargement in 21.6–30% of CKD patients in different studies[7,8.]

Material and Method

This cross sectional observational study design was carried out through the present investigation from Jun 2nd January/2019 to2/July/2019 in order to achieve the objectives of the present study. A non-probability (purposive) sample of 120 patient which including (88) males and (32) females. Who were attending Hemodialysis Unit in AL- Hussein Teaching Hospital. The results according to the following criteria.

Inclusion Criteria: Those patients who are on hemodialysis for > 6 months. Adult patients. Both sexes. Patients who were in stable condition. No other chronic disease except hypertension and diabetes mellitus. Persons who are free from psychiatric illness with the drugs. Patients who agreed to conduct the questionnaire.

Exclusion criteria: Those patients of < 6 months duration of dialysis. Patients known to have H/o CAD or intervention to cardiac problem 12 LEAD ECG was taken in all patients. Patients were excluded if they had an implantable pacemaker in place or if they have severe hyperkalemia (serum potassium >6.0 meq/L), severe hypokalemia (serum potassium <3.0 meq/L) and hypocalcaemia (correct serum calcium <8.0 mg/dl).

The questionnaire consisted of two parts which:

Part I: Demographic and Clinical information: Patient's history, medical records and laboratory information were reviewed to obtain data on patient's age, sex, history of diabetes mellitus, hypertension, duration of hypertension and diabetes mellitus cardiovascular disease, heart rate, blood pressure, serum creatinine, eGFR and urine protein to creatinine ratio.

Part II: All patients underwent 12 lead electrocardiograms (ECG) at the time of admission. Subsequent ECGs if done were not analyzed for study purpose. ECG was interpreted by a qualified physician trained in interpretation of ECG abnormalities. ECG abnormalities were defined based on accepted standard criteria[9,10]. PR interval was considered to be prolonged if it was above 200 msec. Thresh hold criteria for prolonged QRS duration was above 100 msec Corrected QT interval (QTc) was calculated by using following formula: QTc=QT interval divided by square root of RR interval (in seconds). QTc was considered prolonged if it was above 446 msec in females and 444 msec in males. Tachycardia was defined as heart rate above 100 beats/min and bradycardia was defined as heart rate less than 60 beats/min respectively. Right axis was defined as presence of negative QRS deflection in lead I and positive QRS deflection in lead aVF. Left axis was defined as presence of positive deflection of QRS complex in lead I and negative deflection in lead II. ST segment depression was considered to be present if there was down word or horizontal sloping of ST segment greater than 0.05 mV below baseline measured at 0.08 second after J point in two contiguous leads. ST segment elevation was considered to be present if ST segment elevation was present by equal or greater than 0.1 mV and by equal or greater than 0.2 mV in leads V2 and V3, measured at the J point. Q wave was considered to be present if there was any Q-wave in leads V2–V3 equal or more than 0.02 s or Q-wave equal or more than 0.03 s in other leads. Skolow-Lyon indices were used to establish left ventricular hypertrophy.18 Right ventricular hypertrophy (RVH), left and right atrial enlargement, left and right bundle branch blocks and fascicular blocks were identified using accepted standard criteria.[11.]

Results

Total 120 patients were included in this study. Mean age of the study group was 44.7+12.3years . Men were 86 and women were 34 in number . Mean duration of dialysis is 2.5±6 months. At least one ECG abnormality was observed in 89(74.9%) patients. Mean duration of dialysis is 27.4±25.9 months. At least one ECG abnormality was observed in 87(72.5%) patients. hypertension, 84 (70%) had diabetes mellitus, 32 and 35 (29.9%) had known cardiovascular disease. (26.7%) were smokers, 22 (18.3%) had dyslipidemia Mean serum creatinine was 7.2±3.4 mg/dl, mean eGFR was 10.6±9.2 ml/min/1.73m^2 and mean urine protein to creatinine ratio was 3.8±3.9. Of all patients 85.7% had stage V CKD, 7.6% had stage IV CKD and 5.9% had stage III CKD. Majority of the patients (101) had permanent vascular access (84.1%) and only 11 patients had Jugular catheter (9.1%). Rhythm abnormalities were seen in 32 patients (26.6%) and the remaining 88 patients (73.4%) .

Only one patient had sinus arrhythmia and 25 patients had sinus tachycardia. Six patients had ventricular ectopic beats. Mean heart rate in the study group was 90.7+15 seconds. Mean PR interval was 149.75+31.8millisec and mean QRS duration was 95.43+19.20 millisec,

Mean QTc interval was 431.9+27.3milliseconds. Prolonged PR interval was observed in 12 patients and a prolonged QTc was noted in 16 patients (table 1).Factors influencing prolonged QTc and prolonged PR interval could not be studied.

Table 1: Average heart rate, PR, QRS and corrected QT interval in patients with CKD

Mean heart rate (beats/min)	91.8±18.3
Mean PR interval (ms)	137.9±22.3
Mean QRS duration (ms)	93.4±22.2
Mean corrected QT interval (ms)	400.1±57.9

Table 2: CKD patients with abnormal heart rate or intervals

Abnormal Rate or Intervals	Percentage	Frequency
Sinus tachycardia	25	20.8%
VPCs	6	5%
Prolonged PR interval	12	10%
Prolonged QRS duration	12	10%
Prolonged QTc interval	16	12.8%

On resting ECG, most common abnormality found was left ventricular hypertrophy (50%) and T wave changes (34%). Left atrial enlargement was observed in 22.5% and ST segment changes were seen in 23%. LBBB was least common, noted in only 2.5% of study population (table 2).

Table 3: Average heart rate, PR, QRS and corrected QT interval in patients with CKD

Abnormal Findings on ECG	Percentage	Frequency
Left ventricular Hypertrophy	53	45.2%
Left atrial enlargement	24	18.9%
RBBB	14	10.3%
LBBB	5	4.9%
ST segment changes	29	23.4%
T wave changes	41	34.16%
Abnormal Q waves	8	7.4%
Bifascicular block	1	0.8%
Premature atrial beats	6	4.8%
Premature ventricular beats	18	14.4%
Right axis deviation	14	10.4%
Left axis deviation	18	14.4%
Rhythms other than sinus	1	0.8%

Discussion

Our study showed that ECG abnormalities are common in local CKD population with LVH beingthe most common ECG abnormality.At least one ECG abnormality was noticed in 78.4% of all CKD patients. In other studies, abnormal ECG findings were noticed in 50–86% of all patients.12,13 LVH was found in 41.6% of our patient population. Our study results are consistent with Bignotto et al13 and Stewart et al14. However, in a study by Chijiokie et al. LVH was found in 27.6% of all patients.8 Other studies have shown a much higher prevalence of LVH (66–83%) in CKD patients.15, However, the later study showing significantly higher prevalence of LVH was done in hemodialysis patients. Our study population entirely comprised of pre-dialysis CKD patients. Finding of LVH on ECG is significant as it is independently associated with adverse cardiovascular outcomes.22 Left atrial enlargement was found in 22.5% of our patients compared to other studies which have reported a frequency of 21.6–30%.7

In our study, frequency of RBBB and LBBB was found to be 12.8% and 2.5% respectively. Our results are consistent with Nwanko et al which showed a frequency of 15.1% and 10.1% respectively.16 Kestenbaum B et al. found a lower frequency of RBBB as 2.2% and LBBB as 6.0%.8

Presence of Q waves and ST segment deviation were found in 5% and 27.2% in our study similar tofrequency of myocardial ischemia/infarction as 28% in another study.7

Widening of QRS complex was found in 10% of our patients. Prolonged QTc was found in only 12.8% of our patients. Other studies have reported a significantly higher frequency of prolonged QTc ranging from 16.9% to roughly 2/3rd of CKD patients. 16,17

Reason for lower frequency of prolonged QTc in our patient population is not clear but it may be due to difference in patient population, relatively younger age, exclusion of patients with electrolyte abnormalities and infrequent use of medications associated with prolonged QT interval in our patient population.

ECG abnormalities in CKD patients have been found to independently predict cardiovascular event and mortality.7,8 CKD patients with ECG abnormalities may benefit from close follow up and consultation with cardiologist to help reduce cardiovascular event or mortality. Our study has several limitations including relative small sample size, single center and cross-sectional study design. In addition, our study was

conducted in hospital setting with large proportion of patients with advanced CKD. This may have resulted in over-estimation of frequency of ECG abnormalities in CKD patients. However, our study population's characteristics are reflective of patient's profiles in tertiary care facilities in Iraq.

Table 5: Comparison of ECG findings in the studies available.

Variables	Shafi et al	Manjusha and Kumaraswamy	Present
Total no of patients	120	124	120
Mean Age	44.7±12.3	49.9±13.8	44.7+12.3
ECG abnormalities	72.5%	78.4%	74.9%
LVH	41.6%	40.8%	45.2%
LAE	22.5%	17.6%	18.9%
RBBB	5.8%	12.8%	10.3%
LBBB	2.5%	9.6%	4.9%
ST segment changes	23.3%	23.4%	23.4%
Q waves	5%	27.2%	7.4%
Prolonged QT interval	13.3%	49.1%	12.8%

Conclusion

In summary, our study shows that resting ECG abnormalities are common in CKD patients who were hospitalized. LVH is the most common electrocardiographic abnormality. All hospitalized CKD patients should undergo ECG to detect any abnormal findings. Further studies are needed to see whether abnormal ECG findings predict cardiovascular events or mortality in our patient population.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the College of Nursing and all experiments were carried out in accordance with approved guidelines.

Screening of Bio-active Chemical Composition of Vespa Orientali and Investigation of its Anti-Fungal Activity

Ekhlas Al-Shareefi

Lecturer Dr. University of Babylon, Dep. of Biology, College of Science for Women, Iraq

Abstract

Screening of Bioactive Chemical Composition of *Vespa orientali*was assayed for in *vitro* anti-fungal activity against *Asp. flavus, Asp. Terreus., Penicilliumexpansum, Asp. fumigatus, T.horzianum, S.cerevisiae., Candida albicans, T,viride*. GC-MS analysis of *Vespa orientali*revealed the existence of the, Thi-eno- furan-3, 2-amino-4, 6-dihydro, Z-8--Methyl-9-tetra-decenoic acid, I–Propyl-9-tetra-decenoate, Octa-decatrienoic, 2-[(tri-methylsilyl)oxy]-1-[(tri-methyl, 17-Octa-decynoic acid, Oxime-, metho-xy-phenyl-, Edulanll, p-Menth-1-en-3-one,semi-carbazone, 5,7-dodeca diyn-1,12-diol, Methyl 2-O-benzyl -d- arabinofuranoside, Ery-thritol, d- D-Glucose, 6-O-α -D-galactopyranosyl-, Gala-ido- octonic, Desulphosingrin, 2(3H)-Furanone, 3-butyl dihydro-, 24,25- triol, (3β,5Z,7E)-, N-(4, 6-dinyl)- 4-(4-nitro benzylidene amino) benzel, 2,7-Di-phenyl-1,6-dioxopyri-dazino [4,5:2',3'] pyrrolo[4',5'-d]pyridazin, 2-Methyl-9-β-d-ribofuranosylhypoxanthine, Ergosta-5,22-dien-3-ol, acetate, (3β,22E)-, 10-Hepta-decen-8-tri-methoxy-2,3-dimethyl-, 1-Methyl-8-propyl-3, 6-diazahomoadamantan-5-dimethyl-aminomethyl-1H-[1,2,3] triazole, and 6-Octa-decenoic acid. The results of its activity showed that all compounds were highly effective to suppress the growth of *Asp. terreus*.

Keywords: *Vespa orientali, GCMS, Bioactive chemical compounds, Anti-fungal, peptides.*

Introduction

The Oriental hornet, *V.orientalis*, is an insect of the family Vespidae. *V. orientalis*can be found in Asia, Northeast Africa, and parts of Southern Europe[1]. Peptides have a range of anti-bacterial and anti-fungal activities. They have a promising capacity in the therapeutic and prophylactic. They have a good capacity in the healthing and precaution. Insect are found throught the world, with the possible exception of the arctic and Antarctic areas, the ocean depths, and the tops of high mountain peaks. Som are so small, a microscope is needed to see them, others are several inches long. They are so widespread that they can be studied practically everywhere in cities and in farms in the backyard or garden in the home or in the park. However, some insects are harmful. They can truly be regarded as people major competitors for food on this earth. They destroy crops by eating the roots, seeds, stems, leaves or of fruit of plants. They attack livestock, weakening or sometime killing it. They even get into processed food, forcing you to discard it. These peptides display an anti-microbial outcome by destroy the microbic membrane and do not simply allow microbes to initiate pharmaceutical resistance. Currently, membrane mechanisms underlying the anti-microbial effects of peptides are proposed by different modes: the toroidal-pore, barrel-stave mode, and disorganized toroidal-pore are the typical modes.

Materials and Method

Vespa orientalis specimens were collected from rural areas - the center of Iraq. The whole body were crushed in a clean mortar using pestle. Methanol was used as solvent control.

Antimicrobial Assay: The microorganisms used in the antifungal screening assays were:

The studied yeast and fungi, *Asp.flavus, Asp. terreus, Penicilliumexpansum, Asp. fumigatus, T. horzianum, Saccharomyces cerevisiae, C. albicans, T. viride*. were maintained in potato dextrose agar. In triplicate the tests were carried out.

Gas-chromatgraphy – mass spctrum analysis: The GCMS analysis of the insect powder was made in a (Agilent 789 A) instrument. About 1microletters of the methanol extract was injected into the GCMS apply a micro syringe and the examine was done for 45 minutes. Results of the study were based on examination of variance (ANOVA).

Results and Discussion

Identification of Biochemical Compounds: Insect vary in their growth patterns. All begin as eggs and end up as adults. But between the egg and the adult stage there is an intermediate growth from called the immature stage. It's during this stage which differs in different groups of insect that growth takes place. Insect growth is accompanied by series of periodic shedding of the exoskeleton.

V. orientalis displayed a good effect against different types of fungi. Asp.terreus was the most sensitive. Chromatogram GCMS examination of the methanol extract of *Vespa orientali* showed 39 major peaks. *Asp. flavus* 3.96±0.18 mm, *Aspergillusterreus* 4.01±0.20, *Penicilliumexpansum* 1.59±0.09, *Aspergillusfumigatus* 3.91±0.19, *Trichodermahorzianum* 1.89±0.09, *Saccharomyces cerevisiae* 2.04±0.10, *Candida albicans* 4.00±0.20, *Trichodermaviride* 2.63±0.08. *V.orientali* produce important metabolites with medicinal activities. Greatest zone initiate against *Asp.terreus* (4.01±0.21mm) mm, Table 1. These peptides display an anti-microbial outcome by destroy the microbic membrane and do not simply allow microbes to initiate pharmaceutical resistance.

Table 1. Anti-fungal activity of Vespa orientali metabolites.

Fungi	Anti-biotics/Metabolite produce Vespa orientali			
	Metabolite produce of Vespa orientali	Amphotericin B	Fluconazol	Miconazole nitrate
Asp.flavus	3.96±0.18	1.03±0.08	1.80±0.20	1.04±0.04
Asp.terreus	4.01±0.20	2.07±0.09	0.89±0.07	1.95±0.08
P.expansum	1.59±0.09	1.99±0.07	3.80±0.28	0.86±0.03
Asp.fumigatus	3.91±0.19	0.89±0.05	2.09±0.25	1.11±0.06
T.horzianum	1.89±0.09	1.09±0.03	2.05±0.20	1.08±0.04
S.cerevisia	2.04±0.10	1.36±0.07	1.91±0.21	2.09±0.15
C.albicans.	4.00±0.20	0.97±0.09	0.81.±0.04	1.87±0.11
T.viride.	2.63±0.08	1.98±0.06	1.40±0.11	1.39±0.09

Conclusion

39 active constituents had been fixed from *Vespa orientali* by GCMS technique. *In vitro* anti-fungal estimate of metabolite of *Vespa orientali* forms a platform for development of new anti-fungal compounds.

Ethical Clearance: Experimental protocols were confirmed under Dep. of Biology and all tests were carried out with advisable guidelines.

Abstract

This study aims to found the relationship of interleukin-4(IL-4) genetic polymorphism -590 C/Tin association of type-2 diabetes (T2D)development. (50) blood samples were collection from the patients with T2D and (30) samples from healthy group individual from Al-Diwaniyah Hospital. PCR-RFLP was carried out for detection IL-4 genetic polymorphism (-590 C/T) of T2D patients and healthy blood samples .The IL-4 gene polymorphism genotype frequencies were studied in the patients and healthy group, for the CC, CT and TT genotypes, the result revealed significant ($p<0.05$) presence of these genotypes in the patients group compared with healthy group. Also found the TT genotype increased the risk more than 20% in T2D compared with healthy group 3.33%,and CT genotype increased the risk more than 57% in T2D compared with healthy group 30%,while CC was decreased the risk 26% in the T2D compared with healthy group 66.66% . Frequency of allele T increased to 46% in the T2D compared with healthy group 20%. While frequency of allele C was not show any signification. The allele C and T carriage rates were examined, and there was no significant changes in carriage rate for C alleles. However, a significant changes was noticed in carriage rate of T allele(78.7%) in the patients population compared to healthy population. Also the results revealed there were a significant ($p<0.05$), effect of the sex and family history parameter on the IL-4 genetic polymorphism, the females and positive family history of disease 58% and 72% respectively were revealed more occurrence of this genotype in their samples with percentage. Our study was concluded that genotype C/T may be is risk factor in the T2D.

Introduction

T2D is thought to be a multicauses disease that effected by environmental and genetic factors. Persons that share genetic factors and have family history of the disease are at a more risk of developing T2D the in addition to probably similar environment[1]. Recent studies have shown that numerous environmental and genetic factors are associated with T2D [2].

T2D is a disease dependent on immunity that have changes in the cytokine expression pattern [3]. Many studies focused on cytokines and its receptors for their essential role in T2D (2). Increased inflammatory cytokines level in serum including interleukin, interferon-γ, and TNF-α, are documented in T2D[4,5]. IL-4 is the most important cytokines gene, it was originally discovered as a polypeptide consist from 129 amino acids derived from T cell, which is encoded on chromosome 5q23.31. Also it is produced by natural killer (NK), helper T cells and by innate immune system cells, including basophils, eosinophil's and mast cells,[6]. IL-4 play important role in regulates gene expression,cells proliferation and apoptosis, also differentiation in several hematopoietic cells, like, it leads convert the Ig class to the IgE and IgG1[7]. The relation of IL-4 in immunological disturbance such

as diabetes mellitus is well established[8,9]. Many of studies showed that polymorphisms in -590 region can be affected on IL-4 production [10]. Studies showed that T2D is associated with a systemic inflammations due to increased blood level markers and mediators of immune-response. This due to association of increase levels of plasma interleukin with patient have T2D, also with increased insulin resistance,which suggesting its latent role in the T2D development [11].

Therefore, This study aims to found the relationship of IL-4 genetic polymorphism -590 C/Tin association of T2D.

Method

Collections of blood Samples: (50) blood samples were collection from the patients with T2D and (30) samples from healthy group, individual from Al-Diwaniyah Hospital, then the samples storage in freezer until use.

DNA Extraction: DNA were extracted from blood samples by using genomic DNA Mini Kit, (Geneaid. USA). This was done by using Proteinase K for frozen Blood extraction. Then, the extracted genomic DNA purity and concentration were checked by Nanodrop spectrophotometer, after that stored in freezer at -20°C.

PCR RFLP: PCR RFLP used for detection IL-4 gene polymorphism (-590 C/T) of T2D patients and healthy blood samples. The technique was done according to[12]. The forward primers (5'-TAAACTTGGGAGAACATGGT-3) and reverse primers (5'-TGGGGAAAG ATAGAGTAATA-3). (Bioneer company. Korea). After that used AccuPower® PCR PreMix kit.(Bioneer. Korea)to prepare PCR master mix. PCR premix tube contains dried- freeze pellet of (dNTPs 250µM, Taq DNA polymerase, Tris - HCl (pH 9.0) 10mM, MgCl2 1.5mM, stabilizer, KCl 30mM, and tracking dye) then the PCR master mix consist from 5µl of pure gDNA and 3µl of 10pmole of forward and reverse primers, then the volume complete into 20 µl by add deionizer water and mixed by vortex centrifuge. The reactions were done in a thermocycler T100 Thermal cycler (Biorad.USA) as the following thermocycler conditions, initial denaturation 95°C for 5 minutes, then 35 cycle at denaturation 95° C for 30 second, annealing 53° C for 30 second, and extension 72° C for 1 minute and finally extension at 72° C for 5 minutes. The electrophoresis used to examine 195bp PCR products in a 2% agarose gel, and visualized under UV illumination. RFLP step done by using (AvaII, Biolabs, UK) restriction enzyme. products of PCR RFLP were using for detection IL-4 gene polymorphism include CC wild type homozygote, the product undigested by restriction enzyme 195bp band. The C/T heterozygote, the product digested by restriction enzyme into 195bp, 175bp and 20bp band. The RFLP PCR fragments were separated by 3% agarose gel electrophoresis and visualized under UV Transilluminator.

Statistical Analysis: Genotype and allele frequencies were calculated in patients and healthy groups by direct genes counting. Used SPSS software (version 25). For detected odds ratio to compare the importance of various risk factors. P value <0.05 was considered significant.

Results

The present study investigated the effect of sex and family history of disease on the IL-4 genotypes in the T2D patients group compared to the control group. The result revealed that there was a significant effect ($p<0.05$) of the sex parameter on the IL-4 genetic polymorphism. Family history parameter effect on the IL-4 genetic polymorphism was also investigated, the results in table (1) revealed a significant increased ($p<0.05$) of the IL-4 genetic polymorphism within the positive family history of disease in the patients group. The IL-4 genotype frequencies were studied in the patient and healthy group, for the CC, CT and TT genotypes (figure. 1), the results showed a significant ($p<0.05$) presence of these genotypes in the patients group. In addition, this study investigated the allele C and allele T frequencies in the patients group as well as in the healthy group, and the results revealed a significant shifting of two alleles in the patient group (table 3).

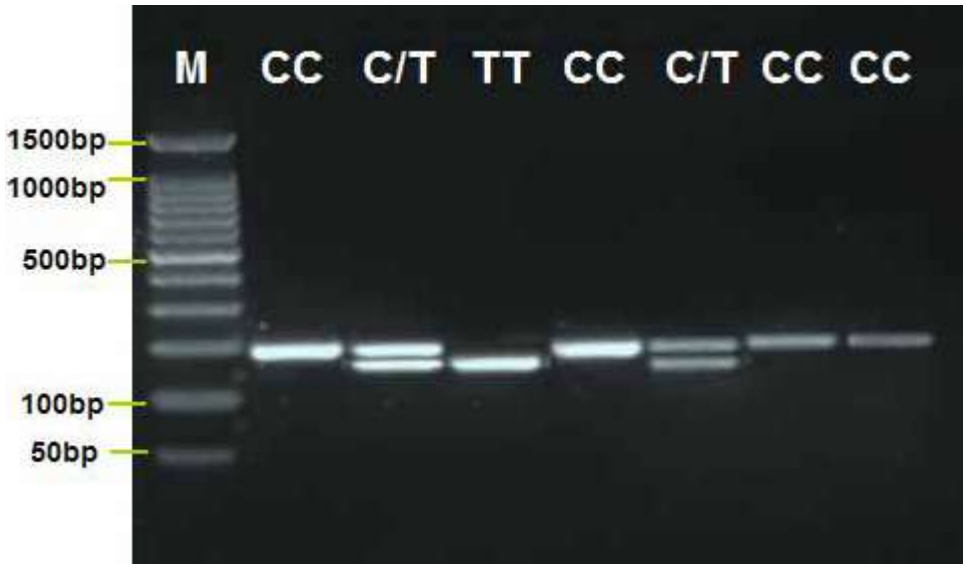

Figure 1: Image show RFLP-PCR product analysis for IL-4 gene polymorphism (-590 C/T) of T2D patients and healthy blood samples by use Agarose gel electrophoresis. This done by using avaII restriction enzyme in 3% agarose. Where M: marker (1500-100bp), (CC) wild type homozygote lanes, the product undigested by restriction enzyme and still as 195bp band. The (C/T) heterozygote lanes, the restriction enzyme digested product into 195bp, 175bp and invisible 20bp band. Whease the (TT) mutant type homozygote lanes, the restriction enzyme digested product into 175bp and invisible 20bp band.

The carriage rate for allele C and T were studied in the patients population compared to the healthy population,and no significant changes was noticed in carriage rates for C allele. However, a significant changes was noticed in carriage rate of T allele in the patients group (Table 4,5).

Table (1): Clinical data of patients and healthy groups

Clinical Data			Healthy Group (30 Cases)	Patients Group (50 Cases)	P value
Sex	Male		13 (43.33%)	21 (42%)	0.07
	Female		17 (56.67%)	29 (58%)	
Family History of Disease		+	11 (36.66%)	36 (72%)	0.07
		-	19 (63.33%)	14 (28%)	

Signification at level O.O5

Table (2): IL-4 Genotype frequencies

Genotype	Healthy Group (30 Cases) N and (%)	Patients Group (50 Cases) N and (%)
CC	20 (66.66)	13 (26)
CT	9 (30)	27 (54)
TT	1 (3.33)	10 (20)
P value	0.04	

Table (3): IL-4 Allele Frequencies

Type	Healthy Group (30 Cases) N and (%)	Patient Group (50 Cases) N and (%)
C	48 (80)	54 (54)
T	12 (20)	46 (46)
Odds ratio (95% CI)	0.668	
P value	0.008	

Table (4): Allele C Carriage Rate

Type	Healthy Group (30 Cases) N and (%)	Patient Group (50 Cases) N and (%)
C(+)	24 (80)	57(89.06)
C(-)	6 (20)	7(10.93)
Odds ratio(95% CI)	4.623	.638

Table (5): Allele T Carriage Rate

Type	Healthy Group (30 Cases) N and (%)	Patient Group (50 Cases) N and (%)
T(+)	10 (21.3)	37 (78.7)
T(-)	20 (62.5)	12 (37.5)
Odds ratio(95% CI)	.340	2.099

Discussion

Complications of T2D become a main causes of death worldwide. The immunity play important roles in the T2D development,cytokines are a important part of the immunity that involve in development T2D complications[13]. Researchers in immunology said the T2D is associated with cytokines disturbance and altered immunity response pattern [14]. Our study used molecular method (PCR method) to detect association between IL-4 genetic polymorphism (-590 C/T) and T2D patientsthat agreed with some researchers that used same the technique [15,16]. The current study found that IL-4 gene -590 C/T Polymorphism showed significant correlation with T2D, this study also suggested that SNP -590 which is located in the IL-4gene promoter region may be a risk factor to develop of T2D. Mediators of inflammation such as family of cytokines and certain chemokine's have proposed to be involved in the events result in diabetes mellitus[17,18,19]. This might give a suggestion that there are a strong link between T2D and IL-4 genetic polymorphisms which might considered as prognostic biomarker for development of T2D. Our study agreed with Bid and colleagues that were reported a significant association between T2D and IL-4 polymorphism in the population of north Indian[20]. Another research found the IL-4-590 C/T heterozygous genotypes might be as risk factor, while the -590 C/C homozygous wild types might be considered protective to T2D[15].

Another study showed there was no signification between IL-4 genotypes in patients and control groups (9).Also[21] Didn't show any significant differences in the IL-4 genetic polymorphism between T1D patients and control groups. The difference between our previous results and those may be that population are different in genetics and race from our studied population.

The IL-4 polymorphisms were more pronounced in the T2D patients, particularly the CC, CT and TT and it revealed a significant relation with family history of disease and sex parameters. This genotypes of the IL-4 gene showed more occurrence in the females with 58%. So, IL-4 polymorphisms revealed that the frequency C/T alleles were a significant increased in T2D patients group. This lead to suggest that SNP has a important role in susceptibility to T2D development.

Also, our study found that the allele C carriage rate (.638) was lower than that in allele T carriage rate (2.099) in T2D group, which is confirmed the previous results. Also our study found that TT genotype increases the risk up to 20% in patients compared to control group 3.33%, and CT genotype increases the risk up to 57%

in T2D compared to control group 30%.While, CC was decreases the risk 26% in the patients compared to control group 66.66% . Frequency of Allele T increased to 46% in the patients compared to control group 20%. While,frequency of allele C not show any significant result. This results suggested that genotypes and alleles are correlated with development of T2D .The current data provided a sight on the cytokine gene heterogeneity role in development of T2D. Additionally, the cytokine genes variants may be a probable indicator for disease susceptibility in Iraq population.

Conclusion

Our study was concluded that genotype C/T may be is risk factor in the T2D .

Challenges of Continuous Nursing Education in Health Agencies

Hussein Ali Abd Al-Abbass[1], Hussein Jassem Alibrahemi[2]

[1]M.Sc. Student in Family and Community Health Nursing, College of Nursing, University of Babylon, Hilla City, Iraq, [2]Assistant Professor in Family and Community Health Nursing, Babylon University, College of Nursing, Hilla City, Iraq

Abstract

Background: Many factors effects on continuous nursing education, like environment of the study or teaching method, stimulation of employees to participate in the courses and participant's satisfaction or outcome, so evaluating such unit is so vital and can strengthen weak points and this leads to better patient outcome and high rates of nurses job satisfaction.

Aims: This study aims to evaluate continuous nursing education in three parts structure, process and outcome, and knowing factors affecting it.

Methodology: Descriptive study design, data collected from three educational hospitals and eight primary health care centers,the approval to conduct the study was obtained from Training and Development Centre in Babylon Health institution, Ethical committee in the nursing college of Babylon and official permissions from Al-Hilla Teaching Hospital, Babylon Maternity and Children Teaching Hospital, Murjan Medical City and Al-Hilla health sectors 1 & 2.

Structure and process data gathered by researcher from continuous nursing education unit manager by answering questionnaire which reviewed by (20) nursing experts, the outcome assessed by nurses who participated in continuous nursing education courses by answering the questionnaire by (250) nurse, convenient sampling.

Results: The finding refers to several infrastructure weak points, low funds leads to decreased learning preparations like smart screens or advanced laboratories and medical equipment for training. The courses scheduling which set by health ministry are less than applied actually, and low focusing about nursing competencies in these courses, there wasn't any coordination between health institutions and higher education to fill knowledge gaps or decrease subjects repetition for nurses, and few nurses takes courses out of their hospitals (abroad).

High rates of participant nurses didn't get money reward and most of them used participation certificate for promotion purposes, though, high rates of nurse's satisfaction about continuous nursing education role, timing commitment, gaining knowledge and scientific materials provided.

Conclusion: The purpose of this article was to describe our evaluation process. Continuous nursing education evaluation is central to the mission and integrity of nursing programs in preparing successful nurses, advanced practice nurses, leaders, and scholars. At a more immediate level, continuous nursing education evaluation is an integral component of continuous quality improvement and of significant benefit in planning and implementing intentional, data-driven, program changes.

Putting continuous nursing education units in high priority in hospitals policies or primary health care centers in financial support will improve its performance and provide an appropriate environment, tools, hiring highly educated lecturers or participating in abroad of their governances or even country, for studying and learning new skills.

Coordination with educational institutions will provide variety in teaching method and filling gaps in the learner knowledge chain, further studies in this field is required that focuses in Health ministry curriculum, separation of hospitals and primary health care centers, and about nurses that didn't engaged in continuous nursing education courses.

Introduction

At all times, human beings have created their lives and started in the world through work. in recent decades Work has undergone big transformations, administrative perspective in Organizations in general have diminished due to the influence of knowledge of technology, theories, economics business, and technical, social, political, and cultural changes of community. Health care organizations was part of this process. [1]

The originator and founder of modern nursing Florence Nightingale. Her notes, "Notes on Nursing," she mentioned the nurses should always learn, by seeking new knowledge and new evidences not only through experience and observation. Florence identified that caring "the same technique we usually perform it" didn't certainly recover clients' health or maintain the best likely setting to support healing and rescue.[5]

The significance of transporting skills and knowledge from theories to clinical practice is vital in establishing credibility in clinical. Achieving it must integrate simulation, practice and theory. The Simulation considered as method to develop deeper education and a dynamic curricular improvement. Mixing of nursing knowledge and skills is improved by simulation use, which result in theoretical conceptions that readily applied more to the patients and their disorders suffering[2]

According to the World Health Organization (WHO), the global standards for nursing education include activities such as:

1. Establishing a global approach to the provision of evidence- based educational programs
2. Applying established competencies to provide a guide for curriculum development
3. Stimulating the creation of nursing (or midwifery) schools and programs to meet national, regional and societal needs and expectations
4. Establishing benchmarks for continuous quality improvement and the progression of education in nursing and midwifery[9].

Nurses Learning: Active learning increases learners' retention of information, improves performance on course assessments, and increases standardized test scores. Results from this study support the concept that when learner nurses are connected with course content, learning outcomes improve over-all. Active learning also improves nurses' perceptions of inclusiveness in the classroom and their self-efficacy. A meta-analysis of science, technology, engineering, and mathematics courses demonstrated that learners in lecture courses were 1.5 times more likely to fail when compared with those in active learning courses. In addition, average examination scores of the active learning course participants were 6% higher than lecture course participants[3].

Within nursing, there is a paradigm shift away from a passive to a more active learner approach. Team based learning uses concept analysis, critical thinking, and problem solving to actively engage the learner, which is especially important in ethics education. In addition, the use of teams may translate well into the use of team based learning for inter-professional ethics education.

The application of learning concepts built into team based learning method reinforces the three components of moral competence-moral perception, moral judgment, and moral behavior. Ultimately, this approach helps to prepare new nurses who are able to embody everyday ethical comportment[6]

[4]demonstrates that without explicit guidance from regulatory nursing colleges, self-care competencies that are important to nursing practice and job sustainability (i.e., relationship, emotional, and spiritual self-care) are not necessarily taught in nursing education programs. The relative lack of attention to self-care competencies in nursing professional practice standards and entry-to-practice competency guidelines may indeed be reflected in a gap between the perceived importance and teaching

of self-care competencies within current nursing education programs.

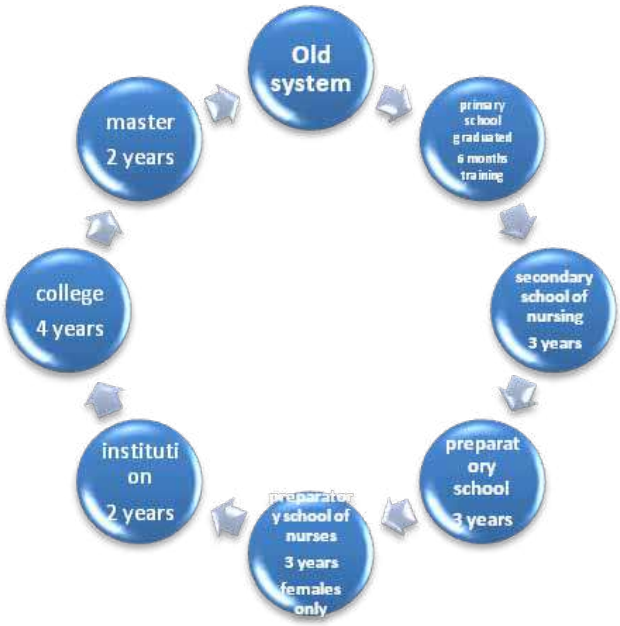

Figure 2.1 Nursing education in past few decades

Figure 2.2 nursing education nowadays

Methodology

Study Design: Quantitative research, descriptive study design was used to evaluate continuous nursing education by dividing it into three parts (structure, process, and outcome)

Administrative Arrangements: To conduct this study, approved formal administrative permissions has been gathered before data collection as shown in appendix (B) as follow:

1. Ethical committee in the nursing college of Babylon accepted the instrument to use in the study.
2. Training and Development Centre in Babylon Health institution approved hospitals access consent form
3. An official permissions were received from Al-Hilla Teaching Hospital, Babylon Maternity and Children Teaching Hospital, Murjan Medical City and Al-Hilla health sectors 1 & 2.

Setting of the Study: The study has been conducted at the continuous nursing education unit of Babylon Maternity and Children Teaching Hospital, Al-Hilla Teaching Hospital, Murjan Medical City and Al-Hilla health sector 1 & 2.

Population and Sampling Plan: The target population (250) nurse which was included in this study, who works in the main teaching hospitals and primary health care centers in Al-Hilla city.

Any nurse who met the research criteria was included in this study regardless of their gender, specialties, or unit. This strategy was used to reflect the general characteristics of continuous nursing education, reduce sampling error, and enhance the representation of the study sample.

Ethical Considerations: Nurses were asked for voluntary participation. Research aims and benefits were explained to participants to help them determine whether to take part or not. Later on they agreed to be a component of the survey, participants were paid an anonymous questionnaire to maintain participants' confidentiality.

Survey Instrument: A great body of relevant literature was extensively reviewed to ascertain the appropriate tool for the recent field. A three part questionnaire was used to evaluate structure, process and outcomes of the continuous nursing education unit, the questionnaire reviewed by (20) expert in nursing profession for validation.

Instrument Description: This scale is an instrument composed of three parts (structure 8 items, process 13 items and outcome 14 items)

Part one (structure) include infrastructure and the media of the CNE units, its items filled by researcher by asking the CNE unit manager.

Part two (process) includes mechanisms, rules, subjects types and resources and competencies, filled by researcher by asking the CNE unit manager.

Part three (outcome) estimates the satisfaction of nurses about CNE, filled by nurses.

Validity of the Questionnaire: The questionnaire was translated (forward and back) by two independent bilingual content expert. The Arabic version that is closest to the original one after it was translated back to English was used in this study. The instrument was presented to (20) panel of content experts.

Reliability of the Questionnaire: Reliability is an instrument ability to measure the attributes of internal consistency of the questionnaire (Wood and Haber, 2014). Data were gathered out of (30) nurse, (10) from Marjan Medical City, (10) from Al-Hilla Teaching Hospital, (10) from Babylon maternity and children teaching hospital. Reliability-testing was used as a statistical analysis method to measure the internal consistency and find out the concordance among the items of the outcomes of CNE unit, which it is the third part in the questionnaire, the satisfaction of the nurses in CNE unit, using the reliability coefficient. The scale had an acceptable level of internal consistency, as determined by a Cronbach's alpha of 0.76.

Data Collection: After the researcher obtained all the required approvals, the process of data collection began in 31th March 2019 to 29th of April 2019..

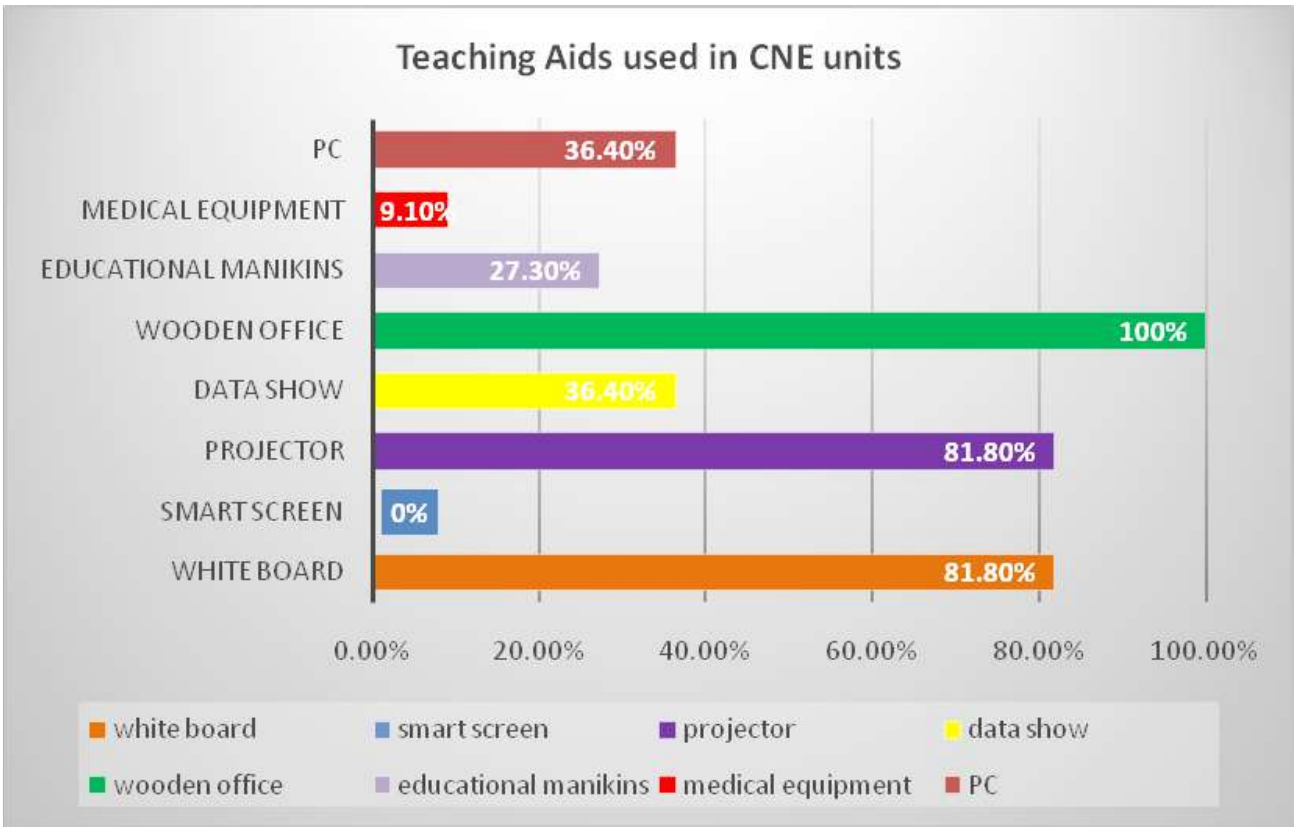
Statistical Data Analysis: Several statistical measures were used by using Statistical Package of Social Sciences (SPSS) version 24, and Microsoft excel (2016).

Results of the Study

Structure:

Lecturers' Certificate	**Freq.**	**Perc.**
Diploma degree	9	81.8
Bachelor degree	2	18.2
Number of halls dedicated to formal nursing education	Freq.	Perc.
No Hall	2	18.2
One Hall	8	72.7
Two Halls	1	9.1
Total	11	100.0

The lecturers graduation certificate who controls the CNE unit have diploma (81.8%) which was the dominate Percentage, and the highest Percentage of formal hall is one dedicated to CNE is (72.7%).



(9.1%) of CNE units who own medical equipment like stethoscope, sphygmomanometer and measurement tapes etc. While only (36.4%) of CNE units having (PC) personal computer. All of the studied CNE units don't have smart screen.

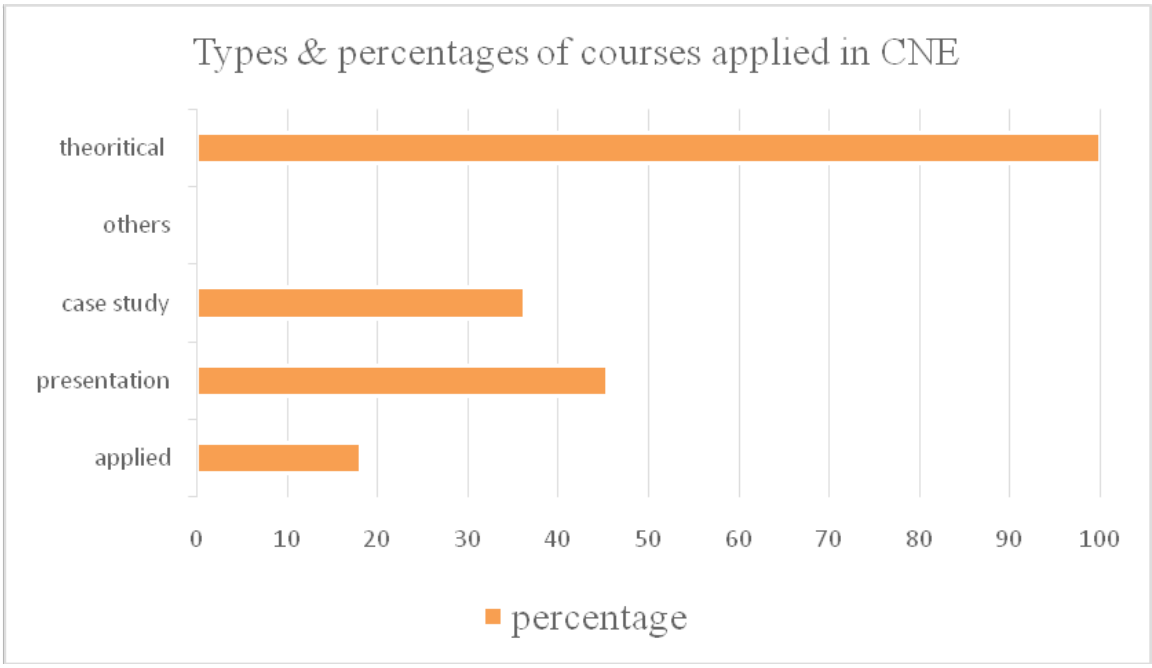
The highest percentage (81.8%) having at least one whiteboard as a teaching aids, (81.8%) have one projector at least used to CNE units. (36.4%) of CNE units own Data show. All of the studied CNE units have a wooden office.

Process:

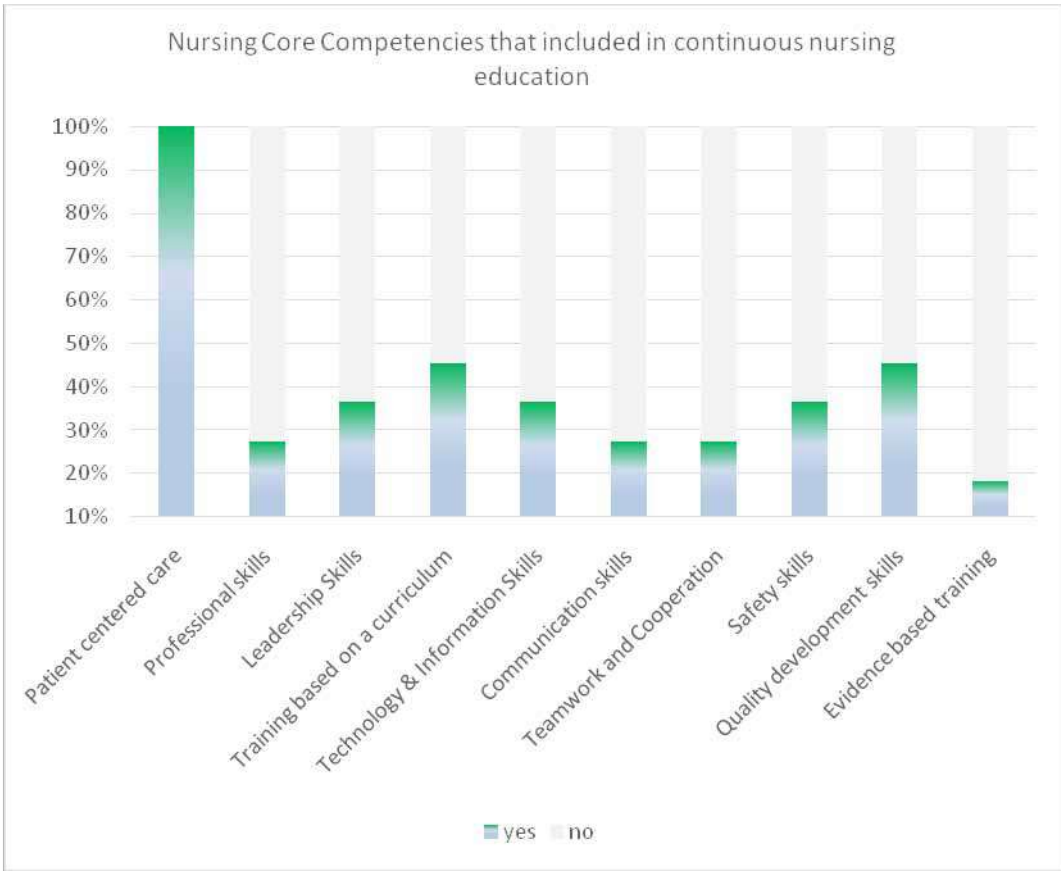
Number of courses scheduled within a month			
		Freq.	**Perc.**
Valid	1-3 Courses	2	18.2
	4-6 Courses	1	9.1
	More than 7 Courses	8	72.7
	Total	11	100.0
Number of courses completed within one month			
		Freq.	**Perc.**
Valid	1-3 courses	3	27.3
	4-6 courses	3	27.3
	More than 7 courses	5	45.5
	Total	11	100.0

Number of courses delivered outside the governorate/ outside the country/year			
		Freq.	Perc.
Valid	None	8	72.7
	Twice	3	27.3
	Total	11	100.0
Is there any instructions that coordinate courses with educational institutions to fill knowledge gaps or non-repetitions in scientific topics?			
		Freq.	**Perc.**
Valid	No	11	100.0

Number of courses scheduled in the curriculum within a month was (7) courses and more, with percentage (72.7%) while the actual applied courses was 5 courses per month with (45.5%), The number of courses delivered outside the governorate/outside the country was (2) in year with percentage (27.3%) while (72.7%) didn't receive any abroad courses. There wasn't any instructions that coordinate curriculum with educational institutions to fill knowledge gaps or non-repetitions in scientific topics.



This chart (4.4) shows percentages of courses types that applied in CNE, (100%) uses theoretical technique while case study technique (36.4), while (45.5%) using seminar presentation technique, the applied (clinical dependent) technique was (18.2%) and no any other type more than that.



This chart (4.6) shows percentages of Nurses core competencies that included in continuing nursing education, (100%) CNE units included patient centered care in their courses, (27.3%)Professional skills. (36.4%)Leadership Skills, (45.5%)Training based on a curriculum, (36.4%) Technology and Information Skills, (27.3%) Communication skills, (27.3%) Teamwork and Cooperation, (36.4%) Safety skills, (45.5%) Quality development skills and (18.2%) Evidence based training.

Third part/outcome:

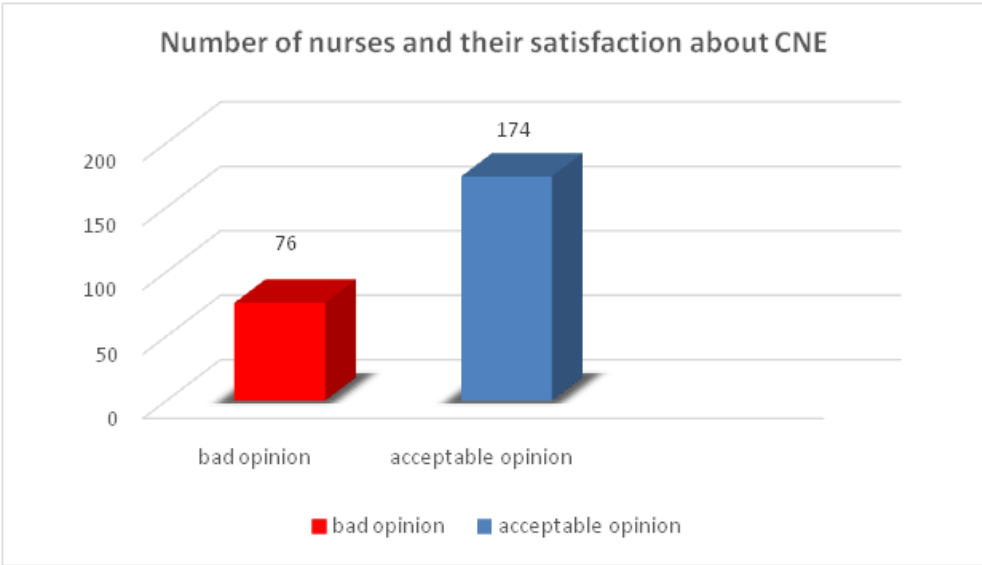


Chart (4.8) shows the total scores of nurse's satisfaction toward CNE activities (76) Nurse expressed their bad opinions or dissatisfied of their CNE units, (174) nurse showed acceptable opinions of CNE units.

Discussion of the Study Results

Part One/Structure: The most remarkable result to emerge from the data is that most of CNE units are managed by one person who controls courses scheduling, teaching, assessing and evaluating weak points in the institution and this is manifested by nurse's shortage in health institutions.

Most of CNE unit managers have diploma certificate and teach higher than his academic level which is related to the health ministry policies which prevents nurses with bachelor degree to work in PHC centers. Some of the halls which dedicated to CNE have less chairs than participants and more than half of them do not have supporting halls which is due to weak infrastructure of these institutions, lack or decreased financial support leads to few of these halls have computer, medical equipment, data show and smart screen, so variation in teaching method or simulation labs is not available.

Part two/process: The most surprising aspect of the data in this part is the lack of commitment of the CNE manager to the curriculum timing because the course scheduling didn't met with actual application and this due to nurse's shortage and/or absence of CNE evaluation. More than two thirds of nurses didn't get any abroad course or at least out of their governance, so getting big image of community problems, taking preventive measures and varying in teachers or method of teaching is difficult to afford.

The finding shows complete absence of coordination between educational and health institutions, filling knowledge gaps to nurses, the reasons for this result are not yet entirely understood which will leads to decreased patients care quality[8] reached that CNE decreases reality shock and fills theory-practice gap.

Part Three: (76) Nurse expressed their bad opinions or dissatisfied of their CNE units, (174) nurse showed acceptable opinions of CNE units.

The majority of nurses recognized that CE activities were effective in improving their knowledge, clinical practice, quality of patient care and motivation for learning.

This result supported by [7] Education and the acquisition of knowledge are likely to have an impact on nurses' job satisfaction and self-concept

Conclusion

This study showed that the present approach of nurses' continuing education needs modification so as to meet nurses' needs and leads to better patient outcome.

Although high percentage of nurse's acceptancy and satisfaction about CNE unit but still the other parts of this study shows weakness of infrastructure and in the mechanism of choosing and applying the curriculum specially in competencies application

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the College of Nursing and all experiments were carried out in accordance with approved guidelines.

Role of 14-3-3η (Eta) Protein as Immunological Marker for Disease Activity in Patients with Rheumatoid Arthritis

Muhannad Mohammed Ali AL-Salami[1], Abeer Thaher Naji AL-Hasnawi[2], Mohammed Abd AbdulHussein Abusabe[3]

[1]MSc. Student, [2]Assist. Prof., College of Medicine, University of Karbala, Karbala, [3]Prof., College of Medicine, University of Kufa, Najaf, Iraq

Abstract

Background: There are few studies had addressed the effect of 14-3-3η (Eta) protein in the activity of rheumatoid arthritis. Therefore, this study mainly aims to evaluate whether 14-3-3η (Eta) protein is related to disease activity in a sample of Iraqi patients with rheumatoid arthritis.

Method: The case- control study included 50 patients with the rheumatoid arthritis, 3 males and 47 females as group I, 34 non rheumatoid arthritis (apparently healthy) control as group II. Serum levels of 14-3-3η (Eta) protein was measured by sandwich ELISA using ELISA minikits (MyBioSource-USA).

Results: Rheumatoid arthritis found high in individuals of age group (45-54). There is a significant (P= 0.02) association between this age of patients and the susceptibility to rheumatoid arthritis. There was a high significant (P= 0.0001) difference between males and females among patients with rheumatoid arthritis, the association was non-significant (P=0.27) between family history and rheumatoid arthritis patients. According to patient's history of smoking, there was a high significant (P=0.002) relationship between rheumatoid arthritis patients and smoking history compared with control. The serum level of 14-3-3 eta protein have a significant (p= 0.025) association with susceptibility to rheumatoid arthritis while Anti CCP showing a high significant P< 0.001 association with the disease. Also there was a non- significant association between Anti CCP, 14-3-3 eta protein with disease activity score-28. Regarding disease duration, 14-3-3 eta protein showing a significant (P= 0.01) association with early rheumatoid arthritis.

Conclusion: There was a significant association between the 14-3-3 eta protein serum level and susceptibility to rheumatoid arthritis. Also, this study was reported a non-significant association between 14-3-3 eta protein and disease activity score -28.

Keywords: *Rheumatoid arthritis, Disease activity score-28, 14-3-3η (Eta) protein.*

Introduction

Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease resulting from both genetic and ecological factors. It has been hypothesized that genetic predilection, in combination with environmental factors, leads to a cascade of events causing synovitis and eventually destructive arthritis [1], affecting nearly 1% of the world population [2]. The clinical manifestation of symmetrical joint involvement include arthralgia, swelling, redness and limiting the range of motion [3].

Chronic inflammation of the synovium in RA is the cause of the clinical manifestations of joint involvement characterized by interactions of resident cells such as fibroblast-like synoviocytes (FLS) with cells of the adaptive (T, B lymphocytes) and innate (macrophages, dendritic cells, mast cells, NK cells and neutrophils) immune system[1]. Several research on probable risk factors has focused on triggers setting off disease, such as microbial/viral agents, cigarette smoking and environmental pollution[5].

Patients with RA live three to 12 years less than the healthy individuals, particularly due to cardiovascular disease, especially in those with high disease activity. The biologic therapies may extend life in those with RA by reversing progression of atherosclerosis [6]. The 14-3-3 preserved regulatory proteins family includes seven isoforms: α/β, γ, δ/ζ, ε, η, θ/τ and σ. These proteins normally exist as ubiquitous intracellular chaperones that interact with over 200 intracellular proteins and contribute to the modulation of their activities.14-3-3 eta protein was detectable at significantly higher levels in the synovial fluid and/or serum from patients with RA when compared with healthy or subjects with other autoimmune condition and bacterial/viral infections. Extracellular 14-3-3 eta protein at detectable concentrations in RA patient serum acts as a signal of cell damage that effectively induces bone-degrading enzymes and pro-inflammatory cytokines [7].

Materials and Method

Fifty RA patients were clinically-diagnosed, 3 males and 47 females, at age ranged between (25- 64) years old, attending to the Rheumatology clinic in AL-Sader Medical City in Najaf Province during the period from October 2018 to February 2019 were included as the test group. In addition, 34 non-RA (apparently healthy) age matched patients attending the outpatient clinic were recruited as control subjects. All participants underwent a complete screening panel, including medical history, clinical examination, and assessment of BMI. Five ml of venous blood were collected from each patients and control groups, collected in gel tubes, slow withdrawal of the blood sample via the needle of syringe to prevent hemolysis. The sample dropped into clean disposable gel tube, serum was separated after 20 minutes at room temperature. The samples were then centrifuged at 3500 rpm for 5 minute and then stored at freeze condition(-20C) until analyzed.

Human 14 -3- 3 (eta) protein ELISA test: Serum levels of 14-3-3η protein were determined by classic sandwich-ELISA using ELISA minikits (MyBioSource-USA).

Statistical Analysis: All statistical analyses were performed by using Statistical Package of Social Science software (SPSS) computer program (Version 22, SPSS Inc., Chicago, IL, USA).

Result

There is a significant association between the age of patients (45-54) and the susceptibility to rheumatoid arthritis (P= 0.02), as shown in table-1. The patients comprised 46 (92%) about females and 4(8%) about males while in control 16 (47%) as female and 18 (53%) as male. There was a high significant (P= 0.0001) difference between females and males among patients with RA and compared with control. However, the association was non-significant (P=0.27) between family history and RA patients. There was a high significant association (P=0.002) between RA patients and smoking history compared with control, as shown in table-2.

Mean BMI among patients was (19.30) compared to (24.47) for control, there is a highly significant difference in the distribution of patients and control subjects (P< 0.001), 48 patients (96%) were rheumatoid factor positive, whereas 2(4%) patients were RF negative, giving a mean of 1.04±0.03, Erythrocyte sedimentation rate (ESR) ranged between (20.0-110.0) among patient group, giving a mean of 50.98±2.69, The mean of Anti CCP antibodies in RA patients was significantly higher (P<0.001) than in controls, (3.56±0.24) and (1.52±0.07), respectively. 14-3-3 eta protein showing a significant (P =0.025) association with patients group, giving a mean of 5.13±0.25 and a mean of 4.38±0.17 among control group, as in table-3.

The mean of Anti CCP antibodies level in RA patients was (3.82±0.30) in high grade of disease activity score-28 (DAS28) and (2.82±0.31) in moderate grade. There was a non-significant association (*P*=0.07*)* between Anti CCP antibodies and DAS-28. Also, 14-3-3 eta protein giving a mean of (5.21±0.28) and (4.90±0.55) among high and moderate grade of DAS-28 respectively. There is a non-significant association(*P=0.58*) with DAS-28 of RA patients, as in table-4. Regarding disease duration, early rheumatoid arthritis (less than one year) and established (more than 3 years), rheumatoid factor and 14-3-3 eta protein showing a significant association with early RA, giving a mean of 1.14±0.10 and 6.11±0.62 respectively in early RA and a mean of 1.00±0.00 and 4.75±0.22 respectively in established RA, whereas Anti-CCP showing a non- significant association giving a mean of 3.91±0.55in early RA and a mean of 3.43±0.27 in established RA, as in table -5.

Table 1: Age distribution among rheumatoid arthritis patients

Age/Years	R.A Patients No. (%)
25-34	5(10%)
35-44	10(20%)
45-54	21(42%)
55-64	14(28%)
Total	50(100%)

Table 2: Distribution of the studied groups according to gender, family history, and smoking habit.

Variable	Cases N(%)	Controls N(%)	P	OR	95% C.I.

*significant p value, RA = rheumatoid arthritis, RF = rheumatoid factor, ACCP = Anti-cyclic citrullinated peptide

Discussion

Rheumatoid arthritis was found high in individuals of age group (45-54) years old, at a percentage (42%). There is a significant association (*P= 0.02*) between the age group (45-54) of patients and the susceptibility to rheumatoid arthritis. This result was associated with a study conducted by[8] who revealed that the majority of RA patients are (40-50) years old. Another study by [9] showed that a peak age of onset is Forties. In the current study, there was a highly significant (*P=0.000*) difference between study groups in the gender. The scattering of RA is higher among females than males. This finding similar to the study by [10] who revealed the sex ratio is typically around 3:1 about females compared with males.

Also, The association was non-significant (P=0.27) between family history and RA. A study conducted by [11], exhibited that RA family history do not related with RA and this result was in the same line with the present study. in contrary, [12] demonstrate that family history is still a significant risk factor for RA.

In addition, there was statistically significant association *(P*=0.002*)* between smoking and RA in present study and this result was in the same line with a study conducted by[13] and[14], whose found a significant relationships between cigarette smoking and development of rheumatoid arthritis. In contrary with[15] who revealed that smoking is independent risk factor for progression in RA . In the current study there was a significant (p= 0.025) association between the level of 14-3-3 eta protein and rheumatoid arthritis. The present study in the same line with a study conducted by[16] who showed that measurement of 14-3-3η complements RF and anti-CCP antibody tests in RA and may improve diagnostic sensitivity. In contrary[17] who demonstrated that measurement of 14-3-3η ETA offered limited additional diagnostic value when compared to RF and ACPA. Furthermore, This study was reported a non-significant (*p= 0.58*) association between 14-3-3 eta protein and disease activity score -28 in contrary with [18] whose reported that 14–3–3η positive RA patients have higher disease activity score. Otherwise, The current study also revealed a non- significant (*P*=0.07*)* association between Anti CCP antibodies and DAS-28.This result was in contrast [19] whose demonstrate that ACCP positive patients exhibited more active disease, expressed by higher disease activity scores -28 (*p<0.001*).

Moreover, in the current study there was a significant (*p =0.02*) association between rheumatoid factor and early RA and this result was associated with[20] who revealed that RF seropositivity was found to be more common in much early RA patients while present study reported a non-significant (*p* =0.38) association of ACCP with the early and estiblished RA. In contrast [21] revealed that ACCP in early RA diagnosis is more than 80%. This study also showed that 14-3-3 eta protein was significantly (*p= 0.01*) high in patients with early RA and this result agreed with [22] who reported that14-3-3η protein were detectable at significantly higher levels in patients with early RA than in healthy subjects and patients with various autoimmune disorders and other arthritides.The differences of these results may be due to the ethnicity in different populations and may be due to the small volume of samples in this study.

An Epidemiological Study of Scabies by Age Groups, Regions and Gender in Diwaniya Governorate

Rana Saleh Al_Difaie[1], Saafa Ressan Abdullah Al_Kaeebi[2], Ahmed Sami Salman[3], Lina Abdulkhademoudah[3]

[1]Lecturer, Biotechnology College, [2]Lecturer, College of Nursing, Al_Qadisiyah University, Iraq, [3]Lecturer, Biologist, College of Nursing, ALQadisiyah University

Abstract

This study included the investigation of scabies parasites, which is one of the external parasitic. It is becoming more polluted and less clean. The diagnosis from the cases reviewed to the dermatologist at Diwaniyah Teaching Hospital showed that there were many cases of skin infections with fungi and bacteria. However, the study was about scabies. The number of cases during 90 days was 120 cases after examination and diagnosis. The study showed the increase in pollution of the city center as well as the lack of ventilation, and the number of injury 29 and by 24 percent, while the lowest number was in two areas are AL- Shafaia and AL-Sudair 13 and the proportion of 10.8 percent. The number of males was 75 and 62.5%, while females were 45 and 37.5% .As for the age groups, the highest number was 41 cases in the ages of 10 years and less than 20 years and by 34% and in the age of less than 10 years were 28 and 23%. The lowest number of cases in 120 cases were 8 cases in children under 30 and over 20 years, and 6.6% .

Keywords: *Epidemiological, scabies, Diwaniya Governorate.*

Introduction

Scabies, also known as the seven-year itch, is a contagious skin infestation by the mite Sarcoptes scabies. [1] The most common symptoms.are severe itchiness and a pimple-like rash.[2] Occasionally, tiny burrows may be .seen in the skin.[2] In a first ever.infection a person will usually develop symptoms in between two and six weeks.[2] During (a second,infection symptoms) may begin in as little as 24 hours.[2] These symptoms can be present, across most of the body or just certain areas such as the wrists, between fingers, or along the waistline.[2] The head may be affected, but this is typically only in young children.[2] The itch is often worse at night.[2] Scratching may cause skin breakdown and an additional bacterial infection of the skin.[2]Scabies is.caused by infection with the female..miteSarcoptes scabies var. hominis.[3] The mites burrow* into the skin to live and deposit eggs.[3] The symptoms of scabies are due to an allergic reaction to the mites.[2]Often, only between 10 and 15 mites are involved.in an infection.[2] Scabies is.most often spread during a relatively,long period of direct skin contact with an infected person (at least 10 minutes) such as that which may occur during sex or living together.[3] Spread of disease may occur even if the person has not developed symptoms yet. Crowded living conditions, such as those found in child-care facilities, group homes, and prisons, increase the risk of spread.[3] Areas with a lack of access to water also have higher rates of disease.[4] Crusted scabies is a more severe form of the disease.[3] It typically only occurs in those with a poor immune system and people may have millions of mites, making them much more contagious. [3] In these cases, spread of infection may occur during brief contact or by contaminated objects.[3] The mite is very small and usually not directly visible.[5] Diagnosis is based on the signs and symptoms.[6]

A number of medications.are available to treat those infected, including permethrin, crotamiton, and lindane creams and ivermectin pills.[7] Sexual contacts within the last month and people who live in the same house should also be treated at the same time.[8] Bedding and clothing used in the last three days should be washed in

hot water, and dried in a hot dryer.[9] As the mite does not live for more than three days away from human skin, more washing is not needed.[10] Symptoms may continue for two to four weeks following treatment.[] If after this time symptoms continue, retreatment may be needed.[10]

Scabies is one of the three.most common skin disorders in children, along with ringwormand,bacterial skin infections.[11] As of 2015, it affects about 204 million people (2.8% of the world population).[8] It is equally common in both sexes.[12] The young,and the old are more commonly affected.[] It also occurs more commonly in the developing world and tropical.. climates.[12] The word scabies is from Latin: scabere, "to scratch".[13] Other animals do not spread human scabies.[3] Infection in other animals is typically caused by slightly different but related mites and is known as sarcoptic mange.

Scabies has been observed in, humans since ancient times. Archeological evidence from Egypt and the Middle East suggests! scabies was present as early as 494 BC.[14] The first recorded reference to scabies is believed to be from the Bible – it may be a type of (leprosy) mentioned in Leviticus c. 1200 BC[15] or be mentioned among the curses of Deuteronomy 28.[16] In the fourth century BC, Aristotle reported on (lice" that "escape from little pimples if they are pricked) a description consistent with scabies.[17]

The Roman encyclopedist and medical writer Aulus Cornelius Celsus (c. 25 BC – 50 AD) is credited with naming,the disease (scabies) and describing its characteristic features.[18] The parasitic etiology of scabies was documented by the Italian physician Giovanni Cosimo Bonomo (1663–1696) in his 1687 letter, (Observations concerning the fleshworms of the human body).[50] Bonomo's description established scabies as.one of the first human diseases with a well-understood cause.[19][]

Pathophysiology: The symptoms are caused by, an allergic reaction of the "host's body" to mite proteins, though exactly which proteins.remains a topic of study. The mite proteins are also present, from the gut, in mite feces, which are deposited under the skin. The allergic reaction is both of; the delayed "cell-mediated" and immediate ((antibody-mediated)) type, and involves IgE antibodies, it is presumed, mediate the very rapid, symptoms on reinfection.[30] The allergy-type symptoms (itching) continue for some days, and even several weeks, after all mites are killed. New lesions may appear for a few days after mites are eradicated. Nodular lesions from scabies may continue to be symptomatic for weeks after the mites have been killed.[31]

Rates of scabies were negatively related to temperature, and positively related to humidity.[32]

Diagnosis: Scabies may be diagnosed clinically in geographical areas where it is common when diffuse itching presents along with either lesions in two typical spots or itchiness is present in, another household member.[33] The classical sign of scabies is the burrow made. by a mite within the skin.[34] To detect the burrow, the suspected area is rubbed with ink from, a fountain pen or a topical tetracycline solution, which glows under a special light. The skin is then wiped,with an alcohol pad. If the person is infected with scabies, the characteristic,zigzag.or S pattern of the burrow will appear across the skin; however, interpreting this test may be difficult, as the burrows0 are scarce and may be obscured by scratch marks.[11] A definitive diagnosis is made by finding either the scabies mites or their eggs and fecal pellets.[35] Searches for these signs involve either scraping a suspected area, mounting the sample in potassium, hydroxide and examining it under a microscope, or using dermoscopy to examine the skin directly.[36]

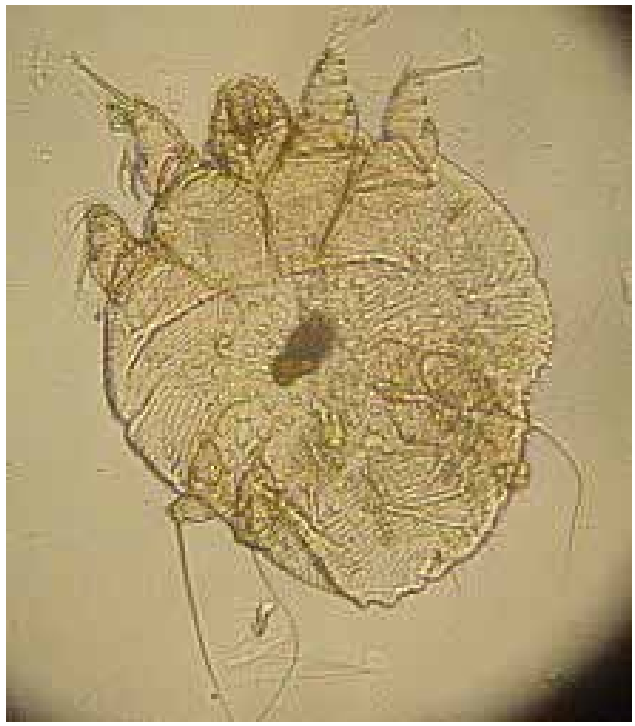

Figure (3): Photomicrograph of an itch mite (S. scabies)

Differential Diagnosis: Symptoms of early scabies infestation mirror other skin diseases, including dermatitis, syphilis, erythematic multi form, various urticaria-related syndromes, allergic reactions, ringworm-related diseases, and other ectoparasites such as lice and fleas.[30]

Prevention: Mass-treatment programs that. use topical permethrin or oral ivermectin have been effective in reducing the prevalence of scabies in a number of populations.[37] No vaccine is available for scabies. The simultaneous treatment, of all close contacts is recommended, even if they show no symptoms of infection "asymptomatic", to reduce rates of recurrence. [38][] Since mites can survive for only two to three days without a host, other objects in the environment; pose little risk of transmission except in the case of crusted scabies, thus cleaning is of little importance.[39] Rooms used by those with,crusted scabies require thorough cleaning[40] .

Materials and Method

A. Material

1. Microscope .
2. Collect 120 samples .
3. Glass slides for dignosis .
4. Potassium hydroxide.

B. Method: The classic mark of scabies are burrows that are shaped by mites inside the skin. To detect burrows, [41] rub the ink-contaminated areas of an ink pen or topical tetracycline solution, which shines under a special light. The skin is then wiped with a cloth containing alcohol. If the person is infected with scabies, the S pattern or the scaly will appear across the skin from the hole area; However, the interpretation of this test may be difficult because burrows are rare and can mask scratch marks. Accurate diagnosis is performed by finding either moths, eggs, and fecal pellets. The search for these markers involves either scavenging the suspected area and collecting the sample in potassium hydroxide and examining it under a microscope, or using a microscope to examine the skin directly. [42]

Results and Discussion

The results shown in Table (1) indicate the percentage of people with scabies in Diwaniyah city center and its districts and areas with the highest incidence of scabies in the city center, where the percentage of infection was 24.16%, while the lowest rate of infection in the district of Sudair and Shafei area 10.8%, while the percentage of infection in the rest of the districts and districts was different. The percentage of infection in the Sunni areas was 16.6%, Al-Daghara 12.5%, Afak and Al-Hamzah Al-Sharqi each 12.5%.

Table (1): Shows the comparison of numbers and percentage of scabies between thy city center and the district

Regions	Number of Infections	Percentage
1. City center	29	24.16%
2. The dagara	15	12.5%
3. Al-sudair	13	10.8%
4. The Sunni	20	16.6%
5. Afak	13	10.8%
6. The shafaia	15	12.5%
7. Eastern Hamza	15	12.5%

Table 2 shows the percentage of infection by sex. The results indicate that males have the highest incidence of infection, with a percentage of 62.5%. The percentage of infection among females is 37.5%. In the present study male patients represent (62.5%) compared with (37.5%) females which come on concordance with that reported by Mustafa et al (1997) reported that on turkey scabietic males represent (52.38%) compared with (47.62%) females. This may be attributed to the similarity on socioeconomic and demographical conditions between Iraq and turkey. This result disagree with that recorded by Lassa et al (2011)[46], they recorded that there was a significantly greater infestation rate between females relative to males in UK which might be attributed to study design and the possibility of exposure to infestation as are results of the type of works that achieving by females beside hygiene measures .Walton et al (2004) [47], discordance with this study the reported that the prevalence of scabies isn't affected by sex.

Table (2): Shows the numbers of infections and percentage of scabies between the male and female.

Sex	Numbers of Infections	Percentage
Male	75	62.5%
Female	45	37.5%

Table (3) shows the percentage of cases of scabies by age group. The highest age group (10-20 years) was the most infected. The percentage of infection was 34.16%, while the age group (20 years) (30%) was the

lowest in the age group, with a percentage of 6.6%, while the percentage of the infection was different among the other age groups. The percentage of infection among the age group (10 years) was 23.3% Where the percentage of infection of the age group less than (10) years, 23.3%, while The percentage of infection among the age group (30-40) years was 11.6%. The percentage of infection among the age group (40-50) years was 7.5%. The percentage of infection among the age group (50-60) (10.8%), where the percentage of infection in the age group and those aged over(60) years 5.8%.

Scabies is most popular in children and young adults, but may happen at any age. These are possible related to customs, family size, and social agents rather than inherent susceptibility. Overcrowding, which is the popular in the underdeveloped countries and is linked with poorness and poor hygiene, help the spread of scabies, among between children and young adults. In such as disease whose transmission requires close personal contact, cultural agents are very important. Therefore transmission especially occurs within families, when one member (fathers and mothers in our study) of a family demand scabies entire family sometimes becomes infested as well as. In a study to identify the source of infestation prison, and military personal were the important agents in the spread of infestation. This may due to overcrowding, population movement. To an extent the wars are a composite of factors. It is probably that war may be translate minor increasing on the incidence of scabies, into a more substantial epidemical. Allergic sensitivity to the mite or it is products appears to play important role on determining the development of lesions other than burrows, and in producing itching . yet, the sequence of immunological events is not clear and demands in addition to elucidation. [45]

Table (3): Shows the numbers and percentages of infection by age groups.

Age Groups	Numbers of Infection	Percentages
Less than 10 years	28	23.3%
10-20	41	34.16%
20-30	8	6.6%
30-40	14	11.6%
40-50	9	7.5%
50-60	13	10.8%
Over 60 years	7	5.8%

Figure (1): Show child infected by scabies

Conclusions

The study showed that the highest infection of scabies was in the center of the city due to population congestion and low ventilation of houses for small area .The study showed clear and high rates of infection in rural areas and villages .Male infection rates were higher than that of females .Through the examination and distribution of infection by age groups, the study showed that the highest percentage of infection was in the young ages of males and females .There were a number of obvious injuries in large ages

Investigation of Escherichia Coli Fim H Gene Occurrence Isolated from Clinical and Environmental Samples

Samah N. Abd[1], Najeh H. Kadhum[2], Hassan M. Abolmaali[3]

[1]B.Sc. in Biology, Department of Microbiology, Science College, Kerbala City, [2]Ph.D. in Biology, Department of Microbiology, College of Medicine, University of Kerbala City, [3]Ph.D. in Genetic Engineering and Biotechnology, Department of Clinical Laboratory Sciences, College of Pharmacy, University of Kerbala

Abstract

Background: *Escherichia. coli* consider as commensal bacterium that can be inhabitant in the small intestinal micro-biota of warm-blooded animals, Urinary tract infections cause by Uropathogenic *Escherichia coli* (UPEC) Are among the most branded infectious diseases in humans. Due to their recurrently incidence in the community and nosocomial infection and evolution of resistance to ordinarily recommended antimicrobial agents.

Objective: The aim of current study was Investigation of *FimH* gene occurrence a virulence factor in *Escherichia coli.*

Materials and Method: Sixty urine samples of women with urinary tract infection symptoms. In addition, samples from different environmental places involving poultry, knacker shops, drainage water, fresh water and sewage water were collected during 22^{ed} November 2017 to 28^{ed} February 2018. Twenty one clinical and twenty three environmental isolates of *Escherichia coli*. The data were analyzed by using the statistical package social system (SPSS).

Results: The biofilm formation were 14(66.6%) strong, 7(33.30%) moderate and weak biofilm producers not exit in clinical isolates, while 13(41%) strong, 8(34.70%) moderate and 2(8.60%) for weak biofilm formation in environmental isolates. Moreover, PCR assay of *FimH* was applied. So,20 isolates (95.23%) were positive results for clinical isolates and 17 isolates (73.9%) positive results for environmental

Conclusion: Uropathogenic *E. coli* had the higher occurrence rate for fimbriae gene (*Fim H*) compared with environmental isolates,Stronger biofilm formation by clinical *E. coli* isolates than by environmental isolates. There is a significant correlation between biofilm formation and probability of *Fim H* occurrence in both clinical and environmental isolates.

Keywords: *Escherichia coli, FimH gene, Biofilm formation.*

Introduction

E. coli consider as commensal bacterium that can be inhabitant in the small intestinal micro-biota of warm-blooded animals, it's a member of the fecal coliform group adumbrated as "indicator organism" that occurrence in environment point to fecal contamination, accordingly, utmost strains are harmless but specific can be pathogenic thus represent important issues to human health[1].

Biofilm defined as; a community of microorganisms encased within a secreted matrix of exo-polysaccharide or EPS, that attached to a surface this term modeled by Dr. Bill Costerton in 1974. Biofilm formation is

Corresponding Author:
Samah N. Abd

considered to be substitute idea to cells grow and lived only in planktonic or single cell state [2]. Urinary tract infections cause by Uropathogenic *Escherichia coli* (UPEC) Are among the most branded infectious diseases in humans. Due to their recurrently incidence in the community and nosocomial infection and evolution of resistance to ordinarily recommended antimicrobial agents[3]. The critical stage in the infection procedure is the establishment to the urinary tract. Ordinarily, without join to epithelia cells bacteria can be wash away by urination route. Uropathogenic *Escherichia coli* or UPEC have many diverse tools for adherence to the uroepithelium, including : fimbriae, which defined as appendages with rod-like shape ascends from the surface of bacterial cell crowning in a top adhesion; fimbrillae, flexible, prolonged conformations with adhesions present throughout the structure for example not only at the top; and afimbrial adhesions such as autotransporters. Moreover, Extensive regulatory systems coordinate expression of these different adhesions [4]. Type 1 fimbriae coded by the genome of *E. coli* about 99% of their strains, Type 1 fimbriae compromise from FimA, the main structural subunit, several minor subunits, and FimH, the adhesion which is found at the top of fimbriae[5].

Subjects and Method:

Ethically, data collection and the design of the study groups were accomplished after the approval on the research proposal was done by Research Ethics Committee of Kerbala Health Directorate to work in its hospitals.

Sixty morning midstream urine were collected from women with urinary tract infection aged from 18 to 60 years. In addition, Samples were taken from different environmental places involving poultry, knacker shops, drainage water, fresh water, and sewage water. Biofilm formation assay and quantification was performed using method followed by [6] with some modifications. Colony PCR method followed by [7] was used for extraction of genomic DNA of *E. coli* isolates and appropriate statistical and descriptive analysis were performed using IBM SPSS V21.

Results

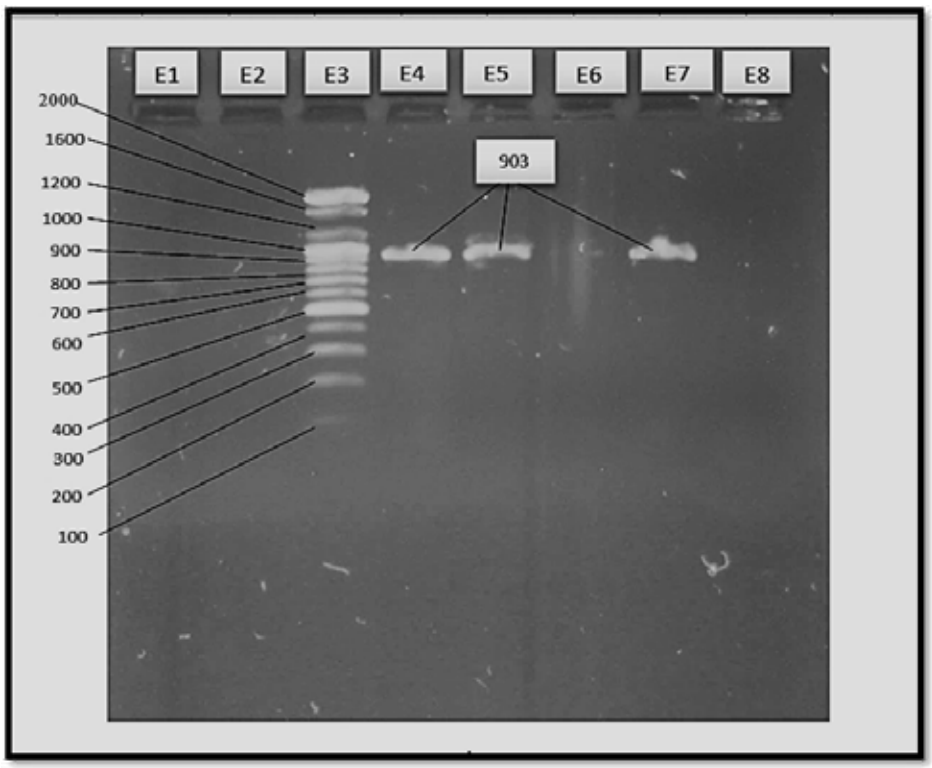

Figure (1): Agarose gel electrophoresis for PCR product of FimH gene, 1.5% agarose, visualized under UV after staining with ethidium bromide at 4volt/cm for 1 hours. laneE1 and E2 negative controls for FimH gene. Lane E3 is size marker (bp). Lane E4 and E5 and E7 is FimHPCR product (903 pb). Lane E6 and E8 is negative results of FimH PCR, All numbers in figure are in base pair.

Biofilm was performed on 21 clinical of *E. coli* isolates comparing with control which contented media only. *E. coli* isolates formed strong and moderate biofilm as the following: 14(66.6%) strong, 7(33.30%) moderate, while weak biofilm producers not exit in clinical isolates,*E. coli* isolates formed strong, moderate and weak biofilm as the following:13(41%) strong, 8(34.70%) moderate and 2(8.60%) for weak or non-biofilm formation in environmental isolates. In current study PCR was applied on 21clinical and 23 environmental isolates for *FimH* gene as showed in figure (1).Results showed that *FimH* gene had the higher occurrence represent 95.2% in clinical isolates. While *FimH* gene had lower occurrence represent 17(73.9%) in environmental isolates.

Discussion

Besides all human infectious diseases, urinary tract infections had a high prevalence and in the majority of cases *Escherichia coli* is a dominance bacterium which can cause pyelonephritis and cystitis [8].Additionally, virulence genes as well as patients-related factors are equally responsible for the development of infections and also that virulence genes may help such isolates to persist even with appropriate chemotherapy and be responsible for recurrent infections [9]. Consequently, the aim of the present study was determination occurrence of the *FimH* gene that associated with adherence to host surface leading to UTI initiation . Moreover, study by Bronzato *et al*., 2017[10] emphasized that high frequency of *FimH* gene, the adhesion-encoding gene is associated with epithelial cell invasion in uropathogenic *E. coli.*

In current study; the results were obtained for the biofilm formation in clinical isolates, which seem to be similar to study emphasized by Neupane *et al*., 2016[11] which found higher occurrence of strong and moderate biofilm other than weak biofilm in uropathogenic strains of *E. coli*.

Moreover, biofilm formation in environmental isolates, results approximate similar to study ascertain by Wang *et al*, 2016[12] this study emphasized the ability of *E. coli* to biofilm forming from poultry and found sizable rate of weak biofilm formation among them.

Also, Correlation coefficient statistically measured between biofilm formation and probability of *FimH* occurrence (r) = 0.5542 for 21 clinical isolates while (r) = 0.34 for 23 environmental isolates.

Conclusion

Uropathogenic *E. coli* had the higher occurrence rate for fimbriae gene (*FimH*) compared with environmental isolates.Stronger biofilm formation by clinical *E. coli* isolates than by environmental isolates. There is a significant correlation between biofilm formation and probability of *FimH* occurrence in both clinical and environmental isolates.

Dental Health Status among Adult Population in Karbala City

Karama M.T AL-Nuaimy

B.D.S, M.SC. Assist Prof. Department of Dentistry, Al -Zahrawi University College Karbala, Iraq

Abstract

This study done to evaluate the oral health status (dental caries,periodontal disease and treatment needs) in Karbala city the adult individuals sample include 250 individuals age ranging between 20-40 years of both sexes using sharp dental caries explorers with W.H.O periodontal probs to detect periodontal health by use of DMFT index of W.H.O (1997) and CPITN by W.H.O (1987).

The mean DMFT for the total sample was (3.98 + 0.15)which was increased with increasing age for different age groups with significant difference in the mean DMFT for total boys and girls has been found .The results also showed that the total number of health 468 with a mean of 1.12 tooth/person in need of treatment is the most prevalent needed one surface frilling And 308 teeth with a mean 1.01 tooth/person needed two or more surface filling.

According to highest CPITN there was significant difference between boys and girls in calculus at $P \leq 0.05$ and shallow pockets at $P \leq 0.01$. The results also revealed that the mean number of healthy sextants for the total sample was 4.13 while for bleeding and calculus were 0.82 and 0.31 respectively .It means that the treatment need for periodontal disease is more toward oral hygiene procedure and prophylaxis as general. The dental health education program is an essential activity for promoting optimal oral health and preventing oral disease.

Keywords: *Dental Health Status, DMFT of Adult, CPITN OF Adult.*

Introduction

The periodontal disease is one of the most wide spread disease all over the world and more prevalent among population of the developing countries. Periodontitis is a bacterial infecting of all parts of the periodontium including gingiva, periodontal ligament, bone and cementum, which results in irreversible destruction to the tissue of periodontium [1-3]

Usually periodontal disease begins at childhood as gingivitis which increases in severity in the early " ten " years and it may lead to the development of periodontitis which is associated with pocket formation.[3-5]

While there are many factors that affect prevalence and severity of dental caries and periodontal disease, the most important factors are age, sex level place of residence, parental influences education level and socioeconomic status [6-8]

The purpose of this study were to estimate the prevalence and severity of dental caries and periodontal disease in adult population in karbala city can help in planning preventive dental health program

Material and Method

The survey was conducted during the period between October 2017 to April 2018 on 250 randomly selected in karbala city of adult people seeking for dental treatment in different departments of dental college (in karbala city), age ranging between 20 - 40 years old, divided in to 2 age groups of 10 years intervals 20 - 30 and 30 - 40 years respectively.

The clinical examination was carried out by one examiner at the dental college using plane mouth mirrors, sharp dental curies explorer and W . H . 0 periodontal probes to detect periodontal health

The indices used for assessment of dental condition were as follows

1. DMFT by W . H . 0 methodology for caries status and treatment need (1997)[7] to obtain and calculate decayed (D) missing (M) and filled (F) for each tooth
2. Community periodontal index of treatment needs (CPITN) by who (1987)[9] for assessment of gingival and periodontal health status and their treatment needs Each sextant was assigned a code number which recorded the condition of the Worst affected site in the sextant the subject were classified in to treatment need

Categories according to the highest code number assigned to any of the sextants in particular individual

The statistical analysis of the data included the means, standard deviation and standard error by using ducan's multiple range test, analysis of variance (ANOVA), F test and KruskalWallis test

Results

The age and gender distribution of 250 subjects comprising 132 males and 118females was divided into 2 age groups with an interval of 10 years for age group (table 1) .

Table (2) showed there was no significant difference in the mean DMFT for total males (3.90) and total females (3 . 60), but there was significant difference in the mean DMFT and its components between different age groups and the caries prevalence was increased with age of both sexes,

Table (3) illustrated the number of teeth in the total sample that required treatment, it showed that the treatment need for person for the total sample was in need of one surface filling, followed by two or more surface filling.

Table (4) Showed that the total sample distributed according to the highest CPITN code by age and sex it has been found that only (88) person are healthy in all age groups and the highest value was in the age group (30-40) years the most frequently periodontal condition was calculus it has been found the significant difference between males and females for calculus of $p \leq 0, 05$, and deep pocket at $p \leq 0.01$.

Table (5) showed the mean number of sextants by person the mean number of healthy sextants for the total sample was (9.79) while for bleeding (5, 06) an for calculus was (1,11).

The mean number of healthy Sextant for all age groups were nearly the same, while bleeding code was decreased with increasing age the mean number for calculus and pocket sextants was increased with age but not for all age groups.

Females tended to have health and had less bleeding and calculus Sextants compared to males .

Table (6) demonstrated the distribution of sample in need to oral hygiene education Scaling and those with no need for treatment more than half of the sample showed no need to any type of periodontal treatment (score 0) and less than half of sample need oral hygiene instruction.

Table (1): Distribution of the sample by age and sex

Age (Year)	Male No	Female No	Total No
20-30	68	64	132
30-40	64	54	118

Table (2): The mean DMFT and its components

Discussion

Caries experience was measured by the DMFT index while is valid, simple and reproducible index for assessment of dental caries this method ensures that the data collected in a wide range of environment is comparable it is also provides a standard measurement of oral disease and condition as base for planning and evaluating oral health.

The results of this study have shown that there was increase in caries prevalence with increasing age for both sexes, this increase in caries experience with age may be attributed to differences in dietary habits,

The results of this study have also shown that there was no significant difference in the mean DMFT values for total males and total

Females this was in accordance with studies conducted in developed and developing countries [10,11]

Concerning treatment needs, it has been shown the majority of the sample required one surface filling followed by 2 or more surface filling.

This was in contrast with study conducted on adult population on in Spain[11.12(

The world wide acceptance of the CPITN which has proved to be simple and effective method for measuring and minority the prevalence and severity of periodontal disease at the community level[14,15]

The CPITN has been increasingly adopted in dental health services and has proven to be a useful tool for planning and monitoring periodontal treatment and establishing population periodontal health goals[14,15]

Results also revealed that there was a significant difference between males and females in 'calculus at $p \leq 0.05$ and pocket more than 5mm depth at $p \leq 0.01$ level females tended to have higher percentage of healthy gingiva .this may be due to the fact that there were differences in practice of oral hygiene between sexes, girls tend to practice better oral hygiene .this results was in agreement with other study[15]

The results showed that calculus was the most frequently observed periodontal condition in the total population while in the age group 30-40 years the periodontal condition most frequently observed was shallow pocket. The findings of this study suggested that periodontal disease prevalence range from low to moderate, when compared with other studies

The prevalence of gingival bleeding was lower in the first age group and higher in the second age groups the mean number of health sextants for two age groups are nearly the same as the bleeding which will decrease with increasing age .it was in agreement with other studies[16,17]

The results indicated that treatment need for periodontal disease is more toward oral hygiene procedure followed by scaling.

Conclusion

Dental caries and periodontal disease are very important public health problems in the most of developing countries therefore, an efficient dental health care instruction program showed be constructed to achieve an acceptable standard of oral hygiene, so dental health education program for those people is an essential activity for promoting establishing and maintaining optimal oral health and preventing oral diseases.

While the need for treatment was concentrated on instruction in oral hygiene and prophylaxes which can be developed by dental hygiene staff.

Abstract

Study objective is measurement the sensitivity of CA125,CA15-3, CA19-9, CEA, NSE, and α-FP in the both pleural effusion and ascites and diagnosis theiretiologyin comparison with cytology.

Method: This study is prospective study, 98 patients who admitted to Al-Hilla Surgical Teaching Hospital, 42 patients with pleural effusion and 56 patients with ascites. The investigations were done and include sugar and protein analysis, direct smears, tumor markers tests (CA125,CA15-3, CA19-9, CEA, NSE, and α-FP), and cytology are done for diagnosis of metastatic cancer in both effusions, or by histopathology if negative cytology are result.

Results: Pleural effusion (42 patients) are divided into 16 (38.1%) and 26 (61.9%) for benign and malignant effusion respectively, ascites (56 patients) are 33(58.9) and 23(41.1%) for benign and malignant ascites. The age group 71-80 and male gender group is the higher percentage in both effusions. Sensitivity and accuracy in pleural fluid CEA (30.8% and 57.1%), CA15-3 (26.9%,54.8%)respectively, and in ascitic fluid CA125 and CA19-9 (26.1%, 69.6%).Tumor markers have significant association inpleural effusion (CEA and CA15-3) and ascitic fluid (CEA, CA125, and CA19-9). Sensitivity and specificity of cytology in ascitic fluid (65.2%, 96.9%) and in pleural effusion (57.7%,93.8%)respectively with significant association in both effusion . In pleural effusions, CEA+ cytologyresult 44.2%, 64.3%, and In ascitic effusion, CA125 + cytology show 45.7%+77.7%, for sensitivity and accuracy respectively.

Conclusion: Tumor marker of both effusions have low sensitivity and high specificity. The combination tumor markers with each other and with cytology resulting in considerable increase in their diagnostic efficacy and they can use as director for invasive procedure cytology remain the highest sensitivity (in compare to tumor markers) and would bed one before other invasive tools.

Keywords: *Pleural effusion, Ascites, Cytology, Fluid tumor makers.*

Introduction

According to data 2015 of World Health Organization, there are about 10 million of new cancer disease per year and about 6 million cancer patients are die from that disease[(1)].

The pleural effusion is collections of fluid in the pleural cavity and 90% of its etiology are related to congestive heart failure, cancer, and pneumonia[(2)] .

Ascites is pathological collection of liquid in peritoneal cavity[(3)] and it caused by enterocoelia and peritoneum malignancies, tuberculosis, kidney disease, heart insufficiency, and others[(4)] .

Cytological procedure may not give final diagnosis up to 40% from all cases and so, there is additional diagnostic techniques such as fluid-soluble tumor marker are added[(5)].

The CA125, CEA, and NSE are applied for initial detection of lung cancer[(6)] and CA19-9 with CEA for pancreatic malignancy[(7)]. Also, there are widespread

tumor markers that are applied for clinical used and they include α-fetoprotein (α-FP), CA125, and CEA[8].

The aim of this research is to study the sensitivity of CA125,CA15-3, CA19-9, CEA, NSE, and α-FP in the both pleural effusion and as cites andto diagnose their metastatic cancer in comparison with cytology .

Method

This research is prospective study, and it included entire 98 patients who admitted to Al-Hilla Surgical Teaching Hospital, 42 patients with pleural effusion and 56 patients with as cites. The study is done in period between January/2016 to September/2018.

The biochemical (sugar and protein analysis), direct smears, tumor markers tests (CA125,CA15-3, CA19-9, CEA, NSE, and α-FP), and cytology are done for diagnosis of metastatic cancer causing both effusions, andapproved by clinical findings.

Benign ascitic and pleural fluid patients shows inflammatory or tuberculosis cytology.Malignant ascitic and pleural fluid is approved by positive cytology or previous diagnosis by histopathology.

Cut off value of tumor markers according to the company kits are CEA: <2.5ng/ml, CA125: <35U/ml, CA19-9: < 30U/ml, CA15-3: < 30U/ml, α-FP: < 10U/ml, NSE : < 12.5 ng/ml. This cut value are represent the upper normal limit healthy individuals .

The 98 patients are divided into 70 male and 28female with age group that ranging between 40-80 years old.

The pleural and peritoneal fluid samples are divided into two specimens, one fluid specimen for cytology and other samples for measurement of fluid tumor markers level.

The statistical evaluation of present research was using SPSS software (version 22) . Continuous data are calculated as median, mean±SD, and range. Pearson´s chi square (X2) and Fisher's Exact Test are valued to demonstrate the association between categorical data. *P* value ≤ 0.05 is regarded as significant.

Results

The among 98 patients, 42 patients with pleural effusion are divided into 16 (38.1%) and 26 (61.9%) for benign and malignant effusion respectively, and 56 patients with as cites are 33(58.9) and 23(41.1%) for also benign and malignant as cites.

The age group 71-80 is the higher percentage that demonstrate 50% and 53.8% in benign and malignant pleural effusion respectively, at the same time, the male is more percentage than female. While,patients with as cites, there are the similar findings regarding age group 71-80 and gender male (Table 1).

Table 1: Association of age and gender with benign and malignant effusion in both pleural and ascitic sites .

Parameters		Benign Pleural Effusion N(%)	Malignant Pleural Effusion N(%)	P Value
Age (Binned group) (years old)	40-50	2(12.5%)	2(7.7%)	*0.545
	51-60	4(25%)	3(11.5%)	
	61-70	2(12.5%)	7(26.9%)	
	71-80	8(50%)	14(53.8%)	
Gender	Male	10(62.5%)	21(80.8%)	*0.281
	Female	6(37.5%)	5(19.2%)	
		Benign ascitic fluid N(%)	**Malignant ascitic fluid N(%)**	**P Value**
Age (Binned group) (years old)	40-50	6(18.2%)	4(17.4%)	^0.849
	51-60	7(21.2%)	5(21.7%)	
	61-70	7(21.2%)	6(26.1%)	
	71-80	13(39.4%)	8(34.8%)	
Gender	Male	24(72.7%)	15(65.2%)	^0.548
	Female	9(27.3%)	8(34.8%)	

*Fisher's Exact Test, ^Pearson chi-Square

Most tumor markers (in comparison benign and malignant cases) of ascitic fluid (CEA, CA125, CA19-9,and CA15-3) show more significant difference (P value =0.009, 0.003, 0.003, and 0.064 respectively), in contrast to pleural effusion are also had association but less significant *P* value (CEA= 0.016, and CA15-3=0.033).

In other side, cytology reveals highly significant association in both pleural and ascitic fluid (P =0.001 and 0.000 respectively)and with its value has higher level in positive malignant of both fluid (Table 2).

Table 2: Comparison of tumor markers and cytology between pleural and ascitic fluid regarding their etiological bases (benign and malignant).

Tumor markers	Benign pleural effusion N(%)		Malignant pleural effusion N(%)		P Value
	Positive	Negative	Positive	Negative	
CEA(ng/ml)	0(0%)	16(100%)	8(30.8%)	18(69.2%)	*0.016

Cytology	1(3.1%)	32(96.9%)	15(65.2%)	8(34.8%)	^0.000

*Fisher's Exact Test, ^Pearson chi-Square

Tumor markers are generally low level of sensitivity and high specificity (100%). Sensitivity and accuracy are more in pleural fluid CEA (30.8% and 57.1%), CA15-3 (26.9%,54.8%), and CA125 (23.1%,52.4%) respectively. However, both ascitic fluid CA125 and CA19-9 have upper value in sensitivity and accuracy (26.1%, 69.6%). Cytology is important parameter in differentiate between malignant and benign pleural and ascitic fluid. Sensitivity and specificity of cytology in ascitic fluid (65.2%, 96.9%) are more than pleural effusion (57.7%,93.8%)respectively (Table 3).

Table 3: Tumor markers and cytology are measured by sensitivity, specificity, positive predictive, negative predictive, and accuracy in both pleural effusion and ascitic fluid.

Markers	Sensitivity %	Specificity %	Positive predictive value %	Negative predictive value %	Accuracy %
Pleural Effussion					
CEA (ng/ml)	30.8%	100%	100%	47.1%	57.1%
CA125 (U/ml)	23.1%	100%	100%	44.4%	52.4%
CA19-9 (U/ml)	15.4%	100%	100%	42.1%	47.6%
CA15-3 (U/ml)	26.9%	100%	100%	45.7%	54.8%
α-FP (U/ml)	3.8%	100%	100%	39.0%	40.5%

Markers	Sensitivity %	Specificity %	Positive predictive value %	Negative predictive value %	Accuracy %
NSE (ng/ml)	3.8%	100%	100%	39.0%	40.5%
Cytology	57.7%	93.8%	93.8%	57.7%	71.4%
Ascitic Fluid					
CEA (ng/ml)	21.7%	100%	100%	64.7%	67.9%
CA125 (U/ml)	26.1%	100%	100%	66.0%	69.6%
CA19-9 (U/ml)	26.1%	100%	100%	66.0%	69.6%
CA15-3 (U/ml)	13.0%	100%	100%	62.3%	64.3%
α-FP (U/ml)	8.7%	100%	100%	61.1%	62.5%
NSE (ng/ml)	0%	100%	0%	58.9%	58.9%
Cytology	65.2%	96.9%	100%	78.0%	83.9%

Table 4 shows that combination of tumor markers alone without cytology yield no change or may be lower value of sensitivity specificity, positive predictive, negative predictive, and accuracy but the *p* value is highly significant more than the *p* value in Table 2 when the tumor markers and cytology are alone without combinations.

Table 4: The combination tumor markers and cytology are analyzed by statistical parameters level (sensitivity, specificity positive predictive, negative predictive, accuracy, and p value) in both pleural effusion and ascitic fluid.

Tumor Markers	Sensitivity %	Specificity %	Positive predictive value %	Negative predictive value %	Accuracy %	P value
Pleural effussion

Discussion

The ascitic effusion hasetiological risk of malignancy, the cytology is main non-invasive procedure for diagnosis such disease, but this procedure is resulting 30%-50% negative test in malignant as cites, and this negative result in cytology is overcome or decrease by using laparoscopy [9] .

It recommended that combined ascitic CEA with cytologymay helpful in distinction between benign and malignant as cites and this must be done with each doubtful malignant patient when cytology is negative[10]. In present study, that combination of many tumor markers with cytology leads to increase sensitivity of these markers. So combination of CEA and CA19-9 with cytology in as cites lead to change sensitivity from21.7%

and 26.1% to 43.5% and 45.7% respectively.*P* value is alsochanged from 0.016 and 0.28 to 0.00 and 0.00 for CEA and CA19-9 respectively and it is become highly significant.

In compared to other studies with as cites, Sari et al[11] found sensitivity and specificity in as cites for CA19-9 are 19% and 94.5% respectively.Kaleta et al[12] got sensitivity and specificity for CEA are 31% and 95%; for CA19-9 are 30% and 95%; and forα-FP are 17% and 95% respectively. Jume et al[13] has results that sensitivity and specificity in as cites for CA125 are 39.7% and 98.8% respectively.Fang et al[4] found sensitivity and specificity for CA15-3 are 23.4% and 98.56% respectively. Fang et al[4] and Jume et al[13] found that sensitivity of cytology in as cites are 56.81% and 65.5% respectively.So the reflection idea from our (in table 3 and table 4) and these above data in as cites, the sensitivity of these tumor markers is low to be diagnostic for malignant as cites, but their specificity are high enough to exclude malignant as cites. In our study, The higher accuracy is for cytology (83.9%)to differentiate between benign and malignant ascitic fluid.

Also, we compared to other studies with pleural effusions,Q-L Laing et al[14] shows that sensitivity ranges of CA125,CA15-3, and CA19-9 are 17%-100%, 30%-80%, and 13%-89% respectively, and their specificity are 50%100%, 75%-100%, and 73%-100% respectively, and this is approximately similar to our result (table 3). Gulden etal[15] use cut off value of kit company (similar to our study) to yield diagnostic role of CEA, CA15-3, CA19-9, and CA125 in pleural effusions because most of studies (above researches) is depend on using receiver operator characteristic analysis to give the highest sensitivity and specificity in association with specific tumor marker concentration.

Gulden et al[15] demonstrate that sensitivity of CEA, CA15-3, CA19-9, and CA125 are 41.66%, 38.8%, 25.7%, and 85.7% respectively. Their specificity are 100%, 100%, 92.4%, and 41.2%respectively, this is slightly difference from our result except for CA125 that show highly difference in sensitivity and specificity (table 3). Also, Gulden et al[15] combined many tumor markers to show if there changing in sensitivity and result that sensitivity of CEA+CA15-3 and CEA+CA125are 28.6% and 31.4% respectively, this outcome value of this combination is proximate to our result that yield sensitivity 28.8% and 26.9% for CEA+CA15-3 and CEA+CA125respectively.

A combined unsuitable tumor markers may lead loss their efficacy for diagnosis and particularly when primary tumor was undiagnosed[5].

The sensitivity of pleural cytology examination in our study is 57.7%. many studies give similar result, Kjeldsberg et al [16]and Light et al [17] show that result of pleural cytology are 50%-60% and 70% respectively. This difference because the sensitivity level of cytology is correlated on the amount of good morphological cancer cells and cytopathologist skills and that is specifically for pleural effusion because problem in differentiation between normal (or reactive) mesothelial cells from malignant mesothelioma cells[18].

Several studies provide that relationship between tumor markers in benign andmalignant effusions (as cites and pleural fluid) are significant (comparable to our study) and those are Gulden etal[15] and Antonangela et al[5].

The conclusion of this study, tumor marker of both as cites and pleural effusion have low sensitivity and high specificity, and we cannot confirm malignant diagnosis with first result (low sensitivity)but we can exclude it (high specificity). Also, the combination tumor markers with each other and with cytology lead considerable increase in diagnostic efficacy of tumor markers but to be dependable level for malignant diagnosis and they can use as guide for invasive procedure to be highly diagnostic . The *P* value show association of tumor marker and cytology with both malignant effusions and this value is highly significant when there combination of tumor markers together and with cytology.

Finally, cytology remain the highest sensitivity (in compare to tumor markers) and it can be used as first line for investigation before invasivehistopathological examination.

Clinicopathological Evaluation of Odontogenic Tumors in Iraq (A Fifteen Years Retrospective Study)

Bashar H. Abdulla[1], Wasan H. Younis[1], Luay Hatem Jalil[2], Muna S. Merza[3]

[1]Professor (Ph.D.), Department of Oral Diagnosis, College of Dentistry, University of Baghdad, Iraq, [2]F.I.B.M.S. (Maxillo-Facial Surgeon),Department of Dentistry, Al-Rafidain University College, Iraq, [3]Professor (Ph.D.), Department of Oral Diagnosis, College of Dentistry, University of Baghdad, Iraq

Abstract

Background: The purpose of this study was to determine the occurrence of clinically and histopathological diagnosed odontogenic tumors during the period of 15 years in Iraqi population.

Materials and Method: A total of 3652 biopsy specimens from the histopathological report's archive of oral pathology laboratory in Oral Diagnosis Department/College of Dentistry/Baghdad University were assessed histologic finding of odontogenic tumors for 15-year (1999-2015) .Clinical data regarding age, gender, and site of lesions were collected from biopsy reports and patient's files.

Results: A total of 145 (3.97%) odontogenic tumors were reported. Ameloblastoma was very mutual odontogenic tumor 49(33.8%), thenkeratocystic odontogenic tumors 29 (20%), peripheral odontogenic fibroma 18 (12.4%), odontogenic myxoma13(9%), and odontoma 11(7.6%), only 5 cases (2.8%) had malignant change, (97.2%) of cases were benign. Odontogenic tumors occurred more in males with most cases appearing in the second and third decades of life. Conclusion: odontogenic tumorsshown a low incidence among oromaxillofacial lesions and low rate of malignancy changing.

Keywords: *Odontogenic Tumors; Clinicopathological Evaluation.*

Introduction

Odontogenic tumors (OTs) are uncommonobjects that set up a varied group of illnesses with different clinical and histopathological structures[1,2]. In 2005histological typing of this lesion and some pathological changes were update and renewing by WHO[3]. The Para keratinized variant of odontogenic keratocyst is considered one of common changing and update and now viewed as keratocystic odontogenic tumor (KCOT)[4,5]. Many articles and studies collected related to frequency and incidance of OT from different parts of world [6-11], but no one of these studies had data on prevalence of OT in Iraq. So the aim of this study was to define the frequency and prevalence of OTs as WHO classification from the histopathological report's archive of oral pathology laboratory in Oral Diagnosis Department/College of Dentistry/Baghdad University were assessed histologic finding of odontogenic tumors for 15-year (1999-2015) and to match these data with studies from further geographical areas of the world.

Method

The histopathological report's archive of oral pathology laboratory in Oral Diagnosis Department/ College of Dentistry/Baghdad University, were reviewed retrospectively for OTs from (1999-2015). Odontogenic tumors were categorized into 2 chief groups: benign plus malignant and 3 subdivisions based on the types of odontogenic tissues involved: epithelial odontogenic tumors (odontogenic epithelium with mature fibrous stroma, without odontogenic ectomesenchyme) (EOTs), mixed odontogenictumors (odontogenic epithelium with odontogenicectomesenchyme, with/without tissue formation) (MixOTs), and mesenchymal odontogenic tumors(mesenchyme and/or ectomesenchyme, with or without odontogenic epithelium) (MOTs). Demographic

variables: age, gender, type of histopathological changes and place were data collected. 2 anatomic areas, maxilla and mandible were allocated: anterior (begin from the midline and end to the distal surface of the 2nd premolar teeth), posterior (begin from the mesial surface of the 1st molar and end more distally). Our data was analysis by using SPSS 22, were P-value less than 0.05 considered significant.

Results:

Frequency:145 persons from 3652 patients were identified such as odontogenic tumors, frequency of OTs was 3.97% from total biopsied specimens, 140 patients (97.2%) were benign, while only 5 patients 5(2.8%) were malignant. So according WHO classification 95 patients (65.5%) identified as epithelial odontogenic tumors 19(13.1%) cases were mixedodontogenic tumors,and 31(21.4%) cases were mesenchymal odontogenic tumors. Ameloblastoma (AME) was the more common tumor 49 patients (33.8%) which involving of entirely histological kinds, followed by keratocystic odontogenic tumors (KCOT) 29 (20%), odontogenic fibroma (OF)18 (12.4%), odontogenic myxoma (OMYX) 13(9%), and odontoma (OD)11(7.6%).The rest were other tumors 25 (17.2%). (Figure 1,2,3).

Age and sex: Of the 145 odontogenic tumors patients, 79 (54.48%)were males and 66(45.52%) were females. According to the age of patients it is differ from 2 years old to 80 years old, mean 32.19 years. The most incidence rate of occurrence in 3rd decades of life then by 2nd decade, and most common OT occur in 2nd decade of life was KCOT, then AMEs. While most common OTs occur in 4th decade was AMEs. Regarding malignant OTs the five reported cases appeared to occur in later decades of life as show in tables (1,2).

Table (1): Occurrence frequency, gender, and gender ratio of OTs

Tumor type	Frequency		Male	Female	Male/Female ratio
	No.	%

Total	10	28	52	25	16	8	4	2	145

Location: the site distribution of OT revealed that the maxilla was exaggerated in 46(31.72%) cases while mandible in 93(64.13%) cases with five cases include both maxilla and mandible and the remaining two cases with no site mentioned in the available reports. The posterior region of the mandible appeared to be involved more than anterior region while the anterior maxillaarea was further main site than the posterior as show in table (3).

Table (3): Site distribution of OTs.

Discussion

OTs are originated from epithelial, mesenchymal and or ectomesenchymal basics of the tooth-forming system. These varied tumorseven though uncommon but carriage an important therapeutic as well asdiagnostic trial, so awareness offrequency and plain clinical structures have good use in diagnosis and management[10]. So many studies done in different countries shown significant geographic difference in the frequency of OTs [10,11,12,17,18]. In this study the frequency rate was (3.97%) of total oral lesions documented from January 1999 to December 2015, this results similar to study done in Asia (3.9%)[7], more than middle east (1.9%)[6], south America was (1.82%)[10,15], but in north America was (1.55%) and in Iran was (1.9%)[11]. but in south Africa was lower than this study (9.6%)[19], in India was (5.7%)[9], while in turkey was 7.38%[23]. In current study show that benign tumors are most common OTs, agreement with prior studies done in many countries wild word, while just five cases were malignant[6,7,8,9,10,11].Epithelial OTS were the most frequent subdivision of OTs followed by the mesenchymal ones .This finding come in agreement with previous reports from China, Egypt, Brazil, and

Libya,but in contrast to series from other countries like: USA, Mexico, Turkey[16,20,21-7,8,10,13].

In the present study, Ameloblastoma was the most frequent OT, followed by keratocystic odontogenic tumors, odontogenic fibroma, and odontogenic myxoma.

AME also considered the most common OTs this show in many studies done in many countries in middle east Asia and Africa in there population[6,8,9,13,14,17–19]. While another studies reported that KCOT was most common OTs[7,15,16,20].

According to the gender, male is more to have timers than female except in OF, OD and OMYX. This results is agiant the results appear in studies done in Iran, turkey, brazils and Mexico this studies show that females most have tumor than males except in AMEs and OFs [6,10,15,16] . while other studies done in India and China and Egypt show that malignant tumors were more significant and usual in males patients and agreed with this fact [7,9,17].

According to the age of patients it is differ from 2 years old to 80 years old, mean 32.19 years, the most incidence rate of occurrence in 3rd decades of life then by 2nd decade, this results agreed and similar to previous studied done in Iran [6].

and most common OT occur in 2nd decade of life was KCOT, then AMEs, disagree with other studies done in turkey show that OD was more common OTs occur in 2nd as well as 3rd decade followed by KCOT[23].

In current study AMEs was most common tumors occur in 4th decade of life this is agree with previous study from turkey displayed that usual and common OT in 5th as well as 6thdecades were AMEs plus KCOTs, this highly incidence of tumor in elderly age group may due to multicystic epithelial features of EOTs [23,12,21].

Regarding malignant OTs the five reported cases appeared to occur in later decades of life. In patient with OD, occur more in age group less than 30 years old, study done in turkey agreed with this results [23], but not agree with other studies done in many countries in world[6–8,10,11,14,15,18,20,22] the site distribution of OT revealed that the maxilla was exaggerated in 46 (31.72%) cases while mandible in 93(64.13%) cases, this is more occur inmandibular lesions, with exception for complex odontomas, the maxilla to mandible proportion (3:6.5) this is similar to studies done in many sites in world[10,13,15,16,20].

Data obtainable in the patients withtumor placedposteriorly or anteriorly was very limited, so AMEs showed highly significant of occurrence in posterior part of mandible, while OD occurred more in anterior part of the maxilla, this results agreed and similar to study done in other countries [7, 8, 13, 15, 16, 20, 23].

Conclusion

The present study provides epidemiological information about relative frequency of OTs, which in relation to other geographical areas revealed great variation that may be attributed to socioeconomic and genetic factors.

Retrospective studies of the frequency of OTs and tumors in many region in world will help the examiner (pathologist, maxillofacial surgeon) to understanding this lesions and managing it.

Prevalence of bla_{VIM}, bla_{IMP} and bla_{NDM} Genes in Carbapenem Resistant Pseudomonas Aeruginosa Isolated from Different Clinical Infections in Diyala, Iraq

Lina Abdulameer S. Alsaadi[1], Abbas Abood F. Al-Dulaimi[2], Hadi R. Rasheed Al-Taai[3]

[1]Post Graduate, Lecturer, Department of Biology, College of Sciences, [2]Prof. Dr. Department of Biology, College of Education for Pure Sciences, [3]Prof. Dr. Department of Biology, College of Sciences, Diyala University, Iraq

Abstract

The study aimed to determine the prevalence of *bla*-genes *(bla_{IMP}, bla_{VIM}* and *bla_{NDM})* encoding MBLs among the isolates of *P. aeruginosa*, which were recovered from various clinical samples from hospitalized patients in Diyala hospitals. This study was carried out during the period from February 2018 to August 2018. Out of 326 specimens, 81 isolates of *P. aeruginosa* were recovered. All isolates were tested toward the different class of clinically important antipseudomonal agents(18) by using agar diffusion method. The results of resistance were as following: piperacillin 74.07, ticarcillin 85.18%, Amoxicillin-Clavulanic acid 93.82%, Ticarcillin/clavulanic acid 71.60%, ceftriaxone 87.65%, cefotaxime 85.18% and ceftazidime 75.30%, cefepime 80.24%, streptomycin 90.12%, gentamicin 85.18%, tobramycin 65.43%, amikacin 56.79%, ciprofloxacin 67.90%, levofloxacin 72.83%, oflaxacin 69.13%, Aztreonam 50.61%, Imipenem 11.11% and Meropenem 23.45%.In this investigation, antibiotic susceptibility testing of the *P. aeruginosa* isolates showed that 20(24.69%), 25(30.8%), 27(33.33%), and 9(11.11%) of the isolates were MDS, MDR, XDR and PDR, respectively. Based on the results from susceptibility testing, 19 (23.45%) of *P. aeruginosa* isolates were found to be resistant to at least one of carbapenems. Out of 19 of carbapenem resistant *P. aeruginosa*isolates, 16 (84.21%) were found to produce MBL.Among 16 phenotypic Metallo β-lactamase isolates the results achieved by using PCR revealed that 9 (56.25%) isolates have bla_{VIM} genes, while 4 (25%) isolates carried bla_{NDM}genes. No bla_{IMP} was detected among carbapenem resistant strains in this study.

