Indian Journal of Public Health Research & Development

Print-ISSN: 0976-0245-Electronic-ISSN: 0976-5506, Frequency: Quarterly (Four issues per volume)

Indian Journal of Public Health Research & Development is a double blind peer reviewed international journal. It deals with all aspects of Public Health including Community Medicine, Public Health, Epidemiology, Occupational Health, Environmental Hazards, Clinical Research, and Public Health Laws and covers all medical specialties concerned with research and development for the masses. The journal strongly encourages reports of research carried out within Indian continent and South East Asia.

The journal has been assigned International Standards Serial Number (ISSN) and is indexed with Index Copernicus (Poland). It is also brought to notice that the journal is being covered by many international databases. The journal is covered by EBSCO (USA), Embase, EMCare & Scopus database. The journal is now part of DST, CSIR, and UGC consortia.

Stress in Families of Children with Disabilities

Sheila Christopher[1], L. Cresenta Shakila[1], R. Leema Suganya[2], Angel Selvaraj[2]

[1]Associate Professor, [2]Assistant Professor, [2]Assistant Professor P.G & Research Department of Rehabilitation Science, Holy Cross College (Autonomous), Tiruchirappalli, Tamil Nadu, India

Abstract

Background: The institution of family is considered essential for the existence of society. Family serves as a shock absorber in times of crisis and stress. Having a child with disability in a family is not the same as having a child without a disability. This study intends to portray the characteristics of families with children with mental retardation. The various forms of stress experienced by these families and their expectations, experiences and limitation are described during the course of the study.

Materials and Method: Parents of Mentally Retarded children from 7 special schools for children with disabilities in the urban limits of Trichy District were chosen for the study. Family Interview for Stress and Coping in Disabilities (FISC-MR) was the tool used for the study.

Results: Fathers reported more stress related to their child's temperament and their relationship to their child. Mothers reported more stress from the personal consequences of parenting. Fathers were more sensitive to the effects of the family environment whereas mothers were more affected by their personal support networks.

Conclusion: The delicate balance of family relationships can be strengthened or broken by the impact of stress felt by the parents of these special children.

Keywords: *Stress, Family, Mental Retardation, Disability.*

Introduction

The institution of family is considered essential for the existence of society. Family serves as a shock absorber in times of crisis and stress. Having a child with disability in a family is not the same as having a child without a disability. Presence of a special child in a family is known to impact families in varied ways. Past research has focused much on the mother and child. We know less about fathers and their role in families with children with disabilities. Mothers are frequently the spokesperson for the family, and hence we do not truly have an individualized family opinion or feeling. Hence fathers need to be specifically included in order to obtain a holistic picture about the experiences of the family **(1).**

Parents of children with special needs were chosen for the study. This study intends to portray the characteristics of families with children with mental retardation. The various forms of stress experienced by these families and their expectations, experiences and limitations are described during the course of the study. Most researchers have found that having a child with a disability increases family stress**(2).** A comprehensive picture of stress experienced or perceived by families caring for children with disabilities and certain key coping resources available for the family which are likely to modify the perceived stress have been studied as part of this research.

(3) In a study on predictors of distress and well-being in parents of young children with developmental delays and disabilities: the importance of parent perceptions found that moving from family-centered to child-centered models of service delivery can be stressful for parents as their young children with developmental delays and disabilities transition into school. The results of this study highlight not only the importance of including positive as well as negative outcomes in research with

parents but also the importance of including parent characteristics such as coping strategies (e.g. reframing and empowerment/self-efficacy) as potential predictors of outcome in such studies.

Poorer emotional well-being contributed to higher stress and was more frequent among mothers, single parents and those whose children had behavior problems. Having other dependents living at home and more sources of informal support improved the emotional wellbeing of parents but not their stress or family functioning.[4] One research study[5] identified that parenting a child with an intellectual disability is not always a negative role; it is a role that parents find both rewarding and empowering. Yet high levels of parent stress, illness, anxiety, and depression are apparent as found out by[6].

[7]Feelings of loss in parents of children with infantile cerebral palsy was studied. These parents experience stress in the first stage of the diagnosis and when the severity of the cerebral palsy is greater. Emotional intervention on the part of health care providers is needed to aid parents in facing the various obstacles encountered throughout their child's up-bringing.

A study of this kind will enable counselors, therapists and rehabilitation professionals who work with the parents of special children understand the variety of emotional reactions experienced by parents and help in developing and strengthening innovative psychosocial models of treatment. This study will ultimately help towards a better understanding of parent's unique concerns, problems and feelings.

Materials and Method

Aim of the Study:

1 The general aim of this study is to assess the psychosocial implications faced by families of children with disabilities.

2 To describe the socio-demographic background of parents with children with disabilities.

3 To assess the stress experienced by such families.

Families (mothers and fathers) of children with special needs were chosen as the universe for this study. This study was conducted on all the 7 Special Schools for Children with Disabilities located within the Trichy city limits a town in the state of Tamil Nadu, South India. Due to the limited size of the sample all the families (500), which include 500 mothers and 500 fathers, were taken for the study. Hence the census method has been adopted.

The initial data collection was done with a self-prepared Socio-Demographic Schedule. Family Interview for Stress and Coping in Disabilities (FISC -- MR):This tool is a semi-structured interview schedule developed by Dr. Sathish Chandra Girimaji et.al., 1999 at NIMAHNS, Bangalore to evaluate stress and its mediators in the families of children with Mentally Retardation. It attempts to systematically elicit and quantify **(i)** the stress experience (perceived) by families caring for a child with disabilities and **(ii)** certain key coping strategies specific to disability employed by the families that are likely to modify the perceived stress (mediators). Scoring: FISC-MR has 2 major sections: Section-I has 4 areas and a total of 11 sub-scales, whereas Section-II has 5 areas and a total of 9 sub-scales.

A consent for the purpose of study was obtained from the parents. The tool was administered to the sample of 1000 respondents (500 mothers and 500 fathers. After briefing they were administered the questionnaires. Item wise explanation was given in the vernacular. The responses to the scales were scored with the help of the standardized scoring key to obtain an overall index for all the scales. The data thus collected was analyzed using the SPSS package.

Results and Discussion

Fathers and mother's perception of stress remains almost the same with a high of 50.6% and 48% . Mothers experience more stress in family care than fathers. A Study [8] compared mother and father's perception of the effect of young children with and without disabilities and mothers reported more stress than did fathers. The burden of child care generally falls on the shoulders of the mother who happens to spend more time with the special child. [9] Fathers reported more stress related to their child's temperament and their relationship to their child. Mothers reported more stress from the personal consequences of parenting. Fathers were more sensitive to the effects of the family environment whereas mothers were more affected by their personal support networks.

There is significant difference between nuclear and joint families with regard to the various dimensions of stress like family care, social stress and overall stress. Though the size of the family does not have an impact

on stress yet it is found that nuclear families experience a slight more stress than joint families. [10] Results of a study on parental stress showed a higher level of stability in parental stress and a modest degree of consistency over time in family functioning in families of children with disabilities. [11]One study has also reported that parents living in joint or extended families face greater extra demands, career adjustments, mental worries, emotional reactions and strained relationships.

Parents from urban families experience more stress and greater emotional reactions than parents from rural families. This could be because of the busier style of living and more challenges faced by parents in urban areas than rural areas. [11] Urban parents experience more social and financial stress than rural parents. This could be because of the greater awareness of the condition of disabilities among urban parents and the social stigma attached thereof.

Whether the child is a boy or a girl, there is no significant difference in terms of stress experienced by parents. This finding is aptly supported by one more finding[12]. that family stress was not affected by the sex of the mentally retarded child. A study focused to examine the relationship between child characteristics and stress reported by mothers. There was no significant difference between amount of stress reported by mothers of boys and girls [13].

The degree of impact, frustration, or disappointment does not correlate directly with the degree of deficiency. There is no significance between the level of retardation and stress.[14] A study assessed the quantity of stress in mothers of children with disabilities of different etiologies. The degree of the children's disabilities as well as conspicuous behavior correlated positively with maternal stress. There was a positive relation between the level of disability and the total family stress and its components [12]. But in most studies, the severity and nature of the child's intellectual as against physical impairments on behavior problems seem to be unrelated to reported levels of stress [15]

Several researchers have compared stress in parents of children with disabilities to that reported by other parents. Studies have been fairly consistent in finding normative levels of levels of stress reported during the infancy period [16], followed by increasing stress levels during early childhood [17], and high stress levels during middle childhood [18]. Middle childhood appears to be a particularly vulnerable time for parents of children with disabilities; stress levels are higher than at any other childhood phase [19]. Middle childhood may be a particularly vulnerable period for parents because they expect children's behaviors to be better regulated than in earlier years.

Table 1: clearly indicates that there is a negative correlation between income and social stress and family size and social stress for fathers. When there is more income, social stress decreases. When the size of the family increases social stress decreases. But when the age of the child increases financial stress also increases. As children grow older, the demand for caring also increases. Therefore, as the age of the child increases financial stress also increases. There is also a negative correlation between income and family care, the age of the mother and age of the child with regard to social and financial stress.

Table 1: Karl Pearson's Correlation between Dimensions of Stress and Demographic Variables

S. No	Dimensions of Stress	Age		Income		Family Size		Age of Child	
		Father	Mother	Father	Mother	Father	Mother	Father	Mother
1	Family Care	-0.20	0.083	0.064	-0.154**	-0.029	-0.111**	0.000	-0.065
2	Family Emotional Stress	-0.016	-0.067	0.049	-0.005	0.050	-0.196**	0.003	-0.071
3	Social Stress	-0.047	-0.120**	-0.149**	-0.048	-0.101*	-0.271**	-0.024	-0.220**
4	Finance Stress	0.058	-0.161**	0.046	-0.046	-0.073	-0.190**	0.097*	-0.185**
5	Overall Stress	-0.025	0.011	0.034	-0.119**	-0.061	-0.292**	0.022	-0.184*

Hauser-Cram et al. (2001) Both mothers and fathers had increasing levels of stress related to their child with a disability from the early through middle childhood years, fathers showed greater increases in stress than mothers during the early childhood period [20] In addition, increasing patterns of stress were found for mothers with less helpful social support networks and for fathers with fewer problem-focused coping skills.

In a study [21] eighty- two (82) Israeli families. Results indicated that when the number of children in the family was smaller, they reported being more stressed by the child's disability. With regard to mothers, there is a negative correlation between the family size and the various dimensions of stress. It is evident that when the family size increases the overall stress decreases.

The inter correlation **(Table 2)** was done to find out the relationship between the various dimensions of stress for both parents. The inter correlation matrix between the various dimensions of stress clearly indicates a significant positive and negative correlation between the parameters and overall effect of stress. There is a significant positive correlation between social stress, and overall stress for mothers. But there is a significant negative correlation between family emotional stress and financial stress. Fathers experience a significant positive correlation between family care and family emotional stress and overall stress. It is evident that both fathers and mothers feel that when family cares increase family emotional stress and social stress, also increase.

Table 2: Inter Correlation Matrix between Various Dimensions of Stress for Both Parents

Various Dimensions of Stress		Family Care		Family Emotional Stress		Social Stress		Financial Stress		Overall	
		Mother	Father	Mother	Father	Mother	Father	Mother	Father	Mother	Father
Family Care	Mother	1.000									
	Father	0.056	1.000								
Family Emotional Stress	Mother	-0.318**	-0.005	1.000							
	Father	-0.024	0.143**	0.050	1.000						
Social Stress	Mother	0.129*	-0.018	-0.008	-0.019	1.000					
	Father	-0.003	0.068	0.032	0.238**	0.064	1.000

	Father	0.029	0.687**	0.037	0.688**	0.003	0.541**	-0.002	0.350**	0.046	1.000

There are many times when the raising of children is absolutely exasperating particularly with a special child. This research clearly points to the importance of the family system in promoting positive development of children with developmental disabilities, their mothers and fathers. The delicate balance of family relationships can be strengthened or broken by the impact of stress felt by the parents of these special children. It is therefore essential that such investigations be undertaken because families of children with developmental disabilities, like all families, deserve to be nurtured in ways that will optimize their functioning and ultimately help special children lead meaningful lives.

Ethical Clearance: This study was undertaken with the consent from the participating families. The parents of children with disabilities were the main respondents for the study. The institutional research and review body explicitly approved the conduct of this research.

Physical Activity Measurement Using Accelerometer in Phase-I Cardiac Rehabilitation

Shilpa Gupta[1], Arun G Maiya[2], Kalyana Chakravarthy[2], Stephen Rajan Samuel[3]

[1]Assistant Professor, Dept. of Physiotherapy, Institute of Health and Allied Sciences, Muradnagar, Ghaziabad, India, [2]Professor and Dean, Manipal College of Health Professions, Manipal Academy of Higher Education, Manipal, Karnataka, India, [3]Assistant Professor, Dept. of Physiotherapy, University of Sharjah, UAE, [4]Assistant Professor, Dept. of Physiotherapy, Kasturba Medical College, Mangalore, Manipal Academy of Higher Education, India

Abstract

Background: Cardiovascular disease (CVD) is the leading cause of death and disability worldwide. Cardiac rehabilitation (CR) is important in improving cardiovascular fitness. Estimating physical activity (PA) levels and Energy Expenditure(EE) in Phase-I CR using Accelerometer can help in understanding cardiovascular fitness better.

Method and materials: PA of 16 participants post Coronary Artery Bypass Graft (CABG) and Percutaneous Transluminal Coronary Angioplasty (PTCA) in Phase-I CR was measured using Actigraph accelerometer. Metabolic Equivalents (METs) and average of daily EE(in Kcals) and steps taken were calculated. Correlation of the Six minute walk distance (6MWD) on the day of discharge and PA levels measured by Actigraphaccelerometer was done.

Results: PA energy expenditure averaged 283.71 Kcals/3days, step counts/day 4861.50, METs 5.79 and the EE in light and moderate intensity activities were 1.01 Kcals and 5.72 Kcals respectively. The time spent in these activities were 62.25 minutes in light intensity and 2 minutes in moderate intensity activities.

Conclusion: PA measured by Actigraph accelerometer was of low to moderate levels in Phase-I CR. There was a weak correlation between PA levels measured by Actigraph accelerometer and 6MWD achieved at the time of discharge.

Keywords: *Cardiovascular disease, Phase 1 Cardiac rehabilitation, Physical activity, Accelerometer.*

Introduction

Cardiovascular disease is the leading cause of death and disability worldwide. In 2015, out of 17.7 million CVD deaths, 7.4 million occurred due to coronary heart disease.(1) With increasing urbanization and sedentary lifestyles, prevalence of Coronary Artery Disease (CAD) being doubled in rural areas (3-4%) and quadrupled in urban areas (9-11%) in the past 4 decades in India.(2) Increased risk factor prevalence and lack of preventive approaches have been primary factors in the currently accelerating CVD epidemic in India. The magnitude of CVDs continues to accelerate world-wide, increasing the demands for increased awareness and stronger and more specific prevention and cost-effective management.

Physical inactivity is the 4th leading risk factor for mortality and is an independent risk factor for CAD. In adults, participation in 150 minutes of moderate PA each week is estimated to reduce the risk of CAD by approximately 30%.**(1)** PA increases functional capacity and reduces the risk of re-hospitalization of cardiac

Corresponding Author:
Arun G. Maiya
Professor and Dean, Manipal College of Health Professions,Manipal Academy of Higher Education,Manipal, Karnataka, India

patients, and improves the prognosis and quality of life of patients with CAD.[3] Meta-analysis of clinical trials have proved that exercise based CR reduces the mortality rates of CAD patients.[4] Benefits of exercise based CR program are now largely demonstrated resulting in 30% decreased mortality.[5]

The World Health Organization has defined "CR as the sum of activities required to favorably influence the underlying cause of the disease, as well as the best possible physical, mental, and social conditions, so that they may, by their own efforts, preserve or resume, as normal a place as possible in the society.[6] CR mainly consists of 4 phases. The Phase-1 is the acute phase and involves the hospitalized period of the patient following acute MI, Phase-2 is the convalescent stage which is the immediate post-discharge period, Phase-3 is the training phase of supervised structured outpatient CR program and Phase-4 is the long-term maintenance program.[7, 8]

Physical fitness has been defined as "a set of attributes that people have or achieve that relates to the ability to perform PA". [9]Therefore, to detect changes in this variable it is important to accurately measure PA. The ability to measure PA behavior is useful, not only to understand the association between PA and health but also for many other reasons, such as to monitor trends in behavior and to evaluate the effectiveness of interventions and programs. Currently, the most widely used research method for measuring PA don't yield objective data.[10]

In CR, PA is routinely measured either subjectively or objectively. Subjective measurements of PA have their own limitations, therefore, measurement of PA with motion sensors such as Triaxial Actigraph accelerometer provide objective quantification. Accelerometers are electronic sensors capable of measuring and storing measurements of the intensity, frequency, pattern, and duration of activity.[11] Triaxial accelerometers show good correlation between accelerometer output and EE measured by doubly labeled water.[12]

Inter and Intra instrument reliability of Actigraph accelerometer has been found to be good and the use of this device has been validated in CR.[13] Even though the accelerometer is gaining popularity in PA measurement, there is a dearth of studies in India regarding the use of accelerometers for estimating the PA levels and EE in Phase-I CR, therefore, the aim of this study is to identify objective data for estimating PA levels in Phase–I CR.

Materials and Method

An observational study, with convenience sampling was carried out on 16 patients, who had undergone CABG and PTCA and were referred for Phase 1CR.

44 participants were screened for the inclusion and exclusion criteria, of which 16 (9 CABG and 7 PTCA) met the inclusion criteria.

Inclusion and Exclusion Criteria: Patients included were CAD subjects with low to moderate risk[14] immediate post-PTCA and post CABG.Patients were excluded for the following reasons:

1. Patients at high risk. Patientson prolonged mechanical ventilation for more than 48 hours after the medical/surgical intervention or episode of CAD
2. Orthopedic and neurological conditions which prevent participation in exercise
3. Individuals who were not ready to wear accelerometer.

All patients underwent structured Phase-I CR program in the hospital till discharge which comprised of 5 steps. The total length of stay for CABG and PTCA on an average was 4 days and 2 days respectively.

Actigraph accelerometer was given to the patient to be worn on the wrist for 24 hours till discharge. 24 hours PA (excluding bathing and sleeping) was recorded using the accelerometer. EE in kilocalories and MET's were interpreted with the accelerometer at the end of the day.

According to the American Thoracic Society guidelines, prior to discharge, a submaximal stress test was performed by all the patients using the 6MWT, and MET's achieved in the test were recorded on the Actigraph accelerometer. [15]

Statistical Analysis: Data were analyzed using SPSS version 15. Descriptive analysis was used to estimate the patient characteristics included in the study, the median and IQR of total Energy expenditure (KCals) till the day of discharge and the median and IQR value of average MET's till the day of discharge. Pearson's correlation coefficient was used to determine the correlation between METs measured by Actigraph accelerometer during six-minute walk test (6MWT) and the distance covered during the 6MWT.

Results

The mean age of participants with the anthropometric measurements in (years) was 56.43±10.93 SD, mean weight in (kg) of the participants was 65.56±13.41 SD and the mean BMI (kg/m^2) was 23.32±4.94 SD. The clinical characteristics of the included participants were, Hypertension (n=7); Diabetes mellitus (n=5); Obesity (n=1) and HTN+DM (n=3).Out of 16 participants, 10 were males and 6 were females. Descriptive statistics were used to determine the median and interquartile range values of measurement of the amount of PA and is represented in Table 1.

Table 1. Measurement of PA level using Actigraph accelerometer during Phase-I CR

Parameter	Median (IQR)
Energy expenditure (Kcals)	283.71 (167.25 - 628.87)
Step counts/day	4861.50 (3484.25 – 6933.75)
METs	5.79 (4.69 - 7.27)
Time (minutes)	148.5 (115.0 – 310.25)

The amount of PA and the time spent in light and moderate PA are presented in Table 5. The EE and the time spent in light intensity activity (PA corresponding to < 3 METs); moderate intensity activity (PA corresponding to 3-6 METs); vigorous intensity activities (PA corresponding to >6 METs) are given in table 2.

Table 2. The duration and intensity of PA measured by Actigraph accelerometer in phase I CR

Physical activity	Intensity of PA in Kcals Median (IQR)	Time spent (min) Median (IQR)
Light	1.013 (58.54 -2.011)	62.25 (30.07-1.023)
Moderate	5.727 (0.70 -16.08)	2 (0.25-5.41)

The descriptive statistics were used to determine the mean 6MWD covered by the participants at the time of discharge. It was found to be 45% of the predicted distance. (Table 3)

Table 3. Mean six-minute walk distance in phase I CR

Parameter	Mean ± SD
6MWD (meters)	252.125 ± 68.24
% predicted 6MWD	45.18 ± 14.50

Correlation between 6MWD and METs measured by Actigraph accelerometer at the time of discharge was analyzed using Pearson's correlation coefficient test. The mean & SD for 6MWD was 252.125 ± 68.24 and METs during 6MWD 11.06 ± 1.44 with r-value 0.347 and p-value 0.187.No correlation was found between the 6MWD and the METs measured.

Discussion

Demographic and clinical characteristics: The present study focused on measuring PA levels using Actigraph accelerometer in Phase-I CR and correlating the 6MWD with the METs measured by Actigraph accelerometer. PA levels were measured in Phase- I CR of CABG and PTCA patients in a tertiary care hospital. Participants on an average had co-morbidities such as diabetes mellitus, obesity, and hypertension. As these co-morbidities affect the functional capacity of the patients, this could have influenced their PA levels in our study.

Out of 9 participants who underwent CABG, 3 had triple vessel disease and 6 double vessel diseases respectively. However, all participants who underwent PTCA had only one vessel involved. The number of grafts harvested could have influenced the PA as well as the site of the graft taken. For example, the great saphenous vein taken from the lower limb can affect the mobility of the participants.[16]

Physical activity in CR: CAD patients have a reported benefit post-PA, however, vigorous exercises can have dangerous effects. [17]In the present study, Actigraph accelerometer was used to quantify the PA levels of the participants in Phase-I CR. In the present study, we observed that the EE and the time spent in the light intensity activity by the participants was more as compared to the moderate intensity activity. Whereas, none of the participants were involved in vigorous intensity activities.

Studies document that benefits associated with participation in CR, include stabilization and potential regression of CAD.[18] To halt the disease progression, it is recommended that a minimum of 1500 kcal/week of EE is required for participants undergoing CR program.[19] The amount of EE to be achieved by the end of phase-I CR is currently not known. The objective measurement of EE using Actigraph accelerometer during Phase-I CR may help in formulating the guidelines for PA prescription.

The results presented in the study are in median and IQR values, for the betterment of understanding, the comparisons from the other studies are done in mean and SD values. In the present study the average daily EE in Kcals (142.86 ± 121.47) was more than the Kcals (128.6 ± 77.8) measured in a study by Izawa et al. [15] The probable reason for more EE reported in our study could be due to the use of a Triaxial accelerometer which takes into account all the three axis during any activity as compared to uniaxial accelerometer which monitors only one axis which was used in the above-mentioned study.

EE was measured in Kcals of the participants by Actigraph accelerometer at the end of each day. The mean EE on Day 1 was 139.41 ± 146.38 Kcals and that of Day 2 was found to be 175.88 ± 120.27 Kcals.

The mean daily MET's measured by Actigraph accelerometer was 3.9 ± 1.9. It has been recommended that participants of CR should achieve 5-6 METs for completion of Phase-I and is also one of the criteria followed to start with Phase-II CR.[19] The participants in our study achieved the target METs. As Actigraph accelerometer gives an accurate measure of PA in free-living conditions, it can be used to objectively monitor the metabolic equivalents achieved by the person and therefore, can be used to provide a tailored program.

The average daily no. of steps (5146.43 ± 1997.14) in this study was similar to the step counts (4588.0 ± 2056.3) reported by Izawa et al, [15] in Phase-I CR indicating that the step counts measured might also be the appropriate target values to achieve necessary EE recommended for secondary prevention in cardiac patients. [19]At present, there are no guidelines for the required step counts during Phase–I CR. As the accelerometer is accurate to measure the step counts, it can be used to promote PA levels in Phase-I CR.

Six-minute walk test in CR: Walking performance is a good indicator of patient's progress and physical status, hence, the 6MWT is routinely used to assess the patient's performance.[15] In our study, the mean 6MWD was found to be 252.125 ± 68.24 meters (i.e. 45.18% of the predicted value) which were less as compared to a study in which the mean 6MWD of participants was 470 ±151.76 meters.[20] The probable reason for this decrease in 6MWD can be the difference in length of stay in hospital which, in our study was shorter due to early discharge.

Correlation between Six-MWT and METs measured by Actigraph accelerometer: 6MWT which gives a measure of functional capacity is used as a marker for prognosis in patients with CVDs undergoing CR.[15] Currently, there is no method of measuring PA levels other than self-reporting or dairy or 6MWT at the hospital exercise clinics. Often conducted in a clinical setting, 6MWT may be contaminated by factors pertaining to the clinical environment and the clinical coordinator of the patients being tested. Regardless, 6MWT still remains as the more readily used measure of functional capacity.

Actigraph accelerometers have been looked upon as an objective means to measure the patients PA in free-living conditions, hence 6MWT by objective monitoring will overcome some of the limitations or contamination that prevail in the current method of 6MWD measurement and assessment. We hypothesized that PA levels during phase 1 CR may influence the functional capacity of the cardiac patient measured by 6MWT prior to discharge from the hospital. However, there was no correlation between 6MWD covered and the METs measured by the Actigraph accelerometer during 6MWT.

One important observation was noted that all patients post-surgery on an average got discharged by the fourth day (CABG) and second day (PTCA), even though the existing protocols recommend 1-7days of Phase-I CR. The PA levels measured in our study may not be generalized for Phase-I CR due to variations in the hospital protocols.

The limitations of this study areonly 3 days of monitoring due to early discharge of participants and sub-group analysis for CABG and PTCA was not done due to a small sample size. Future scope for research could focus on measurement of customized rehabilitation programs using the accelerometer.

Conclusion

In the present study, PA measured by Actigraph accelerometer was of low to moderate levels in Phase-I CR. There is a weak correlation between PA levels measured by Actigraph accelerometer and 6MWD achieved at the time of discharge.

A Study to Assess the Effect of Childbirth Education on Intrapartum Coping behaviours of Primiparous Women in a Selected Maternity Center of a Tertiary Level Hospital in Pune

Shobha Naidu (Retd)[1], Deepak Sethi[2]

[1]Assoc. Professor, Deputy Director, HOD, Obstetric & Gynaecological Nursing Symbiosis College of Nursing (SCON), Senapati Bapat Road, Pune, [2]Asst. Professor, HOD, Medical Surgical Nursing Symbiosis College of Nursing (SCON), Senapati Bapat Road, Pune

Abstract

Introduction: Child birth is a normal physiological process, yet gaining confidence by enhancing knowledge about childbirth can be considered an important factor influencing a parturient's birthing experience.

Method: A prospective quasi-experimental study conducted on 60 registered primigravidae attending the ANC OPD of a hospital at Pune. 30 included in the intervention group, received 3 sessions of CBE. The effect of this measured intranatally by a self-developed Intrapartum Behavioural Observation Checklist. The coping behaviours of the intervention group measured and compared against 30 primigravidae women who received conventional antenatal education.

Results: Primigravidae were poorly informed about childbirth preparedness and not prepared for the experience of childbirth. Majority had no concept regarding the severity of pain, duration of labour and coping measures stress of labour.

Significant reduction in episiotomy rates, use of analgesics and improvement in coping behaviours found among the experimental group. Hence the research hypothesis was accepted, level of significance = 0.001.

Discussion: Gaps identified in the knowledge and practice of childbirth preparedness among primigravidae in urban Pune. Also analyzed the positive effects of childbirth education on intrapartum coping behaviours of primiparous women. Episiotomy rates and use of intrapartum analgesics were less in the Intervention group. Intrapartum behavioural compliance and exhibition of positive self-care, intra partum coping behaviours were also significantly high.

Conclusion: The findings of this study indicate that the short term; need based childbirth educational intervention demonstrated a highly significant impact on the intrapartum coping behaviours of primiparous women.

Keywords: *Childbirth education, intrapartum coping behaviours, primigravidae women.*

Introduction

Childbirth is a normal physiological process, yet it is a life changing experience for the woman becoming pregnant for the first time. Gaining knowledge about childbirth can be considered an important factor influencing a parturient's birthing experience. [1,2,3]

Background of the study: When the woman is well informed regarding the events that she would

Corresponding Author:
Shobha Naidu (Retd)
Assoc. Professor, Deputy Director, HOD, Obstertric & Gynaecological Nursing Symbiosis College of Nursing (SCON), Senapati Bapat Road, Pune-411004

experience during the process of labour, her role in the child birthing process and the information regarding the intrapartum coping behaviour would probably make a positive physical and psychological impact on the postnatal mother. A quasi-experimental, multi-time series research study conducted by Krish J A in 2003, revealed a significant inverse relationship between maternal confidence for labor and fear of childbirth was found throughout the period of gestation.[4]

A qualitative analysis done by Ibach F et al on knowledge and expectations among 30 African women indicated, primigravidae were inadequately prepared for the experience of childbirth[5]. A study conducted in 2006 byMutiso SM et al to evaluate the birth preparedness and complication readiness among 394 antenatal clients in an antenatal clinic at Nairobi, Kenya, revealed that education and counseling on different aspects of birth preparedness was not given to all respondents. [6] A similar cross sectional descriptive study was conducted in Rewa district of MP, India, by DeokiNandan et al to assess birth preparedness and complication readiness intervention among 2022 respondents including Pre natal and post natal mothers and health care providers. The researchers concluded that the birth preparedness index of the study population was low (47.5%).[7] Rising cesarean sections among primigravidaeis another concern.[12,13,14]Mukherjee S N on rising cesarean section rate, it was quoted cesarean section on demand in absence of any specific risk are increasing. Inadequately informed women choose CS to avoid painful natural childbirth. [12][15]

Evidences show that childbirth preparation classes have the potential not only to increase pregnant women's intrapartum coping ability with labor pain but also to reduce stress during the processes of pregnancy and childbirth [16,17]

Midwives hold an important key to positive foeto-maternal care around the time of childbirth that will contribute to a good start for the baby and mother during the critical period of human life.[1]

Need for the study: During the investigators experience as a midwife, in the labour room it was observed that most of the time the primigravidae parturients were anxious, took more time to understand and follow the instructions given to them and unable to cope up with the normal labour.

Statement of problem: A study to assess the effect of child birth education on intrapartum coping behaviours of primiparous women in a selected maternity center of a tertiary level hospital in Pune.

Aim of the study: To compare the intrapartum coping behaviours of the primiparous women in intervention group who received the childbirth education developed by the investigator with the control group of primiparous women who received conventional antenatal health education.

Objectives of the study:

1. Identify the gaps in the existing knowledge of primigravidae women regarding childbirth preparedness.
2. Develop a childbirth education based on the assessed knowledge needs.
3. Assess the effect of childbirth education on intrapartum coping behaviours of primiparous women in the intervention group.
4. Assess the effect of conventional antenatal education on intrapartum coping behaviours of primiparous women in the control group.
5. Compare the intrapartum coping behaviours of primiparous women between intervention group and control group.

Research Study:

1. Sample 60 term primigravidae women
2. Intervention group n=30 :Imparted childbirth education in OPD
3. Control group n=30 :Conventional antenatal education received in OPD
4. Register of attendance maintained-Coding of each participant done
5. Outcome measurement done by observer using
6. Intra Partum Behavioural Observation Checklist in labour room
7. Coding data - cross checked
8. Data compilation, Analysis and Interpretation

Findings:

Socio demographic profile of the knowledge assessment sample under study: Majority (95%) of the women were in the reproductive age group of 18-25 years and among them 25% belonged to the teenage group. Maximum respondents (80%) hailed from joint families. Majority belonged to middle class (60%) and upper middle class families(35%).

Their educational status ranged from primary level till graduation. Many of them, 60% were educated upto higher secondary level and the rest combinely had completed primary and secondary level of education and only 5% were graduates. All the participants (100%) included in the study were housewives.

Sample characteristics as pet the existing knowledge of primigravidae women regarding childbirth preparedness: The information gathered indicated gross knowledge deficit regarding childbirth preparedness. The highlights of the findings are as given below.

Nobody was aware about the stages of labour and and the procedure of childbirth. Majority (75%) of women reported that they were unaware about bag of waters. Maximum (80%) were unaware about the approximate duration of labour in a first time mother. Few primigravidae were aware regarding the impending signs and symptoms of labour. Passage of blood/blood mixed vaginal discharge and commencement of labour pains were the signs, which got the maximum response whereas back pain and rupture of membranes as an impending sign of labour fetched the least of responses.

Majority (90%) of the women did not know the correct place and time of reporting for labour on or after commencement of labour process.Only a few women (20%) knew that labour pains were intermittent and progressive.

Most of the study population (55%) knew regarding examination of pregnant abdomen/uterus but very few (15%) were aware about digital vaginal examination as a kind of intrapartum assessment. Also, there were few primigravidae (20%) who were unaware about the types of intrapartum monitoring. Majority of women (75%) were unaware of the purpose of doing PV examination during labour. 10% out of 25% who knew the reason for performing a PV examination, had history of first trimester abortions.

Many (65%) women reported as having no knowledge and access to knowledge regarding birth preparedness. The sources of information from which the primigravidae women gained knowledge of childbirth were mainly through books/ magazines, friends and family members.

Though few women (35%) reported having information about birth preparation and process, only 5% among them opted for all aspects on child birth preparation and child birth process. When few of them (15%) reported their understanding of childbirth preparedness as financial preparedness for birth related expenditures, most of them (60%) understood it as physical and psychological preparation of a pregnant woman. 10% associated it with arrangement of a support person during labour whereas more than half of them(55%) linked it with preparation of a vehicle for transportation. Only few (5%) thought about arranging a blood donor and 10% related it to preparation of antenatal kit for hospital stay.

Nearly half of the assessment population had done a few preparations for childbirth, of which attendance for regular and essential antenatal checkups ranked high (75%), while a quarter of them had not done any child birth preparation.

Maximum (95%) women were unaware about certain breathing techniques that would help them to relax during labour and childbirth. Less than half of the assessment population (45%), was aware about the practice of episiotomy during childbirth.

Most of the primigravidae (95%) did not know the time of resuming first meal after childbirth, and the breast feeding practices were not popular among first time mothers.

Overall, it was found that majority of the primigravidae population (85%) had poor knowledge regarding childbirth preparation, and a few (15%) had average knowledge about childbirth preparation.

Sample characteristics according to the sociodemographic profile of the samples under study: The average education in the experimental group was morein the Intervention group (20% and 53.3% up to intermediate level and higher secondary level respectively against 56.6% from control group educated up to higher secondary level and 23.3% being graduates. Also, a few women (3.3%) from intervention group were illiterate.

Majority of the participants i.e. 96.6% of the intervention group and 86.6% of the control groups were housewives. The rest of the study population was reported to be self employed. Average income in the control group was higher than that reported in experimental the group. A minor percentage of 3.3% of the Intervention group and 13.3% of the control groups belonged lower socio economic strata.

Most of (63.3%) of the Intervention group and some (46.6%) of the control group hail from joint/ generation families while 36.6% of the Intervention group and 53.3% of the control groups belong to nuclear families.

On an average, participants in the experimental group were younger than those from the control group. 93.3% of the Intervention group and 76.6% of the control group were from the age group of 25-35 yrs. However it was seen that, 6.6% of each Intervention and the control group belonged to teenage group. Rest of the control group (16.6%) population belonged to elderly age group of beyond 35 years.

Description of Intrapartum Data: Women who underwent vaginal delivery without an episiotomy were more (30%) in intervention group than in control group (20%) whereas episiotomy rates were seen higher in control group (76.6%) than in Intervention group (60%). However incidence of vacuum extractions was same (3.3%) in both the groups.

Proportion of women who did not use any intrapartum analgesics was more (83.4%) in Intervention group than in control group (66.7%).Use of epidural anesthesia, however, was same (3.3%) between both the study groups.

Description of the stage wise intrapartum coping behaviours

1. Intrapartum coping behaviours in first stage of labour were better in the intervention group (mean- 69.06) than in control group (mean- 56.56).
2. The coping behaviours of the intervention group (mean- 20.33) in second stage was highly significant compared to control group (mean- 16.26)
3. The mean scores of the intervention group (mean- 9.16) in their third stage was also found more than that of control group (mean- 7.20 with a highly significant p value of less than 0.001.

Description of compliance to selected intrapartum coping behaviours: At the base-line, the compliance to intra partum instructions of the Intervention group (M = 9.5667, SD = 1.2228) was higher than that of the control group (M = 8.6333, SD = 2.2664), however, the difference was not statistically significant, (Mann-Whitney Z =1.621, p = 0.105.)

The compliance to intrapartum communication of the first time mothers with the labour room staff for the Intervention and control group was analyzed to be higher in the intervention group with a significant p value of 0.005.

The statistical analysis show a highly significant difference in the self carebehaviours of the intervention group (Mean scores of Intervention group-26.7.SD=4.457 and mean scores of control group=21.2.SD=3.942. Z=4.297)

The compliance to breathing relaxation was seen significantly high in intervention group than in control group (Intervention group mean scores 32.3667. SD=4.8386. Control group mean scores=24.1667. SD=5.91365. Z=4.607)

A significant difference existed inIntervention group's compliance to Physical preparation and self reporting (mean scores of intervention group= 42, mean scores of control group= 34.33. SD (intervention)= 6.280, SD (control) =8.809. Z=3.002)

Significant behavioural modification in women who were taught self care activities during labour. Mean scores for cooperation during per-vaginal examinations, periodically emptying bladder, having no bad breath, performing abdominal massage, and absence of dehydration were higher in intervention group than in control group with a significant p values for each.

Scores of intrapartum coping behaviours of primiparous women who received childbirth education: Primiparous women (40%) reported to have excellent intrapartum coping while (53%) had good coping. A few (7%) had averagely coping. No participant in the intervention group had poor coping.

Scores of intrapartum coping behaviours of primiparous women who received conventional antenatal education: No Participant from the control group had excellent intrapartum coping. Most of them (60%) had average coping and some of them (37%) were reported to have fairly good coping. Only 3% had poor intrapartum coping.

Comparison of the intrapartum coping behaviours of primiparous women between the study groups: There was highly significant difference in the intervention group's compliance to intra partum coping during periodic and single observation of intrapartum coping behaviours. (Total scores mean scores (trial) = 162.57 (control) = 130.77 SD (trial) =17.60 SD (control) =23.06 Z=4.734 P=<0.001).

Maximum women in the control group(25) reported good intrapartum coping scores in contrast to 11 women from control group. Similarly 5 women in the control group reported to low intrapartum coping scores against the 19 women from control group.There were neither any scores representing poor coping among women in trial group nor an excellent coping reported in control group. The difference is highly significant with a p value of <0.001.

Conclusions

There exists a gross knowledge deficit among primigravidaeregarding childbirth preparedness.The findings of this study indicated that the short term; need based childbirth educational intervention demonstrated a highly significant impact on the intrapartum coping behaviours of primiparous women.

Discussion of the Findings: Primiparae- 30 in the control group and 30 in the intervention group in were included. Most of the women were housewives with familyincome of above Rs.5000/per month. Many in the study groups had lower education levels and were younger i.e. below 25 yrs.

The intrapartum coping behaviours of the mothers of the intervention group who received CBE were significantly better than the control group. This result has rejected the null hypothesis H0 that there was a highly significant difference in the intrapartum coping behaviours among the intervention group and control group with a level of significance of 0.001.

Conclusion

The findings of this study indicate that the short term, need based childbirth educational intervention have highly significant impact on the intrapartum coping behaviours of primiparous women. The findings from this study contribute to the deep understanding of the effect of childbirth education classes that will be useful for the development of prenatal midwifery services.

Conflict of Interest: There is no conflict of interest that exist in the present study.

Abstract

Context: This study is aimed to analyse heavy metal content and antioxidant potential of three types of Jamun honey samples from Western Ghats of India. Ash, pH, and colour intensity were anlyased. Heavy metal analysis for Arsenic (As), Lead (Pb), chromium (Cr) and Mercury (Hg) were carried out using inductively coupled plasma - optical emission spectrometry (ICP-OES). Total polyphenol (TPC), total flavonoid content (TFC) and antioxidant assays such as 2, 2-diphenyl-1-picrylhydrazyl (DPPH), ferric reducing antioxidant power (FRAP) were performed. Comparative studies of Jamun honeys revealed strong correlation between TPC and TFC as significant radical scavenging activities. Colour values represented strong correlation with TPC and TFC at (r= 0.9) and FRAP at (r= 0.8) whereas a negative correlation with IC 50 values of DPPH at (r= -0.6) was observed.

Keywords: *Honey, Unifloral, Antioxidant, Heavy Metals.*

Introduction

Honey is a natural high energy source, carbohydrate food processed by honey bees[1]. In human history, honey is not only used as nutrient but also used as a drug delivery system in medicine. In recent years, industries utilize honey for cosmetic and drug production. Commercial advertisements have created the awareness of honey consumption amongst the human population[2]. Honey has enticed flavour, colour, aroma and texture largely due to the presence of volatile oils, aromatic acids, carotenoids, flavonoids and polyphenols. Because of this unique and complex nature, it exhibits some biological potentialsuch as antibacterial, anti-inflammatory, antiviral, antioxidant, and anticancer activities[3]. Studies have shown that physicochemical characteristics of honey depend predominantly on the quality, source of nectar, geographical region, and processing of honey [4]. The unifloral honey has majority of nectar from flower of a specific plant species and when compared with multifloral honey it exhibits a similar range of biological properties containing identical constituents in varying concentrations[5].

Honey does contain elements as minor constituent. Presence of metal in honey is largely based on elemental composition of the nectar with regards to its botanical origin, soil and geography of source plants. Honey can also be contaminated with heavy metals during packaging and processing or due to industrial and agriculture pollution. Due to recent increase in consumption of honey as nutraticals, it may set a base for heavy metal toxicity in population. India being a large consumer of honey there is still lack of information regarding heavy metal content of Indian honeys.[6, 7]

Unifloral Jamun honey samples were collected from mountain ranges of Western Ghats. Jamun is fruit from Jamun tree (*Syzygium cumini*) and so honey called as Jamun honey. The plant parts, i.e. bark, leaves, seeds and fruits are extensively studied for their antioxidant properties and used for the treatment of medicinal ailments such as constipation, diabetes, ringworm infection, pharyngitis, dermopathy [8]. Thus the nectar collected by bees to produce honey form this plant gives us the perspective to explore the physicochemical, heavy metal analysis and antioxidant potential of Jamun honey from Western Ghats India.

Materials and Method

Reagents and Instruments: Gallic acid, Quercetin, $FeSO_4.7H_2O$, F-C reagent (Folin Ciocalteu), DPPH, 2,4,6-Tris (2-pyridyl)-1,3,5-triazine (TPTZ) were purchased from Hi-Media Laboratories Pvt. Ltd. Methanol, Sodium carbonate, Ferric chloride, acetate buffer and dilute HCl, aluminium chloride, sodium nitrite and sodium hydroxideall chemicals are of analytical grade. UV spectrophotometer (SHIMADZU spectrophotometer UV-1800).

Honey samples: Collection and Preparation: Honey samples were collected during the year 2015-16 from honey hunters and apiaries of Ponda area (Goa state)(J-1), Pune (J-2) and Mahabaleshwar (Maharashtra state) (J-3) of Western Ghats of India. Collected samples werefiltered and stored in air tight containers at room temperature under hygienic conditions until analysis.

Melissopalynological Analysis: In the present study, based on the recommendations of International Commission for Bee – Botany[9] honey samples which had pollen count of similar plant species (*Syzygium cumini*) with more than 45% was considered as unifloral Jamun honeys.

Physical Analysis: Ash content and pH analysis was performed according to official reported analysis method: AOAC 1990 guidelines[10]. Colour intensity was estimated with previously mentioned method of Beretta Get al. [11]

Phytochemical estimation:

Total polyphenol content: Total polyphenol content was determined by F-C reagent methodin 96 well plateeach well had 150 µL solution containing standard or 10% honey solution, freshly prepared F-C reagent and 7.5% of sodium carbonate. The platewas incubated in dark for 30min and absorbance was measured at 630nm[12]. Gallic acid (5 -160 µg/ml) was used as standard and results were expressed as mg Gallic acid equivalents (GAE) per 100gm of honey.

Total flavonoid content: Total flavonoid content was estimated using aluminium chloride method[13]. The Quercetin (12.5-800 µg/ml) was used as standard and results were expressed as mg of Quercetin equivalents (QE) per 100gm of honey.

Antioxidant activity:

2, 2-diphenyl-1-picrylhydrazyl (DPPH) assay

The free radical scavenging ability of honey samples was determined according to the method of Brand-Williams et al.,[14] with required modifications. Honey samples of 100µL were allowed to react with 1900µL of the DPPH solution for 1h. The reaction mixture was read at 517nm and the standard Gallic acid concentration was ranging from (200-6.25 µg/ml). The results were taken in triplicates and% of radical scavenging activity was expressed by using the formula:

$$\% \text{ of Radical Scavenging Activity} = [Abs_{(blank)} - Abs_{(sample\ Honey)}/Abs_{(blank)}] \times 100$$

Ferric reducing antioxidant power (FRAP) assay: The assay was performed with FRAP reagent based with minor modifications[15]. Briefly, reaction solution contained 200µl of 10% honey sample, 1800 µl of FRAP reagent. The solution was incubated in dark condition for 10min at room temperature and absorbance was measured at 593 nm. $FeSO_4.7H_2O$ (100-1000 µM) was used as assay standard for calibration per 100gm of honey and results were expressed in triplicates as micromoles of ferrous equivalents (µM Fe (II)) of per gram honey solution.

Heavy metal analysis: Honey sample digestion was carried out in a microwave assisted extraction system Milestone START D (MilistoneSrl., Italy). The digested samples were quantitatively analyzed for heavy metals such as Arsenic, Lead, chromium and Mercury in an Inductivity Coupled Plasma–Optical Emission Spectrometer (iCAP 6300 Duo, Thermo fisher Scientific, Cambridge, England) with dual configuration (axial and radial) and iTEVA (version 2.8.0.97) operational software. ICP multi-element standard solution (CertiPUR, Merck) was used for preparation of calibration solutions. Yttrium was used as internal standard[16].

Statistical Analysis: Analyses were made in triplicate and data obtained are expressed as the mean ± standard deviations. Comparison of inter sample concentrations for study parameters were tested using Kruskal Wallis ANOVA. While, correlations were established using Pearson's correlation coefficient (r) in bivariate linear correlations ($p<0.01$). These correlations were analysed using Graph pad prism version 7 and SPSS software with statistical significance set at $p < 0.05$.

Findings and Discussion

To our knowledge, it's the first study reporting physicochemical, heavy metal analysis and antioxidant potential of Indian Jamun honey from Western Ghats of India. The Melissopalynological analysis depicts maximum percentage of pollen grains from the Jamun tree (*Syzygium cumini*)in all three honey samples [J-1(94.6%), J-2(67%), and J-3(92.4%)] collected from the Western Ghats of India. The findings for ash content, pH and colour intensity are presented in Table 1. The ash content of Jamun honey samples varies from (0.14% -0.42%) which is according to the reference range of <0.6% [17]. The ash content mainly depends on the floral origin, which represents the mineral and trace elements content. The pH range of the Jamun honey in the present study was found to be acidic i.e., (4.17 to 4.48) and are comparable with ranges of the Tualang and Manuka honey[18]. Colour of honey samples indicates that Jamun honey (J-3) with dark brown in colour has highest colour intensity along with higher level of polyphenol and flavonoid content than the (J-2), (J-1) honey. Therefore, the higher colour intensity specifies the maximum presence of MRPs, phenolic and flavonoid compounds which are previously established to contribute for antioxidant properties[19].

Table 1: Physical characters, Colour intensity of Jamun honey samples from Western Ghats of India.

Sample	pH	Ash (%)	Colour intensity(450nm)
J-1	4.17	0.42	0.530±0.24
J-2	4.29	0.27	0.339±0.03
J-3	4.48	0.14	0.836±0.43

Phytochemical estimation: The total polyphenol content in the tested Jamun honey sample ranges between 31.67±0.00 mg to 77.90±18.73GAE/100gm. J-3 honey sample was observed with a significant difference ($p<0.05$) in terms of polyphenol and flavonoid content as compared to other two honey samples (Fig. 1). Supporting this study observations, several earlier studies have been reported for polyphenol content in different honey samples such as Tualang (251.7 ± 7.9 mg GAE/Kg)[20]. On the other hand, total flavonoid content ranges between 25.84±7.83 to 51.20±16.35 mg of QE/100 gm which is comparable to Algerian honey (54.23 ± 0.62 mg catechin/kg)[21]. Previous research have presented that polyphenol and flavonoid content depends on floral source and their geographical origin[22]. Honey sample from Mahabaleshwar region (J-3) has higher polyphenol and flavonoids which is directly accountable for higher antioxidant potential.

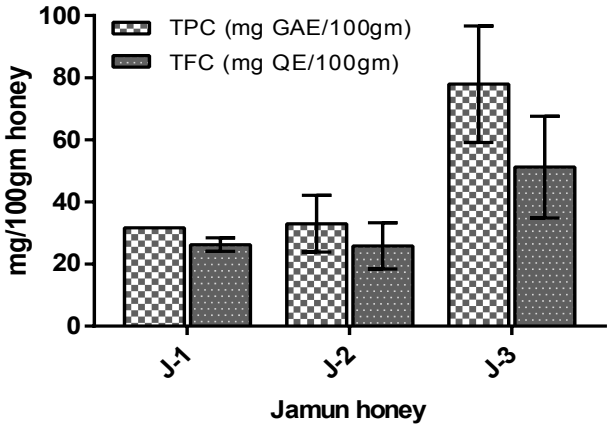

Figure 1. Phytochemical estimation of Jamun honey samples

Antioxidant Assays: DPPH investigates the hydrogen /electron donating capacity of samples and is reduced in presence of an antioxidant molecule. The current study represents DPPH IC 50 values ranging from 27.69±0.61 to 46.95±2.74 mg/ml (Fig 2). The J-3 honey displayed the significant ($p < 0.05$) highest level antioxidant potential at lower concentration when

compared to other honey samples and is comparable to DPPH activity for Tualang honey (41.30%)[20], Algerian honey (44.55%)[21], Indian honey samples (>50%)[23].

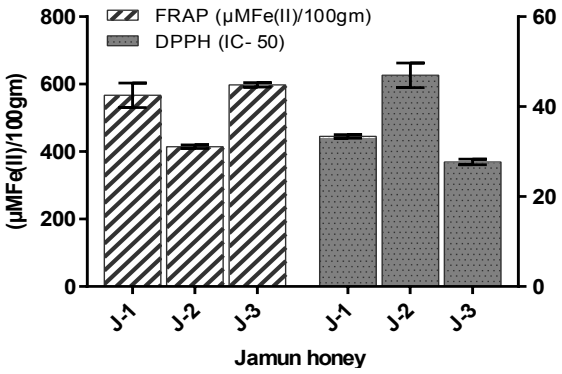

Figure 2. Antioxidant assay of Jamun honey samples

Ferric reducing antioxidant power FRAP assay is based on the ability of analyte towards reducing the ferric to a ferrous couple (Fe^{+3}/Fe^{+2}). The mean value of the Jamun honey for the assay was in the range of 410±0.01 to 600±0.01 µMFe (II)/100gm. As assumed,J-3 exhibited the significantly ($p< 0.05$) quantity of antioxidant activity when compared with J-1 and J-2 (Fig 2). The previous documented FRAP value of other honey samples from different regions are: Malaysian Tualang honey (576.91 ± 0.64 µMFe (II)/100 g)[20], Sudanese honey (567.8±0.6-1340.2±8.6Mm)[24].

Heavy metal analysis: Heavy metals such as Mercury, Chromium and Lead were below the detection limit in all honey samples only Arsenic was detected in Mahabaleshwar (J-3) honey with 0.55±0.42 ppm. Results are comparable to other studies[6, 7] and indicate consumption of these Jamun honey may have no toxic effects.

Correlation: Colour, Phytochemical, and Antioxidant Properties: The correlation has been summarized in Table 2. A very high positive correlation was detected between polyphenols and flavonoid content (r = 0.9) and high negative correlation with DPPH at (r = -0.7) indicating high radical scavenging activity by both phytochemicals in the sample. A moderate positive correlation between FRAP assay and polyphenols and flavonoid content at (r= 0.6). Correlation observed in the present study revealed an overview that Jamun honey with dark colour possesses high amount of TPC and TFC, which aids in free radical scavenging activity.

Table 2: Pearson Correlation amongst Total Polyphenol content (TPC), Total flavonoid content (TFC), antiradical power (DPPH), FRAP values, honey colour, pH.

	TPC	TFC	DPPH	FRAP	COLOUR	pH
TPC	1					
TFC	0.999**					
DPPH	-0.710	-0.7373				
FRAP	0.610*	0.641*	-0.991			
COLOUR	0.910**	0.926**	-0.937	0.883**		
pH	0.999**	0.997**	-0.687	0.585*	0.896**	1

**Correlation is significant at the 0.01 level;*correlation is significant at the 0.05 level.

Conclusion

Since, the Western Ghats of India is rich in flora and fauna, the honey obtained from this geographical distribution show a good antioxidant potential with below detection limit of heavy metals. Present study signifies that unifloral Jamun honey has higher antioxidant with medicinal and biological properties associated with high grade of nutritional value for health benefits of the population. Herbal chemist is recommended to specifically use Jamun honey for their drug preparations and observe the effects which help in promoting local honey consumption by consumers. Study with large sample size and other biological aspects of this indigenous honey are to be explored.

Short Term Effect of Isolytic Contraction on Hamstring Flexibility in Asymptomatic Subjects with Hamstring Tightness: A Randomised Controlled Trial

Shubham Kamble[1], Radhika Chintamani[2], Vaishali Jagtap[3]

[1]BPTh (Intern), [2]Assistant Professor, Department of Orthopaedic Manual Therapy, [3]Assistant Professor, Department of Musculoskeletal Sciences, Krishna Institute of Medical Sciences Deemed to be University, Karad, Maharashtra, India

Abstract

Aim: To Study short term effect of Isolytic contraction on Hamstring flexibility in asymptomatic subjects with hamstring tightness with respect to active knee extension test, Straight Leg Raise test and Lumbar Lordosis Index.

Objectives: The Objectives of the study are as follows:(1) To find effect of Isolytic contraction on hamstring flexibility. (2) To find effect of Isolytic contraction on static and dynamic hamstring flexibility.

Method: This study was conducted for the duration of 6 months. 300 subjects of age 20 to 40 years were screened out of which 276 subjects were selected for the study depending on the inclusive and exclusive criteria. Asymptomatic subjects with AKT <20 degree in the age group of 20 to 40 years were included in the study. These subjects were then divided into 2 groups Pre-treatment assessment and Post-treatment assessment were recorded.

Results: Statistically significant differences in the AKT, SLR, and LI were seen between the two groups. AKT (Right) It indicated that it was extremely significant ($p < 0.0001$) and ($p = 0.0079$) in the interventional group subjects. AKT (Left) It indicated that it was extremely significant ($p < 0.0001$) and ($p = 0.6384$) in the interventional group subjects. SLR (Right) It indicated that it was extremely significant ($p < 0.0001$) and ($p = 0.1199$) in the interventional group subjects. SLR (Right) It indicated that it was extremely significant ($p < 0.0001$) and ($p = 0.2819$) in the interventional group subjects. Intra group analysis of these values within the group was done using Wilcoxon test and the Inter group analysis between the groups was done by Mann-Whitney test.

Conclusion: The study results concluded that there was a significant result using isolytic contraction on hamstring flexibility in asymptomatic subjects having hamstring tightness with respect to Active knee extension test, Straight leg raise test and Lumbar lordosis index.

Introduction

Hamstring tightness is one of the most common musculoskeletal problem faced by individuals. Many studies had found out that maximum 70% of adult population was suffering with hamstring tightness and mostly it causes with the age group 20-40 years.

[1]Tightness in hamstring muscles leads to hamstring injuries and hamstring injuries are the most common type of injury among individuals. These injuries are slow to recover, make high health expenditure and decrease the performance level of the individual. [1]

Many of the etiologies have found that hamstring tightness gives rises to numerous numbers of musculoskeletal problem. "Inability to extend the knee completely when the hip is flexed accompanied by discomfort or pain along the posterior thigh and/or knee is usually attributed to hamstring muscle tightness". Clinically, hamstring muscle length is not measured directly but instead, it is represented indirectly by angular measurements of unilateral hip flexion with the knee extended. Hamstring muscle tightness is defined as Knee Extension Angle (KEA) greater than 20 degrees where KEA is the degree of knee flexion from terminal knee extension. [1],[3]

Hamstring Tightness: Muscle tightness is caused by a decrease in the ability of the muscle to deform, resulting in a decrease in the range of motion at the joint on which it acts. Inability to achieve greater than 160° of knee extension with hip at 90° of flexion is considered as hamstring tightness. Hamstring tightness leads to hamstring injuries and hamstring injuries are the most common type of injury. These injuries are slow to recover, make high health expenditure and decrease the performance level of the individual.[3]

Method

1. **Type of Study:** Experimental Study
2. **Design of Study:** Randomized Control Trial
3. **Sampling Method:** Simple Random Sampling
4. **Study Duration:** 6 months
5. **Place of study:** Krishna Hospital, Physiotherapy Department
6. **Sample Size:** 276
7. **Target Population:** Both Male and Female With Positive Active Knee Extension Less Than 20 Degree

Criterion of the Study: Inclusion Criteria

1. Asymptomatic subjects
2. AKT<20 degree
3. Age: 20 to 40 years

Exclusion Criteria:

1. Previous Hamstring injury
2. History of low back ache
3. Open Wound on posterior aspect of thigh
4. Osteoporosis of lumbar spine, hip and knee joint
5. Soft tissue injury relating to hamstring and low back region
6. Hamstring Strain both acute and chronic
7. Fractures around lumbar spine, hip and knee

Procedure: An approval for the study was obtained from the Protocol committee and institutional Ethical Committee of KIMSDU. This study was conducted for the duration of 6 months. 300 subjects of age 20 to 40 years were screened out of which 276 subjects were selected for the study depending on the inclusive and exclusive criteria. Asymptomatic subjects with AKT <20 degree in the age group of 20 to 40 years were included in the study. The study was undertaken after obtaining the approval of Protocol committee and the Institutional Ethical committee of KIMSDTU. These subjects were then divided into 2 groups by where the Type of Study was Experimental study, Design of Study was Randomized Control Trial and Sampling Method was Simple random sampling Pre-treatment assessment and Post-treatment assessment were recorded. Subjects in Group A were given Isolytic contraction + HMP+ Passive manual stretching intervention while subjects in Group B were given conventional treatment. i.e. HMP+ Passive Manual stretching. Where isolytic contraction was performed with a rapid movement with 3 sets of 15 repetition. And Passive manual stretching, 3 sets were given with a hold time of 15 sec. Pre-treatment and Post treatment Assessment with the help of outcome measure of SLR, AKT and lumbar lordosis index were taken and statistics was done. consent of all the participants was taken.

Results

A. Active knee extension test: Active knee extension test Comparison of pre-intervention and post-intervention within the group (Right and Left Side).

Table No. 1

	Side	Pre	Post	P value	Inference
Group A	Right	31.768±6.858	44.70±11.254	<0.0001	Extremely significant
Group B	Right	31.299±5,455	35.86±5.294	<0.0001	Extremely significant
Group A	Left	33.78±6.470	51.036±20.020	<0.0001	Extremely significant
Group B	Left	33.45±4.774	38.47±4.892	<0.0001	Extremely significant

Table No. 2: Active knee extension test Comparison of pre and post AKT Between the group (Right and Left Side)

	Side	Pre	Post
Group A	Right	31.768±6.858	44.702±11.254
Group B	Right	31.29±5.455	35.868±5.294
P value	Right	0.0079	<0.0001
Inference	Right	Not significant	Extremely significant
Group A	Left	33.783±6.470	51.036±20.020
Group B	Left	33.45±4.774	38.474±4.892
P value	Left	0.6384	<0.0001
Inference	Left	Not significant	Extremely significant

Table No. 3: B. Straight Leg Raise: Comparison of Pre-Interventional and Post Interventional SLR within the group (Right and Left Side)

	Side	Pre	Post	P value	Inference
Group A	Right	51.1231±11.191	71.28±12.477	<0.0001	Extremely significant
Group B	Right	53.014±8.755	58.48±8.736	<0.0001	Extremely significant
Group A	Left	53.52±13.945	73.405±13.320	<0.0001	Extremely significant
Group B	Left	55.189±11.711	60.810±11.457	<0.0001	Extremely significant

Table No. 4: Comparison of Pre-Pre and Post-Post SLR between the group (Right and Left Side)

	Side	Pre	Post
Group A	Right	51.123±11.191	71.282±12.477
Group B	Right	53.014±8.755	58.481±8.735
P value	Right	0.1199	<0.0001
Inference	Right	Not significant	Extremely significant
Group A	Left	53.521±13.945	73.405±13.320
Group B	Left	55.189±11.711	60.810±11.457
P value	Left	0.2819	<0.0001
Inference	Left	Not significant	Extremely significant

Table No. 5: C.Lumbar Lordosis Index Comparison of Pre and post LI within the group

	Lumbar Lordosis index		P value	inference
Group A	Pre	Post		
	56.90±14.568	44.22±13.408	<0.0001	Extremely significant
Group B	51.97±10.987	48.41±11.042	<0.0001	Extremely Significant

Table No. 6: Comparison of Pre-Pre and Post-Post of LI in between the group.

	Pre	Post
Group A	56.90±14.568	44.22±13.408
Group B	51.97±10.987	48.41±11.042
P value	0.0017	0.0050
Inference	Very significant	Very significant

Discussion

The current study is aimed to find short term effect of isolytic contraction on hamstring flexibility in asymptomatic subjects with hamstring tightness using a randomized control trial. 276 subjects were selected based on the inclusion and exclusion criteria and were allotted in 2 groups. Objectives of this study were to find whether there is any effect of isolytic contraction on hamstring flexibility, because in general the subjects with hamstring tightness can lead to Low back Pain, Limited hamstring flexibility, Risk of Hamstring strain, Poor core stability, Increased lordosis, Increased Fatigue, Tight hip flexors and many more musculoskeletal problems which may lead to limitation in daily activity may it be athlete or old individual. [5]

Prevalence of Hamstring tightness was taken into consideration, according to previous studies conducted, concluded that the age of 20 to 30 has been the most population having tight hamstring. According to study 40.17% were the male population affected.[1] So considering the population a total of 300 sample were screened and depending on the inclusive and exclusive criteria of the study 276 sample were included in the study.

According to previous studies of Ballantyne F, Fryer G, McLaughlin P; 2003. The Effect of Muscle Energy Technique on Hamstring Extensibility. The study concluded that 'There is significant increase in hamstring extensibility following MET, where Muscle energy technique produced an immediate increase in passive knee extension. This observed change in range of motion is possibly due to an increased tolerance to stretch as there was no evidence of visco-elastic change. Results showed A significant increase in range of motion at the knee ($p< 0.019$) following a single application of MET to the experimental group. No change was observed in the control group.[11] When an identical torque was applied to the hamstring both before and after the MET, no significant difference in range of motion of the knee was found in the experimental group. Where as compared to isolytic contraction is proven to be more effective than then the controlled group with the results showing extremely significance because the physiological evidence shows increased in tone, stretching and repetitive work on antagonist muscle increases the flexibility with no injury. [11]

Similarly, Sonal et al; 2016. Comparison between Post Isometric Relaxation and Reciprocal Inhibition maneuvers on hamstring flexibility in young healthy adults. The study concluded that both PIR and RI are effective techniques to improve hamstring flexibility is better and effective technique as compared to RI. As per the present study isolytic contraction is proven to be more effective than then the controlled group with the results showing extremely. [21]

Gayle Silveira, Mark Sayers, Gordon Waddington – Department of Health, Design and Science, University of Canberra, Effect of dynamic versus static stretching in the warm-up on hamstring flexibility, March 3, 2011, the intervention study comparing the effects of static and dynamic stretching routines in the warm-up on hamstring flexibility demonstrated that dynamic stretching enhanced static as well as dynamic flexibility. Static stretching on the other hand did not have an impact on dynamic flexibility. This has implications for the use of static stretching in the warm-up for dynamic sport. The role of static stretching for injury prevention in dynamic sport is also being questioned.[14]

[1]Dr. Shweta P. Pachpute [2]Nancy Patel [3]Dr. Seema Saini, EFFECT OF STATIC STRETCHING ON STRENGTH OF HAMSTRING MUSCLE, Static stretching showed significant change in pre and post RM of hamstring muscle and active knee extension test. There was significant improvement of hamstring muscles flexibility and strength after giving static stretching in female population. So, it is possible that females who are unable to participate in traditional strength training activities may be able to experience gains through static stretching. As mentioned in the above study. [22]

Considering the above 2 literatures of Dr Shweta she concluded that static stretching is more effective whereas Gayle Silveira concluded that Dynamic stretching shows a great difference of impact that can increase hamstring flexibility than static, But in the present study where in the group B it shows passive stretching is less effective than the control group because, where comparing it with isolytic contraction, it is more effective than dynamic

as well as static stretching. According to the outcome measure.

The present study presents the subject of 276 sample were dived into 2 groups Group A and Group B. subjects were given explanation what subject is going to receive and what benefits and its effects are, the subjects were asked to sign a consent form, Treatment for both the groups was started 2 months prior Group A was given HMP, Passive Static Stretching and Isolytic contraction and Group B was given HMP and Passive Static Stretching. Range of Motion, Straight Leg Raise test and Lumbar Lordosis Index was assessed after the treatment and before the treatment. Pre-Treatment and Post Treatment Assessments was done for the comparative study between these 2 groups. Reposes will be recorded and results were seen to be extremely significant. As the mechanism responsible for increasing the hamstring flexibility is proven to be effective after hot moist pack the isolytic contraction on the antagonist muscle helps in lengthening the muscle as well as allows the muscle to tone. Bidirectionally support the tighten hamstring which gives a flexible movement to the muscle and increases flexibility. [3], [8]

Conclusion

The present study provided evidence to support the use isolytic contraction on hamstring flexibility in asymptomatic subjects having hamstring tightness. Statistically there was extremely significant difference in both the values showing significantly more improvement in subjects of Group A when compared to subjects in Group B, hence it can be stated Short term effect of isolytic contraction in hamstring flexibility in asymptomatic subjects with hamstring tightness has proven to be effective extremely significant. The authors do not have any conflict of interests.

Conflict of Interest: The author declares that there are no conflicts of interest concerning the content of the present study.

Funding: The study was funded by Krishna Institute of Medical Sciences Deemed to be University, Karad.

Ethical Clearance: The study was approved by Institutional Ethics Committee, KIMSDU.

Abstract

The aim of this study was to assess the level of salivary L-Fucose and Heat Shock Protein 70 in subjects in subjects with Oral Potentially Malignant Disorders and Oral Cancer.

Method & Results: The study was done among 90 subjects - 30 healthy subjects, 30 subjects with Oral Potentially Malignant Disorders and 30 subjects with Oral Cancer. Saliva samples were collected and the levels of L-Fucose and HSP-70 were determined. Data obtained was analyzed using ANOVA test for the comparison between the groups. Post hoc tukey`s analysis was used for comparing the study groups to the control group.The levels of L-Fucose and HSP-70 in saliva were increased significantly in subjects with Oral potentially malignant disorders and Oral Cancer in comparison to the healthy subjects.

Conclusion: Elevated levels of HSP 70 and L-fucose in saliva in oral potentially malignant disorders and oral cancer indicate their usefulness as biomarkers for early prediction.

Keywords: *Saliva, Oral Cancer, HSP 70, L fucose*

Introduction

On a global scale, cancers of the lip, oral cavity and the pharyngeal regions were estimated to be accountable for 529,500 incident cases and 292,300 deaths in 2012, thus making it responsible for approximately 3.8% of all cancers and 3.6% of deaths.[1]According to global reports, cancers of the oral cavity region are grouped and together represent the 6th most common form of cancer in the world.[2] Oral cancer is generally detected in the advanced stages, regardless of the accessibility to the oral cavity during clinical examination, the commonest reason being initial misdiagnosis and negligence of the patient or the treating professional, apparently reducing the survival in spite of therapeutic measures.[3] Squamous Cell Carcinoma's account to nearly 90% of tumors in the oral cavity, with adenocarcinoma/minor salivary tumors make up 5%, and 2% each with verrucous carcinoma and lymphoma 2% . The rest are unusual sarcomas or odontogenic tumours.[4]

Heat shock protein–70(HSP70) is present in the body and body fluids like blood, lymph, spinal fluid and saliva. They are categorized as intracellular HSP70

(iHSP70) and extraellular HSP70 (eHSP70). eHSP70 activates the production of pro-inflammatory cytokines via binding with toll-like receptors (TLR)-2 and TLR-4, causing inflammation.[5,6]In the oral cavity, eHSP70 plays the part of mucosal defense which includes entrapping, agglutinating, opsonization of bacteria, and inhibition of pathogenic adhesion to the mucosal surface.[7] HSP70prevent apoptosis due to direct physical interaction with apoptotic molecules, which are also overexpressed in many tumor cells.[8]

Fucose is a monosccharide which is a usual constituent of many N and O-linked glycans and glycolipids elaborated by the mammalian cells.[9]The existing literatures about the levels of L-Fucose activity and HSP 70 in saliva is scarce. Thus, the information obtained from the study could be useful in determining L - Fucose as a salivary biomarker in the diagnosis of oral potentially malignant disorders and oral cancer. It would also be useful in determining the association of salivary HSP70 with oral potentially malignant disorders and oral cancer.

Material and Method

The present study is an observational study. After obtaining ethical clearance (Cert. No: ABSM/ EC13/2016) by the institution, the participants were provided with a written informed consent before data collection. The study sample comprised of 90 subjects in the age group of 20–60 years who were divided into 3 groups of 30 each.

Control Group : 30 healthy subjects without any oral lesions

Study Group 1: 30 subjects with oral potentially malignant disorders

Study Group 2: 30 subjects with oral cancer.

Method of Collection of Data: The study was conducted for a period of 2 years from 2016-2018. Informed consent was obtained from the patients included in the study along with recording of detailed case history and thorough examination of the oral cavity.

Saliva Collection: The subjects were asked not to consume any food 2 hours prior to the collection of saliva.[10] Following a mouth rinse, they were asked to sit with their head tilted forward and asked not to speak or swallow any saliva. They were then asked to spit into a sterile container every minute for 8-10 minutes. The collection of saliva was limited to the hours between 9:00 A.M and 11:00 A.M to minimize diurnal variation.

Heat Shock Protein 70 (Hsp70) Estimation: The estimation of HSP 70 in Saliva was done using ELISA kit method, procured from Hysel India Pvt Ltd. This kit (Bioassay Technology Laboratory Cat.No-E1813Hu) utilized enzyme-linked immune sorbent assay (ELISA) based on the Biotin double antibody sandwich technology for the purpose of assaying the Human Heat shock protein 70 (HSP70). Heat shock protein 70 (HSP70) was added to the wells, which are pre-coated with Heat shock protein 70(HSP70) monoclonal antibody and then incubated. After this step, anti HSP70 antibodies labelled with biotin were added to unite with streptavidin-HRP, which formed an immune complex. Unbound enzymes were removed after incubation and washing. Substrate A and B were added. Then the solution turned blue and changed into yellow with the effect of acid. The shades of solution and the concentration of Human Heat shock protein 70 (HSP70) were positively correlated.

Estimation of L Fucose: The estimation of L-Fucose was done based on the method of Winzler.[11]Fucose is a methyl pentose which is present in the glycoproteins. The assay can be done by dissolving ethanol precipitated proteins of the serum in alkali, heating with sulphuric acid and then determiningthe colour by adding cysteine. The colour production by hexoses under the above conditions is rectified by determination of absorbance at two wavelengths.

Findings: The present study was done to evaluate the levels of HSP-70 and L-fucose in saliva of oral potentially malignant disorders and oral cancer. The data collected was entered into Microsoft Excel spreadsheet and analyzed SPSS 20.0 from IBM incorporated.

The mean salivary HSP-70 levels in the control group was 2.87ng/ml, while the mean salivary HSP-70 levels in Study group 1 was 4.48ng/ml and 5.23ng/ml in Study group 2. (TABLE 1). On comparing salivary HSP-70 levels of Control Group (2.87ng/ml) and Study Group I (4.48ng/ml), difference was statistically significant ($p<0.001$). Similarly, when salivaryHSP-70 levels of control group were compared with levels of study Group II (5.23 ng/ml),significant differences were obtained ($p<0.001$). When a statistical comparisonbetween salivary levels of HSP-70 levels of study group I and study group II was done, significant differences were obtained ($p<0.001$). (TABLE NO.2 & 3)

The mean salivary L-Fucose levels in the control group was 18.27 mg/dl, while the mean salivary HSP-70 levels in Study group 1 was 23.26mg/dl and 27.61 mg/dl in Study group 2. (TABLE 1). On comparing salivary L-Fucose levels of Control Group (18.27mg/dl) and Study Group I (23.26mg/dl), difference was statistically significant (p<0.001). Similarly when salivary L-fucose levels of control group were compared with levels of study Group II (27.61 mg/dl), significant differences were obtained (p<0.001). When a statistical comparison between salivary levels of L-fucose levels of study group I and study group II was done, significant differences were obtained (p<0.001). (Table No. 2 & 3).

Discussion

Human saliva is a clear, slightly acidic (pH=6.0-7.0) biological fluid comprising of a mixture of secretions from parotid, submandibular, sublingual glands, the minor glands beneath the oral mucosa and gingival crevicular fluid.[12]From a Salivary specimen, multiple samples can be collected from the same individual at the optimum time for the purpose of diagnostic data.[13]It is now gained recognition as having a chief role in various biomedical basic and clinical areas.[14]Saliva contains an array of analytes like protein, mRNA and DNA, and can be used as a biological marker for translation and clinical applications.[15]

The total amount of protein in whole saliva ranges between 0.5 to 3 mg/ml.[16]Saliva contains Heat Shock Proteins like HSP 60, 70 and 90.[17] HSP 70 has crucial extracellular actions as noticeable from experiments involving exogenous HSP 70 administration to human promonocyte cells prior to tumor necrosis factor-alpha (TNF-α) exposure where the numbers of apoptotic and necrotic cells were reduced significantly. HSP 70 which is present in saliva involves passive transport from blood serum.[18]

In the present study, the salivary HSP 70 levels in Oral potentially malignant disorders had increased significantly on comparison with controls. Though the literature on saliva pertaining to HSP 70 is scarce, studies have been conducted in serum and in tissues, which have been subjected to immunohistochemistry. NJ Mary et al conducted that HSP 70 levels in serum increased significantly in oral leukoplakia on comparison with the controls.[19]Heat shock proteins are the primitive defense system in all living organisms. They are a class of functionally related proteins which increase expression in cells when exposed to increased temperature or stresses like infection, irradiation, ethanol, oxidants and heavy metals.[19,20,21]

Patil et al, in their study which examined tissues of leukoplakia subjected immunofluorescence along with controls, proved that there was an increase in the expression of HSP 70 in leukoplakia.[22]As the grade of dysplasia increased, the intensity of staining also increased thus indicating that over expression of HSP 70 occurred during oral carcinogenesis, concluding that an overexpression of HSP 70 could be a marker of epithelial dysplasia.[22] Similar results were seen in our study, where saliva was analyzed for HSP 70 levels. HSP 70 is secreted in saliva, the major route being the passive transport from blood serum or salivary gland cells.[18]

In the present study, there was significant increase in the levels of HSP 70 in oral cancer when compared to controls. This was similar to the study done by Hegde et al, where an increased level of salivary HSP 70 was found in patients who were undergoing radiotherapy for head and neck cancer.[23] Heat shock factor 1, a transcription factor is responsible for maintaining the expression of HSP 70. HSP 70 imparts thermo tolerance and protein folding during post translation import into the mitochondria. It also prevents proteins which are denatured partially from aggregation, allowing unfolding during stress and thermal stress.[24]

In the present study, the salivary L-fucose levels were increased in oral potentially malignant conditions and oral cancer on comparison with the controls. This has been in accordance to the study conducted by Pradeep et al.[25]Fucose is a monosaccharide.[26]The universal characteristic of cancer is the unusual glycosylation. The addition of L-fucose at the terminal end of the oligosaccharide, called fucosylation mediates several biological functions. By modulating their surface to increase fucosylation, tumor cells cause several abnormal characteristics like decreased adhesion and uncontrolled tumor growth.[26]

Saliva is a biological fluid which is clinically informative and is useful for novel approaches to clinical and laboratory diagnosis, management, monitoring and prognosis of patients with oral and systemic diseases.[14] Hence our study highlights the significance of saliva as a non-invasive diagnostic tool measuring the levels of salivary HSP 70 and L-fucose in oral potentially malignant disorders and oral cancer.