Keywords: *P. aeruginosa, Antimicrobials, Carbapenems, MBL, bla_{VIM}, bla_{IMP}, bla_{NDM}.*

Introduction

Pseudomonas aeruginosa strains, especialy multidrug-resistant, have caused serious problems in many countries, including Iraq. The increasing prevalence of nosocomial infections produced by multidrug-resistant (MDR),extensively drug resistant (XDR) and pandrug-resistant (PDR) *Pseudomonas aeruginosa* strains poses a grim challenge forantimicrobialtherapy[1]. *P. aeruginosa* is an opportunistic pathogen involved in many infections worldwide, such as respiratory infections, urinary tract infections, hospital-acquired pneumonia, wound and soft tissue infections, and bacteremia in immunocompromised patients, including patients with thermal injuries[2,3]. *Pseudomonas aeruginosa* infections are problematic due to its intrinsic as well as acquired resistance to many effective groups of antibiotics [4].

Carbapenem resistance among clinically isolated *Pseudomonas aeruginosa* is a great concern worldwide, as this class of antibiotics is among the last resorts to eradicate infections with Gram-negative species [5]. The prevalence of multidrug-resistant *P. aeruginosa* (MDRP) non-susceptible to quinolones and aminoglycosides in addition to beta-lactams is reported worldwide [6]. Carbapenems are β-lactam antibiotics. It binds to pencillin binding proteins (PBP) and hinder the production of cell wall of microorganism [7].*Pseudomonas aeruginosa* isolates acquire resistance to carbapenems via several

mechanisms including overexpression of efflux systems, change or lack of outer membrane proteins (such as OprD porin), chromosomal AmpC beta-lactamase, production of carbapenemases and production of metallo-β-lacramases (MBLs). The presence of these mechanisms can lead to treatment failure in Carbapenem therapy of *P. aeruginosa* infections overall named heteroresistance[8]. The most important carbapenemases produced by *P. aeruginosa* are zinc-dependent metallo-beta-lactamases (MBLs) capable of hydrolyzing imipenem, meropenem, ertapenem, and cephalosporins, but not monobactams and aztreonam[9]. There are various MBL genes among carbapenem-resistant *P. aeruginosa* including Verona integron-encoded MBL (VIM), imipenemase (IMP), Germany imipenemase (GIM), New Delhi MBL (NDM), Sao Paulo MBL (SPM), and Florence imipenemase (FIM)[10].

Genes responsible for the MBL productions in *P. aeruginosa* are typically part of an integron structure and are carried on transferable plasmids or transposons, but also might be a part of chromosomes. Accordingly, due to its integron-associated genecassettes, *P. aeruginosa* isolates producing MBL are capable for resistant to the several antibiotics in addition to carbapenems, causing the advent of MDR *P. aeruginosa*. Moreover, these genetic determinants are transferable to other Gram-negative species, extending the antimicrobial resistance rate and complicating the treatment of infected patients [11]. MBL-producing organisms infections is linked with greater rates of mortality, morbidity, and healthcare costs.The international epidemiology of MBL-producing *P.aeruginosa* is still unknown in most countries [12], which at least due to partly lack of proper screening and recommendations.Therefore, it is necessary tounderstand theepidemiology, molecular characteristics, and resistance mechanism of Metallo-β-lactamase-producing *Pseudomonas aeruginosa* (MPPA) to control infection and prevent a possible global health crisis. However, little information is available on the distribution of MBL producing isolates and colonal infections with these isolates in Diyala, Iraq. The aim of this study was to determine the prevalence of *bla*-genes (bla_{IMP}, bla_{VIM} and bla_{NDM}) encoding MBLs among *P. aeruginosa* isolated from clinical specimens in some hospitals in Diyala.

Materials and Method

Isolation and Identification of Bacterial Isolates: A total of (326) clinical specimen from both gender with different age were collected from the beginning of February 2018 to the end of August 2018, from patients in different hospitals of Baquba city. The isolates were identified by their colony characteristic, gram-stain and confirmed by the pattern of biochemical profiles using Vitek 2-GN system.

Antibiotic Susceptibility Testing: To estimate potential resistance of *P. aeruginosa* isolates against 18 items of antibiotics from different classes, all isolates had been subjected to antibiogram test according to (CLSI-2017)[13], for Pipracillin, Ticarcillin, Amoxicillin-Clavulanic acid, Ticarcillin/clavulanic acid, Cefotaxime, Ceftriaxone, Ceftazidime, Cefepime, Ciproflxacin, Levofloxacin, Oflaxacin, Gentamicin, Amikacin, Tobramycin, Streptomycin, Aztreonam, Imipenem and Meropenem.Detection of *P. aeruginosa* phenotypes based on the drug resistance patterns. Multidrug-resistant (MDR) phenotype is defined as *P. aeruginosa*, which is resistant to more than one antimicrobial agent in three or more antimicrobial categories. Extensively drug-resistant (XDR) phenotype is defined as *P. aeruginosa*, which is resistant to more than one antimicrobial agent in all the antimicrobial categories, except in two or less. Pan drug-resistant (PDR) phenotype is defined as a bacterium which is resistant to all antimicrobial agents in all antimicrobial categories.

Phenotypic detection of MBL: Imipenem-EDTA combined disc test (CDST) was used for identification of MBL-producing isolates according to [14].

DNA Extraction and polymerase chain reaction (PCR) amplification: Genomic DNA was extracted from isolates using extraction Kits of Genomic DNA, Purification depending on instruction of manufacturing company (Promga USA).All carbapenem-resistant isolates were screened by standard PCR conventional using specific primers for bla_{IMP}, bla_{VIM} *and* bla_{NDM}genes as shown in table (1). PCR reaction tubes were transferred into thermal cycler that was programmed as following: initial denaturation for 5 mints at 95°C, (the conditions for each cycle were: 30 sec. at 94 C̊, 30 sec. at 54, 55, 60°C and 30 sec. at 72°C), and final extension at 72°C for 5 mints. Amplified PCR products were detected by agarose gel electrophoresis.

Table (1): The primers used for MBLs genes detection

Primer	Oligo sequence (5'-3')	Product size bp	Annealing temp°C	Reference
bla_{IMP}	F-5` CTACCGCAGCAGAGTCTTTG3` R-5` AACCAGTTTTGCCTTACCAT3`	587	54	15
bla_{VIM}	F-5`-GTTTGGTCGCATATCGCAAC-3` R-5`-AATGCGCAGCACCAGGATAG-3`	384	55	16
bla_{NDM}	F5`-AATGGAATTGCCCAATATTATGC-3` R-5`-CGAAAGTCAGGCTGTGTTGC-3`	491	60	17

Statistical Analysis: Statistical analysis was performed with Graph Pad Prism version 6 software,percentages were used for the comparison between samples of the study. Dataanalysis was done using Chi-square for the comparison of categorical data.

Results and Discussion

A total of 81 clinical isolates of gram negative bacteria primary identified as *Pseudomonas aeruginosa* were collected from different clinical sources.The source of these isolates were as follows : 24(29.62%) isolates from Wounds, 21(25.92%) isolates from Burns,17 (20.98%) isolates from urine, 13 (16.04%) isolates from ears and the last 6 (7.40%) isolates from sputum.

Antimicrobial Sensitivity Test: Eighty one *P. aeruginosa* isolates were screened for their resistance to 18 different types of antibacterial agents .Results in table (2) show that isolate varied in their resistance and sensitivity to the antibiotics. It was found high resistance tobeta lactams, aminoglycosidesandflouroquinolones. Resistance to monobactam was moderate when 50.61% of isolates being resistant to aztreonam. While the lowest resistance was observed for carbapenems. Profile of antibiotic resistance to other antibiotics is shown in table (2). In this investigation, antibiotic susceptibility testing of the *P. aeruginosa* isolates showed that 20(24.69%), 25(30.8%), 27(33.33%), and 9(11.11%) of the isolates were MDS, MDR, XDR and PDR, respectively.

Table (2): Antibiogram susceptibility of Pseudomonas aeruginosa isolates

Antibiotic	Resistant isolates No. & %	Sensitive isolates No. & %	p-valuea
Pipracilin	60 (74.07%)	16 (19. 75%)	0.008
Ticarcillin	69 (85.18%)	9 (11.11%)	0.005
Ticarcillin/clavulanic acid	58 (71. 60%)	17 (20.98%)	0.009
Amoxicillin/Clavulanic acid	76 (93.82%)	4 (4.93%)	0.001
Cefotaxime	69 (85.18%)	8 (9.87%)	0.005
Ceftriaxone	71 (87.65%)	5 (6.17%)	0.004
Ceftazidime	61 (75.30%)	18 (22.22%)	0.008
Cefepime	65 (80.24%)	12 (14.81%)	0.017
Ciprofloxacin	55 (67.90%)	26 (32.09%)	0.073
Levofloxacin	59 (72.83%)	22 (27. 16%)	0.056
Oflaxacin	56 (69.13%)	18 (22.22%)	0.042
Gentamicin	69 (85.18%)	10 (12.34%)	0.008
Amikacin	46 (56.79%)	27 (33.33%)	0.051
Tobramycin	53 (65.43%)	17 (20.98%)	0.038
Streptomycin	73 (90.12%)	6 (7.40%)	0.007
Aztreonam	41 (50.61%)	30 (37.03%)	0.064
Imipenem	9 (11.11%)	65(80.24%)	0.023
Meropenem	19 (23.45%)	50 (61.72%)	0.038

a: P-value was calculated using the Chi-square test in terms of the R & S group.

Pseudomonas aeruginosa isolates across countries are increasingly resistant to a higher number of antimicrobial agents. Ali [18] described that among 60 isolates of *P. aeruginosa*, 30% resist to 14 different antibacterial agents. Study by Tawfeeq[19] in Iraq revealed that resistance percentage to Cefotaxim (60.34%) and Pipracillin (59.48%).Results conducted in current study agreement with Al-Wasity [20] who reported that *P.aeruginosa* isolates from Baghdad hospitals developed resistance to different antibiotic classes, including flouroquinolones in high resistance rates were 64.5%, 74.2% of isolates resistant to ciprofloxacin and Levofloxacin, respectively.

Based on the results from susceptibility testing, 19 (23.45%) of *P. aeruginosa* isolates were found to be resistant to at least one of carbapenems. Susceptibilities of the isolates to imipenem and meropenemare listed in table (2). Imipenem showed better activity (72.83%) thanmeropenem (61.72%) in study period. Resistance for carbapenems by disk diffusion was originating in 9(11.11%) isolates for both meropenem and imipenem, and in 10 (12.34%)isolates for meropenem alone, respectively.

Metallo β-lactamase production in P. aeruginosa: All *P. aeruginosa* isolates that were resistant to carbapenems (n=19) were further investigated for the presence MβLs genes. Among 19 isolates of *P. aeruginosa* 16 (84.21%), of the isolates were MBL producers, the remaining *P. aeruginosa* isolates 3 (15.78%) were non-MBL producers (Fig. 1).

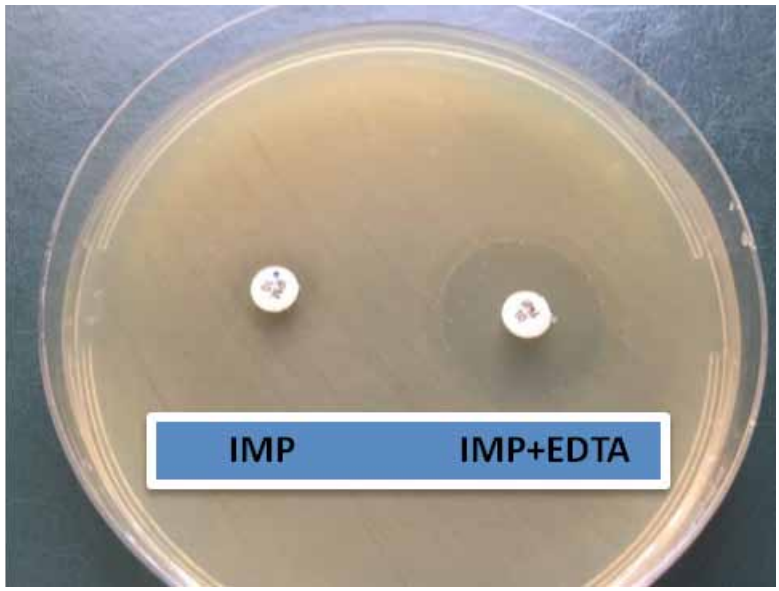

Figure (1): Combined disc diffusion test MBL positive

In the present study, 84.21% of carbapenem resistant *P. aeruginosa* isolates have Metallo β-lactamase, and this result agreed with Al-Shara[21] who found that 78% of carbapenem resistant *P. aeruginosa* isolates from patients have MBL enzyme, also agreed with Kazeminezhad [16], who demonstrate 73% of carbapenem resistant isolates in have MBL enzyme inTehran/Iran.Early detection of these MBL producing isolate in a routine laboratory could help to avoid treatment failure, as often the isolates producing this enzyme show a susceptible phenotype in routine susceptibility testing.

Molecular detection of MBLs genes: Among 16 phenotypic Metallo β-lactamase isolates the results achieved by using PCR revealed that 9 (56.25%) isolates have bla_{VIM} genes (Fig. 2), while 4 (25%) isolates carried bla_{NDM}genes (Fig. 3).No bla_{IMP} was detected among Imipenem resistant strains in this study.The percentage of bla_{VIM}gene in the current study was higher than previous study in Saudi Arabia wasnoted bla_{VIM} appearedin 29.4% of isolates [22]. In another study in Some Hospitals in Bagdad (60%) of isolates carried bla_{VIM} genes, this result agreed with current study[23].

While studyin Wasit province by[24]showed that 94.44% percentage of carbapenems resistant *P. aeruginosa* isolates have bla_{VIM}gene,this result disagreed with current study.

The percentage of bla_{NDM} genein the current study was lower than previous studyinIraq by[25],showed that 50% percentage of carbapenems resistant *P. aeruginosa* isolates have bla_{NDM} gene. In Slovakia, study was reported bla_{NDM} gene in 6 isolates(20%).

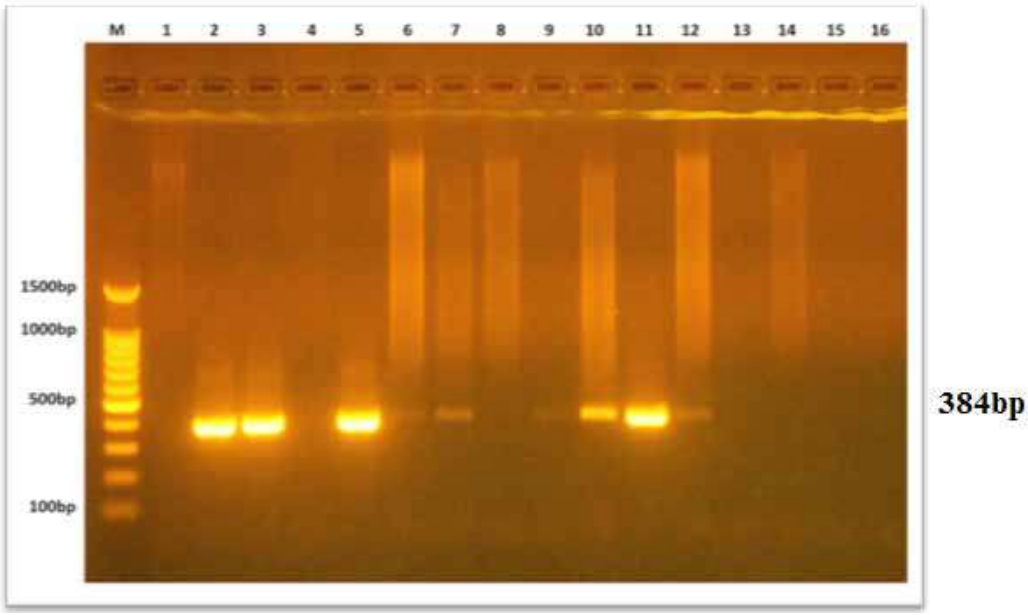

Fig. (2): Gel electrophoresis of amplified PCR product for the detection of MβLbla$_{VIM}$ gene (384bp) run on 1% agarose (90 min at 70 volt), stained with ethidium bromide, lane 1-16 P. aeruginosa isolates; M:Marker DNA ladder (100bp); Lanes 2, 3, 5, 6, 7, 9, 10, 11, 12 positive for bla$_{VIM}$

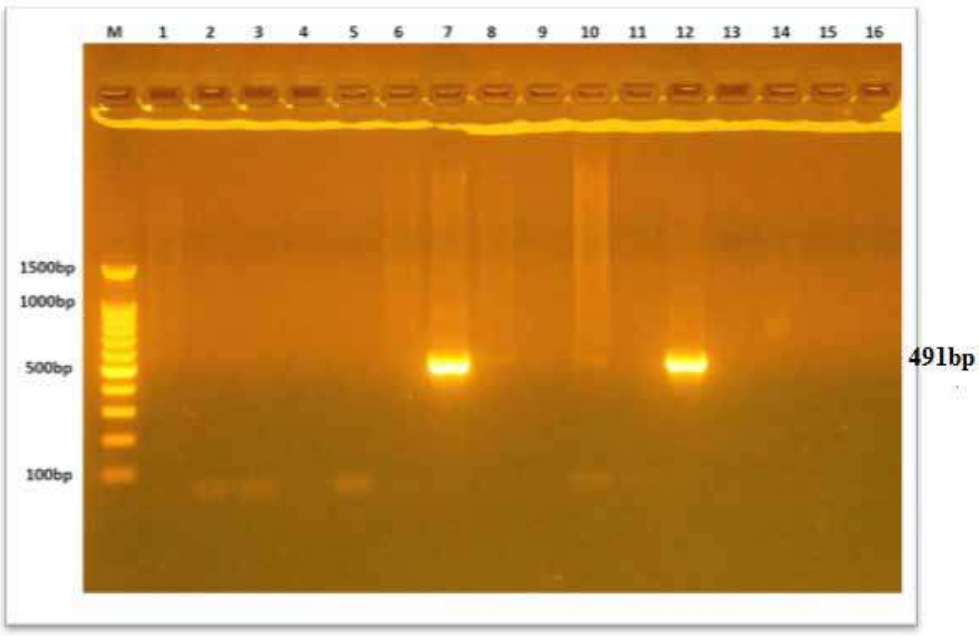

Fig. (3): Agarose Gel electrophoresis of amplified PCR product for the detection of MβLs bla$_{NDM}$ gene (491bp) run on 1% agarose (90 min at 70 volt), stained with ethidium bromide, lane 1-16 P. aeruginosa isolates; M: Marker DNA ladder (100bp); Lanes 7, 8, 10, 12 positive for bla$_{NDM}$.

Conclusions

We can conclude Rate of occurrence of bla_{VIM} and bla_{NDM} producers was highest amongcarbapenem-resistant *Pseudomonas aeruginosa* isolated from clinical samples in Diyala hospitals. Therefore, the detection of bla_{VIM} *and* bla_{NDM} positive *P.aeruginosa* isolates in this study indicates importance of strengthening surveillance toprevent the nosocomial infection and dissemination of *bla*genes in Diyala.

Estimation of Caspase-8 in Patients with Systemic Lupus Erythematous and it is Relationship with Disease's Activity

Amna Esmaeel Al-araji[1], Sawsan M. Jabbar AL-Hasnawi[2], Ali alkazzaz[3], Shawqi Watheq Mohammed Ali[4]

[1]Department of Medical Microbiology and Immunology, College of Medicine, University of Kerbala, Kerbala, Iraq, [2]Al-Hussein Medical City, Kerbala, Iraq, Al-sader Medical City and Al-Hakeem hospital, Al-Najaf, Iraq and Merjan Medical City, Babyl, Iraq

Introduction

Many research groups studied the relationship between SLE & apoptosis as some enzymes of apoptosis considered to be the cause of relapsing of disease, such as caspases 8 & 3. So the correlation between both is still a debate issue. This study aimed to: Assess level of caspase-8 among SLE patients. This done by:

1. Measurment of caspase 8 level by ELISA technique.
2. Clarify the relationship between caspase 8 levels and SLE activity by measuring ds-DNA and ANA levels.

Method: Subjects enrolled in this study were categorized into two groups: patients and control groups, The patients were of both sexes with ages ranging from (10-55 year),The study carried out during the period from December, 2017 through August, 2018. This study was conducted on patients attending Al-Sadder Medical City, AL Hakeem General Hospital in Al-Najaf, AL-Hussein Medical City in Karbala and Marjan Medical City in Babyl, All these provinces in Iraq. From the Rheumatology and Nephrology out clinics in those hospitals. Forty Five patients (5 males & 40 females), Collect appropriate amount of blood from each patient for: Assessment of ds- DNA and ANA. Assessment of apoptosis marker (caspase-8) using ELISA technique.

Results: The level of caspase 8 show significant correlation among patients with SLE than control (P. value = 0.023) . furthermore,ANA and ds-DNA were high significant in patients compare with control (P-value < 0.001 and P. = 0.001) respectively .

Keywords: *Caspases-8; systemic lupus erythmatosus; Apoptosis; ds-DNA; ANA.*

Introduction

Systemic lupus erythematosus (SLE) is an auto-immune disease with a wide spectrum of clinical immunological abnormalities[(1)].A characteristic hallmark of SLE is the production of autoantibodies against nuclear components[(2)].To understand the pathogenesis of SLE it is important to know how self antigens become available and immunogenic to immune system, many researchers believed that apoptosis play a crucial role in autoimmunity, including SLE[(3)]. Disturbances in apoptosis and any defect in clearance of apoptotic cells, increases exposure of modified autoantigens to the immune system[(4)]. Apoptosis is a programmed cell death that follows characteristic biochemical and morphological features. Apoptosis can be induced by extrinsic (e.g., Fas ligand), or intrinsic factors (e.g., DNA damage)[(3)].Accompanied with changes in chromatin structure and composition[(5)]. cells finally disintegrate into apoptotic blebs[(6)]. These stimuli

lead to activation of caspases and changes in the plasma membrane[7].SLE Disease Activity Index (SLEDAI), developedat the University of Toronto in 1992, is a global scorereflecting all aspects of disease activity[8]. SLEDAI has certainlimitations in that it does not score some life threateningmanifestations such as pulmonary haemorrhage andhaemolyticanaemia. It is heavily weighted for centralnervous system and does not take into account theseverity of manifestations. Gladman et al[9].definedthat an increase in SLEDAI score of more than threewas a flare, SLEDAI score that was within three pointsof the previous score was persistent disease and a scoreof zero was remission. A change of SLEDAI score ofmore than 12 is a severe flare according to another study[10,11].The mechanism between caspase-8 and SLE is complicated,The level of caspase-8 have an inverse relationship with the activity of the disease, So the current study aimed to: Assess level of caspase- 8 among SLE patients.This done by:

1. Measurment of caspase 8 level by ELISA technique.
2. Clarify the relationship between caspase 8 levels and SLE activity by measuring ds-DNA and ANA levels .

Subject and Method

Study Population: Patients group: This study was conducted on patients attending Al-Sadder Medical City, AL Hakeem General Hospital in Al-Najaf, AL-Hussein Medical City in Karbala and Merjan Medical City in Babyl these provinces in Iraq. From the Rheumatology and Nephrology out clinics in these hospitals. Forty Five patients (5 males & 40 females) with age range between 10-55 years, and duration of disease between 1 year -25 years included in this study who were clinically checked by Specialist and laboratory diagnosed as SLE.

Control group For the purpose of comparison,a group of 45 (5 males and 40 females) apparently healthy control persons were included(healthy, normal subjects with no family history of SLE, without any medical disease and chronic disease) with age range between 10-55 years. Their age ranges and gender is matched to that of patients. All groups (patients & control) have been informed about the study and its aims and their agreement were taken.

Specimen collection: Five ml of venous blood were drawn from each patients and control groups, collected in gel tubes, slow withdrawal of the blood sample via the needle of syringe to prevent hemolysis. The sample dropped into clean disposable gel tube, serum was separated after 20 minutes at room temperature The samples were then centrifuged at 3500 rpm for 5 minute and then stored in to separated three eppendorf tubes at freeze condition(-20C) until analyzed. Assessment of ANA, dsDNA and Assessment of apoptosis marker (caspase-8).

Laboratory Assays:

Kits	Sourse
Human CASP3 (Caspase 3) ELISA Kit	Elabscience
Human CASP8 (Caspase 8) ELISA Kit	Elabscience
dsDNA-G Kit	CHORUS
ANA- screen Kit	CHORUS
(C4) Kit	Genrui
(C3) Kit	Genrui

Statistical Analysis: Data of both studied groups were entered and analyzed using the statistical package for social sciences (SPSS) version 25. Descriptive statistics presented as mean, standard deviation, standard error, range, frequencies and proportions. All continuous variables were tested for statistical normal distribution using histogram and normal distribution curve, statistical tests were applied according to the distribution and type of variables. Student's t test for two independent samples was used to compare two means of a continuous normally distributted variable, and Mann-Whitney U test for two independent samples was used to compare non-normally distributtedcontineous variables. Chi-square and Fisher's exact (when chi-square inapplicable) tests used alternatively to compare frequencies. Bivariate Pearson's and Spearman's correlation test, and regression curve estimation analysis were used to assess the correlations. Correlation coefficient (R) is an indicator of the strength and direction of correlations; its value ranged zero (complete no correlation) to one (perfect correlation) the higher R value close to one indicated stronger correlation, the positive (no sign) R value indicated a direct (positive) correlation and the negative signed R indicated an inverse correlation. Level of significance of ≤ 0.05 was considered as significant difference or correlation. Results and findings were presented in tables and figures with explanatory paragraphs using the Microsoft Office 2010 for windows.

Results

The mean caspase 8 of SLE patients was (27.73±1.16) which was significantly lower than that

of controls which was (30.51±1.21), (P. value = 0.023), (Table 6).

Table 6. Comparison of Caspase-8 levels of SLE patients and controls

Caspase 8	SLE Patients (n = 45)	Controls (n = 45)	P. value
Mean	27.73	30.51	0.026 Mann-Whitney U test
SE of Mean	1.16	1.21	
Minimum	3.56	19.01	
Maximum	32.92	32.92	

The comparisons of mean Antinuclear Antibodies (ANA) levels of SLE patients and controls revealed that SLE patients had significantly much higher mean ANA than controls, 6.41±0.69 and 0.92±0.41, respectively, (Table 2), (P<0.001).

Table 2. Comparison of ANA levels of SLE patients and controls

ANA	SLE Patients (n = 45)	Controls (n = 45)	P. value
Mean	6.41	0.92	< 0.001 Mann-Whitney U test
SE of Mean	0.69	0.41	
Minimum	0.40	0.22	
Maximum	12.00	2.30	

The mean Anti ds-DNA antibodies level in SLE patients was significantly higher than in controls, (74.59±11.02) and (11.37±4.69), respectively, (P.value = 0.001), (Table 3)

Table 3. Comparison of Anti ds-DNA levels of SLE patients and controls

Anti ds-DNA	SLE patients (n = 45)	Controls (n = 45)	P. value
Mean	74.59	11.37	0.001 Mann-Whitney U
SE of Mean	11.02	4.69	
Minimum	7.00	7.00	
Maximum	180.0	35.5	

Discussion

Based on recent findings as described above, our work focused on the association the caspase 8 and immunological marker of SLE.

Apoptosis is a highly controlled process (12), and plays an important role in pathogenesis of SLE. In current study, we examined the level of Caspase-8 in seria patients and control using and protein levels using ELISA technique and aclarify the relationship between caspase 8 levels and SLE activity by measuring ds-DNA and ANA levels.

The current study, found that the main first result is comparisons of mean Antinuclear Antibodies (ANA) levels of SLE patients and controls revealed that SLE patients had significantly much higher mean ANA than controls.

The main second result is the mean Anti ds-DNA antibodies level in SLE patients was significantly higher than in controls.

The main third result is the mean caspase 8 of SLE patients was significantly lower than that of controls which was, (P. value = 0.023), (Table 6) which was consistent with our results[13]showed that the expression level of FasL, caspase 8 was decreased in SLE patients and in female, which was in agreement with the results of some previous studies.

Another study corresponds with our study, Mass et al (2002) assessed the expression level of a number of genes involved in apoptosis in SLE patients, and observed the reduced level of caspase 8 in these patients[14].

Comparing the results of male and female SLE patients in present study we showed that apoptosis rate was decreased, and expression of caspase 8 in gene level was lower in female than male. The reason for this difference between male and female patients is not clear, but differences in sex hormones may be involved[15]. And others indicated that the level of prolactin was increased in female and male SLE patients, and the level of DHEA and progesterone as hormones having immunosuppressive effects were decreased[16].

Previous study that showen, Apoptotic rate is increased in patients with systemic lupus erythematosus, Interaction of death receptor (Fas) with its ligand (FasL) activates caspase-8 which is necessary for transduction of apoptosis signals in extrinsic Pathway In the intrinsic pathway, any decrease in antiapoptotic proteins such as Bcl-2 leads to the activation of caspase-9 and the transduction of apoptosis signals[15].

The results in previous study[17] showed that there was no significant difference in apoptosis rate in protein level neither among lupus patients and control groups nor between male and female patients with their appropriate controls, which was in accordance with results of some previous studies[4].

In a number of previous studies, apoptosis rate has been reported to be increased in patients with SLE[3], whereas in other studies no difference was observed between SLE patients and controls when Fas molecule was assessed instead of apoptosis[3], which was not compatible with our results.

Caspase-8 deficiency has been recently associated with human diseases, Caspase-8 also carries important non-apoptotic functions[11].

Most SLE patients enrolled in the present study were in the early stages of SLE and either took no drugs or consumed corticosteroids. Wang et al reported increased apoptosis rate in SLE patients, while nothing was mentioned in their study about the medications used for patients[4]. and Caricchio et al [18] studied 13 and 25 SLE patients with similar drug dose as our study, respectively, and reported that the percentage of apoptotic cells and the expression level of Fas molecule was the same in SLE patients and healthy controls, which was comparable to our results.Different study results seem to be to someextent influenced by differences in patients' medication regimens. The differences may also be partly affected by different methodologies used in several studies.

In the current study, the mean caspase 8 of SLE patients was (27.73±1.16) which was significantly lower than that of controls which was (30.51±1.21), (P. value = 0.023)

In Iraq in Tropical-Biological Researches Unit, College of Science, University of Baghdad[19] confirmed that The sera of SLE patients were positive for ANA (100.0%) while none of the control[19].

Another study in Iraq, where explained that ANA was Positive in 90% with SLE patients and with rare precent in healthy control, Antibodies to dsDNA in patients serum are increased comparing with the control[20].

These results were confirmed in the present study, the level of caspase 8 is low wih the increase activity of disease also caspase3 in(table 7)that mean the level of extrinsic pathway correlate with serology and clinical SLE activity in our patients, the anti-dsDNA antibodies is more specific than ANA in diagnostic SLE .

Many studies did not correspond to our current study,Previous study showenthe presence of anti-ANA antibodies is not in itself diagnostic or even predictive of disease in some cases[21].

Previous study, sustained anti-dsDNA antibody production may appear that may relate to SLE. In the other situation, a transient antibody profile may appear that may not relate at all to SLE[22].

Other study confirmed differences in levels anti-dsDNA,This study was specifically focused on those patients with changing antids DNA levels, and it became clear that changes in anti-ds DNA content associated with the three different complement components (Clq, C4, and C3).

Some methodological limitations should be considered in the interpretation of our results: the small sample size of the groups studied,different genetic variation between contries,most our patients they take medication, also to technical failure because ELISA may fail to detect caspases, in general because of the different techniques used in the measurementcaspases, ANA & ds-DNA.

Conclusion: ther are important changes in the level of caspase-8 in SLE, The level of caspase-8 have an inverse relationship with the activity of the disease.

Gold Nanoparticles Targeting Human Cervical Cancer Cells

Hayat Awadh Merkadh[1], Fatimah Mezaal Hameed[1]

[1]*Lecturer Ph.D. Al-Diwaniya Maternity and Child Teaching Hospital, Al-Diwaniya province, Iraq*

Abstract

The most disturbing gynecologic malignancies is cervical cancer particularly in the developing world with the same high incidence in Iraqi women. Cervical carcinoma has a high rate of mortality. The high death rate is associated with presence of human papillomavirus (HPV) infection. Cervical carcinoma is hard to treat, and conventional therapies are very aggressive which lead for the need for new approaches of therapy. Nanoparticles is a promising treatment modality to produce non-toxic and efficient cancer therapy. Gold nanoparticles (AuNPs) accumulate in cancer cellsselectively. The current work was aimed to study cytotoxicity and cell death induced by AuNPs on cervical carcinoma cells. Method: Cytotoxicity of AuNPs was assessed by MTT viability assay and analysed using multiple comparison ANOVA tests. Results: AuNPs nanoparticles from 12.5 up to 50 µg/mL for 72 hours showed concentration-dependent killing activity.

Keywords: *Gold nanoparticles (AuNPs), cytotoxicity. Cell death.*

Introduction

The most disturbing gynecologicmalignancies is cervical cancer particularly in the developing world[(1)]. The new cervical cancer cases are about 569,847 diagnosed annually worldwide (estimates for 2018)[(2)]. Human Papillomavirus (HPV) infection is associated with the cervical cancer[(3)]. In Iraq, cervical cancer ranked 9th most common cancer in Iraqi women aged 15 to 44 years[(4)].The most frequent type of cervical cancers is squamous cell carcinoma (SCC) which is about 85%[(5)]. There are known risk factors associated with cervical cancer in addition to HPV infection, such as cigarette smoking and smoke carcinogen (benzo[a]pyrene, BaP)[(6)]. Human papilloma virus (HPV)subtypes that cause cancer is genotype 16 that cause SCC and genotype 18 that cause adenocarcinoma[(7)].It is well reported the importance of HPV infection in different type of benign and malignant tumors. It is well established that there is association between HPVs with cervical cancer[(8)]. Moreover, environmental pollutions associated with conflicts may be another source for increase cancer related cases [(9)]. There were numerous attempts to overcome resistance to conventional therapiesto accomplish a considerable therapeutic effect in malignant tumorsby using gold nanoparticles [(10, 11)]. The resistant of cancer while there is treatment for long time, will causeprogressivetype of malignant tumors, requires the development of novel therapeutic modalities to overcome chemo-resistance and enhanceprolong surviving effect[(12)].Nanoparticles is a promising treatment modality to produce non-toxic and efficient cancer therapy[(13,14)]. Nanoparticles carry unique chemical and physical features[(15)], these features utilized in biomedicalapplications[(16)] such as cancer[(17)]. Nanoparticles were combined with other cancer targeting agents to enhance therapeutic effects [(14)]. The search for more effective therapy is needed, therefore we designed the current study to use Gold (AuNPs)nanoparticles as anti-cervical cancer therapy which hold promise for clinical application.

Materials and Method

Maintenance of Cell Cultures: The human cervical cancer cell line, Hela were cultured in basic MEM media (Usbiological, USA) supplemented by 10% fetal bovine serum (FBS), 100 units/mL penicillin and 100 µg/mL streptomycin(Capricorn- Scientific, Germany).

The cell line is authenticated regularly. Hela cell line was subcultured using trypsin-EDTA when confluent monolayer was achieved and incubated at 37°C in 5% CO^2 humidified incubator[18,19].

Gold Nanoparticles: The current work used highly stable gold nanoparticles (AuNPs) of 10nm size, they are designed for biomedical applications[11].

Cytotoxicity determination using MTT assay: The Hela cells were seeded at concentration of 10000 cells/well in 96 multi-well microplates. The cells were suspended in 10% FBS MEMmedium and allowed to grow for 80% confluency. Gold NPs were added at several concentrationsfrom 3.2 to 100µg in triplicate and incubated for 72 hrs. at the end point, the MTT stain wasaddedat a concentration of 2µg/ml. After 3h incubation at 37ºC,Dimethyl Sulfoxide(DMSO) was added to all wells.The measurement of absorbance was done at 580 nm using biochrommicroplate reader. Results of the assay were shown as a percentage of proliferation relative to control cells [20, 21].

Statistical Analysis: The collected data were statically analyzed using multiple comparison ANOVA testsusing Graph Pad Prism 6.07; values were presented as the mean±S.D of the triplicates.

Results

Gold NPs suppress Hela cervical cancer cells: The killing effect of Gold nanoparticleson human cervical carcinoma cells Helaafter 72hof exposure was shown infigure 1. The cytotoxicity of GNPs on Helacervical carcinoma cells was significant in compare to control not treated cells. The GNPscytotoxicity was significantly elevated with the increase in concentration as shown in table 1. the effective concentrations were 12.5, 25 and 50µg/ml. The results of the cytotoxicity experiment suggest that gold nanoparticlescan be valuable anti-cervical cancer therapy. Hela cells treated with AuNPs exhibited detachment and pathological morphological changes. IC50, which is the inhibitory concentration that kills 50% of the cells, was 8.713µg (Figure-2). The cytopathological changes revealed apoptotic induction in Hela cells when observed under phase contrast inverted microscope. The untreated cells displayed that the cells preserved their unique morphology; most of the untreated cells were attached to the tissue culture plate.

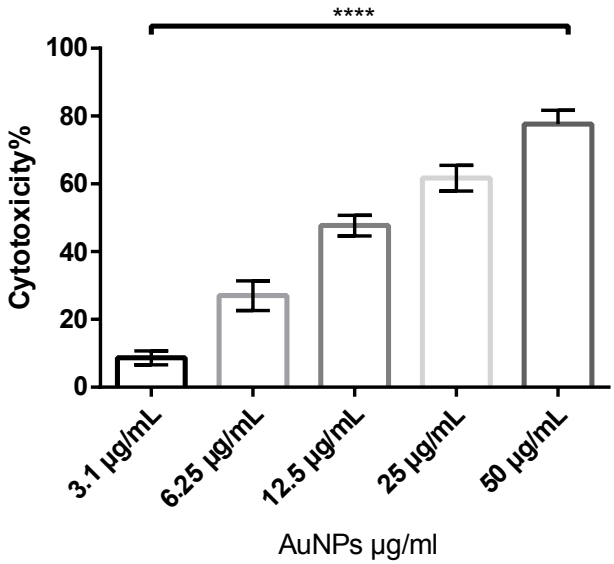

Figure 1: Killing effect of goldnanoparticles in cervicalcancer Helacells was measuredvia the MTT viability assay. The Hela cells were exposed to gold NPsfor 72 h with different concentrations. The effective concentration of AuNPs nanoparticles were from 12.5 to 50 µg/ml.

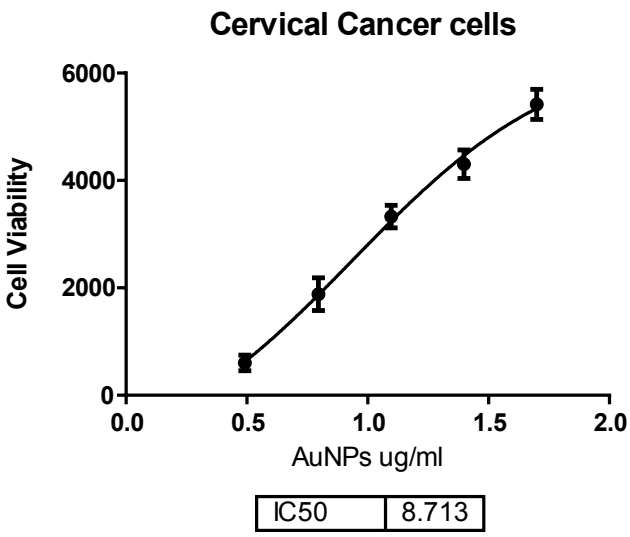

Figure 2: IC50 value for Gold NPs in Hela cells was 8.7µg/ml, this dose reflects sensitivity of cervical cancer cells to nano gold.

Discussion

In the current experiment, the antiproliferative activity of AuNPs nanoparticles to human cervical cancer cells was investigated. Nanoparticles is considered an important drug delivery method for cervical Cancer treatment [22]. Gold nanoparticles reported to havean anti-cervical cancer properties[23]. The study results showed that AuNPs exposure to cancer cells cause significant cytotoxicity in mostdoses tested. Gold nanoparticlescaused viability reductionin exposed cancer cells.It is reported that biosynthesized gold nanoparticles exposed to Hela cervical cancer cells cause DNA damage, G2/M arrest, and apoptotic cell death via caspase activation [23]. Cell death cytologicalfeaturesof rounding and cell detachment as observed under the inverted microscope. Furthermore, generation of reactive oxygen species (ROS) is enhanced by gold nanoparticlestreatment[10, 24]. Moreover,couple of studies [25,26]showedthat20nmgoldnanoparticlesdecreasecancer cellsgrowth mouse model.AuNPs may alsouse as delivery agents for phytochemicalssuch as Gallic acid or chemotherapeutic agents such as doxorubicin can be used asreplacementfor cervical cancer therapy to decrease radiotherapy and chemotherapyside effects [27, 28]. Retinoic acid loaded on gold nanoparticle showed promising anti-cervical cancer effect [29]. The IC50 dose estimated was 8.713 µg/mlin cervical carcinoma cells.Pharmacokinetic and bio-distribution investigation for AuNPs in tumor bearing animal model showed that gold nanoparticleshave high stability when conjugated with therapeutic agents and radiotherapeutic enhancement[30]. Nanoparticles hold very promising activity against cervical cancer [31]. Furthermore, cervical cancer and HPV need to find alternative treatments. Nanoparticlessuggestedpromisingin cervical cancer treatment by thecapacity to target and internalize cancer cells[32]. In conclusion, the present study proved that gold nanoparticlescan be used for cervical cancer therapy.

Conclusion

Gold nanoparticles have anti-cervical carcinoma cells activity by cell death induction.

Bacteriological and Molecular Typing of Acne Vulgaris Etiology in the City of Baghdad

Mawj Abbas Fadhel[1], Luma Yousif Mehdi[2], Hiba Hikmat Maqdasi[3]

[1]AL-Wasti Teaching Hospital, Section of Laboratory, Baghdad, [2]Health and Medical Technical College, Baghdad, Middle Technical University, [3]Al-Kindi Teaching Hospital, Section of Dermatology, Baghdad, Iraq

Abstract

This study focuses and diagnosis bacteria involved in acne vulgaris . Method (culture, biochemical test, vitek 2 system, api 20 A, PCR) were used for isolation and identification. Results recorded that the most frequent etiological bacteria isolated anaerobically from acne patients was prevalence Propionibacterium acnes (40%), and the most common aerobic pathogen bacteria species were Staphylococcus epidermidis (27%), Staphylococcus aureus (24%) specific primer design for *recA* gene of *P. acne* confirmed and suggesting higher outbreak in the acne lesions with sever form, and the specific primers design for *mecA* gene of *S.epidermidis* were detected for methicillin resistant *Staphylococcus epidermidis* (MRSE) using target gene *mecA* confirmed and suggesting outbreak with mild form acne patients.

Keywords: *Acne vulgaris, P. acne, S . epidermidis, S.aureus.*

Introduction

Acne vulgaris is one of the most common dermatological disorders that afflict people in their adolescence. Many of the risk factors that may affect the occurrence of the disease, such as genetic factors, hormonal, stress, increased sebum secretion, abnormal pore different that cause local duct obstruction, bacterial biology of the local duct[(1)], anaerobic bacteria *Propionibacterium acnes* and *Staphylococcus epidermidis* plays an important role in causing acne[(2),(3)]. Androgen secretion is the main cause of adolescent acne and other environmental factors. Conditions of stress and emotional disorders may aggravate acne[(4)]. There is significant evidence suggesting a possible pathogenesis acne vulgaris role for *Staphylococcus aureus* . This is in variance to some study which implicated both *S. epidermidis* and *P. acnes* as cause bacteria acne vulgaris[(5)]. The isolate microbial flora from patient of acne that appear possible to lead to pathogenesis acne includes: *P. acnes, S. epidermidis, S. aureus*[(6),(7)].

Materials and Method

One hundred discharging pus samples were taken from patients suffering frominflammatory acne skin conditionwith mild (29), moderate (50) and sever (21) degree and include (48 males and 52 females) with ages (11-30) years by using a sterile cotton swab,during the first of February 2019 until the end of May 2019, from Al-Kindi Teaching Hospital/section of Dermatology,

Isolation and Identification ofP. acnes:was done as described by [(8)], using blood (Oxoid, UK)and brucella agar media (Himedia, India), Gram stains, biochemical Tests and API 20A test (BioMerieux, France) [(9)]DNA was “extracted from broth samples by “employment of Genomic DNA” “Purification kit” (Promega, USA). Primers design for (*recA gene*) of *P. acne*wereused” (forward, 5 ’-CTGTGCCTTTATTGACGCCG-)and” (reverse, 5’-CGCACCGGTCATCT-) (NCBI, Bioneer, korea)expected products of amplification was (283bp), PCR “amplifications were carried” out in total reaction “volumes” of 20 ulcontaining Forword primer (1.5 ul) and Reverse primer (1.5 ul)D.W (12 ul)Template DNA (5ul). The “amplification” thermo “cycle parameters” condition were5min at 95ºC30 cycles of 30 sec at 95ºC, 30sec at 58ºC, 30sec at 72ºC5min at 72ºC .

Isolation and Identification of *S.epidermidis*: was done as described by [(10)], using blood (Oxoid, UK) agar mediaand. Culture Mannitol salt (Himedia,India), Gram stains,biochemical Tests: catalase,coagulase sensitive to the antibioticnovobiocindisk, Vitek 2

system(bioMérieux, France),DNA was "extracted from broth samples by "employment of Genomic DNA" "Purification kit" (Promega, USA).Primers design for(*mecA gene*)forisolateswere detected by Polymerase Chain Reaction (PCR) formethicillin resistant *Staphylococcus epidermidis*(MRSE) using target gene *mecAS. epidermidis*wereused"(forward,5 ' - A A A G G G C G T G G A A G T A A C G A -) and"(reverse,5'-TTT GAT GGC TTA TGCGCACG-) (NCBI,Bioneer,korea)expected products of amplification was216bp,PCR "amplifications were carried" out in total reaction "volumes" of 20 ulcontainingForword primer (1.5 ul) andReverse primer(1.5 ul)D.W(12 ul) Template DNA(5ul). The "amplification" thermo "cycle parameters" condition werewere5min at 95ºC30cycles of 30 sec at 95ºC,30sec at 60ºC,30sec at 72ºC5min at 72ºC.

Isolation and Identification of *S.aureus*: was done as described by[11],using blood (Oxoid,UK) agar media andCulture Mannitol salt (Himedia, India),Gram stains,biochemical Tests:catalase, coagulase sensitive to the antibioticnovobiocin disk, Vitek 2 system (bioMérieux, France).

Results and Discussion

Results suggested the most frequent etiological agent isolated anaerobically bacteria from acne patients was *Propionibacterium acnes* (50%), and the most common aerobic pathogen bacteria species were *Staphylococcus epidermidis*(29%), *Staphylococcus aureus* (24%) as presumptive isolates.

Current data were in agreement with the study done in Iran by: [12]showed a predominance of *P. acnes* (57%), followed by *S. epidermidis* (32%) and *S. aureus* (5%) and with the other study done in Cairo [13] showed P.acne (56%) cases and *S.epidermidis* (39%),*S. aureus* (14%),but with another results done in India [6] presented by cultured aerobic and anaerobic condition showed *P.acne* (66%), *S.aureus* (65%)and *S.epidermidis* (5%),

But another studies by [14] examined the species of bacteria aerobically and anaerobically isolated from 100 Korean acne patients. Among the bacteria isolated, *S. epidermidis* (36 patients) was the most common, followed by *P. acnes* (30 patients), dis agreement with a study from[15]inIndia found that the average of infection with *S. epidermidis* was (53%), *S. aureus*, and *P. acnes* were (41%), (33%) respectively,and in another results in Erbil city[17] found *S.epidermidis* (27%), *P.acne* (13%), *S.aureus* (3.6%) and found 23 other types of bacteria .There is different results microbial profile in our study because the variations geographic location; diet, quality of the life,strains of bacteria, treatment used and others factor can be effect on the results [16].

*P.acne*colonies on BBA appeared as glistining, round and opaque with difference colors, included white, yellowish and gray. The colonies grew larger in size over time compare with young colonies (1-2) mm. Also, colonies with weak or no hemolysedwhen grow on BBA,Gram positive bacillis, pleomorphicand was appeared in different arranging. These results coincide as mentioned with pervious results in Iraq[18],[19].

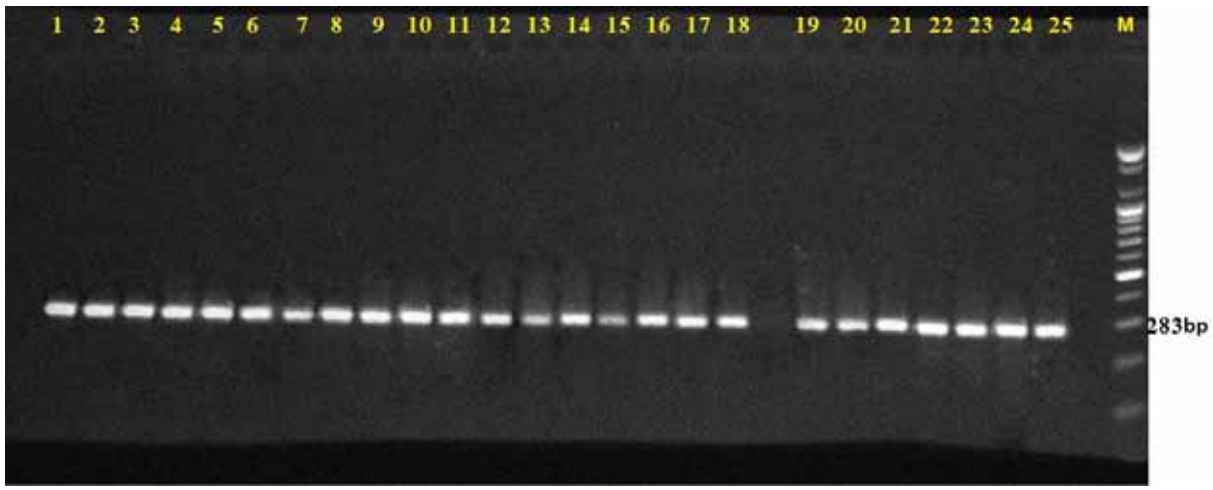

Figure (1): Agarose gel electrophoresis of PCR amplification produce for Propionibacterium acne,expected products of amplification are 283bp (lanes 1-25: samples,lane M: marker 1000bp, 1% agrose gel and 70 Volt for 1 hr. in TBE buffers.

The presumptive *P. acnes* isolates showed positive results forindole,gelatin, catalase and negative results foresculineand urea se results agreement with[20],43%) of *P. acne*were confirmed according to API 20 A system carried out quick and easily for the biochemical test identification' of anaerobic bacteria. Our result as showed in figure (1) presents the PCR product electrophoresis onagarose gel (1%),PPA specific primer design for *recA*gene of *Propionibacterium acne* (283bp)(design by NCBI, Bioneer)were used to performed PCR,(40%) isolates were confirmed as *P. acnes*,suggesting higher outbreak in the acne lesions with sever form[21].A study by[22], revealed that *p.acne* in samples was confirmed with aid of analysis of *recA* gene sequence. Genotype of *P. acnes* is *recA* (types I, II, and III) each of the *recA* genotypes has a characteristic phenotype and *recA* type I is dominant in isolates from acne vulgaris[22]. Molecular method approach has been largely performed in several laboratories, due to its high sensitivity and specificity as well as rapid.

Colonies of*S. epidermidis* appeared white, opaque and smooth colony on blood agarmedia,by Gram stain showing Gram positivecocci, clusters, which often in groups similar to grapesresults agreement with[23]. positive results forcatalase,coagulase negative,mannitol non fermenter andsensitive to the antibioticnovobiocin results agreement with[24].

The result of vitek 2 system (bioMérieux)was used for confirmation of *S .epidermidis* isolates,the results showed that out of (29%) presumptive isolates (27%) of them were confirmed as*S.epidermidis* by Vitek-2 GP system and agree with the studyby [25].Our result as showed in figure (2) presents out of (29%) presumptive isolates,(27%) of them were positive formethicillin resistant *Staphylococcus epidermidis* MRSE target gene *mecA*,confirmed and suggesting outbreak with mild form acne patients[3].The increasing antibiotic resistance confuse a great defy for the management infections and shows that the isolation recurrence of methicillin resistant *S. epidermidis* (MRSE) can reach 80% [26] and the patterns of resistance of *S. epidermidis* to antimicrobial agents is essential for the diagnosis and directing infections[27],[28]random overuse of antibiotics has led to the development of antibiotic-resistant strains which are occurring more frequently.

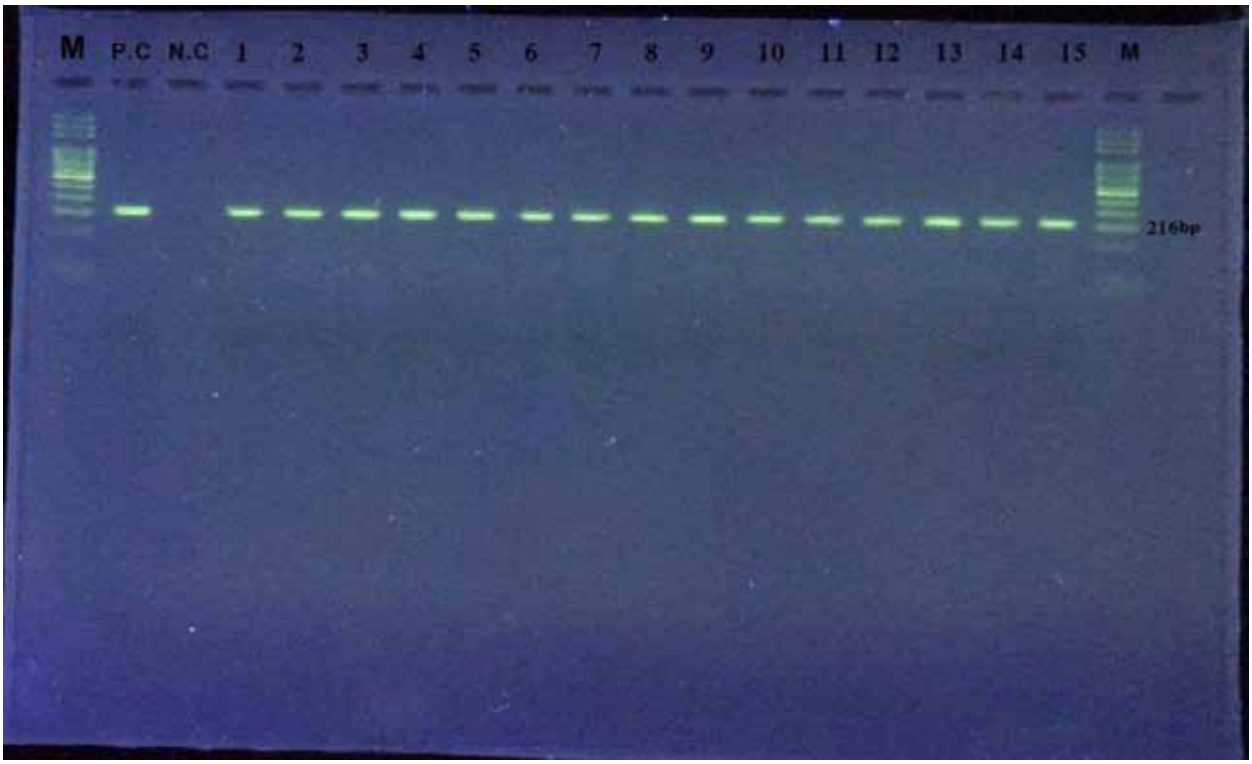

Figure (2): Agarose gel electrophoresis of PCR amplification produce (mecA) S. Epidermidis, expected amplification products are 216bp (lanes1-15:samples, lane M: marker 1000bp, 1% agrose gel and 70 Volt for 1 hr. in TBE buffers.

Colonies *S.aureus* appeared smooth golden yellow, produce clearing zone surrounding their growth on blood agar media andby Gram stain showing Gram positivecocci under a microscope and forms grapes-like clusters, results was coincided as mentioned by[29] . The results coagulase and catalase positive and mannitol salt agar fermenter yellow colorand susceptible to novobiocin results was coincided with a study in[30] final identification was confirmed by vitek 2GP system (bioMérieux) with moderate acnecases presented given highest *S.aureus* this result agree with the study [31]was conduct to assess the new VITEK 2 system (bioMérieux) for identification and antibiotic susceptibility tests of gram-positive cocci. The GP card provide aspeed and reliable identification of most species, whatever their origin

Ethical Clearance: The Research Ethical Committee at scientific research by ethical approval of both environmental and health and higher education and scientific research ministries in Iraq

Determination of the Best Level of Cognition for Category-10 Table-Tennis Athletes with Special Needs

Salwan Sameer Jasim[1], Raafat Abdulhadi Kadhim[1], Hisham Hindawi Howaidi[1]

[1]*College of Physical Education and Sports Science, University of Al-Qadisiyah, Diwaniyah, Iraq*

Abstract

The research addressed the importance of cognitive abilities in the field of physical education in general and table tennis in particular. The aim of the current research was to identify the best level of cognitive abilities for category-10 table-tennis athletes with special needs (C-10-TTASN), hence the importance of the research was to increase the knowledge and provide the sport science literature with valuable information about the C-10-TTASNs through research in the psychological areas of different levels in this class and the search for the role of the psychological aspect in this level. There are significant differences between the psychological profiles of the three categories (high, medium, and weak) which have effects on the classification of C-10-TTASNs. The research methodology and field procedures were also included. The descriptive methodology was used involving three players from the Iraqi national team. The results showed that there was a variation in the level of the profile between the three players according to the ten levels. The profile of the first player was better than that for the other players. The profile of the second player was better than that for the third player.

Keywords: *Cognition, Reha Com.*

Introduction

The game of ping-pong was originated in 1890 emanating from the game of tennis, which was then widespread in England and France, and was practiced at home using different types of rackets and balls made of cork and wood. It was also played on the dining tables and was called using the name (ping pong) because of the sound of the ball while hitting the surface of the table. Then, the game had spread in Europe gradually[1–3].

Table tennis is one of the most famous games among the players with special needs who can compete with the healthy ones. The game requires a high degree of vigilance and attention by the player's commitment and control to return the light ball to the opponent and requires a large degree of reactions by making quick decisions as required by the game [4–6]. The psychological factors associated with sport training and competitions clearly affect the individual's sport level and have not received adequate attention from scientists or trainers until very recently, and there are still many psychological problems associated with sport activity that urgently needs to be addressed by research. It has been referred to the psychological profile as a set of tests representing psychological dimensions or knowledge and skills of that determines the strength and weakness of an individual and is in the form of graphic representation. The profile is an important model in the field of evaluation of psychological preparation for the competition and aims to help the player to identify the strength and weakness in a range of factors related to performance in the sport competition. The players with special needs are the group of athletes that were not adequately highlighted through research conducted despite the advanced results they have achieved in local and international competitions, which sometimes, outperforming the results of the healthy peers [7,8].

The aim of the current research was to identify the best level of cognitive abilities for category-10 table-tennis athletes with special needs (C-10-TTASN) by identifying the differences between psychological profiles and their impact on the classification of players for three levels (high, medium, and weak). There are significant differences between the psychological

profiles of the three categories (high, medium, and weak) that have effects on the classification of category-10 table-tennis athletes with special needs (C-10-TTASN).

Materials and Method

Sample Players: The research sample was selected, which includes 10 players from category-10 table-tennis athletes with special needs (C-10-TTASN) of the Iraq national team, and three players were chosen in a deliberate manner representing the strong, medium, and weak levels according to their classification in the last tournament that took place.

Experimental Design: The researcher used the descriptive method of case study and comparisons to address the research problem.

Tests:

Vigilance Test: The technical aspects associated with the nature of this game requires a high degree of alertness and concentration of attention of the player, so the researchers conducted the vigilance test after a direct look at the RehaCom system, https://www.rehacom.com/what-is-rehacom.html. Through the use of the sources of the test and conducting personal interviews and direct inquiry, it was easy conducting and identifying accurately the accredited results of the test.

This test has an advantage over the paper and pen tests in obtaining objective results as it is characterized by high credibility as the system RehaCom is a global and codified system, as well as ensures us to save effort through computerized automated presentation.

Test form:

The reaction time in vigilance is checked under two circumstances: First: In order to measure the intrinsic alertness to maintain the response for as a long period of time as possible, a geometric shape appears at a fixed location that changes randomly within short intervals. The task of the subject is to react as quickly as possible to the shape that was changed by pressing the required keyboard button

Second: In order to measure the phasic alertness (short-term attention concentration), the figure appears on the screen at a fixed location that before changing at a random interval, a warning signal is heard.

Method of Application: The test begins with a message on the screen in case the reaction is early, before the appearance of the shape and before changing it randomly, and the exercise phase does not end unless the reactions are correct in all attempts to exercise, and the performance of the test in two parts and called simple design ABBA as follows:

- Try without a beeping sound
- Try with audio signal
- Try with audio signal
- Try without a beeping sound

In the first stage of the test, the response time of the subject is measured in a simple click of a full square on the screen. In the second stage, the response time of the same visual alarm is measured upon hearing the sound of the signal before the square appears. The subject hits the right keyboard key upon hearing the audio signal and before the box fully appears.

The duration of the test: The test took a maximum of six minutes excluding the exercise phase.

Statistical Analysis: In the analysis of the results two types of z-value are calculated as shown in the following:

- An alert value for mental alertness (without sound signal) by averaging all reactions without the sound signal (intrinsic alertness).
- An alert value for mental alertness (sound signal) by calculating the average of all reactions by the sound signal (phasic alertness).

The mental alertness test also measures the following data:

- Measuring the average reaction time and speed process, as it is considered that the slowdown in performance below the normal level (z-value 2-, 3-) may be due to mental stress.
- The level of performance is measured from changes in reaction time, as well as the high degree of standard deviation (SD) indicates a low level of normal excitement status of the subject.
- Delay in response and prolonged reaction refer to the speed of mental stress in the subject, which reduces active mental responses.

A Chi-square test was used to differentiate between each two players (first and second), (first and third), and

(second and third). To determine the validity of the results, the distance between each of the two players was obtained by subtracting the raw values between the tree comparisons.

Results

Mental Alertness:

Without the Sound Signal: The results of the mental alertness without the sound signal are shown in table (1).

Table 1: The results of the mental alertness without the sound signal.

Player	Response	Response time	Response SD	Z-value	Significance
1	332	334	32	31	0
2	275	256	55	13	0
3	286	279	56	12	0
Significance level	0.046	0.004	0.021	0.002	0
Chi sq. value	6.143	11.09	7.688	12.25	0

Table 2: The results of the mental alertness distances between players without the sound signal.

Variables	Comparisons	Distances	Chi sq	Freedom degrees	Significance level
Response	First and second	57	5.352554	1	0.020692
	First and third	46	3.423948	1	0.064257
	Second and third	-11	0.215686	1	0.642347
Response time	First and second	78	10.31186	1	0.001322
	First and third	55	4.934747	1	0.026322
	Second and third	-23	0.988785	1	0.32004
Response SD	First and second	-23	6.08046	1	0.013669
	First and third	-24	6.545455	1	0.010515
	Second and third	-1	0.009009	1	0.924382
Z-value	First and second	18	7.55814	1	0.005974
	First and third	19	27.4	1	0.000000165
	Second and third	1	8.227273	1	0.004127

In table (1), we find that the results of the three players are significant and for all variables, so there are differences between the players, and for the purpose of identifying the order of players, Chi-square value was calculated for each two players as in tables, and the results found that player 1 is the best.

In table (2), we show the distances between the players to indicate the best parameters of each one of them and via the results of the Chi-square test, as the distance between the first and second player in the reaction variable was (57) which is greater than the that from the comparisons, first and third and the second and third, (46) and (-11), respectively, and thus the preference is for the first player.

In the case of reaction time, the distance between the first and second player was the largest (78); however, the distances of the comparisons, first and third and the second and third, (55) and (-23), respectively. According to that, the preference was for the first player.

As for the SD of the reaction variable, the distance between the first and second players was (-23). The preference is for the first player because it has less SD than that from the second player. The distances between the first and third players was (-24), and between the second and third was (-1).

With the sound signal:

Table 3: The results of the mental alertness with the sound signal.

Player	Response	Response time	Response SD	Z-value	Significance
1	343	333	34	92	0
2	292	288	73	44	0
3	253	246	41	36	0
Significance Level	0.001	0.001	0.000156	0.000000113	0
Chi sq. value	13.76	13.1	17.52703	32	0

Table 4: The results of the mental alertness distances between players with the sound signal.

Variables	Comparisons	Distances	Chi sq	Freedom degrees	Significance level
Response	First and second	51	6.916	1	0.008542
	First and third	90	19.63	1	0.00000937
	Second and third	39	15.15	1	0.0000992
Response time	First and second	45	6.544	1	0.010524
	First and third	87	17.97	1	0.0000225
	Second and third	42	15.03	1	0.000106
Response SD	First and second	-39	14.21	1	0.000163
	First and third	-7	0.653	1	0.418923
	Second and third	32	8.982	1	0.002726
Z-value	First and second	48	16.94	1	0.0000386
	First and third	56	67.4	1	1.63E-16
	Second and third	8	18.5	1	0.000017

In Table (3), we find that the results of the three players are significant and for all variables, so there are differences between the players, and for the purpose of identifying the order of players, Chi-square value was calculated for each two players as in tables, and the results found that player 1 is the best.

In table (4), we show the distances between the players to indicate the best parameters of each one of them and via the results of the Chi-square test, as the distance between the first and second player in the reaction variable was (51) which is greater than the that from the comparisons, first and third and the second and third, (90) and (39), respectively, and thus the preference is for the first player.

In the case of reaction time, the distance between the first and second player was the largest (45); however, the distances of the comparisons, first and third and the second and third, (87) and (42), respectively. According to that, the preference was for the first player.

As for the SD of the reaction variable, the distance between the first and second players was (-39). The preference is for the first player because it has less SD than that from the second player. The distances between the first and third players was (-7), and between the second and third was (32).

Discussion

The results revealed that the reaction variable played a big role in the psychological aspect as it is the basis of alertness and through which a player is prepared for the game. It turns out that the player who was attentive had a high reaction that enables him to make a quick and correct decision. In addition, the right alertness also allowed him to take the right position that enabled the player to respond to the action of the opponent (computer, here), and this is similar to the real life of performing the table-tennis game. It is not possible to get the best playing performance without a high-speed reaction because of the small playing field and the high-speed moving ball which requires high alertness using different senses especially eyesight that induces eye nerve-brain stimulation and responses. The response after brain-analyzing the image may not exceed one

second. This response and its time are determined according to the level of alertness [9,10].

Hence, the psychological model that should be chosen for table tennis players must be a level of vigilance which is up to a rate of more than 332 (milliseconds) to match the conditions of the game, as one of the most important requirements of the table-tennis player is to be characterized by a high reaction for obtaining the best game scores. This is due to the high-speed optical stimuli that occurs in a small field, three meter, with the high-speed, 100km/hr, moving ball, and this is why a table-tennis player must have high degree of alertness[11–15].

Conclusion

There are variations in the levels of alertness among the three players according to the ten levels. The profile of the first player is better than that from the other players. Moreover, the profile of the second player is better than that from the third player.

Role of VAC a and CAG a Genes in Detection and Identification of Helicobacter Pylori

Ghydaa H. Aljeboury[1], Mohsen Hashim Risan[2], Rebah Najah Algafari[1]

[1]Biotechnology Research Center, [2]College of Biotechnology, Al-NahrainUniversity, Iraq

Abstract

A total of (130) samples of stomach ulcer were collected from patients suffering from peptic ulcer who visited three different hospitals in Baghdad. The results showed that after bacterial culturing on the MacConkey agar and Columbia agar and selective media of *Helicobacter Pylori* bacteria under(5% O_2, 10% CO_2, and 85% N_2), detected that 45 isolate were belong *Helicobacter pylori* that represent(35%).After testing the sensitivity test against *Helicobacterpylori* against 10 antibiotics, the sensitivity test for 10 antibiotics demonstrated the efficacy of the antibiotic cephotaxim and rifampicin in the elimination of the bacteria. The resistance ratio was 10%. The tetracycline and duxacycline antibiotic were 10% 20% and were resistant to erythromycin and chlarthromycin30%, while the resistance to amoxicillin was 100% and the resistance ratio was 80% for both metronidazole and sprofluxacin, while gentamycin had a resistance ratio of 50%.

Keywords: *Helicobacter pylori, PCR, 16SrRNA.*

Introduction

Helicobacter pylori infection, a highly prevalent pathogen, is a major cause of chronic gastritis and peptic ulcer and a risk factor for gastric malignancies, antibiotics-based *Helicobacter pylori* eradication treatment is 90% effective,however, it is expensive and causes side effects and antibiotic resistance[(1)]. Wounds of stomach related framework is considered as the most famous infections around the world, which are identified with poor nourishment, thriving and sanitation conditions and additionally hereditary and natural effects. Ulcers as irresistible maladies, which taint stomach related framework, had been found by [(2)] and viewed as another period with respect to the ideas and treatment of gastro duodenal. It was observed that *Helicobacter pylori* to be the fundamental driver of gastritis, peptic ulcers and gastric disease. *Helicobacter pylori* is considered as an effective pathogenic bacterium that instigates gastritis in all discovered tainted patients and perceived as class-I cancer-causing agent that especially colonizes the gastric epithelial cells of human [(3)]. The contamination caused by *Helicobacter pylori* is typically happen in the early youth and continues long lasting if not treated with antimicrobial operators [(4)]. *Helicobacter pylori* is a standout amongst the most well-known bacterial pathogens that taints human around the world [(5)]. Two of the virulence factors that have been implicated in this process are cytotoxin-associated gene A (*CagA*) and vacuolating cytotoxin A (*VacA*), which are cytotoxins that are injected and secreted by *Helicobacter pylori*, respectively. Both of these virulence factors are polymorphic and affect a multitude of host cellular pathways. These combined facts could easily contribute to differences in disease severity across the population as various *CagA* and *VacA* alleles differentially target some pathways[(6)].

Materials and Method

Stomach Ulcer Sample Collection: A total of 130 stomach ulcer biopsy samples from male and female were collected for survey from (May 2017 to May 2018) from different hospitals in Baghdad governorate, Alkadimya Hospital, Center of Digestive Tract and Liver disease, Alyarmoq Hospital. Age of patient range from (19-73) year. All samples were placed in separate sterile cotton swab with transport media to prevent contamination and were immediately transported to the laboratory in a cool box with ice packs, and transported to the laboratory within 30 minutes of collection.

Identification of Helicobacter Pylori: Microscopic Examination of Helicobacter pylori:

A loopfull of *Helicobacter pylori* isolates was fixed on a microscopic slide, then stained by gram stain to examine cells shape, grouping, reaction and non-spore forming [7].

Cultural Characteristic of Helicobacter pylori isolates: In order to isolate *Helicobacter pylori*from samples that may contain different varieties of bacteria, selective media should be used to inhibit the growth of the more rapidly growing components of the enteric bacterial flora because *Helicobacter pylori*isolates multiply much more slowly than other enteric bacteria[8].

Biochemical Tests of Helicobacter pylori isolates: One presumptive *Helicobacter pylori*colony from each selective agar plate was sub cultured and tested by standard microbiological and biochemical procedures, differentiated at species level by Gram stain, oxidase and catalase test, hydrogen sulfide production and susceptibility to nalidixic acid by using a commercially available species differentiation kit API CAMPY (bioMérieux, Marcy-'Etoile, France).

Api CAMPI Identification for Helicobacter pylori Isolates: Identification was carried out by sub culturing of selected colonies grown on selective medium agar (Columbia agar with supplement) into CAMPI microtubes gallery. This system is designed for the performance of more than 20 standard biochemical tests from a single colony grown on plating medium. Inoculation of the galleries was done with sterile pasture pipette and five ml of tap water dispensed into tray provide a humid atmosphere then incubated under micro aerophilic condition for 24 hr. After that reagent added for reading the galleries, each positive reaction was given a value 1,2 or 4 according to the position of the test in its group, so a value from 0 to 7 digit observed was then looked up in the index and the identification is determined .

Sensitivity of Helicobacter pylori to Antibiotic: Ten ml of nutrient broth were inoculated by each bacterial isolate, then incubated under micro aerophilic condition for 24 hr. to log phase (OD_{600} about 0.35) giving ($1*10^8$) cell/ml of broth. After that, 0.1 ml of the inoculated broth was transferred and spread by sterile cotton swab on Muller-Hinton agar plates surface in three different planes (by rotating the plate approximately 60˚ each time to obtain an even distribution of the inoculums). The inoculated plates were then placed at room temperature for 30 minutes to allow absorption of excess moisture. With a sterile forceps the selected antibiotic disks were placed on the inoculated plates and incubated under micro aerophilic condition for 18 hr in an inverted position. After incubation, the diameter of inhibition zones was measured by a ruler (mm). Results were determined and compared according to the National Committee for Laboratory Standards [9]. Also,DNA Extraction of Helicobacter pylori isolates explain in details in [10].

PCR of genes targeted a 16SrRNA and virulence genes (CagA & VacA): The DNA from all isolates was amplified by PCR as a control for DNA extraction *Helicobacter pylori*species confirmation by analysis of the 16*SrRNA* and (*Cag & Vac*) genes,Amplification of these genes were carried out in a master mix volume of 25ul containing (5ul Taq PCR Premix G _SPIN kit) and 10 picomols/µ(1ul) Forward primer and10 picomols/µ(1ul) Reverse primer DNA (1.5µl), Distill water(16.5µl) table(1). The primers were lyophilized, they were dissolved in the free ddH_2O to give a final concentration of 100 pmol/µl as stock solution and keep a stock at -20.

Analyses Sequence of *Helicobacter pylori*isolates were done, the 1500bp fragment of 10 isolates of *Helicobacter pylori16SrRNA* gene was sequenced. Sequence alignment using Blast and Bio edit was used to sequence and the results were compared with data obtained from gene bank which is available at NCBI online .as in table(1) show the optimum condition of detection (16SrRNA genes) and *Cag* and *Vac* of *Helicobacter pylori.*

Table 1:The specific primer of genes (16SrRNA) and virulence factor of Helicobacter pylori

	Reverse	5'-AGCTAAAAGCGGTGGAGTAT -'3	53.7	45.0%	

Results and Discussion

Isolation and Identification of Helicobacter pylori: One hundred and thirty stomach ulcers samples, chronic gastritis ulcer, duodenal, duodenitis, gastric cancer were collected from patients suffering from symptoms referred as stomach ulcers infection, of whom 46 were female and 84 male were (15-73) years old. After the patients were subjected to a periscope examination, the prevalence of chronic gastric inflammation was observed at 36%, the stomach ulcer observed by 29%, while the duodenal ulcer, duodenitis appeared at 14.5%, 12.5% respectively and the percentage of gastric cancer appear as 4.5%, as shown in table (2).

Table 2: Clinical cases that included in the specimen collection for identification of Helicobacter pylori

No.	Clinical cases	No.	Percentage %
1	gastritisChronic	47	36%
2	Gastric ulcer	38	29%
3	Duodenal ulcer	19	14.5%
4	Duodenitis	16	12.5%
5	Gastric cancer	6	4.5%
6	Normal Case	4	3%
	Total no.	130	100%

Identification of Helicobacter pylori: The forty five isolation was diagnosed based on the tests used for this purpose, which is the form of colonies, the color of a grams stain, the urease enzyme test and the enzyme test, oxidase and catalase and motility test and obtained (20) isolates were subjected to other tests as well as previous tests, which included test the growth at 25ºC and 42ºC and the sensitivity test of the antibiotics cephalotoxin and nalidixic acid. CAMPY test and molecular diagnosis were made to 10 isolates of pathogenic bacteria.

Cultural Characteristics of Helicobacter pylori: *Helicobacter pylori* bacteria colonies appeared after the incubation period (3-4 days) in low-air conditions (5% O_2, 10% CO_2, and 85% N_2) at 37°C; small, circular convex in diameter (2-1ml), looks like to a drop of water or grey. That is, the form of colonies corresponds to the diagnostic description of the bacteria[11, 12].

Biochemical test of Helicobacter pylori: Several biochemical tests were done for characterize *Helicobacter pylori* which can be summarized as urease, oxidase, catalase, motility tests.All 20 isolates gave gram negativesmall convex circle pale in color, motile and urease, oxidase, catalase positive result.

Sensitivity Test of Helicobacter pylori for antibiotics: The emergence of prevalence of antibiotic resistance strain is considered as a major therapeutic problem that could be explained by several hypothesis such as, the influence of excessive and/or in appropriate antibiotic use [13], transmission of resistant isolates, among people, consumption of food from animals that had received antibiotics, and greater mobility of individual worldwide have also contributed to the extension of antibiotic resistance [14]. The results indicated that the local isolation of the *Helicobacter pylori* was 100% resistant for amoxicillin and 10% for antibiotics, rifampicin and cephotaxim, and 20% resistance to tetracyclin and doxycycline, six isolates resistant to erthromycin and clarthromycin 30%

resistance, antibiotic resistance ratio gantamycin is 50%, and the resistance to ciprofloxacin is equal to 80%. Moreover, results indicated in table (3) show the frequency of resistance *Helicobacter pylori* isolates to used antibiotics.

Table 3: Frequency of antibiotic resistance of Helicobacter pylori isolates.

Antibiotic	Symbol	Resistant isolates	
		Number	Percentage (%)
–β-lactam penicillin			
Amoxicillin	AMX	20	100%
–Cephalosporins			
Cephotaxim	CTX	2	10%
– Aminoglycosides			
Gentamycin	GM	9	50%
– Tetracyclines			
Tetracycline	TE	4	20%
– Quinolons			
Ciprofloxacin	CIP	16	80%
– Others			
Metroidazole	MT	16	80%
Clarthromycin	CLR	6	30%
Rifampcin	RA	2	10%
Arythromycin	E	6	30%
Ducoxy cycline	Do	4	20%

CAMPI Api for characterization of Helicobacter pylori: During incubation (in microaerobic conditions),metabolism produces color changes that are either spontaneous or revealed by the addition of reagents. The second part of the strip (assimilation or inhibition tests) is inoculated with a minimal medium and incubated in micro aerophilic conditions. The bacteria grow if they are capable of utilizing the corresponding substrate or if they are resistant to the antibiotic tested. The reactions are read according to the Reading Table. The identification software can also be used[15].

Detection of 16SrRNA, Cag A, VacA genes: Ten *Helicobacter pylori* isolates from current study were subjected to molecular analysis by PCR for confirmation of the microbiology results,we used PCR to detect the presence or absence of *16srRNA* and virulence-associated genes in the *Helicobacter pylori*isolates however this technique does not evaluate gene function, and does not give information about expression levels, nor does it describe deletions or insertions in the gene sequence,all of which may contribute to virulence that associated with clinical signs patient who sever from stomach ulcer .Primers were used in current study target to amplify the (*16SrRNA*) *16srRNA* gene was the first genes tested in current study for diagnosis of *Helicobacter pylori* isolate because it has considerable length (1,500bp), and it is ubiquitous in members of the *Helicobacter pylori*[16],and has been utilized extensively for rapid detection and identification of *Helicobacter pylori* species. The product size of 16srRNA gene was 900 bp as shown in figure (1) in all bacterial isolates our data contribute to previous discussions by [17]who conclude that it is not possible to differentiate between the species on basis of 16srRNA. The second gene detected was cytotoxin associated gene (*Cag A*) associated gene. cytotoxin associated gene (*Cag A*) is widely distributed among Gram-negative bacteria and it best characteristic of the toxins produced by *Helicobacter pylori* isolates, It had been described as an important virulence factor of this pathogen that are related with more prominent aggravation and expanded danger of ulcers and malignancy in people,figure(2) among *Helicobacter pylori* isolates all 10 isolate possess the gene for *CagA,VacA* they all express this gene due to point mutations and deletions and the levels of expressed toxin activities are strain-dependent, this supported and reported by [18], our data also contribute to former studies that concluded the mutation in these gene, could reduce

the adhesion and invasion of the bacteria, or could be attributed to the immune status of the host and the number of infective organisms that affecting virulenceassociated gene.

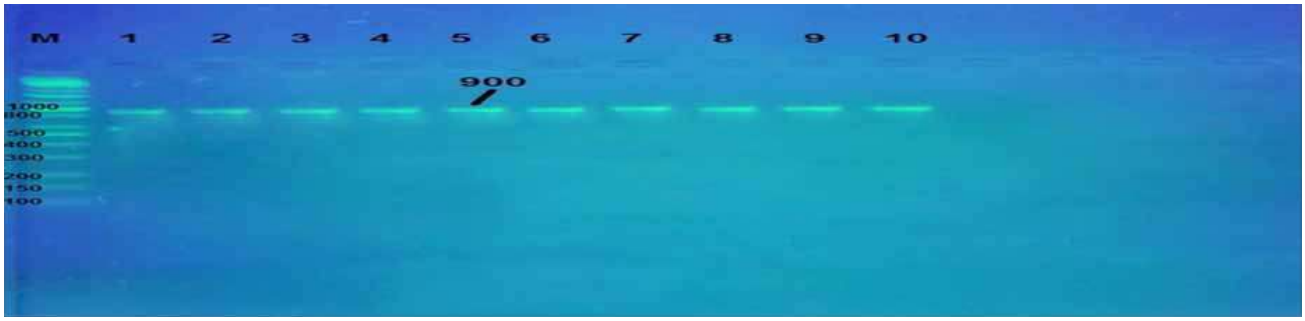

Figure 1: PCR product the band size 900 bp of Helicobacter pylori 16S ribosomal RNA gene The product was electrophoresis on 1.5% agarose at 5 volt/cm^2. 1x TBE buffer for 1:30 hours. N: DNA ladder (100)

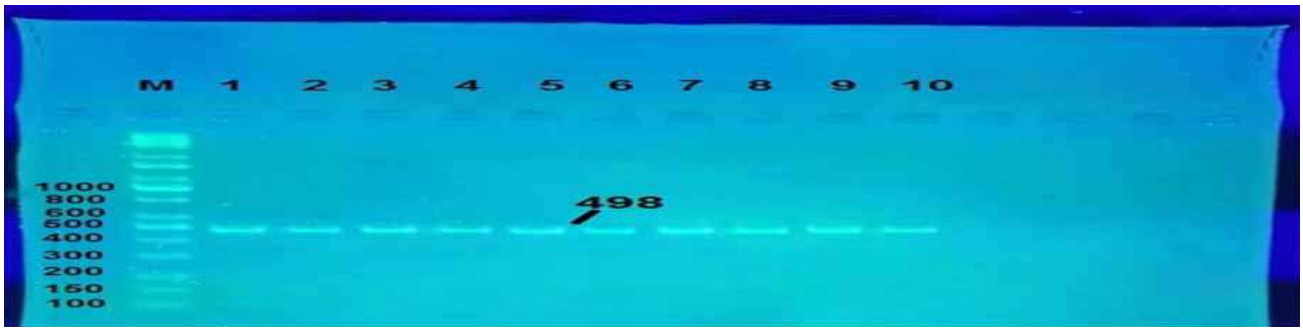

Figure 2: PCR product the band size 498 bp. of Helicobacter pylori Cytotoxin associated gene A (CagA) gene The product was electrophoresis on 1.5% agarose at 5 volt/cm^2. 1x TBE buffer for 1:30 hours. N: DNA ladder (100)

Conclusion

According to the results of the sensitivity test, one of the isolates of the *Helicobacter pylori* 4(HpG 4) was chosen for being resistant to all antibiotics (except amoxicillin). Primers were designed to diagnose both *Helicobacter pylor*i a gene which were detected and diagnosed by the presence of a *16SrRNA* gene. Genetic primires were designed to detect the virulence genes of *Helicobacter pylori*, *Cag* and *Vac* gene. The genes in ten isolates of *Helicobacter pylori* were investigated.

Abstract

The importance of the research is that it looks for the most precise constraints of the selection process and gives indicators for the teacher and sports educator to take all the details regarding the driver and examine them carefully, some may be a defect or strength during the discovery of talent and hence came this study, which is the first nationwide and looking at the duration of the student The researchers used the descriptive method in the method of comparisons to suit the research problem. The sample of the research was chosen by the researcher, (54) students divided into (27) students with incomplete pregnancy and (27) students with full pregnancy, the main findings showed that students with full pregnancy they overcame pupils with incomplete pregnancies in both muscle strength and speed.

Keywords: *Physical capacity, full load and incomplete pregnancy.*

Introduction

The scientific acceleration and development in all specialties and the associated cognitive superiority has become necessary to interest in education on the use of modern educational method and new technologies in line with this development and scientific progress.

Therefore, the physical education is looking at the particles that will discover the talents and avoid the obstacles. Perhaps the topic of selection is looking at the most accurate details, including the subject of the birth of an embryo of incomplete pregnancy (premature birth), which is the occurrence of contractions in the uterus regular and continuous enough to occur before the birth of growth Fetus for the week 37, starting from the period of fetal capacity to life outside the uterus, which is within 20 weeks, and 20 weeks ago is an abortion and not premature birth, and between 20 - 32 weeks, the term premature birth, accounting for about 5.5% of total births, But at the same time lead to 50% of deaths In newborns.[1] Despite the importance of the subject of physical abilities in sport, this subject has not been researched and studied to the extent that it is reflected in sports at the age of 8-9 years." Although the physical level of students is close but we notice differences in growth and Education is due to the pre-school stage, and there are differences that emerge as a result of students playing sports and sports.[2] For example, we see speed is a component of physical abilities that reflect the extent and compatibility of the mechanism in which the neuron works. Unusual, here we see all two elements associated with some where speed is One of the basic components of motor performance in most sports activities are linked to force because the power status is one of the most important components of motor performance if not the most important because each movement depends on the strength of power to lose the human movement, and affect the strength in some physical qualities such as speed and rotation and hence we find that training Physical fitness in general is to do all muscle work leading to the upgrading and improvement of fitness and development to a high degree under the conditions of conditions appropriate to the scientific stage.[3]

The importance of the research as it looks for the most precise obstacles to the selection process and gives indicators for the teacher and sports educator to take all the details concerning the driver and examine

them carefully, some may be a defect or strength during the discovery of talent and hence this study, which is the first nationwide and looking at the duration of the student Do they have physical connections.

Research Aim: Identify the differences in physical abilities between children born full and incomplete pregnancy of students aged (8-9) years.

Hypothesis: There are statistically significant differences in physical abilities among children born to complete and incomplete pregnancies for students aged 8-9 years.

Research methodology and field procedures:

Research Methodology: The researchers used the descriptive approach in the method of comparisons as appropriate to solve the research problem.

Community and sample search: The researchers identified their research community from primary school students in the third grade at the age of 8-9 years in the academic year 2018-2019 in Dhi Qar Governorate. The total number of students is 495 students and students from nine schools (Barada Boys School, Al Batha School for Boys, School of Confrontation, Sheikh Al Batha School, Qutaiba School, Jabal Al Sabr School, Al Ezz School).

The sample of the research was chosen by the third-grade students aged 8-9, with 54 students divided into 27 with incomplete pregnancies and 27 with full pregnancy. The percentage of the sample was 10.90%) And Tables (2.1) show the distribution and homogeneity of the sample.

Table (1). Shows the distribution of the sample

Gender	School Name	Total Number	Sample	Percentage
Boys	Sheikh Al Bathaa School	61	6	9.83
	Al Batha School	72	8	11.11
	Barda Boys School	67	8	11.94
	Al - Rawdatain School	43	2	4.65
	Al - Batha Martyrs School	55	6	10.90
	Al Qatif School	67	6	8.95
	El Ezz School	54	8	14.81
	Qutaiba School	32	4	12.5
	School confrontation	44	6	13.63
Total		495	54	%10.90

Table (2). Shows the homogeneity of the sample

Gender	Variables	Units	Mean	Median	SD	Skewness
Male	Length	Cm	128.6	129	4.73	-0.95
	Mass	Kg	26.48	26	5.34	0.81

Table (2) shows that the values of the splicing coefficient were between ±1, indicating the homogeneity of the research sample.

Identification of physical abilities and tests: The physical abilities of the subject and their tests were determined by distributing the questionnaire (1) to a group of experts and specialists, where the abilities that were obtained (80%) and above were neglected and the minimum was neglected. (75%) and more of the opinion of the arbitrators.[4] The research then asks to conduct the tests for each physical capacity under study, which was chosen through the use of previous studies and was presented to the same experts and obtained their approval by 100% The virtual honesty of the tests, despite the use of tests in the Arab and Iraqi environment and that m The researchers conducted an exploratory experiment on Wednesday, 14/11/2018 on a sample of non-research sample and the community of origin. They are 8 students aged 8-9 years. The aim of the exploratory

experiment was to identify the obstacles that Testing and disposal of the tests, finding out the suitability and efficiency of the instruments and devices during the tests used, knowing the compatibility of the tests with the level and abilities of the students, knowing the length of time taken for each test, the knowledge of the efficiency of the auxiliary team and checking the stability of the tests through the application of tests and the correlation coefficients between them. The correlation coefficients were high, which achieved consistency and objectivity, and Table (3) shows that.

Table (3). Shows stability and objectivity coefficients

Tests	Stability coefficient	Subjectivity coefficient
Jump wide of constancy	0.83	0.92
Jogging 30 meters	0.80	0.91
Jogging between characters	0.81	0.96

Specification tests:

Explosive power test:[5]

Name of test: Wide jump of stability for maximum distance (1) meter.

Objective of the test: measure the explosive force of the two men.

Tools used: flat ground does not expose the individual to slide, measuring tape, line drawn on the ground (starting line).

The method of performance: The laboratory stands behind the starting line and feet slightly spaced, swing the arms in the bottom downwards with the knees bend half and tilt the trunk until they reach the start of the start of swimming, from this situation swinging the arms firmly with the extension of the two legs along the trunk and push the ground Feet firmly in an attempt to jump as far as possible

Registration: The jump distance is measured from the starting line (the inner edge) until the last trace of the laboratory left near the starting line, or when the heel touches the ground, and the laboratory has two attempts to register the best.

The speed test:[6] Name of test: the enemy for a distance of 30 meters (2).

Objective of the test: Measure the maximum speed in the run

Tools used: a track or a space sports area of not less than 50 m and display at least 5 m, stop time number 2.

Performance method: We draw 3 parallel lines on the ground and the distance between the first line and the second 20 m, between the second line and the third 30 m, the laboratory stands behind the starting line, and from the high start at the signal, the laboratory running up to a maximum of up to the second start line and ends at the end of the line the third.

Registration: The laboratory records the time taken from the beginning of the second line until the moment of passing the finish line in the second and parts, and allows the laboratory to perform two attempts after giving a standard rest to record the best

Fitness test:[7] Name of test: Running the zigzag between the barriers (jogging between the characters) (in numbers) (3).

Purpose of the test: measure agility:

Tools used: four-track athletics, stopwatch: Method of performance: The four barriers are placed on a single line so that the distance between each barrier and another 180 cm and the distance between the first barrier and the starting line 360 cm Note that the starting line parallel to the barriers and length of 180 cm and painted on the ground next to the barriers numbers, the laboratory stands at the starting point and then run immediately When you hear the start signal using the route that is set to continue to run in this method (30) continuous seconds and at the end of (30) seconds record the number of place where time ends with the calculation of the number of full cycles of the test and displayed by number.

Research Procedures: The researchers went to the targeted schools for the purpose of conducting the research for the period from 2/12 to 26/12/2018. After meeting with the principals of schools and physical education teachers in these schools and after explaining the research procedures and meeting the students from the target boys, 2) on the students and asked them how to answer them and how to fill the information in them, and set a specific period of three days for the purpose of receiving information, and after collecting all forms from schools have emptied the information and categories according to the duration of the pupils of the boys and researchers have derived from this information Of those with full pregnancy.

Results

Table (4). Shows the computational and standard deviations and the value t calculated for the physical abilities tests of students with full and incomplete pregnancies

Test	Units	Complete pregnancy n = 27		Pregnancy is incomplete n = 27		Value (t) calculated*	Statistical Significance
		Mean	SD	Mean	SD		
Wide jump of stability for maximum distance	Cm	112.31	7.93	107.2	6.88	2.13	Sig.
Enemy for 30 meters	Sec.	6.44	0.66	7.14	0.25	5.05	Sig.
Running down the barriers	Sec.	7.5	1.03	7.20	0.88	0.81	Non sig.

* The value (t) of the table is equal to (2.01) degree of freedom (52) and the level of significance (0.05)

Table (4) shows that the value of the arithmetic mean of the students from the full load in the wide jump test, the enemy for 30 m, the zigzag run respectively (112.31 cm, 6.44 seconds, 7.5 seconds) and standard deviation respectively (7.93, 0.66, 1.03) The value of the computational mean of the students from the full load in the same tests was respectively 107.2 cm, 7.14 seconds, 7.20 seconds, and standard deviation respectively (6.88, 0.25, 0.88). The calculated value (t) was respectively (2.13, 5.05, 0.81). It is clear that the value of t calculated in the wide jump and enemy tests for 30 m is greater than the tabular value of (2.01) and the degree of freedom (52) (0.05). This indicates that there are significant differences in the tests of explosive force and speed between the students born of full and incomplete pregnancy and for the benefit of full pregnancy students, while it was found that the value of t calculated in the running test between the barriers less than the value of (t) (2.01) with a degree of freedom (52) and a significance level (0.05). This indicates that there were no significant differences in the fitness test among students born of full and incomplete pregnancy.

Discussion of Results

Table 4 shows the superiority of students born from full pregnancy in terms of muscle strength and speed, as well as the absence of significant differences between students with full and incomplete pregnancies.[8] The researchers attribute these differences to the fact that the strength and speed classes of abilities, The physiological organs of the human body in terms of the physiological section of the muscle and the number of motor units as well as the type of muscle fibers fast and slow (red and white) and therefore there is a strong correlation between these two levels, Muscle strength plays a large role in the level of speed, Where the results of practical and scientific experiments indicate that there is a significant correlation between the two elements of strength and speed,[9] the muscle or muscle group cannot contract quickly if it does not have sufficient strength for this performance, and that pupils born from incomplete pregnancy show symptoms of non-growth,Therefore, the premature birth of a child implies that his or her physical development is not yet complete, which makes the premature child vulnerable to health problems and complications at higher rates than those of normal-born children such as growth and development problems, lung disease, weak immunity, vision problems, Hearing and physical weakness make the child more vulnerable to childbirth .[10]

The researchers also see that the two types of muscle strength and speed of inherited abilities that move with the child from birth and that most of the children born early may show them in the structure of physical and mental in the long term, while we see that the fitness characteristic of the motor capacity acquired from the ocean did not There is a significant difference between those who have full and incomplete pregnancies. Kinetic abilities develop through the ocean, which comes from practice and continuous and repeated training.[11]

Conclusions

1. Students with full pregnancy outperformed students with incomplete pregnancy in both muscle strength and speed.
2. The differences were not significant between students with full pregnancy and pupils with incomplete pregnancy in fitness.

Ethical Clearance: The Research Ethical Committee at scientific research by ethical approval of both environmental and health and higher education and scientific research ministries in Iraq.

Conflict of Interest: The authors declare that they have no conflict of interest.

Effect of Salpingectomy Versus Fallopian Tubes Cauterization for Management of Hydrosalpinx on the Future Females' Ovarian Reserve

Mufeda Ali Jwad[1], Wasan Adnan Al-Jubori[1]

[1]Lecturer in High Institute of Infertility Diagnosis and Assisted Reproductive Technologies, Al-Nahrain University, Iraq

Abstract

Background: Injury to the distal end of the fallopian tube (ampulla), and its fimbria, causes the end of the tube to close. Glands within the tube produce a watery fluid that collects within the tube, producing hydrosalpinx which should be blocked surgically before starting in vitro fertilization by salpingectomy, clumping or cauterization in two sites that may influence the vascularity of the adjacent ovarian tissue affecting the IVF results later on.

Aim of Study: To compare between the effect of salpingectomy and cauterization of the fallopian tubes on the ovarian reserve and ovarian vascularity in females undergoing tubal surgeries for hydrosalpix.

Subjects Materials and Method: The present study was done on 30 infertile females with history of primary or secondary infertility who were diagnosed as having bilateral or unilateral hydrosalpinx by hystrosalpingogram (HSG). These females were divided into two groups, the first group (n=15) were subjected to laparoscopic tubal ligation using cauterization in two sites for each tube, while the other group (n=15) were undergone more aggressive method which is salpingectomy (severed and sealed).

An assessment of their antral follicle count (AFC), anti-Müllerian hormone (AMH) and calculating the ovarian artery pulsatility index (PI) and Doppler index of vascular resistance in the ovarian vessels (resistant index of stromal blood flow - RI) was done for all females before and after surgery.

Results: The results of age, AFC, AMH level, RI, and PI was recorded before and after doing their surgeries in both groups. The statistical analysis recorded no significant difference ($p>0.05$) in all these parameters before and after subjecting to surgeries, but when these parameters were compared within each group only resistance index showed significant difference ($p<0.05$) in the group underwent tubal cauterization while in the other group who underwent salpingectomy a significant difference ($p<0.05$) was recorded in AFC and highly significant difference ($p<0.01$) in AMH level.

Conclusions: The negative effect of salpingectomy on ovarian reserve is more than that of tubal cauterization.

Keyword: *Tubal cauterization, salpingectomy, ovarian reserve, pulsatility index, resistant index.*

Introduction

One of the most common causes of female infertility is hydrosalpinx. It may interfere with fertility through lowering implantation and pregnancy rates after in- vitro fertilization. This may be due to mechanical factors, toxicity of the hydrosalpingeal fluid, and receptivity dysfunction [(1)].

Salpingectomy (removing part of a fallopian tube) is done to improve in vitro fertilization (IVF) success rate and preferred over salpingostomy. Hydrosalpinx may half the IVF success rate [2]. This led the United Kingdom's National institute of Health and Clinical Excellence guidelines (NICE) to recommend laparoscopic salpingectomy before assisted reproductive technologies (ART) when hydrosalpinx was diagnosed through hystrosalpingography (HSG) and by ultrasound[3].

These Guidelines are also supported by data analyzed in a recent Cochrane review emphasizing a superior pregnancy rate when patients with tubal disease underwent laparoscopic salpingectomy (or at least tubal occlusion) prior to IVF treatments especially if enlarged enough to be visible on ultrasound and in particular for those affected bilaterally [4, 5]. These studies have resulted in the Cochrane library recommendation of salpingectomy for hydrosalpinges [6,7].

It is generally believed that the fluid holds a key position in impairing the implantation potential. However, aggressive tubal surgery may impact fertility and ovarian reserve because of its effects on ovarian tissue of the same side [8].

Subjects Materials and Method: The present study was done on 30 infertile females attending high institute of infertility diagnosis and ART during the period from 2016-2018. These females were diagnosed as having bilateral tubal obstruction with unilateral or bilateral hydrosalpinx as diagnosed by hystrosalpigogram and ultrasound for presence of tubal dilatation. An ultrasound assessment of their AFC and day 3 AMH was measured by electro chemiluminscense immunoassay (ECLIA).

Doppler ultrasound assessment: All patients underwent single transvaginal color imaging, as well as pulsed Doppler spectral analysis by the same physician in a quiet and comfortable location; with an empty bladder to normalize blood pressure and pulse rate between the 3rd and 8th days of the menstrual cycle to avoid changes in blood flow due to ovulation and corpus luteum. The number of antral follicles in both ovaries, visualization of the ovarian arteries and the blood vessels within the ovarian stroma was done for all patients.

The ovarian artery located lateral to the upper pole of the ovary, near the infundibulopelvic ligament. The stromal vessels of the ovary were identified as color signals within the ovarian stroma. A pulsed Doppler range gate was placed across each vessel, aiming for an angle of insonation close to 0° between the Doppler beam and the vessel. Then two blood flow indices were automatically calculated: the pulsatility index (PI); the resistance index (RI) of the bilateral ovarian vessels. The normal resistant index and pulsatility index is (0.62±0.04, 0.97±0.04) respectively [9].

These patients acceptance for undergoing a laparoscopic tubal occlusion was signed. At least 2 months post- surgery reassessment of the same patients for the same parameters was done including AFC, AMH, PI and RI.

Findings: This prospective comparative study was done between two groups of females. The first group (n=15) underwent tubal cauterization in two sites while the other group underwent tubal blockage by salpingectomy (severed and sealed) (n=15). The age of females, type of infertility, antral follicle count, antimullarian hormone, ovarian vessels pulsatility index and stromal blood flow resistant index were recorded for all infertile females included in the present study (table-1).

A comparison was done for age, AFC, AMH level, ovarian vessels PI and stromal blood flow RI between the group who underwent salpingectomy and those who underwent tubal cauterization before doing their operations. The results showed no significant difference ($p>0.05$) for all these parameters (table - 2).

Within each group comparison was done between the results of AFC, AMH level, ovarian vessels PI and stroma blood flow RI before and after doing the operation. In the group who underwent tubal cauterization; the results recorded no significant difference ($P>0.05$) in AFC, AMH and PI while significant difference ($p<0.05$) was recorded in RI of ovarian stroma (table-3).

While in the second group who underwent salpingectomy; the same parameters were compared before and after doing surgery and showed significant difference ($p<0.05$) in AFC, highly significant difference ($p<0.01$) in AMH level but no significant difference ($p>0.05$) in both PI and RI of ovarian blood flow (table-4).

A comparison was done for AFC, AMH, RI and PI between the group of females who were subjected to tubal cauterization and those who underwent salpingectomy after surgeries. The results showed no significant difference in all parameters (table-5).

Discussion

Tubal ligation may reduce the ovarian blood flow and lead to tissue damage to the ovary that may result in a significant decrease of the total follicular pool. It was suspected to induce several adverse effects such as irregular menstrual cycles, dysmenorrhea, and climacteric symptoms [10, 11].

In the present study al females included were having normal ovarian reserve before subjecting to surgeries as documented by having AFC and AMH to be within normal range.

Age was documented previously as being one of the most predicting markers for fertility assessment [12]. In the present study, it was found that there was no significant difference in the mean age between the group who underwent tubal cauterization and those who underwent salpingectomy. This finding indicated that both groups had comparable age which is important to eliminate any variable that may affect the results of the procedure type on ovarian reserve as the recent studies have shown that poor ovarian response is a first sign of ovarian ageing (early ovarian failure or early menopause) [13].

Many markers of ovarian reserve have been considered in the last few decades, but an ultimate marker still has not been proven. Response prediction through ovarian reserve testing is superior to that through chronological age alone. The antral follicle count (AFC) and anti-Müllerian hormone (AMH) are currently considered to have the best sensitivity and specificity to predict the ovarian response, despite them having 10–20% false-positive rates [14], so these parameters were also recorded for both groups and found to be within normal range and no significant difference was found between the two groups indicating that the groups were comparable regarding their ovarian reserve.

The previous studies showed that prophylactic bilateral salpingectomy in some patients with ultrasound-visible bilateral hydrosalpinges improved the IVF outcome. In addition to pregnancy rate, ongoing pregnancy and live birth rate were increased with laparoscopic salpingectomy for hydrosalpinges prior to IVF [6]. But one of the problems caused by salpingectomy is the possibility of impairing the ovarian function after the procedure. The most important blood supply to the Fallopian tube is the medial tubal artery, which originates at the same point as the median ovarian artery. If the salpingectomy procedure is not properly performed close to the tube, it may disrupt the normal blood flow to the ovary. So in the present study pulsatility index and resistance index were measured by color Doppler ultrasound which showed no significant difference between the two groups.

For the group of females who were subjected to fallopian tubes cauterization the results showed no significant difference in antral follicles count, early follicular AMH and ovarian artery pulsatility index which indicated that this procedure has minimal effect on ovarian vascularity and consequently on their function. These results were in accordance with that of Ercan et al 2012 [15]. Only resistance index was significantly less after operation this may be due to development of collateral vascular circulation that may resolve the ischemic effect of the procedure as discussed in previous studies[16, 17].

In the present study the other group who were subjected to more aggressive procedure which is salpingectomy showed significant decrease in antral follicle count (AFC) and highly significant decrease in the early follicular AMH level that indicates the development of poor ovarian reserve which negatively affect IVF result later. This may be explained to be the result of tubal sterilization procedure which could destroy the vascular structures adjacent to fallopian tubes, such as the tubal branch or ovarian branch of the uterine artery in the mesosalpinx, causing an altered blood supply to the ovaries. The diminution of blood flow could affect the ovarian reserve due to possible ischemia in the ovary. As a result ovarian response to gonadotropin signaling may decrease after this relative ischemic effect causing subsequent impairment of follicular growth [18, 19]. Relative ischemia in the ovaries created by the destruction of the vascular mesosalpinx may first affect the preantral and small antral follicles, resulting in a decrease in AMH levels. This effect might also reduce the number of cyclically recruited follicles, causing a decrease in AFCs. These results did not agree with previous studies of Findley et.al.,2013. But it agree with that of Goynumer et al., 2009 [20, 21].

Regarding the Doppler study of this group before and after salpingectomy there was no significant difference between them and this agree with previous studies of Kelekci et al., 2005 and 2004 [22,23]. But in other studies an elevation in pulsatility and resistance indices were reported. The authors explained these elevations by the increase in local vascular resistance after tubal sterilization [16].

Table (1): Patients' general clinical parameters

Parameters		Values
Age (Years)		31.18±1.15 (mean±SER) Range 19-40
Type of infertility	Primary infertility (%)	40.91%
	Secondary infertility (%)	59.09%
Antral follicle count		14.63±0.74 (mean±SER)
Antimullarian hormone level		2.23±0.31 (mean±SER)
Ovarian artery pulsatility index		1.62±0.45 (mean±SER)
Ovarian stromal vessels resistance index		0.87±0.07 (mean±SER)

Table (2): A comparison of all parameters between the group who underwent salpingectomy and those who underwent tubal cauterization before surgeries.

Parameters	Tubal cauterization group	Salpingectomy group	p-value
Age (years)	29±2.02	32.33±1.59	0.34^{NS}
Antral follicle count	15±1.36	14.4±1.2	0.78^{NS}
Antimullarian hormone level	2.81±0.65	2.1±0.29	0.46^{NS}
Ovarian artery pulsatility index	1.76±0.15	1.56±0.17	0.27^{NS}
Ovarian stromal vessels resistance index	0.97±0.16	0.85±0.13	0.64^{NS}

NS: No significant difference (p>0.05)

Table 3: Acomparison of ovarian reserve parameters before and after surgery within the group who underwent tubal cauterization.

Parameters	Tubal cauterization group before surgery	Tubal cauterization group after surgery	p-value
Antral follicle count	15±1.36	15.2±0.84	0.13^{NS}

The Effectiveness of Retaliatory Force Exercises in Developing the Explosive Power of Two Legs and Arms and the Accuracy of the Spike in the Badminton of Young Players Under the Age of 18 Year

Jabbar Ali Kathim[1] Rami Jabbar Kadhim[2], Hussein Mnaty Sachit[3]

[1]Al-Qasim Green University, Department of Student Activities, [2]Babylon Educational Directorate, Al_Waely Secondary School for the Distinguished Boys, [3]University of Kerbala, The College of Physical Education and Sport Sciences, Iraq

Abstract

The problem of research is that most young players with badminton do not have sufficient muscular strength for the muscles of legs who have a big role in the accuracy of the strike. This was observed through the personal experience of the two former players and interested in badminton and through the interviews that were conducted with Most trainers of the youth category and through the belief of researchers in scientific research as the correct scientific step to solve problems, exercises were designed to refine the explosive capacity of the muscles of the two legs and their impact on improving the accuracy of the strike in the field of badminton for young players 18 years old .

Research aim to prepare exercises regressive force to develop explosive power in the muscles of legs, arms and accuracy spike in the badminton players for young people under 18 years old. The researchers used the pilot approach to experimental design with pre-test and post-test for the two groups (experimental and control) to suit the nature of the research. The research community was determined by the players of the Mahaweel Sports Club with ages (16-18) for the training season 2018-2019 of 14 players. The sample was selected in a comprehensive inventory method and the sample was divided into two groups (experimental and control) with seven players per group. One of the most important conclusions was the positive effect on the development of explosive force of arms and legs using the reactive power exercises of the experimental group and all tests. The reason for the development of the experimental group was the result of the independent variable use of aftershocks for the development of explosive force of the arms and legs, Develop the skills of the precision of the spike in the badminton.

Keywords: *Explosive power, legs and spike.*

Introduction

It is recognized in sports training that it is an organized process aimed at reaching the individual to achieve the best achievements in the field of specialization and within the limits allowed by his physical, psychological and social abilities. The progress in the levels of achievement of sports events in general and badminton especially because of the high adaptations of the body's clean bodies during the use of different method to train muscle strength because it is one of the main performance factors for most sports games and events, requiring training in all sports activities, but vary in amounts And differentiated details from one activity to another and may have precedence in a particular activity without another, because force is an important function that the body cannot perform movements without its presence in the muscles.[1]

One of the first requirements for badminton is to develop its physical characteristics of the force in its explosive type for the purpose of integrating it with the players "because the development of the base of fitness elements specialized in tennis is important for both

performance and health of the sport, the first concern is on the uses of power to develop muscle capacity for good performance, The basic skills of badminton are explosive power.

In this sense, the importance of research in achieving the goal of developing the explosive force of the two legs and the arms of the players is shown by following the method of strength training exercises used in the development of muscles of the two legs and arms working in the skill of beating overwhelming, which depends on the strength and speed of the muscles of the two legs and the arm of the skill.[2]

Research Aims:

1. Prepare the exercises of the force of a rebound to develop the explosive capacity of the muscles of legs and arms and the accuracy of the spike in the badminton of young players under 18 years.
2. Identify the effect of aftershocks in the development of the explosive power of the muscles of two legs and arms and the accuracy of the spike in the badminton of young players under 18 years

Hypothesis: There is a positive effect of the exercises of aftershocks in the development of the explosive capacity of the muscles of the legs and arms and the accuracy of the spike in the badminton of young players under 18 years.

Research methodology and field procedures:

Research Methodology: The researchers used the experimental approach with the pre-test and post-test experimental design of the two groups (experimental and control) to suit the nature of the research.

Community and Sample research: The research community was determined by the players of Al Mahaweel Sports Club at the age of (16-18) years for the training season 2018-2019 of 14 players. The sample was selected in a comprehensive inventory method and the sample was divided into two groups (experimental and control) with seven players per group. Homogeneity and equivalence of the sample:

In order to make the researchers work in the right direction and to emphasize the objectivity of the work, the researchers found the homogeneity and equivalence between the two groups of research in terms of physical measurements (length, mass, training and time) using the appropriate statistical treatments in order to know the truth of the differences between the two groups of research and as shown in Table (1, 2).

Table (1). Shows the homogeneity of the sample

Variables	Units	Test value (Leven)		Level of significance
		Calculated	Standard error	
Age	Year	1.432	0.454	Non sig.
Training age	Year	0.783	0.980	Non sig.
Mass	Kg	0.059	0.564	Non sig.
Length	Cm	1.121	0.320	Non sig.

Table (2). Shows the mean, standard deviations, calculated value (t), and significance of differences in tests examined between the control and experimental groups in the pre test

Variables	Units	Control Group		Experimental Group		(t) Calculated	Mistake percentage	Significance of differences
		Mean	SD	Mean	SD			
The explosive power of the two legs	Cm	30.00	3.37	29.86	4.10	0.071	0.431	Non sig.
The explosive power of the arms	Meter	2.742	0.399	2.671	0.446	0.316	0.331	Non sig.
The accuracy of the spike	Grade	9.897	1.934	9.998	1.754	1.983	0.398	Non sig.

Tests used in Research:

1. **Vertical jump test for Sargent:**[3] Purpose of the test: Measure the muscle capacity of the two legs in the vertical jump up.

Tools:

- A panel of wood painted black with a width of 1 م m and a length of 1 م m, with lines drawn in white and the distance between each line and the other (2) cm.
- Smooth wall not less than the height of the land of 3.60 m.
- A piece of chalk or plaster powder, a piece of cloth to clear plaster marks after reading all attempts by the laboratory.
- The blackboard can be removed with a piece of wood that is installed on the wall.

Measures:

- Fixing the blackboard or a piece of wood on the wall so that the bottom edge is at a height allowing the shortest laboratory to perform the test and make sure that the plate is installed away from the wall with a distance of not less than (15) cm, so as not to contact the wall during the jump up.

Test Instructions:

- Both feet must be pushed from a steady position.
- Before jumping up, the lab swings the arms forward and down to adjust the timing of the movement, to reach the maximum height possible.
- The laboratory is given three to five consecutive attempts and is calculated as a result of the best attempt.
- Measurements are taken for the nearest (1) cm.
- Jump up be feet together from the position of stability and not take a step or upgrade.
- Do not extend the chalk pieces outside the fingers so as not to affect the results.
- The arbitrator is preferred to stand on a table or ladder near the board so that he can read the results of the various attempts clearly.

Calculation of grades: The degree of the laboratory is the number of centimeters between the line that reaches it from the position of the stand and the mark to which it reaches as a result of the jump to the highest close to the nearest (1) cm, and Figure (7) shows the performance of the test.

2. **Test the throwing of the medical ball weighing (2) kg of hands over the head of the sitting position on the chair:**[4] Objective of the test: Measure the explosive force of the arms and shoulders.

Possibilities and tools: Medical ball weighing (2) kg, measuring tape and chair with belt and trunk fixed and tight.

Performance Specifications: The laboratory is placed on the chair and the medical ball is held by the hands above the head. The trunk is attached to the edge of the chair. The belt is placed around the lab trunk and is held from the back by an airway to prevent the laboratory from moving forward while throwing the ball in the hands. Three attempts to score his best.

Registration method: The distance between the front edge of the chair and the nearest point the ball places on the ground is calculated.

3. **Test the accuracy of the spike in the badminton:**[5] Purpose of the test: Measure the accuracy of the spike in the badminton.

Performance Specification: The player is 120 cm from the front line, ready to perform the skill and the gap between the feet is 60 cm or chest width.

The trainer sends a feather to the area where the skill is to be performed and in the form determined by the player in advance and the condition is displayed and performed by the player prior to the execution of the test.

Registration method: The number of attempts is five attempts and the final score is 15 because each attempt score of three (3 - 2 - 1) includes all attempts.

Pre Tests: The researchers conducted the pretests on Sunday, 1/12/2018 at 3:00 pm. After giving the researchers a brief explanation of how the tests were performed and the purpose of the tests, then taking the measurements of length, weight, age and training.

Suggested exercises: The exercises were implemented during the special preparation period as follows:

- The proposed exercises started on 1/12/2018.
- Exercise period in weeks: (8) weeks.

- The total number of training units: (24) training units.
- Number of weekly training units: (3) units.
- Weekly training days: (Sunday - Tuesday - Thursday).
- Total training time: (90) minutes.
- Time of the main section of the module: (30-45) minutes.
- Training method used: high intensity training and repetitive training.

Posttests: After the completion of the implementation of the exercise vocabulary within the prescribed period and then conducting the tests for the research on 5/2/2019 at 3:00 pm in the stadium of Mahaweel Sports Club, the researchers took care to provide conditions similar to pretests in terms of time and place, perform the tests).

- Training intensity used: (85-95%). Of the extreme intensity of the player's performance.

Results

Table (3). Shows the mean difference, standard deviation and the value of (t) and the significance of differences between the results of pre and posttests of the control group in the variables under research

Ests	Units	Pretest		Posttest		(t) Calculated	Mistake percentage	Significance of differences
		Mean	SD	Mean	SD			
The explosive power of the two legs	Cm	30.00	3.37	30.14	3.63	5.213	0.005	Sig.
The explosive power of the arms	Meter	2.742	0.399	3.300	0.432	7.136	0.000	Sig.
The accuracy of the spike	Grade	9.864	1.875	11.435	3.985	4.698	0.003	Sig.

Table (4). The difference in the mean and its standard deviation and the value of (t) and the significance of the differences between the results of the pre-test and the experimental group in the variables in question

Tests	Units	Pretest		Posttest		(t) Calculated	Mistake percentage	Significance of differences
		Mean	SD	Mean	SD			
The explosive power of the two legs	Cm	29.86	4.10	44.71	4.11	3.778	0.004	Sig.
The explosive power of the arms	Meter	2.671	0.446	4.478	0.508	3.897	0.040	Sig.
The accuracy of the spike	Grade	9.896	1.543	13.043	4.985	3.328	0.002	Sig.

Table (5). The value of (t) and the error level and the significance of the differences between the results of the post-test of the control and experimental groups in the variables under consideration

Tests	Units	Control group		Experimental group		(t) Calculated	mistake percentage	Significance of differences
		Mean	SD	Mean	SD			
The explosive power of the two legs	Cm	30.14	3.63	44.71	4.11	5.221	0.007	Sig.
The explosive power of the arms	Meter	3.300	0.432	4.478	0.508	4.762	0.000	Sig.
The accuracy of the spike	Grade	11.435	3.985	13.043	4.985	3.832	0.003	Sig.

Discussion of Results: The results in Table (3, 4 and 5) show significant differences between the pre and post measurements of the experimental and control groups and for the post-test. There are also significant differences between the control group and the experimental group and for the experimental group that used the aftershocks. Several variables interfered with the airstrikes that included explosive power exercises in a new mode of increasing both power and speed, long jumps of stability,[6] vertical jump, and arm-throwing operations, all of which contributed significantly to the development of force The weight of the arms and the two legs working and intertwined in the skills of the spike in the badminton through the throwing of medical balls and weight in different situations, which strengthened the load of muscles for longitudinal loads, which in turn developed the adequacy of the relationship of tide and shortness in the muscle and also when the development of strength of the two legs, there is a correlation relationship when the strength of the muscles of the two legs The results of explosive power expressed by vertical jump.[7]

The common pathway pathways lead to the ability of the plyometric for the possible improvement of neural pathways and neuromuscular cooperation during training, leading to increased strength output through improved muscle group collaboration.[8]

It should be noted that the development of the performance capacity can be obtained by producing the highest possible power in the shortest possible time. This situation is characterized by high strength and relatively low strength repressive exercises, which produces a link between power and speed, An explosive act and that the development of explosive power will be through the implementation of the exercises plyometric, which strengthens the saying that.[9]

The researchers attributed the improvement in the accuracy of the spike to the strength training exercises, which worked to develop the explosive force of the arms and legs and thus positively affected the skill performance of the skill of beating overwhelming because of the close link between the explosive ability of muscles and legs and the accuracy of the spike in the badminton, The ability to detonate the arms and legs of the role of positive and influential in the performance of skill, especially in the skill of the spike because it is the ingredients of the actual performance and the correct skill.[10]

Conclusions

1. A positive effect in the development of the explosive force of the arms and legs has been demonstrated by the use of the reactive power exercises of the experimental group and all tests.
2. A positive effect on the accuracy of the spike in the badminton has been demonstrated by the development of explosive force of the arms and legs using the reactive power exercises of the experimental group and all tests.
3. The reason for the development of the experimental group was the result of the use of the independent variable of aftershocks for the development of explosive force of the arms and legs, which effectively affected the development of the skill capabilities of the accuracy of the spike in the badminton.

Microscopic Vision of an Experimental Infection Effect with Candida Glabratayeast in the Histological Structure of the Heart and Lungs in Immunosuppressed Male Mice and Other Normal Mice

Khulood Naji Rasheed[1], Milad A. Mezher[2], Idrees Khalaf Thamer[3]

[1]College of Science-Tikrit University, [2]College of Education for Pure Science-Tikrit University, [3]College of Veterinary Medicine-Tikrit University, Iraq

Abstract

The research was conducted to study histological structure of heart and lungs in male mice after being experimentally infected with *Candida glabrata* yeast isolated from the patient visitors of Tikrit Teaching Hospital suffering from Invasive Candidiasis (38 males, 25 females) between the ages of 15 and 82 years. The results showed pathological histological changes in both heart and lungs of male mice experimentally infected with the *C. glabrata* inhibitory immunosuppressant, which consisted of sloughing the basal membrane of the endocardium, as well as sarcoplasm degeneration of myocardial cells. In lungs the histological sections showed occurrence of extensive hemorrhage in and around alveoli and emergence of lymphocytes around the bronchioles as well as congestion and bleeding of blood vessels. While the results of the normal mice group (non-immunosuppressant) showed pathological histological changes represented by the local degeneration of heart sarcoplasm muscle, and in lungs have shown severe congestion of blood vessels and capillaries around alveoli as well as emergence of RBCs and desquamation of epithelial cells in the trachea with a local lymphocytic aggregation compared to the control group.

Keywords: *Heart; histological structure; Microscopic vision.*

Introduction

The genus *Candida* consists of a large number of species reaching up to about 200 species, but the pathogen is only about 20 species which are responsible for Invasive Candidiasis in humans and animals. It is characterized by the presence of ferocity factors that contribute to the invasion and colonization of host tissues(1). Therefore, the degree of infection varies between acute, moderate or chronic. Recently, there has been an interest in Candidiasis fungi due to the widespread of diseases caused by these fungi such as cutaneous skin infections as onychia, paronychia, intertrigo, mucocutaneous infections like oral thrush, vaginitis, and systemic infections such as fungemia, endocarditis, meningitis, pneumonitis,osteomyelitis, etc. (2-5).

Myocarditis-endocarditis or pericarditis by *Candida* is due to the spread through the blood, and then adhesion to the damaged areas of heart. These yeasts usually settle in the endocardium on the valves as well as the entrance of the left ventricle to the aorta causing endocarditis with the possibility of a hole occurring in the heart valves and thus loss of functional control that may develop to severe heart failure, as well as complications that may be a threat to life if not treated quickly, such as the occurrence of clots that may flow into the arteries feeding the body organs causing infarctions or it may lead to pneumonia, respiratory distress, increased heart rate, severe drop in pressure, or loss of consciousness. The disease occurs as chlamydia diffused throughout the heart muscle in the normal tissue. It occurs at a rate of 50% in people with widespread Candidiasis (6).

Material and Method

The sample was obtained from the blood (Candidemia) and a number of steps were taken to examine the isolatewith diagnosis.

The Brain Heart Infusion Agar/Broth media was used to isolate the yeast and increase the vitality of the isolates before it was used in experiments [7]. It was prepared from brain and heart infusion (37 gm), agar (20 gm), distilled water (1000 ml). The media was incubatedat (37°C) for (72) hours followed by microscopic examination and then transplanting on a sabouraud dextrose agar media prepared from the sabouraud dextrose agar (65 gm) and distilled water (1000 ml), incubated at (37°C) for (48) hours for purification and diagnosis of the isolate[8,9]. The morphological characteristics of the colonies represented by color and texture were observed and the isolate was identified and diagnosed depending on that, as well as some chemical examinations, with direct microscopy after pigmentation [10; 11].

In terms of histological study, male mice of the Balb/c strain were used of (6) weeks in age with weights ranging from (22 to 28)gm. They were divided into four groups with (5) mice in each group, as follows:

- The first group: injected with (0.1 ml) of subcutaneous hydrocortisone drug for four days,and on the fifth day it was injected with (0.3 ml) of *C. glabrata*yeast suspension in the tail.
- The second group: injected with (0.3 ml) of *C. glabrata* yeast suspension in the tail.
- The third group: injected with (0.1 ml) of subcutaneous hydrocortisone for four days.
- The fourth group: injected with (0.1 ml) of distilled water and was considered as a control group.

The mice of the four groups were kept in normal conditions and monitored daily until the symptoms were shown (15) days after the injection. They showed underweight, redness of the ear, severe sweating, hair color changed to pale yellow, as well as one fainting case and two fatalities in the third group (injected with hydrocortisone drug and *C. glabrata* yeast suspension). The reason for injecting the mice with hydrocortisone drug is that it is an immunosuppressant or inhibitor for the purpose of increasing the rate of the experimental infection and comparing it with the normal group injected only by the yeast suspension, and then comparing them with the control group.

Then,slides were made by the sectioning method for heart and lung tissues using method of Scheuer and Chalk, as well as Evans and Richardson[12;13]and then examined and photographed under the microscope with different magnification forces.

Results and Discussion

The histological sections of immunosuppressed and non-immunosuppressed male mice infected experimentally with *C. glabrata* yeast showed several histopathological changes in heart and lung compared to the control group.

The histological pathological changes in heart and lungs were:

***The Heart:** The histological sections in the first group of mice showed a number of histological changes represented with appearance of a thickened basement membrane of endocardium and which sloughed from the tunica intima (Fig. 1), with degeneration of sarcoplasm of myocardium cells, particularly near the tunica intima and congestion of the branches of coronary arteries and appearance of RBCs outside the blood vessels (Fig. 2).

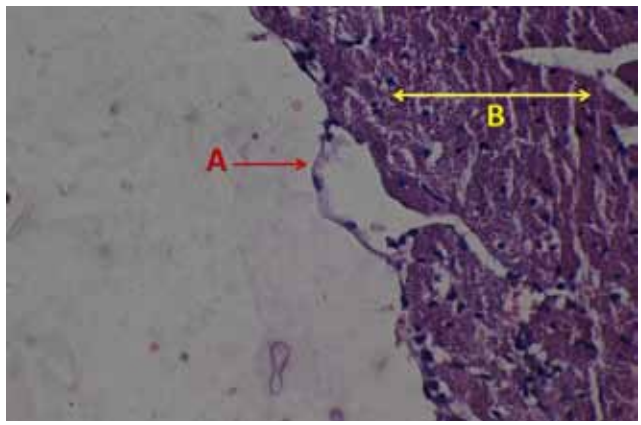

Figure 1: Section in heart of a mouse from the first group showing the sloughing of basement membrane of endocardium (A), as well as appearance myocardium in section (B). Hematoxylin and eosin stain. X40.

While the histological sections of heart in the second group of miceare normal in general in the cardiac muscles, with a number of histological changes represented bya local degeneration of the sarcoplasm and hemorrhage in blood vessels of the coronary arteries, as well as appearance offibers loosened from each otherin a number of heart muscles (Fig. 2).

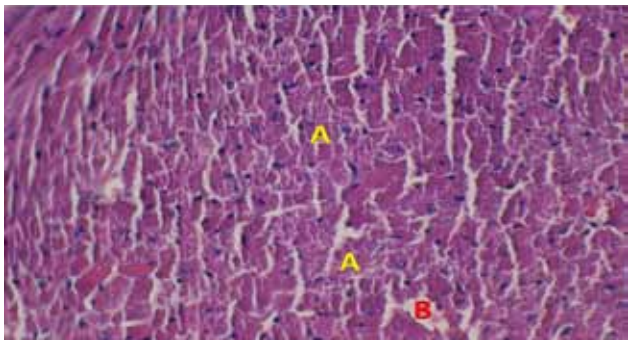

Figure 2: A section in heart of a mouse from the second group in which there is local degeneration of the sarcoplasm of myocardium (A), with hemorrhage in blood vessels of the coronary arteries (B). Hematoxylin and eosin stain. X40.

As for the histological sections of heart in the third group of mice, it appeared normal in the size and shape of the cardiac muscles in general, with a number of histopathological changes represented with loosening of the cardiac muscles and weak interconnections between them (Fig. 3).

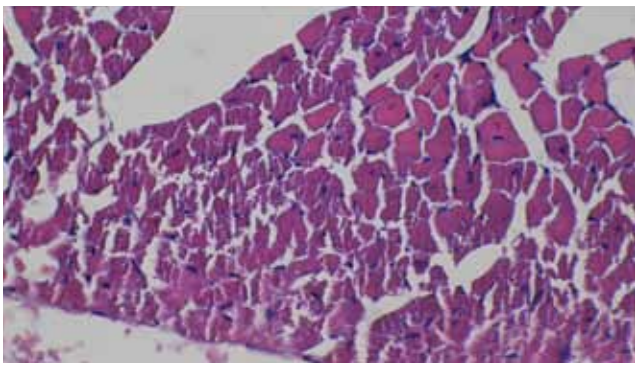

Figure 3: A section in heart of a mouse from the thirdgroup detecting the loosening of cardiac muscles, as well as their fibers. Hematoxylin and eosin stain. X40.

*** The Lungs:** The histological sections in the first group of mice showed a number of histological changes represented with occurrence of extensive hemorrhage in and around alveoli (Fig. 4).

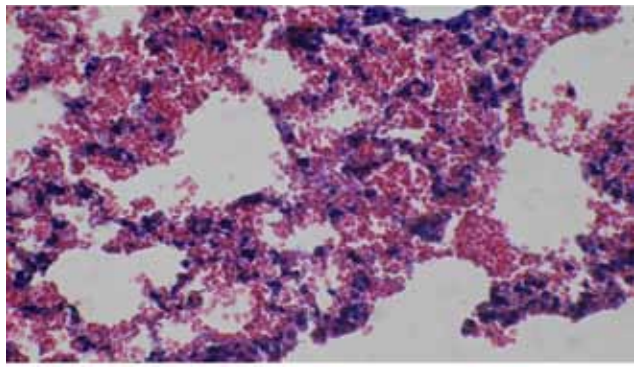

Figure 4: A section from a mouse lung of the first group in which extensive hemorrhage is observed in and around alveoli. Hematoxylin and eosin stain. X40.

While the histological sections of lung in the second group of mice showed a number of histological changes in the form of severe congestion in capillaries in between alveoli, and some of these alveoli consisted of RBCs in their cavities (Fig. 5).

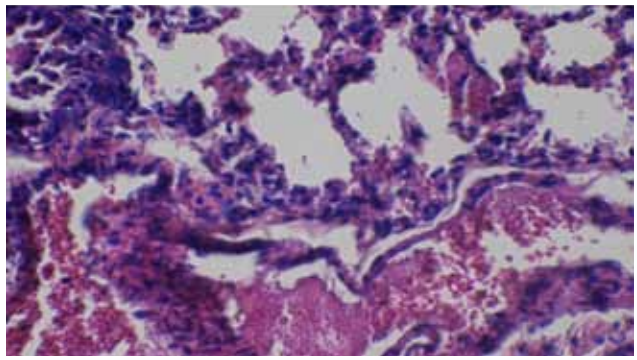

Figure 5: A section from a mouse lung of the second group in which there is a severe congestion of blood vessels and capillaries around alveoli. Hematoxylin and eosin stain. X40.

The histological lung sections of the third groupof mice showed a number of histological changes, such as congestion in certain blood vessels in certain areas of the tissue, appearance of RBC soutside the blood vessels, and a local aggregation of lymphocytes (Fig. 6). The sections clearly showed alveoli and its walls lined with epithelial cells and surrounded by interstitial connective tissue.

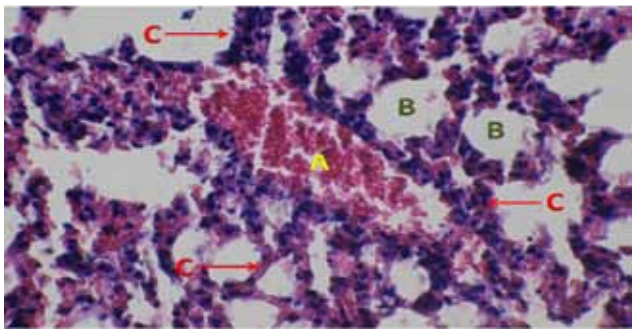

Figure 6: A section from a mouse lung of the thirdgroup detecting congestion in blood vessels (A), alveoli (B), and alveolar wall (C). Hematoxylin and eosin stain. X40.

The most important factors of virility of *Candida* genus is the ability of adhesion and penetrating host tissues, the possession of degenerating enzymes, the production of toxins, the ability to withstand different temperatures, the possibility of morphological shift from one form to another, as well as presence of cell wall which is considered the site of adhesion to host cells and then colonizing tissue and secretion of pathogens [3(.

The two most important physiological barriers for growth of fungi in human tissues are high temperature and redox potential[14;15].

C. glabrata cell surfaces possess specialized proteins in their cell walls called adhesions [16] similar to those found in *C. albicans*[17]. In addition to their normal life roles they work to achieve adhesion with host cells including phagocytes, epithelial and endothelial cells, and thus neutralize host defenses. Thus, it achieves links with host cell membrane proteins and carbohydrates such as fibrinogen, fibronectin, and laminin by forming a fibril layer containing multiple saccharines (i.e., it is of a protein and saccharine nature) on their cell surfaces [18]. Its ability to form biofilm helps its survival and is considered a distinguished characteristic and can escape from the host's defenses, as well as increase its resistance to anti-fungal and its ability to withstand the pressure of competition from other microbes[19;20].

The possession of *Candida* yeast for hemolysin as a blood lyse agent grants it another important ferocity factor for it works to release hemoglobin as an important source of iron, which in turn is an important factor for growth in the body of the host, as well as the lyse of WBCs, especially neutrophils that are active in the resistance to being infected with *Candida* as well as macrophagesand, therefore,the process of phagocytosis becomes inefficient [21;22].

The ability of *Candida* yeast to produce hydrolytic enzymes (constitutive and inducible) helps it invade the host's tissues by breaking or altering the host cell walls components, leading to rupture membranes of these cells or losing its functions. Although the components of these membranes are mostly lipids and proteins, therefore, these biochemical components were targeted by these enzymes[23], including phospholipase enzyme which analyzes phospholipids, and proteinase enzyme which analyzes the peptide bonds in protein molecules[24]. In addition, these enzymesenhance the adhesion of *Candida* yeast to host cells, increasing their ferocity in invasion and destruction of its tissues. The seriousness of Candidiasis ranges between Mucosal Candidiasis infection which is a condition often observed in patients with acquired immunodeficiency syndrome (AIDS) and Systemic Candidiasis infections[25].

The appearance of histological changes in both heart and lung tissues of the mice experimental groups above mentioned indicates that the *Candida* yeast species have many ferocity factors that enable it to invade and infect host tissues including their adhesion ability [26] as well as its ability to produce protein and lipid lyse enzymes since carboxy protease enzymes breakdownImmune globulin IgA while the lyse enzymes of the type aspartyl protease facilitate invasion by breaking keratin and collagen in the basal membrane of the lining of blood vessels [27].

Effect of Educational Modules in Learning Some Types of Handball Scoring for Students

Khalil Hamid Mohammed Ali[1], Iman Darwish Gary[2], Abbas Abdulhamza Kadhem[1]

[1]University of Kerbala, Faculty of Physical Education and Sports Sciences, [2]Ministry of Education, The Directorate of Education Karbala, Iraq

Abstract

The teaching method are no longer meeting the educational requirements that have increased during the current century. The need to expand educational services has multiplied day by day, which requires the development of modern teaching method to meet these challenges facing the educational process.

Therefore, the researchers tended to identify educational leaflets because they help the learner to acquire information in an orderly and intentional manner, and then take into account the link between motor skills and theoretical and emotional information and also link between new information and previous information in the structure of knowledge to reach a holistic view of the situation and the perception of its components, which leads to raise Efficiency of the educational process.

The research objective to: Identify the impact of unit's prepared educational leaflets in learning some types of scoring handball students under research. The research community was represented by students of the second phase, Faculty of Physical Education and Sports Sciences-University of Karbala for the academic year 2018-2019 and from my division (A, C) where a sample of (40) students was selected in a random stratified manner in an equal manner and by (20) students for each division, where Division (A) represented the experimental group and learned to use educational brochures while Division (C) control group used The method used in the college of explanation and demonstration.

After a statistical analysis of the data, the researchers came to several conclusions. The presence of a positive effect size as a result of teaching using the educational leaflets of the experimental group, as well as the group that learned in the method followed (explanation and presentation) but in varying proportions.

Keywords: *Educational, modern teaching; health behavior; modules and learning.*

Introduction:

Education is one of the most important areas in the developed societies, where it is indispensable, therefore, the field of education is receiving great attention, especially in our era because of the scientific progress and technological development in various areas of life, especially education.

The educational process, including the challenges of the times, faces many of the problems that have become the focus of study in the field of education. Scientific research is the tool of society to solve its problems, and the strategies of educational systems in the face of these problems may vary according to different educational reality in the world, and none of these systems can Educational system to overcome its problems without working to renew itself and find a modern system of education that is new in its objectives, content, method and means so that all factors affecting the educational process, and the various self-abilities of the learner, and all the means assigned to education to be subject to The benefit of the educational process so that education comes to fruition desired.[1]

The choice of the teacher for the appropriate teaching method has become one of the important pillars on which the success of the educational process is measured, where the effectiveness and success of any

method is measured by the amount of processes used by the learner's abilities to understand what he is learning. Knowledge, and show skills in choosing the appropriate teaching method which helps to have interaction between the teacher and the learner and between the learner and the teaching material.[2]

Through the experience of researchers and the use of experienced professors and specialists in the teaching of handball course for students of the second phase in the Faculty of Physical Education and Sports Science University of Karbala found that there is difficulty in learning motor skills, in addition to the inability to link between different motor skills in addition to technical performance The skills lack accuracy and good compatibility between the elements of movement and the emergence of many technical errors, which are reflected on the results of students, and thus affect the failure to achieve educational goals at different levels. Handball is a popular team game, for all age groups because of the excitement and excitement as a result of the development of the level of players physically and skillfully.[3]

Research Hypothesis:

1. There is a positive impact of the educational units using educational brochures, in the level of skill performance of some types of handball for students.
2. There are significant statistical differences between the two groups (experimental and control) in learning the skill level performance of some types of scoring for students and for the experimental group.

Research Methodology: The researchers used the experimental method using the experimental design of two groups, one experimental and the other control, using the pre and post measurement of both groups.

Research community and sample: The research community represented the second stage students/ Faculty of Physical Education and Sport Sciences for the academic year 2018-2019, distributed on four divisions (A, B, C, and D). Division B represented the control group and after the exclusion of a number of students practicing the game of handball and repeaters and thus became the number and the two divisions (40/students) and by (20) students and each group.

Selecting offensive skills under consideration: The researchers identified the offensive skills under consideration by referring to the description of the second stage course in the faculty, namely: scoring of all types (flagellation scoring of stability and movement-scoring high jump and long), then was surveyed for some scientific references in the field of handball, tests and measures to determine a set of tests Attacking skills (under research).

Table (1). Percentage of expert consensus on the most appropriate tests measuring offensive skills (under consideration)

Skills	Tests that measured	Repetition (Number of Approval)	Percentage (%)
Scoring Carbaj stability	Carbajscoring of stability from behind the circle (9) m	13	92.85
	Receiving then scoring of stability	8	57.14
Carbaj scoring of the movement	Dribbling in a straight line and then scoring of the Carbaj movement	11	78.57
	Dribbling in a zigzag and then the scoring of the motion	7	50
High jump scoring	Shooting high jump from a distance of (9) meters	12	85.71
	High jump	8	57.14
Long jump scoring	Continuous jumping then shoot long jump	7	50
	Scroll and receive and then shoot long jump	11	78.57

Distribution of the research plan (for the pilot group) over the program weeks:

A. The research plan using the educational leaflets included (6) weeks to implement the teaching units and lecture time (90) minutes divided into (30) minutes to teach the educational aspect, (60) minutes for the applied side, and was applied in the period (6/3/2019) until (23/4/2018), The remaining lectures were devoted to the teaching of the rest of the handball course, and this division is due to the

researcher as the teaching plan in the faculty did not specify a time dedicated to teaching (the educational aspect and another applied).[4]

B. Preparation of educational units using educational leaflets: The educational units were constructed using educational leaflets for some types of scoring in all types (whip of stability and movement - high jump and long) by reference to scientific references such as: Time distribution of the plan of the handball course and by two lectures a week each time (90) minutes for (6) weeks duration The basic experience, then the educational units were presented to the professors experts and specialists in the field of teaching method and handball Appendix (1) and the experts suggested some modifications in the objectives of the educational units have been modified and expressed their approval of the proposed units.[5]

The researcher has followed the following steps when designing educational brochures:

1. Identifying Objectives: The researchers considered that the objectives of the educational units using the educational leaflets are clear in terms of the general goal, which is translated into behavioral objectives formulated with precision and specific.
2. Educational leaflets: The leaflets were designed according to the steps of media preparation (name of the skill - the sample of the study - the general goal of the brochure procedural behavioral objectives - place - learning time - some important information about the skill learned - the educational progression of the skill).

Pretests: After the completion of the preparation of research tools in terms of scientific transactions (honesty, consistency and objectivity) were conducted pre measurements in the tests of some types of scoring (under research) on the research groups (experimental and control) for the period (4-5/3/2019) and the presence both the researchers, the teacher of Article and the assistant team.

Homogeneity and equivalence: In order to control the variables that affect the accuracy of the results, the researchers used to verify the homogeneity of the research sample of the variables studied as shown in Table (2).

Table (2).Shows the homogeneity of the members of the research sample

Variables	Experimental group N = 20		Control group N = 20		Value (t)
	Mean	SD	Mean	SD	
Weight (kg)	73.65	3.84	71.95	5.63	1.12
Overall body length (cm)	169.5	5.7	172	6.28	1.11
Age (years)	20.94	2.1	21.3	1.95	0.35

* The value of (T) tabular at the level and at the value (0.5) = 2.021

The equivalence of the two research groups:

Table (3).Shows the equivalence of the two research groups (experimental - control) in the study variables

Skills	Tests	Experimental group N = 20		Control group N = 20		Value (t)*	Sig.
		Mean	SD	Mean	SD		
Scoring Carbaj stability	Carbaj scoring of stability from behind the circle (9 m)	19	3.569	20.80	2.526	1.841	0.073
Carbaj scoring of the movement	Bouncing in a straight line and then scoring Carbaj of the movement	3.411	0.352	3.551	0.348	1.266	0.213
High jump scoring	Accurate jumping high jump from a distance of (9) meters	4.050	0.945	4.450	1.356	1.082	0.286
Long jump scoring	Scroll and receive and then scoring long jump	6.333	0.519	6.406	0.421	0.492	0.626

*Tabular value (t) at degrees of freedom (38) and significance level (0.05) = 2.021

Implementation of educational units: The educational units were implemented on the two research groups in the period from (6/3/2019) to (21/4/2019), which is two lectures per week (90) minutes divided into (30) minutes to teach the educational side, (60) minutes for the side Applied for a period of (4) weeks the duration of the basic experiment, according to the timetable of the course of handball, has been teaching to the experimental group using (educational leaflets) and the control group according to the method used by the teacher.[6]

Posttests: After the completion of the application of the basic experiment was conducted after the tests of the two research groups in the tests of offensive skills (under research) on (22-23/4/2019) and the same conditions of pretest.

Results

Table (4). Mean, standard deviation and value (t) between the pre and post averages of the experimental group in tests of some scoring types (under consideration)

Tests	Pretest		Posttest		Value (t)*	Mean Diff.	SD diff.	Effect size
	Mean	SD	Mean	SD				
Carbaj scoring of stability from behind the circle (9 m)	19	3.569	26.250	5.350	6.211	7.250	5.220	1.389
Bouncing in a straight line and then scoring Carbaj of the movement	3.411	0.352	2.953	0.354	5.414	0.458	0.378	1.211
Accurate jumping high jump from a distance of (9) meters	4.05	0.945	6.150	1.089	8.768	2.100	1.354	1.551
Scroll and receive and then scoring long jump	6.333	0.519	5.817	0.528	7.865	0.516	0.293	1.759

*Tabular value (t) at degrees of freedom (38) and significance level (0.05) = 2.021

Table (5). Mean, standard deviation and the value of (t) between the mean of pre and post measurements of the control group in the tests of some types of scoring (under consideration)

Tests	Pretest		Posttest		Value (t)*	Mean Diff.	SD diff.	Effect size

* The value of (t) tabular at the significance level (0.05) = 2.021

Discussions

These results are an indication of the role of the proposed teaching units in accordance with educational levels in the emphasis on linking educational experiences with each other and that previous experience is a guide to new experiences and all this contributed to the achievement of learning objectives in a better manner and continuous and permanent and continuous.[7]

In addition to the consolidation of information in the minds of learners and clarity of the knowledge structure of students, which led to the possibility and ease of recall and application of information in new situations, which shows through the implementation of what students have studied in the theoretical side through the application of skills with a set of individual, even and group exercises that lead to the arrival of students to the stage Good performance in the applied lecture.[8]

The results of the study are consistent with the assertions of meaningful learning is based on what remains in the learner's cognitive structure helps to re-learn any new information similar or similar to the information previously learned, and that in case of forgetting For some information, the basic concepts lose some of its sub-elements, but continue to retain the new meanings it has acquired, and thus continue to be able to facilitate the entry of new information to the cognitive structure of the learner. Added that the speed and effectiveness of learning depends on the learner's ability to make connections between the learning material and the repository of his knowledge structure and to link previous information with new concepts.[9]

This is confirmed by the findings of study which proved that the organization of information related to the learner's cognitive structure is useful in memorization, recall and retrieval processes, and leads to a clearer learning effect. Given the results of the skill tests, it was found that the mean values of the telemetric measurements were higher in all tests, which are important. The researchers refer to these results to present the content of the course of the handball (under research) in a more organized manner where the interaction of expertise, whether emotional dynamics. The material in the framework of the interdependent kidney and the realization of all its components and interconnections, thus the first hypothesis, which states there are statistically significant differences between the mean scores of the pre- and post-measurements of the experimental group in some types of scoring and in favor of post-measurement is validated.[10]

Conclusions

1. The presence of a positive impact as a result of teaching using educational leaflets for the experimental group, and the method used (explanation and presentation) for the control group for some types of handball scoring (under research).
2. The experimental group that was taught using educational leaflets outweigh the control group that was taught by the method followed (explanation and presentation) in the performance level of some types of scoring (under research).
3. The results achieved proved the effectiveness of educational units prepared by researchers through the development of the variables under study.

Association between Diabetic Retinopathy and (Albumin/Creatinine) Ratio in Diabetic Patients

Aberabdul amir[1], Haiderabdulhameed Rashid[1], Hind A. Mahdi[1]

[1]*College of Medicine, AlNahraineUniversity, Iraq*

Abstract

Introduction: Diabetes mellitus is a quickly upward illnesses in our world and it develop a chief community health problem. Diabetes is a sources of multiple long-term complications that have significant effect on the patients and society, the illness mostly touches peoples in their most creativeages diabetes has multiple systematic complications with macro-vascular and micro-vascular problems. Micro-vascular illness such as retinopathy, neuropathy, nephropathy and cardiovascular illnesses are a common problems of diabetes and it have a significant interrupting on the community & public health. Method: Across sectional study involved 75 patients with diabetes M. done in Al-Emamain Al-Kadhumain medical city from period September 2018 to July 2019, we organized questionnaire involved age of patients, gender, type of DM and duration of illness. Also all patents send for lab. To investigate HbA1c and albumin/creatinine ratio. Examination of fundus done after application of mydriatic eye drops (tropic amid) and used slit limp bio microscope and 90 D lens. Results: 75 patients included in our study, age of patients 51.4±13.7 years old, duration of Diabetes M. 7.1±4.2 years, 47 (63%) male included in our study and 28 (37%) female, also 12 (16%) of patients type 1 DM and 63 (84%) type 2 DM, there is significant association (P-value <0.05)between degree of retinopathy and (albumin/creatinine) ratio; 29% of patents with microalbuminuria and 16% of patients with macro albuminuria, 9% of patients with ADED have macro albuminuria, 5% of patients with PDR have macro albuminuria, while 16%of patients with NPDR have microalbuminuria, 8% of patients with PDR have microalbuminuria.

Conclusion: Albuminuria/creatinine ratio is linked with theretinopathy in patients who have diabetic. So micro and macro albumin urea may be marker of proliferative retinopathy development so need close follow up.

Keyword: *Diabetic retinopathy, HbA1c, (albumin/creatinine) ratio.*

Introduction

Diabetes mellitus is a quickly upward illnesses in our world and it develop a chief community health problem. Diabetes is a sources of multiple long-term complications that have significant effect on the patients and society, the illness mostly touches peoples in their most creative ages. diabetes has multiple systematic complications with macro-vascular and micro-vascular problems. Micro-vascular illness such as retinopathy, neuropathy, nephropathy and cardiovascular illnesses are a common problems of diabetes and it have a significant interrupting on the community & public health. Diabetic retinopathy (DR) and nephropathy reflected one of the publicreasons of visual damage[(1)], and end-stage renal illness correspondingly in persons of both developed and developing civilizations[(2)]. Diabetic retinopathy is divided into two stages non-proliferative and proliferative stages. The stage of non-proliferative retinopathy usually appears lately in the first decade or early in the second decade of disease and the early pathologic changes consist of increasing thickness of the basement membrane endothelium and decrease in the pericytes number together with capillary micro aneurysms. Diabetic retinopathy also presented as new vessels formation in optic disc and the retina which proliferated into vitreous and causing eventually increase in fibrous tissue as well as vitreous hemorrhage and retinal tractional detachment[(3,4)]. It has been shown that individuals with diabetic retinopathy have a 25 times increased chance of losing their sight

comparing to normal individuals[5]. Reduction in visual acuity is moreover connected with proliferative harms or maculopathy. Numerous studies have been approved to discovery the issues that hasty retinopathy such as durationof the hyperglycemia, kind of diabetes, alteration in hormonal level, microalbuminuria, genetics, pregnancy. Some recommend that with the usage of new therapeutic and surgical method for handling diabetic retinopathy, lead to decrease the incidence of blindness up to 90%[6], yet the available treatment options for the diabetic retinopathy are usually suboptimal in regard to restoring vision and for the prevention of further loss of vision .So it is of great importance to identify the local incidence of diabetic retinopathy, the progression rates and regression with treatment whether medical or surgical, and more importantly the associated risk factors in order to understand the disease and more importantly modifying such factors whenever it is possible that could help in decrease the incidence of diabetic retinopathy or at least slowing the progression of the visual impairment associated with diabetic retinopathy[7]. The aim of study is to find association between degree of retinopathy and level of albumin/creatinine ratio.

Material and Method

Across sectional study involved 75 patients with diabetes M. done in Al-Emamain Al-Kadhumain medical city from period September 2018 to July 2019, we organized questionnaire involved age of patients, gender, type of DM and duration of illness. Also all patents send for lab. To investigate HbA1c and albumin/creatinine ratio. Normal of HbA1c was 7 so above it mean hyperglycemia. Early morning albumin/ creatinine ratio classified to Norm albuminuria less than 30 mg/g, micro 30 – 300 mg/g and > 300 mg/g macro albuminuria[8].Examination of fundus done after application of mydriatic eye drops (tropic amid) and used slit limp bio microscope and 90 D lens. Also the degree of retinopathy classified to :

NO = No retinopathy, NPDR= No proliferative Diabetic Retinopathy, PDR = proliferative Diabetic Retinopathy and ADED = advance diabetic eye disease [8]. Analysis of data done by SPSS 22, for analyzed the association between variables used Chi- square for categorical data and spearman correlation for continuous data of HbA1c and albumin/creatinine ratioP- value < 0.05 mean significant association.

Results

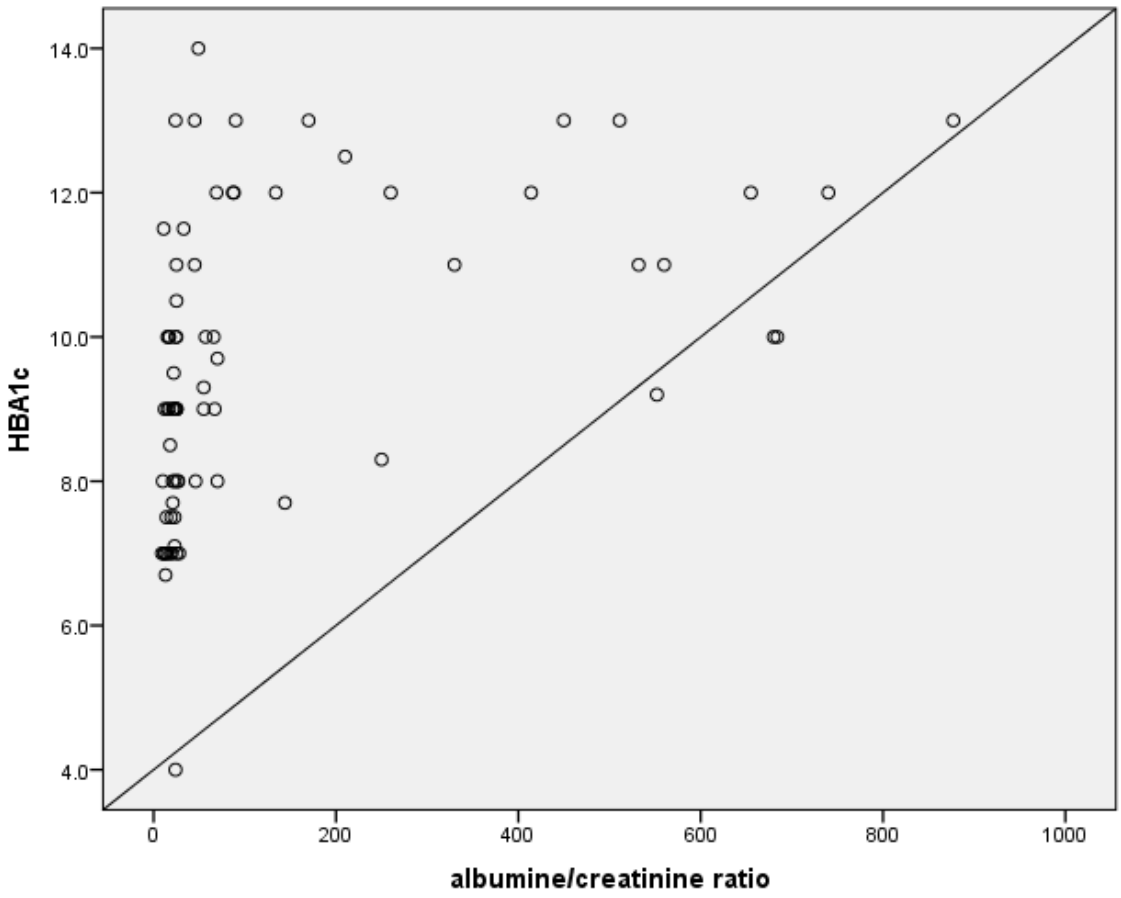
75 patients included in our study, age of patients 51.4±13.7 years old, duration of Diabetes M. 7.1±4.2 years, 47 (63%) male included in our study and 28 (37%) female, also 12 (16%) of patients type 1 DM and 63 (84%) type 2 DM. From table (1); show there is no significant association between age, gender and type of DM with degree of retinopathy, while according to duration of DM (years) there is significant association with positive correlation between it and degree of retinopathy especially after 5-10 years duration 40% of patient with ADED retinopathy.

Table (1): Association between variables and types of retinopathy

Variables	**Retinopathy**						
Age	**No**	**NPDR**	**PDR**	**ADED**	**Total**	**X^2**	**P-value**
≤30 years	4 (5.3%)	1 (1.3%)	1 (1.4%)	1 (1%)	7 (9%)	0.67	0.89
>30 years	31 (41%)	19 (25%)	10 (13%)	8 (11%)	68 (91%)		
Gender							
Female	21(28%)	14(18.7%)	9 (12%)	3 (4%)	47(62.7%)	5.6	0.13
Male	14(18.7%)	6 (8%)	2 (2.7%)	6 (8%)	28(37.3%)		
Type of DM							
1	6 (8%)	2 (2.7%)	3 (4%)	1 (1.3%)	12 (16%)	1.8	0.6
2	29(38.7%)	18 (24%)	8 (10.7%)	8(10.7%)	63(84%)		
Duration							
<5 years	23 (30.7%)	8(10.7%)	1(1.3%)	0(0.0%)	32(42.7%)		
5 –10years	9(12.0%)	7(9.3%)	7(9.3%)	7(9.3%)	30(40.0%)	20.78	0.002**
>10 years	3(4.0%)	5(6.7%)	3(4.0%)	2(2.7%)	13(17.3%)		

P- value< 0.05 * (significant).

All patients' HbA1c%, mean and SD (9.6±2.1) and about (albumin/creatinine) ratio mean and SD132.6±212 mg/g. so there is significant positive correlation between HbA1c and (albumin/creatinine) ratio. When increase in HbA1c lead to increase in (albumin/creatinine) ratioas show in fig (1).



Correlation Coefficient = 0.61, P-value = 0.0001**

Fig (1): Correlation between HbA1c and (albumin/creatinine) ratio.

In our study there is significant association (P- value <0.05) between degree of retinopathy and (albumin/ creatinine) ratio; 29% of patents with microalbuminuria and 16% of patients with macro albuminuria, 9% of patients with ADED have macro albuminuria, 5% of patients with PDR have macro albuminuria, while 16%of patients with NPDR have microalbuminuria, 8% of patients with PDR have microalbuminuria, so when degree of retinopathy become more advance lead to increase (albumin/creatinine) ratio. As show in table (2).

Table (2): Association between types of retinopathy and (albumin/creatinine) ratio.

			Retinopathy				Total
			NO	NPDR	PDR	ADED	
Albumin Creatinine	Below 30 mg/g Norm albuminuria	Count	33	7	1	0	41
		% of Total	44.0%	9.3%	1.3%	0.0%	54.7%
	30 _ 300 mg/g microalbuminuria	Count	2	12	6	2	22
		% of Total	2.7%	16.0%	8.0%	2.7%	29.3%
	above 300 mg/g macro albuminuria	Count	0	1	4	7	12
		% of Total	0.0%	1.3%	5.3%	9.3%	16.0%
Total		Count	35	20	11	9	75
		% of Total	46.7%	26.7%	14.7%	12.0%	100.0%

Pearson Chi-Square = 67.603, P-value = 0.0001**

According to table (3) our study show significant association (P-value <0.05) between HbA1c and degree of retinopathy, so when degree of retinopathy become more advance lead to increase HbA1c, in the table; 85% of patients with HbA1c more than 7, so 27% of patients with NPDR and have HbA1c>7, 15% of patients with PDR and have HbA1c >7 and 12% of patients with ADED and have HbA1c >7.

Table (3):

			Retinopathy				Total
			NO	NPDR	PDR	ADED	
HbA1c	7 and below	Count	11	0	0	0	11
		% of Total	14.7%	0.0%	0.0%	0.0%	14.7%
	above 7	Count	24	20	11	9	64
		% of Total	32.0%	26.7%	14.7%	12.0%	85.3%
Total		Count	35	20	11	9	75
		% of Total	46.7%	26.7%	14.7%	12.0%	100.0%

Pearson Chi-Square = 14.732, P- value = 0.002**

Discussion

Diabetic retinopathy is visual and a vascular problemsrelated to diabetes M., it is defined as a gradually progressive alterations in the vessels of retina, rise in vascular permeability, retinal hypo perfusion and propagation of retinal vessels. So retinopathy reflected as one of problems of diabetes [9]. In this study there is a significant association between duration of diabetes with degree of retinopathy especially NPDR with incidence 26% similar to study done by Kiran; NPDR was higher than PDR in all the patients. A significant association (0.0001)[10–12].

In our study there is positive colleration between HbA1c and (albumin/creatinine) ratio R= 0.61, P-value = 0.0001, similar to study done byU. Anandh; R= 0.14 and P-value 0.001[13].

Numerous studies were approved the occurrence of retinopathy and albuminuria in patients with diabetics, These revisions had diverse rates between 16 to 53.4%for retinopathy [14].this study displayed the occurrence rate of 53% in other study the occurrence rate was 39.3%[8]. The used of different approaches in those study lead to difference in the rate, the population and or different in blood sugar level. The incidence rate of our study was 43% while in another study was 22% of microalbuminuriain diabetes patients[8,15] and 154% in study done by[8,16]. In this study there is significant association between the degree of retinopathy and albuminuria/creatinine ratio, similar to study above had the same significant association [14].Our study showed also the significant association between HbA1c and degree of retinopathy and also significant association between duration of illness and degree of retinopathy similar to study done by Masoud R Manaviat had the same significant association due to harm of vessels in retina and kidney[8]. Klein et al showing that microalbuminuria may be seen in 29.2% of patients with insulin and 22% of non-insulin patients. So, insulin may have a part in nephropathy [17].Renal harm may hasten retinopathy also positive correlation between microalbuminuria and heart disease[12,13]. So albumin inurine may be a mark of kidney illnesses and could be a reflect of vessel injury. In our study also there was significant association between HbA1c and degree of retinopathy (P- value = 0.002**), agreed with this result a study done by PragatiGarg[9], and other studies; a significant association between severity of diabetic retinopathy and HbA1c ($p < 0.001$)[10,18,19].

Conclusion

Albuminuria/creatinine ratio is related with theretinopathy in diabetic patients. So micro and macro albumin urea may be marker of proliferative retinopathy development so need close follow up.

Ethical Clearance: The Research Ethical Committee at scientific research by ethical approval of

both environmental and health and higher education and scientific research ministries in Iraq.

The Effect of Socioeconomic Level on Dental Caries among Preschool Children in Baghdad City

Mariam F. Abonayla[1], Athraa M. Alwaheb[2]

[1]Dentist, in Baghdad, Ministry of Health and Environment, [2]Professor in Preventive Dentistry, College of Dentistry,University of Baghdad, Iraq

Abstract

Background: Dental caries and periodontal disease are the most common oral problems. It may start early in life and if not treated may end with tooth loss. Oral health is influenced by the socioeconomic status in which the socialization of the child takes place.

Aim of the Study: The survey was made to investigate the effect of socioeconomic status on dental caries of preschool children.

Subjects and Method: The total sample composed of 893 children aged (4-5) year selected randomly from different kindergartens in Baghdad governorate. WHO 2013 index was used for assessment of the dental caries experience and questionnaire was send to parents to assess their knowledge and behavior.

Results: Results showed that the prevalence of dental caries was 98% for the total sample, highly significant differences were seen between SES and dental caries experience dmfs of primary teeth, highly significant relation between SES and parents knowledge in all questions except questions concerning tooth decay and crowding of the permanent dentition was no significant while in behavior questions a highly significant relation was seen in all questions except questions concerning the type of bristle of the brush and preferable time for eating sweets was no significant . Conclusion: Preschool children in Baghdad were found to have a high prevalence of dental cariesSES effect on the dental condition. Hence this survey highlighted the need for children to dental health education programs and public and school preventive measures among those children.

Keywords: *Socioeconomic status, Dental caries, Preschool children.*

Introduction

Dental caries most commonly affect children, the impact of the oral conditions on children life include: difficulty with chewing, oral pain, missed school days due to their cumulative dental caries experience and changes in emotional e.g being upset and worrying about being different as well as anxiety or distress about their mouth(1).

The association between social and economic condition and dental caries prevalence has been observed, Inequalities in the distribution of dental caries were observed and socioeconomic factors were found to be strong predictors of the prevalence of oral disease in preschool children, family income, occupational prestige, and educational attainment are measures of SES that have been found to influence an individuals life opportunities(2).

Iraq is one of the developing countries that exhibited an increase of dental caries prevalence and severity. Many of studies found that dental caries prevalence showed low while the other studies was high prevalence (3,4).many studies conducted to revel the relationship of socioeconomic status with dental caries all these studies depended on one or combination parameters of socioeconomic level, In the economically developing countries the prevalence and severity of dental caries has increased with industrialization and exposure of these populations to western diets. The families with higher

level of education,higher income, better occupation have higher caries experience which is attributed to the reason of consuming more refined sugar and cariogenic foods[5].

This study was conducted on group of preschool children 4-5 year old living in Baghdad governorate to find out the effect of socioeconomic level on dental condition.

Subjects and Method

A sample of 893 preschool children 4-5 year old were selected randomly from different kindergartens in Baghdad governorate (471 boys and 422girls) from urban areas in Baghdad city, from different kindergartens distributed in the city. The study received approval from the Research Ethics Committee of the College of Dentistry, University of Baghdad, Iraq.

Knowledge and behavior questions was recorded by 20 questionnaire[6], which consist of: Question knowledge of parents about the mouth and teeth (Q1. and 2 concerning the number of decidous and permanent teeth, tooth composition. Q3, 4 and 6 concerning tooth decay. Q5, 8 and 10 concerning crowding of the permanent dentition, and early loss of the primary teeth and thumb suking habits. Q7concerning the benefit of fluoride Q9.concerning visit to dentist), Question about the behavior of the parents (Q11,12, 13,16 and19 concerning the frequency of the tooth brushing, brushing technique, use of dental floss and tooth picks, the way that child used to brush his teeth and the type of bristle of the brush respectively .Q.14 concerning the preferable time for eating sweets. Q15 concerning the number of visits to the dentist Q17 and 18 concerning with toothache of child and dental decay respectively. Q20. concerning the use of tooth in bad habits).

Intra oral examination of dental caries status was recorded according to WHO 2013[9] using CPI probe. Dental caries was measured by dmft/s for deciduous teeth.

The statistical data analysis was approached by using statistical package (SPSS) ver. (23.0) in order to analyze and assess the results of this study through application of descriptive data analysis, by frequencies and percentages. Inferential data analysis, these types of analysis were used to test hypotheses by accept or reject it, which include the following; Spearman Rank Correlation test, analysis of variance and significant at $p \geq 0.05$.

Results

Results showed that the prevalence of dental caries was 98% for the total sample. The mean dmfs (13.180).

The highly significant of relation dmfs with the level of SES found p value equal to 0.0000.

Highly Significant differences were seen between knowledge questionnaires and dental caries experience dmfs of primary teeth, some knowledge questions were no significant,the question about concerning crowding of the permanent dentition, and early loss of the primary teeth the dmfsp value=0.172 and the question about tooth decay the dmfsp value=0.985 also the question about thumb suking habits the dmfs p value=0.150 and the question about visit to dentist the dmfs p value=0.086.

No significant differences were seen between behavior questionnaires and dental caries experience dmfs of primary teeth except the quesion about use of tooth in bad habits highly significant p value=0.000, and question about way that child used to brush his teeth p value=0.001.

Table (1): Caries Experience (Mean±SE) of Primary Teeth and dmfs in Relation to parents knowledge Questionnaires

Discussion

In this study, the prevalence of dental caries was found to be high for primary school (4-5) year children. This percentage was more than study done in Indian[7] and more than some Iraqi studies[3,8,9,10]. The high caries prevalence recorded by this study may partly be attributed to lower fluoride level in drinking water in Iraq that was ranging between 0.12-0.22 [11],and may also related to other factors related to the socioeconomic condition and living style of the families[12].For the diagnosis and recording of caries-experience; dmfs indices was used in present study. This indices allows measurement of the past caries-experience indicated by missing and filled fraction, and the present caries by the decayed fraction. In addition, dmfs index allow the measurement of dental caries by severity. The mean dmfs value was (13.180) compare with other Iraqi studies[14,15].

This study showed that the mean of ds fraction (12.205) was higher than ms and fs components of dmfs index, which is an indication of a poor dental treatment. Which is mean that even if treatment is present, it is directed toward extraction rather than restoration. This result is in agreement with other studies [8,13,9] .

In this study, the knowledge questionnaire has highly significant difference with SES, may be attributed that low knowledge group compared to children from high SES families. This discrepancy differences in the home learning environment. and in parent beliefs[16], except the question about dental caries and crowding in permanent teeth had no significant difference. Also the study showed that there was highly significant difference in the relation behavior questionnaires to SES, may be attributed,The relationship between family life events and rates of maternal reports of child behavior and child rearing problems preschool-aged children. Mothers experiencing a large number of life events reported higher rates of child rearing problems[17],except the question about type of bristle and preferable time of eating sweet had no significant difference.

Conclusion

This survey highlighted the need of children to preventive measures and dental health education and improvement of dental knowledge and attitude towards good oral hygiene.

Acknowledgment: I thank all the participants in the study and Dr. M. Galib for helping in the data analysis and statistical work.

The Effect of Submucous Dexamethasone Injection on the Post-Operative Sequelae After Impacted Third Molar Surgery

Zainab Wahab Hadi[1], Sahar Shakir Al-Adili[1]

[1]B.D.S. Iraq, Ministry of Higher Education and Scientific Research, University of Baghdad, College of Dentistry, Department of Oral and Maxillofacial Surgery

Abstract

Background: Different method were attempted by many researchers to reduce postoperative inflammatory response following surgical extraction of lower wisdom teeth because this is a very common procedure and is usually associated with pain, difficulty in mouth opening and swelling. Aims: To assess the effect of sub mucosal injection of 4mg/1ml dexamethasone on reduction of postoperative pain, facial swelling and trismus following the surgical extraction of impacted lower wisdom teeth.

Materials and Method: forty patients were selected to be included in this randomized clinical study with a total number of 42 impacted mandibular third molars, they divided randomly into two groups, control and study group of twenty patients for each, patients in the study group received 4mg/1 ml submucos injection of dexamethas one, while patients in the control group received placebo (normal saline) five minutes after local anesthesia administration, and surgical removal of impacted teeth was done after further five minutes. evaluation of mouth opening and swelling was done as a baseline and on the second and seventh post-operative days after surgery, while pain was scored daily until the 7th postoperative day by the patient according to numerical rating scale. Assessment of trismus was done by measuring the maximum interincisal distance swelling was evaluated by measuring the distance between five selected points. Every one of these factors in addition to the time of surgery were compared between the two groups.

Results: Study group showed less limitation in mouth opening than control group but there was no statistically significant difference between them however study group showed a significant reduction in pain scores on the first and the second post-operative days and a significant improvement of swelling compared with the control group at the 48 hour follow up.

Conclusion: Submucosal injection of dexamethasone was effective in minimizing facial swelling, Pain and trismus after surgical extraction of mandibular third molar.

Keywords: *Impacted third molar, corticosteroid therapy, submucosalinjection, dexamethasone.*

Introduction

Impacted tooth is defined as a tooth, maintained in the jaw,beyond its normal time of eruption. Impaction also can be defined as a pathological problem in which a tooth fails to erupt into its correct functioning position[(1)].

Surgical extraction of lower third molar is one, of the most, common minor oral surgical, procedures practiced on a daily basis, in oral and maxillofacial surgery [(2)]. Difficulty of extraction vary from relatively easy to extremely difficult depending on many factors, for example, depth and angulation of the tooth in relation to investing bone and ascending ramus of the mandible, and bone density[(3)] many surgical elements, like the design

of flap or time of the procedure, can affect postoperative symptoms after lower third molar surgery,though it is frequently associated with symptoms, like pain, and signs, like swelling and trismus [4]. Also these post-operative sequelae varies according to the individual physiologic inflammatory response [5]. understanding the predisposing factors of postoperative morbidity is necessary in determining treatment options and the intellectual preparation of the patients[6]different method were attempted to reduce postoperative sequelae after lower third molar surgery. [7]Corticosteroids are one of the most widely employed medications administered to control these complications.[8]

The most wideley used type of corticosteroid is Dexamethasone which has a substantial effect on the resolution of inflammation.[9].

However, the use of sub mucosal route of administration of dexamethasone injection in the surgical removal of impacted lower wisdom teeth remains under investigated.but data from many studies suggests that the sub mucosal injection of dexamethasone leads to a reduction in the postoperative signs and symptoms following impacted third molar surgery[10,11].

Materials and Method: forty patients were selected to be included in this randomized clinical study with a total number of 42 impacted mandibular third molars. They divided randomly into two groups: control and study group of twenty patients for each (Acomputer-generated random numbers were used for simple randomization of subjects).

The inclusion criteria of the selected patients was No history of any uncontrolled systemic diseases or any recent antiinflammatory drug intake (1 week) or being under long term treatment with NSAIDs, steroids, or antihistamines.

Pregnant women or any patient with acute infection or patients allergic to corticosteroids were excluded from this study.

A specially designated case sheet was filled. radiographical examination (Orthopantomogram (OPG) and a periapical radiograph) in addition to clinical examination was done for all the patients prior to the surgery after that subjects were informed about the study protocol and a written approval was gained preoperative evaluation of Mouth opening was checked by the researcher by using a sliding caliper and determine the distance between the incisal edges of the upper left to the lower left central incisor.

At 48 hour and 7th day visit, evaluation of mouth opening was done, by using similar method of preoperative evaluation and by the same examiner. Calculation of the percentage of trismus was done by measurement of preoperative value minus postoperative value divided by preoperative value multiplied by 100.[12]

Swelling was estimated by using The measuring tape to calculate the distance between 3 selected planes: tragus to the outer corner of the mouth, tragus to the soft tissue pogonion and the distance between lateral angle of the eye and angle of the mandible. These measurement are done prior to the surgical removal of the impacted third molar as well as on the second and the seventh postoperative days.

calculation of swelling was done by the sum of the three measurements divided by three and percentage of facial swelling was calculated as preoperative measurement minus postoperative measurement divided by preoperative measurement multiplied by 100. [12]

Pain evaluated by using numeric rating scale.

All surgeries were performed under local anesthesia using lidocaine hydrochloride 2% with adrenaline 1:80,000 (septodent, France) in 2.2 ml glass cartridge(2 carpules).

Five minutes after the application of lingual, inferior alveolar nerve block, and infiltration anaesthesia for long buccal nerve, each patient received a submucosal injection by using insulin syringe of 1 ml dexamethasone or 1 ml placebo based on their group either study or control which was selected randomly(0.5ml in the lower buccal vestibule near the intended area for surgical removal of impacted mandibular molar and 0.5 ml in the retromolar area of the same side). A further 5 min after the application of dexamethasone or placebo, incision was performed and reflection of a mucoperiosteal flap on the buccal side to gain adequate access to the field, overlying bone must be removed for exposure.

bonecutting was done under continuous irrigation with normal saline, and sectioning of the tooth was done when needed .tooth was removed from the socket then inspected for any sharp edges then it was irrigated thoroughly with normal saline. the flap adapted to the underlying,then suturing with 3/0 black silk

The time of the procedure was recorded from the first cut of incision to the end of suturing subtracting the time for any obstacle or delaying issue from the total time

All patients had instructed to take systemic antibiotic which consist of Amoxicillin 875 mg/Clavulanate 125 mg tab. once daily for 5 days, or if the patient allergic to penicillin Azithromycin tab. 500 mg once daily for 5 days

The analgesic was (paracetamol tab 500 mg. for 3 days) and instructed to request additional analgesics tabs of the same type in the event of aggravated pain episodes

Statistical Analysis: The data analyzed using Statistical Package for Social Sciences (SPSS) version 25. The data presented as mean, standard deviation and ranges. Categorical data presented by frequencies and percentages. Independent t-test (two tailed) was used to compare the continuous variables accordingly between study groups. Z-test was used to compare the categorical variables accordingly between study groups. Paired t-test was used to compare the continuous variables preoperatively and in the 1st and 2nd follow up postoperatively. A level of P – value less than 0.05 was considered significant.

Findings: A total of 40 Iraqipatients were included in this study,patient's age was ranging from 17 to 40 years with a mean age of 28.85 years .of total 60% were males and 40% were females.

The radiographic analysis of the angulation of the impacted teeth according to winters classification showed that the majority of impacted third molars in this study were mesioangular (50%), (35.7%) were Horizontal, (11.9%)were Vertical, (2.4%)were Distoangular.

Position B was the most frequent depth according to Pell and Gregory classification(64.3%), Position A: (31.0%), Position C: (4.8%).class I(42.9%),class II (57.1%), class III(0%).

At the 1 st follow up (48 hour)percentage of swelling was less in the study group than in the control group and the difference was statistically significant between two groups (P-value = 0.001), but no statistically significant difference was found between two groups on 7thpost-operative day follow up,while for trismus the difference was statistically non-significant at both follow up periods.

Table 1: Comparison of swelling between study and control groups in first and second follow up

Swelling (%)	Group		P- Value
	Control Group Mean±SD	Study Group Mean±SD	
First follow up	6.49±1.11	1.05±0.5	0.001
Second follow up	3.26±0.47	3.01±0.53	0.11

Means of pain scores according to NRS was less in the study group than in control group from the first to the seventh post-operative days but still statistically non-significant, except for the first and the second post-operative days in which the difference was statistically significant.(5.8 versus 4.28, P= 0.001; and 4.9 versus 3.45, P= 0.001 respectively).

Table 2: Difference by group of NRS for seven postoperative days

Postoperative Pain	Study Group		P- Value
	Control group Mean±SD	Study Group Mean±SD	
Day One	5.8±0.87	4.28±0.71	0.001
Day Two	4.9±0.99	3.45±0.75	0.001
Day Three	3.12±1.26	2.55±0.75	0.093
Day Four	2.21±1.37	1.85±0.81	0.317
Day Five	1.56±0.89	1.3±0.65	0.3
Day Six	0.81±0.54	0.65±0.67	0.416
Day Seven	0.43±0.31	0.2±0.41	0.069

Table 3: Comparison in limitation of mouth opening between study groups in first and second follow up

Mouth opening limitation (%)	Study Group		P- Value
	Group A Mean±SD	Group B Mean±SD	
First follow up	- 41.63±10.02	- 39.65±9.8	0.52
Second follow up	- 9.14±4.55	-7.92±3.8	0.35

Discussion

The surgical removal of impacted third molar is the most common surgical procedure in oral and maxillofacial surgery [13]. Impacted third molar surgery commonly involves elevating the mucoperiosteal layer, guttering the bone adequately, and performing an odontectomy. These procedures cause severe soft tissue and bone damage and inevitably lead to the release of various inflammation mediators, including bradykinin, histamine, and serotonin, which precede pain, swelling, and trismus after third molar surgery.[14]

Corticosteroids have potent anti-inflammatory activity and have been used at different dosages and through various routes of administration to lessen the inflammatory effects of third molar surgical removal[15]

Dexamethasone has the highest anti-inflammatory potency among synthetic corticosteroids which is 20-30.[16]

In 2017, a systematic review and meta-analysis by Chen et al. found a significant effect for the reduction of early and late oedema and early trismus following submucosal dexamethasone administration5. No significant result was found for the reduction of late trismus[17] use of dexamethasone to minimize edema is due to the fact that Corticosteroids are known to reduce fluid transudation, and edema. Their anti-inflammatory role is explained by the principle of endogenous protein synthesis which blocks the enzymatic activation of phospholipase A2. This in turn blocks the release of arachidonic acid from components of cell membrane thereby finally inhibiting substances related to thromboxane such as prostaglandins and leukotrienes.[18] pain is a significant postoperative complications, and it mainly arise from inflammatory response.

Several biochemical mediators are involved in the pain process, particularly histamine, bradykinin and prostaglandins,The intensity of postoperative pain ranges from moderate to severe during the first 24 h after surgery, with the pain peak being within the first 12 h when a medium-acting local anesthetic is used[19] prostaglandin formation is inhibited by corticosteroids, thereby facilitating some analgesic effects[20] a systematic review conducted by O'Hare et al. in 2019 concluded that, pain was reduced in terms of the VAS score on days 1, 3, and 7 postoperative in patients who received submucosal dexamethasone compared with placebo or no intervention and the maximal reduction of postoperative pain occurs in the early postoperative period.[21]

Conclusion: in conclusion submucosal administration of dexamethasone is simple and effective method to reduce pain,swelling and trismus after surgical removal of impacted third molar.

Conflict of Interest: There are no conflict of interest for both authors.

Hypothyroidism, Prolactin and Function of the Pituitary-Gonadal Axis in Iraqi Patients with Chronic Kidney Disease

Athraa K. Falhi[1], Noori M. Luaibi[2], Ali J. Alsaedi[2]

[1]Biology Department, College of Science, Mustansiriyah University, Iraq,
[2]Professor, Consultant Nephrologist, Medical City, Baghdad-Iraq

Abstract

The present study was aimed to examine the associations among chronic kidney disease(CKD) and hormonal status byevaluation levels of: Luteinizing hormone (LH) and Follicle-stimulating hormone (FSH), Prolactin,Estrogen (E2) and Progesterone (P4)for females and Testosterone for males along with thyroid hormones (TSH, T3, andT4) in CKD patients. The study included 50 patients who are diagnosed to have CKD stage-5, their ages ranged between 20-50 years (25 males and 25 females) who attended the Nephrology and Transplant Center in Medical City of Baghdad- Iraq from April 2018 to July 2018, and 20 matched apparently healthy as control, their ages ranged between 20-48 years (10 males and 10 females). The study showed a highly significant ($P<0.01$) increase in LH, FSH levels in CKD patients compared to the control group. Highly significant ($P<0.01$) increase in Prolactin level as compared to healthy individuals and highly significant ($P<0.01$) decrease in E2 level in CKD females patients compared to the control group, while there was non-significant ($P>0.05$) decrease in P4 level in CKD female patients compared to the control group. On the other hand there is significant ($P<0.05$) decrease in Testosterone level in CKD males patients compared to the control group. In parallel TSH was recorded a highly significant ($P<0.01$) increase in CKD patients in comparison with control. While T3 and T4 levels highly significant ($P<0.01$) decrease in CKD patients in comparison with control.

Keywords: *CKD, Hypothyroidism, Prolactin, LH, FSH, E2, P4, Testosterone.*

Introduction

Chronic kidney disease (CKD) is a progressive deterioration in kidney function that is normally a result of disease or injury to the glomerular or tubular structures within the nephron and advances until the kidneys cannot maintain homeostatic [1].Hormonal dysfunction in CKD is clinically accompanied by sexual dysfunction that influences the life quality of these patients. In advanced stages of CKD, these sexual dysfunctions can be more evident, several changes in hormone levels have been demonstrated, these changes can be because of decreased renal excretion and disturbance of the endocrine system because of uremic effects [2].Thyroid hormones are necessary for growth and development of the kidney and for the maintenance of water and electrolyte homeostasis,CKD upsets thyroid function in many ways, including low circulating thyroid hormone concentration, insufficient binding to carrier proteins and altered iodine storage in the thyroid gland,low T3 is the hallmark of main disturbance [3].Prolactin is a hormone secreted by the pituitary gland and is involved in the lactation, it is normally considered as an inhibitor of gonadotropin releasing hormone(GnRH)[4].Probably both the decline of renal prolactin clearance and increased production rate (caused by the inadequate dopaminergic inhibition of prolactin release) contribute to hyperprolactinemia in patients with CKD[5].Prolactin accumulation causes the inhibition of pulsatile secretion of GnRH as well as the decrement in the testosterone synthesis, which results

e-mail: sznl@uomustansiriyah.edu.iq

in worsening of sexual functions and infertility[1,6]. In CKD patient, level of Luteinizing hormone (LH) and Follicle-stimulating hormone (FSH) rise up [7].Due to high level of gonadotropins (LH and FSH) and low level of gonads hormones Estrogen (E2) and Progesterone (P4) in female, Testosterone in male result in a situation which is called hypergonadotropichypogonadism but this increase is not enough to reverse hypogonadism and it means that there is a problem in GnRH[4,7]. In uremic patients, GnRH releasing from the hypothalamus and GnRH-LH signal are impaired. In these patients, bioactivity of LH changes and then a series of function inhibitors of LH are made [4].

Material and Method

The study was carried out at Nephrology and Transplant Center in Medical City of Baghdad- Iraq from April 2018 to July 2018. This study included two groups, patients and control group. The study included 50 patients are diagnosed to have CKD stage 5, their ages ranged between 20-50 years (25 males and 25 females) and 20 control their ages ranged between 20-48 years (10 males and 10 females).Blood samples were collected from all groups for estimation of (LH, FSH, Prolactin, E2, P4, Testosterone, TSH, T3, and T4),All biomarkers were estimated in serum of all subjects by using an automated quantitative COBAS e411 test (from Roche, Germany).

Results

In this study the level of LH (7.10±0. 57) was highly significant increased (P<0.01) in comparison with control (3.62±0.45). Also,the level of FSH showed high significant increase (P<0.01) in patients group (8.01±0.50) when compared with control group (4.79±0.55), Table (1).

Table 1:Comparison between patients and control in level of LH, and FSH.

Group	Mean±SE	
	LH mIU/ml	FSH mIU/ml
Patients	7.10±0. 57	8.01±0.50
Control	3.62±0.45	4.79±0.55
T-Test	1.897 **	1.732 **
P-value	0.0005	0.0004
** (P<0.01): Highly Significant		

On the other hand Prolactin level in patients group (19.85±1.96) highly significant increase (P<0.01) in comparison with control group (8.93±2.56)as shown in Table (2).

Table 2: Comparison between patients and control in level of Prolactin

Group	Mean±SE of Prolactin ng/ml
Patients	19.85±1.96
Control	8.93±2.56
T-Test	27.001 **
P-value	0.0047
** (P<0.01): Highly Significant	

The mean of serum E2 and P4 levels in the females of the study groups are summarized in Table (3). E2 level (7.89±1.17) in patients group observed highly significant decrease (P<0.01) in comparison with control group (20.80±5.04), while P4 levels showed non-significant decrease (0.407±0.06)in patients compered to control group (0.408±0.10) .

Table 3: Compare between patients and control (Female) in E2 and P4.

Group	Mean±SE	
	E2 Pg/ml	P4 ng/ml
Patients	7.89±1.17	0.407±0.06
Control	20.80±5.04	0.408±0.10
T-Test	7.318 **	0.249 NS
P-value	0.0008	0.997
** (P<0.01): Highly Significant; NS: Non-Significant.		

The present study displayed, significant decrease (P<0.05) in Testosterone level in male patients with CKD (1.57±0.25) in comparison with healthy control group (2.73±0.58).as shown in Table (4).

Table 4: Compare between patients and control (Male) in level of Testosterone.

Group	Mean±SE of Testosterone ng/ml
Patients	1.57±0.25
Control	2.73±0.58
T-Test	1.097 *
P-value	0.0387
* (P<0.05): Significant	

On the other hand, in this study, as shown in Table (5) TSH level in patients group (12.12±1.97) revealed high significant elevation (P<0.01) in comparison with control (1.73±0.24), while T3 level (0.970±0.05) revealed high significant (P<0.01)decrease in patients

group in comparison with control (1.43±0.11), also high significant (P<0.01) decrease in T4 (6.81±0.32) in patients group when compared with control group (9.21±0.25).

Table 5: Comparison between patients and control in TSH, T3 and T4.

Group	Mean±SE		
	TSH mu/ml	T3 ng/ml	T4 mg/dl
Patients	12.12±1.97	0.970±0.05	6.81±0.32
Control	1.73±0.24	1.43±0.11	9.21±0.25
T-Test	6.256 **	0.229 **	1.059 **
P-value	0.0015	0.0001	0.0001
** (P<0.01): Highly Significant			

Statistically,the finding in Table (6) indicate a correlation coefficient between thyroid hormone and other parameter in this study. As showed there is a highly significant (P<0.01) positive correlation between TSH with FSH and significant (P<0.05) positive correlation between TSH with LH. There is non-significant positive correlation between TSH with Prolactin, while there is significant (P<0.05) negative correlation between TSH with E2 and non-significant negative correlation between TSH with P4, and Testosterone.On the other hand, there is non-significant positive correlation between T3 withE2, P4 and Testosterone. And there is high significant (P<0.01) negative correlation between T3 with FSH and non-significant negative correlation between T3 with LH, and Prolactin.Also, this study showed high significant (P<0.01) positive correlation between T4 with E2, non-significant positive correlation between T4 with P4 and Testosterone. And highly significant (P<0.01) negative correlation between T4 with LH, and FSH. While there is non-significant negative correlation between T4 with Prolactin.

Table 6: Correlation coefficient between TSH, T3, T4 with other parameters of patients.

Parameters	Correlation coefficient-r and Level of significant		
	TSH	T3	T4

Discussion

Several changes in hormone levels have been demonstrated in patients with end stage renal disease (ESRD),these changes can be because of decreased renal excretion and disturbance of the hypothalamic pituitary gonadal axis because of uremic effects [2,8]. There are many studies in the world that have been dealt with LH and FSH levels in CKD patients one of these, is a study which has come in supporting results of this study has been stated byAnatharamaa and Schmidt[9],who they found that changes in pulsatile release of GnRH and LH reduce feedback inhibition of LH production (because of low levels of testosterone) contribute to high serum LH levels, FSH secretion is also increased in CKD patients. With ESRD there was a significant increase in LH and FSH and development of pattern of hyper gonadotropic hypogonadism, which indicates that uremic metabolite tend to increaseCKD effect on testes and ovaries more than hypothalamic or pituitary function [10].

Previous studies go in agreement with the results of this study which reported high elevation in levels of prolactin among occurrence CKD patients [11-13]. A study done by Hylander andLehtihet.[10],on young and middle aged men with CKD, showed that 30% of patients had hyperprolactinemia and this go in agreement with results of this study. Edey.[14],found that the endocrine complications of hyperprolactinemia are manifest through disruption of pulsatile GnRH and this leads in turn to hypergonadotropichypogonadism.

The results of this study agree with those that have been found with previous studies [4,6,12],who showed that low concentration of E2 has been seen in uremic patients, nevertheless it has insufficient concentration in the puberty, while in the second half of menstrual cycle serum P4 concentrations are decreased due to the defective follicle luteinization. In this study P4 levels are slightly decreased with no significance compared to the control group, many other authors also approved this resultwho found that mean P4 levels in patients were not significantly different from those of control subjects[11,15]

In the current study, the results of testosterone in male patients indicated significant decrease (P<0.05) in CKD patients, and this result was also approved by many other authors as testosterone which is normally reduced in CKD patients and when LH level is arise in response to low levels of testosterone, so that the hypothalamic pituitary axis in CKD is reset in such a way that it is more sensitive to the negative

feedback inhibition of testosterone[9,10,16,17]. Rathi and Ramachandren.[18], showed that low testosterone is due to decreased production, increased metabolic and dialytic clearance, alteration in testosterone binding capacity[19, 20].

This study showed that gonadotropin hormones LH and FSH, have positive correlation with serum TSH and negative correlation with T3,T4 in men and women with CKD. This result was in agreement with Saran *et al.*[21], which found that serum level of FSH and LH are significantly high in cases of high TSH and low T3, T4. In another study Hapon*et al*.[22] have shown that change in thyroid hormones does not influence the classical preovulatory patterns of LH and FSH secretion in rats, and this finding disagrees with the results of this study. The finding of this study is in agreement with the findings of a study done by GoswamiBinita*et al*. [23] and Fupare*et al.*[24],whom they found that patients with elevated TSH and low levels of T3,T4 had hyperprolactinemia. Kumkum*et al*. [25],in their study they found a positive correlation between low T3, T4 and elevated levels of TSH with prolactin. AffiaTasneem*et al*. [26], in their study they measured serum Prolactin and TSH levels in 1365 patients (46 males, 1319 females), They found 33% had low levels of T3,T4, in hyperprolactinemic patients. A previous study demonstrated positive correlation between TSH and Prolactine in hypothyroid women [27].

In this study, E2 hormone was positively correlated with serum T3, T4 and negatively with TSH, and this result was in agreement with Saran *et al.*[21] and Santin*et al*.[28], which reported that E2 decrease secretion of TSH and increases secretion of both T4 and T3, and they revealed that E2 is directly stimulating the thyroid gland to produce more thyroid hormone, which will also contribute to lowering TSH.Current study showed a negative non-significant correlation between TSH and P4, and positive non-significant correlation between T3, T4 and P4. The results of this study showed a negative non-significant correlation between TSH and testosterone and positive non-significant correlation between T3,T4 and testosterone. The correlation between thyroid hormone and testosterone demonstrated by Donnelly and White[29], which reported that men with low levels of T3, T4 and high levels of TSH have an affliction that is known to disturb normal gonadal function.

Conclusion

This study confirms the noxious role of CKD in hormonal disruption and sexual function.

Mood Disorders in Rheumatoid Arthritis

Kareem Nasir Hussain

[1]*College of Hammurabi Medical, University of Babylon, Iraq*

Abstract

The mood disorder refers to a sequence of mood episodes. Mood disorder are further classified as depressive (major depressive or bipolar) The course of this disorder is characterized as unipolar or bipolar. The aim of the study is to show the relationship between the mood disorder and rheumatoid arthritis and to classify some of the relationship between etiology,symptoms and underlying biochemical processes. Method :Use in this study Three appendix to asses the cases A cohort study composes of 50 patient suffering from rheumatoid arthritis with repeated mood disorders the samples was chosen from both outpatient in Rheumatology unit in IMAM- Al -Sadek teaching hospital and Margin teaching hospital the study was carry out during the period from the first Oct. 2018 through the first April 2019 for each patient critical interview was done by sociodemographic data was recorded according to- appendix A-. The interview was based on national institute of mental health diagnostic interview schedule (NIMH-DIS). Quetionnare designed t0 assess Mood Disorders which include question specific for the diagnosis of depression (72-99) and for mania (100-117) where used to confirm the diagnosis- appendix B-. and proposed 2007 Revised American Rheumatism Association criteria for Rheumatoid Arthritis -appendix C-3. The Result of study revealed the following result the feature of the mood disorder in rheumatoid arthritis where studied in 50 patient a total of 40% meat criteria for mood disorders based on (NIMH-DIS) it's This slightly more in females and more in married patients

Conclusion: This study proved that most of the mood symptoms in rheumatoid arthritis case appeared to be of mild severity and more often showed symptoms of fatigability work retardation, sadness and less suicidal feeling.

Keywords: *Rheumatoid Arthritis; Mood Disorders.*

Introduction

Mood refers to the internal emotional state of an individual and it is also defined as a pervasive and sustained emotion that in the extreme markedly colors one's perception of the world.(1)Affect refers to the external expression of emotional contents . Affect and emotion are commonly used interchangeably .

In mood (affective) disorders, the fundamental disturbance is a change in mood or affect usually to depression (with or without anxiety) or to elation. This mood is normally accompanied by a change in the overall level of activity, and most other symptoms are either secondary to, or easily understood in the context of such changes. Most of mood disorders tend to be recurrent

There are some of the terms have been used in the DSM-IV-TR as follows:

- Mood syndrome: is a group of mood and other symptoms occurring together for a minimum period of time (specified as two weeks for a depressive and a "distinct period" for a manic episode). A mood syndrome can occur in a schizoaffective disorder or an organic mental disorder, as well as an affective disorder (9)
- Mood episode: is a term restricted to mood syndromes occurring in the absence of either an organic disorder or a 'non – mood' psychiatric disorder (that is schizophrenia, schizoaffective disorder, or delusional disorder) (4)
- Mood disorder: is a term refers to a sequence of mood episodes. Mood disorders are further classified

as depressive (major depression) or bipolar. The course of disorder is characterized as unipolar or bipolar.

In summary, the classification of mood disorders in ICD - 10 is quite complicated, and makes provision for a wide range of detailed distinctions, but is singularly free of assumption about disease entities and causation[8]

Classification in (DSM-IV-TR), differs only in minor ways from its predecessor. The detailed criteria for a major depressive episode are different and now make it possible for the diagnosis to be made in the absence of a depressed mood, provided there Is anhedonia. The criteria for melancholia[2] are also changed, with diagnostic weight now is given to a good previous response to antidepressants or ECT and to full recovery from a previous episode. There is also a new set of criteria for seasonal mood disorder [3] ز Mood (affective) disorders periodically disable many people over the world. Although manic disorders are comparatively rare, depression is, quite possibly, the most widespread serious and costly psychiatric disease afflicting humankind today. It is at least ten times as prevalent as schizophrenia. severe depression affects fully 2 - 3% of the world's population[6].

The life time expectancy of developing unipolar depression is approximately 20% in women and 10% in men, the onset can occur from childhood through senescence, but 50% of the patients have the onset between ages 20 and 50, the mean age being about 40. In general, more often in divorced or separated individuals. There is no correlation between social class and unipolar depression [2]

The life time expectancy of developing bipolar disorder is about 1% in both men and women. The mean age of onset is earlier than that of unipolar disorder, the range begins from childhood to 50 years. It may be more common in divorced and single individuals than among married persons. Bipolar disorders are more frequent in the upper social class [5] a group of individuals who experience their symptoms in response to an identifiable life event and whose depression remits rapidly and often spontaneously. This may account for up to half the depressed individuals in the community Second, there is a group of depressed individuals whose depression lasts longer and recur more frequently. Third, there is a group of chronically depressed individuals, many of whom might be regarded as having a personality disorder [3].

The frequency of episodes and the pattern of remissions and relapses areboth very variable, though remission tend to get shorter as time goes on and depression to become commoner and longer lasting after middle age[8].Most of mood disorders tend to be recurrent and the onset of the individual episode is often related to stressful events [8].

to appendix a. The interview was based on national institute of mental health diagnostic interview schedule (NIMH-DIA). question specific for the diagnosis of depression (72-99) and for mania (100-117) where used to confirm the diagnosis appendix b. 3 .Result study revealed the following result the feature of the mood disorder in rheumatoid arthritis where studied in 50 patient a total of 40% meat criteria for mood disorders based on (NIMH-DIS) it'sThis slightly more in females and morein married patient.

Conclusion this study proved that most of the mood symptoms in rheumatoid arthritis cases appeared to be of mild severity and more often showed symptoms of fatigability work retardation, sadness and less suicidal feeling.

Result

The 50 patients with rheumatoid arthritis screened by (NIMH-DIS) national institute of mental health diagnostic interview schedule question specific for the diagnosis of depression (72-99) and for mania (100-117) were used to conform the diagnosis the NIMH-DIS is a fully structure interview designed to enable physicians to make accurate psychiatric diagnosis according to three diagnostic system DSM,FEIGHNER CRITRIA and RESEARCH DIAGNOSTIC CRITRIA so they meet the predetermined criteria for mood disorder, while in non- rheumatoid patient among fifty patient screening 38% reach as in table 1among female patient with rheumatoid arthritis screened 80% where mood disorder while it was 35% among males as in table 2The rheumatoid patients divided into 3 age group the distribution of mood disorder according to these groups is shown in table 3.mood disorder among 40 married patient and ten single patient is shown in table 4.About 10% of mood disorder rheumatoid patient had received psychiatric treatment previously as shown in table 5.The predominant depressive symptoms in rheumatoid and non- rheumatoid chronic medical patients were nearly similar,apart from more fatigability than work retardation in R. A,the reverse in non-rheumatoid patients as in table -6- Discussion: R.A pain lead to depression,depression may worsen pain perception .Depression and pain are akin to the proverbial chicken and the egg .chronic pain can lead to depression,and feeling down in the dumps can worsen the perception of pain. The researchers asked 56 people with R.Ato complete questionnaire designed to assess their Depression and anxiety levels .A year later during follow up, researchers found a strong association between the N umber of sore joints and scores on how participant were feeling in general[15]. This study comparable with our study which proved the association between the pain and the mood disorders the above results have shown that mood disorders are common phenomena among rheumatoid & other chronic medical patient.

That are 40% among rheumatoid and 38% among non-rheumatoid patient as in table 1by application of chi -square test and Z-Test we noticed that there is no significant difference in distribution of mood disorders among rheumatoid and non-rheumatoid patient. This prevalence of mood disorder among rheumatoid patients is consistent with that in other studies. A study investigating 50 adult female patients with rheumatoid arthritis, control cases where 50 patients admitted in the same hospital. 29% revealed distinct mood disorders[10]. A 15 years follow up study of 74 female patients with classic rheumatoid arthritis was performed with special emphasis on overt psychopathology during the clinical course of the illness 40% had mood disorders[14] Several studies have demonstrated that post stroke mood disorders are frequent sequel of cerebrovascular disease occurringin up 50% of stroke patients(9). mood disorder increase with age as shown as in table -3 -this maybe related to the fact that psychological mechanism which permitted coping with stress at an earlier may have diminish gradually,as well as chronicity of illness may play the same role. There is more mood disorder in married patient than single as in table-4- this may be due to the lowering of self-esteem,the possible loss of love and admiration of the husband or wife and the fear of being not wanted physically here too chronicity may play the same rule. A study examine the relationship between the health status of rheumatoid arthritis wife it was found that higher mood disorder where associated with lower family cohesiveness,functioning and higher conflict in subjects,less expressiveness in spouse [13]. The mood disorders referred to variety of psychiatric facilities in New Haven reported as 3 times as many events in six month before the onset as much as control from surrounding population as in table-5-.[11].Work retardation and fatigability may reflect real incapacity and disability of the patients due to physical illness[1]. The study of mood disorders in medical patients, found that when compare with mood disorders in psychiatric unit,suicidal thinking and guilty feeling were found little but more likely to manifest pessimessim,agitation, helplessness,anxiety,and retardation[11].Rate of Depression, Anxiety, and Bipolar Disorders are higher in people with R.A.Researcher in Manitoba –Canada, studied more than 60,000 people with R.A and Healthy-Individual. The incidence of Depression was 45 percent higher, and Bipolar Disorder was 20 percent more common.[16].

Pattern of Mechanical Intestinal Obstruction in Al-Yarmouk Teaching Hospital

Ammar Fouad Abdulrazaq[1], Mohammad Faraj Dawod Al. Jafary[2], Hanan Hazim Mohammed Noori[3]

[1]General Surgeon, Department of Surgery, Al-Yarmook Teaching Hospital, Baghdad, Iraq, [2]General Surgeon, GIT, Department of Surgery, Al-Yarmook Teaching Hospital, Baghdad, Iraq, [3]Specialist in Gynecology and Obstetrics, Head of Department of Gynecology and Obstetrics, Al-Qaim Hospital, Al-Anbar Province, Iraq

Abstract

Background: The effective treatment of patients with intestinal obstruction is essential and requires initial rapid diagnosis and therapeutic intervention.

Aim of Study: To determine the causes, the accuracy of preoperative diagnosis, and other epidemiological characteristics of intestinal obstruction in Al-Yarmouk Teaching Hospital in Baghdad, Iraq.

Patients and Method: A prospective study was conducted in the Surgical Department of Al-Yarmouk Teaching Hospital for a period of two years (from Jan 1999 to the end of Dec 2000) and included 178 patients admitted and proved to be diagnosed with mechanical intestinal obstruction.

Results: Of the 178 patients enrolled in this study; maximum incidence was seen in patients aged between 40-59 years with male predominance (62.4%). Abdominal pain and constipation, were presenting in majority of cases (87.6% and 83.1% respectively). Common causes were hernias, adhesions and bands (35.4% and 28.6% respectively). Small bowel was involved in 69.7% cases and large bowel in 30.3%. Laparotomy was the main option for management (69.1%). The mortality rate was 9.5% and death is associated significantly with aging and volvulus and intussusception as causes of intestinal obstruction.

Conclusion: Acute intestinal obstruction still a major cause of morbidity and mortality which was associated with aging, compound volvulus and intussusception. Hernias and adhesions were the leading causes of intestinal obstruction. Abdominal pain and distension, and constipation were seen in majority of cases. Laparotomy was the most common method of intestinal obstruction management in our institute.

Keywords: *Intestinal obstruction, mechanical, small bowel, large bowel, Iraq.*

Introduction

Intestinal obstruction (IO) is defined as obstruction of the passage of the intestine for its contents[(1)]. It is a commonly encountered problem in gastrointestinal surgery all over the world[(2)]. Despite advances in surgery, bowel obstruction remains a difficult problem with significant morbidity and mortality due to disrupted gastrointestinal flow. Consequently, IO is associated with considerable clinical burdens, major financial expenditure, frequent emergency room visits and economic loss from time spent away from duties[(3)]. In the last century, significant changes in etiological factors of IO have occurred from changes in epidemiologic and environment factors, health services provision and education[(3)]. It may occur in both small and large intestines. However, obstruction in the small bowel is more prevalent[(4)]. Of all IO, mechanical IO forms an important part of pathologies that necessitate emergency

surgical interventions[5] and is a significant cause of morbidity and mortality, especially when associated with bowel gangrene or perforation[6].The clinical signs and symptoms which could be helpful in diagnosis of IO are usually abdominal pain, vomiting, abdominal distention, and absence of flatus or feces passage[7]. There are several causes of IO and their relative incidence varies in different populations, between countries and has alsochanged over the last decades. Several factors are described to be responsible for these differences. Socioeconomic factors and diet have mostly been incriminated to be responsible for the observed difference[8].The most important risk factor for mechanical small bowel obstruction is prior abdominal surgery causing postoperative adhesions usually[9]. Patients with a history of prior abdominal or pelvic surgery, and particularlycolorectal surgery, appendectomy, gynecologic surgery, prior adhesiolysis, and resection of malignancy are prone to adhesive small bowel obstruction[10,11]. Optimal outcomes at the end of life rely upon a careful analysis of the patient, their pathology, and the likely benefits to be gained from intervention, be they psychological, social, or to enable further adjunctive treatment[12]. Considering the importance of IO and its life-threatening complications, learning about the epidemiological characteristics of the disease and determining its prevalence can be effective in management of this disease and providing essential sources for its early diagnosis. The present study aims to determine the most important and frequent causes, the accuracy of preoperative diagnosis, and other epidemiological characteristics of IO by using the data that was collected from single institute during the last two years.

Patients and Method

Study design,setting and sample size: A prospective study was conducted in the Surgical Department of Al-Yarmouk Teaching Hospital for a period of two years (from Jan 1999 to the end of Dec 2000) and included 178 patients admitted and proved to be diagnosed with mechanical IO.

Diagnosis of IO was based on the history, physical examination, supported by radiological evidence of obstruction (Plain x-ray of the abdomen). Physical findings which usually present in cases of complicated IO were put in mind including (Abdominal tenderness, rebound tenderness or muscle guarding, tachycardia > 100 beats/mints, fever > 38 C°, pain suggestive of strangulation, palpable abdominal mass or irreducible hernia, and shock). Patients with incomplete records or with functional causes of IO were excluded.

Patients first admitted to the surgical causality unit, necessary resuscitation done for the patients including intravenous administration of at least one liter of ringer lactate or normal saline solution, antibiotic administered and measures for associated diseases. Laboratory investigations were done including (complete blood count, blood group and Rh, serum electrolytes, blood urea, and random blood sugar).

Data collection tools: A questionnaire had been applied to all patients to collect the needed information, the questionnaire was filled by the researcher through direct interview with the study patients. It included questions to gather information on certain socio – demographic variables (age and gender), site and cause of IO, time between presentation and surgery, preoperative provisional diagnosis, clinical findings suggesting strangulation and complications).

Statistical Analysis: The data analyzed using Statistical Package for Social Sciences (SPSS) version 25. The data presented as mean, standard deviation and ranges. Categorical data presented by frequencies and percentages. Chi square test was used to assess the association between mortality rate and certain information. A level of P – value less than 0.05 was considered significant.

Results

In this study,200 couples were enrolled. The age was ranging from 10 to 90 years with a mean of 40.2±10.8 years and the mainly affected age was from 40 – 59 years (35.5%). Regarding gender, proportion of males was higher than females (62.4% versus 37.6%) with a male to female ratio of 1.65:1. The highest incidence of IO occurred in small bowel (69.7%), the most prevalent presenting symptoms were abdominal pain (87.6%) and constipation (83.1%), and the most common cause of IO was hernia (35.4%) as shown in table (1).

Table 1: Distribution of study patients by general information

Variable	No. (n=178)	Percentage (%)
Age (Years)		
<20	16	9.0
20 - 39	44	24.5
40 - 59	63	35.5
≥ 60	55	31.0

Neoplasms	32	17.9
Fecal impaction	12	6.8
Volvulus	8	4.5
Intussusception	4	2.3
Miscellaneous	8	4.5
Site of IO		
SMALL Bowel Obstruction (SBO)	124	69.7
LARGE Bowel Obstruction (LBO)	54	30.3
Clinical presentation		
Abdominal pain	156	87.6
Constipation	148	83.1
Abdominal distension	124	69.7
Vomiting	112	62.9
Bowel sound	46	25.8

More details about the causes of IO is shown in table (2). Inguinal hernias constituted the largest no. of hernia cases (55.9%). Regarding cause of adhesions and bands, appendectomy was the most common condition that causing adhesions and bands (35.4%). Sigmoid colon neoplasms represented more than third of neoplasm that cause IO (37.5%).

Table 2: Distribution of study patients by certain details of IO causes

Variable	Number	Percentage (%)
Type of hernia n= 63		
Inguinal	34	55.9
Para-umbilical	15	23.8
Incisional	8	12.7
Femoral	4	6.4
Internal	2	3.2
Cause of adhesions and bands n= 51		
Appendectomy	18	35.4
Gynecological surgery	12	23.5

Site of neoplasm		
Small bowel lymphoma	1	3.2
Right colon	2	6.3
Left colon	6	18.7
Sigmoid colon	12	37.5
Recto-sigmoid	8	25.0
Rectal	3	9.3

Of the 178 patients, 69.1% were operated while 30.9% responded to conservative management as shown in figure (1).

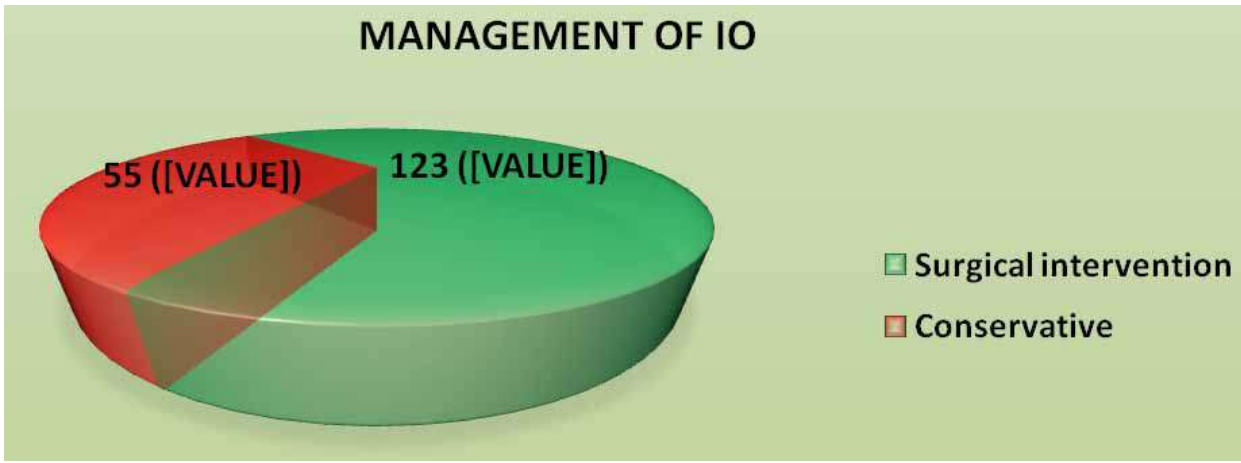

Figure 1: Distribution of study patients by type of management of IO

Among 123 patients who underwent surgical operation, we noticed that all cases with hernia or volvulus were operated within the 1st 24 hrs., one case was operated in the 4th day and other case was operated in the 5th day; these two cases were diagnosed with neoplasm as shown in table (3).

Table 3: Time between admission and operation according to cause of IO

Cause of IO	Time between admission and operation					Total (%) n= 123
	1st 24 hrs. (%) n= 108	2nd day (%) n= 8	3rd day n= 5	4th day n= 1	6th day n= 1	
Hernia	63	0	0	0	0	63
Adhesion and band	16	3	2	0	0	21
Neoplasm	13	4	2	1	1	21
volvulus	8	0	0	0	0	8
Intussusception	3	1	0	0	0	4
Fecal impaction & Others	5	0	1	0	0	6

In this study, from those 123 patients who undergone surgical operation, 19 (15.4%) patients found to have complicated (ischemic) IO. From those 19 patients, 17 patients were diagnosed preoperatively as complicated. The sensitivity of preoperative diagnosis was 89.4%, specificity was 94.2%, positive predictive value was 73.9%, negative predictive value was 98%, and accuracy rate was 93.5% as demonstrated in table (4).

Table 4: Sensitivity, specificity, and accuracy of preoperative diagnosis

Preoperative Diagnosis	Operative finding		Total (%) n= 123
	Complicated	Simple	
Complicated	17	6	23
Simple	2	98	100
Total	19	104	123

As shown in table (5), the mortality rate in this study was 9.5% (17 patients). The highest prevalence of death was seen among elderly patients (21.8%) and in patients presented with intussusception (75%) with a significant association between prevalence of death and both of age (P= 0.002) and cause of IO (P= 0.001).

Discussion

Bowel obstructions till one of the most common surgical emergencies worldwide[13], management of which requires quick, appropriate diagnosis and, rational and proper treatment[14]. In this study, the mean age was 40.2±10.8 years with a male predominance (62.4%). This results are consistent with other published studies as studies conducted by Souvik A et al in 2010 [15], and Doumi EB et al in 2008 [16] when they reporting mean ages between 39 and 42 years, and male predominance rates of 60 - 70%. Significant regional variation in the causes of IO has been noticed among various studies as this study showed that the most common cause of IO was hernia (35.4%) and adhesions and bands (28.6%) similar to a studies conducted by Mohamed A et al, 2017 (Hernia 31.4% and adhesions 25.2%)[17], and by Thampi D et al, 2014 (Hernia 30% and adhesions 40%) [18]while a study conducted by Manafi A et al, 2009 showed that the common causes of IO were mostly due to volvulus (76%) and neoplasm (15%) [19], and the most common underlying cause of IO in Saudi study 2010 was found to be adhesive obstruction[13]. In Iraqi community, it was believed that due to poverty, lack of education, and general fear of surgery, patients were reluctant for elective surgery of hernias and this might lead to a large number of hernias presenting as obstructed/strangulated bowel obstruction. There is also a parallel increase in the number of laparotomies, and this has raised the incidence of adhesive obstruction in our institute. In this study, the small bowel was more preferred site for obstruction than large bowel (69.7%). Similar studies also reported that SBO was the most common type of IO whereas LBO was relatively less common[1, 13, 20].

This fact may help us to know that socio-economic factors and diet might be responsible for the causes of IO in some developing countries. The most presenting features in this study were abdominal pain (87.6%), constipation (83.1%), and abdominal distension (69.7%). It was comparable to various studies done by Thampi D et al[18], Malik AM et al[13] and Mohamed A et al [17]. The minor differences noted maybe due to the difference in time of presentation to hospital invarious setups. The mortality rate in this study was 9.5% which is comparable with various studies by Souviket al (7.35%) [15], Viji G (9%)[21], and Madziga AG et al (9.14%) [22].Poor outcomes have beennoted in elderly patients and those with early development of bowel gangrene like compound volvulus and intussusceptionand acute mesenteric ischaemia and also in cases of malignancies.

In conclusion, acute IO still a major cause of morbidity and mortality. Aging and compound volvulus and intussusception are the most important associated factors for mortality. Hernias and adhesions were the leading causes of IO. Abdominal pain and distension, and constipation were seen in majority of cases. Small bowel obstruction was more prevalent than large bowel obstruction. Laparotomy was the most common method of IO management in our institute.

Ethical Clearance: The Research Ethical Committee at scientific research by ethical approval of both environmental and health and higher education and scientific research ministries in Iraq.

Conflict of Interest: The authors declare that they have no conflict of interest.

Infection Rate of Trichomoniasis among Women in AL Hilla City

Maani Seher Abid Al-Kahfaji

Department of Microbiology-college of Medicine–University of Babylon, Iraq

Abstract

Trichomoniasisis a very common parasitic disease transmitted sexually in the world.The infection caused by unicellular,flagellated parasite *Trichomonas vaginalis*. The present study was conducted from January to April 2019 to investigate the infective rate of trichomoniasis in women attending family planning unit in maternity and children hospital in Al-Hilla city . A total of 255 women of different ages (>20-50)yr. were enrolled in this study. All of them were screened for trichomoniasis by wet mount preparation. A consent was taken from all participant which included(age, area of residence, marital status,pregnancy status, use of contraceptive in addition to the symptoms. Out of 255 women, 67 (26.27%) revealed positive results for trichomoniasis. According to age groups the results showed the highest rate of infection (39.6%) in (21-30) yr. age group. The infection rate was high among women lived in rural areas was reach(67.45%) than women lived in urban areas was reach (32.54%). Non- Pregnant women showed higher infective rate of trichomoniasis than pregnant women (65.86% and 43.13%), respectively. The infection rate in married women was(62.74%) and unmarried women was (37.25%) .The present study showed high rate of trichomoniasis (67.84%) in women that use contraceptive, while the lower rate of infection with trichomoniasis (32.54%) in women that non-using contraceptive. The present study showed there were significantlly differences ($p<0.05$)correlation between trichomoniasis in women with (age,residency, marital status, pregnancy status and using or non-using of contraceptive).

Keywords: *Trichomoniasis, women, infection rate, pregnant,contraceptive.*

Introduction:

Urogenital trichomoniasis is one of most common diseases transmitted by sexual intercourse and distributed worldwide, the disease spread usually in females more than males,and caused by infection with a flagellated unicellular parasite *Trichomonas vaginalis* and cause inflammatory reactions,vaginal dischargeand vulvar itching for infected women [1]. Man is the only known best host of parasite transmitted during sex, and occasionally by fomites [2]. Infected individuals without any clinicalfeatures are responsible for spread the infection to others healthy individuals. Trichomoniasis in womeninhabits the lower genital tract of the body and most commonly infect (vagina,urethra or vulva) while in men, the most commonly infection is found in the prostrate, urethra or epididymis causing prostatitis and urethritis [3].Transmission of *Trichomonas vaginalis* to neonates via passage of infected birth canal is also imaginable in pregnant women[4] trichomoniasis in women causes profuse vaginal discharge,vulvular burning, irritation and itching, of the genital tract, dysuria, or profuse discharge with unusual bad smell that may be yellow,white or green in color and sometimes frothy vaginal discharge [5] . The World Health Organization estimated the prevalence, ranges about sixty to eighty present based on wet mount microscopy [6]. Demonstration of source of this infection is challenging because of numerous pathogens can cause vaginal infection and many other infections. Useful tests for diagnosis trichomonas include analysis of vaginal fluid, wet mount technique, culture media and Gram s stain [7]. Direct examination of wet mount examination of women, vaginal swabs is less expensive technique and most rapid, for demonstrate. Trichomonas vaginalis [8]. Trichomoniasis may be increase the danger of acquire or spread other infection that transmited sexually. Some studies showed that trichomonas

infection can increase the susceptibility to other co-infection like bacterial infection and urogenital irritation that increases the endangering of viral infections, or to pass the viral pathogens into a sex partner [9]. High rate of trichomoniasis ranging from 21 to 42.6 present in the general population especially in pregnant women. The infection rate of trichomoniasis has been occurs vary depending to place of living or community setting,marital status and age [10].

Subjects and Method

The present study was aimed to evaluate the infection rate of trichomoniasis and its relationships with epidemiological and demographic factors among women attending the family planning unit in maternity and children hospital in Al-Hilla city during the period from January to April 2019. Initially,an informed consent was taken from the contributor then, the information were recoded (age, marital,pregnancy and residency status, use of contraceptive)in addition to clinical symptoms (vaginal discharge, itching,burning, dysuria). Vaginal discharge swab was obtained from posterior vaginal fornix after putting a woman at lithotomic position in non-pregnant women while press secretion and discharge were sweep from the passage of the vulva and modicum deep in vagina with sterilized cotton swabs in pregnant women. The swabs obscure in a tube with one ml of a sterile normal saline, then the suspension was used to prepare wet mount slides and they were immediately examined microscopically at 40x, 100x power according to [11] for demonstrate the parasite oval shaped,jerky motile, flagellated trichomonas vaginalis. Then results were tabulated and analyzed.

Statistical Analysis: Statistical data analysis were done by using the SPP program software,version (17), and chi square analysis test (x2) with (P) value <0.05 for statistical analysis of the results of this study.

Results

Table 1: Infection rate of trichomoniasis according to age groups

Age groups	No. of exam	%	No. of infected	%
>20	25	9.803	9	13.43
21 - 30	101	39.6	31	46.26
31 -40	94	36.8	20	29.85
41 - 50	35	13.72	7	10.44
Total	255	%100	67	%100

P. value <0.05 is statistically significant

In the present study (255) women from(> 20 -50) yr. were arranged in to four categories .the result recorded higher infection rate(46.26%)and (29.85%) among the age groups (21-30),(31-40)respectively while the lower infection rate (10.44%) among the age group(41-50)as show in table 1 .

Table 2: Infection rate of trichomoniasis according the residency status

Residency Status	No. of exam	%	No. of infected	%
Rural	172	67.45	47	70.14
Urban	83	32.54	20	29.85
Total	255	%	67	%

P. value<0.05 is statistically significant

The present study showed higher infective rate Trichomoniasis among women lived in rural areas (70.41%) as compared with women lived in urban areas (29.85%) .the result reveals significant differences (p<0.05) between them as show in table 2.

Table 3: Infection rate of trichomoniasis according the pregnancy status

Pregnancy Status	No. of exam	%	No. of infected	%
Pregnant	110	43.13	21	31.34
Non-Pregnant	145	56.86	46	68.65
Total	255	%	67	%

P. value <0.05 is statistically significant

The results of present study found that high rate of infection were observed in non-pregnant women(68.65%) than pregnant women (31.34%). The results showed statistically significant as in table3.

Table 4: Infection rate of Trichomoniasis according the marital status

Marital Status	No. of exam	%	No. of infected	%
Married	160	62.74	55	82.08
Unmarried	95	37.25	12	17.91
Total	255	%	67	%

P. value<0.05 is statistically significant

The infective rate with Trichomoniasis in married and unmarried was (82.08%) and (17.91%) respectively statistically differences (P<0.05) between the infective rate in two status as reported in table 4.

Table 5: Infection rate of trichomoniasis according the contraceptive using

Contraceptive	No. of exam	%	No. of infected	%
Users	173	67.84	44	65.67
Non-users	82	32.15	65.67	34.32
Total	255	%	23	%

P. value<0.05 is statistically significant

Infection rate of Trichomoniasis was more common between women who useing contraceptive (65.67%) than those did not using contraceptive (34.32%) as in table 5.

Discussion

In the present study, 255 women from(>20 to 50) yr. old were arranged in to four categories. 67 (26.27%) revealed positive results for trichomoniasis. According to the age group the result recorded high infection rate(46.26%) of trichomoniasis among the age group (31-40) yr. which in agreement with similar studies in Baghdad,Iraq[12,13]and [14] in Dohok,Iraq . Also in agreement with [15]who demonstrated that the infection rate is high in the young age andrisk than other age,on the other hands this finding disagreement with some studies done by [16,17] and study in Kirkuk,Iraq[18]. This suggests that greater sexual activity responsible for high rate of infection of this age group. The present study showed alower infection rate of trichomomiasis among women lived in urban areas (29.85%) as compared with women lived in rural areas (70.41%) this finding may be due to the scope and quality of health care, socioeconomic conditions, life style and educational status of the women setting in rural areas,the results agreement with the study of [19]in Tikrit,Iraq also agreement with study done in India [20]. The present study reveals the high infection rate of trichomoniasis was (68.65%)in non-pregnant women compared with pregnant women was(31.34%) this finding may be due to the variation in sample size of pregnant and non-pregnant women examined in present study or because of that pregnant women make attend antenatal clinics where they check out and treated in bureaucracy antenatal clinics. This results agree with study done by [21] in Iraq who indicated that the infective rate innon- pregnant women(20.0%) higher than in pregnant women was (9.09%) while the results of present study disagree with some study done by[22-24]reported that the pregnant women more insecure to infection with tricomoniasis than non-pregnant women.The observation of present study is reveal that the infection rate of trichomoniasis varied with the marital status of the women, the highest infection rate among the married women (82.08%) and less among the unmarred women (17.91%). One of the reasons for the lower infection rate of Trichomoniasis in unmarried women that is a disease fundamentally transmitted sexually. [25] reported that two to three million of trichomoniasis with clinical symptoms occur mainly among sexually active women. The results of present study is agree with similar studies that showed high rate of trichomoniasis among married women in compare with unmarried women[26-28]. Regarding to use of contraceptive the present study was recorded more frequently of trichomoniasis (65.67%) in women that were contraceptive users than in women that did not use contraceptive(34.32%) .This result was also recorded by [29]. The effect of contraceptive may create suitable condition that is good hospitable for parasite because of the contraceptives changes the normal condition of the genital tract and alter the usual lubricant secretions then causes damage to the epithelial lining of vagina through which sexually transmitted pathogenic organisms such as *Tricomonas vaginalis* may invade the urogenital tract easily[30,31].

Conclusion

Trichomoniasisis the most common disease spread amongwomen during sexualy active age.The studies on it relatively scantly in Iraq,Also there is a very poor awareness about trichomoniasis among women with high risk to infection such as married and urban lived women. Thus,we need plans which aims to improve the knowledge about the disease in populations,Also future epidemiological studies in various areas of country are required to promote understand the prevalence of trichomoniasis

Genotyping of Epstein-Barr Virus in EBV-Positive Burkett's Lymphoma in Anbar Province (Western of Iraq)

Mothana Ali Khalil

Department of Microbiology/Virology, University of Anbar, College of Medicine, Iraq

Abstract

Background: Epstein-Barr virus (EBV) is the first identified human virus with a proven association with the pathogenesis of cancer including Burkitt's lymphoma (BL). Two subtypes of EBV, type A and B have been identified based on divergence in the nuclear protein genes (EBNA) 2, 3, 4 and 6.

Objectives: This study aimed to determine the genotype of EBV in BL cases in Anbar province (Western of Iraq).

Materials and Method: This study was conducted at Anbar Medical college-Ramadi city, Iraq and the molecular analyses were carried out at private laboratories in Baghdad city during the period from January 2017 to December 2019. The expression of EBV-to-EBV-encoded small RNA in BL cases was detected by the in situ hybridization technique (EBER- RISH). EBV DNA was extracted from formalin-fixed, paraffin-embedded tumor blocks of BL cases. One-stage polymerase chain reaction (PCR) and two-stage (nested) PCR assays were performed with the primers common for both EBV genotypes and the primers specific for EBV types 1 and 2, respectively. PCR reaction was employed for EBV Genotyping using sets of primers flanking the EBNA-2.

Results: EBV genomes were detected in all BL, and EBV type 1 virus (EBV type A) infected the majority of EBV-positive BL cases (85/90) (94.44%), while EBV type two (EBV type B) was detected in five cases only (5.56%).

Conclusion: Predominant of EBV Type 1(EBV type A) in the Iraqi positive BL cases.

Keywords: *EBV, Burkett's lymphoma, genotyping, PCR.*

Introduction

Epstein-Barr virus (EBV) also called human herpesvirus 4 (HHV-4) affecting more than 90% of individuals worldwide[1]. Most primary EBV infections are asymptomatic [2,3]. Reactivated EBV infections are associated with serious complications such as lymphoproliferative disorders and malignancy [1, 3-6].

Epstein–Barr nuclear antigen 1 (EBNA-1) and the two small noncoding Epstein–Barr RNAs (EBERs) (latency I) have been generally thought to be the only EBV genes expressed in Burkitt's lymphoma (BL)[3,6,7]. Variations in the EBV genome made it possible to distinguish two (02) subtypes of the virus: EBV-1 and EBV-2 (or EBV-A and EBV-B types) [3,8,9, 10,11,12].

There are three subtypes of BL: endemic BL, sporadic or non-endemic BL, and immunodeficiency-associated BL[11]. Endemic BLcommonly seen in children aged 4–9 years affecting the facial skeleton involve the maxilla or mandible and Jaw tumors[4,11, 14,15, 16, 17]. Sporadic BL, affecting mainly abdominal viscera [14] typically seen in patients less than 35 years of age[7,17]. Immunodeficiency-associated BL occurring in association with the HIV infection[16].

In Iraq, there are not enough data are available for the EBV genotypes in EBV positive BL cases. This study aimed to determine the genotype of EBV in BL cases in Anbar province (Western of Iraq).

Materials and Method

Study Setting: The study was a retrospective cross-sectional design to investigate the presence of the DNA and genotypes of EBV from primary archives tissue samples of the pathologist Dr.Arkan AL Essawi, in AL-Anbar medical college during period from January 2017 to December 2019, and the molecular analyses were carried out at private laboratories In Baghdad city.

Ninety cases previously diagnosed as BL were retrieved from the archives. Hematoxylin and eosin stained slides of 90 biopsies from 64patients were reviewed for confirmation and classification according to the criteria from the WHO-proposed list of lymphoid neoplasms [17] by pathologist Dr.Arkan AL Essawi. Archived slides were reviewed by two pathologists for confirmation of diagnosis and tissue adequacy for extracting of DNA. Detection of EBV in BL cases were done in the previous study[18].

The demographic data of these patients' biopsies were obtained from an information sheet volunteered by the clinicians. Statistical analyses were based on non-parametric method and a P value <0.05 was considered significant. The study was retrospective, so informed consent not taken from the patients. This study was approved by the Microbiology Department, Anbar medical College, University of Anbar, Ramadi city, Iraq.

Method

In Situ Hybridization: The expression of EBV-to-EBV-encoded small RNA in Burkitt's lymphoma (BL) cases was detected by the in situ hybridization technique (EBER- RISH)were performed according to the manufacturer's instructions.

PCR Amplification:

DNA extraction: EBV DNA was extracted from formalin fixed paraffin-embedded tumor blocks of (BL) cases according to procedure describe previously [19].

Detection of EBV DNA: Detection of EBV DNA in BL casesaccording to the manufacturer's instructions (Merck, Darmstadt, Germany).The amount and purity of DNA were determined by spectrophotometer. DNA was stored at 80º C until use. The supernatant containing DNA was used directly for PCR amplification.

Genotyping of EBV: EBV Genotyping was carried out when the virus was detected by in situ hybridizations. Genotyping was carried out when the virus was detected by PCR. A nested PCR procedure was performed as previously described [20]. Amplification of the EBNA-2 gene was performed according to a nested PCR procedure by using the two primer pairs as showed in table 1. These primer pairs generated products of 300 bp for type 1(type A), and 250 bp for type 2 (type B) of EBV (Fig 1). The reaction products were examined by direct visualization using Ethidium bromide stain as a fluorescent dye in agarose gels (2%) under UV transilluminator.

Table (1): Primers used for EBV genotyping

Primers	Sequence (5'-3')	Use in the PCR reaction EBNA-2
EBNA-2F	5'TTT CAC CAA TAC ATG AACC 3'	1st reaction sense
EBNA-2I	5'TGG CAA AGT GCT GAG AGC AA 3')	1st reaction Antisense
EBNA-2C	5'CAA TAC ATG AAC CRG AGT CC 3'	Nested reactive sense
EBNA-2G	5'AAG TGC TGA GAG CAA CCG GC 3'	Nested reaction antisense type-1
EBNA-2B	5' TTGAAGAGTATGTCCTAAGG3'	Nested reaction antisense type-2

Results

All Burkett's lymphoma biopsies were EBV-positive using in situ hybridization (ISH) technique.

A total of 90 EBV- positive BLbiopsies belong to 60 males and 30 females, for a male to female ratio of 2:1. The main sites of presentation are the gum and maxilla 41/90, (42.55%) and lymph nodes 26/90, (28.88%). Other common sites included the abdominal viscera 10(11.11%), 3/90 (3.33%) for each of testes andovary, tonsil, Nose and brain 1/90, (1.12%). The remaining three (3.33%) biopsies were taken from other sites (orbit, bone marrow, the soft tissue of the neck, upper thigh, and the infra-spinal region) (Tab 2).

PCR amplification of the EBNA-2 gene to determine the type of EBV was successful all of the 90 EBV-positive BL cases (Tab 2). In 85 of the 90 cases (94.44%), a 300-bp product was identified by PCR consistent with type A EBV (EBV Type 1), whereas in five of the 90 cases (5.56%), a 250-bp product was consistent with type B EBV (EBV Type 2). No case demonstrated both EBV subtypes in the same sample (Tab 2).

Among the EBV-positive cases, 53 of 90(58.88%) belonged to children younger than 17 years with median age 6 years, 37 of 90 (41.12%) were adults with Median age 28 years. (Tab 1).

Figure (1): Shows the results of EBV types 1(types A) (300 bp) and EBV types 2 (types B) (250 bp) detection in EBV-positive Burkett's lymphoma cases

Table (2): Demographic Characteristics, Localization of Tissue Site and genotyping of EBV among the EBV-positive Burkett's lymphoma cases

Characteristic	Total No. 90
Sex	
Male	53 (58.88%)
Female	37 (41.12%)
Median age (Years)	
Younger than 17 year	6. years
Adults	28 years
Localization	
Gum and maxilla	41/90 (42.55%)
Lymph nodes	26/90 (28.88%)
Abdominal viscera	10/90 (11.11%)
Tests and ovary	3/90 (3.33%)
Tonsil	3/90 (3.33%)
Nose	3/90 (3.33%)
Brain	1/90 (1.11%)
Others Orbit, bone marrow, the soft tissue of the neck, upper thigh, and the infra-spinal region	3/90 (3.33%)
Genotyping of EBV	
EBV type 1	85 (94.44%)
EBV type 2	5 (5.56%)

Discussion

In the current study, Among the EBV-positive BL cases, 53 of 90(58.88%) belonged to children younger than 17 years with median age 6 year, 37 of 90 (41.12%) belonged to adults with median age 28 year (Tab.2) and these results is in accordance with several authors [5, 13, 15] who showed that the majority of EBV-positive BL of pediatric cases in ages ranging from 5 to 9 years, whereas in the United States it is slightly higher,10 years [7,13]. it was in contrast to the previous studies among children from North America where the median ages 19.2 years[17].

Results regarding the medium age of adultswho EBV-positive BL in present study were consistent with previous reports that showedsporadic BL is typically seen in patients less than 35 years of age[18,24],whereas it was the difference from the previous study in North America [7,17] that showed a mean age occurring in the 19.2 years.

Regarding gender distribution of EBV- positive BL biopsies in current study (Tab 2) were consistent with previous reports that showedBL was more frequent in malesin low-risk areas like Europe[19, 5,23], conversely to other studies females were more affected than males, [23], contrary to early African reports where males and females were almost equally affected[15, 25].

In the present study, type A EBV (EBV Type 1) was the most common genotype detected in 94.44% (85/90) of the EBV+ BL cases whereas five of the 90 (5.56%) EBV^+ BL cases were type B EBV (EBV Type 2) (Tab 2). These findings were in agreement with Robaina et al. [8] and Naresh[9], Hassan et al. in Brazil [14] who found the overwhelming majority of EBV infections were due to genotype A. Similar results from developing countries [12,7,11], Egyptian and Turkey studies [26,27], Western and Asian countries [24],whereas other studies found that both types A and B EBV have been identified at high frequency in equatorial Africa and Central West region[10,28].

It is unknown why BL was rarely associated with EBV-2 (type B virus) [1,11]. The ability for transformation to the EBNA2B genotype is stronger in immuno compromised patients, such as those with HIV infection and in an individual as low cellular immunity is postulated to enhance the expression of genotype B [9,19, 28]. In Australia, genotype B infections were reportedly six-fold higher in HIV-infected patients than in the general community [1,9], whereas other studies report the dominance of Epstein Barr virus genotype A in HIV-infected patients [16]. The explanation for this result may be due to EBV-1 is more efficient to transform and immortalize infected B lymphocytes in vitro; whereas, EBV-2 is reported to be a weaker transformer[16].

Using of EBER-RNA in situ hybridization is the standard for EBV diagnosis in BL biopsies as described previously while PCR procedures are used for EBV typing [29, 30]. PCR-based method are used for strain determination (type-1 or 2)[29].

Regarding the positivity of all BL biopsies for EBV using in situ hybridization (ISH) technique,These findings are in agreement with several studies in tropical Africa [5,4,16], South America [28], Northeast of Brazil (~80%) [30]. Conversely, in sporadic BL in developed countries, and EBV association has been demonstrated in 15 to 30% of cases [1,8,11], and a lower association in patients from Argentina and Chile [31]. However, recent works suggest that low socioeconomic status and an early EBV infection can be associated with a higher prevalence of EBV+ BL in low-incidence areas.

Regarding the main sites of BL biopsies at the presentation in our patients, was more consistent with the endemic variety of BL as in North African patients [11,16,28] that showa facial or jaw tumor at the same time an abdominal mass similar to finding that observed in other parts of the Middle East [14,19, 11,16]. Finally, detection and genotyping of EBV in pathology samples is relevant since its high prevalence in some cancers makes the virus a promising target of specific therapies.

Acknowledgment: The author thanks Dr. Arkan Al-Issawi, Assistant professor of the pathology, Anbar Medical College, Iraq, Department of Pathology to provide us with the reading of histopathology of BL cases in the current study.

Abstract

The study was conducted on a group of adult female white rabbits aged between 5-10 months and weights ranging between 700-1500g, the groups included one male and two female adult rabbits, a group of which was orally administered oral contraceptives at a concentration of 30mg 28kg of body weight per day for a period of 28 days while a group of 40 mg was injected group a concentration of 40 mg; -1 kg of body weight per day and for the same duration of the extract of the rue plant. Animals were treated comparatively with distilled water The results of the histological study also showed satisfactory changes in the tissue of rabbit ovaries dosed with pill Pregnancy where hyperplasia has been observed and a decrease in the numbers of mature primary and secondary follicles. Atresia follicle has been observed. The histological study also revealed the occurrence of graffian follicular oocyte degradation and shrinkage, and the occurrence of thickening in the follicular cells and bleeding and blood congestion in the interstitial space and hyaline follicles in the cortical layer, but in the medulla region was observed rupture and necrosis and dissolution and disaggregation of stroma cells, and the occurrence of inflammatory cells and the occurrence of degeneration (fatty and hyaline and hydropic) Not for the occurrence of necrosis of fibrous and cellular integration as observed expansion vasodilation of blood vessels The study also showed a thickening of follicular cell nuclei. For the injected group at a concentration of 40 mg. Kg-[1] body weight has reduceddecress the number of mature follicles. The small size of the egg in the follicles of Krav, and the emergence of glass degeneration and the emergence of follicular follicles, while maintaining the number of primary and secondary follicles similar to the control group, also did not notice the occurrence of rabbits injected plant extract.