Conclusion

Elevated levels of HSP 70 and L-fucose in saliva in oral potentially malignant disorders and oral cancer indicate their usefulness as biomarkers in the early prediction. This study also establishes the significance of saliva as a non-invasive diagnostic tool, where even the presence of small quantities of such biomarkers can be detected. More such salivary studies should be undertaken on a larger scale to establish the efficiency of both HSP 70 and L fucose as biomarkers.

Knowledge Attitude and Practices of Biomedical Waste Management among Dental Practioners in Karad City Maharashtra, India

Surabhi Mahajan[1], Shiva kumar K.M.[2], Vidya Kadashetti[3]

[1]Intern, Public Health Dentistry, [2]Professor & Head, Public Health Dentistry, [3]Assistant Professor, Oral Pathology & Microbiology, Forensic Odontology, School of Dental Sciences, Krishna Institute of Medical Sciences Deemed to be University, Malkapur, Karad, Satara (Dist.), Maharashtra, India

Abstract

Introduction: Biomedical waste is generated routinely in high amounts in the dental office, the correct disposal of which bears importance to the dentist, staff and healthcare workers. This is the first of its kind study in the city of Karad which will provide an important insight into the proper method and knowledge of disposal of health care waste by the dental practitioners. The application of this study will be in accessing the legal necessity and social responsibility of the healthcare personnel's in the effective management of biomedical waste.

Materials and Method: The study population included 100 private practitioners in Karad City, Maharashtra. A self-administered questionnaire was distributed to assess the knowledge, attitude and practices regarding dental waste management. Descriptive statistics was used to summarize the results.

Results: Out of 100 study participants, 73 (73%) were males and 27 (27%) were females. The maximum number of participants belonged to the age group of 34-38 years (29%). Undergraduate qualification was more (80%) and 43% participants had an experience of 0-5 years. Chi-square analysis showed a highly significant association between participant who attended continuing dental education (CDE) program and their practice ofdental waste management.

Conclusion: Lack of knowledge and professional training in disposal of biomedical waste becomes a direct threat to the humans as well as the environment. CDE programs would help bring about a change in the management of healthcare waste.

Keywords: *Biomedical waste, dentist, hospital waste.*

Introduction

The health care sector produces a huge amount of biomedical waste in the course of curing health problems. The management of hospital waste or biomedical waste is considered as an important aspect to avoid various hazards to the humans and environment. Since this waste keeps generating continuously, it is the legal necessity and social responsibility of every healthcare professional to meticulously segregate and dispose the waste.[1] Biomedical waste means any waste, which is generated during the diagnosis, treatment and immunization of human beings or in research activities pertaining thereto or in the production or testing of biological, and including categories mentioned in Schedule 1 of the Government of India's Biomedical Waste (Management and Handling) Rules 1998.[2]

Corresponding Author:
Dr. K.M. Shivakumar

e-mail: shivakumarkm1@gmail.com

On an average per day per bed, 0.5-2 kg waste is generated in India. Annually 0.33 million tons of hospital waste is generated in India. Biomedical waste not only poses great threat to the environment and the general population, but also to the ones who handle it and carry out the disposal.[3] 15% of the total waste generated is infectious and hazardous. This waste pertains to be a threat to the living as well as the non living thing.[4]

This waste plays a significant role in the spread of pathogens like HIV, Hepatitis B & C. Dental offices generate a large amount of biomedical waste daily. This waste is of equal harm to the environment and atmosphere as to the humans.[5] Lack of knowledge persists regardless of the professional training and thus, necessary measures to deliver awareness is the need of the hour.[6,7] Hence this study has been undertaken to assess the knowledge of dental practitioners in Karad city, understand the practices of waste disposal, train the healthcare workers and to take measures in establishing a protocol.

Materials and Method

A cross-sectional study was conducted among the dental practitioners in Karad city, Maharashtra, India from December 2018 to February 2019.

A pre-tested, self-administered, closed-ended questionnaire was designed for recording all the relevant data pertaining to general information of the study participants and knowledge and practices regarding dental waste management in a private clinic. Ethical approval was obtained from the Institutional Ethics Committee of KIMS Deemed to be University, Karad. Questionnaires were adopted from previous studies and modified.[1,8] A few new questions were formulated, some questions were modified while some were considered unnecessary and removed since this did not hamper with the fluidity of the questions.

The questionnaire consisted of 18 questions to assess the knowledge and the practice of biomedical waste management. The questions were grouped under Knowledge/Cognizance, Attitude and Practices/ Execution of biomedical waste and its management.

Questions to access knowledge were of a multiple choice type, only one response being the correct one. Questions to access attitude were presented in positive or negative response format (Yes/No/Don't Know). Questions regarding practice were of multiple choice type, including the various method which may be implemented in routine practice. Each correct and incorrect response in the knowledge section and each yes and no or don't know for the attitude and practice question are to be given 1 and 0 mark, respectively.

The study sample was collected. The study population comprised of 112 private dental practitioners, of which 100 dental Practioners gave consent to participate in the study. The study participans were given sufficient time to answer the questionnaire and the questionnaire was collected back on the same day or the next day. Questions about KAP were assessed for scores individually. Descriptive summary using frequencies, proportions and cross tabs were used to present study results. The collected data was entered in Microsoft excel sheet and subjected to statistical analysis. Statistical significance was analyzed using Chi-square test. The level of significance was set at 5%. The Statistical Package for Social Sciences (SPSS) version 21.0 was used for the statistical analysis.

Results

Table 1: Demographic distribution of Practicing Dentists in Karad according to age gender, qualification and experience

Sociodemographic variables	n (%)
Age in years	
23-28	8(8)
29-33	24(24)
34-38	35(35)
39-43	19(19)
44-48	5(5)
49-53	4(4)
54 & Above	5(5)
Gender	
Male	73(73)
Female	27(27)
Qualification	
BDS	80(80)
MDS	20(20)
Experience (in Years)	
0-5	43(43)
6-10	35(35)
>10	22(22)

A total of 100 participants were recruited for this study, with a 100% response rate. As shown in Table

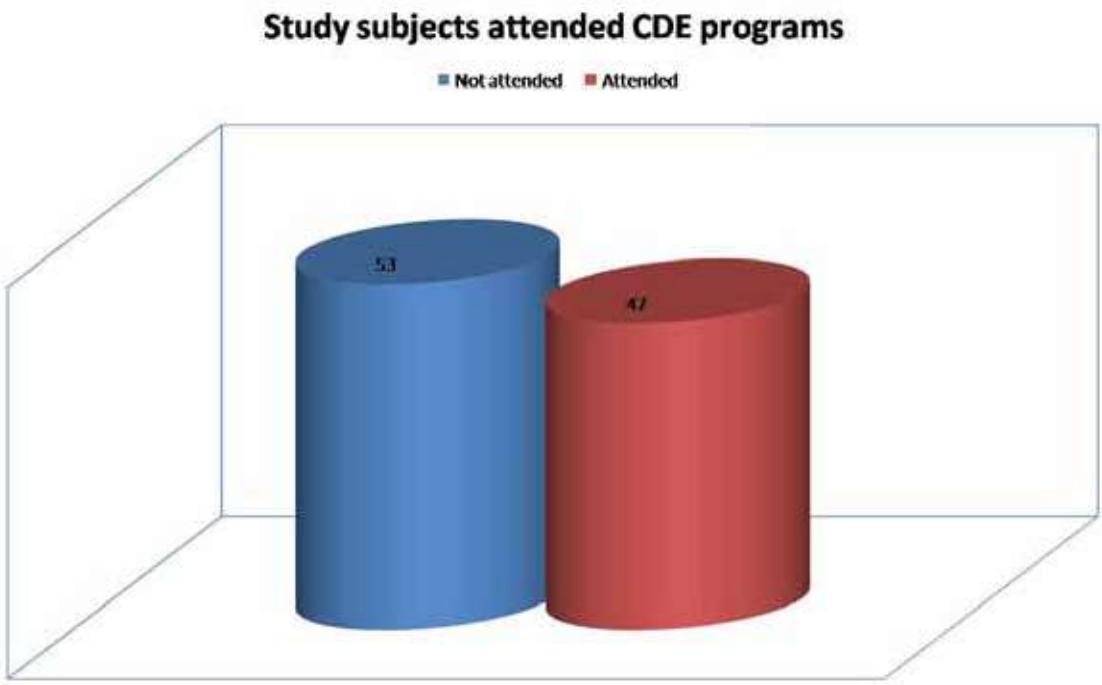
1, 73(73%) participants were males and 27 (27%) were females. The maximum number of respondents belonged to the age group of 34-38 years (35%). Respondents with undergraduate qualification were more (80%) compared to postgraduate qualification (20%). 43 (43%) participants had an experience of 0-5 years.

Table 2: Association between CDE program and knowledge scores of dental waste management

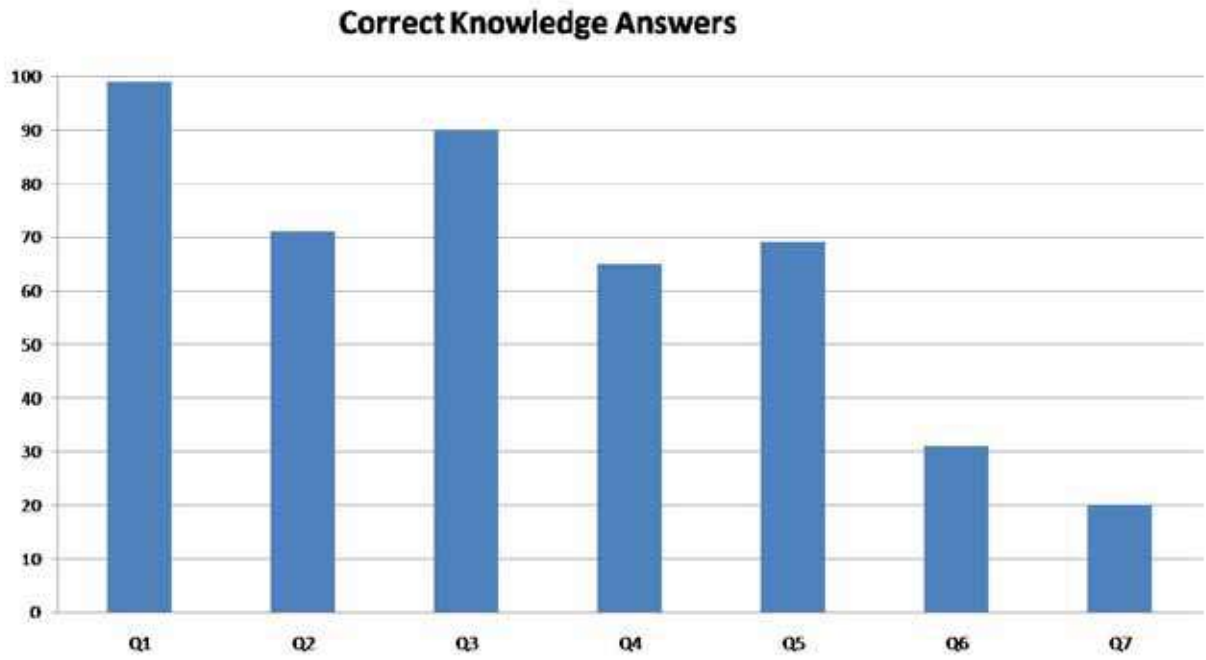
CDE Program	Knowledge Scores					Chi-Square Value	Df	P value
	Very poor	Poor	Average	Good	Total			
CDE								
Attended	1	12	19	15	47	53.95	3	0.628 (NS)
Not Attended	1	11	29	12	53			
Total	2	23	48	27	100			
P<0.05 Significant (S); p>0.05 Not significant(NS)								

Table 3: Association between CDE program and Practice scores of dental waste management

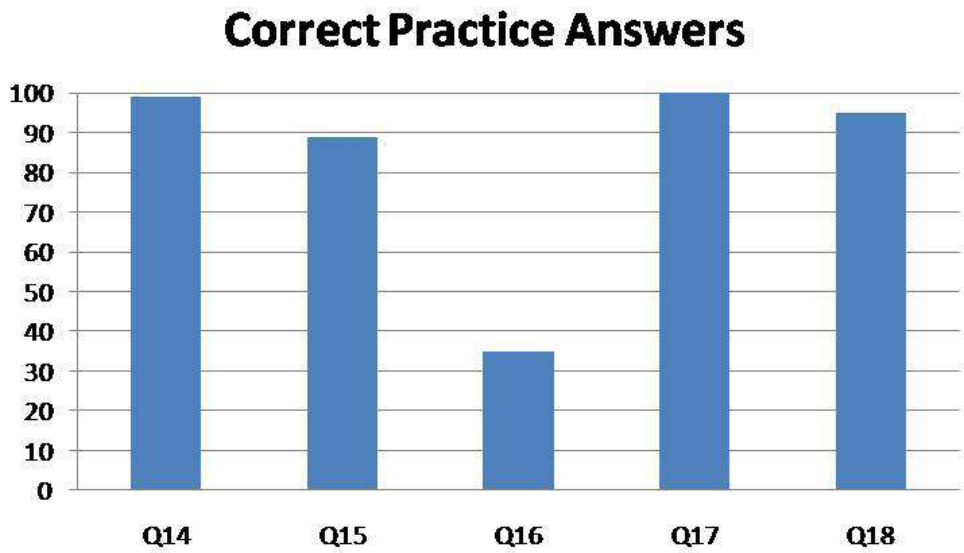
CDE Program	Practice Scores					Chi-square Value	Df	P value
	Very poor	Poor	Average	Good	Total			
CDE								
Attended	0	9	21	17	47	9.83	3	0.0152 (S)
Not Attended	0	12	25	16	53			
Total	0	21	46	33	100			
P<0.05 Significant (S); p>0.05 Not significant(NS)								



Graph 1: Distribution of Study subjects as per CDE programs attended



Graph:2 Distribution of Respondents by correct Knowledge answers



Graph : 3 Distribution of Respondents by correct practice answers

Graph 1 shows that 47 participants have attended CDE programs on dental waste management.

Graphs 2 and 3 show that the distribution of respondents by correct knowledge and practice answers.

Table 2 shows the association between CDE program an knowledge scores of dental waste management. Knowledge score was good among 31.91% subjects who attended CDE programs.

Table 3 it is evident that good waste management practice was observed in those who attended CDE programs 36.17% compared to those who did not attend CDE programs. Association between CDE program and practice scores of dental waste management was statistically significant (<0.05)

Discussion

Hospital waste generation is a continuous process.

This waste needs to be disposed in place or, it may serve to be a potential carrier for various diseases and pollution. A major contribution to this waste is from dental clinics. Dental waste consists of a wide range of materials from amalgam, cements and files to bloody cotton swabs, needles and human anatomical waste.

Although the dental profession is a team effort, management of biomedical waste is done at an individual level. The dental waste travels through the hands of numerous individuals and thus, monitoring of proper disposal is one of the many tasks the dental professional needs to observe.In order to assess the present situation and to gain insight on the efforts that need to be undertaken to help with the cultural needs, a learning instrument (questionnaire) based on the knowledge, attitude and practices of the dentist has been arranged.[1,5] 100 subjects involved in this study, including 80 graduate and 20 post-graduate qualification. 99% subjects reported to be aware of the different categories of biomedical waste and that efficient segregation of this waste was carried out in their practice. While, only 71% of these subjects had knowledge of the color coding given by the biomedical waste management in India. 65% individuals showed knowledge of the use of yellow bag/containers to dispose human anatomical waste.

96% subjects reported to be registered with a certified waste carrier service to recycle or dispose the biomedical waste generated in the clinic. 34% dental clinics were registered with a private biomedical wastage service. Most of the private dental clinics did not show much use of dental amalgam. 69% private dental professionals were aware of mercury spill kit being the most effective way to remove accidental spill of mercury. This result is similar to a study conducted at dental clinics in Karnataka, India.[1] 89% subjects informed that they used needle burn to dispose infected needles.

In the present study, 47% of the participants have attended CDE program based on biomedical waste management, the results of which showed increased awareness and better practice of waste disposal. 78% subjects are willing to attend training on biomedical waste management or think they need more knowledge regarding the issue. Although specialized waste carrier services are available in India, dental professionals and students need to be made accustomed to the availability of these services.

Conclusion

Insufficient professional training regarding this topic becomes a major contributor to the neglect of biomedical waste management. Lack of awareness and interest fails one to register their clinic under certified waste management services. Dentists should be focused not only in delivering healthcare needs up to the mark but also, taking responsibility of the effects of waste generated routinely.

Limitation of Study: As this study was confined to the only single city but this topic is relevant to large regional area so more extensive studies with larger and broader population cohort are required for better assessment and implementation of biomedical waste guidelines.

Gynaecological Manifestations of Systemic Malignancies

Swarnabindu Banerjee[1], Barnini Ghosh[2]

[1]Assistant Professor, Department of Medical Oncology, [2]Post-Graduate Trainee, Department of Radiation Oncology, Medical College & Hospital, 88 College Street, Kolkata

Abstract

Context: Round cell tumours and haematolymphoid malignancies presenting with gynaecological symptoms are not infrequent. Often, those are a component of a symptom complex which has a clue towards the aetiology. Round cell tumours or haematolymphoid malignancies presenting solely as structural lesions of the female genital tract are really uncommon. A series of 10 such cases are depicted here.

Aims:

1. To study the epidemiological pattern among these patients
2. To assess the prognosis of such cases

Settings and Design: Single institutional observational study

Method and Material: Cases were selected from the case record files and data collected. CT scan of (Thorax +Abdomen + Pelvis)was done in all cases. The diagnosis was established by histopathology and immunohistochemistry in each case.

Statistical Analysis Used: Descriptive statistics used for analysis

Results: Median age of presentation was 25 years. Median duration of symptoms was 3 months, most commonly pain abdomen. Fallopian tubes and ovaries were involved in 90% cases, with pelvic and retroperitoneal lymphadenopathy in 80% cases. Majority of the underlying malignancies were haematolymphoid malignancies.

Conclusions: Clue to suspicion of underlying round cell tumours or haematolymphoid malignancies are younger age, mass lesion of uterus and adnexa, regional lymphadenopathy and absence of ascites. Earlydiagnosis is necessary since the above group of diseases represent curable malignancies even at advanced stages so we need to treat before their performance score deteriorates.

Keywords: *Haematolymphoid malignancies, gynaecological manifestations.*

Introduction

Haematolymphoid malignancies and round cell tumours presenting with gynaecological symptoms are not infrequent. Often these manifestations are components of a symptom complex, having a clue towards the aetiology. However, round cell tumours or haematolymphoid malignancies presenting solely as structural lesions of the female genital tract are really uncommon. The most common worldwide type of Non-Hodgkin Lymphoma (NHL) is Diffuse Large B-Cell Lymphomas (DLBCL)[1]. Majority of the DLBCLs originate in the lymph nodes, but ≤40% initially have extranodal presentation[2]. Differences in molecular pathogenesis, clinical presentation and natural history

Corresponding Author:
Dr. Barnini Ghosh
Post-Graduate Trainee Department of Radiation Oncology Medical College & Hospital, 88 College Street Kolkata-700073

indicate that extra nodal DLBCLs are distinct entities [2]. The World Health Organization (WHO) Classification describes three clinical variants of Burkitt lymphoma – endemic, sporadic and immune-deficiency-associated types. Endemic Burkitt lymphoma usually occurs in African children, 4–7 years old, with a male:female ratio of 2:1, involving the jaw and other facial bones, kidneys, gastrointestinal tract, ovaries, breast and other extranodal sites[3]. Sporadic Burkitt Lymphoma occurs worldwide –Most common site of involvement being the abdomen, specially the ileocaecal area. Other sites such as ovaries, kidneys, omentum, Waldeyer's ring may be involved [4]. Lymph node involvement is more common among young adults than children[5]. Patients may have malignant pleural effusion or ascites[3,5]. Ewing's Sarcoma is the second most common malignant bone tumour in children and young adults, though, rarely, it may be of extraskeletal origin[6]. Patients with extra osseous Ewing's sarcoma (EES) are usually of higher mean age and less likely to be male or White, compared to patients with skeletal tumours[7]. Commonly affected extraskeletal sites are - paravertebral spaces, lower extremities, head and neck and pelvis[8]. Other rare locations of EES include the retroperitoneum, omentum, orbit, skin and chest wall[9]. Extraskeletal tumours are more likely to arise from axial locations and less likely to arise from the pelvis[9]. Here we have depicted a series of 10 cases of systemic malignancies with an aim to study the epidemiological pattern and assess the prognosis.

Materials and Method

A single institutional observational study was carried out at a tertiary care cancer hospital. Cases were selected from the outpatient, indoor and day-care records. CT scan of (Thorax + Abdomen + Pelvis) was done in all cases. The diagnosis was established by histopathology (image guided biopsy or laparotomy) and immunohistochemistry in each case. Epidemiological data with respect to age, type of malignancy, sites of involvement, method of diagnosis, chemotherapy drugs used, duration of therapy, grade III/IV adverse effects,outcome were recorded and analysed using descriptive statistics. The median follow up duration was 3.5 years.

Results

Total 10 cases were selected and studied. The age at presentation varied from 5 years to 45 years, the median age at presentation being 25 years. Median duration of symptoms was observed to be 3 months.

The common presenting symptoms and their frequency are shown in Fig 1.

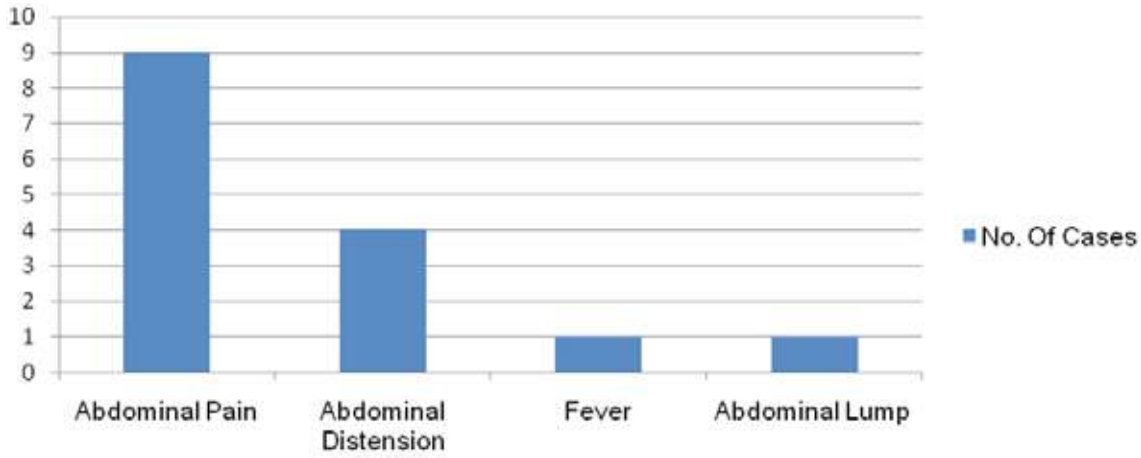

Fig 1: Presenting Symptoms

The diagnoses were established by the following method:

1. CT guided core biopsy from adnexal mass in 1 case
2. CT guided core biopsy from retroperitoneal lymph node in 1 case
3. Immunophenotyping of ascitic fluid in 1 case
4. Immunophenotyping of bone marrow in 1 case
5. Rest by laparotomy

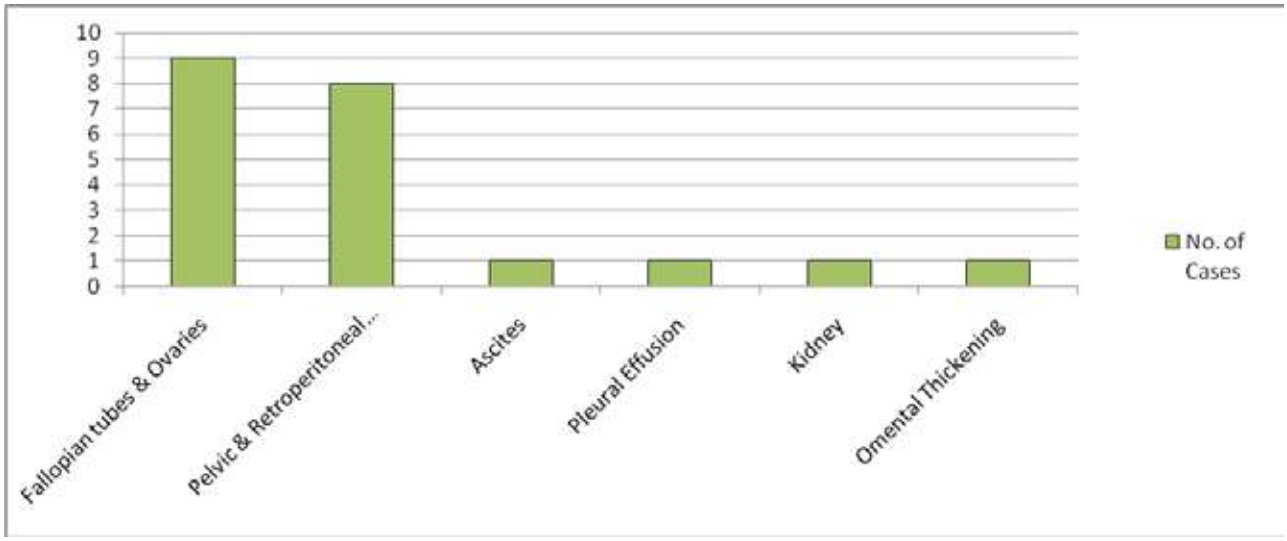

Fig 2: Sites of Involvement

The common sites of involvement along with their frequencies are shown in Fig 2.

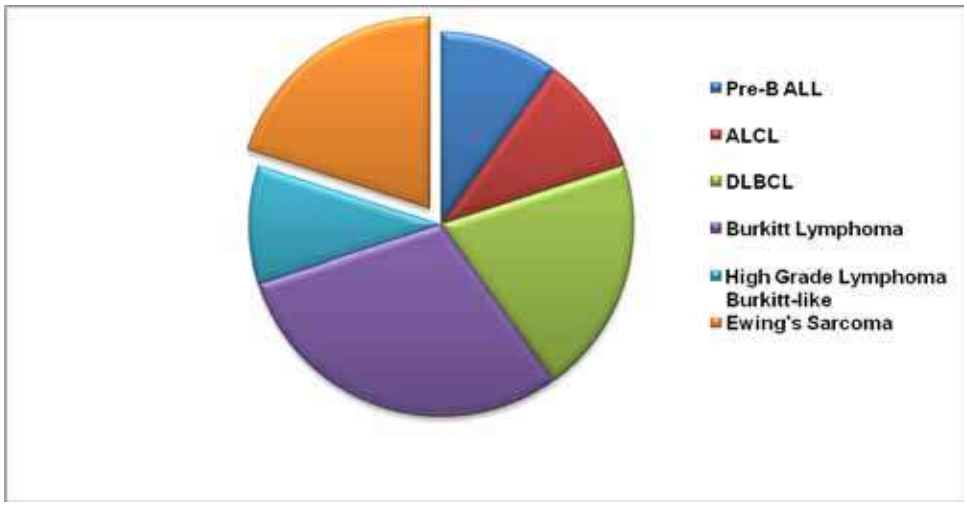

Fig 3: Underlying Malignancy

Fig 3 shows the distribution of underlying malignancies found in the 10 cases.

Of the 2 cases of Ewing's Sarcoma, 1 was paracervical and the other was ovarian.

The median latency from symptom onset to the start of treatment was 1.5 months.

The patients were treated with multi-agent noncrossresistant chemotherapy according to the existing guidelines.

1 case of Burkitt Lymphoma and 1 case of DLBCL suffered toxic death on treatment.

Discussion

It is quite clear that haematolymphoidmalignancies outnumber others .Clue to the suspicion of round cell tumours or haematolymphoid malignancies are younger age, mass lesion of uterus and/or adnexa, regional lymphadenopathy and absence of ascites. Earlydiagnosis is necessary since the above group of diseases represent curable malignancies even at advanced stages so we need to treat before their performance score deteriorates.

Conflict of Interest: None

Source of Funding: Self

Ethical Clearance: The study was conducted in accordance with the ethical standards of IEC.

A Study to Assess the Effectiveness of Structured Teaching Programme on Knowledge Regarding Substance Abuse and its Impact on Health among Higher Secondary Students among Atulya Healthcare Pune

Tejashri Ligade[1], Sagar Kulkarni[2], Aejaz Ahmad[3]

[1]Tutor, Symbiosis college of nursing, S. B.Road, Pune. [2]EMT Trainer, Atulya Healthcare, Pune, Maharashtra, [3]OT trainer Atulya Healthcare, Pune, Maharashtra

Abstract

Context: Healthcare professionals are crucial in the identification and accessibility to treatment for people with substance abuse. The objective of the study was to assess students' knowledge towards substance use disorders and examine the consequences of these on health.[1] Substance abuse is a social problem, not in India alone, but the entire world. The use of drugs has its own culture and history, which varies from country to country. The problem of substance abuse is growing at an explosive rate and in just little over a decade it has spread its malevolent tentacles to almost every part of the globe surmounting almost all barriers of race, caste, creed, religion, sex educational status, economic strata etc.As the first experience of substance abuse often starts in adolescence, and studies have shown that drug use is mainly related to cigarette and alcohol consumption, an initial exploration of substance abuse prevalence, including cigarette and alcohol, seems to be the first step in preventing and controlling drug consumption.[3]

Keywords: *Knowledge, substance abuse, impact on health.*

Introduction

Alcohol is only drug whose self-induced intoxication is socially acceptable.[1] Worldwide alcohol accounts for 3.3 million deaths yearly which represent 5.9% of all deaths.[2] Use of alcohol depends upon many environmental factors such as economical development, culture, ease of availability and alcohol policies of the area. This phenomenon is palpable in India, as its on road of rapid transition economically and socially. This transition can easily be noted by surge in figures of per capital alcohol use, as it has increased from 3.6 liters in 2003 – 05 to 4.3 liters in 2008 – 10 of which almost half of alcohol comes from unregulated market.

If their experimentation could be prevented by making them aware about the abuse and its consequences, the prevalence of the substance abuse can be reduced[2] Substance abuse has become a global phenomenon. It has affected almost every country, although its extent and characteristics differ from region to region. It is said, that at least 40 million people throughout the world are regular substance or drug abusers. The problems of drug abuse are seen in semi-urban and along the border areas of India. The period of adolescence is a vulnerable period in the life of an individual. The increased vulnerability in this period related to psychological factors like curiosity, poor impulse control, run away from reality, psychological distress and so forth. The social factors like peer influence, lack of clear identity, and self or intra-familial conflict also expose the adolescent to substance abuse.[4]

Statement of the Problem: "A study to assess the effectiveness of structured teaching programme on knowledge regarding substance abuse and its impact

on health among higher secondary students at Atulya Health Care Pune."

Objectives of the Study:

1. To assess the pre- test knowledge regarding substance abuse and its impact on health among adolescent students.
2. To evaluate the effectiveness of structured teaching on knowledge regarding post-test score.
3. To find out association between selected demographic variables and study findings.

Operational Definitions:

1. **Knowledge:** In this study knowledge refers to the correct response and understanding of the knowledg regarding substance abuse and its impact on health as measured by structure knowledge questionnaire.
2. **Substance Abuse:** Substance abuse refers to the harmful or hazardous use of psychoactive substances, including alcohol and illicit drugs.

Population: The study population for this study is higher secondary students.

Sampling and Sampling Technique:

Sample: The samples for the study were the higher secondary students studying Atulya healthcare, Pune.

Sample Technique: Sampling is the process of obtaining information about on entire population by examining only a part of it.

A purposive sampling technique was used to select the sample for the present study, which will meet the purpose of the study.

Inclusive Criteria: Students who are,

1. Studying in Atulya healthcare, Pune, willing to participate in this study.
2. Present at the time of data collection.
3. Will be able to read and write Marathi and English.

Exclusive Criteria:

1. Students who are not present at the time of data collection.
2. Not willing to participate in the study.
3. Not able to read and write Marathi and English**.**

Tool: The instrument used by data collection was self-administered closed-ended questionnaire which consist of two sessions.

Content Validity and Reliability: The content validity of the instrument was assessed by obtaining opinion from 8 experts. The experts suggested simplification of language, reorganization and addition of certain items. Appropriate modifications were made accordingly and the tool was finalized.

Reliability was assessed using Pearson's coefficient correlation and found reliable.

Data Collection:

Section I

Demographic Data: It consists of demographic variables like sex, religion, family type, occupation of parents and socioeconomic status.

Section II

Structured Self Administered Questionnarie: It consists of 25 closed ended questions to assess the knowledge regarding "substance abuse and its impact on health". This includes introduction, definition, prevalence, etiological factors of substance abuse, commonly used psychotropic substances and its impact on health.

Reliability: The reliability of the tool was established by test method using a correlation coefficient method. The reliability was found to be significant (r=1).

Table 1: Depicts the demographic variables in terms of numbers and percentage

Sr. No.	Demographic Variables	Number	Percentage
	Sex		
1)	**a)Male**	13	43.33%
	b)Female	17	56.67%
	Religion		
	a)Hindu	30	100%
2)	**b)Muslim**	-	-
	c)Christen	-	-
	d)Other	-	-
	Family Type		
	a)Single	9	30%
3)	**b)Joint**	13	43.33%
	c)Nuclear	8	24.67%
	d)Other	-	-
	Occupation of Parents		
	a)Labor	3	10%
4)	**b)Government employee**	10	33.33%
	c)Farmer	15	50%
	d)Private employees	2	6.67%
	Socioeconomic Status		
	a)Less than 10,000	-	-
5)	**b)20,000-30,000**	8	26.67%
	c)30,000-50,000	9	30%
	d)More than 50,000	13	43.33%

Section: II Assessment of level of knowledge regarding substance abuse and its impact on health among higher secondary before the implementing of structure teaching program Area, wise comparison of mean, SD, and mean percentage of pretest knowledge scores about substance abuse and its impact on health among higher secondary college students.

Table No: 2. Depictscomparison of mean, SD, and mean percentage of pretest knowledge scores

Area	Max Obtainable Score	Pre-test		
		Mean	SD	Mean (%)
Introduction	3	1.9	0.64	63.33
Definition	1	0.17	0.70	17
Prevalence	2	1.1	0.64	55
Causes	5	3.33	1.3	66.6
Commonly used Psychotropic Substance Abuse	9	4.8	1.5	53.33
Impact on Health	5	2.6	1.14	52
Overall	25	13.9	5.92	55.6

Table no. 2 Shows that the highest mean score [4.8+ 1.5(SD)] which is 53.33% of the total score obtained in the area of "knowledge oncommonly used psychotropic substance abuse" whereas lowest mean score [0.17+ 0.70(SD)] which is 17% of the total score was in the area of "knowledge on definition of substance abuse"

It reveals that the students had average knowledge in the area "knowledge on commonly used psychotropic substance abuse" and below average knowledge in the area "knowledge on definition of substance abuse".

Further the overall mean was 13.9 +5.29(SD) which is 55.6% of the total mean score, which reveals that the students had poor knowledge in the area "introduction, prevalence, etiological factors and impact on health of substance abuse".

Comparison of pre-test and post-test level of knowledge on substance abuse and its impact on health among higher secondary students.

Table No: 3. DepictsComparison of pre-test and post-test level of knowledge scores.

Sr. No	Level of Knowledge	Pre-test Score		Post-test Score	
		Number	Percentage	Number	Percentage
1	**Adequate** (17-25)	9	30	29	96.67
2	**Moderate** (9-16)	20	66.67	1	3.33
3	**Inadequate** (0-8)	1	3.33	-	-

Table No.3: Shows that during pre-test 66.67% of higher secondarystudents had moderately adequate knowledge, 30% of higher secondary students had adequate knowledge and 3.33% of higher secondary student had inadequate knowledge whereas, during post-test 99.67% of student had adequate knowledge and 3.33% of student had moderate adequate knowledge.

Regarding substance abuse and its impact on health among higher secondary before the implementing of structure teaching program Area, wise comparison of mean, SD, and mean percentage of pretest knowledge scores about substance abuse and its impact on health among higher secondary college students.

Conclusion

The present study access the knowledge level of higher secondary students at Atulya healthcare, Pune. Regarding the, "substance abuse and its impact on health" and found that the students having 29 (96.67%) had adequate knowledge, and 01(3.33%) of students had moderate knowledge regarding "substance abuse and its impact on health".

Conflict of Interest: Nil

Source of Funding: The present study is self-funded.

Ethical Clearance: Ethical Clearances obtained from the college committee and informed consentwas taken.

Abstract

Context: Stroke is one of the common upper motor neurological disorders with the overall worldwide prevalence of 3% . Majority of post-stroke individuals develop abnormal pelvic muscles function and pelvic tilt which can affect the trunk and lower limb functions. Proprioceptive neuromuscular facilitation less commonly used to treat the acute stroke population. Thus, we conducted this case study to evaluate the clinical usefulness of selective PNF on the pelvic pattern in two subjects with acute post-stroke hemiparesis. Both cases were treated with routine and selective PNF techniques such as rhythmic initiation, the dynamic and stabilizing reversal in anterior elevation and posterior depression pattern for 30 minutes, daily for 4 consecutive weeks. Trunk impairment scale and PALM device were used to assess the trunk balance and pelvic tilt respectively before and after 4 weeks of treatment. Both cases were improved with a clinically meaningful difference. Therefore we also precede this treatment protocol in our randomized clinical trial further.

Keywords: *Hemiplegia, Pelvic Symmetry, Neuromuscular Facilitation, Diagonal Movement Pattern, Trunk Control.*

Introduction

Stroke is one of the common upper motor neurological disorders which affect 3% of overall worldwide population[1]. Post-stroke individuals develop the abnormal function of sensory, motor, cognitive and other higher cortical neurons;[2] ultimately hemiparesis alter the neuromuscular control of muscles in the various body segments such as limbs, neck, trunk, and girdles. Further altered neuromuscular functions cause difficulty to balance while performing static and dynamic activities[3].

Poor sensory-motor integration in the trunk and pelvis producespelvic mal-alignment which can affects the trunk and lower limb functions[3,4]. Altered pelvic alignment due to poor trunk-pelvis dissociation and reduced hip muscular control acting around pelvis may account for asymmetric weight distribution onto a most affected lower limb during walking[4]. The most of stroke patients have poor trunk control and forward lean posture with anteriorly tilted pelvis which causes poor postural stability of the lower trunk[4,5].

Zakaria et al. have shown a correlation between pelvic tilt and trunk control in post stroke[5]. And Suruliraj et al. state that more lateral pelvic tilt towards the affected side and an anterior pelvic tilt in bilaterally are commonly seen in patients with hemiparesis[4]. So,

the management of pelvic mal-alignment is an essential step to improve the functional recovery in patients with acute stroke.Dubey et al. reported that the management of pelvic mal-alignment is beneficial in improving the trunk and lower extremity movement[6]. Therefore, pelvic bridging, and trunk stabilization, postural correction, balance and coordination exercises were used to manage the pelvic mal-alignment[7,8,9].

Even though various individual exercise protocols were used to manage the pelvic asymmetry, it is evident that there is a lack of training which can activate synergistic muscles in relation to functional pattern movements of the pelvis[10,11,12]. Apart from the weakness of the pelvis and trunk muscles, the impaired proprioception has been considered for the poor trunk control and pelvic mal-alignment after stroke[4,11]. Therefore, various techniques of proprioceptive neuromuscular facilitation (PNF) are also used to treat pelvic mal-alignment among patients with stroke[10,11,12].

PNF is a dynamic evaluation and treatment tool to improve the dynamic strength, flexibility, coordination, and specific muscle recruitment[12,13,14]. Some studies documented the various types of PNF techniques on trunk, pelvis and lower limb pattern to improve the respective regional functions[13,14]. But previous studies have used generalized techniques rather than selective PNF techniques in hemiparesis or hemiplegic cases[12-14]. So we have decided to treat the hemiparesis subjects using selective PNF techniques in order to effectively manage the mal-alignment of the pelvis and improve the trunk control.

Case Report: There were 2 patients with post-stroke hemiparesis referred to physiotherapy treatment by the general physicians. According to the medical records, both patients were medically stable to undergo physical therapy program; therefore they were referred to PT interventions. Each patient was further assessed by a neurological physiotherapist in order to plan and apply for the individualized treatment program on each patient.

As per the medical record and reference letter of physician, a 40 years old male patient was suffering from left-sided hemiparesis over a period of 30 days since from the onset of stroke. On the day of PT assessment his systolic and diastolic BP were recorded as 130 and 90 respectively, BMI 22.65 and MMSE score of 30. He communicated verbally to the people around him and he also followed the instruction of assessing clinician which suggested us there is no cognitive impairment in him. Gait observation revealed that there is a circumduction gait with moderate pelvic hike and increased lumbar lordosis. And he was able to walk independently with mild support of stick and importantly he faced difficulty while turning and staircase walking. The pelvic alignment was measured with the help of PALM device[15] which showed that 15 degree of pelvic malalignment and trunk impairment scale (TIS)[16]score was 17.

61 years old female patient with right-sided hemiparesis over the period of 13 days was assessed by PT assistant and her systolic and diastolic BP were recorded as 140 and 90 respectively; BMI 24.83 and MMSE score of 29. She was experiencing mild oromotor dysfunction with lower quadrant facial paralysis and however, she was able to follow the instruction of assessing clinician. Gait observation revealed that there is a circumduction gait with moderate pelvic hike and increased lumbar lordosis. Her static standing balance was good enough to stand for 1 minute without any major sway. But dynamic standing balance and balance reaction while turning were poor. The pelvic alignment was measured with the help of PALM device[15] which showed that 20 degree of pelvic malalignment and trunk impairment scale[16] score was 13.

Based on the pelvic malalignment and reduction in the pelvic movement in both cases we decided to apply the PNF technique. We hypothesized that application of selective PNF on the hip may stimulate both deep and superficial sensory receptors and may improve the movement quality by increasing the ROM, muscle strength, and stabilization of pelvis corresponding to the lower trunk and proximal lower hip. Prior to the selection of specific PNF techniques in the anterior elevation and posterior depression pattern, the movement quality was assessed through this pattern passively and actively[13-14].

After positioning the patient in side-lying comfortably, one hand of the therapist was placed over the ischial tuberosity and another hand over the ASIS using lumbrical grip. Then the anterior elevation and posterior depression pattern was produced passively and repeated several times to provide the information regarding the movements to the patients. Later the patients were asked to imitate the same movement pattern; at the same, we observed the movement quality throughout the pattern[13-14].

Active rhythmic initiation was performed repeatedly for five minutes (2 minutes session of two sets, 1-minute rest between them). Once the patients were well aware of the movement pattern, then repeated stretches were applied wherever required to the muscles in order to facilitate the effective movements. First 3 days of intervention only rhythmic initiation was applied on both patients to adequately activate the muscles and achieve the full range of motion. Later half of the week, dynamic reversal and stabilizing reversal techniques were applied alternatively for the total duration of 20-30 minutes with adequate rest between the sets of treatment. From the second weeks onwards all three techniques were applied for the total duration of 30 minutes, two sessions in a week. Both patients were treated for 4 weeks with pelvic PNF and routine care[7-10].

After the four weeks of intervention, pelvic symmetry and trunk control ability was assessed using PALM device and trunk impairment scale respectively. In case 1 post-treatment pelvic asymmetry was reduced to 7 degrees with the difference of 8 degrees, and trunk impairment score was improved to 20 from pre-treatment score of 17. Similarly in case 2 also palm device score was reduced to 12 and improvement in trunk impairment with TIS score of 19. These outcomes from the two cases show significant improvement in the pelvic asymmetry and trunk impairment after the 4 weeks of PNF application along with routine care.

Discussion

Based on the clinical usefulness of PNF in peripheral muscles weakness caused by peripheral and central nervous system dysfunction we have decided to treat the abnormal pelvic positioning in post-stroke hemiparesis individuals[7-10]. Importantly we treated 2 different age individuals in this experiment to know the effectiveness of PNF in the post-stroke population and its clinical usefulness. Abnormal pelvic tilt and changes in the trunk balance among these two patients support the findings of Suruliraj et al[4,11] where they found excessive anterior and lateral pelvic tilt among the post-stroke subjects.

The change scores of pelvic malalignment and trunk impairment scale from baseline to post-intervention assessment (4 weeks) among the two subjects suggest that there is a reduction in the pelvic malalignment and improvement in the trunk balance. These outcomes indicate the clinically meaningful improvement in the pelvic symmetry and trunk balance post application of selective PNF technique among the post-stroke individuals.

As per our understanding about the PNF use in the pelvis, the selection of appropriate PNF technique which gives specific importance to increase the ROM, coordination, and strength is important to achieve the meaningful difference in the respective clinical outcomes[7-9]. So, we have selected rhythmic initiation, dynamic and static reversal PNF techniques in these two post-stroke hemiparetic individuals. Rhythmic initiation was implemented to facilitate muscle work and improve the range of pelvic motion in the pattern of anterior elevation and posterior depression. Dynamic reversal and stabilizing reversal were used to improve the dynamic and static muscle work respectively in order to achieve good muscle strength, intra and intermuscular coordination[13-14].

Wang et al on 15 post-stroke subjects with abnormal lower limb muscle tone was treated with rhythmic initiation and combination of isotonic and achieved the immediate reduction of spasticity and muscle tightness in the lower limb muscles[10]. Joshi et al experimented trunk PNF techniques (45 minutes) using the pattern of movement to improve the trunk control and achieved improvement in trunk control[13]. But they have not applied the pelvic PNF techniques and specialized PNF techniques were also not used in their study.

Shinde et al used the PNF to improve the trunk lateral flexion, Kumar et al used 30 minutes of PNF to improve the mobility function, and Kim et al applied 10 minutes of PNF for 6 weeks (thrice a week) to improve the functions of hemiplegic side[17]. Overall these studies have used rhythmic initiation, dynamic and stabilizing reversal, and rhythmic stabilization PNF techniques. But the frequency and duration of intervention have differed among these studies.

Conclusion

Based on the outcomes from these two subjects in the pelvic symmetry and trunk control suggest that there are indications for the effectiveness of selective PNF techniques among the subjects with post-stroke hemiparesis. Furthermore, we also are conducting a randomized control trial to evaluate the definite use of selective PNF in post-stroke hemiparetic subjects.

Conflict of Interests: We declare that there is no conflict of interests in term of finance, concepts and

method and publications among the authors participated in this study

Source of Funding: Financial assistance related to material purchase, laboratory investigations and other expenses was provided by NITTE (Deemed to be University), Mangaluru, India.

Ethical Approval: Prior to the study ethical approval was obtained from institutional ethics committee of Nitte Institute of Physiotherapy,Mangaluru, India.

Abstract

Background: The scapula plays a key role in nearly every aspect of normal shoulder function. Alteration in scapular position and motion is found in association with most shoulder injuries. This alteration is term as scapular dyskinesis. Prevalence of scapular dyskinesis is about 67 to 100% . But many literature focus on treatment after occurrence but very few aim at prevention during immobilization phase.This made indeed to study the effect of scapular position – motion maintenance programme during shoulder immobilization phase.

Objectives: To determine the effect of scapular position -motion maintenance exercise programme during post traumatic shoulder immobilization phase, To compare the effect of scapular position -motion maintenance exercise programme and conventional physiotherapy during post traumatic shoulder immobilization phase.

Method: A Total of 40 subjects were selected aged between 20 to 50 years. They were divided into two groups. Group A (experimental) and group B (conventional). Both groups received treatment for 6 weeks for a duration of 30 minutes. The outcome measure used wereVAS, Posture assessment, pectoralis minor muscle length,Linnies test and scapular assistance test.

Result: The study concludes that experimental group (scapular position- motion programme)proved more efficacious in reducing risk of scapular dyskinesisin patients with humerus fracture during immobilization phase as compared with conventional treatment.

Keywords: *scapular dyskinesis, Immobilization phase, proximal humerus fracture, exercise therapy*

Introduction

Effective shoulder position, motion, stability, muscle performance and motor control are largely dependent on the scapular performance. Mechanically, the coordinated coupled motions between the scapula and humerus, is called scapula humeral rhythm.[1]Scapular Dyskinesis is found in association with various shoulder pathologies, although exact relationship between dyskinesis and clinical pathology is doubted.In case of nerve injury, fracture, Ac separation, muscle detachment, the injury results in dyskinesis, affecting shoulder function. In some cases like labral tear, rotator cuff disease, dyskinesis may be causative,creating pathomechanics that predispose the arm to such injuries.[2]Humeral fractures accounts for approximately 7 to 8% of all adult fractures, further incidence has been reported to increase with age. Proximal humerus fractures being most common(50%) of all humerus fractures.[3]According to a study "Prevalance of scapular dyskinesis in patients with

Corresponding Author:
Dr. Sandeep Shinde
MPTh, Department of Musculoskeletal Sciences.
Karad, Maharashtra, India

Distal radius fracture with or without shoulder pain" by Hector it was found that almost 80% of all patients with distal radius fracture showed scapular dyskinesis, with an increase in value 90.9% in group of patients with shoulder pain.[4] Scapular Motionsprovide optimal muscle length – tension ratios for accurate movement pattern, and promotes muscular energy conservation during arm motion. The most common causative mechanisms of scapular dyskinesis is soft tissue alterations i.e inflexibility or tightness of pectoarlis minor creating anterior tilt and protraction, glenohumeral internal rotational deficits, which creates a wind up of scapula on thorax leading to horizontal abduction.[5]

One of the most important abnormalities in abnormal scapular biomechanics is the loss of linking function in kinetic chain.[6] The scapula and shoulder are dependent links in kinetic chain. It helps transferring the forces from the large segments, the legs and trunk, to the smaller, rapidly moving small segments of the arm. If scapula becomes deficient in motion or position, transmission of the large generated forces from the lower extremity to upper extremity is impaired. This creates a situation of catch up in which more distal segments work at a higher level of activity for compensation of the loss of proximally generated forces. Calculations depicts that 20% decrease in kinetic energy delivered from hip and trunk to the arm necessitates an 80% increase in mass and 34% increase in rotational velocity at shoulder to deliver the same amount of resultant forces to hand .The kinetic chain is the most efficient system for developing energy and force.[7-8]

Scapular diskinesis causes weakness, tightness and muscle imbalance. most of the scapular motion and position can be treated by means of physical therapy relieving the symptom associated with in flexibility or trigger points, re-establishing muscle strength and activation patterns.[9] But many literature focus on treatment after occurrence but very few aim at prevention during immobilization phase. This made indeed to study the effect of scapular position – motion maintenance programme during shoulder immobilization phase which primarily focuses on linking function of kinetic chain.

Materials and Methodology

This experimental study was carried out with 40 subjects in Krishna Hospital Karad. A total of 40 subjects was divided equally into two groups by Simple random Sampling (Group A and Group B). Subjects were in immobilization phase with proximal humerusfracture. Both males and females between the age group of 20-50 years were included.

The Inclusion criteria in this study was Age group of 20 – 50 age,Both the genders and Patients with Proximal Humerus post reduction or post operative immobilization phase andExclusion criteriawas Neurological condition, Non cooperative patients, Patients with Fracture of scapula, Patients with External fixators, Patients with distal neurovascular deficit and Patients with rib and spinal fractures.

The Outcome measures was Pain assessment – VAS scale,Posture assessment, pectoralis minor muscle length and special test for Linnies test and scapular assistance test.

The materials used in the study was Plinth, Towel, Inch-tape, Swiss ball, Pressure biofeedback, Data collection sheet, Consent form.

Procedure: An approval for the Study was obtained from the Protocol committee and institutional Ethical committee of KIMSDU scapular dyskinesis.Subjects who fulfilled the inclusion and Exclusion Criteria was divided into two groups. Informed consent was taken from each of the subject prior to Participation. Instructions weregiven to the subjects about techniques performed. A total of 40 subjects were divided equally into two groups by Simple random Sampling (Group A and Group B). The subjects were divided into two groups according random allocation.

Pre-test: Visual Analogue Scale (VAS) and Posture assessment, pectoralis minor muscle length and special test for Linnies test and scapular assistance test was used to assess the Subjects.

Group A:

The treatment program wasinclude: First 3 week scapular stabilization exercise and next 3 week spinal stabilization exercise will be added with scapular stabilization exercise.

Group A (Experimental)[10-12]

Week 1

1. Posture training
    - Scapular retraction exercise
2. Isometric exercise for scapular muscle
    - .Shoulder Depression
    - Shoulder Protraction
    - Shoulder retraction

Week 2

Scapular stabilization exercise

1. Scapular clock exercise on a wall
2. T to Y to W exercise on swiss ball

Week 3

Scapular motion exercise (closed chain stabilization)

- Static close chain exercise (weight bearing)

Week 4

Spinal stabilization exercise was added with scapular stabilization

- **Pressure biofeedback in supine**
- Lumbar flexion

1. Multifidus facilitation
2. Alternate single leg heel touch
    - Lumbar extension

1. Oblique abdominal facilitation
2. Alternate single leg heel touch
    - **Lumbarmultifidus activation**
    - **Transv. erseabdominis activation**
    - Abdominal hollowing: activation of transverses abdominis in crook-lying position.
    - Abdominal hollowing: activation of transverses abdominis in sitting.
    - Abdominal hollowing: activation of transverses abdominis in four point kneeling.
    - Activation of multifidus from sitting to lumbar neutral position

Week 5

Swiss ball exercise

- Sitting knee raise on swissball
- Abdominal slide
- Lying trunk curl with leg lift
- Wall slides

Week 6

1. Pelvic floor exercise
    - Pelvic bridging
2. Diaphragmatic strengthening exercise
3. Single leg standing on foam

Group B (Control group)

- Rest
- Isometric exercise for scapular muscle(Shoulder Depression,Shoulder Protraction,Shoulder retraction), active exercise (daily for 6 weeks)

Post-test: Visual Analogue Scale (VAS) and Posture assessment, pectoralis minor muscle length and special test for Linnies test and scapular assistance test was used to assess the Subjects.

Data Analysis: Between the group comparison

Table No 1: Baseline parameters comparison between both the groups (visual analog scale, Linnies test, pectoralis minor muscle length)

Group A & B

Discussion

The present study "Effect of scapular position - motion maintenance exercise programme during post traumatic shoulder immobilization phase" was conducted to see the effect of scapular stabilization and spinal stabilization exercise during immobilization phase in post traumatic shoulder. The scapula is anatomically and mechanically linked with shoulder function. Alteration in scapular position and motion is found in association with most shoulder injuries, termed as scapular dyskinesis. In a previous study "Prevalence of Scapular dyskinesis in patients withdistal radius fractures with or without shoulder pain" by Hector states that prevalence of Scapular Dyskinesis is shown in 80% of all patients with Distal Radius Fracture, with an increasing value of 90.9% in patients with shoulder pain.The ratio was found to be 10 times greater in patients with Distal Radius Fracture accompanying with shoulder pain.[13]

A group of adult population with proximal humerus fracture treated conservatively with plaster cast or closed reduction were evaluated. In a similar study by Ayhan Et. Al .stated following findings: Distal Radius Fracture had

influence on scapular motion, exhibit altered scapular kinematics, increased posterior tilt, internal and upward rotation.[14-16] Further the study added to find the quality of motions at scapula if more proximal structures were affected. Another study by Edward Sheilds, "Scapular dyskinesis following displaced fractures of the middle clavicle"similar results were noted,Scapular Dyskinesis is common after displaced middle third clavicle fractures.[17] In the present study we found a significant relation of scapular dyskinesis with proximal humerus fracture .Though there is no enough literature to support this evidence, but may studies approve findings of Scapular Dyskinesis occurrence after or with shoulder injuries. In a previous study by Mathew B."Prevalence of scapular dyskinesis in overhead and non overhead athletes" reported that Scapular Dyskinesisin overhead athletes (61%) was more compared to those with non overhead athletes(33%).[6]In a previous study by Poonam SS, "effect of desensitization method during the early mobilization phase in post fracture conditions of upper extremity" reported that combination of desensitization along with the conventional physiotherapy was effective in decreasing pain, improving ROM and muscle strength than the conventional therapy alone.[18]Another study by Diksha U, "Effect of movement with mobilization in supraspinatus tendinitis" had noted that movement with mobilization, ultrasound, TENS and exercises are effective in management of supraspinatus tendinitis.[19]

The majority of studies included utilized visual observation of abnormal scapular rhythm to identify scapular dyskinesis. Two major abnormalities noted were scapular winging and scapular tilting. Scapular tilting was found in almost all subjects in Group A and Group B.Scapular winging was present in 8 subjects in Group A and 6 subjects in Group B.This interprets the fact not all patient with scapular tilting present with scapular winging. The mean pain values recorded using VAS showed a significant level of pain in both groups with pre values of 7 in Group A and 6.65 in Group B. There was a significant reduction in pain levels post treatment with 4.8 and 3.9 mean values respectively. The two main components scapular motion and scapular position were assessed using Kiblers classification and Linnes test respectively. According to Kiblersclassification it was found that majority of subjects belonged to Type I dyskinesis with 12 subjects(60%) in group A and 14 subjects(70%) in group B. This interprets that inferior angle positioning was severely affected .Group A was found to be more effective in correction of this fault by reduction of number from 12(60%) to 4(20%) as compared to Group B in which only 7 subjects(35%) showed corrections. Also subtype 3 and 4 that is medial border prominence and excessive superior border elevation was found to be noted though there rates were relatively less as compared to Type 1. Post treatment it was found that Group A had 14 Subjects (70%) showing T4 subtype that is symmetric and normal scapulae and group B had 7 subjects(35%) which showed thatcorrection of scapular motion rate was almost double in Group A proving efficacy of scapular positioning program.The second component that is linnies test added to the results of Kiblers classification by providing objective findings. The results of Linnies test showed significant results in group A. However group B showed not significant results. This measure although a subjective approach doesn't much count on the therapist findings rather the results are patient based .From the above gained results we can state that scapular position and motion programme is more effective in prevention of scapular dyskinesis.

Dyskinesis may be caused by multi factors such as bony causes, joint causes, neurological causes and soft tissues causes of alteration. Bony causes include thoracic kyphosis or clavicle fracture non-union or shortened mal-union. Joint causes include high grade acromioclavicularinstability, glenohumeral joint internal derangement. Neurological causes include cervical radiculopathy, long thoracic or spinal accessory nerve palsy. Soft tissue mechanisms for scapular dyskinesis involve inflexibility or intrinsic muscle problems. The upper and lower trapezius force couple may be altered, with delayed onset of activation in the lower trapezius, which alters scapular upward rotation and posterior tilt. Altered scapular motion or position both decrease linear measures of the subacromial space, increase impingement symptoms, decrease rotator cuff strength, increase strain on the anterior glenohumeral ligaments and increase the risk of internal impingement. [1]The Mechanism contributing to scapular dyskinesis primarily include the following factors like Inadequate serratus anterior activation, excess upper trapezius activation, pectoralis minor tightness, posterior glenohumeral joint soft tissue tightness, thoracic kyphosis or flexed posture. This associated effects leads to lesser scapular upward rotation and posterior tilt, greater clavicular elevation, greater scapular medial rotation and anterior tlit, greater scapular anterior tilt, greater scapular medial rotation and anterior tilt, lesser scapular upward rotation.[13]

This study had some limitations but were majorly due to the small sample size. Further studies can be done on a larger sample size including more age groups. Also similar studies can be done taking into account some other fractures like distal humerus fractures, radius fractures, wrist fractures, elbow dislocation.

Conclusion

The study concludes that experimental group (scapular position- motion programme)proved more Efficacious in reducing risk of scapular dyskinesis patients with humerus fracture during immobilization phase as compared with conventional treatment.

Abstract

Background: Non-adherence to hand hygiene practices is a well-known factor contributing to healthcare-associated infections in any healthcare setting. Mere knowledge of such practices doesn't guarantee the compliance to the practices by healthcare personnel. In this study we explored the quantum of adherence to handhygiene practices, the opportunity missed, the steps and the duration to be followed for hand hygiene practices and the training gap among the healthcare providers.

Methodology: A six-month cross-sectional study using a mixed-method approach of observations, interview and feedback mechanism is used to find the effectiveness of hand hygiene practices and any training gap to prevent healthcare-associated infections. Observations for two thousand opportunities for hand washing and written interview of 40 healthcare workers is carried out on hand hygiene practices at a neonatal intensive care unit of coastal Karnataka, India.

Results: The hand hygiene practices were as low as 0% observed while performing an non-invasive activity like clearing an alarm at the bedside. There is a gap found in the duration of hand-washing practices, hand hygiene before and after any care activity is performed on the neonate. This gap resulted in the spread of healthcare-associated infections.

Conclusion: During the infections control training emphasis should also be given on the opportunities and hands on practices of hand hygiene.

Keywords: *Hand hygiene; Infection control; healthcare-associated infections; Neonate; India.*

Introduction

Handwashing is the foundation for infection control practices[1]. Healthcare providers are trained and empowered to practice hand hygiene during their formal training. There can be a high rate of healthcare-associated infections if the perception and practice of hand hygiene are mismatched[2]. Performing hand hygiene and compliant to complete hand hygiene practices are two different avenues. When all the five steps of hand hygiene are not performed in timely manner is considered

ineffective and when all steps are completed with appropriate time duration hand hygiene is considered to be effective[1]. There can be instances when one may presumes completing optimum hand hygienebut it is not. We are exploring the gaps in training adherence to the steps needed to be followed, the opportunity missed for hand hygiene practice and maintaining stipulated time for each step by healthcare provider.

Materials and Method

In a neonatal intensive care unit (NICU) of a tertiary care teaching hospital situated at coastal Karnataka, India, a cross-sectional study was carried out for six months duration July 2017-Jan 2018. Hand washing and hand hygiene practices of all the healthcare workers were recorded for all the five moments and steps of hand washing as suggested by the world health organization. The questionnaire on five moments of hand hygiene was prepared;content and face validation were done. A sample size of 40 healthcare workers considering a 95% confidence level for a definite population N=44 with 5% confidence limit were selected for written interview based on their availability and consent for participation. The healthcare workers working in NICU responded on these questionnaires that include five physicians, 23 nurses,six paramedic trainee and six pediatric postgraduate trainees. Eighty observations at each opportunity for a total two thousand chances of performing hand hygiene were observed for these healthcare providers randomly on different time interval, preferably at non-peak hours using a checklist. The observations and questionnaire were related to WHO five moments of hand hygiene[1]. Ineach observation, if any step or opportunity was missed or partially completed,it was considered as non-compliance. Completion of activity as per the standard was considered as compliance with the practices. The data obtained was entered in Microsoft excel was analyzed further using R software version 3.1.1. The qualitative variables were summarized as number and percentage. The difference between the reported and observed practices is considered as a gap that needs to be focused on further training on hand-hygiene practices. Institutional ethic committee approval was taken with IEC approval number "MUEC/014/2016-17". Informed written consent for participation was obtained from all the participants before interviewing them.

Findings: Two thousand observations and forty interviews on twenty-five variables were carried out for healthcare workers at NICU. There was a mismatch in the practices observed and knowledge of hand hygiene reported among healthcare workers. We categorized observations and responses under three subheadings; time duration, hand hygiene before an activity and hand-hygiene after an activity performed.

Time Duration: Nearly 65% of healthcare workers reported that the ideal duration for hand washing with soap and water is <20 sec. However, only 12.5% healthcare workers practice handwashing with soap and water for >40 sec. 75% opportunities to carry out hand-washing practices were of less than 20-sec duration with soap and water. None of the healthcare workers reported the durations of hand hygiene using hand rub solution as 21 to 40 sec and we also observed the similar findings. Only one opportunity was recorded complying to 21-40 sec duration of hand hygiene using hand rub solution (Table 1).

Table 1: Showing time duration for hand hygiene practices by healthcare workers

Variables	Observations n=80	Reported n =40	The gap in reported vs observed*
	n (%)	n (%)	(%)
Duration of hand washing with soap and water			
05-20 sec	60 (75.0)	26 (65)	-10
21->40 Sec	20 (25)	14 (35)	-10
Duration of hand disinfection with hand rub solution (Min)			
05 - 10 Sec	62 (77.5%)	4 (10%)	-67.5
11- 20 Sec	17 (21.2%)	36(90%)	+68.8
21 - 40 Sec	1 (1.2%)	0 (0)	+1.2

* The gap is the percentage difference between reported and observation practices. A positive or negative gap of more than 20% is considered a significant gap in practice.

Table 2: Hand hygiene practice before any activity

Variables	Observations n=80	Reported n =40	The gap in reported vs observed*
	n (%)	n (%)	(%)
Compliance for practice hand hygiene before having contact with neonate	53 (66.2)	23 (57.5)	-8.7
Clean hands before providing personal care activities: handling, moving, bath/sponge, feeding, changing linen, etc.	33 (41.2)	23 (57.5)	+16.3
Clean hands before delivering care and other non-invasive treatment: applying oxygen mask, giving a massage.	67 (83.8)	23 (57.5)	-26.3
Clean hands before Performing a physical non-invasive examination: Taking pulse, blood pressure, chest auscultation, recording ECG.	30 (37.5)	22 (55)	+17.5
Clean hands before Instilling eye drops, examining mouth, nose, ear with or without an instrument, inserting a suppository, suctioning mucous.	34 (42.5)	27 (67.5)	+25
Clean hands before Dressing a wound with or without an instrument, applying ointment On vesicle, making a percutaneous injection/puncture.	76 (95)	32 (82.5)	-12.5
Clean hands before Inserting an invasive medical device	68 (85)	35 (87.5)	+2.5
Clean hands before Preparing food, medications, pharmaceutical products, sterile material.	80 (100)	25 (62.5)	-37.5

* The gap is the percentage difference between reported and observation practices. A positive or negative gap of more than 20% is considered a significant gap in practice.

Hand hygiene before an activity: Reported compliance for hand hygiene before contacting neonate, handling or moving baby or applying a mask or giving massage was 57.5%, but observations showed more compliance than reported 83.8% and 57.5% respectively. While performing non- invasive procedures or examination reported hand hygiene was always more than the observed. Considering any opportunity to perform hand hygiene duringnon-invasive procedure reported and observed wasas low as 37.5% and 0% respectively. In case of performing hand hygiene before invasive procedure, reported and observed was always >80% (Table 2).

Table 3: Hand hygiene practices after an activity

Variables	Observations n=80	Reported n =40	The gap in reported s observed*
	n (%)	**n (%)**	**(%)**
Clean hands after the contact with a mucous membrane and with non-intact skin end.	78 (97.5)	28 (70)	-27.5
Clean hands after A percutaneous injection or puncture; after inserting an invasive medical device	80 (100)	34 (85)	-15
Clean hands after Removing an invasive medical device.	18 (22.5)	33(82.5)	+60
Clean hands after Removing any form of material offering protection (napkin, dressing, gauze, sanitary towel, etc.).	22 (27.5)	29 (72.5)	+45
Clean hands after handling a sample containing organic matter, after clearing excreta and any other body fluid, after cleaning any contaminated surface and soiled material (soiled bed linen, diaper etc.).	63 (78.8)	34 (85)	+6.2
Clean hands after providing personal care activities: handling, moving, bath/sponge, feeding, changing linen, etc.	44 (55)	20 (50)	-5
Clean hands after Delivering care and other non-invasive treatment: applying oxygen mask, giving a massage.	26 (32.5)	20 (50)	+17.5
Clean hands after Performing a physical non-invasive examination: Taking pulse, blood pressure, chest auscultation, recording ECG.	67 (83.8)	18 (45)	-38.8

Variables	Observations n=80	Reported n =40	The gap in reported s observed*
	n (%)	n (%)	(%)
Clean hands after an activity involving physical contact with the patients' immediate environment: changing linen, holding a side of the cradle, clearing sides of cradle.	2 (2.5)	20 (50)	+47.5
Clean hands after A care activity: adjusting perfusion speed, clearing a monitoring alarm.	0 (0)	11 (27.8)	+27.8
Clean hands after Other contacts with surfaces or inanimate objects: leaning against the cradle, leaning against a side table /ventilator.	0 (0)	14 (35)	+35
Practice hand hygiene after having contact with neonate?	53 (66)	24 (60)	-6
Practice hand hygiene after removing gloves?	26 (32.5)	29 (72.5)	+40
Wear gloves when hands may be contaminated with bodily fluid (e.g. Suctioning)	65 (81.2)	33 (82.5)	+1.3

* The gap is the percentage difference between reported and observation practices. A positive or negative gap of more than 20% is considered a significant gap in practice.

Hand hygiene practices after an activity: Reported compliance towards hand hygiene practices post non-invasive procedure was nearly 50% whereas observed was as low as 2.5% . Hand hygiene compliance was reported less than 35% post touching any part of the neonatal environment and observed was nearly 0% . Compliance for hand hygiene was recorded better, >60% in post invasive procedure/ touching any mucosal part of neonate & the noted observations showed >95% compliance (Table 3).

Discussion

No healthcare worker want any patient especially neonate to suffer from healthcare-associated infection because of any preventable cause. Maintaining good hand hygiene is vital for infection control practices, but mere awareness on how to perform handwashing is an incomplete effort to achieve a goal. The healthcare worker may be aware of the hand hygiene practices required to follow hence they reported at various instances the hand hygiene practices is required. However due to various reasons the practice is not followed and that can be captured through observations[3]. There are reports supporting our findings that there is a gap in the awareness and practices among healthcare workers for handwashing practices[4–6]. The very fact that even the healthcare providers were not aware of performing hand hygiene post touching the neonatal environment or clearing the alarm provides scope to work further and improve on training programs. Any invasive procedure requires thorough handwashing using soap and water, whereas for non-invasive activities like clearing an alarm or changing linen etc., a handrub disinfectant solution should be used[7]. Invasive activities do include any contact with bodily fluid during the procedure. Many training programs are carried for healthcare workers tooptimize hand hygiene practice. There are limited training opportunities to learn when to perform hand hygiene practices[8]. Routinely in healthcare organizations professionals are also not made aware of the quantity of liquid soap solution or hand-rub solution required for appropriate hand hygiene. The study not only highlights the importance for the healthcare workers to learn and plan for training program on how to perform hand-washing but also when to perform which type of hand hygiene is equally important to prevent healthcare-associated infection. Studies have reported that a single classroom training approach may not work alone, rather a multimodal approach including role-play, video and game activities may show better results[9,10]. Whenever we are planning for handwashing campaign or training program, we need to prepare holistically to get optimum desired outcome. The healthcare workers also need to be clarified on the quantity of hand hygiene substance either soap or disinfectant solution along with clear demarcation on which practice to follow in which circumstances. As it was observed the healthcare workers were not clear whether to use hand rub solution or do handwashing or do both the practices. The significant importance of making the hand dry after any hand hygiene practice was missing that was captured during observations. The difference in reporting and observation practices gives insight to the training team about the focus area. If the gap is considerably high, as we considered a gap>20%

as high, such instances need immediate special attention and training.

Conclusion

Training on hand washing must include sessions on when to perform hand hygiene how to perform, and the minimum duration required for optimum hand hygiene. Various identified opportunities should be enlisted in healthcare settings to minimize any mis-opportunity.

Conflict of Interest: All the authors declare of no conflict of interest.

A Study to Assess the Effectiveness of Protocol on Care of Newborn in Phototherapy on Knowledge and Practice among Nurses at Selected Hospitals in South India

V. Santhi[1], S. Nalini[2], Lisy Joseph[3]

[1]Lecturer, [2]Lecturer, [3]Lecturer, Faculty of Nursing, Sri Ramachandra Institute of Higher Education & Research(DU), Porur, Chennai

Abstract

Background: The present study assess the Effectiveness of Protocol on Care of Newborn in Phototherapy on Knowledge and Practice among Nurses at Selected Hospitals in South India

Method and Material: A pre - experimental one group pre and post test study design was used to collect all the necessary and relevant data from nurses. The study was conducted in the maternity ward and phototherapy unit of two hospitals. Based on inclusion criteria 50 nurses were selected and non probability convenient sampling techniques were used.

Results: In pre test level of knowledge of nurses regarding care of newborn in phototherapy, 17 (34%) had inadequate knowledge, 19 (38%) had moderately adequate knowledge and 14 (28%) had adequate knowledge. In post test majority of 44(88%) had adequate knowledge, 6 (12%) had moderately adequate knowledge and no one had inadequate knowledge. The improved mean value for knowledge was 10.43 with "t" value of 13.47 and improved mean value for practice was 6.78 with "t" value of 17.26. This results shows the high statistical significance at $p<0.001$.

Conclusion: The study concludes that there was a significantly improvement of knowledge and practicable in post test after administration of protocol. Thus protocol was observed to an effective tool to improve the knowledge and practice on care of newborn in phototherapy and it may be useful to implement future reference.

Introduction

Newborns are considered to be tiny and powerless beings, completely dependent on others for their adaptation in the external environment. Within one minute of birth the normal newborn adapts from the dependent fetal existence to an independent being capable of carrying on the physiological processes. This transition, in many babies takes place in a smooth, uneventful way.

In controversy to the above, a few newborns face some minor disorders. During the process of physiological adaptation for its survival, the neonate has to face many life threatening problems, such as asphyxia, hypothermia, hyper bilirubinemia, infections etc.

One of the most important minor disorder that occur in the newborn during the transition phase is

hyperbilirubinemia. It is the yellow discoloration seen in the skin and sclera due to an increase in the serum bilirubin level. Excess amount of bilirubin in the blood that causes hyperbilirubinemia. **(Halliday, H. L. 1989)**

Globally, 65% of the newborns develop hyperbilirubinemia making it one of the most common problems in the majority of the newborn.(**William,W. Hay,. 2009).**In India approximately 4 million babies are born every year. Of them, 60 to 70% of the newborns develop hyperbilirubinemia. These statistics indicate that hyperbilirubinemia is a very common condition.

Stokowski, L. A.[3] (2006) said that proper nursing care enhances the effectiveness of phototherapy and minimizes complications. Nursing responsibilities include ensuring effective irradiance delivery, minimizing skin exposure, providing eye protection and eye care, carefully monitoring thermoregulation, maintaining adequate hydration, promoting elimination and supporting parent-new born interaction.

Nurses play a vital role in providing comprehensive care for neonates on phototherapy based on their needs. Meticulous and appropriate nursing care during phototherapy is the best way to prevent the complications.

Newman & Esterling[4] (2000) stated that according to the British Columbia Reproductive Care Program of Neonates, hyperbilirubinemia is a common neonatal problem especially during the 1st week of life when approximately 50 percent of all newborns have visible jaundice, of them 8-20 percent of term neonates exceed the total serum bilirubin values of 13 mg/dl, and need phototherapy.

All the above studies tell about the various complications that occur due to phototherapy, and stress that prevention can be possible with good care of the newborn. Neonates need close monitoring and careful nursing measures to improve their health status and to prevent complication.

During this time nurses play a very vital role in preventing complications and maintaining the well being of the newborn. With growing technology in the health sciences and increasing specialization of the Nursing profession, more rigorous control is required to ensure that nurses should possess sound scientific knowledge and skills to deliver safe and quality care.

Asha P. Shetty [5] (2003) conducted an experimental study, to assess the effect of photo therapy among full term newborn with a view to develop a nursing care protocol. The study concluded that, most often newborns with hyperbilirubinemia are treated with phototherapy which was effective. It was noted that development of a valid protocol for care of newborns in phototherapy would help practicing nurses to act promptly and independently.

Many studies in this area have been conducted in the western countries and protocols have been developed. But in India the investigator has observed that there is no specific protocol used by nurses while caring for babies in phototherapy. Hence the care provided was observed to be inadequate and many complications arose for the newborns. Having this in mind the investigator took up the responsibility of preparing a protocol to be followed while providing care for babies in phototherapy and also decided to test the effectiveness of the protocol through a pre- experimental study. The investigator tries to focus the effectiveness of the protocol which is cheap and resourceful intervention to care for the newborn during phototherapy and to assess the knowledge and practice among nurses for the same.

Method and Material

The study was designed to assess the the effectiveness of protocol on care of newborn in phototherapy on knowledge and practice among nurses at selected hospitals, Madurai. Investigator obtained formal permission from the administrative officer of Kasthuriba hospital and from the medical director of Leonard hospital, Madurai prior to the initiation of the study

Study Design: A quantitative research approach includes the research design in this study was pre experimental one group Pretest – Post test study design was considered to be the most appropriate to achieve the set of objectives in this study. The objectives were to assess the pre & post test level of knowledge and practice of nurses regarding care of newborn in photo therapy. To compare the pre and post test level of knowledge and practice of nurses regarding care of newborn in photo therapy. To correlate the mean improvement level of knowledge and practice among nurses regarding care of newborn in phototherapy. To associate the mean improvement knowledge and practice scores on care of newborn in phototherapy with selected demographic variables. The study was conducted in maternity

ward and photo therapy units of two hospitals viz... Kasthuriba hospital and Leonard hospital, Madurai. Kasthuriba hospital is a 200 bedded hospital which has well established maternity ward and photo therapy unit. Totally 35 - 40 newborns were admitted per month for the treatment of hyperbilirubinemia. Leonard hospital is a 250 bedded hospital.The phototherapy unit has 15 phototherapy machines in which 25-30 newborns were admitted per month for the treatment of hyperbilirubinemia. Totally 25 nurses are employed, all of them are posted in the maternity ward and phototherapy unit in a rotation.