Introduction

Herbal remedies are well-known in the Iraqi society and are well-known among his sons, for their confidence in the effectiveness of these plants in the treatment of diseases[1]. The use of these plants may be due to their appropriate price and very low or no toxicity compared to other chemical drugs[2]. These natural substances have proven effective in treating and healing many diseases, especially infectious diseases[3]. Chemical treatments, such as birth control pills that contain both the estrogen hormone that is in the form of Ethinylestradiol and Progesten. These hormones work to prevent pregnancy by inhibiting the pituitary gland and hypothalamus, which inhibits the release of follicle-stimulating hormone (FSH) and luteinizing hormone (LH) As progesterone injections and other drugs negatively affect the near and long term on a woman's body and fetal health, it has been noted[4]. These drugs cause thrombosis, mesenteric vein thrombosis, artery occlusion, gastrointestinal disorders etc[5]. One natural herb that has been used to prevent pregnancy is Rutagraveolen Proteins s, known as Rue, a perennial herbaceous plant. It belongs to the Rutaceae family, and the medical and therapeutic importance

of Ruta is attributed to its possession of many active (Alkaloids, Coumariens, Phenolic, Proteins, Tannins, Resines, Glycosides, Volatile oil) The most important compounds of the plant are Rutin and Quercetin[6]. Proteins, Tannins, Resines, Glycosides, Volatile oil). The most important compounds of the plant are Rutin and Quercetin[6]. This inhibits the secretion of pituitary hormones FSH, LH and hypothalamus, which affects the growth and maturation of ovarian vesicles and the formation of the luteal body[7]. As well as its effect on smooth muscles of the uterus causing increased mobility which prevents the implantation of the fetus[8]. That inhibit the secretion of pituitary hormones FSH The plant is also used to treat diarrhea and skeletal disorders and as an antibiotic against various bacteria and fungi and in the treatment of nerve tumors.The aim of this study is to influence the contraceptive pills and the alcoholic extract of the pulling plant on the histological structure of adult rabbit ovaries.

Materials and Method

Preparation of hot alcoholic extract of the rue plant: Continuous extraction apparatus (Soxhlet Apparatus) was used according to the method described by[9] (Soaked ground samples were soaked in saxolite for 24 hours using 70% methyl alcohol solvent (60-80°C) and 250 ml or 10 g/100 ml. After completing the process that took (8-10) hours and until the disappearance of the green solvent color in the Batch, then concentrated the solutions to the dry stage under pressure rarefied by using the rotary evaporator device kept the plant in sterile sealed tubes until used in subsequent experiments as well as the process of separation And diagnosis.

Animals: Six white rabbits were collected from the Institute of Embryology and Infertility Research/ Al-Nahrain University. Their weight ranged between 700-1500 g and their ages were between 5-10 months. It was adapted and reared at the Animal House of the College of Veterinary Medicine, University of Diyala for one month before conducting experiments where Brushed with sawdust and cages were sterilized and cleaned during the experiment period, provided with water and appropriate ration, which consisted of dried bread, vegetables and barley and provided the appropriate environmental conditions of temperature and ventilation.Animals were randomly grouped and rabbits were marked with different colors to distinguish between them. Each color indicated a concentration of injected or dosed concentration. Then the adult rabbits used in this study were randomly divided into 3 groups comprising each group (2) female rabbits with an adult male rabbit. Females were injected with birth control pills and injected with alcoholic extract for 28 days. The first group: (control group) dosed physiological solution,Group 2: Orally administered oral contraceptive pills dissolved in water at a concentration of 30 mg.Group III: injected subcutaneously with alcoholic extract of the extracting plant at a concentration of 40 mg.

Results and Discussion

Histological changes of the ovarian rabbit dosed with birth control pills: The results of the present study showed that there were many histopathological changes in the tissue of rabbit ovaries administered to the pill at a concentration of 30 mg.kg-1 Changes were seen in the cortex and medulla regions, where pathological changes in the cortical layer included hyperplasia of the ovaryA decrease in the number of Oocyte and secondary follicle cells was also observed. In contrast, atresia follicle was formed compared to the control group females as shown in Figure (1).

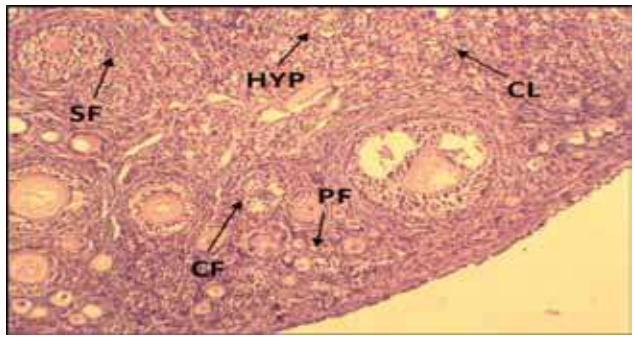

Fig. 1 Cross-sectional section of the ovary of a female rabbit inoculated with COCP at a concentration of 30 mg.kg^{-1} for 28 days. Cellular hyperplasia (HYP), primary follicles (PF), secondary follicle (SF), corpusletum (CL), follicular follicles (AF).(40x H & E).

This is due to the effect of negative contraceptive pills on both the pituitary and hypothalamus. FSH is less secreted by the gland, the hormone responsible for follicular growth, which negatively affects the size of the follicles. This increases the thickness and thickening of the coated layer of cystic follicles and natural follicles[10]. This may be due to the effect of birth control pills on the hypothalamus (especially hypothalamus), especially synthetic progesterone, in disrupting pituitary secretions. GnRH hormones, which secrete FSH in less than normal, and inhibit FSHRNA secretion and thus

inhibit hormone receptors on the surface of the ovary by its effect on Protein secreted by the pituitary gland thus affects egg cell formation and division process, inhibits maturation and egg cell formation and reduces the number of primary follicles or atrophy in the ovary[11]. Histological sections also indicated vasodilation with hemorrhage and congestion. Clearly in the area of the cortex as it was noted that the thickening of the nuclei of the warp cells (pyknosis) and the death of some cells (cell dead) according to Figure (2).

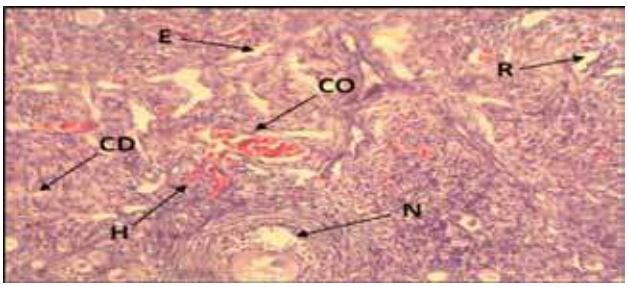

Figure (2) Cross-section in the ovary of the rabbit female vaccinated with a drug (COCP) at a concentration of 30 mg.Kg^{-1}. The section explains: hemorrhage (H), congestion (CO), thickening (P), cell death (CD), rupture (R), necrosis (N), edema (E) (40x H & E).

Suhail *et al*. (2014)[12] have confirmed that low-dose progesterone hormone indirectly affects the function of hormones secreted by the pituitary gland and thus inhibits the development of follicles and may inhibit ovulation This is due to the inability of the cells of the ovary tissue to adapt to the changes caused by the negative impact of synthetic hormones, thus occurs the nuclei (Pyknosis) in the cells of the layer of the medulla and cortical layer of the ovary, which is a phase of cell death Perhaps the reason for the negative COCP effect and the pressure it causes on the walls of blood vessels leading to the expansion of blood vessels in the pulp and cortical area of the ovary, as a result of response to pressure and an increase in Rapid flow of blood leading to dilatation of the artery (Artriole resulting from neurological consultation and thus generating greater pressure on the sphincter before the capillaries (Prebloodcapillary Constrictor) The resulting accumulation of blood in the ovarian capillaries results in an increase in the speed of the bloodstream in dilated veins[13,14]. The appearance of the edema, which represents the first stage of the occurrence of inflammation Vascular filtration increases, followed by arterial dilatation and an increase in the speed and flow of blood volume in the arteries leading to an increase in hydrostatic pressureIntravascular fluid resulting in an increase in the movement of fluid from within the capillary blood vessels towards tissues, which is represented by physiological fluids (Transudates)[15]. The combined oral contraceptive pills (Hemorrhage) between the stroma cells of the endodontic layer in the ovaries administered by hormone-induced rabbits may be due to rupture. In the vascular walls represented by a basement membrane causing the red blood cells (RBC) to break out and spread within the tissues of the pulp layer of the affected ovary [16].

Histological changes of rabbit ovaries injected with plant extract: Histological sections of female ovaries injected with a dose of 40 mg.kg^{-1}b.w. showed that the effect of the extract was Reduce the number of mature follicles and mature follicles without eggs and the emergence ofhyaline degeneration within the vesicles Mature with the preservation of the cortex stock of primary and secondary follicles in numbers parallel to the control group but a decrease in the number of courpusletum of the ovary and the occurrence of necrosis and degeneration in courpusletumand also the presence of follicular follicles but in small numbers in the cortical layer of the ovary as shown in Figure (3, 4, 5)

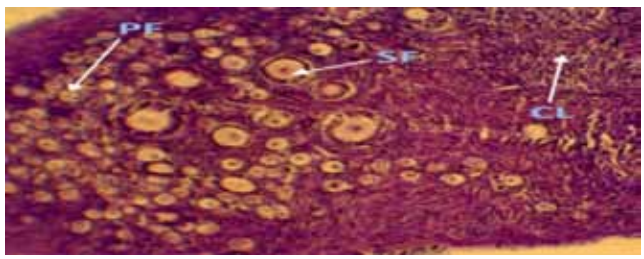

Figure (3) Cross-section of bleached tissue treated with alcoholic extract of the extracting plant at a concentration of 40 mg.kg^{-1}. The section illustrates: primary follicles (PF) and secondary (SF) courpusletum (CL)(40x H & E).

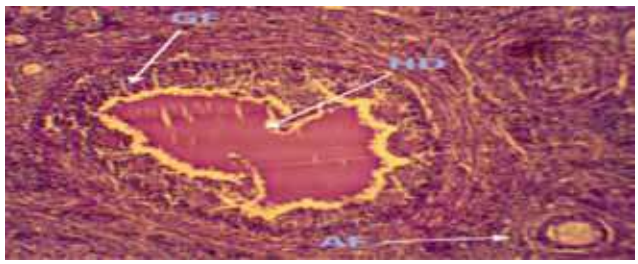

Figure (4) Cross-section of bleached tissue treated with alcoholic extract of the extracting plant at a concentration of 40 mg.kg^{-1}. The section illustrates:atristle follicles (GF) graffian follicles (GF) hyaline degeneration (HYD) (40x H & E).

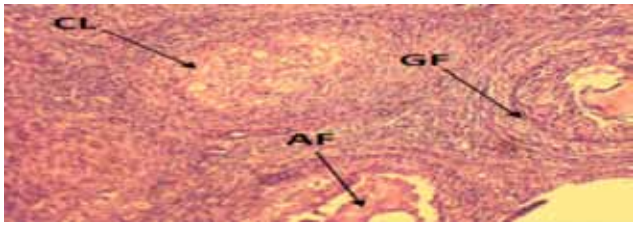

Figure (5) Cross-section of bleached tissue treated with alcoholic extract of the extracting plant at a concentration of 40 mg.day. The section illustrates: courpusletum (CL), Atristle follicles (AF) Graffian follicles (GF) (40x H & E).

The decrease in the development of bleached follicles may be attributed to the effectiveness of the alcoholic extract of the Rue plant in reducing the secretion of follicle-stimulating hormones and luteinizing hormones[17]. In his study, the leaves of the Rue plant have a role in inhibition of the pituitary gland leading to a decrease in the numbers of primary and secondary follicles and mature follicles, while the study of researchers[18](The alcoholic extract of the succulent plant may cause a change in the hormonal balance resulting in an increase in the length of the pre-estrus cycle. As a result of an increase in the level of estrogen (estrogen), which adversely affects the growth and development of follicles at different stages as a result of negative feedback As noted in the present study, there is little yellow corpus letum in ovarian tissue This is due to the high levels of the hormone prolactin, which causes an increase in the rate of irregular menstrual cycle and therefore a decline in growth of the yellow body accompanied by a decrease in the concentration of hormone LH and FSH[19].Hyaline degeneration in rabbit ovarian tissue in granular layer of graffian follicles and vitreous degeneration within the interstitial spaces of the stromathe cause of vitreous degeneration is due to the deposition and accumulation of protein in the cell cytoplasm as a result of the dissolution of amino acids. The[20] study also confirmed when treated with quercetin mice at 10 $mg.kg^{-1}$ per day isolated from a succulent plant; there was a significant reduction in the number of primary and secondary follicles.Which may be follicular follicles in the ovary resulting in depletion of ovarian reserve and failure of ovarian function and also cause a 70% decrease in pregnancy in mice This can be explained by the effect of quansin, which inhibits the action of TG2, the enzyme responsible for inhibiting ovarian action and the division and proliferation of fertilized egg cells[1,21].

Abstract

Background: A lifelong persistence of latent human cytomegalovirus (hCMV) infection may result and/or associated with Hodgkin's lymphoma (HL). The B-cell lymphoma-2 (BCL2) is an anti-apoptotic molecule expressed in non-neoplastic lymphoid tissue (hyperplastic lymph node) while down-regulated in normal germinal center B cells.

Objective: Is to analyze the concordant impact of BCL2 expression and hCMV infection on tissues from a group of patients with Hodgkin's lymphoma.

Patients and Method: Eighty formalin-fixed, paraffin-embedded lymph node tissue-biopsies enrolled in this study; 40 from HLand 40 with unremarkable pathological changes. Detection of hCMV was done by chromogenic in situ hybridization (CISH) technique while immunohistochemistry (IHC) was used for the BCL2 protein expression.

Results: In HL, the hCMV-positiveCISH and the BCL2-positive IHC reactions were detected in 35% and 42.5% of tissues, respectively. The correlation between hCMV and BCL2 was highly significant (P= 0.002).

Conclusions: The significant co-expression of BCL2 and hCMV genes in HL tissues could point for their possible role in either lymph node pathogenesis or carcinogenesis.

Keyword: *hCMV, Hodgkin's lymphoma, BCL2, CISH, IHC.*

Introduction

Hodgkin lymphoma (HL) and Non-Hodgkin's lymphomas (NHL) are two lymph nodes (LN) malignancies, where NHL is comprising approximately 85% of cases and 15% for HL.[1] Human cytomegalovirus (hCMV) is double-stranded DNA virus, encodes more than 200 protein products,[2] and may persist lifelong following asymptomatic primary infections,entering in a latency phase.[3]The virus is an opportunistic for a variety of cases having an impaired cellular immunity.[4] Reactivation of CMV can arise in immunosuppression states, either iatrogenic or secondary to systemic medical conditions.[5] Subsets of genes, including immediate early genes, has an important role to reactivate the latency state.[6] A poly-cistronic locus (UL133-UL138) contains genes involved in regulating latency, viral immune escape and cell tropism.[7] It is estimated that more than 90% of population in the developing countries are infected with hCMV.[8] Although hCMV is not a recognized oncogenic virus, observations have demonstrated that this virus has been correlated with gastric cancer and T-cell lymphoma[9] and might be associated with Hodgkin and NHLs.[10,11] Also, hCMV is an important cause of morbidity and mortality in leukemic patients. However, the incidence of hCMV in patients with lymphoma is not known.[12]

The BCL2 is a human proto-oncoprotein located in the membranes of the nuclear envelope, endoplasmic reticulum, and in the outer membrane of mitochondria.[13] It can occur as BCL2 alpha (active and membrane bound) or BCL2 beta (an inactive cytolic, contributing to the survival activity of BCL2).[14] The BCL2 protein expression is found in follicular lymphoma and some cases of diffuse large B-cell lymphoma.[15]The BCL2 expression in HL is frequently observed,almost 54% of classical HL cases revealed a variable proportion Hodgkin RSBCL2-positivecells.[16,17] The rise of BCL2 expression has a bad prognosis and is associated with relapses in young patients with classical HL.[18,19]

This study was done to unravel the rate as well as impact of either hCMV or BCL2 in a group of Iraqi patients with HL.

Materials and Method

A retrospective case-control studyrecruited 80 formalin fixed, paraffin-embedded LN tissue blocks, among them 40 tissue biopsies from HL with different grades as well as 40 LNs with unremarkable pathological changes used as an apparently healthy controls (AHC). The diagnosis of these tissue blocks were based on their accompanied records. One section was mounted on ordinary glass slide and stained with hematoxylin and eosin and a consultant pathologist reexamined all these tissues for further confirmation of their diagnosis, while other section were mounted on charged slides to be used for CISH and IHC.

The detection of hCMV by CISH kit (Zyto Vision GmbH,Fischkai, Bremerhaven, Germany) was performed on 4µm-paraffin-embedded tissue sections.

The CISH technique was applied according to the kit manufacture instructions. Positive CISH reaction for hCMV stains (blue) using digoxigenin-labeled hCMV probes and counter stains (red) by Nuclear Fast Red.

The IHC/Detection system (Abcam, England) was used to demonstrate the BCL2 protein expression in cells using primary biotinylated anti-BCL2 protein antibodies. The bound primary antibody is then detected by secondary antibody which contains specific peroxidase-labeled polymer conjugated to goat anti-mouse immunoglobulin. The chromogen solution (substrate) 3,3′-Diaminobenzidine produces a brown-color precipitate at the antigen site in these tissues as positive reaction and counter-stained by Mayer's Hematoxylin (Blue).

Positive cells were determined as the average percentage of positive cellscounted in 10 different fields of 100 cells for each sample. A scale of 0-3 was used for relative intensity with 0 corresponding to no detectable IHC reaction, and 1, 2, 3 equivalents to weak, moderate, and strong intensity of reaction, respectively. Cases were assigned to one of the following percentage score categories: 1%-25% (score 1; low), 26%-50% (score 2; moderate) or > 50% (score 3; high).[20]

Statistical analyses were done by SPSS program, version 21. Chi square test was used for testing relationships between categorical variables.Spearman's rho was used to test the correlations between different variables.*P*-value <0.05was considered significant.

Results

The highest percentage of HL patients was seen in grade I (45%) followed by grade II (30%) and the lowest was in grade III (25%).

hCMV-CISH expression in HL patients: Fourteen out of forty (35%) LN tissue biopsies with HL showed positive CISH reactions for hCMV-DNA (Figure 1). The AHCLNtissues revealed 5% (2/40) positive signals. The comparison between the percentage of hCMV-CISH reaction in AHC group and patients group showed highly significant statistical difference,*P*=0.002 (Table 1).

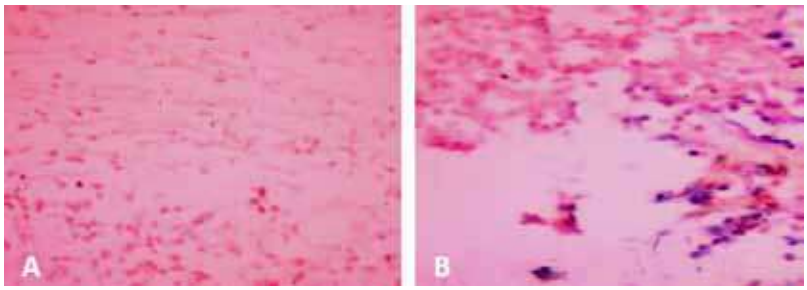

Figure 1 Lymph node sections in Hodgkin Lymphoma:CISH reaction for hCMV detection ×40. (A) Negative reaction; (B) positive reaction with low score and strong signal intensity.

Table 1: CISH reaction on LN biopsy sections to hCMV in patients with HL.

hCMV	HL (no.=40)	%	AHC (no.=40)	%	P-value (Z test)
Negative	26	65%	38	95	0.002
Positive	14	35%	2	5	

A. Positive hCMV-CISH signal scoring: The highest percentage of hCMV score signaling (17.5%; 7/40) was found in the high score (Score III), whereas (10%; 4/40) and (7.5%; 3/40) were found within moderate (Score II) and low (Score I) scores, respectively (Table 2). There was statistically significant difference among them (*P*=0.02).

B. Signal intensity of hCMV-CISH testing: The percentage of hCMV-infected cells that were evaluated for the intensity ofhCMV-CISH reactions showed moderate signal intensity in 15% (6/40), weak signal intensity in 12.5% (5/40) and strong signal intensity in 7.5% (3/40). The statistical analysis showed significant difference (*P*=0.03).

Table 2 Distribution of hCMVsignal scoring and intensity associated with HL by using CISH technique

P-value (χ^2 test)	Hodgkin lymphoma (n=40)			hCMV-CISH	
	% out of 14	% out of 40	No.		
		65	26	Negative	
		35	14	Positive	
0.02	21.4	7.5	3	I	Signal Score
	28.6	10	4	II	
	50	17.5	7	III	
0.03	35.7	12.5	5	Weak	Signal Intensity
	42.9	15	6	Moderate	
	21.4	7.5	3	Strong	

BCL2-IHC expression in patients with HL: Among the 40 Hodgkin lymphomatous tissues, 42.5% (17/40) exhibited positive BCL2-IHC reaction (Figure 2).

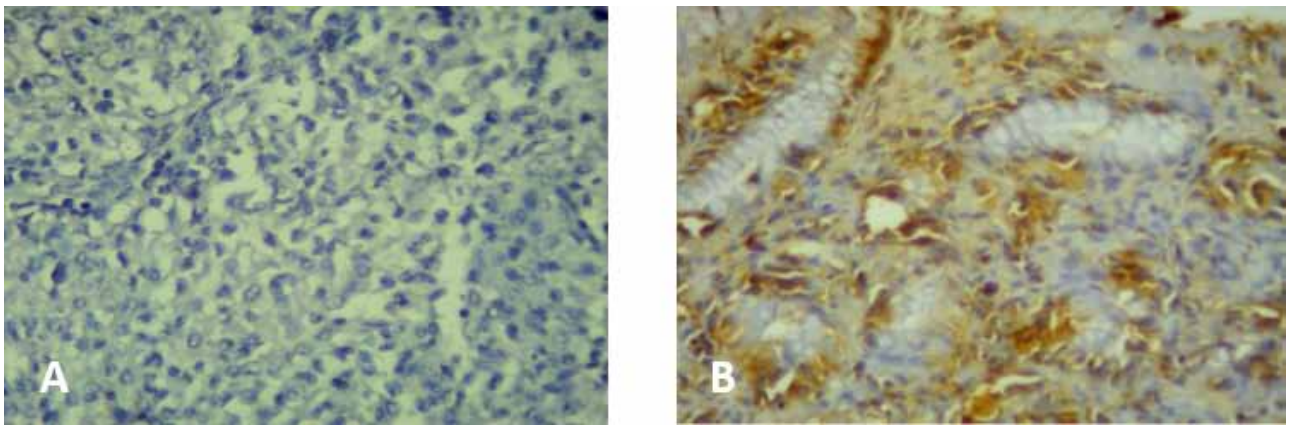

Figure 2: LN sections in HL:IHC staining of BCL2 protein ×40. (A) Negative reaction, (B) Positive reaction

A. BCL2-IHC score signal in HL: The signal scores were as follows: 20% (8/40) score I followed by 15% (6/40) and 7.5% (3/40) in score II and score III, respectively (Table 3). Statistically significant difference was noticed between low, moderate and high BCL2 scoring of tissues, (*P*=0.01).

B. BCL2-IHC intensity signal in HL: The intensity signals were weak (Intensity I) in 22.5%, followed by 15% moderate (Intensity II), and 5% strong (Intensity III). There was statistically significant difference, (*P*<0.03), between various intensities of tissues in HL group (Table 3).

Table 3 The percentage of BCL2-IHC score and intensity signaling in HL

P-value (χ^2test)	Hodgkin lymphoma (n=40)			BCL2-IHC	
	% out of 17	% out of 40	No.		
		57.5	23	Negative	
		42.5	17	Positive	
0.01	47.1	20	8	I	Signal Score
	35.3	15	6	II	
	17.6	7.5	3	III	
0.03	52.9	22.5	9	Weak	Signal Intensity
	35.3	15	6	Moderate	
	11.8	5	2	Strong	

Correlations between the grades, hCMV and, BCL2 in LN tissues from HL patients: A highly significant correlation was found between hCMV and BCL2 markers in HL (*P*=0.002). Similarly, there is a strong positive relationship between BCL2 and grade of HL (*P*=0.007). However, there are no significant correlations among hCMV and other markers (Table 4).

Table 4: Spearman's rho statistical testing of age, grade, hCMV-CISH and BCL2-IHC to evaluate the studied markers in HL.

Spearman's rho		Age Groups (Years)	Grade	hCMV	BCL2
Grade	r	-0.125			
	P	0.442			
hCMV	r	0.030	0.133		
	P	0.855	0.412		
BCL2	r	0.152	0.419	0.483	
	P	0.350	0.007*	0.002*	

*Correlation is highly significant (P<0.01).

Discussion

The highest percentage of HL patients were seen in grade I (45%) followed by grade II (30%) and the lowest was in grade III (25%). Although grade I is the most prevalent in Iraq but it is much less than reported in western studies (54.5%).[21,22] This could mark for more frequent intermediate and high-grade lymphomas in Iraqi patients than expected worldwide. This variation is probably attributed to the small number of patients in this study or patients are attending lately at medical care centers when the low grade have evolved into higher grades.

hCMV pp65is found to be involved in numerous significant events in the tumor progression and is the most abundant viral protein during active infection has been detected in biopsies of patients with NHL and HLs (57% and 49%), respectively.[23]In Iraq, and up to our best knowledge no research study on hCMV in HL tissues was done.

BCL2 over expression plays an important role in lymphomagenesis and extension of survival of malignant cells for the apoptosis process blocking or slowing down.[24] The BCL2 over expression in HL is a predictor of poor outcome and shorter survival.[16,25]It had a prognostic significance for development of primary refractory HL.[26]

In this research, 42.5% of HL group showed positive BCL2-IHC detection signals. This result is broadly consistent with those done by other studies(62.5%, 42.9%, 54%, and 54%, respectively).[27]Jakovica*et al*.[28]found that 31% of HL patients exhibited BCL2-protein overexpression was associated with worse outcome. The altered expression of BCL2 and apoptosis regulators proteins in HL may prevent apoptosis and as such confers a worse prognosis.This is supported by studies done by Rassidakis*et al*.[25] and Montalban*et al*.[29]However, Koh *et al*.[30]study revealed that BCL2 protein was found in only 14% of patients with Hodgkin/ Reed-Sternberg (HRS) cells, and was not associated with overall survival and event-free survival. In this respect, Kim *et al*.[16] stated that the genetic mechanism, behind BCL2overexpression in HRS cells, is unknown.

In our study, a high percentage 52.9% of HL group were found to have weak BCL2 signal intensity, while the moderate intensity was represented in 35.1%, followed by the strong signal intensity in 11.8%. Comparable results were found by LeBrun*et al*.[34]who reported a presence ofBCL2expression in Hodgkin cells in 63% tissues.However, strong staining was present in only 7 cases (22%) and weak staining in 41%. Also, our results are consistent with those ofRassidakis*et al*.[25] who found that BCL2 is expressed in HRS cells in 61% of patients with HL.In BCL2-positive HL, the majority of HRS cells express BCL2 but the intensity of expression is variable. The strong staining intensity was (25%). However, there was a variation in weak staining intensity (36%) whereas, in present study it was (5%). Immunohistochemical stain intensity is frequently interpreted as being proportional to the protein that interacts with the primary antibody. However, the relationship between the stain intensity and amount of protein is not always so simple. However, it was found that some positive BCL2 IHC staining can occur in the absence of BCL2 mutation and some mutations in BCL2 do not result in positive IHC staining.

In conclusion, the detection of hCMV along with BCL2 overexpression in HL patientssupports the hypothesis of an important role for CMV along with mutated and/or defected *BCL2* gene in HL development.

Normal Anatomical Variants of the Paranasal Sinuses at Computed Tomography Scanning

Ahmed Abdulsalam Abdulhussein Al-Ali[1], Noor Kathem Al-Waely[1]

[1]*College of Medicine, Al-Nahraine University, Iraq*

Abstract

Background: Recognition of PNS (Paranasal sinus) anatomic variants is particularly important in preoperative workup of patients with sinonasal pathology. CT (computed tomography) scanning can give exquisite details on sinus anatomy and pathology and is the main modality used to image the paranasal sinuses so the aim of the study isto evaluate certain anatomic variants of the paranasal sinuses in patients referred to the CT unit in Al-Immamain Al-Kadhymain Medical City. Patients and Method: We retrospectively analyzed the CT scans of the paranasal sinuses for patients referred to the CT unit in Al-Immamain Al-Kadhymain Medical City/Baghdad, Iraq for a period of 12 months . All the patients included in the study underwent standard CT scan of the PNS. Results: A net sample size of 188 was analyzed by the current study. Female: Male ration was (1.26:1).The incidence of septal deviation in the study sample was (51.06%) slightly more cases were deviated to the right (51.4%) than to the left (48.95%).Paradoxical middle turbinate's were observed in(18.6%), middle turbinate aeration was observed in (58.5%) on the right and (53.1%) on the left. The incidence of variant air cells were as follows: Onodi (24.4%), Haller (11.1%), and Aggernasi (87.7%). Conclusion:The percent of most of the anatomical variants in our study sample was approximate to the percent published in the literature with the most common anatomic variants encountered being septal deviation followed by aerated middle turbinate's whether unilateral or bilateral. The most frequent air cell was Aggernasi present in 87.7%.

Keywords: *PNS, anatomic variants, CT scan, septal deviation, variant air cells.*

Introduction

The paranasal sinuses are subject to variation between individuals and between sides in the same individual with regards to size (aeration) and bony septations[(1)]. The most common variation of the nasal septum is deviation. The septum is usually deviated out of the midline to some degree in 20% to 79% of the population[(2)]. It is usually deviated in its inferior portion nearby the chondrovomeral junction and can also accept an S-shaped arrangement with anrolling deviation onto both sides of the midline [(2)]. Septal pneumatization, additionaldescribed variant, may occur anteriorly from the crista galli or posteriorly from the sphenoid sinus [(2)]. Septal spurs are seen in connotation with septal deviation and may be bonded with the together turbinate's [(3)]. The middle turbinate is focus to variations in size and form. The turbinate is regularly pneumatized the so-called 'concha bullosa'. This pneumatization can be in anterior or posterior, or both [(4)]. The turbinate may be paradoxically curved which refers to an infer medially curved turbinate edge with the concave surface against the nasal septum and usually occurs bilaterally [(5)]. The AggerNasi Air Cell (ANC) is the greatestcontinuous and anterior of the ethmoidal air cells.The grade of ANC pneumatization varies and has aimportantoutcome on both the size of the frontal sinus ostium and the form of the recess [(6)]. Infraorbital (Haller) Air Cells aresituated inferior to the ethmoidal bulla and growing into the floor of the orbit. They may narrow the maxillary ostium, particularly if infected. The reported frequencies of Haller cells varyin the literature (up to 45%)[(7,8)]. Onodi cells are posterior ethmoidal cells extending into the sphenoid bone adjacent to the optic nerve. The nerve is at risk when surgical excision of these cells is performed [(9)]. Focal small corticated faults in the lamina papyracea are found in more than 0.5% to 10% of the population

and are not clinically important[10].This study aims to evaluate the frequency of certain anatomical variants of the paranasal sinuses in patients referred to the CT unit in our hospital.

Material and Method

This retrospective cross sectional study was undertaken in Al-Immamain Al- Kadhymian Medical City for a period of 12 months from August 2017 to August 2018.Included in the study were all CT scan exams of the paranasal sinuses in the CT unit of Al-Immamain Medical City requested for evaluation of certain pathological conditions or for planning prior to surgery. We excluded patient with extensive sinonasal pathology e.g. polyposis, extensive sinusitis, malignancy, trauma or any disease that obscure the visualization of normal anatomical structures. Patients under 13-year old were also excluded from the study. Data collection: Two hundred and fifty one patients were recruited for the study, of these patients 31 were excluded (27 patients had extensive sinonasal polyposis, 28 patients had marked pansinusitis, and 8 were < 13-year old) so the net results were based on 188 patients. Examination procedure: The CT examination was performed using the 256 slice MDCT(Multidetector CT) scanner Somatom Definition Edge (Siemens medical systems, Erlangen, Germany), the following parameters were utilized: variable Kv(Kilovolt) (100-120), variable mAs(Milliamperage second) (30-45),0.6 mm slice thickness with image reconstruction into the coronal plane from axial image dataset.Total DLP(Dose length product) approximately 60-70 mGycm. Image interpretation: The CT examination of eligible patients was reviewed and evaluated by a specialist radiologist. We evaluated the anatomic variants of nasal septum (deviation side, single or double curve, septal spur, aeration..), variants of the nasal turbinates (aeration, paradoxical turbinate, hypoplastic, aplastic …), abnormalities within the PNSs (sepate within maxillary sinus, aplasia of the frontal sinus), variant air cells (Onodi, Aggernasi,Haller), and lamina papyracea dehiscence. Statistical analysis: Data were analyzed using the commercially available software statistical package for social sciences (SPSS). The presentation of data was in the form of frequency and percent in tables and cross tables.

Results

A total of 188 CT scans were analyzed. Of these 83 (44.1%) were male and 105 (55.9%) females as

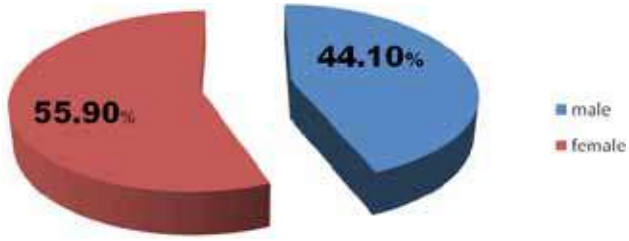

Fig. (1): Gender distribution.

The age range of the study sample was 13y - 72y (mean age was 30 years). Deviation was found in 96 (51.06%) cases, of these cases 49 (51.04%) were deviated to the right and 47 (48.95%) of them were deviated to the left. The majority of deviated nasal septa in females were to the left side while in males most deviated nasal septa were to the right there was no difference between male and female in septal deviation as in table(1).

Table (1): Septal deviation according to gender

			Septal		Total
			Left	Right	
Gender	Female	Count	29	23	52
		% of Total	30.2%	24.0%	54.2%
	Male	Count	18	26	44
		% of Total	18.8%	27.1%	45.8%
Total		Count	47	49	96
		% of Total	49.0%	51.0%	100.0%

CHI square (Fisher's Exact Test) = 2.106, P value = 0.15 > 0.05 (not significant).

Also, there is an association between septal deviation and middle turbinate size see (table 2). Also 75 out of 96 cases of nasal septal deviation (78.1%) had a single curve and 21 (21.87%) of them had double (S-shaped) curve. Regarding the septal spur it was present in 57 of the cases, 30 (52.6%) of them had left sided spur, figure 1(A) and 27(47.3%) of them had right sided spur figure 1(B).

Table(2): Middle turbinate according to gender

			Middle Turbinate		Total
			Left Middle Turbinate	Right Middle Turbinate	
Gender	Left Septal Deviation	Count	16	27	43
		% of Total	16.3%	27.6%	43.9%
	Right Septal Deviation	Count	30	25	55
		% of Total	30.6%	25.5%	56.1%
Total		Count	46	52	98
		% of Total	46.9%	53.1%	100.0%

CHI square (Fisher's Exact Test) = 2.912, P value = 0.1 > 0.05 (not significant).

Septal aeration: Out of 188 cases, 141(75%) had septal aeration and all of these aerated septa had their aeration from the sphenoid sinus,Superior turbinate: Out of the 188 cases evaluated, 174 patients (92.5%) had both superior turbinate's present, in 11 out of 188 (5.8%) cases were both absent and in 2(1.06%) case only the right was present and 1(0.53%) case only the left present (figure 2). Regarding superior turbinate aeration 66 cases had aeration, 12(18.1%) had right sided aeration, 21 (31.8%) of them had left sided aeration and 33 (50%) of them had bilateral superior turbinate aeration and in all of them (66 cases) the source of aeration was the ethmoid air cells.

Greater number of patients with left septal deviation had right middle turbinate aeration while patients with right septal deviation had left middle turbinate aeration (table 3).

(Table 3): Paradoxical middle turbinate

		Septal				Total
		Left Large	Left Small	Right Large	Right Small	
Left septal deviation	Count	2	9	12	0	23
	% of Total	5.4%	24.3%	32.4%	0.0%	62.2%
Right septal deviation	Count	9	1	0	4	14
	% of Total	24.3%	2.7%	0.0%	10.8%	37.8%
Total	Count	11	10	12	4	37
	% of Total	29.7%	27.0%	32.4%	10.8%	100.0%

CHI square = 26.217, P value = 0.0001^{**} < 0.05 (significant).

Paradoxical middle turbinates were found in 35 out of 188 cases (18.6%). Of these 12 were bilateral (34.2%) see (figure 3).Frontal sinus: regarding frontal sinus size, small sinus was seen in 64 cases (25%), large sinus in 47(35.04%) and the frontal sinus was absent (figure 10) in 7 cases (3.7%), fig 4. Haller cell : In 21 of cases Haller cells were present, 9(4.7%) were right sided, 8(4.2%) were left sided and only 4(2.1%) was bilateral (figure 5). Inferior turbinate aeration: was present in only 1 case (figure 14). laminapapyracea dehiscence: was present in only 1 case (figure 6).

From table 4 in our study air cells consist of 3 types of cells; onodi RT 8.5%, and left 70.5%, while other type; haller consist of RT 4.7% and left 4.2% and last type agger; RT 1.06% and lefrt 0.053%.

Table 4: Air cell distribution according to type

Types	Right	Left	Bilateral	Total
Onodi	16 (8.5%)	14 (7.5%)	16 (8.5%)	46 (24.5%)
Haller	9 (4.7%)	8 (4.2%)	4 (2.1%)	21 (11%)
Agger	2 (1.06%)	1 (0.53%)	0 (0%)	3 (2.1%)

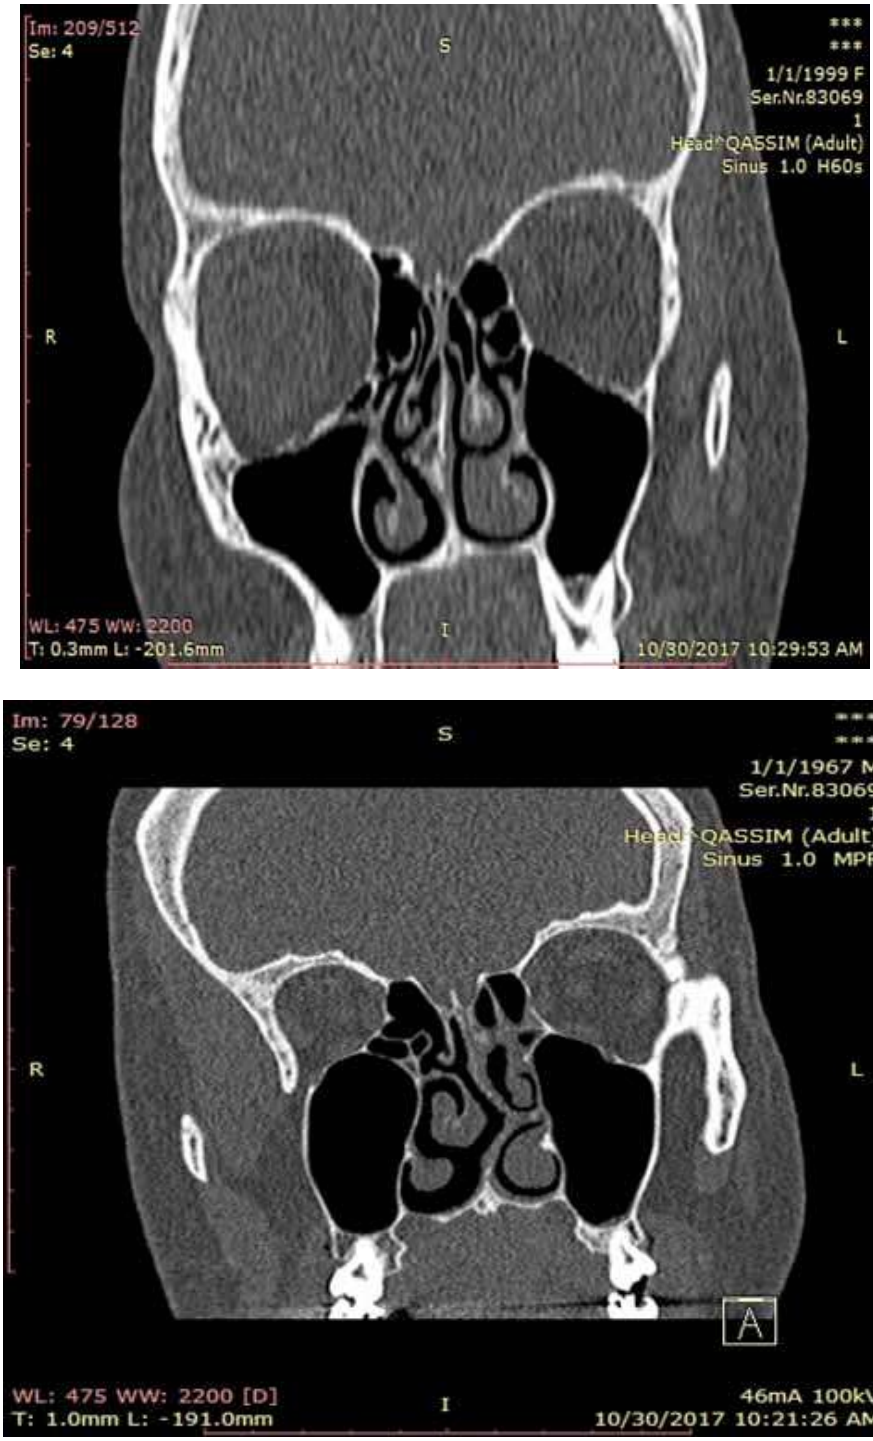

Figure 1: (A) right septal spur without septal deviation, (B) left septal deviation with septal spur fused to the lateral nasal wall

Figure 2: Note there are bilateral superior turbinate which show complete aeration. Left septal deviation is noted with septal spur

Figure 3: Bilateral paradoxical turbinate

Figure 4: The frontal sinuses are aplastic.

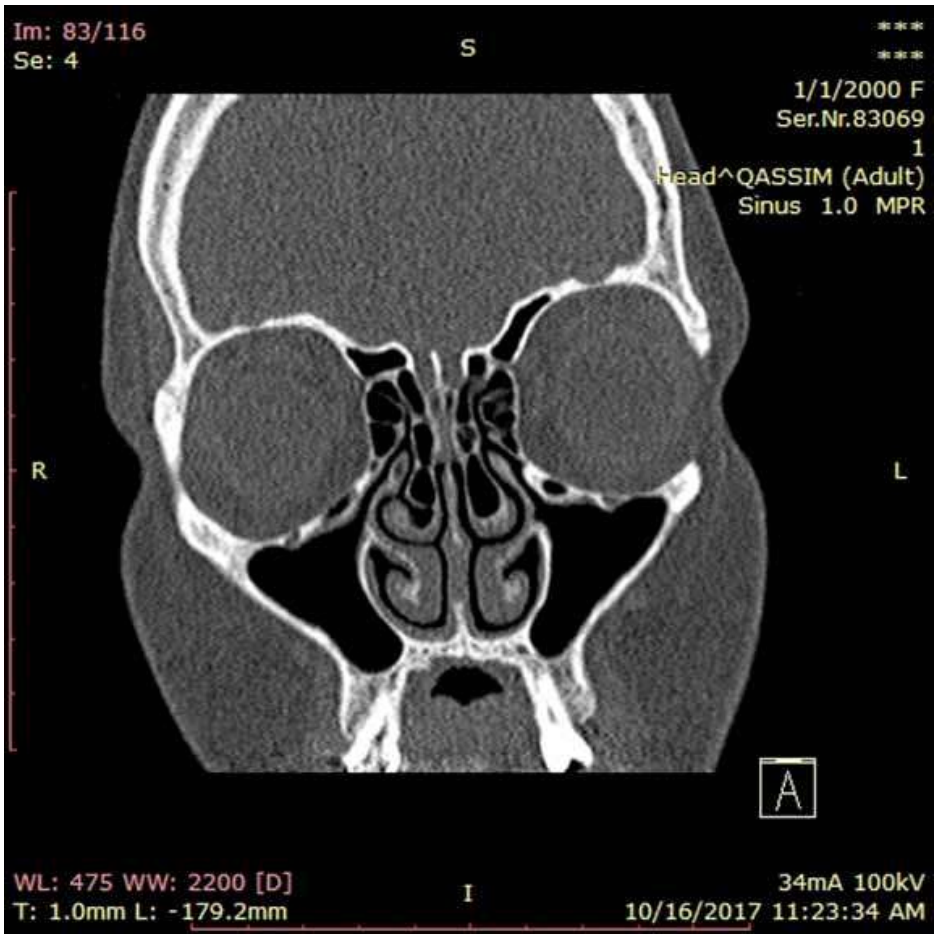

Figure 5: Bilateral Haller cells. Aerated middle turbinates are noted.

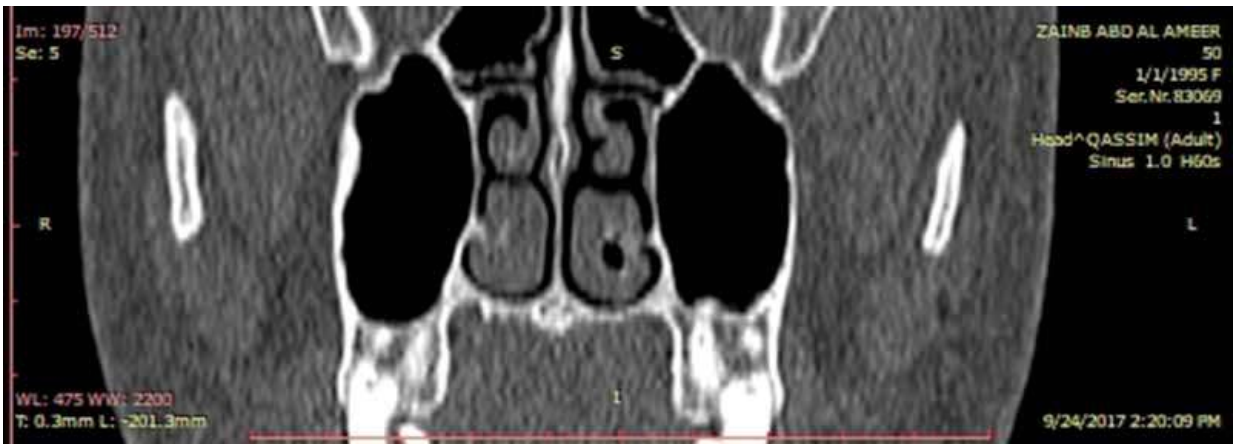

Figure 6: Partial aeration of left inferior turbinate is seen.

Discussion:

Anatomic structural variations of the paranasal sinuses have a practical significance during surgical procedures conducted on the sinuses by ENT (Ear, Nose and Throat) surgeons. Preoperative detection of the clinically significant variations has dramatically improved owing to the improvement in modern imaging techniques utilized for evaluating the sinuses namely computed tomography (CT) scanning. 1: Nasal septum: Septal deviation: In this study, septal deviation was observed in 51.06% (96 out of 188). Of these cases, 49

(51.04%) were deviated to the right and 47 (48.95%) were deviated to left, 75 (78.1%) of them were single curve and 7 (21.8%) of them were double curve (S-shaped).Nearly similar to our results, Earwaker[11], found that 44.25% of his study sample had septal deviation (354 out of 800). Of these, 185 cases (52.3%) were deviated to the right and 169 cases (47.7%) were deviated to the left. Double curve septal deviation was observed in 21 (21.87%). In another study[12], it was found that 23(20.91%) out of 110 cases evaluated had septal deviation. Septal spur:We observed that out of the 96 cases with septal deviation, 57 (59.3%) had septal spur. Of these cases 30 (52.6%) of the cases had left sided spur and 27 (47.3%) of them had right sided spur. We observed single case with right septal spur but no septal deviation. This percent is higher than that seen in previous studies. Earwaker found that 34% of patients with septal deviation had septal spur and unlike our results found left sided spurs twice as common as right sided ones[11]. Shpilberg et al have documented septal spur in 32.3% of patients with septal deviation[13].Superior turbinate: The superior turbinates were both present in 174 out of 188 cases (92.5%), both absent in 11(5.8%) cases and in 2(1.06%) case only the right was present and 1(0.53%) case only the left present regarding superior turbinate aeration 66 (35.1%) cases had aeration, 12(18.1%) had right sided aeration, 21 (31.8%) of them had left sided aeration and 33 (50%) of them had bilateral superior turbinate aeration and in all of them (66 cases) the source of aeration was the ethmoid air cells.Onwuchekwa and Alazighafound superior turbinate pneumatization in 6.36% and absence of both superior turbinates was observed in 0.91% of cases[12]. Earwakerfound that superior turbinate aeration was present in 12.3% (98 case) of which 34.7% (34 case)were bilateral[11]. Paradoxical middle turbinate: Paradoxical turbinates were observed in 35 patients (18.6%), 65.7% of these were unilateral (13 right sided and 10 left sided) and 34.2% bilateral.Al-Abri et alreported an incidence of paradoxical middle turbinates approximate to our results (13%)[14]. Earwaker found higher percent of paradoxical turbinates 40.3% (323 out of 800) of these 69.3% were unilateral and 30.7% bilateral[11]. On the other hand Onwuchekwa and Alazigha found that only 1.82% had Paradoxical middle turbinate[12]. Frontalsinus :In the current study, 35.04% of patients had small frontal sinus and in 3.7% the sinus was absent. Earwaker found out of 800 cases[11], 4% of cases had small sinus and 5% had absent sinus. Also Onwuchekwa and Alazigha reported 4% incidence of frontal sinus hypoplasia with no reference in his study to aplasia of the sinus[12].About air cells consist of 3 types: Onodi cellIn this study, the overall percent of Onodi cell was 24.4%. This percent of Onodi cells was higher than that previously reported by several studies. In Al-Abri et al[14] study, the percent of Onodi cells was 7.5%(27out of 360 cases), also another study by Onwuchekwa and Alazigha[12] observed Onodi cells in 7.27% (8 out of 110 cases). haller cell: The percent of Haller cells in the evaluated sample was 11.17% which is lower than that observed by the researcher in Al-Abri et alstudy which found that the percent of patients who had Haller cells was (24%)[14], a percent which is approximate to that reported by Onwuchekwa and Alazigha (20.91%)[12]. Aggernasi: these were present in 165(87.7%) out of 188 cases it was absent in 20(10.6%) cases, 2(1.06%) cases only the right present and in 1(0.53%) case the left was present although the reported incidence of Aggernasi cells is variable according to the definition used. Several previous studies reported very high incidence of Aggernasi cells in the range of 96-98.5% [11,8].

Conclusions: The percent of most of the anatomical variants in our study sample was approximate to the percent published in the literature with the most common anatomic variants encountered being septal deviation followed by aerated middle turbinate's whether unilateral or bilateral.The most frequent air cell was Aggernasi present in 87.7%.

The Relationship between Malondialdehyde, Uric Acid and CRP in GDM Pregnant Women During Different Trimesters

Allaa Jamel Shhaeat[1], Ahmed Aboud Khalifa[1]

[1]*Department of Biology, College of Science,University of Misan, Iraq*

Abstract

GDM Common medical complication of pregnancy, it's increasing enormously worldwide in the recent decades especially in developing countries, the onset of GDM occurred, due to islet β cell function defect .There are a close relationship between the GDM,OS, antioxidants and inflammation .The aim of this study was the assessment to oxidative stress factor changes, UA and CRP in pregnants women with GDM in misan province . The study included (30) GDM pregnant women, (25 -35) years. The study has during Nov.2018 to Feb. 2019 . Diagnosed parameters done by *ELISA,* and mindray (BS -230) .Our results reveledall parameters increased during pregnancy, highest increase in the third trimesters, it is increased significantly ($p \leq 0.05$) in comparison with the first and second trimesters.

Keywords: *GDM, oxidative stress, uric acid, CRP. Introduction:*

Introduction

Gestational diabetes mellitus (GDM): It is a common medical complication of pregnancy, the prevalence of GDM differs depending on the regions and the country, about half of women with a history of GDM develop type 2 diabetes out of 25% pregnancies develop GDM [(1).]GDM defined as any degree of glucose intolerance with onset or first recognition during gravidity, it is impaired glucose tolerance and IR with first onset during pregnancy[(2-3)].Various risk factors associated with development of GDMsuch as developing type 2 DM,maternal obesity[(4)], and low-grade inflamemation [(5)]. GDM caused an elevation in OS occurred by more ROS production in mitochondria[(6)].

Oxidative stress (OS): Defined as a state characterized by an imbalance between pro-oxidant molecules, and antioxidant defenses, OS result of overproduction of reactive oxygen species (ROS) in relation to antioxidant defense levels, excessive ROS production and resulting OS may contribute to aging and several diseased states affecting female reproduction [(7)] . OS increased during pregnancy due to some changes in such biomarkers (TC, TG,LDL and UA), these changes were demonstrated by a rise in lipid peroxidation [(8)] .

Malondialdehyde (MDA), and 8-iso-prostaglandin F2α (8-iso-PGF) best marker to OS[(9)].MDA is the product of polyunsaturated fatty acid peroxidation, this aldehyde is a highly toxic molecule and should be considered as more than just a marker of lipid peroxidation, its interaction with DNA and proteins has often been referred to as potentially mutagenic and atherogenic [(10)] .

Uric acid (UA): It is the final product of purine metabolism [(11)] . Its considered as a powerful scavenger of singlet oxygen, peroxyl radicals and hydroxyl radicals [(12)]. Moreover, UA can become a pro-oxidant by forming radicals in reactions with other oxidants, these radicals seem to target predominantly lipids (LDL and membranes) rather than other cellular components, at the same time, the hydrophobic environment created by lipids is unfavorable for the antioxidant effects of UA[(12-13)], and oxidized lipids can even convert UA into an oxidant [(14)] . Study in (2017) considered the UA as one of the diabetogenic factor during pregnancy via their IR effect and this relationship occurred due to two proposed mechanisms : 1. UA causes endothelial dysfunction and decreases endothelial NO production leads to decreased glucose uptake and development of IR [(15-16-17)] . 2.UA may induce IR and causes inflammation and OS in

adipocytes, which is a contributor to the development of metabolic syndrome [18] . On the other hand, high level of UA in early pregnancy indicated that metabolic state may affect adversely pregnancy outcomes, it is possible that of the women who develop GDM, those with elevated first-trimester UA are the women who are at risk to develop type 2 diabetes, thus, we postulate that elevated first-trimester sUA helps in the prediction of GDM and developing type 2 DM [15] .

C-reactive protein (CRP): It is a protein produced in response to inflammation to control it via activating the complementary immune system [19], it's considered as a sensitive marker of chronic inflammation and a risk factor for diabetes and mortality[20-21]. Study in (2018) showed the relationship between the CRP and insulin resistance,IR was elevated with high CRP levels in both men and women [22] . In pregnancy many studies indicated that an early CRP determination may help in the prediction of adverse pregnancy outcome, preeclampsia and GDM[23-24].CRP elevated in GDM,these elevation increases with gestational weeks during pregnancy from 5 to 20 weeks and from 28 to 32 weeks, and modest elevation in CRP later in pregnancy may be expected to occur and reflects the immune adaptations during pregnancy [25]. In addition, the maternal immune system is also altered during pregnancy creating a state of balance between enhanced immune response in the form of increased circulating levels of CRP [26].Besides that, higher level of CRP in women who developed GDM growing evidence implies inflammation in the pathogenesis of type II diabetes which is directly correlated with IR [27-28]. Study in (2016) showed the glucose intolerance and GWG,that affected on CRP levels [29].

Material and Method

Subjects :Our study has been done at al - Sadr educational hospital, child and birth governmental hospital, golden medical clinic, altayf laboratory, sample selected according to the following criteria :

- Fasting plasma glucose (5.1–6.9 mmol/L) (92–125 mg/dL) .
- 1-hour plasma glucose (10.0 mmol/L) (180 mg/dL) following a 75 g oral glucose load .
- 2-hour plasma glucose(8.5–11.0mmol/L) (153–199 mg/dL) following a75 g oral glucose load (30).

Blood Samples: Five milliliters of venous blood samples were drawn,and left at room temperature for 10 minutes for clotting, centrifuged 3000 rpm for 5 minutes, then serum was separated and transported for storage. MDA diagnosed by myobiosourse (USA) ELISA human kit, CRP and UA by mindray (BS -230).

Statistical analysis :Statistical analysis was performed by SPSS (23) .It was performed ANOVA, followed by LSD at($p \leq 0.05$) significant level.

Results

The concentration of MDA in different trimesters: The MDA concentration in the second trimester (6.600±0.722ng/ml)increased($p<0.05$) in comparison with the first trimester (4.750±0.672 ng/ml) .In the third trimester (7.110±0.810 ng/ml) increased ($p<0.05$) in comparison with the first trimester, but have no significant difference with the second trimester . (Table 1, Figure 1) .

The levels of uric acid in different trimesters: The UA in the second trimester (5.176±0.913 mg/dl) increased ($p<0.05$) in comparison with the first trimester (4.716±0.800 mg/dl) .In the third trimester (5.990±0.935 mg/dl) increased ($p<0.05$) in comparison with the first and second trimesters . (Table 1, Figure1) .

The levels of CRP in different trimesters: The CRP level in the second trimester (8.790±0.290 mg/l) have no significant difference in comparison with the first trimester (8.560±0.189 mg/l) .

In the third trimester (12.66±0.576 *mg*/l) increased ($p<0.05$) in comparison with the first and second trimesters . (Table 1, Figure1) .

Discussion

Our results reveled the OS factors increased during gestation that's due to the elevation metabolic rate of the placenta causes increased generation of ROS, MDA concentration increase, in GDM pregnant because the oxygen free radicals and lipid peroxidation products increase in GDM (excessive production of free radicals observed in group of study), its insufficient removal results in damage to cellular proteins, membrane lipids, and nucleic acids, the presence of high levels of MDA in the present study may relate to the glycemic control,that's lined with other studies [31-32] .

Table (1): The concentration of MDA (ng/ml) and levels of uric acid (mg/dl) and CRP (mg/l) during different trimesters in GDM pregnant women .

Trimester Parameters	1st	2nd	3rd
MDA	4.750±0.672^{A}	6.600±0.722 ^{B}	7.11±0.810 ^{B}
Uric Acid	4.716±0 .800^{A}	5.176±0.913^{B}	5.990±0.935^{C}
CRP	8.560±0.290^{A}	8.790±0.341^{A}	12.660±0.576^{B}

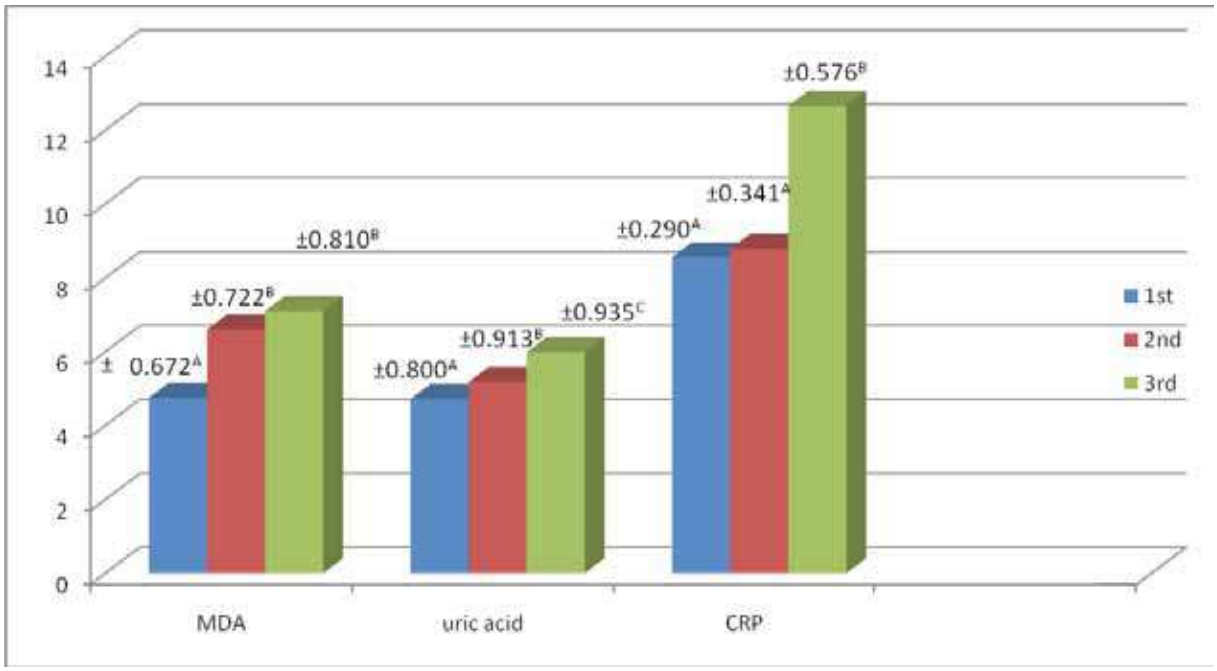

Figure (1): The concentration of MDA (ng/ml), uric acid (mg/dl),and CRP (mg/l) levels during different trimesters in GDM pregnant women .

The values represent the mean±SD.

Similar capital letters represent no significant difference between trimesters .

Different capital letters represent a significant difference ($p<0.05$) between trimester .

In the other hand, our results of UA levels improved fact, the antioxidant system was stronger than peroxidation during pregnancy, that's confirm the antioxidant role for uric acid, that's agreement with other studies [33-34] . UA levels increase, because the placenta leads to overproduction of UA which serves as a marker of the disease,hyperuricemia may predate proteinuria by several weeks [35-36] . This elevation predicate a GDM as our results show,furthermore it is considered a risk factor for development GDM because the correlation between UA and IR, probably because hyperisulinemia would cause lower renal UA excretion, and different role for the UA it is an antioxidant role in the GDM group[37-38-39 -40-41] .Besides that these increase suggesting excessive free radical production evokes a response to combat OS because different role for UA an antioxidant property, our result in oxidative factor confirms that, and that lined with other study [42] . CRP levels increased ($p\leq0.05$) in trimesters, that's due to the CRP may excessive with GWG,and IR. That suggest a decrease ability of pregnant women with GDM to compensate for OS which manifested as increased IR, reduced insulin sensitivity,and β-cell dysfunction, that's lined with other research [24]. Inflammatory and stress responses mediate IR, and inflammatory mediators play an important role in the development and progression of GDM,the elevation of CRP levels have been associated with abnormalmetabolic conditions such as IR, hyperglycemia, and type 2 DM, that's lined with other study[43].

Conclusion

In summary, our observational study provides the important role of placenta, it's increase OS markers and uric acid,moreover the GWG increase CRP all these increases occurred in GDM pregnant.

Ethical Clearance: The Research Ethical Committee at scientific research by ethical approval of both environmental and health and higher education and scientific research ministries in Iraq

Conflict of Interest: The authors declare that they have no conflict of interest.

The Effect of Teaching in Educational Complexes Using Harmonic Exercises to Improve Motor Compatibility and Some Basketball Offensive Skills

Emad Toma Radi[1], Mentdhar Hussen Sabt[1], Louay Abdulsattar Salal[1]

[1]Mustansiriyah University/Faculty of Basic Education,
Department of Physical Education and Sport Sciences, Baghdad-Iraq

Abstract

The research included the introduction, the importance of the research and the goal of the research:

- Identify the effect of using teaching in educational complexes according to harmonic exercises to improve motor compatibility.
- Recognize the impact of the use of teaching in educational complexes according to harmonic exercises to improve some offensive skills basketball.

The researchers used the experimental method as well as the research sample, the students of the preparatory stage in Al-Khadra School (30) divided into two equal experimental and control groups and included a number of educational units (7) units applied to the research sample where teaching was used in educational complexes. Using harmonic exercises on the experimental group.

The research reached the most important results of them:

- The results showed that the experimental group that used teaching in the educational complexes and harmonic exercises in improving the motor compatibility and learning some skills in basketball (long hand over the shoulder and the freshman and scoring from the free throw line) over the control group.
- The results showed that the control group that used the teaching followed by the teacher in learning some skills and motor compatibility in basketball.

Keywords: *Complexes exercises, harmonic, offensive and basketball.*

Introduction

In light of the great scientific and cognitive advancement in the fields of life, information is now being published at the time of its birth, and the field has expanded for all those who have a bright idea and a good opinion to publish it via the internet to be the subject of research in an international seminar. In this scene, the groups of teachers should take advantage of this reality to advance the educational process at all levels of its educational institutions. It has become obligatory for the teacher of physical education at various stages of study from kindergarten to university care and development towards the correct performance of sports skills as much as given to take care of the level of achievement and development.

In general, the role of the teacher and teacher in the past limited to the delivery of information and transfer

of knowledge to students, but today with the new developments and with the challenges of the modern era has become its role is changed and renewed by modern preparation curricula in line with the challenges of this era of factors affecting the development of physical education lesson are teaching method The method of learning, which have witnessed a clear expansion in recent years, because of their importance in the education of students to raise their motivations and needs cognitive, physical and skill.[1]

This is what has been overlooked by many researches, which is the care of the physical education teacher for the direction of the correctness of the technical performance and the level of achievement of students who need the so-called teaching complexes. Teaching in the educational complexes works to "raise the level of individual management for himself and his environment, and awareness of his ambitions and problems combined, and this requires him to be able to analyze and understand not only through educational stages, but continuously expected to go through the individual educated.

All sports require a special degree of motor compatibility rates and conditions vary according to the type of sport practice and skill required and almost no type of sports of that compatibility, including basketball, which is one of the most widespread games in the world and practice by both sexes and includes a range of defensive and offensive skills And the vehicle, which requires a set of physical and motor abilities and thus it is natural compatibility between the organs of the body in order to perceive and bring out the skill properly and high accuracy and the fact that the ability of compatibility is one of the basic pillars in building the performance of the motor and skills right Curse in all overlooked cases.[2]

Research Hypotheses:

1. There are statistically significant differences between the results of pretest and posttest tests of the experimental group and the control group in improving the motor compatibility and learning some skills in basketball.
2. There are statistically significant differences between the results of the experimental group and the control group in the motor compatibility and learning some skills in basketball and for the benefit of the experimental group.

Research Methodology: The researchers used the experimental method.

The Research Sample: The research sample is represented by the fourth grade literary students in Al-Khadraa for boys in Baghdad/Al-Karkh governorate for the academic year 2017-2018. A student where the proportion of (60%) and they are divided into two divisions, Division A and Division (B) If the Division (A) was chosen to be the experimental group and Division (B) to be the control group.

Homogenization of the sample: The researchers performed homogeneity in some growth rates (height, age and weight) as shown in Table (1).

Table (1). Shows sample homogeneity

Variables	Mean	SD	Median	Skewness
Age (Year)	15.20	0.33	15.00	2.44
Weight (Kg)	64.90	6.00	65.00	0.20
Length (cm)	169.20	5.40	169	0.30

The table shows that the skewness coefficient in growth rates is confined to the real boundary (±3) and thus the sample is homogeneous.

Research tools and means of gathering information:

- Legal basketball balls.
- Legal basketball court.
- Tape measure.
- Medical balance.
- Electronic stopwatch.
- Hand calculator type SONY.
- Glove number 4.
- Persons-adhesive tape.

Tests used in research:

1. Test name: throw and receive balls:[3]

- Purpose of the test: to measure the compatibility between the eye and arm

2. (test high dribblefor a distance of 20 m dominant arm):[4]

- Purpose of the selection: measure the speed of the high bandwidth.

3. Choose one-handed passing over the shoulder (long):[5]

- Purpose of the selection: Measure the accuracy of one-handed scrolling over the shoulder on the target.
- The maximum score is 30 degrees.

4. Free throw test:[6]

- Purpose of the test: To measure the accuracy of the free throw scoring from behind the free throw line.

Pilot Study: The researchers carried out the exploratory experiment on a sample of the students who were excluded from the main experiment (10) on Sunday 19/11/2017 and the experiment was repeated seven days later on 26/11/2017.

- Knowledge of the efficiency of the tools and the team working assistant and know the time required to explain the tests and their application.

The tests used in the research have scientific bases and have been applied to the Iraqi environment and obtained the scientific bases, but the researchers deliberately conducted the scientific bases as shown in table (2).

Table (2). Shows validity, stability and objectivity

Variables	Validity	Stability	Objectivity
Compatibility	0.90	0.81	0.94
The dribble	0.92	0.85	0.95
Handling over the shoulder	0.94	0.88	0.96
Scoring from the free throw line	0.94	0.89	0.96

Tribal Tests: When the researchers to conduct pre-tests on 27-28/11/2017.

The main experiment is the introduction of teaching in educational complexes and harmonic exercises: Researchers have introduced the teaching in the educational complexes in the curriculum of the Directorate of Education Baghdad - Department of Technical Affairs/Curricula and books for the preparatory stage and also prepared and prepared educational units including harmonic exercises * and inserted within the curriculum, which amounted to (7) educational units and began to apply from (3/12/2017) (To (24/24/2017) The last educational unit was divided into (2) educational units for long-handling over the shoulder (2) educational units for the tomato and (3) educational units for scoring from the free throw line and he introduced the harmonic exercises in the units Dedicated to selected skills which lasted for 4 weeks (2) teaching units per week and the time of the educational unit (45 Min.) and took the total time of the units (315 Min.).

Posttest Tests: The post-test was conducted on 26-27 December 2017.

Results

Presenting, analyzing and discussing the results of the pre- and post-tests of the experimental and control groups for compatibility and basketball skills:

Table (3). Shows the arithmetic media, standard deviations and the calculated and tabular (t) value in the pre- and post-tests of compatibility and basketball skills of the two groups

Abilities and skills	Groups	Pretest		Posttest		(t) calculated	(t) tabulated	Type of significance
		Mean	SD	Mean	SD			
Compatibility	Experimental	3.46	0.46	8.04	0.59	24.35	1.76	Sig.
	Control	3.44	0.56	6.25	0.64	13.40		Sig.
Long passing over the shoulder	Experimental	11.15	1.30	19.20	0.85	19.0		Sig.
	Control	10.90	1.40	15.60	0.96	8.01		Sig.
Dribble	Experimental	13.70	1.90	10.90	1.23	6.21		Sig.
	Control	13.73	1.88	11.91	1.91	2.60		Sig.
Scoring from the free throw line	Experimental	3.70	0.97	7.14	1.05	7.60		Sig.
	Control	3.30	1.0	4.80	0.85	5.12		Sig.

Table (3) shows that the first and second experimental group advanced the tests of compatibility and long handling over the shoulder, drum and scoring from the free throw line and for the benefit of the post-test. The researcher attributes this to the use of teaching in educational complexes and the introduction within the curriculum, which depends on learning Self-making makes learners more positive and makes it more adoption of the same bug in the learning process and works to give the freedom of the learner in the choice to achieve the objectives set and the teacher works on guidance and guidance and provide feedback (Provide that every individual is characterized in the background and speed of learning as well as teaching method and how to activate the cycle in the process so that it becomes the learner's learning process axis at the time to be a teacher as a mentor and assistant to the learner .[7]

As well as worked to give a good opportunity for learners from the optimal use of time allocated and not wasting and that the harmonic exercises that have a clear impact on the progress of the experimental group in all variables, where prepared appropriately with the research sample in terms of estimating the situation of orientation ability for time and space and control the movement of the body in space and time The perception of the status of the body and changes for the stadium and movement and the ability to link motor coordination and this gives the quality of harmonic exercises prepared by the researcher, [8]which focused on improving the compatibility between the body parts and skills in basketball that developed free movement Training of the umbilical response exercises and kinetic linkage between movements within the rhythm will lead to the development of motor speed of the body and show through the movement of the body as a whole or in the movements of the upper limbs.[9]

Table (4). Shows the arithmetic and standard deviations for the two posttests of the experimental and control groups of motor and skill basketball

Abilities and skills	Experimentalgroup		Controlgroup		(t) calculated	(t) tabulated	Type of significance
	Mean	SD	Mean	SD			
Compatibility	8.04	0.59	6.25	0.48	10.29	1.70	Sig.
Long passing over the shoulder	19.20	0.85	15.60	0.96	9.95		Sig.
Dribble	10.90	1.21	11.91	1.91	1.89		Sig.
Scoring from the free throw line	7.14	1.05	4.80	0.85	8.90		Sig.

Table (4) shows that there are significant differences between the experimental groups and the control group in the results of the post test of the motor compatibility and basketball skills. As shown in the test of long handling over the shoulder we find that the value of (t) calculated (9.95), which is greater than the value of (t) tabular and this confirms the presence Significant differences between the two groups in this test for the benefit of the experimental group In the skill of (Dribble) we find that the value of (t) calculated (1.89), which is greater than the value (t) spreadsheet adult and this confirms the existence of significant differences between the two groups in this test and for the benefit of the experimental group. The calculated value of (t) was (8,90), which is greater than the value of (t) tabular adult and this confirms the existence of significant differences between the two groups in this test and for the benefit of the experimental group.[10]

We note from Table (4) that the experimental group that was introduced teaching in educational complexes curriculum was more influential in the improvement and development of motor compatibility and skills basketball and this confirms the effectiveness of teaching in educational complexes according to harmonic exercises, which was implicitly consistent with learning skills and has played an effective role for progress The experimental group and where the educational complex is an educational unit includes a specific subject and contains elements of learning that may be different and multiple primary objective of increasing student interaction and active participation in the various activities that provide the educational complex to reach the educational goal To a specific unit of educational and powerfully high (teaching that gives a sense of educational complexes student achievement that the value achieved in accordance with a particular

focus of the goal expert defined in specific and short) period of time.[11]

The organization of educational units for teaching in the educational complexes of the variables under study, where the activities are designed according to the needs of the subject and the specific goal and taking into account the sequence in the presentation of the content of skills and take into account the individual differences between learners as well as developed a set of exercises that allow learners an opportunity to practice and perform the duty in educational situations The teaching in the educational complexes is characterized by it provides flexibility in the choice of activities and learning according to its own speed and self-ability in learning and provide the conditions that give the learner a positive role in each educational situation in a run.[12]

The researchers believe that the improvement and development of kinetic compatibility comes through the implementation of exercises introduced to the curriculum followed by the learners, which was necessary and necessary to improve the compatibility and skills of basketball (that kinetic differentiation and reaction are the most important harmonic abilities and therefore can be considered that harmonic exercises Target those abilities and complement educational or training courses and improve the learning process). The progress achieved on the experimental group and the skills of long hand over shoulder, and the skill of Dribble and scoring from the free throw line because the skills require compatibility between the arm and sight and arm and the rest of the limbs and members of the body and require the compatibility of neurological and muscular where appropriate exercises have been selected To serve the requirements of the selected skills, which are carefully designed and highly planned to achieve the goal (Planning is the important means that works to determine the goal set in the plan accurately and prevents dependence on dispersion).[13]

Conclusions

1. The results showed that the experimental group that used teaching in the educational complexes and harmonic exercises in improving the motor compatibility and learning some skills in basketball (long hand over the shoulder and the freshman and scoring from the free throw line) over the control group.
2. The results showed that the control group that used the teaching followed by the teacher in learning some skills and motor compatibility in basketball.

The Impact of Qualitative Exercises in the Development of Some Basic Skills in Football for the Cubs

Mohammed Abbas Saeed[1] Alaa Hussein Ali Hamza Al-Humairi[2], Maytham Lateef Ibraheem[3]

[1]Ministry of Education/Directorate General of Holy Karbala Education, Iraq, [2]Ministry of Education, Directorate General of Education Babylon, Iraq, [3]University of Babylon, The College of Physical Education and Sports Science, Iraq

Abstract

Football has witnessed a significant development in the levels reached by the players, especially their physical, motor and skill levels. This is what we see today through what they offer while playing in world tournaments. Training programs often emphasize the physical and skill aspects of the players and not focusing on the aspects related to motor skills.

It has emerged in recent years and unquestionably a great development in football events where it is one of the games that require a high physical effort and skill to play the ball strongly impulsive, with coordinated movements where the player can perform the kinetic duty with minimal effort and high accuracy that economize on the use His physical and psychological abilities are balanced, as this leads to the fact that if two players with the same skill level and planning, the player with a physical level, motor and psychological high will be able to control the course of the game, so the skill side plays a big role in the game of football.

The problem of research was reflected in the skills weakness of the Cubs of football, especially passing and scoring, and this is attributed to the lack of motor programs in this category, and this causes a weak performance in the skills of many of the qualitative skills of the game.Here, the researcher considered that the development of specific exercises aimed at developing some of the basic skills of Cub football through the combination of motor and skill training to serve the goal of research.

Keywords: *Qualitative exercises; qualitative exercises; basic skills and weakness Health.*

Introduction

Football has witnessed a significant development in the levels reached by the players, especially their physical, motor and skill levels. This is what we see today through what they offer while playing in world tournaments. Training programs often emphasize the physical and skill aspects of the players and not focusing on the aspects related to motor skills[1-3].

It has emerged in recent years and unquestionably a great development in football events where it is one of the games that require a high physical effort and skill to play the ball strongly impulsive, with coordinated movements where the player can perform the kinetic duty with minimal effort and high accuracy that economize on the use His physical and psychological abilities are balanced, as this leads to the fact that if two players with the same skill level and planning, the player with a physical level, motor and psychological high will be able to control the course of the game, so the skill side plays a big role in the game of football[2,4,5]. The problem of research was reflected in the skills weakness of the Cubs of football, especially passing and scoring, and this is attributed to the lack of motor programs in this category, and this causes a weak performance in the skills of many of the qualitative skills of the game[6].

Here, the researcher considered that the development of specific exercises aimed at developing some of the basic skills of Cub football through the combination of motor and skill training to serve the goal of research.

The research aims to:

- Preparation of qualitative exercises to develop the development of some basic skills of football cubs.
- Identify the impact of qualitative exercises to develop some basic skills of football cubs.

From the research objectives, the research hypothesis

- There is a positive impact of qualitative exercises to develop some basic skills of football cubs and for the benefit of the experimental group.

Research methodology and field procedures

Research Methodology: The researcher used the descriptive method of the survey method and the experimental method with two equal groups to suit the nature of the research.

Research community and sample: The research community included the players of Babylon Clubs for the season 2018-2019 and the number of 32 players are divided into four clubs, the club of Babylon, Hilla, Baladi and Mahaweel, where they were divided randomly (lottery) into two control and experimental groups (20) players for each group (10) players.

Data collection tools, means and devices used: Scientific sources. Resolution. the interview. Observation and experimentation. Testing and measurement. Legal stadium (1). Colored strips, 1 metric tape and 2.5 cm red tape. Computer type (Dell)) 5040) number (1). A Japanese-made digital camera (Nikon). Chinese Medical Balance. Balls (24). Digital stopwatch. Colored signs (red, blue, yellow, green) 12 training collars (10). Agility ladder (6). Educational objectives (1 m).

Field research procedures

Identify research variables: Researcher's field experience in the field of football training has a role in determining the variables of the research under study namely passing and scoring for the Cubs of football, but the researchers worked to take the opinion of many experts and specialists.

Identify skill tests: The skill tests under study were determined by the expertise of researchers as well as from scientific consultations with experts and specialists.

1. Test the accuracy of football passing:

Test Name: Receipt and delivery.

Objective of the test: To measure the accuracy of the performance of passing football.

The Tools Used: A legal football field, 5 legal football balls, a tape measure, small targets with a width of 1 meter and a height of 0.5 meters, a pre-prepared evaluation form.

Performance Specifications: Standing (5) players in a straight line and the distance between the player (2meters), and the players in front of the five goals away from them (30) meters stand the player tested in the middle between the player (1) and goal (1) and when you hear a signal Start The player receives the ball from the player number (1) and then the rapid rotation within the specified distance (2) located in the middle of the distance between the five goals and the line cross, and then passing the ball towards goal (1) and thus repeated the attempt with his teammates.

Method of registration: Calculated two degrees for each injury, and one score if you touch one of the officials, and does not count any score in the absence of injury to the target, the total score of the test (10) degrees.

2. Test the accuracy of football scoring performance:

Test Name: Scoring towards the goal divided into boxes.

The objective of the test: To measure the accuracy of the performance of scoring football.

Tools Used: a legal football field, a number of legal football (5), a tape to identify the scoring area, a form of assessment prepared in advance.

Performance Specifications: (5) balls are placed on the penalty line, which is (18) yards from the goal line and the distance between the ball and another (1) yards, as the player scoring in the areas indicated by the test and according to their importance and difficulty and sequentially the ball after another to be tested Of jogging mode.

Method of scoring: Calculates the number of injuries entering the specified goals from both sides so that the scores of each of the five balls are calculated as follows:

1. (5) Grades when the ball enters the zone number (5).
2. (4) Degrees are given when the ball enters area No. (4).

3. Gives (3) degrees when the ball enters area No. (3).
4. (2) Is given two degrees when the ball enters the zone No. (2).
5. Is given a score when the ball enters (1) the goalkeeper's place.
6. Zero grades shall be given in case of extending the boundaries of the five numbered areas.
7. In the case of touching the ball of the tape is calculated for the highest area according to the numbered areas.
8. The total score test (25) degree.

Specify specific exercises: Through the technical expertise of the researcher in the field of training, he designed (12) special exercises between physical, motor and skills, and nevertheless, the researcher presented them to specialists in the sports field and then all of them (100%) agreed to these exercises.

Pilot Study: The researcher conducted a pilot experiment on four cubs of football on Monday 10/12/2018.

Scientific bases of research variables: The researchers used to extract the objective test passing and scoring for the eye and man as it depends on the time has reached (0.95), as well as extracting the coefficient of stability through the test and returned, the results came as in the table following:

Table (1). Shows the stability parameters of the motor tests under study

S	Tests	Stability
1	Passing	0.94
2	Scoring	0.93

Pretests: The researchers conducted a pre-test on the variables under study on Monday, 17/12/2018.

Homogeneity and equivalence: The researchers made homogeneity and equivalence among the members of the research sample, as in Table (1)

Table (2). Values (F) and (t) for homogeneity and equivalence

Independent Samples Test							
Research variables	Levene's Test for Equality of Variances		t-test for Equality of Means				
	F	Sig.	t	df	Sig. (2-tailed)	Mean Difference	Std. Error Difference
Passing	0.507	0.486	0.318	18	0.754	0.20	0.62893
Scoring	0.201	0.660	0.355	18	0.726	0.198	0.55705

From the values of (Sig.) Of (F) in table (2) of more than (0.05) in all variables we infer from this as a homogeneity process exists, and through the values of (Sig.) Of (t) of more than (0.05) This means that there is no significant difference for all variables and this will give the researcher initiation on one starting line.

Perform specific exercises: After conducting the pre-tests of the research groups, the specific exercises were carried out during (8) weeks (3) training units per week (Sunday, Tuesday, Thursday), with a total of (24) training units where (5) exercises were put to the training unit where the time was The training unit (60) minutes and took (40) minutes from the time of the training unit, which is the main section, which was the implementation of exercises, has been implemented during the preparation period for the training method of high intensity and repetitive training as these exercises aimed to develop passing and scoring for the Cubs of football. Develop these exercises appropriately for the current study as it worked this exercise Reduce boredom and the desire to repeat more of the repetitions applied to the experimental group.

Posttest tests: After completing the twenty-four training modules, the researcher conducted the post-tests of the research variables under study for both groups on Saturday 16/2/2019.

Results

View the results of the passing, scoring and ground strike tests of the Cubs of football and the experimental and control groups

Table (3). Shows the mean of the experimental group scores, standard deviations and the value of (t) in the pretest-post test of the research variables under study

Paired Samples Test							
Research variables		Paired Differences			t	df	Sig. (2-tailed)
		Mean	Std. Deviation	Std. Error Mean			
Passing	Pre-Post	7	1.41421	0.44721	15.652	9	0.000
Scoring	Pre-Post	1.057	1.10203	0.34849	3.033	9	0.014

Table (4). Shows the mean of control group scores, standard deviations and the value of (t) in the pre-posttest of the research variables under study

Paired Samples Test							
Research variables		Paired Differences			t	df	Sig. (2-tailed)
		Mean	Std. Deviation	Std. Error Mean			
Passing	Pre-Post	5.3	1.94651	0.61554	8.610	9	0.000
Scoring	Pre-Post	0.582	.52837	0.16708	3.483	9	0.007

Discuss the results of the two research groups: Through the values of (Sig.) For all the variables in the previous two tables of less than (0.05) for all variables and for the control and experimental groups and this shows that both groups have evolved, and this confirms the effectiveness of the exercises used by the researcher to develop passing and scoring, so that we can know which groups Evolved by a larger revision table (5).

Table (5). Shows the mean of the experimental and control group scores and their standard deviation and the value of (t) in the post-posttest of the research variables under study

Independent Samples Test					
Research variables	t-test for Equality of Means				
	t	df	Sig. (2-tailed)	Mean Difference	Std. Error Difference
Passing	4.881	18	0.000	1.5	0.30732
Scoring	2.304	18	0.033	0.67300	0.29215

Through Table (5) which shows the values of (Sig.), Which is less than (0.05) for passing skill and more for scoring; here we can know here that the evolution occurred for both groups and that the great development that came in favor of the experimental group and the researcher attributes that development to exercise[7-10]. The quality applied to the experimental group, which was codified according to the scientific equations studied and calculated to suit the levels of players to change from the training routine, and create a new training atmosphere, and the desire to repeat a greater number of iterations, as evidenced by the findings of the researcher[10,11].

Here we see that it is no secret to anyone today has become the majority of trainers keep pace with scientific development at the sports level because of the availability of all means to raise their scientific and practical levels and the best evidence of this is to inform them on the training curricula for global teams, whether at the level of group games or individual, and therefore we found the development of the control group By close to the evolution of the experimental group[8-10].

Conclusions

In the light of the findings of the researchers through the field experiment and using the appropriate statistical method concluded the following:

1. Qualitative exercises have been instrumental in the development of passing and scoring in football cubs.
2. The use of qualitative exercises and save effort and time for the coach and the player in the development of passing and scoring for the Cubs of football well and is suitable for training this category of ages.
3. The use of qualitative exercises has a positive impact on the interaction of players during the exercise and attendance and the desire to repeat a greater number of repetitions.

Assessment of the Antimicrobial Resistance of Urinary Escherichia Coli and Some Factors Related to Urinary Tract Infection in Karbala Patients

Jaafar Jaber[1], Maysaloon Adnan Abdul Razzak[2], Fouad Oudah Kadhim[3]

[1]Assist. Prof. Dr. Jaafar Jaber, Private Sector, Ministry of Health, Iraq, [2]Dr. Obstetrics and Gynecology Department, College of Medicine, Kerballa University, Iraq, [3]Diploma of Clinical Pharmacy, Private Sector, Ministry of Health, Iraq

Abstract

Background: Urinary tract infection is one of the most common type of infectious disease encountered in the practice of medicine. Antimicrobial resistance is huge problem cause of a great concern throughout the world.

This study was curried out to assess the antimicrobial resistance of urinary *E. coli* and some factors related to urinary tract infection.

Results: Out of the 100 patients studied, the urine samples of 49 patients were found to have culture positive; and out of these, the urine samples of 28 patients were positive for urinary *E. coli*. Thus the prevalence was 57.1% for *E. coli*, and 42.9% for other type of bacteria such as *Staphylococcus aureus, Hemolytic streptococci, Klebsiella spp., Proteus spp., Enterococcus spp*. and *Pseudomonas aeruginosa.*

The results of sensitivity tests showed that the resistance of *E. coli* was about 10 times higher for nitrofurantoin, ceftazidime and ceftriaxone; relative to amikacin, ampicillin and imipenem.

Aim of the study: Assessmentof the antimicrobial resistance of urinary *E. coli* and some factors related to urinary tract infection in Karbala patients .

Conclusions: *Escherichia coli* remains the most common pathogens isolated form urine samples of patients with urinary tract infection . The resistance of uropathogenic *E. coli* to antimicrobial drugs has been gradually increasing for commonly used drugs.

Keywords: *Karbala patients; Escherichia coli; antimicrobial resistance; factors.*

Introduction

UTIs are most common bacterial infection account for significant morbidity and health care costs. [1].

UTI is predominantly a disease of females due to anatomic and physiologic differences after age of 50years [2] after age of 50years,UTI most common in male than female due to prostatic hypertrophy in men.[3].

Most UTIs are caused by single bacterium that mainly lived in bowel and rarely they may be due to viral or fungal infection.[4]

Escherichia coli is a Gram-negative bacterium. There are many serotype of this organism, only a few of these are responsible for infections uropathogenic *E. coli* (UPEC) [5].

Aging is associated with an increased in the susceptibility to UTI due to alteration in the vaginal and periurethral flora and reduction in the estrogen level from menopause in women [6] .

UTI in more frequent and more sever diabetic patient because of glucose in the urine which promotes bacterial growth and impairs leukocytes functions [7].

The incidence of acute clinical pyelonephritis is about 25% to 35% in untreated bacteriuric women [8].

Obstruction to urine flow at all anatomic level caused by stone is a key factor increasing susceptibility to UTI [9].[10] .

Urinary catheterized increases the risk UTIs, longer time catheterization associated with bacterial growth [11].

Bactericidal antibiotic are superior to bacteriostatic agent in treating in relapsing infection. [12] antibiotics are considered the most effective method of treatment for bacterial infections [13,14].

The prevalence of antibiotic resistance stems primarily from the promiscuous nature of bacteria, as susceptible bacteria may acquire resistance genes from plasmids and other horizontally transferred genetic material, resulting in evolution by leaps [15,16]

Aim of the study: Assessment of the antimicrobial resistance of urinary *E. coli* and some factors related to urinary tract infection in Karbala patients .

Patients and Method

Patients selection:

The study retrospective,cross sectional was conducted at outpatient urology department in Al-Hussein teaching hospital in Karbala city, from august 2012 to October 2012.

A total number of 100 patients (78 male and 22 female) were randomly selected included in study, all of them lived in Karbala city. The patients ages were 25-65 years. All patients were clinically diagnosed and examined by urologists for signs and symptoms of urinary tract infections.

Ethical approvals were obtained from the local research ethical committee in Karbala health care office according to the proposal format for research project protocol from WHO. All patients gave verbal informed consent to participate in the research.

Inclusion criteria/Exclusion criteria: Inclusion criteria: All patients that not used antibiotics previously and had the signs and symptoms of urinary tract infections and have positive results in the urine culture test for E. coli were included in the study. They were 28 patients out of the 100 patients visited the urology department for UTIs.

Exclusion criteria: All patients that had negative results for urine culture (51 patients) and patients that had negative results for E. coli but positive for other types of bacteria (21 patients) were excluded from the study.

Results

Distribution of uropathogens in patients:

Out of total of 100 patients, 51 patients had negative results of urine culture (-ve). The remaining 49 patients had positive results (+ve). From these positive results, only 28 patient had *E. coli* in the culture test, the number of females were 22 patients (78.51%) while males were 6 patients (21.49%). While 21 patients had other types of bacteria.

Table (1)show the distribution of urinary tract pathogens and the prevalence in percentage.

Table (1): Distribution of isolated urinary tract pathogens and the prevalence in percentage (N=49 patients).

No.	Organism isolated	No. of patients	Prevalence (%)
1	Escherichia coli	28	57.1%
2	Staphylococcus aureus	6	12.2%
3	other Staphylococcus spp.	4	8.1%
4	Hemolytic streptococci	3	6.1%
5	Klebsiella spp.	3	6.1?%
6	Proteus spp.	2	4.1%
7	Enterococcus spp.	2	4.1%
8	Pseudomonas aeruginosa	1	2%

Alteration in some parameters of urinalysis in patients with urinary tract infection caused by E. coli:

The alteration in some urinalysis parameters in patients with urinary E. coli infections from the normal level are presented in table (2).

Table (2): Alteration in some parameters of urinalysis in patients with urinary E. coli (N=28 patients).

No.	Parameters of urinalysis	Prevalence of alteration from the normal level (%)
1	Pus cell	100%
2	Bacteria	100%
3	Red blood cells (R.B.Cs)	20%

Antimicrobial resistance in the urine culture of patients with urinary tract infection caused by E. coli:

The results of sensitivity tests in the urine culture of patients with urinary *E. coli* are presented in table (3). It is obvious from this table that *E. coli* is highly resistant to Nitrofurantoin. Whereas, on the other extreme, the lowest resistance of *E. coli* was for Ampicillin and Imipenem.

Table (3): Antimicrobial resistance in the urine culture of patients with urinary *E. coli* (N=28 patients).

No.	Antimicrobial agent	Resistance (%)
1	Nitrofurantoin	35.7%
2	Ceftazidime	28.6%
3	Ceftriaxone	28.6%
4	Co-amoxiclave	25%
5	Ciprofloxacin	25%
6	Gentamicin	21.4%
7	Trimethoprim-sulfamethoxazole	20%
8	Amikacin	10.7%
9	Ampicillin	3.6%
10	Imipenem	3.6%

Discussion

E. coli was isolated in(57.1%) cases in this study. While (59%) was the isolation of *E. coli* has been reported in many other studies in India [21]. The difference in the prevalence rate of *E. coli* in this study and other studies is low. [22].

Staphylococcus aureus was the second most common uropathogens appeared in this study (12.2%). There is small difference between the present results and (17%) was the result of other study conducted in Iraq [23]. The high percentage of *Staphylococcus spp.* is the main bacteria that cause skin infection and easily to cause contamination and infection of urinary tract[24].

The other bacteria found in the patients urine of this study was *hemolytic streptococci* with percentage of (6.1%) that more than in the result (1.8%)of study in Canada[38]. And *proteus spp.* Contribute to (4.1%), which resemble to the finding other study that was (4.1%) [25]. However, the percentages of other pathogens such as *enterococcus spp.* and *pseudomonasaeruginosa* were (4.1%) and (2%) respectively, that differ from results of other studies were (14%) for *enterococcus spp.* and (3.4%) for *pseudomonasaeruginosa*[25]. This may be due to demographic variation, drug use between different communities that lead to some pathogens to be more predominant than others.

In the present study, high percentage of *E. coli* infection was found in females which was (78.5%), while in males was (21.5%). These percentage is more than the result of other studies that was (77.4%) in females and (22.6) in males [26] which may be due to difference in the age of marriage, the number of deliveries, contraception and health care education between the communities. The oral contraceptive use has also increased risk of UTIs which appear to be related to the alteration in vaginal flora that allow for the bacterial over growth and subsequent infection [27].

The signs and symptoms had great prevalence rates with values (73.3%), (73.3%), (66.7%) and (53.3%), respectively. This may be considered as the typical symptoms of lower UTI[28]. On the other hand, fever was (46.7%), nausea (33.3), diarrhea (20%) and vomiting (13.3%). These signs are mainly associated with upper UTI [29].

The risk factors for UTI. Including recurrent infections (46.7%) and elderly (33.3%). These values are higher than in other study[30] which were (17%) for recurrent infection and (15%) for elderly. The higher percentage found in this study is probably due to the fact that the patients in Iraqi community do not visit hospitals until the disease become big problem and effect on the patient's life, especially in elderly who are associated with more medical problem and lower health care.

The changes of urinalysis parameters were pus cell (100%) and bacteria seen (100%). These results indicate the presence of bacteriuria in the patients studied. Which highly specific for UTIs. Red blood cells (R.B.Cs) were (20%). This may indicate presence of renal stone that cause irritation and bleeding in the urinary tract[31].

The resistance rate for nitrofurantoin was (35.7%). This value is greater than the resistance rates found in previous studies which were (6.7%) in Canada [25]and (1.9%) in USA [32]. This high difference between the results of the present study and other studies may be due to highest antibiotics consumption rate in Iraq which has been identified as strongest risk factors for antimicrobial resistance, especially nitrofurantoin [33].

The other antibiotics tested in this study was ceftriaxone which also showed large value of resistance

(28.6%), in comparison with other studies which were (4.4%) [32] and (2.3%) [34]. This variation in observation was expected and may be a result of increasing excessive use particularly to ceftriaxone which are used in large quantities in both hospitals and the outpatient settings.

For co-amoxiclave and ciprofloxacin the resistance found in this study was 25% which is different than other study [33] which was (17.1%) for ciprofloxacin and (5.3%) for co-amoxiclave. These results differ from the study in Iraq is probably due to the fact that these two drugs are considered as widest drugs used for empirical therapy of UTI.

For gentamicin and trimethoprim-sulfamethoxazole (TMP-SMX), the results of resistance distribution found in this study were (21.4%) and (20%), respectively. However, in comparison with other studies were(7.5%) and (4.6%) for gentamicin, and for TMP-SMX were(22.1) and (39.3%)[32],[35]. These justifications are also applied for trimethoprim-sulfamethoxazole (TMP-SMX),as in the Outpatient isolates of *E coli* in the United States show resistance rates ranging from 15% in the upper Midwest to greater than 40% in the southwest and south-central United States[36].

The result of resistance for amikacin found in this study was (10.7%) which is less than the result reported from other study which was (27,8%)[37]. This may be due to restriction in use for treatment of UTI.

For ampicillin and Imipenem, the resistance observed in the present study was (3.6%), while in other study, the resistance rate was (56%) for ampicillin [34]. This great difference may result from the fact that ampicillin is limited or not used for UTI recently in Iraq and therefore lesser resistance development. Another study revealed that Imipenem sensitivity to urinary *E. coli* was (100%) [32]. The explanation for this result may be due to Imipenem use in Iraq is associated some times without regarding the limitations for prescribing. [38].

Conclusion *Escherichia coli* remains the most common pathogens isolated form urine samples of patients with urinary tract infection .Urinalysis is helpful as a mean of excluding bacteriuria. The resistance of uropathogenic *E. coli* to antimicrobial drugs has been gradually increasing for commonly used drugs. Thus, the knowledge of antimicrobial resistance among uropathogenes is essential to provide appropriate cost effective therapy.

Abstract

One of the important pathogen with increasing resistance rate in hospitalized patients is *Staphylococcus aureus*. The useful results for antimicrobial activity of CCCP made it a proper candidate to enhance the inhibitory effect of some certain antibiotics like Ciprofloxacin. The aim of this study was to investigate the Inhibitory effects of CCCP on the gene expression of *nor*A efflux pump and decrease Ciprofloxacin resistance in *Staphylococcus aureus*. Thirtyisolates of*S. aureus* were acquired from different clinical specimens at the Baquba teaching hospital. Susceptibility test to ciprofloxacin was done by disk diffusion test and broth dilution method. Activity of the efflux pump was recognized using CCCP as an chemical efflux pump inhibotor. MIC of CCCP was evaluated with muller hinton Broth dilution method. Bacterial culture was performed and *nor* A gene expression was examined by Taqman qRT-PCR by one-step and .The expression of *nor*A was significantly decreased in these isolates when were treated with CCCP & Cip. Our results showed that CCCPcan increase ciprofloxacin susceptibility through inhibition of the *nor*A efflux pump. Combination of CCCP with ciprofloxacin can reduce the antibiotic resistance.

Keywords: *Staphylococcus aureus, CCCP, Antibiotic Resistance, Efflux Pump Inhibitor, norA.*

Introduction

In recent years, several studies have supported drug efflux as a player in the emergence of resistance toward antibiotics and other antimicrobials in *S. aureus* [1],[2]. One of several contributing mechanisms to bacterial is the action of membrane-based efflux proteins with broad substrate profiles, known as multidrug resistance efflux pumps (MDR-EPs) . In bacteria there are six distinct families of transporter proteins: the Small Multidrug Resistance (SMR) family, the Major Facilitator Superfamily (MFS), the Multidrug and Toxic Compound Extrusion (MATE) superfamily, the ATP (adenosine triphosphate)-Binding Cassette (ABC) superfamily and the Resistance Nodulation Division (RND) family [3].Recently, a sixth bacterial efflux pump group was described, namely the Proteobacterial Antimicrobial Compound Efflux (PACE) superfamily [4].The MFS is a large family of secondary-active transporters. They use the proton motive force (PMF) as energy source [5],[6].The most extensively studied efflux pumps in *S. aureus* are those belonging to the MFS family, with NorA as a representative example [7] . One of the important Inhibitor compound is (CCCP) was used as efflux pump inhibitor[8]. This compound destroys oxidative phosphorylation and concentration gradient of cell membranes and inhibits the activity of efflux pump in bacteria and the procedure of this method

is similar to MIC test[9]. Efflux Pumps Inhibitors (EPIs), which are compounds targeting the efflux activity and/ or pump components, have been identified as promising therapeutic agents, as they may restore the activity of standard antibiotics[10].

Material and Method

Bacterial Isolates: Thirtyisolates of *S. aureus* were acquired from different clinical samples at the Baquba teaching hospital; these sampls including nasal, wound, blood, ear,burn,UTI infection.Samples taken and right away transported to the microbiology laboratory. The *S. aureus* identification was done according to standard procedures[11].Bacteria were stored at -80°C as 20% glycerol stocks and subculture on mannitol salt agar at 37°C before testing[12].

Susceptibility determination: Disk diffusion method was used on Muller- Hinton agar to determine resistance or susceptibility to cCiprofloxacin, conforming to clinical laboratory standards institute [13]. Ciprofloxacin disc (Cip: 5µg). Plates incubation at 37C^{o} for 24 hours. Results have been record and bacterial sensitivity was obtained through measure the diameter of the inhibition zones according to [13].

Minimum Inhibitory Concentration (MIC): We were re-examined all of the strains by disk diffusion method, through Muller Hinton broth dilution method based on [13]. Stock solution of Ciprofloxacin was prepared at final concentration of 10 mg/ml by dissolving 500 gm of Ciprofloxacinin 4.1 ml distilled water and the volume was completed to 10 ml and prepared a serial dilution of Ciprofloxacinbetween (1-2048)µg/ml according to [13]. The presence of active efflux pump inhibitor system, (CCCP) was used. Stock solution of CCCP was prepared at final concentration of 25µg/ml by dissolving 0.5 gm of CCCP in 9.5 ml of 50% ethanol and prepared a serial dilution between (1-2048) µg/ml according to [13].

Identification of norA in S. aureus by PCR: Eighteen of *S.aureus* was determined by the presence of the *nor*A *gene* by PCR as described by[14]. *S. aureus* isolates were tested for the presence of the 620-bp PCR product of the *nor*A gene using the primer: forward, TTCACCAAGCCATCAAAAAGand reverse, CTTGCCTTTCTCCAGCAATA. PCR was performed with an initial denaturation at 95 C0 for 5 min by one cycle, followed by 30 cycles of denaturation at 94 C0 for 30 Sec, annealing at 60°C for 15 Sec and elongation at 72°C for 1 min. The final elongation step was at 72°C for 7 min by one cycle.

RNA Extraction: The RNA was extracted from the *S. aureus,* isolates using a commercial TRIzol extraction kit (promega, USA) according to the manufacturer's instructions.

Primers and Probes preparation: The*nor*A primers, housekeeping gene *gmk* and probefor the *S.aureus* were supplied by promega Company. The name and sequence of primer and probe are listed in table (1).

Table (1): Primer,probe and housekeeping gene are used in the gene expression in this study

Primer Name	Primer sequences 5`……..3`	Reference	Annealing Tem
norA-F	` TTTGTTTTCAGTGTCAGAATTTATGTTTG	This study	55
norA-R	` GGCTTGGTGAAATATCAGCTATTAAAC		
gmk-R	ATC GTT TTA TCG GGA CCA TC	[15]	55

norA-p	6FAM*- AGGCATAACCATACCAGCACTCATACCACC-BHQ1*	This study	

*6FAM, 6-carboxyfluorescein; *BHQ, black hole quencher/*p*, probe

qRT-PCR program: The qRT-PCR program to detect the gene expression of the *nor*A, gene was set; thus, the following qRT-PCR programwas adopted in table (2).

Table (2): RT-PCR program

Extension	Annealing	Denaturation	Initial Denaturation	RT. Enzyme Activation	Amplified gene
72^{o}C/30 sec	55^{o}C/30 sec	95^{o}C/30 sec	95^{o}C/10 min	37^{o}C/15 min	*nor*A
40 cycle	40cycle	40 cycle	One cyle	One cyle	

The ΔCt between the target gene and the reference gene is calculated in the following equation:

ΔCt = Ct target gene - Ct reference gene

Then the difference between the ΔCt of the unknown and the ΔCt of the calibrator is calculated, giving the ΔΔCt value, as the following :

ΔΔCt = (Ct target - Ct reference) sample - (Ct target-Ct reference) calibrator The normalized target amount in the sample is then equal to $2^{-\Delta\Delta Ct}$[16].

Results

Susceptibility Determination: Among 30 isolated of *S. aureus*, that tested by disc diffusion method, 18 of them were ciprofloxacin resistance (60%). Between ciprofloxacin resistant isolates, 18 of them had the activated efflux pump according to CCCP results. The effect of pump Inhibitor on the treatment of efflux pump shown in table (3).

Table(3): Effect of efflux pump inhibitors on MIC of Ciprofloxacin in clinical isolates

Molecular detection of norA gene: Sixteen of 18 *S . aureus* isolates were positive for *nor*A gene. The results illustrated in fig(1) demonstrated that 16 MRSA isolates were (88%) harbored *nor*A gene.

Detection of norA gene expression by qRT-PCR by one-step: The study of gene expression was conducted by select (6) *S.aureus* isolates from different sources. These isolates were tested after being treated with the Ciprofloxacin separately and treated by combination of Ciprofloxacin plusCCCP. In order to utilize qPCR for measuring changes in RNA transcript levels, there are several factors that must be taken into account. For one, it is important to ensurethat RNA samples are of high quality and are not contaminated with significant amounts of genomic DNA that may yield false-positive amplification in the downstream qPCR reaction. Second parameter to consider is the choice of a "one-step" (cDNA synthesis and qPCR occur sequentially in the same master mix [17] . Third, a detection method must be chosen, using either fluorescently labeled primers/probes, or that fluoresce when bound to the double-stranded PCR product, since a new probe must be synthesized for each gene of interest [18].In this study we explain the potentiating effect of (CCCP) against expression of efflux pump genes in *S.aureus*. We used *gmk* (guanylate kinase) housekeeping gene an endogenous control .The Reference gene was used in the gene expression to clarify its expression. It remained constant in the cells or tissues under investigation and different conditions [19]. The experiment of the quantitative RT-PCR reaction was completed by using six (6) from eighteen (18) of MRSA isolates accordingly to their source . The different sources of these isolates were distributed as (SA3 wound, SA7, urin, SA8, blood, SA18ear, SA15burn,SA10,nasal) .The quantitative changes in the mRNA expression levels were determined using comparative threshold cycle (CT) method ($2^{-\Delta\Delta Ct}$) for MRSA isolate present in table (4).

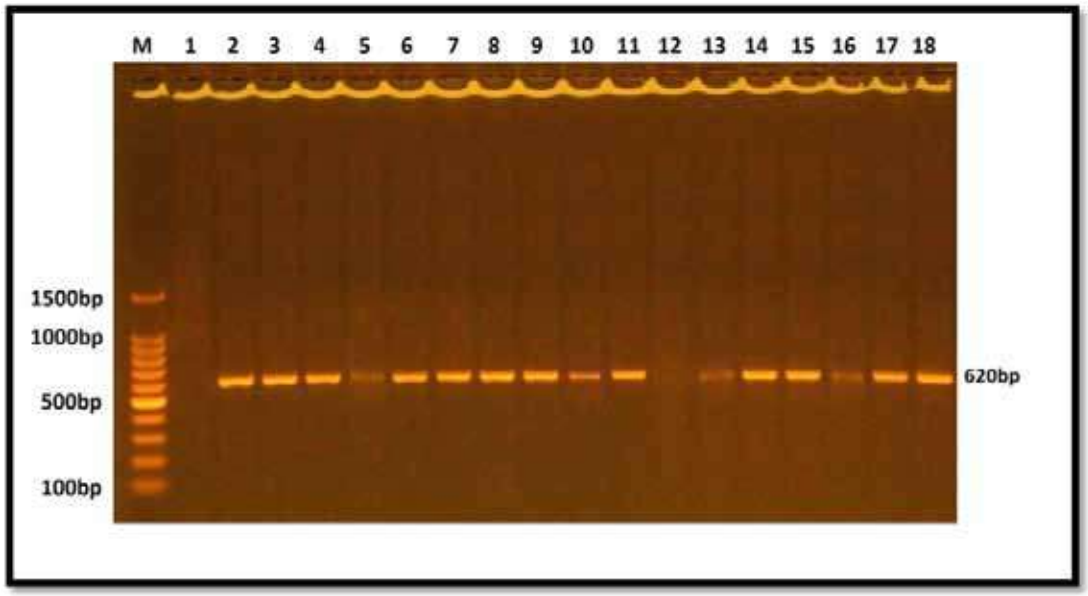

Figure (1): Agarose gel electrophoresis (2% agarose, 7V/cm, for 90 min) for norAgene (amplified size 620 bp) lanes 1-18 compared with (100 bp) DNA ladder lane 4M(SA1,12) negative amplification of norA gene, (SA2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 13, 14, 15, 16, 17, 8) positive amplification of norA gene.

Table (4): Gene expression of norA gene measured by qRT- PCR using FAM and BHQ1 Expression of norA gene compared with control (gmk refrencegene)

	1.7	-0.7	-2.1	31.1	33.2	15cccp	
	0.5	0.9	-0.6	19.8	20.4	10cccp	

The results demonstrated that four strains (SA3,7,15,18) revealed over expression of *nor*A after treated by sub concentrations of Ciprofloxacin, no over expression of *nor*A was observed in two isolates (SA8,10) after treaeted with Ciprofloxacin. Also six isolates evaluated in the presence of CCCP & Cip by qRT-PCR analysis, gene expression of the *nor*A was decreased in four isolates that treated with CCCP

& Cip as well as in more than half of strains only in (SA7) it remained the same as and (SA15) increase of gene expression them increase is very minor .Our result revealed that the isolates after treated with Ciprofloxacin have strong significant according to *p-value* at P<0.05 in all isolates except SA7 . Also our results show significant according to *p-value* at P<0.05 after treated with CCCP & Cip in three isolates (SA7,15,10). These results indicate higher quantitative gene expression of *nor*A.One isolates have been deposited in the National Center for Biotechnology Information (NCBI) with the accession number as Lc490694 for *nor*A and the name of strain ISTM12 also same strain deposited in NCBI for 16sRNA and accession number MK775201.1

Discussion

Emergence and extension of antibiotic resistance among bacteria have led to the essential endeavor on the discovery of new antibacterial materials and modulators of antibiotic resistance. There are various mechanisms of antibiotic resistance in *S. aureus*. One of the most principal of them is the efflux pumps, which pull out antibiotics and reduction the intracellular concentration of the antibiotic[20].Our results confirm to the results of [21] which showed the gene expression was various among isolates and the gene expression increase with increasing MIC of ciprofloxacin of *S.aureus* isolates . Also [22] in Pakistan revealed that the efflux pump gene *nor*A in *S.aureus* showed an increase in expression in the presence of Ciprofloxacin and over expression of *nor*A was >3. The study carried by [23] in China showed over expression of *nor*A in 25 isolates from 51 isolates (49.01%) by qRT-PCR.Although different EPIs such as CCCP have been reported to block the ATP-binding site of the *nor*A gene resulting in the inhibition of antimicrobial efflux and improved antimicrobial efficacy . Efflux pump activity alone is not responsible for fluoroquinolone resistance, mutations/ deletions may occurs in the QRDR, *nor*Acoding [24]. Therefore, the addition of CCCP did not completely inhibit FQ resistance .This study was to investigate the inhibitory effects of CCCP on the expression of NorA efflux pump and decrease ciprofloxacin resistance in *S. aureus.* Synergistic potentiation of antibacterial effect of Ciprofloxacin withefflux pump inhibitor CCCP as well as serve as potent efflux pump inhibitors of *nor*A expression . *S. aureus* and other pathogenic bacteria show altered expression patterns of their virulence genes at different infection sites depending on the growth conditions within each tissue. Therefore, analyses of gene expression regulations under conditions that mimic host environments are important for determining bacterial pathogenesis.

Conclusions

In this study high proportion of efflux pump gene *nor*A of MRSA isolates were recognized in patients of Baquba teaching hospital Nonetheless, strong correlation was observed between phenotype and genotype of these isolates. The present study measured the synergistic effect in combination CCCP with Ciprofloxacin. This experiment also showed that the primer and probe for *S.aureus* targeting efflux pump gene was highly specific for expressing and RT-PCR has shown great probabling for detecting viable pathogens.

Serum Citrin and γ-Glutamyl Transferase as Biomarkers for Infantile Cholestasis Severity

Mostafa Al-Bassam[1], Hassan H. AL-Saeed[2], Hala Sameh Arif[3]

[1]Lecturer Ph. D. Department of Pharmacy, Al-Israa University, Baghdad, Iraq, [2]Assist Prof. Dr. Department of Chemistry and Biochemistry, College of Medicine, Al-Nahrain University, Baghdad, Iraq, [3]Assist Prof. Dr. Department of Pediatric, College of Medicine, Al-Nahrain University, Baghdad, Iraq

Abstract

One of the most important parameters to evaluate severity and type of cholestasis disease is gamma-glutamyl transferase and citrin protein measurements. The objective of this study was to assess the clinical value of serum citrin protein with gamma-glutamyl transferase in children with cholestasis.60 subjects with diseases and 25 healthy subjects distributed intothree groups, citrinand gamma-glutamyl transferasewere measured for all case and control studies by enzyme linked immunosorbent Assay. The results showed serum citrin has a highly significantly decreased in an intra- and extrahepatic cholestasis groups when compared with control ($P<0.001$), serum gamma-glutamyl transferasehas a highly significantly elevated in an intrahepatic cholestasis group when compared with control ($P<0.003$). From these findings it was concluded that serum gamma-glutamyl transferase level is a good marker in determining the severity of cholestasis disease, serum citrin may be useful in future to diagnose the cholestasis caused by citrin deficiency.

Keywords: *γ-Glutamyl transferase (GGT), Biliary atresia (BA), Alagille syndrome (AGS), Progressive familial intrahepatic cholestasis (PFIC), Idiopathic neonatal hepatitis (INH), Citrin deficiency (CD).*

Introduction

In neonate the jaundice is common, usually secondary to unconjugated or indirect hyperbilirubinemia, prolonged beyond 14 days of life, of new-onset, or at high levels, it must be evaluated for potentially life-threatening causes, such as evolving hepatobiliary dysfunction or infection. Cholestasis is the end effect of obstruction of the normal excretion of bile from the liver, giving rise to the abnormal accumulation of bile salts, bilirubin and lipids and abnormal level of GGT in the blood, the cholestasis in the infant may present as jaundice, pruritus, fat-soluble vitamin deficiency, or may evolve following or during acute liver failure,also anatomic or functional biliary obstruction is often reported by the presence of acholic stools[1], dark urine or acholic stools or examination findings of hepatosplenomegaly and as cites[2].

Biliary Atresia (BA): Is defined as biliary obstruction caused by progressive fibrosis of intrahepatic and extrahepatic bile ducts with an unknown pathogenesis, if isn't treated immediately[3].

Alagille syndrome (AGS): Is an autosomal dominant disorder affected by defects in the notchsignalling pathway that affect multiple organ systems with phenotypic variability, AGS can be diagnosed clinically through the existence of as a minimum three of five major features: chronic cholestasis, ocular abnormalities, peculiar face phenotypes, skeletal abnormalities and cardiac disease[4-5], also one of most important syndrome is related with a paucity of interlobular bile ducts histopathologically[6].

Progressive familial intrahepatic cholestasis (PFIC): Define as mutations in several genes encoding proteins involved in bile acid homeostasis cause neonatal

e-mail: mstf_muhamad@yahoo.com

cholestasis. Progressive familial intrahepatic cholestasis (PFIC) types 1, 2 and 3 are a group of cholestatic situations caused by mutations in ATP8B1, ABCB11 and ABCB4 respectively, and defects in TJP2, encoding tight junction protein 2, can also cause severe cholestatic liver disease[7-8].Several heterozygous variants in known PFIC genes may participate to disease in some cases[9], but up to one third of cases stay idiopathic[10].Infants usually have deep pruritus, but may also are presented with jaundice resulted from the cutaneous and intrahepatic accumulation of bile acids, respectively[11].A significant clinical finding in individuals with PFIC types 1 and 2is the existence of a normal or low GGT out of proportion to the degree of cholestasis[12]. Patients with PFIC type 3 have increased GGT[2].

Idiopathic neonatal hepatitis (INH)

Is a term employed to explain prolonged neonatal intrahepatic cholestasis in the first six months of life, whose histopathological lesion is characterized by the existence of "giant cells", in the lack of other causes of type obstructive, infectious or genetic in whom a significant cause could not be recognized, the occurrence of INH is approximately 15% of neonatal cholestasis cases[13].

Citrin Deficiency (CD): Is a mendelian disease existencebecauseofbiallelicmutationsofSLC25A13gene and in neonates of infants called neonatal intrahepatic cholestasis caused by citrin deficiency[14]. The protein product of this gene is designated as citrin, which, as the liver-type aspartate/glutamate carrier isoform 2 (AGC2), its role to export aspartate from the mitochondrial matrix in exchange for cytosolic glutamate and H+, playing significant roles in the urea cycle and malate-aspartate shuttle[15-16].Failure to thrive and dyslipidemiaare main in neonatal intrahepatic cholestasis caused by citrin deficiency[17-20].Specific metabolic and genetic diagnosis tests are time-consuming, costly and only available in a small number of academic centers, and they typically take weeks to months, these have restricted its use in the early diagnosis and treatment of infantile cholestasis, so to rapidly and correctly manage clinical patients, hard works are needed to develop the efficacy and accuracy of early diagnosis for infantile cholestatic patients[21-22].

γ-Glutamyl Transferase (GGT): Also one of the most important parameter to evaluate the severity of cholestasis disease is (GGT) measurement, which it is a plasma membrane-bound enzyme, is an essential catalyst which facilitates glutathione hydrolysis, it is established in many organs, but its presence in the liver has animportant diagnostic use, the main role of cellular GGT is the metabolism of extracellular reduced glutathione, permitting precursor amino acids to be incorporated and reused for intracellular glutathione synthesis[23].In Allagile syndrome about 3 to 20 times of normal GGT[1], Low/normal levels of GGT in idiopathic neonatal hepatitisinfants may be a predictor of more severe but recoverable disease[24].

Materials and Method

The study was executed during the term from January 2018 to June 2018 this study included 80 subjects with diseases and 25 healthy subjects and distributed into three groups : first group includes 40 patients with intrahepatic cholestasis diseases, second group: includes 20 patients with extrahepatic cholestasis diseases and third group: represents the apparently healthy control group which comprises of 25 subjects who do not suffer from liver disease or any chronic illness and matched with age and gender to patient groups. All samples were collected from Baghdad, Iraq, Al-Imameen Al-Kademen Medical City, Digestive Center at Medical City and Child's Central Teaching Hospital. The exclusion criteria were representing by selected thepatients who were do not suffered from dyslipidaemia and diabetes mellitus or any other disease that may interfere with the study and patients who were not underwent any type of therapy such as ursodeoxycholic acid and were stopped the treatment two weeks before investigations. The preparation of blood sampleswere done by collectedabout five millilitres of blood that obtained from veins of patients having cholestasis and healthy control subjects.Blood samples were left for 20 minutes at room temperature. After coagulation, sera were separated by centrifugation at 3000 rpm. for 10 min, aspirated and stored at -20 until assayed for GGTand citrin. They were measured using enzyme-linked immunosorbent assay (ELISA) kits.The human gamma-glutamyl transferase and human SLC25A13/ citrin kits were obtained from kono Biotech Company. Ethical approval was obtained from institutional board review of school of medicine, Alnahrain University with reference number 14/75/666/01102017.

Data were analyzed using SPSS v.20 descriptive statistic were expressed as median and range. Inferentialstatistics were done by using Mann-Whitney test for dichotomous variables and Kruskal Wallis test for trichotomous variables.

Results

Table (1): Comparison between control vs three study groups by Mann Whitney test

Parameters		Control N=25	IHC N=40	EHC N=20
Citrin (pg/ml)	Median	175.0	49.5	40.5
	Range	49.0-802.0	17.0-700.0	11.0-69.0
	P value		<0.001	<0.001
GGT (ng/L)	Median	395.0	175.5	485.0
	Range	164.0-1573.0	80.0-1694.0	122.0-950.0
	P value		0.003	0.918

Table (2): Comparison between intra and extrahepatic cholestasis groups by Mann Whitney test

Parameters		IHC N=40	EHC N=20	P value
Citrin (pg/mL)	Median	49.5	40.5	0.121
	Range	17.0-700.0	11.0-69.0	
GGT (ng/L)	Median	175.5	485.0	0.183
	Range	80.0-1694.0	122.0-950.0	

Table (3): Comparison of citrin and GGT in IHC group according to cause by Kruskal Wallis test

Parameters		Allagile Syndrome N=12	PFIC N=15	Undiagnosed N=13
Citrin (pg/mL)	Median	53.0	45.5	45.5
	Range	17.0-700.0	32.0-88.0	31.0-157.0
	P value	0.601		
GGT (ng/L)	Median	1157.0	159.0	161.0
	Range	200.0-1694.0	105.0-242.0	80.0-659.0
	P value	0.002		

The median of serum citrinin the control, intra and extra-hepatic cholestasis groups were (175, 49.5 and 40.5) pg/ml respectively, has a highly significantly decreased in an intra- and extrahepatic cholestasis groups when compared with control (P<0.001) but the median serum γ-glutamyl transferase in the control, intra and extra-hepatic cholestasis groups were (395, 175.5 and 485) ng/L respectively,has a highly significantly elevated in an intrahepatic cholestasis group when compared with control (P<0.003) and has no significant difference when compared the extrahepatic cholestasis group with control group (P= 0.918) according to the Mann Whitney test as shown in table (1).

There was no statistical difference between the intrahepatic cholestatic patients and extrahepatic cholestatic group in serum citrin and serum γ-glutamyl transferase (p = 0.121 and 0.183) respectively according to the Mann Whitney test as shown in table (2). There was no statistical difference in serum citrin when compared the causes type of an intrahepatic cholestasis group (p = 0.601).Alsothere was a significant elevated in serum γ-glutamyl transferase when compared Allagile syndrome group with PFIC and undiagnosed groups of an intrahepatic cholestasis group (p = 0.002) according to cause by Kruskal Wallis test as shown in table (3).

Discussion and Conclusion

γ-glutamyl transferase showed decreased in patients with intrahepatic cholestasis group but in extrahepatic cholestasis group showed no differnce when compared with control group due to low level of γ-glutamyl transferase in the type progressive familial intrahepatic cholestasis and idiopathic neonatal cholestasis when compared with control as agreed with the result of previous study [24], a probable mechanism be presents to account for the low GGT levels and its association with worse liver disease. Perhaps defects in the hepatocellular canalicular adenosine triphosphate (ATP) dependent transport system drawn in bile formation and transport like to PFIC 1 or 2 may be also be occupied,

heterozygosity for the ATP8B1 gene or the ABCB11 gene has been postulated and, previously, heterozygosity for the bile salt export pump (BSEP) gene has been reported in association with transient neonatal cholestasis and normal GGT[25], as shown in table (1).But there is no difference when compared intrahepatic cholestasis group with extrahepatic cholestasis because each group had high level of γ-glutamyl transferase due to type of cholestasis: Allagile Syndrome and Biliary Atresia which agree with the result of previous study[26-27], as shown in table (2).

According to the present data, the results of this study for the correlation analysis were showed a positive correlation between γ-glutamyl transferase, citrin and allagilesyndrome and progressive familial intraheptaiccholestasis groups as shown in table (3).

In allagilesyndrome and progressive familial intraheptaiccholestasis patients the citrin showed no difference when compared with undiagnosed group of intrahepatic cholestasis but γ-glutamyl transferase showed significant correlation with outcome of these groups in such it was elevated in allagilesyndrome group when compared with progressive familial intraheptaiccholestasis and undiagnosed groups in which these results were in agreement with previous studies[24,27], so there was a significant decreased in an undiagnosed group in which this study suggest that undiagnosed group patients they were probably had either progressive familial intraheptaiccholestasis or idiopaticneonatal hepatitis after biopsy diagnosis making the chance of happening one of them that could suggested from the level of γ-glutamyl transferase in sera as agreed with the results of previous studies[24].

This study revealed that low levels of citrin was associated with thesis that may cholestatic patients have citrin deficiency origin of cholestasis disease, which agree with the finding of the significant association between the low levels of citrin and cholestasis disease may be attributed to mutation in SLC25A13 gene that responsible for citrin protein/carrier synthesis caused citrin deficiency[18,22,28-29].

Limitations: One of most difficult issues is the number of patient that suffer from cholestasis in Iraq and their knowledge how to get early to specialist centers for diagnosis when they suffer from jaundice in long term which may be having cholestasis in fact.

Conclusion

No studies have examined the relationship between citrin protein as biomarker and cholestatic diseases in humans, and this present study suggested the citrin protein as possible biomarker in laboratory biochemical findings to distinguish in future the intrahepatic cholestasis as citrin deficiency type from other metabolic or genetic types and to exclude specific metabolic and genetic diagnosis tests which are time-consuming, costly and only available in a small number of academic centers, and they typically take weeks to months. This new citrin biomarker test help in future for the early diagnosis and treatment of infantile cholestasis caused by citrin deficiency and to rapidly and correctly manage clinical patients and help the researchers in future to depend on this study results to develop the citrin method for evaluation the cholestatic patients by increase the number of patients.

Acknowledgments: From my deep heart special thanks to all staff members of Al- Emamain Al-Kadhemyiayn medical city, Child's Central Teaching Hospital and Digestive Center at Medical City especially dearDr.Yassir AL-Aniand all staff members in Department of Chemistry and Biochemistry in Al-Nahrain College of medicine.

Ethical Clearance: The Research Ethical Committee at scientific research by ethical approval of both environmental and health and higher education and scientific research ministries in Iraq

Conflict of Interest: The authors declare that they have no conflict of interest.

Some Metal Complexes of Mixed 1, 10 Phenonthroline and Schiff Base Ligand; Syntheses, Spectroscopic and DNA Cleavage Studies

Sabrin Fadal Hammed[1], Hasan A. Hasan[1], Mohammed Mahdi Jawad[2]

[1]Post Graduate student, University of Baghdad-College of Education, Ibn-Al-Haitham-Chemistry Dept., Iraq,
[2]Prof. Dr. University of Baghdad-College of Education, Ibn-Al-Haitham-Biology Dept., Iraq

Abstract

Two series of metal complexes were prepared in this study, the first set from reaction of metal salts with Schiff base (HL^1) as a primary ligand (which prepared by condensation of Benzdine, 2-hydroxynaphthaldehyed and 9-anthracen carbaldehyed in a one pot step with 1:1:1 molar ratio. The second series was synthesized by reaction of two mixed ligands [HL^1] and 1,10-phenanthroline [L^2] with the metal saltes in a 1:1:1 molar ratio. The Schiff base ligand and mixed ligand chelates characterization based on spectroscopic method; FT-IR, UV-Vis, ^{1}H-NMR along with elemental analysis, metal content, melting point, magnetic susceptibility and conductance measurements. The Schiff base ligand and mixed ligand complexes were found to have the general formulae $[M(L^1)_2(H_2O)_2]$. $H_2O$and $[M(L^1)(1,10phen)]$ Cl. H_2O, where (M=Mn(II), Co(II), Cu(II), Ni(II), Zn(II) and Cd(II) respectively. Octahedral geometrical structures were proposed for (HL^1) complexes while a tetrahedral structure was proposed for the mixed ligand complexes. The interactions of prepared compounds with DNA were investigated by gel electrophoresis and Ultra-Violet spectroscopy. The results of DNA binding and cleavage experiments displayed that some metal complexes were able to interact with DNA in intercalative mode, these results suggested the possible utilization of metal complexes for pharmaceutical applications.

Keywords: *Schiff-base ligand,Benzdine, DNA cleavage, DNA Interactions.*

Introduction

Heterocyclic compounds classified as important class of compounds due to the high biological activities (anticancer, anti-inflammatory, antifungal and antibacterial) [1]. Some natural products, like nucleic acids, plants, chlorophyll and alkaloids contain heterocyclic system in their structure. Because of its ability to form stable complexes with many transition metals, heterocyclic compounds considered as important materials in coordination chemistry[2]. The components of the prepared (HL) ligand{L Khokra, 2016 #160;L Khokra, 2016 #160;L Khokra, 2016 #160;L Khokra, 2016 #160}[Benzdine, 2-hydroxynaphthaldehyed and 9-Anthrylcarboxaldehyde], were commonly used in the field of medicinal chemistry because of their pharmacological, photographic and catalytic application[2,3]. Schiff bases derived from 2-hydroxy-1-naphthaldehyde have attracted a great interest for their photophysical and biological properties (non-linear optical behavior, thermo and phototropism). In the present study Schiff base ligand HL^1 derived from the condensation of Benzdine with 2-hydroxynaphthaldehyed and 9-anthrace carbaldehyed and its mixed ligand complexes in the presence of (1,10-phen) 1,10- phennanthroline as a secondary ligand have been prepared and characterized using different spectroscopic tools and thermal analyses. Furthermore, DNA cleavage properties of the metal complexes also have been evaluated[4].

Materials and Method

Chemicals: All chemicals used were of the analytical grade of highest purity available. They included binzidine (Sigma/USA), 2-hydroxynaphthaldehyed (Aldrich/USA) and 9-anthracarbaldehyed (Sigma-Aldrich). The metal salts of $MnCl_2$. $4H_2O$ (B.D.H), $CoCl_2$•$6H_2O$(Merck), $NiCl_2$•$6H_2O$, $ZnCl_2$, $CuCl_2$•$2H_2O$ (Fluka) and $CdCl_2$ (BDH) were used. Organic solvents were spectroscopic pure included absolute ethanol Sigma- Aldrich and Dimethyl sulfoxide (DMSO), acetic acid and Chloroform were providing from Sigma-Aldrich/USA.

DNA extraction and cleavage: DNA was extracted from donors blood samples following the protocol leaflet of gsync^{TM} DNA extraction kit from Geneaid/Taiwan.

Physical measurements: Melting points for prepared complexes were measured by electro thermal (Stuart melting point apparatus). Infrared spectra were recorded as potassium bromide by a Shimadzu 8400S FTIR spectrophotometer in the range 4000-400 cm^{-1}. The electronic spectra of the compounds were recorded by using double-beam (UV-Vis) spectrophotometer type UV 160A. ^{1}H- NMR spectra was acquired in DMSO–d^6 solution using a Brucker-400 MHz at University of Tehran, Islamic Republic of Iran. The Chloride contents were determined using potentiometer titration method on a (686–Titro processor– 665. Dosimat Matron/Swiss). Mass spectra of ligand HL^1were obtained by Electron Impact mass spectroscopy using Agilent Technologies Mod.5975C VL MSD. The spectra were recorded at University of Tehran, Islamic Republic of Iran. Electrical Conductivity measurements of the complexes were made with DMSO (10^{-3}mole.L^{-1}) solutions using model 4071 digital conductivity meter. Thermogravimetric analysis was carried out using Differential Scanning Calorimetry (DSC) on STA PT-600 Linseis Company/Germany. The measurement was conducted under argon atmosphere at a heating rate 10ºC/min. Samples were recorded at College of Education for Pure Science (Ibn Al-Haitham) Baghdad University.

Synthesis:

Synthesis of ligand [HL^1]: The ligand was prepared from the reaction of (0.155g,1mmol) 2-Hydroxynaphthaldehyed and (0.185g,1mmol) 9-anthracencarbxaldehyed with Benzidine (0.16g5,1mmol) in (30ml) ethanol with continuous stirring and (4-5) drops of (CH_3COOH) glacial acetic acid. The reaction mixture was left under reflux at (70-80°C) in water bath for (5-6) hrs. Orange color product was obtained, separated by filtration after cooling, and finally washed with ethanol hot. This product yield was almost quantitative (63%) ($C_{38}H_{26}N_2O$) Molecular Weight: 526.64 g/mol. The reaction is shown in (scheme 1). Yield (0.9g,%63), M.P=215°C. IR data (cm^{-1}): 3437 ν (OH), 1622 (w)ν(C=N), (1159, 1309) ν (C-N). The 1H NMR spectrum of the ligand in DMSO-d6 showed peaks at; δH(300 MHz, DMSO-d6: 9.9(OH), 8.9, 8.92(-N=C – H),6.58-8.2 (Ar-*H*),(3.29-3.45)(HDO).

Synthesis of ligand [HL^1] complexes.

Synthesis of $[Mn(L^1)_2(H_2O)_2]$ (1): The metal complexes were prepared by adding (25ml) of ethanol solution of metal chloride (0.197g,1mmole) with ethanol solution of the prepared Schiff base (0.165g, 2mmole) followed by drop wise addition of KOH. The respective ligand, maintain the stoichiometric (1: 2) metal: ligand ratios. Reaction mixture was heated under reflux for (3-4) hours with constant stirring on a magnetic stirrer on a water bath and the solid metal complex compound that precipitated out were filtered and then washed several times with hot ethanol. Yield (73%) of the title complex [$MnC_{78}H_{56}N_4O$.],m.p: (275) was obtained. See Scheme (2).M(II) = Mn, Co, Ni, Cu, Zn, Cd, n= 6(Co, Ni), 4(Mn), 2(Cu), 0(Zn, Cd), m=0; n=0

Synthesis of $[Co(L^1)_2(H_2O)_2]$(2), $[Ni(L^1)_2(H_2O)_2]$ (3), $[Cu(L^1)_2(H_2O)_2]$(4), $[Zn(L^1)_2(H_2O)_2]$(5) and $[Cd(L^1)_2(H_2O)_2]$(6)

A similar method to that mentioned in synthesis of Co (II) complex was used to synthesized the complexes of [HL^1] with MCl2.nH2O M(II) = [Cd (n=0),Zn (n=0), Cu (n=2), Mn (n=4), Co (n=6) and Ni (n=6)] ions. The physical properties of the complexes and their reactant quantity displayed in (Table 1).

Synthesis of the mixed ligand complexes: The present mixed ligand chelates were synthesized by adding solution of (20mL) (60-70ºC) of the Schiff base ligand (1mmol, 0.5g) and (1,10-phenanthroline) (1mmol, 0.17g) with stirring and gradually to ethanolic KOH solution (1mmol, 0.19g) of metal chloride dissolved in absolute ethanol (20 mL). The mixture in each case was in stoichiometric amount (1:1:1) (Metal: ligand: (1,10-phen)) molar ratio. The resulting mixtures were refluxed for (4h) where upon the complexes were precipitated. They were separated by filtration, washed many times with ethanol and recrystallized from hot ethanol and

finally dried in air, the synthetic rout presented in Scheme 3.

Results and Discussion

FT-IR spectrum of ligand [HL^1]: The FT-IR spectrum for (HL^1) showed a strong broad band at (3433) cm^{-1} may indicates the presence of (N…H-O) and (NH…O-H) groups intramolecular hydrogen bonding due to phenolic OH groups of the phenol–imine forms, compared with the peak of the 2-hydroxy-1-naphthaldehyde at (3100) cm^{-1}[5]. The spectrum showed band in the region(1622) cm^{-1} stretching frequency of azomethine group (C=N) .The appearance of this band and the disappearance of the tow aldehydic carbonyl (C=O) bands of the 9-anthracarbaldehyed and 2-hydroxy-1-naphthaldehyde at (1650 and 1668) cm^{-1} respectively, and disappearance of two bands of NH_2 groups, which indicated the involvement of the primary amine and aldehyde groups in the formation of the Schiff base. The medium intensity bands observed for ligand in the (1309) cm^{-1} was assigned to υ (C-O) phenolic group vibration[6].

The Electronic Spectrum of ligand [HL^1]: The Electronic spectrum of [HL^1] shows peaks of shortest wave length presenting at (270 nm) (37037.04 cm^{-1}) (e_{max}=1.865 molar $^{-1}$ cm^{-1}) and (327 nm) (30581.04 cm^{-1}) (e_{max}=1.396 molar^{-1} cm^{-1}) may be assigned to (p–p* or n–p*) transition of Schiff base aromatic rings [7]. Finally the peak at the range (433 nm) (23094.69 cm^{-1}) (e_{max}=2.179 molar^{-1} cm^{-1}) in the Schiff base spectrum may be belonged to the (C=N)imine group and this peak may refers to the keto-amine quinoid tautomer shape of the Schiff base [8].

^{1}H-NMR Spectrum of ligand [HL^1]: The ^{1}H NMR spectra of naphthalimine derivative (HL^1) show that both phenol–imine form and keto–amine form are in equilibria.aromatic rings protons assigned by the multiplet chemical shifts at (d=6.58-7.45ppm) range [9]. The sharp signal at chemical shift (d=8. 9 and 8.92 ppm) can be assigned to the proton of the imine group proton (C=N)[10]. The singlet chemical shift at (d=9.85 ppm) may attributed to NH group, this confirmed the fact that there is ketotautomerism for the synthesized ligand[11]. The signal at (d=9.9 ppm.) may be considered to the OH proton in the carbaldehyde ring because of H.B. intramolecular type with the nitrogen (N) atom from the naphthalene ring(NH…O-H) and (N…H-O)[12].The spectrum displayed chemical shifts at (δ_H = 2.51ppm and3.29ppm) referred to DMSO, and the presence of water molecules in the solvent respectively[13].

Mass Spectrum of [HL^1]: The mass spectrum of (HL^1) is depicted in Figure (1). The parent ion peak adopted at m/z$^+$ = 526.6 [M+1]$^+$ for $C_{38}H_{26}N_2O$; requires = 526.6[14] .The other peaks detected at m/z+ = 349.5-105.15 correspond to $[C_{24}H_{17}N_2O]^+$-$[C_7H_8N^+]^+$.

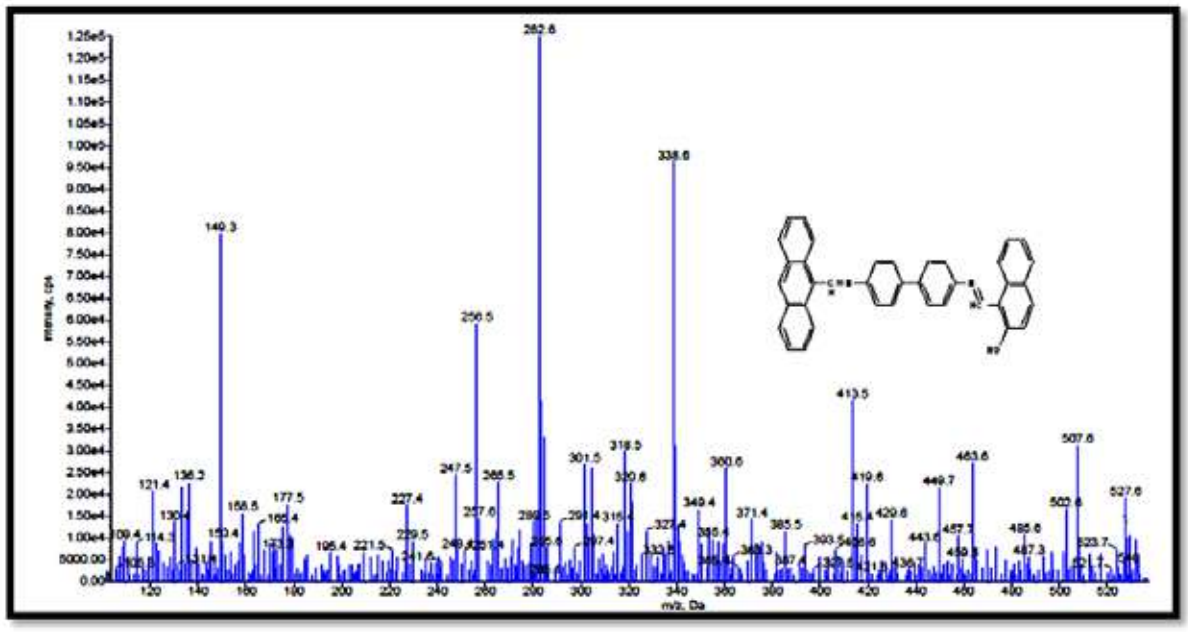

Fig. (1): GC-Mass spectrum of ligand [HL^1]

Thermal Decomposition of ligand [HL^1]: The thermo gram for ligand [HL^1] is placed in Figure (2).In the TGAcurve, peak recognized at 346.34ºC is related to the loss of (Oxygen) portions, (det. = 3.01534%, calc. = 3.0326%). The second step at 470.93ºC that designated the loss of ($C_{21}H_{15}N$) fragment, (obs. =53.35%, calc. = 53.38%). The third step at 595.34ºC is related to the loss of ($C_{12}H_{10}N$) segments, (obs. = 12.46%, calc. = 12.92%). The DSC analysis curve proved peaks at (248.4, 267.6, 595.34)ºC refer to an endothermic decomposition process. Peaks Observed at 346.34 and 470.93ºC were related to exothermic decomposition processes. The exothermic and endothermic peaks may demonstrate ignition of the natural ligand in an argon atmosphere. The last endothermic pinnacle may imply the ligand bond breaking [15].

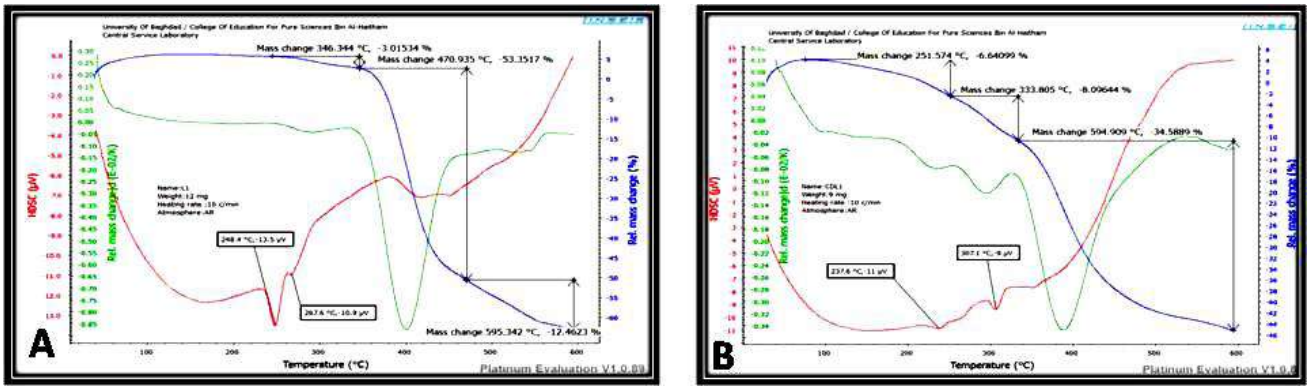

Fig. (2): (TGA and DSC) thermo gram of, A: [HL^1]Cl$_2$ and of, B: [Cd(L^1)$_2$(H$_2$O)$_2$] in an argon atmosphere

DNA Cleavage: Three types of DNA cleavage can be distinguished, namely 1-DNAhydrolysis,2-oxidativecleavage and 3-photochemical cleavage, although the last two categories are quite closely related to each other. The interaction of metal complexes with DNA via intercalation has been explored byagarose (gel electrophoresis) and UV-Vis spectroscopy[16]. Many researchers attempt to study the interaction of DNA with small molecular models, because this is the target inside the living cells in order to try treating a wide range of diseases. The present study included the use of gel electrophoresis to ensure the occurrence of DNA cleavage by incubation times 1 and 24 hours. The results showed that the longer the incubation period of the chemical compound in the presence of DNA More interaction achieved; that means the occurrence of DNA cleavage will be more, In addition to gel electrophoresis, the use of ultraviolet spectroscopy for chemical compounds in the presence of DNA for 1 and 24 hours was observed which results showed that the highest absorption peak of the compound before the addition of DNA and after the addition of DNA where a difference in the absorption peaks was observed and this indicates the occurrence of interaction between DNA and chemical compound[17].

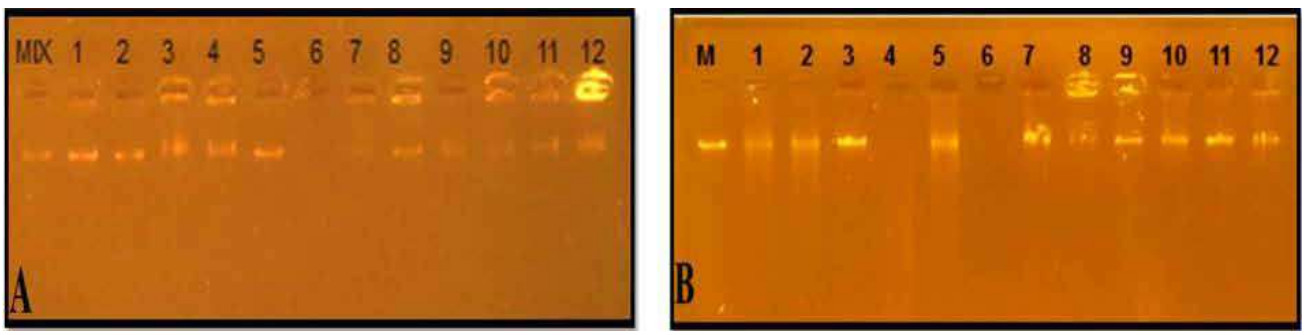

Fig. (3): Electrophoretograms of cleavage of DNA by metal (II) complexes (10µg/mL) in the absence of external agent at pH = 7.1, 1h incubation at 37°C. Lane(mix), DNA+DMSO)control(;

Ligand one=1-((1E)-((4'-((anthracen-9-ylmethylene) amino)-[1,1'-biphenyl]-4-yl) imino) methyl) naphthalen-2-ol+ metal . Ligand two=HL^1+1, 10-phen+metal

While UV-Vis spectroscopy changes in light absorption when mixing complexes with DNA was observed, and calculated according to comparison with the control sample.

The Relation between Adermatoglyphics and Dental Malocclusions of Iraqi Adults

Sami K. Al-Joubori

Assistant Professor, Department of Orthodontics, College of Dentistry, University of Baghdad, Baghdad-Iraq

Abstract

Background: Dermatoglyphics is studying the surfaces of the hands and feet for epidermal ridges. Orodental patterns developed emberiologically at the same time. Various types of malocclusion have genetic predisposition affected environmentally. These malocclusions usually accompanied by various dermal patterns which are specific for each class.

Aims of the Study: To compare the dermatologyphics characteristic of patients with various classes of malocclusions.

Methodology: The patients were divided into four groups:

Group 1: class I, group 2: class II Div 1, group 3: class II Div 2, Group 4: class III malocclusion. The finger and palmar prints were recorded and analyzed for each type of pattern.

Results and Conclusion: The class II Div 2 pattern was correlated with higher frequency of whorls, while in class III, there was increased appearance of arches and radial loops with decreased incidence of ulnar loops.

Keywords: *Dermatoglyphics,Iraqi Adults; dental malocclusion.*

Introduction

Dermatoglyphics which includes the study of skin patterns and fingerprints, is one of the oldest sciences. Cummins and Midlo defined "Dermatoglyphics", as the study of complex configurations of the dermal ridges on palmar and planter surfaces of the hands and feet[(1)]. The appearance of these dermal configurations starts in 12th week of intra uterine life and they are completed by the 24th week. Thereafter, the only change is in their size. It has been reported that Dermatoglyphics associate with a number of conditions. One of these conditions is dental malocclusion. Palate and dentition developed at nearly the same time as the dermal patterns and this can explain the association between the dental malocclusion and Dermatoglyphics [(2)]. Many studies had been done to study the relationship of Dermatoglyphics with Dentistry. Most of these studies were done to investigate the relation between periodontal diseases and caries with Dermatoglyphics[(3-6)]. Only few studies have been conducted on the correlation of malocclusions with Dermatoglyphics [(7-11)]. These studies were either inconclusive or they did not handle all the parameters. The present study was a comprehensive study which was done to study the correlation of the finger and palm patterns with variouskinds of sagittal malocclusions.

Material and Method

This study was conducted at the department of orthodontic, college of dentistry, university of Baghdad. The sample consisted of 96 (subjects) attending the

department of treatment of malocclusions, ranging in age from 18-25 years. They were divided into 4 groups of 24 eachand each group was divided into Male and female groups of 12 each.

Exclusion Criteria:

- Patient who received orthodontic treatment in early age or those who are currently undergoing orthodontic treatment.
- Patient who had features of syndromes except malocclusions.
- Patient with big restorations or prostheses that can affect the geometry and volume of the crown.
- Patient with a trauma history or surgical procedures performed in the orofacial region.

Group 1: 24 subjects, with angle class I malocclusion.

Group 2: 24 subjects with angle class II Div I malocclusion.

Group 3: 24 subjects with angle class II Div 2 malocclusion.

Group 4: 24 subjects with angles class III malocclusion

For all groups, there was no evidence of skeletal malocclusion, so all subjects were considered as skeletal class I.

Procedure for Obtaining Palm and Finger Prints: Ink and roller method was the method of choice for the palm and finger prints recording as described by Cummins and Midlo (1). Before starting the prints recording, the hands of each subject were washed with soap and water in order to get rid of any dirt, sweat, or oily secretions and then the hands were dried using clean towel. Using an inking slab, little amount of ink was displaced over it and rolled over it until a thin film of ink covered the entire slap surface. The patient was instructed to stand in front of inking plate at a distance equal to the length of fore arm and to gently press the right hand palmar surface over the inking slab. The palmar surface was then pressed gently over a white, clean paper and removed immediately. The same method was achieved for the left hand. For the individual finger print recording, the finger bulb was pressed in a right angle over the inking plate and then the finger was rolled and turned. Finally, the finger was placed on a white paper on the same rolling manner to get a clean rolled impression of each finger [Figure. 1].

The palm and finger prints of the individuals were considered under the following headings.

The Pattern on the Fingers of both Right and Left Hands: Arches, whorls, ulnar loops, radial loops, twined loops and central pocket loops were separately calculated for each digit. The occurrence frequency was recorded separately for right and left hands and then, combined scores for each of these were recorded (12). [Fig. 1]

Total Finger Ridge Count: Ridge count indicates the number of ridges between the triradius and the core or between two triradii. Ridge counts for patterns of finger tips were done by following the method of Cummins and Midlo[1,12], The Total Finger Fridge Count (TFRC) demonstrate the ridge counts of all fingers .

Atd Angle of each Hand: The axial triradius‘t’ is an important landmark on all normally developed hands. This triradius is found near the proximal palmar margin, superficial to the wrist bones, near to the axis of the fourth metacarpal bone. The position of the triradius can be various in the proximal-distal direction.

The position of the axial triradius in the proximal region of the palm, near the wrist crease and it is denoted by the symbol “t. The method which is most widely used to interpret the position of axial triradius in the palm is the ‘atd’ angle. This angle is formed by lines drawn from the digital triradius ‘a’ to axial triradius and to ‘d’. The more distal is the position of axial triradius, the larger is the ‘atd’ angle. Palms with patterns in hypothenar area may have more than one axial triradius. In such cases, the widest ‘atd’ angle i.e. the angle from the distal ‘t’ was recorded [figure-2].

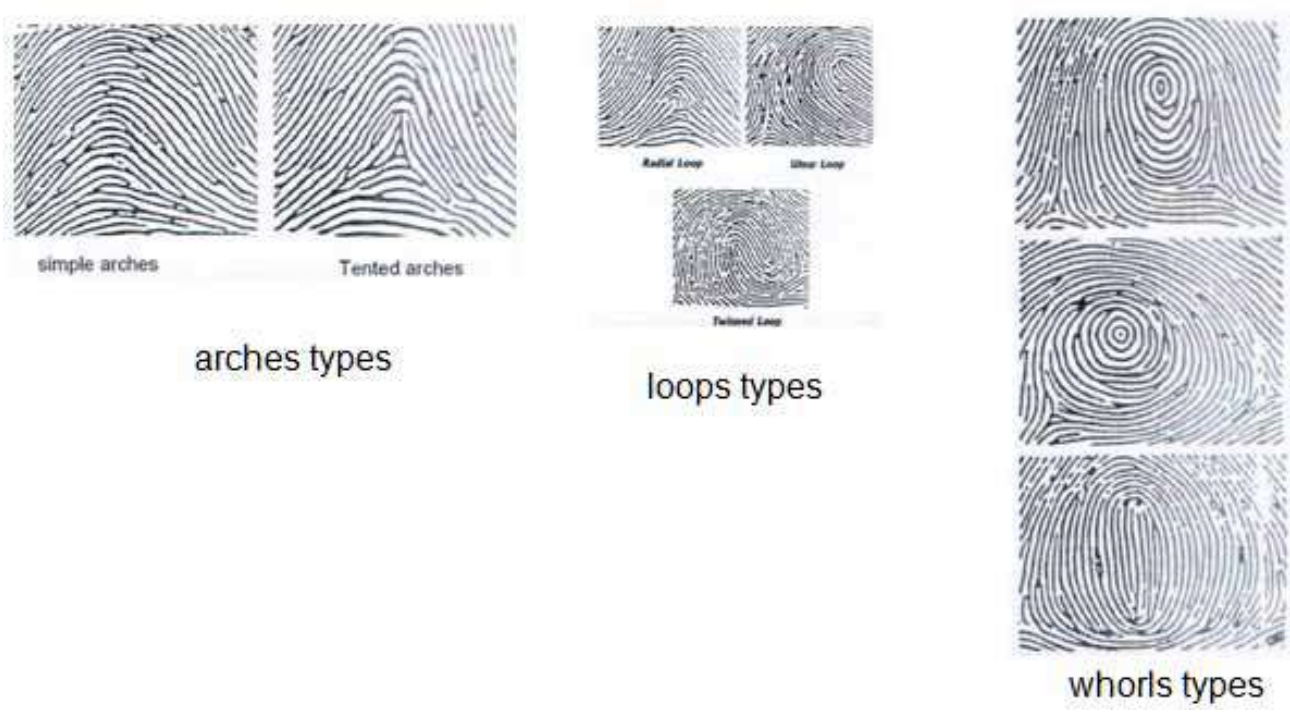

Figure 1: Finger Print Pattern Types

Results and Discussion

The frequency of digit patterns of class I (control), class II Div 1, class II Div 2 and class III on right and left hand combined showed increase arches in the experimental groups compared to control group and was found to be statistically significant ($p < 0.05$) due to x – linked inheritance. The frequency of digital patterns of the experimental groups showed decrease whorls compared to control group which was not found to be statistically significant which was also due to x – linked inheritance (Table 1).

The frequency of ulnar loops increased in class II malocclusion where as it decreased in class III malocclusion compared to control group and was not statistically significant because of the presence of extra genetic material which increase or decrease the ulnar loops. Similar findings were observed by kharbanda et al[7].

The frequency of radial loops is total increased in class II Div 2 and class III malocclusion groups and decreased in class II Div 1 which may be due to x. linked inheritance and the same finding were reported by forbes (15). (table-1).

The percentage frequency of digital patterns of males and females of each group were assessed. It was showed that the total finger ridge count was higher

in males than females in all groups. The percentage frequency of arches was higher in females than males while concerning whorls it was higher in males than females in all groups (table-2) . Holt[16] showed that in males the presence of each 'X' chromosome diminishes the total number of ridges in patterns nearly 3 times as much as does the presence of each 'Y' chromosome and in females the reduction of ridges seen as 'X' chromosome complement increase and is less regular.

The percentage of finger ridge count decreased in all experimental groups when compared to control group (table-3) because this is entirely determined by one or more additive or co-dominant genes and also the finger ridge count follow a polygenic mode of inheritance. Similar finding were reported by penrose and loesch".[17]

The mean value of "atd" angle decreased in all experimental groups compared to the control group on both right and left hands (table-4). This is because the plam grows more in length than breadth and the same was reported by penrose[18].

From this study we can conclude the followings: Class II Div 1 pattern accompanies the increase in frequency of arches on digit II and ulnar loops on digit IV except on digit I.

The class II Div 2 pattern accompanies the increase in frequency of arches on digit III and IV and decreased frequency of whorls except on digit I.

The craniofacial class III pattern accompanies the increase in frequency of arches on digit III and radial loops and the decrease in frequency of ulnar loops except on digit II and IV and whorl except on digit I.

No significant dermatoglyphic findings could be associated regarding digit V (small finger) with malocclusions.

Some Cardiac Indexes of Doping in Sport Comparative Analysis between Doping Users and Non-Doping Users

Mohannad N. Kzara[1], Mohammed H. Shaalan[2], Saad M. Farman[1]

[1]AL-Mustaqbal University College, Department of Physical Education and Sports Sciences, Alhila, Iraq,
[2]Directorate General of the Education of Babylon, Alhila, Iraq

Abstract

At present, the world is undergoing a major development in all life's aspects, which positively reflected on fundamental sciences and sport sciences. The principle of winning the match or losing depends on decent competition between sports teams. Steroids have been used in the past in the Olympic competitions since the 13th century when bicycles' racers in France used a medical mixture prepared from the substances of the (caffeine).

Belgium athletes used sugar pieces and others used alcohols. The first incident of drug-death-related, took place in 1882 when the British athlete Lenition died of using a large mixture of heroin and cocaine during a 200 kilometres bicycles' race between Bordeaux and Paris. In 1951 during the Winter Games in Oslo ice skitters used nitrogen and many capsules used as stimulants were found in homes as well.

Using steroids affects positively the athlete physical health fitness. However, this positive aspect contains side effects that have an impact on the athlete user's health. Experience has been proven that these side effects and damages sometimes reached to the extent of sudden death. For instance, if we assumed that one of the high-level athletes of any of the sports aspects of which the level is determined by muscular strength such as weight lifting, throwing, in the athletics …etc., giving specific doses of the fourth set of these steroids leads to an increase in the physiological section of different muscular groups. Especially if taking these steroids is accompanied with private exercises of athlete muscular strength where the fibres' size increases. The number of the fibres remains constant, thus leads to an increase in the muscular strength, which is already linked with the distance increases in the case of throwing and weight increase in the case of weight lifting.

Using steroids leads to a positive impact on the athlete's physical fitness, however, this positive aspect contains negative effects of users and negatively affect the athlete individual's health.Hence the importance of research is reflected in the study of the comparison between who take steroids and dietary supplements and others of who do not, from the standpoint of the sports hall trainers.

Keywords: *Cardiacindexes, Doping and Sport.*

Introduction

There has recently been an increase in the conversation about athletes use of doping and has occupied an important space in both international newspapers and magazines. After their widespread in various types, this prompted the researchers and the concern people to actively study the pros and cons that occur to the doping users.

Iraq is one of the countries that has been broadly influenced by doping, especially in the official institutions such as clubs and federations. In some case, informal ones such as bodybuilding halls and physical fitness centres. This is called to find out the positives about this subject and diagnose the negatives and stand on them.[1]

Many sports institutions aspire to reach an advanced level in order to precede their competitors and to develop the physical and sports level. For other

purposes, through using unnatural elements and inject them in the body or take through the mouth before or after the races. Therefore, researchers have sought to highlight this important subject. It has become a source of concern to many athletes, trainers and others of those who take steroids without enough knowledge of the possible damages.[2]

Sports dopes vary of each other, there are some, which increase the physical fitness, some develop the kinetic abilities and others work on building the body huge. The international bodies have banned most of these dopes for their danger to the general health asserting that it leads to extraordinary efforts, and beyond the heart bearing capacity.

Besides its long-term effects, there are some dopes expand the blood vessels causing health problems such as a sharp drop in the blood. Also, some dopes are restricted to old people as they are beyond the heart ability to work. Hence, the research demand is reflected in knowing some of the cardiovascular indicators on the doping users and dietary supplements and others in the sports physical fitness halls(gyms).The continuous use of dopes causes health problem as they stimulate the body's functions to alert the nerves system. Many specialists in this area warn against taking dopes especially the masculine ones that are used for bodybuilding, this excessive use to dopes might sometimes lead to death.[3]

Also, many trainers in physical fitness' training or in sports centres know nothing about the dopes and their near-far level effects. Some players used dopes excessively, ignoring the negative effects. Therefore, the researchers wanted to highlights on dopes and their effects on the heart through comparative research between dopes users and non- dopes users. We assumed at the beginning of the research of having significant statistical differences and cardiovascular indexes amongst doping users in bodybuilding halls.

Based on the above, the objectives of this study, have been set as follows:

1. Recognizing some cardiovascular indexes to dopes users in bodybuilding training centres.
2. Recognizing some cardiovascular indexes of non-dopes users in the same centres.
3. Making a comparison of some cardiovascular indicators of dopes users and others in bodybuilding training centres.

And for achieving these objectives, the human aspect of this study has been set to be the bodybuilding players in the sports centre (gyms) in Babylon City for a period of 10 weeks.

Materials and Method

1. Research methodology: the researcher used the descriptive approach in comparison way to match the research objectives.
2. Sampling: the number of dopes users has reached (31) players and non- dopes users were (31) players. The average age of the two groups players is between 25- 30 years.
3. Devices and facilities:
    a. The research facilities include the following:
        - Interview
        - Questionnaire
        - Tests and measurement
        - Observation
    b. Devices and instruments used in the research are:
        - Pressure device
        - Device of (Polar) hears rate measure
        - Graphical analysis

Research Procedures:

1. **Prepare a questionnaire to the centres' supervisors:** The researchers have prepared a questionnaire containing two questions to identify steroids users of others, according to the supervisors' view. It is difficult to obtain information from the players might be for social or personal reasons.
2. **Determining the research's variables:** The researchers selected the heart's research variables (resting systolic pressure, resting diastolic pressure, resting pulse, voltage pulsation and voltage resistance) depending on several scientific sources in this area.[4]
3. **Select tests for variables:** The researcher used several the regulated devices to conduct the tests for hearts indicators:
    a. Pressure device
    b. Device of Polar

c. Ruffier Dickson testing for heart resistance to voltage[5]

Ruffier Dickson Test: The heartbeats were counted following Ruffier Dickson method which contains three different times:

1. In comfort we leave the athlete to rest for a while when he/she inters into the hall then to calculate his/her heartbeats.
2. Immediately at the end of the exercise he/she is about to do
3. One minute after the end of the exercise.

The examining method depends on the following protocol:

- *FC_0 (Determining the resting pulses)*:The person stretching on the bed then we count pulses through hand wrist or neck within 10 seconds then multiply the total by 6 to get the number of the pulses per minute.
- *FC_1 (Determining the heartbeats immediately after the exercise)*: the athlete performs 30 squatting or flexing times, within 45 seconds by the same rhythm, were the legs at a distance of 20 cm. immediately after the end of the exercise to count the pulses in the same way and record that.
- *FC_2 (Determining the heartbeats after one-minute)*: after the end of the exercise, the athlete to rest for one minute then to count the pulses in the same way, time must be controlled carefully.

To work out Ruffier Dickson index, the following formula was used:

$$Ruffier\ Index = \frac{RC0 + FC1 + FC2 - 200}{10}$$

Where the coefficient of 200 is heartbeats average for high strength exercise for 10 seconds. Ruffier Dickson test result is compared to the table (1) to determine the level of adaptation.

Table (1): Interpreting the results of Ruffier Index (heart is adapted to exercise)

Index	Interpretation
< 0	Very good adaptation to exercise
0-5	Good adaptation to exercise
5-10	Average adaptation to exercise
10-15	Insufficient adaptation to exercise
15 <	Poor adaptation to exercise – further medical consultation is necessary

Identifying the obstacles and the problems that might encounter in the researching procedures (exploratory experiment) are taken into consideration, and summarised in the following:

- Perform tests to find out the time spent
- The sample individuals' acceptance of the tests
- Response of the Assistant Workforce

For statistical analysis, (SPSS) software were used.

Results and Discussion

The results of the two groups under investigation (dopes users and no- dopes users) are illustrated in table (2). Table (2) shows that there are differences and variances in the arithmetical means' values of tests of both groups (users and non-users) as well as there are differences and variances in the standards deviations. Whereas the sig-values of all are smaller than the (0.05) value, which indicates to a significant differences between the primary and secondary tests of the steroidsand nutritional supplements users' group.

Table (2): Shows the standard deviations, arithmetical means of the two groups

Research Variable	Sample Numbers		Means		Standard Deviation		Sig-value	Significant Type
	User	Non-user	User	Non-user	User	Non-User		
Resting Diastolic Pressure	31	27	9.29	7.66	0.78	0.77	0.00	Significant
Resting Systolic Pressure			13.52	12.03	0.93	0.64	0.00	Significant
Resting Pulse			76.52	70.33	2.43	1.55	0.00	Significant
Heart Effort Resistance			7.80	3.74	1.16	0.85	0.00	Significant
Diastolic Pressure During the Physical Efforts			10.35	9.11	0.79	0.32	0.00	Significant
Systolic Pressure During the Physical Efforts			14.25	13.52	1.09	0.55	0.02	Significant
Pulses During the Physical Efforts			174	171	4.62	2.52	0.03	Significant

Throughout, what has been displayed in the above tables, it is shown that there are significant differences in all study variables. This means that there is a differentiation in health level of the two groups. For Diastolic and Systolic Pressure, it was shown that there were differences in favour of the dopes' users during resting time as well as during the physical stress.

High blood pressure is one of the most serious health problems that the steroids' user might be exposed to. This problem has been described as a deadly health problematic might be caused by doping.

Taking drugs and steroids pills results in rapid, immediate and sudden activation of the blood circulation. The high blood pressure of the dopes' user, who is likely to be infected, increase simply by starting with a certain stress and then causing another double infection. The sudden rise in the blood pressure may lead to death[6].

Although dietary supplements are less harmful than dopes, but they have negatives that may accompany the athlete, such as, the creatinine, over-taking it may cause negative symptoms, taking overdoses may damage the kidney and it might also cause fluid retention in the body[7].

As for other measured variables during pulse resting and physical stress too, there has found a significant difference between the two groups especially the rise in heartbeats rate of users. This may threaten the heart and infect it with arteries deceases. Scientists describe that as one of the most serious deceases that infect the heart, as the drugs substances have a direct effect on the blood cholesterol and rise it in a noticeable extent. It hinders blood pumping to the different organs and tissues of the body. Also, it leads to the stress of the heart's muscle and to a sudden feeling of tiredness. Thus, the non-users' heartbeats rates are suite the exerted efforts (i.e. the more physical effort increases, the more the heartbeat increases steadily.[8]

Conclusions

We can draw the following analysis' results:

- There are significant differences in the research variables between the dopes' users and no-dopes users in favour of the users.
- Rising of heartbeats rates of the two groups after the physical efforts comparing to the resting times.
- Decreasing in heartbeats rates of non-dopes' users during resting time as a result of the athletes' adaption in comparing to dopes' users.
- Diastolic and systolic pressure was high during resting and efforts amongst steroids' users

Clinico-cytological Correlation of Cervical Pap Abnormality

Hamssa Hussein Aloan[1],Zainab Ali Issa[2]

[1]Al-Salhiya Health Center, Baghdad, Iraq, [2]Al-Yarmook teaching Hospital, Baghdad, Iraq

Abstract

Background: Few studies reported in Iraq about the clinicopathological correlation of Pap Smear results, and non was reported about this correlation among private clinic patient, as the knowledge of the authors. Therefore, this study was developed to study the clinic-pathological correlation of the Pap smear cytology results and the clinical presentation of the private clinic patients

Patient and Method: Cross sectional study of (144) patients presented to the privet clinic, during the period 1st January-1st September 2018. Information regarding age, job parity, marital status symptoms and patient complain and clinical examination of the patient was obtained via a structured questionnaire. The presenting signs & symptoms were compared with the Pap-smear findings and other factors. Cytological study done by cytopathology specialist. Conventional pap smear were used. Cytology was reported using Bethesda system. A single combined smear, was done for each patient by sampling the endocervix, first to obtain the cell sample. Scraping the ectocervix with the spatula and spreading the material rapidly onto the upper end of the slide. Spreading the endocervical material through the ectocervical material to the end of the slide. This procedure Performed quickly to prevent drying artifacts. Fixation of the slide done using spray fix by thoroughly soaking the cellular sample while holding the spray fixative container about 6-8 inches from the slide. Then allowing spray fixative to evaporate.

Results: NILM (negative for intraepithelial lesion or malignancy) found among 21(14.6%) of the patients 20 (13.9%) had cervicitis, and 1(0.7%) had atrophic changes in the cervix), Atypical Squamous Cell Undetermined Significant (ASCUS) 73(50.7%), followed by Low-grade squamous intra-epithelial lesion (LSIL) 39(27.1%), and High-grade squamous intra-epithelial lesions (HSIL) 9(6.3%). Squamous cell carcinoma was found among 2(1.4%) of the cases.

Conclusion: Iraqi women attending the priate clinic had high level of intraepithelial abnormality, even if it lower than other countries but it in need to be controlled by cervical cancer screening program, the common presenting symptom with increased rate of with various stages of intraepithelial lesion were post coital bleeding, and Irregular vaginal bleeding.

Keywords: *Conventional Pap smear, cervical cancer, clinical presentation.*

Introduction

Cervical cancer is the 2nd leading cause of cancer death among women 1, most of the cases occur in developing countries. 2 cervical cancer incidence in Iraq, estimated to be 2.1 per 100.000 popula-tions 3. About (23.2%) of the Iraqi women had abnormal intraepithelial lesions. Most of the cervical abnormality is due to HPV infection, the prevalence of HPV infection among Iraqi women with intraepithelial lesion was (23.2%).4 the incidence of cervical cancer has decreased by more than 50% in the past 30 years, largely due to the increasing use of cervical cancer screening with cervical cytology 5. Invasive cancer of the cervix results from the progression of pre-invasive pre-cursor lesions called cervical intraepithelial neoplasia (CIN),

Corresponding Author:
Zainab Ali Issa
Al- Salhiya Health Center, Baghdad, Iraq
e-mail: zatum95@gamil.com

or dysplasia. Not all pre-cursor lesions will progress to invasive can-cer many of the mild and moderate lesions may regress1.the cytological changes which appear in pre-invasive lesionsare nuclear enlargement, multinucleation, hyperchromasia with thin cytoplasm and perinuclearholo, in addition to the koilocy-totic atypia.[6]

Cytological abnormalities was classified according to Bethesda classification reporting system as: atypical squamous cells of undetermined significance(ASCUS), low grade squamous intra-epithelial lesion (LSIL) and high grade squamous intra epithelial lesion (HSIL).[7] Cervical cancer can be prevented through screening programs, designed to identify and treat the precancerous cytological abnormalities, it is able to identify about 90%of cytological abnormalities.[8] Developed countries stories show that population based pap test screening among sexually active women decreased the mortality and morbidity from cervical cancer about 40%.[9] In Iraq instead of increased rates of cancer and mostly diagnosed at advanced stage, there is no cancer screening programs only early detection clinics was present.[10,11] Few studies reported in Iraq about the clinicopathological correlation of Pap Smear results, and non was reported about this correlation among private clinic patient, as the knowledge of the authors. Therefore, this study was developed to study the clinic-pathological correlation of the Pap smear cytology results and the clinical presentation of the private clinic patients

Patient and Method

Cross sectional study of 144 patient presented to the privet clinic, during the period 1stjan-1stsept 2018. Inclusion criteria include married for at least 3 years, non pregnant, age $\geq$ 21 years, or married for at least 3 years, presented with signs and symptoms of .

Eclusion criteria: women with active vaginal bleeding, hysterectomy, and women with frank growth and/or who had never been sexually active or had undergone prior treatment for CIN or cancer cervix, or had unsatisfactory Pap smear were excluded from the study. Pap smear was done for all the patient.

Information regarding age, job parity, marital status symptoms and patient complain and clinical examination of the patient was obtained via a structured questionnaire. The presenting signs & symptoms were compared with the Pap-smear findings and other factors.

Cytological study done by cytopathology specialist. Conventional pap smear were used.Cytology was reported using Bethesda system.

A single combined smear, was done for each patient by samping the endocervix, first to obtain the cell sample. Scraping the ectocervix with the spatula and spreading the material rapidly onto the upper end of the slide. Spreading the endocervicalmaterial through the ectocervical material to the end of the slide. This procedure Performed quickly to prevent drying artifacts. Fixation of the slide done using spray fix by thoroughly soaking the cellular sample while holding the spray fixative container about 6-8 inches from the slide. Then allowing spray fixative to evaporate.

Statistical analysis and data management: The Statistical Package for Social Sciences (SPSS, version 18) was used for data entry and analysis. Chi (χ^2) square test, and t- test was used to compare means and proportions of different factors among different groups of study sample. P value of $\leq$ 0.05 was regarded as statistically significant. Bar charts and tables used to present the data

Results

NILM (negative for intraepithelial lesion or malignancy) found among 21(14.6%) of the patients. 20(13.9%) had cervicitis, and 1(0.7%) had atrophic changes in the cervix), Atypical Squamous Cell Undetermined Significant (ASCUS) 73(50.7%), followed by Low-grade squamous intra-epithelial lesion (LSIL) 39(27.1%), and High-grade squamous intra-epithelial lesions (HSIL) 9(6.3%). Squamous cell carcinoma was found among 2(1.4%) of the cases, as shown in table 1.

Table 1: The patient distribution according to the pap smear cytology results

Pap Smear Results	Frequency	Percent
NILM (Negative for intraepithelial lesion or malignancy)	21	14.6
ASCUS	73	50.7
Low-grade squamous intra-epithelial lesion (LSIL)	39	27.1
High-grade squamous intra-epithelial lesions (HSIL)	9	6.3
Carcinoma	2	1.4
Total	144	100.0

*Inflammatory cervicitis, reactive changes and atrophic changes

The mean age of the patient was 39.8±11.9 years, rang(19-70 years), the mean age for carcinoma was 51±16.9 years it was higher than the HSIL (42.2±12.2), LSIL (38.6±12.4), ASCUS (39.3±11.6), NLIM (41.5±11.9), this relation statistically not significant P > 0.05, as shown in table 2. Regarding parity, there was no difference among groups except for seq. cell ca. (4±1.4), rang (3-5), that is lower than the, HSIL (4.7±3), LSIL (4.4±2.3), ASCUS (4.5±3.1), NLIM (4.2±3.2), this relation statistically not significant P > 0.05, as shown in table 2.

Table 2: The correlation of the pap smear results, age, and parity.

Pap who classification		Parity			Age			
	N	Rang	Mean	Std. Deviation	N	Rang	Mean	Std. Deviation
NILM	21	(0-11)	4.2	3.2	21	(19-60)	41.5	11.9
ASCUS	73	0-11	4.5	3.1	73	(21-63)	39.3	11.6

There is a significant relation between the Pap smear results and patient presenting symptoms: the only symptom that associated with seq. cell ca. is the Post menopausal bleeding (PMB) 1(33.3%) diagnosed as seq. cell ca. and 1(3.8%) of those had other symptoms (external genital warts) had seq.cell ca.

Most symptoms associated with increased rate of intra epithelial lesion was Post coital bleeding(PCB), 5(13.5%) NILM, and 32(86.5%) different stages of intraepithelial lesion.

Irregular vaginal bleeding also commonly presented with various stages of intraepithelial lesion 12(92.3%), while abdominal pain was dominantly diagnosed as LSIL 4(57.1%), these relations is statistically significant, as shown in table 3.

Table 3: The correlation of Pap smear cytology and the presenting symptom

Symptom	Pap smear cytology result					Total
	NILM	ASCUS	Low-grade squamous intra-epithelial lesion (LSIL)	High-grade squamous intra-epithelial lesions (HSIL)	Carcinoma

Discussion

NILM (negative for intraepithelial lesion or malignancy) found among 21(14.6%) of the patients 20(13.9%) had cervicitis, and 1(0.7%) had atrophic changes in the cervix,this was lower than fund by Barzanjy B K et al [12](88.4%), Atypical Squamous Cell Undetermined Significant (ASCUS) 73(50.7%), Low-grade squamous intra-epithelial lesion (LSIL) 39(27.1%),and High-grade squamous intra-epithelial lesions (HSIL) 9(6.3%). Squamous cell carcinoma was found among 2(1.4%) of the cases,

It goes with Mezaal MI,[13] in Baghdad 2017,that Pap smears exhibiting lesions in the forms of NILM, ASCUS, LSIL, HSIL and Squamous Carcinoma were observed in (31.1%), (23.3%). (22%),(20%) and (3.3%) respectively, and goes with Abdulraheem A F, and KhudhairiJ M[14] 2014 in Baghdad HSIL (20%), sequamous carcinoma (1%), and with Abdulla K N et al15 2016 which found HSIL(29%), and LSIL(48%) among patient with unhealthy cervix attending gynecology clinic.

But these figures were higher than what found by Barzanjy B K et al[12]ASCUS (2.9%) to the presence of LSIL (6.3%), HSIL (2.1%) and invasive carcinoma (0.1%).And Al-Rubaiee et al 2006[16], which found (3.6%) of the sample was HSIL, and LSIL (33.7%).The difference is due to the fact that patients in our study were seriously ill and complain of chronic discharge, or irregular vaginal bleeding as it done among private clinic patients. In Saudi Arabia Magdy Hassan Balaha et al[17] found that(53.3%) of screened patient had abnormal pap cytology, and only (40%) of these abnormal cytology was diagnosed as LSIL and HSIL. in Telangana (2017) the HSIL represent (25%), LSIL(62.9%)of theTertiary Care Centre patients with Gynecological Complaints.[18]There is a significant relation between the Pap smear results and patient presenting symptoms: the only symptom that associated with seq.cell ca. is the Post menopausal bleeding (PMB) 1(33.3%) diagnosed as seq. cell ca. and 1(3.8%) of those had other symptoms (external genital warts) had seq.cell ca. Most symptoms associated with increased rate of intra epithelial lesion was Post coital bleeding(PCB), 5(13.5%) NILM, and32(86.5%) different stages of intraepithelial lesion. Irregular vaginal bleeding also commonly presented with various stages of intraepithelial lesion 12(92.3%), while abdominal pain was dominantly diagnosed as

LSIL 4(57.1%). Diagnosis of HSIL was (13.5%), of the post coital bleeding presentation, this lower than what found by Abdulla K N, et al[15] 2016 in Baghdad(44%), and higher than Obeidat RA, and Saidi SA[19] that studied cytological presentation of patient presented with post coital bleeding and found it (3.8%) had HSIL and cervical cancer (0.4%). LSIL was (16.2%) of post coital bleeding in this study this waa lower than found previously in Iraq (49%)[15]. ObeidatRA,and Saidi SA[19] (2012) found that (8.3%) of the post coital bleeding presentation was diagnosed as LSIL

Cervical cancer was (33.3%) of the post-menopausal bleeding presentation, and none of the post coital and irregular vaginal bleeding, while Obeidat RA, Saidi SA[19] found that (0.4%)of post coital bleeding presented patient had cervical cancer.

Abnormal vaginal bleeding was diagnosed as HSIL in (7.7%), this was lower than Abdulla K N, et al [15] 2016 in Baghdad (16%) .

Vaginal discharge diagnosed as LSIL among (36.2%) and non was diagnosed as HSIL, this was higher than found by Salih MM et al[20] 2017 LSIL (2%), and HSIL (1%).

The high percentage of sequamous intraepithelial lesions that found among private clinic patient which was higher than reported in other countries indicate the need for screening program to be implemented in Iraq and to consider the private as well as the public health services, in implementation.

Conclusion

Iraqi women attending the priate clinic had high level of intraepithelial abnormality, even if it lower than other countries but it in need to be controlled by cervical cancer screening program, the common presenting symptom with increased rate of with various stages of intraepithelial lesion were post coital bleeding, and Irregular vaginal bleeding.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the Al- Salhiya Health Center, Iraq and all experiments were carried out in accordance with approved guidelines.

Effect of Vernald Way (VAKT) for Multiple Senses, Health Care and Clinical Learning in Dealing with Hardship and Written to the Reading First Stage Pupils

Hashim Radhe Chither

Assist. Prof., Department Basic Property, University of Babylon, College of Basic Education

Abstract

Current research aims at identifying the impact of vernald way (vakt) for multiple senses to address the hardship I have written and reading the first primary stage pupils with special needs in Babylon, and this study was conducted in primary schools under the special education classes – Centre, in order to achieve the goal Search follow Finder experimental method, then choose Finder school Safieddine ornaments the midair school trial sample jeweler school officer, reconnaissance search sample number/9 first grade students raise for the experimental group in the school of Safieddine number/10 students from the first grade. Breeding for control group at the midair school, and took the same test researcher with ten paragraphs check a handout and persistence, and achievement test Finder dish on my sample experimental and research officer at 30/4/2019, then use in squared Pearson correlation coefficient and (Ki 2) and t-test for equality Independent waltbiain statistical method for processing data, and results from the experimental group than the control group, indicating that the method vernald (vakt) for multiple senses may bluff and superior.

Keywords: *(Vernal Parana (vakt) Para as maramihang mega) (panda dam an pagbabasa) (nakasulat and harp).*

Introduction

I stop Finder on the magnitude of the problem and the difficulties experienced by pupils in special education in learning reading and writing in the previous discussion, so I felt that running reading and written hardship Wizard experience I have disabled the first primary stage using the method vernald (vakt) for the senses. That dyslexia is a specific learning difficulties, is nervous, and correct identification difficult features or freewheeling words and poor spelling and ability to interpret symbols, these difficulties are often the result of a deficit in the phonologic level of language, and are not proportional to the cognitive capacities Yen and proper education, notes of the secondary consequences of the problem of difficulties in comprehension and literacy and clerical experience weakness hindering the development of vocabulary and background knowledge [13]. And that reading and writing are a major problem for pupils who have learning difficulties, where 80% of the those students have difficulty reading and writing on various skills, and that more than 25% of regular students they need to specialize in teaching reading and writing, and here lies the importance of teaching a Are built on proven scientific basis, specialized studies abound in recent years looking for effective teaching method and strategies for teaching pupils who have problems with reading and writing prevent attainment expected of them based on their environmental and health conditions to study. That the problems and difficulties in reading and writing to students with learning disabilities tend the vast majority of them who receive services with learning disabilities have problems and severe difficulties in reading and writing skills, and some are hard to cure, studies and research dealing with difficulties and problems Reading and writing have learning disabilities that their papers and their books or their books replete with numerous errors in spelling and grammar and structure, and complexity of the characters and styles of handwriting errors and dominated by the lack of control and regulation, often omit some words such as characters or characters The end or the Middle, and may

add some letters that are not associated with the word, and often the sentences they use short and disjointed and lacks meaning or content[10]. Researcher finds difficulty in reading and writing or reading and written hardship is one important cornerstone of academic learning difficulties, if not the key determinant and most importantly, where many researchers in the field of learning disabilities, dyslexia and writing represents the main reason Behind the school failure, dyslexia and writing case where the pupil is different from others in the processes of thinking and learning and skills take him auditory and Visual information storage and handling symbols, called in linguistic and non-linguistic communication processes and learning, where he finds Pupil difficulties in translating language to express ideas, thoughts, or understand the meaning of written words. Since in addition to learn reading and writing skills should continue to exercise it in the absence of practice reading and writing of pupils may have negative effects on children who are already defined categories and nominated for dyslexia and literacy, is a disorder that appears in pupil unable to learn Reading and writing despite having psychic powers despite receiving the appropriate education and training on how to read and write appropriate social and cultural background and dyslexia and writing in this case based on difficulties recognizing constitutive origin [13]. And pupils who suffer from problems with fluency literacy cannot distinguish words accurately reading the word punch slowly and without compiling the words complete sentence meaning, and many problems with reading, writing and reading decoding problems in reading the text orally by pupils who suffer from Learning disabilities and pupils who suffer from real problems in deciphering the words replacement to suffer from (dislkisia/dyslexia) and often suffer from slow learning. And pupils who suffer from written hardship usually have poor written production, their intelligence and abilities do not appear when looking at something they write, and there are indications written hardship among pupils, and this is evident in that they usually write short sentences and taking an abnormally long time in writing and This is due to a problem written hardship, their usually unreadable and using the eraser too much as well as leave spaces between words, characterized by frequent mistakes and clerical due to adapt the sound with the appropriate literal format, so that it does not represent the sounds heard in the word. Teaching method the method intended to provide skill to the pupil, there is no way or pattern tutorial or tools or means to suit all pupils with special needs in the classroom, and the severity and type of disability were factors affecting use of method and strategies and means, and shall Be modalities and styles and teaching strategies in special education variety based on oriented therapeutic diagnosis especially multi-sensory learning. There is no doubt that students who have difficulties in learning to read and write with impaired sensory perceptions as auditory or visual perception, pupil with dyslexia and writing down his ability compared to the average child in the process of receiving and analysis of information, and thus more in need To use more than one sensory channel in the process of learning these skills, meaning the urgent need to recruit more than cognitive tool in the learning process of association between written symbols and sounds it function defines a multiplayer mode senses[13].

Methodology

This chapter includes select research methodology and sampling procedures and prepare his tool and applied and the statistical method used in analyzing data.

Sample Search: Into adopted experimental method, because it is suited to the nature of his research, for being not only describe the current status of the event or phenomenon but also a clear and intentional interference by the seeker in order to reshape reality appears to use certain changes procedures and then note the results accurately, analysis and interpretation [18].

Action Research: Experimental Design: The experimental design is the plan Finder to get answers to questions and contains everything from currency researcher wishes to determine the problem and formulating hypotheses end data analysis and conclusions expected in access [25], depending type of experimental design On the nature of the problem and its variables and conditions sample, so the researcher adopted on experimental design with a partial seizure being compatible with the happenings of the current search, Figure 1.

Igbos (1):

Experimental na Disney Para samganaghahanap:

H	Combos	Independent variable	Dependent variable	Gadget
1.	Pilot	Parana ng Vernald (vakt) Para samaramihangmga panda dam	Koleksyon	Mental passbook
2.	Optical na	Tradisyunalnapamamaraan	Koleksyon	Pagsusuri ng mas magi.

Research community and appointed by:

Search Community: Saving all members of society or items or things that have properties one can observations (alagrsh, 2015 92), the researcher community primary school is opened in which rows of special education for boys and girls in the province of Babylon Centre for academic year (2018-2019), as a For the current search selection requires schools to be field of the search experience, the researcher visited the General Directorate of education Babylon book basic education faculty/14005 in 19/11/2018, approached school above-preparation and training departments of primary schools with special education classes with her book/2174 at 28/11/2018, and a copy to the Department of planning and statistics researcher visited the section got schools that opened the ranks of special education.

Search Sample: the sample is a subset in the original community, chosen in a certain way, and includes a number of elements of society and should be representative of the original community for uncles findings fully community (other meanings, 2012:86)

Sample School: in the midair school for boys picked because they contain special education first stage row elementary student population in/10 students, and then choose either school boys Safieddine being contains a row of first stage special education where pupils had/9 pupils, in a nest Weasel was a school for boys, experimental group Safieddine, the midair school for boys group officer.

Equal sets of search: Before the start of the experiment the researcher keen to conduct statistical research groups equal variables believed to affect the outcome of the experiment, including:(Chronological age calculated in months-school for parents-academic achievement for mothers), the researcher has obtained the data on those variables from direct pupils, school record, and after data collection and statistical treatment show that the calculated values are smaller than scheduling freedom degree values (17) and when Level indication (0, 5) this shows that statistically equivalent research collection in chronological age in school for parents.

Requirements:

Experience Duration: In began his experience on Sunday 17/2/2019, equal period to search groups pupils, and ended on Monday, 29/4/2019.

Select material: select in scientific material that will study for two sets of experimental and research officer during a trial and a number of book reading decision taught to pupils in primary school year first phase (2018-2019) [8]

Preparation of teaching plans: teaching plan is a package of regulatory measures established by the teacher to ensure the success of the process of teaching and learning goals, and described as a plan guide and teacher-oriented, then they are not rigid is applied literally, as well as their Flexibility to be adjustable and change [2], as the educational process could not successfully go without prior planning, so the researcher prepared a syllabus for my reading topics for first grade that will be studied in the experiment, in the light of educational content and objectives Behavioral school article in accordance with the method vernald (vakt) for multiple senses of the experimental group, according to the traditional method for the control group, and the view finder anmozegitin plans of those plans to a group of experts in education and psychology and teaching method to solicit their views And their proposals, in the light of his researcher observant experts the necessary amendments until ready for application.

Search tool: the achievement test preparation: tests a sample of paragraphs or questions varied types of interpretation and translation for each paragraph of a certain predetermined, upon sentencing an individual

or group of individuals, a group of various stimuli to provoke certain responses to the individual And estimate that by giving him the proper degree reflect the desired behavior availability [18], since the current search requires preparation test paragraphs pupils search groups to see the impact of the independent variable (vernald) in the dependent variable (address the hardship of reading books ABI) into test subjects taught in the course of decision taking into account test validity and reliability and objectivity.

Scoping Sample: Sample test Finder dish chosen reconnaissance ksdia-Zahawi school for boys consisting of number/9 special education students in the first grade and that was on Sunday, 14/4/2019.

Reliability Test: Reliability refers to the consistency of the results obtained from the application calendar tool for several times, is the steady results and not steady the instrument itself [14], since the first test was applied researcher on exploratory sample on Sunday two weeks after 14/4/2019 was prepared Article on Sunday 28/4/2019 test on the same sample, after correcting the results and apply the Pearson correlation coefficient turns out that stability is (0, 81) which is surely good, so I got the tool ready for application on a sample research pilot and officer.

Apply the Final Test: After you complete the search tool finalized researcher devoted Tuesday 30/4/2019 deadline for test pilot research and collection officer and assist teachers who studied art, and after completion of the test results have been corrected was given one degree For a correct answer and 0 for a wrong answer or abandoned.

Interpretation of results: the results of the experimental group viewed than a statement of method-vernald (vakt) for multiple senses to control group that studied the regular way, and returns an into because.

- That special education students with learning difficulties including dyslexia and writing so modern vernald way motivate came to participate and learn as well as special hardship cringe.
- Vernald method (vakt) for multiple senses all senses so that enables pupils to benefit from the other senses is the sense of weakness, served and was promoter of learning.
- Vernald method (vakt) for multiple senses using intensive teaching of approximation concepts which encourage students and measurement in learning to read and write.
- The incentives recommended by the vernald method has positive effects on recurrence behavior of learning to read and write among special education students.
- Vernald method (vakt) for multiple senses found its way into the hearts of students interacting with the parameter was encouraged to discover their strengths and bright positive points to learn reading and writing.

Conclusions

- Vernald method (vakt) in teaching reading and writing to the disabled helped outweigh the experimental group control group.
- Vernald manner helped students from the receiver position to the position effective participant in the learning process and become their focus learning process.
- Students with dyslexia and writing found FOMC vernald way (vakt) for multiple senses to benefit from other senses is deactivated.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the University of Babylon/College of Basic Education, Department Basic property and all experiments were carried out in accordance with approved guidelines.

Evaluation of Antimicrobial Activity and Study of Raman Spectra for Malachite Green Dye in Aquaculture in Solid State and Liquid State

Hwraa Abd Al-kreem Alewe[1], Lazem Hassan Aboud[1], Mohamed Hamza[1]

[1]*Department, Laser physics, Science Collage for Women,Babylon University, Iraq*

Abstract

This papers include the study of Raman spectra for different forms (solid and liquid) of the malachite green dye. Three concentrations (10^{-3},10^{-4},10^{-5}) Ml of dye solution are prepared in the water solvent and Raman spectra were measured using a wavelength laser beam (532 nm) A total of (11) major vibration patterns were obtained for the dye in concentration (10^{-3}) and (6) vibration patterns in concentration (10^{-4}) while the number of vibration patterns (5) in concentration (10^{-5}) Using a (pld) technique, a solid form(film) of dye was prepared on its own, When Raman spectra was measured, (8) vibratory patterns appeared, while the vibration patterns of dye were decreased when the dye film was prepared with the polymer. Vibration patterns were observed in all models prepared The most prominent (C-N str,C-H ben,C=C str).

Introduction

Visible radiation, which is emitted from most organic dyes, helps to be used as an effective medium in dye lasers. This has been considered the first tunable laser in the visible spectrum because it possesses a broad fluorescence spectrum, This allowed the laser output to be toned at any value selected within this broad range .Because of the abundance of fluorescent dyes, it is possible to select compounds that can produce laser emission, in any part of the ultraviolet, Visible, Near-infrared. The dye lasers produce a laser output, which can be toned to the wavelength range of 340 nm to 1.2 μm, depending on the type of dye used[1]. That distinguishes dye laser from solid and gas state lasers can be used as an effective medium in the liquid state. This results in high optical quality, which facilitates cooling operations and high pulse repetition rates. This leads to be a gain for a dye solution that is much larger than a gain in the gaseous state, plus it has to be approximated to the gain of solid state materials. Hard plastic rods - made from dyes embedded in plastic materials - can be used as effective media. The active medium in the organic dye laser is a fluoride organic material. Typical materials used as an effective medium are (Rhodamine), belonging to the (Xanthenes) family. These material are formed from their strong absorption ranges located in the visual ray region, and these substances are stimulated by optical pumping[2]. The dye used in this research is malachite green antimicrobial in aquaculature[3]. The signal that stand out from the dye lasers is a short pulse with wide spectral contents. These lasers are excite by the use of flashlights that are specially designed to produce high output power and It has a short period of pulse output. In addition, the dye laser has a high conversion efficiency, so it can produce short pulses, as:

$$\gamma_{gain} \propto 1/\tau$$

τ: Pulse time - γ: gain

These pulses can reach nanoseconds (10-9 n.sec) and pichoseconds (10-12p sec).Therefore, dye lasers will eliminate many of the constraints that stand in front of spectral studies that require high analytical ability, especially in the field of element enrichment, the separation of isotopes, as well as in the field of industrial and medical applications [4].Polymers are large molecules made up of small, interconnected units called the monomer. Polymers are sometimes crystalline and sometimes noncrystalline or a mixture of the two

[5]Most polymers lacking high electrical conductivity, so their uses are limited to their chemical and mechanical properties. As for the electrical uses of polymers, they are limited to electrical insulators because they have good electrical insulation properties [6].One of the organic polymer isolates poly astlen (PA) was discovered in 1977Which is characterized by the possibility of converting it into a polymer connector by treating it with appropriate defects through oxidation and reduction [7].Also, different types of ring and aromatic polymers have been discovered which behave in the same manner as these polymers have led to the formation of a new type of polymers called Conducting Polymers[8]. As this type of polymers very quickly got great attention and wide by researchers because the main reason behind the interest of researchers with these polymers is the possibility of using these materials in electronic applications, in addition to the acquisition of electronic circuits integrated dimensions under microwaves can be using these Polymers are easier to use than inorganic semiconductors[9]. As the use of this type of polymers in electronic applications led to the opening of a new branch called Molecular Electronics[10]. Some problems arose in the early stages of the discovery of this type of polymers. These problems hindered the development of these polymers. One of these problems is that they cannot be damaged in any of the solvents (Insoluble) or their fusion (Infusible).But in recent years, conductive polymers have been found to be able to melt and melt by adding some chemicals to the monomer unit[11]. The conductivity of some conductive polymers can be increased by increasing the rate of impurities. Among the polymers that are connected is the polymer (polyniline), which is considered one of the important polymers, and one of the characteristics of this polymer is the possibility of dissolution. This led to its presence in a conductivemanner which is thermally and environmentally stable [12]. Polyniline polymer is characterized by high electrical properties (in the process of pitting) with proton acids, and can be found polyoleylene either in the form of insulation (base) or salt (conductive) [13].

Raman Spectroscopy: The Raman Effect occurs when electromagnetic radiation impinges on a molecule and interacts with the polarizable electron density and the bonds of the molecule in the phase (solid, liquid or gaseous) and environment in which the molecule finds itself. For the spontaneous Raman effect, which is a form of inelastic light scattering, a photon (electromagnetic radiation of a specific wavelength) excites (interacts with) the molecule in either the ground rovibronic state or an excited rovibronic state. This results in the molecule being in a so-called virtual energy state for a short period of time before an inelastically scattered photon results. The resulting inelastically scattered photon which is "emitted"/"scattered" can be either of higher (anti-Stokes) or lower (Stokes) energy than the incoming photon as shown in Figure 1. In Raman scattering the resulting rovibronic state of the molecule is a different rotational or vibrational state than the one in which the molecule was originally, before interacting with the incoming photon (electromagnetic radiation). The difference in energy between the original rovibronic state and this resulting rovibronic state leads to a shift in the emitted photon's frequency away from the excitation wavelength, the so-called Rayleigh line. The Raman effect is due to inelastic scattering and should not be confused with emission (fluorescence or phosphorescence) where a molecule in an excited electronic state emits a photon of energy and returns to the ground electronic state, in many cases to a vibrationally excited state on the ground electronic state potential energy surface.

If the final vibrational state of the molecule is more energetic than the initial state, the inelastically scattered photon will be shifted to a lower frequency for the total energy of the system to remain balanced. This shift in frequency is designated as a Stokes shift. If the final vibrational state is less energetic than the initial state, then the inelastically scattered photon will be shifted to a higher frequency, and this is designated as an anti-Stokes shift. Raman scattering is anexample of inelastic scattering because of the energy and momentum transfer between the photons and the molecules during the interaction. Rayleigh scattering is an example of elastic scattering, the energy of the scattered Rayleigh scattering is of the same frequency (wavelength) as the incoming electromagnetic radiation.

A change in the molecular electric dipole-electric polarizability with respect to the vibrational coordinate corresponding to the rovibronic state is required for a molecule to exhibit a Raman effect. The intensity of the Raman scattering is proportional to the electric dipole-electric dipole polarizability change. The Raman spectra (Raman scattering intensity as a function of the Stokes and anti-Stokes frequency shifts) is dependent on the rovibronic (rotational and vibrational energy levels of the ground electronic state) states of the sample. This dependence on the electric dipole-electric

dipole polarizability derivative differs from infrared spectroscopy where the interaction between the molecule and light is determined by the electric dipole moment derivative, the so-called atomic polar tensor (APT); this contrasting feature allows one to analyze transitions that might not be IR active via Raman spectroscopy, as exemplified by the rule of mutual exclusion in Centro symmetric molecules. Bands which have large Raman intensities in many cases have weak infrared intensities and vice versa. For very symmetric molecules, certain vibrations may be both infrared and Raman inactive (within the harmonic approximation)[14].

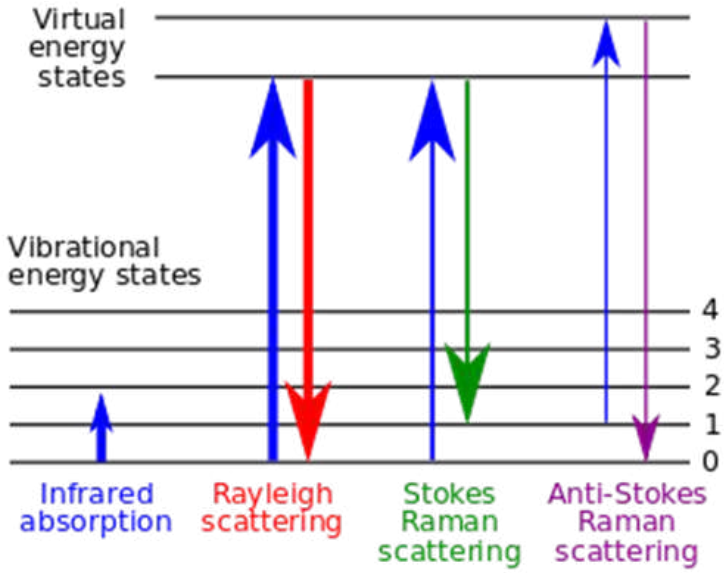

Figure 1: Energy-level diagram showing the states involved in Raman signal. The line thickness is roughly proportional to the signal strength from the different transitions[15].

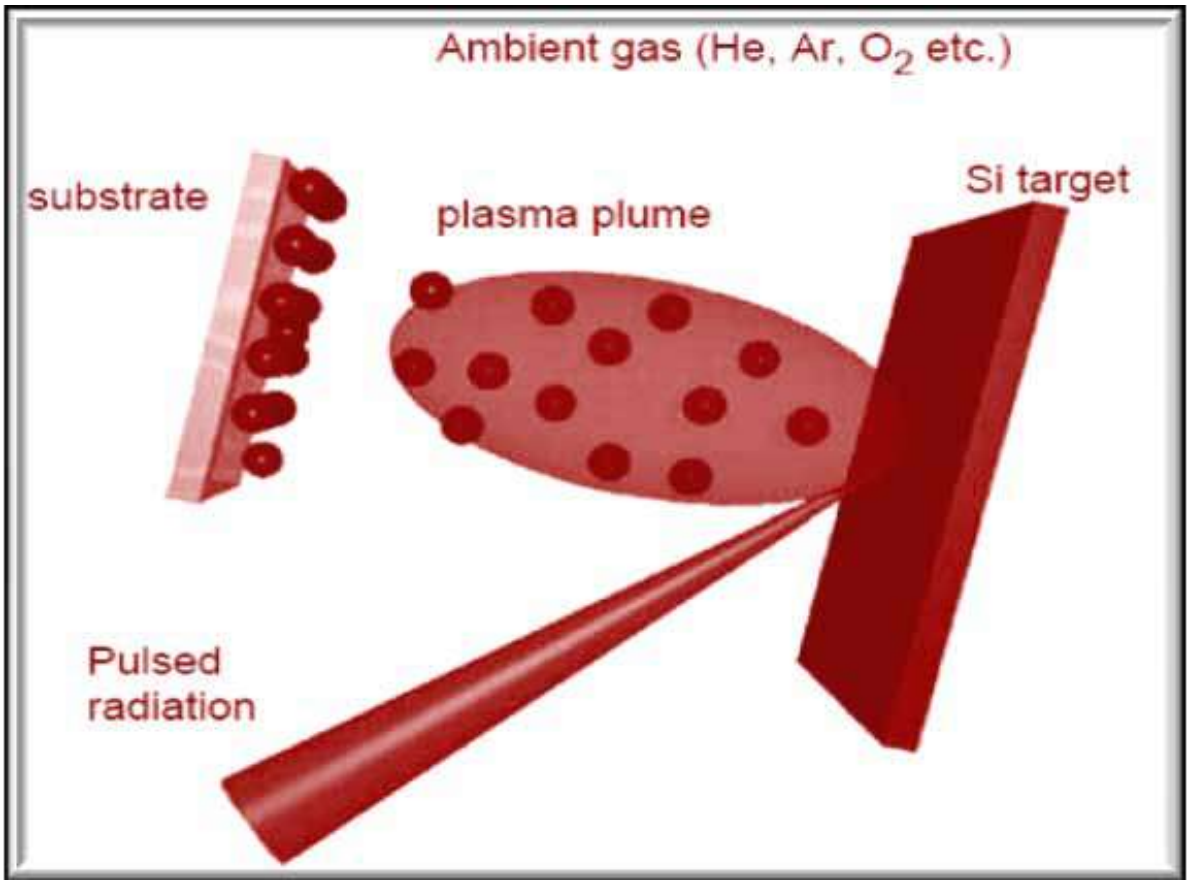
Pulse laser deposition mechanism (PLD): The process of scraping of the material occurs when the laser pulse is subjected to the hard target and is under gaseous conditions. And that the materials can be deposited on a slice or assembled or shaped in a powder. Although some applications such as applications fuel cells [carbon nanotubes] need to produce powder with nanoparticles[16,17]. However, most applications require nanoparticles in thin films.

Figure (2) shows the mechanism of pulse laser deposition. Lasers are usually used at UV wavelengths (192-248 nm) or through the second and third compatibility of the Nd-yag laser with wavelength (355,532 nm) and plasma is weakly absorbed for these wavelengths, reducing the effect of plasma on the skimming process.This technique is performed by focusing the laser beam on the target surface, which rotates at a 45° incidence angle. The energy density is usually between 108-109 W/cm^2.The incidence laser induce the plasma cloud to expand perpendicularly to the surface of the slide, which is placed on a rotary surface only a few centimeters from the targetThe slide holder is kept at room temperature or heated to improve the adhesion of the film to the chip. These slides are usually carried out with inert gas (He, Ar) and the gas is maintained at a low pressure (0.01-20 Torr). They are discharged from the air before being filled with gas.

The target material shall be placed in a high vacuum chamber and shall be at an angle of 45° with the incidence pulse laser. The atoms and flying ions are deposited from the target on the base, where the surface of the target and the surface of the base are parallel but have a certain distance[18].

1. The laser beam is placed directly on the surface of the target, and the focal lens is used. It is suitable for the laser beam to pass through an optical window that allows the laser beam to pass into the sediment chamber or use a glass door to allow the laser beam to pass.

2. The target material is rotated at levels x, y for the laser beam, so that the focus of the laser beam is ensured to remain regular with each pulse.
3. Before sedimentation, the sedimentation bases are heated primarily to make the film highly adhesive.
4. When gas and film material interaction are needed during the membrane growth process, the vacuum chamber of the laser deposition system is equipped with different gases such as (He, Ar, O2) and others.



Figure(2). Pulse laser deposition mechanism[17]

Preparation of the Samples: A concentration of 1x10-4 M l malachite green dye solution in cloroform solvent was prepared. The powder was weighting using an electronic balance type (BL 210 S) Germany having a sensitivity four digits.

$$W = \frac{M_W \times V \times C}{1000} \quad ...(1)$$

where

W: weight of the dissolved dye (gm)

Mw :molecular weight of the dye (gm/mol)

V: the volume of the solvent (ml)

C : the dye concentration (mol/l)

Different concentrations were provided according to the following equation:

$$C_1V_1 = C_2V_2 \quad ...(2)$$

where

C1: primary concentration

C2: new concentration

V1: the volume before dilution

V2 :the volume after dilution

Deposition of samples by laser pulse deposition: The pulsed laser deposition method was used to prepare nanoparticles of nanoparticles. This system consists

of the main parts shown in Fig. 5-3) consisting of the discharge chamber, the Nd-YAG pulse laser with a wavelength of 1064nm, a convex lens made of quartz with a focal length 30cm, window made of quartz glass, pressure control screen, rotary pump, spread pump, there are a set of steps we follow to prepare membranes which are as follows:

1. Clean the vacuum chamber using acetone alcohol and a soft cloth with attention to leaving the room for 24 hours exposed to air .
2. Put the floors of glass number 4 on the slide holder so that it is against the target on the rotor target holder so that the distance between the target and ground 4cm .
3. The Nd-YAG laser beam focuses on 140mj and pulse 150 of the PANI polymer using a convex lens with a focal distance of 30cm on the rotor target at a 45° angle.
4. Close the discharge chamber with all the valves closed and start the discharge by opening the rotary pump valve and when the pressure reaches 10^{-3} mbar The rotary pump valve is closed and the pump pump valve is opened until the chamber vacuum is reached 10^{-5} mbar.

Fig(3): Pulse laser deposition system.

5. Heat the floor using a halogen lamp until the temperature reaches 250C to increase the adhesion of the material to the ground.
6. After reaching the discharge required with the survival of the vacuum chamber valve is open, the laser pulses are given and the result is the case of the plasma that contains the particles that will be deposited on the ground.
7. Get the membranes are injected with a material poly aniline on the glass floors and undergoes visual and structural tests and electrical.

Results and Discussion

Conclusions

By studying the Raman spectra of prepared liquid samples it was observed that vibration patterns decreased with less concentration. When studing the Raman spectra of the solid form of dye (dye film), 8 vibration patterns were obtained. When studying the Raman spectra of the polymer film (poly Aniline), two types of vibration emerged. When adding polymers to the dye and studying Raman spectra, we note that the vibration patterns were reduced to (5).

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the Science Collage for Women, Babylon University, Iraq and all experiments were carried out in accordance with approved guidelines.

Abstract

Considering to progresses in the scientific reproductive research in both clinical medicine and basic science, in vitro fertilization (IVF) is one of the assisted reproductive technologies (ART) that is widely used for treatment infertility and increasing of pregnancy rate at infertile couples. In this study it was examined the effect of repaglinide on in vitro fertilization and embryo cleavage in mice oocytes. It was used female NMRI mice at 8 weeks old that after superovulation with injecting 5 IU of PMSG, followed by injection 5 IU of hCG at 48 h later. After preparation of sperm for in vitro insemination, MII oocytes randomly divided in two groups; control without repaglinide in IVF medium and treatment with 1µM concentration of repaglinide in IVF medium. Fertilized 4–6 h post IVF were oocytes washed and put in 50 µl droplets of culture medium. IVF and embryo development was assessed for 24, 48, 72, 96 and 120 h. The results showed that, in vitro fertilization, embryonic cleavage rate and the parameters of blastocysts quality such as the total cell number, trophectoderm (TE), ratio of TE/ICM and size of blastocyst in the repaglinide group were significantly higher than the control.

Keywords: *Repaglinide, Oocytes, In vitro fertilization, Embryo cleavage, Mice.*

Introduction

Human reproduction research has been focused on both scientific aspects and development of method for infertility treatments. One of the method of assisted reproduction technology that widely used to treat of infertility, is in vitro fertilization of oocyte[1]. During natural conditions, oocytes from mammalian species are fertilized in the fallopian tube, and the female reproductive tract provides the safe environment that the zygotes progress into cleaved embryos[2]. During the IVF process, gametes and the pre-implantation embryos are exposed to in vitro conditions, which are not completely similar, the oviducts and uterus as a natural environment[3]. In the current decade, in the IVF field significant advances have been made with an emphasis on improvement of clinical pregnancy outcome, for example in the many aspects such as induction of ovulation, drugs and diets, designing different cultivating systems and specially IVF culture media that play a major role in this success [4,5]. There are numerous commercially available culture media that contain various components including nutrients, vitamins and growth factors[6]. However, the evidence for a role of the composition of IVF culture media in these outcomes is often insufficient and controversial. The current media are mostly designed based on data from many years of laborious animal studies which are not always transferable in human embryology[7]. The greatest success and considerable information concerning *in vitro* culture requirements for

different stages of preimplantation embryos have been reported for mouse embryos due to similarity of the basic metabolic pathways between human and mice [8]. In the all animal species, calcium signals have critical roles in the fertilization and the progresses of developmental events [9]. A rise in intracellular Ca^{2+} is require for resumption of meiosis in the oocyte and causes to triggering the embryonic developmental program that called egg activation [10].ATP-sensitive potassium (KATP) channels have been identified in the cell membranes of cardiac, skeletal, smooth muscle and oocyte, which connect the cell metabolism and membrane electrical activity.

Materials and Method

All chemicals were purchased from Sigma Chemical Corporation (St. Louis, MO) and Life Global USA) unless repaglinidethat purchased from Farabi Corporation, Iran. Adult female and male National Medical Research Institute (NMRI) mice were kept under standard conditions (20-25˚C temperature, 50% humidity and 12 hours dark–light period) and fed with food and water. This experiment were performed according to the ethical guidelines for the Care and Use of Laboratory Animals in Razi University.

Collection of MII oocyte: Female mice aged 6–8 weeks (n= 30) were superovulated withintraperitonealiy injection of 5 IU of pregnant mare serum gonadotropin (PMSG) and fallowed by injection of 5 IU human chronic gonadotropin (HCG) after 48 h of injection of PMSG. 16–18 h after HCG injection, the superovulated female mice were dissected by cervical dislocation and MII oocytes were collected from the oviduct and cleaned from cumulus cells by pipetting.

Preparation of sperm: Caudal epididymis of 12 weeks old male mice were removed and cut in several zones. They placed in 1 ml of Hams-F10 medium containing 16 mg/ml of BSA and incubated at 37°C in 5% CO2/air for at least 30 min to allow sperm dispersion and capacitation. Then, by employing the swim-up technique, the supernatant containing motile spermatozoa was removed carefully. This solution was used to make 100-150 ml droplets of sperm suspension.

In vitro fertilization: IVF was performed as previously described with some modifications (Giritharan *et al*., 2007). MII oocytes were randomly divided in two groups and placed in the droplets of in vitro fertilization medium (IVF medium). In the control group IVF medium containing of Life global medium containing 16 mg/ml of BSA. In the repaglinide group IVF medium supplemented with 1μM concentration of repaglinide. 10 μl of sperm suspensions (final concentration of 1×10^6 sperm/ml) were added to 100 μl droplets of IVF medium that consist of a group of about 10 MII oocytes overlies by mineral oil and, incubated for 4-6 h. Then the oocytes were pipetted to remove the attached sperm and examined under a microscope for the presence of a second polar body or two pronuclei (2 PN) to confirm fertilization.

Embryo Culture: At 4–6 h post-IVF, the zygotes from control and repaglinide groups were cultured in groups of 10 zygotes per 30-μl drop of culture medium (life global medium consisting 4 mg/ml of BSA) that overlie by mineral oil and incubated at 37°C and 5% CO2.

Embryo Monitoring: The embryos were monitored daily under an inverted microscope (Olympus, IX71: Japan), and the embryo developmental rate was recorded at 24, 48, 72, 96 and 120 h post-IVF. At the end of culture period, the expanded blastocysts with a clear inner cell mass (ICM) were randomly selected by another observer and made ready for size measurement and differential staining.

Blastocyst Measurements: Blastocyst quantitative measurements of morphological features were performed according to the method described previously for human embryos (Richter*et al*., 2001). They were taken with the use of the measurement program for the Digital camera (Olympus; DP 72). Blastocyst diameter (from outer zona to outer zona) was recorded, along with the longest length and widest perpendicular width (in micrometers). A single size measurement for each blastocyst was calculated by using Factor Analysis. Blastocyst shape was quantified by calculating a roundness index (RI; RI = length divided by width). Blastocyst size was quantified by calculating length + width/2

Differential staining of blastocyst: According to the expanding, expanded and partially hatched stages, the blastocysts selected for calculating the number of total blastomeres by differential staining assay. Differential staining to separate the inner cell mass and trophectoderm cellswere done according to the method described by Park *et al*., (2002). Briefly, the zona-intact blastocysts were first incubated in 500μl of 100 μg/ml of propidium iodide (PI, Sigma) and 1% Triton X-100 at 37◦C for up to 10 s or until trophectoderm

visibly changed color to red and shrank slightly under a dissecting microscope.

Statistical analysis: All of the data were analyzed with SPSS software program (version 19: SPSS. Link., Chicago, IL) and the percentage IVF rate and embryo development rate was analyzed by chi-square test.The blastocyst measurement and cell number was evaluated by T-test and indicated as means±standard error of the mean (SEM).For differences between control and treatment groups, $p<0.05$ was considered statistically significant.

Results

In vitro fertilization rate: The effect of supplementation of IVF media with repaglinide on in vitro fertilization of MII oocyte seen from the percentage of pronucleus formed at 4-6 h post- IVF. In vitro fertilization rate for control and repaglinide groups were respectively; 84.64±0.18 and 94.36±0.05 that significantly difference was observed between two groups (Table1).

Evaluation of embryo development: The effect of supplementation of IVF medium with repaglinide on preimplantation embryo development examined from the percentage of the forming of 2 cells, 4-8 cells, morula and blastocyst at 24, 48, 72, 96 and 120 h of in vitro culture (Tab1, Fig1).Results showed that at 24 h of culture the percentage of 2-4 cells in the control and repaglinide groups were 78.30±4.23,5.21±2.80 and 81.74±2.88,9.31±3.40, respectively; there was significant differences in 4 cells embryos. At 48 h of culture the percentage of 4-8 cells embryos were 59.16±1.52,17.97±0.77 and 57.98±0.69,28.72±1.04, respectively; there were significant differences in 4-8 cells embryos. At 72 h of culture the percentage of 8 cells- morula-blastocyst were 29.53±4.99, 45.33±7.97, 1.77±1.44 and 19.8±4.07, 63.23±3.35, 6.20±1.86, respectively;significant differences was observed in 8 cells embryos, morula and blastocyst. At 96 h of culture the percentage of morula and blastocyst were9.72±1.53, 61.88±5.16 and 9.19±2.60, 73.93±3.46, respectively;there was significant differences in blastocysts stage. At 120 h of culture the percentage of blastocyst and degenerated embryos were 71.22±4.67, 5.33±2.20 and 84.52±2.27, 2.03±1.00, respectively; significant differences were observed between control and repaglinide groups.

Table 1: Embryo development in the control and repaglinide groups at different time of in vitro culture

Groups	0h N. MII	4-6h Fertilized oocyte%	24h 2-cell% 4-cell%	48h 4-cell% 8-cell%	72h 8-cell% Mor% Blast%	96h Mor% Blast%	120h Blast% Deg%
Control	235	84.64±0.18[a]	78.30±4.23[a] 5.21±2.80[a]	59.16±1.52[a] 17.97±0.77[a]	29.53±4.99[a] 45.33±7.97[a] 1.77±1.44[a]	9.72±1.53[a] 61.88±5.16[a]	71.22±4.67[a] 5.33±2.20[a]
Repaglinide	225	94.36±0.05[b]	81.74±2.88[a] 9.31±3.40[b]	57.98±0.69[b] 28.72±1.04[b]	19.8±4.07[b] 63.23±3.35[b] 6.20±1.86[b]	9.19±2.60[a] 73.93±3.46[b]	84.52±2.27[b] 2.03±1.00[b]

Data are presented as means±SEM. N: Total number. a/b Values within columns with different superscripts are significantly differences (chi-square test, $p < 0.05$)., Mor: morula; Blast: blastocyst; Deg: degenerated.

Measurement of blastocyst diameter and cell number: At 96h post-IVF, the parameters relate to the blastocysts quality such as the total cell number, trophectoderm (TE), inner cell mass (ICM), ratio of TE/ICM, shape and size of blastocysts were assessed (Tab2, Fig2). Results indicated that the mean of total cell number in the control and repaglinide groups were 52.27±1.38 and 63.44±0.90, respectively;the mean of TE cell number were 37.62±1.08 and 46.17±0.61, respectively; the mean of ICM cell number were 14.65±0.49 and 17.24±0.34, respectively; ratio of TE/ ICM were 2.62±0.08 and 2.69±0.03, respectively; shape of blastocysts were 0.97±0.02 and 0.99±0.02, respectively and size of blastocysts were 68.17±0.69 µm and 80.22±0.53µm. Significant differences were observed in thetotal cell number, TE cell number, ratio of TE/ICM and size of blastocysts in the repaglinide group in comparison to the control group, but there were not a significant difference in the ICM andshape of blastocysts between control and repaglinide groups.

Table 2: Comparison of blastocysts cell number and size in the control and repaglinide groups after 96h of in vitro fertilization of mice MII oocytes

Group	N. Blastocysts	N. Total cells	N. TE	N. ICM	TE/ICM	Size of blast (µm)	Shape of blast (RI)
Control	30	52.27±1.38 a	37.62±1.08a	14.65±0.49 a	2.62±0.08 a	68.17±0.69 a	0.97±0.02 a
Repaglinide	30	63.44±0.90b	46.17±0.61b	17.24±0.34 a	2.69±0.03 b	80.22±0.53 b	0.99±0.02 a

Data are presented as means±SEM. N: number. a/b Values within columns with different superscripts are significantly differences (t-Test, $p < 0.05$). TE: trophectoderm; ICM: inner cell mass.

Discussion

Repaglinide with hypoglycemic activity is widely used for the treatment of non-insulin-dependent diabetes mellitus, which by inhibition of K-ATP channels on the pancreatic β cells membrane, via opening the voltage gated calcium channels and subsequently increasing of intracellular calcium lead to depolarization of the cell membrane and finally insulin secretion from these cells [11]. In this study, we examined thein vitro fertilization and embryonic cleavage rates of mice MII oocytes, after supplementation of IVF medium with repaglinide. Our results showed that supplementation of IVF medium with 1μM concentration of repaglinide, cause to significantly improvement, in the IVF rate and subsequently embryo development rate during in vitro culture. Ultimate goal of in vitro fertilization studies such as examine of basic molecular physiological, morphological process during IVF of gametes are used for human infertility treatment and produce of embryos in the domestic animal industry The preimplantation mammalian embryos at the in vivo condition, for more development influenced by autocrine, paracrine and endocrine factorsThe results from study of Blancato and Seyler (1990) showed that incubation of sperm and eggs with a Ca^{2+} channel blockers such diltiazem and 8-(N,N-diethylamino)octyl-3,4,5-trimethoxybenzoate (TMB-8) at 30 and 3 μM concentrations caused to depression of fertilization and depressed progression of mouse embryos from 2-cell to blastocyst stage at compared with controls.

Conclusion

Despite the importance of gametes quality on embryonic development, often suboptimal embryo culture conditions are largely responsible for poor in vitro embryo development. Many efforts have been made to improve the formulations of IVF culture media for more improvement of pregnancy and implantation rates. Considering this subject, our results suggest that supplementation of IVF medium with repaglinide can be improve the in vitro fertilization and developmental competency of preimplantation mouse embryo.

Kurdish Traditional Herbal Medicine to Treat Mouth Thrush

Fouad H. Kamel[1], Shawnim Abdulla Ismail[1], Sangar Sabah Sabir[1], Adnan N. Albidani[2]

[1]Erbil Medical Technical Institute, Erbil Polytechnic University, Erbil, Iraq, [2]College of Bilad Alrafidan University

Abstract

Natural plant products are one of the important fields of research for the prevention of immunological complications. Recently, herbal medicine and plant extracts have been utilized as a substitute for commercially accessible chemical drugs for control of infection diseases. Because of chemical drugs have unpleasant side effects and caused rug-resistant microorganisms. This study aimed to evaluate the effect herbal mixture of *Rhuscoriaria* L. and peppermint water extract on five common oral bacteria. The well-plate system in BHIA (Brain Heart Infusion Agar) medium was used for primary assessment of the antibacterial properties of water extract plants. The minimum inhibitory concentration (MIC) of the extract was determined against each microorganism using macrodilution method. Diameter of the zone of growth inhibition was proportional to theconcentration of the extract tested. This study found that the largest MIC was observed to be against *Staph.aureus.* Despitethe usage of herbal combination of *Rhuscoriaria* L. and peppermint water extract has been recorded in prevention of mouth thrush for 10 donor patients. Therefore, both materials have a great potential to be developed as a safe and strong antibacterial activity against pathogens concerned with oral infections.

Keywords: *Rhuscoriaria L., Menthapiperita L., Water extracts, Antibacterial activity.*

Introduction

Medicinal plants have been used to treat various diseases since ancient times[1].Many species of plants reported to have pharmacological properties through different secondary metabolites[2-4]. Recent studies indicated that bioactive compounds have increased interest in plants as potential therapeutic agents with antimicrobial activities[5,6] these agents have fewer side effects, better patient tolerance, and relatively less expensive compared to conventional antibiotics[7]. According to World Health Organization (WHO), more than three quarters of the world population depend on plants and their extracts for health needs[8]. In this connection, Sumacis the common name forgenus (Rhus) containing more than 250 individual flowering plant species in the Anacardiaceae family[19]. Rhuscoriariacan grow in non-agricultural areas and it is commonly used as a spice by grinding the dried fruit with salt and also widely used in the Middle East Asiamedicinalherb, especially for wound healing[10,11]. The extracts of R. coriariafruit have been showed to contain high levels of polyphenols for example, anthocyanins, Gallic acid, and hydrolysable tannins[12]. A variety of biologically active phytochemicals of R. coriariautilized within natural medicinal products as antibacterial,antiseptic, antiviral, anti-dysenteric, anti-diarrheic, antispasmodic, astringent, hepatoprotective, protisticide, analgesic, antiulcer, ant gastric, antioxidant and anti-inflammatory[13]. Peppermint or mint (Menthapiperita L.) is also an important medicinal plant belonging to the Labiatesfamily [14]. The leaves are stalked opposite, toothed and the flower is irregular in shape [15]. Peppermint leaves contains around 0.5-4% volatile oil consisting of 50-78% free menthol, menthofurane, monoterpene, and traces of jasmine 0.15% to significantly improve the quality of the oils[16]. Herbalists consider Peppermint as an astringent, antiemetic, antiseptic, carminative, analgesic, diaphoretic, antimicrobial, mild bitter, rubefacient, and

stimulant [17-19]. In addition, menthol and peppermint oil have moderate antibacterial effects on both gram-positive and gram negative bacteria[20]. Watery extracts of peppermint leaves were antiviral [21,22].Oral health greatly affects the overall quality of life, and poor oral health has a greatlyaffects chronic conditions and systemic diseases[23]. In the oral cavity,more than 700 bacterial species were detected.Some of these bacteria were implicated in oral diseases like caries and periodontitis [24]. Many oral infections are corrected by herbal medicines[25]. To the best of our knowledge, there are no available reports on the optimizingthe extraction of polyphenols as alternative natural Kurdish treatment on bacterial and viral infection of the mouth. Therefore, in this study has been attempted the use and identificationof medicinal plantsthat are used in safelytraditional medicine to treat mouth infection.

Materials and Method

Sample Preparation: *Rhuscoriaria* and Peppermint locally agriculture in Kurdistan region werecollected from the Erbil bazaar.

a. Extract preparation. In order to prepare the extract, 100mL of water was added to 10 g of *Rhuscoriaria* and the mixture was boiled for 5 minutes.

b. Extract preparation of peppermint by adding 100mL of water to 10 g of peppermint leaves and then boiled on burner for five minutes.

c. The *Rhuscoriaria* and peppermint were combined together in water and again the mixture was boiled for about 5 minutes.

In all cases the mixture stored at room temperature for 2 hours to allow the infusionprocess. Lastly, the obtained mixture was filtered through Whatman No.1 filter paper. After that, the extract could be used directly in treatment or were dry at 40ºCand stored in a sterile bottle at 4°C.

Pathogenic Microorganisms: *The bacterial strains including *Streptococcus mutants*, *Staph.aureus*, *E.coli* and *Pseudomonusaeruginosa* of patients after lab diagnosis [26] were received from medical laboratory in ministry.

*Microbial suspension with a bacterial count of 1.5 x 10^8 CFU/mL was prepared with normal saline solution[27]. The prepared microbial suspension for each bacterial strain was cultured on plates containing Brain Heart Infusion Agar and then wells with 6 mm diameter were created[28].

100 µl of the extract solution prepared with sterile distilled water at ratio 1:1, 1:2, 1:3, 1:4, 2:1, 3:1, 4:1gm of *Rhuscoriaria*: Peppermint gradually per 100 mg/ml of sterile water.

The tests were done in three replicates and all plates were stored at 37° C overnight. To determine the MIC afterwards, the diameter of growth inhibition zone was measuredcompared to the negative control group.

Treatment of patients with Thrush:

Ten donors of diagnosed oral thrush infection had being treated with prepared herbal mixtures by swabbing over the thrush three times daily.

Result and Discussion

In this research, primary evaluation of the antibacterial effect the herbal mixture of *Rhuscoriaria*L. and peppermint water extracts were done utilizing the well-plate technique[29].For each bacterial strain subjected to distinct extract levels, the mean diameter (mm) of the growth inhibition area is concluded in Table(1)*Rhuscoriaria*L. And peppermint water extracts demonstrated antibacterial impact on the contemplated microscopic organisms since the growth of all five bacterial strains were repressed by different concentrations of the extract. The growth inhibition area diameter was proportional to the extract concentration of *Rhuscoriaria*L. and peppermint within the third ratio. However, diameter of the growth inhibition zone began to decrease at (1:4) ratio for *Rhuscoriaria*L. and peppermint, respectively. The size (diameter) of growth inhibition area ranged from 6 to 20 mm.

Staph.aureus was noted with the biggest growth inhibition zone as a consequence of extract exposure was at (4:1) ratio. Similarly, these observations were recently reported by other researcher [30].

Table (1): Presented effect of different Rhus:Pepp.ratio on microbial growth(MIC diameter)

Ratio Rhus: Pepp.	MICdiameter of microbial growth inhibition zone measured in mm				
	Str. mutants	Staph.aureus	E.coli	Ps.aeruginosa	Candida.
1:1	6	7.5	6.5	7	7
1:2	6.5	6.5	7	7.5	7
1:3	8	9	8	8.5	8
1:4	6	6	6	6	6
2:1	11.5	13	12	11.5	13
3:1	17	17	17	17	16.5
4:1	19.5	20	19	18.5	19.5

Treatment of patient with Thrush: Ten donors of diagnosed oral thrush infection had being treated with prepared herbal mixtures by swabbing over the thrush three times daily. After that, the patients fill painless within few hours, while they healing of infection. In addition, the healing of donor patients with thrush is a practical guide to the use of this herbal mixture as a popular positive healing treatment among people.

Conclusion

The herbal medicines have shown to have a wide array of biological properties like antioxidant, antimicrobial, and anti-inflammatory effects. As concluded that both products have activity against pathogenic bacteria whatever the sumac extract killed the bacteria while the other one (mint)acts as a mild anesthetic. Therefore, the findings of this research are very encouraging and indicate that this herb should be explored further to investigate its potential in the treatment of infectious diseases. For the future study, as the combinations of several spices could be proven to possess higher inhibitory effects on specific bacteria than those of individual spices.

Evaluation of Students' Self–management and Academic Achievement in the University of Baghdad

Basima J. Jasim

Instructor, Al-Kindy College of Medicine, University of Baghdad

Abstract

Objective(s): To evaluate university students' self-management and academic achievement; to compare between these students relative to their self-management and academic achievement; and to determine the relationships between these students' self-management, academic achievement and their socio-demographic characteristics in the University of Baghdad. For the period of November 2nd 2018 to May 30th 2019.

Method: A descriptive design, using the evaluation and comparison approaches, is employed throughout the study. Two self-evaluation questionnaires are constructed for the purpose of the presents study. Content validity and internal consistency reliability are determined for the study instruments through a pilot study. A non-probability, purposive sample, of (80) university students is selected from the Medical Colleges, College of Engineering, College of Sciences and College of Education in the University of Baghdad. Data are collected through the use of the study instruments and the structured interview technique as means for data collection for the period of February 21st 2019 to March 20th 2019. Data are analyzed through the application of the descriptive statistical data analysis approach which includes frequency, percentage, mean, total score and range and inferential statistical data analysis approach of Analysis of Variance and Multiple Linear Regression.

Results: The study depicts that most of the college students experience fair to good level of self-management and good level of academic achievement.

Conclusion: The study concludes that students do not present differences in their self-management and academic achievement. Self-management is affected by students' gender and education and academic achievement is influenced by students' socioeconomic status

Keywords: *Evaluation, Comparison, Self-management, Academic Achievement, University of Baghdad.*

Introduction

Self-management is a key assistant for all learning (for children and adults!) for both materials and academic courses, and other content areas, or skills. Self-management allows students to follow through plans to complete the tasks, and study of the tests, and continue to focus in the classroom. In adults, it is important that the objectives of access in the field of learning, such as the development of new professional skills [(1)].Self-management helps students become successful learner. It refers to the strategies, techniques and method that we use to guide the activities and behaviors effectively when it comes to the study, including self-management, setting goals, planning and time management. Self-management is an essential skill that will help them throughout their lives [(2)].Students should be invited to the learning management process in the classroom. Here are some of the tools used by many teachers to enable students to self-management [(3)].It found self-management techniques to be more effective in student behavior management interventions mediated by the teacher. When self-management strategies are related to behavioral interventions and equal Functionally, the students increased the amount of time in the job, and showed social behaviors more convenient, and completed more tasks. Self-management interventions

for student self-monitoring include: notes both the students and records the target behaviors and self-assessment: It compares the performance/her with the specified criteria and self-education student is directed oriented student behavior through the use of personal data and setting goals: Students set a target and create a personal commitment and guidance for progress towards this goal [4].Academic achievement for students is the current level of student learning. More specifically, for the purposes of each student succeed in the accountability act (ESSA), academic achievement refers to the percentage of students in the school that meets their learning standards currently classroom level or beyond. This achievement is measured using tests at the state level in math and reading. Achievement is measured also by using assessments in the case of science, but will not be used scientific assessments of accountability under ESSA. Often measure the academic achievement of the students in terms of the semester or cumulative average point for graduates (GPA) or the number of courses or credit hours that have been completed [5].Research concerned with the phenomenon of academic performance of students during the learning process based on the average score points (GPA). In this regard, students' ability to control the factors that affect the learning process, which is called academic self-management affected. A successful student is regarded as the one who is able to control the factors which influence their learning process. A study is conducted to verify the role of academic self-management in improving students' academic achievement. The quantitative methodology with a simple random sampling technique is employed. The total samples are (105) students of Padjadjaran University. The results show that (78%) of the subjects possessed high academic self-management, meaning that the majority of subjects used academic self-management to control factors which influence the learning process. The final model of academic self-management can be used in order to empower students to improve their academic achievement, so that they have capital to move forward and build their future (6).Based on the early stated evidence, the present study ought to evaluate students' self-management and academic achievement at Colleges in the University of Baghdad.

Methodology

A descriptive design, using the evaluation and comparison approaches, is carried throughout the present study to evaluate colleges students' self–management and academic achievement; to compare between these students relative to their self-management and academic achievement; and to determine the relationships between these students' self-management, academic achievement and their socio-demographic characteristics in the University of Baghdad for the period of November 2nd 2018 to May 30th 2019.The study is conducted on students at Medical Colleges (Medicine, Dentistry, Pharmacy and Nursing), College of Engineering, College of Sciences, and Ibn Al-Rushud College of Education in the University of Baghdad. A "non-probability" purposive, sample of (80) university students, is selected. The sample is comprised of (20) students from Medical Colleges (Medicine, Dentistry, Pharmacy and Nursing), (20) students from College of Engineering, (20) students from College of Sciences, (20) students from Ibn Al-Rushud College of Education. It is consisted of (40) males and (40) females and (18-27) years old. Each student, who has participated in the present study, has signed a consent form for the agreement to be involved in the study and as prerequisite for the ethical consideration. Two questionnaires, Students' Self-management (21) items and Students' Academic Achievement (20) items, are constructed for the purpose of the study throughout review of relevant literature and consultation with a panel of experts.A pilot study is carried out from January 7th 2019 to February 20th 2019 to determine the internal consistency reliability and content validity of the study instruments. The internal consistency reliability of the questionnaires is determined through the use of split-half technique and the computation of Cronbach alpha correlation coefficient. A purposive sample of (20) student is gathered for the purpose of the reliability of the study instruments. The results indicate that the correlation coefficient is ($r = 0.87$) for the self-management questionnaire and ($r = 0.88$) questionnaire to the academic achievement questionnaire. Such scores reveal that the study instruments are adequately reliable measures for the concepts underlying the present study. Content validity of the study instruments is determined by panel of (12) experts. These experts are faculty members at the early mentioned colleges in the University of Baghdad. They are provided with copies of the questionnaires and asked to review and evaluate the study instruments for content clarity and adequacy. Their responses depict that the study instruments are valid measures for the phenomena underlying the study. Data are collected through the use of the study instruments and the structured interview technique as means for data collection for the period of February 21st 2019 to March 20th 2019. Data is analyzed

by applying descriptive statistical data analysis approach which includes the frequency, percentage, mean, total score and range and inferential statistical data analysis approach which includes analysis of variance and multiple linear regression.

Results

Table (1): Overall Evaluation of the Colleges Students' Self–management

Frequency and Percentage	Levels	List
4 (5%)	Poor (21–34.33)	1
30 (37.5%)	Fair (34.34–43.67)	2
46 (57.5%)	Good (43.68–63)	3

This table depicts that most of the college students have experienced good level of self-management (57.5%) but more than one third of them have experienced fair level of self-management (37.5%).

Table (2): Overall Evaluation of the Colleges Students' Academic Achievement

Frequency and Percentage	Levels	List
0 (0.0%)	Poor (20–22.33)	1
0 (0.0%)	Fair (22.34–34.67)	2
80 (100%)	Good (34.68–60)	3

This table depicts that all of the colleges' students have experienced good level of academic achievement (100%).

Table (3): Analysis of Variance for the Comparison between Students Relative to Their Self-management

Source of Variance		Sum of Squares	Df	Mean Square	F	Sig.
SMM	Between Groups	1149.633	11	104.512	1.752	0.218
	Within Groups	477.167	8	59.646		
	Total	1626.800	19			
SME	Between Groups	591.383	11	53.762	0.353	0.944
	Within Groups	1219.167	8	152.396		
	Total	1810.550	19			
SMS	Between Groups	846.833	11	76.985	0.657	0.746
	Within Groups	937.167	8	117.146		
	Total	1784.000	19			
SMEDUC	Between Groups	495.667	11	45.061	0.506	0.854
	Within Groups	712.333	8	89.042		
	Total	1208.000	19			

SMM= Self-management of Medical Students, SME= Self-management of Engineering Students, SMS= Self-management of Sciences Students, SMEDUC= Self-management of Education Students, df= Degree of Freedom, F= F- statistics, Sig.= Level of significance at $p \leq 0.05$

The results, from this table, reveal that there are no significant differences between self-management for students with regard to the type of total differences.

Table (4): Analysis of Variance for the Comparison between Students Relative to their Academic Achievement

Source of Variance		Sum of Squares	Df	Mean Square	F	Sig.
AAM	Between Groups	1150.050	18	63.892	0.354	0.890
	Within Groups	180.500	1	180.500		
	Total	1330.550	19			
AAE	Between Groups	1072.050	18	59.558	0.191	0.966
	Within Groups	312.500	1	312.500		
	Total	1384.550	19			

Source of Variance		Sum of Squares	Df	Mean Square	F	Sig.
AAS	Between Groups	957.300	18	53.183	0.879	0.700
	Within Groups	60.500	1	60.500		
	Total	1017.800	19			
AAEDUC	Between Groups	1465.500	18	81.417	0.563	0.801
	Within Groups	144.500	1	144.500		
	Total	1610.000	19			

AAM= Academic Achievement of Medical Students, AAE= Academic Achievement of Engineering Students, AAS= Academic achievement of Sciences Students, AAEDUC= Academic achievement of Education Students, df= Degree of Freedom, F= F- statistics, Sig.= Level of significance at $p \leq 0.05$

Results are presented from this table that there were no statistically significant differences between the academic achievements of students with regard to the type of college.

Table (5): The Relationship between Students' Self-management and their Socio-demographic Characteristics

Model	Unstandardized Coefficients		Standardized Coefficients	T	Sig.
	B	Std. Error	Beta		
(Constant)	52.395	6.342		8.262	0.000
Gender	-8.624	2.441	-0.455	-3.533	0.001
Education	3.661	1.147	0.432	3.192	0.002
Socioeconomic Status	0.005	0.126	0.003	0.039	0.969

Dependent Variable: Self-management B= Regression Coefficient, Std. Error= standard error, t= T-test, Sig.= Level of Significance

This table depicts that there is highly significant relationship between students' self-management and their gender and education only and age is excluded out of the regression model.