Study Population: Fifty nurses who are qualified and working in maternity ward and phototherapy unit were included in this study

Inclusion Criteria: The nurses were working in photo therapy units and maternity wards and nurses were qualified as Diploma, B.Sc (N) Postbasic and B.Sc Basic (N).

Description of the Tool: A non probability convenience sampling technique was used in this study. The tool of the study has three section.

Section A: The demographic variables which includes age, gender, professional education, year of experience in service, total year of experience in phototherapy unit and source of information.

Section B: A structured knowledge questionnaire, it's consists of 30 multiple choice questions with 4 options and a single correct answer. Correct answer carries 1 mark and wrong answer carries-0 mark.The Questions covered the following aspects -Knowledge about hyperbilirubinemia–13, Knowledge about phototherapy – 7 and Care of newborn in phototherapy - 10.

The knowledge and practices score range as follows

Range	Score
> 75%	Adequate knowledge
50 – 75%	Moderately Adequate knowledge
< 50%	Inadequate knowledge

Section C : The observation check list has 25 items. The items were in the 'Yes' or 'No' form. The score for yes is 'one' and No 'Zero'.

Content Validity And Reliability Of The Tool: Content validity of the tool and protocol was got from three nursing experts in the field of obstetrics and gynecological nursing and two medical (DGO) experts. The reliability of the tool was established by using test-retest method to assess the reliability for knowledge with the same samples at different timings. The reliability score r = 0.9. To assess the reliability for the observational check-list, inter -rater method was used. The r value was 0.87. It indicated highly positive correlation.

Data Collection Procedure: The formal permission was obtained from the administrative officer and from the medical director of hospital, Madurai. The data for the study was collected with in the period of 4 weeks. During data collection period the investigator worked from 8 am to 4 pm for 5 days a week. The investigator covered 3-4 nurses per day. After getting their oral consent the investigator collected the pre test data using structured questionnaire to assess the knowledge and observational check list for assessing the practice. Each nurse took 30 – 40 minutes to answer all the questions. The investigator spent 25-30 minutes for assessing the nurses' practice on care of newborn in phototherapy. After the completion of the pre test data collection, the protocol on care of newborn in phototherapy was administered to the nurses. After 7 days post test was conducted by using the same structured questionnaire and observational check list for the same samples. The data obtained were analyzed using both descriptive and inferential statistics.

Findings: The findings from the study are tabulated, analyzed and interpreted below. In relation to demographic variables, the majority of 14 (28%) were in the age group of more than 31 years, 40 (80%) were females, 28 (56%) had completed GNM.

Table 1 : Frequency and percentage distribution of the Pre test & Post test level of knowledge of nurses regarding care of newborn in phototherapy. N=50

VARIABLES	Pre Test						Post Test					
	Inadequate (< 50%)		Moderately Adequate (50 – 75%)		Adequate (> 75%)		Inadequate (< 50%)		Moderately Adequate (50 – 75%)		Adequate (> 75%)

Table 3 : Comparison of pre test and post test level of Knowledge and practice among nurses regarding care of newborn in phototherapy. N= 50

	POST TEST		
VARIABLES	**Mean**	**S.D**	**' r' Value**
Knowledge	28.12	2.88	0.813 ***
Practice	23.02	2.48	

*** P < 0.001

Table 4 : Correlation between the overall mean improvement level of knowledge and practice of nurses regarding care of newborn in phototherapy. N = 50

With regard to level of knowledge the post test mean score was 28.12 and S.D was 2.88. With regard to level of practice, the mean was 23.02 and S.D. was 2.48 .The calculated 'r' value was 0.813 which show that there was a positive correlation between the overall mean improvement level of knowledge and practice at a statistically significant level of $p < 0.001$.

The present study supported by Milly **Mathew (2003)** on the topic can the self instructional module improves the nurse's knowledge on neonatal hyperbilirubinemia. The findings revealed that the self instructional module was effective in increasing the knowledge level of nursing personal with a t value of t=15.68 at p<0.5 level. The correlation r value between the knowledge and practice was r=0.93 which showed a good positive correlation.

Discussion

The present study was done to assess the effectiveness of protocol on care of newborn in phototherapy on knowledge and practice among nurses at selected hospitals, Madurai. The implementation of protocol was effective intervention during phototherapy

on the nurses and the overall health profession. Data were analyzed from 50 nurses. The overall pre test mean score was 16.24 with S.D was 2.55 and the post test mean was 23.02 with S.D was 2.48 and the calculated 't' value was 17.26 which had statistically high significance at $P < 0.001$ level. The protocol was found to be effective in improving the practice of nurses regarding phototherapy

Regarding association of mean improvement level of knowledge of nurses regarding care of newborn in phototherapy with selected demographic variables of source of information at $p<0.05$. The other demographic variables have no significant association with the knowledge of nurses. Regarding practice the results revealed that there was no statistically significant association of the mean improvement level of practice with the selected demographic variables.

Conclusion

The present study was conducted to assess the effectiveness of protocol on knowledge and practice regarding care of newborn in photo therapy among nurses in maternity ward and photo therapy unit of Kasthuriba and Leonard hospitals at Madurai, 2009. From the results of the study it was concluded that protocol on care of newborn is an effective method to improve the knowledge and practice level of nurses. The findings revealed that the nurses, who had good knowledge about care of newborn in photo therapy, will have good practice too.

Ethical Clearance: Taken from institutional ethical committee faculty members

Source of Funding: Self funding

Conflict of Interest: Nil

Implications:

Nursing Practice: Nurses working in maternity ward and photo therapy unit should have adequate knowledge and practice about care of newborn in photo therapy . The nurses should update their knowledge by in service education and continue nursing education programs. Nurses who have good knowledge and practice regarding care of newborn in photo therapy will be able to promote the newborns health and thereby reduce the neonatal morbidity and mortality.

Nursing Administration: The administrator has important role in creating awareness to increase the knowledge about care of newborn in photo therapy. In order to develop professional knowledge she has to make arrangements to conduct regular in-service education and continue nursing education programs on care of newborn in photo therapy.

Nursing Education: The nursing curriculum should be strengthened to enable nurses to excel in knowledge and practice of care of newborn in photo therapy. Students should be encouraged to have hands on experience in photo therapy units. Monitoring and assessing the newborn condition during photo therapy should be included as a clinical procedure.

Nursing Research: The findings of study can be disseminated to clinical nurses and student nurses through web site, literature, journals etc. The findings of the study will help the professional nurses and nursing students to improve their knowledge and practice

Recommendations:

1. The protocol can be placed in the maternity and phototherapy units for the nurses to read and follow.
2. A similar study can be conducted by increasing the samples size in different setting for better generalization.
3. A comparative study can be done at various setting.
4. A comparative study can be done on knowledge and practice between diploma nurses and B.Sc nurses.

Limitation:

1. The investigator faced difficulty in seeking permission in selected hospitals.
2. The investigator faced ample difficulty in collecting related literature as there was an only limited study on knowledge and practice among nurses.

Abstract

Context: Health was declared as fundamental human right by WHO constitution of 1948. The major key role playing factor in HAQ rankings is the universal health care programme and health schemes which are initiated and ran by the government. Health care provision is incredibly complex and many nations around the world spend considerable resources trying to provide it. Developed countries have their own insurance scheme which benefits its population and meets their health care needs. No uniform one-size-fits-all operational model exists when it comes to the successful implementation of a scheme. For instance, multinational insurers who are successful in one country have met failure in other countries. Developing country like India must try to improve their health care system by following certain initiatives incorporated by other countries. Low income countries like Africa and Nepal need to take extra measure to improve health insurance program and to provide quality care to their people. It is evident that there are an enormous number of ways that health care insurance programs vary around the world. There is a need to identify the characteristics of the most effective systems and the most equitable ones which could serve as a framework by all countries.

Keywords: *Health for all, Health coverage across the globe.*

Introduction

Health is a state of complete physical, mental and social well-being, and not merely the absence of disease or infirmity.[1] Health was declared as fundamental human right by WHO constitution of 1948.[2] The major key role playing factor in HAQ rankings is the universal health care programme and health schemes which are initiated and ran by the government.[2] Universal health coverage (UHC) ensures that all people have access to needed health services (including prevention, promotion, treatment, rehabilitation and palliation) of sufficient quality to be effective while also ensuring that the use of these services does not expose the user to financial hardship.[3] To achieve UHC, a country must address legal coverage and rights, health workers shortages, extension of health care shortages and quality of care.[4] Health care provision is incredibly complex and many nations around the world spend considerable resources trying to provide it.[5] The strength of the case for investing in health varies among countries.[6] The return on investment is likely to be highest for emerging economies: They can obtain significant improvements in health outcomes (eg life expectancy) through modest increases in health expenditures.[6] The basic idea of this review is to provide an insight on health coverages across various countries and there path towards universal health coverage.

Health coverage in various countries: Many countries have their own insurance scheme which benefits its population and meets their health care needs. No uniform one-size-fits-all operational model exists when it comes to the successful implementation of a

scheme. It is not just standard processes or manuals or actuarial formula or stabilised systems that can work seamlessly across geographies such that the success is assured.[7]

High income countries: High income countries according to World Bank are United States, Germany and Singapore, Canada, Japan and Gulf countries. Important principle of The affordable care act of 2010 or OBAMA care in United states is to improve quality of care which is achieved by establishing new agencies, boards, commissions and other Government entities[8]; The 2010 Affordable Care Act (ACA) dramatically changed many features of the US health care system and should greatly reduce the number of Americans who are uninsured.

The German government sponsors mandatory universal insurance coverage for everyone, including temporary workers residing in Germany.[9] The German system uses a unique point-based global budgeting system to control annual health careexpenditures whereby the targeted expenditures are achieved by ensuring that total payments to all providers of a given specialty are equal to the total budget for that specialty in a year.[10]If salary of German residents is less than 59400 euros per year or 4950 euros per month then membership is made mandatory. It covers in patient hospitalisation, OP services as well as dental care.

Singapore has a unique-to-the-world health care system where the dominant form of insurance is mandatory self-insurance supported by sponsored saving, although complementary and special insurance programs are also central to their system.[11] It provides UHC through a combination of government subsidies, multi-layered healthcare financing schemes and private individual savings all at national level. It provides Government subsidy 80% of total cost in public hospitals and primary care polyclinics. It is supported by 3M's system namely Medisave, Medishield and Medifund.

Japan has a mandatory insurance system which is comprised of an employment-based insurance for salaried employees, and a national health insurance for the uninsured, self-insured and low income, as well as a separate insurance program for the elderly.[10] Health insurance benefits designed to provide basic medical care to everyone are similar. They include ambulatory and hospital care, extended care, most dental care and prescription drugs.

Canada has a universal single-payer, sponsored health insurance system called Medicare which is administered independently by the thirteen provinces and territories. Every citizen and permanent resident is automatically covered. As of 2012, Canada spends about 11% of GDP on healthcare expenditures covering about 70% of healthcare expenditure.[2]

In Gulf countries major healthcare challenges has hampered the efforts towards ensuring UHC across the region. Mandatory health insurance is one of the measures adopted to achieve UHC. Qatar has initiated the upgradation of health care services by launching an e-health program. Saudi Arabia is digitalizing its hospitals and PHC patient medical records through healthcare information and management systems society (HIMSS). UAE in 2011 had launched integrated electronic medical record system to link public hospitals and clinics across Dubai and the Northern emirates through health information system- Wareed[12]

Middle income countries: China, India and Mexico are middle income countries. Chinese government has established a multilevel medical security system including universal health care system, commercial medical insurance and a medical charity aid. Over 90% of the population has basic insurance coverage in China. Three insurance schemes available in China as of 2011 is Urban employee basic medical insurance, Urban resident basic medical insurance and new rural cooperative medical system. Chinese government health care covers both sectors of population groups equally inorder to work on urban rural disparity.[13] In Mexico the government run system operates Clinics and hospital throughout the country in Mexico to provide health at low price.[14] Whereas in India according to model based estimate by WHO through public and private sector is estimated to be INR 1,713 / Capita / Year between 2014–2015. Average medical expenditure for hospitalization in urban patient has increased to 126% and rural patient to 160% and same year GDP / Capita grew by 121% .[15]

Need for health insurance: India is presently in a state of health transition facing a shift from infectious diseases to non-communicable diseases that are now emerging as the leading cause of mortality. According to National Health Accounts (2014-15) 62.6% of total health expenditure in India (2.4% of GDP, Rs. 2394 per capita) by householdis Out of pocket expenditure[15]which is defined as expenses that patient or family pays directly to health care provider without

a third party (Insurer, State) is limited withappropriate health insurance.[16]People having no access to any form of health insurance scheme are being forced to make OOPE pushing 60 million Indians to poverty each year.[17]

Although India has been witnessing a staggering growth in the health insurance sector, still only 15% of the population is protected by medical care insurance coverage and 5% of the population buy a plan voluntarily of their own accord which suggests that Indian insurance industry has still a long way to go. The reason behind such a low acceptability is not the affordability factor, but the lack of awareness and unwillingness on the part of the potential buyers. The likelihood of utilising health care services increases with genuine health insurance scheme in place. Such schemes should be focused on achieving a two-way objective, to tell people how imperative is it to get a health care insurance and to build the trust and credibility of insurers among them.[18]Global disease burden in India 2016 report suggests that deaths due to communicable, maternal, neonatal and nutritional diseases is 27.5% and Non communicable diseases is 62% in men and 52% in women; if each citizen is insured nearly 89.5% of disease burden could be averted.[19] A recent data suggest that 80% of hospitals are in urban area though it comprises of only 31% of country's population and availability of qualified physician in urban area is 11.3 per 10000 population when compared to 1.9 per 10000 population in rural area. 65% of rural population have no access to essential medicines and cannot afford to medical expenditure.[20]Health insurance scheme are designed to provide employment to rural poor besides creating rural infrastructure so that urban-rural disparity in the country could be reduced.[21]

State based health insurance schemes (2007-2017): Some states have its own health insurance scheme for its people and they are explained in detail. Aarogyasri scheme was launched in 2007 (continued as Dr NTR Vaidya Seva (2015) AarogyaRaksha scheme (2017). It is a unique community health insurance scheme being implemented in Andhra pradesh. It provides financial protection upto 2 lakhs to BPL families in a year for treatment of serious ailments requiring hospitalisation and surgery.[22]Chief Minister comprehensive health insurance scheme was launched in 2012 in Tamil Nadu. It provided cover for all major ailments and ensured advanced healthcare for low income and unorganised group. Its aim was to benefit 1.34 crore families with annual income of 72000 or less. The sum assured under the scheme is 1 lakh every year for a period of 4 years with total value of 4 lakh, in case of certain procedures it will be raised 1.5 lakh per annum.[23] In 2013 Sanjeevani Swasthya Bima Yojana was launched as a comprehensive health insurance scheme for citizen of Dadra Nagar Haveli and Daman and Diu. Under this scheme premium for BPL families will be borne by the UT Administration and for those families with income of 1 lakh- 2 lakh 50% will be by UT administration and 50% by their own.[24] Mukhyamantri Swasthya Bima Yojana was launched in 2016 in Uttarakhand for all BPL and APL families (except those on govt. salary or govt. pension or in tax payer category). It provided a cover of Rs. 50000 per eligible families and in same wake second phase with a base cover of Rs. 50000 covering 1206 diseases and critical cover package of Rs. 125000 covering 458 diseases.[25]

Nationwide health insurance (2003-2018): At National level, health insurance schemes were implemented between 2003 -2018. Universal health insurance scheme was launched in 2003 and available for individuals as well as in a group. Age criteria 5 to 70 years and children between 3 months to 5 years are eligible if one of the parent is covered. It gives hospitalisation benefit of INR 30000 per family per policy inclusive of maternal benefit. Total expenses for any one illness is limit to INR 15000 excluding maternal benefits and also covers accident and disability.[26] Rashtriya Swasthya Bima Yojana in 2013 was different from the previous policy with regards to target group which included BPL families and defined categories of unorganised workers. RSBY has been the only scheme in India launched on a Pan India basis, which aimed at universal health coverage.[27-29] Beneficiaries are entitled to hospitalisation coverage of Rs 30000 per annum for most of diseases that require hospitalisation. Additional transport expenses are also provided to the beneficiary.[28]

Under RSBY health protection mission/ Pradhan Mantri Rashtriya Swastya Suraksha Mission later renamed as Pradhan Mantri Jan Arogya Yojana was launched in 2018 at Ranchi Jharkhand. It provides coverage of 5 lakh/family/yr and benefits 10.74 crore families; 8.03 in rural and 2.33 in urban areas through a network of empanelled health care providers. Key feature of the scheme is that the beneficiaries can avail of services anywhere in India and there is no compromise on family size and age.[28] Budget allocation is approximately 12000 crores and 60:40 is the ratio for fund transfer from central and state government. Target group is poor, deprived rural families and identified

occupational category of urban workers' families as per Socio economic caste census 2011. All enrolled families under Rashtriya Swasthaya BimaYojana (RSBY) not featured in the targeted groups as per SECC data has also been included.[30]

Low Income Countries: Most of the African countries and Nepal belong to low income group. In Nepal to provide affordable care, quality health services, easy access and health security coverage Social health security development committee was established. It works by raising funds from healthy people and spending the same for needy.[31]In Ghana rapidly expanding National program is run by the government. In Nigeria most of the schemes are run by private investors and shareholders. In Tanzania and Uganda some programs are functioning through their own hospitals and clinic by employing their own staff on regular basis. Government must take extra measures in these low income countries to improve health insurance program and to provide quality health care to their people.[32]

Conclusion

It is evident that there are an enormous number of ways that health care insurance programs vary around the world. There is a need to identify the characteristics of the most effective systems and the most equitable ones which could serve as a framework by all countries. In accordance to health for all agenda set by Alma Ata declaration in 1978[1] every country is struggling to provide an efficient health care system to its people. Health has become a basic need with emerging health care challenges. Health care delivery system in each country aims to reach the ultimate goal of universal health coverage, with effective utilisation of resources and by strategic planning this goal can be achieved in all countries across the globe.

Unmet Need of Objective Monitor to Evaluate Performance Status in Lung Cancer Patients

Reema Shyamsunder Shukla[1], Yogender Aggarwal[2], Shreeniwas Sheelawant Raut[3], Rakesh Kumar Sinha[4]

[1]Assistant Professor, School of Bioengineering Sciences and Research, MIT-ADT University, Loni Kalbhor, Pune, [2]Assistant Professor, Bio-Engineering Department, Birla Institute of Technology, Mesra, Ranchi, Jharkhand, India, [3]Medical Oncologist, Curie Abdur Razzaque Ansari Cancer Institute, Ranchi, Jharkhand, [4]Professor, Bio-Engineering Department, Birla Institute of Technology, Mesra, Ranchi, Jharkhand, India

Abstract

Context: Quality of life (QOL) of lung cancer patients can be improved by using modern technical tools. There is a necessity to develop a system which incorporates all the functions to evaluate severity of the disease and critical condition of the patients. There exists a need of an objective monitor for monitoring performance of lung cancer patients with parameters of HRV, SPO_2 and Peak Expiratory Flow Rate (PEFR). A questionnaire-based survey was carried out in cancer physicians, surgeons and radiotherapists. Total 100 clinicians participated in this questionnaire, 35 medical oncologists, 35 oncosurgeons and 40 radiation oncologists. The analysis of this survey showed that presently ECOG (Eastern Cooperative Oncology Group) scale was preferred to KPS (Karnofsky Performance Status) scale (70% versus 30%) because of simplicity to remember. The popular parameters preferred among clinicians were SPO_2 (45%), 2D Echocardiography (30%), chest X-ray (42%). But for HRV test, all the clinicians (100%) rejected the availability of test facilities. SPO_2 and PEFR were also rated as mobile tools for assessing the performance. ECOG Scale was easier to utilize than KPS for understanding the performance Status in cancer patients. It is suggested that HRV, SPO_2 and PEFR could be an added value to improve the QOL in cancer patients.

Keywords: *KPS, ECOG, monitor, questionnaire, PEFR, SPO_2.*

Introduction

Karnofsky performance status (KPS) scale scoring was initiated by Dr. David A. Karnofsky and Dr. Joseph H. Burchenal in 1949[1]. It was designed to evaluate the degree of cancer patient activity and medical care necessities. Eastern Cooperative Oncology Group (ECOG) score or Zubrod score was initiated by C. Gordon Zubrod, rated as 0 with perfect health to 5 with death. It is simpler than KPS. The ECOG is used to decide the treatment and prognosis for the patient and assess the progress of the disease[2]. The degree of patient activity and medical care requisites can be measured by the KPS[3]. KPS scaling factor is explained in detail in Table 1[4]. ECOG scaling factor is explained in detail in Table 2[5].

Langley recognized the different components of the autonomic nervous system (ANS), with the term "sympathetic" limited to the thoracic outflow of the autonomic system; he suggested the term "parasympathetic" to assign its cranial and sacral outflows[6]. Brain haemodynamics can be studied in response to sensory stimulations by measuring haemoglobin oxygen saturation (SPO_2). It can be used to evaluate the effects of chemotherapy and radiotherapy on tumors[7]. Heart rate variability (HRV) along with pulmonary function test (PFT) can be an aid for early

prognosis of cardiac disease[8]. It is hypothesized that quality of cancer patients can be improved by knowing the performance status (PS) through various media. The ECOG scale is preferable over KPS because of its simplicity of interpretation. HRV would help us understand the severity of the disease and the ANS dysfunction. SPO_2 and PFT would add an aid to the quality evaluation process. Therefore, a single multiparameter monitor exhibiting HRV, SPO_2, PFT would make the clinician's task simple to evaluate the PS using ECOG Scale.

Method: The questionnaire for clinicians in order to assess the patients' performance.

Duration: The questionnaire-based survey was conducted by clinicians for advanced cancer patients from 01/03/2015 to 01/02/2016.

Results

All the clinicians were familiar with both KPS and ECOG scores. However, in practice there was a high preference to ECOG score than KPS score (70% versus 30%). The only reason for this was simplicity and ability to remember the score.

Eighty four percent doctors agreed that there is interclinician variation in labeling the patient PS. This difference was rated as "considerable" by 35% doctors and as "gross" by 65% doctors. All the doctors agreed that there is a scope of improvement in the evaluation of PS. Sixty two percent doctors agreed that there will be alteration in management of the patient with respect to change in performance and it may prevent unnecessary hospitalizations and investigations, while 38% doctors opined that they give importance to clinical examination and investigations than patients' performance.

Fatigue (56%) was the most common symptom with deterioration of performance of cancer patients followed by dyspnea (32%) and vague complaints (23%). Regarding the preferences of different systems for clinical evaluation of deteriorating performance, 37% doctors gave foremost importance to cardiac, 33% doctor to pulmonary system while 21% doctors gave importance to metabolic parameters, i.e., blood investigations. Neurological and gastrointestinal systems were evaluated only when there were localizing symptoms rather than in general deterioration of performance.

Table 1. Karnofsky Performance Status Scale (KPS) (Adapted from[4])

Percentage	Work carried out
100	No health issues
90	Meagrely symptomatic
80	Can carry out activity with exertion
70	Self caring but cannot perform ones activity
60	Can carry out activity of ones needs but help is necessary
50	Needs help often and medical assistance too
40	Needs personal attention and on bed more than 50%
30	Almost bedridden, badly disabled and hospitalization required
20	Totally bedridden, person attention by family and medical personnels
10	Bedridden, deadly, critical condition
0	Dead

Table 2. Eastern Co-operative Oncology Group (ECOG) scale of Performance Status (PS) (Adapted from[5])

ECOG	MEANING
0	Normal Activity
1	Exhibits symptoms and ambulatory
2	Less than 50% on bed but difficulty in carrying out day to day activities
3	More than 50% on bed
4	Bedridden

In general, there was consensus (73%) that objective tool for monitoring performance is necessary. The parameters preferred were SPO_2 45%, 2D Echocardiography 30%, chest X-ray 42% . However, for HRV test, all the clinicians (100%) rejected the availability of test facilities. However, 74% of clinicians underlined its need as one of the test to evaluate ANS dysfunction and probable deterioration in cancer associated performance. SPO_2 and peak expiratory flow rate (PEFR), a parameter of PFT test were also rated as mobile tools for assessing performance, i.e., home based monitoring. Correlation of various parameters plotted against time in days/ months was a need for 58% clinicians. Moreover, 66% clinicians also wanted some parameter to evaluate the recent short term performance (For example. Hemoglobin A 1C predicts blood glucose control in recent past 2 months).

Thus, detection of subclinical deterioration of performance was a felt need by most (77%) of the clinicians. Sixty five percent doctors pointed to the ANS evaluation for this subclinical progression.

Discussion

Performance status (PS) using ECOG scale of performance stated in Table 2, clinical stage and surgical treatment provided to the lung cancer patients can determine their survival rate[9]. HRV parameters importantly had a correlation with the ECOG PS grade although are not the only parameters[10]. Fatigue is observed on a wider scale as a side effect in NSCLC patients[11]**.** KPS was less capable than ECOG PS to distinguish patients with varied prognosis. ECOG can predict the functional status better and therefore is preferred to KPS[12]. HRV is derived from ECG (Electrocardiogram) signal and can be utilized to know the status of the ANS. HRV analysis can evaluate overall cardiac health and the ANS activity controlling the cardiac activity[13]. HRV conveys know-how on the sympathetic-parasympathetic autonomic balance and thus about the hazard for sudden cardiac death (SCD) in these patients[14]. There was no change in PFT values after Stereotactic Body Radiotherapy (SBRT) was given in Stage I lung cancer patient[15]. Also, it was found that there was no change in SPO_2 as well as PFT value in Non Small Cell Lung cancer (NSCLC) patients followed by SBRT[16]**.** But the pulmonary function may deteriorate more in few lung cancer patients after radiotherapy is given and the level of deterioration is more in chronic obstructive pulmonary syndrome (COPD) NSCLC patients which affects their quality of life (QOL)[17]. Invasive haemodynamic monitoring is essential in lung cancer patients from admission to discharge or death[18]. The study of cognitive dysfunction is essential in small cell lung cancer (SCLC) before prophylactic cranial irradiation because more than 80% of subjects are susceptible to get brain metastasis[19]**.** Any gastrointestinal malignancy ceases to develop in NSCLC patients unless there is lung metastases[20]**.**

Conclusion

The present subjective performance scales in lung cancer patients are vague and subjected to interpersonal difference of opinions. Clinicians need a better objective monitor of performance score. Further, noninvasive monitors are preferred over invasive monitors. Cardiac and pulmonary systems are more focused for evaluation whenever deterioration of performance is complained by patient and relatives. Moreover, ECOG scale is preferred over KPS scale to determine the performance status. HRV analysis may be helpful for studying autonomic system dysfunction. The SPO_2 and PEFR parameters can further add to scope of improving the QOL of patients.

Treatment Seeking Behaviour among TB Patients Registered Under RNTCP in District Bareilly

Ratnesh[1], Hemalatha Umashankar[2], Sudeepa D.[3]

[1]Tutor, MD Community Medicine, Department of Community Medicine, Dumka Medical College, Dumka, Jharkhand, India, [2]Assistant Professor, [3]Professor, Department of Community Medicine, TOMCH&RC, Bangalore, Karnataka, India

Abstract

Background: Tuberculosis (TB) is a major global health problem and ranks the second leading cause of death from an infectious disease worldwide. India is the highest TB burden country accounting for more than one fifth of the global burden of tuberculosis. The objectives were **(1)** To assess the treatment seeking behaviour of TB patients registered under RNTCP in a select district and **(2)** to determine the default rate in patients having history of treatment interruptions.

Method: A cross-sectional study was conducted among the TB patients registered during 1st April 2014 to 31st March 2016 under RNTCP for DOTS in Bareilly. Purposive sampling was carried out, 10 DMCs were selected in district Bareilly of which a total of 2010 TB patients were interviewed.

Results and Conclusions: In the present study majority of the patients were in the age group of 20 - 39 years (35.0%), male (55.7%) and were sputum positive (69.5%) Cases with a history of treatment interruption had a very high default rate of 23.3% while cases that didn't interrupt their treatment had a low default rate of 3.93%. This association was found to be statistically significant. People who had a positive history for treatment interruption had seven times more risk of becoming a defaulter.

Keywords: *Tuberculosis, Default, Treatment seeking behaviour, Treatment interruption.*

Introduction

TB has coevolved with humans for many thousands of years and perhaps for several million years. It is caused by Mycobacterium tuberculosis. It primarily affects lungs and causes Pulmonary TB (PTB). It can also affect intestine, meninges, bones and joints, lymph glands, skin and other tissues. [1] TB is transmitted mainly by droplet nuclei generated by sputum-positive patients with PTB. [2]

In India under RNTCP, TB prevalence per lakh population was 195 in 2013. TB incidence per lakh population was 167 in 2014. TB mortality per lakh population was 17 in 2012.[3] Despite these achievements still one-third cases of TB remain undetected in India and poor treatment adherence.

The objective of the present study was to know the treatment seeking behaviour of TB patients registered under RNTCP in district Bareilly and find the default rate in patients having history of treatment interruptions.

Method

A cross sectional study was conducted in district Bareilly over a period of 1 year from August 2015 to July 2016 to determine the treatment seeking behaviour and default rate among TB patients registered under RNTCP by using a pre designed, pretested semi-structured questionnaire. TB patients registered under

RNTCP for DOTS in Bareilly district for treatment from 1st April 2014 to 31st March 2016. There are 45 DMCs in district Bareilly. Out of these DMCs, 10 DMCs were selected randomly by using lottery method. Interview of the TB patients registered in the DMCs was taken at the health facility or by making home visits for the selected patients. A total of 2010 TB patients were interviewed during the study period.

The study protocol was approved by the Institutional Ethics Committee. Informed consent was collected from the participants and confidentiality was assured. Patients who were not willing to give consent or moved out of the geographical area or were not available for interview on two subsequent visits were excluded from the study.

A TB patient who did not start treatment or whose treatment was interrupted for 2 consecutive months or more was defined as Defaulter.

Results

Table 1: shows the socio-demographic characteristics of 2010 subjects who participated in the study in which the age distribution revealed that maximum subjects (35.0%) were in the age group of 20 - 39 years, followed by 28.1% belonging to 40 - 59 years, 24.3% belonging to <20 years and 12.6% belonging to > 60 years. Male cases contributed 55.7% of the study population.

Table 2: reveals that majority of the cases that is 69.5% were sputum smear positive while 15% were sputum smear negative and in 15.5% cases sputum examination was not done as they were extra pulmonary cases.

More than two third (83.1%) of the cases were taking treatment in the category I while the rest (16.9%) were undergoing treatment of category II.

Table 3: shows the distribution of cases according to their first contact to the health system by the cases on the onset of their symptoms which revealed that 765 (38.1%) study subjects took their first symptomatic treatment from private practitioner followed by 32.6% individuals who went to hospitals, 11.4% cases took treatment from local quacks, 10.6% cases took treatment from chemist while only 7.2% cases went to the DOTS center for their treatment.

Table 1: Socio-demographic characteristics of the study participants

Characteristics	Frequency (N=2010)	Percentage
Age		
<20 Years	489	24.3
20 - 39 Years	703	35.0
40 - 59 Years	565	28.1
> 60 Years	253	12.6
Gender		
Male	1119	55.7
Female	891	44.3
Locality		
Urban	1050	52.2
Rural	960	47.8
Religion		
Hindu	1123	55.9
Muslim	887	44.1
Family Type		
Nuclear Family	777	38.7
Joint Family	748	37.2
Three Generation Family	485	24.1

Table 2: Distribution of TB cases according to their type and category

	Frequency (N=2010)	Percentage
Smear Status		
Smear Positive	1398	69.5
Smear Negative	301	15
Extra Pulmonary TB Cases	311	15.5
Category of Treatment		
Category I	1670	83.1
Category II	340	16.9

The biggest source of suspicion of tuberculosis in study subjects was suggested by a doctor (72.9%), followed by self-perception (13.9%), suggestion by health worker (9.3%), an effect of the awareness campaign (1.4%) and only 0.8% cases had an effect of media.

Maximum number of cases that is 40.2% were diagnosed tuberculosis at DOTS centre while 33.9% and 25.9% were diagnosed at other government hospitals and private clinics respectively.

Table 3: Distribution of TB cases according to their treatment seeking behaviour

	Frequency (N=2010)	Percentage
First symptomatic treatment was taken from		
Private Practitioner	765	38.1
Hospital	656	32.6
Local Quacks	230	11.4
Chemist	214	10.6
DOTS Centre	145	7.2
Suspicion of TB aroused by		
Suggested by Doctor	1465	72.9
Self-Perception	279	13.9
Suggested by Health Worker	187	9.3
Suggested by Peer Group	34	1.7
Effect of Awareness Campaign	29	1.4
Effect of Media	16	0.8
Place of Diagnosis		
DOTS Centre	808	40.2
Government Health Centre	681	33.9
Private Clinic	521	25.9
Time Taken for treatment to start after the diagnosing TB		
< 2 Weeks	1890	94.0
> 2 Weeks	120	6.0
History of treatment interruption		
Yes	562	28
No	1448	72

Table 4: Default rate according to the history of treatment interruption

History of treatment interruption	Total TB Patients	Defaulters	Default Rate
Yes	562	131	23.3
No	1448	57	3.93
Chi-Square value = 179.233; df = 1; p-Value = < .001			

p-Value<.05 is considered as significant

Almost all the cases (94%) started their DOTS treatment within the 2 weeks of the time period while only 6% of the cases showed delay in treatment more than 2 weeks.

Approximately one fourth of the cases (28%) showed an interruption and break in their continuity of the treatment.

It is evident from table - 4 that cases who had history of treatment interruption had a very high default rate that is 23.3% while cases who didn't interrupted their treatment had a low default rate of 3.93%. The association came out to be statistically significant. (p value< 0.001)

Logistic regression was applied on the history of treatment interruption, by keeping patients who didn't have any treatment interruption history in reference category; it was observed that people who had a positive history for treatment interruption had 7 times more risk of becoming a defaulter.(p value =0.001) (Table 5)

Table 5: Risk of defaulting from treatment according to the history of treatment interruption by applying logistic regression

History of treatment interruption	Defaulter	Non Defaulter	Odds Ratio	Confidence Interval (95%)		p-value
				Lower limit	Upper limit	
Yes	131	431	7.417	5.336	10.309	.001
No	57	1391	Reference	-	-	-

p-Value<.05 is considered as significant

Discussion

There were total 2010 TB cases interviewed in the present study. Nearly one third of the TB cases, i.e. 703 (35.0%) were from the age group 20 - 39 years of age.

The findings of this study are similar to the findings of **Sumer C et al (2012)[4]** where most of the TB patients were in the age group of 16 - 24 years (26.95%). Whereas study done by **Roy N et al (2011)[5]** the 27.84% of the study population was in the age group of 25 - 35 years.

In the present study out of 2010 TB patients, 1119 (55.7%) of the study participants were male, 1050 (52.2%) from urban area and 1123 (55.9%) were Hindu by religion.

The above finding is similar to **Verma AK et al (2007)[6]** where out of 130 participants 55.8% were male. And in the study conducted by **Gupta S et al (2007)[7]**45.77% of patients were residents of Urban area. Whereas study done by **Varshney AM et al (2010)[8]** 74% of the study participants were Hindu by religion.

In 2010 TB cases, 765 (38.1%) cases took their first symptomatic treatment from private practitioner; Suspicion of TB was aroused by Doctor in 1465 (72.9%) cases; most of the cases i.e. was diagnosed TB in DOTS centre and almost all the TB patients i.e. 1890 (94%) started their treatment within two weeks after getting diagnosed for TB while only 562 (28%) gave a history of treatment of interruption.

The findings of this study is similar to the findings of **Varshney AM et al (2010)[8]** in which 52% of the study participants had first time consulted private practitioner for their illness and 48% from Government physician.

Sudha G et al[9] in their study highlighted that private health care facilities were the first and preferred point of contact for 57% of urban and 48% of rural participants. Chest symptomatic opted for self-medication in urban and rural 33% and 21% respectively.

Suganthi P et al[10] in their study in Bangalore slums found that 72% first approached private health facilities. The choice of first health facility depended primarily on distance from a residence and faith in the health care services. Predominant reasons for subsequent visits to other health facilities were persistence of symptoms and referral.

In the study by **Rajeshwari R et al[11]** patients first consulted private practitioners more frequently than government providers (54% vs. 27%; $p<0.001$). Most patients resorted to self-medication (61%) or pharmacies (7%).Only 20% were diagnosed at the health facility where thy first sought care; the others shopped around for care at various health facilities before a diagnosis of tuberculosis was made. Nearly half of all the patients had to visit three or more health facility before a diagnosis of tuberculosis was made.

Conclusion

Default is one of the unfavourable outcomes for patients on DOTS and represents an important challenge for the control program.Poor treatment adherence increases the risk of drug resistance, treatment failures, relapses, deaths and prolonged infectiousness, which is a hurdle to the success of TB programs.

Invitro Evaluation of Shear Bond Strength of Orthodontic Brackets Cemented to Natural Teeth Treated with Various Soft Drinks

Ravi Gupta[1], Arun Prakash C.[2], Amith A. Singh[3]

[1]Assistant Professor, Department of Conservative Dentistry, Faculty of Dentistry, Melaka Manipal Medical College (Manipal Campus), Manipal Academy of Higher Education, Manipal , Karnataka India, [2]MDS, Consultant Prosthodontist, Vellore, India, [3]Assistant Professor, Department of Prosthodontics, Manipal College of Dental Sciences, Manipal Academy of Higher Education, Manipal, Karnataka India

Abstract

Introduction: The common problem during the orthodontic treatment is debonding of brackets which leads to failure of orthodontic treatment. The purpose of this study was to determine the effects of four soft drinks (Coca-Cola, 7Up, Tropicana orange, minute maid apple juice) on the shear bond strength of orthodontic brackets.

Aim: To evaluate the shear bond strength of orthodontic brackets cemented to natural teeth treated with various soft drinks

Materials and Method: A total of 50 extracted human premolars were collected and stored in normal saline solution. They were cleaned and cemented with edge wise stainless steel brackets using composite. Then they were cycled in the said four soft drinks for 2 hours up to 7 days. The samples were tested for their shear bond strength using Universal testing machine (INSTRON) with a cross head speed of 0.5mm/min. The values were tabulated and analyzed statistically using ANOVA.

Results: The lowest mean resistance to shearing forces was shown by the control group (18.74 ± 5.15 Mpa) followed by 7Up group (20.17 ± 6.76 Mpa), orange juice group (21.79 ± 5.15 Mpa), Coca Cola group (24.58 ± 11.68 Mpa) and highest resistance to shearing forces by apple juice group (26.04 ± 1.31 Mpa). There was no statistically significant difference among the groups.

Conclusion: No significant differences were observed in bond strength of the teeth among the different groups suggesting that consumption of soft drinks after cementation of orthodontic brackets do not significantly affect in de-bonding the brackets.

Introduction

In developing countries, there is an increasing trend in consumption of soft drink, especially among young people.[1,2] This habit often continues into adulthood. Soft drinks contain high sugar content and a pH of < 5.5 which is below the critical level that will cause enamel demineralization leading to dental erosion and

also microleakage beneath the orthodontic brackets in patients undergoing orthodontic treatment.[3,4,5] This is a matter of concern among dental practitioners.

Debondingof brackets during orthodontic treatment is commonly seen.[6] Hence, patients receiving orthodontic care need proper attention.

The causative factor for bond failure is due to acidic foods and drinks with thelow ph in the diet of the patient which increases treatment time.[6,7]This might also have an erosive influence on the hydroxyapatite component of teeth.[8,9]Coca-colais categorized as the most carbonated drink (50%) which contains high levels of citric acid and phosphoric acid that should be seen as a true hazard for patients with orthodontic appliances.[1,3]Very few studies have been conducted in the past to evaluate the effect of soft drinks on the bond strength. Coca-cola, 7-Up, Orange juice and Apple juice are widely available in the market and is very popular among adolescents undergoing orthodontic treatment. The purpose of this study was to determine the effects of these four soft drinks (Coca-cola, 7-Up, orange juice and apple juice on the shear bond strength of orthodontic brackets in vitro.

Materials and Methodology: This in vitro study was conducted at the department of conservative dentistry and prosthodontics, Melaka Manipal Medical College, Manipal. Ethical Clearance was obtained from the Institutional Ethical committee**.**

1) Sample Selection: The software G*Power 3.0.10 was used to estimate the required sample size for the study. A total of 50 extracted human premolars were collected and stored in normal saline solution. The teeth selected for the study were free from enamel cracks, caries, and fillings. These teeth were fixed in self-cure acrylic blocks using aluminium tubes (Figure 1). Fifty 0.022'' stainless-steel edgewise orthodontic brackets (Centrino Standard MBT ®) with a base surface of 12.2 square mm were used in this study. (Figure 2)

2) Bonding of Brackets: All 50 teeth were cleaned and polished thoroughly using pumice slurry before the bonding procedure. The teeth were etched using 37% phosphoric acid gel (DETREY Conditioner 36, Dentsply, UK) for 30 seconds as per the manufacturer's instructions. The teeth were rinsed with water spray and air dried until a frosty white appearance was seen on the etched buccal surface.

A thin uniform layer of Spectrum® bond- Nano-Technology Dental Adhesive (DENTSPLY, UK) was applied using a brush on the buccal surfaces of each tooth and also onto the base of the orthodontic brackets following manufacturer's instruction and the bonding agent was cured. A flat-ended composite filling instrument was used to apply the required amount of Spectrum® dental composite (DENTSPLY, UK) onto the buccal tooth surface as well as the base of orthodontic brackets.

The bracket was then pressed firmly into the centre of the crown of the tooth mesiodistallyand along the long axis of the tooth immediately (Figure 3). Excess (composite) was removed from the bracket using a sharp scaler.

The composite was light-cured using Densply LED light curing unit on all four sides of the bracket edge, 10 seconds per side at a distance of 1-2mm.

3) **Immersion and Storage:** The samples were then immersed in 5 different groups of beverages once daily for 2 hours. This process continued for seven days. Then they were washed with water and stored in distilled water at a temperature of 37 degree Celsius until the testing.

4) De-bonding Testing: The samples were tested for their shear bond strength using the Universal testing machine (INSTRON) with a cross head speed of 0.5mm/ min. The values were obtained in Newton. The values which were obtained in Newton were converted to Mega pascals by dividing the total area with 12.2 square mm which is the area of the single bracket. (Figure 4)

Statistical Analysis: Anticipating an effect size of 0.6 and to test the null hypothesis at 5% level of significance with 80% power the required sample size was 40. It was increased to 50 (10 per group), anticipating 20% failure during testing. Mean of the debond testing was compared applying Welch ANOVA followed by Post Hoc Games-Howell test using software SPSS version 15. $P<0.05$ was considered statistically significant.

Results

Table 2 shows the group-wise summary (mean and SD) andthe result of group mean comparison. Considering unequal variance (Levene test of homogeneity of variance ($P<0.001$)) group means were compared applying Welch Anova (Robust test of equality

of means). Welch ANOVA indicated a significant difference in the group means (F (4,11.37)=3.61, P=0.038). Post Hoc Games-Howell test for pair-wise comparison did not show any significant difference in the group means. Mean resistance was maximum for Distilled water (mean=26.04) and was least for Apple juice (mean=18.74). The difference in mean of these two groups was not significant (P=0.08).

Among the selected values, the lowest mean resistance to shearing forces was shown by apple juice group (18.74 ± 5.15 Mpa) followed by 7Up group (20.17 ± 6.76 Mpa), orange juice group (21.79 ± 5.15 Mpa), Coca-Cola group (24.58 ± 11.68 Mpa) and highest resistance to shearing forces by control group (26.04 ± 1.31 Mpa).

A considerable amount of intergroup variation was seen in the coca-cola group. All the other groups showed lesser inter group variation.

Table 1: Beverages were divided into five groups in this study : (Table 1)

Groups	Beverages Used
Group 1	Control – Distilled water
Group 2	Tropicana Orange Juice (PepsiCo.)
Group 3	7 – UP (PepsiCo India)
Group 4	Tropicana Apple Juice (PepsiCo.)
Group 5	**Coca-Cola (Coca-Cola India Pvt. Limited)**

Table 2: Mean resistance to shearing forces.

Soft drinks	n	Mean	Standard. Deviation	Welch Anova F (4,11.37)	P-value
Apple Juice	7	18.74	5.15	3.61	0.038
Orange Juice	7	21.79	5.15		
7 UP	7	20.17	6.76		
Distilled Water	7	26.04	1.30		
COCA COLA	7	24.58	11.68

Discussion

Several studies have reported that consumption of acidic beverages like cold drinks leads to debonding of orthodontic brackets due to decrease retention.[1-6]

This is an in vitro study, designed to reproduce in vivo situation. In the experiment, different drinks that are commonly consumed by target groups which are Coca-Cola, 7Up, Orange Juice, Apple Juice, and also distilled water (control) are used as manipulative variables.

The immersion times and schedules used in the many past studies varied widely. In our study, 50 specimens divided equally were kept for 2 hours, in respective drink groups daily for seven days. The remaining time it was kept in distilled water to mimic the normal oral environment. In this way, we can assume that these drinks were consumed 3 – 4 times a day considering 45 minutes to consume one drink.[5]

Coca-Cola was the most acidic drink followed by 7 UP. The apple and orange juices were also acidic. Both Coca-Cola and 7 UP contains citric acid which gives the acidity to the drink. The apple and orange juices contain calcium citrate and ascorbic acid. All these soft drinks have demineralizing effects on the teeth surface.

The cementing of brackets under one operator minimizes the error and standardize the cementing force. During debond testing using the Instron machine with a shear head speed of 0.5 mm/min.

Also, it is noteworthy to note that the inter group variations obtained in the Coca-Cola group were higher compared to the other groups.

The results obtained are similar to the results of Navaro's et al[5] study who reported that bond strength values for teeth treated in Coca-Cola and Schweppes Limon were not significantly different from those in their control group. Also, our results were in consistent with a study done by Suparssaraet al[10]

This result contradicts with some of the studies conducted[11,12] that found Coca-Cola showing areduction in shear bond strength of orthodontic brackets. Based on the study, the teeth were immersed in Coca-Cola thrice a day, while our study only immersed the teeth once daily in respective drink groups. Hence, the study might have abetter imitation of soft drink consumption by target groups. Coca-Cola is an acidic media,and it can decalcify tooth (Borjan a Ferrari). Calcium may leach out from the teeth, thus soften and erodes the dental hard tissues. This will then facilitates abrasion. Furthermore, the structure of bisphenol A glycidyl methacrylate-based composite resins which is the main composition of the adhesive used in the study will be degraded with acid and acidic drink consumption as mentioned as suprssra et al.[12] The matrix of the adhesive will soften which leads to filler leaching out, thus lowering the bond strength of the brackets (Hobson RS).

The limitation of this study was an unexpected increase in the failure rate of teeth (lesser sample size) could be one of the reasons for the insignificant difference in the group means. Hence further study may be required by increasing the sample size.

There are many factors that may affect the results. For example, the experiment done is an in vitro study, which the teeth used are extracted from different patients, at different times, of different age. Hence, the mineralization level of each tooth differs as it is affected by their lifestyles, oral hygiene and age factor. Also, the biggest disadvantage in these studies is that the data of beverages consumed by the individual before the bonding is often unknown, which could be a major factor while comparing the results.

Furthermore, the teeth used are premolars, which have aconvex surface. The bonding position of the brackets is not always consistent between different teeth. Thereby, affecting the force applied during the debonding process might vary. Therefore studies are required.

Conclusion

No significant differences were observed in bond strength of the teeth after debonding among the different groups suggesting that consumption of soft drinks after cementation of orthodontic brackets do not significantly affect debonding of orthodontic brackets.

Conflict of Interests: The authors declare no conflict of interests.

Understanding the Basics of Research as a Beginner: A Highlighter

Ravi shankar M.V.[1], Vidya C.S.[2]

[1]Assistant Professor, [2]Associate Professor Dept. of Anatomy JSS Medical College JSS Academy of Higher Education & Research, Mysuru.

Abstract

Context: Research has grown beyond leaps and bounds; scientific progress solely depends on inquisitiveness and tireless coordination of teamwork. The word research is so attractive for a beginner, the student fraternity is overwhelmed about this process. Irrespective of any field, now the research is becoming an indispensable part of the educational system. This article is intended to create basic awareness about research and its components, especially for the research-oriented students in the field of medical, paramedical, allied health sciences, etc.

Keywords: *Research, bioethics, clinical trials, good clinical practice*

Introduction

Biomedical research is based on fundamental biological scientific principles, which will focus onpersonal healthcare and public health. Basic research is also called as bench side research; it deals with in-vitro and in vivo experimental models involving the organisms or animals to obtain a valid outcome to further try on the humans. When the basic research results are tried on clinical patients it is called translational research, which is solely intended to trial the results of basic research from bench side to bedside, clinically by using patients virtually[1].

Research is practiced by humans since the time of evolution on earth. In history, the ancient practice of folklore medicine stands as the best example for the oldest model for clinical research; with the time it has gradually evolved through trial and error method. India is at the forefront of contributing to the field of clinical research; medical science like Ayurveda, Siddha, Unani; their medical literature has mentioned the use of medications for several human ailments for thousands of years. Based on its principles, Ayurveda has mentioned therapeutic interventions, and a number of herbs and mineral formulations applied directly to the human subjects with the sole purpose of alleviating human sufferings[2,3].

Classification of type of study:

Basic Research: The basic medical research deals with understanding the functional, cellular or molecular mechanisms in primates through in vivo or invitro studies.

Preclinical Research: Preclinical research deals with the study on humans, which further supports the clinical trials on patients.

Clinical Research: It is conducted on patients in the hospital or on the selected population; it is supervised by physicians.

What is the Research Question.?: It is the main inquiry of the issue which needs to be addressed through research. The research question should be clear, targeted and simple.

Corresponding Author:
Dr. Vidya C.S.
Associate Professor, Department of Anatomy JSS Medical College, JSS Academy of Higher Education & Research., Mysuru**:**570015
Mob No**:** 9449679386
e-mail: vidyacs@jssuni.edu.in

What is a Pilot Study.?: It is the study performed on a small scale by using a minimum number of participants/subjects. This study gives every opportunity to the researcher/investigator to understand all aspects of the main study including its feasibility, sample size, time duration, troubleshooters, etc.

What are the Study Parameters.?: Parameters are study exponents in the research; which are later subjected to analysis.

Bioethics: Bioethics deals with the study of ethical dimensions of medicine and biological sciences. Important principles of bioethics are including Autonomy (respect to self-governing), Beneficence (best interest of the subject), Non-maleficence (causing no harm) and Justice (fair treatment)[4]

Basicresearch in Non-Human Primates: Research on non-human primates is a prerequisite for conducting trials on subsequent levels. Animal experiments mean, the use of animals preferably mammals in the experiments for education and research. The basic experiments use nonhuman primates like rats, mice, rabbits, hamsters, guinea pig, monkey, chimpanzee, dog. It can also be done by using fruit flies, cell lines, fish, etc. There are millions of animals that will be sacrificed worldwide for the sake of research every year. Experiments performed by using both vertebrates and non-vertebrates, but using the vertebrates will be taken into account as they are under more strict ethical vigilance. For research, all these animals should be procured from the authorized breeders who are registered under CPCSEA (committee for control and supervision of experiments on the animal) guidelines or from the recognized higher research centres.

Importance of animal testing in biomedical research: In the field of biomedical research, the use of the animal model experiments stands as "**Hall Mark**" of an interventional research study. The great scientists like Aristotle, Erasistratus Galen, etc. have tried their initial experiments on the animals for scientific purposes[5]. Age back, the use of animals got much attention, particularly to test the surgical procedures or use of drugs or devises before applying them clinically to humans. In spite of heavy criticism by the public and the animal protection activists there is a rise in several basic research experiments on animals; because in history, we have learned about the adverse effects of drugs that were used directly on patients. Causing harm to the animals can't justify the human benefit. But still,animal-based research outcome retains its importance in several aspects including, toxicological studies, where the animal experiment model stands as an inevitable tool in supporting the increasing hierarchy of evidence. In the present situation to justify the rationality and inevitability of the use of animals in the experiments we need to follow principles of 4R.

Replacement: Use of alternate to animal model Ex: in silico i.e. use of computer modeling, in vitro cell line studies, etc.

Reduction: Method which minimizes the number of animals in experiments

Refinement: It deals with the reduced invasiveness, by adopting improved, non-invasive, non-painful procedures by using the most appropriate method[6].

Rehabilitation: As a 4th component, the rehabilitation of animals will be done after its justified usage[6].

Toxicity Study: It is a branch of science deals with the toxins and poisons and their effect and treatment. As per US food and drug administration (FDA),for the development of a new drug entity, it is essential to conduct toxicity tests in the biological subjects[7].

Trials Before Regulations: In the olden days, before formulating guidelines for clinical research activities, any individual or group of people would be a part of the research event; it was tried on the helpless community like war prisoners or people who convicted under crime, children, patients, aged people, etc. The direct use of drugs like thalidomide and Elixir Sulfanilamide on humans has resulted in the death of the study participants. Based on such consequences of unethical trials on humans, the present era has formulated a code that is mainly focused on obtaining voluntary consent. By considering theabove discrimination in the clinical research, a judgment formulated with a code known as "Nuremberg code" which has streamlined the research at all levels with the sole intention to protect the safety and dignity of the participants to achieve more precise and valid outcome[8].

History of Clinical Trials: The credit of clinical research goes to a Scottish physician Dr. James Lind, M.D. (1716–1794) has treated the disorder called scurvy in sailors, where patients were presented with the sign

of bleeding through their gums. He has noticed thatthe administration of the orange and lemon has shown drastic improvement in their condition[9].

Regulations of Clinical Trials:

Good Clinical Practice (GCP): It is an international ethical and scientific standard protocol for conducting biomedical and behavioral research involving human participants; which protects participants' safety, rights and confidentiality at all levels[10].

International Conference on Harmonization (ICH): It is an international council that bringing together the regulatory authorities and pharmaceutical industry to discuss the technical aspects of drug registration. ICH's regulations are intended to achieve greater harmony worldwide to ensure safety, effectiveness, and quality of medicines; which are developed and registered in a hassle-free manner[11].

Institutional Ethics Committee (IEC): It playsa role in appointing members; it will review the protocol and informed consent forms (ICF), and periodic progress of the study[12]

World Medical Declaration of Helsinki: It is developed by the World Medical Association (WMA) in the year 1964; it is including ethical guidance for physicians and all other participants in the research team involving in clinical trials on human subjects. This rule binds all the research participants to the applicable law under its declaration[13]

Role of the Investigator: All trial investigations are conducted by qualified and trained persons who are personally supervising the work.

Sponsor for Trials: The sponsor fora clinical trial may include an individual, anindustry, an institution, etc. which takes the responsibility of initiation, management, financing, and auditing. They are also taking the responsibility of subjecting the study participants under sufficient insurance coverage, and compensating the subjects in any untoward incidence or reactions[14].

Role of Statistics in Research: Since the time of conception of the research protocol, the statistics play an important role to format different components of research like study design, conduct, sample size, data analysis, reporting, etc. they are essential to derive a valid and precise conclusion.

What is the Placebo Effect.?: Placebo is an inert substance without any therapeutic value; it is used to compare with standard control groups. The psychosomatic profile is an important factor to be considered in assessing the placebo drug response. The placebo effect can be better appreciated in the alleviation of symptoms of the pain rather than any other condition[15].

Clinical Trials: Clinical trials are research study on human subjects, which is intended to evaluate the effect of biomedical interventions like vaccines, drugs, treatments, devices, new ways of using known drugs or to study drug interactions, etc. The study may also include the evaluation of behavioral interventions[16].

The ultimate goal of CT is to ascertain the drug safety of the subject, risk and benefit ratio before its final approval for marketing. There are many factors involved in research, out of which some are can be controlled, and some others are beyond one's control. Randomization means being nonselective to any application or intervention. Randomization in clinical trials is considered as the basis for the "Evidence-based Medicine"[17].

Blind Experiments: Bias is the main concern of the clinical trials where blinding becomes essential to reduce the bias and increase the validity of the outcome. Blinding is a process where one or the other participants in the study were deliberately kept unaware of intervention. Blinding is an important factor to ensure objectivity in the clinical trial by avoiding or preventing the conscious and unconscious bias in the study[18].

Types of Blind Trials: Open clinical trials: it is the trial where all the level of study participants in the research group will be knowing the intervention.

Single-blind study: where the subject alone in the research study is unaware of intervention.

Double-Blind Study: where the subject, as well as the researcher both, are unaware of the intervention

Triple-Blind Study: where the subject, researcher, and analyserare unaware of intervention. At the end of the study result analysis, all masked or blinded interventions will be disclosed.

Protection of Subjects: The protection of the clinical trial participants at all levels is an important issue. Concerned authorities should take care of all necessary precautions to address personal, social and

legal issues during and after completion of trials. Any relevant issues should be addressed, and it should be properly compensated for the loss. It is essential to ensure proper compensation for all the study participants who are involved in the clinical trials.

Importance of Informed Consent (IC): Clinical trial participants are strictly volunteer in its true sense without coercing them for any benefit. Informed consent is an important prerequisite before allocating any human subject to the clinical trials. Privacy and confidentially of IC should be maintained in all the circumstances. It is very much essential to know whether the subject is a literate or illiterate, or whether he is fit to give valid consent. The investigator should explain and clarify all the doubts of participants regarding the research protocol before taking consent[19].

Types of Clinical Trials:

Screening Trial: screening for the possibility of occurrence of diseases in a healthy population

Prevention Trail: it deals with the prevention of disease by using supplements, vaccines, devices, lifestyle modifications, etc.

Diagnostic Trail: it deals with the accuracy of the disease

Treatment Trail: it deals with the effectiveness of treatment in diseased

Conventionally the CT is Having the Following Phases:

Phase 0: It is an Exploratory Investigational New Drug (IND) Study. It will be conducted first on humans; it is also known as human micro-dosing studies by using the sub-therapeutic dose. It is conducted by using 10-15 numbers of limited volunteer healthy human subjects to understand the pharmacokinetics, pharmacodynamic activity,and safety of a new drug or a molecule.

Phase I or Clinical Pharmacology Trial: It is also called "First in Man", done in small groups with 20-100 in number in healthy volunteers. It is to assess safety through pharmacovigilance and the details of the pharmacokinetic and pharmacodynamic effects of a drug. Dose escalation trial can give an idea about the appropriate maximum tolerable dose which can be used under subsequent trials.

Phase II or Exploratory Trial: The third phase of the clinical trial can be done in 200-300 number of larger healthy human volunteers. It is done in Phase I A is to assess the clinical efficacy or biological activity, and Phase II B is to assess and match the optimum dose, benefit with minimum side effects

Phase III trial or Confirmatory Trial: It is a randomized control multicentric trials in a large number of volunteer patients in a group of 300-3000 or more. Such trials are more expensive, time-consuming and difficult to handle, especially while dealing with chronic disease conditions or disease with a long latency/ incubation period.

Phase IV or Post-marketing Surveillance: Called post-marketing surveillance trial. It involves a pharmacovigilance study after receiving permission to market an approved drug. If the drug/treatment is found satisfactory in three phases, then it will be approved under the country's national regulatory authority for its use in the general population. Phase IV trials are invariably always under the research radar.[20,21]

Multicentric Clinical Trials: It includes a large number of participants from different parts of the world, including a wide range of populations; which will compare the results of different centers.

Accessibility of Clinical Trial Reports: Accessing clinical trial data or information is an important prerequisite to tackle the challenges before considering them under policymaking. Archiving the clinical trial documents is a must, which helps to analyze the data retrospectively in a systematic manner. Now online updates are available on the registered websites which are developed at the national institute of health under the national library of medicine. CT information is always accessible to any common man, through website clinical trials govand also through Cochrane Library, it is a collection of databases in medicine and other healthcare specialities[22,23]. The ultimate goal of accessing the clinical trial results is to introduce newer government policies and regulations to provide improvised health care facilities for the benefit of the population at large.

Conclusion

For a beginner, the present review will highlight the components of basic research, preclinical and clinical research. It has created basic awareness about the ethical factors involved in the research at different levels.

Ethical Clearance: Obtained from Institution ethical committee

[1]PhD Student, Department of Community, Medicine, Shri B M Patil Medical College, Hospital & Research Centre, BLDE (Deemed to be University), Vijayapura, Karnataka, India, [2]Professor and Head, Department of Community Medicine, Shri B M Patil Medical College Hospital & Research Centre, BLDE (Deemed to be University), Vijayapura, Karnataka, India, [3]Professor and Head (Retd), Department of Medicine, BJ Medical College, Pune, Maharashtra, India

Abstract

Background: Synergistic effect of malnutrition, food insecurity and poor standard of living pour significant changes and poor outcome in already compromised PLHAs due to increased financial burden as well as emotional breakdown.

Objective: To assess the nutritional status , food insecurity and standard of living (SLI) with rural urban differences and their association if anyamong the PLHAs who have been stablished with one year of treatment

Methodology: A facility based cross-sectional study on PLHAs was carried out in tertiary care centre of western Maharashtra with a sample size of 246. Data was collected by means of pretested semi structured questionnaire after taking Institutional clearance. Strict confidentiality was maintained throughout the study.

Results: The mean age of the study participants was 43.37 years with majority (50.9% rural, 39% Urban) were secondary class educated. Only 20% of urban and 8.5% of rural had income above 10,000 per month. Maximum (48.2 %) of rural were doing heavy works (construction/agricultural) while majority of urban were unemployed (30.5%) followed by business (21%) work. 36.9% (Rural) and 28.6 % (Urban) had spouse positive for HIV status. Even after one year of treatment, only 36.9% rural and 41% urban PLHAs were having CD4 count above 500. 49.6% (Rural) and 46.7% (Urban) were food insecure while 27.7% (Rural) and 14.3% (Urban) had low standard of living. 36.2% (Rural) and 30.5% (Urban) were undernutrition with 51.8% (Rural) and 54.3% (Urban) having abnormal waist circumference. BMI Category had statistically significant association with SLI and food insecurity in urban participants while it was not statistically associated with rural participants

Conclusions: Inspite of freely delivered ART for one year and majority having good adherence rate, there were actionable changes in nutritional changes among PLHAs of both rural and urban areas. Neglected factors like food insecurity and standard of living needs to given special focus to affectively crub the high incidence of undernutrition among them. Immediate long term measures need to be taken to provide them adequate food and basic amenities of life with secure Job status.

Introduction

HIV/AIDS is modern day epidemic with estimated total of 36.7 million people living with HIV/AIDS (PLHAs) globally[1] and 21.17 lakhs Nationally[2]. With sustained international focus and recent scientific

advancement, measures are been taken to curtail the epidemic. In this view, Global strategy has been adopted to end the AIDS epidemic by 2030 with zero new HIV infections, HIV related deaths and discrimination and making people live longer healthier life[3].

With the latest WHO and NACO policy of starting the Anti-Retroviral treatment (ART) at the diagnosis level, will go a long run in making PLHAs lead a happy comfortable life similar to any lifestyle disorders like diabetes and hypertension. However there are various other factors which would determine how well PLHAs lead their life and maintain their clinical stability. Important among them are socio-economic conditions and nutritional status which form the pillars for ART accessibility, adherence, action and disease stability per se.

Nutritional status depends on various factors such as food insecurity, standard of living, income status, awareness level, diet-drug interaction, loss of weight due to opportunistic infections and disease per se[4].

Synergistic effect of malnutrition, food insecurity and poor standard of living pour significant changes and poor outcome in already compromised household conditions due to increased financial burden as well as emotional breakdown. With this even a minor amount of weight loss would result in significant morbidity and decreased survival rate among PLHAs[5]. It is also hypothesized that rural people maybe incurring higher impact due to these as compared to urban PLHAs due to lack of resources, income generation and facilities hinting the need for a study these differences. Undernutrition is thus one the significant factor for increased morbidity and mortatality among PLHAs inspite of ART and highlight the importance of measures to be taken to improve nutrition including food security and standard of living in addition of free ART availability[6].

In view of above, this study was carried out among the PLHAs who have been stablished with one year of treatment with the objective to assess the nutritional status , food insecurity and standard of living (SLI) with rural urban differences and their association if any

Methodology: A facility based cross-sectional study on people living with HIV/AIDS was carried out in tertiary care centre of western Maharashtra. Considering the prevalence of food insecurity, undernutrition and Standard of living (SLI) as per previous studies[7,8,9], the sample size was calculated as 246. Adult PLHAs who came for collecting the medicines, after completion of one year of treatment and consented to be part of the study were included in the study based on systematic random selection. PLHAs with permanent residence were taken for the study while migratory PLHAs with opportunistic infections, HIV wasting syndrome and those who didn't consent for the study were excluded. Institutional clearance was obtained, Informed consent was taken from all study participants as per format and strict confidentiality was maintained throughout the study

Data Collection: Data was collected by means of pretested semi structured questionnaire which included basic demographic profile along with anthropometric measurements, clinical parameters, food insecurity scale[10] and parameters assessing household status using standard of living scale[11]. Urban/rural status, Standard of living, food insecurity and nutritional status were the main variables in the study. Data was entered in excel sheet and was analyzed using stata version 10 and rural urban differences among various variables was studied.

Standard of living (SLI) index was defined in terms of ownership of household goods (as per the NFHS-2 survey principals[11]) by adding the nine components (Table 1). Out of total score of 9, household with 1-3 marks were labelled as low SLI, 4 to 6 scores as medium SLI and 7 to 9 scores were labelled as high SLI. All households were categorized into food secure and Food insecure by means of WHO Household food insecurity access scale (HFIAS) Measurement Tool[10]. Nutritional status was categorized into underweight, Normal and overweight based on WHO BMI (Body mass Index) classification for Asians

Results

The mean age of the study participants was 43.37 years with majority (50.9% rural, 39% Urban) were secondary class educated. 22.9% of urban and 8.5% of rural were college and above educated. 20% of urban and only 8.5% of rural had income above 10,000 per month. Maximum (48.2 %) of rural were doing heavy works (construction/agricultural) while majority of urban were unemployed (30.5%) followed by business (21%) work. 36.9% (Rural) and 28.6 % (Urban) had spouse positive for HIV status. 51.1% (rural) and 41% (urban) were female

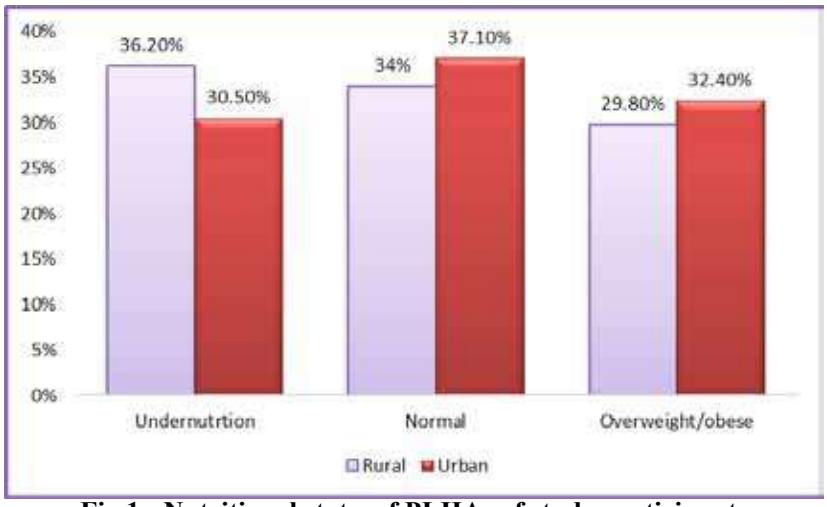

Fig 1 : Nutritional statusof PLHAs of study participants

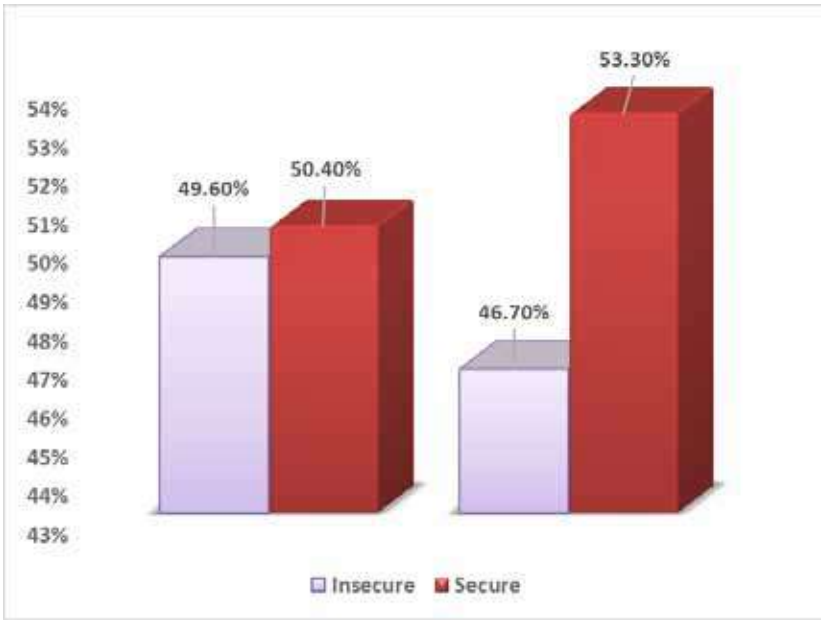

Fig 2: Food insecurity status of study participants

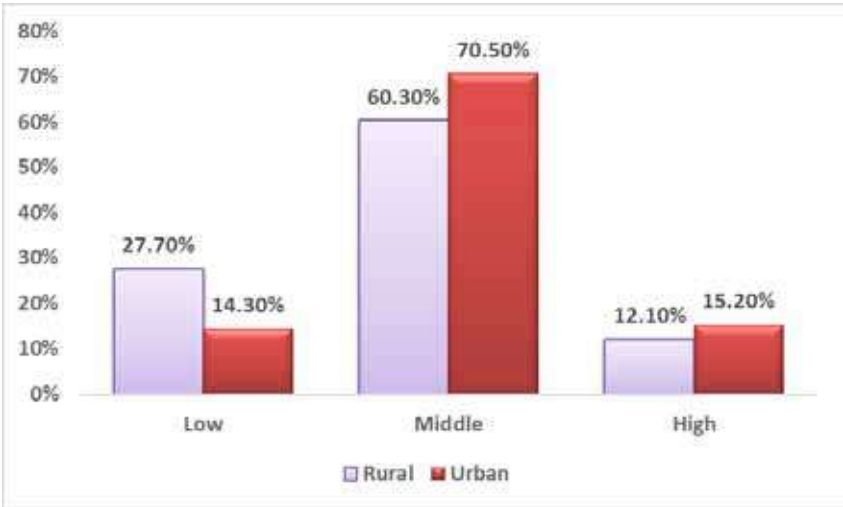

Fig 3: Standard of living status of study participants

ART adherence was above 90% (as per pill count) among 89.9% rural and 96.2% urban. Majority (92.4% urban, 89.4% rural) had started their ART at the time of detection. Even after one year of treatment, only 36.9% rural and 41% urban PLHAs were having CD4 count above 500.49.6% (Rural) and 46.7% (Urban) were food insecure (Fig 2) while 27.7% (Rural) and 14.3% (Urban) had low standard of living (Fig 3). 36.2% (Rural) and 30.5% (Urban) were undernutrition with 51.8% (Rural) and 54.3% (Urban) having abnormal waist circumference. BMI Category had statistically significant association with SLI and food insecurity in urban participants while it was not statistically associated with rural participants

Discussion

Nutritional status has multidimensional effect on HIV disease progression. It hampers immune system, thereby increase the frequency, severity, duration and complications of infections, the symptoms of which lead to increase weight loss and thereby starts the viscous cycle. In our study, in rural areas, majority (36.2%) were undernutrition while in urban areas majority (37.1 %) had normal BMI followed by 32.4% obese/overweight and 30.5% being undernutrition. The higher number of undernutrition in rural areas may be due to most PLHAs in rural areas had income less than 5000 (77.3%) than urban areas (42.8%) and majority were doing Heavy (construction/agriculture) job getting less pay and more energy expenditure.To co-relate undernutrtion, majority (63.1%) of rural had CD4 count less than 500, even after ART of one year.

In a study carried out in Iran by Hamzeh B et al[12], mean BMI of PLHAs men and women was 22.12 and 25.54 KG/m2. Although the malnutrition was seen in 42.2 % but undernutrtion was seen only in 11.08% and rest were obese/overweight. Majority of undernurtion was seen in men and married PLHAs and main reason was low consumption of diet as compared to standard recommendations. In the contrary, in our study,the under nutrtion was quite high (36.2% Rural and 30.5% Urban) with low CD4 counts (less than 500) inspite majority of them had 90% ART adherence for one year,

While another study carried out by Anand D et al[7]in India showed mean BMI of PLHAs was 19.73 KG/m2 with 40 % under nutrtion among PLHAs which was much higher as compared to our study among both rural and urban PLHAsand major reason was poor consumption of diet (both quantity and quality).

Food insecurity being an important marker for malnutrition even in PLHAs. In our study only 50.4% of rural and 53.3% of urban were food secure. The higher percentage of under nutrition in rural (36.2%) and urban (30.5%) areas in spite of one year of free ART probably hints at higher level of food insecurity (Urban – 49.6%, Urban-46.7%) among them. In our study, BMI had statistically significant association with food insecurity among Urban PLHAs only but not the rural ones

Dasgupta P et al[13]in a study in Darjeeling, India showed that 50.9% of the PLHAs were food insecure. Higher education, higher standard of living and males has statistically significantly associated with high food security while poor morbidity status, more people with HIV positive status in family were associated with high food insecurity. PLHAs used to take loans , burrow money from family, friends and banks to cope up with financial hardship.

Gebremichael DY et al[5]conducted a study in Central Ethiopia showed that 23.6% of PLHAs were malnutrition, 35.2% were food insecure. Important factors which led to malnutrition were no job, clinical morbidity, low CD4 counts and opportunistic infections and importantly the food insecurity similar to our study. Similar findings were also seen in a study carried out by Thapa R et al[14]in Nepal where in one out of five PLHAs were undernourished and important contributing factors being low literacy, low CD4 counts, home care, clinical morbidity and opportunistic infections. The study also assessed the Quality of life domains among the PLHAs and found to be statistically significant association with Body mass Index.

Water sources, water processing technique, sanitary facilities, overcrowding and house type which determine the standard of living have an important influence on the health of

household members, especially PLHAs. In our study, only 12.1% rural and 15.2% urban were having high standard of living while majority (Rural – 60.3%, Urban -70.5%) were having middle SLI. As per NHFS 2 survey[11], Standard of living index was low in 24.1 % of Urban and 61.7% rural households with Bihar (57%) being highest in low SLI where as in our study on PLHAs households - 27.7% rural and 14.3% urban had low SLI which had influence on nutritional status. We couldn't find any other studies comparing the standard of living among rural and urban PLHAs

Conclusions

Inspite of freely delivered ART for one year and majority having good adherence rate, there were actionable changes in nutritional changes among PLHAs of both rural and urban areas. With freely available ART, the neglected factors like food insecurity and standard of living needs to given special focus among both Urban and rural areas to affectively crub the high incidence of undernutrition among them. Immediate longterm measures need to be taken to provide them adequate food and basic amenities of life with secure Job status.

Reading Skill of Deaf Students from Ludhiana Punjab

Renu Thakur[1], Sangeeta Pant[2], Jaikishan Jaya Kumar[3]

[1]Senior Optometry Faculty; Sankara Academy of Vision, Sankara Eye Hospital, Ludhiana, Punjab, India. [2]Dean; Chitkara College of Education, Chitkara University Punjab, [3]Chief Operations Officer / Senior Project Advisor; Center for Computational Brain Research, Indian Institute of Technology Madras Chennai, Tamil Nadu india

Abstract

Context: Learning to read is a complex cognitive perspective, it's a child ability to decode, analyze and construct linguistic meaning from a the written print; reading include identification of alphabets, bond of spellings and assessing them in memory i.e. word reading, phonic awareness and knowledge of alphabets are the base of learning to read[15];Total 60 students were enrolled in the study, 30 deaf and 30 age-matched hearing, all the students were from age group of 8.5 to 11.5 years (50% male and 50% female in each group); extensive eye examination was performed prior to the study, all the participants were free from Ocular and systemic pathology. Two different tests were performed for reading skill; Reading comprehension was evaluated with ADR I Net Dynamic reader, and English reading tool was used, the tool was developed and used by Pratham-ASER Centre to evaluate reading speed; both the test showed statistically significant difference; (P-Value of <0.001) were deaf students had scored less marks in reading comprehension test and they were slow in reading speed also; deaf were taking more time to read in comparison of hearing students (P-Value of <0.001).

Keywords: *Reading Speed, Reading Comprehension.*

Introduction

Auditory impairment is the sensory deficiency which is commonly seen among human population, which is affecting a huge amount of pollination approximately 250 million people are suffering from auditory impairment in the world[1]. In India, 63 million people that is (6.3%) suffering from significant hearing impairment [2]. Children who are born with deafness with bilateral hearing loss less than 70–89 dB are called severe loss and children who are>90 dB hearing losses are referred to as deaf [3].The psychosocial difficulty is seen among hearing impaired children's which is ranging from 20 to 50 % which eventually reflected in their behavior and social wellbeing[4]. TheConsequences of the hearing impairment leads to the inability to understand the communicate which eventually delay in their language development, which can affect their educational achievement's, which eventually lead to social isolation and stigmatization[5].