Table (6): The Relationship between Students' Academic Achievement and their Socio-demographic Characteristics

Model	Unstandardized Coefficients		Standardized Coefficients	t	Sig.
	B	Std. Error	Beta		
(Constant)	32.861	9.824		3.345	0.001
Gender	5.667	3.781	0.357	1.499	0.138
Education	-0.407	1.777	-0.057	-0.229	0.819
Socioeconomic Status	0.556	0.195	0.381	2.856	0.006

Dependent Variable: Self-management B= Regression Coefficient, Std. Error= standard error, t= T-test, Sig.= Level of Significance

This table indicates that there is highly significant relationship between students' academic achievement and their socioeconomic status only and age is excluded out of the regression model.

Discussion

Findings out of the data analysis indicate that most of the colleges' students have practiced fair to good level of self-management. Such findings are very obvious in the overall evaluation of colleges' students' self-management (Table 1). This can be interpreted in a fashion that the colleges' students have experienced this varied level of self-management as result of their inadequate background relative to such management. It has been reported that successful learner can achieve own learning goals through self-management. It denotes to approaches, procedures and method that can be castoff to straight students' actions and performances efficiently. When it originates to study, self-management contains goal setting, planning and managing the time.

Self-management is a main ability that will benefit students during their life [2].Self-management helps students control impulses, set goals, and get organized so they can be strong self-motivators. Students who can regulate their emotions, control impulses and manage stress are more likely to identify goals and consistently meet them. The students have to be provided with goal-setting, the breadth and depth of research on the topic of self-management and how growing this skill can temper the current problem. Students will assess strategies that schools and other educators use to empower students with self-management mindsets and skills and tweak them so they are relevant to the classroom and students. While there are relatively simple self-management interventions, it is important to note that this course will not provide a cure-all methodology, but strategies and foundational knowledge to grow the students' self-management skills in the long term [7]. Findings out of the data analysis reveal that all of the colleges' students have experienced good level of academic achievement. Such findings are very noticeable in overall evaluation of colleges' students' academic achievement (Table 2). This can be justified in a manner that the colleges' students are well-oriented toward this achievement regardless to their educational background or colleges. Academic achievement is the current level of student learning. More specifically, academic achievement refers to the percentage of students in the school who meet the education standards currently classroom level or beyond. This achievement is measured using tests at the state level in math and reading. Achievement is measured also by using assessments in the case of science, but will not be used scientific assessments of accountability under which ESSA. Why Does Academic Achievement Matter? A standards-based education system promotes equity by establishing a baseline of knowledge and skills that all students, regardless of their background, should master as part of their education. Measuring academic achievement provides key information about students' mastery of standards. Identifying schools where many students are struggling to achieve proficiency on state tests provides a reasonable starting point when searching for schools that would most benefit from support. Looking at academic achievement data in combination with other information helps to prioritize schools for support. More broadly, academic achievement for all students is one of the key goals of the public school system, and mastery of state standards provides students with useful skills for a fulfilling and productive life. While not all aspects of achievement can be efficiently measured and compared statewide, it is important to include some measurement of academic achievement when evaluating and prioritizing support for schools. The tests used to measure academic achievement are meant to provide system-level data about how schools, districts, and the state are functioning. An individual student's scores should not be used to determine, for example, which courses they can or cannot take during their K-12 years. Schools should look at multiple sources of student-level data when planning instruction and support for individual students [8].Such comparison shows that there are no differences between colleges' students' self-management (Table 3) and academic achievement (Table 4). In general, such findings present evidence that these students almost share the same level of self-management and academic achievement regardless of differences in their area of study or specialty. Analysis of such relationship indicates that there is highly significant relationship between students' self-management and their gender and education (Table 5). Such findings can be explained in a mode that the better the students' education the well they perform self-management, as well as male and female students present different application of self-management through their study. There is also a very important relationship between the academic achievement of the students and their socioeconomic status (Table 6). This can be clarified in a way that the better the students' socioeconomic status the advanced their academic achievement. A study is looking at the relationship between socio-economic status (SES) peer academic achievement and individual. Results of the study indicate that the social status of the family, peers, in particular, has a large independent and objective academic achievement on the impact of the individual, which is only slightly less than the social status of the family of the individual [11].

Conclusion

Most of the colleges' students experience fair to good level of self-management and good level of academic achievement probably due to their education and orientation. Colleges' students do not present differences in their self-management and academic achievement due to the level of their consciousness of such issues. Self-management, for students, is affected by their gender and education. Academic achievement is influenced by the students' socioeconomic status.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the -Kindy College of Medicine, University of Baghdad, Iraq and all experiments were carried out in accordance with approved guidelines.

Health Promotion Program about Sun Protection among Outdoor Workers in Helwan University

Mona Mohamed Abd El-Maksoud[1], Donia Atef Ibrahiem[2]

[1]Assistance Professor in Community Health Nursing, Faculty of Nursing, Helwan University, Egypt. Currently at Nursing College-Abha, King Khalid University, Saudi Arabia, [2]Lecturer in Community Health Nursing, Faculty of Nursing, Helwan University, Egypt

Abstract

The current study aimed to assess the effect of health promotion program about sun protection among outdoor workers in Helwan University. Design: A quasi-experimental design was used. Setting: This study was conducted at the Landscape and Campus outside Cleaning in Helwan University.

Sample: A purposive sample of 90 workers was recruited.

Tools: An interview questionnaire was used to assess workers' knowledge regarding effects of the sun and sun care issues, their attitudes and practices regarding sun protection before and after program.

Results: Revealed that more than half of workers were exposed to sun burn and sun stroke in the last twelve months. Also, they had poor level of knowledge, inadequate practices and negative attitudes regarding sun protection at pre-intervention. However, after intervention, the outdoor workers had good level of knowledge with adequate practices for sun protection and positive attitudes, with highly statistically significant differences between pre–post interventions. Conclusion: the study revealed that the intervention seemed to change the knowledge, practices and attitudes of subjects toward sun protection. This, in turn implies that awareness to sun protection could be important to reduce risk of skin cancer in Egypt.

Keywords: *Health Promotion Program, Sun Protection, Outdoor Workers.*

Introduction

Sunlight is the main source of ultraviolet radiation (UVR). All people need some sunlight, but too much sun exposure can be dangerous and cause so much damage. The amount of damage caused by the UV rays depends on the intensity and the duration of the exposure. The greatest burden of disease from most exposure to UVR, are cutaneous malignant melanomas and non-melanoma skin cancers developing. In addition, UVR causes sunburn, skin photo-ageing, cortical cataracts, and reactivation of herpes of the lip.[1] There has been a significant increase in the incidence of skin cancer throughout the world in the last few decades, although increasing public awareness of the dangers of skin cancer and advancement of diagnostic, about 2–3 million cases of non-melanoma skin cancer and 132,000 cases of malignant melanoma skin cancer are diagnosed every year over all worldwide. Studies have found that 65–90% of the cases of melanoma skin cancer are caused by UV rays.[2] Recently, Abeck[3] found that, more than three million non-melanoma skin cancers and 150. 000 melanomas are diagnosed around the world annually, and found that high levels of ultraviolet exposure led to a larger number of new cases.

Subjects and Method

Research Design: A quasi-experimental design was used in the current study.

Setting: The present study was conducted in Helwan University Landscape and Campus outside cleaning sites.

Subjects and Sampling: A Purposive sample which included all available outdoor workers was recruited for they study, their total numbers was 105 workers and the actually included in the study were 90 workers working at Landscape and Campus outside cleaning in Helwan University

Tools of Data Collection: Based on the literature review and pervious studies, the researchers developed data collection instruments. It was written in Arabic language, and included the following interviewing questionnaire:

Part I: A structured questionnaire to assess demographic data of population such as, age, gender, educational level, marital status, residence, type of work, time of sun exposure, history of sun burn, history of sun stroke, and family history of skin cancer.

Part II: Workers' knowledge regarding sun risk factors and effects on health: Questions assessed the workers' knowledge about effects of the sun and sun care issues as time of sun exposure, and measures to protect self from sun exposure.

Scoring System: For knowledge items, a correct complete answer was scored (three points) and a correct incomplete answer was scored (2), while the wrong answer or don't know was given (1). According to workers answers, their knowledge was categorized into "Good knowledge" (43-63) "Average knowledge" (22-42) and "Poor knowledge" (< 21).

Part III: Workers' attitude regarding sun protection: it contains questions about workers attitudes and beliefs regarding sun protection such as:place of work requires us to protect from the sun, working in the sun is in itself something that deeply disturbs me; working under the sun is part of worker daily life.

Scoring System: For attitude items, agree answer was scored (3) and not sure answer was scored (2), while the not agree was given (1). According to workers answers, their attitudes were categorized into positive attitude (27-39) and negative attitude < 26 points.

Part IV: workers' "done and not done" practices regarding sun protection: It includes questions about behaviors of workers regarding sun protection

Scoring System: For practice items, always answer was scored (3) and sometimes answer was scored (2), while never was given (1). According to workers' answers, their practices were categorized into adequate practices ≥ 60% and inadequate practices <60%.

Validation of the Tool: Three experts in Community Health Nursing revised it and some modifications were done according their opinions. The content and face validity of the study tools were measured to evaluate the individual items as well as the entire tools used for the study as being relevant and appropriate to test what they wanted to measure.

Reliability of the tool: Reliability was applied by the researchers for testing the internal consistency of the tool, by administration of the same tool to the same subjects under similar conditions two times 15 days apart. Answers from the repeated testing were compared (Test-retest reliability was (0.82) and Cronbach's Alpha reliability was 0.890.

Operational Design: The study to be completed passed through different phases which included: preparatory phase, pilot study, and field work phase.

Preparatory phase: A review of the past and current available related literature covering all aspects of the research subject using available books, journals, articles and nursing magazines in order to get a clear picture on the research problem, as well as to develop the study tool for data collection, and preparing sessions and designing booklet for program.

Pilot study: It was conducted on 11 workers; they represented about 10% of the total study sample. The aim of the pilot study was to evaluate clarity, feasibility, applicability as well as the time estimated to fill the developed tool. According to the obtained results modifications such as omission, addition and re-wording were done. The pilot study was excluded from the main study sample.

Fieldwork: After having been granted the permission to collect data, the researchers met with the workers to explain the aim of the work, methodology and estimated duration of its fulfillment. By this time,

the tool was developed after extensive review of the related literature, validation by experts, and finalized through pilot-testing.

Assessment Phase: Before distribution of the questionnaire, the researchers met with the workers, introduced themselves, and explained the aim and benefits of the study as well as its procedures to obtain their consent and to establish trust relationship and gain their cooperation and confidence.

Procedure: A review of the previous and recent Arabic and English related literature covering various aspects of the problem was done, using available books, articles, periodicals, journals and internet search to get acquainted with the research problem and develop the study tool. Potential subjects were approached by the researchers, at that time the nature and purpose of the study were explained.

Administrative Design: Permission for carrying out the study was obtained by submission of an official letter from the Director of the Faculty of Nursing, Helwan University to the Director of workers at Helwan University. The letter indicated the purpose of the study and its procedures.

Statistical Design: Data entry and statistical analysis were performed using personal computer software, the Statistical Package for Social Sciences (SPSS), version 20.0. Suitable descriptive statistics were used such as; frequency, percentage, mean and standard deviation. In addition, correlation coefficient (r) test was used to estimate the closeness association between variables. Paired t test was used to compare mean score between both studied variables. The p-value is the degree of significance and using the correlation (r) test.

Table (4) shows that there are highly statistically significant difference between pre and post workers' practices at all items of the health promotion program. So, this table reflects the positive improvement of health educational promotion program ($p < 0.000$).

Table (5): Mean and standard deviation of total scores of practice pre & post of health promotion program (No= 90).

Total practice score Mean±SD		Paired t-test	P-value
Pre-practice	13.8778±3.56584	11.892	0.000**
Post-practice	21.3333±4.79466		

**Highly significant (P<0.001)

Table (5) shows highly statistically significant improvement in the workers' total mean scores of practice level in the post–test than that of the pre–test ($P< 0.000$).

Table (6): Mean and Standard Deviation of Total Scores of Attitude Pre/Post of Health Promotion Program (no= 90).

Total of attitude scores Mean±SD		Paired t-test	P- value
Pre attitude	24.4667±2.41345	10.483	0.000**
Post attitude	31.0222±5.73179		

**Highly significant (P<0.001)

Table (6) reveals highly statistically significant improvement in the workers' total mean scores of attitude levels in the post–test than that of the pre –test ($P < 0.000$).

Consistent with the prior research findings, the results of the current study revealed that the intervention program for outdoor workers regarding sun protection practices indicated better improvement in their practices with statistically significant differences from pre to post program. As well, a study done by Duffy et al.[15] reported that the implementation of the sun safety intervention was an effective method to change behaviors of operating engineers in USA related to sun protection during work time especially during summer period. Similarly, Houdmont et al.[17] found that after intervention the participants demonstrated significant positive change on their behavior measures; the most change was in using of a shade/cover when working in the sun. Inconsistent with the previous results a research done by Malik[16] which indicated that the behavior changes of respondents did not show statistically significant results from before to after the intervention. As well, Bahakim et al.[13]found that most of participants in their study were aware about the effect of sun and had positive attitude about sun safety. However, proper sun exposure practices and sun protection practices was low.

Conclusions

The results of this study have specified a low level of awareness among the outdoor workers as regards sun exposure dangers and sun protection measures. Majority of them had negative attitude toward sun protection. Additionally, this study indicated that sun protection practice was generally inadequate among outdoor workers, as well as more than half of them had sunburn and sunstroke in the past year. The health promotion program led to statistically significant improvement in knowledge, changing attitudes, and behaviors among outdoor workers about sun protection and safety. Continued efforts in this forum can potentially lead to develop policy at work area for the protection the workers from sun harmful effect.

Conflicts of Interest: There are no conflicts of interest.

Financial support and sponsorship: Nil

Ethical Clearance: A written consent was taken from the workers' Director. An oral consent was obtained from each worker, who agreed to participate in the study. They were assured that anonymity and confidentiality of information given will be guaranteed

and they have the right to withdraw from the study at any time without given any reason.

Cyclic Fatigue Resistance of One Curve, Hyflex EDM and Neolix NiTi Files in Simulated Curved Canals

Mirvet M. Rashad[1], Ahmed H. Ali[1], Adel F. Ibraheem[2]

[1]Lecturer, [2]Professor, Department of Restorative and Aesthetic Dentistry, College of Dentistry, University of Baghdad, Baghdad, Iraq

Abstract

Objectives: The aim was to evaluate the cyclic fatigue resistance of One curve (OC), Hyflex EDM (HEDM) and Neolix (NE) files in simulated curved canals.

Study Design: Forty-five NiTi files in three groups (n=15 files/group) of OC, HEDM and NE files, respectively tested in a custom-made cyclic fatigue testing device designed to have 60º curvature in a stainless-steel simulated canal with 5 mm radius of curvature. All files rotated until fracture occur to determine the time to fracture, number of cycles to fractures (NCF) and length of the fractured fragment. Scanning electron microscope (SEM) was used to examine the fracture surface topography of the broken instruments (n=2/group). ANOVA and Tukey test was used to statistically analyses the results at significance level at 95% confidence level.

Results: OC files needed more time to fracture compared to HEDM and NE files ($p<0.05$), respectively, However, there was no significant difference of NCF between HEDM and OC file ($p>0.05$). NE file has significantly lower NCF than that of HEDM and OC file ($p<0.05$), respectively. There was no significant difference between all files in the mean length of the fractured fragment ($p>0.05$). SEM images of NE showed more pores compared to OC and HEDM, however, OC revealed rougher fractured surface than that of HEDM and NE.

Conclusions: OC and HEDM showed comparable resistance to cyclic fatigue in simulated curved canals, despite metallurgical differences among those NiTi file systems. NE files showed the lowest resistance to cyclic fatigue compared to HEDM and OC file.

Keywords: *One curve, cyclic fatigue, Hyflex, Neolix, C-Wire.*

Introduction

Advantages of the introduction of the rotary NiTi files into endodontics compared to conventional stainless-steel hand files were numerous such as efficiency in cutting, faster preparation time and better preservation of the canal geometry [1, 2]. Nevertheless, there is always the risk of breakage of these files because of cyclic fatigue and torsional stress, despite their super-elastic properties [3, 4]. The cyclic fatigue cause breakage in files after repeated cycles of tension and compression occurs, which causes mechanical failure and fracture of the instrument, usually, this occurs often in curved canals clinically [5, 6]. Because of this and to decrease the chance of fracture and improve the flexibility of these instruments, different approached have been proposed including metallurgical modifications of NiTi alloys and modifications in cross-sectional designs of these instruments [7, 8]. Recently, many file systems introduced

to the field that possess different material properties and designs including One curve (OC) (Micro-Mega, Besancon, France), Hyflex EDM (HEDM) (Coltene/ Whaledent, Altstatten, Switzerland) and Neolix (NE) (Neolix, châtres-la-Forêt, France). The newly introduced OC, which made with C-wire technology, has a variable cross-section combined with continuous rotation to ensures excellent cutting efficiency and a perfectly centered trajectory. On the other hand, HEDM is manufactured by the process of electro discharge machining (EDM), which involve using electric current to machine the alloy in a well-controlled and repeatable way difficult to be achieved with conventional techniques [9]. Similarly, wire-cut electrical discharge machining process was used to produce NE to improve cutting efficiency and result in faster root canals preparations. Previous studies showed the superior cyclic fatigue resistance of HEDM [9, 10] and OC [11], against other NiTi files, however, there is no study comparing the cyclic fatigue resistance of these metallurgically different files to the knowledge of the authors

Materials and Method

Cyclic Fatigue Resistance: Forty-five NiTi files in Three groups (OC, HEDM, and NE) (n=15 NiTi rotary files/system) were used for this study. All instruments have comparable size (OC (size 25, taper 0.06), HEDM (size 25, various taper) and Neolix (size 25, taper 0.12). all instruments were tested for single step cyclic fatigue resistance using custom-made device, designed to have single 60^{o} curvature simulated canals, the center of curvature of the simulated canals was approximately 5 mm from the tip of the instrument and the simulated canals have 5mm diameter. The device consists of the main-frame to which mobile wood support is connected to the electric handpiece and a stainless-steel block containing the simulated canals. The electric handpiece is mounted on a mobile device to allow precise and reproducible placement of each instrument inside the simulated canal. All instruments were used with a Wave one endodontic motor (Dentsply Maillefer, Ballaigues, Switzerland). The device is shown in figure (1).

The simulated canal was filled with distilled water and a glass cover was fixed by a clipper above the stainless-steel block before insertion of the file inside the canal. All instruments were rotated according to manufacturer' recommended speed and torque. HEDM operated with 500 RPM and torque 2.5 N.cm., OC operated with 300 RPM and torque 2.5 N.cm., NE operated with 300 RPM and torque 1.5 N.cm. The instance of fracture was based on visual observation of the fracture occurring in the instrument. Time of the fracture recorded in seconds with a stop-watch. The time (T) to fracture in seconds converted to minutes and multiplied by the speed (RPM) to obtain the number of cycles to fracture (NCF) for each instrument according to the equation, NCF= RPM×T. The length of the fractured instruments was measured to determine the length of the fractured piece of each file. All specimens were tested by an endodontist with a minimum of five years' experience. SEM topographical analysis of the fractured instruments was performed using SEM microscope (FEI Co., Ltd., Cambridge) for two specimens from each group.

Statistical Analysis: The data of time to fracture, NCF and length of the fractured fragment were analyzed by (SPSS 24.0; SPSS Inc, Chicago, IL) one-way ANOVA and Tukey test were used to determine any statistical difference amongst groups at a significance level of 95% confidence interval.

Results

The data of time to fracture, NCF and length of the fractured fragment are presented in Table (1). There was a significant difference between all files regarding time to fracture ($p<0.05$). The mean time to fracture of OC, HEDM and NE files were (3.545, 2.418 and 1.852 minutes), respectively. OC time to fracture was significantly higher than that of HEDM and NE ($p<0.05$ and $p<0.05$), respectively. There was a significant difference in NCF between all three files ($p<0.05$). The mean NCF of OC, HEDM, and NE were (1053.5, 1118 and 505.5), respectively. There was no significant difference between HEDM and OC in NCF ($P>0.05$). However, NE has a significant lower NCF compared to that of HEDM and OC $p<0.05$, respectively. There was no significant difference in the length of the fractured fragment among different types of files ($p>0.05$). The mean length of the fractured fragment was (4.497, 3.506 and 3.992 mm) for OC, HEDM, and NE, respectively.

SEM images of the surface topography of the fractured instruments are presented in figure (2). HEDM and NE instruments showed the crater-likesurface texture on the unfractured surface of the instruments (Figure 2 A and B). On the other hand, OC showed smooth surface topography on the unfractured surface (figure 2 C). All instruments showed a resilient fracture of cyclic fatigue failure. NE fractured surface showed

more pores (arrows Figure 2 K) compared to OC and HEDM. At higher magnifications (1000x, 2000x and 5000x), the topography of the fractured surface of OC showed higher roughness than that of HEDM and NE respectively (Figure 2 D-L).

Discussion

One of the most common complications during root canal preparation is the fracture of the NiTi rotary file during the procedure [12]. It was reported that the fracture of the file during clinical use, mainly related to cyclic fatigue [13, 14].The present study evaluated and compare the cyclic fatigue resistance of the different NiTi file systems manufactured from different alloys and after different heat treatment in simulated single curvature canals. An artificial canal block was used to standardize the conditions and minimizes the influence of other mechanisms of failure (including torsional stress) aside from cyclic fatigue [15]. For testing the cyclic fatigue, the extracted tooth was not an ideal model because the objective of this study was to determine the physical properties of the files, and there are no two root canals perfectly identical. Heat generation during the testing procedure because of friction between the walls of the simulated canals and the instrument can occur. Also, local temperature elevation may affect the cyclic fatigue resistance of the NiTi rotary files[16,17]. To control the local temperature, a lubricant or coolant during the testing procedure was recommended [16]. in the present study, distilled water was used to prevent the elevation of the temperature. Cyclic fatigue resistance is measured by the number of cycles to fracture (NCF) when NCF increased the fracture resistance increased. Some studies depend on the number of cycles to fracture[18,19], others depend on the time to fracture[15]. In the present study, the number of cycles and the time to fracture were calculated. Cross section design, type of the alloy and the manufacturing process influence the cyclic fatigue of NiTi instruments[20]. The improved cyclic fatigue of OC can be attributed in part to the use of C-Wire technology by using proprietary heat treatment with a controlled memory property. The austenitic transformation temperature is elevated by thermal processing of NiTi alloys [21], to improve the performance of the instrument by enhancing arrangement of crystal structure [22]. It has been reported that OC was more resistant than other heat treated and conventional NiTi alloy files in resisting cyclic fatigue [11]. In other studies, The HEDM file showed the highest resistance to cyclic fatigue compared to other NiTi files, where Spark-machined peculiar surface is the main feature of HEDM, the cyclic fatigue resistance of HEDM files was higher than Hyflex CM file (HCM, Coltene/Whaledent)[9,10]. Also, HEDM resists cyclic fatigue significantly better than ProTaper Universal and Pro-Taper Gold files[23]. HEDM was the first instrument manufactured with EDM technology, which is a non-contact thermal erosion process. EDM cause local melting and partial evaporation of minor portions of the materials by generated electrical sparks, leaving surface finish with a typical crater-like [24]. Metallurgical differences between HEDM and OC did not cause a difference in cyclic fatigue lives of both files in the present study. Even there was a difference in rotations speed between both files, which may influence the cyclic fatigue of rotary endodontic instruments [25], the cyclic fatigue resistance of HEDM and OC was comparable.

Also, it has been reported that small core diameter improve instruments' cyclic fatigue [23, 26]. OC has the lowest taper (0.06) compared to HEDM (various taper) and NE (0.12), therefore, OC had the lowest core diameter compared to other tested NiTi files. Beside the metallurgy of the alloy, this finding could be considered as another factor that might enhance the cyclic fatigue resistance of OC instrument. Apart from a metallurgical difference of these rotary systems, the cross-sectional design of the files is different which may contribute to their cyclic fatigue resistance. OC hasa variable asymmetrical cross-section in single file. HEDM files has three different cross-section designs; The rectangular cross-section at the tip provides more 'core material', which provide a higher resistance to fracture of this file; Then the trapezoidal cross-section in the middle and finally near the handle, the cross section become triangle which increases the flexibility of file there [27]. NE has a non-homothetic rectangular section along the blade.Several studies have reported that the dimension of the cross-sectional area is a more important factor in cyclic fatigue resistance than the type of alloy [9, 23]. Comparison of the cross-sectional areas of the OC, HEDM, and NE requires further investigation. In the current study, the presence of various factors that can influence the cyclic fatigue resistance of a file, such as the properties of the materials, design, and dimensions of the instrument. These factors cannot be eliminated in total as they are specific for each file system. This hardens the quantification of the effect of each variable on the cyclic fatigue life of the tested NiTi files [13]. However, clinicians need to choose the suitable instruments to shape curved canals and avoid fracture of

the instrument, it can be concluded that OC and HEDM files were comparable to each other and more resistant to cyclic fatigue than NE file in simulated curved canals. However, *in vivo* studies need to confirm the findings of this study.

Table 1: Mean±Standard deviation of Time to fracture, NCF and length of the fractured fragments after cyclic fatigue test.

Variables	Groups	Descriptive statistics					p-value
		N	Mean	S.D.	Min.	Max.	
Time to fracture (min.)	One curve	15	$3.545^{a,b}$	0.415	2.9	4.2	P<0.05

Pediatric Hodgkin Lymphoma in Sulaimaniya Province of Iraqi Kurdistan

Awayi Ghazy Abdulkareem[1], Basil Kadhim Abdallah[2], Zhian Salah Ramzi[3], Jamal Ahmad Rashid[4]

[1]Pediatric Nursing Department, College of Nursing, University of Sulaimani, [2]Department of Pediatric Hematology and Oncology, Hiwa Hospital, [3]Community Health Department, College of Nursing, University of Sulaimani, [4]Pediatric Department, College of Medicine, University of Sulaimani, Kurdistan Region, Republic of Iraq

Abstract

Background: Hodgkin lymphoma (HL) is a highly curable malignancy. It is a unique neoplasm, in which the malignant cell, the Reed-Stenberg cell (RSC), it constitutes approximately 40% of all lymphomas that present during childhood.

Objective: Obtain local data on the pattern of childhood and adolescent Hodgkin lymphoma in our community at presentation and then compare it with the international figure.

Patients and Method: Eighty five patients with newly diagnosed pediatric Hodgkin lymphoma were admitted to Hiwa Hematology/Oncology hospital in the Sulaimaniya province of Iraqi Kurdistan were included in this study.

They were studied prospectively from March 2006 to March 2014.

Result: Data analyzed using SPSS software; version 13 and P-value obtained by Chi-square test, a median age at diagnosis was about 13.7 years with peak age of incidence was between 15-18 year, with male predominance. Most common site of the primary tumor was cervical lymph nodes; Nodular sclerosis was the most common histopathology and the majority was stage IIA.

Conclusion: The stage in our study was age dependent but neither there was relation between the site of the primary tumor and the risk categories nor relation between risk categories and sex.

Keywords: *Hodgkin lymphoma, Stage, Sex distribution, Risk Category.*

Introduction

Formally known as Hodgkin's disease, Hodgkin lymphoma (HL) is a highly curable malignancy. It is a unique neoplasm in which the malignant cell, the Reed-Stenberg cell (RSC), represents only a small proportion of cells constituting the bulk of the tumor. It also has very particular clinical characteristics and distinct biological behavior.

Hodgkin lymphoma is a rather rare malignancy in the pediatric population; however, it constitutes approximately 40% of all lymphomas that present during childhood and is the most common malignancy in adolescents and young adults. In all age groups, Hodgkin lymphoma is highly sensitive to chemotherapy and irradiation. In fact, Hodgkin lymphoma was the first cancer to be cured with radiation therapy alone or with a combination of several chemotherapeutic agents. The

cure rate for children and adolescents with Hodgkin lymphoma has steadily improved over the years, particularly with the introduction of combined radiation and multiagent chemotherapy.[1] This therapeutic success has come at the price of serious long-term toxicities, such that a 30-year survivor of Hodgkin lymphoma is more likely to die of therapy-related complications than from Hodgkin lymphoma. Therefore, the therapeutic paradigm has shifted toward reducing treatment-associated toxicity while maintaining high cure rates. This new paradigm has lead to the current risk-adapted, response-based approach to the treatment of Hodgkin lymphoma. [2, 3, 4]

Patients and Method:

Eighty five patients with newly diagnosed pediatric Hodgkin lymphoma were admitted to Hiwa Hematology/ Oncology hospital in the Sulaimaniya province of Iraqi Kurdistan were included in this study.

They were studied prospectively from March 2006 to March 2014.

Inclusion Criteria:

1. All children and adolescents aged 18 years or younger.
2. Both male and female.
3. Histopathologically proved Hodgkin lymphoma.
4. Newly diagnosed patients who were not treated previously by chemotherapy.

Exclusion Criteria:

1. Age more than 18 years.
2. Relapsed Hodgkin lymphoma or previously treated with chemotherapy.

Study requirements included: All the targeted patients had their Sulaimaniya facilities of hitopathological diagnosis, CBC, blood film, ESR, liver function test, serum alkaline phosphates, hepatitis B serology, hepatitis C serology, human immunodeficiency virus serology, renal function test, serum electrolyte, serum LDH, serum ferritin level, abdominal U/S, CXR, Echocardiography.

CT-scan and/or MRI of the primary site, chest and abdomen.

Bone marrow aspirate and trephine biopsy was done for those with one or more of the following criteria:

1. Patients with clinical stage III or stage IX.
2. Patients with B symptoms.
3. Patients with cytopenia on CBC.
4. Patients with elevated serum alkaline phosphates.

PET scan and EB virus Study were not done for the majority of the case because it was not available.

The patients were staged according to the Modified Ann Arbor Staging system.[1, 5, 6]

Results

Among 85 patients with HL studied, 59 patients (69.41%) were male and 26 patients (30.58%) were female. The male: female ratio was 2.27:1.

Figure 1 shows sex distribution of HL in our study.

A median age at diagnosis was about 13.7 years with peak age of incidence was between 15-18 years. Table 1 and figure 2 show the age distribution.

Table 1: Age Distribution of HL at Diagnosis.

Age in years	No. of patients	Percent (%)
0-4	4	4.7
5-9	17	20
10-14	25	29.4

The most common site of the primary tumor was the cervical lymph nodes which were the primary site of the tumor in 48 out of 85 patients (56.47%), followed by isolated mediastinal primary which occurred in 13 patients (15.29%), axillary lymph nodes primary in 8 patients (9.41%), primary inguinal lymph nodes involvement occurred in 7 patients (8.23%), retroperitoneal lymph nodes primary in 5 patients (5.88%) and isolated splenic involvement occurred in 4 patients (4.7%). Figure 3 shows the percent of the patients in relation to the site of the primary tumor.

Among the 85 patients with HL studied 44 patients (51.76%) were NSHL, 23 patients (27.05%) were MCHL, 12 patients (14.11%) was LRCHL, 1 patient (1.17%) were LDHL and 5 patients (5.88%) were NLPHL.

Regarding Staging of the studied patients, 9 patients (10.59%) were Stage I, three of them (3.53%) with B symptoms, 37 patients (43.53%) were Stage II, 12 of them (14.12%) with B symptoms, 31 patients (36.47%) were Stage III, 9 of them (10.59%) with Stage III B and

8 of patients (9.41%) were Stage IV, three of them with Stage IV B.

According to their Hodgkin Lymphoma Risk Categories depending on the Stage and Number of Nodal Sites and the presence of Bulky Disease, favorable-risk pediatric Hodgkin lymphoma (stage IA or IIA with < 3 nodal sites, and some IIIA without bulky disease) were occurred in 31 (36.47%) patients, intermediate-risk disease (stage IIA bulky disease with extension or =3 nodal sites, stage IB, IIB, stage IIIA, stage IVA) in 42 (49.41%) and advanced or unfavorable pediatric Hodgkin lymphoma (all other patients that were not included in the favorable or the intermediate risk groups) in 12 (14.12%) patients.

Figure 6 shows the percentage of the Risk categories.

Our study showed that there is significant correlation between age and risk categories with favorable risk category occurred more in younger age and high risk category found in older children and adolescent.

Table 2 shows the relation between age and the risk categories.

Chi square test showed that the difference among the Risk Category and the Age was statistically significant (P- value = 0.02997).

Table 2: Relation between Age and the Risk Categories (P-value = 0.02997*).*

Risk Categories Number/(Percentage)			
Age in Years	**Favorable Risk Group**	**Intermediate Risk Group**	**High Risk Group**
0-4	2 (50%)	1 (25%)	1 (25%)
5-9	12 (70.59%)	4 (23.53%)	1 (5.88%)
10-14	9 (36%)	13 (52%)	3 (12%)
15-18	8 (20.51%)	24 (61.54%)	7 (17.95%)

This study found that there was statistic significant correlation between age and sex as there was more male predominance in young patients less than 10 years, while male to female ratio tend to be decrease with increasing age.

Table 3 shows Age in Relation to the Sex (P-value =0.03408).

Table 3: Age in Relation to the Sex (P-value =0.03408).

Age In Years	Male No./total (%)	Female No./total (%)
0-4	3/4 (75%)	1/4 (25%)
5-9	15/17 (88.24%)	2/17 (23.53%)
10-14	20/25 (80%)	5/25 (20%)
15-18	21/39 (53.85%)	18/39 (46.15%)

Also there was significant correlation between Age and Histopathology of HL in our study with MCHL found to be more common among children less than 10 years old (P-Value = 0.05).

Table 4 Shows the Relation between Age and Histopathology.

Table 4: Relation between Age and Histopathology (P-Value = 0.05).

Age In Years	NSHL No./Total (%)	MCHL No./Total (%)	LRCHL No./Total (%)	LDHL No./Total (%)	NLPHL No./Total (%)
0-4	1/4(25%)	1/4(25%)	1/4(25%)	0/4(0%)	1/4(25%)
5-9	2/17 (11.8%)	8/17(47.1%)	5/17(29.4%)	0/17(0%)	2/17(11.8%)
10-14	16/25(64%)	5/25(20%)	3/25(12%)	0/25(0%)	1/25(4%)
15-18	25/39(64,1%)	9/39(23.1%)	3/39(7.7%)	1/39(2.6%)	1/39(2.6%)

This study showed that there was significant statistic relation between histopathology and risk categories, with more advance risk categories were found in LDHL and NSHL, and favorable risk group was found in LRCHL and NLPHL (P-value = 0.00827). The relation between risk categories and histopathology was showed in table 5.

Table 5: Risk Categories to Histopathology Correlation (P-value = 0.00827).

Risk Categories	NSHL No./Total (%)	MCHL No./Total (%)	LRCHL No./ Total (%)	LDHL No./Total (%)	NLPHL No./ Total (%)
Favorable Risk Group	17/31(54.84%)	2/31(6.45%)	9/31(29%)	0/27(0%)	2/31(6.45%)
Intermediate Risk Group	21/42(50%)	15/42(35.71%)	3/42(7.14%)	0/42(0%)	3/42(7.14%)
High Risk Group	6/12(50%)	5/12(41.7%)	0/12(0%)	1/12(8.3%)	0/12(0%)

There was no significant statistic relation between the site of the primary tumor and the risk categories in our study. Table 6 shows this relation (*P-Value = 0.78195).*

Table 6: Primary Site in Relation to Risk Categories (P-Value = 0.78195).

	Risk Categories		
Site of the primary tumor	**Favorable Risk Group (No.)**	**Intermediate Risk Group (No.)**	**High Risk Group (No.)**
Cervical lymph nodes	21	23	4
Mediastinal primary	2	8	3
Axillary lymph nodes	3	3	2
Inguinal lymph nodes	2	4	1
Retroperitoneal lymph nodes	2	2	1
Spleen	1	2	1

Also there was no significant statistic relation between risk categories and sex as shows in table 7 (P-Value = 0.66731).

Discussion

Pediatric Hodgkin's Lymphoma Cancer continues to be the leading cause of death in children younger than 15 years old, and lymphomas are among the most common cancers seen in children. Fortunately, survival rates for childhood cancers have increased significantly over the years. Children respond to and deal with chemotherapy better than adults. Today, 96% of children diagnosed with Hodgkin's disease will survive 5 or more years. However, those with high-risk disease continue to have poor outcomes.

The total number of cases studied was eighty five, over a period of eight years.We found that males were affected more than females with The male: female ratio was 2.27:1; also our study found that there was significant correlation between age and sex as there was more male predominance in young patients less than 10 years, while male to female ratio tend to be decrease with increasing age, this figure is similar to male: female ratio in most large studies which showed that children younger than 5 years show a strong male predominance (M:F = 5:3) and children aged 15 to 19 years show a slight female predominance (M:F = 0.8).[7,8]

Peak age incidence at presentation in our study was (15-18) years which was represent (45.9%), In the United States, the incidence of Hodgkin lymphoma is age-related and is highest among adolescents aged 15 to 19 years (29 cases per million per year), with children ages 10 to 14 years, 5 to 9 years, and 0 to 4 years having approximately threefold, eightfold, and 30-fold lower rates, respectively. In non-European Union countries, there is a similar rate in young adults but a much higher incidence in childhood.[9]

A median age at diagnosis was about 13.7 years in our study which was younger than that showed by study done in USA (median age: 15.6).[10, 11]

This younger median age at diagnosis in our study might resulted from possibly relation to EB virus infection in earlier age in our region, but this needs to be confirms by studying the EB virus genomes in the HL cells.

Conclusion

Pediatric Hodgkin's Lymphoma was higher in male than female in our community. A median age at diagnosis was about 13.7 years with peak age of incidence between 15-18 years and the majority of the patients presented with cervical lymph nodes primary at the time of diagnosis. Nodular sclerosis histopathology is the most common. Most of the patients had stage II with Intermediate risk category. There was strong correlation between age and advanced stage which meant that stage is age dependent and significant correlation between age and sex as there was more male predominance in young patients less than 10 years. Also there was significant correlation between age and histopathology of HL in our study with mixed cellularity found to be more common among children less than 10 years old. Neither there was relation between the site of the primary tumor and the risk categories nor relation between risk categories and sex. Despite absence of PET scan for the majority of patients for proposed risk stratification system for purpose of risk categories, significant number of our patients got intermediate and high risk category.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the College of Nursing, University of Sulaimani, Kurdistan Region, Republic of Iraq and all experiments were carried out in accordance with approved guidelines.

Association between Social Media Addiction and Life Satisfaction among University Student

Qahtan Q. Mohammed

Assistant Professor, Psychiatric and Mental Health Nursing Department, College of Nursing, University of Baghdad, Iraq

Abstract

Objectives: The present study aims to assess the level of social media addiction and the level of life satisfaction among university students; and to determine the association between social media addiction and life satisfaction.

Methodology: A descriptive, cross-sectional design that is initiated for the period of January 1st to May 1st, 2018 on a sample consisted of (200) students which was selected by convenient sampling method from five colleges at University of Baghdad that are: College of Nursing, College of Arts, College of Sciences, College of Physical Educations, and Ibn Rushed College of Education. The questionnaire is designed and adopted which consists of three parts; the first part is contained the covering letter and the demographic variable of the students, the second part is concerned with Social Media Addiction Scale, and the third part concerned with Satisfaction with Life Scale. The data have been collected through the utilization of the self-administrative report as a mean of data collection and analyzed by application of statistical package for social science IBM SPSS (v. 24)

Results: The result referred that student are showing moderate level of social media addiction (60%) and moderate level of life satisfaction (66.5%). there is strong positive correlation between life satisfaction and social media addiction among students evidenced by high significance at p-value= 0.005.

Conclusions: The study concluded that social media addiction is positively influence the life satisfaction evidenced by positive association.

Keywords: *Social Media Addiction, Life Satisfaction, University Students.*

Introduction

Interpersonal relationship is the key for satisfying human's needs to belong and relate with others [1]. Recently, in the last decades, coincidently with the development of information technology, particularly the quick deployment of internet-related social media applications such as Facebook WeChat, Instagram, or other applications; the patterns of interpersonal communication are dramatically changed [2,3]. It has been shown that dependence on social media networks is associated with various health problems and psychological problems [4,5]. Social media addiction can be seen as one form of internet addiction, in which the individuals show a forcing behavior to access social media usage [6]. The individuals who have been addicted on social media use are frequently worried about their social media accounts and are driven by uncontrollable motive to use the social media applications [7]. The researches about social media addiction refer that individual with such addiction have many symptoms that can be manifested in mood, cognition, physical and emotional reactions, in addition to psychological and interpersonal relationship problems; the incidence of social media addiction was approximately 12% among users over social network sites [8]. "According to the Internet World Stats (2017), the number of Internet users worldwide has reached to four billion. The proportion of Internet and social media usage (e.g. Facebook) to population is 27.7 and 11.7% in Africa; 45.2 and 13.4% in Asia; 77.4

and 39.9% in Europe; 59.6 and 55.8% in Latin America; 56.7 and 30.3% in the Middle East; 88.1 and 62.1% in North America; 68.1 and 51.7% in Australia. In Turkey is 59.6% and that of social media (Facebook) is 53.2%." [9]. It has found that life satisfaction as well as self-esteem to be the predictor of internet addiction [10]. There are some conflicting outcomes with respect to the effect of social media on life satisfaction; from one view point, an extraordinary group of research demonstrates that there is a positive connection between life satisfaction and social media use. On the other side, there is a connection between the intensity of social media use and life satisfaction [11].There are growing number of researches about the connection between social media usage and human psychology. Some of them demonstrate that people who are using social media network are tending to be happy. Others look into life satisfaction as personal contentment. An argument demonstrates that people with low level of life satisfaction are improving their psychological well-being by joining in social media. The important argument about the connection between life satisfaction and social media usage and how it lead to problematic usage is that individuals are trying to spend more time on using of social media applications to avoid the feeling of dissatisfaction and then seeking psychological satisfaction [9]. For these reason, the current study is focusing on determining the association between social media addiction and life satisfaction among university students after determining the intensity of social media addiction and level of life satisfaction.

Objectives of the Study: The present study aims to assess the level of social media addiction and the level of life satisfaction among university students; and to determine the association between social media addiction and life satisfaction.

Methodology

The design of the study is descriptive, cross-sectional design that is initiated for the period of January 1st to May 1st, 2018; an assessment approach is applied in order to achieve the earlier stated objectives.The ethical consideration of research is achieved by obtaining the agreement from the Committee of Research Ethics at College of Nursing, University of Baghdad. In addition, the agreements of the students were asked for participation in research by filling the participation consent in covering letter of the questionnaire. For the purpose of administrative and arrangements issues for conducting the research, the permission was asked from University of Baghdad, Department of Students Affairs, in addition, the secondary permission were obtained from the colleges that involved in this study. The permission facilitates the entrance of researcher to the colleges and meeting the students.The setting of the study includes five colleges at university of Baghdad that are: College of Nursing, College of Arts, College of Sciences, College of Physical Educations, and Ibn Rushed College of Education. These colleges were selected by researcher through simple random method (pool sample).The sample of the study includes (200) undergraduate students who are studying at the colleges that mentioned above, the researcher used the convenient sampling method (non-probability sample) in which the students were selected purposively. According to Soper [12], the sample size that must achieve the parameters of anticipated effect size of 0.15, the desired statistical power level of 0.80, one predictor, and a probability level of 0.05; the minimum required sample size would be 54.The questionnaire of the study is designed by researcher which consists of three parts; the first part is contained the covering letter and the demographic variable of the students as well as the variable related to social media usage; the second part is concerned with Social Media Addiction Scale; and the third part include the Life-Satisfaction Scale.Social Media Addiction Scale was adopted [13] and consisted of 30 items which were rated into three levels of Likert scale and scored the follows: yes (3), to some extent (2), no (1). The level of addiction was estimated by calculating the cut off points for the total mean of scores for the scale as mild=30 - 50, moderate= 51 - 70, and severe= 71 - 90. Life Satisfaction with Life Scale was adopted [14] and consisted of 5 items which were rated into five levels of Likert scale and scored the follows: strongly agree (5), agree (4), neutral (3), disagree (2), and strongly disagree (1). The level of satisfaction was estimated by calculating the cut off points for the total mean of scores for the scale as low=5 - 11, moderate= 12 - 18, and high= 19 - 25. The reliability and validity of the two scales were depended on the reliability and validity of the original scales that refer they were valid and reliable[13,14].The data have been collected through the utilization of the self-administrative report as a mean of data collection. The questionnaire was distributed after being willing to answer the questionnaire and participate in the study. Statistical analyses were conducted by using statistical package for social science (IBM SPSS Statistics) version 24.0. Data analysis was employed through the application of descriptive and inferential statistical approaches to achieve the objectives of the study.

Results

Table 1: Distribution of the Students according to Variables related to Use of Social Media Account

No.	Variables		f	%
1	Having Laptop	No	103	51.5
		Yes	97	48.5
		Total	200	100
2	Having smartphone	No	0	0
		Yes	200	100
		Total	200	100
3	Having Account	No	0	0
		Yes	200	100
		Total	200	100
4	Hours of using account	3 hours	89	44.5
		4 – 6 hours	74	37
		7 – 9 hours	37	18.5
		Total	200	100

f: Frequency,%: Percentage

This table reveals that (48.5%) are having laptop, and all of the students having smartphones (100%). All of the students also are having accounts on different applications (100%). (44.5%) of the students are spending three hours on using these applications.

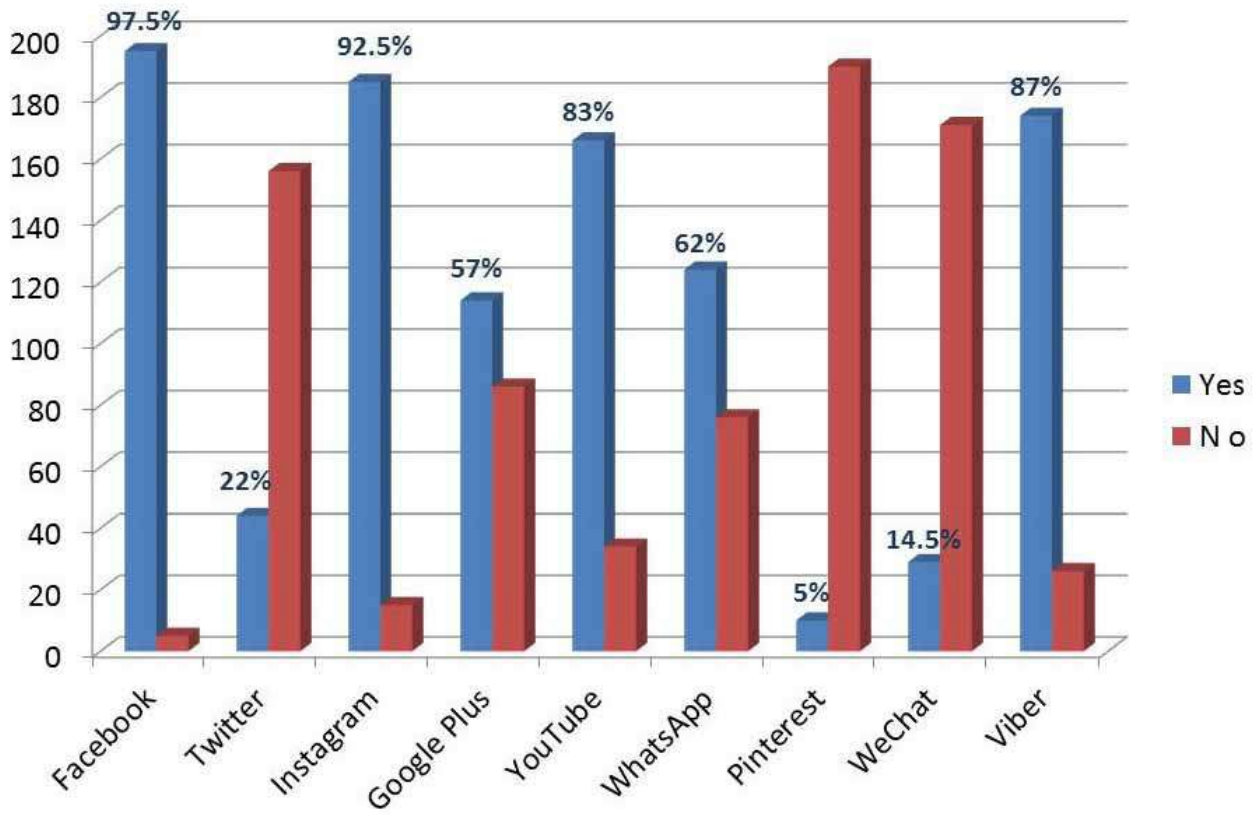

Figure 1: Distribution of the Students according to Use of Social Media Account (N=200)

This figure indicates that most of the students are having Facebook, Instagram, YouTube, and Viber accounts (97.5%, 92.5%, 83%, and 87%), only (22%) of them are having Twitter accounts, and (57%) are having Google Plus accounts, (62%) are having WhatsApp accounts, only (5%) are having Pinterest accounts, and only (14.5%) are having WeChat accounts.

Table 2: Level of Social Media Addiction among Students

Levels of Addiction	f	%	M.S	SD
Mild	48	24	1.92	0.629
Moderate	120	60		
Severe	32	16		
Total	200	100		

f: Frequency,%: Percentage, M.S: Mean of score, SD: Standard Deviation, Mild= 30-50, Moderate= 51-70, Severe= 71-90

This table indicates that students are showing moderate level of social media addiction (60%).

Table 3: Level of Life Satisfaction among Students

Levels of Addiction	f	%	M.S	SD
Low	19	9.5	2.15	0.562
Moderate	133	66.5		
High	48	24		
Total	200	100		

f: Frequency,%: Percentage, M.S: Mean of score, SD: Standard Deviation, Low= 5-11, Moderate= 12-18, High= 19-25

This table shows that (66.5%) of the students are moderately satisfied with their life while only (24%) of them are highly satisfied.

Table 4: Correlation between Social Media Addiction and Life Satisfaction of Students (N=200)

Correlation		Addiction	Self-Esteem
Addiction	Pearson Correlation	1	0.220**
	Sig. (2-tailed)	--	0.002
Self-Esteem	Pearson Correlation	0.220**	1
	Sig. (2-tailed)	0.002	--

This table indicates that there is strong positive correlation between life satisfaction and social media addiction among students evidenced by high significance at p-value= 0.005 respectively.

Discussion

The descriptive analysis of the students' demographic variables refer that are males, from third and fourth academic stage, from morning studies, and are students at scientific colleges. The highest percentage among the students is having laptop, and all of them having smartphones, and having accounts on different applications. Less than half of the students are spending three hours on using these applications. Such findings may reflect the needs for using the technology in education especially for scientific colleges. But from the other side, this may presents that they using smartphones and laptops for entertainment. The last statistics about using smartphone in Iraq refers that the number of mobile phone subscription is increasing from 2002 to 2017, in which the number of users in 2017 is refer to (33.34) million [15]. Regarding use of social media accounts, the students are having Facebook, Instagram, YouTube, and Viber accounts as popular social media sites. The researcher sees that the students are using these social media for communication and entertainment purposes. Most of the social media statistics refer that Facebook is the popular among users; the last statistics about social media in Iraq refers that the users of Facebook are present (53.38%), YouTube users are (41.21%), Twitter (3.45%), Instagram (1.05%), and Pinterest (0.83%) [16]. such statistics provide a supportive evidence for current study results. The findings regarding social media addiction among students refer to moderate level of addiction. This finding may be not a confirmative diagnosis of social media addiction, but at the same time is considered as indicator that should be taken in consideration of mental health among students and other individuals. Consideration of such findings may explain some of the reason behind social media addiction; the most of these reasons is the mood status represented by depression, anxiety, weakness in communication skills, and social fear as well as fear of the future. All these symptoms may lead the students to use social media networking to get rid of this mood status. Young individuals who use social media networking sites are unaware of the time spent in the use of those sites, which leads them to ignore their responsibilities in real life over time. Individuals who find it difficult to form relationships in real life will use social media networking. On the other hand, some young individuals cannot maintain the level of communication with friends and family in the real life, so, leading them to make communication over social media networking. A study provides supportive evidence for this study that found

significant social media addiction among his sample [17].Regarding the finding of life satisfaction, the students were showing moderate life satisfaction. Satisfaction with life is one of the indicators that indicate the mental health of the individual, so the level of satisfaction with life among students in the current study indicates that students perceive their lives as being full of various pressures, including those related to the educational environment, including those related to daily life. The finding is slightly different from others studies results such as the study of Behlau who found a high level of life satisfaction among the students [(18)]. The main objective of current study is to determine the association between social media addiction and life satisfaction; the bivariate correlation analysis of finding indicates that there is strong positive correlation between life satisfaction and social media addiction among students. A study has supportive evidence for this study that found a significant relationship between Facebook addiction and life satisfaction [11]. The interpretation of the current study finding is depicted with the contents of related literature that the students who perceive life dissatisfaction will emerge in the use of social media accounts. So, they will avoid the perception of dissatisfaction. Sahin stated "the main argument about how life satisfaction leads to problematic internet or social media use is that people prefer to spend more time on the internet so as to avoid the feeling of dissatisfaction and to seek psychological satisfaction" [9]. Therefore, the positive relationship in current study may be interpreted based on this hypothesis that stated by Sahin.

Conclusions

Based on the results, the study concluded that university students showing moderate level of social media addiction and life satisfaction scores, and social media addiction is positively influence the life satisfaction evidenced by positive association.

Assessment of Psychosocial and Physical Factors Associated with a Substance Re-abuse after Treatment among Patients with Addiction at Psychiatric Teaching Hospitals in Baghdad City-Iraq

Hassan A. Hussein[1], Iman H. Alwan[2], Kareem R. Sajit[1]

[1]Assist. Professor, [2]Instructor, Department of Psych. Nursing, College of Nursing, University of Baghdad, Baghdad City, Iraq.

Abstract

Background: The high rate of relapse is an especially frustrating problem and one of the most problems that face the substance abusers after a period of treatment remains old news. Little studies are documented about the addiction relapse in Iraq.

Objective: The current study aims to assess the causative factors affecting the substance abuse-related relapse. And find out the relationship between the clinical and demographic characteristics with relapse.

Methodology: A descriptive study was conducted from November 20th 2016 to May 1th 2017 on addict patients in Baghdad City. Purposive (non-probability) samples of 30 relapsed addicts who are inpatient in Ibn-Rushd Psychiatric Teaching Hospital and the Psychiatric unit of Baghdad Teaching Hospital who had undergone treatment for substance dependency and they had at least one episode of relapse during the period of addiction. The study uses the self-administrated questionnaire. The data has been analyzed by using the descriptive statistics (Frequencies, Percentages, Means and Standard Deviations (SD) and the inferential statistics (Chi-square to find out the relationships between the socio-demographic and clinical characteristics of addicts with relapse).

Results: The findings of the current study revealed that all relapsed patients are males with age ranged from 20 years to more than 50 years. The highest percentages of the addict patients were addicted to alcohol and two third of them have one previous admission. The results indicated that the factors of psychosocial and physical are associated with relapse to problematic alcohol or illicit drug use. There is no significant relationship between socio-demographic and clinical characteristics with relapse.

Recommendations: The researchers recommended may be there treatment programs focusing on teaching the clients how to cope with the relapse and control the feeling of craving for alcohol drink and substance abuse.

Keywords: *Substance Abuse, Relapse, Addiction.*

Introduction

Substance abuse is a global and an important challenging and costly health problem which leading to physical, mental and psychiatric outcomes in persons, families and communities(1). It has a profound effect on all areas of society;this includes high costs in terms of healthcare provision, the effect on individuals in

Hassan A. Hussein
Department of Psych. Nursing, College of Nursing, University of Baghdad, Baghdad City, Iraq
e-mail: faun_79@yahoo.com

terms of physical and psychological problems and their families, and has harmful effects on society through criminal and violence issues[2]. There are 76.3 million people with alcohol use disorders worldwide and 15.3 million with drug use disorders[3]. Al-Hemiaryetal, 2015 reported in their survey that there is a high rate of alcohol and drug abuse in Iraqi population [4]. Relapse means the return to uncontrolled substance use, it occurs when a client resumes an abusive pattern of use after a period of treatment, the problem of relapse remains to be challenge to many substance abusers post treatment for substance dependency [5]. Many factors are being associated with relapse such as peer group influence, poor family support and personality characteristics [6]. Insufficient rehabilitation phase, lack of programming for the occupation of addicts after discontinuing, low self–esteem, presence of family problems, negative mood states, presence of addicted friends and contaminated environment, are cited as a cause of relapse [7]. Motivation to stop substance abuse and insight into the addiction problems are good prognostic factors to avoid relapse [8]. The abstinent individuals who are contributed in rehabilitation program should be integrated back into society unless the treatment may fail; craving and relapse depend on successful treatment [9].

Objectives of the Study:

The study aims to:

1. To assess the factors of substance abuse related relapse among addicts person.
2. To find out the relationship between the cause of relapse and demographic characteristics forthose populations.

Methodology

A descriptive analytic study was conducted from November 20th 2016 to May 1st 2017 on addict patients in Baghdad City. Purposive (non-probability) samples of 30 relapsed addicts who are inpatient in Ibn-Rushd Psychiatric Teaching Hospital and the Psychiatric unit of Baghdad Teaching Hospital who had undergone treatment for substance dependency and they had at least one episode of relapse during the period of addiction. The study uses the self-administrated questionnaire. To assess the causes of relapse the study adapted from the reasons for drinking and drug use questionnaire by Zywiak et al. (1996)[10]. The questionnaire comprised three parts:

a. The socio-demographic characteristics of the addict patients such as: age, marital status, educational level, residence, occupation and monthly income.

b. The data related to substance abuse such as: type of substance abuse,previous admission,the main reason for you taking the first drink.

c. Assessment of the causes of substance abuse related relapse (20 items), and it is consist form (20 items) gives a total score. The score ranged from 1-3 (3= agree, 2=neither agree nor disagree, 1= disagree) the score was interpreted as disagree (1-1.33), neither agree nor disagree (1.34-2.67), and agree (3.68-4.00).

The data has been analyzed by using the descriptive statistics (Frequencies, Percentages, Means and Standard Deviations (SD) and the inferential statistics(Chi-square to find out the relationships between the causes of the relapse and the socio-demographic characteristics of addicts).

Results

Table 1: Distribution of the sample according to the data related to substance abuse

No.	Characteristics		f	%
1	Types of substance abused:	Alcohol	11	36.7
		Narcotics	9	30.0
		Both	10	33.3
		Total	30	100
2	No. of Previous relapses:	One	18	60.0
		2 – 3	11	36.7
		4 – 5	1	3.3
		Total	30	100.0
3	The main reason for you taking the first drink:	social factors	16	53.3
		psychological factors	6	20.0
		physical factors	3	10.0
		other factors	5	16.7
		Total	30	100.0

This table indicated that more than half of sample are alcohol abused (36.7%) and 33.3% of them are abusing alcohol and narcotics, while only 30.0% are abusing narcotic only. The previous admission shows that more than half of them are admitted to the hospitals once (60.0%). Regarding the main reason for you taking the first drink, the analysis of data shows that more frequent reasons are social factors (53.3%).

Table 2: Descending distribution of the sample according tothe causes of substance abuse relapse (N=30)

No.	Reasons for drinking again	M	SD	Sig.
1	I felt angry with myself because things were not going my way	2.53	0.681	H.S
2	I felt frustrated with myself because things were not going my way	2.90	0.403	H.S
3	I felt bored	2.30	0.837	S
4	I felt anxious	2.47	0.730	H.S
5	when I saw alcohol I just had to give in	2.90	0.403	H.S
6	I felt sad	2.23	0.679	S
7	I was in a good mood and felt like getting high	2.20	0.847	S
8	I wanted to see what would happen if I tried drink	2.20	0.887	S
9	I just felt tempted to drink out of the blue and went off to get a drink	2.40	0.814	H.S
10	Someone offered me a drink	2.67	0.711	H.S
11	I felt frustrated because of my relationship with someone else	2.50	0.630	H.S
12	I was with others having a good time and we felt like getting drunk together	2.13	0.937	S
13	I felt others were being critical of me	2.63	0.615	H.S
14	I saw others drinking	2.43	0.817	H.S
15	I felt could not cope with my stressful work environment	2.23	0.774	S
16	I was transferred to another more stressful department at work	1.47	0.776	S
17	I felt physically ill.	1.93	1.129	S
18	I felt pain.	2.00	1.220	S
19	I felt ill or in pain but this was not due to withdrawal from alcohol.	1.88	1.039	S
20	I discovered I have a terminal illness/my health began to deteriorate due to my health status.	1.65	0.783	S
	Total	2.34	0.747	H.S

No: Number, M: Mean, SD: Standard Deviation, Sig: Significant

This table reflects the mean distribution of the questions related to reasons for drinking and takes drugs again after treatment. All items are showing significant to high significant its mean the respondents are agree with questions relating to reasons for drinking again after treatment.

Table 3: Association between demographic variables and relapse among Substance Abusers (N=30)

Relapse / Characteristics	Chi-square	d.f	P-Value ≤ 0.05	Significance
Age	65.420	57	0.208	N.S
Level of education	96.091	95	0.449	N.S
Marital status	61.286	57	0.325	N.S
Residence	45.119	38	0.199	N.S
Occupation	77.987	76	0.415	N.S
Monthly income	43.275	38	0.256	N.S

d.f: degree of freedom, P: Probability, N.S: Not significant, S: Significant

This table shows that socio-demographic characteristics of substance abusers are not associated with causes of relapse at p-value ≤ 0.05.

Table 4: Association between Clinical Characteristics and relapse among Substance Abusers (N=30)

Relapse / Characteristics	Chi-square	d.f	P-Value ≤ 0.05	Significance
Types of substance abused	96.091	38	0.592	N.S
No. of Previous relapses	47.540	57	0.810	N.S
Causes of treatment seeking	49.958	57	0.734	N.S

d.f: degree of freedom, P: Probability, N.S: Not significant, S: Significant

This table indicates that there is no significant association between clinical characteristic of substance abusers and cause relapse at p-value ≤ 0.05.

Discussion

The findings in table (1) show that all addict patients were males with age ranged from 20 to more than 50 years with mean 24.65 years and SD = 6.883, this may be due to men tend to drink more than women,and they are more likely to be substance abusers and they have a financial independence in this age which allowing them to easily acquire an addictive substance, this result was consistent with Sharma etal, 2012 who reported that all subjects in their study were males[6], and close to Matoo et al., (2009) who found the mean age was 30±(9.3) years old who live in urban area[11]. Hammerbacher and Lyvers, 2005 who found that the clients were over 18 years of old with mean 31.8 years[12]. Table (1) also indicated that the highest percentage of subjects in the sample are married and were at primary level of education, and they reported a barely sufficient monthly income, these results were similar to findings of Kassani et al, 2015 who found that married subjects were more than other groups[1], and close to Sharma etal, 2012 who reported that the highest percentage of the sample were at primary educational level and had lower middle class of socio economic status[6].

The current study results show in table (2) indicated that the highest percentage (36.7%) of the addict patients were addicted to alcohol; In Iraq, easy availability of alcohol more than other types of substances, Al-Hemiary etal, 2015 reported in their survey that the prevalence of alcohol abuse in Iraq was higher than drug abuse[4]. The findings also revealed the number of previous relapse was one relapse (63.3%). This result is similar with study of Kaundal et al., (2016) who reported the 56% patients had one relapse and 44% patients had two relapses in the past[13]. So, the result show the main reason for taking the first drink was social factors. This result is consistent with study of Chetty,(2011) who found that their first drink was due to peer pressure[5].

The findings in table (3) revealed that the psychosocial and physical reasons are main causes for drink and take drugs again. This result was consistent with Zhuang et al., 2012 a number of studies have shown that alcohol and drug relapse in patients was related to the three aspects of physical, psychological and social factors[14].The researcher suggested the widespread and easy availability of drugs and alcohol linked to increase tendency to substance abuse thus will increase the chance of relapse too. Also may be explained by that in the anticipation stage of the addiction cycle which is commonly called “craving” a person begin to seek substance again after a period of abstinence.

In table (4) the findings revealed that there is no significant relationship between socio-demographic variables and relapse. This result is contradict with study of Kaundal et al., (2016) there is a significant association of relapse among patients with alcohol and drug dependence syndrome with demographic and psychosocial variables[13]. Also this result is consistent with study by Anton et al., 2006 who said ‘’although widely researched for an extensive period of time; little is actually known and documented about the exact causes of relapse. Even less is known about the effect of personal and demographic contributors to relapse’’ [15]. The current study results show in table (5) that there is no significant relationship between clinical variables related addiction and relapse. This result is inconsistent with Kaundal et al., (2016) who found the clinical parameters such as the number of previous relapses emerged as significant determinants of relapse[13]. The researchers explain this result that the patients who had relapsed in this study had experienced a higher number of undesirable life events, low self-efficacy and negative coping behavior.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the College of Nursing, University of Baghdad, Baghdad City, Iraq and all experiments were carried out in accordance with approved guidelines.

Slow Learners: Across-Sectional Study among Primary School Children in Kirkuk City

Qasim H. Muhammed[1], Nazar A. Mahmood[1], Abid S. Kumeit[2], Jasim M. SHindi[3]

[1]Lecturer, Community Health department, College of Nursing, Kirkuk University-Kirkuk, Iraq,
[2]Lecturer, Adult Nursing Department, College of Nursing, Kirkuk University-Kirkuk, Iraq,
[3]Psychiatric Consultant Physician at Azadi Teaching Hospital, Kirkuk, Iraq

Abstract

Background and Aims: Slower learners are pupils who have lower IQ scores than the average score of 100 but do not fall into mental disabilities. This study aimed to describe the sociodemographic characteristics of primary school children as well as to explore certain factors related to slow learning among these children in Kirkuk city

Methodology: A constructed questionnaire was completed by 102 randomly selected children, who were diagnosed with a slow learner, in Kirkuk city, during 2017. The questionnaire consisted of two parts, the first related to sociodemographic variables and the second related to clinical findings. Frequency, percentage, and Chi-Square Goodness of Fit were used for statistical analysis using SPSS version 19.

Results: The study revealed that more than half of the pupils were male which constitute (63.7%), more than half of their parents had low educational level, and most of them had moderate economic status (60.8%), majority of them live with both parents (87.3%).

Conclusion: In spite of the limitations of this study, it could be fairly concluded that low birth weight, type of delivery and genetic factors were considered as predictive factors for slow learning. So, more antenatal care had recommended for all mothers, especially who had risks of pregnancy.

Keywards: *Slow Learner, School Children, Males, Females.*

Introduction

Slow learner, that is a child with limited scope for attainment, is distinct from the mentally handicapped child. The slow learners are not interested in studying under traditionally accepted systems of education their handicap is related to their scholastic performance.[1] Normally, learners have an average IQ between (85_115). Whereas, slow learners have intelligence test scores below the average score but above the range of mental impairment. The number of children with this problem is about 14% as this percentage increases the remaining students who have problems in special education.[2]

The slow learner does not learn successfully due to general socio-cultural problems, related to residence, poverty, parents relationships, personal factors are related to long illness, long absence from the school, poor cognitive characteristics, frustrating past language classroom experience, while the environment variables include, poor home facilities for learning skills, adverse parenteral attitudes toward education, inappropriate opportunities in school (large classes), poor quality of teaching, repeated changes of school and consequent

changes in teaching styles and content. The emotional factors are related to the feeling of inadequacy and lack of confidence in self, extreme timidity and anxiety giving rise to a poor level of attainment, negative attitude to school and teachers.[3]

In general slow learners may exhibit some or all of these characteristics depending on their age and degree of problems of acquiring knowledge at school, they are recurrently immature in their relation with others, they cannot do multifaceted activities,and do very slowly and poorly in school, they lose track of time and cannot convey what they have learned from one task to another well, with inability to have long term goals and dealing with symbolic materials i.e language, numbers, and concepts is very limited and inferior to that of average students, slow learners prefer concrete learning to abstract learning, they gain from direct teaching and do not acquire skills incidentally.[4]

Special education in Iraq for slow learners starts at the age of six years from the first grade and continues until the fourth grade. Students who pass in the fourth grade continue with their classmates. Each class consists of 6 to 12 students. The curricula of these classes are the same as those of their colleagues in the academic curriculum. But there is a difference in the teaching method of that group.[5] The current study, therefore, is an attempt to describe sociodemographic attributes of the primary school children, besides exploring some related factors of slow learning among primary school children in Kirkuk city.

Methodology

This was a cross-sectional study carried out at primary schools in Kirkuk city for the period of first January, to the end of March 2017. Non-probability sampling a purposive sample of 102 pupils who were diagnosed with the slow learner by a group of specialists in Kirkuk Education Directorate. A special questionnaire was constructed for proper data collection based on an extensive review of related kinds of literature and studies. It consisted of two parts, the first related to sociodemographic variables and the second related to the health information related to the study sample. The validity of the instrument was done by (6) experts and test-retest technique was used to determine reliability. A descriptive (frequency and percentage) and inferential statistics (Chi-Square Goodness of Fit) were used for data analysis using SPSS version 19. An ethical issue of the participant was considered through taking their parent consent to participate their children as a sample in the study

Results

Table 1. Distribution of the study sample (N=102) according to some health history information

Health History Information	Frequency	Percent	p- value
	F	%	
Type of delivery			
Normal	86	84.3	0.001
Cesarean	16	15.7	
Total	**102**	**100**	
Birth weight			
<2.5 kg	65	63.7	0.006
≥2.5 kg	37	37.3	
Total	**102**	**100**	
Problems of			
Speaking	48	47.7	<0.001
Hearing	16	15.7	
Visual	23	22.5	
Total	**102**	**100**	

Discussion

According to the findings of table (1) show that the majority of slow learners (84.3%) had history of normal delivery and the remaining (15.7%) of them had delivered by caesarian section. There are some problems during childbirth that affect the baby. For example, the umbilical cord wrapped up prevents oxygen from reaching the fetus, which in turn causes brain problems and then problems in learning in the future.[6] Regarding to birth weight of children, more than halve (63%) of them were under (2.5 kg). there are several factors for low birth weight (<2.5 kg), and most of these factors have existed during pregnancy like Injury or ailments, cigarette smoking, alcohol drinking, which might lead to other negative consequences.[6] Osman (2012) elicited that problem in speaking, hearing and visual abilities considered as genetic causes of slow learners.[7] In the present study most of the members of the sample had problem in speaking and hearing abilities so that, they are vulnerable for learning problems including slow learning.

Conclusion

Most of the slow learners were young children, male pupils outnumber female pupils, their parents had low educational level, they have moderate economic status, majority of them live with their parents (father and mother), and most of them had no other family members with slow learner. Low birth weight, type of delivery and genetic factors were considered as predisposing factors for slow learning. So that, more antenatal care should be provided for all mothers especially those with high risk of contributing factors during pregnancy.

Conflict of Interest: None of the authors have any conflicts of interest to declare.

Source of Funding: The research was performed independently, there is no funding.

Ethical Clearance: The project was approved by the local ethical committee in University of Kirkuk. Informed consent was taken from each students parent.

lncRNAs as New Biomarkers in Systemic Lupus Erythematosus: A Prospective Study

Olfat Gamil Shaker[1], Yasser Hussein Nassar[1], Tamer Atef Gheta[2], Randa Mohamed Essameldin Moussa Erfan[3]

[1]Professor, [2]Lecturer, Medical Biochemistry and Molecular Biology Department, Faculty of Medicine, Cairo University, [3]Lecturer, Rheumatology and Rehabilitation Department, Faculty of Medicine, Cairo University

Abstract

Aim: To investigate serum levels of two Immune-related functional lncRNAs, growth arrest-specific transcript 5 (GAS5) and metastasis-associated lung adenocarcinoma transcript 1 (MALAT1), in Egyptian patients with SLE and to evaluate their relationship with disease activity.

Method: The present study was a case-control study that was carried out on 39 patients with SLE and 46 age and sex-matched healthy controls. The expression levels of GAS5 and MALAT1 were measured using by real-time polymerase chain reaction (PCR).

Results: There were statistically significant differences between cases and controls in GAS5 ($p < 0.001$) and MALAT1 expression ($p < 0.01$). The mean GAS5 was significantly higher in the control; while the mean MALATI expression was significantly higher in SLE patients. The ROC curve revealed that GAS5 was a good discriminant with AUC 0.849 with sensitivity 93.5% and specificity 74.3%. Moreover, MALAT1 was a good discriminant to differentiate cases from controls with AUC 0.3 with 95% CI (0.162 - 0.438), the most suitable cut-off point was ≥ 2.1 with Sensitivity 93.5% and Specificity 72.5%.

Conclusion: GAS5 and MALAT1 may serve as potential biomarkers for the diagnosis and monitoring of the SLE, both lnRNAs exhibited a good diagnostic accuracy to discriminate between SLE patients and healthy controls.

Introduction

Systemic lupus erythematosus (SLE) is a progressive, chronic, disorder that affects multiple systems with recurrent episodes of exacerbations and remissions[1]. According to recent epidemiological figures, the estimated global incidences of SLE ranges from 0.3-23.2 per 100 000 person-years[2]. Although the exact pathogenesis of SLE is still unclear, it is widely believed that the disease arise as a result of abnormal autoimmune process; patients with SLE were found to have defective clearance of apoptotic cells with subsequent development of auto-antigens and dysregulated immune responses (affecting both innate and adaptive immunity)[3,4]. Various environmental and hormonal factors were linked to increased risk of SLE in genetically susceptible individuals[5]. SLE is characterized by wide range of clinical manifestations that mainly affects women in their reproductive age, patients with SLE often present with fatigue, weight loss, myalgias and muscle weakness, recurrent infection, and migratory polyarthropathy[6]. Moreover, a considerable proportion of the patients present with multiple systems affection

such as lupus nephritis, pericardial disorders, valvular abnormalities, and cognitive dysfunction[7].

Therefore, it is critical to diagnose SLE early and identify patients with increased risk of high disease activity in order to optimize SLE outcomes. Over the past few decades, a wide spectrum of biomarkers have emerged for early detection of SLE including antibodies, complement and complement split products, cytokines, chemokine biomarkers, and epigenetics-related biomarkers such as noncoding RNAs[8]. The noncoding RNAs are regulatory RNAs that control many biological process such cell cycles, apoptosis, and remodeling[9]. Long noncoding RNAs (lnRNAs) are the largest proportion of mammalian non-coding transcriptome (larger than 200 nucleotides) that are key components of many structural, activating, and/or functional roles within the body[10]. Previous study has shown that lnRNAs play significant role in the pathogenesis of different diseases such as cancer and neurological disorders[11,12]. Recently, a growing body of evidence reported increased expression of a number oflnRNAs in SLE patients. Owing to their immune-related functions and regulatory role in apoptosis, lnRNAs are proposed to contribute significantly in the molecular pathogenesis of SLE[13]. Thus, they may serve as accurate biomarkers of SLE development and activities.

We performed this study to investigate serum levels of two Immune-related functional lncRNAs, growth arrest-specific transcript 5 (GAS5) and metastasis-associated lung adenocarcinoma transcript 1 (MALAT1), in Egyptian patients with SLE and to evaluate their relationship with disease activity.

Materials and Method

Study Design and Patients: The present study was a case-control study that was carried out from November 2017 to August 2018 in the Medical Biochemistry Department, Cairo University. The study included 39 patients who were diagnosed with systemic lupus erythematosus (SLE) and 46 age and sex-matched healthy controls. Adults patients (aged >18 years old) with diagnosis ofSLE according to the 2012 Systemic Lupus International Collaborating Clinics (SLICC) criteria were included[14].We excludedpatients who had any other illnesses that might affect the results of the study such as chronic liver, familial hypercholesterolemia, thyroid and parathyroid diseases, and malignancy as well as any other rheumatic disease.

Data Collection: All patients were subjected to full history taking and clinical examination including SLE Disease Activity Index (SLEDAI). In addition, we recorded the results of complete blood count (CBC), bleeding profile, and kidney function tests. The expression levels of GAS5 and MALAT1 were measured using by real-time polymerase chain reaction (PCR).

Expression levels of the studied lncRNAs: Whole blood samples (5ml) were taken from SLE patients and controls. Serum was separated from the whole blood for quantitative expression of long non-coding RNAs by real-time PCR.RNA was extracted from serum by miRNeasy extraction kit (Qiagen, Valenica, CA) using QIAzol lysis reagent according to the manufacturer's instructions. Sixty ng of total RNA were used in the reverse transcription (RT)step in final volume 20µl RT reactions using RT2 first strand Kit (Qiagen, Valenica, CA) according to the manufacturer's instructions. Serum expression levels of the studied lncRNAs were evaluated using GAPDH as internal control and ready made primers (MALAT-1 and GAS-5) and Maxima SYBR Green PCR kit (Thermo, USA) according to the manufacturer's protocol. The primer sequences for GAPDH were as follows: F 5′-CCCTTCATTGACCTCAACTA-3′, R 5′-TGGAAGATGGTGATGGGATT-3′.

Twenty µl reaction mixtures was used in RT-PCR by mixing 10µl master mix, 1µl readymade assay primer, cDNA, and RNAase-free water using Rotor gene Q System (Qiagen).

PCR conditions were as follow: 95°C for 10min, followed by 45 cycles at 95°C for 15s and 60°C for 60s. The cycle threshold (Ct) is the number of cycles required for the fluorescent signal to cross the threshold in real-time PCR. Gene expression relative to internal control ($2^{-\Delta Ct}$) was calculated. A melt curve analysis was done to ensure specificity of the corresponding RT-PCR reactions. Fold change was calculated using $2^{-\Delta\Delta Ct}$ for relative quantification. Using the data analysis of web portal, we calculated fold change/regulation with ΔΔCT method, in which ΔCT was calculated between gene of interest and an average of reference genes, followed by ΔΔCT calculations [ΔCT (patient) – ΔCT (control)]. Fold change is then calculated using $2^{-\Delta\Delta CT}$ formula.

Study's Outcomes: The primary outcome in the present study was the association between the expression levels of GAS5 and MALAT1 with SLE. The secondary outcome was the relation between the expression of the two lnRNAs and the activity of the disease.

Statistical Analysis: Data entry, processing, and statistical analysis were carried out using SPSS version 22.0. Frequency tables with percentages were used for categorical variables and descriptive statistics (mean and standard deviation) were used for numerical variables. The normality of the data was assessed using the Shapiro-Wilk Test. Tests of significance (Chi-square, student's t-test, or Mann Whitney's test) were used according to the normality of the data. The recessive operative characteristics (ROC) curve was performed to assess the diagnostic performed of studied gene expressions in discrimination between SLE patients and control group. A p-value<0.05 is considered statistically significant.

Results

The present study included 39 patients with SLE and 46 normal controls were included. The mean age of the patients was 29.68 ±6.96 years; while the majority of patients were female (89.7%). The mean duration of disease of the included patients was 5.72 ±5.53 years. The mean ESR and CRP was 51.69 ±36.14 mm/hr and 1.81 ±3.86mg/L. In addition, the mean total leucocyte count was 6.70 ±2.96 x1000 cell/mm^3. Regarding kidney function, all mean renal function parameters were within the normal range at the baseline. Only 33.3% of the patients had vasculitis, and only one patient (2.6%) had myositis. On the other hand, 33.3% and 46.2% of the patients had arthritis and pericarditis, respectively. In addition, 15 (39.1%) of patients were ANA positive and only 5 (10.9%) patients were DNA positive. The mean of C3 of the included cases was 54.13 ±35.13 mg/dl and C4 level was 10.12 ±10.02 mg/dl.The mean of SLE disease activity index (SLEDAI) in included cases was 5.75 ±5.32. Table 1 shows the baseline characteristics of the included patients.

Table 1: Baseline characteristics of the included subjects

Variables	Patients (N =39)	Control (N =46)	P-value
Age (Years)	29.68 ±6.96	33.5 ±9.5	0.1
Age at Onset (Years)	24.42 ±5.08	----	----
Disease Duration (Years)	5.72 ±5.53	-----	-----
Gender, No (%) 1. Female 2. Male	 35 (89.7%) 4 (11.3%)	 39 (84.7%) 7 (15.3%)	 0.46
ESR	51.69 ±36.14	----	----
CRP	1.81 ±3.86	-----	-----
TLC	6.70 ±2.96	----	----
PTC	248.78 ±91.92	-----	-----

Pericarditis	21 (53.8%)	-----	-----
SLEDAI score	5.75 ±5.32	-----	-----

*Data are presented as mean (SD), median (IQR), or No. (%)

In term of the primary outcome of the present study,there were statistically significant differences between cases and controls in GAS5 (p <0.001) and MALAT1 expression (p <0.01). The mean GAS5 was significantly higher in the control; while the mean MALATI expression was significantly higher in SLE patients (Figure 1). The ROC curve analysis revealed that GAS5 was a good discriminant to differentiate cases from controls with AUC 0.849 with sensitivity 93.5% and specificity 74.3%. Moreover, MALAT1 was a good discriminant to differentiate cases from controls with AUC 0.3 with 95% CI (0.162 - 0.438), the most suitable cut-off point was ≥ 2.1 with Sensitivity 93.5% and Specificity 72.5% (Figure 2 & 3).

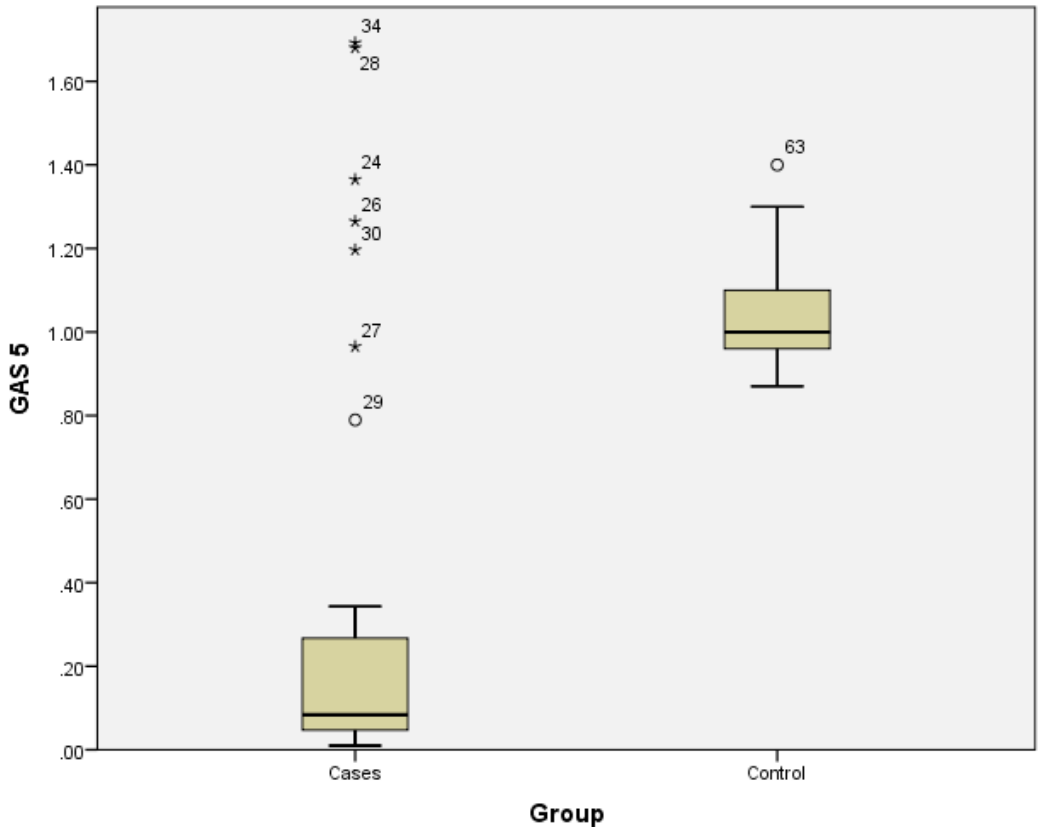

Figure 1: The difference in GAS5 expression

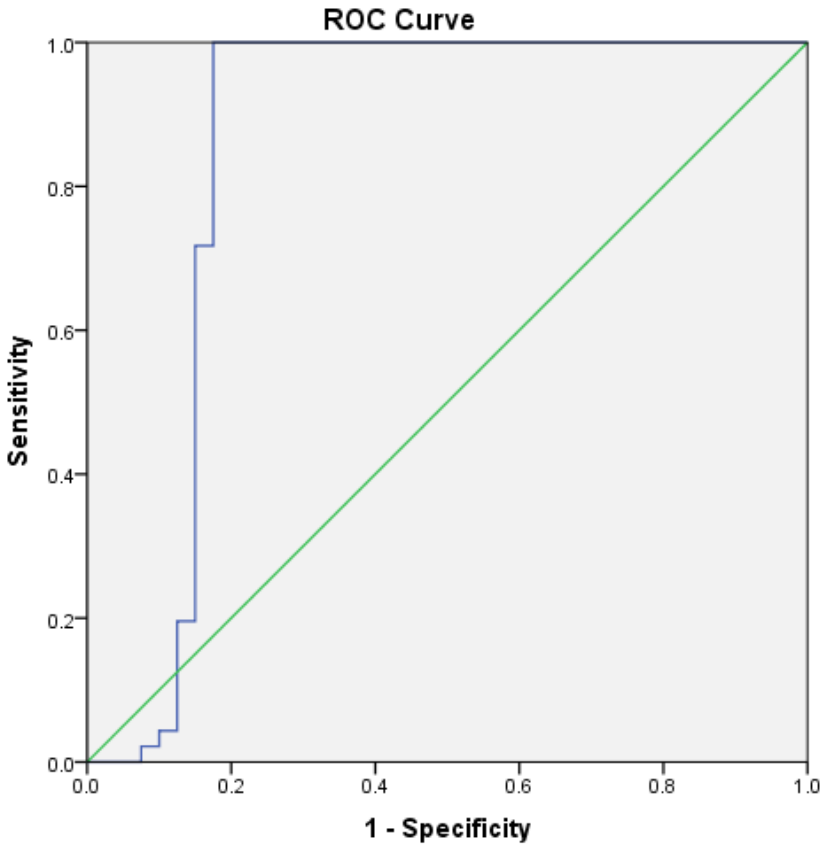

Figure 2: ROC curve analysis to explore the discriminant ability of GAS5 to differentiate between cases & controls

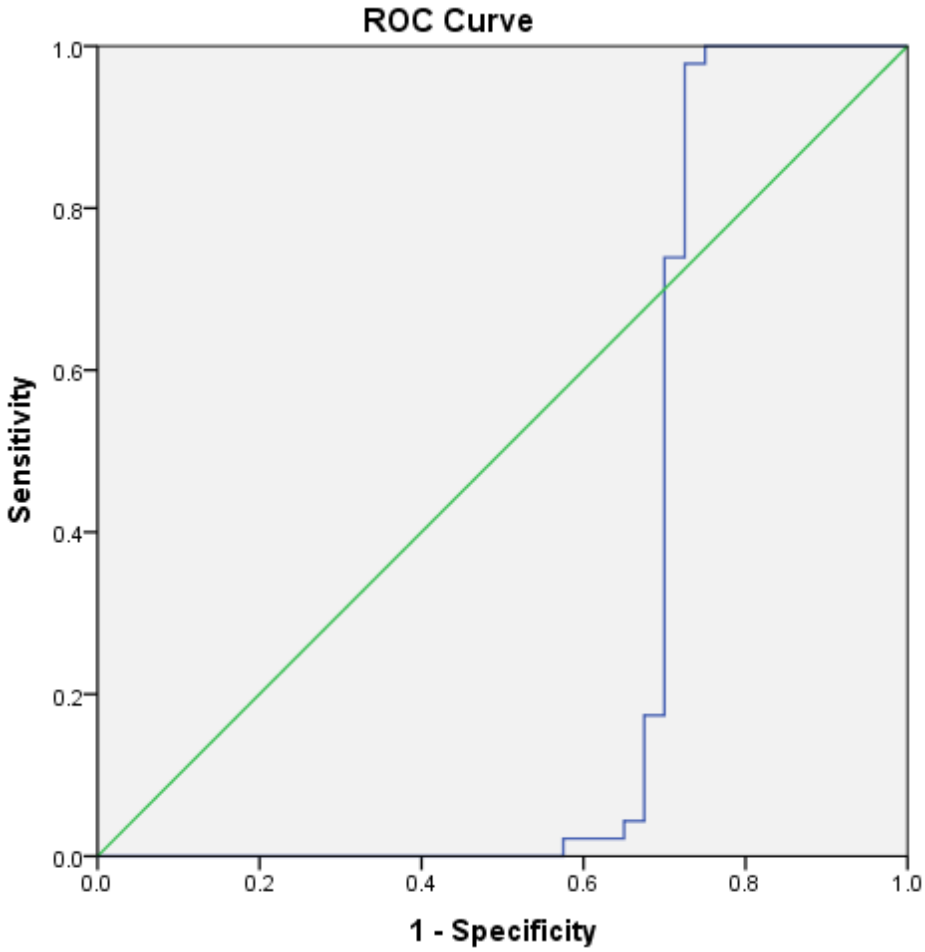

Figure 3: ROC curve analysis to explore the discriminant ability of MALAT1 to differentiate between cases & controls

Notably, patients with rash and mucosal ulcer had statistically significant higher GAS5 (p =0.037 and 0.002, respectively). Similarly, Patients with vasculitis had statistically significant lower MALAT1 (p =0.023).The correlation analysis showed that there were statistically significant negative correlation between MALAT1 and GAS5 (r =-0.314; p =0.003). In contrary, there were no statistically significant correlations between clinical variables and GAS5 or MALAT1.

Discussion

In the present study, both GAS5 and MALATI yelled good diagnostic performances for the detection of SLE. At cutoff values of <0.3, the GAS5 had a sensitivity of 93.5% and specificity of 74.3% for the detection of SLE. Similarly, an expression of MALAT1 of ≥ 2.1 had similar performance. On the other hand, the expression of both lnRNAs correlated significantly with some of the disease activities.

Over the recent few years, lnRNAs were implicated in the development and progression of many diseases including cardiovascular diseases, cancers, and autoimmune disorders[15–17]. Owing to their role in the development of immune system, lnRNAs are promising biomarkers for many autoimmune diseases including SLE. In the present study, we demonstrated that both GAS5 and MALATI yelled good diagnostic performances for the detection of SLE. At cutoff values of <0.3, the GAS5 had a sensitivity of 93.5% and specificity of 74.3% for the detection of SLE. Similarly, an expression of MALAT1 of ≥ 2.1 had similar performance. In concordance with our findings, Wu and colleagues[18] performed a two-stage study to explore the plasma levels of five lncRNAs (GAS5, linc0949, linc0597, HOTAIRM1 and lnc-DC) and their potential as SLE biomarkers. Compared with healthy controls, the expression level of GAS5 was significantly down-regulated. When SLE patients were divided according

to the presence of LN, the results showed that the levels of GAS5 was also significantly down-regulated in both subgroups relative to healthy controls. Furthermore, the plasma level of GAS5 could distinguish SLE from healthy controls with 65.03% sensitivity and 93.75% specificity. Similarly, Suo and colleagues[19] assessed the expression of GAS5 and microRNA (miR)-21 in SLE, and attempted to explore their association with clinical features. The results revealed that GAS5 was significantly lower in CD4+ T cells of patients with SLE compared with those in control subjects; however, there were no significant differences in GAS5 expression regarding the presence of nephritis. Another prospective study by Li and colleagues[20] included 85 SLE patients and 71 healthy controls to investigate the lncRNAs expression levels. It was found that GAS5 expression level was significantly lower in SLE patients than healthy controls.

Regarding MALAT1, Yang and colleagues[21] analyzed the expression of MALAT1 in 39 SLE patients and 45 matched normal controls. They found that MALAT1 was abnormally increased in the patients with SLE and predominantly expressed in monocytes. In monocytes of patients with SLE, silencing MALAT1 significantly reduced the expression of IL-21. Furthermore, their study demonstrated that MALAT-1 exerts its detrimental effects by regulating silent information regulator 1 (SIRT1) signaling.

The present study also investigated the association between clinical characteristics of SLE patients and the expression of both GAS5 and MALAT1. Patients with rash and mucosal ulcer had significantly higher GAS5. In addition, patients with vasculitis had significantly lower MALAT1. Similarly, Suo and colleagues[19] reported that the levels of GAS5 were higher in patients with ulceration than in those without.

There was no significant association of the SLEDAI with the GAS5 or MALAT1. However, Wu and colleagues[18] reported that GAS5 level was significantly lower in more active SLE patients than in less active cases. In addition, GAS5 level was negatively associated with SLEDAI-2K score in patients with SLE. Moreover, plasma level of GAS5 was also negatively correlated with the ESR.

We acknowledge that the present study has number of limitations. The sample size of the included patients was relatively small which may affect the generalizability of our findings. Moreover, the study was single-center experience. In addition, we could not control for potential confounding factors such as different clinical characteristics and different treatment strategies among patients.

Conclusion

In conclusion, GAS5 and MALAT1 may serve as potential biomarkers for the diagnosis and monitoring of the SLE, both lnRNAs exhibited a good diagnostic accuracy to discriminate between SLE patients and healthy controls. Moreover, GAS5 and MALAT1 were significantly higher in patients with rash and mucosal ulcer; while there was no statistically significant correlation between disease activity and lnRNAs expression. However, due to the descriptive nature of the present study, further studies on the exact role of lncRNAs in SLE pathogenesis are still needed.

Dandruff Disease; Reason and its Right Solution

Alaa H. Al-Darraji

Assist. Prof., Chemistry Department, College of Science, Lecture in Misan University, Misan, Iraq

Abstract

More than half of the world's population has dandruff, and people spend more than ten billion annually to defeat them. This study found by known experimental tests that dandruff is a mix of different molecules; saturated fatty acid, died cells and dust. A fifteen teenagers (22-25 years old) were randomly choiced for investigating some important information about dandruff. These teenagers indicate that they used many treatments last years without getting good results also they mentioned that dandruff appear in winter and it disappears at summer. In addition, they feel embarrass when see that their hairs have dandruff and sometimes itchy or hard one causing pain leading to unlikely behavior. This research contain the right treatment for this unlikely disease.

Keywords: *Dundruff, Malasezzia, Combing, Fungi and white crusts.*

Introduction

Malasezzia species inhabit the skin of all warm blooded animals and cause a myriad of problems, from allergies and infections in humans and horses to ear infections in cats. Admittedly, nonlethal skin conditions aren't serious infectious diseases like AIDS or bird flu, but several features make our research both interesting and broadly applicable[(1)].

Dandruff is a common scalp condition in which small pieces of dry skin flake off of the scalp. If you have dark hair or you're wearing dark colors, you may notice the flakes in your hair or on your shoulders. Dandruff may also make your scalp itch.

Many people believe that dandruff is caused by poor hygiene, but this is not true. Although infrequent shampooing can make dandruff more obvious, researchers are still studying the causes, which appear to be complex. The most effective way to treat and control dandruff is to use dandruff shampoo and scalp treatments[(2-4)].

Experimental Part:

This section was included three parts:

A. For identifying the dandruff nature is it oils or not! a copper acetate test was used for dandruff samples as follow:

   Put dandruff samples in 5 ml of ether for each then add five drops from copper acetate 10% to dandruff samples and noticing the product's color [(5)].

B. Salkowski test was done for characterizing is dandruff is fatty acid like or cholesterol like molecules. Put dandruff samples in 5 ml of ether then for each sample add 5 ml from concentrated sulfuric acid. Shake until two layers has appear, upper layer should have red color while lower one has green, this colors for compounds like cholesterol molecule[(5)].

C. Samples of dandruff were sent to biology department to recognize which species exist in dandruff samples[(6)].

D. Randomly 50 teenagers (22-25 years old) were asked about dandruff disease during them lives are they got it or not? In addition to another questions.

Results

Oil kind in Dandruff samples is saturated fatty acid with dust and died cells remnants [6]. Biology staff indicate that the dandruff samples contain a kind of Malassezia fungi either Malassezia globosa or Malassezia restricta. They indicate that it is difficult to recognize between which Malassezia kind is because they do not have necessary database. However, they show that above fungi have about 8 species. They

have given following picture about what they found in dandruff sample:

Figure (1): Malassezia fungi that appear in dandruff sample[6]

The 50 teenager about 49 from them have a dandruff recently or before that. They insure that this disease increase at winter than other seasons, in addition, they used many treatments but there is no sufficient one treated this disease 100% it keeps return each winter. Moreover, these teenager feel embarrassing when see white species of dandruff on their clothes.

Discussion:

Anatomy of each hair of human's bodies that their follicles contain special glands release specific oil called sebum that consisting from triglycerides and fatty acids (57%), wax esters (26%), squalene (12%), and cholesterol (4.5%) [6]. Experimental part show that dandruff samples do not contain cholesterol or other like molecules. However, cholesterol has less percent difficult to cause dandruff or maybe they have small activity but it is not like triglycerides or wax ester.

Malassezia fungi should have lipase enzyme able to break the ester bond of triglycerides or wax ester resulting; free fatty acids, glycerol and wax molecules. These lipids have special properties make them look like magnetic mass attracting other molecules such as dust or remaining of died cells producing white species called dandruff. In fact, free fatty acids have low melting points so they appear at cold weather while do not at hot weather because they condense at cold weather.

Dandruff reason is so clear but getting rid of this unlikely white species is hopeless because fighting of fungi creatures is useless. This fact is well known because all fungi when facing bad circumstances they form fungal spore can stand with strong conditions easy to spread out over air molecules to another person causing dandruff again and so on therefore removing of Malassezia fungi is hopeless with its spore in addition they are normal flora existing in most creatures [6].

Either it result from special fungi or another reason dandruff disease is unlikely disease so this research find that doing right combs in one time for at least two days should lead to remove dandruff, right combs means not strong but normal and well. This behavior should do for all hair over the scalp for removing different fungi, cells remnant…etc. In addition, fungi species need dark, net, quiet medium[4] so repeating comb each two days will removing above conditions leading to remove this annoying fungi. Therefore, well combing for all scalp each two days is good treatment for dandruff, it is amazing treatment.

Most teenager of this research indicated that they do not combing all them hair they comb only upper hair adding special lipids to do nice style. These aspects absolutely lead to dandruff. Most behaviors of teenager lead to dandruff therefore well combing for all scalp one time for each two days should successfully removing dandruff.

Conclusion:

Human's scalp normally excrete lipids such as triglyceride or cholesterol for wetting hair of the scalp, each hair have its gland that have above lipids. There are fungi species have lipase enzyme able to hydrolyze these lipids called Malassezia. It is a fact that there is no successful treatment for fungi species because if anyone remove them their spores should come back again or another person must transfer them again so this way there is no successful treatment for dandruff. Teenagers indicated that dandruff crusts come after the shower due to water molecules forced hydrophobic lipids for aggregating each other. Therefore, best treatment for dandruff is well combing each two days for removing all above things.

Processes Correction of Hybrid Problem-Based Learning Tutorial Sessions

Altaf Bandy

Family and Community Medicine, College of Medicine, Jouf University, Sakaka, Kingdom of Saudi Arabia

Abstract

Background: Globally, many variants of problem-based learning are operational in medical colleges. The hybrid variant of problem-based learning (PBL) is a difficult venture and needs special consideration. As a part of self-assessment process, medical schools need to have mechanisms in place to enable "Independent learning and self-directed promise" of PBL philosophy. This study gathered students' perceptions on PBL tutorials sessions to course correct any deviations in hybrid PBL implementation.

Method: Using a pre-validated questionnaire, this cross-sectional study conducted from February 2019 to March 2019, collected students' feedback on their experience with the processes of the PBL in College of Medicine at Jouf University. Students' responded to the questionnaire on a five-point Likert scale. For simplicity, the responses were grouped "agree", "neutral", and "disagree." Chi-square test assessed variation between groups.

Results: Forty-three students' returned the fully completed questionnaire: 23 (53.48%) were females and 20 (46.5%) were males. Interactive learning component of PBL received higher rating (65.1%): a significantly ($p < 0.01$) higher degree of agreement by the female students. Opinion on content similarity between PBL and lectures was shared equally (50%) by female and male students. The students were skeptical about the fairness in tutors' evaluation of students in PBL sessions, however, more male students were satisfied ($p<0.01$) compared to female students.

Conclusions: The study concludes existence of similarity of contents between lectures and PBL sessions. Tutors' attitudes and tutor's fairness in evaluation of students' PBL sessions is a concern. Limiting the number of supporting lectures, training students and tutors in PBL processes are studys' suggestions for successful implementation of hybrid PBL strategy.

Keywords: *Cognitive skills, Hybrid-PBL philosophy, Tutor dynamics, Tutor feedback, Preclinical skills.*

Introduction

The original form of problem-based learning (PBL) is currently non-existent[1]. More and more medical schools around the globe have opted for this instructional strategy. The characteristics of these medical schools and local constraints shaped its implementation, giving birth to a number of variants of problem-based learning[1-6]. PBL has undergone evolution, the implementation of genus PBL has resulted in the development of many species all striving for the basic promise of PBL philosophy[7,8].

One review on hybrid PBL implementation came up with the core condition of having PBL tutorials of small groups and the independent study, however, other emphasize on instructional method of traditional lectures, clinical skills and labs to support the PBL theme and to keep them at the minimum and not excluded[9,10].

With the near absence of the pure PBL strategy, the flourishing hybrid strategy is commonly seen in practice; hence some researchers have coined the term of standard PBL to describe the hybrid PBL strategy [1,11,12].

Hybrid PBL instructional strategy implementation is a challenging task, the supporting lectures, subject-related labs and the skill labs are delivered by the subject experts, thereby the system runs the risk of transmitting knowledge directly which is in conflict with the independent learning and self-directed promise of PBL philosophy. Furthermore, chances of adding more topics to the side by side lecture-based strategy is a common practice, rendering the second PBL session ineffective[13-16]. Faculty involved with the implementation of hybrid PBL curricula lacks an overall orientation on the philosophy of PBL and rather receive a focused initial training on running the PBL session, which they conceive as routine small group discussion as in traditional curricula[1].

Over the years, many medical colleges in Saudi Arabia has moved away from the traditional instructional teaching to new PBL instructional strategy and have mostly implemented the hybrid PBL instruction strategy[17-19]. Many reports from Saudi Arabia on the hybrid PBL strategy are satisfactory[20-24]. However, many of these findings are based on the information collected from the preclinical phase students highlighting the probable element of bias of positive responses.

The College of Medicine at Jouf University implements hybrid PBL System that forms an integral part of preclinical phase of undergraduate medical study. The teaching staff mostly come from conventional lecture-based curriculum, however, they receive an orientation on the processes of PBL tutorials sessions. There is every possibility of a conflict between the concept and reality in implementation. In this backdrop, the current study gathered opinions from the clinical phase students regarding the processes of PBL tutorial sessions.

Method

This cross-sectional study involved the fourth year students of College of Medicine at Jouf University. The study conducted between February 2019 and March 2019 included both female and male students who have passed the preclinical phase. The first three years of basic sciences (preclinical phase) in an integrated system in which students learn in PBL sessions augmented by lectures, skill labs and laboratory classes. Since the inception of College of Medicine at Jouf University, there has been no change in teaching strategy.

A pre-validated questionnaire collected information on the perception regarding the PBL sessions[25]. The participation was voluntary and required a proper consent. The sample size was calculated by epi-info 7 software. A conservative guesstimate of 12% of the participants' having good perception regarding the PBL session, 42 students were required at 95% confidence level and 5% margin of error. The questionnaire was distributed to the fourth year students during the midday break. Eight statements evaluated the students' feedback on the processes involved in the PBL session. Three questions evaluated the perceptions of tutor preparedness for the PBL session and about the evaluation processes of the students' contribution in the session. The local committee on bioethics (LCBE) at Jouf University approved the study protocol vide no: 5-16-4/1440.

Statistical Analysis: Statistical Package for Social Sciences version-20 (IBM Corporation, Armonk, NY USA) was used for data analysis. The data was coded before entry. The five-point Likert scale responses were merged as "agree" "neutral "and "disagree". Chi-Square test was used as a test of significance to measure variation between the males and females. The results were considered significant at a p-value of <0.05.

Results

A total of 47 questionnaires were received from the fourth year students, four questionnaires were incomplete. The 43 remaining questionnaires were analyzed, 23 (53.48%) from the females and 20 (46.5%) from male students. The overall mean score of agreement to the eight questions was 6.11± 3.27. The results show, 40% of males and 30% of females agreed to replace the PBL for lectures respectively. The females (52.2%) were more in agreement with the statement on receiving adequate training on PBL sessions. A higher proportion (65.1%) of the students felt that the PBL is an interactive method of learning, females reporting a significantly ($p < 0.01$) higher level of agreement. Repetition of the contents between PBL and lectures was a common concern shared equally (50%) by females and males (Table 1).

Table 1: Students perception on the processes of the PBL session

Questions	Categories	Total Participants n (%)	Male n (%)	Female n (%)	P-value
PBL can substitute lectures	Agree	15 (34.9)	8(40.0)	7(30.4)	0.80
	Neutral	9(20.9)	4(20.0)	5(21.7)	
	Disagree	19(44.2)	8(40.0)	11(47.9)	
There is proper students' training before starting the PBL session	Agree	20(46.5)	8(40.0)	12(52.2)	0.60
	Neutral	9(20.9)	4(20.0)	5(21.7)	
	Disagree	14(32.6)	8(40.0)	6(26.1)	
PBL is an interactive method of learning	Agree	28(65.1)	8(40.0)	20(87.0)	0.002
	Neutral	4(9.3)	2(10.0)	2(8.7)	
	Disagree	11(25.6)	10(50.0)	1(4.3)	
There is a repetition between PBL and lectures	Agree	22(51.2)	10(50.0)	12(52.2)	0.31
	Neutral	12(27.9)	4(20.0)	8(34.8)	
	Disagree	9(20.9)	6(30.0)	3(13.0)	
Students contribute equally in PBL session	Agree	13(30.2)	6(30.0)	7(30.4)	0.69
	Neutral	11(25.6)	4(20.0)	7(30.4)	
	Disagree	19(44.2)	10(50.0)	9(39.2)	
I give feedback to the others	Agree	25(58.1)	16(80.0)	9(39.2)	-
	Neutral	8(18.6)	0(0.0)	8(34.8)	
	Disagree	10(23.3)	4(20.0)	6(26.0)	
I contribute in group discussions Students contribute equally in PBL session	Agree	36(83.7)	18(90.0)	18(78.3)	-
	Neutral	4(9.3)	2(10.0)	2(8.7)	
	Disagree	3(7.0)	0(0.0)	3(13.0)	
I attend PBL session on time	Agree	39(90.7)	18(90.0)	21(91.3)	-
	Neutral	4(9.3)	2(10.0)	2(8.7)	
	Disagree	0(0.0)	0(0.0)	0(0.0)	

Overall mean of agreement: 6.11±3.27

Approximately half (51.2%) of the students' agreed tutors' preparedness for the PBL session. The majority of the students were either neutral (32.6%) or disagreed (20.9%) with the fairness of tutors' student evaluation of sessions. The male students showed a significantly ($p < 0.01$) higher agreement with fairness in the evaluation process compared to females (60.0% vs 34.8%) (Table 2).

Table 2: Students perception about tutors' facilitation of sessions.

Questions	Categories	Total Participants n (%)	Male n (%)	Female n (%)	P-value
Tutors are prepared to run the session	Agree	22(51.2)	10(50.0)	12(52.2)	-
	Neutral	6(14.0)	0(0.0)	6(26.1)	
	Disagree	15(34.8)	10(50.0)	5(21.7)	
Tutors evaluate students in fair way	Agree	20(46.5)	12(60.0)	8(34.8)	0.01
	Neutral	14(32.6)	2(10.0)	12(52.2)	
	Disagree	9(20.9)	6(30.0)	3(13.0)	
Tutors feedbacks were helpful to improve students' performance	Agree	23(53.5)	10(50.0)	13(56.6)	0.33
	Neutral	7(16.3)	2(10.0)	5(21.7)	
	Disagree	13(30.2)	8(40.0)	5(21.7)	

Overall mean of agreement: 1.51 ±1.26

Discussion

Many medical schools across the globe have adopted problem-based learning as an innovative student centered learning strategy. This new educational strategy helps develop collaborative and cognitive learning, and interpersonal communication skills consistent with the desired attributes of a competent physician[25-29].

Medical schools in this part of the world have adopted PBL instructional strategy, assuring a high quality medical practice consistent with international standards. Education ministry in Saudi Arabia has endorsed this new instructional system resulting in the increased adoption of the hybrid PBL system in medical schools across the nation. In the current study, interactive learning component of the PBL received a high (65.1%) perception rating consistent with earlier reports describing the PBL an innovative instructional strategy improving the learning outcomes compared to traditional strategies[30-32]. This finding is also in agreement with reports from medical schools across Saudi Arabia[22,33-35]. This finding supports interactive learning component of the hybrid PBL system in the College of Medicine at Jouf University. The PBL derived interactive learning skills not only helps students' knowledge to bloom but also has a positive effect on the harmony of small group discussions[15,36]. Azer (2005) reported that group dynamics are proportional to interpersonal interactions, ability to arrive at the hypothesis to resolve the problem in the tutorial session and students' training in critical thinking[37] It is essential to maintain proper group dynamics for better outcomes of a PBL sessions. However, reports have also blamed PBL educational strategy as time consuming with no impact on the gain in knowledge[38]. These conflicting finding about the PBL strategy across medical schools necessitates evaluation of the processes of PBL tutorials that can help in course correction and prevent a dysfunctional hybrid PBL system.

In the current study, 83% of the students' showed a positive perception in the group discussions. It has been noted that students' preparation holds key of a purposeful participation in the group discussions[21]. In our study fewer students' showed dissatisfaction in the group discussions that might indicate sufficient time slots for self-directed learning between the first and last PBL session and may also point to an effective academic advising by the faculty to achieve the learning objectives of the PBL scenario. This skill of group discussion learned in the preclinical phase may help students' understanding of the clinical subjects and needs reinforcement during bedside teaching sessions. The faculty involved in clinical teaching should be encouraged to devote sufficient time for group discussions in clinical phase to keep this skill persistent for long-term learning. Cognitive skills and persistent motivation affect the outcome of the tutorial group. Student interactions and knowledge sharing during PBL sessions are features of a successful implementation of PBL tutorial sessions[6,39].

The number of supporting lectures in the hybrid PBL should be minimum and should not directly transfer the knowledge that extinguishes the problem trigger[4], hence the supporting lectures on the weeks' theme should be unbiased for the success of the PBL philosophy. In general, more than one third of participants agreed PBL can substitute the lectures and another one half of participants perceived the content repetition. This finding highlights the need for medical education specialists and a need to rectify these issues to avoid a dysfunctional hybrid PBL implementation.

The other components that affect a successful PBL implementation include the tutors' facilitation process and the students' training on the PBL, both of which are critical to avoid the dysfunctional hybrid PBL implementation. Students' training on PBL is important for purposeful group discussions and overall tutorial group productivity[40]. Nearly half of the participants agreed to receive a training about PBL tutorials that is essential for the success of PBL session. The positive impact on students' training has been reported in literature[41]. Reports from KSA have shown lack of orientation and training of students' end up with a poor performance of PBL sessions[25]. For the successful implementation of hybrid PBL, several limiting factors are considered that include, educational environment, tutor learner attitude, PBL scenarios and the optimal assessment method[32]. In the current, only half of the participants opined satisfaction with tutors' preparedness for the PBL tutorial session.

Tutors positive attitude has been reported as an important factor in the implementation of a successful PBL program[32]. However, other reports have highlighted the tutor dynamics in enhancing or suppressing the development of PBL skills of critical thinking and collaborative learning skills among the students[17,40]. These less positive perceptions about

tutors' attitude ask questions. Faculty development program in College of Medicine at Jouf University need to focus on tutor skills for success of the hybrid PBL strategy[42-45]. Tutors constructive feedback is crucial for the improvement of student learning outcomes[21, 46]. Tutors feedback towards the end of session helps the students to identify their weakness and strengths. In the current study, half of the students were satisfied with the tutors' feedback in the improvement of their performance.

Our study participants presented with conservative estimates on the tutors' evaluation of students' in the PBL sessions. The majority of the students were either neutral or disagreed with the fairness of their evaluation by the tutor. Similar finding has been earlier reported from Saudi Arabia[25]. The perception on tutors' attitude and fairness in the assessment process highlight the need for tutor trainings.

The results of this study should be interpreted in the lights of some limitations. These limitations in the current study need to be addressed in future researches. The first real limitation lies in the single centre study that may not reflect the perceptions of medical students across the country. Second limitation is questionnaire-based data collection. Thirdly it involves students of the clinical phase only that might have affected the lack of seriousness of responses. The choice of the study participants is the strength of the study. The study involves students from the clinical phase having no compulsion of being positive in their responses. Furthermore, proving insights about the PBL processes retrospectively after furthering their experience with clinical phase teaching could be presumed more rational than preclinical experiences only. The future research should include in depth discussions with preclinical and clinical phase students and tutors to identify the barriers in successful implementation of hybrid PBL strategy

Conclusions

PBL tutorial sessions are effective interactive sessions, however, repetition of the contents between the PBL and lectures exist. Fairness in students' evaluation by tutors remains a concern. The study advocates revising PBL strategy in College of Medicine at Jouf University to improve the outcomes of PBL sessions with special emphasis on reducing the number of lectures and an effective evaluation by the tutors.

This study offers suggestions of potential benefit to the implementation issues of hybrid PBL strategy. Sufficient number of time slots for self-directed learning (SDL) can help students' complete the learning issues for the 2nd PBL session and enhance group discussions. Improving problem trigger of scenario, minimizing the frequency of supporting lectures and by avoiding direct transfer of knowledge will foster self-directing learning. Students' pre-PBL training and training of tutors' on the facilitation process is of importance to bypass a dysfunctional hybrid PBL. Effective assessment method of students' during PBL sessions as well as a well-constructed PBL scenario can help successful outcome. Tutors training on the evaluation of PBL sessions through faculty development program can bring positive attitudinal change and fairness in the assessment.

Abstract

Background: Mumps is a disease caused by the mumps virus. It spread from human-to-human via direct contact or by airborne droplets. Initial signs and symptoms often include fever, muscle pain, headache, poor appetite, and feeling generally unwell. This is then usually followed by painful swelling of one or both parotid salivary glands

Method: A cross sectional study conducted in Al-Yarmouk teaching hospital during the period from January 2017 through December 2018. All patients of different ages and from both sexes diagnosed with mumps were included in this study.

Results: Most infections 72.1%occur in age groups ≥15 years. The high percentage of cases occur in males (62.5%). Cases reported among the vaccinated patients in all age groups, 16 patients (55.2%) of children were ≤14 years of age. Those who don't know about their vaccination state constitute (77.3%) of patient aged ≥15. There was a significant association between immunization state and age. High percent of infection in 2017 were in March (14.4%), April (10.6%) and January (7.7%) while lowest rates of infection were showed in year 2018 for the same period.

Conclusion: The role of vaccination was limited in protection of patients against mumps disease; third booster dose of mumps vaccine is recommended to prevent future epidemics.

Keywords: *Mumps, Baghdad, vaccination.*

Introduction

Mumps is a disease caused by the mumps virus[(1)]. It spread from human-to-human via direct contact or by airborne droplets. Initial signs and symptoms often include fever, muscle pain, headache, poor appetite, and feeling generally unwell[(2)(3)]. This is then usually followed by painful swelling of one or both parotid salivary glands[(3)(4)]. Symptoms typically occur 16 to 18 days after exposure and resolve after 7 to 10 days[(1)(2)]. About one third of people have mild or no symptoms, these are often more severe in adults than in children[(2)]. Immunity is generally life long and develop after either inapparent or clinical infections[(5)].Live mumps vaccines are available as monovalent mumps vaccine, bivalent measles-mumps (MM) vaccine, and trivalent measles-mumps-rubella (MMR) vaccine. Following the use of mumps vaccine in the USA in the late 1960s, disease incidence declined dramatically, and by the 1980s very few cases were reported[(6)]. However, large,

sporadic mumps outbreaks began to appear globally, involving a high percentage of persons with a history of vaccination[7].In Iraq, the total number of mumps' cases reported in 2003 was 7051 case. The number of cases increased to 11821 during January to April 2004. There was a dramatic reduction in the number of cases (less than 1500) reported in the following 8 months (May to December 2004)[8].

Studying mumps antibodies, Quasim (2010) in Mousal city found seropositivity against mumps virus among different age groups was 68%[9]. Study done by Baiee and Hatif (2018) they found that about half of the patients (56%) were vaccinated against the mumps disease in two districts located in the southern region of Babylon governorate[10]. Park et al. (2007) examine the discriminate between primary and secondary vaccine failure in a highly vaccinated population for mumps after an outbreak of mumps occurred in Gyeonggi, Korea in 2006[11]. Vaccination coverage during the years 2008 and 2009 was 92.4% and 93.6% respectively indicating a highly vaccinated population in the village in Orange County in New York State where the mumps outbreak occurred[12].WHO recommends immunization coverage of 90% to prevent outbreaks of mumps[13].

Aim of Study: The current study designed to determine the rate of occurrence of mumps in 2017-2018(minor outbreak) in Baghdad.

Patients and Method

A cross sectional study conducted in Al-Yarmouk teaching hospital during the period from January 2017 till December 2018.

All patients of different ages and from both sexes diagnosed with mumps were included in this study. Data were obtained from the hard and soft records in the "Communicable Disease Control Program"/public healthunit.

Data were grouped tabulated and presented as frequencies ant percentages Chi-square test was performed using statistical package for Social Sciences (SPSS) Version 24.0. P-value of 0.05 and less was considered as significant.

Results

The total number of cases were 104, the range was 2-68 years, and the mean and standard deviation of age was (27.08±15.287).

Table-1 showed the older age group represented the largest one 75(72.1%), they were at the age group of 15 years and older. The smallest age group 29(27.9%) were of the less and equal 14 years. Male were affected more than female in this study (62.5% and 37.5% respectively). Higher percentage of occupation were the employed 51(49%) while the lowest rate was in those without working 7(6.7%).

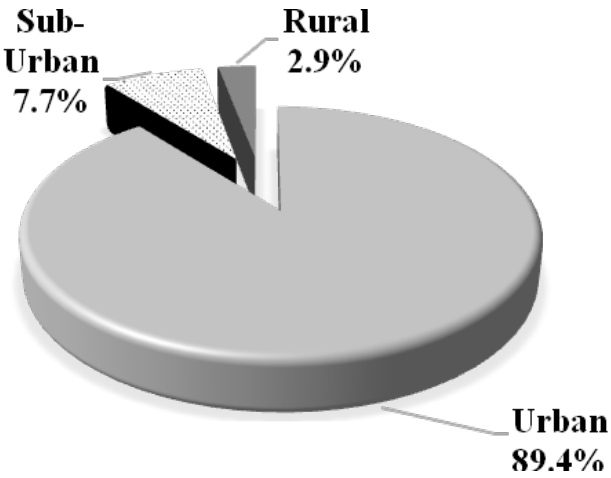

Figure 1: Distribution of patients according to residency

Figure-1 represented the residency of the patients where 89.4% came from urban area, 7.7% came from suburban, and the remaining 2.9% were from rural areas.

Table 1: Main characteristics of the study sample

Variables (N=104)	N	%
Age Groups		
≤14	29	27.9
≥15	75	72.1
Gender		
Male	65	62.5
Female	39	37.5
Occupation		
Employee	51	49.0
Worker	9	8.7
Not working	7	6.7
Student	26	25.0
Child	11	10.6

Bar chart in figure-2 shows that the highest frequency of cases in year 2017 occurred in March (14.4%) and the lowest in December was not cases registered and most cases in the year 2018 in October, November and December were the same percent (4.8%) and lowest in June was (0%).

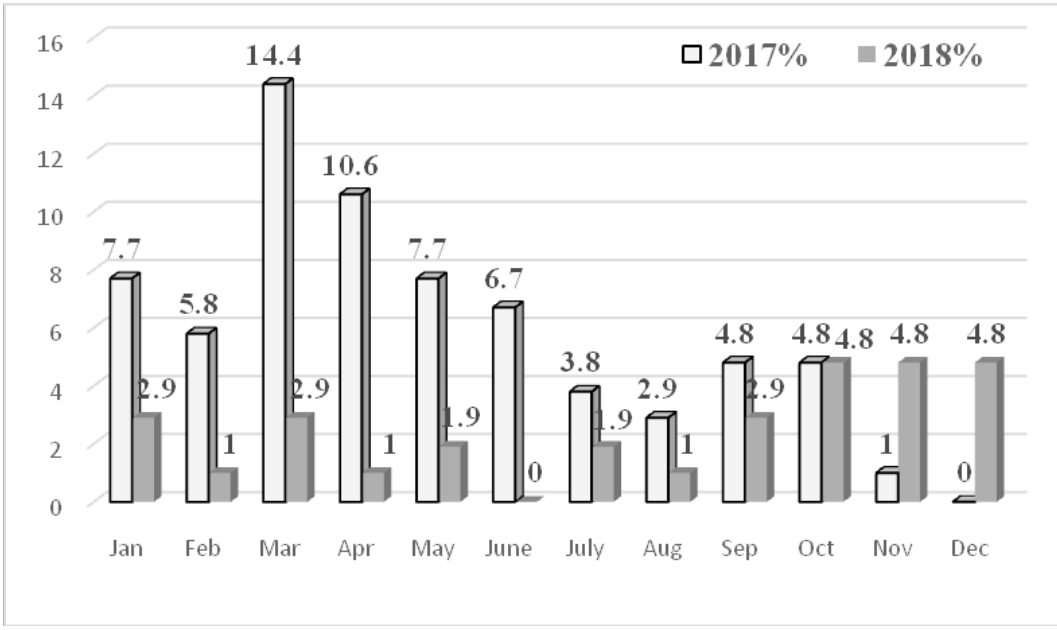

Figure 2: Distribution of cases according to months in years 2017 & 2018

Cases of mumps reported among the immunized patients in all the age groups, 16 patients (55.2%) of children were ≤14 years of age. For those aged ≥15 the rate of occurrence of mumps was higher among the Don`t know about their vaccination constitute (77.3%). Significant association between immunization state and age was (P = 0.002).Patients of both sexes had the infection in spite of being vaccinated male (33.8%) and female (25.6%). Although the relationship between immunization state and infection was not significant (P = 0.653) (table-2).

Table 2: Distribution of immunization status according to age and gender

Variables	Immunization								P-value
	Yes		No		Don`t Know		Total		
	N	%	N	%	N	%	N	%

Table 3 showed the highest rate of recorded mumps cases was during Springs (39.4%) followed by Autumn at a rate of (23.1%) which is very close to that during Winter (22.1%) the lowest rate was during Summer (15.2%). Children and adult encounter the infection mainly in Spring (41.4%)and (38.7%) respectively. The highest infection rate among male was in Spring 44.6%) and among female was during Autumn (35.9%). There was no significant relationship between season of recorded cases in one hand and the age and gender in the other hand P=0.173 and P=0.081 respectively.

Discussion

Age, gender and occupation: Three quarter of patients in this study were adult, age ≥ 15 years old. This agree with Jasminka et al. study in 2015 in Vojvidina, Serbia who found most of their study samples occurs in age groups of 15 29 years of old [(14)]. But disagree with Areej study in 2018 in Baghdad who found most of the patients were in the age group below 15 years of age[(15)].

Regarding the gender, the results of our study demonstrated that males affected more than females, this could be explained by that male more moving outside doors and they usually engaged in different types of work leading to high person to person contact. This findings went with the findings of Areej, in 2018[(15)] and with Jasminka et al. in 2015 in Vojvidina[(14)].

Regarding the occupation, About half of the sample were employee, Yu G et al. in 2018 found in his study in Guangxi, China that slightly higher than half of the patients were students[(16)].

Residence: Regarding the residence, the results demonstrated that the higher percentage of exposure in urban areas (89.4%), Baiee HA, Weli H, 2017 in Babylon province, Iraq which agree with this study who found most of study samples in urban more than rural areas[(10)].

Time (Month`s exposure): The results of this study revealed that the higher percentage of exposure was in March 2017 followed by the percentage in October, November and December 2018, Baiee and Hatifin 2017 in Babylon province, Iraq showed results that disagree with this study,they found most of most of cases were in January[(10)] Again disagree with Areej in 2018, who depict most cases occurred in January[(15)].

Immunization Status: Regarding immunization status the results illustrated that the higher percent of cases occurred among immunized patients in age groups ≤14 years, this disagree with Jasminka et al. in 2015, Serbia which depict high cases occurred in age groups 20 - 29 and 15 - 19 years of old respectively[(14)]. Also disagree with Whelan et al. in 2010 in Netherlands who found most cases recorded in cases aged 22 years of old vaccinated with two doses [(17)].

We found that infection affect vaccinated patients of both sex with male affected slightly more than female. This in agreement with Orlikovaet al. 2016 in Czech Republic which demonstrate higher males affected than females[(18)].

Season occurrence with age and gender: during spring season highest number of cases reported in age group of ≤ 14 years this in contrast to Yi-Chienet al. 2015 in Taiwan which illustrated that most cases in summer season[(19)].

Regarding to the gender the results illustrates that the higher percent of males cases occurred in spring but the higher percent of female cases occurred in autumn which agree with Sawsan and Al-Hasnawi, 2018 in Karbala, Iraq which showed that most males infected in March (spring) season while most females in the last of November (autumn) and first December (winter)[(20)].

Ethical Issue: A formal clearance was taken from the Ethical Committee of Al-Yarmouk teaching hospital. All used data were confidentially kept for the purpose of the study.

Source of Funding: Self-funding

Conflict of Interest: We declare that there was no any conflict of interest.

Treatment Options of Peyronie's Disease

Mohammed Abdel Malek Hasan[1], Ehab Rifaat Tawfik[1], Alayman Fathy Hussien[2], Adel Mohammed Ali Salheen[3]

[1]Professor, [2]Professor of Urology, [3]Specialist Surgeon, Department of Urology, Faculty of Medicine, Minia University, Egypt

Abstract

Objective: Peyronie's disease (PD) is a localized fibrous scar in the tunica albuginea of the penis resulting in a palpable penile plaque, penile pain on erection, penile curvature and erectile dysfunction. This study evaluated our own experience with clinical outcomes after different method of treatment for PD.

Patients and Method: The study included 62 patients with PD aged from 33-72 years. Two groups of patients were evaluated, the first one (Non-surgical) included 44 patients, 30 of them treated with oral therapy and 14 patients had intralesional Verapamil injection. The second group (Surgical) included 18 patients, 10 had plication of the tunica albuginea in the contralateral side of the fibrous plaque, and 8 patients had penile prosthesis implantation.

Results: Oral therapy associated with improvement of penile bending in 50% and improvement of painful erection in 40%. Intralesional Verapamil injection results in improvement of penile bending was 56% and improvement of painful erection 70%. The plication of the tunica albuginea results in improvement of penile bending 80%, improvement of painful erection 70% and improvement of erectile function 60%. With penile prosthesis implantation, all patients had improvement of penile bending and 83% of them had improvement of painful erection. Post-operative patient's satisfaction increased gradually by time from 3 to 9 months.

Conclusion: The proper choice of treatment for PD affects its outcome. For surgery, the preferred option is plication in mild to moderate deformities with considerable penile length while penile prosthesis is reserved for patients with erectile dysfunction.

Introduction

Peyronie's disease (PD) is a connective tissue disorder of the penis which affects the tunica albuginea with excessive fibrosis and plaque formation, but the exact etiology and pathophysiology remain unclear[1].

Non-surgical treatment of PD includes oral, intralesional and shockwave therapies. For the acute phase, there are numerous available oral drugs, but with weak scientific evidence. For intralesional injections, collagenase clostridium histolyticum is currently the only approved drug for the management of PD and a palpable plaque with dorsal or dorsolateral curvature >30°, whereas calcium channel blockers and interferons (IFN) remain as off-label options[2].

Surgical treatment of PD is indicated in cases with significant, stable deformity and associated with high success rates [3]. The surgical management should aim to correct the curvature, preserve erectile function and penile length, and minimize morbidity. The available evidence-based data could not determine the best surgical treatment of PD[4].

The aim of this study was to evaluate outcome of the treatment modalities of PD either non-surgical or surgical treatment to overcome this public clinical problem.

Patients and Method

This observational prospective study included 62 patients with PD, characterized by mild to moderate degree of penile angulation and painful erection, who attended the outpatient, Urology and Andrology clinic at Minia University Hospital, from December 2013 to September 2018, after approval from the department of ethical committee.

The patients were divided according to the method of treatment into 2 distinct groups: non-surgical or surgical. The inclusion criteria for non-surgical group were: acute phase of the disease with short duration from its onset (3-6 months), and preference from the patients who refused the surgical intervention. The inclusion criteria were for surgical group were severe penile angulation during erection to the degree that it affected patient's sexual life with his partner, failure of medical treatment for at least 6 months therapy, and erectile dysfunction not responding to oral therapy. The exclusion criteria for non-surgical group were: severe penile angulation, and severe degree of erectile dysfunction. The exclusion criteria for surgical group were: major renal or hepatic impairments, history of myocardial infarction or cerebrovascular strokes, and uncontrolled diabetes mellitus.

The patients were evaluated by medical and sexual history, Questionnaire for PD [5], and physical examination during the first visit according to initial evaluation and treatment provided to them. The patients were divided into two main groups. The first group (non-surgical), included 44 patients who received oral therapy with L-Carnitinine, Vitamin E and Colchicine for 6 months (n= 30), or intralesional injection with verapamil injection (n= 14). The second group (surgical), included 18 patients, 10 of them were operated upon for Tunica Albuginea plication (Figure 1- A, B, and C), and the other 8 patients were operated upon for penile prosthesis implantation surgery (Figure 1- D, E, and F) when there were severe degree of erectile dysfunction. All of patients in the surgical group were followed in outpatient clinic every 1 week for 1 month, then every 2 weeks for 2 months and every 2 months for 1 year. Postoperative patient satisfaction was estimated at 3, 6, and 9 months using the Modified Erectile Dysfunctions Inventory of Treatment Satisfaction (MEDITS) questionnaire.

The statistical analysis was performed using the IBM-SPSS statistics software version 20. Continuous variables of data were represented as mean and standard deviation and qualitative data were represented as number and percentage. Differences in the mean of continuous variables were analyzed using t student test. Differences in the percentage of qualitative variables were analyzed using Chi-square test. The values $P < 0.05$ were regarded statistically significant.

Results

The included patients aged from 33 years to 72 years with mean age of 50.9 ± 7.2 years, and the highest incidence (38.7%) was from 51 to 60 years old. The results of penile Doppler Ultrasound included arterial insufficiency in 40 patients (65.3%), and venous leak in 22 patients (34.7%). In 18 patients who underwent surgical intervention, the preoperative risk factors were smoking (83%), diabetes mellitus (66%), hypertension (50%). and previous penile trauma (50%).

Regarding the effects of oral therapy and intralesional therapy on penile bending and erectile function (Table 1), 15 out of 30 patients (50%) who received oral therapy had significant improvement in curvature from 30 degrees to 18 degrees, and only 12 cases (40%) had improvement of painful erection. In a group of 14 patients who received intralesional therapy, 8 patients (56%) had improvement in penile curvature from 40 degrees to 22 degrees with a decrease in plaque size from 3 cm to 2.2 cm, and 10 patients (70%) showed improvement of painful erection. As regards results of surgical intervention (Table 1), 8 cases out of 10 (80%) developed improvement of penile bending from 40° to 10° after Tunica Albuginea plication, whereas all patients of penile prosthesis implantation (100%) developed improvement of penile bending from 45° to 0°.

Regarding the postoperative outcome in the group of 18 patients with surgical intervention (Table 2), early postoperative pain was addressed as discomfort in 11 patients (61%), tolerable in 4 patients (22%), and distressing in 3 patients (17%). Postoperative edema detected in 6 patients (33%), 3 of them had DM and the other 3 were hypertensive. Persistent pain during intercourse was detected in 6 patients (33%), 2 of them (11%) after plication of tunica albuginea and the other 4 patients (22%) after penile prostheses surgery

and resolved within few weeks. Superficial wound infection was detected in 5 patients (28%) and managed successfully, three of them were diabetic.

The MEDITS questionnaire was used to determine postoperative patient satisfaction (Figure 2). There was gradual increase in means of (MEDITS) from 3, 6 and 9 month respectively. The score was 72.3±18.8 at 3 months, 80.3±17.2 at 6 months and 84.2±16.7 at 9 months after surgery, which had a statistically significant difference ($P < 0.01$).

Table 1: Effects of different method of treatment of 62 patients with PD on penile bending and erectile function.

Variables	Non-surgical treatment			Surgical treatment		
	Oral therapy (n=30)	Intralesional injection (n=14)	P-value	Tunica Albuginea plication (n=10)	Penile prosthesis implantation (n=8)	P-value
Improvement of bending	15 (50%)	8 (56%)	0.71	8 (80%)	8 (100%)	0.19
Improvement of painful erection	12 (40%)	10 (70%)	0.06	7 (70%)	7 (87%)	0.40

Table (2): Postoperative outcome in the group of 18 patients with surgical intervention.

Variables	Surgical treatment (n=18)
Early postoperative pain:	
- Discomfort	11(61%)
- Tolerable	4 (22%)
- Distressing	3 (17%)
Postoperative edema	6 (33%)
Persistent pain during intercourse	6 (33%)
Superficial wound infection	5 (28%)

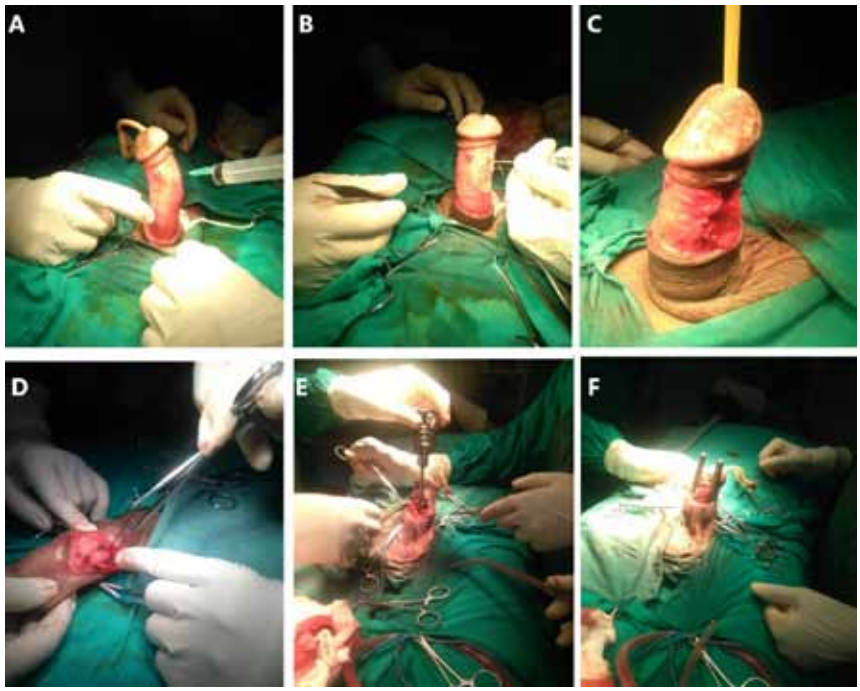

Figure 1: Tunica Albuginea plication: A) degloving of penile skin and intra cavernously injection with saline. B) Plication of other side of the deviation. C) Correction of the deviation. Penile prosthesis implantation: D) Penoscrotal incision and placement of stay sutures. E) Dilatation of cavernous tissue using urethrotome. F) Implantation of the penile prosthesis.

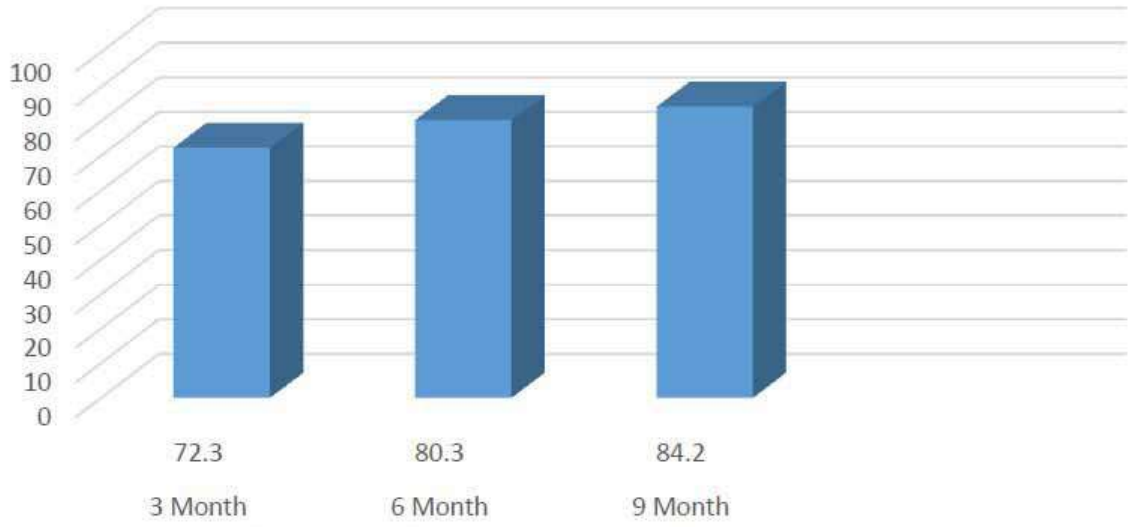

Figure 2: Mean scores of Modified Erectile Dysfunctions Inventory of Treatment Satisfaction (MEDITS) Questionnaire at 3, 6 and 9 months after surgery.

Discussion

There are many options for treatment of PD with a variation in their indications and outcomes. In our cases of oral therapy with a combination of Vitamin E, Colchicine, and L-Carnitine for 6 months, penile bending improved in 50% and only 40% showed improvement of painful erection. Use of Colchicine alone or combined with vitamin E has conflicting results in literature. Prieto Castro et al [6] reported decrease in the plaque size and improvement of the curvature in the vitamin E – Colchicine group with significant difference in comparison to ibuprofen group. Safarinejad MR [7] stated that the combination of vitamin E and colchicine might be a useful therapeutic option during the early stages of PD in patients with specific criteria of inflammatory activity. Moreover, we added L-camitine in the treatment of PD as it has antioxidant properties and its antiproliferative effects on endothelial cells.

In our study, intralesional injection of verapamil in 14 patients resulted in 56% improvement in penile bending and 70% improvement in painful erection. The intralesional verapamil injections could be advocated for the treatment of nonqualified acute phase or chronic plaques to stabilize disease progression or reduce penile curvature [8]. Longer treatment periods of concentrated Intralesional verapamil in younger men with small plaques but large curvature have been shown to receive the optimal benefit [9].

Surgical management allows for rapid and reliable correction of penile deformities that can be sustained for patient life. As no one procedure could be considered as a universal surgical standard of care or the optimal procedure, many procedures exist as penile plication, plaque incision/excision with grafting, and penile prosthesis implantation. But, penile reconstructive procedures do not fall into the domain of all urologic surgeons [10]. In our study, we performed plication surgery in 10 patients and penile prosthesis implantation in 8 patients. The plication procedures, the most common surgical treatment for PD, are attractive due to their good results as high degree of curvature correction and their relatively low risk of adverse effects. With the presence of many techniques for plication, the success and satisfaction may vary with the technique, but these differences do not reflect superiority of one technique over another and direct comparisons across the observational studies cannot be made [11].

In our study, 80% in the plication group and 87% in the prosthesis group had improvement in penile pending (curvature) with curvature correction rates range from 40% (with plication)-100% (with prosthesis). In literature the overall patient satisfaction ranges from 68–100%. The literature shows plenty of studies in which the curvature correction rates range from 42–100% [10]. Patient satisfaction after surgery may be related to straightening and improved sexual performance; while

dissatisfaction may correlate with many factors as postoperative penile shortening, erectile dysfunction, pain, change of penile shape, and worsening of curvature and sensation. Therefore, it is useful to inform the patient preoperatively about the suspected penile length loss by illustration on the long side of the penis, as measured during erection by measuring the difference in length between the long and short side of the penis [12].

In our study, the patients with penile prosthesis got 100% curvature correction and 100% satisfaction. Prosthesis implantation remains the gold standard treatment for PD requiring surgery especially that occurring concurrently with refractory erectile dysfunction. It's appropriate for severe deformity refractory to non-surgical management or failed plication/grafting, and with profound penile instability [11]. PD deformity correction rates with penile prosthesis implantation range from 84–100% [13]. Review of observational studies in literature reported curvature improvement of greater than 80% [14].

In conclusion, the choice of treatment for PD depends on the phase of the disease, stabilization of the plaque, and the presence of erectile dysfunction, which affect the outcome of treatment and patient satisfaction. The surgical procedure can allow rapid and reliable outcomes for correction of PD when the plaque is stabilized. The plication techniques are preferred for mild to moderate deformity with considerable penile length, and the penile prosthesis implantation is reserved for patients with erectile dysfunction.

Port Terminal Analysis Operation Towards Health, Safety, Security and Environment (HSSE) Approach

Wisata Taruna[1], Haryoto Kusnoputranto[2], Raldi Hendro Koestoer[3], Agus Edy Soesilo[4]

[1]Graduate School of School of Environmental Science, University of Indonesia, [2]Department of Environmental Health, Faculty of Public Health and School of Environmental Science, University of Indonesia, [3]School of Environmental Science, University of Indonesia and Ministry of Economic Affairs, Republic of Indonesia, [4]Ministry of Transportation, Republic of Indonesia, Jakarta, Indonesia

Abstract

Health Safety Security and Environmental (HSSE) are common concept used to assess company's operating performance and their supply chain majority in prominent company with high risk exposure. However, this concept has largely been underutilized within the ferry port terminal's operation. This study asks whether the HSSE principles can applied in the ferry port terminal in Indonesia in regard sustainable aspect. In particular, it examines whether Ferry port terminal of Merak can be considered as Ecoseaport. It focuses on major ferry port terminals at inter-island hub because of the increasing volume and movement of people and vehicles in the last five years. This research is aligned with the Indonesia government policy on 'Maritime Axis' and is relevant with the cancellation of the Sunda Strait bridge development. Through at system dynamics simulation, this research ultimately aims to contribute to the improvement of knowledge of stakeholders that will influence a concept formulation and implementation of policy and stands appropriately of HSSE aspect. A System Dynamics approach of this research is intended to analysis and formulated all those elements involved in ferry port terminal operation against wharf capacity, port carrying and supportive capacity, passenger, vehicle and motorcycle inflow and vessel availability to transporting and movement. It was concluded that during Muslim's feast period with number of passenger, motorcycle and vehicle stock were drastically increased than normal operation. This will affect to HSSE performance, especially health aspect which corresponding with escalate on number patient to be visited to health posts against safety, security and environmental dimension. Whilst vessel frequency for passenger and vehicle loading purpose are stagnant mode since in 2018 as per simulation being constructed. Meanwhile, health cases reported by port medical officer is becomes major concerned which need takes into attention by port management operation and governmental related parties.

Introduction

Merak port was situated in Banten Province Indonesia, is a public port inter island that serving between western tip of Java and southern Sumatra island with approximelay 30.6 km away. Port harbour Merak is the gateway of cross paths land connecting between Java and Sumatra island[1]. Merak port has land area coverage of approximately 15 hectares, with physical boundaries territorial at north and east side to the hills, west and south side to Sunda strait. Inter island ferry port at Bakauheni is a public port that serving the crossing between the south end of Sumatra to tip of western Java island. To realize an effectiveness and efficient of transportation system, it should be directed to improve services by bringing together to their interests or expectation amongst relevant services parties. Whereas number of vehicle and motorcycle are continue increased every year, especially during holiday and

e-mail: wisata.taruna@gmail.com

annual muslim's feast period in regard home coming and back flowing traditions to their home town. In the view, area for services improvement related to infrastructure and supporting facilities are essential implemented and shall taken into immediate effectively and efficiently to be able its transportation system has realible, quality services, pricing affordability, safety and bring HSSE concept into their operations[3].

One of strategy to improve ferry port terminal is by implemented Ecoseaport concept, instead of Ecoport terms that normally use in Europe. A port by implement Ecoseaport or green concept may lead to healthy and environmental sounds to develop port is being useful in terms of social, economic and ecological, and become a prerequisite in respect port which would like to compete in the global transportation arena (Despina et al., 2011). Through Ecoseaport concept, various of environmental issues in the port such a deteriorated of sea water quality, air pollution and noise, reduce biodiversity, reduction of health condition and safety are systemically designed, implemented, monitored, reviewed, re-implemented and organize by port management, including stakeholder[2]. This cycle will continues endlessly or never ending process for environment quality improvements (Rickard and Egels, 2012). Ecoseaport is concept for environmentally sound port, which directs the development of port to be useful, and environmentally (Pavlic et al., 2014). The management priority shall take for environmental sustainability, energy efficiency and reduce the impact to marine ecosystems and coastal areas[4].

Material and Method

This study employed both qualitative and quantitative method and exploratory design with sequential procedure. The initial is applied for qualitative then proceed with quantitative. SPSS (Statistical Package for Service Solutions) was used for processing the questionnaires. The system dynamics thru powersim studio 8 Enterprise application are intended to formulate HSSE (Health Safety Security and Environment) performance as ecoseaport pillar being constructed at ferry ports terminals, against users and available facilities, including wharf space during annual going back home town during peaks period. HSSE data performance reference are consisted of health, safety, security and environmental cases against passengers, motorists and anyone who utilize ferry port terminal facilities. Secondary and primary data's that was obtained quantitative and qualitatively have also carried out to aim and getting an accurate picture of the systematic and relationship between determined variables through data collection and analysis[7]. The qualitative method acquired through focused interviews, and quantitative are then used to synthesize the dynamic of ferry ports management principle for Ecoseaport, particularly with regard to HSSE aspect.

Findings and Discussion

The causal loop diagram to construct the model consists of 10 (ten) loops with details of 3 (three) positive (reinforcing) and 7 (seven) negative loops (balancing). There were 26 (twenty six) identified variables used to develop a dynamic model of sustainable ecoseaport on inter-island ferry port terminal. The main variables used as stock are passengers, vessel trips, health posts, and number of health. The dynamic sustainability model for ferry port terminal based to ecoseaport through HSSE concept approach in Merak, Banten Province, was compiled by simplifying several variables that were thought to influence real conditions. Simplification is done by setting the limits and assumptions of the model. The limits set forth in the model are focused on the dynamics of health cases that are influenced by endogenous variables and do not include exogenous variables, i.e. cases of passengers which visiting health posts that must appropriately handle at the ferry port terminal as the most predominant driven factor, rather than other aspects i.e. safety, security and environmental. The assumptions used to construct dynamic models in research methodology during the peak flow of homecoming period are as follows:

a. The dynamics number of passengers, motorists, small vehicles, and large vehicles entering the port are considered constant.

b. Peak passengers occur at night time, in the range H-7 and H+7 from peak of homecoming flow period is within fixed conditions.

d. The variability of user behavior of ferry port terminal against HSSE perception and insight, is considered as the driven factor for ecoseaport dimension is constant[8].

e. The case number of safety, security and environmental aspect in the element of eoseaport is not so dominant compared to health cases and assumed to follow trend based on yearly reference data.

h. The type and pattern of illness need to be treated are similar with yearly reference data[1].

Simulation Business as Usual (BAU) and Intervention: Data simulation against passenger in terminal, vessel trip, health case and health post provided by ferry port terminal operator starting from reference data in 2012 until 2029 are mentioned as following table.

Table 1. Number of Passanger, Vessel Trip, Health Cases and Health Post within Simulation Business as Usual (BAU) year 2012-2029.

Year	Passenger in Port Terminal (People)	Vessel Trip	Number of Health Posts (Unit)	Health Cases (People)	
			BAU	BAU	Intervention
2012	1,453,465	100	5	467	467
2013	1,496,662	109	5	489	489
2014	1,541,143	114	5	512	512
2015	1,586,946	116	5	537	537

Source: Data extracted using powersim studio 8, 2018

Structural Intervention: The validity results are verified by using the AME (Absolute Mean Error) method. After calculating the AME value for passenger growth, number of vessel trips, health cases and number of health posts were 3.68%, 8.58%, 11.57%, and 3.70% respectively. These values are still below the error tolerance threshold for the controllable variable, which is 30%, so it can be stated that the dynamic model of ecoseaport for ferry port terminal crossing interisland sustainability, through the HSSE concept approach, in Merak, Banten Province is declared valid.

To enable controlling health case from passenger during peak time period, some strategies need further implemented to decrease the number, whilst terminal area, wharf and loading time are never significantly changes time by time. Business as usual simulations are carried out to predict behavior trends of models that are construct at a certain time. The simulation period is set for 17 years from 2012-2029 by considering the implementation of 2 (two) periods of Indonesia presidential election starting in 2019, which seaport function must to be taken into consideration to accelerate maritime industry development and inland road infrastructure across Java and Sumatra island as most of population density in Indonesia[5]. Based on the simulation results, it can be seen that passenger growth, number of vessel trips, health cases and the number of health posts to be provided will continue to increase until 2029 by following to the exponential growth pattern. However, the number of vessel trips has been maximized in 2018 (Figure 1).

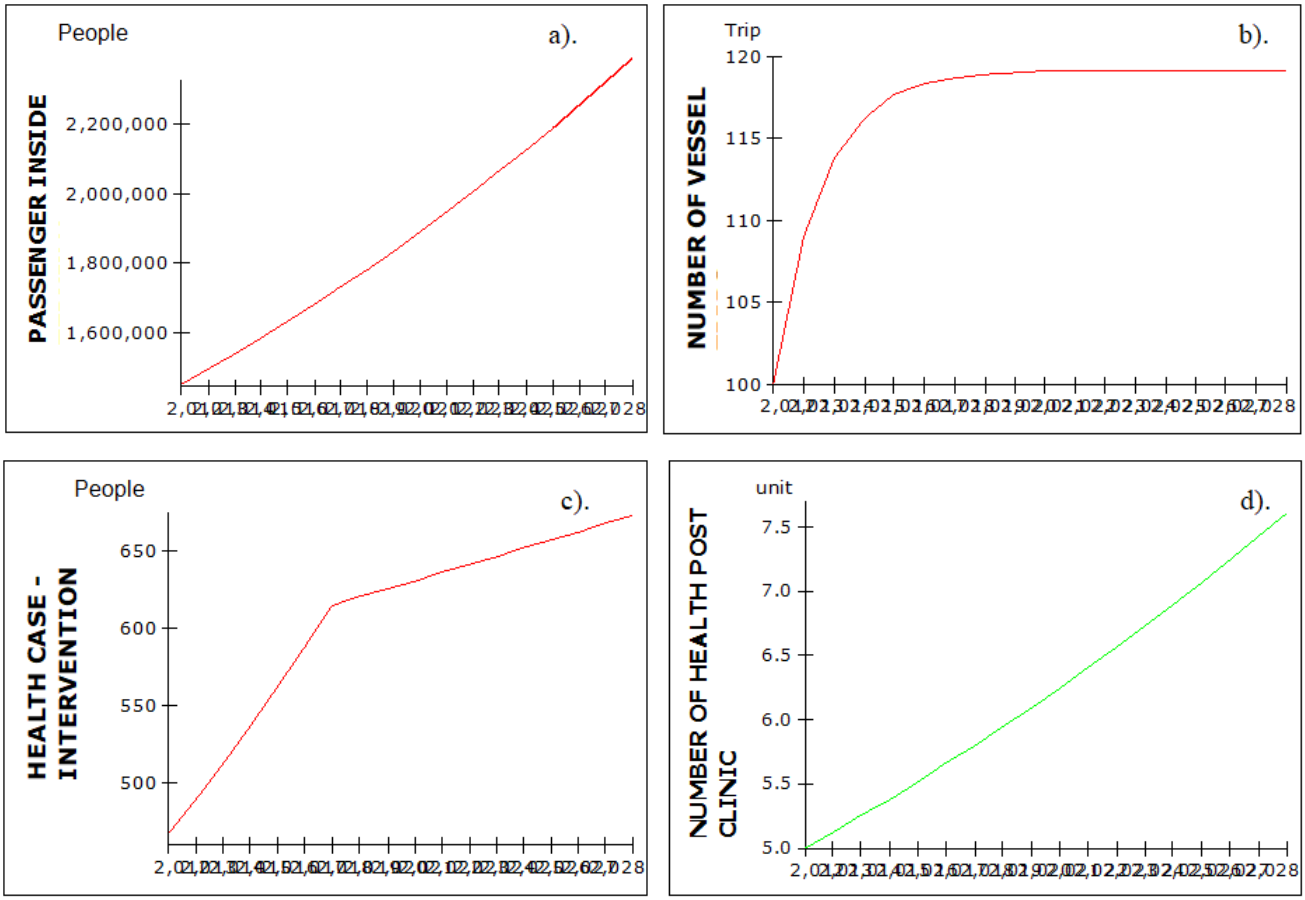

Figure 1: Business as usual simulation, (a) passenger growth, (b) number of vessel trips, (c) health cases - intervention, (d) number of posts health at Merak Port-Indonesia, 2012-2029.

The results of the structural interventions conducted showed that the reduction in the number of health cases in 2029 will 673 cases with the need for 8 health posts. This decrease is equivalent to 32.2% of the total health cases over business as usual conditions (Table 1).

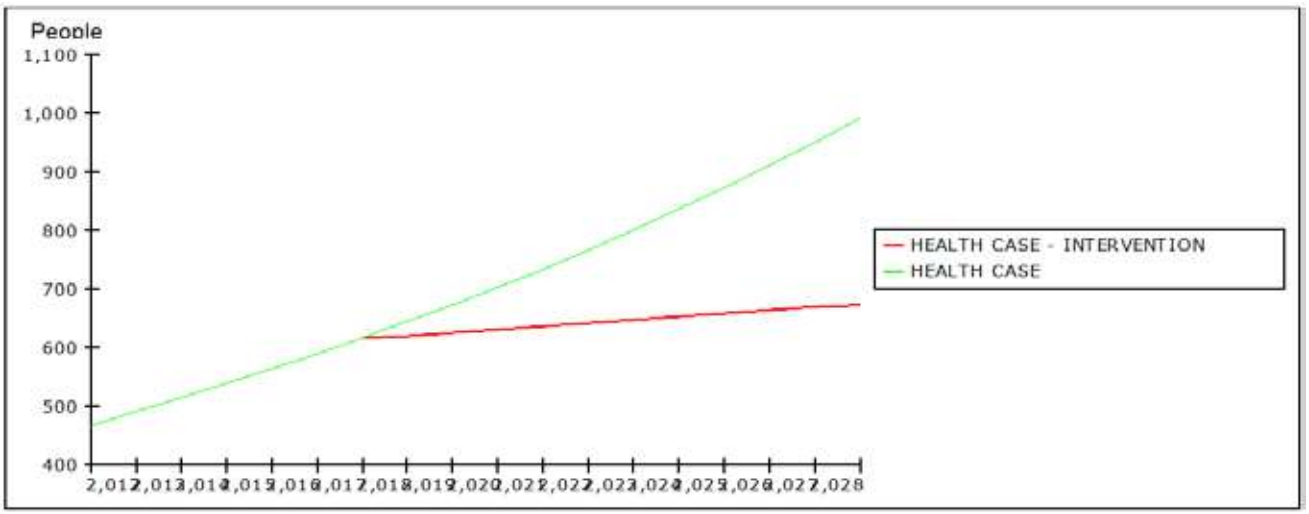

Figure 2: The ecoseaport ferry port terminal inter island model sustainability simulation, at Merak port by approaching HSSE concept 2012-2029, start in 2018 with a scenario of structural intervention in the number of health cases.

Refer to deep into detail on above figure analysis, most of respondent have a disparity opinion in regard HSSE aspect. The trend of health cases seems to continue to increase, in line with the condition of passengers entering the terminal, so the outcome of the intervention results must certainly be managed to the minimum level. Therefore, in the future, other structural and functional interventions that involve leverage variables are needed to be executed. It is assumed that the leverage variables of the health aspect in the dynamic model of sustainable ecoseaport are affected by fatigue due to the queue, or all the way long toward the port. This is reinforced by the average number of cases that must be handled by medical personnel, the highest 3 (three) diseases are respiratory disorders, myalgia-fatigue, and digestive disorders. Therefore, control programs as an intervention step can begin with subjects related to the queue reduction program and promotion of health programs on above mentioned highly health cases may arise[6].

Based on the simulation results of ecoseaport sustainable model at ferry port terminal, Merak, province Banten Indonesia through the HSSE concept, it can me mentioned that number of health cases pattern will continue to increase along with the increase in the number of passengers each year, with the number of wharf space and vessel capacities tend to remain constant. Structural interventions will have performed to decrease by 25% from 4.1%/year to 3.1% per year against a program to reduce the number of health figures will reduce the number of health cases equivalent to 32.2% compared to business as usual conditions. However, the reduction is certainly not in the ideal condition if reflected and associated with the assumptions that being applied to construct this model.

Health cases predicted will potential continue for the future along with the interpersonal mobility of people, materials and goods, and current construction of infrastructure networks massively worked between the islands of Java and Sumatra or vice versa. This may encourage the behavior of passengers entering the sea port Merak and the number of patients visiting health posts based solely on assumptions concerning behavior, not on the extension of economic factors and the efficiency value of traveling between Java and Sumatra or vice versa, could be another driven factor in the increase in health cases at the Merak ferry port. Therefore, other intervention scenarios must still be tested and trial by involving any other leverage variables[7]. Another structural intervention that can be done is to add economic sub models with profits variable as stock such ticket sales and port operational costs respectively as inflow and outflow structure. These interventions need to be supported by functional interventions that can reduce the port operating costs and vessel without diminished a HSSE aspect as a sustainable dimension driving element in the Merak ferry port, Banten. The manifestation of the structural intervention must then be designed in an integrated policy for environmental protection and economic growth of the port area and mapping important issues in port operations and establishing key elements, aligned with the concept of the European Union Co-founder (2012). The intervention program can be done to reduce the risk of health cases such as preparing tents for motorists before entering the port, tents for dock services, stretcher equipment to anticipate fainting passengers, portable toilets to minimize the movement of passengers already inside the port, which directly implicating the passenger density rate and the risk of the occurrence of health cases.

Conclusion

1. Based on the simulation results of ecoseaport sustainable model at ferry port terminal, Merak, province Banten Indonesia through the HSSE concept, it can me mentioned that number of health cases pattern will continue to increase along with the increase in the number of passengers each year, with the number of wharf space and vessel capacities tend to remain constant. Structural interventions will have performed to decrease by 25% from 4.1%/year to 3.1% per year against a program to reduce the number of health figures will reduce the number of health cases equivalent to 32.2% against business as usual conditions.
2. Health cases predicted will potential continue for the future along with the interpersonal mobility of people, materials and goods, and current construction of infrastructure networks massively worked between the islands of Java and Sumatra or vice versa. This may encourage the behavior of passengers entering the sea port Merak and the number of patients visiting health posts based solely on assumptions concerning behavior. Therefore, other intervention scenarios must still be trialed by involving any other leverage variables. Another structural intervention that can be done is to add economic sub models with profits variable as stock such ticket sales and port operational costs

respectively as inflow and outflow structure. These interventions need to be supported by functional interventions as well that can reduce the port operating costs without diminished a HSSE aspect as a sustainable dimension driving element in ferry port terminal. The manifestation of the structural intervention must then be designed in an integrated policy for environmental protection and economic growth of the port area and mapping important issues as aligned with the concept of the European Union Co-founder (2012). The intervention program can be done to reduce the risk of health cases such as preparing tents for motorists before entering the port, tents for dock services, stretcher equipment to anticipate fainting passengers, portable toilets to minimize the movement of passengers inside the port, which directly implicating to the density rate and risk occurrence on health cases.

CM Wire Endodontic Files Cyclic Fatigue after Irrigant's Immersion

El Mallah S.S.[1], Khalil H.F.[2]

[1]Lecturer of Endodontics Faculty of Dentistry Fayoum University, [2]Lecturer of Endodontics Faculty of Dentistry The British University in Egypt

Abstract

Aim: Cyclic fatigue and scanning electron microscope analysis of a new preheated machined CM wire endodontic files after immersion for 5 and 10 minutes in irrigants.

Materials and Method: Twenty four size 20 Mpro files were used in this study divided into four groups according to irrigant of 6 files each; saline, chitosan 0.3%, chitosan 0.5% and ethylene diamine tetra acetic acid (EDTA) 17%. Files were immersed in irrigant for 5 or 10 minutes. Cyclic fatigue tests were performed using a static cyclic fatigue testing device. Parameters reported were time to fracture, number of cycles to failure and mean length of unfractured segments. The fractured segments were scanned using a scanning electron microscope to determine the crack initiation site and number of crack origins.

Results: A statistically significant difference existed in mean time to fracture between the different irrigants. At 5 mins immersion time for time of fracture and number of cycles to failure with Chitosan 0.3 group showing the highest mean. At 10 mins immersion time, there was no statistically significant difference but existed only in mean time to fracture between the two immersion times within Chitosan 0.3 and EDTA groups. There was no statistically significant difference in mean length of fractured segments between all groups at 5 mins immersion time but only existed. At 10 mins immersion time within EDTA group. Scanning electron microscope photomicrographs showed that 100% of samples of group 2 chitosan 0.3 showed one site of crack origin.

Conclusion: Chitosan 0.3% had the least destructive effect on the files.

Keywords: *Cyclic fatigue, CM wires, Chitosan, SEM.*

Introduction

Nickel-titanium instruments are trusted in endodontics over stainless steel.(1) Mpro file (Foshan stardent equipment co, gungdon, China) is a controlled memory file machined from a CM wire previously subjected to athermomechanical processing procedure that shows outstanding clinical fatigue resistance(2) and can retain the shape of the canal even when out of it.(3) Cyclic fatigue fracture occurs when the file rotates around a curved root canal with repeated extension and compression cycles in the region of maximum bending stress.(4,5). Gambarinietal.(6), Praisarnti et al.(7) and Zender(8) recognized factors affecting the fatigue resistance of NiTi rotary files as material properties, cross-sectional design, metal surface treatments, metallurgical characterization and root canal irrigants.

Chemomechanical preparation reduce bacterial populations located in root canal.(9) Choice of irrigant depends on its effectiveness as lubricants, smear layer removal and efficacy on virulent bacteria present in the

canal.[10] The most common chelatingirrigant solution is ethylenediamine-tetraacetic acid (EDTA) is used for the final irrigation of the root canals. Chitosan is a cationic biopolymer obtained from chitin of crustacean exoskeletons,[11] which was proposed to be useddue to biocompatibility, no toxicity, bioactivity, biodegradability, selective permeability, antimicrobial activity, adsorption capacity and chelation ability[12] Ametrano et al. and Kuhn et al.,[13,14], stated that NaOCl and 17% EDTA solutions increased Protaper files surface roughness indicating deterioration that act as stress concentration areas and cause microcracks that may file's cyclic fatigue resistance.

This study focuses on the effect of root canal irrigation on the cyclic fatigue and study of the fractured surface of CM wires NiTi instruments after immersion in four irrigants for either 5 or 10 minutes. The irrigants used are saline, chitosan 0.3%, chitosan 0.5% and EDTA 17%.

Method

Twenty four size 20 MPro files (Foshan stardent equipment co, limited gungdon, China) were used in this study, divided into four groups of 6 files each according to irrigant: Group I saline, Group II chitosan 0.3%, Group III chitosan 0.5% and Group IV EDTA 17% . Each group was further divided according to immersion periods :5 and 10 minutes.

Before testing, each file was observed for defects with stereo microscope (Leica MZ 12.5, Heerbrugg, Germany) under ×10 magnification. The chitosan irrigants were prepared using powder (Sigma-Aldrich Chemical Co., Germany) dissolved in 1% acetic acid at room temperature. The concentration of the final solutions were 0.3 and 0.5 mg/mL. All files were cleaned after immersion in ultrasonic cleaner to remove traces of irrigants.

Fatigue tests were performed using a static cyclic fatigue testing device, composed of two parts First section consisted of the stainless steel block part, which has an artificial canal with an inner diameter of 1.5 mm, a 60° angle of curvature, a curvature radius of 3 mm and has a Plexiglass preventive cover. The latter section included an Instron universal testing machine (Massachusetts, USA)machine with a hand piece holder part that positioned the hand piece in a precise relationship to the stainless steel block when testing file inside the artificial canal. The two main parts of the apparatus were attached to a steel base. The file to be tested was inserted in the artificial canal to Working length of 16 mm. The motor was set at a Continuous rotational speed 450 rpm and Torque of 2 newton and all files were rotated until fracture occurred .

Parameters recorded were time to fracture, number of cycles to failure and mean length of unfractured segments using a digital micro caliper.

The detached fragment was examined under scanning electron microscopeat various magnifications (400x to 1000x) (Quanta 250 FEG, with accelerating voltage 30 K.V., Magnification 14x up to 1000000. FEI company, Netherlands)to identify the crack initiation site and number of crack origins per group.

Results

The cyclic fatigue study statistical analysis was performed using IBM SPSS Statistics Version 2.0 for Windows. Data was presented as mean and standard deviation (SD). The significance level was set at $P \leq 0.05$. Kolmogorov-Smirnov and Shapiro-Wilk tests were used to assess data normality.

Because of the small sample size, a non-parametric test was used. Kruskal-Wallis test followed by Mann-Whitney U test was performed to compare between the different irrigants at each immersion time. Mann-Whitney U test was conducted to compare between the two immersion times within each irrigant group.

Time to fracture and Number of cycles to failure (NCF):At 5 mins immersion time, there was a statistically significant difference between the different irrigants. Chitosan 0.3 group showed the significantly highest mean value while the control group showed the lowest. At 10 mins immersion time, there was no statistically significant difference between Chitosan 0.3, Chitosan 0.5 and EDTA groups. The saline and EDTA groups had significantly lowest mean value. Within the saline and Chitosan 0.5% groups, there was no significant difference at the two immersion times but it existed within Chitosan 0.3% and EDTA groups.

Un Fractured segment length: At 5 mins immersion time, there was no statistically significant difference in mean length of unfractured segments between saline, Chitosan 0.3% and Chitosan 0.5% groups. At 10 mins immersion time, there was no statistically significant difference in mean length of unfractured segments

between the saline and Chitosan 0.3% groups. Chitosan 0.5% and EDTA groups had no statistically significant difference in mean fracture length. Within the saline, Chitosan 0.3% and Chitosan 0.5% groups, there was no significant difference in mean length of the unfractured segments between the two immersion times but it existed within EDTA group.

The scanning electron microscope study: The photomicrographs of magnifications 400x to 1000x were viewed blindly by two viewers and the number of crack origins per group were recorded. From the overall view, the crack initiation site were identified by noting the chevron pattern, also called ''herringbone marks''[15] on the fracture surface. The fractographic appearance of a fatigued metallic material always progresses from the crack origin to a zone of fatigue striations and, finally, a region of dimple rupture[16].

Results of crack origin sites showed 3 sites per sample in 100% of Group I (saline). One site in 100% of samples of Group II (Chitosan 0.3%) and 2 sites in 100% of samples of Groups III (Chitosan 0.5%) and IV (EDTA)

The number of crack origins did not get affected by the immersion times applied.

Discussion

The removal of pulpal tissue, microorganisms, and their products is important for successful root canal treatment[17,18]. In studies examining the cyclic fatigue resistance of NiTi files, it is difficult to eliminate all factors can affect study results.[19] Although using extracted human teeth in cyclic fatigue studies represents clinical conditions, it is not possible to standardize the anatomical variations of teeth;[20] Thus in the present study, standard stainless steel artificial canals were employed to minimize various factors that can influence the results.

Capar et al[21] reported that HyFlex CM file had high resistance to cyclic fatigue. Authors attributed that to the thermomechanical processes applied during its production and emphasized that other CM files could show same property. Both Hyflex and the Mpro file share same thermomechanical processes applied during production. The NiTi instruments were immersed in saline, Chitosan 0.3%, Chitosan 0.5% or EDTA 17% at 37°C for 5 or 10 min.

Factors influencing the fatigue resistance include file design, cross-sectional geometry and diameters of core, tip size, taper[22] radii, degree of curvature, rotation speed, torque, and movement kinematics.[23, 24] In the present study, we used one type of file and same size in standardized artificial canals (60° angle of curvature and a curvature radius of 3 mm) and same rotation speed (450 rpm), rotation type (continuous) were set to leave only two variables the type of irrigant and the time of immersion of the file in it.

Our results of the time to fracture and number of cycles to failure in the cyclic fatigue part of the study showed that chitosan 0.3% recorded the highest mean 12.93 ± 4.21 minutes and 5821.5 ± 1895.35 cycles to fracture while the saline recorded the lowest mean 2.82 ± 0.10 and 1230.33±161.69 cycles to fracture. EDTA and chitosan 0.3 % had a significantly different value from 5 to 10 minutes, they had a more corrosive action by time elapsed to become closer to the mean recorded by chitosan 0.5 %. These results came higher than those recorded by Bhattand Rajkumar[25] and shen et al.,[26] where hyflex CM and typhoon files. The difference in the results may be due to different methodology where they used the EDTA gel during the test not as an immersion irrigant before testing. Our results were also higher than the results of Dagna et al.,[27] where they used dynamic cyclic fatigue testing after immersion of Mwire files in EDTA for 1 min or 5 mins. Increased fracture resistance of the file scan be due to the crack propagation mechanism which presented asa large number of highly branched cracks that propagates very slowly in contrary to superelastic NiTi form where only a few fatigue cracks nucleates and propagates at faster speed.

The results of the unfractured segment length showed files breakage at apical 5 mm in all groups. At 10 minutes files broke more coronally at the 10 mm range with no significant difference among groups. Our results came close to those by pedullaet al.,[28]. The EDTA group the 10 min group was significantly different than the 5 min group but still in the middle part of the file at the 10 mm range.

In the scanning electron microscope study, the photomicrographs were viewed blindly by two viewers and the number of crack origins per group were recorded. Results showed 100% of Group I (saline) showed 3 sites of crack origins per sample. 100% of samples of Group II (Chitosan 0.3%) showed one site of crack origin, 100% of samples of Groups III (Chitosan 0.5%) and IV (EDTA) showed two sites of crack origin. According to del Carpio- Perochena et al 2015[11] chitosan had same chelating effect as EDTA and had the potential to be used as an alternative to EDTA in root canal, this may explain the similar effects they had on the file when chitosan was used in a higher percent 0.5%, another similarity of action may be due to the preparation of chitosan solution by its dissolution in acetic acid.

Conclusion

Chitosan 0.3 % did not decrease cyclic fatigue and caused low number of crack origins of the preheated machined CM wire Mpro endodontic files when used for 5 or 10 minutes.

Source of Funding: This research is independently funded by the researchers and authors.

Conflict of Interest: We the authors have no conflict of interest with any researchers and companies

We funded this research independently and we both contributed to the practical part of the study and the theoretical part

Ethical Clearance: This study is an invitro study that did not need an ethical committee approval cause no animal or human trial were involved and no human teeth or serums were tested.

Effect of Educational Protocol on Improving Nurses' Knowledge and Practice Regarding Skin Traction

Hend Elham Mohammed[1], Eman Sobhy El-Said[1], Amira Mostafa Fahmy[2]

[1]Lecturer of Medical & Surgical Nursing, Faculty of Nursing, Minia University, [2]Lecturer of Medical & Surgical Nursing, Ain Shams University, Egypt, [3]Lecturer of Nursing Administration, Faculty of Nursing, Minia University

Abstract

The highest prevalence of traumatic fractures that need to use of orthopedic intervention such as skin traction has increased. This study aimed to the effect of educational protocol on improving nurses' knowledge and practice regarding skin traction. A quasi-experimental research design was used on convenience sample composed of 26 nurses working at orthopedic unit at Minia University and Minia General Hospitals. A Structured interviewing questionnaire about skin traction nurses' knowledge questionnaire and nursing skin traction observational checklist were used. A significant improvement in nurses' knowledge and practice about nursing care and principles of skin traction in post test. Implementation of the educational protocol. Increased nurses education and training for skin traction and periodic evaluation measures for these nurses should be constructed.

Keywords: *Educationalprotocol, Nurses, Skintraction.*

Introduction

Traction is the application of a pulling force to a part of the body to correct direction and magnitude for immobilize fractured body part and obtain its therapeutic effects through an extended period, include skin or skeletal traction. Skin traction may cause pressure exerted on the skin which results in skin damage and a risk of ischemia[(1)].

Orthopedic nursing specialty mainly focuses on musculoskeletal disorders, and complications[(2)]. An orthopedic nursing role is providing high quality nursing care to traction patients, through providing standardized patient care that is evidenced based practice, as performs musculoskeletal assessment, assists with traction, and administers prescribed pain medication. An orthopedic nurse support and train the patient for mobility, educates the patient correct technique about how to protect their joint and bone health, and develop nursing care plan to minimize complications[(3,4)].

Nurses should have a high level of nursing knowledge and standardized care for effective practice by education which is the most important aspect of orthopedic nurse role. An orthopedic nurse is an excellent educator that gives patients detailed, simple and comprehensive information. Who are well versed in educating patients on the risks and complications of orthopedic treatment and surgery[(5, 6)].

Nurses are also responsible for family members education who have may be involved in patients' care as concerns about pain management, and discharge service coordination[(7)].

Nursing is deliberate as caring for a patient in a set of health related situations. This caring also involves teaching about health and the prevention of illness; nurses play a key role in promoting higher standards of health[(8, 9)]. The nurse should be updated her knowledge and practice in the current field.

The educational nursing protocol contains basic

Corresponding Author:

Lecturer of Medical & Surgical Nursing, Faculty of Nursing, Minia University
e-mail: hendelham@yahoo.com

guidelines for nursing knowledge and practices which would improve the quality of nursing care for skin traction patients[10].

Significant of the Study: Fractures are common with younger patients resulting from high-energy physical traumas such as motor vehicle accidents and usually occur in the absence of any underlying disease[11].

Traction is commonly used for treating hip or femur fractures with regard to this fact and taking into account the vital role of orthopedic nurses in the care of patient with traction. So special orthopedic nursing training protocol was used and presented to these nurses in order to increase nurses' knowledge and also improve their practice to overcome these possible complications and increase the efficiency nursing care.

Methodology

Aim: The current study aims to investigate effect of educational protocol on improving nurses' knowledge and practice regarding skin traction.

Hypothesis: There are positive effect of educational protocol on improving nurses' knowledge and practice regarding skin traction.

Method :

A quasi-experimental research design was utilized to meet the aim of this study. A convenience study sample who were available nurses present during time of data collection, who were working at orthopedic unit with total number (26), in both Minia University and General Hospitals. Tools, A Structured interview questionnairewhich was developed by the researcher it contains: Socio-demographic characteristics of nurses and their knowledge about skin traction[12].An observational checklist was adopted from Royal College of Nursing, (2017)[13] and modified by researchers. The total scores ranged from 0 to 37 scorepercentage. The nurses' practice and knowledge were satisfactory level if the score is 60% or more and unsatisfactory if less than 60%.

A pilot study on (10%) from nurses, was conducted to test clarity & completeness of the study tool According to the results of pilot, the needed modification, omissions and/or additions were done.

Validity and Reliability: The tools were submitted to a panel of five experts in (Medical & Surgical-Nursing Administration) at Minia and Assuit University to confirm content validity. Reliability of the tools were done and calculated statistically by Cronbach's alpha test = (0.87).

Procedure: The researcher's prepared educational booklet after assessment of nurse's knowledge to identify the weak point, and then give educational protocol skin traction care as using soft wear presentation- based on the review of relevant literature and books about nursing care of a patient with skin traction. The fieldwork was carried out through a period of 6 months starting from March to August 2018. The researchers first introduced themselves to nurses and give them a complete background about the study, then the pre-test format was distributed in order to collect the required data. The content of the protocol was designed based on the actual educational needs assessment of the studied nurses. Consequently, the educational protocol was done through six sessions. The whole was implemented during morning shifts. The period was estimated for each session ranged from 30 to 45 minutes. The first two sessions began by explaining the theoretical information about definition of skin traction, causes, precipitated factors and modalities of management the next four sessions were concerned to the practical part about principles of traction and nursing care of traction. Finally, a summary of what has been taught during the previous session also the objectives of the new session were always done before beginning any session.

Teaching method of the theoretical part was introduced using discussion, demonstration and re-demonstration. Each nurse was given a copy from hand-outs powered by photos, an open conversation was made between researchers and nurse to ensure that he understands, answer any query and verify information and practice. The effect of the learning protocol on the nurses' condition was reached by assessing the nurse's scores immediately and after two month educational protocol (follow up).

The statistically analysis was done using SPSS-22 statistical software package. The content of each tool was analyzed and statistical significance was used at P. value <0.05

Results

Table (1): Distribution of personal data characteristics for studied nurses n = 26

Items	No	%
Age/Years:		
< 20	2	7.6
20 < 30	16	61.6
30 < 40	8	30.8

Table (5) shows a significant statistical difference between nurses' practice and demographic characteristic. It was observed that the highest practice in post-test and follow up was among 20 < 30 years, bachelor and experience from 5:10 years.

Table (6): The correlation between the total scores of the nurses' knowledge and practices in the studied hospitals n= 26

Knowledge	Practices	
	r	P. value
Minia University Hospital	0.92	0.001*
Minia General Hospital	0.90	0.001*

*= Significant

Table (6) demonstrates strong positive correlation r (0.92 – 0.90) between nurses' knowledge and practice in both hospitals respectively.

Discussion

This research indicates that unsatisfactory knowledge about skin traction and their complication, principles of traction and nursing care,and observed the highest percent of nurses didn't attain any training, before the implementation of the educational protocol. While there was an improvement in the level of knowledge post implementation of the protocol which noticed that the majority of the nurses have a satisfactory level of knowledge in follow up. There was high significant statistical difference in total nurses' knowledge about skin traction. These study findings were consistent with the study findings of[14] who reported that more than two thirds of nurses had a sufficient knowledge regarding care of patients with external fixation

Also there is an agreement between this study results and the results of study that is done by [5]showed that only 12% of the respondents had knowledge on complication of skin traction. The current research study is contradictorywith[8],who demonstrated that distributing the respondents who participated in this study, one-third had high level of awareness, majority had moderate level of awareness and 6.4% had low level of awareness.

The present study showed that the majority of nurses were unsatisfactory practice pre application of protocol. While there was an improvement in the level of practice post and follow up post implementation of the protocol,

which agreement with[15] reported that most of the studied nurses had an unsatisfactory total practice support to the research results, the practice of respondents, less than half had high level of practice. Additionally[11] mentioned that nurses should increase their knowledge and performance in the field of management of patients in orthopedic departments, which disagree with[16] reported that majority of nurses had poor practice scores related to nursing care plan after application of traction.

The present study that the relation between the studied sample practice pre/post and follow up protocol about skin traction and their characteristics; there was a significant statistical difference between nurses' practice and demographic characteristic. It was observed that the highest practice in post-test and follow up was among 20 < 30 years, bachelor, and experience from 5:10 years. In contrast [8]reported in their studies that found association between level of awareness and age and education,also between level of practice and age, education, and occupation.

In the current study revealed that the positive correlation between the total scores of the nurses' knowledge and practices in the studied hospitals, evidence these findings were in congruence with [7]which illustrate that there is a highly statistically significant positive correlation between total nurses' knowledge scores and total practice scores.

Conclusion & Recommendations: Lack in nurses' knowledge and practice regarding skin traction care before application of the educational protocol, while improvement was observed after application of an educational protocol .Training- based on education services for nurses may motivate their knowledge regarding nursing management of the orthopedic patients.

Sonographic Measurement of Renal Parenchymal Thickness in Healthy Adults

Israa Mohammed Sadiq[1], Kermanj Ismail Bakr[2]

[1]MBChB (Tikrit University), DMRD (Baghdad University), [2]MBChB (Al- Mustansariy University), FIBMS Radiology (Iraqi Board for Medical Specialization), Department of Surgery, Radiology, College of Medicine, University of Kirkuk, Kirkuk, Iraq

Abstract

Background: Renal parenchymal thickness (RPT) was found to be a vital parameter that can offer prognostic information on end-stage kidneys diseases. The aim of the current study was to establish normal RPT value in our population; and to reveal its relationship with age, height, and weight.

Method: It was a cross-sectional analytic study conducted in the department of radiology/Azaditeaching hospital at Kirkuk city, where the sonographic assessment of RPT was performed from January 2016 to May 2018 for 253 adults with different complaints; Individuals with history of medical disorders/drugs known to affect the kidney, malignancy, pregnancy, those who had renal variant/pathology during ultrasound examination and abnormal laboratory tests were excluded from the study. Differences of RPT between two sides and gender were assessed with student's t-test, and its correlation with age, height, and weight were assessed with the Pearson's correlation coefficient (r).

Results: In males, the mean value (SD) of right RPT was 18.2(3.2) mm, and left RPT was 18.9(3) mm. In females, it was 16.4(2.4)mm in the right kidney and 16.9 (2.4) mm in left kidney. There was no statistical difference between RPT of the right and left kidneys ($p = 0.0001$). The RPT was significantly thicker in males (18.6 mm versus 16.7 mm) (P= 0.0001). There was significant moderate and strong negative correlation with age in right and left kidney respectively. There was a positive correlation with a person's height and weight which was significant(P= 0.00001).

Conclusion: Our population parenchymal thickness values are different from others, it is 18.6 mm male and 16.7 mm in female, parenchyma is considered thin if it was less than 13 mm in males and 10 mm in females, its decreased with age, taller and more obese persons have thicker parenchyma on both sides.

Keywords: *Adults, healthy,measurement,Renal Parenchymal thickness (RPT), Sonographic.*

Introduction

Renal parameters measurement by ultrasound is vital when evaluating patients with probable renal disease;[1] however, it requires prior information of actual normal renal measurement values in each specific population. Cortical thickness is differing according to ethnic group according to height and weight or even in twins.[2,3,4] Chronic systemic diseases such ashypertension and diabetes also affect the kidneys parameters including the parenchymal thickness. [5]Renal ultrasound is inexpensive, simple and can be done at the bedside to provide the clinician with kidneys important anatomical details with low inter-observer variability. [6] Renal length and cortical thickness have been studied widely in animals and their parameters are well documented[7,8]. In humans, on the other hand, there have been only a few

studies considered to measure these parameters in adults who do not have a renal disease.[9]

Since RPT measurement can offer prognostic information on end-stage kidneys diseases.[10] This study was done to develop our population unique RPT in adults devoid of renal diseases,and to define its relationship with age, height, and weight.

Materials and Method

The permission was obtained from the Azadi Teaching Hospital Committee and informed consent was obtained from each individual before data collection was begun.

Study Group: This study was a cross-sectional study conducted in the department of Radiology in Azadi Teaching Hospital/Kirkuk/Iraq within a period from January 2016 to May 2018, for 253 adult patients how referred to perform abdominal ultrasound examination for different causes. The exclusion criteria were patients with known renal disease, conditions that were known to affect the kidney, such as diabetes and hypertension, those with prolonged use of toxic drugs, malignancy, and pregnancy. Those who had congenital renal variants, and renal pathology during ultrasound examination were excluded from the study too. Other criteria for exclusion was those with abnormal laboratory tests, including blood urea nitrogen >20 mg/dL, serum creatinine >1.2 mg/dL;the presence of protein casts, or more than five white and red blood cells in the general urine examination. The laboratory tests were done at the same hospital. Age in years, weight in kilograms, and height in centimeters for each patient were recorded.

Ultrasound examination: was done using 3.5 MHZ convex transducer (Fukoda Denshimachine; Tokyo, Japan) in lateral position during suspended respiration, longitudinal image inmidsagittal scan for kidneys was displayed and its outline, poles and central sinus echocomplex was seen. Dorsal RPT was measured at the middle third of the kidney. RPT was measured as the distance between renal cortex–perinephric fat interface and renalsinus–Parenchymal interface (Fig 1). The patients required no prior preparation. The examination was done by the same radiologist with 14 years of experience in abdominal ultrasound examinations.

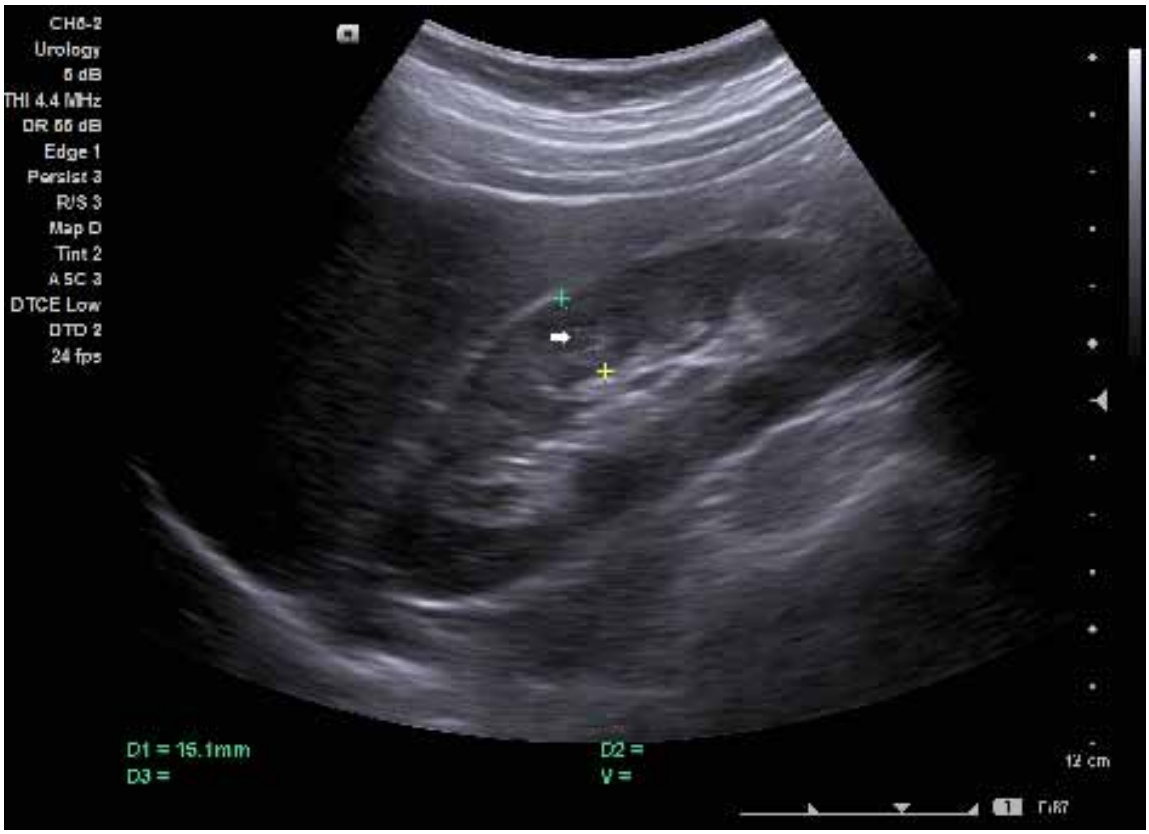

Fig 1. Ultrasound scan in sagittal section of right kidney for 25 years old female with epigastric pain. Renal parenchymal thickness (arrow) equals 15.1 mm.

Statistical Analysis: Differences of continuous variables between 2 independent groups were assessed with student's t-test. The Relationship of RPT with age, height, and weight were assessed with Pearson's correlation coefficient (r). Statistical analysis was performed using. Statistical Package for the Social Sciences (SPSS) 18.0 software package (Version 18).

Results

The range, Mean and standard deviation values of the study sample characteristics and their RPT were seen in table 1.

Table 1: Descriptive data of study sample and their renal parenchymal thickness.

Parameters		Mean (SD)		t value	P value
		Female ([a]N=125)	Male (N=128)		
Age (Year)		40.9(15.9)	41.3(14.8)	0.4662	0.6415
Height (cm)		163.1(3.1)	172.6(3.6)	22.4692	0.0001
Weight (kg)		73.3(14.8)	87.2(12.4)	8.1049	0.0001
RPT [b](mm)	Right	16.4(2.1)	18.2(3.2)	5.2764	0.0001
	Left	16.9(2.4)	18.9(3)	5.8470	0.0001

[a] Number, [b] renal parenchymal thickness.

The total number of subjects included was 253, there were 128 male (50.6%) and 125 (49.4%) females. In males, the mean (SD)values of, age was 41.3(14.8) years, height was 172.6(3.6) cm, weight was 87.3(12.4) Kg, and right RPT was 18.2(3.2) mm while left RPT was 18.9(3 mm). In females, the mean value of, age was 40.9(15.9) years, height was 163.1(3.1) cm, weight was 73.3(14.8) Kg, and right RPT was 16.4(2.4) mm, while left RPT was 16.9(2.4 mm).A statistical significant difference was not founded between RPT of right and left kidneys in both genders (P= 0.080 in female, P= 0.072 in the male), but the renal parenchyma was significantly thicker in males (18.6mm) than females (16.7 mm) (P= 0.0001).

There was a negative correlation between RPT and age (Table 2). The correlation was moderate, significant (r = -0.66, P =0.00001) in the right kidney, while it was strong and significant (r= -0.82,P=0.00001) in the left kidney.

Table 2: Renal parenchymal thickness according to age.

Age (Year)	RPT[a] (mm)		Total N[b]	Percentage
	Right Kidney	Left Kidney		
18-27	17	18.1	52	20.55
28-37	18.3	18.9	68	26.78
38-47	17.4	18.5	50	19.76
48-57	17.7	18.4	34	13.43
58-67	16.3	16	40	15.81
68-77	16	14.1	9	3.55

[a] Renal parenchymal thickness, [b] Number.

Right and left renal parenchyma was thicker in taller persons (table 3). On both sides there was significant (P = 0.00001) strong positive correlation between RPT and person's height (r = 0.92 in the right kidney and r = 0.88 in the left).

Table 3: Renal parenchymal thickness according to height.

Height (cm)	RPT[a] (mm)		Total N[b]	Percentage
	Right Kidney	Left Kidney		
155-159	15.3	16.3	10	3.95
160-164	16.8	17.1	74	29.24
165-169	16	17.2	66	26.08
170-174	18.6	19.4	64	25.29
175-179	18.5	18.1	32	12.64
180-184	19.3	20	7	2.76

[a] Renal parenchymal thickness, [b] Number.

There was a positive correlation between the RPT and person's weight (table 4). In the right kidney, this correlation was strong significant (r=0.88, P= 0.00001),while in the Lt kidney it was weak significant (r=0.38, P=0.00001).

Table 4: Renal parenchymal thickness according to weight.

Weight (Kg)	RPT[a] (mm)		Total N[b]	Percentage
	Right Kidney	Left Kidney		
50-59	16	17.4	15	5.93
60-69	16.8	17.3	21	8.30
70-79	16.7	16.3	24	9.49
80-89	16.9	17.9	34	13.44
90-99	19.2	20.4	25	9.88
100-110	18.7	17.5	8	3.16

[a] Renal parenchymal thickness, [b] Number.

Discussion

The mean value was 18.6 for males and 16.7 in females; these results were more than other studies[1,8,11-13] and less than an African study, [4] but it was comparable to Iranian, Pakistanian and Austrian studies[15-17] these different values in different races probably were due to both genetic and environmental factors.

In the current study we founded that the difference of RPT between each kidney was not significant statistically like an Indian study.[8] Other studies found that left kidney had significantly thicker parenchyma than the right kidney;[4,11-14] the common and easiest way for comparison between right kidney examined from front (hepatic window) with left kidney examined from the flank (spleen window) might be the cause of thicker parenchyma of the left kidney as the front renal parenchyma is anatomically thin where the hilus is present.[19] Males had significantly thicker parenchyma than the females, mostly due to their taller and bulkier bodies; this was the same as other studies.[11,12,18]

We founded a negative correlation between RPT and the age, previous studies result were generally agreed with this[4,8,14] this change was attributed to changes in the renalvasculature, and genetic factors,[20,21] other mechanisms including, interstitial fibrosis, glomerulosclerosis might also contribute.[16]. There was a positive correlation between RPT and people's height and weight, which was similar to other studies,[8,12,14] asbigger patients will have a larger blood volume requiring larger kidneys for filtration.[22]

Conclusion

Our population parenchymal thickness values are different from others, it is 18.6 mm male and 16.7 mm in female, parenchyma is considered thin if it was less than 13 mm in males and 10 mm in females, its decreased with age, taller and more obese persons have thicker parenchyma onboth sides.

Conflict of Interest: None.

Relationship between Parasitic Infections in Protozoa and Female Secondary Infertility

Kawther A.M. Al-Mussawi[1], Inam Joudah Radhi [2], Hameedah Hadi Abdulwahid[3]

[1]Assistant Professor, Department of Biology, [2]Assistant lecturer, Department of Chemistry, College of Education for Pure Sciences, University of Kerbala, [3]Obst & Gyn Teaching Hospital, Karbala Health Directorate, Ministry of Health, Iraq

Abstract

Parasitic diseases in protozoa are endemic in many countries around the world, especially in developing countries, and infertility is a major burden. Such infections may be infertile through damage to the female reproductive system. There are some parasitic primary animals such as *Trichomonasvaginalis* which may cause genital tract abnormalities, cervical tumors and tubal and non-anomalous pelvic infections in women. *Toxoplasma gondii* causes endometriosis, dysplasia of reproductive tract and synthetic disorders such as intrauterine adhesions. Some epidemiological studies are indicate that infections with protozoa in women who suffer secondary infertility are higher than those of healthy controls. Some drugs used to treat giardiasis cause infertility in male rats by inhibiting of spermate in the epididymis, which reduces it's viscosity.

Keywords: *Infections, Protozoan parasites, Secondary infertility.*

Introduction

There are many parasites that have a role in women's miscarriage in different ways. 35% of women with an infertility suffered ovarian dysfunction and post-inflammatory changes in the ovarian duct and surrounding Pretorian membrane caused by infectious diseases[1]. Granulomatous salpingitis caused by parasitic infection is a rare cause of tubal obstruction[2] . Infection can cause significant damage to the human reproductive system and animals, including chronic cervical and endometriosis, dysplasia of the reproductive tract, decrease of sperm movement and deformation, synthetic disorders such as adhesions within Uterus and urged the immune mediators that interfere with the gametes or fetal tissue[1]. It has been shown that the reasons related to infection play an important role in the rate of infertility in developed countries[3].

Protozoa areunicellular microorganisms and are a major health problem worldwide because of their increased prevalence and incidence. The clinical symptoms are closely associated with the pathological effects and their location in the host, whether in the blood, tissues or intestines. Among the parasitic protozoa that cause secondary infertility in women is the *Trichomonasvaginalis*, a flagellated that spreads all over the world and live in the urogenital system of humans. In females, in the urethra, and in the epididymis and prostate gland in males[4]. It is transmitted mainly bysexual intercourse, which is considered to be a sexually transmitted parasites. It may be transmitted through western sanitary seats or through the use or exchange of towels or wet clothing with this parasite secretions. In some studies, tubal infertility was repeated twice in women who reported a history of trichomoniasis compared with non-patient women[5-6]. El-Shazly and his group found that *T. vaginalis* is present in 14.58% of the women who are sterile compared to the control group[7].

Toxoplasma gondii is a intercellular protozoan that

e-mail: kawtheralmusswe@gmail.com

effect 20-80% of the world's population in different regions[8-9]. There are some studies that have indicated the relationship between toxoplasmosis and infertility in females, and that the incidence of non-symptomatic latent toxoplasmosis has latent on the early development of fetus. Some studies have found that the incidence of congenital disease in women with infertility is higher than that of healthy women[10-11].

Some studies on laboratory animals have shown that infection with *T. gondii* can cause infertility in experimental animals. Chronic toxoplasmosis in rats female can cause endometriosis, impaired ovaries, weak follicles, atrophy in the ovaries and uterus, decrease in reproductive performance, adrenal glands inflation, vascular inflammation, cessation of menstrual dysplasia and failure to reproduce in experimental mice[12-13-14].

Giardia lamblia is a protozoan flagellate that reproduce in in the small intestine, forming colonies that cause giardiasis. The parasite is attached to the small intestine by the adhesion ventral disc. The trophozoite can absorb its nutrients from the small intestinal cavity. *Giardia* can infect the human, It is also one of the most common parasites that can infect other mammals such as cats, dogs, beavers, cows, deer and sheep also infect birds[15]. Giardiasis spread when eating food or drinking water contaminated with the dormant stage of the parasite (cyst) or through arrive of a part of the faces of the mouth through non-healthy practices of some people. Cyst of the parasite can survive for weeks or months in cold water and may therefore be found in contaminated wells, water systems, stagnant water systems, falling running water from the mountains can also be found in urban water tanks as well as in treated wastewater, and the teasing phase is resistant to traditional method of sterilizing water with chlorine or ozone[16]. Symptoms of giardiasis include diarrhea, malaise, steatorrhea, abdominal cramps, bloating, lack of desire to eat, weight loss, flatulence and nausea[17].

Secondary infertility is defined as a condition affecting women and men despite the occurrence of intercourse regularly and without using any means of contraception for at least 6 months and despite the occurrence of pregnancy[18-19].

Materials and Method

The study was approved by the Iraqi health ministry, a prospective study was conducted based on the hospital during the period from February to July 2019, where the adoption of a woman suffering from secondary infertility, who visited the hospital for women and obstetric education in Karbala (a city located 110 Km south-west of Baghdad), collected venous blood distributed in gel tube, as well as samples were obtained from the vagina.

Serological detection of toxoplasmosis: The serum was separated from the blood collected by centrifugation (3000 rpm for 10 minutes), and then kept in sterilized Eppendorf tube at -20Cº until they were used for serological assays. Serums were tested for IgG and Ig Manti-toxoplasmosis by the enzyme-testing kit (ELISA). In both types of tests, the manufacturer's instructions were followed.

Detection of Trichomonasis: A pap smear was obtained by a specialist gynecologist. Two swabs were approved. The swab was clamped in 1-2 cm in the endocervical canal by 2-3 rotations. The swabs were collected based on the manufacturer's instructions.

Swabs were immersed in a sterile tube containing 1 mL of normal saline solution, the samples examined for 10 minutes at least, positive samples containing one or more of *T. vaginalis* described by their jerky movement and morphology,swabs labeled of the patient's name and date of collection . The wet swab was examined in wet mount preparation[20-21-22].

Results and Discussion

Among 212 women examined, 162 (26.5%) were positive for toxoplasmosis and it was 30.3 % in the both of age groups of present study. Toxoplasmosis is a worldwide parasitic disease, affecting most population groups, Statistics based on the measurement of antibody parasites in serum individuals indicate that the incidence of infection in the world ranges from less than 10% to about 90%[23], Substantial differences between the different strains of *T.gondii* are important factors,Differences in the severity of virulence were observed between the parasite's strains,Some of them are virulence and non-virulence[24]. A few medical studies have been conducted on the relationship between toxoplasmosis and female infertility. Kaňkovă & Flager has been reported that latent toxoplasmosis has adverse effects on the early development of fetuses in mothers[25]. A number of recently published studies have shown that chronic toxoplasmosis infection in infertile women is more significant than healthy women[10-11]. Zhou *et al*., is reported that the prevalence of chronic

toxoplasmosis in infertile couples has reached 34.83% and was significantly (12.11%) higher than fertile couples[27]. Toxoplasmosis has undesirable effects on the reproductive capacity of both males and females[28]. An unexpectedly high correlation was observed between *T.gondii*and secondary infertility (66.7%) more than primary infertility (33.3%)[28], *T.gondii* cause damage deformities of genital tract, tubal inflammation and effects on semen quality[26-29].

It was found that the incidence of infection with trichomonasis 44.4% in infertile women, Previous studies have shown that *T.vaginalis* infection has high rates of recurrence due to its high resistance to metronidazole[30], this makes these microorganisms a serious infection of the reproductive system. Trichomoniasis is not routinely screened in patients with symptoms and the infection can last from 3-12 months in the reproductive system. Elderly patients with asymptomatic trichomoniasis are classified as carriers of long-term disease without any symptoms[31-32-33]. Patients with *T.vaginalis*have no symptoms of 70-100% of males versus women 35-85% . Recently, *T.vaginalis* have been isolated from the fallopian tubes and peritoneal fluid, suggesting that moving *T.vaginalis* may be able to invade the genital tract stream[34-35]. There have been many studies that have found that *T.vaginalis* cause damage to the genitourinary system and various types of cells and tissues such as connective and muscular tissues due to the excessive cytotoxic effect suggesting a high risk of reproductive failure[36-37]. *T.vaginalis* is associated with cells, leading to shrinkage of the cell membrane, cell hemorrhage and apoptosis, These changes in cell structure can appear under a microscope, characterized by intensive chromatin and form dense vacuoles in the cytoplasm [36].

Trichomoniasis in women is associated with inflammation of the vagina, endometritis and can lead to inflammatory responses in the mucous genital tract, which increases the risk of pelvic inflammatory disease[38-39]. Vaginal trichomoniasis is associated with up to 30% acute salpingitis and 16% postpartum endometriosis cases during pregnancy as well as 30% premature births and 30% low birth weight infan6ts[40]. Trichomoniasis paves the way for many parasitic bacteria for inflammatory processes and thus increases the risk of reproductive failure and increases the risk of infection with 1.5-3 times of HIV[41-31-42].

The incidence of infection with *Giardia lamblia*is 29 % in women with secondary infertility. It was found that some drugs used to treat giardiasis cause infertility in male rats by inhibiting of spermate in the epididymis, which reduces it's viscosity[43].

Table (1): The infection in female secondary infertility and female controls.

Group	Number of Causes	Number of positive causes (%)			p-value
		G.lamblia	T.vaginalis	T.gondii	
Female Secondary infertility	162	47 (29)	72(44.4)	43(27)	0.000
Female controls	50	17 (34)	17 (34)	16 (32)	
Total	**212**	**64(30.1)**	**89(42)**	**59 (28)**	

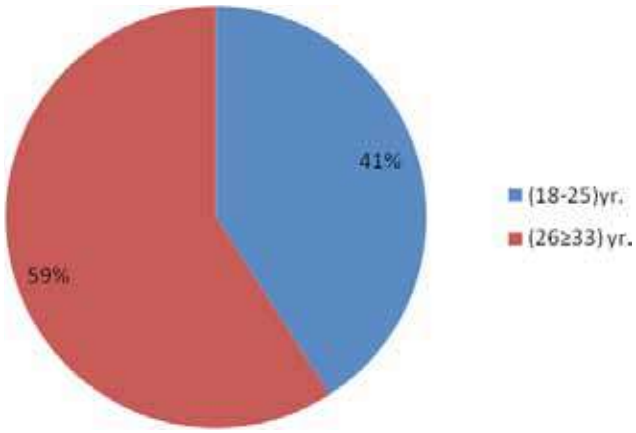

Fig. (1): The percentage of secondary infertile women according to their ages.

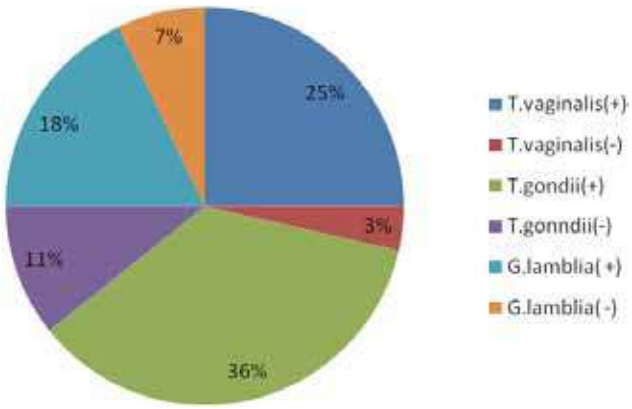

Fig. (2): The percentage of secondary infertile women according to their causes.

Table (2) :Correlation between the parameter under study of secondary infertile women.

Parameters N= 162	Parameters N= 162	r	p-value
Female Secondary infertility	Age	0.015	0.190
	Abortion	0.000	0.426*
Age	Abortion	0.043	-0.160*
Abortion	Female Secondary infertility	0.000	0.357**

*Correlation is significant at the 0.05 level., **Correlation is significant at the 0.01 level.

Table (3): The infection in female secondary infertility with protozoa according to their ages.

Age (Year)	Total number of examined causes	Direct test				ELISA test	
		Number of positive causes		Prevalence of infection (%)		Number of positive causes	Prevalence of infection (%)
		T. vaginalis	G.lamblia			T. gondii (IgG, IgM)	
18-25	56	16	23	28.5	41.0	17	30.3
26 ≥ 33	10	22	62	21.0	58.4	22	21.0
Total	162	38	85	23.4	52.4	39	24.0

Conclusions

The results of this study suggest that parasitic infection in protozoa may be an important cause of infertility according to the widespread spread of the parasites. Therefore, further studies are recommended to better understand the relationship between this infection and infertility as well as screening both the couple when treating infertility as these parasites are sexually transmitted diseases.

Ethical Clearance: This study was approved by institutional Ethics Committee from institute veterinary medicine committee, college of veterinary medicine, University of Kerbala.

The Link between Demographic Profiles with Depression among Elderly Women in Private Care Institution

Nurunsaadah S.[1], Lukman Z.M.[2], Zulaikha M.Z.[1], Bukhari W.M.Y.[1]

[1]Post Graduate Student, 2Prof, School of Social Work, Faculty of Applied Social Sciences, Sultan Zainal Abidin University, Gong Badak Campus, Terengganu, Malaysia

Abstract

Depression among elderly women living in nursing home based on demographic profile become a phenomenon in many developed countries. In most research, depression has been identified as a negative feeling that can lead to death. Depression among elderly women occur when they are 60 years and above once their children grow up and married. Then, there retired from occupations and their spouse died and make they live alone. Thus, this study aimed to identify the factors of demographic profiles have an impact on depression among elderly women. This research was conducted at a private institution in Terengganu, Malaysia with 78 elderly women as respondents quantitatively. The questionnaires from Patient Health Questionnaire 9 (PHQ-9) were adopted to analyse the risk of elderly having depression and feeling lonely in nursing home. The result showed the factors of demographic profile have an impact on depression among elderly women in private institution its strength and significant.As a conclusion, the study on depression among elderly women in nursing home is important to raise awareness about this alarming issue in the society especially among elderly women.

Keywords: *Depression, demographic profiles, elderly women, private care institution.*

Introduction

Depression are prevalent among elderly women in the institution [1]. In a cross-sectional study by Barg et al. (2006), it was revealed that in persons 65 years and older, the perceived adequacy of emotional and tangible support was clearly associated with depressive symptoms three years later [2]. According to Adams et al. (2004), the elderly women living in retirement, nursing homes and institution, away from previous homes and neighborhoods and separated from extended families, will continue to increase[3]. There are living in facilities for the elderly women will have to modify to a changed living situation, and this modification can lead to fatal psychosocial problems of depression in the absence of positive social networks[4]. The elderly women and depression related when they are 60 years old and above when their children grow up and married [5]. Then, there are retired and their spouse died and make they live alone[67].

Material and Method

Population and Sampling: The population of the study wasthe 78 elderly women in welfare institution in Terengganu, Malaysia during the years 2017.

Instruments: An individual information frame, the PHQ-9 were utilized as the information gathering devices in the exploration.

PHQ-9: This poll screening the dejection among elderly. The PHQ-9 is a self-regulated adaptation of the PRIME-MD demonstrative instrument for basic mental clutters. The PHQ-9 is the misery module,

which scores every one of the 9 DSM-IV criteria as 0=not by any means, 1=several days, 2=more than a large portion of the days and 3=nearly consistently. The PHQ-9 was finished by 6,000 patients in eight essential consideration facilities and 7 obstetrics-gynecology centers. Moreover, standard legitimacy was evaluated against an autonomous organized emotional well-being proficient (MHP) meet in an example of 580 patient's especially elderly women.

Findings:

Respondent Backgrounds: Table 1 shows the marital status of the respondents who participated in this survey. Among the elderly women in PKWTNS, only 2.6 percent were single, (n=2). Similarly, only 3.8 percent were married, (n=3). The majority of the elderly women were widows at 93.6 percent (n=73). The age distribution of the respondents, the percentage of those who were, 60-64 and 70-74 years old was the same at 30.8 percent, with 24 respondents for each age group. Next, 19.2 percent (n=15) were of 65-69 years old while 17.9 percent (n=14) were between 75-80 years old. The smallest age group was the 80 and above, with only 1.3 percent (n=1). Meanwhile, the level of education of the elderly women participating in this research was low. The majority at 53.8 percent (n=42) only finished lower secondary education (SRP), while 18 percent (n=14) had no education experience whatsoever. Only 28.2 percent (n=22) received basic education (SPM). The working history of respondents in this research were majority of the respondents were self-employed (60.2 percent, n=47). Those who were not working comprised of 26.9 percent (n=21). Out of all of the respondents, only 10.3 percent (n=8) were public workers while 2.6 percent (n=2) were working in the non-government sector. Many of the elderly women interviewed came from small families. Table 1 shows that the majority of the respondents at 46.2 percent (n=36) had only 1-4 children. The next largest group was with 5-9 children that comprised of 37.2 percent (n=29) of the respondents. Only 12.8 percent (n=10) had 10-14 children in their families, 1.2 percent (n=1) had 15-19 children and 2.6 percent (n=2) had no children. Besides, the person(s) whom the respondents spent most their time before coming to PKWTNS are almost half of the respondents (47.5 percent, n=37), lived alone prior to coming to institution. The remaining 52.5 percent were living with someone else, of which 3.8 percent (n=3) was with a husband or spouse while 48.7 percent (n=38) either lived with children, relatives, or others. Below the table shows the reasons to live in PKWTNS. The majority of them want a better life in the institution (21.8 percent) because they lack caretakers (19.2 percent), or because they have a family conflict (14.1 percent). A few respondents mentioned that they live in PKWTNS because they do not want to disturb their children (11.5 percent), or have been abandoned by children (10.3 percent) and lack of energy in doing household chores (6.4 percent). Other reasons for choosing to live in an institution are due to loneliness (10.3 percent) and being poor (6.4 percent). Table 1 shows the level of depression among elderly women in PKWTNS. Using the PHQ-9 instrument, only 7.7 percent (n=6) of the respondents were classified as normal (0-4) with no depression. About 12.8 percent (n=10) of the respondents were classified as having minimal depression (5-9) while 55.1 percent (n=43) were classified as having mild severity of depression (10-14). Meanwhile, 24.4 percent (n=19) of respondents were classified as having moderate severity of depression (15-19). None of the respondents in PKWTNS were classified as having high levels of depression (more than 20).

Table 1: Respondent Backgrounds

Respondent's Background	Frequency (n=78)	Percentage (%)
Marital Status		
Single	2	2.6
Married	3	3.8
Widowed	73	93.6
Age		
60-64	24	30.8
65-69	15	19.2
70-74	24	30.8
75-80	14	17.9
More than 80	1	1.3
Level of Education		
SRP	42	53.8
SPM	22	28.2
No Education	14	18.0
Working History		
Not Working	21	26.9
Self-employed	47	60.2
Public Worker	8	10.3
Non-government	2	2.6
Number of Children		
1-4	36	46.2
5-9	29	37.2
10-14	10	12.8

Respondent's Background	Frequency (n=78)	Percentage (%)
15-19	1	1.2
No Children	2	2.6
The Majority of Elderly Women Spent with		
Self	37	47.5
Husband/Spouse	3	3.8
Children	20	25.6
Relatives	17	21.8
Others	1	1.3
Reason for Choosing to live in institution		
Do not Want to Disturb Their Children	9	11.5
Abandoned by Children	8	10.3
Family Conflict	11	14.1
Lack of Caretakers	15	19.2
Lack of Energy in doing Household Chores	5	6.4
Want a better life in the Institution	17	21.8
Poor	5	6.4

The Level of Depression		
0-4	6	7.7
5-9	10	12.8
10-14	43	55.1
15-19	19	24.4
More than 20	0	0

The findings of regression analysis show the impacts of independent variables that are factors of demographic profile on respondents' depression. Based on the correlation analysis, only four factors showed insignificant value, network and communication and trust. Only factors with significant correlation value can be measured by the effects of regression analysis.

Table 2: Model Summary

Institution	Model	R	R Square
Private Institution	1	0.754	0.716

The r square value in the Model Summary in table 2 shows the amount of variance in the dependent variable that can be explained by the independent variables. In the research, the independent variables together account for 71.6 per cent of the variance in the depression scores. The r value (0.754) indicates the multiple correlation coefficient between all the entered independent variables and the dependent variable.

Table 3: Regression

Model	B	Std. Error	Beta	T	Sig.
Frequency of visitors	2.038	0.065	0.402	31.460	0.00
Period of stay	0.157	0.035	0.381	4.495	0.00
Level of health	-0.115	0.045	-0.269	-2.543	0.03

The coefficient for period of stay was 0.157. Hence, for every unit increase in frequency of visitors score, researcher expect a 0.157 point increase in the depression score keeping the scores for variables period of stay and level of health fixed. The result obtained was statistically significant ($p=0.00 < 0.05$). This is statistically significant ($p=0.03 < 0.05$). The coefficient for frequency of visitors was 2.038. Hence, for every unit increase in frequency of visitors score, researcher expect a 0.065 point increase in the depression score keeping the scores for variables period of stay and level of health was fixed. This result is statistically significant ($p=0.00 < 0.05$). Symbol of t and Sig. was a constant is significantly different from zero at the 0.05 alpha level as in $p=0.00 < 0.05$. Therefore, based on Table 3, a multiple regression was run to predict depression from frequency of visitors, period of stay and level of health. These variables statistically significant predicted depression, $F = 25.143$, $p < 0.05$, $R2 = 0.716$. All three variables added statistically significantly to the prediction, $p < 0.05$.In this section, the researcher will discuss further on the relationship between depression and factors of demographic profiles among elderly women in private care institution. Meanwhile, the distribution of frequency of visitors was found that there was a significant relationship between frequency of visitors and depression among elderly women in institution. However, in this section, focus will be given on the residents who were never visited by their children, neighbors, friends, and relatives. It is human nature the lack of attention from loved ones could lead to mental illness, especially depression[8910]. Hence, residents who did not have any visitors were detected as having depression. Elderly women who stayed longer in homecare tend to have depression [1112]. In the present research, it was found that most of the residents are staying more than 12 months. Hence, this might be another factor in most of the institution residents having depression. This statement is also supported by other researches which indicated that the elderly who are staying at nursing homes tend to have depression, regardless of having proper activities because for them, staying with children is more important than staying

in the nursing home[13,14,15]. Table 3 shows that the prevalence of depression was higher in elderly women who were staying in institutions for longer more than 12 months a (37 people) as compared to those staying for less than 6 months (18 people). The rationale behind the increased prevalence of depression with increasing duration of stay could be due to the feeling of loneliness from the outside world especially in an institution [161718]. Thus, there are significant positive relationships between duration of stay with depression and loneliness among elderly women.The relationship between levels of health with depression is a well-known issue and has been reported by numerous other researches. The literature suggests that depression may increase the risk of the subsequent level of health among elderly women. According [192021], many elderly women have diabetes and other chronic medical conditions that are associated with an increased risk of depression. The presence of a chronic medical illness may in fact decrease the chances of recognition and therefore treatment of depression in the setting. The more severe condition of the illness, the higher the risk of depression[22]. A meta-analysis of interventions among elderly women with diabetes and depression showed that both psychotherapies and antidepressants were efficacious in treating depression among the elderly women with diabetes. In the study, the relationship between financial support and depression among elderly women in institution was investigated. According to[23,24] most elderly women are economically disadvantaged. In those cases, the economic crisis especially unemployment acts as a precipitant among elderly women. It is therefore especially important to screen for depression among them during these periods of economic hardship. In other researches by[25] depression among elderly women was found to be related to financial difficulties and poverty where lack of financial support was cited as the most prevalence factors for the occurrence of depression.

Conclusion

As a conclusion, the study on the link between demographic profiles with depression among elderly women in private care institution is important to raise awareness about this alarming issue in the society especially among elderly women. Hence, the findings of this research will give a better understanding regarding function of the nursing home in reducing depressions and loneliness among them.

Laparoscopic Sleeve Gastrectomy Versus Laparoscopicmini-Gastric Bypass in Management of Morbid Obesity and its Comorbidities

Tantawi Abdel Naeem Mohamed[1], Salah Abdel- Razik[2], Ayman Mohamed Hassanien[2], Tohamy A. Tohamy[2], Ashraf Abdel Azeem[2], Mohamed Mostafa Taha Zaazou[3]

[1]Assistant Lecturer, [2]Professor, General Surgery, Faculty of Medicine, El Minia University Hospital, [3]Assistant Professor of General Surgery, Faculty of medicine, Misr University for Science and Technology, Egypt

Abstract

Background: Laparoscopicmini-gastric bypass (MGBP) is gaining popularity among the bariatric procedures today and laparoscopic sleeve gastrectomy (SG) as a single-stage procedure fort he treatment of morbid obesity is becoming increasingly popular.

Patients and Method: Between October 2014 and July 2018, 100 obese patients were randomized, operated upon, and followed up for 24 months in Al Minia University Hospital. A total of 50 patients underwent SG, and 50 patients underwent MGBP. The mean BMI of all patients was 47.8±5.5kg/m^2, their mean age was 30±8.3 years and 80% of them were female. Patients were followed up at 1, 3, 6, 9, 12,15,18,21 and 24 months.

Results: Age, sex, BMI, and comorbidities were equal. The mean operative time for SG was 86.9 ± 51.6 min and that for MGBP was 108.4 ± 41.8 min; the percentage of 1-year excess weight loss was similar (76.2±4.49% for SG and 80.3±8.3% for MGBP). The comorbidities were significantly improved after both procedures, except for type 2 diabetes mellitus, which showed a higher resolution rate after MGBP.

Conclusion: Laparoscopic SG regarding excess weight loss is comparable to laparoscopic MGBP in short-term follow-up (2 year) with less metabolic effect. Further long-term studies are needed.

Keywords: *Comorbidities, diabetes mellitus, mini-gastric bypass.*

Introduction

Obesity is a major health burden worldwide, and although it was considered a disease of the western world, it seems to have expanded to the developing world.[1]. Significant obstructive sleep apnea (OSA) is present in 40% of obese persons and venous thromboembolism in 12% [2]. More than 70% of patients with sleep apnea present with obesity[3]. Conservative measures, Conservative measures physical exercise, have proven inadequate[4]. Depending on the type of operation, gastrointestinal surgery is also very effective in the resolution of diabetes [5]. Traditionally, the primary mechanisms through which bariatric surgery achieves its outcomes are believed to be the mechanical restriction of food intake, reduction in the absorption of ingested foods, or a combination of both [6]. Furthermore, little is known regarding the effect of the various surgical procedures on glycemic control and T2DM remission[7]. SG was first described in 1999 as part of the biliopancreatic diversion duodenal switch procedure. Subsequently, LSG has been performed as as tan dal one procedure[8]. Although these procedures have proven to be good therapeutic options for some patients such as gastric leaks, whichpose a

Phone No.: 01005651501

particularly difficult challenge when they occur near the angle of His, potentially generating severe clinical conditions that require reoperation, and may even cause death[9]. Mini-gastric bypass (MGBP), first reported by Rutledge, was proposed as a simple and effective treatment of morbid obesity. MGBP is a modification of the Mason's loop gastric bypass, with weight loss results similar to laparoscopic Roux-en-Y gastric bypass (LRYGB)[10], which was the most favored bariatric procedure in America.[11]. However, controversies about the relative safety of this procedure remain, mainly the incidence of marginal ulcer and reflux esophagitis[12].

Patients and Method

It was done from October 2015 to July 2018. All patients were evaluated pre operatively (full examination, obesity and its comorbidities). Patients were chosen and divided randomly into two groups in accordance to their admission to the study: the first group underwent LSG, whereas the second group underwent laparoscopic MGBP. All patients were evaluated regarding operative time, postoperative recovery, complications, resolution of comorbidities, and percent excess weight loss (% EWL). Results were recorded intraoperatively, early postoperatively, and at 1 month, 3 month, 6 month, 9 month, 12 month, 15 month, 18 month, 21 month, and 24 month intervals. Written informed consent was obtained from all the patients to be included in this study.

Statistical Analysis: Data were collected in tables and then analyzed with respect to χ^2 and *P* value. Data were fed tot he computer and analyzed using IBM SPSS software package version 20.0 (IBM Corp., Armonk, New York, USA). *P* values less than 0.05 were considered significant.

Results

MGB. Overall, three patients with T2DM had complete and three had partial resolution in SG, whereas nine patients had complete and two partial resolution in MGB; three patients had complete and two partial resolution regarding hypertension in SG and five complete and three partial resolution in MGB; dyslipidemia remission was seen in four patients and improved in two patients in SG and seven patients had remission and one improved in MGB. There was resolution of osteoarthritis, OSA, and polycysticovary in all patients in both groups. Bleeding was seen in three cases in SG, where two of them were managed conservatively and one needed exploration, and only one case in MGB, which was managed conservative. Wound infection was recorded in one case in SG and in two cases in MGB. Postoperative nausea and vomiting was seen in five cases in SG and in two cases in MGB; all were managed with antiemetics. Moreover, four cases had port site hernia in SG and two in MGB. Symptomatic cholelithiasis was obvious in both groups; in SG, eleven patients were managed conservative and three patients needed surgery, whereas in MGB, six patients were managed conservatively and one needed surgery.

Table 1: Comparison between the two groups according to operative time and postoperative recovery (days)

Operative time and postoperative recovery (days)	Sleeve gastrostomy (*n*=25)	Mini-gastric bypass (*n*=25)	t	P

Discussion

A systematic analysis with pooled data from 19 prospective studies adjusted for age, study, physical activity, alcohol consumption, education, and marital status, over 160 000 deaths, showed that overall for men and women combined, for every five unit increase in BMI, a 31% increase in risk of death was observed[13-14].

There is strong published evidence that bariatric surgery is the only effective means to sustain long-term weight loss, and this weight loss is also associated with the resolution of obesity-related comorbid conditions, which increase the risk of mortality associated with obesity[15]. In our study, there were 19(38%) patients with T2DM8 in SG and 11 in MGB, 14(28%) patients with hypertension six in SG and eight in MGB, and 14 (28%) patients with dyslipidemia, with six in SG and eight in MGB.

Plamper *et al*. [16] described in their study comparing SG with MGBP that both groups were comparable for age, preoperative weight, and BMI as well as the distribution of the associated comorbidities.

In our study, there were 19(38%) patients with T2DM, eight in SG and 11 in MGB; 14 (28%) patients with hypertension, six in SG and eight in MGB; 14 (28%) patients with dyslipidemia, six in SG and eight in MGB; seven (28%) patients with OSA, three in SG and four in MGB; 13 (52%) patients with osteoarthritis, seven in SG and six in MGB; three (12%) patients with PCO, one in SG and two inMGB.

Weight loss is reported in many different ways. Sczepaniak *et al*. evaluated the weight loss has been reported as absolute weight loss, percentage of total weight loss, % EWL, percentage of excess BMI loss, and percentage of patients with successful weight loss[17].

Boza *etal*.[18] have reported excellent results of 1000 consecutive LSG procedures with a mean EWL of 84.5% at 3-year follow-up and with minimal weight regain after the first postoperative year. In our study, mean % EWL

was 32.05% at 1 month,45.05%at 3 months, 67.6% at 6 months, and 76.22% at 12 months in SG and was 22.13% at 1 month, 39.75% at 3 months, 63.32% at 6 months, and 80.31% at 12 months inMGB.

Laparoscopic MGBP in morbidly obese patients with T2DM has been proved to be effective in prospective randomized controlled trials [19], and in extensive reports in the literature[20], Lee *et al*. [21] have suggested that the efficacy of T2DM remission was similar regardless of BMI, and they recommend that more free use of gastric bypass should be considered in Asian patients with T2DM. We found three patients with T2DM had complete and three had partial resolution in SG whereas nine had complete and two had partial resolution in MGB; three patients had complete and two had partial resolution in hypertension in SG, whereas five had complete and three had partial resolution in MGB; dyslipidemia remission was seen in four patients and improvement in two patients in S Gandseven patients with remission and one with improvement in MGB; and resolution of osteoarthritis, OSA, and poly cystic ovary in all patients in both groups.

The primary risk factor for T2DM is obesity, and 90 % of all patients with type 2 diabetes are either over weight or obese[22]. Gill *et al*.[23] found that SG results in T2DM resolution ranging from 80% to 96% in morbidly obese subjects. Laparoscopic MGBP in morbidly obese patients with T2DM has been shown to be effective [23]. Schauer *et al*.[24] recently demonstrated the superiority of the RYGB over a SG for the morbidly obese patients with remission of T2DM at 3 years.

Obesity is associated with an increased risk of GERD, with up to 50% of morbidly obese patients suffering from this condition. Prachand and Alverdy also concluded that the incidence of GERD seems to be more frequent after LSG [25]. There is no doubt that □0.5–1.0% of the patients develop malnutrition requiring surgical correction – reversal or shortening of biliopancreatic limb, or conversion to sleeve – after MGB [26].

In the entire literature, there is only one reported case of Petersen's hernia after MGB[27]. No internal hernia was recorded in our study, and only four cases developed symptomatic acid ref lux in SG and seven cases developed symptomatic (bile) reflux in MGB. It is believed that MGB results in less dumping and reactive hypoglycemia compared with RYGB. Carbajo *et al*.[28] did not see any dumping syndrome in their study.

Conclusion

LSG regarding EWL is comparable to laparoscopic MGBP in short-term follow-up (1 year) with less metabolic effect. Further long-term studies are needed.

Abstract

Genital tract infection is a major source of morbidity in sexually active individuals. Reported rates of STD underestimate the exact problem of infection because the majority of STDs are asymptomatic and therefore go undetected especially in our community. The aim of this study was to investigate for the prevalence STD pathogens in females. 184 urogenital swabscollected from outpatient femalesthen analyzed by Real-Time PCR for eight different pathogens (Neisseria gonorrhoeae, Chlamydia trachomatis, Herpes simplex virus, *Trichomonas vaginalis*, Hepatitis viruses B & C, *Mycoplasma genitalium* and Human papillomavirus).90.21% of samples resulted positive for one of the targets named above. PCR is a beneficial diagnostic technique for STDs since it has a highly specific and sensitive. the most prevalence pathogen was Human papilloma virus 40.96%.

Keywords: *STD; Neisseria; Chlamydia; Herpes; Mycoplasma; Trichomonas; Hepatitis; Papillomavirus.*

Introduction

The term of Sexual transmitted diseases STDs define of an infection caused by more than 30 varied bacteria, viruses and parasites which are transmitted through sexual intercourse[1] and are a main cause of chronic and acute infection and their consequences like ectopic pregnancy, malignancy, infertility and death of neonates worldwide, not only in developing, but also in developed countries[2,3]. Reported of STD rates underestimate the exactproblem of infection because the majority of STDs are asymptomatic and undetected especially in our community[4]. Whereas many of these infections are preventable and curable but the morbidity and mortality related with STD remain high. The incidence STD pathogens is increasing for the first time in a decade even increasing in resistance to antibiotic is fast evolving too[5,6]. WHO estimates that STDs are one of the five groups of diseases for which adults in the world most commonly search for medical assistance, contain a series of diseases of various infectious agents, in which sexual transmission remains a main epidemiologic role, from time to time the infectious agents can spread in a diverseroutes, from mother to her baby,by blood transfusion or tissue transfer[7,8]. The problem with STDs are asymptomatic infections and about 70% of females with chlamydia infections and gonococcal experience no symptoms at all and so STDs can be passed on unawares way[6]. This type of infectious diseases caused by virous agents like bacteria, viruses,protozoa or arthropods that are mostly acquired by sexual contact[9]. All of above increasing the necessity for more sensitive, rapid and diagnostic examinations to decrease the prevalence of it. Whereas the complications of STDs can be serious, but on other side, several of these consequences are preventable if suitable, efficient, sensitive, specific and ease of handling appropriate and rapid screening is done to those are strongly suspected. The main purposes of diagnostic tests for STDs are helping in typical cases diagnosis, atypical cases, asymptomatic infections and likewise various infections[10]. However, not all sexual contacts with these microorganisms cause infections, then not all infections developing to be long-term problems, which propose that main factors for instance microbiota of vagina, host immunity status, pathogen appropriateness and load may modulate the natural

history of these infections[11]. The current diagnostic tests for STDs are fraught with some challenges, with delay in results, absence of specificity and sensitivity. Though, Molecular diagnosis method is a new technique contributed to more fast diagnosis and effective treatment[5]. These method are suitable for organisms that are unculturable or difficult to culture since molecular diagnostic method offer elevated sensitivity, specificity and rapidity[10]. Based on the above, this study was done to determine the prevalence of STD pathogens in females by molecular diagnosis method.

Material and Method

Patients: We conducted a cross-section study among all patients who had go to the STD clinics. The study took place from April/2016 to December/2018. The information was collected via a questionnaire filled with the help of a physician during an interview. The patient was questioned for precise signs and symptoms at the time of inclusion. Since a patient subject to contact tracing has a higher risk of being positive for a specific STI.A total of 184 urogenital swabs was collected from 184 outpatient females with suspected genital infections or presenting with vaginal discharge to our study clinics. Urogenital swabs were sorted into 2 ml of sterile PBS, then were vortexed to use in DNA extraction step as shown by Liang and co-workers[12].

DNA extraction: was carried out via "AccuPrep Genomic DNA Extraction Kit"/BIONEER/South Korea. While for viral Extraction we used "Viral Nucleic Acid Extraction II" from Geneaid/Taiwan.

PCR Kits:

- Real-time PCR kit of Chlamydia and Neisseria gonorrhoeae from Liferiver/China.
- Singleiplex PCR kit from Sacace Biotechnologies/ Italy used for HSVdetection.
- "AccuPower® HPV 16 and 18/Korea" is a diagnostic kit aimed at detection of HPV.
- "RealAccurate®TVMGres" Kit used to detect *T.vaginalis* and *M.genitalium*.

Every single test was done in keeping with the manufacture's instruction provided with each kit and all amplified products were subjected to electrophoresis via 1.5-2% of agarose gel.

Results

184 urogenital swabs were received and processed in the study period collected from females suffered for different reproductive problems, 166 samples were positive for one of eight types of organisms causing STD detected in this study. Table 1 summarizes the socio-demographic features of the participants. The mean was 37.7 year and Median of female was 32.40 year. The age range was 18 to 50 years, with near to 25% of the participants being younger than 29, and more than 75% was younger than 39. Overall, 48.91% attended secondary school. All females were classified with vaginal discharge or warts or abdominal pain but no woman was classified as vaginal discharge alone. Females which attending to reproductive clinic services because of infertility problems was 10.32% and 5.43% suffered spontaneous abortions.

Table 1: Sociodemographic analyses of sexual transmitted diseases

Variable	(n =184)	%
Female	184	
Baghdad/Iraq	184	
Age Groups (Years)		
=<19	26	14.13
20–29	22	11.95
30 – 39	117	63.58
40-49	13	7.06
=>50	6	3.26
Married	155	84.23
Single	29	15.76
Symptoms	134	72.82
Infertility	29	15.76
Infected partner	21	11.41
Education: Yes	162	88.04
No	22	11.9
Educational Level		
None	22	11.95
Primary school	46	25.0
Secondary school	90	48.91
Higher education	26	14.13

Our PCR-based assay was established for the detection of eight major STIsin addition to a novel internal control DNA sequence for each one. Positive samples had been identified by PCR and showed one band at a specific DNA fragment of all STD pathogens in the first round of reaction when examined by gel electrophoresis as showing in Figure1 & 2.

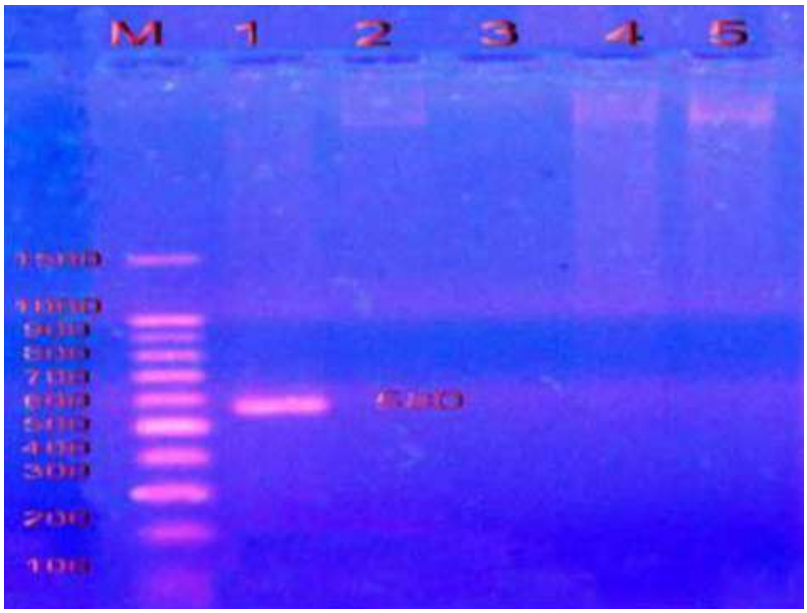

Figure 1: Electrophoresis of PCR product, lane-1positive for HSV.

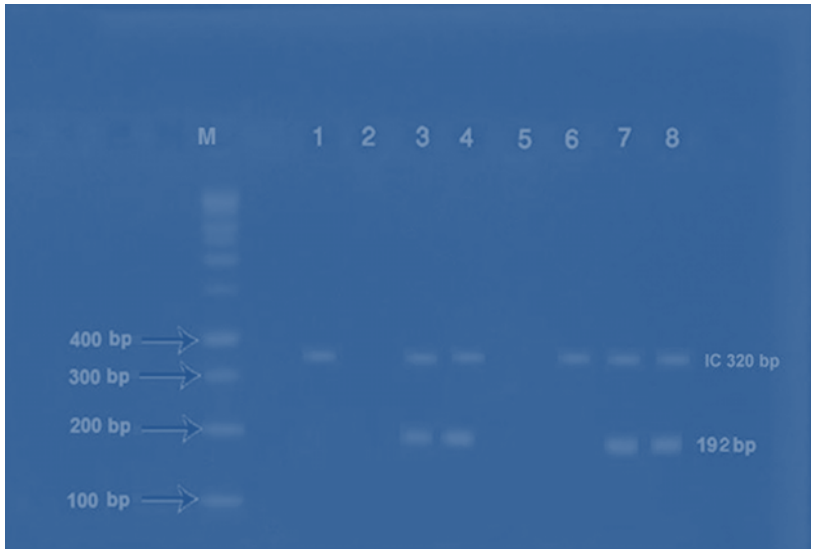

Figure 2: PCR product on 2% agarose gel, using Ethidium bromide.3, 4 and 7 positive samples. Lanes 5,6 negative samples

Table 2: Prevalence of STDs pathogens

Organism	Positive	%
Neisseria gonorrhoeae	39	23.49
Chlamydia trachomatis	10	6.02
Herpes simplex virus1	10	6.02
Trichomonas vaginalis	21	12.65
hepatitis B virus (HBV)	2	1.20
hepatitis B virus (HCV)	4	2.40
Mycoplasma genitalium	12	7.22
Papillomavirus	68	40.96
Total	**166**	**100%**

As shown in Table 2; Of the 184 urogenital swabs collected form suspected females with STD,68 swabs were positive for HPV and it was the most frequent agent with 40.96% once considered in isolation and no cases of infection by Human Immunodeficiency Virus was diagnosed.

Discussion

STDs are often asymptomatic, difficult and very expensive to diagnose. This is mainly correct in countries with restricted health facilities of diagnosis and treatment. Then there is a social stigma attached to

people with STIs which lead them to looking for care from other alternative providers. Therefore, people embarrassed of looking for consultation from physicians in early stage of their infection. Identifying the genetic material of a pathogen doesn't necessitate the pathogen should be alive contrasting culture. It also doesn't need the infection to have occurred a long enough time ago for people to have developed a detectable specific antibody. which means that PCR can detect some diseases earlier than other tests, Even better. STDs can be detected without needs to be concerned about keeping samples alive or testing at exactly the right time. Our results clearly showed that women between 19 to 39 years old are mainly affected by STI which is also consistent with a study performed in China which found that 20-39 years the most prevalence age of STD[12]. HPV infection is associated with the rising in prevalence of HPV-related cancer, nonetheless, at present there are no clinical precise guidelines differentiating in treatment between cancers which HPV positive or negative[13]. However, PCR test validation data showed that this technique is appropriate for the detection of HPV-DNA in specimens with a very high sensitivity and specificity. In our study, HPV was detected in 40.96% of positive patients for STD with the highest prevalence than all other detected pathogens in women. Amorim and co-workers detected high intensities of this virus among women tested in Brazilian study on woman with cervical lesions[14].For practical purposes, diagnosis of *M.genitalium* is limited to PCR, as culture is extremely slow taken months, insensitive and challenging[15]. In our study, *M.genitalium* 7.1% has a higher incidence than *C.trachomatis* 6.02%in sample collected from females. Studies of *C.trachomatis* and *M.genitalium* in changed subpopulations have been obtainable over the years, and these demonstrate that the incidence and rate of these STIs change significantly in diverse situations, and this result similar to Sweden study done in 2018 showing that the incidence of *M.genitalium* was higher than *C.trachomatis* in study population 9.6-7.1%[16]. The majority of bacterial vaginosis serve as a common causative agent of "vaginal discharge syndrome" that has been described in other studies like[17,18,19]. Using PCR for detection of STIs was most common assay for diagnosis of *N.gonorrhoeae* which consider as a significant health problem, especially with many evidences of increasing of resistance to antibiotics[20]. Our research showed the positive rate of *N.gonorrhoeae* was 23.49%, which was close enough to previous reports with rate 24.0%[17], but much higher than others 0.7%, 0.8% and 0.16 Sequentially[18,20,21].