Effect of Deafness on Reading: Phonological awareness and knowledge of sound is building block for reading, educational and psychological research suggest and support this evidence; profoundly deaf students are visually depended while reading; visual senses play major role in formation of sentences for them[16]Deaf students do not have phonological awareness facility; they have limited or zero excess to spoken language; which affect their reading skill [17].Reading is always a challenge to deaf students; hearing students learn to read by suing phonic sound; which is absent in deaf readers; deaf students can't describe the difficulties in reading [6] Deaf students always perform lower than the hearing group in reading skill; although deaf readers are visually depended for understating or learning to read; visual

way of communication in deaf infants by their parents can be establishing the base of visual communication [7]. The Reading is one of the most complex behavior that is composed of many skills at a time, thus no single reading test assesses all aspects of reading completely. The Reading assessment should link directly to a widely accepted definition of reading, by Understanding the principles & relationships of assessment and instruction should enable teachers to select procedures that will assist in identifying and describing students' achievements and progress in reading [8].

Material and Methodology

60 students were enrolled in the study, 30 deaf students (congenital deaf;deafness equal or more than 90%) from, The Deaf Children School Humbra Road, Kitchlu Nagar, Ludhiana – 141001 and 30 Hearing students from Peace public school Ferozepur Road, V.P.O. Bhanohar, Ludhiana. (Both group had 50% Male and 50% Female participants); Informed consent was taken from all students, who participated in the study, including the consent explained to the hearing-impaired children by relevant instructors. Students participants in this study needed to satisfy the following criteria to be included in the study: Best corrected visual acuity of 6/6 and a near visual acuity N6, using the relevant Snellen acuity chart for distance and the standardized reading chart for near. Ocular abnormalities were ruled out using standard anterior and posterior eye examination. The Reading comprehension was evaluated with ADR I Net Dynamic reader. [9]. And English reading tool was used developed and used by Pratham-ASER Centre to evaluate reading speed; this reading tool is having five level Levels being: first is Beginner second is Letter; third is Word and fourth Paragraph and last one is fifth i.e. Story[10]The students were divided in two groups; Deaf and age-matched hearing group; two different test type was used, first wasADR I Net Dynamic reader for reading comprehension and second one is English reading tool by Pratham-ASER Centre to evaluate reading speed (Hard copy). In dynamic reader student is seating 16 inches away from the screen and 12 font size prints is moving 60 word per minute speed in front of the screen, were student need to read that story and once the story is completed there are 10 questions were asked based on the story and student need to tick the correct answer; whereas in Reading speed tool 5 different levels are there; first level is graded as '0' if students is not identifying any alphabet; second level is few alphabet if student identify them correctly he/she moves to next level where 3rd level where student need to read small spelling and in 4th level small paragraph and last 5th level story. For deaf students special educators help was taken were students were using ASL (American Sign Language) evaluation and documentation was done by special educator from the respective deaf school.

Result

Total 60 subjects were enrolled in the study, 30 Deaf and 30 hearing;the data was analyzed with the help of STATA 11.2 (College station TX USA) and Wilk test for normality.The reading comprehension by Test ADR I Net Dynamic Reader showed significant difference hearing group was better than the deaf group with mean difference of 8.28 and p-value of 0.001 (Deaf Mean ± SD 0.36 ± 1.06 and Hearing Mean ± SD 8.64 ± 1.06) deaf students had scored very less in reading comprehension in comparison of hearing students; deaf students were unable to answer most of the questions related to story. The reading speed test by Pratham-ASER Centre the reading speed was evaluated and (time was noted in seconds) compare with age matched hearing students, The Statistical analysis was performed by student T-Test and 2nd level (identification of alphabet) deaf group took more time than hearing group (Deaf Mean ± SD 15.49 ± 5.56 & Hearing mean ± SD 10.40 ± 1.22 ; P-Value of <0.001); for 3rd level (small spelling) (Deaf Mean ± SD 27.99 ± 8.26 & Hearing mean ± SD 5.36 ± 1.55 ; P-Value of <0.001) deaf were slower than hearing; for 4th level (small paragraph) (Deaf Mean ± SD 51.75 ± 12.20& Hearing mean ± SD 8.34 ± 1.44 ; P-Value of <0.001) deaf took more time to read; and the last level (story) (Deaf Mean ± SD 104.81 ± 39.57 & Hearing mean ± SD 19.17 ± 2.84 ; P-Value of <0.001) deaf were taking more time to read than hearing; in all level deaf students were taking more time to read, as they were joining the alphabets and making all spellings, on the other hand the observation indicates that the deaf students do have letter identification knowledge although they take more time to read.

Discussion

Our result shows that deaf students do have reading comprehension problem and the reading speed is decreasing as the levels are getting complicated which is correlating with Reading comprehension research was done by Lisa M. Bickham were the respective author had found that deaf students do struggle in reading comprehension in comparison with hearings

students[11]. Fiona and Kate had done research on deaf students reading skill; they have done comparison of deaf and hearing children's reading comprehension were the respective author had found deaf children's were weaker in reading skill when compared with the age matched hearing children's which eventually affect their achievement's[12] our study do support the findings of Fiona and Kate. Rachel I. Mayberry had done research on cognitive development of deaf children; the respective author study indicates the deafness delay in the language, the cognitive development is directly propositional to language which in general leads to cognitive changes[3]Cognitive Development in Deaf Children by Dr. Sharmista in 2013, the respective author had taken 28 deaf and 31 hearing students; Raven's colour metrics and cognitive development status test was used; Visual perception did not show much difference; 4% difference between hearing and deaf group but there is a significant difference in achievement and as deafness in increasing reading ability decreases[13].Hearing subjects read by converting print material into phonological code that impact their auditory language system; but deaf subject use visual information for reading according to Duncan in 1984; whereas author has taken 43 subjects (age between 18-40 years); on computer screen various stimulus is shown to all subjects[14].Academic activity especially reading has been affected in hearing impaired subjects ; deaf students normally show below average in reading skill and vocabulary when they are compare with age matched hearing subjects the research dine by Fagan et al in 2007 [18]. Learning how to read is one of the critical developmental task which is based on developmental social and vocational development; which is a challenge for deaf subjects according to Musselman in 2000 [19].

Conclusion

Our goal of the study is to find out the reading skill of deaf children's of deaf school and compare with age matched hearing students hence Our study like to conclude that reading comprehension difficulties are seen in deaf students when they are compare with age matched hearing students and deaf students had shown lower reading speed as compared with age matched hearing students in all level from identification to reading story; although deaf students were slow in identification but none of the deaf student have not made any mistake in identification that indicate there is an awareness of letter and they could read by joining the alphabet's and making spelling; but very few understood the meaning of story whereas they have scored less in reading comprehension also; we like to conclude with our study that yes deaf students do have reading problem but at the same time they have awareness of letter also which is statistically significant low in comparison of hearing students; this study can be useful for all special educators teaching deaf students to enhance their teaching strategies taking in evidence that deaf students do have awareness of letter and they do read by joining the alphabet's.

Ethical Clearance: The evaluation was noninvasive hence the clearance was not required. (applied in Chitkara university for ethical clearance in case it is necessary)

A Twin Inside a Twin/Fetus–in- Fetu–Review Article

RituYadav[1], PoonamAhlawat[2]

[1]Assistant Professor, Faculty of Nursing, SGT University, Gurugram,
[2]Lecturer Faculty of Nursing, SGT University, Gurugram

Abstract

Context: The case was described in a British medial journal in 1808 and is thought to occur in about one in every 500,000 births[1]. In recent years, similar births have occurred in India, Indonesia and in Singapore[3]. It is the process in which baby carries a twin inside them is called fetus in fetu.This is a rare condition characterized by abnormal embryogenesis in a diamniotic, monochorionic pregnancy[4]. Covering is made up of a fibrous membrane that contains some fluids (equivalent to the amniotic fluid) and a fetus attached by a cord or pedicle. In the uterus, the growth of an FIF initially similar to its twin, but stops suddenly because of either the vascular dominance of the host twin or any defect in the parasitic twin [2]. Parasitic twin mostly seen anencephalic, but in almost all cases its vertebral column and limbs are present (91% and 82.5%, respectively).

Keywords: *Twin; Fetus in fetu; Abdomen masses; Embryogenesis; diamniotic; Monochorionic; Fibrous membrane; pedicle.*

Introduction

The condition is defined as a monozygotic twin gets assimilated into the abdomen of its sibling during developmental phase. Often Feuts in fetu is seen with differential diagnosis of any abdominal mass[7]. Unlike teratomas, it is a benign disorder. It is commonly present in the retroperitoneum(80%) but cases have been also reported in other sites in body like cranial cavity(8%), oral cavity, neck, mediastinum, back, sacrococcygeal region(8%) and scrotum[8]. In most of the cases, single parasitic fetus is present however number can range from 2 to 5.

Path Physiology: According to parasitic twin theory Fetus inside fetu is a parasitic fetus developing within its host twin. It is observed that very early in a monozygotic twin pregnancy both fetuses share a common placenta, one fetus wraps around and envelops the other. The enveloped twin develops as a parasite, in which its survival depends on the survival of the host twin. The parasitic twin is anencephalic and without some organs is not able to survive on its own. As the host twin has to provide nourishment to the enveloped twin from the nutrients received over a single umbilical cord resulting in death before birth.

Case Presentation: March 20, 2019

A Colombian woman has given birth to a baby whose abdomen contained the tiny, half-formed — but still growing — body of her own twin sister[3].

This type of birth, an example of "fetus-in-fetu," is very rare but not unprecedented[3].

The latest case was even more unusual, because doctors clearly identified the fetus-in-fetu during the pregnancy, said Dr. Miguel Parra-Saavedra, a high-risk pregnancy specialist in Baranquilla, Colombia, who oversaw the birth[3].

He first saw the mother, Monica Vega, when she was in her 35th week of pregnancy, five weeks short of

Mob No: 9711200369
e-mail:rituyadav2886@gmail.com

a full-term birth. Her obstetrician believed her fetus had a liver cyst.

But, using color Doppler and 3D/4D ultrasound imaging, Dr. Parra-Saavedra was able to see that the fluid-filled space actually contained a minuscule infant, supported by a separate umbilical cord drawing blood where it connected to the larger twin's intestine[3].

"I told the mother, and she said, 'What? No, doctor, this is impossible,'" Dr. Parra-Saavedra said. "But I explained step by step, and she understood[3]."

He alerted a local television news network, which followed Mrs. Vega, who is now 33, through the birth of her daughter, Itzamara, and the surgery to remove Itzamara's partially formed twin.

(Dr. Parra-Saavedra had developed relationships with several journalists during Colombia□s Zika outbreak in 2016, because he treated mothers whose babies had microcephaly, or small heads, caused by the virus[3].)

On Feb. 22, when Itzamara was at 37 weeks and weighed about seven pounds, doctors decided to deliver her by cesarean section, because they feared the internal twin would crush her abdominal organs.

The next day, they removed the fetal twin by laparoscopic surgery. It was about two inches long and had a rudimentary head and limbs, but lacked a brain and heart, Dr. Parra-Saavedra said[3].

fetus-in-fetu is sometimes misdiagnosed as a teratoma, a tumor that may contain bones, muscle tissue and hair. A DNA comparison is being done, but Dr. Parra-Saavedra has no doubt that the fetuses started out as identical twins from the same ovum.

Because the smaller fetus took nourishment from its sibling, it is called a heteropagus or parasitic twin[3].

Some heteropagus twins are born conjoined to their healthy siblings, while some grow partially inside and partially outside their twin's body.

The fetus-in-fetu condition is believed to arise soon after the 17th day of gestation, when the embryo flattens out like a disc and then folds in on itself to form the elongated fetus[3].

Doctors believe that in exceedingly rare cases, the twin embryos only partially divide, and the larger one wraps around the smaller.

The condition may go undetected for many years. In 2015, a 45-year-old Englishwoman living in Cyprus underwent surgery for what appeared to be a four-inch tumor on her ovary[3].

On dissection, the growth turned out to have a partially formed face with an eye, a tooth and black hair. Doctors concluded that it was a twin she had absorbed while in her mother's womb.

Itzamara is doing well, Dr. Parra-Saavedra said. "She has a little scar on her abdomen, but she is a normal baby now except that the whole world is talking about her[3]."

Case Presentation: 2. A 15-year-old boy presented to hospital with history of abdominal swelling since birth which progressively enlarged recently. He also complaints of abdominal pain and was unable to tolerate orally for 1 week prior to admission. On examination, there was tender, hard mass over central part of abdomen[9].

Investigations: CT abdomen and pelvis revealed a big intra-abdominal mass 14×18.5×23.8 cm that extends up to the sub hepatic region with inferior extension into anterior pelvis. Components in favour of a fetus that were observed within the mass include deformed skull, vertebral body and long bones. CT angiography was done to find out the feeding vessels involved. CT angiography shows multiple small arteries supplying the wall of the mass. No tumour markers were seen preoperatively[9].

Differential Diagnosis: The differential diagnosis of this condition can be organised teratoma[7].

Treatment: Laparotomy was done through a midline laparotomy incision with detection of a 15×10 cm intraperitoneal mass with multiple big feeding vessels attached to small bowel mesentery. The mass was perforated over pelvic region with 1000 cc pus aspirated. A gestational sac weighing 2.5 kg was taken out, and when opened, a 1.6 kg non-viable baby seen with shortened and malformed upper and lower limbs, hypoplastic trunk, long hair, developed male genitalia with pubic hair, imperforated anus, fused malformed eyes, vertebra and normal baby skin covered with vernixcaecosa. There was no mouth, umbilical cord or placenta attached to it[9].

Outcome and Follow-up: Postoperatively, the

baby was handed over to the family for ritual funeral as requested by family. Histopathological examination (HPE) of the sac enveloping the fetus observed a fibrous cyst wall with focal area lining of mature squamous epithelium with many hair shafts and some muscle in subepithelialstroma. The postoperative period of the patient was uneventful. Alpha-feto protein (AFP) taken 3 months postoperation was normal and the patient has no active complaints during subsequent follow ups[9].

Conclusion

Fetus in fetu is very rare condition. Before any operation is carried out on a patient, imaging studies should be conducted to differentiate this condition from teratoma. Surgical excision is a curative procedure, and a macroscopic examination of the sac should be done after twin or multiple fetus in fetu are removed. The literature cites less than 200 cases worldwide of twin fetus in fetu.

Effect of Jacobson's Progressive Relaxation Technique Over Sleep Disturbances and Quality of Life in Chronic Rheumatoid Arthritis

MariyamFarzana[1] , Mukesh Kumar[2]

[1]Asst Professor, Srm College Of Physiotherapy, [2]Student Srm College Of Physiotherapy.

Abstract

Background: Rheumatoid arthritis is a chronic inflammatory disease of the immune system affecting the synovial tissue of the joint, tendon sheath and bursae. The symptoms are joint pain, stiffness, joint swelling, deformity, functional disability and sleep disturbance. Rheumatoid arthritis is three times more frequent in women than men. There are various study done on Rheumatoid arthritis on their pain management and reducing deformity but there is lack of study on their sleep disturbance and quality of life.

Objective: To find out the effect of Jacobson's progressive relaxation technique on sleep disturbance and quality of life in chronic Rheumatoid Arthritis.

Methodology: Experimental study with a convenient sampling of 30 Rheumatoid arthritis subjects with age group of 20-70 years received Jacobson's progressive relaxation technique 1 session per day for 10 days.

Outcome Measures: Sleep disturbance was evaluated using Pittsburgh sleep quality index (PSQI) and quality of life was evaluated by using Short form health survey-36(SF-36)

Results: Statistical analysis was done by SPSS software version 22, which showed significant improvement in both sleep disturbance and quality of life in chronic Rheumatoid Arthritis.

Conclusion: Thus, Jacobson's progressive relaxation technique has shown significant result in improving sleep disturbance and quality of life in chronic Rheumatoid Arthritis.

***Keywords*:** *Jacobson's progressive relaxation technique, Rheumatoid Arthritis, sleep disturbances, Quality of life.*

Introduction

Rheumatoid arthritis (R.A) is a chronic inflammatory disease of the immune system (Autoimmune disease) which affects the synovial tissue of the joint, tendon sheath and bursae. Its symptoms ranges from joint pain, stiffness, joint swelling, deformity in multiple regions especially in hands and feet, functional disability, erosive synovitis and sleep disturbances.[1,2]

Corresponding Author:
S.F. Mariyam Farzana
Asst professor, SRM college of physiotherapy,
email id: mariyamfarzana86@yahoo.com

Rheumatoid arthritis has been one of the most crippling disease affecting mankind because of its numerous manifestations and involvement of multiple joints. Rheumatoid arthritis affects the joints symmetrically, but it is a systemic disease in which anaemia, fatigability, weight loss and fever are prominent feature.

Its three times more frequent in women than men (3:1) and it affects between 0.1 and 0.5% of adults in developed countries.[3] The age of onset may be as young as 16 years. The major symptoms of Rheumatoid arthritis also include fatigue and poor sleep quality affecting more than 50-70% of the patients. Poor sleep in Rheumatoid

Arthritis is contributed to increased pain and fatigue and also associated with depression.[4]

Sleep is naturally recurring state of mind characterized by a temporaryloss of consciousness, reduced interaction with surroundings, and a state of inactivity and it can be reversed by an external stimulus. Sleep is important for the functioning of human body and many biological process which are important for the human body which can be impaired without sleep.[5] Sleep disturbance is the deviation from normal sleep pattern and which may include poor sleep quality,non-restorative sleep, difficulty in falling asleep, early morning awakening, numerous nightly awakenings, fatigue and daytime sleepiness.[6]

As this disease progresses, patient's functional impairment increases which often leads to work disability and it also increases the burden on patient's families, care-givers and society. The daily activity of the patient's also decreases due to pain and fatigue.[7] The quality of life in Rheumatoid Arthritis is reduced in serval ways, such as their physical health, level of independence, environment and personal beliefs.[8] The quality of life of the patient reduces due to functional impairment in which the patient cannot perform his daily life activity due to pain and fatigue which is most common symptom of rheumatoid arthritis.[9] The Health related quality of life in Rheumatoid arthritis is reduced and its associated with increased levels of pain, reduced physical activity and disease activity.[10,11]

Evidences from other studies of chronic disease suggests that number of other factors to have an impact, including gender, body mass index (BMI), age and disease severity.[12,13,14]

Relaxation is one of the best method to reduce musculoskeletal pain and the symptoms of stress.[15] Jacobson's relaxation technique is also known as progressive relaxation technique. Jacobson's progressive relaxation technique involves contracting and relaxing the muscle. His techniques relax the entire body by releasing muscular tension that accumulates when a person experiences a stressful situation. this technique not only cures taut muscles and cramps, but also reduces the intensity of pain and relieves stress and anxiety.[16]

Jacobson demonstrated the deep relationship between muscle, thoughts and emotions which affected the level of muscular tension. This method is based on concentration of attention in a muscular group by paying attention to the sensation it produces. This technique requires about 15-20 minutes to complete the relaxation technique. It is performed in a dim light room and shouldn't be disturbed by other people and it is done on a floor, on bed or in a chair.

Method

Study Design and Sample: This is an experimental type of study done for 10 days in SRM Medical College Hospital and Research Centre, kattankulathur, Kanchipuram, India. About 30 samples with chronic Rheumatoid arthritis were selected and explained about the procedure and informed consent were obtained and explained them thatthe information obtained will be kept confidential.

Chronic Rheumatoid arthritis samples between 20-70 years both male and female were included in the study. Samples been treated with hypnotic and anti-depression drugs were excluded from the study.

The samples were evaluated using Pittsburgh Sleep Quality Index (PSQI) and Short Form Health Survey-36 (SF-36) for their sleep quality and Quality of life respectively.

Procedure: A sample size of 30 subjects with age group of 20-70 years, both male and female subjects with a referral from rheumatologist was taken for the study. The subjects with chronic Rheumatoid Arthritis (more than 2 years) were randomly selected for the study.

Jacobson's progressive relaxation technique was clearly explained and taught to the subjects and a trail session was demonstrated to the subjects. The subjects should make them comfortable on the floor, on the bed or in a chair. The subjects were asked to perform this technique in their home in a dim light room, if possible and shouldn't be disturbed by anyone and subjects should switch off their mobile phones. The subjects were asked to perform this technique for 10 days, one session per day and progression is made by repeating about twice per day. The subjects were regularly monitored by telephone.

After 10 sessions of Jacobson's progressive relaxation technique, the post-test was taken immediately. The completed questionnaire was returned, and scoring was done to evaluate the sleep disturbances and quality of life. The scored data was then given for statistical analysis to evaluating the sleep disturbance and quality of life.

Pittsburgh Sleep Quality Index: The Pittsburgh Sleep Quality Index (PSQI) contains 19 self-rated questions and 5 questions rated by the bed partner or roommate (if one is available).Only self-rated questions are included in the scoring. The 19 self-rated questions items are combined to form seven "component" scores, of which has a range of 0-3 points. "0" indicated no difficulty and "3" indicated severe difficulty. The seven components are then added to yield one "global" score, with a range of 0-21 points. "0" indicates no difficulty and "21" indicated severe difficulty in all areas.

Short Form (36) Health Survey: The Short Form (36) Health Survey is a 36-item, patient-reported survey of patient health. It consists of eight scaled scores, which are the weighted sums of the questions in their section. Each question has a score of 0-100, in which zero is equivalent to "maximum disability" and 100 is equivalent to "no disability". It was reported as easy to understand and acceptable for the respondents from the subjects.

Results

Table 1shows that the mean value of Pittsburgh Sleep Quality Index (PSQI) score in pre-test is 15.57 and post-test is 9.67, which shows there was a significant improvement in sleep quality among Rheumatoid Arthritis patients treated with Jacobson's progressive relaxation technique for a period of 10 days.

Table 2 shows the mean value of Short Form-36 health survey (SF-36) score, pre-test is 25.18 and post-test is 51.05 which shows there was a significant increase in Short Form-36 health survey (SF-36) score which indicates a improvement in quality of life among Rheumatoid Arthritis subjects treated with Jacobson's progressive relaxation technique for a period of 10 days.

Table:1. Pre-Test and Post-Test Mean Values of Pittsburgh Sleep Quality Index (Psqi) Among Rheumatoid Arthritis Patients Treated With Jacobson Relaxation Technique For A Period Of 10 Days (N=30).

Pittsburgh Sleep Quality Index	Mean	N	SD	T-Value	P-Value
Pre-test	15.57	30	0.81	26.63	0.00*
Post-test	9.67	30	0.21		

P value <0.05

According to Table 1, the pre-test mean value of Pittsburgh Sleep Quality Index (PSQI) score is 15.57 and the post-test mean value is 9.67, which shows significant changes in quality of sleep as measured by Pittsburgh Sleep Quality Index (PSQI) score with a P value of 0.00.

Table:2. Pre-Test and Post-Test Mean Values of Short Form-36 Health Survey (Sf-36) Among Rheumatoid Arthritis Patients Treated With Jacobson Relaxation Technique For A Period Of 10 Days (N=30).

Short form-36 Health Survey	Mean	N	SD	T-Value	P-Value
Pre-test	25.18	30	3.19	-21.71	0.00
Post-test	51.05	30	5.79		

P value <0.05

According to Table 2, the pre-test mean value of Short Form-36 Health Survey (SF-36) score is 25.189 and the post-test mean value is 51.059, which shows significant quality of life, with a P value of 0.00.

Discussion

This study determines the effect of Jacobson's Progressive Relaxation Technique in subjects with chronic Rheumatoid Arthritis.

Rheumatoid Arthritis said to be one of the crippling disease and sleep problem and pain were associated with poor quality of life in Rheumatoid Arthritis patient as stated by **M Purabdollah et al, 2015.**[18]

The subjects who fell into the age group of 20-70 years, both genders and who were diagnosed from Rheumatoid Arthritis were selected and the study was analysed on 34 subjects. Four subjects were dropped out from the study due to personal and communication problem. These 30 subjects were treated with Jacobson's progressive relaxation technique for 10 days.

The results of this study shows that there was a significant improvement in quality of sleep post the management of Jacobson relaxation technique for a period of 10 days($p<0.05$). This results goes in hand with

NerimanTemel Aksu et al; (2017) concluded that progressive muscle relaxation prevents a decline in patient-reported sleep quality following pulmonary resection.

Yunping Li et al;(2015) suggested that progressive muscle relaxation practice is effective in improving

anxiety, depression, and the mental health components of Quality of life in patients with pulmonary arterial hypertension.

This can be better explained by the fact that relaxation training brings the body system back into balance by deepening breathing, reducing stress hormones, slowing down heart rate and blood pressure, and relaxing the muscles.In addition to its calming physical effects, research has shown that the relaxation response also increases energy and focus, combats illness, relieves aches and pains, heightens problem- solving abilities, and boosts motivation and productivity.

It is argued that anxiety, worry and depression plays an important role in emergence and development of sleep disturbance in chronic Rheumatoid Arthritis patients. As said above Progressive muscle Relaxation can relieve stress and anxiety thus also improve the Quality of sleep of these patients.

ElhamAmini et al;(2016) concluded that Progressive muscle relaxation program causes a significant improvement of sleep Quality than Aerobic exercises.

C Austad et al;(2016) concluded that sleep disturbance is related to pain, fatigue and disease activity in Rheumatoid Arthritis patients.

So Jacobson may benefit the patients to have a better quality of sleep which indirectly will influence their quality of life which has been proved by the results of this study which states that there was a improvement in short form-36 health survey (SF-36) after training chronic rheumatoid arthritis patients for a period of 10 days($p<0.05$).

This result goes in hand with **Yildrim et al** who demonstrated that progressive muscle relaxation program caused a significant improvement of Quality Of Life and relieved anxiety among Chronic Renal Failure patients.

Mishra et al (2012) concluded that exercises were more effective in reducing depression and sleep disorders and improve physical functions in cancer patients.

Thus, by all its benefits, this study recommends the use of progressive muscle relaxation technique give patients a comfort and improves the quality of sleep thereby enhances their Quality of Life. Furthermore, the Quality of sleep assessment can be widely practiced in Chronic Rheumatoid arthritis patients as it has a high influence over Quality of Life of such patient, the improvement of which is the ultimate aim of physiotherapy. Many therapists treat only the pain of the Rheumatoid Arthritis patients and were mostly negligent to the ill effects of sleep disturbances that are quite common among such patients. The sleep disturbance may again have a negative effect on their disease and the physiotherapy management also. So, we physiotherapist should give importance to the sleep disturbances and encourage and build confidence in these patients to practice the relaxation techniques regularly at home.

Conclusion

This study concludes that there was a improvement in sleep and Quality Of Life among chronic Rheumatoid Arthritis subjects after application of Jacobson's progressive relaxation technique for 10 days. This study further recommends that the sleep disturbances assessment and management with Jacobson relaxation technique should be given its importance in Physiotherapy management of Chronic Rheumatoid Arthritis patients.

Ethical Clearance: Obtained from Institutional Ethical committee, SRMIST.

Comparison of Therapeutic Ultrasound and Low Level Laser Therapy Over Pain and Scar Health in Post Episiotomy

Mariyam Farzana[1], R.Shanmuga priya[2]

[1]Asst. professor, SRM College of physiotherapy, SRMIST. NO B2 Asha Kiran, Akshaya Colony, 1St Avenue, Mugappair. Chennai, [2]student, SRM college of physiotherapy

Abstract

Background: Episiotomy is a surgical procedure made in the perineum of the gravida in the late second stage of labour in order to facilitate delivery of the fetus.various study had done on episiotomy to relieve pain but there is a lack of study on scar health in episiotomy.

Objective: To find out the effectiveness of therapeutic ultrasound and low level laser therapy over pain and scar health in post episiotomy.

Method: Quasi-Experimental study 10 subjects with age group of 25 to 30 years into two groups (GROUP A & GROUP B). GROUP A (5 subjects) treated with therapeutic ultrasound. GROUP B (5 subjects) treated with low level laser therapy. Outcome measures for pain and scar healing was evaluated using Numerical Pain Rating Scale(NPRS) and Patient and Observer Scar Assessment Scale (POSAS).

Results: There is no statistically significant difference in the post test mean values of Numerical Pain Rating Scale(NPRS) between GROUP-A and GROUP-B with the significant value of 0.216 ($p>0.05$). There is a significant difference in the posttest mean values of Patient and Observer Scar Assessment Scale(POSAS) between GROUP-A and GROUP-B with the significant value of 0.042 ($p<0.05$).

Conclusion: This study concludes that low level laser therapy promotes the scar health better than the Therapeutic Ultrasound in episiotomy.

Keywords: *Therapeutic Ultrasound, Low Level Laser Therapy, Episiotomy*

Introduction

Episiotomy is a surgical procedure made in the perineum of the gravida in the late second stage of labour inorder to facilitate delivery of the baby. This procedure is done to widen the introitus and straighten the lower end of birth canal and the incision is made between the anus and vulva. Episiotomy can reduce the amount of maternal pushing and it also reduces the trauma to the vaginal tissue[1].

Episiotomy was first described by Sir Fielding Ould in the year 1742[2]. Episiotomy is done in more than 90% of vaginal deliveries in India and it is done mostly to primiparous mothers (88.31%)[3]. The perineum in primiparous mothers is less elastic than the multiparous mothers[4].

Perineum is very sensitive area, and the muscles are involved in sitting, walking, squatting, urination and defecation[5].Delivery may lead to overstretching of the vagina, causing tears in the perineal tissue between the vagina and rectum. Perineal tears are more common during childbirth to avoid that episiotomy is done. An

incision in this region cause pain and discomfort in doing daily activities such as sitting and feeding the baby[6].

There are two types of incision in episiotomy they are mediolateral and midline incision[7].The mother who underwent episiotomy will have more blood loss, risk of improper wound healing and increased pain at the time of early puerperium[8].

Therapeutic ultrasound is given two days after vaginal delivery inorder to reduce perineal pain and to promote scar healing. The mechanism of this therapy will improve tissue repair and reduce pain[9]. The biophysical effect of therapeutic ultrasound will promote wound healing, changes in cellular protein synthesis, increased the collagen content, increased blood flow and vascular permeability[10].

The first known trail report for the ultrasound therapy for the relief of pain on the episiotomy incision was published (foulkes 1980). Therapeutic ultrasound is widely used inphysiotherapy to treat soft tissue injuries. dyson 1987 concluded that ultrasound has a better effect on tissue repair and pain relief in soft tissue injuries.

The waves produced from ultrasound through the propagation of molecular collision and vibration which increased the molecular motion and produce the microfriction between the molecules. The heat generated from friction will increase tissue permeability and facilitates soft tissue healing[11].

Low Level Laser therapy is given for two days after delivery to promote scar healing. The application of Low Level Laser therapy was first introduced by EndreMester in the year 1968[12]. Low Level Laser therapy is also known as Low Intensity Low Level Laser Therapy(LLIT), Biostimulative Therapy(BT), Low Level Laser PhotoTherapy(LPT).

Low Level Laser therapy (low-level Low Level Laser therapy L.L.L.T) is the use of red or infra redlight which aids in soft tissue healing and helps in relief of pain. The effect of Low Level Laser therapy is photobiostimualtion which helps in the production of ATP that gives more energy which makes the tissue to play role in healing process[13]. The mechanism of pain reduction in Low Level Laser therapy is by increasing the local and systemic microcirculation and the synthesis of nitric oxide will improve the blood flow to the particular region[14]. The effect on Low Level Low Level Laser therapy on pain relief is due to the action of endorphins and endogenous pain relievers[15].The various effects of Low Level Laser therapy are anti-inflammatory, anti-edematous, high rates of ATP, increased cellular function and increase in tissue oxygenation and nutrition[16].

The biostimulatory effects of Low Level Laser therapy acts on ulcers, granulomas, burns ,wounds and trauma and stimulate the local cell metabolism in damaged tissue[17].Low Level Laser therapy plays a major role in relief of neurological pain, relief of inflammation and oedema and prevention of tissue death[18].

Method

Study Design and Sample: This is an Quasi-experimental type of study done for 3days in SRM Medical College Hospital and Research Center, kattankulathur about 10subjects were included in the study and clearly explained about the procedureand informed consent was obtained and explained them that the information obtained will be kept confidential.

Primiparous women with age between 25 to 30 were included in the study. Numerical Pain Rating Scale (NPRS) and Patient and Observer Scar Assessment Scale (POSAS) were used to assess the pain and scar health and the score is considered as pre-test score.They were randomly assigned into two groups, Group-A and Group-B.

Procedure: Women who were selected for the study, had been explained about the purpose of the study and informed consent form was obtained. Then the assessment was taken from the patient.

Subjects were then divided into 2 groups, Group A (5 subjects), Group B (5 subjects)

Group A: subjects were allotted with the treatment of therapeutic ultrasound.

Group B: subjects were allotted with the treatment of Low Level Laser Therapy.

Group A (5 subjects): Subjects who were treated with ultrasound underwent the following procedure.

The subject was advised to clean herself and the procedure was completely explained to the subject. The subject is then positioned in side lying with lower leg straight and upper leg bent up and supported with pillow covered with mackintosh so that the perineum is visible from back. The therapist stand behind the subject at the

foot end. Proper ethics and safety measures were taken. Ultrasound equipment (Electrocare) was used for this treatment. The head of the ultrasound is covered with condom and gel is applied over the treatment head. Then another condom is filled with water and gel is applied to outside of the condom. The water filled condom is directly placed over the episiotomy area and the treatment is given accordingly for 6 minutes Parameters used

Frequency: 3MHZ

Intensity: 0.5W/cm2

Pulseinterval: 1:1

Duration: 6minutes

Mode: Pulsed mode

Method: water bag method

GROUP B (5 subjects): Subjects who were treated with Low Level Laser Therapy underwent the following procedure

The subject was advised to clean herself and the procedure was completely explained to the subject. The subject is then positioned in side lying with lower leg straight and upper leg bent up and supported with pillow covered with mackintosh so that the perineum is visible from back. The therapist stand behind the subject at the foot end.A piece of sterile cotton was pushed into vagina to preventcontamination of working field by vaginal discharge or blood.

A graduated wooden spatula is used to measure the length of the incision of episiotomy. Low Level Laser therapy machine(Electrocare) was used for this study. The wound exposed to Low Level Laser therapy irradiation of one spot after another using spot size of 0.8cm for 3minutes.

Parameters used are:

Frequency: 2 J/cm2

Duration: 3 minutes

Method: Non contact method

Both the treatment is given for 3days from Post Natal Day (PND) 2,I session a day.

Numerical Pain Rating Scale (NPRS) will be assessed before and after the treatment.

Scar is assessed after 4weeks by using Patient and Observer Scar Assessment Scale (POSAS).

Results

According to Table 1 there is a significant reduction in the mean values of Numerical Pain Rating Scale(NPRS) in Group A treated with Therapeutic Ultrasound and Group B treated with Low Level Laser therapy, but when both groups are compared there is no statistically significant difference in the post test mean values of Numerical Pain Rating Scale(NPRS) between GROUP-A and GROUP-B with the significant value of 0.216 ($p>0.05$).

According to Table 2 there is a significant reduction in the mean values of Patient and Observer Scar Assessment Scale(POSAS) inGroup A treated with Therapeutic Ultrasound and Group B treated with Low Level Laser therapy, but when both groups are compared there is a significant difference in the post-test mean values of Patient and Observer Scar Assessment Scale(POSAS) between GROUP-A and GROUP-B with the significant value of 0.042 ($p<0.05$).

Table 1: Comparison of Post-Test Values of Numerical Pain Rating Scale(Nprs) Between Group-A Treated With Therapeutic Ultrasound And Group-B Treated With Low Level Laser Therapy.

Treatment	N	Mean	Std. Deviation	Wilcoxon Signed Ranks	P-Value
THERAPEUTIC ULTRASOUND	5	5.80	0.837	-1.236	0.216
LOW LEVEL LASER THERAPY	5	7.00	1.225		

p>0.05 This table shows p value is greater than 0.05, Hence,there exist no significant difference in Numerical Pain Rating Scale (NPRS) between Group A treated with Therapeutic Ultrasound and Group B treated with Low Level Laser Therapy.

Table 2: Comparison of Post-Test Value of Patient and Observer Scar Assessment Scale(Posas) Between Group-A Treated With Therapeutic Ultrasound and Group-B Treated With Low Level Laser Therapy

Treatment	N	Mean	Std. Deviation	Wilcoxon Signed Ranks	P- Value
THERAPEUTIC ULTRA SOUND	5	113.60	2.191	-2.032	0.042*
LOW LEVEL LASER THERAPY	5	55.60	6.542		

P value <0.05 According to table 2 there is a significant difference (P<0.05) in the post-test mean values of Patient and Observer Scar Assessment Scale(POSAS) between Group A (113.60) and Group B (55.60).

Discussion

This study compares the effectiveness of Therapeutic Ultrasound and Low Level Laser Therapy over pain and scar health in post episiotomy patients.

About 10 subjects who fell in the age group of 25-30 years, satisfied both inclusion and exclusion criteria were included in the study. Group-A (5 subjects) were treated with Therapeutic Ultrasound and Group-B (5subjects) were treated with Low Level Laser Therapy.

There is a significant reduction (P<0.05) in the mean values of Numerical Pain Rating Scale(NPRS) in Group A subjects treated with Ultrasound and there is a significant reduction (P<0.05) in the mean values of Numerical Pain Rating Scale(NPRS) in Group B subjects treated with Low Level Laser Therapy for three days.

Therapeutic Ultrasound is a high frequency machine which is inaudible and it consist of mechanical vibration. The electrical energy is acoustic energy when the crystals gets deformed and this effect is called piezo-electric effect[19]. The tissue permeability is increased due to increased micro-friction between the molecules[20].

Therapeutic Ultrasound increase the blood circulation and improves the skin and cell membrane permeability which leads to reduction of pain,removes the waste products and promote wound healing.

EL Hag and coworkers stated the cause for anti-inflammatory effect of Therapeutic Ultrasound as follows, increased protein synthesis, more number of mast cell production. The above causes leads to reduction in swelling and improves the vascular permeability[21].

Low Level Laser Therapy produces a beam of radiation which differs from the ordinary light. By the end of 1960, **EndreMester**stated that the Low Level Laser therapy can be given for wound healing. The energy production in the Low Level Laser therapy is by quantum theory.

The Low Level Laser therapy must consist of a lasing medium (solid, crystal or semiconductor), resonating chamber and the energy source. For therapeutic purpose two method of application are used in Low Level Laser therapy such as grid method and scanning method. Low Level Laser therapy is found to be effective in pain reduction both acute and chronic pain by improving the healing process and reducing the swelling.

According to **Dyson and Young 1986,** the low level Low Level Laser therapy is effective for wound healing by increasing the changes and the release of chemical mediators.According to **David Baxter 1994** the energy density plays an important role in pain reduction and promotion of wound healing[22].

The results of this study shows that with the Patient and Observer Scar Assessment Scale(POSAS) is found to have a significant effect over scar healing in both Group A treated with Ultrasound and Group B treated with Low Level Laser Therapy for three days.

The effect of Therapeutic Ultrasound on wound healing is due to increase in the growth of the tissues and facilitate repair of soft tissue by the mechanism of acoustic streaming.

In Inflammatory Phase, degranulation takes place in mast cell and release the histamine which leads to the collagen formation. In proliferative phase, Therapeutic Ultrasound promotes wound contraction by development of myofibroblast in that injured region. In remodeling phase the tensile strength of the scar tissue is improved by collagen activity and tissue extensibility.

The effect of Low Level Laser therapy on wound healing is due to absorption of Low Level Laser therapy light by mitochondria which stimulate the electron transport chain and produce AdenosineTriPhosphate(ATP).**Passarella 1988** stated

that Low Level Laser therapy also has an effect on DNA synthesis, cellular activation and granulation tissue formation[23].

When comparing both the groups it was found that there was no statistically significant difference in the reduction of pain between Group A and Group B ($p>0.05$) which shows that both Ultrasound and Low Level Laser Therapy has similar effect over reduction of pain.According to the statistical analysis which is calculated by Wilcoxon Signed rank Test, there is a significant difference ($p<0.05$) between both groups in scar health which is assessed by the Patient and Observer Scar Assessment Scale(POSAS) and it was found that GROUP-B subjects treated with Low Level Laser Therapy has a better effect over scar health improvement than the GROUP-A subjects treated with Therapeutic Ultrasound ($p<0.5$).

Acto myosin plays an important role in myofibrobalsts contraction by shrinking the border of the wound which reduce the size of the wound during soft tissue healing.

According to **Tuner and Hode 2002,** Low Level Laser therapy produces a non-thermal effect and is an ideal treatment for wound healing by reducing the pain and promotes tissue healing[24].The effect of Low Level Laser therapy in pain reduction is due to its effect on pain relievers such as endorphin and encephalin.

Both modality has better effect in reducing pain and improving scar health. But this study documents that Group-B (Low Level Laser therapy Therapy) has significant improvement in scar healing than GROUP-A (Therapeutic Ultrasound). According to this study, Low LevelLaser Therapy has significant effect on scar health and prevent the complication of dyspareunia.

Conclusion

This study concludes that both Low Level Laser Therapy and Therapeutic Ultrasound is effective in reducing the pain. Low Level Laser Therapy promotes scar health than the Therapeutic Ultrasound. So Low Level Laser Therapy is effective in improving the scar health in post episiotomy.

The Effect of Specific Training on Selected Physiological Variable among Kabaddi Players

S.J, Albert Chandrasekar[1] , K. Jaya Prakash[2]

[1]Asst. Professor, Dept. of Physical Education and Sports Sciences, SRM IST, Kattankulathur, [2] M.Phil. Research Scholar, Dept. of Physical Education and Sports Sciences, SRM IST, Kattankulathur.

Abstract

Context: The purpose of this study was to find out the effect of specific training on selected physilogicalvariable among school boys kabaddi players from government higher secondary school koomapatti..The age of the subjects ranged from 15to18 years. The selected subjects n=30 were divided into one experimental group and one control group at random. The investigator selected a training that is specific training for kabaddi players which improved certain selected physiological fitness variables namely Resting Heart Rate. As the result of field training the physical fitness level of the kabaddi would improve. The experimental group endured the training activities for 6 weeks with a schedule of six days whereas the control group remained with no activities. The data procured in prior and after the training programme was examined. To find out difference between experimental and control group of Resting Heart Rate t-ratio was employed and the level of significance was set at 0.05. The results of the study showed that the Resting Heart Rate of the experimental group was significantly improved than the control group.

Keywords: *Specific training, Resting Heart Rate, Kabaddi, Experimental group, Control group*

Introduction

Physical events such as scoring goals or crossing a line first often define the result of a sport. However, the degree of skill and performance in some sports such as diving, dressage and figure skating is judged according to well-defined criteria.[1]This is in contrast with other judged activities such as beauty pageants and body building, where skill does not have to be shown and the criteria are not as well defined. Records are kept and updated for most sports at the highest levels, while failures and accomplishments are widely announced in sport news.[2]Sports are most often played just for fun or for the simple fact that people need exercise to stay in good physical condition. However, professional sport is a major source of entertainment.

e-mail: albertanitha@gmail.com

Physical Education and Sports: Physical education and training organized instruction in motor activities will contribute to the physical growth, health, and body image of the individual. The historical roots of physical education go back as far as the ancient Chinese who had a well-developed system of exercise and physical training.[3]

In ancient Greece the Athenians were concerned with both physical and mental development; consequently they accorded gymnastics, sports, and rhythms an important educational role. During the period of the Roman Empire and later during the middle ages, physical education was primarily used as a form of military training. Interest in physical education as a part of the total individual's development was revived during the Renaissance.[4] It was not until the 19th cent., however, that systems of gymnastics were developed in several European countries, notably Germany, Sweden, and England. During same period gymnastics spread to the United States. Interest in the new system led to a movement to have compulsory physical training in American public schools and to establish

physical education in colleges and universities. The first department of physical education at an American college was established at Amherst, 1860.

Sports Specific Training: Sports Specific Trainers can help improve strength, flexibility and stamina to improve performance in specific sports.[5] Options include increasing arm strength for tennis playing or improve strength and core stability providing better balance playing. Sports specific training is all about developing physical conditions to improve performance and skills at a particular sport. Also understanding the needs of the game training practicing at the correct pace in order to meet sports requirements.[6]

Kabaddi: India's efforts to popularize Kabaddi has paid rich dividends as the country has won all the Asian Games gold medals, since the game was introduced in the 1990 Beijing Games. Talking about the techniques of the game, there are two teams that occupy the opposite halves of a field.[7]In turns, one team sends a 'raider' into the other half, in order to win points. The raider, who goes inside has to touch any one of the teammates from the other team and immediately run back to his line, without even once letting off his breath during the whole raid and chanting the word "kabaddi".[7] On the other hand, the members of the other team have to grab the raider down before he reaches his line.

Statement of the problem: The purpose of this study was to find out the effect of specific training on selected physiological variable among school boys kabaddi players.

Methodology: To achieve the purpose of these study 30 boys kabaddi players were selected at government higher secondary school koomapatti. The age of the subjects ranged from 15to18 years. The selected subjects were divided in to one experimental group and one control group at random. The investigator selected a training that is specific training for kabaddi players which improved certain selected physiological fitness variables namely muscular Resting Heart Rate. As the result of field training the physical fitness level of the kabaddi would improve.

Resting Heart Rate:

Purpose: To measure the subjects' resting heart rate.

Equipments: Stethoscope and stopwatch.

Procedure: The resting heart rate of each subject was recorded in the early morning after getting out of bed and sit at rest comfortably in a chair for few minutes. The resting heart rate was obtained through auscultation i.e. using the bell of the stethoscope is placed to the left of the sternum just above the level of the nipple. Then the stop watch was started with the heartbeat. Counted the first beat as zero and continued for 30 seconds. This procedure was repeated on three separate mornings.

Scoring: Resting heart of the subjects was recorded on three successive mornings. The average of the three recordings was arrived at and recorded as the subjects resting heart rate. The unit of measurement was initially taken for 30 seconds and the beats per minute of the subjects were calculated by doubling the number of beats to arrive at and per minute calculation.

Results and Discussions

Table I: Analysis of 't' ratio for the pre and post test of Control and Experimental Group on Resting Heart Rate

Variable	Group	Mean		SD		Sd Error	Df	't' ratio
		Pre	Post	Pre	Post			
Resting Heart Rate	Control	77.07	77.73	2.81	2.55	0.33	14	2.00
	Experimental	77.33	75.73	4.15	3.73	0.16		9.80*

* Significance at 0.05 level of confidence.

The data analysis done statistically from the table I indicates that the mean values of pre-test of the training groups To find out difference between experimental and control group of Resting Pulse Rate. Difference in two groups t-ratio was employed and the level of significance was set at 0.05. Experimental group pre and post-test

mean value were 77.33, 75.73 respectively. In Control group pre and post-test were mean value was 77.07, 77.73 respectively. In experimental the obtained t-ratio 9.80 was greater than the table value 2.15 so it found to be significant. In control group the obtained t-ratio 2.00 was lesser than the table value 2.15 so it was found to be insignificant.

Discussing on Findings: The result of the study indicates that the experimental group namely training group had significantly improved the selected dependent variables namely Physiological Variable when compared to the control group. It is also found that the improvement caused by training when compared to the control group.

Discussion on Hypothesis: It was hypothesized at the beginning of the study that there would be significant improvement on selected criterion variables such as specific training (physiological variable) due to training for the experimental group as compared to the control group. The present study produced similar results. Hence, the research hypothesis of the investigator was held true.

Conclusions

The results of the study concluded that the Resting Heart Rate of the experimental group was significantly improved than the control group.

Urinary Intestinal Fatty Acid Binding Protein "IFABP" as a Marker for Gut Maturation in Preterm Babies

Samir Tamer Abd-Allah [1], Hanan Mostafa Kamel[2], Madeha Abd-Allah Sayed[3]

[1]Department of Pediatrics, Faculty of Medicine, Minia University, El Minia,Egypt. [2]Department of Clinical pathology, Faculty of Medicine, Minia University, El Minia, ,Egypt, Lecturer of pediatrics,Pediatric Department, Faculty of Medicine, Minia University,

Abstract

Objective: Formula-fed premature babies have a higher incidence of developing necrotizing enterocolitis (NEC) than breast-fed babies which may be caused by breast milk induced gut maturation. The effect of breast milk on maturation of the gut has been widely studied in animal models and recently in humans.

The aim of this study: Is to evaluate the effects of breast-feeding on maturation of the intestine in premature babies by measuring the postnatal values of a specific enterocyte marker which is urinary intestinal fatty acid binding protein (I-FABP).

Method: Maturation of the gut was studied in 60 premature babies(<37 weeks of gestation) without gastrointestinal morbidity. 30 of them were exclusively breast-fed and the other 30 were formula-fed. Urinary I-FABP levels as the measure of gut maturation were measured at 7th, 12th, and 22ndpost-natal days.

Results: In breast-fed babies, there was a statistically significant increase in urinary I-FABP levels between 7th and 12th days after birth compared with formula-fed babies ($p< 0.01$)

Conclusions: The pattern of postnatal changes in urinary I-FABP levels suggests a delayed physiological response causing significantly delayed gut maturation in formula-fed babies compared with breast-fed ones.

Keywords: *Breast-feeding, formula feeding, intestinal fatty acid binding protein,gut maturation, mucosal damage, necrotizing enterocolitis.*

Introduction

Human milk (HM; milk from the infant's own mother) feedings during the Neonatal Intensive Care Unit(NICU) hospitalization reduce the risk of prematurity-related morbidities in a dose-response manner for very low birth weight babies. (1)

These morbidities include late onset sepsis, necrotizing enterocolitis, chronic lung disease, retinopathy of prematurity, prolonged NICU hospitalization ,increased health care costs , and long-term health and educational problems. (2)

Breast milk is a known source of molecules that act synergistically to protect the gut barrier and enhance the maturation of the gut-related immune response. So During the perinatal period, nutrition is the principal contributor for immunological and metabolic development, and microbiological programming. (3)

Breast milk is the gold standard for preterm nutrition and influences the development of intestinal microbiota and immune system through its bioactive components. (4)Preterm infants altered gut microbiota interaction(2) with an immature immunologic intestinal response

Corresponding Authors:

triggers proinflammatory and counter-inflammatory cytokine response. Necrotizing enterocolitis (NEC) is the most common gastro- intestinal emergency in the neonatal intensive care unit (NICU) which is due to excessive inflammatory response against commensal bacteria by the immature intestine following mucosal injury in the postnatal period. (5)

Its prevalence is largely related to birth weight and gestational age (G.A.)with approximately 1 in 10 very low birth weight infants (<1500 g) developing NEC.(5)

Breast-fed newborns are protected against NEC development through improved gut maturation and becausethere is an estimated 3 to 10 folds risk reduction in infants fed with breast milk compared with those fed with formula milk(6)

Patients and Method: Sixty preterm babies were enrolled in this study, thirty of them were breast-fed preterm babies (Group I) while the other thirty newborns were formula-fed ones (Group II).

All of the babies admitted to the NICU of the Minya University Hospital of children between August 2015and March 2016were eligible for participation.

Patients were included if they met the following inclusion criteria: <37 weeks of gestation, first enteral feeding within 7 days after birth, and diet consisting of either exclusively breast milk or exclusively formula milk. The only exclusion criterion was development of significant gastrointestinal pathology during the 30-daystudy period, defined as disease of the gastrointestinal tract necessitating surgery, antibiotic treatment, cardiopulmonary support, or discontinuation or reduction of enteral feeding.

Initiation of feeding and advancement of feeding volumes were realized according to the local protocol. The standard guidelines consisted of early initiation of oral feeding within few days after birth depending on the infant's gestational age and general condition.

Feeding volume was increased gradually and discontinued if there were signs of feeding intolerance including bilious gastric retentions, abdominal distention, emesis, or bloody stools.

Sample collection:1-blood samples: 5 ml of venous blood samples were taken for complete blood count, Total and direct bilirubin , and CRP using fully automated chemical auto-analyzer Dimension-ES, USA.

2- Urine samples: Urine samples were collected on the 7th, 12 th, and 22th day after birth.

Samples were collected either from a urine bag connected to an indwelling catheter or from a cotton wool swab placed in the diaper and squeezed through a syringe barrel into a collection tube. Samples were then frozen at -20°C till the time of analysis.

Urinary I-FABP levels were measured by ELISA.

Statistical Analysis: The numerical data were presented as means – standard deviations while non numerical data were presented as percentage. Two tailed-tests were used to analyze differences between the two groups.

P-values less than 0.05 were consideredstatistically significant. The magnitude of correlationswas determined by Pearson's correlation coefficient.

All the data were analyzedby statistical package Prism 3.0 (GraphPad software, SanDiego, CA, USA). Figures were done by Microsoft Office Excel 2007

Results

In the present study, there was a significant statistical difference between breast-fed and formula-fed preterm babies regarding Duration of NICU admission in days (p< 0.01**)which was higher in formula-fed preterm babies compared to breast-fed ones,while there was no significant statistical difference between the two groups of patients regarding gestational age (mean±SD33.1 ± 2.2, 32.9 ± 2.1respectively), sex (p< 0.01), and birth weight (mean±SD 0.9 ± 0.7,0.1 ± 0.6,-0.97 ± 0.4 respectively).p (p< 0.01 *(Table1.)*

There was significant higher incidence of Co-morbidities like respiratory distress and sepsis in formula-fed preterm babies compared to breast-fed ones (p< 0.01) for both. Seventy three percent of obese children 26.3% of overweight ones were having NAFLD. *(Table2)*

Regarding Signs of feeding intolerance between groups in the form of stopping of feeding, their frequency, and duration, all were significantly higher in in formula-fed preterm babies compared to breast-fed ones (p< 0.01) for all. Serum platelets were compared to healthy ones (mean±SD for ALT 71.3 ± 21.4, 41.3 ± 19.1, 30.3 ± 4.4 and Serum TLC(mean±SD for AST 69.8 ± 24.5,36.8 ± 5.5, 30.0 ± 4.4 respectively) (p< 0.01 and

0.05 respectively).staff CRPmean±SD for AST 69.8 ± 24.5,36.8 ± 5.5, 30.0 ± 4.4 respectively) (p< 0.01 *(Table.3)*

There was negative correlation between BMI,weight, cholesterol, TG and ALT and serum visfatin levels. (p<0.01 for all). *(Table.4)*

Discussion

FABPs is a set of widely expressed cytoplasmic proteins with small molecular weight and excellent organ specificity, which are immediately secreted into the systemic circulation upon the damage of cells[7]

As a member of the FABPs family, FABP2, which is a *FABP2* gene encoding protein, accounts for up to 2% of the cytoplasmic proteins in the mature enterocyte, and it is responsible for the intake alongside with the transport of polar lipids like fatty acids from the lumen of the small bowel.[8]

FABP2 is a water soluble cytosolic protein with a small molecular weight of 14-15 kDa, and it is initially located in the mature enterocytes of the small intestine. FABP2 is also named as intestinal-type FABP (I-FABP). [9]

Because of its small molecular size, FABP2 is believed to be delivered to the circulation immediately upon the loss of the integrity of the cell membrane and filtering of theglomerulus with a renal excretion of 28% and a considerable half-life of 11minutes. So, it is supposed to be detectable in urine.[10]

Thus, varying FABP2 expressions in the urine could exactly reflect the severity of thecell damage to the intestinal epithelia, making it possible to use FABP2 as a trustable indicator of the disease progression[11].

This study was carried out to assess the diagnostic utility of theurinary I-FABP levels as a new marker for gut maturation in breast-fed preterm neonates compared to formula-fed ones.

In the present study, breast-fed babies and formula-fed ones showed no significant statistical difference regarding gestational age (p=0.71), sex (p< 0.60)and , birthweight (p< 0.88). These findings agreed with the study of Kostan W2014 who stated that there were no significant differences in GA, birth weight, or sex between the 2 groups; however, there was a trend of lower median GA in the breast-fed group.

Our study shows that Prematurity was the primary reason for admission to the NICU in all of the babies and that the duration of NICU admission in days was higher in formula-fed preterm babies compared to breast-fed ones (p**< 0.01)** .

The results of our study show a significant higher incidence ofCo-morbidities like respiratory distress and sepsisin formula-fed preterm babies compared to breast-fed ones (p< 0.01) for both . This agrees with the study of [12] who explained the beneficial effects of breast milk and its immunomodulatory and anti-inflammatory effect, and high concentrations of secretory immunoglobulin A, CD14, transforming growth factor-b, erythropoietin, and interleukin-10 in breast milk.

In our study, total volume of enteral feedings was recorded every day to investigate whether the type of feeding correlated with feeding intolerance**.** Feeding intolerance is defined as episodes of discontinuation of enteral feeding or frequency and cumulative amount of gastric retentions.

We found that signs of feeding intolerance including feeding stoppage, number of episodes, and duration of those episodes were significantly higher in in formula-fed preterm babies compared to breast-fed ones (p< 0.01) for all**.** . This could be explained by that early breast milk feedings, especially colostrum, promote the growth,maturation, and protection of the gut epithelial border.

In agreement with our study, [13] explained the mechanisms by which breast-feeding improves intestinal maturation. For example, analogues of growth factors or human milk oligosaccharides. The preterm infant's high need for trophic factors should be taken into account. Added to that, his study underlines the importance of breast milk use in preterm infants.

Our results also agree with the study of [14] who found that human milk feedings have been shown to stimulate healthy gut microflora, reduce intestinal permeability, and interfere with the translocation of bacteria from the gut lumen to the mucosa, and appear to be the most critical as VLBW infants transition from intrauterine (e.g., swallowing amniotic fluid) to extrauterine nutrition in the early post-natal period.

Commercial formulas may have a separate detrimental impact on these processes during these early postnatal exposure periods, via up-regulation of inflammatory processes, GIT epithelial cell toxicity, and other mechanisms.[15]

Ethics Approval and Consent to Participate: The study was conducted according to the declarations of Helsinki and approved from the faculty of medicine scientific committee in Minia

University (No: 116-5-2016): Written consents were obtained from patients and/or caregivers.

Relationship Individual Factors with Sickness Absence in Hospital

Samsul Arifin[1], Abdul Rohim Tualeka[2]

[1]Department of Occupational Health and Safety, School of Public Health, University of Airlangga. [2]Department of Occupational Health and Safety, School of Public Health, University of Airlangga

Abstract

Background: Workers in health industries are more likely to have health problems. Health problems may result in in sickness absence. High rate of sickness absence can decrease productivity and consumer satisfaction.

Objectives: To analyse individual factors with types of sickness absence.

Method: Retrospective study design. Data collection was done using secondary data in the form of sickness absence data report of hospital in 2017. A binary logistic regression test was used to identify the significance of correlation of age, sex, years of service and marital status correlation with types of sickness absence.

Results: Of 416 workers, 100 people submitted 163 sickness absence letter with the total of 653 days. Women workers with age range of 26-45, who were married and with 5 years of service were the group with the most sickness absence. Short term sickness absence was the most common type. The results of multivariate binary logistic regression showed that age (p value = 0.659 and Exp (B) = 0.783), sex (p value= 0.929 and Exp (B) = 0.945), years of service (p value = 0.620 and Exp (B) = 0.866), marital status (p value = 0.773 and Exp (B) = 0.837) variables were not significant.

Conclusion: There is no significant relationship between individual factors and type of sickness absence.

Keyword: *Sickness absence, workers, hospital*

Introduction

Based on Canadian Institute for Health Information (CIHI) in 2000, workers in health care are 1.5 times more likely to call in sick or leave work on disability compared to workers in industries other than health care. The average duration of 11.8 days of sickness absence is higher than workers in other fields which is 6.7 days.(1)

Hospital workers sickness absence results in not only decreased productivity but also affect consumer satisfaction. This is supported by the study of Duclay et al (2015) conducted in a hospital in France, concluding that the attendance of the hospital staff correlated with patient satisfaction in the hospital.(2)

Unhealthy workers are prone to sickness absence. Sickness absence is divided into 2 types. Short term sickness absence (fewer than 4 days) and long term sickness absence (longer than 4 days). Short term sickness absence is more common than the long term one. Long term sickness absence is generally caused by serious or severe illness.(3) It is important therefore to identify individual correlation factors with the types of sickness absence.

The objective of this study is to analyse the individual correlation factors with the types of sickness absence of workers in hospital X in 2017.

Method

This type of research is an observational analysis study with a retrospective research design. The population is workers who call in sick in hospital in Malang, Indonesia . During the period of 2017, the total number of workers was 416 people with 100 workers submitted sickness absence, amounting to 163 sick letters (spell) and 653 days of sickness absence. The research variables studied included the characteristics of workers, namely age, sex, years of service and marital status, and types of sickness absence. Data collection was carried out using secondary data in the form of hospital worker's sickness absence data in 2017. The data obtained were analyzed descriptively using cross tabulation. Binary logistic regression test was used to test the significance of parameters in a multivariable manner.

Findings: The frequency distribution of hospital workers by age can be seen as follows (see Table 1). Based on table 1 it can be seen that 56 people (56%) who submitted sickness absence were in the age group between 26 to 45 years.

Table 1:The Frequency Distribution of Workers by Age in Hospital in 2017

Age	Total (n)	Percentage (%)
17-25	36	36
26-45	56	56
>45	8	8

Table 2: shows that 79 workers (79%) who called in sick were women.

Table 2: The Frequency Distribution of Workers by Sex in Hospital in 2017

Sex	Total	Percentage (%)
Women	79	79
Men	21	21

Table 3 shows that 73 workers (73%) who called in sick were married.

Table 3: The Frequency Distribution of Workers by Marital Status in Hospital in 2017

Status	Total	Percentage (%)
Married	73	73
Unmarried	27	27

Table 4: Shows that 61 workers (61%) who called in sick had years of service of less than 5 years (see Table 4).

Table 4: The Frequency Distribution of Workers by Years of Service in hospital in 2017

Years of Service	Total	Percentage (%)
0 – 5 years	61	61
6 – 10 years	13	13
11 – 15 years	13	13
16 – 20 years	9	9
>20 years	4	4

Most of the workers (79%) submitted short term sickness absence (see Table 5).

Table 5: The Frequency Distribution of Workers by Attendance in Hospital in 2017

Attendance	Total (n)	Percentage (%)
Short term	79	79
Long term	21	21

Negelkerke R Square in Table 6 shows a value of 0.16 or 16%. This means that the dependent variable can be explained by 16% independent variables. That is, all independent variables affect the dependent variable simultaneously in the range of 16%, while 84% are influenced or explained by variables not included in this study.

Table 6: Model parameter estimation test

Step	-2 Log Likelihood	Cox & Snell R Square	Nagelkerke R Square
1	101,728[a]	,011	,016

It can be seen in Table 7 that the p-value (sig.) is more than 0.05, meaning that age, years of service, marital status and sex not significantly influence the types of sickness absence.

Table 7: Univariable Significance Test Results

	S.E.	P Value	Exp(B)	95% C.I.for EXP(B)	
				Lower	Upper
Age	,554	,659	,783	,264	2,322
Years of Service	,291	,620	,866	,490	1,530
Marital Status	,618	,773	,837	,249	2,809
Sex	,637	,929	,945	,271	3,295
Constant	1,402	,793	,692		

Discussion

As many as 56% of workers who submitted sick letters were aged 26-45 years. This is consistent with a cross sectional study conducted on 1200 workers by Sorevi et al (2013) at Mazandaran university hospital, where the frequency of sickness absence was most common among workers aged 38 - 41 years. [4] Likewise, the study conducted by Isah et al (2008) concluded that the number of sickness absence was significantly correlated with the age of workers.[5]

Of the 100 people who submitted sick letters, 79% of them were women. This is consistent with a 602 nurse cross sectional study in Brazil in 2008-2012 conducted by Marques et al (2015) which stated that 92.9% of sickness absence were female nurses.[6] According to Kurniawidjaja (2010), female workers, especially those who are married, are more often called in sick because they have multiple roles, that is, aside from work duties, they also have to provide domestic services to their children and husbands, plus the role of educating children so that they have no problems in their studies. [6,7]

About 73% of those who called in sick were married. According to Kurniawidjaja (2010), sickness absence of married workers is related to household problems such as divorce, children and workload. In fact, women who are married have a higher sickness absence or absenteeism in general, and non-medical factors are thought to contribute. [7]

Workers with the years of service less than 5 years submitted most sick letters, amounting to 61%. This is consistent with the research of Linggarwati et al (2017) which stated that workers with short years of service will be more likely to be absent which may be because they are still adjusting to the environment and workplace conditions. Workers who have worked for years have better attendance because they do not need to adjust to the environment or working conditions.[8] According to Kurniawidjaja (2010), workers with longer years of service usually have fewer sickness absence than those who have worked for less than a year, presumably because older workers have better working relationships. [7]

79% of workers submitted short term sickness absence. This is in accordance with Kurniawidjaja's opinion which stated that 80-90% of sickness absence are short-term ones. Usually, short-term sickness absence is acute and mild in nature, such as diarrhea, red eye disease, common cold or sore throat. However, if it occurs 12 times or more in one year, for example 3 to 6 times in 3 months, the risk factors and pattern need to be analyzed both medically and non-medicall.[7] The study conducted by Tripathi et al (2010) on 385 nurses in India concluded that two-thirds of sickness absence were short-term absences and this was attributed to the low morale of workers.[9]

Based on variable statistical test, age, years of service, gender and marital status did not significantly influence the types of sickness absence. This was consistent with studies conducted by Mollazadeh et al (2018) in hospital workers in Iran, which concluded that there was no correlation between sex and marital status with workers' absenteeism.[3] This result is also supported by a research conducted by Linggarwati (2017) concluding that sickness absence does not have a significant relationship with age, gender, years of service and level of education. From the results of statistical tests, the variables of age, years of service, gender and marital status have an effect of about 16%, while 84% are influenced or explained by variables not included in this study.[8] According to Kurniawidjaja (2010) there are 3 factors influencing sickness absence, which are individual factors, geographical factors and organisational factors.[7] The unanalysed factors of this study include geographical factors, comprising of climate, ethnicity, epidemic, insurance system, retirement age. While organisational factors include company scale, work type, occupational hazard, work shift, personal policy, health facility and industrial relationship. While the individual factors that have not been analyzed from this study are job satisfaction, distance of travel to work, social activities.

Conclusions

Based on the results of the analysis it can be concluded that there is no significant relationship between individual factors with the types of sickness absence. Limitations in this study are limited to only a few individual factors. Subsequent research will be better if it is complemented by the inclusion of variables of organizational factors and geographical factors in the analysis of sickness absence.

Conflict of Interest Statement: The authors of this research declare that there is no conflict of interest related to this study.

Because it uses secondary data. This study does not use ethical tests

Source of Funding: All funds used to support this research comes from the researchers themselves

Climate Variability and Dengue Hemorrhagic Fever in Surabaya, East Java, Indonesia

Sandra Choi Ning Tang [1], MusofaRusli[2], Pudji Lestari[3]

[1]Faculty of Medicine, UniversitasAirlangga, Surabaya, Indonesia, [2]Department of Internal Medicine, UniversitasAirlangga, Dr.Soetomo Hospital, Surabaya, Indonesia, [3]Department of Public Health, Faculty of Medicine, UniversitasAirlangga, Surabaya, Indonesia.

Abstract

Background: Dengue hemorrhagic fever is an arboviral infectious disease that has occurred frequently as an extraordinary event due to its fast spread and lethal potential in Indonesia. The vector *Aedes aegypti* is sensitive to climate variability. This study determines the relationship between climate variability and dengue hemorrhagic fever in Surabaya, East Java, Indonesia from 2009 to 2017.

Subject and Method: This study used the monthly dengue hemorrhagic fever incidence obtained from the Surabaya Health Office and the monthly climate variability parameters (average temperature, rainfall, humidity) obtained from the Indonesian Agency for Meteorology, Climatology and Geophysics and website www.worldweatheronline.com. Data analysis was done using One-Sample *Kolmogorov Smirnov Test* and Spearman non-parametric correlation test.

Results: The results showed a correlation between all three climate variability parameters with dengue hemorrhagic fever incidence (average temperature $p<0.05$, $r=-0.603$; rainfall $p<0.05$, $r=0.407$; humidity $p<0.05$, $r=0.7$).

Conclusion: Average temperature is negatively correlated to dengue hemorrhagic fever incidence, while rainfall and humidity are positively correlated to dengue hemorrhagic fever incidence. This study shows preliminary evidence on the correlation of climate variability and dengue hemorrhagic fever in Surabaya, East Java, Indonesia.

Keywords: *Climate variability;dengue hemorrhagic fever incidence; average temperature; humidity; rainfall; Surabaya*

Background

Dengue fever (DF), an infectious disease, and its more severe manifestation dengue hemorrhagic fever (DHF) are the fastest emerging arboviral infectious disease in tropical and subtropical countries. It is estimated 2.5 billion people are at risk of dengue infection, while an estimated 50 million dengue infections occur worldwide with 500 thousand people requiring hospitalization for DHF annually [1] .

The first reported cases of DHF in Indonesia occurred in Jakarta and Surabaya in 1968 [2]. The incidence rate has increased ever since with expanding endemic regions and has affected most of the provinces in East Java [3,4]. Surabaya was recorded as the province with the highest DHF incidence rate in East Java back in 2012 [3], with very high coping range index (CRI) levels in 2007-2009 and 2011-2012 [5].

DF and DHF are caused by dengue viruses (DENV), which form the dengue complex in the genus *Flavivirus*, family *Flaviviridae*. This self-limited, systemic viral infection is caused by four antigenically related viruses (DENV 1-4) found circulating in the tropical and subtropical regions of the world [6,7] and transmitted by the female *Aedes aegypti* and *Aedes albopictus* mosquito species. As a tropical country, Indonesia with a monsoonal wet season and a dry season provide an optimum habitat to support the breeding of *Aedes aegypti* mosquitoes and spread of its virulent infection [8]. Climate variability plays an important role in the epidemiology of vector-borne diseases That affects human health and spread of diseases. It is a complex study that requires a thorough understanding of the links with the climate and disease [9]. Examples of the climatic variables included in climatic factors are qualitatively the temperature, humidity and rainfall [10,11].

Further quantitative analysis needs to be done to understand dengue dynamics with climate[13].There is no specific treatment available to treat the virus and efforts to curb dengue transmission in South-East Asia region are not largely successful [1]. Recent findings also found an increasing trend for global dengue epidemic potential in temperate regions over time [14].

To date, there are only a few research studies [15] done on the effect of climatic variables on the spread of DHF in Surabaya. Therefore, the aim of this study is to investigate the relationship between climate variabilityand dengue transmission in Surabaya, to be able to plan effective vector control and DHF surveillance programs to prevent the endemicity of DHF in Surabaya.

Subjects and Method: This study was an ecological descriptive study with a retrospective time-series analysis approach.This study was conducted in Surabaya, a city area with 326.37 km^2[16], with a sample size of 2,862,406 inhabitants.

The secondary data DHF cases and climatic data from 2009 to 2017 were collected. DHF case incidence data diagnosed based on WHO clinical criteria andobtained from the Surabaya City Health Office. Climatic data which were the average temperature, rainfall and humidity were collected from the Indonesian Agency for Meteorology, Climatology and Geophysics and the public online website www.worldweatheronline.com.

SPSS statistical software package version 16.0 was used for the statistical analysis. One-Sample *Kolmogorov Smirnov* Test was used to evaluate the cumulative distribution function for the data. The Spearman non-parametric correlation test was used to examine the relationship between monthly climatic data and DHF incidence.

Results

1. Profile of Dengue Hemorrhagic Fever Incidence from 2009 to 2017 in Surabaya, Indonesia

During the study period from 2009 to 2017, there were 12,672 dengue hemorrhagic fever (DHF) cases reported (Figure 1 (a)), with the highest in 2010 (3379 cases, IR of 116 per 100,000 person-years), and the lowest in 2017 (325 cases, IR of 11.3 per 100,000 person-years). Total DHF cases and IR incidence rate (Figure 1 (b)) had sudden increases in 2013 and 2016, while CFR (Figure 1 (c))was the highest in 2014 (2.1) and lowest in 2009 (0.3).

DHF cases recorded were highest from March to May and were the lowest in September (Figure 1 (d)). Monthly DHF cases fluctuated similarly to the monthly rainfall (Figure 1 (f)) and monthly humidity (Figure 1 (g)), while the monthly average temperature had a low thermal variation of less than 10 degree Celsius (Figure 1 (e)).

Figure 1: Profile of DHF cases from 2009 to 2017 in Surabaya, Indonesia(a) Annual total DHF cases (b) Incidence rate (IR) of DHF cases (c) Case fatality rate (CFR) of DHF cases (d) Monthly total DHF cases (e) Monthly average temperature and monthly DHF cases (f) Monthly rainfall and monthly DHF cases (g) Monthly humidity and monthly DHF cases

2. Relationship between Climate Variability and Dengue Hemorrhagic Fever

The One-Sample *Kolmogorov Smirnov* Test showed that the monthly average temperature, monthly rainfall, monthly humidity and monthly total DHF cases from 2009 to 2017 were not in normal distribution (p-value = 0.000).

Spearman non-parametric correlation test found significant correlations (p= 0.01) between monthly average temperature and monthly total DHF cases (r= -0.603); between monthly rainfall and monthly total DHF cases (r= +0.407); and between monthly average humidity and monthly total DHF cases (r= +0.700).

Discussion

1. Profile of Dengue Hemorrhagic Fever Incidence from 2009 to 2017 in Surabaya, Indonesia: It is difficult to say whether the DHF case profile in Surabaya from 2009 to 2017 has improved compared to previous decades due to the fluctuating trend pattern of DHF cases over the past 50 years [2].

The "down sloping" trend of DHF incidence in recent years could be due to the effective surveillance and vector control programs carried out by the Surabaya City health officials[17]. Thermal fogging, mass larviciding, insecticides, and health awareness programs were reasonably successful in eradicating dengue transmission [18]. However, the intermittent spikes of CFRs over the study period could be due to the lack of awareness amongst the community albeit effective government mosquito-control regimes[19]. The complex dynamics of climate also influenced the ecology and caused increased vector density after rainy seasons in Indonesia[11].

2. Relationship Between Climate Variability and Dengue Hemorrhagic Fever: Ae. aegypti population dynamics are sensitive to changes in temperature, and the survival of the species increased in general when temperatures increased [30,31]. Kramer and Ebel found that adult mosquito survival rates were linked with lower temperatures [32] while Lambrechts et al. found that vector competence is reduced in *Ae. aegypti* for flaviviruses when the mean temperature fluctuations are above 18°C, and increases when the mean temperature fluctuations are below 18°C [33]. Increased rainfall increases the potential breeding sites of *Aedes* mosquitoes [34], leading to an increased propagation of mosquitoes, increased vector density [10], and increased risk of dengue virus transmission. This relationship is unclear though because*Ae. aegypti* is a domesticated species that breeds indoor primarily [35]. However, it is possiblethat the domestication process of mosquitoes may increase its competence to transmit human virus [36], because the oviposition behavior of vectors in different environments still remain unknown [37]. Flooding may also increase the vector densities and increase dengue virus transmission rate [38–40].This is because more breeding conditions of *Aedes* mosquitoes are formed when the increased water levels during floods recede [41].

The rising humidity influences the feeding pattern of *Aedes* mosquitoes, increasing the survival and lifespan of the mosquitoes [34]. Humidity was also found to be the most reliable indicator in dengue incidence models due to its more stable impact ondengue incidence[27]. Several studies found significant correlations between humidity and dengue cases with seasonal periodicities [22,42]. However, there is cautioning to interpret the results of this climate variable due to its biological causation from rainfall and temperature [42]. This is because the humidity is influenced by the rainfall and temperature of a region.

3. Limitations of Study: The limitations of this study are the unconfirmed and underreported DHF cases, and the mosquito spatial distribution abundanceand virulence. Other determinants not studied were the non-climatic factors socioeconomic development, vector control capacity, surveillance programs, drainage cleaning programs in Surabaya, herd immunity for DENV, increased human mobility, altered human-host interaction, demographic changes and regional climate phenomenon such as ENSO.

4. Implications of Research: The findings of this study will provide new evidence on the relationship between climate variability and DHF in Surabaya in recent years and may aid in the development of disease prediction models in the future.The application of these findings into public health measure designs may help mitigate the transmission risk of dengue disease.

Conclusion

From our findings, it is concluded there is a significant correlation between climate variability and DHF incidence in Surabaya, East Java, Indonesia from 2009 to 2017. The application of these findings into public health measure designs may help mitigate the transmission risk of dengue disease.

Abstract

Context: Polycystic ovary syndrome has always been an enigma, and it still continues to be. In addition to an ovulatory subfertility, women with PCOS show an increased danger of pregnancy complications , obesity , so the effect of this issue isn't simply constrained to reproductive age, however all through life. A total of (128) samples (50 normal Weight and 78 obese groups) . Those samples was collected from the Kamal Al-Samarraie hospital, Ministry-of Health in Baghdad-Iraq from April 2017- August 2017. The aim of this present study to was to detect association from polymorphism ADIPOQ gene (rs12495941) with risk of Polycystic ovary syndrome for Iraqi women patients and compare between ADIPOQ gene of Iraq population with gene bank of NCBI . Examine Interleukin-18(IL-18), Tumor necrosis factor alpha (TNF-α) of Polycystic ovary syndrome Iraqi women patients. TNF-α , and IL-18 showed significantly change($p<0.05$) in Obese with PCOS and low weight with PCOS groups when comparing with control group. followed by no-significant change ($p>0.05$)when comparing between Obese without PCOS and low weight with PCOS groups ,also shows significant change($p<0.05$)when comparing between low weight with PCOS and control group.The results show substitution three Transition A>G and G>A , six Transversion T>G, T>A, and C>A , showed 98% identified with a standard in Gene Bank from patients group while having 100% identified with a standard in Gene Bank with the control group.

Keywords: *Polycystic ovary syndrome,Interleukin-18(IL-18),Tumor necrosis factoralpha(TNF-α), ADIPOQ gene.*

Introduction

Polycystic ovary syndrome is the most well-known endocrinopathy influencing reproductive aged women .While some women may present symptomatic and others asymptomatic, it does affect women physically, psychologically, metabolically, endocrinologically and reproductively [(1).]The status was first portrayed in 1935 by the American gynecologists Irving F Stein and Michael L Leventhal, both working at the Department of Obstetrics and Gynecology, Michael Reese Hospital, Chicago, USA from whom its original name of Stein-Leventhal syndrome was taken, they described the clinical, the macroscopic characteristics and histological features of PCOS for the first time [(2).] TNFα is a dominant pro-inflammatory cytokine vital for immunity to infectionsand expressed mainly in monocytes, macrophages and adipose tissue. However, its extravagant production is contributory in chronic inflammation and disease pathology [(3).]Studies on reproductive biology have proven that these pro-inflammatory cytokines promote ovarian function and the processes of ovulation, fertilization, and implantation in women with PCOS [(4).] Moreover, TNF-α can also play an important role in the development of cardiovascular disease. A higher

levels of TNF-α were reported to be connected with an increased risk of future myocardial infarction [5].IL-18 is a potent pleotropic cytokine, member of the IL-1 family, ambidextrous to induce IFN gamma, GM-CSF, TNF alpha and IL-1 in immunocompetentcells,so as to activate death by lymphocytes, and to up-organize the expressing of chemokine and their receptors [6]. Adiponectin is encoded by the gene ADIPOQ situated in the chromosomal area 3q27 .It comprises of three exons and two introns, [7].Human adiponectin is encoded by the 16-kb gene recognized as ACDC (adipocyte C1q and collagen field containing gene). ACDC is situated in a district of chromosome3 that has been appeared to contain a quantitative trait locus (QTL) connected to phenotypes identified with metabolic disorder [8]. Several single-nucleotide polymorphisms (SNPs) and mutations of the ADIPOQ gene were shown in Japanese and Europe populations to be associated with obesity [9].

Materials and Method

Samples Collection: This case-control study involves of a total (128) samples (50 normal Weight and 78 obese groups) . Those samples was collected from the Kamal Al-Samarraie hospital, Ministry-of Health in Baghdad-Iraq from of April 2017- August 2017. Five milliliters of blood was collected from each patient and control then separate 2ml into EDTA tube and 3ml into gel tube after waiting for a minute centrifuged the tube at 3000 rpm for 5 min.

Measurements: Enzyme-linked immunosorbent assay (ELISA) were utilized to estimate the serum level of Human IL-18 ELISA Kit,and Tumor necrosis factor ELISA Kit according to the manufacturer's instructions (bioaimscientific,andMabTag) respectively.

PCR Amplification: The DNA was extracted by utilizing (Geneaid DNA Mini Kit) according to manufacturer's instructions, primer used in this study wereADIPOQ gene(rs12495941)sense F: (5′-TAGTGAGCCGAGATTGTGC -3′) and a anti sense primer R:5′-(TCCTTAGGCATGTAGCTTTCC 3′)'obtained from AlphaDNA company (Xian Chang Sun *etal.,* 2017) . The PCR amplification is performed in a total volume of 25µl containing 1.5µl DNA, 12.5µl Green Master Mix PCR (Promega, USA), 1µl of each primer 10 pmol then nuclease-free water is added into a tube to a total volume of 25µl. Thermo cycling conditions were as follows: initial denaturationat 4 min at 94°C, followed by 28 cycles of denaturation 94 °C for 30 sec, annealing at 62°C for 30 sec, extension at 72 °C for 30 sec and a final extension of 72°C for 5min. The PCR products were separated on 1% agarose gel. The gel is left to run for 60min with a 70volt/65 mAmp current. Following electrophoresis, visualization was conducted with a UV trans illuminator after ethidium bromide staining. The sequencing of ADIPOQgene(rs12495941) gene was performed at Macrogen,utilizing their ABI 3730xl genetic analyzer (Applied Bio systems, US).

Statistical Analysis: The Statistical Analysis System-SAS (2014) program was utilized to impact of various factors in study parameters.. Least noteworthy contrast LSD test (ANOVA) was utilized to analyze between method between various factors in this study.

Result and Discussion

The levels of TNF-alpha , and IL-18 showed significantly change($p<0.05$) in Obese with PCOS and low weight with PCOS groups when comparing with control group. followed by no-significant change ($p>0.05$)when comparing between Obese without PCOS and low weight with PCOS groups ,also shows significant change($p<0.05$)when comparing between low weight with PCOS and control group.As seen in table (1).

Table (1): Levels ofTNF-alpha, IL-18 ,in PCOS women and healthy controls.

Parameters Groups	TNF-alpha (ng/ml) (mean±SD)	IL-18 (pg/ml) (mean±SD)
Group 1 (Obese with PCOS)	A 1.2040±0.5796	A 26.139±3.660
Group 2 (low weight with PCOS)	B 0.5674±0.0655	B 12.832±0.266
Group 3 (Obese without PCOS)	B 0.6426±0.0517	B 12.391±0.297
Group 4 Healthy control	C 0.3456±0.0852	C 3.040±0.377
LSD	0.209	3.275
P-value	0.0073	0.0069
Significant	Significant	Significant

*different letters mean significant difference

Adipose tissue discharges a cytokine called TNF-a which is a key component in mediating IR [10]. This cytokine not only stimulates IR but also causes HA and is present in follicular development. It therefore plays a part in the pat ho physiology of PCOS. Development of

IR in humans has been linked to hyper expression of the TNF-a in muscle and adipose tissues through decreasing tyrosine kinase activity in the insulin receptors. Our test results corroborated those of [11]. In their experiment they found that there were significant differences between PCOS patients in serum TNF-a and insulin. [12]found that TNF-a levels in PCOS patients were significantly higher than those in controlled studies. When [13,14] carried out tests they found that women with PCOS exhibited higher levels of IL18 than controlled groups. In both the aforementioned studies the level of IL18 correlated to the insulin sensitivity index. More recent tests have shown that there is no difference in IL18 between obese PCOS and the obese control group. This reveals that when obesity is controlled , the PCOS effect disappears completely [15] posits that in the future, studies should classify subjects according to BMI classes so as to better highlight the independent association among IL18 and PCOS[16].

One and a half µl of genomic DNA was used for each PCR reaction. A conventional PCR protocol was utilized to analyze simultaneously the presence of ADIPOQ gene(rs12495941).The presence of the ADIPO gene(rs12495941) was identified by 360bp, as shown in figure(1).

Figure (1): Amplified fragment of Adiponectingene ((RS:12495941)after electrophoresis on agarose gel (2%) for 1x TBE buffer for 1:30 hours. M: DNA ladder (100bp).

The repeat of nucleotide the amplified product of ADIPOQ gene (rs12495941) gene by direct sequencing. Our sequences were compared with the reference sequence from in national center biotechnology information(NCBI) Gene Bank.

After alignment of product amplification of ADIPO gene for patients group having three Transition one A>G and two G>A in Locations (15655, 15679,and 15685nucleotide)respectively , six Transversion T>G, C>A, and fourT>A in Locations (15429,15719, 15671, 15713, 15715, 15731nucleotide) under sequence ID: NG_021140.1, and have number score (685) bits, and expect (0.0). From the Gene Bank, found that part of ADIPOQ gene having 98% compatibility with standard in Gene Bank as shown in Figure(2) ,and table(2).

Table (2): Represent type of polymorphism of ADIPOQ gene.

Sequence ID	Nucleotide	Location	Type of substitution
ID: NG_021140.1	T>G	15429	Transvertion

Conclusions

Our study concluded in patients of Polycystic ovary syndrome is increased as compared to healthy controls as evidenced by increased (TNF-α, IL-18) in patients group. ADIPOQ gene having 98% compatibility from patients group while having 100% compatibility of the control group with a standard in Gene Bank

Abstract

Context: The purpose of this study was to find out the Effect of ladder training on selected physical and physiological variables among college men football players. In order achieve the purpose of the study the thirty players from G.T.N Arts College and S.B.M College of Engg in Dindigul were taken as subjects. The age groups of the subjects were between 17 to 25 years. Thirty men football players were selected and the subjects were divided into two groups consist of 15 subjects. G.T.N Arts College acted as experimental group (group I) S.B.M College of Enggs acted as Control group (group II). Each subject was oriented in the procedure to the administration of the test. The subjects were formed a random group design consisting of Ladder training given to experimental group and control group, of 15 each, the control group not given any kind of Ladder training. After the experimental period of six weeks in progression, post test scores were obtained from all the two groups. The differences between initial and final scores on physical variable considered as the effect of Ladder training on subjects. The mean differences were tested for significance using 'F'-ratio set at 0.05. The result of the study reveals that ladder training would positively improve the college men football player Physical variable significantly.

Keywords: *Ladder training, Speed, Football, Experimental group, Control group*

Introduction

Physical Education is one of the most ancient arts of the humanities. In its broadest interpretation physical education is defined as the art and science of voluntary purposeful and active human movement.[1] It is clear that physical education is concerned with a fundamental mode of human expression.[2] Physical education and training organized instruction in motor activities will contribute to the physical growth, health, and body image of the individual. The historical roots of physical education go back as far as the ancient Chinese. 2500B.C, who had a well-developed system of exercise and physical training.

Fitness: Fitness is the ability to live a full and balanced life. The totally fit person has a healthy and happy outlook on life. Fitness is the young man's absolute necessity.[3] It breeds self- reliance and keeps man mentally alert. Physical fitness is essential for human beings to adjust well with his environment as his mind and body are in complete harmony.

Physical Fitness: The term "Physical" refers to movement, whereas the prefix "bio" is added to illustrate the biological importance of these three abilities.[4] Physical Fitness is one's richest possession. It cannot be purchased. It has to be earned through a daily routine of physical exercises. It is self-evident that the fit citizens are a nation's best assets and weak ones its liabilities. Physical fitness is necessary for achieving success in sports without a high level of physical fitness and individual will not be able to withstand the stress and strain caused to the body by various games and sports. To achieve success in the international competitions and to attain high sports performance superior physical fitness is a must. Physical Fitness is the development and maintenance of strong physique and sound functioning of organs to the end.[5]

Sports Training: It must be understood on a wider sense since physical exercises undoubtedly are the principle means to improving performance. But the sports performance is improved by other means also which should be included in the concept of sports training. Such means, which are most commonly used along with physical exercise, are theoretical instructions, discussions, and tasks of observations, physiotherapeutic measures for recovery from fatigue, psycho regulative procedures and so on.[6]

Ladder Training: The agility ladder is a time tested and proven effective tool for improving our footwork.[7] The training effect is similar to jump rope, but with several advantages. First, agility ladder training is multi – directional. In most sports, we are not staying in one sport. We are moving forward, sideways and sometimes backwards, second, our feet are also allowed to move independently more complex patterns than jumprope allows. And third, the cycle time can be result is that you can train your feet to move quickly through complex footwork patterns. The benefits to any ground based sport are huge.

Statement of the Problem: The purpose of this study was to find out the Effect of ladder training on selected physical variable among college men football players.

Methodology: In order achieve the purpose of the study the thirty players from G.T.N Arts College and S.B.M College of Engg in Dindigul were taken as subjects. The age groups of the subjects were between 17 to 25 years. Thirty men football players were selected and the subjects were divided into two groups consist of 15 subjects. G.T.N Arts College acted as experimental group (group I), S.B.M College of Engg acted as Control group (group II). The subjects were formed a random group design consisting of Ladder training given to experimental group and control group, of 15 each, the control group not given any kind of Ladder training. After the experimental period of six weeks in progression, post test scores were obtained from all the two groups. The differences between initial and final scores on physical variable considered as the effect of Ladder training on subjects. The mean differences were tested for significance using 'F'-ratio.

Administration of Test: Speed(50 meters)

Purpose: The aim of this test is to determine acceleration and speed.

Equipment: Measuring tape, stop watch, Chunnam, score sheet, subject, whistle, 10m thread, timer, pen etc.

Procedure: Maximum 50 meters standard track in 6 or 8 line, Warm up, including some practice. Standing position (hands cannot touch the ground), with one foot in front of the other. The front foot must be behind the starting line. Once the subject is ready and motionless, the starter gives the instructions "set" then "go". The tester should provide hints for maximizing speed (such as keeping low, driving hard with the arms and legs) and the participant should be encouraged to not slow down before crossing the finish line.

Scoring: Two trials are allowed, and the best time is recorded to the nearest 2 decimal places.

The table 1 showed that the pre test mean values on speed of ladder training group and control group are 7.76 and 7.73 respectively. The obtained 'F' ratio 0.15 for pre test mean was less than the table value 4.20 for df 1 and 28 required for significance at 0.05 level of confidence on speed. The post□test mean values on speed of ladder training group and control group are 6.72 and 7.27 respectively. The obtained 'F' ratio 5.81 for post□test mean was greater than the table value 4.20 for df 1 and 28 required for significance at 0.05 level of confidence on speed. The adjusted post□test means of ladder training group and control group are 6.71 and 7.28 respectively. The obtained 'F' ratio 10.13 for adjusted post□test mean was greater than the table value 4.21 for df 1 and 27 required for significance at 0.05 level of confidence on speed.

The adjusted post mean values of ladder training group and control group on speed are graphically represented in the Figure 1.

Table 1: Analysis of Co-variance for the Pre, Post and Adjusted Post Test Mean Values for Ladder Training Group and Control Group on Speed

Test	Ladder Training Group	Control Group	Source of Variance	Sum of square	Df	Mean Square	'F' ratio	Table Value
Pre Test Mean	7.76	7.73	Between	0.009	1	0.009	0.15	4.20
			With in	17.525	28	0.626		
Post Test Mean	6.72	7.27	Between	2.296	1	2.296	5.81*	4.20
			With in	11.070	28	0.395		
Adjusted Post Test Mean	6.71	7.28	Between	2.447	1	2.447	10.13*	4.21
			With in	6.520	27	0.241		

*Significant at 0.05 level of confidence.

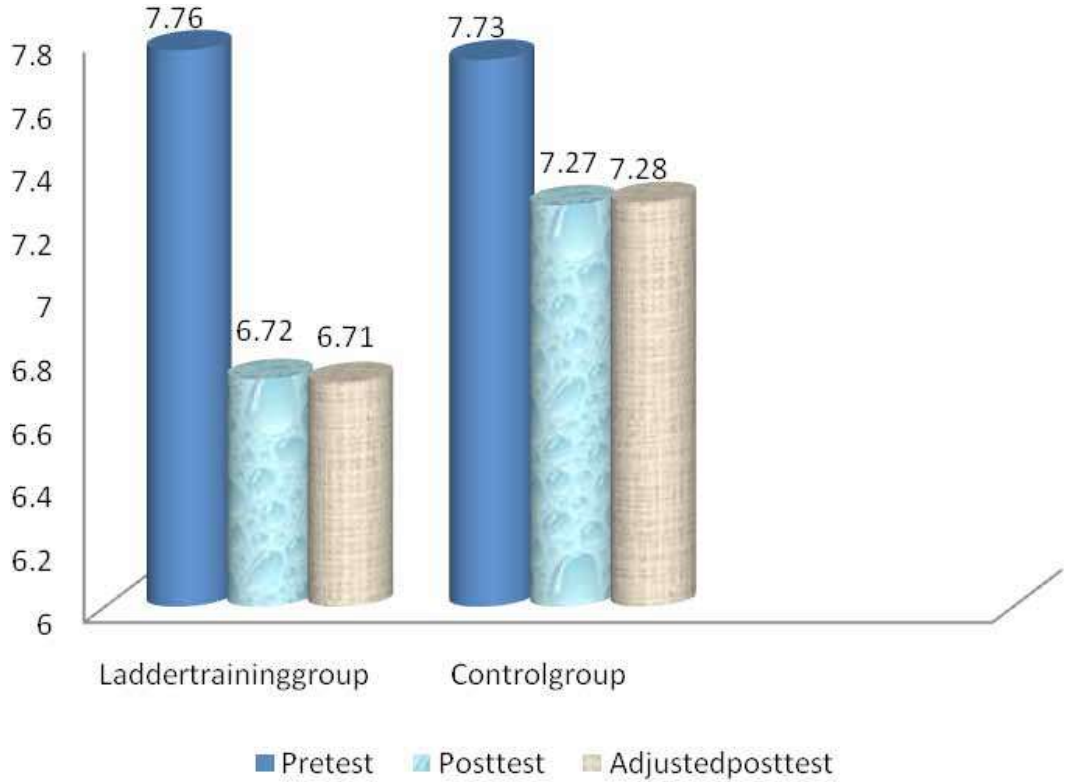

Figure 1: Bar Diagram Showing the Pre, Post and Adjusted Mean Values of Ladder Training Group and Control Group on Speed

Discussing on Findings: The goal of the investigation is to find whether there is any effect on those selected variables in the effect of Ladder training and further to find improvement on training group. The obtained 'F' ratio showed that there was significant difference between experimental groups and control group in performance of speed.

Discussion on Hypotheses: It was hypothesized that there would be a significant difference in selected physical variables on speed. The results of the study revealed that there is a significant difference in selected physical variables on speed due to effect of Ladder training. Hence the investigator hypothesis was accepted.

Conclusions

The result of the study reveals that ladder training would positively improve the college men football player Physical variable significantly.

C2 Lateral Mass Vertebrae Anthropometry for Evaluating C2 Straight Lateral Mass Screw Fixation

Sarrah Dwiananda Mayasafira[1], Joni Susanto[2], Eko Agus Subagio[3]

[1]Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia. [2]Department of Anatomy and Histology, Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia. [3]Department of Neurosurgery, General Hospital of dr. Soetomo, Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia

Abstract

Background: The cervical vertebra is an important vertebra as there are blood vessels in its surroundings from the brain to the entire vertebrae. Cervical injury has the most fatal consequences when it occurs as high as C1-C2. If instability occurs in the C1-C2 vertebrae and atlantoaxial joints, the procedure of surgical techniques include cervical arthrodesis or spinal fusion. C2 straight lateral mass fixation is one technique that can be used for fixation in patients with spinal cord compression and anomalous vertebral artery by inserting shorter screws in the lateral mass of the C2 vertebrae from the posterior direction. There have been not many references similar to the present study of anatomy to discover the screw characteristics needed in this technique.

Aim: This study aimed to identify the length of the lateral mass in the C2 vertebra for the purposes of the C2 straight lateral mass screw fixation technique.

Method: This research was an observational descriptive study with cross sectional design that observed the results of cervical CT-Scan. Observation was made using the RadiAnt DICOM Viewer application and measurements were based on a sagittal cross section. The length was measured from the posterior parallel to the posterior longitudinal ligament (PLL). The initial mean was measured on the right and left side; afterwards, the final mean is the total mean of both sides.

Result: From 10 samples, there were mean long lateral masses of C2 vertebrae on the right side of 13.511 ± 1.081 millimeters, the left side of 13.444 ± 1.396 millimeters, and the final mean of 13.48 ± 1,216 millimeters. It was rounded to an average of 13.5 ± 1.2 millimeters.

Discussion: The line parallel to the posterior longitudinal ligament (PLL) is more posterior than the line parallel to the foramen transversum wall which causes the measured length to be shorter. This is useful for the C2 straight lateral mass screw technique as it avoids the possibility of lesions in the vertebral artery.

Conclusion: The average lateral mass length in the population of Surabaya is 13.5 ± 1.2 millimeters.

Introduction

The cervical vertebrae consist of 7 bone spaces, namely C1-C7.[1] The cervical vertebra has a transverse foramen in each segment through which the vertebral artery passes.[2] The vertebral artery is tasked with vascularizing the brain; hence, cervical vertebrae injuries

and failure to identify can cause serious complications.[3] The most fatal consequences can occur in the upper cervical area, both in the crania cervical junction and in the C1-C2 vertebrae.[4] This is because the anatomical structure of the C1 and C2 vertebrae is unique and has a close relationship with the vertebral arteries.[5] Cases of C1-C2 injuries that have dislocations should be surgically removed.[6] The principles of cervical vertebrae surgery are stabilization and prevention of nerve decompression, optimizing the results of actions, and avoiding complications that may occur if non-surgical measures are performed.[7]

Cervical arthrodesis is a surgical treatment that unites one vertebra with another vertebra.[8] This technique can be performed on any cervical vertebra in accordance with the location of the injury. Fusion of vertebrae as high as C1-C2 is used for fusion due to instability in the C1-C2 vertebrae and atlantoaxial joint.[9, 10]

Because of their unique and biomechanical properties, most cervical vertebrae stabilization studies have focused on modification of fixation in C2 vertebrae.[11] Trans-articular fixation resulted in limitations on flexion and extension movements.[12] Meanwhile, the C2 pedicle technique by Harm further reduces the risk of lesions in the vertebral artery compared to the Magerl technique; however, it is still not possible to be used in patients who have anomalies in the vertebral artery.[13] The C2 laminar screw technique is used to avoid lesions in the vertebral artery[14], but this technique is not recommended for patients who require laminectomy to decompress the spinal cord.[15]

To explore the contraindications to the C1-C2 technique, a study in Japan stated that there were 238 (24.4%) cases accompanied by the incidence of compression of the cervical spinal cord[16] and another study asserted that of 200 patients, there were 66 patients with High-Riding Vertebral Artery (HRVA) and 90 patients with narrow pedicles after being detected using thinly-sliced pedicular-oriented CT (TPCT).[17] The high number of these two numbers makes it possible for both conditions to occur in an individual; consequently, other techniques are needed for patients with the mentioned condition.

C2 straight lateral mass fixation is one technique that can be used for fixation in patients with these two conditions. Fixation is performed by inserting shorter sized screws in the lateral mass of the C2 vertebrae from the posterior direction, as is the case in Korea which reduces the risk of bleeding in HRVA patients with C2 fixation by using shorter screws.[18] To date, there are not many references regarding this technique, therefore further studies on the anatomy of the C2 vertebrae are needed to support this fixation technique. Many modifications have been made to avoid complications. This is carried out by changing the entry point of the screw and the direction of screw installation.[19] These modifications can affect the required screw characteristics, such as length and diameter.

Method

This study aimed to measure anthropometric C2 lateral mass vertebrae from the lateral side for the C2 straight lateral mass screw fixation technique in order to determine the appropriate screw requirements and minimize complications that can occur. An observational analytic with cross-sectional approach was used.

Sample: The research samples were the results of the CT scan taken from the Mitra Keluarga Darmo Satelit Hospital, Surabaya in the period of August-November 2017. The sampling technique was conducted by using total sampling with the inclusion criteria of CT scan results as high as vertebrae C1-C7, while the exclusion criteria included CT Scan results with abnormalities of vertebral anatomy as high as C1-C7 and patients who are not domiciled in Surabaya.

Research Instrument and Data Analysis: The instrument used to measure the CT scan result was RadiAnt DICOM Viewer Application version 4.1.6. The length of the lateral mass of the C2 vertebra was measured at the point of 3 millimeters superior to the facet line, median lateral mass, and anterior-superior direction parallel to the facet until the posterior longitudinal ligament (PLL). The PLL boundary point was initially marked. Afterwards, the length was measured on the slice showing the lateral mass picture from the posterior to the marked point. The initial mean was calculated on the right and left sides; then, the final mean was obtained from both sides. The measurement results were then processed using Microsoft Excel 2016.

Result

The total CT scan results sampled in this study were 10. Observation of radiology results was carried out for 1 week to determine the mean lateral mass in each sample. Lateral mass is the mass located in both right and left

lateral of C2 vertebrae. The length of the C2 vertebrae lateral mass was measured from the sagittal cross section at the point of 3 millimeters superior to the facet line, median lateral mass, anterior-superior direction parallel to the facet to the PLL limit.

Referring to the observation results, it was obtained the mean lateral mass of C2 vertebrae from 10 samples of 13.511 ± 1.081 millimeters with a minimum value of 12.006 millimeters and a maximum value of 15.496 millimeters. Whereas, the mean lateral mass of the C2 vertebrae from 10 samples was 13.466 ± 1.396 millimeters with a minimum value of 11.343 millimeters and a maximum value of 15.630 millimeters (Table 1). The mean left and right lateral mass of the C2 vertebrae obtained a mean total of 13.448 ± 1.216 millimeters with a minimum value of 11.334 millimeters in both sides and a maximum value of 15.630 millimeters in both sides (Table 2).

Tables

Table 1: The Length of C2 Vertebrae Lateral Mass

No	The Length of Right Lateral Mass (mm)	The Length of Left Lateral Mass (mm)
1	12.443	11.343
2	14.618	15.213
3	14.412	13.765
4	12.982	13.863

Discussion

C1-C2 Trans-articular Screw Fixation is the technique that produces the most rigid outcome.[12] The entry point of this technique is at 2-3 millimeters superior-lateral from the facet to the axial isthmus in medial;[12] then, it is forwarded to the C1 lateral mass. C1-C2 joints are very functional in rotational movements and with a little flexion-extension. Hence, the fixation in this area will cause limitations on flexion-extension movements, lateral swelling, and rotational movements. The screw mounting direction of this technique reduces freedom of movement in all directions so as to achieve a state of high stability. This technique can also prevent slippage between segments.[20] This technique is also an indication for C1-C2 instability due to rheumatoid arthritis, odontoid process fracture, os odontoideum, C1-C2 arthrosis.[12] This technique is contraindicated for the condition of vertebral artery anomalies in segments as high as C1-C2, axial isthmus that is too small, deformities in segments as high as C1-C2, prominent kyphosis in the cervical-thoracic junction, and destruction of the atlas bone lateral mass.

C2 Pedicle Screw Fixation connects the vertebral body with the posterior component of the atlas bone. The screw is mounted obliquely from the pediculus to the vertebral body.[15] The advantage of this technique is that it can protect joints between C1-C2. In addition, it is possible to remove the screw after stability returns to restore movement to C1-C2. Compared with the trans-articular technique, this technique further reduces the risk of injury to the vertebral arteries.[13] The technique is indicated for C1-C2 instability caused by trauma, tumors, and inflammation, for non-fusion odontoid process fractures, unstable Jefferson fractures, and repair

in failed odontoid screw fixation.[13] Contraindications are if there are anatomic variations in the vertebral artery.[13]

The entry point of the screw in the C2 Laminar Screw Fixation technique is between the spinous and lamina process, and is directed across the direction of the lamina on the contralateral side.[21] This technique is intended for 20% of patients who have anatomic anomalies that are contraindicated in trans-articular screw or pedicular screw techniques, because there is a risk of vertebral artery injury.[22] If there is a condition that requires decompression of the spinal cord, laminectomy of the axis bone is needed and this technique cannot be performed.[15]

C2 Pars Screw Fixation has the same entry point and direction as the trans-articular technique. The difference with the trans-articular technique is the depth of screw fixation that does not go through the atlas bone.[15]

Based on the results of the study, there have been no similar results from other references to the present study. However, a study with a similar concept was conducted in Los Angeles regarding the lateral mass of the C2 vertebra that used the same entry point and direction as this study and produced an average of 17.0 millimeters on both sides.[23] A case study conducted in Egypt on the evaluation of the efficacy and safety of C2 pars/pedicle screws also has a different number from this study, which used a screw with a size of 16 millimeters for the C2 vertebrae.[24]

The difference in results among studies can be caused by several factors. A factor that may be influential is the anterior border of the measurement. Measurements performed in research in Los Angeles was started from the posterior to the point before the transverse foramen wall,[23] which is different from this study which has a limit to the point parallel to the PLL.Observation results show that the line parallel to the PLL is more posterior than the line parallel to the transverse foramen wall. This causes the length measured in this study is shorter. This is useful for the C2 straight lateral mass screw technique because it avoids the possibility of lesions in the vertebral artery (Picture 1).

Another factor that might influence differences in results is morphological variation in each different population. A previous study conducted in India has shown that the average antero-posterior length of the right and left C2 vertebrae superior facets were 16.61 ± 1.33 millimeters and 16.70 ± 1.49 millimeters respectively.[5] This result is different from a similar study conducted in Turkey with an average of 17.5 ± 14 on the right side and 17.5 ± 1.5 on the left side.[25] Specific references regarding differences in the lateral mass length of the C2 vertebrae were not found. However, the differences in the results of the two studies above may allow for differences in the lateral mass.

Limitation: There are several limitations in this study. A factor from the author that might be influential is the lack of accuracy in the measurement process. The small number of samples is also a disadvantage in this study. Retrieval of data in only one hospital is presumed to be insufficient to describe the lateral mass length of the entire population in Surabaya.

Conclusion

The mean of C2 vertebrae lateral mass length is 13.5 ± 1.2 millimeters.

Conflic of Interest: The authors declare that they have no competing interests.

Source of Funding: The authors declare that this study was not self-funded.

Ethical Clearance: This study received a certificate of ethical clearance from ethical commission of Faculty of Medicine, Universitas Airlangga Indonesia.

Preferred Learning Method of Undergraduate Medical Students

Saurabh Shrama[1] ,Sartaj Ahmad[2], Bhawana Pant[3], Deepak Kumar[4], Kaynat Nasser[5]

[1]Associate Professor, Deptt of Community Medicine, [2]Associate Professor, Medical Sociology, Swami Vivekananda Subharti University, Meerut (U.P.), [3]Professor, Deptt of Community Medicine, [4]Assistant Professor, Deptt of Community Medicine, [5]Assistant Professor (Biostatistics), Dept of Community, Medicine, Subharti Medical College

Abstract

Background: Learning style is the way students begin to focus, internalize and remember new and difficult information. Identifying the learning styles of medical students will enable the faculty to use appropriate Teaching and Learning method to increase the grasping ability of students. Purpose of the study was to assess the preferred learning styles of medical students by using VARK questionnaire .

Method: This was a cross-sectional study based on the VARK (Visual, Auditory, Read & write and Kinesthetic)questionnaire done among 414 medical students of Subharti Medical College Meerut UP. The VARK questionnaire was administered to 1st year 86(20.7%), 2nd year 91 (22%), 3rd year 116 (28%), and final year 121 (29.3%) students. The students were categorized as visual learner, auditory, read/write or kinesthetic, depending on the predominant option they chose.

Results: Of the total 414 medical students participated in the study. 24.1%,25.8%,14.2% and 5.70% were unimodal, bimodal, trimodal and quarimodal modality as their preferred modality of learning. Among the unimodallearners the percentages of students who preferred visual(20%), auditory (35%), reading/writing (12%), kinesthetic (33%). AV(29.9%) followed by AK(26.1%) were most preferred bimodal modalities of learning. AVK(44.1%) was most preferred trimodal modality of learning. There was no significant difference among different year of medical students for preferredunimodal modalities of learning (p=0.55), different bimodal modalities of learning (p=0.9) and different trimodal modalities of learning.

Conclusions: Audio visuals which includes short movies, video clips and animated versions are most preferred modalities for exciting and interesting learning. Kinesthetic learning which includes ECE (early clinical exposures) role plays, case presentation, simulations etc works more on affective and psychomotor component of learning and gives a better understanding, adds meaningfulness to the topic and renders a long lasting memory. A teaching session which includes all the modalities makes a strong, positive and permanent impression on a students mind about the subject.

Introduction

Medical education is a continuous process which requires both students and instructors to update themselves regularly. There are several challenges medical education is facing, one of which is imparting a large amount of knowledge within a limited time period in a manner it is effectively retained, interpreted and remembered by a student. This has resulted in important changes in the field of medical education, with a shift

from conventional teaching to the use of problem-based, student-centered and interactive learning. Most medical curricula have implemented creative method of teaching and learning to changeable degrees. [1].Students in a medical college belong to different socioeconomic and cultural backgrounds, have varied prior educational experiences, different levels of competencies, and perhaps even different preferential method of learning. Teaching is a process of presentation of knowledge while learning is many times multi-factorial and depends on the mind-set of each individual student. Students have different preferences when it comes to the assimilation and processing of the information. [2]Learning habit of a learner means how he processes information and it varies with each individual. Learning results in gain of knowledge and skills. If the method of information delivery to the learner suits their particular learning habit,they learn even better. . [3]

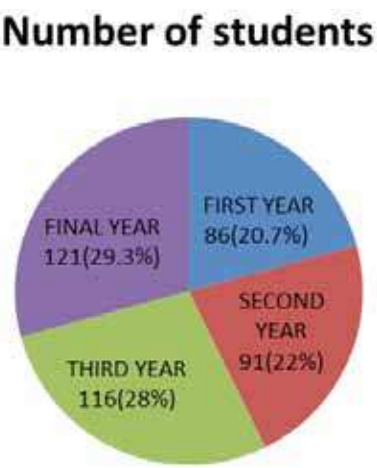
Three learning habits have been identified according to the VARK model as visual, auditory and kinesthetic. Another learning habits added to this, the Read- write habit (VARK model) and this was developed by Fleming and Bonwell. Fleming's learning habit inventory is the most commonly used model of learning which is also known as VARK questionnaire.[4]The VARK is a tool that categorizes learning habit according to Visual, Auditory, Read/write or kinesthetic modes as indicated on a simple preference survey.[5] The VARK questionnaire is a 13-item, self-reported, multiple-choice questionnaire that can be completed within a time span of 10–15 minutes. The VARK questionnaire was selected for the assessment of learning habits in our study because it is a concise, simple survey Questionnaire, and was pre-validated by the peer group.[6]

Material and Method

This was a cross-sectional study based on the VARK questionnaire among the medical students of Subharti Medical College, Meerut ,UP. The study was done after obtaining the permission from the institutional ethics committee. All the volunteer students from first to final year MBBS participated in the study after written informed consent. The VARK learning styles assessment questionnaire was administered .Students were given a time of 15 minutes to fill the questionnaire. The students were categorized as visual learner ,auditory, read/write, kinesthetic depending on the predominant option they chose. If they opted a single sensory preference they were considered as unimodal, two as bimodal, three as trimodal and all four s quadrimodal. Their learning styles were analyzed by using frequency and proportions. Chi square test was used. A 'p' value of <0.05 was considered as statistically significant. The aim of this study was to describe learning styles of medical students in Subharti Medical College, Meerut UP.

Results

Figure 1. Showing distribution of students according to year of MBBS



Distribution of the total 414 students participated in the study according to year of MBBS is given in figure 1. More students were from third and final year as compared to first and second year because in last two years intake of students was less in college.

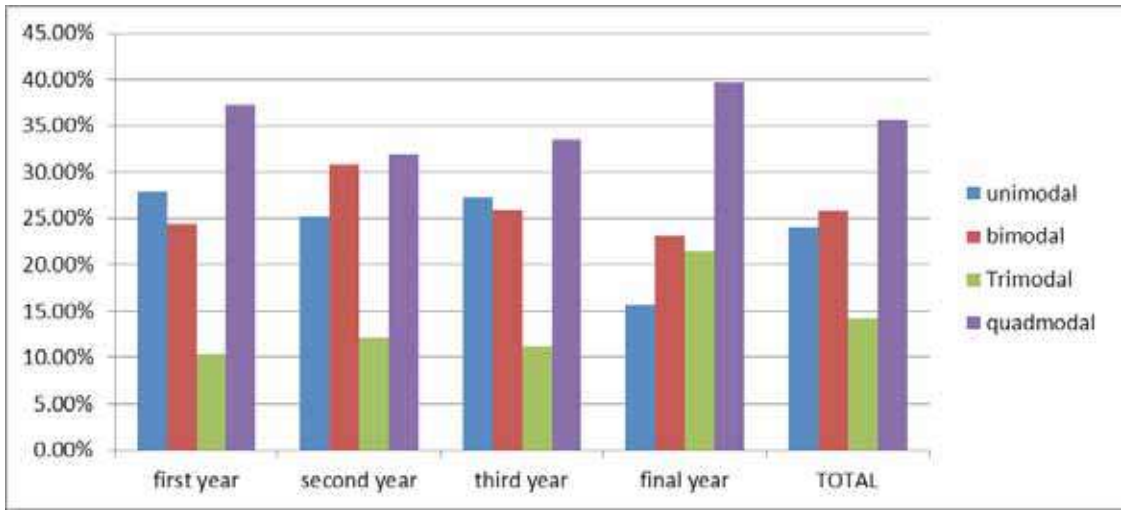


Figure 2. Graph showing the distribution of students according to preferred modality of learning.

Distribution of preferred modality of learning and year of MBBS is in figure 2. Quadrimodal modality was most preferred among all the years. There was no significant difference among different year of medical students for modality of learning (p=0.11)

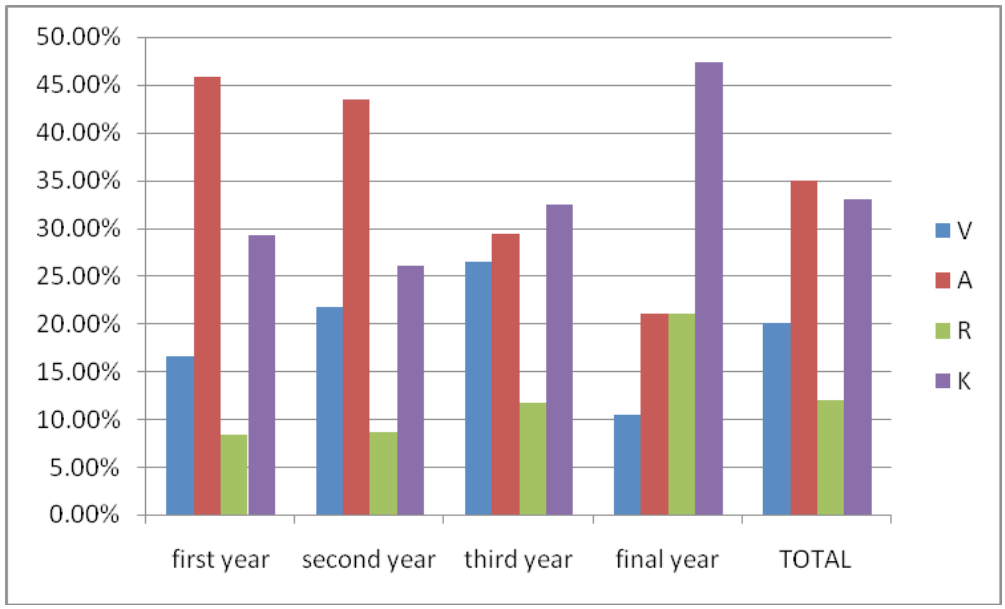

Figure 3: Graph showing distribution of students according to preferred UNIMODAL modality of learning

Among the unimodallearners the percentages of students who preferred visual (20%), auditory (35%), reading/ writing (12%), kinesthetic (33%)shown in figure 3. Auditory was most preferred in first and second year while kinesthetic was more chosen in third and final year.

Table 1: Table showing distribution of students according to preferred BIMODAL modality of learning.

	AV	VR	VK	AR	AK	RK
First Year	23.80%	9.50%	19.00%	14.30%	23.80%	9.50%
Second Year	32.10%	10.70%	21.40%	3.60%	25.00%	7.10%
Third Year	33.30%	6.60%	20%	3.30%	26.60%	10.70%
Final Year	28.60%	7.10%	7.10%	17.90%	26.70%	10.7%
Total	29.90%	8.40%	16.80%	9.30%	26.10%	9.30%

The distribution of learning preferences among bimodal modality of learning is shown in table 1.AV followed by AK comes out to be most favorite among all the years.

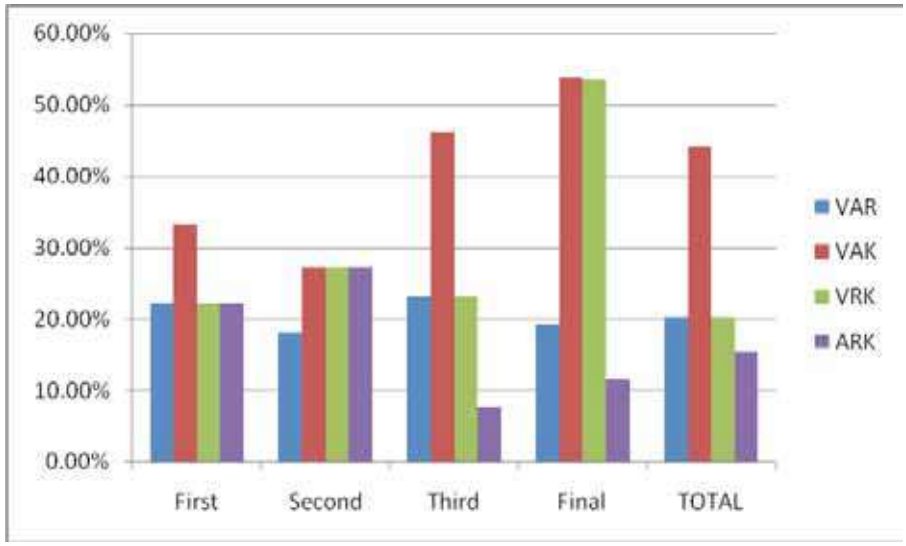

Figure 4: Graph showing distribution of students according to preferred TRIMODAL modality of learning.

The distribution of learning preferences among trimodal modality of learning is shown in figure 5. VAK is most preferred among all the student across different year of MBBS.

There was no significant difference among different year of medical students among different modalities of learning (p=0.11),different unimodal modalities of learning (p=0.55),different bimodal modalities of learning (p=0.9).

Discussion

VARK questionnaire was used in our study to assess the preferred modality of learning among undergraduate medical students. Awareness about the learning styles helps the faculty in identifying and solving the learning problems and also helps reduce the frustration levels of students. Current situation demands the transition from the passive traditional didactic lectures to problem-based learning and to achieve this, the faculty needs to apply multiple teaching method which suit the different learning preferences for a better outcome. Method which promote thinking and improve problem solving as well as decision-making abilities should be used. Students learn in different ways using variety of method to convert the information into long term memories.

In our study, the VARK questionnaire was administered to 1st year 86(20.7%), 2nd year 91 (22%), 3rd year 116 (28%), and final year 121 (29.3%) students. The students were categorized as visual learner, auditory, read/write or kinesthetic, depending on the predominant option they chose. Of the total 414 students participated in the study the distribution according to year of MBBS is given in figure 1. Distribution of preferred modality of learning and year of MBBS is in figure 2.there was no significant difference among different year of medical students for modality of learning (p=0.11). Among the unimodal learners the percentages of students who preferred visual (20%), auditory (35%), reading/writing (12%), kinesthetic (33%) shown in figure 3. The distribution of learning preferences among bimodal modality of learning is shown in figure 4. The distribution of learning preferences among trimodal modality of learning is shown in figure 5. There was no significant difference among different year of medical students among different modalities of learning (p=0.11),different unimodal modalities of learning (p=0.55),different bimodal modalities of learning (p=0.9) and different trimodal modalities of learning (p=???). if we compare first and second year students with third and final year students we found there was an increase in preference for kinesthetic modality of learning as medical student reaches third and final year it may be because of introduction of more clinical or patient based activities in last two years.

In a study done by Navin R et al (2013), 55% of

the medical students preferred using a single sensory modality while learning i.e., they had unimodal learning preferences, while the rest 45% preferred using two or more sensory modalities i.e., they were multimodal.[7] A study conducted by Chinmay S, et al. (2013) in Bhavnagar Medical College revealed that among 1st year MBBS students, the highest preference was given to Aural followed by Kinesthetic, Read/Write and Visual.[8] In a study done by Usha GS et al (2013) suggested that final MBBS students the most preferred mode was visual.[9]

Visual learners process information best through agents like graphs, flow charts and pictures. Aural learners process and internalize information by listening to lectures, attending tutorials etc. The Read/write learners are the students who like to take notes verbatim and reread these repeatedly. Finally, the kinesthetic learners like to acquire information through experience and practice. They prefer to learn information that has some connection to the reality.[10] In the present day scenario, majority of the medical students have preference for several learning habits, and yet medical faculties teach predominantly in a single mode i.e. the lecture. Listening to lectures is basically a passive learning method that encourages mere memorization and note-taking as the means of assimilating knowledge.[11]

In our study for bimodal modality of learning AV(29.9%) followed by AK(26.10%) were most preferred among all the years. Videoclips,short movies and animated movies creates interest in subject and explains the topic in comprehensive manner. While kinesthetic modality which includes case presentations, role plays adds to affective and psychomotor component of learning and if its mixed with AV modality the combination may makes a strong, positive and permanent impression on a student's mind about the subject.

Many of the studies have shown that the teaching method that caters to multiple modalities of learning styles, enhances performance by the students. Some of the strategies that can be included for the benefit of students in academics are Objective Structured Clinical/ Practical Examination (OSCE/OSPE), integrated teaching, e-learning, early clinical exposure to patients in OPDs and wards, increasing use of models, lending the hand-outs of power point presentations, audio recording of lectures, and computer assisted learning. Discussion in class, cooperative learning exercises, role-plays, simulations, debates, and games are active learning strategies that can be used which promotes enthusiasm and motivation. It involves thinking through reasoning and improves problem solving and decision making skills which can be improved from the beginning of the course itself. Teaching method should include combinations of audio visual aids to help them shift from unimodal to multimodal learning style. Hence it is thought that discussion in class role play and debates can be introduced to the students as they enter the course to make them multimodal learners.

Conclusion

Multimodal way of teaching and learning is most preferred among all the students across different stages of their medical education. Students prefer more of a method which includes their active participation in the subject and hence creates curiosity about the topic. Audio visuals which includes short movies, video clips and animated versions

are most preferred modalities for exciting and interesting learning. Kinesthetic learning which includes ECE (early clinical exposures) role plays, case presentation, simulations etc works more on affective and psychomotor component of learning and gives a better understanding, adds meaningfulness to the topic and renders a long lasting memory. A teaching session which includes all the modalities makes a strong, positive and permanent impression on a student's mind about the subject. This will make the educational experience more fruitful and productive.

Effect of Smoking & Alcohol on Hypertension in Various Professionals a: Cross Sectional Study

Shailesh Gupta[1], Shruti Gupta[2]

[1]Senior Resident BPS GMC(W) Department of Community Medicine Sonepat Haryana India , [2]Research Fellow Centre of IVF & Reproduction SGRH Delhi India

Abstract

Objective: To study the effect of smoking & alcohol on hypertension in various professionals.

Method: A cross sectional study was done from 1st August 2015 to 30th August 2017 in district Bareilly. A Predesigned & Pretested questionnaire was used comprising of demographic data, alcohol & tobacco use. Three types of professionals were included in this study: Doctors, Managerial staff, School teachers from the teaching institutions.

Results: The Smoking history among professional groups found that majority of doctors (67.70%) were smokers followed by managerial staff (60%) and school teachers (30%) &p-value (<0.001) was found statistically significant.Alcohol consumption history among professional groups found that majority (60%) doctors were alcoholic followed by (43.08%) managerial staff and (30%) school teachers and p-value (<0.001) was found statistically significant.

Conclusion: In this study among professional groups the association of hypertension with alcohol and smoking was found highly significant.The odds of developing high blood pressure and its adverse consequences in professional groups can be minimized by promoting a healthy lifestyle.

Keywords: *Hypertension, Professional, Bloodpressure*

Introduction

Hypertension also known as high or raised blood pressure is a global public health issue. It is a major risk factor for stroke and coronary heart diseases and is a major contributor to the onset and progression of chronic heart failure and chronic kidney failure.[1] The global prevalence of raised blood pressure defined as systolic and/or diastolic blood pressure ≥140/90 mmHg in adults aged 18 years and over was around 22% in 2014. The number of hypertensive individuals is anticipated to n early double from 118 million in 2000 to 213 million by 2025.[2]

In India, hypertension is the leading non communicable disease risk and estimated to be attributable for nearly 10 per cent of all deaths.Even the majority of those who are diagnosed do not get treated to control the blood pressure. Smoking is a strong independent risk factor for cardiovascular diseases. Smoking causes an immediate increase in blood pressure and heart rate that persists for more than 15 minutes after one cigarette. People who smoke show higher ambulatory blood pressure levels than non-smokers.

Some studies have shown that the use of oral snuff or smokeless tobacco may predispose a person to higher systolic and diastolic blood pressures and significantly increase the risk for myocardial infarction.[3]

Epidemiological data shows a linear relationship between alcohol consumption and hypertension prevalence. Reducing alcohol consumption can lower systolic blood pressure by an average of 3.8 mmHg in patients with hypert ension.[4] Hypertension is more common amongst people from upper social class because of the presence of multiple factors such as sedentary jobs, lack of physical activity, rich diet, alcohol intake, smoking, and tobacco use. Boden-Albala and Sacco reported a study & found that especially current smoking was found to be a crucial and extremely modifiable independent determinant of stroke.[5]McNagnyet al conducted a study to find the association of cigarette smoking and Hypertension in African Americans significantly which were more likely to be current smokers and less compliant with medication when compared with controlled hypertensive [6]Zilkenet al study showed the relationship between alcohol consumption and blood pressure (BP) in healthy normotensive men with daily consumption of red wine, dealcoholized red wine or beer. The only way to curb the problem of hypertension is by its prevention.

Keeping this in view the present study was done to find out the effect of smoking & alcohol and its impact on hypertension among three professional groups, doctors, school teachers and managerial staff of Bareilly, Uttar Pradesh.

Objective: To study the effect of smoking & alcohol on hypertension in various professionals.

Material and Method

Study Design: This cross sectional study was done in three professional groups; doctors,school teachers and managerial staffsfrom 1st August 2015 to 30th August 2017. **Study Tool:** A Predesigned & Pretested questionnaire comprising of alcohol use & tobacco use was prepared in English language after reviewing the available literature. **Study Area:** The cross sectional study was done in district Bareilly, Uttar Pradesh. **Study Population**: The study was done in three professional groups i.e. doctors, school teachers and managers working on regular basis in the institutions. **Sampling technique:** The study subjects were selected randomly from three professional groups**.**

Inclusion Criteria: All individual willing to participate from each profession, have been included in the study.

Exclusion Criteria: Subjects with co-morbid conditions were not included in the study. Subjects not willing to participate were also excluded.

Sample Size Estimation: According to a study conducted by Ramachandran et al[7] on young physicians in India, the Using prevalence of hypertension 35.6%. Absolute error was taken as 5% and the required sample size was 352. The Sample size is rounded to 390. The study includes 3 professional groups i.e. doctors,school teachers and managerial staff. Therefore the total sample size is divided into 3 parts and 130 sampling units are assigned to each professional group.

- **Current Smoker:** An adult who has smoked 100 cigarettes in his/her lifetime and who currently smokes cigarettes.[8]
- **Alcoholic:** An adult who were consuming alcohol regularly at the time of interview.

Result

The Smoking history among professional groups found that majority of doctors (67.70%) were smokers followed by managerial staff (60%) and school teachers (30%). Whereas majority of school teachers (70%) were non smokers followed by managerial staff (40%) and doctors (32.30%) and p-value (<0.001) was found statistically significant.

Alcohol consumption history among professional groups found that majority (60%) doctors were alcoholic followed by (43.08%) managerial staff and (30%) school teachers and p-value (<0.001) was found statistically significant.

Hypertension among professionals with smoking habit found that 68.46% doctors, 69.23% school teachers and 74.62% managerial staff were hypertensive with smoking habit. Whereas 17.69% doctors, followed by 14.62% school teachers and 8.46% managerial staff was hypertensive with non smoking habit. A p–value <0.001 was found to be statistically significant among all professionals.

Hypertension with alcohol habit among professional groups found that 56.92% doctors, 26.16% school teachers and 31.54% managerial staff was hypertensive with alcoholic habit. Among all study subjects 38.21% were hypertensive with alcoholic habit. 60% school teachers, 51.54% managerial staff and 29.22% doctors were found hypertensive who was non alcoholic. Among all study subjects 46.92% were hypertensive with non

alcoholic habit. The association between professional groups with habit of alcohol was found significant by χ^2 test and p–value came out to be 0.000 for doctors and 0.009 for managerial staff, while insignificant for school teachers with p-value 0.825. The association among all study subjects and alcohol was found insignificant with p-value 0.621.

Table 1: Association of hypertension with smoking habit among various professional groups

Smoking habit	Doctors (130)		School teachers (130)		Managerial staff (130)		Total	
	HTN N (%)	Non HTN N (%)	HTN N (%)	Non HTN N (%)	HTN N (%)	Non HTN N (%)	HTN N (%)	Non HTN N (%)
Smoker	89 (68.46)	5 (3.85)	90 (69.23)	7 (5.38)	97 (74.62)	5 (3.85)	276 (70.77)	17 (4.36)
Non smoker	23 (17.69)	13 (10)	19 (14.62)	14 (10.77)	11 (8.46)	17 (13.07)	53 (13.59)	44 (11.28)
Total	112 (86.15)	18 (13.85)	109 (83.85)	21 (16.15)	108 (83.08)	22 (16.92)	329 (84.36)	61 (15.64)
p-value	0.001		0.001		0.001		0.001	
$\chi 2$	20.690		22.535		48.676		86.430	

Table 2. Association of hypertension with alcohol habit among various professional groups

Alcohol habit	Doctors		School teachers		Managerial staff		Total	
	HTN N (%)	Non HTN N (%)	HTN N (%)	Non HTN N (%)	HTN N (%)	Non HTN N (%)	HTN N (%)	Non HTN N (%)
Alcoholic	74 (56.92)	4 (3.08)	34 (26.16)	5(3.84)	41 (31.54)	15 (11.54)	149 (38.21)	24 (6.15)
Non alcoholic	38 (29.23)	14 (10.77)	78 (60)	13 (10)	67 (51.54)	7 (5.38)	183 (46.92)	34 (8.72)
Total	112 (86.16)	18 (13.84)	112 (86.16)	18 (13.84)	108 (83.08)	22 (16.92)	332 (85.13)	58 (14.87)
p-value	0.001		0.825		0.009		0.621	
$\chi 2$	12.424		0.049		6.807		0.245	

Discussion

The present study showed association of hypertension with alcohol habit among professional groups and found that 56.92% doctors, 26.16% school teachers and 31.54% managerial staff were hypertensive with alcoholic habit. Among all study subjects 38.21% were hypertensive with alcoholic habit. Whereas 29.23 doctors followed by 60% school teachers and 51.54% managerial staff were hypertensive with non alcoholic habit. Among all study subjects 46.92% were hypertensive with non alcoholic habit. A highly statistical significant difference was found by applying by chi square test and p–value came out to be 0.000 in doctors, 0.825 in school teachers and 0.009 for managerial staff. Among all study subjects a significance was found with p-value 0.621 which is similar to the findings of study reported by Zilkenet al [9]relationship between alcohol consumption and blood pressure (BP) in healthy normotensive men with daily consumption of red wine, dealcoholized red wine or beer. The results of the study showed that both red wine and beer significantly (P<0.05) increased systolic BP i.e. 2.9 and 1.9 mm Hg.

In this present study association of hypertension among professionals with smoking habit found that 68.46% doctors, 69.23% school teachers and 74.62% managerial staff were hypertensive with smoking habit. Whereas 17.69% doctors, followed by 14.62% school teachers and 8.46% managerial staff was hypertensive with non smoking habit. A chi-square test for significance was applied and p–value <0.001 was found that is highly significant among all professionals which is similar to the findings of McNagny et al [6]studied

the association of cigarette smoking and hypertension in African Americans (221 subjects). 86 patients had uncontrolled HTN (mean BP=192/106 mm Hg) and were significantly more likely to be current smokers and less compliant with medication when compared with controlled hypertensive. BodenAlbala and Sacco (2000)[5]study reported that smoking has been associated with increasing risk of hypertension, diabetes, hyperlipidemia and cardiac diseases.

Conclusion: In this study among professional groups the association of hypertension with alcohol and smoking was found highly significant. The odds of developing high blood pressure and its adverse consequences in professional groups can be minimized by promoting a healthy lifestyle with emphasis on nutrition aspects, reduced salt intake to less than 5 g of salt per day, avoiding excessive use of alcohol & Stopping tobacco use and exposure to tobacco products. It is recommended to follow medical advice and prescribed medications for lowering blood pressure.

Credibility of Health Care Advertising: An Empirical Understanding of its Multi-dimensional Structure and Scale Validation with Special Reference to Children's Health Food Drinks

Indu Manish Kumar[1]

[1]*Asst Professor, Department of Commerce and Management, Amrita School of Arts and Sciences, Amrita Vishwa Vidyapeetham, Kochi, Kerala, India.*

Abstract

Context: Advertising techniques need to be transformed based on the observations of the perceptions of consumers since they can be the directional force to any advertising aimed at those groups. The study fruitfully provides an empirical understanding about the multiple components of advertising credibility of consumer healthcare products. One of the major tasks undertaken in this research was to develop a scale which is statistically reliable and valid to measure advertising credibility in the current marketing environment of Kerala with special reference to children's health drinks.

Keywords: *Advertising credibility, corporate credibility, endorser credibility, message content credibility, consumer health care, health food drinks.*

Introduction

The tough competition in the market and large volume of advertisements make the consumers confused regarding purchase decision making. There is a tendency in the minds of consumers to distrust advertising and to doubt about the genuineness of producers and products. Sometimes they feel exploited by the advertisers. This often results in the failure of advertisements and loss of money. The opportunity for consumers to raise voice and file complaints against non-credible/ misleading advertisements again increases the risk of facing legal actions. According to Rodgers and Moore[1], advertisements that lack credibility, are often ignored or avoided by consumers. Hence knowledge about the perceived credibility of advertisements and consumer psychology may help the advertisers and marketers to avoid mistakes and adopt the right advertisement tactics. In fact, from a careful review of past-related works the researcher could observe that still gaps existed in areas of existing knowledge related to advertising credibility in terms of variables, dimensions, scales,sample, context etc. The previous studies conducted in this area approached advertising credibility with limited dimensions and items. Therefore, this paper attempts to develop a valid scale to measure Advertising Credibility. Children's Health Food Drinks segment is opted to study the dimensions and structure of perceived advertising credibility.

Credibility of Advertising: Credibility has been identified as one of the most important characteristics of a persuasive message which frequently affect the result of persuasive messages[1,2]. Advertising credibility can be defined as "the extent to which the consumer perceives claims made about the brand in the ad, to be truthful and believable''[3,4]. Rodgers and Moore[1] argue that the advertisements those lack credibility are generally ignored or avoided by consumers. According to Lafferty

and Goldsmith[5], irrespective of media type, advertising credibility is a crucial inspiration for creation of attitude and subsequent behaviors.

Dimensions of Advertising Credibility: Perceived credibility of an advertisement is influenced by numerous factors, especially by the firm's credibility, the credibility of the person who brings a message[6] and the credibility of the information content[7]. As per the literature advertising credibility has three components:

Advertiser / Corporate Credibility: Corporate credibility is defined as "the extent to which consumers believe that a firm can design and deliver products and services that satisfy customer needs and wants"[8], and has been found to have direct, positive impacts on attitude toward the ad, attitude toward the brand, and purchase intention[2,6,9].

Endorser Credibility: An endorser is an individual,recognized by the public and uses this recognition on behalf of a consumer good, by appearing with it in an advertisement [10]. Endorser credibility in this research indicates a term used to specify a communicator's positive characteristics and trustworthiness that affect the receiver's acceptance of a message[6,11]. Endorser credibility is further be classified into three: -'Expertise','Trustworthiness' and 'Attractiveness'[6, 9,11].

Message Content Credibility: Quality of message or argument is another important determinant of ad credibility. In a study Austin and Dong[12] tried to determine if the sender along with the message would have anyimpact on the total credibility of the information. They concluded that the perceived credibility of the information is more influenced by the message than by the sender.

Objectives of the Study:

1. To understand the structure of perceived advertising credibility
2. To develop and validate a multi-dimensional scale for measuring perceived advertising credibility

Research Methodology: Exploratory and descriptive research design and survey approach have been used for the study. A preliminary study was conducted to understand the dimension structure of advertising credibility which comprised a focus group interview and pilot study. The sample for the focus group interview consisted of 50 mothers of children between 5-15 years old, and who are the consumers of CHFD and who watch TV commercials and 6 experts from advertising industry and 4 experts from marketing research. The in-depth interviews with 50 respondents were conducted and the as the second stage a pilot study was conducted by collecting responses from 50 respondents from Kochi, a South Indian City, and ensured the reliability of the instruments used for data collection.

The children's health food drinks (CHFD) industry is selected for studying the credibility of advertising communication. The CHFD brands selected for the study are Horlicks, Bournivita, Complan and Boost. The sample for the study was taken from the six corporations of Kerala state namely Kozhikode, Trichur, Kochi, Kollam, Kannur and Thiruvananthapuram. The mothers of children between 5-15 years were surveyed. For the selection of the wards (divisions) under study and for the selection of the sample respondents from the wards, multistage random sampling is used. The 2011 census document and 2015 voters list of the corporation were taken as sampling frame. The research instruments included structured questionnaires, advertisement story board and recorded TV commercials. The mothers were informed to respond to the questions related to the advertisements of their most preferred children's health drink brand. A total of 1252 responses were used for data analysis.

Measurement Tool Development: The results of focus interview and literature review gave insights in to the dimensions that should be highlighted in the study. After identifying the three relevant dimensions of ad credibility (corporate credibility, endorser credibility and message-content credibility) through focus interview, the items from validated scales used in the previous research were taken to construct the scale for advertising credibility. To measure corporate credibility 7 item scale is used based on the scale developed and validated by Newell and Goldsmith [13]. The endorser credibility measurement (13 items) was based on the scales of Ohanion, R.[11] and Goldsmith, etal. [6]. The message/content credibility scale is developed based on the measures of Kemp, Deena G.[14], McKenzie and Lutz[4] and Wang [15] and focus group study.

Data Analysis and Discussion: The verification and cleaning of the collected data was done initially. Verification of Missing Values was done using

frequency test, Outliers using Z-scores, Normality and Randomness using Kolomogorov-Smirnov test with Lillefors significance correction. Skewness and kurtosis are used to ensure non-normality doesn't exist to a problematic level. Durbin- Watson statistics was found 2.046 thus established independent observations and "Runs" test was used to confirm randomness. Content validity is ensured through extensive literature review which helped also in the development of the constructs [16]. In this research a pilot study is conducted to ensure that the content validity concept is not violated. Criterion-related validity is ensured by using a common scale (five-point Likert scale) for measurement throughout the questionnaire.

Exploratory Factor Analysis: The next step in the scale validation procedure is to discover the dimension structure of perceived advertising credibility using the EFA. After considering the pilot study results, eliminated 3 items and finally 27 scale items have been used to measure advertising credibility. Exploratory factor analysis (Maximum Likelihood) was done using varimax rotation and the items with loading above 0.5 are taken while items with low loading were dropped. To assess the internal consistencya reliability test was conducted. Following Nunnally's suggestion[17] it is ensured that for all the constructs the Cronbach alpha coefficients were greater than 0.70.

The KMO Measure was 0.940 and the Bartlett test was significant with p< 0.001. The Chi-square value of 14267.39 with 351 degrees of freedom affirmed the quality of data for further analysis and served as basis for factorization. The EFA provided four components with an 'Eigen value' greater than 1, which together explained over 54.013 percent of the variance. The items used to measure Advertising credibility is shown in Table 1.

After EFA the factor structure evolved with four dimensions. The 27 items used in the scale were classified into 4 dimensions such as Corporate credibility, Message-content credibility, Endorser credibility- Trustworthiness and Endorser credibility- Attractiveness which is given in Table 2. The single dimension endorser credibility is divided into two subgroups here –'trustworthiness of endorser' and 'attractiveness of endorser'.The themes behind the items were the basis for naming the factors. The factors extracted in each case are given in tables below with Cronbach alpha coefficients.

Confirmatory Factor Analysis Using Warp PLS 5.0: The CFA was done to confirm the factor structure model of Advertising credibility construct. The main objective of conducting confirmatory factor analysis is to check the model fit ie., whether the predefined model is fit with the observed data. Confirmatory factor analysis tested the construct validity of Advertising credibility using Warp PLS 5.0 software as it is the most advanced research tool. The results for the measurement model of Advertising credibility showed an acceptable fit.

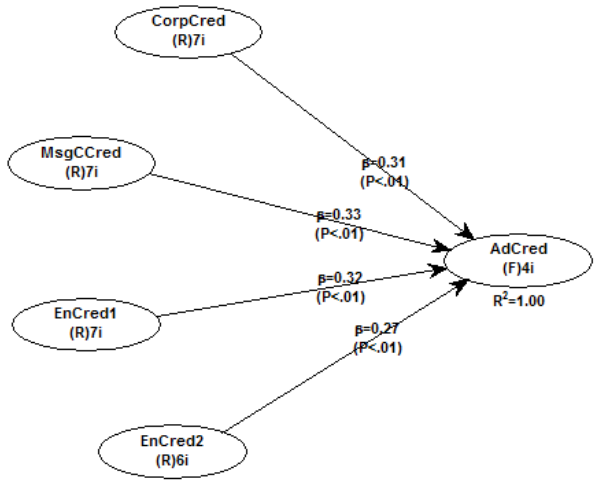

Figure 1: CFA Model - Advertising Credibility

The various fit criteria are reported below: Average path coefficient/APC=0.308, P<0.001 and Average R-squared/ARS=1.000, P<0.001 which was found significant. Average adjusted R-squared/ AARS=1.000, P<0.001. AVIF=1.876 which is acceptable if <=5 and ideally <= 3.3. TenenhausGoF/ GoF=0.744, which should be >= 0.1,>= 0.25, >= 0.36 for small, medium and large effects respectively. Sympson's paradox ratio SPR=1.000 which is acceptable if>= 0.7, ideally = 1. R-squared contribution ratio (RSCR)=1.000 which can be accepted if >= 0.9, ideally = 1. The other fit criteria are given in Tables 4 and Table 5.

Results

The combined loadings and cross loadings of every indicator is significant as p-value is less than 0.05. P values less than 0.05 are desirable for reflective indicators. The indicator weights for latent variables are 0.314, 0.336, 0.318, 0.267 for corporate credibility, message-content credibility, endorser credibility-trustworthiness, endorser credibility-attractiveness, respectively.

The reliability of reflective constructs has been established as all composite reliability coefficient and Cronbach alpha values were above 0.7. For formative constructs, reliability is not a crucial consideration. It is noticed that all average variance extracted values were > 0.5, p- values of the loadings were <0.05. The loadings were equal to or >0.5 and cross loading were <0.5. Thus, the convergent validity of reflective indicators is established. The convergent validity of the formative construct. Advertising credibility is also affirmed by observing that the corresponding AVE was > 0.5 and VIF found <0.5 for all formative indicators and weights were significant at p-value less than 0.05. Since the square root of the average variance extracted was higher than any of the correlations involving that latent variable, the discriminant validity also was confirmed.

Table 1: Measures of Advertising Credibility.

Item code	Items used in the advertising credibility scale	Item code	Items used in the advertising credibility scale
CC1	The Company has great amount of experience.	EC1	The persons appeared in the ad seems Trustworthy
CC2	The Company is skilled in what they do.	EC2	The persons appeared in the ad seems Dependable
CC3	The Company has great expertise.	EC3	The persons appeared in the ad seems to be Honest
CC4	The Company does not have much experience	EC4	The persons appeared in the ad seems Reliable
CC5	The Company is honest.	EC5	The persons appeared in the ad seems Sincere
CC6	I trust the Company.	EC6	The persons appeared in the ad are knowledgeable
CC7	The Company makes truthful claims	EC7	The persons appeared in the ad are Experienced
MC1	The information about the Product is Truthful	EC8	The persons appeared in the ad seems Qualified
MC2	The health care communication is believable	EC9	The persons in the ad are Skilled
MC3	The overall presentation of the matter is convincing	EC10	The persons in the ad seems Classy
MC4	The communicated message is clear and understandable	EC11	The persons in the ad seems Elegant
MC5	The ad is informative	EC12	The persons in the ad looks Attractive
MC6	The content and presentation are ethical	EC13	The persons in the ad are Beautiful
MC7	The communication by the characters seemed unbiased

Conclusion

Measuring and building credibility in advertising communication lessens consumer's doubt about the intension of marketers and enhances the advertising effects which will positively contribute to an increase in sales. This again will save the companies from the possible legal actions invited by the non-credible advertisements. The empirical investigation into the dimensionality of ad credibility after confirmatory factor analysis, revealed four ad credibility dimensions containing 27 ad credibility attributes.

The factor construction developed after EFA had items with adequate loadings and less conflicting cross loadings. All the 27 items could be classified into 4 dimensions such as Corporate credibility, Message-content credibility, Endorser credibility- Trustworthiness and Endorser credibility- Attractiveness. Almost all the dimensions identified as significant contributors to ad credibility. The CFA model of Advertising Credibility came out as good model with adequate fit and satisfied other quality parameters. This research contributes valid output to equip corporates and their ad agencies to assess the perceived credibility of their advertisement and to study its linkage with other brand related and purchase related variables. Based on such studies they can frame suitable advertising and marketing strategies. Since health is a sensitive issue, consumers are less willing to take risk and involvement in information search for healthcare products is more. This also highlights the need for a credible communication from society's point of view.

Ethical clearance: The procedures followed were in accordance with the ethical standards of the responsible committee on human experimentation (institutional and national) and with the Helsinki Declaration of 1975, as revised in 2000 (5).

Service Quality Perceptions to Wards Health Insurance Products

Mahfuja Begum[1]

[1]*Research Scholar, Department of Economics, Gauhati, University*

Abstract

Context: A healthy and competent workforce is the biggest asset of any nation and therefore, it is an important objective of every progressive government to ensure health for all. In this regard, insurance is the backbone in managing the risk of the country. In today's globalised world of fierce competition, providing a quality service to the customers is the key for existence and success of any business. Service quality or quality of service is said to be a function of three variables, viz., expectation, perception and performance. The main objective of this paper is to identify the service quality of health insurance products and services offered by the public and private health insurance companies and to identify the key factors contributing to the service quality. The study is based on primary data. The gaps between perception and expectation scores on various dimensions of service quality of health insurance products have been captured by the SERVQUAL tool.

Keywords: *Insurance, Health, SERVQUAL, Dimensions, Service quality*

Introduction

Health is a state of physical, mental, social well being and not nearly the absence of disease or infirmity. Providing a security net for ensuring availability of quality and affordable healthcare to the population is the prime goal every nation aspires for. According to NFHS – 3, in spite of the emergence of a number of health insurance programmes and health schemes, only 2 percent of households in Assam reported that they have any kind of health insurance that covers at least one member of the household. But some evidences show that steadily the health insurance coverage is increasing. It may be because of the fact that people become aware of the high health care cost, incoming of the private players in insurance field and government health care/insurance schemes along with involvement of community based health insurance schemes. Assam now stands at the threshold of transition of the industry to the next level. Health insurance would be one of the key tools to supplement and compliment the present health financing options.[1]The Health Insurance Company's main aim to create an ideal environment for health insurance business with a satisfied customer at the core. Three core areas are identified namely service quality, customer satisfaction and role of hospitals for studying the marketing perspective in health insurance. Parasuraman, Zeithaml and Berry (1990) mention that service quality is an extrinsically perceived attribution based on the Customer's experience about the service that the Customer perceived through the service encounter.[2]

Objectives: To find out the gap between expectation and perception score in health insurance product service quality.

Research Questions: In order to guide the study and achieve the above objective, the following research questions are formulated

1. How is the service delivered by the health insurance providers perceived by their customer and does it meet the expectations of their customers?

2. Which dimension is doing well among all five dimensions in health insurance sector?

Data Sources and Methodology: The geographical location for the present study has been selected purposively as Tinsukia district of Assam. The district is further stratified into development blocks. Tinsukia district has seven developmental blocks namely, Guijan, Hapjan, Itakhuli, Kakopothar, Margherita, Saikhuwa and Sadiya. Since the study is mainly concentrated in rural areas, thus the top three blocks namely Margherita, Kakopothar and Hapjan have been selected as these blocks have highest number of rural population respectively. In the next step, one Gaon Panchayat (GP) from each sample block having the highest population is taken as sample GP. AgainLekhapani GP of Margherita block, Kakojan GP of Kakopathar block, Hatijan GP of Hapjan block has highest number of rural population in their respective block. Thus these three GPs are selected as sample GP. 10% of the total villages of each sample GPs have been taken as sample villages. Lastly a total of 208 households have been selected for the field survey. A five pointlikert type scale is used in this study to evaluate the 5 health insurance service quality dimensions. Respondents were asked to provide ratings of both expectation and perceptions on the provided statements related to service quality. The service quality statements used in the study were rated by using five pointlikert scale with 1 indicating 'strongly disagree', 2 indicating 'disagree', 3 indicating 'neutral', 4 indicating 'agree', and 5 indicating 'strongly agree'. Thus the difference obtained from subtracting the expectation scores from the perception score revealed the gap between customer's expectation and their perception of the service quality. The study period has been selected from May – July 2019. Respondents are basically the customers of New India Insurance Company (Public Sector Insurance Company) and Bajaj Allianz (Private Sector Insurance Company). According to the SERVQUAL tool, services quality of health insurance companies can be measured by the gap between expectations and perceptions of consumers on 5 dimensions of service quality namely reliability, assurance, responsiveness, professionalism and fairness in dealings.[3]

Reliability Gap: Reliability implies the ability to perform promised service dependably and with accuracy. Reliability is connected to the consistency of performance and dependability on the service. Here it is determined if the company give the service in theright way the first time and keeps to its promises every time.[4] The term reliability refers to the ability of a health insurance company to consistently perform according to its specifications.

Table 1: Mean score/Standard deviation of perception and expectation on Reliability:

Reliability Attributes	Mean of perception score (P)	SD of perception score	Mean of expectation score (E)	SD of expectation score	Gap score P - E
The company gives all the required information	2.2260	0.94	3.2596	1.04	-1.0336
The company pointed out the best choice for me	1.6875	0.76	2.4087	0.78	-0.7212
I feel more confident when I purchase a policy	2.4087	0.82	3.1971	0.96	-0.7884
The Company's promises are reliable.	2.0529	0.85	2.9904	1.01	-0.9375
The company is consistent in providing quality services	2.1250	0.93	3.3317	0.94	-1.2067
Total	**2.10002**	**0.86**	**3.0375**	**0.946**	**-0.93748**

Source: Compiled from field survey

The table 1 shows the mean and standard deviation on the reliability dimension in the service quality of insurance policy holders about their companies. The total mean score and standard deviation on the perception on reliability attributes towards the service quality of insurance companies are 2.10002 and 0.86 respectively and for reliability expectation scores it is 3.0375 and 0.946. It is found that the mean perception score for 'feeling more confident when they purchase a policy is highest i.e. 2.4087 whereas it is highest for the fifth attribute which is related to consistency in providing quality service i.e. 3.3317.Again for all four statements on reliability, it is seen that the mean expectation scores are greater than the mean perception scores which shows some difference in magnitude of gap score among the five items. It can be noted that attribute

2 has the lowest mean gap score (-0. 72) which is related to "pointing out of Best Choice for the customer by the health insurance company. It indicates that people are comparatively less dissatisfied in this attribute than the other four attributes. Again attribute 5 has the highest mean gap score (-1.2067) which is related to consistency in providing quality service.

Assurance Gap: Assurance means that employees' behavior will give customers confidence in the firm and that the firm makes customers feel safe.[5] It also means that the employees are courteous and have the necessary knowledge to respond to customers' questions.

Table 2: Mean score/Standard deviation of perception and expectation on Assurance:

Assurance Attribute	Mean of Perception Score (P)	SD of Perception Score	Mean of Expectation Score (E)	SD of Expectation Score	Gap Score (P – E)
I feel that I can always trust this company	2.1827	0.89	2.4471	0.88	- 0.2644
The company follows the motto "Customer is the king".	2.3510	0.91	2.5481	0.89	-0.1971
The company gives sincere commitment in servicing The claims	2.3077	1.02	3.0625	0.85	-0.7548
The company deserves recommendation for new Customers	2.1346	0.78	2.8976	0.76	-0.763
Company gives more importance to the satisfaction of customers rather than profit gain.	2.673	0.95	2.956	1.78	-0.283
Total	2.32988	0.91	2.78228	1.032	-0.4524

Source: Compiled from field survey

It can be observed that the process execution time and kind and politeness of the employees are noticeable factors contributing to the average assurance gap. Employee's expertise and knowledge on the company's operations hold a big hand in satisfying the customers in terms of service quality. Efficient and knowledgeable employees are always a big boon for any organization. It can be noted that, out of all the attributes for assurance, attribute 7 i.e. "The company follows the motto customer is the king" has the lowest mean gap score (-0.1971) In terms of expectation, attribute 6i.e. "I feel that I can always trust this company" has lowest mean, whereas in terms of perception attribute 9 i.e. "Company gives more importance to the satisfaction of customers rather than profit gain" has lowest mean gap score. Few respondents think that some of the staffs appear not to be quick and efficient, as they tend to make errors or ask seniors to help them.