In this study,6.02% of positive patients for Human herpes virus, which close to result of a study done by Grech in 2017 found that 5.3% of females have HSV[21]. Nonetheless, in other Iraqi study done in 2018 shown that just 2 of 200 samples collected from females attending the Gynecology outpatient which lesser than our results[22]. In Turkey, Dinc reported a frequency of HSV in women was 2.2%[23]. Chlamydial infections are one of the major contagious diseases in sexually active individuals which cause bacterial STI like urethritis and mucopurulent cervicitis in women[20]. In our study *C.trachomatis* percentage is 6.02% which very near to the result of a study done by van Lierethat 6.8% of urogenital swabs detected by molecular assay was positive for *C.trachomatis*[24]. While a study done in Italy exposed that just 23 of 1272 specimens collected from female patients were positive for *C.trachomatis*[20]. In an Iranian study done on women with abortion found that 15.32% of samples diagnosed with *C.trachomatis* which could be an evidence of role of this organism in abortion[25]. In our study, the prevalence of *T.vaginalis* was 12.65%.This finding was comparable with other study from Iraq, in which the prevalence of *T.vaginalis* was 14.5% besides 19.0% in Zimbabwe and 11% in Egypt[26,17,27]. However,this result was lesser than the incidence of *T.vaginalis* in pregnant women posttreatment 40% reported by Lazenby and Thompson in 2019[28]. In a study conducted in UK in 2014 suggest that 10–50% of women associated with asymptomatic infection with *T.vaginalis*[29]. HBV can cause infections by sexual transmission but can also causing infections via many other routes. As atypical STD, infection of HBV is well documented and could present in all natures of populations[30]. Though, hepatitis C virus not documented as STD. The present study has informed a low prevalence of HBV and HCV among screening women, which was 1.2% and 2.4% respectively, these results were very close to study done by Godha and co-worker in 2019 found that prevalence HBV was 1.09% and HCV 0.61%[31].In other study done by Niama and co-worker found that prevalence of HBV and HCV were 4.2%,0.7% respectively[32].

As a final point, this study could limit in small size of the samples and its retrospective design[33]. On the other hand, a lot of other studies suggest that is co-infection between two or more STI pathogens in the same specimen, However, such as this association wasn't confirmed in our study. Our data suggest the presence of eight analyzed pathogens that found samples

collected from sexually active women and detection of STD pathogens by real time PCR presented to be a very sensitive and specific technique for diagnosis STD pathogens in females' urogenital swabs.

The Impact of Social Media on Undergraduate Medical Students in the University of Kerbala, Iraq

Inam Abbood AL-Ibrahimy[1], Ali Abdulridha Abutiheen[2], Basheer Akeel AL-Ali[3]

[1]Student in Higher Diploma of Family Medicine, [2]Assistance Professor, [3]Lecturer,
Department of Family and Community Medicine, College of Medicine, University of Kerbala, Karbala, Iraq

Abstract

Background: Social networks refer to web-based and mobile applications available on various platforms that allow users to exchange information, ideas, feelings, files, update their status and interact with other user-generated contents over internet. Social networks are becoming increasingly popular among university students.

Objectives: Explore the impact of social media on undergraduate medical students in the University of Kerbala and to determine the factors affecting the attitude and practice of medical students to the social media networks.

Method: A cross sectional study, was conducted among medical students, of both gender, from first to sixth stage in University of Kerbala/Iraq. The total sample collected was 774 students, 40 students were excluded, and accordingly, the sample was 734 students. The data were collected using a valid self-administered questionnaire that was modified to be suitable for Iraqi society. Student T test and Analysis of variance test were used to identify factors correlated with the impact of social media and p-value at the level of less than 0.05 is considered as significant value.

Results: About 98.2% of the medical students were used social media daily, they were used more than 4 sites to access, Majority of them used Telegram 93.7%and YouTube 89.6%. spent about 6 hours/day, more than 10 time/day, they were used social media during free time, more active at night, also the students had got a benefit from the site of college. There was a high significant difference between positive impact and stage, time spent. While there was no significant correlation with duration of sleep at night.

Conclusions: Overall, the impact of social media on undergraduate medical students in the University of Kerbala was positive. There was no significant correlation between gender, time spent on social media, duration of sleep at night and students' performance.

Keywords: *Social media, medical students, Telegram.*

Introduction

Social media (SM) is a form of electronic communication intended to create online communities, it is one of the factors that can affect our life style[1-2]. Fifty years ago, no one knew a term of "Social Media". But now, everyone knows about it[3]. In the beginning, the Facebook was created as social networking for college students. YouTube was launched in 2005, Twitter was launched in 2006, it was known as social networking and microblogging site[4-6]. Worldwide, the number of internet users was 3.9 billion up from 3.65 billion in the previous years and 2.31 billion persons are SM users, delivering 31% global penetration[7-8]. Facebook is the most popular and top-visited SMS[9]. Telegram has

Student in higher diploma of family medicine, College of Medicine, University of Kerbala, Karbala, Iraq
e-mail: daf8877@gmail.com

recently reached 200 million monthly active users[10]. In Iraq the types of SM are Facebook, YouTube, Twitter, WhatsApp, Instagram, Telegram, Viber, Google, Games, Blogs, LinkedIn, VK Kontakte and Q Zone[11]. Internet users in Iraq reached about 19,000,000 users in 2018 and a survey by Arab Advisors Group of Iraqis above 18 years old reported that 77.9% of the responders are using one or more social network[12, 13]. One of the most crucial areas in which SM has made an impact is the world of education[14]. Whether SM sites is favorable or unfavorable, every day, many students are spending countless hours immersed in SM[15-16].

Data on the influence of SM on Iraqi students are limited. The aim of this study was to assess the impact of SM at the College of Medicine, University of Karbala, Iraq.

Subject and Method

A cross sectional study, was done in University of Kerbala among students of both genders, First through sixth stage in college of medicine. From the period of February 15, 2019 till 1st of May 2019, data collection was carried out two days a week. The collected total sample was 774 students,40 students were excluded (because they did not answer the questionnaire completely), accordingly, the sample was 734 students. A specially designed questionnaire has been prepared; it was quoted from other studies which were modified, validated and evaluated by specialists. The data collection was done through a self-administered questionnaire from participant's students. It was designed to include 3 parts The first part of questionnaire includes questions (Q) about sociodemographic status of participant student that consists of 8 questions which include (Gender, age, stage, marital status, father and mother educational attainment, place of residence and household income). The second part consist of 17 questions that include information about how the student uses the social media. The third part of questionnaire was including a statements about the positive and negative impact of social media on medical students. The positive influence statements were about 9 items and the negative influence statements were 9 items also. Questionnaire had been tested by a pilot study included 50 students of collage of medicine for all stages, to assess the clarity of questions, the feasibility of the questionnaire and to overcome any difficulties or related issues that may arise during data collection and to estimate the time needed to complete the questionnaire. Based on a pilot study minor changes were done on questionnaire. Pilot sample was excluded from the study sample.

Statistical Analysis: The data was entered and analyzed using the statistical package for social science program (SPSS version 25). Quantitative data are presented as means, standard deviation while qualitative data are presented as frequency, percentage. Student-T test and F test were used to find the association between categorical variable and continuous variable. To examine correlations, parametric (Pearson's) simple correlation coefficients (r) was used. The mean differences were considered to be statistically significant when the P-value was found to be less than 0.05.

Scoring system of social media impact: Each correct answer was given 1 while incorrect answer and don't know answers were given zero. The impact of SM on participant's students was positive and negative impact for each impact was 9 questions. The analysis on average response on a 4-point scale. The total score of SM impact were 36 score. For a maximum score of 36 points (100%), and the total impact score was calculated as:

$$\frac{Subject\ impact\ score}{Maximum\ impact\ score(36)} \times 100\%$$

Results

The total number of participants was 734 students from college of medicine, with a response rate of (85.6%) in this study 98.2% of medical students were used social media daily, most students were entering more than 10 time/day, more active at night and the students had got a benefit from the site of college as shown in table1.

Table 1: The relationship between positive impact mean score and pattern of SM usage:

		N	Mean	SD	P value
How often do you log to SNSs	Everyday	720	70.42	14.03	0.002*
	Alternate day	7	69.84	8.09	
	Once a week	4	50.00	21.15	
	2-3 times weekly	2	44.44	15.71	
How many times do you enter SNSs a day	Not every day	21	62.96	18.29	0.007*
	Once a day	29	69.83	14.24	
	2-5 times a day	230	69.47	13.25	
	6-10 times a day	159	68.68	12.93	
	More than 10 times	294	72.24	14.86	
At what time are you most active on SM	At the morning	16	65.28	14.20	0.566*
	At the noon	48	70.54	13.69	
	At the afternoon	117	70.49	15.06	
	At the night	552	70.30	14.00	
Benefit from site of medical college	No	264	68.15	14.81	< 0.001*
	Sometime	271	69.75	12.84	
	Yes	198	73.68	14.38	

*F test significant P value ≤ 0.05

All students (100%) were using SM sites, the average time spent by students on SM was (4.64±2.56) hours\day, whereas the duration of sleep was (6.10±1.47) hours at night as shown in table2.

Table 2: The time spent by students on social media sites per a day and the duration of sleep at night

	N	Min	Max	Mean	SD
How many hours do you spend on social media per day?	734	1	12	4.64	2.56
How many hours do you sleep at night?	734	1	9	6.10	1.47

Most students (represent 32%) were using more than 4 sites to access social networking sites as shown in figure 1.

Correlation between negative impact mean score and duration of sleep at night: There is a negative correlation with a high significant difference (Pearson (r) =- 0.153, p> 0.001) between positive impact mean score and age\years for participant's students. There is a direct relationship (positive correlation) with statistically significant difference between positive Mean score and time spent on SM in hours\day, (r=0.103), (p=0.003). There is a positive correlation with no statistically difference between positive impact mean score and duration of sleep at night (r=0.041) (p=0.242).

There is no significant correlation, (r= 0.014, p=0.704) between negative impact mean score and age\years for participant's students. There is a positive correlation) with a high significant correlation between negative mean score and time spent on SM in hours/day, (r=0.153), (p>0.001). There is negative correlation, with

statistically significant correlation (r=-0.083) (p=0.024) between negative impact mean score and duration of sleep at night.

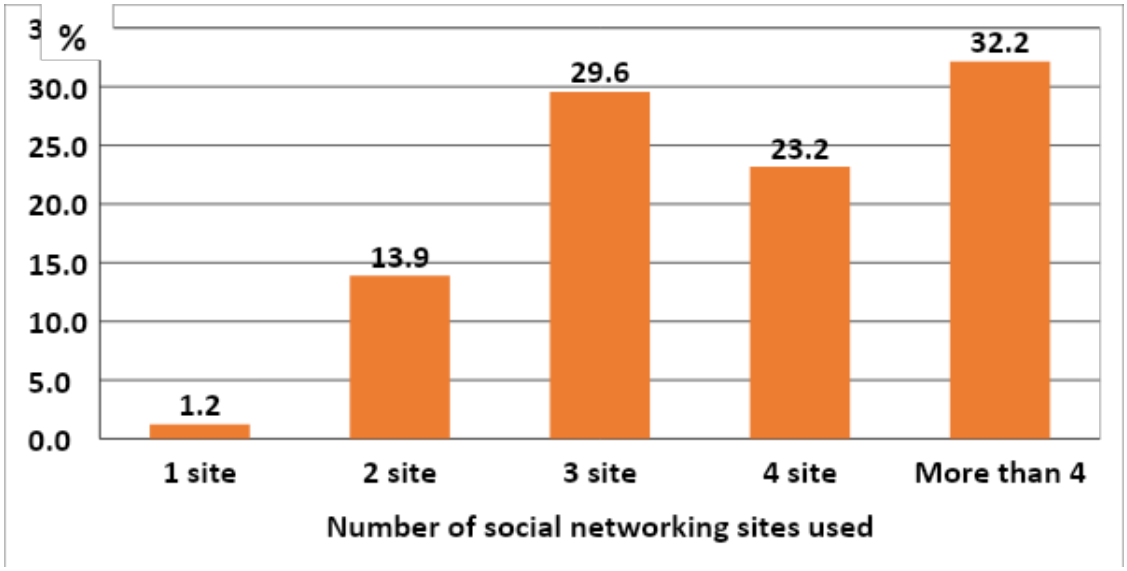

Figure 1: Number of social networking sites used by students.

Telegram was the first social media sites used by students followed by Instagram, then YouTube and Facebook come in 4th place as shown in figure 2.

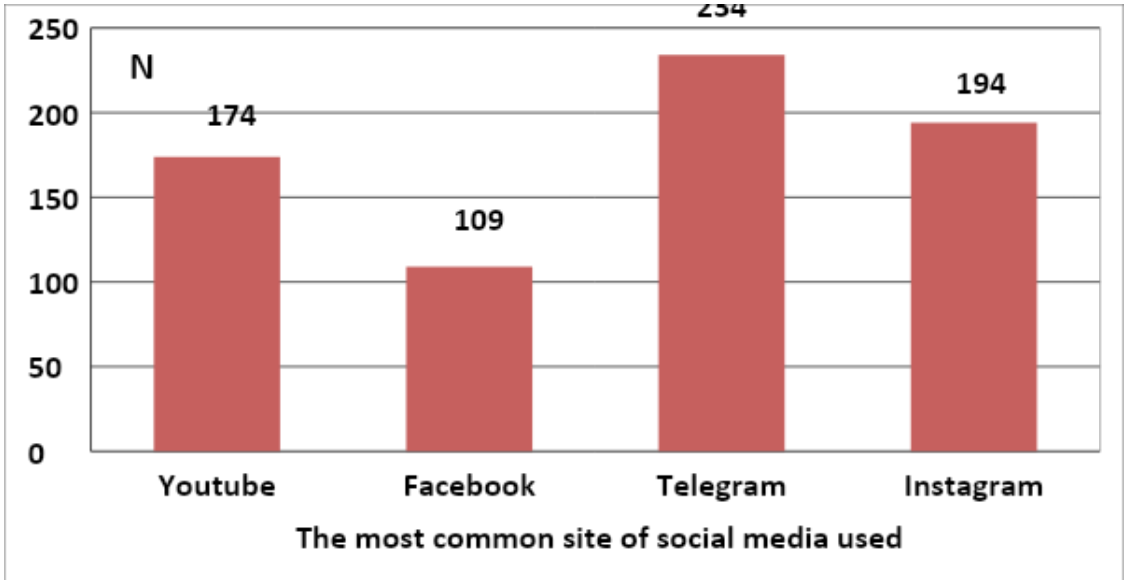

Figure 2: The most common site of social media used by participants.

Discussion

Social networking sites has emerged not only as an effective means of communication during free time patterns rather it has been described as efficacious means of professional communication and professional learning as well as knowledge-management[17]. Regarding to patterns of SM usage. Majority of participants were using SMS daily (98.2%), which was similar to study done in India (2017)(18). also the majority of students were access SMS during free time (97.4%), and they were more active at night (75. 3%).which was similar to a study done in Iran (2016)[1]. Most of students in this study were using more than 4 sites to access SMS while the students in Baghdad (2018), Babylon (2017)

University and Sultanate Oman were use 2 sites[19-21]. About 42% of students were entering SM more than 10 times/day which was similar to a study done in Saudi Arabia (2018)[8]. The mean time spent by students on social networks was (4.64±2.56) hours per day which highlight that medical students have been spending significant time on these social networks. Our results are consistent with a study performed on the students of University of Baghdad (2018) and University of Babylon (2017)[19,20]. Which demonstrated that a significant proportion of students spent more than three hours per day on social networks. While our results are different from a study conducted among medical students in Saudi Arabia (2018),Oman (2013), Ghana (2018), India (2017)[8,18,21,22]. Which reported that most students spent 2 hours per a day and another study reported 60 minutes per a day usage in Italian university (2016) (23). About the duration of sleep at night predominant percentage of students had duration of sleep at night about 6 hours, this result was similar to a study done by Abbas et al in Hilla/Iraq. It is worth mentioning that 7 hours of sleep a day is the minimum number of hours of sleep need for young people between the ages of 18 to 25 years, according to National Sleep Foundation[24]. The Telegram was the most popular site, this result was different from results in Baghdad (2018), Babylon (2017) university in Iraq, Oman (2013), India (2018), Malaysia (2018), Ghana (2018), in which Facebook was the most popular[19-22, 25, 26]. While in Saudi Arabia (2018) the most common site was WhatsApp[8], this different might be due to the students in current study preferred to use the Telegram because it is more speed and more security very easy to use, fast in uploading and downloading files, and easy to connect with members. The predominant number of students had got a benefit from the site of medical college on social websites. This result was similar to study done in Babylon University in Iraq (2015) [27]. The current study showed that the correlation between positive impact mean score and age/ years for participant's students was indirect relationship (negative correlation). there was direct relationship (positive correlation) between positive mean score and time spent on SM in hours\day, this might be due to that the students who use these SMSs more time tend to appreciate their advantages more than the others, and they were find more benefit from SM to improve their educational level. Which was similar to study done in University of Baghdad (2018)[19]. there was direct relationship (positive correlation) but no statistically significant correlation between positive impact mean score and duration of sleep at night, while the correlation between negative impact mean score and age\years for participant's students there was no statistically significant correlation, there was direct relationship (positive correlation) between negative mean score and time spent on SM in hours/day, In current study, there was indirect relationship (negative correlation) with statistically significant correlation between negative impact mean score and duration of sleep at night which was similar to the study done in University of Babylon (2015)[27].

Conclusions

Overall, the impact of social media on undergraduate medical students in the University of Kerbala was positive. There was no significant correlation between genders, time spent on social media, duration of sleep at night and students' performance.

Conflict of Interest: nil

Source of Funding: Self-source of funding.

Ethical Clearance: Study protocol was taken from ethical committee in collage of medicine/Kerbala University.

Analysis on Relationship between Bacillus and Enterobacter Bacteria in Air with Hospital Acquired Infections Potential in Intensive Care Unit of Dr. Wahidin Sudirohusodo Hospital

Owildan Wisudawan B.[1], Anwar Mallongi[2], Anwar Daud[2], Sukri Palutturi[3], Atjo Wahyu[4]

[1]Faculty of Public Health Hasanuddin University, [2]Department of Environmental Health, Faculty of Public Health Hasanuddin University, [3]Department of Health Policy and Administration, Faculty of Public Health Hasanuddin University, [4]Department of Occupational Health and Safety, Faculty of Public Health Hasanuddin University, Makassar, Indonesia

Abstract

Introduction: Poor hospital building environment quality is due to presence of potential sources of airborne microbial and may lead to HAIs (Hospital Acquired Infections). The research aimed to find out the relationship between the Bacillus sp. and Enterobacter sp. in the air with HAIs incident potential.

Material and Method: This research was conducted in Dr. Wahidin Sudirohusodo hospital. This was an analytic observational research with the cross-sectional study design. Samples taken were human samples based on the criteria of the research as many as 61 patients, and the environmental samples were as many as 8 ICU rooms. The data were analyzed using the Chi-square test.

Findings and Discussion: The research result indicates that the air quality related to the microbial pollution in the air in intensive care unit room does not qualify. The result of the microorganism culture and identification is found the HAIs causing bacteria namely Bacillus sp. and Enterobacter sp. Based on the statistic test, the value of p=0.014 (95% confidence intervals) is obtained, so there is the relationship between Bacillus sp. with HAIs incident potential. The Enterobacter sp. bacterium indicates the value of p=0.437 (95% confidence intervals), so there is not have the relationship between the Enterobacter sp. bacterium with HAIs incident potential.

Conclusion: Bacillus in the air has the potential to cause HAIs in the ICU. Aspects of hygiene and sanitation appeared to be important factor in maintaining low microbial load in the air and further research is needed related to fungi and viruses in the air because of the potential source of HAIs.

Keywords: *Bacillus, Enterobacter, HAIs, ICU.*

Introduction

Transmission of airborne microbial infections can occur in ICU (intensive care unit)[1]. Microbial exposure that exceeds the threshold value required in hospital ICU rooms is one of the main causes of HAIs, acute toxic effects, and can even lead to disability to death, especially for people who have immune system disorders[2]. HAIs are variables that have a strong association with length of hospital stay among patients admitted to the ICU[3].

The source and spread of microbial related to HAIs are found in visitor clothing, human activities, the presence of medical staff, other sources such as air dust, soil, and water that can be distributed through air conditioning in room[4], hand hygiene and environmental hygiene and medical equipment[5]. HAIs affect patient

e-mail: wildan.graduates@gmail.com

safety, estimates of deaths associated with HAIs in hospitals were 98.987 where for pneumonia cases were 35.967, blood flow infections were 30.655, urinary tract infections were 13.088, surgical site infections were 8.205, and for infections elsewhere there were 11.062[6,7]. Levels range of HAIs from 2.7%-3.8%[8]. Microbial associated with HAIs are Staphylococcus sp., Micrococcus sp., Pseudomonas sp., Proteus sp., Escherichia coli, Enterobacter sp., Bacillus sp., Cladosporium sp., Aspergillus sp., And viruses[8,9].

Bacillus species belonging to aerobic gram-positive bacilli and reported to cause HAIs. Spread of Bacillus related to HAIs among hospitalized patients in the hospital environment can increase morbidity and mortality in patients with immune system disorders. Environmental reservoir identified for Bacillus sp. including contaminated air and ventilation filtration equipment in the ICU[10].

Enterobacter is a gram negative pathogenic bacterium that can pose a serious triple threat for patients admitted to hospitals throughout the world[11]. Infections caused by spectrum-producing β-lactamase Enterobacter increase cases of death in treated patients mainly related to HAIs[12]. Significant risk factors, identified by multivariate analysis, were the use of antibiotics, the duration of long-term care, patients aged ≥ 65 years, and having a male sex[13]. Extended-spectrum beta-lactamase (ESBL) describes HAIs in ICU care, caused by Enterobacter sp.[14].

The research aimed to find out the relationship between the Bacillus sp. and Enterobacter sp. bacterium in the air with HAIs incident potential. This research is expected to be used as a guide in improving aspects of sanitation and hygiene Hospital so that patient safety factors can be improved.

Material and Method

The type of this research was observational analytic with cross-sectional study design. The process of culture and identification of bacterial types using a tool namely "Microbiological Air Sampler" (MAS) 100 NT and KIA medium (Krigler Iron Agar) which is useful as a differential medium for distinguishing types of microbial. The research sample consisted of human samples and environmental samples. The samples in this research are ICU 1, ICU 2, PICU (Pediatric Intensive Care Unit), NICU (Neonatal Intensive Care Unit), RPK (ICU for Lontara 1), HCU (ICU for Neurosurgery), CVCU (ICU for Cardiac Vascular Care Unit), ICU for Burns. Human samples in this research were all patients treated in the ICU who were at risk of infection, namely being treated for at least 3x24 hours and the results of the patient's medical record analysis with the help of a doctor/nurse. The results of the examination data are then processed using a Chi-square test.

Findings and Discussion

The results of the culture and identification of the types of air bacteria in the ICU showed that overall Bacillus sp. (87.5%) and Enterobacter sp. (50%). The potential for HAIs caused by Bacillus sp. greater than Enterobacter sp. However, the presence of Bacillus sp. and Enterobacter sp. in the air, the level of vulnerability of patients is higher in infections, especially immuno compromised patients. Table 1 shows that ICU 1, ICU 2, and RPK had the greatest influence on the potential occurrence of HAIs where based on culture results and identification of types of bacteria in the air, Bacillus sp. and Enterobacter sp.

Table 1: Results of culture and identification of Bacillus sp. and Enterobacter sp. in the air intensive care unit Dr. Wahidin Sudirohusodo hospital

Type of Room	Identification of Airborne Bacteria
HCU	Enterobacter sp.
ICU 1	Enterobacter sp., Bacillus sp.
ICU 2	Bacillus sp., Enterobacter sp.
PICU	Bacillus sp.
NICU	Bacillus sp.
CVCU	Bacillus sp.
RPK	Bacillus sp., Enterobacter sp.
ICU for Burns	Bacillus sp.

Chi-square test results for Bacillus sp. shows p value = 0.014 (95% confidence intervals) while for Enterobacter sp. shows p = 0.437 (95% confidence intervals). The statistical test results concluded that Bacillus sp. in the air of the ICU room it is associated with the potential for HAIs and Enterobacter sp. in the air the ICU room has no relation to the potential for HAIs.

Research related to microbial in the air conducted by Palawe in the Central Surgery Installation operating room found Bacillus sp.[15]. Another research by Jaffal found Bacillus sp. and Enterobacter sp. in the pediatric intensive care unit, male medical, and female surgical[16].

Bacillus sp. is the dominant microbial found in the ICU room as much as 33.3%[17]. The concentration of bacteria is positively correlated with the number of people in the room[18]. Patients who were admitted to the ICU for few time were 1,241 (9.7%) and 819 (6.4%) were admitted to the ICU. The results showed that 800 patients (6.3%) were identified as having 1 or more HAIs[19]. SSI (surgical site infection) included HAIs which were first identified (n = 882; 38%). The average percentage of HAIs due to SSI in each hospital is 43%[20].

Conclusions

The results of culture and identification of microorganisms in the ICU found bacteria related to HAIs, namely, Bacillus Sp. and Enterobacter Sp. The results of the research statistically concluded that Bacillus sp. related to HAIs. Improvement of hygiene, sanitation and disinfection aspects is needed to control total microbes in the air.

Conflict of Interest: There is no conflict of interest to be declared.

Abstract

Introduction: The swimming pool as one of the public places frequented by people for recreation and physical exercise must have water quality that is protected from Salmonella bacteria that can endanger public health. This study aims to determine the quality of salmonella bacteria and pH (Power of Hydrogen) in Andi Mattalatta Stadium swimming pool water and Hasanuddin University pool water before cleaning and after cleaning.

Material and Method: This research was conducted in the Andi Mattalatta Stadium swimming pool and Hasanuddin University pool water. This was descriptive observational research with a cross-sectional study design supported by laboratory examinations. Sampling each pool water two times ie sampling in the morning (after cleaning) and sampling in the afternoon (before cleaning). Pool water samples were examined in the integrated laboratory of the Faculty of Public Health, Hasanuddin University, using Bismuth Sulfite Agar.

Findings and Discussion: The results showed that the water quality of swimming pool Andi Mattalatta stadium after cleaning was found Salmonella Sp. 8 colony/100 ml with pH: 6.0 and before cleaning was found Salmonella Sp. 30 colony/100 ml with pH: 5.0. The water quality of swimming pool Hasanuddin University after cleaning was found Salmonella Sp. 14 colony/100 ml with pH: 7.0 and before cleaning was found Salmonella Sp. 38 colony/100 ml with pH: 7.0. Water quality of swimming pool Andi Mattalatta stadium and Hasanuddin University pool already has been polluted by Salmonella Sp. and pH quality of swimming pool Andi Mattalatta stadium doesn't qualify.

Conclusion: It is recommended to the pool manager to improve the pool water disinfection system to reduce the total salmonella colonies that endanger visitors.

Keywords: *After cleaning, Before cleaning, pH, Salmonella, Swimming pool.*

Introduction

The swimming pool is the most visited place for recreation or physical exercise. The average visit is 13-24 times/year with an average swimming duration of 67-81 minutes. Men ingest an average of 27-34 ml per swimming event, women 18-23 ml, and children 31-51 ml[1]. Therefore, health risks arising from poor swimming pool water such as bacteriological risk[2].

Outbreaks of water-related swimming pools result from exposure to pathogenic bacteria or chemical agents in treated recreational water sites (eg, pools and hot tubs or spas) or untreated recreational water sites (eg, lakes and oceans). In 2009-2010, public health officials

Corresponding Author:
Owildan Wisudawan B.
Faculty of Public Health Hasanuddin University, Makassar, Indonesia
e-mail: wildan.graduates@gmail.com

from 28 states of Puerto Rico electronically reported 81 outbreaks of recreational water-related diseases to the CDC's Waterborne Disease and Outbreak Surveillance System (WBDOSS) through National Outbreak Reporting. 1,326 outbreak-related cases were reported to result in at least 62 (5%) inpatient cases[3].

Poor bacteriological quality in swimming pool water can pose health risks for swimmers such as gastroenteritis, intestinal inflammation, due to bacterial, viruses, or parasitic infections[4]. The existence of Salmonella sp. in swimming pool water can cause paratyphoid fever[5] because it is a pathogenic bacterium[6].

The CDC (Centers for Disease Control and Prevention) reports that diseases caused by Salmonella are categorized as outbreaks of waterborne diseases and among them cause death by 7% of 6,939[7]. Most people infected with Salmonella experience diarrhea, fever, and stomach cramps between 12 and 72 hours after infection. Salmonella infections can spread from the intestine to the bloodstream, and spread to other parts of the body. In this case, Salmonella can cause death where children under 5 have the highest risk of infection[8].

Visitor behavior and poor swimming pool sanitation are very supportive factors for Salmonella disease transmission. Most diseases often occur due to unclean visitor behavior. For example, most visitors who deliberately urinate in the pool, spit in the pool, do not use clean swimwear and throw garbage around the pool. The poor sanitation is often associated with disinfection systems that are not considered by the pool manager[9].

In addition, related to chemical parameters such as acidity (pH) of a swimming pool must be maintained so that the quality of swimming pool water quality is guaranteed and prevent pathogenic bacteria such as Salmonella sp. to be able to grow and develop. Salmonella sp. is anaerobic facultative bacteria and usually can live well in temperatures between 7- 48° and pH between 4-8[10].

This research was conducted to obtain an overview of water quality before cleaning and after cleaning in the Andi Mattalatta stadium swimming pool and Hasanuddin University swimming pool according to Salmonella Sp and pH parameters.

Material and Method

This research was conducted in the swimming pool of Andi Mattalatta stadium and the swimming pool of Hasanuddin University. This research was an observational study with a descriptive approach supported by laboratory examinations. The laboratory examination process is related to the process of identifying Salmonella bacteria in pool water using the media "Bismuth Sulfite Agar". The sample in this research is the water contained in the swimming pool of Hasanuddin University and the swimming pool of Andi Mattalatta stadium.

The type of sampling used in this research is grab sampling. The frequency of sampling in each swimming pool as much as 2 (two) times, namely sampling in the morning (after cleaning) and sampling in the afternoon (before cleaning).

Findings and Discussion

The swimming pool water of Andi Mattalatta stadium and Hasanuddin University in table 1 and figure 1 shows a significant difference between the total colony of the Salmonella in pool water after cleaning and before cleaning.

Table 1. Examination results of Swimming pool water

Location	Total colony Salmonella Sp./100 ml		Standard of EPA (440/5-86-001) Salmonella Sp./100 ml
	After cleaning (Colony)	Before cleaning (Colony)	
Andi Mattalatta Stadium	8	30	0/100 ml
Hasanuddin University	14	38	0/100 ml

Swimming pool water of stadium Andi Mattalatta after cleaning has Salmonella Sp. as many as 8 colonies/100 ml of water samples and before cleaning has Salmonella Sp. as many as 30 colonies/100 ml water samples. Swimming pool water of Hasanuddin University after cleaning has Salmonella Sp. as many as 14 colonies/100 ml of water samples and before cleaning has Salmonella Sp. as many as 38 colonies/100 ml water samples.

Figure 1: Salmonella examination results with Bismuth Sulfite Agar

The results of the pH measurement of the swimming pool water of Andi Mattalatta stadium and the swimming pool water of Hasanuddin University in table 2 show the difference in the pH of the swimming pool water after cleaning and before cleaning. Swimming pool water of Andi Mattalatta stadium after cleaning has a pH of 6.0 and before cleaning has a pH of 5.0. Whereas the swimming pool water of Hasanuddin University after cleaning has a pH of 7.0 and before cleaning has a pH of 7.0.

Table 2. Results of Measurement pH of Swimming Pool Water Stadium Andi Mattalatta and Hasanuddin University

Location	pH Measurement		pH standard (Permenkes No. 416/Menkes/Per/IX/1990)
	After Cleaning	Before Cleaning	
Stadion Andi Mattalatta	6.0	5.0	6.5 – 8.5
Universitas Hasanuddin	7.0	7.0	6.5 – 8.5

The total bacterial colony of Salmonella sp. found in the swimming pool water of Andi Mattalatta stadium and Hasanuddin University after cleaning and before cleaning do not meet health requirements as determined by the Environmental Protection Agency (EPA 440/5-86-001) Water Quality Requirements for Recreational Activities and Bathing, i.e. 0/100 ml of the water sample. This is caused by the number of visitors doing swimming activities that directly affect the presence of pathogenic microbes and the growth of Salmonella sp. where after cleaning the amount of Salmonella sp. still lacking in the swimming pool water because there is no visitor activity. However, before cleaning the amount of Salmonella sp. experiencing an increase in swimming pool water because has been filled by many visitors who do activities. In addition, the quality of the water source used does not meet bacteriological requirements, the behavior of some visitors who do not comply with the rules imposed by the pool manager which is required to wear a bathing suit before swimming, poor swimming pool sanitation, and disinfection systems that are not given enough attention the management and does not rule out the possibility of Chlor levels given is not proportional to the quantity of pool water and the number visitors. Based on the results of Salmonella Sp. in water is strongly influenced by several factors including pH. Salmonella sp. is known to grow well with a pH between 4-8[10].

Conclusions

The poor quality of swimming pool water is caused by the water management system and visitor behavior that is not considered by the management. It is expected that the pool managers improve the water disinfection system to prevent pathogenic salmonella bacteria.

The Measurement of Urinary Ammonium as an Indicator for Smoking Effect on Acid Base Balance

Ausama Abbas Faisal[1], Maher Ahmed Abed[1]

[1]Lecturer,University of Anbar, College of medicine, Department of Biochemistry, Iraq

Abstract

Respiratory acidosis occurs when the gas exchange between oxygen and carbon dioxide in the lungs is not sufficient. Chronic obstructive pulmonary disease (COPD) which is a general group of diseases, including smoking,that causes respiratory acidosis. The study included 50 smokers and 20 healthy individuals as a control, all of the smokers are: non diabetic, non obese, normal heart and kidneys and no administration of analgesics. The excretion of ammonium in urine and its measurement is a good parameter to quantify acid excretion of kidneys, the excretion of acid is increased when the acidity of blood is increased due to respiratory problems which is the compensation mechanism between lungs and kidneys. They study results showed an increase in urinary ammonium concentration (48.18±1.15 μM) for smokers compared with control group. The high levels of urinary ammonium ions for smokers means that gas exchange is affected by smoking which leads to an increase in CO_2 causing an increase in hydrogen ion concentration [H^+] which is respiratory acidosis. In this case the kidneys compensate the lungs by excretion more hydrogen ions in combination with ammonia derived from glutamic acid as ammonium ions to restore normal pH. Therefore we can use the concentration of urinary ammonium as an indicator for respiratory acidosis induced by smoking.

Keywords: *Respiratory acidosis. Urinary ammonium. Smoking.*

Introduction

Respiratory acidosis occurs when the lungs are unable to excrete adequate amounts of carbon dioxide (CO_2). An increase in CO_2 lowers the pH of blood making it acidic (less than 7.35)[1]. The body hasa compensation mechanism that restores normal pH.The lungs inhale oxygen and exhale carbon dioxide, sometimes lungs are unable to remove sufficient amounts of carbon dioxide because decreased respiratory rate due to main conditions like: asthma, pneumonia, sleep apnea and COPD[2]. Smoking may cause chronic obstructive pulmonary diseases which affect the function of lungs to exchange gases, leading to an increase of carbon dioxide level then an increase in hydrogen ion concentration causing blood acidosis[3]. In case of respiratory acidosis the kidneys will compensate the elevation in hydrogen ion concentration via the formation of excess bicarbonate and via the excretion of hydrogen ions with urine, the hydrogen ions can be excreted with urine by two main pathways, the first predominant pathway is the combination of hydrogen ions with ammonia derived from glutamate to excrete ammonium ions (NH_4^+) with urine, the second pathway is the combination of hydrogen ions with sodium hydrogen phosphate to excrete sodium dihydrogen phosphate[4]. Therefore those with respiratory acidosis have an increase in the concentration of urinary ammonium concentration[5]. The normal value of urinary ammonium for adults is 6-47 μM and 22-26 mEq/L for serum (CO_2)[6]. Smoke inhalation to the lungs has a harmful effect because an incomplete burning of organic material produces carbon monoxide which impairs the blood to transport oxygen[7].

Blood Kidney Tubular Cell:

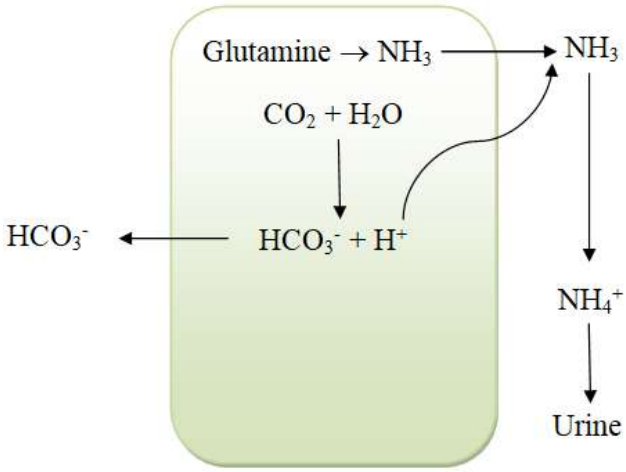

Figure 1: The excretion of hydrogen ions as ammonium by kidneys

Materials and Method

Urinary ammonium concentration was determined for 50 smokers and for 20 healthy individuals by using colorimetric enzymatic method. All the reagents and chemicals were used of a high purity.

Estimation of urinary ammonium: The principle of this test depends upon the reaction of ammonia with α-ketoglutaric acid and NADPH in the presence of L-glutamate dehydrogenase to produce L-glutamate and $NADP^+$. The decrease in absorbance at 340 nm because the the oxidation of NADPH is directly proportional to the concentration of ammonia in the sample. The components of ammonia assay kit are NADPH, α-ketoglutaric acid, ammonia standard solution and buffers. Urine samples should be diluted 1/10 times with distilled water[8,9,10].

Procedure:

1. Pipette in marked cuvette 1 ml of ammonia assay reagent and add 100 µl of urine sample. This is the test cuvette.
2. Pipette in another marked cuvette 1 ml of ammonia assay reagent and add 100 µl of water. This is the reagent blank cuvette.
3. Pipette in another marked cuvette 1 ml of ammonia assay reagent and add 0.05 ml of ammonia standard solution. This is the standard cuvette.
4. Incubate all cuvettes at 35 °C for 5 minutes and read the absorbance for each cuvette at 340 nm.
5. For each cuvette add 10 µl of L-glutamate dehydrogenase solution and incubate again at 35 °C for 5 minutes.
6. Read the absorbance for each cuvette at 340 nm, and repeat the absorbance after 1 and 2 minutes.
7. Calculate the concentration of ammonia from the equation:

Ammonia = $\Delta(\Delta A_{340})$ x TV x MW ammonia x/Ɛ x D x SV x 1000

$(\Delta A_{340}) = A_{Initial} - A_{Final}$.

$\Delta(\Delta A_{340})_{Test} = (\Delta A_{Test}) - (\Delta A_{Blank})$.

$\Delta(\Delta A_{340})_{Standard} = (\Delta A_{Standard}) - (\Delta A_{Blank})$.

TV = Total assay volume in ml.

Ɛ = Millimolar extinction coefficient for NADPH.

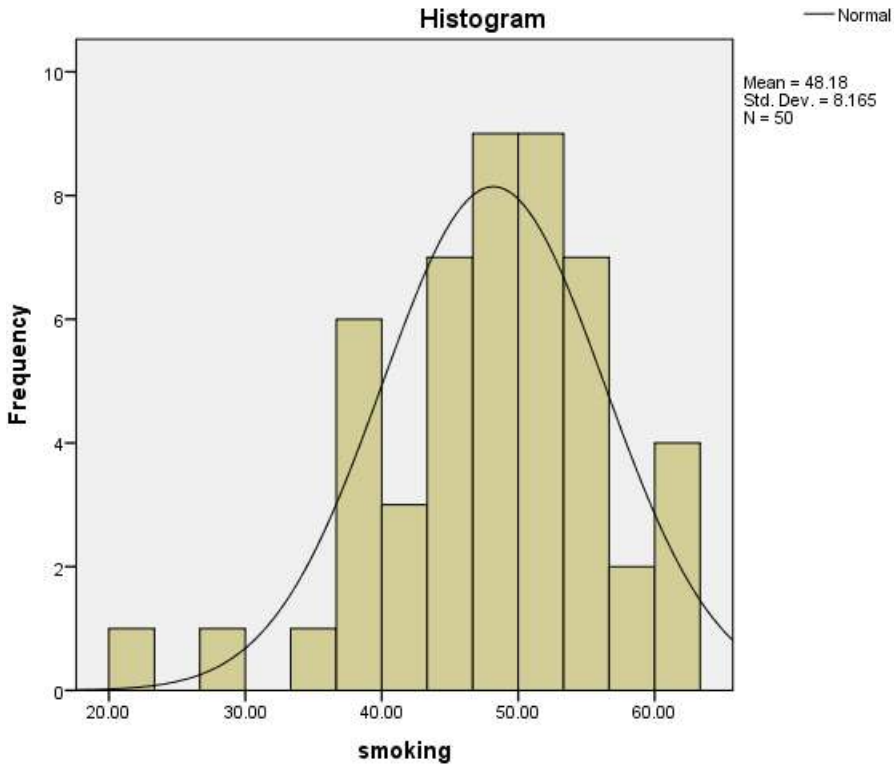
D = light path 1 cm.

SV = Sample volume in ml.

Results and Discussion

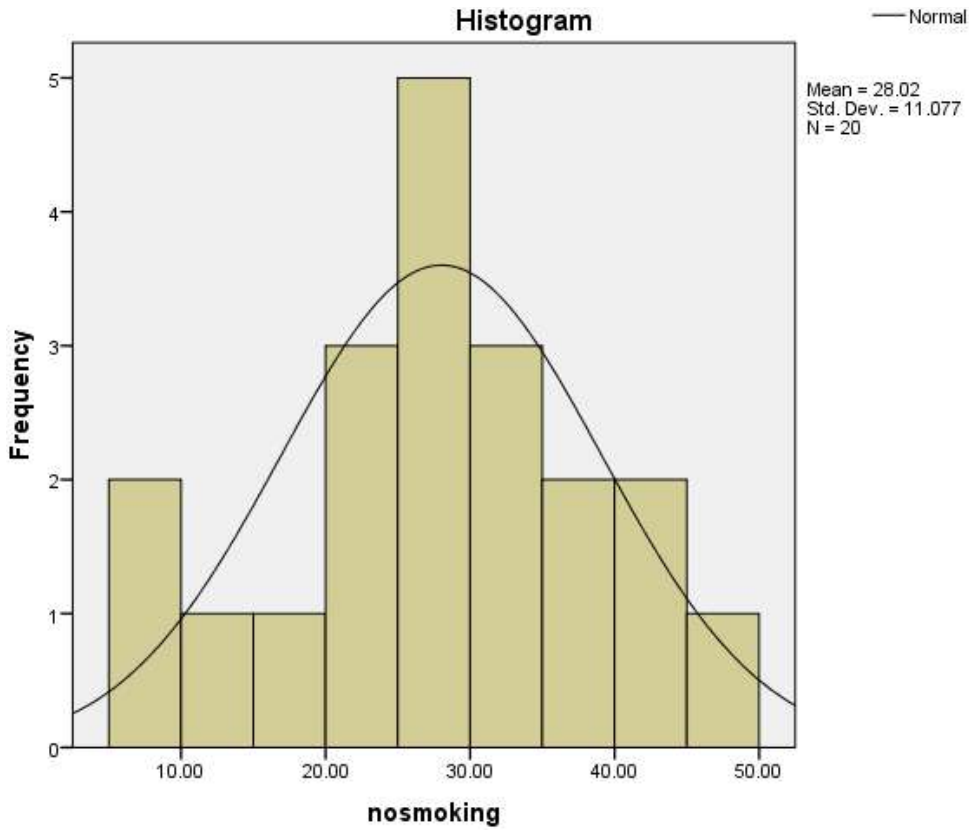
The results of the study showed a significant increase in the concentration of urinary ammonium(48.18±1.15 µM) for smokers compared with control group as shown in histogram 1 and 2. An increase in the concentration of urinary ammonium concentration is an indicator for respiratory acidosis occurrence because smoking may cause chronic obstructive pulmonary diseases which affect the function of lungs to exchange gases, leading to an increase of carbon dioxide level then an increase in hydrogen ion concentration causing blood acidosis.

Concentration of urinary ammonium µM



Histogram 1: Levels of ammonium concentration for smokers.

Concentration of urinary ammonium µM



Histogram 2: Levels of ammonium concentration for non-smokers.

In case of respiratory acidosis the kidneys will compensate the elevation in hydrogen ion concentration via the formation of excess bicarbonate and via the excretion of hydrogen ions with urine, the hydrogen ions can be excreted with urine by two main pathways, the first predominant pathway is the combination of hydrogen ions with ammonia derived from glutamate to excrete ammonium ions (NH_4^+) with urine. Smoke inhalation to the lungs has a harmful effect because an incomplete burning of organic material produces carbon monoxide which impairs the blood to transport oxygen. Therefore the urinary ammonium concentration is considered an indicator to determine the effect extent of smoking on acid base balance. The mechanism of compensation between kidneys and lungs is highly efficient but can be overwhelmed swiftly; therefore any increase in the concentration of hydrogen ions will convert the medium to acidic. From the results showed in histogram 1 and 2, any smoker has an elevation of urinary ammonium must get rid of smoking or to decrease the smoking ratio because, despite pH still within normal range, the concentration and carbonate and the pressure of CO_2 are abnormal, any further increase in the hydrogen ions concentration causes blood acidosis which has a potential effects on health except the other effects of smoking.

Conclusions: the results of the study showed a significant increase in the concentration of urinary ammonium for smokers compared with non smokers;this increase indicates that the smoking affects the balance of acid-base toward acid causing respiratory acidosis. The kidneys compensate this change in pH by excretion of hydrogen ions in many ways. One predominant way is the excretion of hydrogen ions as ammonium;therefore urinary ammonium concentration could be used as an indicator for smoking effect on acid base balance.

Conflict of Interest: Nil.

Ozone Exposure Intake in the Ambient and the Impairment of Pulmonary Function to among Street Sweeper Workers in Jagakarsa District, South Jakarta, Indonesia

Anggun Emelia[1], Haryoto Kusnoputranto[2], Bambang Wispriyono[2]

[1]Student of Graduate Program in Environmental Health, [2]Department of Environmental Health, Faculty of Public Health, Universitas Indonesia

Abstract

This study aimed to analyze the association between ozone (O_3) exposure and the impairment pulmonary function of the highway sweeper workers

This research applied a cross-sectional study design. The respondents of this study were 78 respondents and total samples of pulmonary function measurement were 30 people who have been working for more than 5 years which derived from 6 Villages in Jagakarsa. The measurement of O_3 using an ultraviolet ray absorption method. The respondent data collection and impairment pulmonary functions were conducted through questionnaire distribution, body height and weight, also spirometry measurement. The data analysis was conducted with univariate, bivariate and multivariate analysis.

The average of measurement within 3 days of O_3 concentration was 193.96 ug/m^3. The respondents intake average value is 0.000296 mg/kg/day; respondents age of ≤ 43 years old are 42 people (53.8%); mostly wearing mask when working, there are 68 people (87.2%); respondents who have smoking habit are higher which are 51 respondents (65.4%); most of the respondents who are not doing physical activity are 42 people (53.8%). From 30 respondents, 17 respondents (56.7%) have impaired pulmonary function. The bivariate analysis result shows that smoking habits (p=0.011) and physical activities (p=0.049) have a relation to the impaired pulmonary function. According to the multivariable analysis, the smoking habit has the most influence on the impaired pulmonary function with the Odds Ratio OR =7.779 (95%CI= 1.099-55.054).

The study result shows that there is no significant relationship intake of ozone exposure in the ambient and impaired pulmonary function. There are other factors that may reduce pulmonary function which are ages, smoking habits, and physical activity.

Keywords: *Ozone Concentration, Intake, Pulmonary Function, and Street Sweeper Workers.*

Introduction

Air pollution becomes the source that contributes to producing polluted substances in the atmosphere which can raise a destructive effect on humans and the environment[1]. Air pollution specified in *indoor* or *outdoor* pollution by vapor and solid materials which changes the natural characteristic. Air pollution can occur from natural, anthropogenic and biogenic sources[2,3]. O_3 is the secondary air pollutant that is formed by a chemical reaction between *volatile organic compounds* (VOCs), nitrogen dioxide (NO_2), and carbon monoxide (CO) by heating and sun radiation[3,4,5]. The main sources of ozone are vapor from exhaust and power plants, even natural sources such as trees can also contribute. Ozone in the forming process needs sun radiation which raises

Faculty of Public Health, Universitas Indonesia, Depok 16424, Indonesia
e-mail: haryoto_k@yahoo.com and haryotok@ui.ac.id

the heat at noon at 12.00 pm due to UV ray intensity is higher[6].

In the north part of the earth, O_3 concentration raises until 10 µg/m^3 during 20-30 years lately. The annual average of O_3 concentration in the future in the south of Great Britain raises around 6 µg/m^3[3,7]. According to the National Standard of Ambient Air Quality (NAAQS) in the United States, O_3 average concentration in 8 hours is 0.070 ppm[8]. Annual average of O_3 concentration in ambient air in Jagakarsa Sub-district, South Jakarta is more than annual quality standards which are from 2016-2018 continuously 70,42 µg/m^3; 74,69 µg/m^3; 82,65 µg/m^3 respectively[9].

O_3 is pollutants which considered strong oxidizer, so it can cause a negative impact on human[10]. Short-term radiation by O_3 can cause some health problems related to breathing, including pleurisy, pulmonary function reduction, and breathing symptoms such as cough, wheezing, chest pain, chest heat up, and shortness of breath [11]. The long-term effects of ozone are giving inflammation response, lung damage, and changes in structure and tissue of lung in the early of living [12].

It is globally estimated that 4,2 million early death are related to air pollution. The diseases caused by ambient air in the earth are reaching 43% of all death which is caused by chronic obstructive pulmonary (PPOK)[2]. In Indonesia, The result of Riskesdas (2013) shows that the total case of PPOK occurs at the age of ≥ 30 years consist of 508.330 cases[13]. Respiratory disorders related to the reduction of pulmonary function. There are factors that can influence pulmonary function such as age, smoking, indoor air pollution, outdoor air pollution, allergens, diet, and nutrition, wearing a mask, physical activity[14,15]. The research result of Kim (2011), said that ozone radiation to adults in the age of 19-35 years for 6,6 hours significantly can cause FEV_1 reduction[16]. In addition, the research conducted by Oktavianti (2014), said that there is a relation between ambient air ozone content to the respiratory disorders with the OR value of 3,0[17].

According to the data, a street sweeper is in the group with risk for high O_3 concentration exposure. Therefore, it needs to be conducted a study about the influence of ambient air O_3 exposure intake to the impairment pulmonary function of street sweeper in Jagakarsa Sub-district, South Jakarta. This study aims to analyze the relation between O_3 concentration in ambient air and the pulmonary function of a street sweeper in Jagakarsa Sub-district, South Jakarta.

Materials and Method

Participants: This research applied a *cross-sectional* study design. Population on this study all street sweeper workers in Jagakarsa, South Jakarta. The sampling in this research used *total sampling* with a total of 78 people and measuring pulmonary function were 30 people which were taken in 6 Villages in Jagakarsa with the inclusion criteria of a street sweeper with a working period of (> 5 years).

Data Collection: The type of data in this research was primary and secondary data. Primary data consisted of pulmonary function measurement (spirometry), bodyweight measurement (scale), respondent data consist of age, personal protective equipment (PPE) usage, smoking habits, and physical activity (questionnaire). Respondent data measurement was conducted by the researcher and was helped by 2 enumerators. Secondary data in this research was ambient air O_3 concentration data and environment meteorology condition (temperature, air pressure humidity, wind speed, and direction). Ambient air O_3 concentration measurement used Horiba APOA A370 with the method of ultraviolet ray absorption.

Measurement and Statistical analysis: O_3 data concentration were going to be calculated in exposure intake to the respondents with the formula as follows[18,19]:

$$\text{Intake} = \frac{\text{C xIR x EFx ED x CF}}{\text{BW x AT}} = \text{mg/kg} - \text{day}$$

C = concentration (mg/kg-soil; mg/L-water;-ug/m^3-air)

IR = intake rate (mg soil/day; L-water/day; m^3/day)

EF = exposure frequency (days/yr)

ED = exposure duration (yrs)

CF = soil conversion factor (10^{-6} kg/mg)

BW = body weight (kg)

AT = averaging time (days)

Pulmonary function in measure using spirometry with the results seen is on the values FVC and FEV_1. Indication of normal pulmonary function when the value of FEV_1/FVC ≥ 75% and impaired pulmonary function

when $FEV_1/FVC<75$[20]. The data analysis was conducted by using computer software SPSS 22.0 (R) *for windows*. The data analysis result was conducted with univariate, bivariate and multivariate analysis.

Results

The study result shows that O_3 concentration measurement in air quality monitoring station in Jagakarsa Sub-district is obtained the average of measurement result for 3 days of O_3 concentration which is 193.96 ug/m^3. According to the data, then it is calculated O_3 concentration intake of each respondent based on body weight and period of time. The average respondent intake is 0.000296 mg/kg/day with the minimum value of 0.0001mg/kg/day and maximum value of 0.0021 mg/kg/day. (Table 1).

Table 1. Descriptive Statistic for Respondent Intake

Variable	Mean	SD	Minimum-maximum	95%CI
Respondent Intake	0.000296	0.000252	0.0001-0.0021	0.000239-0.000353

Table 2. The Demographic Characteristic of The Street Sweeper Workers

Variable	N(78)	%
Age		
- ≤ 43 years	42	53.8
- > 43 years	36	46.2
PPE usage		
- used masks	68	87.2
- Not used mask	10	12.8
Smoking habits		
- Not smoking	27	34.6
- Smoking	51	65.4
Physical activity		
- Physical activity	36	46.2
- No physical activity	42	53.8
Variable	N(30)	%
Pulmonary function		
- Normal	13	43.3
- Impaired pulmonary function	17	56.7

According to the study result on 78 respondents, it is obtained the result that respondents who are at the age of ≤ 43 years are 42 people (53.8%). The total respondents who used masks when working is 68 people (87.2%). Respondents who have smoking habits are 51 respondents (65.4%). Most respondents with no physical activity are 42 people (53.8%). Next, the result of pulmonary function measurement, from 30 respondents have obtained 17 respondents (56.7%) who have an impaired pulmonary function. (Table 2).

Table 3. The bivariate result shows that impaired pulmonary function is related to the smoking habits (p=0.011) and physical activity (p=0.049) variables. Next, impaired pulmonary function has no relation with age (p=0.247), PPE usage (p=0.672), and ozone concentration intake (p=0.503).

Table 3. Correlation of Variables with Pulmonary Function

Variable	Pulmonary Function				P-Value
	Normal		Impaired Pulmonary Function		
	N	%	N	%	
Age					
- ≤ 43 years	4	28.6	10	71.4	0.247
- > 43 years	9	56.3	7	43.8	
PPE usage					
- Wear mask	11	45.8	13	54.2	0.672
- Not wear mask	2	33.3	4	66.7	

Variable	Pulmonary Function				P-Value
	Normal		Impaired Pulmonary Function		
	N	%	N	%	
Smoking habits					
- Not smoking	10	71.4	4	28.6	0.011
- Smoking	3	18.8	13	81.3	
Physical activity					
- Physical activity	6	75.0	2	25.0	0.049
- No physical activity	7	31.8	15	68.2	
Respondent intake	13	43.3	17	56.7	0.503

Table 4. The final results of multivariable logistic regression are age, smoking habits, and physical activity variables. The analysis result shows that the smoking variable is related to impaired pulmonary function (p = 0.040). The highest variable influence for impaired pulmonary function is a smoking habit with OR = 7.779.

Table 4. Logistic Regression Model of Pulmonary Function

	B	S.E.	Wald	Df	Sig.	Exp(B)	95%CI
Age	-1.683	1.251	1.809	1	0.179	0.186	0.16-2.159
Smoking habits	2.051	0.998	4.222	1	0.040	7.779	1.099-55.054
Physical activity	2.771	1.430	3.755	1	0.053	15.978	0.969-263.472

Discussion

Air ambient O_3 concentration measurement result for 3 days is 193.96 ug/m^3. This result is still below the quality standard set in Indonesia especially in DKI Jakarta which is 200 ug/m^3 [21]. The measurement result of the average O_3 concentration daily exposure intake is 0.000296 mg/kg BW/day. The previous research said O_3 concentration between 20-80 ppb with the intake average is > 10^{-6} L/minute[22]. According to the research result, ambient air O_3 concentration on respondent exposure intake has no relation to the impaired pulmonary function. According to the research conducted in Belgium, there was no significant relation between O_3 concentration and pulmonary function. This matter can be influenced by other factors such as age and respondent smoking status[23]. In this research, ozone exposure intake is not related to the impaired pulmonary functions, the however impaired pulmonary function can be caused by the other observed variable such as age, PPE usage, smoking activity, and physical activity.

In addition to the research result, it is obtained that age has no relation with the impaired pulmonary function on the respondents (p=0.247). This matter is aligned with the previous study that there is no relation between age and impaired pulmonary function case (p=0.180)[24]. In this study, respondent distribution is referring to the age of ≤43 years. Fargoso (2016) stated that older age-related to pulmonary function reduction[25]. Breathing muscle strength reduces along with the increasing of age which is related to the reducing ability of lung tissue in grasping the air when breathing[26].

The use of PPE is not related to impaired pulmonary function (p=0.672). In this study, most of the respondents wear a disposable mask made of clothes and can be washed after usage. This study is aligned to the previous research which stated that there is no significant relation between PPE usage and impaired pulmonary function of a mask which is mostly worn by the respondents, it is a mask made of white clothes of shirts[27]. Cloth mask might able for particle penetration for almost 97% compared to the medical mask[28].

Smoking habits are related to impaired pulmonary function (p=0.011). This research result is obtained the respondent average period of smoking which is 16 years with the total of cigarette consumption in the average of 10 cigarettes a day. The previous research stated that there is a significant relation to the smoking with FEV1 rate with a total of 10 cigarettes a day for 10

years [29]. Another research explained that the FEV1 rate is significantly related to smoking activity. However, smoking habits are significantly not related to FEV1 on the smoker who rarely smokes once or stop smoking for one year[30].

Physical activity is related to impaired pulmonary function (p=0.049). Physical activity (sport) is mostly done by the respondents in this research are futsal and jogging. Physical activities which are done by using large muscle group (such as walking, power walk, jogging, cycling, swimming, ball sports, and etc) for some minutes can give a person to grasp enough oxygen[31]. Another research found that physical disturbed the FVC and FEV1. Physical activity can increase breathing muscle performance so it can increase FVC and FEV1[32].

Conclusion

The study result shows that there is no significant relationship between ambient air O_3 exposure intake to the impaired pulmonary function. There are some other factors that can reduce the pulmonary function which are age, smoking habits, and physical activity.

Conflict of Interest: Considered no conflict of interest.

Ethical Clearance: This research has been approved by the Ethics Committee of the Faculty of Public Health, Universitas Indonesia.

The Development of T-CBT Model to Improve the Competence of Midwives in Prevention Depression of Sexual Violence Victims

Triana Indrayani[1], Sukri Palutturi[2], Ridwan Amiruddin[3], Agus Bintara Birawida[4], Retno Widowati[5], Rukmaini[5], Owildan Wisudawan B.[7]

[1]Student Doctoral of Public Health, Hasanuddin University, Makassar, Indonesia, Faculty of Health Science, National University, Jakarta, [2]Department of Health Policy and Administration, Faculty of Public Health Hasanuddin University, Makassar, [3]Department of Epidemiology, [4]Department of Environmental Health, Faculty of Public Health Hasanuddin University, Makassar, [5]Faculty of Health Science, National University, Jakarta, [6]Faculty of Public Health Hasanuddin University, Makassar, Indonesia

Abstract

Background: Around 15 million adolescent girls aged 15-19 years old experience sexual violence. Based on data from 28 countries, 90 percent of girls in that country admitted the perpetrators of violence acts were people they knew. This literature review aimed to identify and explain empirical facts of research on sexual violence in children. It also detected the acts early and formulated the prevention of persistent depression. This study explained the influence of applying the T-CBT model on the increasing midwife competence in the service of depressed children due to sexual violence.

Material and Method: The literature sources were from online journal databases published by PubMed, Proquest, Google Scholar, and other sources like Indonesian Child Protection Commission Report, P2TP2A, Indonesian Midwives Association, and relevant theses and dissertations. The data were all documents published in the last 10 years from 2008-2019 collected manually and systematically.

Findings and Discussion: The T-CBT model was proven effective in preventing trauma and severe anxiety in victims of the child due to sexual violence. Empirical facts showed the impact of emotional reactivity and depressive symptoms such as ideas and attempted suicide, as well as emotional distress. The results of other studies also indicated a moderate relationship between psychopathology and objective characteristics of abuse, such as the number and types of violent incidents and the duration of abuse. The obstacles most often experienced by teenagers were having parents with a history of mental illness, intimidation, divorce, or separation from parents, physical, emotional, or sexual abuse, as well as child neglect and traumatic incidents.

Conclusion: The CBT model is a service strategy that strengthens behavioral skills-based interventions, information-based needs, family and parent involvement, and midwife services with a patient-therapist approach, and respects the needs of traumatized adolescents.

Introduction

The cases of violence against women and adolescents are increasing and becoming a serious concern for the government to implement comprehensive, inclusive, and integrative protection. In the 2015-2019 RPJMN, the government has implemented an effort to protect women

and children from violence. The program has been carried out through prevention, service, and empowerment. The adolescents who are victims of sexual crimes generally experience rape, incest or other forms of sexual exploitation, which rarely get legal protection, physical or mental treatment and recovery (deserving legal protection and remedies)[1]. Almost 100% of perpetrators use the mode of giving something to victims, seducing, sexually exploiting through peer calls and electronic transactions. Besides, some perpetrators use the mode by helping victims to do their schoolwork, or telling the fake story with mystical messages. Therefore, it needs an effort to stop more victims of sexual violence by creating a primary prevention model that includes increasing elementary school student's knowledge, actions, and attitudes[2].

15 million adolescent girls aged between 15 and 19 years old worldwide experience sexual violence. According to the data from 28 countries, 90% of girls admited the perpetrators of the first incidents of sexual violence were people they knew. The data from six countries reveal that classmates and spouses are the people most often referred to as perpetrators of sexual violence against adolescent boys[3]. Globally, every 7 minutes a young woman dies due to violence in the United States (Latvia 33%, Lithuania 42%, Macedonia 18%, Moldova 43%)[4]. There are three types of sexual violence in the community, such as sexual abuse (911 cases), non-sexual abuse (708 cases), and rape (669 cases). Moreover, Eastern European countries recorded 247 cases of sexual violence[5].

The United States is one of the countries with a high number of the sexual victim (SV). SV is defined by the Centers for Disease Control and Prevention as sexual acts committed against someone without consent - including forced sex (rape), attempts at forced sexual penetration, unwanted sexual contact, and contactless sexual experiences such as sexual harassment[6]. In Germany, the prevalence rate for sexual abuse is around 25 percent for girls and between 5 and 10 percent for boy[7].

Promotive, preventive, curative, and rehabilitative actions to prevent sexual violence against children can be applied in an integrated manner; in the context of public health. Secondary prevention includes high-risk situations, for example, to stop continuing violence. Reactions to sexual crimes committed are tertiary domains, which the prevention aims to reduce the consequences of abuse and minimize secondary consequences. In addition, therapies and actions to prevent recurrence of trauma to strengthen the psychological and physical health of those affected are needed[8].

Considering a large number of acts of sexual violence against adolescents in DKI Jakarta, it requires an integrated handling strategy. One of the preventive actions for victims of sexual violence against children is to prevent further physical and mental disorders and to deal with psychiatric problems for victims in a primary, secondary, and tertiary manner or a combination of the three categories. The implementation of preventive measures can be through training of parents, teachers, communities, and health workers. Therefore, this literature review aimed to identify and explain empirical facts of research on sexual violence in adolescent girls, early detection, and prevention of severe depression. This study also explained the effect of applying the T-CBT model on the increasing midwife competence in giving the service of depressed adolescents as the victims of sexual violence.

Material and Method

Literature Resources: The sources of literature in the study were from an online journal database such as Pubmed, Proquest, Google Scholar, American Journal of Public Health, European Journal of Women's Studies, BioMed Central, Sage Journal, European Journal of Psych traumatology, and other E-book sources, report of the Indonesian Child Protection Commission, P2TP2A, Indonesian Midwives Association and relevant theses and dissertations. The literature studies were taken from the data of the last 10 years from 2008 to 2019.

Article Management Procedure: The researcher chose articles in several stages, starting from gathering information based on several sources related to the research topic, then incorporating it into Endnote software, summarizing the information in the matrix and integrating the some information, and analyzing as well as synthesizing the data from the articles obtained.

Findings and Discussion

Searching Results: The articles were looked for using relevant keywords (Figure 1) and it successfully identified 750 articles. After sketching the title, abstract, and the research method, it found 80 articles reviewed independently based on inclusion and exclusion criteria; it resulted in 12 synthesized articles.

Data Analysis: The data analysis resulted in 12 articles. The grouping research applied quantitative, qualitative, and review method. The relevant respondents were nurses, doctors, psychologists, and counselors who served outpatient and inpatient practices in hospitals as well as several health care providers. The themes were grouped and collected by longitudinal observation, intervention in the experimental group, clinical practice trials, in-depth interviews, and medical record reports.

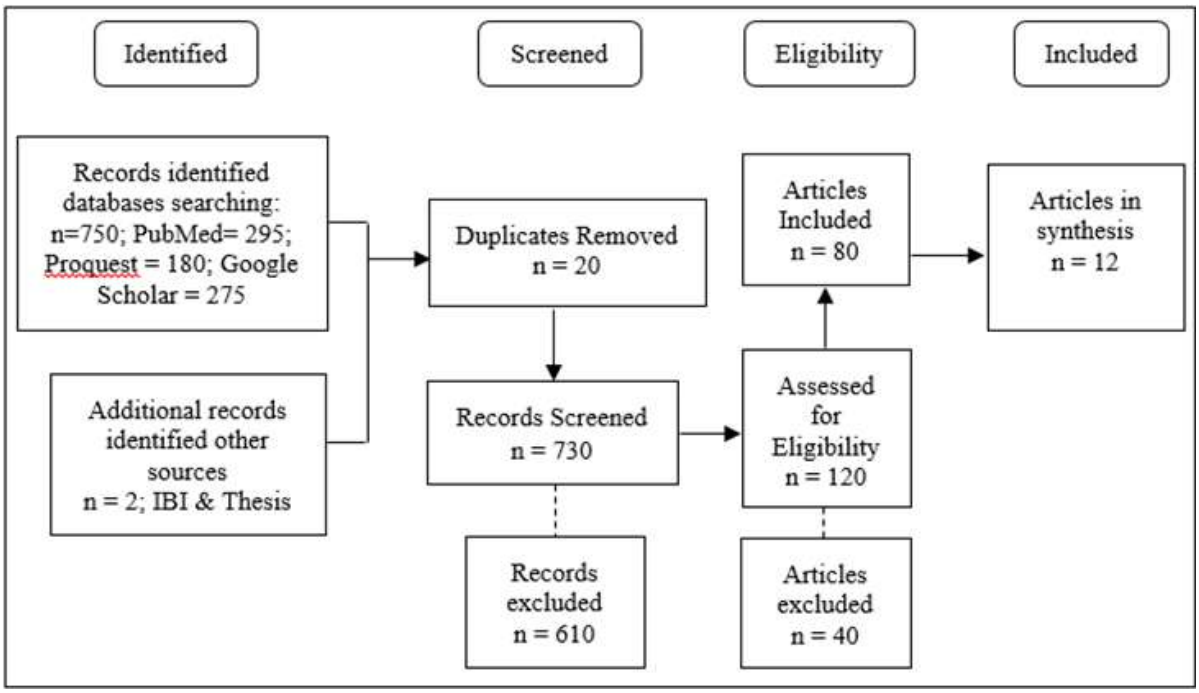

Figure 1: Search flow of article synthesis

The researcher assessed the results of the analysis through the problems arising because of sexual violence in adolescents and the effects of trauma and depression. These impacts generally affected adolescents themselves and their families. Moreover, the researcher also formulated appropriate treatment and prevention to overcome problems, determined dropouts treatment and prevent severe complications. We also evaluated the feasibility of training programs and interventions used to assess their responses and effects of trauma such as TIC, TF-CBT, and TCP-PTSD.

The experience of sexual abuse of adolescent girls, according to McLean has four theoretical conformities in recognizing problems and overcoming their impacts such as the adaptation and integration of CFT into psychotherapy approaches, caring effectiveness, new relationships, and positive affiliations with themselves and others. Hence, there are alternative and positive approaches to regulating emotions, reducing criticism and avoidance in responding to trauma symptoms[9]. Changes in the positive and emotional control are in line with the study of Deblinger. He found the effects of shame as victims of sexual violence treated on the TF-CBT psychotherapy compared to CCT 6, which was conducted for 12 months. Some trauma and depression rates were higher during pre-treatment and positively associated with the treatment of PTSD symptoms[10]. Based on the study of Steil, outpatient treatment of TCD - PTSD could be applied safely to reduce PTSD symptoms as well as comorbid psychopathology in adolescent patients who experience sexual violence[11].

The studies on the theme of intervention programs and training in adolescent trauma management have been widely conducted (Rapee; Agustin; Palfrey and Niimura). The results of the study revealed that the 1-day program consisting of 3.5-hour lectures and 1-hour group discussions influenced the feasibility of the Professional intervention program in the mental health field. The development of a good attitude towards TIC was the main result, as assessed by the Attitude Related Trauma-

Informed Care scale. The workshop was considered relevant and useful to help the doctor's practice that would increase participants' trust, awareness, and attitude[12,13]. At the end of treatment, there was no significant difference between the groups that needed more attention because they were being threatened by the disease or the group that was responding to treatment. Both groups showed a decrease in diagnostic severity, symptoms of social anxiety, depressive symptoms, and disruption of daily life after treatment[14]. Most cases increased at 6 months of advanced treatment. The forms of child abuse consist of physical, verbal, and relational abuse. Experts considered Cognitive-behavioral counseling activities with strict training techniques to deal with abuse and there was a significant impact of cognitive-behavioral counseling activities in minimizing the number of cases of child abuse[15].

Reay in his study reported the role and support of families, especially mothers, who were more active in reporting their family difficulties than fathers. The most common difficulties experienced by adolescents were having parents with mental illness (66%), intimidated (63%) and divorced parents (43%). 69% of total CAMHS clients had traumatic potential (physical, emotional or sexual abuse, child neglect or traumatic events). Furthermore, children/adolescents with a history of trauma tend to have parents with a history of trauma[16].

Harper presented that the difficulty of managing the feelings after getting inpatient treatment created new problems when they could not discuss their problems honestly with their community-based therapists. The participants emphasized the need to get trauma-based care obtained from doctors[17]. Based on the survey results on preliminary data presented by Hanson and Lang it required cross-system professional staff and their role to get feedback on problem definitions and conceptual issues related to TIC. Specifically, they can provide empirical representations, explain the significant gaps between research and TIC practice, and then compare them with important implications for obtaining better services in the future[18].

Bounds stated that the program was assessed in 3 & 6 months. The study yielded significantly lower mean values for emotional distress (−0.67, −0.91) self-injury (−0.30, −0.55), suicidal ideation (45.45, −0.57), attempted suicide (-0.58, − 0.61), and trauma symptoms (−11.8, −16.2, all $p < 0.001$) for 12 months. In the growth curve model, the nurse visit independently decreased with details of emotional distress (38.038), self-injury (−2.020), suicidal ideation (25.025), and effort (32.032). The empowerment group was predicted to experience symptoms of trauma (−0.525) and subsequently was the rest, except for suicide attempts[19]. DeCou and Lynch, succeeded in uncovering the indirect effect of univariate groups of trauma on suicidal ideation through emotional reactivity in adolescents who survived sexual harassment when they were child ($\beta = 0.10$, ACI 95 %: 0.04-0.17), as well as the group's direct effects from depressive symptoms ($\beta = 0.88$, $p < 0.001$). Two other domains of resilience, namely a sense of mastery and a sense of connection did not mediate the relationship between trauma-related stress and the idea of suicide[20]. These findings indicated the importance of emotional reactivity associated with the idea of suicide, as well as the relationship between depressive symptoms and suicide ideas in the clinical population. Moreover, this study also suggested the potential use of skills-based interventions and the need for information and trauma-based policies.

Conclusions

Suitable for midwife competency enhancement were TF-CBT and CCT-centered therapy and modified with training as conducted by Niimura, J., et al and Palfrey, N. et al, namely trauma informed care. thoroughly if reviewed from the time of its evaluation research conducted by Bounds, D.T, et al Canada Child Abuse & Neglect is better because the twelfth month is evaluated even though the possibility of dropout is greater.

Conflict of Interest: There is no conflict of interest to be declared.

Literature Trend Analysis for Hospital Acquired Infection

Yasaman Parsia[1], Shahryar Sorooshian[2]

[1]Researcher, ERAS, Universiti Malaysia Pahang, Pahang, Malaysia,
[2]Senior Lecturer, Department of Business Management, University of Gothenburg, Gothenburg, Sweden

Abstract

Hospital acquired infection is the cause of many issues for health facilities, society and patients. In this study the trend of studies in this field have been analysed systematically. For that the main source of data was Scopus database. Additionally, the gap of literature identified for future studies. This article will enhance the general knowledge on the area for hospital managers, researchers, as well as policy makers.

Keywords: *Hospital acquired infection, Nosocomial infection, Literature trend, Literature gap.*

Introduction

The prevention and the control of the Hospital Acquired Infection (also known as Nosocomial infections or NIs) is the primary responsibility of the community and the health facilities (HFs)[(1-5)]. It is stated[(6)], that the infection control strategies would vary based on their type, need and resources provided by the HFs. Khan, Baig[(7)] stated that despite all the efforts made for preventing the NIs, more work needs to be carried out to control the infections. Though some improvement was observed, more work must be carried out. The monitoring of the NIs is an important step for controlling the infections and is also considered as a basic step for preventing the department-specific infections [(1)].

Material and Method

The current study can be classified as a literature analysis. The data for there search is from Scopus database. Analysis is using Scopus analysing tool and VOS viewer software. Additionally, a qualitative review of a few current study was performed to propose literature gaps.

Finding and Discussion

In this study, the researcher acknowledged 61,559 relevant articles by systemically searching on the Scopus Database with the key words “Nosocomial infection” or “Hospital acquired infection”. Articles from the period 1915–2020 were analysed. Figure 1displays specific distribution of article publication over the targeted years particularly belongs in research area of NIs. As it is shown, most of researches in field of NIs published in 2014, three thousand one hundred articles, and after that the number is decreased to 2895 articles at the end of 2018 based on the information achieved from Scopus database on September 2019.

Also, the articles analysed based on the publisher country from 1915 to 2020. Referring to the result as shown in Figure 2; United States has the greatest number of published articles, 16648 articles, though many other contuse have contributed to the field. Figure 2 is showing the top ten contributors.

Result shows that how many percentages of articles are published in each subject area, Medicine has highest percentage, with 67.2% of total subject area. Immunology with 9.9% is in the second level and the third level belongs to Biochemistry with 5.8%.

Furthermore, the research articles were analysed based on Title, Keywords and Abstract by use of VOS viewer which is a software tool for constructing and visualizing bibliometric networks. In systematic literature review, this software recognized different keywords on

the research area. Keywords of "Nosocomial infection" or "Hospital acquired infection", in Scopus search engine, shows the connections among the keywords and clustered them. The studies that were found were downloaded into Microsoft Excel in a CSV (comma separated value) format to be analysed. Table 1 is from the result of the VOS viewer analysing.

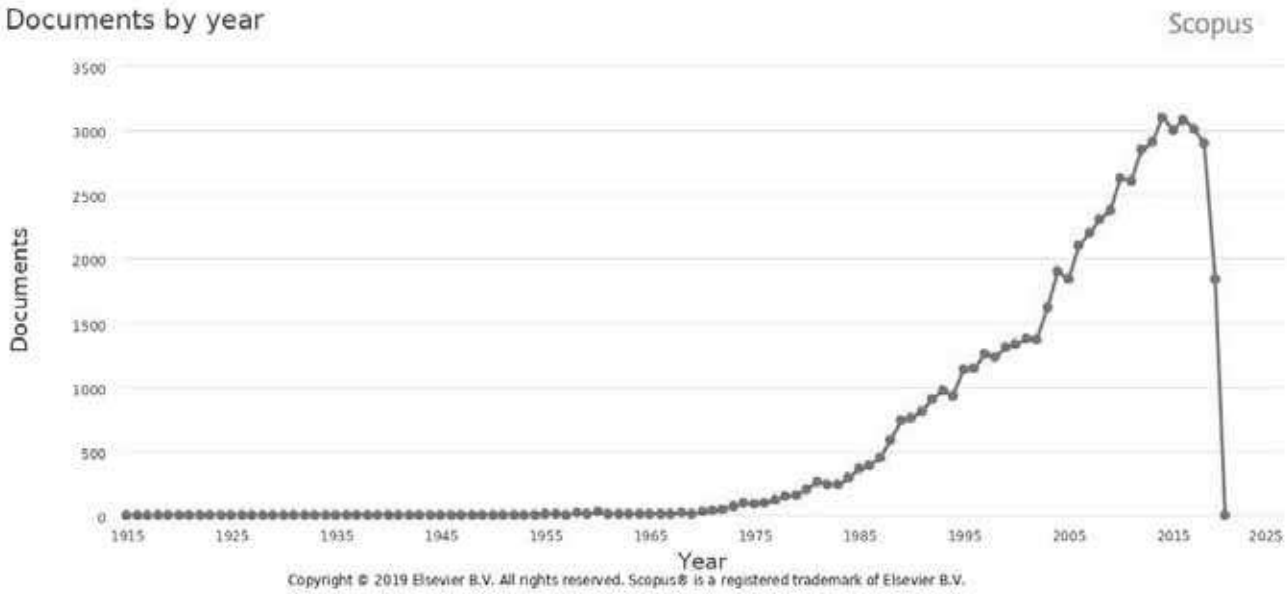

Figure 1: Range of published articles in field of NIs from 1915.

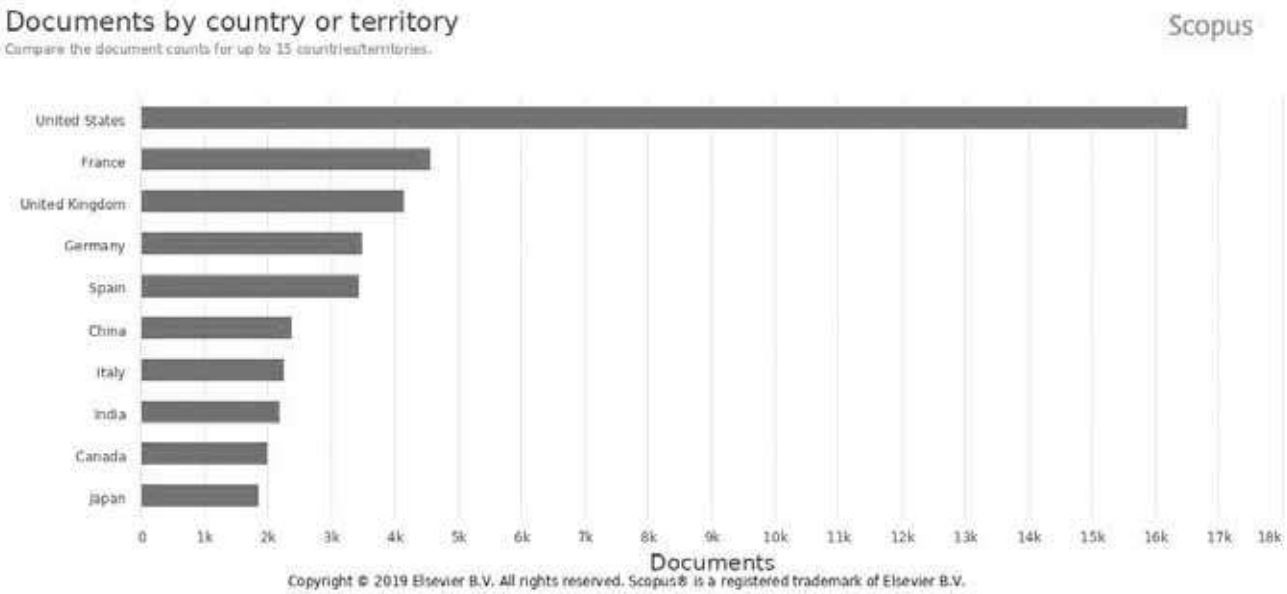

Figure 2: Country contribution to the NI research

The result is an evidence to prove multidisciplinary nature of NI studies. From the result, the keywords in each cluster in Table 1, have high connections. As it is shows in the Table 1, most of the keywords are from to medicine field.

Table 1: The clusters of keywords with Highest Occurrence

No.	Cluster 1	Cluster 2	Cluster3	Cluster 4
1	Adult	Draft genome sequence	Acinetobacterbaumannii	Carbapenem resistant Acintobacterbaumannii
2	Case report	Emergence	Antimicrobial susceptibility	Meta analysis
3	Clostridium	Escherichia coli	Biofilm formation	Nosocomial infection
4	Clostridium difficile infection	HIV	Clinical isolate	Systematic review
5	Control	Investigation	Detection	
6	Diagnosis	Klebsiellapneumoniae	Development	
7	Effect	Molecular characterization	Distribution	
8	Evidence	Molecular epidemiology	Gene	
9	Implementation	Neonotalintencive care unit	Identification	
10	Incidence	Nosocomial outbreak	Resistance	
11	Management	Outbreak	Virulence factor	
12	Occurrence	Staphylococcus aureus

14	Prevention			
15	Sepsis			
16	Surgical site infection			
17	Tertiary care hospital			
18	Ventilator			

In continue, some recent –published researches in fields of NIs are discussed: Some medical researchers have tried to introduce new disinfectants and inhibitors in the area of NIs.Meanwhile, the other groups of researchers have worked on antibiotics in the area of NIs, Next group of researcher try to decline the rate of NIs through some administrative medical protocol, such as, prevention of occur and repeat infections by practicing good hygiene, especially cleaning of hands[8], maintaining aseptic practices after inserting the urinary catheters and similar other urological procedures[9].

Although above studies concentrated in a special group of pathogen microorganisms, there are many types of NIs with the different responsible group of NIs microorganisms. Therefore, the limitation of the reviewed researches just minimizes the risk of one type of NIs, meanwhile, the procedures of this study tried to decrease the total rate of NIs, for all types of them in each HF around the world.

Next to be studied, a group of the researchers in the area of management have worked on cost effective protocol to decrease the financial load because of NIs. In addition, the other group of researchers have worked on the satisfactory of staff used an important indicator of organisational effectiveness in the healthcare.

Based on findings of a research in 2017, using risk management processes including elements of active surveillance and efficient monitoring can help to minimize the risk of NIs [10].In addition, researchers have introduced analytical network process as a tool to identify main reasons of NI and, therefore, the performance of doctors can be systematically calculated, which will greatly benefit the hospital management [11].

Referring to the above discussed studies there are a few whichtried to research on NIs by considering a factor of management, such as, cost, satisfaction, hygiene, quality of service, risk management and etcetera. The research gab in these researches in field of NIs through managerial viewpoint is they did not attention to the multi-criteria chief managerial criteria in their study. However, the present study has considered all the managerial criteria based on the viewpoints of managers

in each HFs and presented a general procedure in this area to minimize NIs risks.

Last but not least, Gazzarata, Monteverde, Bonetto and Savini[12]have designed a surveillance system to monitor the prevalence of multi drug resistant organisms in both infected and colonized patients, to verify appropriateness of antibiotic prescription in hospitalized patients and to interact with other national and sovra-national networks. Service Oriented Architecture approach, different healthcare service specification project standards, local, national and international terminology and clinical document architecture release two were adopted to design the overall architecture of this regional surveillance system. Then, Janowicz [13] evaluate the relations between architectural actions and epidemiological safety in field of NIs, as well as presenting the need for an on-going assessment of architectural solutions by interdisciplinary teams of specialists.

However, some studies have presented guidelines to improve environmental factors and the HF architectural design and layout of HF, by set hand hygiene system in different parts of HF, in order to decline rate of NIs. But, the other group of researchers suggested to use an appropriate architecture hardware and software which helps in monitoring the hand hygiene for decreasing the spread of the NIs [14].Although, the mentioned studies in field of architecture tried to solve the problem of NIs. But they didn't pay attention to department configuration and identify the risky department to remove from HF or selected low risky departments for adding. Most of them focus on interior design factors of HF, such as, air disinfection system and etcetera. Although, the present study tried to attention this missed factor, department configuration, during upgrading and rearchitecting of HF to minimize NIs risks.

Recently, many studies were published which stated that the HF environment (like the design and the layout) played an important role in the pathogen transmission within the HFs and any suitable change in the HF design could decrease the infection risk[15,16]. Some recent studies have explored the impact of the HF environmenton the type of services provided and the quality of life[17]. Despite the fact that many researchers established the link between the architecture of the HF and human health, people are still reluctant to alter the structures of those HFs which affect human health, like cause NIs[18]. Studies on the evidence-based designs have shown that the HF's physical environment along with its layout can affect human health, decrease the treatment duration, reduce the dosage of the medicines and also relieve the stress which is experienced by the patients, their family and the nursing staff[17]. However, Shikder and Price[19] described, the different factors which must be considered while designing an effective healthcare system. A supportive HF environment with a good-quality layout and circulation creates an inviting, engaging, hygienic, calm and productive environment for the patients, their families and the staff[19].

Hussain and Babalghith [20] noted, HFs were places where people sought medical treatment, while the HF staff provided a constant support. Hence, creating a calm environment in the HFs, with proper physical aspects was very important [20]. However, Elf, Fröst [17] stated, a good implementation of the novel techniques and HF models helped in improving the patient health as the patient-related services were associated with the HF environment (or HF architecture). Decisions regarding the healthcare design and architecture are seen to be very important as these designs affect the people and the work processes for a long time and need a financial commitment from the whole community [17]. Many studies recognised the fact that a well-planned HF architecture was beneficial in improving the patient health for many years [18]. In addition, studies [2]stated that a poor HF building could lead to many problems and risks for patients, such as, NI risks and dissatisfied patients. Additionally, a poor HF architecture could prove to be very costly and lead to a lack of confidence in the HF's healthcare system [17]. Also, Dettenkofer, Seegers [21] mentioned, the infection controlling measures are also supported by a good HF architecture (for example, they provide enough space for treating and taking proper care of the patients). However, there are many variations in the HF layout designs around the world, and control of infections by applying specific engineering designs, is still a topic of debate [21]. The scientific research is focused on determining the manner in which an improved design can reduce the risks in the HFs [18]. Hence, the HF design is considered to be an important factor affecting the modern healthcare system and the HFs must be constructed after integrating proper architectural designs, which would further help the patients [17]. Although, Nowadays, a lot of attention is given to the environment in the HFs and its relationship with patient health, which has led to the development of effective designs [17], not enough studies are available to discuss department configuration in HFs.

Conclusion

This study tried to enhance understanding on the importance of the hospital acquired infection for the readers. Existing literature of the field have been analysed with the aim of Scopus database. Lack of knowledge and gaps for future studies have been alarm. Although limitation of the gap analysis was in the small size of reviewed literature, though future researchers may enhance this study with more comprehensive systematic literature review. Scholars and policymakers may use the findings of this study to design their research.

Effect of Smoking on Disease Activity and Functional Impairment in a Sample of Iraqi Patients with Ankylosing Spondylitis

Najlaa Ali Hashim[1], Nizar Abdulateef Jassim[2]

[1]Babylon Health Directorate, Marjan Medical City, [2]Baghdad University, College of Medicine, Rheumatology Unit, Iraq

Abstract

Background: The etiology of AS is unknown, but a combination of genetic and non- genetic risk factors works in concert to produce clinical disease. Smoking has a negative impact on disease activity and functional ability in AS with more severe radiographic damage. The aim of this study is to assess the effect of smoking on AS disease indices (activity, and functional impairment).

Patients and Method: A cross sectional study was conducted on 150 AS patients. Information concerning smoking, demographic characteristics & clinical criteria data were gathered consisted of age, gender, BMI, duration of disease,Ankylosing Spondylitis Disease Activity Score (ASDAS-ESR), Bath ankylosing spondylitis disease activity index (BASDAI),Bath Ankylosing Spondylitis Functional Index (BASFI). All cases were investigated for HLA-B27 and ESR.

Results: A total of 150 patients with AS were involved in this research. The non-smokers constituted 52% of cases. Ex-smokers formed 14.7% of patients. Low grade smokers (<15 pack-year) formed 18% of patients and high grade smoker (15+ pack-year) formed 15.3% of patients. There is a positive relation and statistically significant moderately strong to strong positive linear correlation between AS disease activity, functional impairment. The mean ASDAS, BASDAI and BASFI was the lowest in non-smokers and elevate with increment in the number of cigarette smoking.

Conclusion: AS smoker cases had elevated disease activity & functional impairment.

Keyword: *Smoking in Ankylosing Spondylitis, Smoking & AS Disease Activity, physical function in Iraqi Patients.*

Introduction

Ankylosing Spondylitis (AS) is a chronic, systemic, inflammatory, rheumatic disorder.[1] AS prevalence varies with human leukocyte antigen (HLA)-B27 gene in a given population, 1-2% of all people who are HLA-B27 positive develop AS.[2] It occurs in 0.1-1% of the general population varying according to both geography and ethnical group.[3] HLA-B27 prevalence among AS patients in the Arab world is generally lower than the worldwide.[4] Eighty four percent of Iraqi patients with AS are HLA-B27 positive.[5] It commonly starts in the second or third decade of life, with a male to female ratio (3:1).[6,7] Incident AS was associated with current smoking, especially in those at a higher AS risk.[8] AS etiology is unknown, but a combination of genetic and non- genetic risk factors works to produce clinical disease.[9] AS is known to be highly heritable, as >90% of the risk of developing the disease has been shown to be genetically determined strongly associated with HLA-B27.[10,11] Smoking has a negative impact on disease activity and

Corresponding Author:
Najlaa Ali Hashim
Babylon Health Directorate, Marjan Medical City, Rheumatology Unit, Iraq
e-mail: najlaaali53@yahoo.com

functional ability in AS with more severe radiographic damage.[12, 13] Smoking should be discouraged in those at a higher AS risk, e.g., with a family history or carrying HLA-B27.[8] The aim of this study is to assess the effect of smoking on AS disease indices.

Methodology

A cross-sectional study was conducted at Rheumatology Unit of Baghdad Teaching Hospital from August-2014 to May-2015. A total of 150 Iraqi patients were fulfilling the modified New York criteria for AS (50 current smokers, 21 former smokers, 79 non-smokers) were enrolled in the study. [14] A signed consent from each of the participants was obtained. An ethical approval and official permission were obtained from Baghdad College of Medicine to conduct the study. Data were collected which included the following: sociodemographic data, clinical data, disease duration according to the onset of symptoms, ASDAS, BASDAI, and BASFI. Patients were investigated for HLA-B27 and ESR using the Westergreen method (normal values < 20-30 mm/h according to sex and age).

Evaluation of disease activity:

1. Ankylosing Spondylitis Disease Activity Score (ASDAS-ESR): includes ESR-levels (mm/h) in addition to patient assessment of peripheral joint pain/swelling, total back pain, duration of morning and patient global assessment of disease activity (0 to 10).[15] The scores were categorized according to published cut-offs with low ASDAS defined as < 1.3, moderate ASDAS < 2.1, high ASDAS 2.1- 3.5 and very high ASDAS > 3.5.[16,17]
2. Bath Ankylosing Spondylitis Disease Activity Index (BASDAI): consists of 6 questions about the 5 major symptoms (fatigue, pain in the spine and hips, pain or swelling of the peripheral joints, enthesitis, severity and duration of morning stiffness). The questions are answered on a 10-cm VAS. Higher BASDAI scores indicate higher disease activity. [18]

Evaluation of physical function:

Bath Ankylosing Spondylitis Functional Index (BASFI): A functional index which can accurately assess a patient's functional impairment due to the disease, as well as improvements following therapy consists of eight questions relating to specific functions on activity level and two questions reflecting the person's ability to cope with everyday life. The mean score of 10 items gave the final BASFI score ranging from 0 (easy) to 10 (impossible). [19]

Results:

The majority of study subjects were males (92.7%), with a male to female ratio of 12.6:1. HLA-B27 was positive in 41.1% of cases. The non-smokers constituted 52% of cases. Former (Ex) smokers constituted 14.7% of cases. The currently smokers were classified into low grade smokers (<15 pack-year) constituting 18% of cases and high grade smoker (15+ pack-year) constituting 15.3% of cases as shown in table 1.

The mean BASDAI, ASDAS, and BASFI was lowest among non-smokers and increase in magnitude with increasing amount of smoking to reach its highest mean among those with current high grade smoker (15+ pack -year). The observed positive trend indicating a worse disease status with increase in smoking habit was statistically significant, as shown in table 2.

Table 3 shows that there is no statistically significant relation between status of HLA-B27 phenotype and the mean of the 3 indices of AS activity, and function.

HLA, human leukocyte antigen; n, number; BASDAI, Bath ankylosing spondylitis disease activity index; ASDAS, ankylosing spondylitis disease activity score; BASFI, Bath ankylosing spondylitis functional index; NS; not significant; SD, standard deviation, SE; standard error.

As shown in table 4, only smoking habit had a statistically significant association with mean of BASDAI score after adjusting for HLA-B27 status, age, gender, BMI and duration of the disease. Being a former smoker is expected to increase BASDAI score by a mean of 1.9 compared to non-smokers. Being a low grade smoker is expected to increase BASDAI score by a mean of 2.4 compared to non-smokers. Finally moving to the high grade smoking category is associated with the highest increase in disease activity (2.9 points) compared to non-smokers. The resulting regression model was statistically significant and able to explain 55% of observed changes in BASDAI.

Table 5 show that, smoking habit had a statistically significant association with mean of ASDAS after adjusting for HLA-B27 status, age, gender, BMI and duration of the disease. Being a former smoker is expected to increase ASDAS by a mean of 1.1 compared to non-smokers. Being a low grade smoker is expected to increase ASDAS by a mean of 1.5 compared to non-smokers. Finally moving to the high grade smoking

category is associated with the highest increase in disease activity (1.6 points) compared to non-smokers. Age was significantly associated with this index after adjusting (controlling) for the remaining variables. For each one year increase in age the disease activity is increased by 0.02. The resulting regression model was statistically significant and able to explain 47% of observed changes in ASDAS score.

As shown in table 6, only smoking habit and age had a statistically significant association with mean of BASFI score after adjusting for HLA-B27 status, gender, BMI and duration of the disease. Being a former smoker is expected to increase BASFI score by a mean of 1.7 compared to non-smokers. Being a low grade smoker is expected to increase BASFI score by a mean of 2.5 compared to non-smokers. Finally moving to the high grade smoking category is associated with the highest increase in functional impairment (2.8 points) compared to non-smokers. Age was significantly associated with BASFI after adjusting (controlling) for the remaining variables. For each one year increase in age the functional impairment is increased by 0.04. The resulting regression model was statistically significant and able to explain 51% of observed changes in BASFI score.

Table 4: Multiple linear regression model with BASDAI score as the dependent (response) variable and selected variables, smoking habit as the explanatory (independent) variables.

	Partial Regression Coefficient	P

Current high grade smoker (15+ pack-year) compared to non-smoker	2.8	<0.001

R2=0.51; P (Model) <0.001 is significant.

BASFI, Bath ankylosing spondylitis functional index; BMI, body mass index, HLA, human leukocyte antigen, NS, not significant.

This study revealed that more elevated disease activity (ASDAS), the worse functional impairment (BASFI) in smokers and that there was statistically significant relation with that of nonsmokers. This result is agree Chung HY, et al research [20] and Kaan U[21] which revealed that cigarette smoking was related with higher disease activity (ASDAS), worse functional status (BASFI). In addition; near to Chen C research's results [22]which proved that it was significantly impaired among smokers as compared to nonsmokers. This study disagree with Bouaddi I study which showed that in univariate analysis smoking in Moroccan AS patients proved to be not associated with BASFI.[23] This may be explained by different sample size and using univariate analysis. Also research results evaluated the habit of smoking which involved; duration of smoking, and quantity of smoking (pack-years) with disease activity, functional ability in AS patients and showed that there was an association between the pack-years of smoking and disease activity indices which elevate the magnitude with increasing amount of smoking to reach its highest AS disease activity, functional impairment in those with current high grade smokers (15+ pack-year). The noticed positive trend indicating a bad and worse disease activity with increment in habit of smoking was statistically significant. This is in agreement with Fallahi S et al research results in Turkey[24]. A multivariate analysis proved a significant relation between the pack-years of smoking and the BASDAI. This goes in accordance with results of Chen C[22] who revealed that the higher smoking index in AS smokers causes the poor disease outcome including physical mobility. This research revealed significant moderately strong correlation between AS disease activity (ASDAS, BASDAI), and functional impairment (BASFI). This means that getting worse in one AS disease domain is anticipated to affect in a similar way in another disease domain. These results are in agreement with Kaan U's result.[21]

Conclusion

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the Faculty of Dentistry, University of Babylon, Hillah city, Iraq and all experiments were carried out in accordance with approved guidelines.

Epidemiology of Fibromyalgia in Basra City

Kamal Y.Y. Aldubakel[1], Hiba Abdelmageed Younis[2]

[1]Basra Health Directorate, Basra Medical Rehabilitation Center, [2]Al-Sader Teaching Hospital of Basra, Rheumatology and Medical Rehabilitation Department, Iraq

Abstract

Fibromyalgia syndrome is one the prevalent disabling disorder which may skip diagnosis in outpatient's clinic. The most common symptoms in fibromyalgia may presented commonly with generalized pain, fatigue mooring stiffness, non-restorative sleep, problems of memory and concentration, as well as general symptom. Fibromyalgia syndrome in general population has mean global prevalence (2.7%), in comparison to (15-20%) rheumatology outpatient clinic (15-20%). This research aims at study epidemiology of fibromyalgia in Basra city. This is a cross sectional study carried out on patients attended Basra Rheumatology Clinic. They were clinically examined for fibromyalgia according to ACR criteria 2010. The study conducted in the period from January-March 2018. Study results revealed that the mean prevalence of fibromyalgia in Basra rheumatology clinic was 16.6% with male to female ratio 1:5. The mean score for widespread pain was (10±4.2), and symptom severity was (6±1.7) while the total score was 15. The more prevalent painful site was neck and shoulder. All patients had fatigue, waken unrefreshed and cognitive symptom, headache, and irritable bowel. Intolerance to high sound, bright light and to weather changes was notable in FMS patients.

Keywords: *Fibromyalgia, Prevalence, Fibromyalgia Basra.*

Introduction

Patients with Fibromyalgia (FM) are presented with chronic generalized tenderness & pain in addition to the fact that it is debilitating and frustrating disorder. FM prevalence rate is of 4.9% in the general population[1]. In spite of unclear pathogenesis and treatment[2], FM has been related to the appearance of different types of physical trauma[3], infectious diseases[4], emotional and psychological trauma[5] and genetic agents [6]. There is a significant overlap between FM and depression with many affected persons having both diagnoses [7]; and drugs therapy agents for the depression are usually carried out in the FM therapy[8]. American College of Rheumatology (ACR) founded the criteria for FM in 2010[(9,10)]. By this the common significant diagnostic characteristics were as follows; widespread pain (WPI), score and symptom severity (SS) score including fatigue, un refreshed sleep and cognitive symptoms instead of 18 tender points as in ACR 1990 criteria. Thereafter in 2011 modified ACR criteria for FM was developed, that involve (the WPI and SS for the past week), somatic symptom include only; (headache, depression and lower abdominal pain) for previous 6 month.[11] According to 2010-ACR-criteria for FM diagnosis. FM prevalence in general population was (6.4% in America), (2.1% in Germany) and (0.6% in Thailand)[12]. Globally, the mean prevalence is (2.7% in general population), 4.1% in women and 1.4% in men[13]. General outpatient clinic's prevalence was (1% in Kenyatta National Hospital), but the prevalence in rheumatology outpatient clinic was (13%)[14]. While an American study found (15.9%) of new rheumatology patients have FMS. In Iraq, there is no FM prevalence in general population nor its prevalence in rheumatology clinic, this study aims at finding the FM prevalence in rheumatology clinic.

Methodology

This is a cross sectional study for the Patients attended the rheumatology clinic in Basra General Hospital, were examined for FM according to ACR

criteria-2010 for diagnosis of FM in which the patient who had WPI >7 and SS > 5 or WPI 3-6 and SS >9 with total score >12 will be included in the study as fibromyalgia. The study conducted in the period between January-March 2018, and included (1156) randomly selected patients of both sexes over constant working days and hours. An authorized permission were taken from Department of Medical Training & Research in Basra Health Directorate. Written consents were taken from the patients included in the study. Statistical analysis and data management: The Statistical Package for Social Sciences (SPSS, version 18) was used for data entry and analysis. Chi ($\chi 2$) square test, and t- test was used to compare means and proportions of different factors among different groups of study sample. P value of ≤ 0.05 was regarded as statistically significant. Bar charts and tables used to present the data.

Results: Gender distribution of the study sample were as follows as shown in table 1: females represent (83.9%) in comparison to males were only (16%), with Male; Female ratio was (1:5.3) the mean age was 41.5±11.34 year, and the females were older than males. Almost the majorly of the female were house wife.

Table 1: FMS patient's demographic distribution

Variables	Male N (%)	Female N (%)
Gender No %	31 (16%)	162 (83.9%)
Mean age	41.5±11.34	42.5±11.18
Occupation		
Worker No (%)	26 (83%)	54 (33.3%)
Not work No (%)	5 (16.1%)	108 (66.7)% House wife

Table. 2: Distribution of the study sample according to FM 2010 criteria

Scores	Mean	SD
Mean WPI Score	10.56	4.2 SD
Mean Symptom score	6.15	1.7 SD
Total score	16.03	1.7SD

The WPI local distribution for the FMS patient in our study include: shoulder 85% and neck 83%, lower back 73.5% while less prevalent in pain site chest, abdomen, jaw as shown in table (3).

Table 3: WPI local distribution

Pain Site	No %	Single	Bilateral
Neck	162 (84%)		
Shoulder	165 (85.5%)	18 (9.3%)	147 (76%)
Upper arm	103 (53.4%)	11 (5.7%)	92 (47.6%)
Lower arm	87 (45%)	23 (12%)	64 (33%)
Hip (buttock)	74 (38.3%)	44 (22.7%)	30 (15.5%)
Jaw	42 (21.7%)	18 (9.3%)	24 (12.4%)
Thigh	100 (51.8%)	30 (15.5%)	70 (36.2%)
Leg	124 (64.2%)	28 (14.5%)	96 (49.7%)
Upper back	115 (59.5%)		
Lower back	142 (73.5%)		
Chest	56 (29%)		
Abdomen	45 (23.3%)		

Table 4: FM patient's distribution according to symptom severity

Symptoms Severity	%	SS. Mean Score	SD
Fatigue	94.9	2	
Waken Unsatisfied	97.1	2.16	
Cognitive	93.4	1.76	

The second item in 2010 criteria were the symptom severity. (Table 4). All the FMS patients had waken unsatisfied 97%, fatigue 94%, cognitive symptoms.

Concerning the associated major somatic general symptom study revealed that were as follows; all most all patients complain from headache 90%, and memory problems 72.5%, irritable bowel 68.9% also was reported complain the as well as depression 51% as shown in table 5.

Table 5: Associated Somatic general symptom

Symptom	N (%)
Headache	174 (90%)
Memory	140 (72.5%)
Irritable bawl	133 (69%)
Depression	100 (51.8%)
Nervous	93 (48%)

Also the results revealed that there were associated somatic symptoms in FM patients as follows; high sound or bright light intolerance, abdominal discomfort and weather changes intolerance as shown in table 6.

Table 6: Other associated somatic symptoms in FM patients.

Symptoms	N (%)
High sound intolerance	132 (68%)
Bright light intolerance	128 (66%)
Abdominal pain	100 (51.8%)
Weather changes intolerance	66 (34.2%)
Dizziness	59 (30.6%)
Chest tightness	56 (29%)
Insomnia	55 (28.5%)
Numbness	50 (26%)
Short of breath	48 (24.8%)
Allergy	41 (21.2%)

Study results showed that FMS prevalence in rheumatology outpatient clinic was 16.6%, and is similar to prevalence reported USA (10-20%) [15], and (15.7%), in rheumatology clinic in European countries[4,16]. In Iraq there were studies showed that prevalence of FM in specialized clinics was (58.9%) in Behest's disease, (24%) in irritable bowel disease and (18%) in ischemic heart disease.[17-21]. Females were prevalent in all previous researches. About 90% of FM patient are women [8], male: female ratio 1:9[22]. The ratio of females: males was 4.8:1[23]. In our study the male: female ratio was 1:5.3. The mean age of FM patients was 40-50 years, in comparison to results of other studies (48.5 years), (30-49Year)[14, 15]. All female were older than male, (49.2-year-old women and 39.3-year-old men)[15,24]. In this study the women were of age 42.5 years and men were of age 35.9 years.

According to ACR 2010 criteria, patients with FMS from Basra Rheumatology clinic show mean WPI (10.5±4.17) and for SS (6.15±1.7), which is just like an Egyptian FMS study WPI (11.96 ±3.7) and for SS (7.3±2.4) (18, 24), and similar to what was reported by Wolfe F, Korean study; WPI (11.4±4.4) and the SS (8±2.6), WPI (10.6±0.4), SS (8.4±0.3) respectively[18, 25].

A Korean study found that sex ratio male: female (1:5.5), mean age 49 years [25]. The pain distribution according to the WPI in this research was as follows; shoulders, neck and lower back were more frequent complain, as in Egyptian study; shoulders 95.8%, neck 87.5%, and lower back 83.3[24]. All the FM patient share the high frequency of fatigue, unrefreshed sleep, cognitive symptoms and headache as reported in previous studies[15-18, 26-27]. In this study. FM patients show more intolerance to high sound, bright light and weather changes similar to what found by Julia that FM have increased sensitivities to stimuli in the environment. [28] A French study found that FM women have hypersensitivity to stress and stimuli (clod, moisture, heat, flavors) [29], the generalized increase in sensitivity may be explained by dysfunction of endogenous systems modulating afferent activity.[30] Or due to a generalized disturbance of perceptual thresholds in patient with fibromyalgia not restricted to the perception of pain.[31]

Conclusion

FM is a chronic disorder in which the affected person suffer from a generalized pain and disturbance of sleep, fatigue, cognitive symptom. FM is existed in Iraqi community and prevalent in the rheumatology outpatient clinics. There is an urgent need for more attention and early detection to prevent complications and future life disability. Although FM prevalence and symptom severity frequency may vary according to various factors like cultural, social, and economic characteristics, environmental factor, it require further researches to better understand the FM symptomatology in our community.

Abstract

Background: Ankylosing Spondylitis (AS) is a chronic, systemic, inflammatory, rheumatic disease affecting mainly the axial skeleton, with extra-skeletal manifestations, involving lung and an increased risk of cardiovascular morbidity. This research aims to assess the effect of smoking on pulmonary function test and spinal mobility.

Patients and Method: A cross sectional study was conducted on 150 AS patients. Information concerning smoking history, demographic and clinical data were collected. All patients were investigated for HLA-B27, complete blood count, chest x ray and pulmonary function test. AS metrology index (ASMI) measured depending five measurements.

Results: A total of 150 patients with AS were enrolled in this study (139 male and 11 female) with a mean age 36.7+/-8.2 years and mean duration of the disease 11.6+/-6.9 years. The mean FVC and FEV1 was highest among non-smokers and decrease increasing amount of smoking to reach its lowest mean among those with current high grade smoker but failed to reach the level of statistical significance. Smoking habit and age had a statistically significant association with mean of ASMI after adjusting for HLA-B27 status, gender, BMI and duration of the disease. Being a former smoker or low grade smoker is equally expected to increase ASMI by a mean of 0.85 compared to non-smokers.

Conclusion: Smoker AS patients had worse spinal mobility and restrictive PFT.

Keywords: *Smoking & Pulmonary Function Test in Ankylosing Spondylitis Iraq.*

Introduction

Ankylosing Spondylitis (AS) is a chronic, systemic, inflammatory, rheumatic disease affecting mainly axial skeleton with structural and functional impairments[1]. It may also be associated with extra-skeletal manifestations, involving lung, eye, skin, bowel and an increased risk of cardiovascular morbidity.[2] Incidence of pulmonary involvement in AS is estimated to be 1%, emerging either as interstitial lung disease or as a consequence of chest wall abnormalities.[3-5] AS is characterized by inflammation of the thoracic vertebrae and of costovertebral joints, causing gradual fusion and ossification of the joints, resulting in increased dorsal kyphosis, rigidity of the thorax and permanent chest wall immobility with impairment of chest wall expansion with breathing. [6] AS patient's pulmonary function show a restrictive pattern caused by stiffness with increased FEV1/FVC and reduced lung capacity.[7-9] Both FEV1 and FVC were reduced related to impairment in spinal mobility and correlated with disease activity.[10,11]The incidence of pulmonary involvement in AS is estimated to be 1%, emerging either as interstitial lung disease (fibrosis of the upper lobes of the lungs) or as a consequence of chest wall abnormalities.[3-5] It is characterized by inflammation in the thoracic vertebrae and in the costovertebral joints, causing gradual fusion and ossification of the joints, resulting in increased dorsal kyphosis, rigidity of the thorax and permanent

chest wall immobility with impairment of chest wall expansion with breathing.[6]

AS patient's pulmonary function tests show a restrictive pattern caused by stiffness with increased FEV1/FVC and reduced lung capacity.[7-9] Both FEV1 and FVC were reduced related to impairment in spinal mobility and correlated with disease activity.[10,11]

Smokers do not respond as well to treatment compared with non-smokers, which might be another reason for the higher disease activity and subsequent increased restriction in spinal mobility in AS smokers versus AS non-smokers.[12] Exposure to cigarette smoke results in the depression of phagocytic and antibacterial functions of alveolar macrophages, decrease in primary antibody response, also result T-cell attenuation by impairing the antigen receptor-mediated signaling and a decline in TNF production.[13-16]. The aim of this study is to assess the effect of smoking on PFT and spinal mobility among AS patients.

Patients and Method

This study done at Rheumatology unit in Baghdad Teaching Hospital from August 2014-May 2015. A randomly selected sample of 150 Iraqi AS patients who were fulfilling the modified New York criteria for AS (50 current smokers, 21 former smokers, 79 non-smokers) included in the study. [17] A written consent taken from all patients. Approval and official permission were obtained from Baghdad College of Medicine to conduct the present study. Collection of the data done by taking a detailed medical history and clinical examination, laboratory investigations which include; sociodemographic information, and disease duration. Investigation data: patients were investigated for HLA-B27, complete blood count, chest x ray, pulmonary function test (PFT), evaluated by means of a spirometer included measurements of: FVC-Forced Vital Capacity[8] FEV1 - Forced Expiratory Volume in one second[8] FEV1/ FVC% the absolute ratio: The patients were categorized as having a restrictive ventilator pattern (FVC $\leq$ 80%, FEV1/FVC $\geq$ 70%, decreased or normal FEV1).[8, 9]

Evaluation of Spinal Mobility: Ankylosing spondylitis metrology index (ASMI): Calculating the ASMI score was based on 5 measurements. The score ranged between a minimum of zero and a maximum value of 2. The higher the score the worse is the functional aspect of spine: Occiput-wall distance (cm)-tertile, Chest expansion (cm)-tertile, Modified Schober test (cm)- tertile, Lateral lumber flexion (cm)-tertile, and Fingertip to floor distance (cm)-tertile.[18-20] All 5 scores obtained from the evaluation questionnaire are added, and the total is divided by 5 to obtain the ASMI value.

Results

The majority of study subjects were males (92.7%), with a male to female ratio of 12.6:1. HLA-B27 was positive in 41.1% of cases. The pulmonary function test was labeled as a "restrictive pattern" in 60% of cases. An obstructive pattern was observed in only 2% of cases. The non-smokers constituted 52% of cases. Former (Ex) smokers constituted 14.7% of cases. The currently smokers were classified into low grade smokers (<15 pack-year) constituting 18% of cases and high grade smoker (15+ pack-year) constituting 15.3% of cases as shown in table 1.

Table 1: Demographic and clinical characteristics of study sample

		N	%
1.	Gender		
	Female	11	7.3
	Male	139	92.7
	Total	150	100.0
2.	HLA-B27		
	Negative	83	58.9
	Positive	58	41.1
	Total	141	100.0
3.	PFT pattern		
	Normal	57	38.0
	Restrictive	90	60.0
	Obstructive	3	2.0
	Total	150	100.0
4.	Smoking status		
	Non-smoker	78	52.0
	Former smoker	22	14.7
	Current low grade smoker (<15 pack-year)	27	18.0
	Current high grade smoker (15+ pack-year)	23	15.3
	Total	150	100.0

N, number; HLA, human leukocyte antigen; PFT, pulmonary function test.

As shown in table 2, the mean ASMI, was lowest among non-smokers and increase in magnitude with increasing amount of smoking to reach its highest mean among those with current high grade smoker (15+

pack -year). The observed positive trend indicating a worse spinal mobility with increase in smoking habit was statistically significant. Although the mean FVC and FEV1 was obviously highest among non-smokers and decrease in magnitude with increasing amount of smoking to reach its lowest mean among those with current high grade smoker(15+pack-year), the differences observed failed to reach the level of statistical significance. The mean FEV1/FVC ratio showed no obvious or statistically significant difference between the 4 categories of smoking habit.

Table 3 demonstrate that the status of HLA-B27 phenotype had no important or statistically significant association with mean of the PFT and spinal mobility.

As shown in table 4, only smoking habit and age had a statistically significant association with mean of ASMI after adjusting for HLA-B27 status, gender, BMI and duration of the disease. Being a former smoker or low grade smoker is equally expected to increase ASMI by a mean of 0.85 compared to non-smokers. Moving to the high grade smoking category is associated with the highest increase in ASMI (1.14 points) compared to non-smokers. Age was significantly associated with this index after adjusting for the remaining variables. For each one year increase in age the metrology index is increased by 0.02. The remaining confounding variables, had no statistically significant effect on the mean ASMI. The resulting regression model was statistically significant and able to explain 68% of observed changes in the response variable.

Table 2: The mean of selected indices of AS disease by smoking habit.

Discussion

The negative impact of smoking on AS disease parameters has been reported in various studies, and confirmed more robustly in our study. To the best of our knowledge this study was the first study in Iraq explained the association of cigarette smoking with PFT and spinal mobility in AS patients.

The results showed that AS patients had lowest spinal mobility (including modified Schober test, lateral lumber flexion, chest expansion, occiput-wall distance and fingertip to floor distance) among smokers and statistically significant in comparison to nonsmokers. This finding is in close to the results of Chen C study at (2013)[21]which reported that physical mobility parameters modified Schober test, lateral lumber flexion, chest expansion, occiput to wall distance and fingertip to floor distance were significantly impaired among smokers as compared to nonsmokers.

Also data assessed the smoking habit included smoking duration, and smoking quantity (pack-years) with spinal mobility in patients with AS and revealed that there was a correlation between the pack-years of smoking and PFT and spinal mobility, with increasing smoking duration and quantitiy there is increased ASMI score and decreased in PFT levels

Among those with current high grade smokers (15+ pack-year). The observed positive trend indicating a worse disease status with increase in smoking habit was statistically significant .This is in accordance with the finding of Fallahi S,et al study in Turkey (2013)[22]. A multivariate analysis revealed a significant association between the pack-years of smoking and the ASMI. Also Chen C[21] showed that higher smoking index in AS smokers are associated with poor disease outcome including physical mobility.

This study revealed that the forced vital capacity (FVC) was highest among non-smokers and decrease in magnitude with increasing amount of smoking to reach lowest capacity in high grade current smokers.

This is due to effect of smoking on disease activity also the disease itself due to involvement of costovertebral joint lead to decrease in chest expansion and vital capacity, and these can result in decrease of FVC (restrictive pulmonary pattern). This finding was match the result of Kaan U. [23]Forced expiratory volume in first second (FEV1) was lowest among smokers due to the direct effect of smoking on FEV1 resulting in obstructive pattern .The observed negative trend in this study indicating a worse ventilator function with increase in smoking habit, however failed to reach the level of statistical significance. This finding is match the result of Berdal G. [8] which showed that chest expansion and oxygen consumption were significantly poorer in the group of smokers and ex-smokers. The current study revealed that FEV1/FVC ratio showed no obvious or statistically significant difference between current smokers, former smokers and nonsmokers. As explained previously due to direct and indirect effect of smoking on FVC and FEV1 (decreased) among smokers result in no change in ratio.

Conclusion

Smoker AS patients had worse spinal mobility and restrictive PFT.

Call for Papers / Article Submission

The editor invites scholarly articles that contribute to the development and understanding of all aspects of Public Health and all medical specialities. All manuscripts are double blind peer reviewed. If there is a requirement, medical statistician review statistical content. Invitation to submit paper: A general invitation is extended to authors to submit papers papers for publication in IJPHRD.

The following guidelines should be noted:

- The article must be submitted by e-mail only. Hard copy not needed. Send article as attachment in e-mail.
- The article should be accompanied by a declaration from all authors that it is an original work and has not been sent to any other journal for publication.
- As a policy matter, journal encourages articles regarding new concepts and new information.
- Article should have a Title
- Names of authors
- Your Affiliation (designations with college address)
- Abstract
- Key words
- Introduction or back ground
- Material and Methods
- Findings
- Conclusion
- Acknowledgements
- Interest of conflict
- References in Vancouver style.
- Please quote references in text by superscripting
- Word limit 2500-3000 words, MSWORD Format, single file

All articles should be sent to: **editor.ijphrd@gmail.com**

CALL FOR SUBSCRIPTIONS

About the Journal

Print-ISSN: 0976-0245 **Electronic - ISSN:** 0976-5506, **Frequency:** Quarterly

Indian Journal of Public Health Research & Development is a double blind peer reviewed international Journal The frequency is half yearly. It deals with all aspects of Public Health including Community Medicine, Public Health, Epidemiology, Occupational Health, Environmental Hazards, Clinical Research, Public Health Laws and covers all medical specialities concerned with research and development for the masses. The journal strongly encourages reports of research carried out within Indian continent and south east Asia.

The journal has been assigned international standards (ISSN) serial number and is indexed with Index Copernicus (Poland). It is also brought to notice that the journal is being covered by many international databases.

Journal Title	Print Only
Indian Journal of Public Health Research & Development	**INR 9000**

NOTE FOR SUBSCRIBERS

- Advance payment required by cheque/demand draft in the name of **"Institute of Medico-Legal Publications"** payable at New Delhi.
- Cancellation not allowed except for duplicate payment.
- Claim must be made within six months from issue date.
- A free copy can be forwarded on request.