Responsiveness Gap: his means that the employees of a service firm are willing to help customers and respond to their requests as well as to inform customers when service will be provided and then give prompt service.

Table 3: Mean score/Standard deviation of perception and expectation on Responsiveness:

Responsiveness Attribute	Mean of Perception Score (P)	SD of Perception Score	Mean of Expectation Score (E)	SD of Expectation Score	Gap Score (P – E)
The Company tries to understand the specific needs.	2.4327	0.91	3.3798	0.96	-0.9471
The company actively responds to The inquiries regarding policy matters.	2.4423	0.96	3.3173	0.91	-0.875
The company timely informs us about the new offers.	2.4663	0.93	3.6587	0.99	-1.1924
The company properly informs me as and when my policy becomes due.	2.9758	0.94	3.7564	0.94	-0.7806
Information provided by the company is always Accurate.	2.5477	0.89	3.0567	0.96	-0.509
Total	**2.57296**	**0.926**	**3.43378**	**0.952**	**-0.86082**

Source: Compiled from field survey

This table 3 shows the perception and expectation gap score of various responsiveness attributes. It is evident the attribute 15 i.e. "Information provided by the company is always accurate" has lowest gap score (-0.509). It can be noted that, out of all the attributes for responsiveness, attribute 11 i.e. "The Company tries to understand the specific needs" has the lowest overall mean gap score (2.4327) In terms of expectation, attribute 6 i.e. "I feel that I can always trust this company" has lowest mean, whereas in in terms of expectation attribute 15 i.e. "Information provided by the company is always accurate" has lowest mean gap score. It is seen that in all cases policy holders are not satisfied.

Professionalism Gap: Professionalism is defined as the strict adherence to courtesy, honesty and responsibility when dealing with policy holders or stakeholder in the business environment.

Table 4: Mean score/Standard deviation of perception and expectation on Professionalism

Professionalism Dimension	Mean of Perception Score (P)	SD of Perception Score	Mean of Expectation Score (E)	SD of Expectation Score	Gap Score (P – E)
The company gives the correct information about the service charges and related charges	2.5962	0.86	3.2981	0.82	-0.7019
The company timely informs any new Government Regulations regarding policies	2.7163	0.84	3.4760	0.88	-0.7597
I never felt any communication problem	2.7429	0.81	3.6399	0.85	-0.897
The company tries to avoid probable conflict	2.6754	0.87	3.7462	0.90	-1.0708
Total	2.6827	0.845	3.54005	0.8625	-0.85735

Source: Compiled from field survey

The above table4 deals with the mean and standard deviation on the professionalism of service quality received by policy holders of the insurance policy. The total mean score and standard deviation on the perception professionalism dimension in the service quality of Health Insurance Company are 2.6827 and 0.845 respectively, whereas in case of expectation professionalism dimension the mean score and standard deviation are 3.54005 and 0.8625 respectively. Among the four attributes of professionalism dimension attribute 19 i.e " The company tries to avoid probable conflict" has highest mean gap score (-1.0708) and attribute 16 i.e

"The company gives the correct information about the service charges and related charges" has least gap score (-0.7019)

Fairness in Dealings: Factors consist of trustworthiness, believability and honesty comes under the fairness dimension of any service organization. It means to the level the company has the customers' best interest at heart and job. Factors that affect the fairness are the company name and fame, reputation, personal characteristics and the degree to which the company is connected to intersections with customers.

Table 5: Mean score/Standard deviation of perception and expectation on Fairness in dealings

Fairness in dealings	Mean of Perception Score (P)	SD of Perception Score	Mean of Expectation Score (E)	SD of Expectation Score	Gap Score (P – E)
The company openly discusses the problems	2.5962	0.86	3.2981	0.82	-0.7019
The company has an effective Grievance Redressal mechanism	2.7163	0.84	3.4760	0.88	-0.7597
Company tries to solve the problems at the office level itself	2.8521	0.88	3.8546	0.90	-1.0025
The company handles the conflicts as speedy as possible	2.9745	0.85	3.8123	0.89	-0.8378
Total	2.784775	0.8575	3.61025	0.8725	-0.825475

Source: Compiled from field survey

The table 5 shows that the total mean score and standard deviation on the perception fairness dimension in the service quality of Health Insurance Company are 2.784775 and 0.8575 respectively, whereas in case of expectation fairness dimensions the mean score and standard deviation are 3.61025 and 0.8725 respectively. It is found that the mean perception and expectation score for 'Company openly discusses the problems' are 2.5962 and 3.2981 respectively for insurance policy holders, perception and expectation mean score for 'The company has an effective grievance redressal mechanism' are 2.7163 and 3.4760 respectively for insurance policyholders, perception and expectation mean score for "Company tries to solve the problems at the office level itself" are 2.8521 and 3.8546 respectively for insurance policy holders, the perception and expectation mean score for "The Company handles the conflicts as speedy as possible" are 2.9745 and 3.8123 respectively for insurance policy holders. It is evident the attribute 20 i.e. "The company openly discusses the problems" has lowest gap score (-0.7019). It can be noted that, out of all the attributes for fairness dimension, attribute 22 i.e. "Company tries to solve the problems at the office level itself" has the highest mean gap score (-1.0025). The policyholders feel that all the activities starting from the fixation of premium and claim settlement is not fair and scientific. It demands for more transparency in dealings so that the grievances can be reduced. Seamless movement of information and integration of different stakeholders in health insurance is necessary in this direction.[6]

Gap score for the overall dimension of health insurance services:

Table 6: Mean and gap score for the overall dimension of health insurance services

Dimension	Perception Score	Expectation Score	Gap Score
Reliability	2.10002	3.0375	-0.93748
Assurance	2.32988	2.78228	-0.4524
Responsiveness	2.57296	3.43378	-0.86082
Professionalism	2.6827	3.54005	-0.85735
Fairness in Dealings	2.784775	3.61025	-0.825475

Source: Compiled from field survey

As most of the responses were negative, indicating significant shortfall in meeting customer expectations across all service areas and dimensions of health insurance policies. It is clear that reliability gap (-0.93748) which is highest followed by responsiveness gap (-0.86082), Professionalism gap (-0.85735), fairness in dealings gap (-0.825475), assurance gap (-0.4524). This entire gap can be reduced by minimal promise and maximum performance thus leading to customer satisfaction.

Conclusion:

The health insurance sector has undergone many changes after the adoption of new economic policy which is based on privatization, globalization and liberalization. Customer is the king in the present day market. Today the customer's service preference and demands are keep on changing at a rapid speed. The aim of the health insurance providers is to make the customers comfortable and happy. Health insurance companies should not only have to satisfy the customer but should also trigger to the attitude of the customers towards their insurance company. Each company follows different procedure. So, it is very difficult for the customer's to follow all these procedures. Personal communication is the most influencing medium considered for taking health insurance selection decisions by the policy holders. Customer retention in health insurance is beneficial to both the company and insured in many ways. Immediate attention is needed from the part of the companies to check the percentage of people renewing the policy from the same company.

Unwed Mother: A Socio-Legal Study

Payashwini Sharma[1], Aqueeda Khan[2]

[1]PhD Research Scholar under the supervision of Associate Professor, Dr.Aqueeda Khan, Amity Law School, Amity University, NOIDA, Uttar Pradesh, [2]Associate Professor, Amity Law School, Amity University, Uttar Pradesh.

Abstract

Context: This research evaluated the effects of a social support program on young unwed mothers. Measures of social support, stress, affect, and life events were compiled by 15 program participants and 15 matched controls before and after the program six months later. The results showed significant increases in the size of the family and friend network for program participants relative to controls. Also, program participants reported more involvement in work and school and maintained a high level of positive affect significantly more than controls. The two groups did not differ in reported levels of stress. The implications of the findings for future research and program development were discussed.

Keywords: *Public Health Social Support Health Psychology Program Development Positive Affect*

Introduction

The trends in major research traditions show that the unwed motherhood has been well researched from a variety of disciplinary perspectives in the west especially in the countries like the United States of America, Canada, and UK. From a positivist theoretical paradigm, there are ample amount of research literature available that looked at single parenthood, unwed motherhood, teenage parenthood from descriptive to experimental, from retrospection to prospective, from cross sectional to longitudinal data at local and national levels. However, the phenomenon of illegitimacy or out of the wedlock pregnancy is not new; the recent time has shown a sharp increase as a direct effect of changing family systems in terms of its structure, stability and functioning. Though, the gravity of the phenomenon was well realized in western countries since 1950s and 1960s, and attracted a large amount of research interests from diverse disciplinary perspectives- public health, mental health, demographers, sociologists, anthropologists and social work.

In developing countries like India, where family structure and functioning were relatively firm and stable, had been remained as a protective shield from teenage motherhood. However, India‘s intensive urbanization induced by the scientifically planned and politically accelerated economic development redefined the basic tenets of family relationships and its fundamental properties such as stability and functioning. These fundamental changes had produced a wide range of impacts on interpersonal and intrapersonal relationship contexts in individuals, families and communities and in the broader Indian society.

Teenage pregnancy today, is a widely acknowledged common public health problem worldwide, whereas the problems presented by the pregnant unwed teenagers are among the most difficult and perplexing issues faced by those who work in the fields of health, education and social services (Saran, 1999). No society is immune to teenage pregnancy and it affects every society-developed and developing alike. There is a growing awareness that early child bearing has multiple consequences in terms of maternal health, child health and over all well-being of society (WHO, 2004). Illegitimate pregnancies may have multiple traumatic impacts on the teenager, her boyfriend, her family, her community and ultimately on her yet to-be-born child .Therefore, pre-marital or teenage

Corresponding Author:

PhD Research Scholar under the supervision of Associate Professor, Dr.Aqueeda Khan, Amity Law School, Amity University, NOIDA, Uttar Pradesh

pregnancies is a crucial area of scientific exploration and examination in the context when no segment of society is immune to the causes and effects of the out-of-wedlock teenage pregnancy. Each year the extent of this problem grows. The statistics from worldwide indicate a substantial increase of unwed mothers that warrant multi-disciplinary research response. This trends suggest that the proportion of the adolescent population involved in increased sexual activities were so large that sexually active teenagers can no longer be considered socially deviant, a dominant view of Christian west.

Defining Unwed Motherhood: Does the term unwed mothers include all typologies of single parent women? For this, the researcher critically review the existing research literatures to identity the pattern, characteristics, nature, functions, and inclusiveness of existing definitions that deal with illegitimate pregnancy and subsequent child rearing and family management. In fact, socio-cultural and economic contexts of the society wherein teenage pregnancy takes places set the answers for many of these questions and these answers may vary widely across socio-cultural and economic contexts where teenagers live. There were efforts to define the term unwed mothers from both western and eastern socio-cultural contexts that uniquely responded to sensitive socio-cultural fabric of the society that accommodate these unwed mothers.

An unwed mother is a girl or woman (13-35 Years) who is not legally married to a man by whom she has conceived a child. She may be pregnant or has already delivered a child, whereas the single parent family is defined as a family in which either the father or mother has primary responsibility for bringing up children with only occasional or no contact with the spouse. The single parent family can be formed through death, divorce or separation".

There were isolated efforts to define the concept of unwed mothers and unwed motherhood in the context of aboriginals or tribes, though the purpose was to operationalize the concept that was amenable for empirical investigations, these definitions were limited in conceptual clarity and for inclusiveness of diverse typologies of unwed mothers found in the unique tribal social context that oftenoverlaps[1].

Such typologies may include unwed mothers who married later, widows who have single/multiple sexual relationships and gave birth to children, deserted tribal women who gave birth to children in later sexual relationship outside wedlock relationships etc. Thus, it was operationalized towards an effort to define the term unwed tribal mother as a tribal woman or girl who conceived or/and gave birth to one or more children outside the wedlock of marriage by a man of same tribe, or man of other tribe or a man of non-tribe‖ (Jose *et al*., 2010a). In this definition, the purpose was to define the term "*unwed tribal mothers*" operationally where in emphasis was given only to pregnancy or delivery of children outside wedlock relationships[2]. This definition is silent about a variety of typologies such as widows who delivered children outside of further wedlock relationships, or tribal women who were impregnated in pre-marital sexual relationships subsequently got into to wedlock relationships either with same or other men. A common thread that passes across all types of single parents was the functional aspect i.e., parenting. This was exclusively shouldered by women often with no help either from by whom they were impregnated or from their own families.

Socio-Demographic aspects of Unwed Motherhood: The existing evidence suggests that socio-demographic variables are critical onto the pathways to unwed motherhood while there is a paucity of evidences on socio-demographic pre-dispositions of unwed mothers, from Indian socio-cultural scenario. Thus, current study mostly relied on western empirical literature in order to depict a broader socio-demographic picture of unwed mothers. Sylvia has studied using two socio-economic variables such as the median income of all families and the percentage of families on welfare. US census data was used for this study with a conceptualizing a negative correlation between median income and teenage birth rates. This conceptualization was happened in the background that nationwide study of never-married women aged 15-19, which revealed that an inverse relationship between family income and sexual experience[3]. But a positive relationship between family socioeconomic status and a teenager's likelihood of using contraception was also found in that study with an implication that ―wealthier teenagers are not only less likely to be sexually active, but they also have easier access to contraceptive services, and are more likely to use them. Subsequent studies have also shown that wealthier family's teenagers are more likely to use contraceptives and abortion services.

After examined the association with pre-existing characteristics and teenage pregnancy showed no

statistical associations between the demographic, economic, and educational characteristics of the teenage mothers at registration and whether or not they had a rapid subsequent pregnancy. The variables studied were age, number of years of residence in New Haven, number of parents in the household, total number of persons in the household, ordinal position, number of previous pregnancies, socioeconomic quartile, welfare status, educational goals, or whether or not they were in the age appropriate grade in schools. The authors attributed or explained these extremely surprising results on lack of associations as a result of homogeneity of the study group on many of these variables. The author further reported that this was partly due to the nature of the program (based in a hospital clinic) and partly to the research design (all who participated had to meet the study 29 criteria) Among the pre-existing characteristics, only school status at registration was correlated significantly with subsequent pregnancy those in school were less likely to become pregnant again by 15 months postpartum[4]. However, this result cannot be treated as conclusive because existing studies show strong influence of socio-demographic and economic variables in out of the wedlock pregnancies.

Psychological Aspects of Unwed Motherhood:

Identity of unwed mothers: The adolescence is a developmental stage characterized by multi-faceted event involving every aspect of an individual whereas the identity formation is the critical aspect. The sexuality becomes a dominant feature and makes adolescents prone to risky behaviour that would likely to results in becoming sexually active during early teenage and even in pregnancy. Such incidence is expected to bring a cascade of events that can negatively affect the main social contexts. The impact of pregnancy on the life of unmarried adolescents in the local context, has found that pregnancy as a stressful event that changes an adolescent‘s life completely[5]. Important aspects like financial dependence, negative self-image, sudden responsibilities and changes in aspirations are highlighted. Practical and emotional support was identified as critical for the young mothers‘ well being; without adequate help they are likely to flounder.

Self Concept and Self Esteem: The term self-concept is a general term used to refer to how someone thinks about or perceives themselves. Lewis (1990) suggests that development of a concept of self has two aspects: (1) The Existential Self is ―the most basic part of the self-scheme or self-concept; the sense of being separate and distinct from others and the awareness of the constancy of the self‖. (2) The Categorical self, having realised that he or she exists as a separate experiencing being, the child next becomes aware that he or she is also an object in the world. Just as other objects including people have properties that can be experienced (big, small, red, smooth and so on) so the child is becoming aware of him or herself as an object which can be experienced and which has properties. Carl Rogers believes that self-concept has three different components. They are the view you have of yourself (Self image), how much value you place on yourself (Self esteem or self-worth) and what you wish you were really like (Ideal self). Self-efficacy as a concept refers to being able to picture yourself achieving what it is you want to achieve at the level you want to achieve it. As Bandura had put it, self-efficacy refers to people‘s convictions about their own capabilities for successfully executing a course of action that leads to a desired outcome.

Low self concept had been shown to be associated with adolescent pregnancy and has been associated with decreased attendance at prenatal and post natal care and with repeat pregnancy. Self-efficacy is another factor that can be predicted to influence the prenatal care. Social cognitive theory conceptualizes human functioning as a reciprocal interaction between personal factors such as self-efficacy and outcomes of expectancies, environmental factors, and behaviours[6]. Hence, self-efficacy refers to the people‘s confidence to regulate their motivation, thought process, emotional state, and social environment to effect a given behaviour. Hence guided by social cognitive theory, a peer-centred mastery model group intervention was designed. The programme focused on modelling and rehearsal skills to achieve **(a)** increase knowledge about pregnancy **(b)** prepare for childbirth **(c)** work with self care systems **(d)** including hospitals, clinics and physicians and nurses **(d)** enable expectant mothers to assess her own and her babies‘ health **(e)** prevent an unplanned repeat pregnancy **(f)** improve health self care. 262 pregnant adolescents were randomly assigned to either experimental or control groups of 6-8 participants. Experimental groups were provided peer-centered mastery model group intervention by nurse-midwives.

Family and Social Responses to Unwed Motherhood: Familial and societal reactions to unwedded pregnancy and individuals were reviewed. Literature search has revealed that a limited number

of studies were available with this focus which was in aboriginal context. Such studies discussed that typical reactions of the alleged father to the news of the pregnancy would be annoyance, fear, anger and a desire to escape from the entire situation. Another set of reactions to pregnancies were the boys would react proudly when they learned of their prospective parenthood, and would offer to marry their pregnant girlfriends. Reviewing the responses of men by whom tribal girls in Kerala were impregnated. They placed responsibility and blame of out of the wedlock pregnancy on the victims, denied fatherhood of the conceptions, persuaded women to go for abortion and also refused the responsibility of household and children rearing. It was also reported that men were forced to provide financial security for households and child rearing in the context where they were questioned either by formal and non-formal institutions of justice[7]. The same study revealed that unwed mothers live through a series of positive and negative emotions and psychological responses in their initial periods of pregnancy while some of them felt very happy because during initial periods because they enjoyed their men's support and physical proximity. These mothers reported that, by being impregnated, they could find new meaning for their life and relationships. However, this was not the case for many other unwed mothers. They learned about their pregnancy with shock, disbelief and denial and experienced uncertainty about future, became fearful, felt giddy and weak .Some of them experienced anger towards self which were associated with occasional suicide ideation and actual suicidal attempts. Many perceived that every one stopped loving them and are left alone.

Legal perspectives/Human Rights: Social norms and legal systems that encourage or do not censure men's multiple sexual partners are likely to leave many of the women who become mothers through such unions economically vulnerable. Few men have sufficient wealth to adequately support multiple families and invest equally in each mate and her offspring, yet men continue to father children with multiple partners (Saran, 1999). In addition, structural violence in the forms of stigmatization and discriminations coupled with sexual harassment and violence is likely to restrict women's ability to seek legal redress and even deny access to or fare treatment from locally available non-formal judicial systems. For example, when men responsible for pregnancies deny or refuse to shoulder the responsibility of fatherhood, cases are often filed in police stations,not even reaches to the courts. But most of the time, such cases are settled outside courts with nominal financial assistance and a promise to bear a share of the household and child rearing expenses by men. However, instances are many wherein ongoing financial support for household and child rearing simply remain as promises. As these men suddenly move away from women, contacts also do not exist in many cases where these promises remain unfulfilled .Hence, investigations need to focus on the process and outcomes of both institutional and non-institutional conflict resolutions models in practice that govern the lives of women because very minimal knowledge base is available in this regard (Jose *et al*., 2010c)**.** Similarly, a few social activists and a very limited number of NGOs have taken up the issue on their agenda but they too could not do much to stop the exploitation, resulting inadequate civil society response to facilitate and strengthen access to socially marginalized women's groups. Thus, it is vital to identify what are the capacity building needs of civil society organizations and strengthening them to effectively respond to human rights concerns.

Conclusion

Most of the research studies found out that the crucial problems which tribal communities face today in India are illiteracy, poor health, and poverty, lack of landholdings, unemployment and cultural diffusion. While compiling researches on the status of tribal women with regard to freedom of marriage and family, it is inferred that even though they are struggling for existence, they do not have much difficulties than that of non-tribal women, might be because of the equal status they have enjoyed with men in the social structure of the tribal societies, but they are marginalized within tribal communities in socio economic and political spheres.

A few studies which have been conducted in this field, found many psychological and social factors as the reason for unwed motherhood. Majority of the tribal women were exploited by persons from outside the community and studies found that**,** the psychological problems are high among the unmarried mothers.

There is meager research on the Quality of Life of single parent and the available studies on quality of social life shows that marital status significantly influenced quality of social life. This is implied that unwed tribal mothers were more likely to enjoy less quality social life than married mothers and unwed mothers who later married**.**

Abstract

Background: Epicardial adipose tissue is known to have adverse effect on local coronary health, cardiac structure and function. Echocardiography has shown to be a reliable method to measure the adipose thickness.

Aim: To study the association between epicardial adipose tissue thickness with resting and post-exercise test cardiac output.

Method: A cross-sectional study of 26 overweight and obese subjects in the age group of 20 to 50 was included. Epicardial adipose tissue thickness was measured using M-mode echocardiogram. Resting and post exercise cardiac output, ejection fraction and heart rate recovery were measured during sub-maximal exercise on treadmill.

Results: There was no significant correlation of epicardial adipose tissue thickness with resting and post-exercise cardiac output, ejection fraction and heart rate recovery.

Conclusion: Cardiac output, Ejection fractionat rest and post - exercise, also Heart rate recovery were not affected by epicardial adipose tissue thickness of less than 4mm.

Keywords: *Epicardial adipose tissue, cardiac output, sub-maximal exercise test, body mass index, overweight and obesity, echocardiography*

Introduction

Overweight and obesity are considered as major risk factors for cardiovascular diseases, diabetes, degenerative diseases and cancers.[1] There is an increase in morbidity and mortality resulting from obesity due to lifestyle changes in Indians.[2] Cardiovascular and metabolic diseases are found to be more prevalent in obese individuals with increased visceral adipose tissue.[3] Epicardial adipose tissue (EAT) is the fat located between the myocardium and visceral pericardium[4]. EAT is found to have influenceon local coronary artery health[5,6]. It is the true visceral fat depot of the heart. Increased amount of EAT is associated with abnormal cardiac morphology as it adds to the weight of the ventricles which may further restrict the contraction of heart and pumping ability[7,8]. EAT has been shown to be very closely related to intra-abdominal adiposity, a marker of entire body visceral adiposity, according to

Assistant Professor, Department of Physiotherapy, College of Health Sciences, University of Sharjah United Arab Emirates
e-mail: kreddy@sharjah.ac.ae

various magnetic resonance imaging studies. It is well known that visceral adiposity rather than subcutaneous adiposity is more responsible for health risks associated with fat deposition in humans.[9,10]

Even though the gold standard method to measure EAT thickness is MRI, echocardiography has shown to be a reliable method to measure the adipose thickness. Epicardial fat thickness is measured on a free wall of the right ventricle from both parasternal long – and short- axis views. The largest amount of epicardial fat is usually seen at this right ventricular free wall site. Epicardial adipose tissue is usually seen as an echo-free or if it is massive, hyper-echoic space.[11, 12]Stroke volume can also be measured using echocardiography. Excess VAT has a detrimental effect on sub-maximal aerobic capacity.[13] Fick's principle states that VO_2 peak will occur when the maximal arterio-venous oxygen difference and the cardiac output (CO) reach their maximum during an exercise test.[14] Thus, VO_2 peak is directly related to the maximal arterio-venous oxygen difference and CO. CO has been recognized as the most important measurement in the assessment of cardiac pump function and overall hemodynamic function.[15] The influence of increased amount of epicardial adipose tissue thickness on the cardiac function is unknown. The aim of the study is to determine the association between epicardial adipose tissue thickness and resting and post-exercise cardiac output.

Method and Materials:

A cross-sectional study of 26 subjects with convenience was conducted at Cardiology department, Kasturba Hospital, Manipal. The participants of age between 20 to 50 years with BMI $\geq$ 24.9kg/m^2, both male and female sedentary individuals (who exercise less than 3 Times/week) were included. The participants with any known respiratory and musculoskeletal conditions, those on regular medications were excluded from the study

Approval from the University Ethical Committee was obtained, following which a verbal advertisement was given among all staff and students of the constituent colleges of University. Participants went for a complete cardiac evaluation to rule out any undiagnosed cardiac conditions and then subjects were recruited as per the inclusion and exclusion criteria. A written informed consent was obtained from all the eligible subjects. Procedure was explained to the subjects and following data were documented: Age(years), height(cm), weight(kg), BMI(kg/m^2),body fat percentage and the baseline characteristics like EAT thickness(mm), Heart rate(bpm), Stroke volume(ml/beat), Ejection fraction(%) were measured in the left lateral decubitus position.

A single cardiovascular technician measured EAT thickness, SV using 2-D, B-mode echocardiography, with a Trans-thoracic, parasternal view [long – axis measurement of EAT thickness and apical 4- chambered method for stroke volume (which was calculated using the formula: end diastolic volume {EDV} – end systolic volume {ESV})]. And the EF was measured using M-mode parasternal long-axis view. Subjects were then allowed to walk on the treadmill for 2 minutes to familiarize the instrument. Then test was conducted on the treadmill according to stages of Balke protocol (as per mentioned in the appendices). Test was terminated when the subjects complained of fatigue or reached 75 – 85% of Maximum heart rate (HRmax).The termination criteria for the study include fatigue,onset of angina or angina-like symptoms,significant decrease in SBP of 20mmHg or more,light-headedness, confusion, ataxia, pallor, cyanosis, nausea, or signs of severe Peripheral circulatory insufficiency,excessive increase in BPsystolic>260mmHg, diastolic>115mmHg,0 also when subject requested to stop test for whatever reason and the equipment failure. Immediately after cessation of the test, subjects were made to lie on the left lateral position as before to measure SV and EF,within the first minute and simultaneously HRR was measured at 0, 1st, 3rd, 5th minute. The data was analyzed using SPSS version 19. Pearson's correlation was used to correlate EAT with BMI and body fat percentage, EAT with resting and post exercise cardiac output and ejection fraction, EAT with heart rate recovery. Heart rate recovery pattern was analyzed using repeated measures ANOVA

Results

There was a significant difference in the resting and post-exercise cardiac output. There was a moderate correlation between epicardial adipose tissue thickness and body mass index, but no significant correlation was found between EAT and total body fat percentage. There was a significant rise in heart rate during the first minute of recovery, but it did not return to baseline by the 5th minute of recovery. However, there was no significant correlation found between epicardial adipose tissue thickness and heart rate recovery

	Mean ± SD (n=26)
Age(year)	27.46±8.78
BMI (kg/m²)	30.16±4.41
Body fat percentage	38.35±5.6
EAT thickness (mm)*	2.58±0.447

°BMI – Body Mass Index *EAT- Epicardial Adipose Tissue

Table: 2. Comparison of resting and post-exercise cardiac output and ejection fraction

	Resting (L/min) Mean ±SD	Post-exercise (L/min) Mean ±SD	p value
Cardiac output	3.30±0.8	6.8±1.8	<0.05
Ejection fraction	66.5±3.6	74.5±2.9	<0.05

Table: 3. Correlation of BMI and body fat percentage with epicardial adipose tissue thickness

	r	p value
BMI & EAT	0.424	0.015
Total body fat % and EAT	0.183	0.186

Discussion

This study was conducted to determine the influence of EAT thickness on cardiac function. Increased amount of EAT is known to have a potential active role in the development of cardiovascular and metabolic disorders.[16] But whether excess amount of EAT thickness influences the cardiac function is not known.

In the present study, we investigated the influence of EAT thickness on CO, EF and HRR. We found that all the participants in the present study were under the categories of overweight and obese (Class1 & 2) Indian subjects.The EAT values obtained in the present study were relatively low (1.9mm -3.9mm) [n=26] in comparison with African American (n=50) & Non – Hispanic white (n=106) population (6.7- 8.9mm).[17, 18] We found a moderate correlation between overweight as well as class1 and class 2 obesity with EAT thickness. We could not study the subjects in class 3 obese category.

In our study, a linear increase in the resting and post-exercise cardiac output and ejection fraction was found. It is known that the aerobic capacity is directly proportional to cardiac output and arterio-venous oxygen difference.[19]It has been shown that higher cardiac output in response to exercise testing in overweight people compared with normal –weight people may be explained by higher stroke volume. It is also shown that large differences in VO_2 peak values in general population are due primarily to large differences in maximal stroke volume.[20, 21]

EAT can substantially modulate the cardiac morphology and function.[22]Ejection fraction and stroke volume are good indicators of cardiac function. In this study we found no significant correlation between EAT thickness less than 4mm and resting and post-exercise cardiac output and ejection fraction.We did not find literature on association of EAT thickness with cardiac output and ejection fraction.

Heart rate recovery is a predictor of future cardiovascular events and indicates the autonomic function of the body.[23] We found no significant correlation between EAT thickness and HRR. HRR in the first minute was dropped by more than 20 beats per minutes (mean HRR was 28 bpm), indicating normal autonomic function. However, baseline values were not achieved within the fifth minute. In the study conducted by Kim et al, there was a blunted heart rate response in the 1- and 2- minute of recovery. And the cardiorespiratory fitness which was assessed as VO_2 peak was also reduced in obese men.[24]This study suggests that EAT thickness of less than 4mm does not affect the cardiac function and aerobic capacity was not affected by EAT thickness in overweight, as well as class 1 & 2 obese subjects.

The exact relationship of EAT thickness with cardiac output could not be established because of small sample size and also because of EAT thickness was not more than 4mm.Further studies are required to focus on larger sample size with wider age group distribution. Future research should include all categories of overweight and obesity. There was no significant correlation between epicardial adipose tissue thickness and resting and post-exercise cardiac output. Cardiac output, Ejection fractionat rest and post - exercise, also Heart rate recovery were not affected by epicardial adipose tissue thickness of less than 4mm.

Factors Affecting Risk of Cardiov Ascular Diseases among Hotel Employees in Udupi District, Karnataka

Thirugnanasambantham K[1], Lalitha Ramaswamy[2]

[1] Principal, WGSHA, Manipal Academy of Higher Education, Manipal; Ph.D. Research Scholar, Bharathiar University, Coimbatore, Tamilnadu. [2] Head and Associate Professor, Department of Nutrition and Dietetics, PSG Arts and Science College, Coimbatore,Tamilnadu.

Abstract

Context: Several research has indicated the increasing morbidity and mortality across the globe. Diet, lifestyle habits, stress are the most common risk factors associated with cardiovascular disease (CVD) risk. Hotel employees have been reported to have increased workload and stress which increases their risk to CVD related morbidity and mortality. This paper is a pilot study of the cross-sectional research study undertaken to identify risk factors associated with CVD risk among hotel employees in Udupi district of Karnataka. A structured questionnaire was used to elicit information pertaining to medical history, lifestyle habits, stress, sleep, bowel toxicity, inflammation and pain, blood glucose, blood lipids, diet, blood pressure and weight status. Research identified abnormal blood sugar levels, lipid profile, high blood pressure, high waist circumference and lifestyle habits like smoking and alcohol consumption as common risk factors among hotel employees. Over 69% had moderate to high risk of CVD due to the above mentioned risk factors. A good diet and lifestyle management can modify these risk factors and reduce risk of CVD among hotel employees.

Keywords: *CVD risk, modifiable risk factors, hotel employees, diet and lifestyle habits, stress*

Introduction

According to the Global Burden of Disease study age-standardized estimates (2010), closely a quarter (24.8%) of deaths in India are attributable to CVD. The age-standardized CVD death rate of 272 per 1,00,000 population in India is greater than the global average of 235 per 100000 population[1]. Cardio vascular diseases affect Indians a decade earlier and in their most productive midlife years as compared to the people of European ancestry[2,3]. High blood glucose, blood pressure, body mass index (BMI), and serum cholesterol have been recognized as foremost metabolic risk factors driving this epidemic[4]. Nutritional, behavioral, and developmental risk factors together with diet, smoking, alcohol use, and physical activities have also been identified as major underlying determinants of CVD risks[5].

Dietary practices, physical activity requirements, and job-related stress differ among different occupational groups. Due to a deviation in lifestyle factors across job-related groups, some occupations are at higher risk of metabolic risk factors and consequent non-communicable diseases[6,7]. Although there are abundant researches on the CVD risk factors in connection with various industries and occupations, there is scarcity of research on the prevalence and antecedents of CVD risk factors among hospitality employees.

Earlier, occupational health was related more on physical and chemical hazards in an occupational setting

rather than cardiovascular and other non-communicable diseases that are often thought to be connected with the lifestyle of a person rather than her/his occupation. This is true for hospitality despite being an industry that produces and/or serves food including fast food that is linked to obesity. Prolonged disease risk factors among hotel employees need to be studied and this study one such effort to understand the present status of well-being among the employees of hotels. Within the hotel industry, jobs can be further classified as managerial, executive, clerical, administrative, skilled, semi-skilled, and un-skilled labor. It was initially assumed that upper grades are more at risk because of managerial desk level jobs but later it was realized that occupations may also act independent of these transitional behavioral risk factors. Junior job levels have been associated with greater chances of mortality due to coronary artery disease. Lower occupational levels are associated with low income and minor social recognition. People with low socio-economic status are more susceptible to conditions of ill-health and frequently do not have resources to manage with the consequences of diseases ensuing in discrepancies in health. Hence this study includes employees across the various departments of classified star category hotels in Udupi district. It targets to obtain the risk factors prevalent among hotel employees.

Methodology: A cross-sectional study was conducted a part of pilot study with the aim of identifying factors associated with risk of cardiovascular diseases among hotel employees. Institutional Ethics committee approval was obtained from Institutional Ethics Committee – Kasturba Hospital, Manipal. This paper is a pilot study involving 26 hotel employees in Udupi District who were assessed using a structured interview schedule. Informed consent was taken from all participants before collecting the data. The interview schedule consisted of sociodemographic information, medical history, CVD risk assessment questionnaire[8], physical activity, workload and stress. Physical activity level was calculated using Mets and classified as per ICMR classification. Blood pressure and biochemical tests like blood glucose level and lipid profile, anthropometric measurements like height, weight, waist circumference and hip circumference was assessed with due precautions. CVD risk assessment questionnaire comprised of medical history, lifestyle habits, stress, sleep, bowel toxicity, inflammation and pain, blood glucose, blood lipids, diet, blood pressure and weight status. Based on the sum of score obtained in each of this components, each participant was classified as Low risk (score=-88 to 100; RR<1), Moderate risk (Score= 101 to 220; RR= 1-3), High risk (Score= 221 to 350; RR= 3-5), Very high risk (Score >=351; RR>5). Data thus collected was coded and analyzed using SPSS (v. 16.0).

Findings:

General Information: Table 1 represents general information of participants. Most of the hotel employees were males (84.6%) and belonged to the age group of 30-40 years of age. About of 76.9% of the participants were Hindus followed by 19.2% Christians and remaining (3.8%) were Muslims. Most of the participants were married (92%).

Medical History: None of the participants had a history of CVD or diabetes. About 7.7% of participants' mothers history of cardiovascular disorders followed by 11.5% of fathers who has history of cardiovascular disorders. About 15.4% of the participants had history of type 2 diabetes mellitus among both parents.

Lifestyle Habits: It is recommended to undertake moderate intensity activity for at least 5-6 days per week. Only 11.5% of the participants were involved in exercise as per the standard recommendations. About 34.6% were involved in moderate intensity activity but the frequency of performing exercise was less than 3 times per week. About 30.8% were sedentary activity. This pilot study revealed that most of the subjects were involved in moderate exercise but the frequency per week was less for most of the participants. Physical activity level as recorded as calculated using their activities and the corresponding mets indicates that most of them fall under sedentary or light activity (78.3%) followed by 15.4% of the participants who were moderately active and only 3.8% who were vigorously active. About 42.3% had adequate sleep of 7-8 hours however 15.4% of them snored during sleep.

Majority of the participants (84.6%) never smoked whereas the remaining participants (15.4%) smoked less than 20 cigarettes a day. About 19.2% were exposed to passive smoking which is equally considered to be dangerous as first hand smoke.

Most of the participants (57.7%) never consumed alcoholwhile 23.1% consumed 1 drink daily followed by 7.7% who consumed about 2 drinks per day and about 11.5% who consumed more than 3 drinks per day.

Bowel Toxicity: About 15.4% of the participants complained of bowel related symptoms like lower abdominal pain, bloating, constipation, diarrhea, foul smelling stools etc. Only 3.8% of participants were on oral contraceptives pill for more than 6 months in the last one year. Similarly, only 7.6% of the participants consumed antibiotics for more than 2 weeks.

Inflammation and Pain: Only 7.7% of participants reported signs of inflammation like wheezing, sneezing whereas 3.8% complained of heart palpitations or headache after consuming certain foods.

Blood Sugar: About 11.5% of the participants were diabetics of which only 3.8% reported signs of hypoglycemia like energy level dropping, craving for sweets or chocolates or experience headache or lack of concentration that is relieved by eating.

Biochemical Assessment: Lipid profile, blood glucose level was assessed. About 50% of the participants showed low HDL level whereas, 80.8% showed high LDL, 69.2% showed elevated serum cholesterol level and all participants had a high triglycerides.

Cardiovascular Disorders Risk Assessment

Table 1 Cardiovascular risk assessment of Hotel employees

Modifiable risk factors	Priority based on the score	Percent
Cardiovascular History	Low priority (0-30)	96.2
	High priority (51 and above)	3.8
Lifestyle	Low priority (-35 to -10)	30.8
	Medium priority (-9 to 21)	46.2
	High priority (22 and above)	23.1
Stress	Low priority (-19 to 20)	100.0
Sleep	Low priority (0-5)	69.2
	Medium priority (6 -11)	19.2
	High priority (12 and above)	11.5
Bowel Toxicity	Low priority (0-3)	76.9
	Medium priority (4 -9)	19.2
	High priority (10 and above)	3.8
Blood sugar	Low priority (0-19)	46.2
	Medium priority (20-49)	34.6
	High priority (50 and above)	19.2
Inflammation and Pain	Low priority (0-19)	96.2
	Medium priority (20-42)	3.8
Diet	Low priority (-19 to 6)	92.3
	Medium priority (7 to 13)	7.7
Lipids	Low priority (-15 to 9)	7.7
	Medium priority (10 to 34)	38.5
	High priority (35 and above)	53.8
Blood Pressure	Low priority (0-9)	42.3
	Medium priority (10-29)	26.9
	High priority (30 and above)	30.8
Weight Management	Low priority (0-11)	69.2
	Medium priority (12-25)	7.7
	High priority (26 and above)	23.1
CVD Risk	Low risk (score=-88 to 100; RR<1)	30.8
	Moderate risk (Score= 101 to 220; RR= 1-3)	50.0
	High risk (Score= 221 to 350; RR= 3-5)	15.4
	Very high risk (Score >=351; RR>5)	3.8

Data pertaining to cardiovascular history, lifestyle, stress, sleep, bowel toxicity, blood sugar, inflammation and pain, diet, blood lipids, blood pressure and anthropometric measurements were scored and classified to prioritize based on risk of cardiovascular disorders (Table 1). These findings showed 50% of the participants in the moderate risk, 15.4% high risk, 3.8% very high risk and about 30.8% were classified under low risk of CVD.

Gender wise comparison of CVD riskclearly indicated that females had either low (25%) or moderate risk (75%) of CVD whereas among the males, the CVD risk was distributed across the risk classification with a highest percentage showing moderate risk (45.5%) followed by 31.8% with low risk, 18.2% with high risk and 4.5% with very high risk of CVD.

Discussion

It is evident from the result that personal history or family history is not a risk for hotel employees in South Canara. Family history has been studied for many years as an independent risk factor for CVD risk and mortality[9]. Very few participants performed exercised as per recommendations. American College of Sports Medicine and the Centers for Disease Control and Prevention recommends 30 minutes of moderate intensity activity for atleast 5 days in a week or 20 minutes of vigorous intensity activity for atleast 3 days in a week. Sedentary lifestyle or not performing exercise besides the regular routine is considered as a major risk factor for chronic diseases like heart disease[10].

The study clearly showed that although most of them never smoked, they were exposed to passive smoking. Passive smoking negatively affects the coronary circulation causing increased risk of endothelial dysfunction among healthy non-smokers[11] and also precipitates acute manifestations of CVD[12]. Alcohol is yet another risk factor that has been reported to cause mortality. Among the participants who consume alcohol, only a few had the habit of binging. Although, moderate consumption of wine and beer has cardio-protective effects on both CVD patients and healthy people, binge drinking can cause increased morbidity and mortality[13].

Some of the participants had gastrointestinal symptoms indicating dysbiosis. Dysbiosis is a change in gut microbiota which has been speculated to play a role in cardiovascular health[14]. Consuming antibiotics over a long period of time affects gut microbiota[15] thereby increasing risk of CVD[6]. Inflammation increases WBC count which is an independent predictor of CVD risk[16]. A small number participants reported signs of inflammation like wheezing, sneezing etc. An elevated triglycerides, LDL and a low HDL poses an increased risk of CVD[17].

Most of the participants in low priority for cardiovascular history, stress, sleep, bowel toxicity, blood sugar, inflammation and pain, dietary habits, blood pressure and weight. Most of the participants did not have either personal history or family history of CVD and diabetes. Disturbed sleep is a common symptom that is associated with stress. Since most of the participants were not affected by stress, sleep was also not affected. The main focus of treatment has to focus on abnormal lipid levels and weight status. Abnormal weight status is a risk factor for CVD related death[18].

Majority of the participants were falling in moderate to high risk attributed to abnormal blood glucose, lipid profile, obesity and blood pressure. The study also highlighted a higher risk of CVD among male as compared to females. This risk can be attributed to difference in physical activity, stress, sleep, diet pattern, blood glucose and lipid abnormalities between the gender.

Conclusion

Most of the hotel employees are young adults and also they had a low family history of CVD. The risk of CVD due to these non-modifiable risk factors is not influential.The most common risk factors identified were abnormal blood sugar levels, lipid profile, high blood pressure, high waist circumference and lifestyle habits like smoking and alcohol consumption.Over 69% had moderate to high risk of CVD due to the above mentioned risk factors. The intervention strategies should focus on these modifiable risk factors with an aim to reduce risk CVD risk. A good diet and lifestyle management can modify these risk factors and reduce risk of CVD among hotel employees.

To conclude in general, a research base specific to hotel employees in India is essential to assist employees at all levels to become aware of the risks associated as well as provide basic training to employees periodically. Seek treatment interventions by association with primary health care centers for additional training in the management of CVD. We may need more resources and facilities to tackle the health risks associated with CVD

due to the socio-economic differentials through capacity building and awareness programs and involvement of all stakeholders.

Comparative Evaluation of Depth of Cure of Bulk: Fill Composite Resin and Alkasite Restorative Material by Vicker's Hardness Test

Gowrish Bhat[1], Namrata Khanna[2], Mithra Nidarsh Hegde[3], Vandana Sadananda[4]

[1]Reader, Department of Conservative Dentistry and Endodontics, AB Shetty Memorial Institute of Dental Sciences, Mangaluru, Karnataka, India, [2]Post graduate student, [3]Professor Head of Department, [4]Lecturer, Department.

Abstract

Background: This study evaluates depth of cure (hardness ratio) of a bulk-fill resin composite and an alkasite material in self cure and dual cure mode and compares and evaluates the Vicker's hardness and depth of cure of a bulk-fill resin composite and an alkasite material in self cure and dual cure mode.

Materials and Method: A dual-cure alkasite material and a bulk-fill composite resin were divided into three parts: Group A- bulk-fill resin composite, Group B- self-cured alkasite material and Group C- light-cured alkasite material. The samples were prepared in a stainless steel split mould of 6mm height and 4mm diameter. Vicker's hardness testing was performed to evaluate depth of cure of 4mm at three levels of 0mm, 2mm and 4mm.

Results: The statistics were analyzed using SPSS Software and One- way ANOVA and Post Hoc tests. The data obtained revealed that Cention N showed the greatest depth of cure in dual cure mode.

Conclusion: Most dual cure restorative materials exhibit better strength post light-curing compared to only the self-cure mode.

Keywords: *alkasite, bulk-fill resin, composite, depth of cure, Vicker's hardness*

Introduction

The rationale of this study was to compare and evaluate the claimed depth of cure of 4mm of bulk-fill restorative materials; an alkasite cement cured by itself and dually, with a bulk-fill composite resin.

Resin based composites require isolation, necessary steps for enamel and dentin etching, priming, and bonding, and the gold standard thickness of each increment of 2 mm. However, deeper preparations with 2-mm increments are time consuming and relatively technique sensitive. The validation for this incremental technique is to warrant the penetration of the curing light deeply enough to initiate and complete the curing of the resin, apart from reducing the shrinkage and shrinkage-induced stress associated with polymerization of resin based composites. Recently, the introduction of resin-based bulk-fill composites claim to fill cavities up to 4–6 mm immediately.

Dental bulk-fill resins are increasing in demand, but the clinicians doubt that the in-depth cure may be insufficient. An alternative is possible through newer dual-cured resin based composites that not only save critical clinical time but also provide bioactive properties. Apart from new photo-initiators[1], the given

techniques improve the depth in light-cured bulk-fill resin based composites by reducing the filler–matrix interface by enlarging the filler size[2] and decreasing the amount of pigments. Apart from fast curing and sufficient strength in large increments, modern bulk-fill resin based composites also necessitate the need for an additional feature to make it more acceptable, namely, bioactivity or self-adhesiveness.[3]

The increasing demand for a quick restorative procedure with light-cured, bulk-fill composites raises a doubt whether an adequate depth of cure will be achieved.[4] This factor, along with the trial to offer an aesthetic, basic filling material has proved to be the motivation for the launch of several dual-cure resin based composites in the market, that are also appropriate for a bulk-filling procedure. The bulk fill resin materials also concentrate on bioactive properties that intend to prevent tooth demineralization by releasing acid-neutralizing ions and aid in remineralization. For this sole purpose, one method implemented the addition of alkaline fillers in a methacrylate resin matrix, by introducing a new material category—the alkasites.[5]

Dual-curing resin based composites consists of mixing two components together, each of which, consists of a different initiator system. Currently, dual-cure resin based composites have been mainly used in modern dentistry for core build-up and cementation. However, it needed to be confirmed whether the self-curing polymerization reaction was enough not only in case of impeded light transmittance, but also in the absence of light. On comparing the features of resin based bulk fill composites that were either self-cured or dual-cured, it was found that the impact of light irradiation depended on the final material ranging from no- impact to high-impact.[6] Hence, the concluding factor for a newer dual-cured alkasite cement, apart from its caries preventive ability, is the duration it takes to set, the adequacy of its mechanical properties and early strength, the degree of conversion in depth, and the impact on the properties of the final material with additional light-curing.

The polymerization that is light-initiated facilitates the curing of a material on demand, whereas the polymerization procedure through a redox activation occurs slowly in comparison and may not be conducive enough for a quick restorative procedure that is generally required in modern clinics. The time required to set the material in question should be calculated and adjusted to the required time of a regular clinical treatment, even in the absence of light. Furthermore, the higher refractive index of alkaline fillers when compared to regular silicate glass fillers may alter the filler/resin refractive index match that is crucial for better light transmission for optimum depth. The result would be a more dense material that is able to camouflage the oral cavity or the tooth's structural discolorations effectively rather than the one obtained through several translucent, light-cured, bulk-fill resin based composites.

Materials and Methodology: A dual-cure alkasite material (Cention-N, Ivoclar Vivadent AG, Schaan, Liechtenstein) and a bulk-fill composite resin (Filtek^{TM} Bulk-Fill Posterior Restorative material, 3M^{TM} ESPE, St. Paul, USA) were selected for the study.

The materials were divided into three parts: Group A - bulk-fill resin composite, Group B - self-cured alkasite material and Group C - light-cured alkasite material.

A stainless steel split mold of height 6mm and diameter 4mm was used to prepare 10 Samples from each group.

Group A (Cention N – Self Cure): Powder and liquid was dispensed onto a paper pad in the ratio of about 4.6:1, mixed for about 45-60s and condensed into the mold. They were retrieved after 5 minutes of setting time.

Group B (Filtek Bulk-Fill): The samples were condensed into the mold and cured for 20 seconds with blue LED Light Source.

Group C (Cention N – Dual Cure): The powder and liquid was mixed and the cement loaded into the mold to be cured. The samples were cured for 20 seconds with blue LED Light Source (Kerr Demi^{TM} Ultra Ultracapacitor- 1200 mW/cm^2) and were retrieved immediately after the curing cycle was complete. The samples were all thermocycled (Thermocycler SD Mechatronik, GmbH Dental Research Equipment, Germany) for 5,000 cycles at 5°C and 55°C (dwelling time: cold bath, 30 seconds; hot bath, 30 seconds)

The Depth of cure was measured by Vicker's Hardness Testing Machine (MMT- X7A, Matsuzawa Co., Ltd., Japan).

Results

The statistics were analyzed using SPSS Software

16.0. One- way ANOVA statistical tests were done to compare the three groups and on achieving statistically significant results, Post Hoc test was done.

The results obtained (Table I): showed that Group C (Cention N- Dual Cure) had manifested the most coveted results in comparison to the other two groups. Group C showed best results at all three levels of 0mm, 2mm and 4mm.

Group C had the highest VHN value of 65.08 followed by Group B at 54.63 and lastly group C, at 43.87 and the surface layer of 0mm. Even at the claimed depth of 4 mm, Group C did better with the VHN value of 49.86.

Table 1: Vicker's Hardness Numbers of Group A, B, C at 0, 2 and 4 mm.

Group	Depth	Sample Size (n)	Mean	Standard Deviation
Group A – Cention N - Self Cure				
	0 mm	10	43.87	0.881
	2 mm	10	39.94	0.910
	4 mm	10	32.45	0.820
Group B – Filtek Bulk- Fill				
	0 mm	10	54.63	0.834
	2 mm	10	48.23	0.824
	4 mm	10	41.35	0.921
Group C – Cention N- Dual Cure				
	0 mm	10	65.08	0.820
	2 mm	10	57.31	0.748
	4 mm	10	49.86	0.625
The mean difference is significant at $p<0.05$.				

Discussion:

Currently, bulk-fill resin based composite materials has gained popularity among practitioners owing to the comparative simplicity of the procedure.

Manufacturers, with the help of advanced technology, relate the modifications in the filler content and/or organic matrix as their claim in the main advancement of bulk-fill composite materials i.e, namely increased depth of cure, which probably results from higher translucency, and low polymerization shrinkage stress

Cention N contains an acyl phosphine oxide initiator (Norrish type1 initiator) which requires just one component for radical formation and the photoinitiator, Ivocerin. The presence of this leads to faster polymerization of the resin material and causes better conversion of the monomer to polymer which may have lead to the results developed in this study. Cention N also contains UDMA, DCP, and an aliphatic/aromatic UDMA; which has claimed faster cross-linking of the methacrylate monomers to a high polymer network density and may be responsible for the better depth of cure.[7]

A self-curing material with options for light-curing outlook is the substance of analysis. Although the initiation rate can be very high in the light-curing mode, its significant drawback maybe the fact that the saturation of light energy in depth is quite low. In order to improve this, the alkasite was modified and a redox activation containing a copper salt, a peroxide and a thiocarbamide was added in the powder component.[7]

The use of restorative and viscous composite resins has demonstrated that greater depth of cure up to 4 mm is more effective. [8, 9] It has been found that filler size and content in dental composites may reduce light penetration and this, in turn, has an effect on the depth of the cure.[10,11] The pigments present in shaded composite materials have a direct impact on the depth of cure since these are dense particles that hinder the penetration of light and decrease the degree of polymerization at greater depths while a cavity is being treated.[12]

Filtek Bulk-Fill claims to contain AFM (addition-fragmentation monomers) that react with the methacrylate to keep the physical features of the material intact. The kind of monomers being used have an effect on the Methacrylate composites as they have the ability to shrink in varying degrees during polymerization. Filtek Bulk Fill Posterior Restorative consists of two new methacrylate monomers; their properties have served as a catalyst to gain lower polymerization stress that is necessary for better results.

Filtek bulk fill (bulk fill viscous composite) has shown a higher degree of conversion than the conventional viscous composite. Probably the reduced filler volume fraction is convenient compared to the less viscous conventional composite.[13] The composition of 4 high molecular weight monomers, viz. Bis-GMA, Bis-EMA, UDMA and procrylate in Filtek bulk fill facilitates a higher conversion and Depth of cure . Filtek bulk fill flow composites contain a proprietary monomer equivalent to Bis-GMA and patented as Procrylat

resin.[14] Procrylat is a high molecular weight monomer with low viscosity similar to Bis-GMA but with a lower viscosity, the lack of pendant hydroxyl groups is the only difference between Bis-GMA and Procrylate.[15]

The decreased hydrogen bonding potential is due to the lack of hydroxyl group which reduces the viscosity of the monomer. Also Bis-EMA and UDMA are high molecular weight monomers with low viscosity so the manufacturers adjust the proportions of the 4 high molecular monomers to decrease viscosity and create hard cross link network.[16]

The monomer aromatic dimethacrylate (AUDMA) with a high molecular weight is responsible for reducing the number of reactive groups in the resin. Polymerization stress is caused mainly due to two factors – the shrinkage in the volume and the stiffness in the developing and final polymer matrix. However, AUDMA is capable of combating both these factors.

Another distinctive methacrylate characterizes a class of compounds called addition-fragmentation monomers (AFM). The AFM reacts like any other methacrylate by forming cross-links between the adjacent polymer chains during the process of polymerization. The third reactive site of the AFM splits into fragments during polymerization. This process provides a technique to relax the developing network that results in greater relief from the stress caused. The fragments, however, still preserve the feature that can not only allow them to react with each other but also with other reactive sites of the developing polymer. Thus the physical features of the polymer are retained along with relief from stress.

Conclusion:

Under the limitations of this study, Cention N showed best depth of cure when tested by the Vicker's Hardness Test in dual cure mode. Filtek bulk fill also showed coveted results while maintaining a desirable depth of cure. In self-cure mode, Cention N may not achieve enough curing and we recommend that the alkasite material be used along with light curing protocols.

Abstract

Context: The recent lifestyles of youngstershas changed in such a way that, it led to an impact on their dietary patterns. Nowadays youngsters prefer to go for the food which is available in fast food outlets, although these foods are high in caloric content, sugar, salt and fat some of which will also laden with preservatives, there is a great demand for this foods and the expansion of multinational fast foods are the evidence for its growth. The health implication starts with overweight and hypertension which will reduce the life span. Foods prepared at fast food outlets will be at extreme heat to complete the cooking process. Fast foods have become a prominent feature of the diet among youngsters and the main reason is fast food outlets deliver food quickly which is convenient to lifestyle in metro cities and also in developing countries. A balanced and nutritional diet is required to have a healthy life and it is a responsibility of fast food outlets to full fill the dietary requirements of consumers. The objective of the paper is to highlight the health implications on consuming food and beverages with high calorific value, inadequate cooking, food laden with colorings and additives.

Keywords: *Fast Foods, Food contamination, Inadequate cooking, Food Additives, Health implications.*

Introduction:

The fast food outlets in Chennai have been grown to the max in the recent trend that is because of the people lifestyle with the convenience on receiving food. The foods that are prepared from fast foods outlets will consist high nutritional value with high calories, sugar and fat, and it will lead to various health implications. Consuming food at fast food outlets leads to cardio metabolic disorders and this is considered as a global health issue in recent trend[1].Fast food has strong association with the development of type2 diabetes and cardiovascular morbidity and mortality in adults [2]. Thereare too much of calories found in foods like Fats, salt and sugar, hasinsufficient vitamins, minerals, and protein. Food is a basic need for survival and that has to be in proper ratio according to age and type of work to have a better health, irregular balance in food consumption will leads to bad nutritional value and that will spoil the proper functioning of the body to regulate[3]. In recent trendsnacks such as pizza, burgers, tacos, Fried chicken Club sandwiches, and instant noodles; in additionkebabs fall under the fast food category.Fast food has strong association with the development of type2 diabetes and cardiovascular morbidity and mortality in adults. Food is a basic requirement for human survival;it helps in living healthy. Food and beverageis a basic commodity which fills stomach with satisfaction and makes us happy and emotionally satisfies with taste.Especially after the globalizationfast food outlets has gowned faster in cities, especially in Chennai. The foods which are deep fried have high calories because it fully cooked in fat such as vanaspathi, coconut oil, and ghee, some of the foods have already laden with more calories, Mutton & Chicken kebabs, Kentucky French Chicken, Crumb fried

chicken, Nuggets and croquette are the ultimate sources of unsaturated fatty acids, increasing hypertension, and it leads to blocking arteries on the arterial walls of the heart [4]. Because mainly these foods are fried in full of fat with intense heat due to which there is a substance produced carcinogen acts as a cancer causing agent. In addition it is being served with Acrylamide substance that damages the nervous system; they are also laden with sodium that increases the risk of hypertension and heart diseases. Mutton kebabs, samosas and Patties, from food outlets contain high amounts of unsaturated fatty acids. Foods prepared from margarines, cheese spreads, and frying oils to preserve the food for longer duration will become unhealthy [5].Consuming high calorie foods causing health implications, Fast food outlets are using some additives and colourings which are harmful to health. Fast food items are tastier, but the effects on the health are detrimental[6].

Noodles are most commonly consumed in western countries and it is prepared from unleavened dough. However in today's trend the instant noodles are easy to prepare and it is easy to cook and serve [7], by added preservatives with the addition of certain sodium additives, due to high carbohydrates and sodium it is detrimental to health, as well as it is not containing required proteins, fibre, vitamins. Noodles are coated with wax kind of substances like Propylene glycol and added with MSG (monosodium glutamate) which is not advised for regular consumption[8], It has harmful effects like hypertension, cancer and harmful to health. Foods prepared with preservatives the main reason is to avoid the formation of bacteria in longer storage, The action of preservatives not only preventing the food from spoilage as well as they also can prevent you from pleasure of healthy life[9]. The main effects of food preservatives on the body will be in various degrees with type of preservative added with the food and it also have changes with age and health of a person. The major effects of preservatives are breathing difficulties reducing the preservatives from diet will have relief from diseases like asthma and the another effect will be the behavioural changes in recent years most of the foods contains preservatives and it mainly affects the young generation like children's are becoming more hyperactive the major cause is consumption of foods with preservatives and additives[10]. Preservatives are also containing a substance called carcinogens which has harmful effects when it gets digested it leads to cancer. The rural areas produced foods recipes have both nutritional and medicinal values[11]. Food habit in Chennai among students and youngsters had a tremendous change in the past two decades the most preferred foods are from fast food outlets which have high calorific value, salt and sugar content[12]. In spite of great attention in gathering nutritional needs for daily consumption in order to attain good healthy life style, most of the youngsters are not particular about their food and disregard with their healthy food[13].

Materials and Method

The quantitative and qualitative method of Statistical analysis is carried out by collecting the data's for this research. A total of 140 questionnaires were distributed randomly among the consumers of fast food in Chennai, out of which only 125 were completed and used for analysis. This study was carried out from June 2018 to August 2019 at fast food outlets in Chennai. The Statistical Package for Social Sciences (SPSS 24 version) is used for data analysis and the data comparisons was conducted after the collection of data's from youngsters, who consume food at fast foods in Chennai. Secondary Data has been collected by literature survey.

Results & Discussions

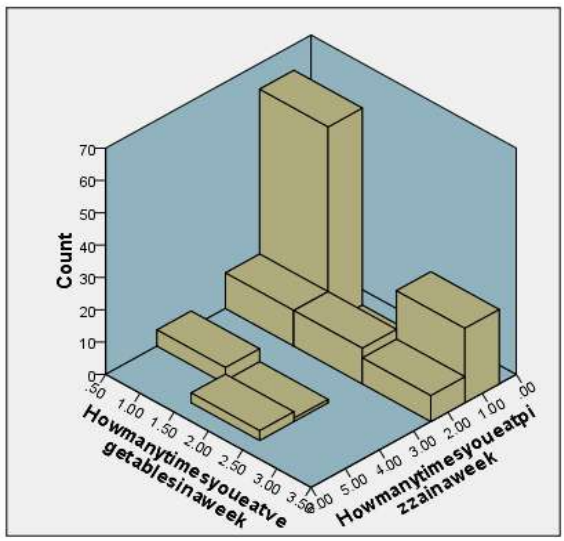

Figure 1: Comparison on consumption of Vegetables with Pizza in a week

In Figure 1: It shows the association in consumption of pizza with vegetables, the results having the value 1 shows as 1 to 2 times consumption in a week, value 2 for more than three times and 3 denotes daily consumption, at this juncture youngsters shows their

interest on consumption of pizza minimum twice in a week comparatively similar with the consumption of vegetables. As well as some of the consumers are aware with health implication on consuming pizza thereby consumption is reduced to twice in a month with the value 4 and also by value 5 indicates that youngsters stopped consuming pizza. The majority is similar for pizza and vegetables with by value 1 twice in a week and the daily consumption of vegetables with the value 3 has an elevation, shows the awareness of health between the consumers.

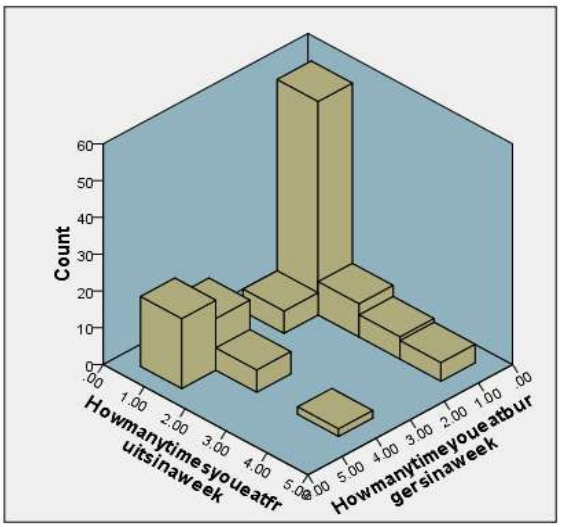

Figure 2: Comparison on consumption of Fruits with Burgers in a week

The Figure 2: Illustrates the comparison between the consumption of burgers with fruits among youngsters in a week, with the value 1 indicating once or twice, 2 for more than three times and 3 stands for daily consumption. Here the results are similar as in the case of consumption of pizza and vegetables, the majority shows once or twice for consumption of fruits and burger in a week and simultaneously only few have habits of consuming fruits in daily basis also it denotes even after knowing the health implications youngsters are addicted to fast foods.

The food choices depend on the age especially youngster's shows higher interest in consuming foods from fast food outlets, thecorrelation study between nature of job and food habits are showing the majority youngsters preferring fast food outlets is significant with Pearson correlation coefficient, *r*, .261 for fried chicken and wish to be regular for consuming pizza with the statistically significant (r = -084) thisvalue shows that youngster from heart of the city is mostly addicted with fast foods by having P-value =.003,shows that youngsters are frequently consuming fried chicken.

The consumption of pizza shows relatively in high frequency with the p-value .350 as it is one of the most popular Italian foods around the globe and the comparison between consumption of vegetables and pizza shows the majority of the consume pizza regularly than vegetables simultaneously many youngsters not consuming fruits regularly by having lesser ratio of consumption in Chennai from more than two decades it is considered as an easily available food[14]. The pizza is loaded with cheese, sauce and also with meat will not get easily digested, due to high calories with fats and other mineral leads to acidity[15]. The basic topping for the pizzas are tomato sauce and it will not go with people who have acidity complaints because tomatoes have high acidic content. The Main reason for acidity is due to people tends to eat more number of pizzas, by substituting their normal diet with pizza like the consumption of sweet has coefficient r = .0005 with p-value .955. However there are various views related with the consumption of pizza in daily life like the ingredients added shows it is a healthy food with so many herbs and vegetables meat and milk products, especially when it is baked with the dietary needs. The stunning taste of pizza makes people to feel why to stop eating it. The major reason is it is heavily added with sodium and carbohydrates; cheese that has high calorie counts a cause of hypertension[16], cardiovascular disease and obesity.Consuming pizza regularly will lead to poor health, results in health implications.

The consumption of burger among youngsters are in regular basis may become detrimental to health the majority of youngsters are consuming burgers with coefficient r = -.121 with p-value .178. The Burgers are mostly rich in dietary cholesterol. It will raise levels of cholesterol in your blood and that leads to hypertension and it became a harbinger for heart disease, this study also show that the consumption of meat also frequent for the consumers who consume burgers with the coefficient r= .363** with a p-value .000 shows a greater significance, furthermore a double hamburger contains 25.2 grams of saturated fat, and ***193*** milligrams of cholesterol that increases the percent of the daily calorific value in diet. By consuming a single-patty stuffed with a burger you can reduce 3.5 grams of saturated fat and 26 milligrams of cholesterol. Generally burgers are with the blend of mayonnaise, meat, cheese, patty and deep fried bacon

added with sauces rich in sugar and sodium, and they tend to raise the cholesterol and sodium levels. So burgers are considered as one of the worst junk foods with more than 1000 calories in each serving which can be raised or reduced according to the preference of a consumer.

The correlation between consumption of sweets and pizza shows the results coefficient r= .005 with a p-value .955 has a higher significance on consumption of Junk food and a most favourite sweet dish of youngsters like Donuts; it is mostly sprinkled or spayed with many colourful and delicious toppings like chocolate, jam and appetizing sugar Candies, due to blending of these ingredients along with the unsaturated oils, sugar and dough fried in intense heat, when fried they release harmful cancer causing substance carcinogens and the unsaturated fatty acids causing harmful effects on the body and the consumption of meat and sweets also has the value (r=-.047) with a p-value .600 shows the significance of consumers. The frequent consumption of these foods will elevate the sugar and cholesterol levels.

Conclusion

This study reveals the food habits among youngsters are mostly related with consumption of foods like pizza, burgers and deep fried meat from fast food outlets[15, 16]. Hence awareness to the fast foods consumer is required and the fast food outlets should have alternatives on their food which have proper nutritional values and without preservatives, food colouring, and food additives. In addition medical practitioners need to know about that these kinds of eating habits are the cause of major diseases which are generally affecting the people in Chennai. The fast food outlets and food handlers should focus on hygiene standards and the nutritional value of the food which in turn help the community to grow with health. Food safety education is essential for food handlers and consumers as poor food habits result in food related diseases.The findings suggest that in modern business trend, it is difficult to stop the foods which are available from the market easily but consumers can opt for the foods which have good nutritional value, pastries are made out of rich milk cream and it is delicious when it is combined with sponge cake, and cake is one of the perfect choices for desserts[10]. Yet, an enticing piece of cake contains sugar and fat combined with all-purposeflour rich in carbohydrates that contain high calories causing high blood glucose levels in the body. Likewise the fresh cream is topped on sponge cake added with chocolate, flavouring essence and some colouring agents are having harmful effects on health when it is frequently consumed.

Study to Evaluate Prevalence, Knowledge and Awareness of Needle Stick Injury among Dental and Nursing: Under Graduate Students

Harshada Zagade[1], Kumar Nilesh[2], Tukaram Zagade[3], Aaditee V. Vande[4]

[1]PG Student, SDS, KIMSDU, Karad, [2]Prof, Dept. of Oral and Maxillofacial Surgery; SDS; Krishna KIMSDU; Karad, [3]Prof, KINS, KIMSDU, Karad, [4]PG Student, SDS, KIMSDU, Karad.

Abstract

Introduction: Blood borne pathogens such as Human Immunodeficiency Virus, Hepatitis B and C viruses are commonly transmitted through needle stick injuries (NSI). Health care workers are the most commonly affected group of people. This study was conducted to test the prevalence, knowledge and awareness among the Dental and Nursing students.

Material and Method: Cross sectional study was done among dental and nursing students. Data was collected through questionnaire and analyzed. Total 410 students participated in the survey, (160 Dental students and 250 Nursing) students.

Results: The nursing students were affected frequently by NSI compared to dental students. 82.76% nursing students while only 22.23% dental students reported the incidence of NSI to the institutional health care department.

Conclusion: The prevalence of NSI was higher in nursing students compared to dental students. Both dental and nursing students lacked the knowledge and awareness about the NSI reporting. Reinforcement of the importance of reporting NSI, knowledge about the management of the same, following the guidelines of universal precautions and proper biomedical waste disposal method especially of the sharps and needles through formulated training programs designed for students would considerably reduce the risk of NSI and transmission of infection.

Keywords: *Occupational, hazard, risk, Infection, transmission*

Introduction

The national institute of occupational safety and health, USA, defines NSIs as those caused by needles such as hypodermic needles, blood collection needles, intravenous stylets and needles used to connect parts of intravenous drug delivery system. [1] Health workers including doctors, nurses, technicians, assistants and trainees are susceptible to the injuries inflicted by contaminated needles/sharp objects. Serious blood borne pathogens, such as human immune deficiency virus (HIV), hepatitis B virus (HBV), and hepatitis C virus (HCV) can be transmitted from these injuries. [2-4]

According to the WHO, 16000 HCV, 66000 HBV and 1000 cases of HIV may have occurred worldwide in the year 2000 among health care workers through their exposure to NSIs.[5,6] NSIs mostly occur during disposal of used needles (23.7%), during administration of parental injection or infusion therapy (21.2%), drawing blood (16.5%), re-capping needles after use (12%) and handling linen or trash containing uncapped

e-mail Id: drkumarnilesh@yahoo.com

needles (16.1%).[7] The annual occupational risk of HIV transmission was estimated at 0.27% for health workers. Among surgeons, the risk was 0.7% (more than twice as high) if no special protective measures were taken.[8] The risk of exposure to occupational hazards is expected to be higher for un-experienced individuals, working in a new environment, such as dental and nursing students during their clinical training. The objective of this study was to assess prevalence, knowledge and awareness of NSIs among the undergraduate dental and nursing students at a tertiary care hospital.

Materials and Method

A cross-sectional questionnaire based survey was conducted among dental and nursing students, after the due approval of institutional ethical committee. Keeping in mind that trainees who are exposed to the clinical work will be prone for NSIs, only third and final year students and Interns (B.D.S.) in faculty of dentistry and second, third and final year (B.Sc.) nursing students were included in the study. A self-administered questionnaire was given to the participants, which included questions designed to evaluate prevalence and assess knowledge and awareness about NSIs among the students. The questionnaire included general information about the needle stick injury, method of disposal of sharps and possible risk of diseases due to improper handling and disposal. Those who volunteered to participate in the survey were asked to read the instructions carefully and respond truly to the questions.

Results

Total of 410 participants, including 160 dental and 250 nursing students completed the questionnaire. The incidence of reported NSI was 18.53% (n=76). Nursing students (23.2%) were almost twice as affected as compared to the dental students (11.25%), which was statistically significant (p=0.0036).(table 1) Although the respondents were well aware of the protocol of reporting NSIs, out of 76 exposures, 24 (31.57%) were not reported. Number of dental students not reporting NSIs was 14 (77.77%), which was much higher as compared to nursing students (n=10, 17.24%).(table 2)

All the dental students participating in the study had knowledge of universal precautions and reportedly used gloves when examining or treating patients, whereas 4% (n=16) nursing students did not compulsorily use gloves while examining patient. 97.5% (n=156) dental students and 65.6% (n=164) nursing students practised recapping of needle after use. Most of the students used single handed method for re-capping the needle (89.7%,n=140) dental and 91.4% (n=150) nursing students).(table 3)

Our study shows poor knowledge among students regarding immediate management of NSIs. Only 18.75% dental and 20% of nursing students were aware of the correct method of using soap and water at the site of exposure after NSI. This correct answer received the lowest response (19.51%) which was extremely significant according to chi square test ($p<0.0001$; chi square value=35.104).(table 4) About 66.25% dental and 56.8 % nursing students had the knowledge about pathogens that can be transmitted through NSIs (which was statistically significant; $p<0.0001$ chi square value=59.667). (table 5) 62% were aware that the risk of transmission of HBV was maximum through NSIs. In this study 61.46% of the participants had taken the HBV vaccination out of which 20.83% dental students and 46.15% nursing students had tested for anti-HBs antibodies after hepatitis B vaccination. 94.63% of students were aware of need of bio-medical waste disposal to avoid accidental NSIs.

Table 1: NSI among students

	Dental	Nursing	Total
Affected	18 (11.25%)	58 (23.2%)	76 (18.53%)
Unaffected	142	192	334
Total	160	250	410

Tuberculosis	0	0
All of above	106 (66.25%)	142 (56.8%)
No response	0	12

Discussion:

WHO has estimated that the occupational exposure of health care workers to diseases such as hepatitis B and hepatitis C is 40%, while that of the HIV infections is 2.5%.[9] 90% of the occupational exposure is reportedly due to NSI. The actual data regarding the NSI in India is insufficient.[10,11,12,13] The importance of occupational health and safety of trainees have been systemically ignored by the medical fraternity, with very limited research conducted in this field.[9,14-15] Trainees are at even greater risk due to their limited clinical experience and hence are known to be a high-risk subgroup.

Various studies have shown a low incidence of reporting of NSIs.[17-20] In a study of sharps injuries among health-care workers in Taiwan, Shiao et al. discovered that 87% of health-care workers sustained at least one NSI, but only 18% incidents were reported.[21] The findings of our study show that 11.25% dental students had NSI, out of which 22.23% was reported. Nursing students showed higher incidence of NSIs, out of which 82.76% cases were reported. Inexperience is possibly an important factor that contributes to high incidence of NSI among trainees/students. The possibility of high risk of NSI among students may also be attributed to increased stress, resulting in anxiety.[22,23]. The incidence of NSI was almost double in nursing students as compared to dental trainees. The likely reason of the same may be greater amount of exposure of nursing students to hospital and ward setup.

In the present analysis 57.5% of the dental students and 84.8% of nursing students were aware of the standard precaution and post exposure prophylaxis guideline. 97.5% dental students had the habit of recapping the needle and 89.74% used the single handed technique. While among the nursing students 65.6% had the habit of recapping the needle and out of them 91.46% used single hand method. The overall result shows that as a technique for safe needle recapping, 70.73% followed the single handed technique while the 26.82% followed double handed technique. Several studies have shown recapping to be an important cause of NSI.[24-27] All training programs emphasize that recapping of needles after use is not to be done and if it is to be done then use single handed technique has to be followed.[28,29] Double handed recapping of needle between the procedures is considered extremely hazardous, with much higher risk of NSI. Present recommendation for recapping needle is to use: single handed scoop method or using needle capping device.[30]

The average risk of HIV infection after a needle stick or direct mucosal cut exposure to HIV-infected blood is 0.3%.[31] The health worker vaccinated against Hepatitis C has lower risk of transmission (0-3 %), as compared to hepatitis B, that is stated as 7-30%. Risk of transmission of hepatitis B infections are more likely and commonest after NSIs.[32] In our study knowledge among dental and nursing students about the pathogens that can be transmitted by needle-stick injury was inadequate. A similar study to evaluate the prevalence and nature of needle stick injuries among nursing students showed that although all the participants were aware of the fact that hepatitis B and C can be transmitted by NSI, over 20% were not aware that infections other than hepatitis B & C can also be transmitted by needle-stick injuries.[33]

As the risk of transmission of hepatitis B is most common with NSI, vaccination against it is highly desirable among the health care professionals. Vaccination regimen followed for the hepatitis B is three-dose regimen where second dose is taken after 1 month followed by third dose after 6 months. Minimum time interval between 1st dose and 2nd dose is 4 weeks, and between 2nd and 3rd dose is 8 weeks.[34,35] In the present study 60% of dental students and 62.4% nursing students were vaccinated against Hepatitis B. A need for strict implementation of vaccination programme for the vulnerable population including the nursing and dental trainees can significantly lower the risk of transmission of infections due to NSI.

For prevention of the sharps injuries it is an important to practice proper bio-medical waste disposal method. Needles and sharps from the hospital waste should be disposed properly and care must be taken while handling them. The handlers must use protective ware including hand gloves and eye glasses.[36] In our study 93.75% dental students and 91.53% nursing students were aware of the proper biomedical waste disposal method and the fact that improper disposal method can cause infection due to sharps/needles and blades. It is recommended to use needle cutters before disposing of injection equipment and the use of sharp boxes which has to be replaced when two- third full.[37] These practices can definitely reduce the chance of sharps injuries to the bio-medical waste handlers, health care providers including the trainees. Reinforcement of the importance of reporting NSI, knowledge of prompt management of the same, adherence to guidelines of universal precautions and proper waste disposal method through formulated training programs designed for medical, dental and nursing trainees/students would considerably reduce the risk of NSI and transmission of infection.

Conclusion

Effect of Mental Imagery Technique on Balance in Postmenopausal Women with Postural Disturbance: A Randomized Controlled Trial

Hulsha Paudyal[1], Suchetha P. S.[2], Dhanesh Kumar K.U.[3]

[1]Post Graduate Student, Nitte Institute of Physiotherapy, Nitte (Deemed to be University), Deralakatte, Mangalore, India, [2]Associate Professor, [3]Professor, and Principal

Abstract

Background: Decreased blood estrogen after menopause causes decreased the sensitivity of higher centers because of impaired postural control in postmenopausal women which can increase the risk of fall.

Objective: To find the effect of mental imagery technique on balance in postmenopausal women with postural disturbance.

Method/Design: 32 PMW who met the inclusion criteria were enrolled in the study. Subjects were allocated in two groups of 16 each into an experimental and control group. Berg balance scale and Balance error scoring system were taken before the start of the intervention and at the end of four weeks. According to the allocated group, BT was given to Group A and BT + MI to Group B thrice a week for four weeks.

Results: There was a significant improvement in Group B in BESS, with p-value <0.01. Comparison between the group indicates the individuals treated with a combination of BT with MI technique significantly improved better than those individual treated with BT alone. Comparison of the mean difference of BBS score between the two groups A and B was not statistically significant.

Conclusion: On comparing the mean difference of BEES it can be concluded that MT along with conventional BT is beneficial for postmenopausal women with postural disturbance when compared to conventional balance training alone.

Keywords: *Balance exercise, Post-menopause, Mental Imagery*

Introduction

Balance by the term is defined as the dynamic process where the body has the capability to maintain equilibrium.[1]Along with advance in age, the female reproductive system undergoes changes leading to menopause which is associated with balance issue. [2,3]

Menopause is the term used when a women experience last menstrual flow and it can be judged only retrospectively. **[4]** When there is stoppage in production of hormones by women's ovaries it causes cessation of menstrual periods and when there is no menstrual period for 12 months, it is known as menopause. [5]In India, the mean age of menopause in women is 46.02 years. **[6]** Risk of fall in PMW is due to loss of balance and increased body sway, so fall prevention management by focusing on exercises aiming to improve balance has to be routinely done. **[7]**

There are various treatment and techniques to treat balance and MI is one of them. [8,9]The illustrative practice of physical activity in the absence of any visible

muscular movements is known as MI. [10]

In PMW, estrogen decreases slowly in the blood which leads to decreased calcium absorption by the bone which reduces its density. Non-contractile collagen tissue, tendon attaches muscles to bone which helps in creating movement at the joint by transferring muscle force from the belly. In menopause even muscle mass decreases. So because of decreased muscle mass and bone density, there will be muscle weakness and osteoporosis. Which causes postural issues thereby affecting postural component of balance which leads to increased fall risk. Decreased blood estrogen causes decreased sensitivity of higher centers because of impaired postural control. As sensitivity by the cortex decreases the load on gaining feedback and information from associated structures of maintaining balance like the vestibular system and cerebellum increases. So this leads to a decrease in their threshold. [11,12,13] Which is permanently stored in memory so it will not be so easy to correct balance disorder until the central mechanism and peripheral structures are corrected. Studies have shown that balance is disturbed in PMW due to the reduction in estrogen hormone.[14,3] Various studies have shown that resistance training, aerobic exercises balance training with feedback are proved to be effective in maintaining the hormonal level in PMW.[15,16] MI which targets the central circuits proved to be effective in balance training in individuals with stroke and geriatric population. [9,17]

To best of our knowledge, there is dearth in the literature that effect of MI on balance in PMW hence in this study we are aiming to identify the problem and are trying to correct it by focussing on the periphery and moulding the central circuits. Thus purely concentrating on central and postural components of balance this will help the women who are in risk at initial stages.

Method

Participants: Current study was a prospective randomised clinical trial carried out in Tertiary Hospital of India between May 2018 to April 2019. Thirty-two healthy postmenopausal women subjects, recruited among women employees were recruited. After obtaining the ethical clearance from the Institutional Ethical Committee, the trial was registered in the Clinical Trial Registry of India (CTRI/2018/06/014493) and an informed consent was taken from the patients. Inclusion criteria were the following: 1) women between the age group of 45 - 64 years; 2)Having amenorrhoea > 12 months; 3) normal or corrected to normal vision; 4)Willing to participate in the study; 5) absence of neurological and orthopaedic disorders; 6) Balance disturbance BBS < or = 52.

Training Design: The participants were randomly assigned to 2 groups: BT (balance training) and BT + MI (Balance training with Mental Imagery). A computerized random list generator (random.org) provided the randomization list. All groups were trained for four weeks, three days per week. Outcome measure BBS[18] and BESS[19] were taken on the first day and after 12 sessions of intervention.

A total of 7 challenging balance exercises performed by participants, for example tandem walking, reach out, one leg standing, Raising the knee rapidly while standing, perturbation training (reactions), (anticipatory), standing on foam surface (see Fig. 1for examples), were used for BT group. Each single exercise lasted 5 min. BT with MI group underwent auditory screening prior to the session for hearing threshold limit check-up. Subjects who where able to hear within normal threshold limit were only taken in the study. After that subjects were given same balance exercises as BT group for 20 minutes and 10 minutes of MI with the help of auditory stimulus using head phone (SENNHEISER HD 206 and IPod shuffle).Considering balance exercises, and mental imagery, both group underwent sessions lasting 30 min. (figure 1 and 2)

Mental Imagery: Subject was asked to sit on a chair in a sound proof closed room and headphone for auditory stimulus (the hearing level 40dBHL). Listening to the auditory stimulus the subject imagined without any movement externally.

First Week: Walking

- Relax, sit comfortably with well back support and slowly close your eyes.
- Inhale deep breath and then gently exhale out the breath, Inhale and exhale deeply. Repeat inhale and exhale 2-3 times.
- Think about a safe and peaceful place, look at green plants outside and feel great climate, try to visualize a clear view.
- Now your eyes look relaxed, and your body is calm.
- Now its time for your muscles contraction
- Presume that you are on a chair and there is a

cooking area next room.

- Contract foot muscles then thigh muscles then lower leg and finally hip muscles.
- Now you have to stand and feel that your legs are trying to initiate a forward movement to go kitchen by lifting your one leg at a time, flexing your knee and hip.
- Attempt to imagine in slow motion the movement which you are performing by balancing yourself and stay relaxed like that till the end of the session. Good going
- You have to walk ahead with attention, feel that you are opening the shelf which is higher in the kitchen.
- Now you are not able to reach normally so you are trying to stand on your toes and balancing yourself to get the things from the shelves and finally you are able to get it.
- Now after getting it you kept it down on the kitchen slab.
- Relax and make yourself comfortable now you have to go to the previous room.
- Promptly we are getting to the previous surrounding of here, listen to the sonances around you. Accompany my count starting backwards 5 to 1, when I say 1 please open your eyes. 5...4,...3,...2,...1.

Mental Imagery practice was continued in increasing activity and complexity of tasks with the Corresponding weeks. [17]

The same training was performed with increasing level of exercise difficulty. The same physiotherapist, blinded to baseline assessment, trained subjects during the exercises.

Statistical Analysis: To compare BBS and BESS before and after the intervention within the group paired t-test was used. The between- group comparison was performed by using independent sample "t" test. The p-value < 0.05 was considered as significant. All data were analysed using the software SPSS 23.

Results

The groups were similar at baseline in terms of demographic variables (age and BMI). Moreover, no significant differences in balance performance were found between the group at T0 (see Table 1,2,3,4)

Comparison of mean difference of BBS score between group A and B was not statistically significant.

However, mean difference on BESS between group A and B was statistically significantly.

	BT	BT+MI	p- value
Sample(n)	16	16	-

Figure 1: Mental Imagery

Figure 2: Standing in foam surface

Discussion

Findings of the present study within the group analysis shows there is significant difference in both the outcome measures (BBS and BESS) in both the group. Whereas between the group analysis for BBS and BESS (Pre and Post) at the end of 12 sessions. Comparison of BBS score between the groups shows there is no statistically significant difference in favour of any group. However, in case of BESS, comparison between the group indicates the individuals treated with combination of BT with MI technique significantly improved better than those individual treated with BT alone.

In this study we can see significant difference only in the BESS because it consists of more complex tasks than BBS. In BESS foam surface is also used were as there is no such component in the BBS which measures the balance in foam surface. The subjects with upper limit of BBS score (48-52) were included in the study which made the subjects to have less scope for improvement on BBS whereas there was more space for improvement on BESS

Steadman et al. (2003)[20], who found that balance training program for only six weeks significantly improves balance, mobility, confidence, and quality of life in patients with balance problems. By this study to promote reflex muscular activation patterns which

is necessary for balance seems to be adequate in four weeks for PMW.

A study conducted by Warner L A (1988)[21] systematic review was conducted on mental imagery and its potential for physiotherapy where it was concluded physical practice combined with mental practice is effective so implementation of this method of treatment is beneficial as Mental imagery doesn't require any sophisticated equipment in similar way Asmita K et al[8](2014) conducted a study effect of Mental Imagery on Balance in Young Adults were result showed better balance in the group with MI and BT after 4 weeks program at a rate of 3 times/week. A comparative study conducted by Tomar J[9](2014) in Geriatric Population where result showed that mental imagery provides additional benefits to conventional physiotherapy and the author concludes that embedded mental imagery may hence be an important therapeutic tool to improve balance in elderly.

As BT along with MI was given in younger and older population but in this study it is given in postmenopausal women were the findings shows better improvement in the group after combination of conventional physiotherapy balance training with MI.

Based on the results the clinical implication of the study is that MI training can be included in the routine balance training for PMW with balance disturbance.

Conclusion

The result of the present study concludes that there was significant difference between the group receiving conventional balance training and the group receiving mental imagery and conventional balance training in postmenopausal women with postural disturbance.

On comparing the mean difference of BEES it can be concluded that MT along with conventional BT is beneficial for postmenopausal women with postural disturbance when compared to conventional balance training alone.

An Observational Study on Factors Associated with Pre-Eclampsia/Gestational Hypertension among Pregnant Women Attending a Tertiary Care Hospital at Udupi

Jenu Maria Thomas[1], Revathi P. Shenoy[2], Parvati V Bhat[3], Asha Kamath[4]

[1]Assistant Professor, Symbiosis Institute of Health Sciences, Symbiosis International University, Pune, India, [2]Associate Professor, Department of Biochemistry, Kasturba Medical College, Manipal, Manipal Academy of Higher Education, Manipal, India, [3]Professor and HOD, Department of OBG, Dr. TMA Pai Hospital, Udupi, Manipal Academy of Higher Education, Manipal, India, [4]Professor & Head, Department of Data Science, Prasanna School of Public Health, Manipal Academy of Higher Education, Manipal, India

Abstract

Introduction: Pre-Eclampsia and Gestational Hypertension are often categorised under the complicated hypertensive disorders in pregnancy. The present study was carried out to observe the maternal age distribution, family history of hypertension, blood group distribution, gravida status, gestational age at delivery and baby weight distribution among healthy pregnant women and pregnant women with PE/GH attending a tertiary care hospital at Udupi district.

Methodology: After obtaining the consent from pregnant women fulfilling the criteria for the study, details on maternal age distribution, family history of hypertension, blood group distribution, gravida status, gestational age at delivery and baby weight distribution were obtained from the patient records. Healthy pregnant were defined as those who had no complications in pregnancy till delivery and cases were defined as the ones who developed GH/PE anytime after 20 weeks of gestation.

Results: The present study identified that among Control 16.7% and among Case 29% had family history of hypertension. Larger percentage of women had blood group of O+ among control whereas it was B+ among case. Among Case, 48.6% women delivered at ≤37 weeks. The babies born to Control women had a birth weight of 3.07±0.38 kg as compared to babies born to women with Gestational Hypertension/Pre-eclampsia which was 2.6±0.32 kg.

Conclusion: The study could identify the distribution pattern of maternal age, family history of hypertension, blood group, gravida status, gestational age at delivery and baby birth weight and among healthy pregnant women and pregnant women with PE/GH attending a tertiary care hospital at Udupi district.

Introduction

Pre-Eclampsia and Gestational Hypertension are often categorised under the complicated hypertensive disorders in pregnancy[1]. Various risk factors have been identified for PE. Age of the mother during conception is the most discussed risk factor. PE reported to occur mostly if the maternal age is to the extremes of

reproductive age (< 18 y or >35 y)[2]. A family history of PE indicates that genetics play a role in the genesis of PE[3]. On a national based cross sectional study on "Prevalence and risk factors for PE in Indian women", it was observed that, in India more than half of the women recruited in the study (55.6%) had features of PE. However, the higher rates (>70%) were observed in the states of Uttarakhand, Bihar, Jharkhand, Kerala and a peak higher rate in Tripura (87.5%)[4]. Women with PE are at higher risk of delivering preterm. The present study was carried out to observe the maternal age distribution, family history of hypertension, blood group distribution, gravida status, gestational age at delivery and baby weight distribution among healthy pregnant women and pregnant women with PE/GH attending a tertiary care hospital at Udupi district.

Methodology: The project proposal, patient information sheet and patient consent were approved by the Institutional Ethics Committee. This study with a case control design and duration of three and half years was carried out in the Department Obstetrics and gynaecology Department of Dr TMA Pai Hospital, Udupi.After obtaining the consent from pregnant women fulfilling the criteria for the study, details on maternal agedistribution, family history of hypertension, blood group distribution, gravida status, gestational age at delivery and baby weight distribution were obtained from the patient records. Healthy pregnant were defined as those who had no complications in pregnancy till delivery and cases were defined as the ones who developed GH/PE anytime after 20 weeks of gestation. Statistically the sample size was calculated as Case: Control in 1:3 ratio. Thus, 41 cases and 124 controls were used for the observational study.

Results

Maternal age distribution among the Case-Control subjects recruited in the study: Among the Control (n=124), 10 women (8.2%) were between 18-22 years of age, 34 women (27.1%) were in the age group of 23-25 years, 60 (48.4%) were in the age group of 26-30 years, 19 (15.6%) were between 31-35 years and only 1 woman (0.8%) had age greater than or equal to 36 years.

Among the Case group (n=41), it was observed that, 4 women (9.8%) were between 18-22 years of age, 7 women (17.1%) were in the age group of 23-25 years, 19 women (46.3%) were in the age group of 26-30 years, 7 (17.1%) were between 31-35 years and 4 women (9.76%) were above the age of 36 years.

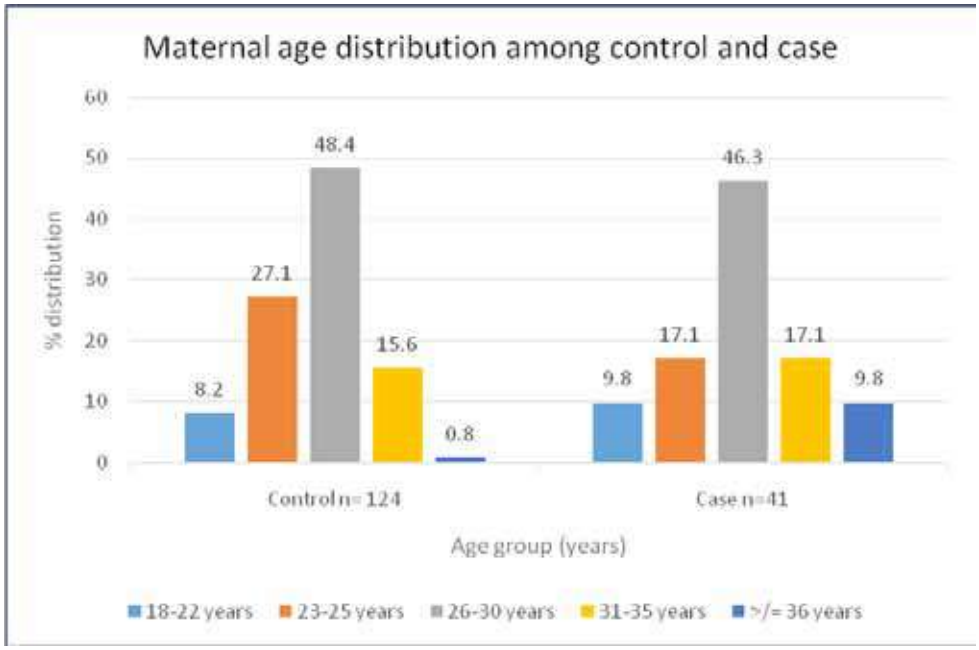

Fig.1. Maternal age distribution among the Case and Control

The mean maternal age among Control was 27.02±3.6 whereas among Case was 28.5±4.7.

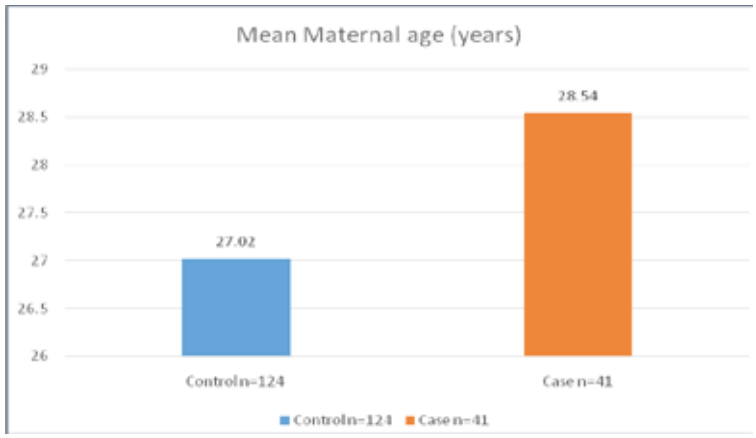

Fig. 2. Mean maternal age of Case and Control

Family history of hypertension among the Case- Control subjects recruited in the study: Among Control 21 women (16.7%) had family history of hypertension whereas among Case 12 women (29%) had family history of hypertension.

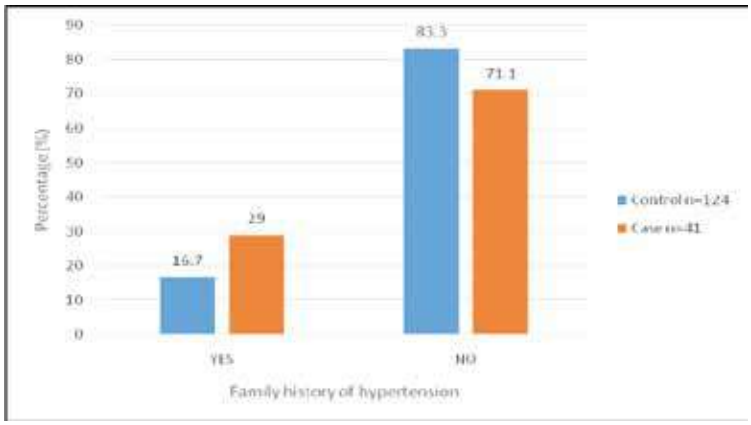

Fig. 3. Family history of hypertension among Case and Control

Blood group distributions among the Case- Control subjects recruited in the study: Among the Control 32 women were A+ (25.9%),2 were A- (1.8), 24 were B+ (19.6%),1 was B- (0.9%), 11 were AB+ (8.9%), none were AB- 0%, 47 were O+ (37.5%) and 7 were O- (5.4%). Among Case, 4 women were A+ (10.3%), 1 was A- (2.6%), 14 were B+ (33.3%), 1 was B- (2.6%), 5 were AB+ (12.8%), 1 was AB- (2.6%), 13 were O+ (30.7%) and 2 were O- (5.1%).

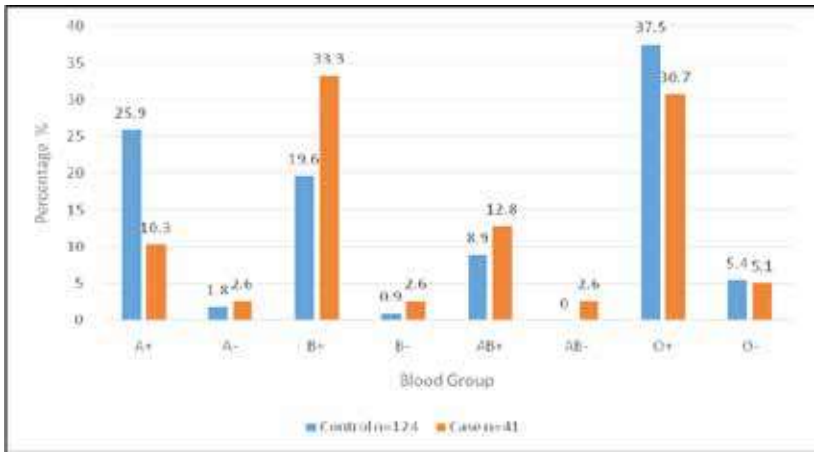

Fig. 4. Blood group distribution among Case and Control

Gravid status among the Case- Control subjects recruited in the study: Among Control and Case, 75 (60.3%) and 26 (62.5%) women respectively were primigravid, 30(24.1%) and 7(17.5%) were gravida 2; and 19 (15.5%) and 8(20%) were gravid 3 and more respectively.

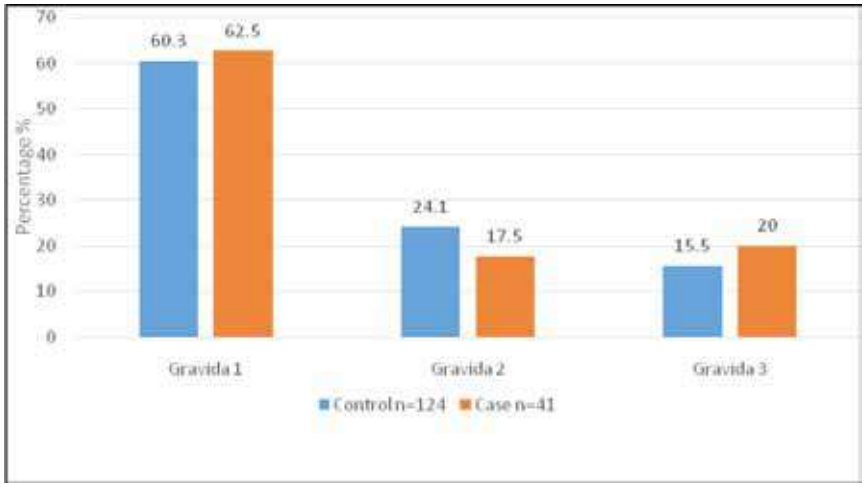

Fig. 5. Gravid status among Case and Control

Gestational age at delivery among the Case- Control recruited in the study: Among Control 20 women (16.4%) delivered at ≤37 weeks, 41 women (32.7%) delivered at 38 weeks, 36 women (29.1%) delivered at 39 weeks and 27 women (21.8%) at ≥ 40 weeks.

Among Case, 21 women (48.6%) delivered at ≤37 weeks, 9 women (22.9%) delivered at 38 and 39 weeks each and 2 women (5.7%) at ≥ 40 weeks.

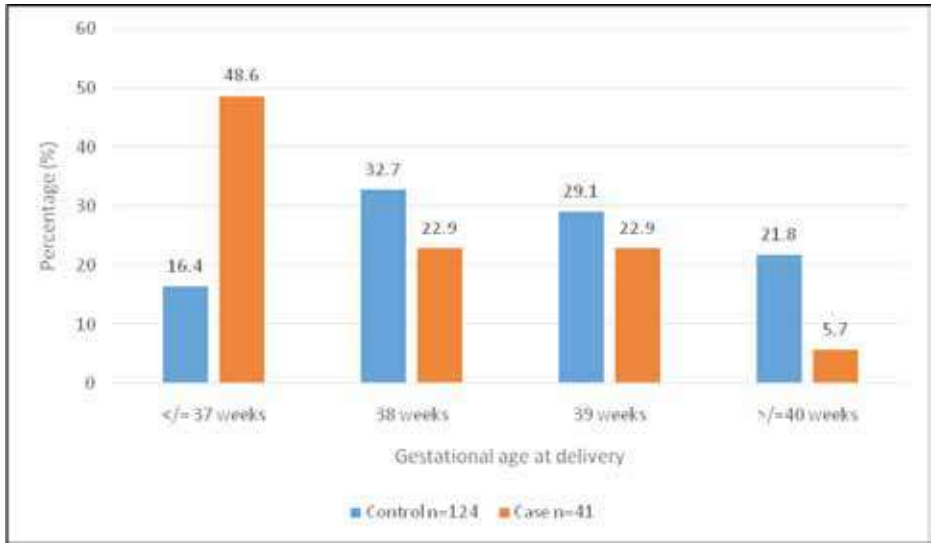

Fig. 6. Gestational age at delivery among Case and Control

Baby birth weight distribution among the Case Control subjects recruited in the study: The babies born to Control women had a birth weight of 3.07±0.38 kg as compared to babies born to women with Gestational Hypertension/Pre-eclampsia which was 2.6±0.32 kg. It was observed that there is statistically significant difference between the baby birth weight of Control and Case.

Discussion

Maternal age is a risk factor for PIH. In the present study, it was observed that a larger proportion of women who developed the disease were in the age group of 26-30 years. Maternal age does not consistently show an association with risks of gestational hypertensive disorders[5]. However, maternal body mass index influences the association of maternal age with incidence of hypertension in pregnancy. In a study, PIH group had large proportion of women with age >30 years as compared to the control group[6]. However, maternal age is not consistently associated with the risks of gestational hypertensive disorders. Maternal body mass index might influence the association between maternal age and the risk of PIH[5]. Increased maternal age is associated with increased incidence of PIH. The risk increased in the age group above 40 years[7].

In the current study it was observed that among Control 16.67% only had family history of hypertension whereas among Case 28.95% had family history of hypertension. There is increased risk of hypertensive disorders in pregnancy in women who had previous history of PE and family history of hypertension and PE[8]. Family history of hypertension and diabetes is often associated with genetic and behavioural susceptibility to the genesis of PE[9].

In the present study, we observed that the proportion of women with B+ blood group were more in the PE/GH group. However, Clark P and Wu O (2008) reported that, there is no association existing between the blood group types and incidence of PE[10]. Studies have reported that AB+ blood group were at higher risk of developing hypertension in pregnancy and O+ was at lowest risk[11,12]. It is also reported that, A or AB blood types, but not B, were at a higher risk of PE compared with O type individuals[13].

Gravida number is also identified as yet another causative factor for PIH. In our study it was observed that among the primigravid, there was larger incidence of hypertension. Also it was observed that, there were a relatively larger proportion of women in gravid 3 and above in the hypertensive group as compared to Control. Primigravidis associated with higher incidence of PIH[14].

We also observed lower birth weight in babies born to women in the hypertensive disorder group as compared to the control group. However, the birth weight of the babies was above the cutoff of 2.5kg defined for low birth weight. In the current study, majority of the mothers in hypertension group delivered at ≤37 weeks as compared to Control where it was 38 and 39 weeks[15]. In their study pre-eclamptic women who delivered ≤37 weeks, had statistically significantly lower birth weight babies whereas babies born to women who delivered ≥37 weeks did not have a difference as compared to the control group.

Conclusion

The study could identify the distribution pattern of maternal age, family history of hypertension, blood group, gravida status, gestational age at delivery and baby birth weight among healthy pregnant women and pregnant women with PE/GH attending a tertiary care hospital at Udupi district.

The Effect of Specific Training on Selected Physical Variable among Kabaddi Players

K.Jayaprakash[1], S.J.Albert Chandrasekar[2]

[1]M.Phil. Research Scholar, Dept. of Physical Education and Sports Sciences, SRM IST, Kattankulathur,
[2]Asst. Professor

Abstract

Context: The purpose of this study was to find out the effect of specific training on selected physical variable among school boys kabaddi players. The age of the subjects ranged from 15 to 18 years. The selected subjects n=30 were divided into one experimental group and one control group at random. The investigator selected a training that is specific training for kabaddi players which improved certain selected physical fitness variables namely muscular strength. As the result of field training the physical fitness level of the kabaddi would improve. The experimental group endured the training activities for 6 weeks with a schedule of six days whereas the control group remained with no activities. The data procured in prior and after the training programme was examined. To find out difference between experimental and control group of Muscular strength t-ratio was employed and the level of significance was set at 0.05. The results of the study showed that the muscular strength of the experimental group was significantly improved than the control group.

Keywords: *Specific training, Muscular strength, Kabaddi, Experimental group, Control group*

Introduction

A sport is an organized, competitive, entertaining and skillful physical activity requiring commitment, strategy and fair play in which a winner can be defined by objective means.[1] It is governed by a set of rules or customs. In sports the key factors are the physical capabilities and skills of the competitor when determining the outcome winning or losing. The physical activity involves the movement of people, animals and/or a variety of objects such as balls and machines or equipment. In contrast, games such as card games and board games, though these could be called mind sports and some are recognized as Olympic sports, require primarily mental skills and only mental physical involvement.[2]

Physical Education is one of the most ancient arts of the humanities. In its broadest interpretation, Physical Education is defined as the art and science of voluntary purposeful and active human movement.[3] It is clear that Physical Education is concerned with a fundamental mode of human expression. Likewise it is an essential form of non – verbal communication which can be communicated very effectively depending and does, express a wider range of emotions while participating in a group towards the activities of Sports Specific Trainers can help improve strength, flexibility and stamina to improve performance in specific sports.[4] Options include increasing arm strength for tennis playing or improve strength and core stability providing better balance playing golf.

Specific Fitness: Specific or task-oriented fitness is a person's ability to perform in a specific activity with a reasonable efficiency. For example sports or military service. Specific training prepares athletes to perform

Corresponding Author:
K.Jayaprakash
M.Phil. Research Scholar, Dept. of Physical Education and Sports Sciences, SRM IST, Kattankulathur.
e-mail**:** srmarunprasannaphd@gmail.com

well in their sports.[5] Examples are 400 m sprint in a sprint the athlete must be trained to work an aerobically throughout the race.

Sport Training: Sport training is done for improving sports performance. The sports performance as any other type of human performance is not product of one single system or aspect of human personality. On the contrary it is the product of the total personality of the sports person. The personality of a person has several dimensions for example physical, physiological, social and psychic.

Sports Specific Training: Sports specific training is all about developing physical conditions to improve performance and skills at a particular sport.[6] Also understanding the needs of the game training practicing at the correct pace in order to meet sports requirements.

Kabaddi: The game Kabaddi includes quick movement along with a great deal of bending, dodging, quick turns, kicks and twists. The participant in Kabaddi requires substantial muscular strength to grasp hold of opponents or to oppose the hold of opponents and get away from them. The skill includes the movements to be understood and carefully practiced during long period, as in any other well ordered game so that participants not only play better but also get satisfaction in plying Kabaddi.[7]

Statement of the Problem: The purpose of this study was to find out the effect of specific training on selected physical variable among school boys kabaddi players.

Methodology: To achieve the purpose of these study 30 boys kabaddi players were selected at government higher secondary school koomapatti. The age of the subjects ranged from 15 to 18 years. The selected subjects were divided in to one experimental group and one control group at random. The investigator selected a training that is specific training for kabaddi players which improved certain selected physical fitness variables namely muscular strength. As the result of field training the physical fitness level of the kabaddi would improve.

Test Administration of Muscular Strength:

(SIT-UPS (1- min)

Purpose: To measure the endurance of the abdominal muscles.

Equipment: The only equipment required is a mat and yardstick.

Direction: From a lying position on the back, the performer flexes his knees over the yardstick while sliding his heels as close to his seat as possible. The yardstick should be held tightly under the knees until the performer is instructed to slowly slide his feet forward. At the point where the yardstick drops to the mat, the tester marks the hard line and seat line to indicate how for the feet should remain from the seat during the bent-knee sit-ups exercise. The hands are clasped behind the head, and the subject raises the trunk by lifting first the head, then the shoulders, and then the back. Each trial by performing five sit-ups for the testers before proceeding with the time trails. The time limits are observed.

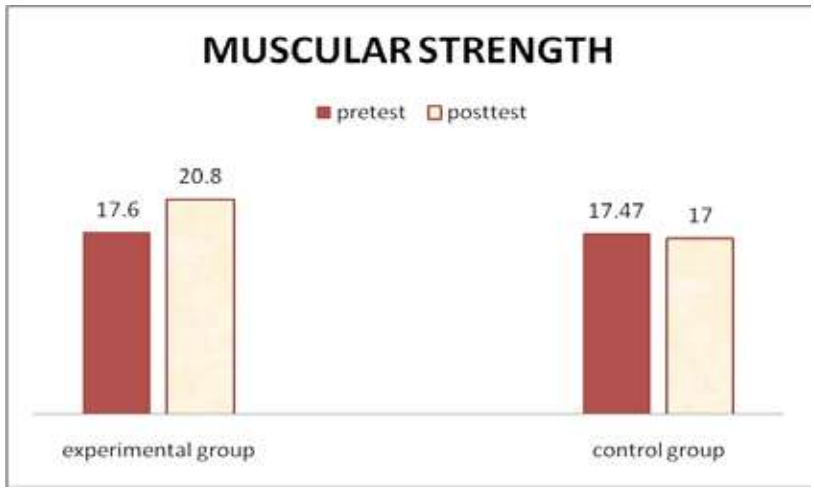
Scoring: The completion of one complete curl up (up and back) counts as one. The sit-up must be performed correctly for it to be counted. For the tempo tests, the test is continued until the subject cannot maintain the rhythm or has reached the target number for the test.

Table 1: Analysis of 't' ratio the pre and post test for Control and Experimental Group on Muscular strength

Variable	Group	Mean		SD		Sd Error	Df	't' ratio
		Pre	Post	Pre	Post			
Muscular strength	Control	17.47	17.00	2.03	2.04	0.43	14	1.07
	Experimental	17.60	20.80	2.20	2.65	0.17		18.33*

* Significance at 0.05 level of confidence.

Table 1: presents the difference between experimental and control group of Muscular strength. Difference in two group's t-ratio was employed and the level of significance was set at 0.05. Experimental group pre and post-test mean value were 17.60, 20.80 respectively. In Control group pre and post-test were mean value was 17.47, 17.00 respectively. In experimental the obtained t-ratio 18.33 was greater than the table value 2.15 so it found to be significant. In control group the obtained t-ratio 1.07 was lesser than the table value 2.15 so it was found to be insignificant. Figure 1 shows the pre and post test mean values of control and experimental group on muscular strength.



*Significance level at 0.05

Figure 1: Bar Diagram Shows the Pre and Post Test Mean Values of

Control and Experimental Group on muscular strength:

Discussing on Findings: The result of the study indicates that the experimental group namely specific training group had significantly improved the selected dependent variables namely Physical Variable- muscular endurance when compared to the control group. It is also found that the improvement caused by specific training when compared to the control group.

Discussion on Hypotheses: It was hypothesized at the beginning of the study that there would be significant improvement on selected criterion variables such as specific training (physical variable) due to training for the experimental group as compared to the control group. The present study produced similar results. Hence, the first research hypothesis of the investigator was held true.

Conclusions

The results of the study concluded that the muscular strength of the experimental group was significantly improved than the control group.

Effect of Selected Yogic Practices on Aerobic Capacity and Anaerobic Power of School Girls

K. Nagajothi[1], N.C. Jesus Rajkumar[2], T. Arun Prasanna[3]

[1]Ph.D Research Scholar, Dept. Of Physical Education And Sports Sciences, Srmist, Kattankulathur,
[2] Assistant Professor, [3]Ph.D Research Scholar.

Abstract

Context: The objective of the present study was to find out the effect of selected aerobic capacity and anaerobic power of sedentary school girls of west Bengal. Subject: twenty five(n=25) sedentary school students were randomly selected as subjects for this study from Atulia Neta Adharsha Vidyapath, North 24 paraganas. The age ranged from 16-18 years. The study was confined in a single experimental group and no control group was considered. In the present study of aerobic capacity and anaerobic power were two variables. Aerobic capacity were measured in terms of maximum oxygen consumption during excersice i.e. VO2 max. Aerobic capacity & anaerobic power were measured respectively by Queens College Step Test and Margaria-kalamenanaerobic power test. A structured yogic training was intervened for six week. Mean and Standard deviation statistical procedure was carried out. The mean of different variables were compared by using t-test statistical significance was tested at 0.05 levels. The results highlighted that there were the significant difference in aerobic capacity between pre and post treatment condition. On the other hand a significant difference was found in anaerobic power between the pre and post treatment condition.

Keywords: *Aerobic capacity, Anaerobic power, Oxygen consumption, Yogic training, t-test*

Introduction

Aerobic (cardiovascular) capacity is one of the most important components of physical fitness. The other components are muscular strength and endurance, and flexibility and low-back function.[1] Cardiovascular fitness is measured as the amount of oxygen transported in the blood and pumped by the heart to the working muscles and as the efficiency of the muscles to use that oxygen. Increasing cardiovascular fitness means increasing the capability of the heart and the rest of the cardiovascular system in their most important task, to supply oxygen and energy to your body.[2]

K. Nagajothi
Ph.D Research Scholar, Dept. Of Physical Education And Sports Sciences, Srmist, Kattankulathur.
e-mail: Srmarunprasanna@Gmail.Com

Having good cardiovascular fitness has many health benefits. For example, it decreases your risk of cardiovascular diseases, stoke, high blood pressure, diabetes and other diseases, cardiovascular fitness is best improved by activities, which employ large muscle groups working dynamically. Such activities include walking, running, jogging, swimming, skating, cycling, climbing and cross- country skiing.

Anaerobic power is energy that is stored in muscles and that can be accessed without use of oxygen.[3] There are two systems utilize this type of power, the phosphogern system and the lactic acid system. Human beings use this form of energy in short burst that cannot be sustained for longer than about two minutes.[4] Considering the research work in this field it concluded that very little effort has been taken so far to find the effect of yoga practice aerobic capacity and anaerobic power on sedentary school children.[5] Accordingly the project is planned to iniative research work related to the effort of selected yogic practice aerobic capacity and anaerobic power of school children from west Bengal.[6]

Materials and Method:

Subjects: A total no of twenty five (N=25) healthy female having age ranged between 18 years were randomly selected as subjects for the present study from, Atuli A Netaaji, Adharth Vidyapith, Norht 24 Paraganas of west Bengal. They were basically the students of classes XII of the instititution. The study was approved by Institutional Ethical Committee. The study was confined into a single experimental group and no control group was considered.

Experimental Protocol: A six weeks yogic training schedule(5 days in a week), study on 25th January up to march 1st week, were intervened on the subject by the researcher the help of instructress, bend and other coaching professionals. Yoga classes were offered five per week, from 8.00-9.00 a.m. for 8 weeks, Saturday-Sunday was considered as rest day of certified yoga instructor led all classes. Each yoga session consisted of 15 minutes of warm-up exercise. The warm-up program focused on slow, dynamic muscular movements, which consist of dynamic lunge shoulder and arm circles, neck rolls, standing forward bend two. The training program was prolonged for 50 minutes of asana, (yoga postures), and 10 minutes relaxation in savasana. The selected names of asana were scheduled as follows. Pranayamas focusedon the quality and ease of breath andisometric muscular contraction. Table 1 presents the training schedule given to the students.

Variable Studied: In this project three variables were studied viz.:

1. Aerobic capacity in terms of VO2 max-Queens College Step Test
2. Anaerobic power- Margaria Anaerobic Power Test or Margaria-Kalamen Power Test.

Measuring Procedure: Height and weight are measured by Anthropometric rod and weighing machine (Tanita, Model: BC-554). To measure aerobic capacity in terms of max Queen's College Step Test (QCST) was administrated on all the selected subjects in pre as well as post treatment condition.

Prediction of Vo2 Max: In brief the step was performed using a stool of 16.5 inches height. Stepping was done for a total duration of 3 minutes at the rate of 24 cycles per minute which was set by a metronome. After completion of the exercise, the subjects were used to remain standing comfortably ad the carotid pulse was measured from the fifth to the tenth second of the recovery period. This 15 second pulse rate was converted into beats per minute(15 sec pulse rate x 4) and the value thus obtained was put in the following equation predict VO2 max in ml/kg/min, as proposed by McArdle et al., 1986.

10 max (ml/kg/min) = 65.81 – (0.1847 x pulse rate in beats per min)

Prediction of Anaerobic Power: The students ready at the starting line 6 meters in front of the first step. On the command "GO", the students sprints to and up the flight of steps, bring three steps at the time (stepping on the 3rd, 6th and 9th steps), attempting to go up the steps as fast as possible. The time to get from the 3rd step to the 9th step is recorded (either using the stop watch or using switch mats placed on the 3rd and 9th steps), starting when the foot was in first in contact with the 3rd step and stopped when the foot contacts the 9th step. Allow three tills of the test, with 2-3 minute, recovery between each trial. Anaerobic power (Watts) calculated from the formula below, where P= Power (Watts), M=Body Mass (kg), D= Vertical Distance, between steps 3 & 9 (meters), T= Time (Seconds), 9.8 is the constant of gravity.

POWER=P=M x D x 9.8/t

The unit of power in S.I system was Jule/second or watts.

Instrument and Tools: Following instruments and tools were used for collecting the data: 1) staircase 12-16 stairs (15-20cm), 2) weight scale, 3) steeping bench (16-17"), 4) Metronome and 5) stopwatch.

Statistical Analysis: In the present study for the sake of analysis of data mean and standard deviation of the variables were calculated. To find out significant difference of mean between the pre and postintervention in different variables statistical t-test was used. The significant of means were tested at $p<0.005$ level of confidence. For statistical calculations excel Spread Sheet of windows version 7 will be used.

Results and Discussion

The mean standard deviation of obtained data belongings to height and weight of collegiate women have been presented in Table-1.

Table 1:- Training Schedule

DAYS	TOTAL TIME- 50 MINUTES (MORNING SESSION- 8.00-9.00A.M.)							
	TIME DIVIDED							
	8 Minutes	4 Minutes	4 Minutes	4 Minutes	4 Minutes	4 Minutes	6 Minutes	6 Minutes
Mon	Suryanamaskar	Padmasana	Sarbangasana	Padahastasana	Noukasana	Matsasana	Narisodhana	Vastrika Pranayama
Tues	Suryanamaskar	Padmasana	Sarbangasana	Padahastasana	Noukasana	Matsasana	Narisodhana	Vastrika Pranayama
Wed	Suryanamaskar	Padmasana	Sarbangasana	Padahastasana	Noukasana	Matsasana	Narisodhana	Vastrika Pranayama
Thurs	Suryanamaskar	Padmasana	Sarbangasana	Padahastasana	Noukasana	Matsasana	Narisodhana	Vastrika Pranayama
Fri	Suryanamaskar	Padmasana	Sarbangasana	Padahastasana	Noukasana	Matsasana	Narisodhana	Vastrika Pranayama

Table 2: Mean and stander Deviation of height and weight of the subject

Height (cm)		Weight (kg)	
pre	post	Pre	post
1.47+0.07	1.47±0.06	54.258±8.22	52.12±7.32

From the table-2 it was found that the mean and standard deviation of pre height of school girl are 1.42±0.07cm, post height of the school girls were 1.47±0.06cm, and the mean and standard deviation of pre weight of school girls were 54.52±8.22kg, post weight of school girls were 52.12±7.32kg.

Table-3: Mean, S.D, Mean Difference, Standard Error, and 't'- Value or Aerobic Fitness & Anaerobic Power Measurementof Sedentary School Girls

NAME OF THE VARIABLES	MEAN ± SD		MEAN DIFFENCE	STANDARD ERROR	T- VALUE
	PRE-DATA	POST-DATA			
AEROBIC FITNESS (ml.kg-1.min-1)	38.52 ± 8.24	43.62 ±7.24	5.10	2.19	2.32
ANAEROBIC POWER	487.84 ±82.32	516.64 ±96.66	28.80	25.39	1.13

Table value of 't' for at 0.05 level of confidence = *2.001

From table-3 It was found d that the mean and the standard deviation of aerobic capacityfrom the sedentary school girls in the pre and post intervention of training were 38.52±8.24(ml.kg-1.min_1) and 43.62±7.24(ml. kg-1.min-1) respectively. Figure -1 indicates the mean value of aerobic capacity of the sedentary schools girls. It was found that in case of aerobic capacity the significant difference was observed between the pre and post intervention condition.

From Table-3 it was observed that the mean and standard deviation of obtained data belonging to anaerobic power as, measured by MargariraKalaman Power Test of Sedentary school girls. The pre and post intervention of training were 487.84±82.32(jule.sec-1) and 516.64±96 (jule.sec-10 respectively. Figure-2 indicates the mean value of aerobic capacity of sedentary school girls. It was found that in case of anaerobic fitness no significant difference was observed between the pre and post intervention condition.

On the basis of analysis of data the following results were obtains for the present project:

(a) In aerobic capacity significant difference was found between the pre and post intervention condition of the sedentary school girls.

(b) No significant difference in anaerobic power was obtained between the pre and post intervention condition of the sedentary school girls.

Conclusion

Thus on the basis of the result it can be concluded that the yogic practices are effective for improving the aerobic capacity but not too much effective for improving anaerobic power.

Effectiveness of Low Level Laser Therapy Versus Ultrasound Therapy with Plantar Fascia Streching in Subjects with Plantar Fasciitis

K.Koteeswaran[1], Ramya K[2], Rajeshwari[3], Manikumar Muthiah[4], Sankara Kumaran Pandian[5]

[1]Associate professor, Saveetha College of physiotherapy,Saveetha University,Chennai, [2]Research Associate, [3]Research Associate, [4]Associate professor, [5]Lecturer, School of Physiotherapy,AIMSTUniversity,Bedong,Malaysia

Abstract

AIM: To find the effectiveness of low level laser therapy versus ultrasound therapy with plantar fascia stretching in subjects with plantar fasciitis.

Materials and Method: Non equivalent quasi experimental study design was used in this study.Total of 30 subjects with plantar fasciitis were selected using non probability convenience sampling technique.30 Subjects was divided into two groups by lot system. Group A received low level laser therapy and Group B received ultrasound therapy and for both the group plantar fascia stretching was given.The outcome measures are FAAM (foot ankle ability measure) and NPRS (numerical pain rating scale). Data collected and tabulated was statistically analysed.

Result: Statistical analysis of post-test, foot and ankle ability measure questionnaire (FAAM) and NPRS (numerical pain rating scale) revealed that there is statistically significant difference seen between Group A and Group B.

Conclusion: From the result, it has been concluded that low level laser therapy with plantar fascia stretching (Group A) is more effective than ultrasound therapy with plantar fascia stretching (Group B) in decreasing pain and improving the quality of life in subjects with plantar fasciitis.

Keywords: *Plantar fasciitis, low level laser therapy, ultrasound therapy.*

Introduction

The human foot is a strong and complex mechanical structure and terminal portion of the limb which bears weight and allows locomotion.[1] The plantar fascia is a dense, fibrous, connective tissue structure originating from the medial tuberosity of the calcaneus. It has three-medial, lateral and central portions.[2]

Plantar fasciitis is a degenerative condition resulting from compressive forces due to repeated trauma to plantar fascia making the foot's longitudinal arch of flat. Traction forces during the gait on support phase leading to inflammation results in fibrosis and degeneration. Plantar fasciitis is the common reason for heel pain for 80 percentage of cases. It affects most commonly people who are between 40 – 60 years of age.[3]

The exact etiology of plantar fasciitis still remains unclear but the risk factors which results in plantar fasciitis includes overuse of plantar fascia, exercises like ballet jumping activities, long distance running, long period of standing, obesity, pregnancy, military recruits, athletes. The patient usually complaints of pain over the medial side of plantar heel, usually when taking first few steps after waking up.[4]

The common site of pain in plantar fasciitis is near to the origin of the central band of plantar Apo neurosis at the medial plantar tubercle of the calcaneus.[5]

The windlass mechanism explains these biomechanical stresses and factors. Plantar fasciitis forms the tie-rod that attaches from calcaneus to phalanges. Vertical forces from the weight of the body travel to medial longitudinal arch in downward direction through tibia and flattens the arch. Further, the ground reaction forces that travel in upward direction on the calcaneus and metatarsal heads, even more leads to flatten of arch as these forces fall anterior and posterior to the tibia. Plantar fascia prevent the collapse of arch by its tensile force and orientation.[6]

Plantar fasciitis tends to improve in most cases regardless of the treatment selected. As a result conservative management is effective for nearly 90% of the patient. The conservative treatments used in management of plantar fasciitis vary widely and are dependent on physician specialty.[

Methodology: The subjects were selected from the Saveetha physiotherapy, outpatient department of Saveetha medical college and hospital. 30 subjects with plantar fasciitis were selected based on the inclusion and exclusion criteria. Detailed procedure was explained to the subjects in the colloquial terms about the safety and simplicity of the procedure. Informed concern were given to those who were interested to participate in this study. Selected subjects were randomly assigned in to two groups 15 in each group by using lottery system. The outcome measure used in this study for pain is numerical pain rating scale(NPRS) and for the quality of life is foot and ankle ability measure questionnaire (FAAM) respectively. For all subjects' pre and posttest values were calculated.

Procedure: Group A Were the subjects who received low level laser therapy along with plantar fascia stretch. Group B were the subjects who received ultrasound therapy along with plantar fascia stretch.

For group A Probe method (continuous) of low level laser therapy was used to treat the subjects. Safety precautions was taken to reduce the risk of exposure of laser light to the eyes. Low level laser therapy was given in painful area for 3 days/week for 2 weeks. The wave length used in the treatment is 830nm for 9 minutes. The irradiation area include 3 point over $3cm^2$.

For group B Ultrasound therapy was given to the subjects in the frequency of 3 MHZ in the pulsed mode (1;4) for 8 minutes with the intensity of $0.5W/cm^2$ for 2 weeks(3days/week).

For both the group plantar fascia stretching was givenwith the hold time for 20-30 seconds with the repetaion of 10 times in the alternative days.

Results

The collected data was tabulated and analyzed using descriptive & inferential statistics. To all parameters mean and standard deviation (SD) was used. Paired t-test was used to analyse significant changes between pre and posttest measurements. Unpaired t test was used to analyse significant difference between the groups. P value <0.05 was considered as statistically significant.

Table 1 represents the FAAM Scale score for group A and B. The group A pre-test mean value is 39.93% (SD 7.93%) and post-test mean value is 66.87% (SD 7.30%).The group B pre-test mean value is 48.20% (SD 13.09%) and post-test mean value is 56.27% (SD 11.81%) .This shows that FAAM Scale score values are gradually increasing in the group A than group B, which is statistically significant.

Table 2 represents the NPRS score for group A and B. The group A pre-test mean value is 7.47cm (SD 1.19cm) and post-test mean value is 3.93cm (SD 0.80cm).The group B pre-test mean value is 6.27cm (SD 0.80cm) and post-test mean value is 5.53cm (SD 0.83) .This shows that NPRS score values are gradually decreasing in the group A than group B, which is statistically significant.

Table 1: Comparison of pre and post test values of FAAM scale for group A and B

FAAM Scale		MEAN	SD	t value	p value
Group A	PRE	39.93%	7.93%	38.8492	0.0001
	POST	66.87%	7.30%		
Group B	PRE	48.20%	13.09%	9.9896	0.0001
	POST	56.27%	11.83%		

Group 1: Comparison of pre and post test values of FAAM scale for group A and B

Table 2: Comparison of pre and post test values of NPRS scale for group A and B

NPRS Scale		MEAN	SD	t value	p value
Group A	PRE	7.47cm	1.19cm	14.9480	0.0001
	POST	3.93cm	0.80cm		
Group B	PRE	6.27cm	0.80cm	4.7845	0.0003
	POST	5.53cm	0.83cm		

Discussion

Plantar fascia is commonly a repetitive micro trauma overloaded injury of the attachment of plantar fascia at the inferior aspect of calcaneus.

The clinical presentation of plantar fasciitis include gradual insidious onset of heel pain. Pain and stiffness are worse in the morning(during first few steps) or after prolonged walking and increased by climbing stairs or doing raising up activity thus impairing the activity of daily life.

Conservative treatment for plantar fasciitis include ultrasound therapy, cryotherapy, low level laser therapy, medication (steroids), stretching, foot wear modification, manual therapy, splint, tapping and strapping.

This study compares the effectiveness of low level laser therapy and ultrasound therapy with plantar fascia stretching in subjects with plantar fasciitis in terms of pain and quality of life.

The subjects with age group of 30-60 years of both gender with plantar fasciitis were selected. 15 subjects in Group A were treated with low level laser therapy with plantar fascia stretching while 15 subjects in Group B were treated with ultrasound therapy with plantar fascia stretching.

The pre-test and post-test values of this study, revealed that there was a statistical difference ($p<0.0005$) in both the groups in terms of pain and quality of life, but there was more improvement in Group A than Group B.

WOLGIN M, et al stated that low level laser effects causes the stimulation of bodies own processes in healing tissue by light [12]. Phototherapy increases the both local and systemic micro circulation of the body thus it relieves pain and swelling [22]. The 2 major areas for which low level laser therapy is used is tissue healing and pain control. Laser therapy is used for pain relief in many conditions in both acute and long term (England 1998). [23] The laser therapy is found to be very effective in various overuse tendinitis conditions. Laser has its effect on prostaglandin synthesis and thus it relieves inflammation. [24]. DR.ZANG said that 3 to 4 treatment are necessary for acute plantar fasciitis if treatment begins 6 to 8 weeks after the onset of symptoms.

Ultrasound has been utilized for pain through the ability of sound waves to introduce molecules of chemical substances through the skin by a process called phonophoresis [25]. Improvements in plantar fasciitis by the application of ultrasound therapy has been reported by Clarke and stenner (1976) [26]. The application of ultrasound therapy for pain relief, along with plantar fascia stretch is commonly indicated alternative therapy for plantar fasciitis [27]. The pulsed ultrasound is believed to have therapeutic benefits and can be applied to acute injuries [28]. The effects of ultrasound therapy are tissue relaxation, increase in local blood flow, scar tissue breakdown. By increasing the local blood flow level it reduces local swelling and inflammation. WATSON (2006) suggested that application of ultrasound to injured tissues, speed the rate of healing and enhance the quality of repair.

Plantar fascia stretching reduces the tightness in the plantar fascia. Plantar fascia stretching recreates the windlass mechanism by decreasing the micro trauma and inflammation. Plantar fascia stretching helps in reducing pain, improving function and gives overall satisfaction compared to standard Achilles tendon stretching exercises [13].

The post mean value in this study of quality of life [foot and ankle ability measure(FAAM)] and pain [numerical pain rating scale (NPRS)] score of Group A treated with low level laser therapy with plantar fascia stretching was 66.87 and 3.93 and Group B treated with ultrasound therapy with plantar fascia stretching was 56.27 and 5.33 at the end of 2 weeks.

Hence is has been proven that the recovery is earlier and faster in relieving pain and improving quality of life in Group A than Group B. Thus these statistical findings could be attributed to the fact that low level laser therapy with plantar fascia stretching works more statistically over ultrasound therapy with plantar fascia stretching

Conclusion

From the result, it has been concluded that low level laser therapy with plantar fascia stretching (Group A) is more effective than ultrasound therapy with plantar fascia

stretching (Group B) in reducing pain and improving quality of life in subjects with plantar fasciitis.

Effect of Expiratory Training and Inspiratory Training with Lumbar Stabilization in Low Back Pain: A Randomized Controlled Trial

Kavya V[1], Dhanesh Kumar K U[2]

[1]Post graduate student of Nitte Institute of Physiotherapy, Derlakatte, Mangalore, Karnataka, India, [2]Prof.

Abstract

Background: Low back is the leading cause of work absence and activity limitation. It is often associated with faulty posture. Postural muscles have role in both postural control and respiration. Thus it is important to address breathing in treatment of low back pain.

Objective: The concept of breathing in low back pain is rarely translated into clinical practice. Thus, the present study will attempt to explore the evidence related to breathing and low back pain. On comparing the effect of expiratory training and inspiratory training with lumbar stabilization, the study will enlighten us whether expiratory or inspiratory training is more beneficial.

Method: The study is an RCT which included 36 subjects of the age group 20-50 years, assigned into three groups: group A (inspiratory training with lumbar stabilization), group B (expiratory training with lumbar stabilization) and group C (lumbar stabilization exercise). The intervention was performed every day in a week for 3 weeks. The outcome measures, VAS, Oswestry disability index (ODI), and stabilizer pressure biofeedback were measured at baseline and 3 weeks after the intervention.

Results: On comparing the outcome measures pre and post, all the three groups demonstrated clinically significant results, while group A produced statistically significant result in improving pain measured on VAS.

Conclusion: The study provides an affirmation for the effect of breathing in low back pain. The effectiveness of the interventions can be translated into clinical practice for the treatment of chronic mechanical low back pain.

Keywords: *Inspiratory training, expiratory training, lumbar stabilization.*

Introduction

Low back pain is one among the most pervasive medical problems, with a global point prevalence of 9.4%. GBD (global burden of disease) 2010 reported it to be first with reference to disability and sixth in overall burden. [1] In Indian population, low back pain prevalence ranges from 6.2% to 92%.[2] Thus, it has been documented to be the most prevalent health dilemma affecting the day-to-day life and a major cause of absenteeism among employers all over the world which brings in extensive economic distress.

Low back pain is defined as pain that occurs between the 12th rib and gluteal fold.[3] Low back pain can be acute (less than 4 weeks), sub- acute (4-12 weeks), and chronic (greater than 12 weeks).[4] Chronic low back pain

has been described to be the reason for sick leave and it has a slow and uncertain recovery rate.[5] About 97% of the cases of back pain that arise from the spine structures like bone, discs, joints, ligaments, meninges, and nerves constitute mechanical low back pain.[6]

Core stability or trunk stability has been defined in terms of a coactivation of global and local muscles.[7] According to Punjabi's hypothesis, spinal instability was defined as "a significant decrease in the capacity of the stabilizing system of the spine to maintain the intervertebral neutral zones within the physiological limits so that there is no neurological dysfunction, no major deformity, and no capacitating pain". The stabilizing system of the spine comprises passive sub system (ligamentous system), active sub system comprising the muscles and tendons, and the neuronal control subsystem. This stabilization system has to work together in harmony so as to fulfil the stability needsof the spine. Lumbar stabilization exercise mainly focus on training the local muscle system (transversusabdominis and lumbar multifidus).[8]

Postural stabilizer muscles are found to do postural control and respiratory function, example transversusabdominis, diaphragm, and the muscles comprising the pelvic floor. These muscles have to function efficiently so as to maintain optimal posture and optimal respiration. Low back pain has been found to be associated with sub optimal respiration and sub optimal faulty posture. Also, diaphragm has an anatomic connection to the lumbar spine. Thus, it is important to address inspiratory muscle training while treating low back pain. Inspiratory muscle training has been found to enhance the lumbar proprioceptive signals which improves trunk stabilizing function of diaphragm.[9]

Maintenance of optimal zone of apposition (ZOA) of the diaphragm is one of the major concerns in both respiratory and postural demands. A smaller zone of apposition reduces the trans-diaphragmatic pressure. Also sub optimal ZOA diminish transverses abdominis muscle activity, which is a major respiratory and lumbar stabilizer muscle. Evidence suggests that expiatory training is more capable of improving the zone of apposition of the diaphragm.[3]

As this concept is rarely translated into clinical practice, the present study will attempt to explore the evidence related to breathing and low back pain. If the intervention is proved to be effective, it can be implemented as a preventive measure in low back pain. As there is derth of literature proving effectiveness of respiratory training in chronic mechanical low back pain, this study would enlighten us whether expiratory or inspiratory training is more beneficial.

Methodology

Study Design: The study is a randomized controlled trial conducted from May 2018 to April 2018 in the department of physiotherapy, in a tertiary hospital in Mangalore, India. After obtaining ethical clearance from the institutional ethics committee, participants with mechanical low back pain diagnosed by an orthopaedician were recruited. 36 subjects of the age group of 20-50 years, with the duration of symptoms for more than 12 weeks and VAS <5 were randomly allocated by block randomization with opaque sealed envelope into three groups: Group A (inspiratory training with lumbar stabilization exercise group), group B (expiratory training with lumbar stabilization exercise group) and group C (control group with lumbar stabilization exercise) with 12 in each group. Outcome measures, VAS scale, Oswestry disability index and stabilizer pressure biofeedback to asses pain, disability and core strength respectively were measured at the baseline and 3 weeks after the intervention by an assessor blinded to the intervention. Patients with any respiratory and cardiovascular pathology, with mental disorder, acute low back pain, tumour, fracture, radiating low back pain were excluded.

Procedure: Treatment was given for 3 weeks out of which, subjects did the intervention under the supervision of the therapist in the first week and it continued as a home for the subsequent 2 weeks, when telephone follow up was given .All the three groups received moist heat application for 10 minutes. Group A recived inspiratory training (for 5 minutes) with lumbar stabilization exercise(for 25 minutes), group B received expiratory training (5 minutes) with lumbar lumbar stabilization (25 minutes)and group C received lumbar stabilization exercise (for 25 minutes) alone.

Group A (Inspiratory training with lumbar stabilization exercise): The participants of this group were given inspiratory training using respirometer along with lumbar stabilization exercise.

Inspiratory Training Using Respirometer: The patients were asked to hold the respirometer in an upright position, exhale normally and then place the lips tightly

around the mouth piece and was instructed to slowly inhale to raise the ball in the chamber to the set target.

- **Frequency :** 15 breaths per minute
- **Repetitions :** 3 sets
- **Rest period :** 1minute after each set
- **Treatment time:** 5 minutes

Group B (Expiratory training with lumbar stabilization exercise)

Expiratory Training Using Balloon And Ball: Subjects has to lie in supine position facing the wall, placing the feet on the wall such that hip and knee are bend at an angle of 90 degree. A squeeze ball was kept between the knees and was instructed to press to engage inner thigh muscles. A balloon had been given in one hand and the other hand has to be raised above head. Now, the patient has to push down the heel of the foot so that the muscles of the back of thigh get engaged. This position had to be maintained throughout the exercise. Then the patient is instructed to keep balloon in the mouth and to inspire through nose and slowly exhale by blowing off into the balloon. Pause for almost 3 seconds with the tongue in resting position to prevent air outflow from balloon. Without pinching neck of balloon the subject has to inhale through the nose. Subjects were instructed to blow out slowly into the balloon so as to avoid any strain to the neck and cheeks.

- **Frequency :** 15 breaths per minute
- **hold time :** 2-3 seconds
- **Repetitions :** 3 sets
- **Rest period :** 1minute after each set
- **Treatment time:** 5 minutes

Group C (Lumbar stabilization exercise)

Lumbar stabilization exercise: It includes

Abdominal hollowing is performed in prone.

Abdominal hollowing in supine.

Abdominal hollowing in quadripod.

Bridging

- **Hold time:** 10seconds
- **Repetitions:** 3 sets of 10 repetitions each
- **Rest time:** 1minute after each set
- **Treatment time :** 25 minutes
- **Normal breathing:** 5 minutes

Statistical Analysis: The obtained data was evaluated using IBM SPSS software version 20.0. "One Way ANOVA with Post Hoc Tukey Test" was used for comparing the pre and post values of VAS, ODI and Stabilizer pressure biofeedback between the three groups. "Paired t- Test was used for within group analysis. The p-value assumed less than 0.005 was considered significant for the study.

Results

In the age distribution between the three groups, the mean age was 26 and a standard deviation of 8.728. The p value produced is 0.725, suggesting age is homogeneously distributed. While, gender is also homogenously distributed with a p value of 0.430.

Even though all the three interventions were effective, analysing the pre post values of VAS, ODI and stabilizer pressure biofeedback between the three groups using One Way ANOVA and Posthoc Tukey test, GROUP A (Inspiratory training with lumbar stabilization exercise group) produced better results in reducing pain measured on VAS scale compared to all the other groups (Table 1). Posthoc comparison of VAS post between group A and C, produced a mean difference of 1.200 and a statistically significant p value of 0.0037. While, Posthoc comparison of VAS difference between group A and C, produced a mean difference of 1.450 with a statistically significant p value of 0.005.

Pre post comparison of outcome measures within the group using paired t test produced statistically significant mean difference in all the outcome measures with a p value of <0.001 (Graph 1, 2, and 3).

Discussion

The association of breathing and low back pain has been studied extensively. Diaphragm functions for respiration as well as stabilization of the spine. Evidence suggests that the coordinated function of breathing and spinal stabilization by core muscles is altered in low back pain.

Results of the study proved the effectiveness of the interventions by demonstrating statistically significant improvement in reducing pain, disability and enhancing core strength on analysing within each group

Expiratory training with ball and balloon in 90-90 bridge position demonstrated optimum ZOA (zone of apposition) of the diaphragm. This optimizes the intra-abdominal pressure essential for adequate spinal stiffness providing optimal spinal stability. As, low back pain is often associated with excessive lumbar lordosis, ideal ZOA also corrects this faulty posture. According to Boyle et al (2010) blowing out using a balloon enhances abdominal muscle activation, which is capable of opposing the diaphragm, further improving the ZOA of the diaphragm. Abdominal activation pulls the ribs inward hence relaxing the paraspinal muscles, which consequently diminish lumbar lordosis and back pain.[3]

Inspiratory muscle training enhance trunk stabilizing function of the diaphragm. Janssens et al (2013) had proposed that low back pain is associated with diaphragm fatigue.[10] With inspiratory muscle training, diaphragm efficiency can be improved, which enhances the respiratory as well as trunk stabilizing function of the diaphragm.[9] Pain gate theory (Mendell L M 2014) and enhancement in trunk proprioception following inspiratory muscle training (Janssens et al 2014) explains mechanism of statistically significant reduction in pain following inspiratory training.[9, 12] According to Borghi Silvia et al (2008), by inspiratory muscle training, efficiency of diaphragm function is enhanced which improves oxygenation to the peripheral muscles along with the muscles surrounding the lumbar spine. Enhanced blood flow to the lumbar muscle spindle improves the proprioception which was previously overwhelmed by nociceptive input.[11, 13] Hodges et al (2005) have proposed that, diaphragm training enhances intra abdominal pressure needed for optimum spinal stability.[9] Thus, inspiratory muscle training enhances stability of the spine as well as reduces low back pain.

Lumbar stabilization exercise programme focuses mainly to achieve neutral zone, which is the part of normal physiological intervertebral motion. According to Punjabi(1992), this requires coordinates activation of the passive system (ligamentous system) and active systems (muscles and tendons) and neuronal control system. Ligaments provide passive support, muscles give active support, neural system receives information about the position and direction of movement and helps the muscles to contract and maintain stability by increasing the stiffness and reducing the size of neutral zone. This improves movement accuracy. Stabilization exercise program therefore focuses to improve movement accuracy thereby reducing low back pain.[8]

Conclusion

On completion of the study, it has been revealed that inspiratory training, expiratory training and lumbar stabilization exercises are effective in chronic mechanical low back pain. Whereas, inspiratory training proved to be superior in terms of improving pain. Limitations of the study included small sample size, no long term follow up. In future, the study could be done in radiating low back pain with long term follow and pulmonary function test can be checked to correlate breathing and low back pain

Conflict of Interest: The authors had declared that there is no conflict of interest

Influence of Self-Efficacy on Student Engagement of Senior Secondary School Students

Kundan Singh[1], Bilkees Abdullah[2]

[1]*Assistant Professor, School of Education, Lovely Professional University, Phagwara, Punjab,*
[2]*Research Scholar, School of Education, Lovely Professional University, Phagwara Punjab*

Abstract

Context: The present study examined to investigate the influence of self-efficacy on student engagement of Senior Secondary School students. The respondents were students from senior secondary school of Jammu and Kashmir. A Sample of 400 senior Secondary School Students (200 boys and 200 girls) were selected from Jammu and Kashmir by employing simple random sampling. T-test, correlations and regression were employed to analyze the data. The study indicated that (a) there exists significant difference between senior Secondary School boys and girls with their self-efficacy (b) there exists Significant Difference Between Private and Government senior Secondary school Students with their self-efficacy (c) there exists Significant Difference Between senior Secondary School Boys And Girls with their student engagement (d) there exists significant difference between private and government senior Secondary school Students with their student engagement. It revealed that significant relationship was found between self-efficacy and student engagement of senior secondary school students. It also found the self-efficacy had significant influence on student engagement of senior Secondary School Students.

Keywords: *Self-efficacy, Student Engagement, Senior Secondary School students.*

Introduction

Self-efficacy refers to a man's conviction that they can proficiently completed at an allocated levels in a specific academic part of information. A man's trust in their ability to make, executes, and guides execution with the ultimate objective to deal with an issue or accomplish an endeavor at an appointed level of capacity and aptitude. Students who are sure about their capacity to execute, to sort out and manage with their basic reasoning or activity execution at an allocated levels of fitness is showing high self-efficacy. Self-efficacy is by and large viewed as a multidimensional develops separated over different spaces of working. Self-efficacy is grounded in principle by[1]. As per Self-Efficacy assumption, Self-Efficacy is a "person's trust in their capacity to compose and execute a given strategy to take care of an issue or achieve an assignment". As indicated by[2] self- efficacy alludes to people's feelings that they can effectively perform given errands at assigned levels. Self- efficacy is the conviction about person's assessed capacity to play out a given task. Self- Efficacy contains convictions individuals have about their capacity to achieve specific results.[3] It is noticed that self-efficacy is the certainty a man has in realizing a particular result. Self-efficacy as persons' confidence about their abilities to make appointed levels of execution that actions affect over events that impact their lives. As shown by him, it chooses how people feel, think, and conscious themselves and carry on.[4] Self- efficacy suggested proposes that Academic Self- efficacy can change in quality as a component of undertaking trouble. Two general classes of academic hope convictions have been assumed. Understanding the distinction between these two types of hope convictions is very important

as people can trust that a specific conduct will deliver a specific (result desire), yet may not trust they can play out that conduct (efficacy desire)". Found that there exists a positive correlation between Mental Health of senior secondary school Boys and girls with their Life Skills and Self-Efficacy.[5] results found that significant relationship was found between academic performance of senior secondary school students with their self-efficacy and social support.[6]

Student Engagement: The idea of student engagement has progressively increased the consideration throughout the most recent decade. It comprehensively alludes to Students' Engagement in actions that gave up to their knowledge accomplishments and their sense of belongings with their educational network. It additionally included actions other than those straightforwardly identified with course work, for example, non necessary companion learning exercises and administration exercises, for example, positions of authority in student tutoring or study group assistance. Found that there exists significant correlation among social support and student engagement of Secondary School Students.[7] Also, engagement is how much students are engage in their learning actions and their commitment is emphatically connected to a large group of preferred results, include student satisfaction and determinations. This definition infers the utilization of three interrelated criteria to evaluate Student engagement levels namely:

Emotional Engagement: refers to the connections among students and their teachers, schoolmates and school. This has likewise been called 'recognizable proof' with school and learning rehearses. Students are engaged in when they feel incorporated into the school and feel a passionate security with the school, its teachers and their companions.

Cognitive Engagement: It can be understand as a student's psychological importance in their own knowledge. At the point when a student is cognitively engage in, student believe, spotlight on accomplishing objectives, are stretchy in their endeavor and familiarize you to dissatisfaction. This is unique in relation to high achievement a student who is performing great may at present be disengaged whether they are wandering and not inspired to endeavor themselves more than is vital to obtain by.

Behavioral Engagement: refers to students' involvement in classroom activities and in learning. This includes holding fast to behavior rules, leaving to exercises as necessary and reaching at classes on time. Essentially, Behavioral Engagement refers to the educational performances that are critical for high students' implementation, which may include cooperation and communication with companions. Moreover, it covers students' investment in various elements of school life, e.g., school community activity and extracurricular actions.

The present study is intended to find out how Student Engagement is related to Self-efficacy. Movements like universlization of elementary education as a fundamental right have improved the quality and quantity of school education in India. Kashmir, being a role model, has better education system as compared to other states. Self-efficacy has a significant task in influencing students' academic Success and Student engagement. Many teachers complain that student's are giving less important to their academic activities, because they were not able to cope up effectively with academic success. Improved Self-efficacy may help to increases Student engagement. In this study investigators try to find out whether Self-efficacy had any significant influence on Student engagement.

Objectives:

1. To compare the difference of self-efficacy of senior secondary school students on the based on gender.
2. To compare the difference of student engagement of senior secondary school students on based on gender.
3. To find out the relationship between self-efficacy and student engagement of senior secondary school students.
4. To find out the influence of self-efficacy on student engagement of senior secondary school students.

Hypotheses:

1. There exists no significant difference of self-efficacy of senior secondary school students on the basis of Gender.
2. There exists no significant difference of Student engagement of senior secondary school students on the basis of Gender.
3. There exists no significant relationship between Self-efficacy and Student engagement of senior

secondary school students.

4. There exists no significant influence of self-efficacy on Student engagement of senior Secondary School Students.

Methodology: Descriptive Survey Method was used. Data was collectedfrom Senior Secondary School students of Jammu & Kashmir, by employing simple Random Sampling technique. The sample consists of 400 senior secondary school Students.

Instruments:

1. Self-Efficacy Scale: this scale was developed by Bhatnagar and Mathure. Self-Efficacy is the confidence that one can successfully complete in a given circumstance. Self-Efficacy Scale plans to study the dimension of self-efficacy in any age group over 14 years. It comprises of 22 items, managing eight factors. Reliability co-efficient of the scale was estimated by test-retest and found 0.79 to 0.86.

2. Student Engagement Scale: This scale was developed by Dogan (2014) and was adopted in Indian context. The scale is a 5-point Likert Scale consisting of 22 items and 3 sub-dimensions (cognitive, emotional, and behavioral engagement). The final set of statements was check for internal consistency using SPSS-22 version. The Cronbach's alpha for the final set of statements was found out to be .765

Procedure: Initially the investigators randomly identified various secondary schools and contacted the authorities of the secondary school personally. The purpose, objectives and relevance of the study were explained to the head of the institution. Then, the tools were directed to the participant after giving necessary instructions to them. Reassurance was given to each that the information collected from them would be used only for research identity and purpose would not to be disclosed. The scoring was done as per the manual and entered the data in to a spread sheet for further Statistical Analysis by using t-test, correlation and Regression to analyze the data.

Results and Discussions

Table 1: There exists no significant difference of self-efficacy of senior secondary school students on the basis of Gender.

	Gender	N	Mean	S.D	t- value	Levels of significance
Self-efficacy	Boys	200	88.03	4.40	6.33	Significant
	Girls	200	84.91	4.96		

According to the above table reflects that the mean scores of boys and girls of senior secondary school students is 88.03 and 84.91 respectively. The S.D for boys and girls Senior Secondary School Students is 4.40 and 4.96 respectively. Further, the t-value is 6.33 which is significant at 0.05 level. So, that there exist significant difference between Senior Secondary school girls and boys in their self-efficacy.

Further it is evident from the table that mean score (88.03) of boys' Senior Secondary School Students was greater than (84.91) of girls Senior Secondary School Students. So, it can be interpreted that boys' Senior Secondary School Students had higher self-efficacy than girls' senior secondary school students.

According to the above results, it confirmed that the hypothesis no. 1, "there exists no significant difference of Self-efficacy of Senior Secondary School Students on the basis of gender" is thus rejected.

Table 2: There exists no significant difference of Student engagement of senior secondary school students on the basis of Gender.

	Gender	N	Mean	S.D	t-value	Levels of significance
Student engagement	Boys	200	90.98	4.18	7.51	Significant
	Girls	200	88.06	3.49		

According to the above table reflects that the mean scores girls and boys of Senior Secondary School Students are 90.98 and 88.06 respectively. The S.D for girls and boys Senior Secondary School Students is 4.18 and 3.49 respectively. Further, the t-value is 7.51 which are significant at 0.05 levels.. So, that there exist Significant Difference Between Senior Secondary School Girls and Boys in their Student engagement.

Further it is obvious from the table that Mean score (90.98) of Boys Senior Secondary School Students was greater than (88.06) of Girls Senior Secondary School Students. So, it can be interpreted that Boys Senior Secondary School Students had higher Student engagement than Girls Senior Secondary School Students.

According to the above results, it can be confirmed that hypotheses no 2 i.e. "there exists no significant difference of Student engagement of Senior Secondary School Students on the basis of gender" is thus rejected.

Table 3: there exists no significant relationship between self-efficacy and student engagement.

		Student engagement	Self-efficacy
Student engagement	Pearson's Correlation	1	.316**
	(sig.2 tailed)		.000
	N	400	400
Self-efficacy	Pearson's Correlation	.316**	1
	(sig. 2 tailed)	.000	
	N	400	400

**correlation is significant at 0.01 levels of significance (2-tailed).

According to the above table it can be seen that Self-efficacy significantly correlated with Student engagement. It is observed that there exists a significant relationship between Self-efficacy and Student engagement of Senior Secondary School Students. From the above table it reflects that coefficient of correlation between Self-efficacy and Student engagement of senior secondary school students is .316 that is significant at 0.01 level of significance. This indicated that there exists a significant relationship between Self-efficacy and Student engagement of Senior Secondary School Students. It also shows that Self-efficacy had significant Influence on Student engagement of Senior Secondary School Students.

Therefore hypothesis 3, namely "there exists no significant relationship between Self-efficacy and Student engagement" stands rejected.

Thus self-efficacy increased student engagement. Self-efficacy plays an essential position in determining student engagement. Students' who have possessed high self-efficacy are very much more engaged in their studies. It is same as in the case that Student engagement and that those who have high self-efficacy show more Cognitive, Behavioral and Emotional engagement. Manikandan and Neethu(2018) supported our study and found that Student engagement is significantly related to academic Stress and Self-efficacy.

There exists No Significant Influence of Self-Efficacy on Student Engagement.

Table 4: Model Summary for Regression Analysis

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.316*	.100	.098	3.899

According to above table shows the correlation coefficient of Self-efficacy and Student engagement of adolescents. The coefficient of correlation is .316* and its square is 0.100 Regression suggests that predictive variables i.e. Self-efficacy can explain 1.0% variance of the criterion variable (Student engagement).

In Order to study the influence of self-efficacy on student engagement ANOVA has been applied on the influence of self-efficacy on student engagement.

Table 5: Summary Of Anova By Regression

Model	Sum of square	df	Mean of square	F	Sig
Regression	673.494	1	673.494	44.304	.000*
Residual	6050.203	398	15.202		
Total	6723.698	399			

According to the above table shows that the results of ANOVA of self-efficacy on student engagement. It is clear that acquired F-value is (44.304) which are statistically significant at 0.01 level of significance which shows the statistically significant Relationship Between self-efficacy and Student engagement. The predictive variable (Self-efficacy) can influence the criterion variable (Student engagement). The above findings revealed that Self-efficacy has significant influence on Student engagement. So there exists significant influence of Self-efficacy on Student engagement. Therefore, regression analysis is allowed and feasible.

Therefore hypothesis 4, namely "there exists be no significant influence of Self-efficacy on Student engagement" stands rejected.

Table 6: Summary of Coefficient Of Regression

Model	Unstandardized Coefficient		Standardizes Coefficient	t	Sig.
	B	Std. Error	Beta		
(Constant) elf-efficacy	66.734 .263	3.422 .040	.316	19.503** 6.656*	.000 .000

According the above table with B=.263 and t=6.656 which is significant at 0.05 level of significance. It implies that Self-efficacy plays an important role in predicting Student engagement. So, it can be revealed that Self-efficacy had significant Influence on Student engagement. The regression equation for predicting student engagement by the predictor variable i.e. Self-efficacy. Therefore, the regression equation formulated from these two variables is given below:

Student engagement = 66.734 + .263× Self-efficacy

Conclusions

The study presented the following conclusions:

- Based on the result analysis it found that there exist significant difference between senior secondary school Boys' and Girls'in their self-efficacy. Boys of senior secondary school students had higher self-efficacy than girls of Senior Secondary School Students.
- There exist significant Difference Between Private and Government senior secondary school students in their Self-efficacy. Government Senior Secondary School Students had higher Self-efficacy than Private senior secondary school Students.
- There exists Significant Difference Between Senior secondary school Girls and Boys in their Student engagement. Boys had higher Student engagement than Girls.
- There exists significant difference between in Student engagement among Senior secondary school students on the basis of Type of School. Government Senior Secondary School Students had higher than Private Senior Secondary School Students.
- Self-efficacy had significant Influence on Student engagement. There exists significant influence of Self-efficacy on student engagement.
- There exists a Significant relationship between self-efficacy and Student engagement of Senior secondary school students. It also shows that Self-efficacy had significant Influence on Student engagement of Senior Secondary School Students.

Implications of the Study: The findings revealed that self-efficacy is significantly correlated with Student engagement; this also has some suggestion. Since self-Efficacy alludes to an individuals' opinion of their capability to arrange and achieve the plan of activity essential to bring about prearranged sorts of engagement and worried about the estimation of what one can achieve with the aptitudes one presently achieves. It suggests that students who are Self-efficacious will in general produce and test elective strategies of activities when they don't at first make progress. This implies that

students ought to be positive to create, have or develop efficacy disposition. This is essential in light of the fact that it could fill up in as a defense that may support the students up regardless of their experience to be engaged. If students are given tasks that are challenging but not too difficult and they experience success upon completion of these tasks that Self-efficacy to learn may increase. As Self-efficacy to learn increases, so will interest, value, and utility. A strategy such as this one would be very useful for teachers to implement. Teachers can organize and design their instructions to have a constructive result on students' self-efficacy to learn which would lead to improved Student engagement and improved learning.

Declaration of Conflict of Interests: The author(s) declared no potential conflicts of interests with respect to the research, authorship, and/or publication of this paper.

Ethical Clearance: All procedures performed in this paper were in accordance with the ethical standards of the institution and the national research committee.

Funding: The author(s) received no financial support of the research, authorship, and/or publication of this paper.

Ruptured Bicornuate Uterus Mimicking Ectopic Pregnancy: A Case Report

Kusum Sharma[1], Renu Yadav[2], Shekhar Sharma[3]

[1]Director, Maternity Fertility and Plastic surgery centre, Near KathputliMandir, Moh-Gopal Garh Bharatpur, Rajasthan, [2]Senior Resident, [3]Senior Resident, Department of Paediatrics, Muzaffarnagar Medical College, Muzaffarnagar, U.P.

Abstract

Introduction: Congenital malformations of uterus occur due to abnormal formation, fusion or resorption of mullerian ducts during fetal life. A normal uterus is formed by fusion of two mullerian ducts which starts at 10th week and uterine development is completed by 20th week. If the two mullerian ducts fail to fuse it results in separate uterine horns also known as Bicornuate uterus.

Presentation of Case: We are presenting a case of 24 year old primigravida presented to us at 15th weeks of gestation who was having amenorrhoea for 3 months and 26 days along with gaseous distention of abdomen and lower abdomen pain for 6-7 days. She again underwent an abdominal ultrasonography at a different centre and it was suggestive of ?abdominal pregnancy. She underwent an abdominal ultrasonography again after 2 weeks of this where she was diagnosed as abdominal pregnancy with minimal as cites. To take further advice she presented to us the next day with both the reports. An assessment of ectopic pregnancy was made, she was counselled and consent for lapratomy was taken. At surgery a gravid bicornuate uterus with pregnancy in left cornua was found. Tubes and ovaries were normal. The conceptus ruptured the left uterine wall and the omentum was found adhered to the uterus. Omentum was ligated. The ruptured left horn was removed at its junction to right horn. Product of conceptus was taken out, pelvis was drained of blood and uterus and abdomen were closed in layers after achieving complete hemostasis.

Discussion: Our patient had ultrasonographic diagnosis of abdominal pregnancy at 15th week so an emergengency laparotomy was done to save patients life. On laparotomy bicornuate uterus with ruptured pregnancy in left horn was found. Blood, fluid replacement therapy and exploratory laparotomy followed by repair of uterus and drainage of pelvic blood was necessary to save patients life.

Conclusion: This case highlights the fact that a bicornuate uterine pregnancy can mimc an ectopic pregnancy and the two should be differentiated.

Keywords: *Bicornuate uterus, Ectopic pregnancy.*

Introduction

Congenital uterine malformations result from abnormal formation, fusion or resorption of mullerian ducts during fetal life[1]. Columbo et al was the first person to report and describe a case of vaginal a genesis in 16th century[2]. Development of genital tract begins as mullerian ducts also known as paramesonephric

ducts, forms lateral to each mesonephros. These ducts grow downwards and join in midline. Uterus is formed by fusion of these two ducts by 10th week. After that, cellular proliferation at the upper portion forms the pyriform shape of uterus. At the same time desolution of cells at lower pole forms the uterine cavity. Uterine development is completed by 20th week. If the two mullerian ducts fail to fuse it results in separate uterine horns of varying degree. Bicornuate uterus is a common defect which occurs due to lack of fusion of fundus of two hemi uteri,however there is only one cervix and vagina. This defect can lead to various obstetrical outcome like miscarriage, malpresentation and premature delivery[3]. The prevalence of congenital uterine malformations ranges from 0.1%to 10% [4] Diagnostic modalities include hysterosalpingography, magnetic resonance imaging and 3 dimensional ultrasonography. Since bicornuate uterine pregnancy is difficult to diagnose, mimicks ectopic pregnancy and is associated with complications[5] we report a case of bicornuate uterus with pregnancy in one cornua which mimicked ectopic pregnancy on ultrasonography. Confirmation was done by laprarotomy. Pregnancy had ruptured the uterus leading to peritoneal adhesions, so it has to be terminated. The uterine and abdominal walls were closed after achieving complete hemostasis.

Case Report: A 24 years old female presented to us with amenorrhoea for 3 months and 26 days along with gaseous distention of abdomen and lower abdomen pain for 6-7 days. There is no history of bleeding per vaginum or medication intake. Obstetric history was g1 p0a0l0. Her appearance was slightly pale and was comfortable. Height was 162cm and weight was 49 kgs. Pulse rate was 102/min, blood pressure was 106/58 mm of mercury in right arm supine postion. Respirory rate was 18/min. Head to toe examination was within normal limits except slight distension of lower abdomen. Abdomen was soft and tender in left lumber are and right iliac fossa. Fundal height was of 18 week pregnancy. On per vaginal examination was insignificant hemoglobin was 10 gm/ decilitre other blood indices were within normal limits.

Before coming to us she underwent an abdominal ultrasonography at a different centre which revealed a normal pregnancy of 15.1 weeks in lower abdomen and it was suggestive of? abdominal pregnancy. She underwent an abdominal ultrasonography again after 2 weeks of this where she was diagnosed as abdominal pregnancy with minimal ascites. To take further advice she presented to us the next day with both the reports. An assessment of ectopic pregnancy was made, She was councelled and consent for lapratomy was taken. At surgery (fig 1) a gravid bicornuate uterus with pregnancy in left cornua was found. Tubes and ovaries were normal. The concept us had ruptured the uterine wall through an opening in superior lateral region (left uterine horn) with continuous bleeding from the edges. Omentum was found adhered to the uterus. Omentum was ligated, left horn was removed, product of conceptus was taken out and sent for histopathological examination. Pelvis was drained of blood and uterus and abdomen were closed in layers after achieving complete hemostasis. Two units of packed cells were also transfused. The patient was stable after operation, post-operative period was uneventful and she was discharged in a healthy condition on fourth post-operative day.

Fig. 1: picture showing gravid bicornuate uterus with pregnancy in left cornua

Fig. 2:

Fig. 1 and Fig. 2 showing two horns of the uterus which were seen at the time of laparotomy.

Discussion

Congenital uterine malformations are common and most of the time asymptomatic. Women with uterine abnormalities have poor reproductive outcome and lower pregnancy rates as compared to women with normal uterus. Uterine anomalies are associated with complications like miscarriage, malpresentation and premature delivery and a need for caesarean section[6]. Our case was a previously unbooked and primi gravid case whose uterine anomaly was found after laparotmy which was done for suspected ectopic pregnancy. The pregnancy led to the rupture of uterus and formation of peritoneal adhesions. Ultimately the pregnancy has to be terminated. Nwosu and co-workers[7] reported a case of a 28 year old women in which the pregnancy in one horn of bicornuate uterus led to rupture of pregnancy. In this case one horn of uterus was removed and she was able to carry out subsequent pregnancies to term. SqnLdr Amit Suri, Lt Col L Satija[8] reported two cases in which one the case was of a 27 years old nulliparous woman who underwent artificial insemination, at 6 weeks presented with bleeding per vaginum, ultrasound showed a healthy gestational sac with a live foetus. Because of recurrent bleeding afterwards ultrasound was done again which revealed two gestational sacs-one in each horn of a previously undetected bicornuate uterus. This case ultimately delivered a healthy baby. While in our case since pregnancy had ruptured the uterus we had to terminate the pregnancy. This case also highlighted the importance of careful ultrasonographical monitoring of pregnancy and bicornuate uterine pregnancy leading to misdiagnosis. LD Aliyu and MK Abdullahi[9] reported a case of a 26 year old women with an obstetric history of $G_6P_{5+}0$ (3 alive). Ultrasound showed empty uterus with mass in right adenexa. Laparotomy was done suspecting ectopic pregnancy, bicornuate uterus was revealed with intact pregnancy. Spontaneous abortion occurred shortly after discharge. Since she had previous pregnancies without complications, this case revealed that even with bicornuate uterus successful pregnancy without complications can be attained, however our case had complication even in her first pregnancy. Reddy Ravikanth[10] reported a case of 32 years old women with repeated complications during pregnancy. During first preganancy it was IUGR baby, during second it was breech presentation with oligohydramnios with IUGR and in third pregnancy she underwent ultrasound which showed 10 week fetus implanted in left cornua of uterus, this pregnancy was also lost at 14 weeks. This case highlighted the complications of congenital anomalies of uterus as in our case and also that recurrent complications in a pregnancy can be due to malformations of uterus and clinician should think in this direction too.

Although bicornuate uterine pregnancy is not that rare, it draws sufficient interest. however it is not necessary that a women with bicornuate uterus can not have normal pregnancies but such women are at higher risk of developing complications like rupture of uterus, IUGR, Oligohydramnios, Malpresentationetc. Ultrasound in experienced hands is a good tool to diagnose uterine malformations but interpretations are operator dependent. Such pregnancies should be managed with extra care. It is necessary for obstetricians to create a patient awareness regarding this condition and its possible outcomes. It is also necessary to make prenatal diagnosis to provide proper care.

Conclusion

We reported this case as to highlight the fact that if uterine anomaly is present, uterine rupture can occur

in early pregnancy. Obstetricians should be aware of this condition and its life threatening potential. Earlysonography should be done but it must not be completely trusted upon as it might mislead the diagnosis of ruptured bicornuate uterus as ectopic pregnancy.

Patient Satisfaction in a Dental Hospital with Respect to Clinician Expertise

L. Sri Varsha[1], Sheeja Varghese[2]

[1]Undergraduate student, Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Chennai, India, [2]Professor,and Head Department of Periodontics, Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Chennai, India

Abstract

Aim: To compare the level of patient satisfaction in a dental hospital with respect to clinician expertise.

Objective: To assess the patient satisfaction in a dental hospital and compare the patient satisfaction between those who were treated by undergraduates, fourth year undergraduates and Compulsory Rotational Interns (CRI) based on the clinician's speed of treatment, explanation and caring and cleanliness.

Background: Patient satisfaction is regarded as an important outcome of care and is one of the major factors that contribute to better patient compliance and consequently to improved clinical outcomes. Measuring patient satisfaction allows for evaluation of health systems, particularly comparisons between different models of care delivery.

Rationale: As teaching facilities, dental school clinics must constantly strive to find a balance between meeting the needs of the patient and meeting the needs of the student, all the while knowing that patients and their satisfaction are critical to the education of our students.

Materials and Method: This study was conducted among the patients undergoing treatment in Saveetha Dental Hospital, Chennai. Feedback was collected from 1500 patients of which 500 were treated by third years, 500 were treated by final years and 500 were treated by CRI (Compulsory Rotational Internship) and the satisfaction level of patient was assessed based on the speed of the procedure, explanation of the procedure, empathy and cleanliness on a scale of 0-10 and the average score was compared among third year undergraduates, fourth year undergraduates and CRI. Statistical analysis was done by SPSS software using Anova and Post-Hoc test.

Results: Overall, the satisfaction score of patients treated by interns were higher in all the categories followed by final years and third years. Interns were significantly better than third years and final years in terms of explanation and cleanliness. But, there was no statistically significant difference between 3rd years, fourth years and interns in terms of speed of treatment.

Conclusion: From this study, it can be concluded that as the level of expertise increases the level of patient satisfaction increases.

Keywords: *satisfaction, cleanliness, explanation, caring, speed of treatment.*

Introduction

Patient satisfaction in dental care is an important aspect of the quality of care that influences the future utilisation of the service. It is regarded as an important

outcome of care and is one of the major factors that contribute to better patient compliance and consequently to improved clinical outcomes. Today, health care is being transformed from a provider centred approach to a patient centred approach in which satisfaction of the patients' needs is part of the definition of quality. A major issue for careful monitoring is recognition of the complex relationship between patients' views of the health care system and their health and illness behaviour.[1,2] Dentist-patient interactions during a consultation, including cognitive and emotional aspects, have been demonstrated to affect patient compliance with clinical advice and follow-up visit. Patient satisfaction with care is a useful measure that evaluates care, including the quality of care and provider-patient relationships. It has been demonstrated that patient satisfaction is a multidimensional concept. Some dimensions of dental care that have been identified are technical or aspects of care related to the process of diagnosis and treatment; interpersonal; accessibility/availability; financial access; efficacy/outcomes; continuity of care; facilities; and general or attitudes about overall care.[3,4] Patient satisfaction measures the process of care, broadly defined as the professional activities associated with providing care which allows for evaluation of health systems, particularly comparisons between different models of care delivery.[5, 6]

The most important aspects considered with regards to dental treatment in this study is explanation about the procedure which involves clinical examination and proper diagnosis followed by explaining about the treatment options and the procedure. The next aspect is caring, where the patient needs to be assured about the safety of the procedure and should be explained about the adverse effects if the patient does not undergo the treatment. The final aspect is cleanliness, which is an important aspect as it is what represents the patient's perception about the doctor. Clean working setup is essential with proper sterilised instruments.

In a dental college, the students undergo training in pre-clinical labs during their first and second year and enter the clinics during third year. Students undergo training in clinics during third year, final year and internship. During their clinical posting, students provide various dental treatments to patients under the concerned specialists supervision

As teaching facility, dental school clinics must constantly strive to find a balance between meeting the needs of the patient and meeting the needs of the student, all the while knowing that patients and their satisfaction are critical to the education of the students. Also, dental school clinics play a prominent role in promoting oral health care. Furthermore, in a dental school setting, the focus on meeting requirements for graduating students must be balanced with patients' satisfaction. Though both care providers and patients benefit from their interaction, patient satisfaction must beprioritised.[7]

Although there are many studies showing satisfaction level of patients pertaining to various aspects in medical field, not many studies are available that determine the patient satisfaction in relation to the clinician expertise. Hence, this study aims in determining the patient satisfaction with respect to clinician expertise ie whether there is any difference in patient satisfaction between those who treated by third year undergraduates, fin

Materials and Method

This study was approved by the Scientific Research Board of Saveetha Dental college. This study was conducted in Saveetha Dental College, Chennai. Feedback is generally collected from all the patients undergoing treatment in Saveetha Dental college. This study consisted of three groups- interns (group 1), final years (group 2) and third years (group 3). Data was collected from the feedback note. 1500 feedbacks were collected of which 500 each belonged to patients who had undergone treatment from third years, final years and interns. The feedback form had three categories- speed of treatment, explanation and caring, cleanliness which were scored on a scale of 10 by the patients. Once the treatment is completed, the patients are asked about their overall experience, if they were satisfied with their treatment or if they faced any difficulties. Mean value was calculated for all the categories and statistical value was determined using Anova and post hoc test.

Results

The mean value of speed of treatment in group 1, 2 and 3 are as follows- 8.862±4.09, 8.674±0.70 and 8.594±0.85. The mean value of explanation and caring in group 1, 2 and 3 are as follows- 8.77±0.72, 8.764±0.79 and 8.61±0.73. The mean value of cleanliness in group 1, 2 and 3 are as follows- 8.73±0.74, 8.65±0.73 and 8.60±0.82. Table 1

The p value of group 1 and 2 in terms of speed of treatment was 0.445, 0.985 in terms of explanation and

caring and 0.210 in terms of cleanliness. The p value of group 2 and 3 in terms of speed of treatment was 0.863, 0.005 in terms of explanation and caring and 0.585 in terms of cleanliness. The p value of group 3 and 1 in terms of speed of treatment was 0.194, 0.003 in terms of explanation and caring and 0.021 in terms of cleanliness. Table 2, 3.

Table 1: Mean value of patient satisfaction

GROUPS	SPEED OF TREATMENT	EXPLANATION AND CARING	CLEANLINESS
	MEAN STDEV	MEAN STDEV	MEAN STDEV
INTERNS (1)	8.862±4.09	8.77±0.72	8.73±0.74
FINAL YEARS (2)	8.674±0.70	8.764±0.79	8.65±0.73
THIRD YEARS (3)	8.594±0.85	8.61±0.73	8.60±0.82

Table 2: Comparison between groups

GROUPS	SPEED OF TREATMENT	EXPLANATION AND CARING	CLEANLINESS
	P VALUE	P VALUE	P VALUE
1 AND 2	0.445	0.985	0.21
2 AND 3	0.863	0.005	0.585
3 AND 1	0.194	0.003	0.021

	3	.048	.049	.585	-.07	.16
3	1	-.130*	.049	.021	-.24	-.02
	2	-.048	.049	.585	-.16	.07

Discussion

The result of this study shows that, overall the patient satisfaction is good as the grade is above eight for all the groups in all the three aspects. Overall, the patient satisfaction in terms of speed of treatment, explanation and caring and cleanliness was higher in interns followed by fourth years and then third years. There was no significant difference in relation to speed of treatment. There was significant difference between groups 2 and 3 (p=0.005), and groups 3 and 1 (p=0.003) in terms of explanation and caring. There was significant difference between groups 1 and 3 (p=0.021) in terms of cleanliness.

A study conducted in Ohio state compared the patient satisfaction between ohio state university dental clinics and ohio state university dental students. Dental satisfaction questionnaire (DSQ) was used for this study and the only items of the DSQ that were significantly different were people are usually kept waiting a long time when they are at the OSU dental clinic (p=0.02) and OSU dental students are able to relieve or cure most dental problems that people have (p=0.02). A possible reason for the longer patient waiting times was that there was a learning curve that first year for all involved—clinic staff, students, and patients. This learning curve resulted in patients being kept waiting longer than before.[8]When compared with our study, the waiting time and speed of treatment was not afactor affecting the patient satisfaction in all the three groups irrespective of their year of study.

A study in Greek recorded the patient's perception and expectations regarding quality of dental care. It was found out that empathy was the most important aspect that needed to be fulfilled followed by assurance, responsiveness and reliability. There was a large quality gap regarding responsiveness, empathy and reliability reflecting the need to improve quality of dental health care,. The examined patients considered that they were not sufficiently informed about oral diseases[9] which is similar in our study. The level of explanation and caring was higher in interns and final years and there was a significant difference between final years and third years, third years and interns.

A study in Ajman university recorded the patient satisfaction level based on their reason for visit and educational qualification of the patient. The major reason for admission (80.0%) was relief of pain . A high proportion of the patients (83.0%) visited the dentist only when they had a problem, just 7.4% came twice a year. The largest category for treatment received (23.0%) was operative treatment, followed by endodontic treatment (19.3%).There was a statistically significant association between the level of education and the dental satisfaction scale. The most highly educated patients were the least satisfied with the treatment provided. Patients who visited the clinic for pain relief were significantly more satisfied than those who visited the clinic for routine care ($P < 0.01$). The dental satisfaction levels were also significantly higher among patients who visited the clinic only when they had problems ($P < 0.05$). [10]

Another study showed the relationship between patient satisfaction and ethnicity. Black patients tended to be the least satisfied; Hispanic patients were only moderately satisfied when compared to non-Hispanic patients.[11]

According to a study conducted in turkey, the type of health insurance was the most significant predictor of patient satisfaction and time spent waiting seems to be the main reason for patient dissatisfaction in dental outpatient clinic in Turkish state hospitals.[12]

Conclusion:

The overall score of all the three groups were above average. There was a significant difference between final years and third years in terms of explanation and caring and interns and third years in terms of cleanliness. From this study, we can conclude that with experience, explanation about the treatment and cleanliness improves as they gain more confidence.

Psychological Effects of Trauma to Anterior Teeth

Lakshmi Nidhi Rao[1], Aditya Shetty[2], Mithra N. Hedge[3]

[1]Lecturer, Department of Conservative Dentistry and Endodontics, A.B. Shetty Memorial Institute of Dental Sciences, Nitte Deemed to be University, Deralakatte, Karnataka State, India,
[2]Additional Professor, [3]Vice Principal and Head of the Department.

Abstract

Context: Dental trauma has a very distressing experience on physical, emotional and psychological aspects of the patient. The aim of the study was to determine the psychological effects of anterior dental trauma on patients.

A questionnaire study was carried out to know the psychological aspects of trauma to anterior teeth based on the Oral Health Impact Profile (OHIP-14) index. It is regarded as the most comprehensive tool for measuring Oral Health Related Quality of Life. This study concentrated only on psychological discomfort and psychological disability. Each item was scored on a five-point scale ranging from "never" (coded 0) to "very often" (coded 4).

The statistical significance of the scores thus obtained and the mean levels of the severity scores between genders and age groups were calculated using the statistical chi-square test. In our study psychological effects to anterior teeth trauma was most observed in the age group of 18-25. Interestingly when the observation was monitored across genders, we observed large psychological effect in females when compared to male gender.

Keywords: *Anterior dental trauma, psychological effects, OHIP index.*

Introduction

Health is described "a complete state of physical, mental, and social well-being of an individual and not just mere absence of disease" (WHO, 1948). This concept of health embraces the bio-psychosocial model of health into which physical functioning, symptoms, emotional and social well-being are holistically incorporated (Kleinman, 1988). Hence health related researchers have rightly focused on health as a multi-dimensional construct.[1]

Corresponding Author:
Prof. Dr. Aditya Shetty
Additional Professor, Department of Conservative Dentistry and Endodontics, A.B. Shetty Memorial Institute of Dental Sciences, Nitte Deemed to be University, Deralakatte, Karnataka state, India
e-mail: shetty_aditya1@yahoo.co.in

Oral Health Related Quality of Life (OHRQoL) forms an integral part of general health and well-being and is recognized by the WHO as an important segment of the Global Oral Health Program (WHO, 2003).[2] It is imperative to evaluate the extent to which the oral diseases impacts on ones normal functioning and psychology.[3]

In the field of dentistry, OHRQo Laddress four dimensions: pain and discomfort; functional aspects concerning the ability to chew and swallow food without difficulty, speaking and pronunciation; appearance and self-esteem; and social aspects reflecting social interaction with others.[4]

So it is fair to qualify that oral health affects various aspects of social life, including social interaction, self-esteem, school and job related performance, specifically when the issues related to anterior dental trauma are involved. Incidents arising from physical fight, traffic

accident and sporting injuries contributes the major cause of anterior dental trauma.[5]

Dental trauma is usually a pain filled experience for most people which can impair oro-facial function, negatively affecting growth, aesthetics and occlusion.[6] Unlike a chronic condition, severe dental trauma causes immediate and unexpected pain. The obvious economic cost apart, it can trigger a series of socio-economic consequences affecting the quality of life and possibly lead to the absence from college or work, disturbances during sleep and changes in the normal daily schedule. This could be further compounded by the stress patients may experience as a result of unhelpful behaviour by their peers, society and family members. The impact is quite significant when anterior dental trauma is involved, which is what this study tries to document via Oral Health Impact Profile(OHIP-14) survey.

Since anterior dental trauma is often caused by accidents that cause life-threatening injuries, limb fractures or concussion, emergency care prioritizes on more important issues. As a consequence of this delay, sometimes it becomes impossible to provide timely treatment that would have otherwise allowed the affected front tooth to be saved.[7]

Dental trauma frequently affects the upper central incisors, most likely because of their position in the mouth and also having less of a protection in comparison with the other teeth. Consequently the position and appearance of the anterior teeth have very important psychological and social impacts on the quality of life of the patient. When injuries to incisors produce pain, poor aesthetics/disfigurement or other psychological effects, patient may avoid smiling or laughing and this can affect their social relationships. So overall this has a very distressing experience on physical, emotional, and psychological levels of the patient which is a matter of great concern.[8,9,10]

OHIP-14 index assesses seven dimensions of impacts of oral conditions on one's quality of life including functional limitation, physical pain, psychological discomfort, physical disability, psychological disability, social disability and handicap.[11] This is widely regarded as the most comprehensive assessment for measuring OHRQoL.

The aim of the study was to determine the psychological effects of anterior dental trauma on patients and to assess the impact of these injuries on the quality of life based on OHIP-14 index.

Materials and Method

The study was conducted in the Department of Conservative Dentistry & Endodontics, AB SMIDS, Karnataka, India. Ethical clearance was obtained from Nitte (Deemed to be University), Cert. No: ABSM/EC07/2019.

The total numbers of subjects were 256 based on approximately 20% incidence of anterior tooth fractures. Patients in the age group of 18 and above with anterior tooth trauma were included in the study. Participation was voluntary, anonymous and started off with patients consent.

Study was carried out to know the psychological aspects of trauma to anterior teeth based on the OHIP-14 index, specifically w.r.t psychological discomfort and disability. Each item was scored on a five-point scale ranging from "never" (coded 0) to "very often" (coded 4).[1,2,10,12]

The OHIP-14 data were captured and details were entered into SPSS tool (v.16; IBM Corp, Somers, NY) for further analysis. The dependent variables were based on the responses to the OHIP-14 were made on a five-point ordinal scale ranging from ‘‘never’’ coded as ‘‘0’’, ‘‘hardly ever’’ coded ‘‘1’’, ‘‘occasionally’’ coded ‘‘2’’, ‘‘fairly often’’ coded ‘‘3’’, to ‘‘very often’’ coded ‘‘4’’. The statistical significance of the scores and the mean levels of the severity scores between genders and age groups were calculated using the statistical chi-square test.

Above Table: Scaptures the percentage distribution of patients responses across the two dimensions namely

psychological discomfort and psychological disability for the scale ranging from "never" to "very often" (p=0.001).

In Table:1, which is related to psychological discomfort scores related to breakdown w.r.t gender, around 70.9% of the male individuals experienced "occasional" psychological discomfort compared to 76.5% impact of "fairly often" in females (p=0.001).

In Table:2, which is related to psychological disability scores related to breakdown w.r.t gender, around 81% of the male individuals experienced "hardly ever" psychological disability compared to 52% impact of "occasional" in females (p=0.001).

In Table:3, which is related to psychological discomfort scores related to breakdown w.r.t age, around 48.8% of the individuals experienced the impacts of "fairly often". Largest contribution to this came from the age group of 18-25 with 90 individuals out of 138(65.2%) experiencing this impact (p=0.001).

In Table:4, which is related to psychological disability scores related to breakdown w.r.t age, around 46.4% of the individuals experienced the impacts of "fairly often". Largest contribution to this came from the age group of 18-25 with 88 individuals out of 138 (63.8%) experiencing this impact (p=0.001).

Age group 18-25 showed higher scores in the psychological disability and discomfort dimension. The comparison across genders showcased a similar significantly higher uptick for women in the psychological dimensions.

Discussion

Psychological trauma occurs as a consequence of an overwhelming amount of stress experienced that exceeds one's ability to copeor integrate the emotions involved with that experience. Effects of the trauma varies according to one's subjective experiences. So, not all who experience a traumatic event will become traumatized psychologically.

Traumatic injuries constitute painful and distressing event with multilevel consequences for patient and their families. Despite being confined in a small body region as is the oral cavity, dental trauma constitutes a relatively common finding in population-based studies. Andersson noted that although the oral region comprises 1 percent of the total body area, oral injuries account for almost 5 percent of all injuries and for a higher proportion among early adults.

Among these anterior dental trauma forms an important and visible part of human anatomy. These are characterized as major public health problems due to their high prevalence and serious aesthetic and functional consequences. Such trauma can significantly disrupt patients' normal functioning and impact dramatically on the quality of life.

Since anterior dental trauma is often caused by accidents that cause life-threatening injuries, limb fractures or concussion, emergency care prioritizes initially on more critical issues. As a consequence of this delay, sometimes it becomes impossible to provide timely treatment that would have otherwise allowed the affected front tooth to be saved.[8]

The psychological and social impact of dental trauma is widely recognized as having consequences that can affect emotional balance, social contact and also well-being of the patient. There is an evidence of increasing necessity to use indices for measuring the impact of oral health on the quality of life. OHIP-14 index has been the flag bearer in this regard and is thus used for this study.

OHIP-14 index is used to measure patient's perceptions of the social impact of oral disorders on their general well-being. It provides a comprehensive system of measurement for dimensions related to discomfort, self-reported dysfunction and related disability arising from oral conditions.[12]

According to Lockeret al., OHIP-14 is a patient-centred assessment. It gives a greater weight to behavioural and psychological outcomes and is found to be better at detecting psychosocial impacts among individuals. Hence it also satisfies the main criteria for the measurement of OHRQoL.

The study outcome captured in above set of tables show cases the percentage distribution of responses across age and gender respectively for the two psychological dimensions for category scale ranging from ''never'' to ''very often'' as captured in the OHIP-14 index. The purpose of this paper was to review the impact of anterior dental trauma on psychological discomfort and psychological disability attributes across various age categories and gender respectively.

Psychological effects dimension based on age criteria: When this psychological effect dimension

was reviewed based on age criteria, it was observed that lowest measured age group of 18-25 had the most psychological impact at 65.2% with the issue tapering down with age.

The younger age group with little maturity has higher psychological impact than the older more mature groups post 25 years of age. Severity of the issue could be higher among lower age groups, since usually nature of accidents occurs from sports or accidents involving rash driving of youngsters.

Psychological impacts of dental trauma for this age group may be severe so aesthetic considerations should not be neglected. It is found to be one of the important considerations of the age group 18-25. Usually dental conditions are the most severe among health issues in early stages of adulthood, however as one age, other health considerations dominate including life threatening ones. It is quite likely as a result of this, older age groups manage the situation in a better way resulting in reduction of psychological discomfort as compared to younger generation.

Equally important is the fact that younger age group usually is just about starting to become independent financially. Hence this is a in-between phase wherein they are largely still reliant on the family for financial support. As a result may neglect the dental treatment at the appropriate time and the effects become severe later on.

Psychological effects dimension based on gender: Interestingly when the observation is monitored across gender, we observe large discomfort in females in comparison with male gender.

Aesthetic dimension forms a key part for female gender, considerations encompass:

1. Beauty affected hence social impact
2. Societal pressure of friends, family, peers and social media like Facebook, Instagram etc.

It is quite likely this impact would be a lot lower among lower income groups as day to day survival is more important compared to other factors.

There are general attributes which adds to the psychological impact and which usually cuts across gender and ages:

1. Affect by presence of blood and visible nature of the dental trauma.
2. Loss of "hours of schooling/work" with economic consequences. Being able to take time from school/work for these procedures might become cumbersome if the dental clinics are not located at comfortable points.
3. Perception of work peers, friends and family members.

Additionally visit to dental emergency can trigger dental anxiety/fear responses among first time visitors. Hence calming effect of dental surgeon, explanation of the procedures in an easy way and anon-hospital like environment goes a long way in helping the patient settle down and reduce the psychological impact.

The data presented in this study provide a insight into patients' feelings and should be considered essential when evaluating further treatment options. In addition to the prognosis and outcomes, clinicians should consider patients' preferences and perceptions as well as the influence each therapy may have on their quality of life both short-term and long-term.

Health psychologists have recognized that behavioural assets such as resilience, social connectedness and optimism have a direct correlation with an individual's quality of life and how well one is able to cope with health conditions.[1]

Conclusion

In our study psychological discomfort to anterior teeth trauma was most observed in the age group of 18-25. Interestingly when the observation is monitored across genders, we observe large discomfort in females in comparison with male gender.

The study covered suburban areas of Dakshina Kannada district, further studies need to be carried out for a larger population set. Irrespective of age and gender, psychological impact if not handled appropriately could have a life-long impact and affect the general well-being of the patient.

This study will help to create need based and critical psychological adjunct services which can be incorporated into various community-based projects, with the basic idea of integrating dental health with overall well-being and quality of life of the patient.

Communication and positive reinforcement method is most effective way in reducing the psychological impact and should be considered a valuable investment.

This is aptly highlighted by Andersson in his editorial: "empathy for our trauma patients is the common denominator."It helps to build a trusting relationship and plays a key role in relieving the distress experienced by the patient.

Conflicts of Interest: There are no conflicts of interest.

Physical Characteristics and Somato Type of Trained Badminton Players

M.Senthil Kumar[1], T. Vinoy Vincent[2]

[1]Assistant Professor, Department Of Physical Education And Sports Sciences, Srmist, Kattankulathur,
[2]M.Phil Scholar

Abstract

Context: The aim of this study was to analyze the relationship among somato type characteristics and physical training of young male and female Badminton players. A total of 30 players (15 males and 15 females), who represented Kerala in national level competitions, were evaluated with the sex as a factor. Different body measurements were recorded following the guidelines proposed by the ISAK such as body mass, height, skinfold thicknesses at different sites (biceps, triceps, subscapular, supraspinale and medial calf), girths (arm relaxed, thigh, and calf) and breadths (biepicondylarhumerus and femur). In addition to anthropometrical analysis, body composition and somato type of the participants had been assessed. A t- test for independent samples was performed to examine the statistical differences between sex groups and a Pearson's coefficient was applied to evaluate the correlation between variables. An endomorph-ectomorph somatotype characteristics was observed for the entire group. Analysis, taking into account the sex factor, revealed an endomorph-mesomorph somatotype for the males and an endomorph-ectomorph somatotype for the females. Data corresponding to body composition contrasted by sex showed higher body fat percentage for the female group than the males. Within the tested age interval range, body fat content in female players was higher than the male counterparts. Although these differences might be the consequence of a normal growth, it was advisable to integrate educational and nutritional strategies in order to maintain an optimum body fat content. Training procedure must be considered to improve the body type for the specific sports event.

Keywords: *Somato type, Badminton, Body mass, Height, Skinfold thickness.*

Introduction

Badminton is an individual asymmetric sport, in which hits are required with great speed and power.[1] Technical actions that take place during the game are unilateral at the trunk and upper extremities level. Thus the dominant side of the player goes into action repeatedly and exclusively.[2] It is an acyclic sport in which work and rest time periods are continuously alternated.[3] Also, the intensity developed during the match makes it mixed activity, taking into account the energetic metabolism. It is a game characterized by consecutive series of fast and powerful hits against a lightweight ball. This has an alternating demand of aerobic-anaerobic requirement, caused by short and intermittent exercise and efforts with incomplete recoveries.[4] Moreover, the dominant arm is totally involved with different positions that link the racket-arm to develop techniques of this sport.[5] The most important physical capacities of the players are endurance and velocity, due to short time high intensity periods under anaerobic metabolism that characterize the match: Players need velocity training while the capacity to face match duration mainly depends of endurance training .[6] However, strength, coordination and flexibility may also have a key role in this sport. It is evident that the physical training is an important factor to reach sport success; several studies demonstrated that, at the same training level, the best performances are obtained by

athletes with more compatible anatomic conditions.[7] Since 1940 numerous studies on body composition influenced the development of somatotyping and, in the last 20 years, many studies had defined the somatotype profile of athletes in different sports. Research interest in anthropometric characteristics and body composition of the players of different sports had been developed during the last decades.[8] Different studies supported the requirement of specific anthropometric characteristics which determine the suitability of the player for best performance in that specificgame.[9]

Statement of the Problem: The main objectives of the present study was to explore the possible role of training in 10-20 years aged male and female right handed Badminton players.

The objectives of the present study were aimed at following points:

1. To compare the effects of similar type of training in male & female Badminton players in similar age ranges.
2. How body type of the players can be improved by improving the physical training method?
3. Whether the body type of the both male and female Badminton players affect their performances.

Methodology: Subjects in the present study male right handed Badminton players (n=14) who were trained for 2 to 8 years with an average age of 13.29(±1.86) years and female right handed Badminton players (n=15) who were trained for 4 to 12 years with an average age of 13.93(±3.13) years participated as subjects. Individual NFHS (National Standard of Living Index) and SCAT (Sports Competition Anxiety Test) were carried out in each subject. Participants of this study were from different places of Kerala with participation experiences at national level competitions. All the players were involved in regular scheduled training programs of 30 min free hand exercises followed by 90 to 120 min game practice with full efforts intermittently for 6 days per week. All the participants were students and do not participate in any other recreational game.

Administration of Test: Anthropometric measurements were done on same day for each subject in same session to avoid technical error. Level 1 Anthropometrists accredited by International Society for the Advancement of Kinanthropometry (ISAK) was involved in the measurements. Method described in the ISAK manual were followed. Stature was measured with an Anthropometric Rod up to 1 mm and body mass was measured with an electronic weighing machine. Skinfold thicknesses were measured with a Slim guide skinfold caliper (CESCORF). Anthropometric tape and sliding caliper (CESCORF) were used to measure circumferences and bone diameter respectively.

Somatotype Heath: Carter method was followed for somatotype rating. The following equations were uses for calculating somatotype. Endomorphy = ─ 0.7182 + 0.1451 × ΣSF ─ 0.00068 × ΣSF2 + 0.0000014 × ΣSF3 where ΣSF = (sum of triceps, subscapular and supraspinale skinfolds) multiplied by (170.18/height in cm). Mesomorphy = 0.858 × humerus breadth + 0.601 × femur breadth + 0.188 × corrected arm girth + 0.161 × corrected calf girth ─ height × 0.131 +4.5. Three different equations are used to calculate ectomorphy according to the height -weight ratio (HWR): If HWR is greater than or equal to 40.75 then, Ectomorphy = 0.732 × HWR ─ 28.58. If HWR is less than 40.75 and greater than 38.25 then, Ectomorphy = 0.463 × HWR ─ 17.63. If HWR is equal to or less than 38.25 then, Ectomorphy = 0.1. 3.4. Body Fat % Durnin and Womersley technique was followed for body density. Body fat% was derived from the equation of Brozek et al.

Physical Performances Flexibility tests (lower back & hamstring flexibility, ankle flexibility, trunk & neck flexibility, shoulder flexibility & elastic leg strength) were performed & agility of the players of both groups was also measured.

Statistical Analysis: Mean values & Standard Deviation of each mentioned parameters of both sexes were calculated. The unpaired two tail T-test was done to compare each of the parameters of the both genders, Probability of error due to random sampling was rejected at the level of $p<0.05$.The correlation (r) is done for all parameters with Body height (cm), Body weight (kg), Fat percentage (%), Hand span of both hands (cm), Arm girth (cm), Calf girth (cm), Biepicondylarhumerus circumference (cm), Biepicondylar femur circumference (cm), Chest circumference (cm), Waist circumference (cm), Hip circumference (cm), Mid thigh circumference (cm) & Upper thigh circumference (cm). by Pearson's Correlation Coefficient (r).

Normal Results and Discussions: The mean value, standard deviation and level of significance of Height (cm), Weight (kg), Body Fat %, Total fat content

(kg), Lean body mass (kg), Lower back & Hamstring flexibility (cm), Ankle flexibility (cm), Trunk & Neck flexibility (cm), Shoulder flexibility (cm), Elastic leg strength (cm), Agility (sec), Hand span of both hands (cm), Handgrip strength of both hands (kg), Arm girth (cm), Calf girth (cm), Biepicondylarhumerus circumference (cm), Biepicondylar femur circumference (cm), Chest circumference (cm), Waist circumference (cm), Hip circumference (cm), Mid thigh circumference (cm) & Upper thigh circumference (cm) of male (n=14) & female (n=15) trained Badminton players, the correlation values & level of significance of Height (cm), Weight (kg), Hand span (cm), Arm girth (cm), Calf girth (cm), Biepicondylarhumerus circumference (mm), Biepicondylar femur circumference (mm), Chest circumference (cm), Waist circumference (cm), Hip circumference (cm), Mid thigh circumference (cm) & Upper thigh circumference (cm) of both male & female trained Badminton are represented. No statistically significant differences were observed in male and female trained right handed Badminton players in Height (cm), Weight (kg), Lower back & Hamstring flexibility (cm), Ankle flexibility (cm), Trunk & Neck flexibility (cm), Shoulder flexibility (cm), Agility (sec), Hand span of both hands (cm), Handgrip strength of both hands (kg), Arm girth (cm), Calf girth (cm), Chest circumference (cm), Waist circumference (cm), Hip circumference (cm), Mid thigh circumference (cm) & Upper thigh circumference (cm) (Table 1). Body fat percentage and total fat content is significantly higher in female than their male counterparts (Table 1), but lean body mass was much higher in male than female players and it was statistically significant Elastic leg strength was found to be higher in male players than female players and it was statistically significant. Shoulder flexibility of male players were significantly higher than the female players at $p<0.05$ level. Both biepicondylarhumerus breadth and biepicondylar femur breadth were slightly higher in male Badminton players than their female counterparts and they were statistically significant.

Discussion on Findings: The variable samples were based on 10 anthropometric parameters needed to determine somatotype characteristics using the Carter and Heath method [18]. The growth and development differences among the participants of these age group (10 -20 year) were very significant to compare them directly through anthropometric measurements, but when determining the somatotype using the Carter and Heath method[18], the only relevant interrelation was between 10 anthropometric parameters and chronological age. That fact nullified the age difference and enabled further comparisons. Fifty percent male subjects belonged to the group dominated by the endomorphic component, but in case of female subjects sixty seven percent had endomorphic component. The group with an accentuated influence of the endomorphic somatotype component but also a highly emphasisedmesomorphic component was characterised by high levels of subcutaneous fat tissue. It included endomorphs, the majority of whom had an accentuated mesomorphic component (mesomorphic endomorphs), followed by those with a balance of the two components (mesomorphic-endomorphic); there were also a few ectomorphs with an accentuated endomorphic component. The 21% of the male population and none of the female population belong to the group dominated by mesomorphic somatotype component. This group comprised subjects with high numerical values for the mesomorphic components compared to the other two somatotype components (endomorphic and ectomorphic). Based on the values of those two less emphasised components, it was possible to further divide the subjects of this group into those dominated by the endomorphic component of the mesomorphic somatotype (endomorphic mesomorphs), those dominated by the ectomorphic component (ectomorphic mesomorphs), and those with a balance of the two components (balanced mesomorphs). The 29% of the males and 33% of the females belong to the group predominant ectomorphs dominated by the ectomorphic somatotype component. The values of the other two components (endomorphic and mesomorphic) were much less emphasised and subdivide this group into two ectomorphic subtypes (mesomorphic ectomorphs and balanced ectomorphs). It seemed to be obvious that a mesomorphic predominance could play a decisive role in any sport, including Badminton. Indeed, several investigations carried out on Badminton players demonstrated a superior muscular development in lower extremities. But in our study it was found that only 21% of the males and none of the females were mesomorphic. In a structurally complex game such as Badminton, competitive success is primarily a result of the quality and degree of technical and tactical knowledge. Accordingly, the differences in the competitive success of the young Badminton players are mostly the result of differing levels of technical as well as tactical skills. Those differences are much more salient at this competitive level than among top senior players where a high level of technical/tactical knowledge can be assumed. Although the existence of suitable morphological features certainly represents an

advantage and plays a role in achieving competitive success (especially among top players), in a technically complex game.

Discussion on Hypotheses: Badminton, it is just one of many factors that influence competitive success. At this age, a player's basic anthropometric characteristics and body constitution is an important factor but far from crucial factor in achieving top competitive results. The predominance of a physique dominated by the mesomorphic and ectomorphic somatotype components only reveals the potential advantage of these types of body constitution in increasing the likelihood of success, but it is not a decisive factor that directly influences competitive success among young Badminton players. Average body fat percentage and average total fat content (kg) were significantly higher in female players as the female players possessed a high quantity of subcutaneous fat. On the other hand average lean body mass (kg) of the male players was significantly higher than their female counterparts as the quantity of subcutaneous fat for the males were comparatively low. Average elastic leg flexibility of the male players was significantly higher than the female, so the leg flexibility of the male players was better than the female players. Average biepicondylarhumerus and biepicondylar femur breadths were found significantly ($p<0.05$) higher in male than female as the bone breadth of the males were high.

Conclusions

In the present study male and female trained Badminton players were analyzed in different ways, like height, weight, body composition, anthropometric parameters, flexibility, elastic leg strength, hand span, handgrip strength and agility. All values were correlated with each other to assess the differences between male and female Badminton players in their musculoskeletal fitness and body type. High correlation values were found between arm girth, calf girth, biepicondylarhumerus breadth, biepicondylar femur breadth, chest circumference, waist circumference, hip circumference, mid thigh circumference and upper thigh circumference in both genders. It was found that there were only 21 % of the males and none of the female players were mesomorphic. But mesomorphy was essential for the improvement of performance in Badminton players. It could be concluded that the physical training procedure might not be specific to the event's demand. Musculoskeletal development of the players did not specify the Badminton event. Endomorphy had been found in both male and female players. Thus the muscle content of the players must be enhanced by improving the event specific physical training and by prescribing proper diet to the players. It is advisable to integrate educational and nutritional strategies in order to maintain an adequate body fat content.

Health Care Services Under Consumer Protection Laws of Union Territories of Jammu and Kashmir: A Socio-Legal Mapping

M.Z.M. Nomani[1], Ajaz Afzal Lone[2], Alaa K.K. Alhalboosi[3], Aijaj A. Raj[4], Zubair Ahmed[5]

[1]Professor, Faculty of Law, Aligarh Muslim University, Aligarh-202001 (U.P./India), [2]Research Scholar, Faculty of Law, Aligarh Muslim University, Aligarh-202001 (U.P./India)

Abstract

Context: Ever since the passing of the *Jammu & Kashmir Consumer Protection Act*, 1987, the doctor-patient's relationship came under critical scrutiny, controversy and litigation. The inadequacy of consumer protections laws results in unavoidable contingency, spiralling cost shifting and inordinate health care complexities. It examines health care services as a matter of consumer rights under *Consumer Protection Act,* 1986, Jammu and Kashmir Consumer Protection Act, 1987 and Consumer Protection Act, 2019. It makes consumers to navigate between hope and despair for access to health care. The paperis driven to analytical study of inadequacy of consumer laws in dealing effectively deficiency of medical service, insufficiency of health care services,lack of medical professionalism and negligence in Sher-i-Kashmir Institute of Medical Sciences (SKIMS), Srinagar by encompassing a legislative survey of consumer laws in inculcating Consumer Right Awareness (CRA) and toning of structural governance of grievance redressal mechanism. The gap between the precept and practice of consumer justice and compensation in health care services is identified for adoption of a robust infrastructural and schematic revamping.

Keywords: *Health Care Services, Consumer Right Awareness, Grievance Redressal Mechanism, Consumer Justice and Compensation.*

Introduction

The health care facilities to the people of the erstwhile state of Jammu and Kashmir (J & K) is marred by constraints of financial resources, difficult topography and terrain, poor road connectivity, low presence of private sector, low accessibility and affordabilityby under- privileged segments of the population. There has been a gradual decay in the health services of J & K over the last three decades. The state is under shadows of infectious diseases like tuberculosis, RTI, UTI diarrhoea disease.[1] there is growing shadow of chronic diseases like hypertension, coronary artery disease, cancers, and diabetes. Factually speaking there are 3,807 health care institutions in the state which is considered the highest number of hospitals in the country. The annual budget for the health sector in J & K is Rs. 2,423-crore. The per capita spending under plan, non-plan and centrally sponsored schemes is estimated at Rs. 1,931 crore.[2] According to the *State's Economic Survey Report,* 2017,there were 4,433 government health institutions in J & K at the primary, secondary and tertiary levels with 6,674 doctors.[3] The paper examines the efficacy of*J & K* Consumer *Protection Act,* 1987 to give effect to *Consumer Protection Act,* 1986 to take care of consumer right awareness among patients for robust health care servicesin two Union Territories of J & K under Jammu and Kashmir Reorganisation *Act,* 2019.

Materials and Method

The material and method applied for the study include analytical method of legal research by

undertaking the legislative survey and scrutiny of consumer laws at central and state levels. These laws are studied under Parsonian Effecttheory in the context of health care services.[4] The comparative consumer law study of *Consumer Protection Act,* 1986,*J & K Consumer Protection Act,* 1987 and *Consumer Protection Act,* 2019 is based on established canons of statutory interpretation. The material and method partakes an empirical framework of SKIMS, Srinagar a premier medical institution in J & K state. The case study is based on Consumer Right Awareness (CRA) under four major parameters which include consumer right awareness, redressal against medical negligence, and recourse to deficiency of medical service and compensation and consumer justice.

Findings: It is important to note that the both *Consumer Protection Act,* 1986, *J & K Consumer Protection Act*,1987 and *Consumer Protection Act,* 2019 are public welfare legislation and has been designed to avoid procedural technicalities, delays, and requirement of court fees to protect consumers availing medical facilities and health care services.[5] It contains three-tier consumer disputes redressal system at the District, State and National levels along with Central Consumer Appellate Authority (CCAA) including right to health and environment.[6]

Central Consumer Protection Act, 1986: The Consumer *Protection Act,*1986 forms the basis of*J & K* Consumer *Protection Act,* 1987 therefore a perusal of this law in brief is imperative. The Act seeks to promote and protect the interest of consumers against deficiencies and defects in goods or services.[7] It also seeks to secure the rights of a consumer against unfair trade practices, which may be practiced by manufacturers and traders. The Act applies to all goods and services unless specifically exempted by the Union Government and covers all sectors, whether private, public, or cooperative. It ordains simple, speedy and inexpensive machinery for redressal of consumer's grievances,the marketing of goods and services to consumers, as well as the relationships, transactions and agreements between the consumers and the producers, suppliers, distributors, importers, retailers, service providers and intermediaries of those goods and services.[8] The application of *Consumer Protection Act,*1986 to health services derives life breath and sustenance from Supreme Court ruling in Indian Medical Association v. V.P. Shantha.[9] In this case the question raised was whether the treatment provided by medical practitioners to their patients would constitute "service" under the meaning of the Act and whether patients would be treated as 'consumers' under the same Consumer *Protection Act*,1986 The court noted that the issues arising in the complaints against medical negligence can be speedily disposed of by the procedure being followed by consumer disputes redressal agencies. Thus the *Consumer Protection Act,* 1986 is pioneering law in protection of consumer from the standpoint of health, environment and consumer justice.[10]

J & K Consumer Protection Act, 1987: The *J & KConsumer Protection Act,*1987 aims to provide effective safeguards to the consumers against defective goods, deficient services and unfair trade practices. The Act provides speedy redressal to consumer complainants by setting up of a District Consumer Redressal Forum and State Commission having jurisdictionto claim of Rs. 10 lakhs and Rs. 30 lakhs respectively. The State Commission will be vested with appropriate appellate and revisional powers. It shall apply to all goods and services except those which are specially exempted by notification by the state government did not specifically exempted health care services provided by government hospitals. It seems profitable to refer section 2(1) (0) as under:

"Service" means service of any description which is made available to potential users and includes the provision of facilities in connection with banking, financing, insurance,transport, processing, supply of electrical or other energy, board or lodging or both,entertainment, amusement or the purveying news or other information, under a contract of personal service.

The necessary penal and punitive provisions have been incorporated for effective redressal of unfair trade practices, defect in the goods, and deficiency of services. The Consumer Commissions are authorized to impose penalties on trader or person against whom complaint is made if he fails to comply with the order of the redressal agency.

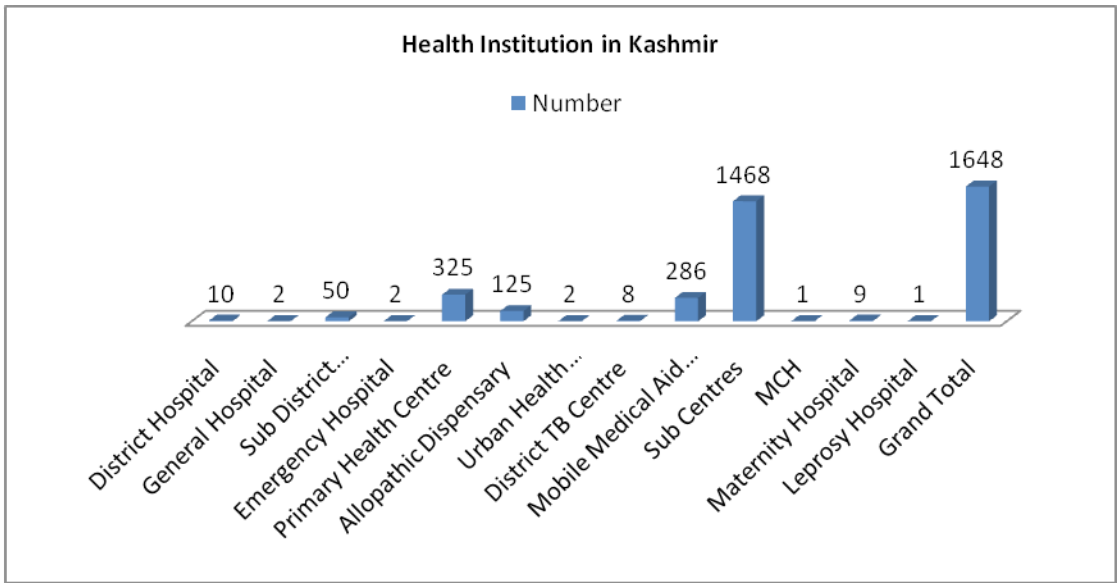
J & K Government Doctors (Relaxation of Restrictions on Private Practice) Rules, 1987: It will be appropriate to see the application of *J & K Consumer Protection Act,* 1987 and *J & K Government Doctors (Relaxation of Restrictions on Private Practice) Rules,* 1987 in holistic perspective in regard to doctor patient relationship and health care services. This is also important to see this law in the context of penalty or punishment may involve imprisonment for a period

not more than 3 years or a fine or both. The complaint mechanism by a consumer voluntary organization, registered society, company and state government will also be scrutinised in pragmatic discourse. Therefore, it is also worthwhile to inquire the synergy of both legislations from the lens of the executive and judicial attitude towards disciplining doctors and foster health care services to patient *vis*-a-visbanning private practice. The J & K High Court in *Dr. Ashutosh Gupta v.State of J & K,*[11] while hearing petition for quashing of Government Order No. 43/HME of 2013 dated 17.01.2013 regarding of banning of private practice by doctors of government medical college, associated hospitals and dental colleges upheld the impugned order of the Government. *In Sukesh Chander Khajuriav. State of J & K,*[12] the J & K High Court dismissed the writ petition regarding validity of J & K Government Doctors (Relaxation of Restrictions on Private Practice) Rules, 1987.

Discussions

The study of health care services under consumer protection laws of J & K health institutions is an empirical study of SKIMS with 900 bedded tertiary care hospital and undergraduate medical college with intake capacity of 100 students. According to survey there are total 1648 health institutions in J & KState.[13]

Selection of Area of Study: SKIMS being premier medical institution in India, it provides additional services including prevention, treatment, rehabilitation, obstetrics, substance abuse, health education, and screening for cancers and other diseases.[14]



The case study of SKIMS is based on four major parameters *viz;* consumer right awareness,[15] redressal against medical negligence, recourse to deficiency of medical service and compensation and consumer justice under the *J & K Consumer Protection Act,* 1987 and *J & K Government Doctors (Relaxation of Restrictions on Private Practice) Rules,* 1987. Located in Soura area of Srinagar, this is the largest medical Institute under *Sher-i-Kashmir Institute of Medical Sciences, (Grant of Degrees) Act, 1983.*[16] *The J & K Consumer Protection Act,* 1987 is not applicable to government hospitals because of free medical care services to patients. But the medical services rendered by doctors and hospitals falls within the ambit of a "service" as defined in Section 2(1) (o) of the Act.

Consumer Right Awareness & Health Care Services: By this analogy persons who are rendered free service are "beneficiaries" and as such come within the definition of "consumer" under Section 2(1) (d) of the Act. Similarly the deficiency of service is spelt out under Section 2(1) (g) which covers diagnostic, surgical and therapeutic service.[17] A sample survey of 100 patients admitted to SKIMS was conducted regarding consumer right awareness to healthcare.[18] The following table and chart-1 shows the nature and depth of consumer right awareness among randomised number of patients is in and out patient department. The simple question regarding the legal literacy of consumer law and redressal agencies were put to these patients.

Table 1: CRA & Health Care Services

Patients	Respondents	Yes	%age	No	%age	Indifferent	%age
In Patients	50	10	20	35	70	05	10
Out Patients	50	12	24	34	68	04	08
Total	100	22	88	79	79	09	09

Source: *Field work*

The above table clearly shows that 22% respondents have knowledge about consumer law or redressal agencies while as 79% respondents said that no they were not having any knowledge about consumer laws however 9% respondent didn't said anything about the information of consumer laws. The legal literacy about the complaint mechanism for the deficiency in medical services is also in abysmally low. When we asked patients about the deficiency of medical services gives rise to grievance redress al at appropriate consumer forum almost 2/3 respondents feign ignorance about it.

Table II: CPA & Grievance Redressal Mechanism

Patients	Respondents	Yes	%age	No	%age	Indifferent	%age
In Patients	50	10	20	35	70	05	10
Out Patients	50	11	22	34	68	05	10
Total	100	21	21	69	69	10	10

Source: *Field Work*

The medical negligence on as the part of health care provider is frequent in J & K that is why the patient affected by medical negligence have faint idea about the complaint mechanism as victims. The Table II shows that 21% respondents have knowledge about complaints in consumer forums. on the basis of data received from respondents 69% respondents said that they were not aware about the concept of complaints in consumer forums, however 10% respondents didn't say anything about the complaints in consumer forums.

Table III: CPA & Medical Negligence

Patients	Respondents	Yes	%age	No	%age	Indifferent	%age
In Patients	50	10	20	34	68	06	12
Out Patients	50	13	26	32	64	05	10
Total	100	23	23	66	66	11	11

Source: *Field Work*

The Comptroller and Auditor General (CAG) of India has reported that 'even the emergency medicine department has been found to be not fully equipped to deal with cases of road traffic accidents having multiple organ injuries including orthopedicinjuries.' This is also pathetic to note that ambulances meant for patients have been found mis-utilized to the extent of 40 to 47 per cent during 2008-12.[19]

Health Care & Medical Negligence: The knowledge regarding negligencein health care services reveals that 23% respondents were aware about the complaints mechanism. Theordinary prudence about medical negligence depicts that 66% respondents don't have knowledge about grievance redressal and 11% remain indifferent to liability of doctors and hospital authorities.

Table IV: Health Care Services & Medical Negligence

Patients	Respondents	Yes	%age	No	%age	Indifferent	%age
In Patients	50	11	22	36	72	03	06
Out Patients	50	10	20	35	70	05	10
Total	100	21	21	71	71	08	08

Source: *Field Work*

Compensation & Consumer Justice: the compensation incase of medical negligence to the patients and their kith and kin also represent empathtic and ignorance. The patient interviewed regarding their response to compensation in case of medical negligence reveals that 21% respondents show that they have knowledge about penal provisions against doctors.[20] Still majority of patients to the tune of 71% said that they were not having any information related penal provisions whereas 8% are either ignorant or indifferent didn't say anything about penal action can be initiated in case of medical negligence on part of hospital and doctor.

Table V: Compensation & Consumer Justice

Patients	Respondents	Yes	%age	No	%age	Indifferent	%age
In Patients	50	08	16	38	76	04	08
Out Patients	50	09	18	36	72	05	10
Total	100	17	17	74	74	09	09

Source: *Field Work*

The apex court ruling has played seminal role in curbing medical malpractice and making compensation an integral part of consumer justice that 17% respondents have knowledge about compensation given by consumer forums and 74% said that they were not having any information related compensation related consumer forums however 09% respondents didn't say anything about compensation provided by consumer courts. This places the consumer justice in a conundrum especially in the aftermath of Supreme Court decision.

Conclusion

The analysis of health care services under consumer laws of erstwhile J & K state now Union Territories of J & K under *Jammu and Kashmir Reorganisation Act,* 2019 reveals that health status of the people has not been able to keep pace with the national targets. The state has a considerable segment of population living below poverty line, inadequacy of healthcare and burden of disease in an environmentally benign setting.[20] The *J & KConsumer Protection Act,* 1987 has not achieved consumer right awareness and assertiveness in realisation health care services. The health services and disease overburden needs proper regulation. This becomes more important in the wake of unrest of decades has worsened the health status of people especially of population living below poverty line. The only salacious aspect is to note that the purpose and object with which the*J & K Consumer Protection Act,* 1987 has been passed has substantially achieved in the ambit of patient's rights notably compensatory justice. But the SKIMS have been found inadequately equipped to deal with accidents and trauma prevention and gross mis-utilisation of ambulance services despite rich infrastructure. The most significant and equally multifaceted as well complex service in the field of consumer grievances is that of medical malpractice and the doctors of SKIMS and other government hospitals of state need to be more circumspect and careful towards medical services to patients to enlarge the realm of consumer justice, access to health and compensatory jurisprudence.

Platelet Rich Fibrin (PRF): Revolutionary Boon to Dentistry

Paridhi Gupta[1], Bhagyalakshmi[2], Raghunath[3]

[1]Post Graduate, [2]Reader, [3]Professor and HOD, Department of Orthodontics and Dentofacial Orthopaedics, JSS Dental College and Hospital, JSS AHER, Mysore

Abstract

Context: With time, the treatment protocol changes and currently there is a new school of treatment called accelerated orthodontics wherein the goal is to shorten the time needed to align the teeth.

Platelets are one of the initiators both in the soft and hard tissue wound healing processes. They contain growth factors such as the platelet derived growth factor, transforming growth factor, Endothelial growth factor, and others. Platelet-rich fibrin (PRF) is a natural biomaterial with favourable results in orthodontics and other specialities with minimal risk.

The following article attempts to summarise the relevant literature regarding benefits of PRF over PRP, focusing on its preparation, advantages and disadvantages of using it in clinical scenarios in medicine and dentistry, due it's minimally invasive technique and low risks.

Keywords: *Platelet-rich fibrin, Platelet-rich plasma, Platelet derived growth factors, Leukocyte platelet rich fibrin, Orthodontic tooth movement, Platelet concentrate,*

Introduction

With time, the treatment protocol changes and currently there is a new school of treatment called accelerated orthodontics wherein the goal is to shorten the time needed to align the teeth. Increased duration of treatment poses various risks like pain, caries, white spot lesions, external root resorption etc.

Numerous options have been put forth to accelerate orthodontics such as:

1. Drugs
2. Surgeries
3. Non-surgical methods (PRP, PRF)

Platelet-rich plasma (PRP) is an autologous concentration of human platelets in a small volume of plasma which releases a cocktail of growth factors. PRP is first generation platelet concentrate. However, using it also presents risk because bovine thrombin, which is used to handle PRP, may generate antibodies to factors V, XI, and thrombin that could cause coagulopathies [1].

Platelet-rich fibrin (PRF) is a natural fibrin-based biomaterial prepared from an anticoagulant-free blood harvest without any artificial biochemical modification (no bovine thrombin is required) that allows obtaining fibrin membranes enriched with platelets and growth factors.

Platelets: Platelets are produced from bone marrow cells called megakaryocytes and contain cytoplasmic granules with platelet-specific and non-platelet-specific proteins (fibrinogen, fibronectin etc.). These dense granules have high concentration of calcium, ADP, ATP and serotonin. However, activation of platelets to achieve the healing and repair process is aided by leukocytes [2].

Matras research in 1970 has led to the extensive use of fibrin glues [3].

In 1997, Whitman et al were the first to use PRP in oral surgical procedures and concluded that it enhanced the osteoprogenitor cells in bone [4].

Choukroun et al [5]first used PRFin 2001 which was derived from human blood and contained blood cells including platelets, B- and T-lymphocytes, monocytes, stem cells and growth factors.

Classification: Dohan et al proposed a classification in 2009 and categorized the products on 2 key parameters:

- The presence of a cell content (mostly leukocytes)
- The fibrin architecture.

This separation defined four main families to regroup the products [6].

1. Pure Platelet-Rich Plasma (P-PRP) Or Leukocyte-Poor Platelet-Rich Plasma: These products are preparations without leukocytes and form a low density fibrin network after activation. Mostly used as a liquid solution or in an activated gel form.

Preparation:

- **Plasmaphoresis:** This was the first method of producing platelet concentrates for topical use. It uses a cell separator that employs a differential ultracentrifugation in which platelets, leucocytes and RBCs are first separated from the PPP, which can then be re-infused to the patient. Optical reader detects the first buffy elements in the serum, that are automatically collected into a separate bag as the platelet concentrate (PRP), when it detects elements of RBCs, platelet collection is interrupted and RBCs, mixed with leucocytes and some residual platelets, are directed towards a third separate collection bag before eventual re-infusion. But the final PRP always contains residual RBCs and leucocytes and this protocol is cumbersome and labour-intensive.

- **Anitua's PRGF (Manual protocol):** Anitua in 1999 described PRGF (Plasma rich in growth factors) wherein venous blood is collected and centrifuged in several small tubes to obtain three typical layers: RBCs, 'buffy coat' and acellular plasma [7].

The upper half of the acellular plasma is called plasma poor in growth factors (PPGF) and is discarded by careful pipetting. The remaining plasma is termed PRGF and is collected with a pipette. Following this, fibrin polymerization is induced by a 10% calcium chloride solution which leads to formation of an unstable PRGF gel after 15-20 min that has to be used immediately. This method is inexpensive but lacks reproducibility [8].

2. Leukocyte and Platelet Rich Plasma (L-PRP): They were developed with an objective of using platelet which are easy to harvest and does not require transfusion laboratory work.

Preparation:

- **Manual Method:** There are mainly two protocols Curasan (Germany) [9] and Friadent-Schutze (Austria)[10]. The first centrifugation step which separates the blood components into three layers is the same as P-PRP. The PPP and buffy coat layers are collected in another tube and are subjected to a second centrifugation step at high speed, which separates the sample again into its components. PRP concentrate obtained is composed of high quantity of platelets, leucocytes and circulating fibrinogen, but it also contains residual RBCs. The concentrate is applied with bovine thrombin and calcium chloride.

- **Automated protocols:** Systems like PCCS (Platelet Concentrate Collection System) by 3I and Smart PReP by Harvest Corp (USA) have been developed. In the PCCS method, citrated whole blood is transferred into the first compartment and centrifuged to obtain the three layers. Then, using a tubular opening and air pressure, PPP and buffy coat are transferred to the second chamber and centrifuged again but for a longer period. Finally, using the same air pressure system, most of the PPP layer is transferred back into the first compartment and discarded[11,12].

The SmartPReP protocol is a multifunctional system, designed to automatically transfer the upper layers (PPP and buffy coat) into the second chamber based on variations in weight and centrifugation speed.

3. Pure Platelet-Rich Fibrin (P-PRF) Or Leukocyte-Poor Platelet-Rich Fibrin: They are preparations without leukocytes and with a high-density fibrin network, exist only in gel form and cannot be injected.

Preparation:

- The only one product commercially available is known as Fibrinet PRFM (Platelet-Rich Fibrin Matrix) kit by Cascade Medical (USA). Small amount of blood is drawn into a collection tube, which has trisodium

citrate as an anticoagulant and separator gel, which is centrifuged for six minutes at high speed. The three typical layers are obtained out of which buffy coat and PPP are easily transferred to a second tube containing $CaCl_2$ wherein clotting process is triggered and the tube is immediately centrifuged for 15 min leading to formation of a stable PRFM clot. It is claimed to be natural concentrate due to the absence of bovine thrombin[11].

4. Leukocyte- And Platelet-Rich Fibrin (L-PRF): Choukroun's Prf: Choukroun's PRF protocol was developed in France [5]. It can be considered as second-generation platelet concentrate because it is natural without any anticoagulants.

Preparation:

- Venous blood is collected in glass tubes and centrifuged at low speed. In the absence of anticoagulants, platelet activation and fibrin polymerization are triggered immediately and three layers are formed: the RBC base layer, acellular plasma top layer and a PRF clot in the middle. The PRF clot forms a strong 3-D fibrin matrix with most of the platelets and leucocytes harvested from the blood. When pressed between two gauzes, the PRF clot becomes a strong membrane which has been used in ENT and Maxillofacial Surgeries etc.
- This method is easy and allows the production of a high quantity of L-PRF clot at low cost.

Biological Activity:

- In vitro activity of L-PRF membrane and P-PRP gel were compared by evaluating the slow release of growth factors and matrix molecules[13,14]. Both the preparations demonstrated slow release of three key growth factors Transforming Growth Factor β1 (TGFβ1), Platelet-Derived Growth Factor AB (PDGF-AB) and Vascular Endothelial Growth Factor (VEGF) along with matrix proteins and Thrombospondin 1 (TSP1) at an interval of 20 min, 1hr, 4hr, 24hr, 72hr, 120hr and 168hr.
- Dohan et al reported that L- PRF membrane remained intact for 7 days and released a large quantity of growth factors continuously [15]. On the contrary, the P-PRP gel released most of its growth factors in the first hours and got completely dissolved in the medium after 3 days.
- These studies concluded that PRF families undergo natural polymerization with release of intrinsic growth factors whereas PRP gel families demonstrate artificially provoked polymerization with extrinsic growth factors leading to their immediate release and destruction.

Clinical Applications:

In Dentistry:

- The L-PRF is mostly used in oral and maxillofacial surgery as L-PRF clots and it presents a volume and shape easy to combine with most surgical techniques, as filling and interposition healing biomaterial or as protection healing membrane.
- In periodontal bone defects to achieve reduction in probing depth and filling of radiographic defect [16].
- Reduction of osteitis in surgical sites of the third molars [17].
- As an adjunct to palatal wound healing after harvesting a free gingival graft [18].
- In multiple extraction cases to preserve the alveolar ridge height [19].
- Bone regeneration around implants, inside the alveolar defect [19].

General:

- Reconstruction of large bone defects post cancer surgery [20].
- Membrane form is used in otological surgeries [21].

Orthodontics:

- L-PRF has been used in PAOO (Periodontally Accelerated Osteogenic Orthodontics). Combining it with traditional bone grafts potentially accelerates wound healing and reduces post-surgical pain, inflammation, infection without interfering with tooth movement or post-orthodontic stability [22].
- A randomized control trial was conducted to study the effect of autologous leukocyte platelet rich fibrin on the rate of orthodontic tooth movement that concluded the rate of movement was higher in the experimental group to that of the control group [23].
- Effects of PRP on the rate of orthodontic tooth movement have been investigated in six skeletally mature male mongrel dogs that showed maxillary tooth movement to be significantly faster on the

experimental side compared to the control side (mean of 15.60mm versus 9.46mm)[24].

- Effects of different concentrations of PRP on alveolar bone density and orthodontic tooth movement shows that injection of both moderate and high concentrations of PRP might accelerate orthodontic tooth movement by decreasing alveolar bone density on para-dental tissues by enhancing osteoclastic activity in a transient way [25].
- PRP and alveolar bone grafting done in cleft patients revealed bone grafts with the use of PRP showed significantly more bone density up to 6-months post-surgery and pain and swelling persisted for longer period in control group [26].

Clinical trials are being conducted to test the efficacy of i-PRF (injectable platelet rich fibrin). i-PRF provides an edge in accelerating treatment with PRF being superior to PRP and the injectable form making it a lesser invasive procedure [27].

Conclusion

The application of different forms of PRF is becoming well established in many fields of both medicine and dentistry. On one hand, its use in implant dentistry and oral surgery may seem obvious, but on the other side its use is still being anticipated in orthodontics. The clinical efficacy of this rapidly evolving area will need to be carefully watched as laboratory based studies are undertaken in clinical practice. Clinical studies have been done already, these are often limited to small numbers of patients and this may, for the time being, limit its widespread use. Further studies should involve well planned randomised controlled trials investigating not only the potential benefits of PRF but also any potential risks or complications.

Compliance of the Cigarettes and Other Tobacco Products Act (Cotpa) 2003: A Baseline Survey in Vijayapura District of North Karnataka

Praveen Ganganahalli[1], Santosh D. Patil[2], Mohd. Shannawaz[3], Prakash Chauhan[4], M.B. Biradar[5]

[1]Associate Professor, [2]Assistant Professor, [3]Assistant Professor, Dept. of Community Medicine, BLDEDU's Shri B.M. Patil Medical College Vijayapura, Karanataka, [4]District Consultant, National Tobacco Control Program, [5]District Surveillance Officer, District Health & Family Welfare, Vijayapura

Abstract

Introduction: According to WHO, tobacco use is considered a single most preventable cause of death. According to Global Adult Tobacco Survey 2009-10, almost 1 in every 2 adult males and 1 in 5 adult females use tobacco in some form in India. In 2003, the Government of India enacted comprehensive legislation for tobacco control called the Cigarettes and Other Tobacco Products (Prohibition of Advertisement and Regulation of Trade and Commerce, Production, Supply and Distribution) Act (COTPA). The purpose of the COTP Act is fulfilled only when the community takes participation in its strict implementation.

Objectives: To measure the level of compliance to COTPA-2003 in Vijayapura district of North Karnataka.

Method: A cross sectional survey was planned to assess the implementation of COTPA 2003 in Vijayapura district by using structured Interview method for a period of two months. Around 250 places were assessed in five taluka head quarters each of the district by using proforma based on the regulations given in Section 4, 5, 6a, 6b, 7,8,9 of COTPA 2003.

Results: Implementation level found in the district was 30% for section-4, 84% for section-5, 92% for section-6a, for 64% section-6b and 99% for section-7, 8, 9.

Conclusions: COTPA includes measures that are intended to protect residents from exposure to secondhand smoke, to significantly restrict tobacco advertising and to eliminate easy access to tobacco products by youth. The COTPA-2003 implementation in all the taluka headquarters of district is found less as expected. The reason may be less awareness regarding the act & the punishment followed after violation.

Keywords: *COTPA, Compliance, Section, Tobacco, Regulation.*

Introduction

According to World Health Organization, tobacco use is considered a single most preventable cause of death.[1] Tobacco use kills one-third to one half of all lifetime users prematurely. Tobacco-related illnesses account for 1 in 10 adult deaths worldwide, and if current trends continue, one billion people are estimated to die from tobacco use in the 21st century.[2,3]

India is the third largest producer of tobacco worldwide and ranks second in total tobacco products consumption. According to Global Adult Tobacco Survey 2009-10, almost 1 in every 2 adult males and 1 in 5 adult females use tobacco in some form in India. Smokers are not the only ones sickened and killed

by tobacco; scientific evidences have unequivocally established that exposure to second hand smoke is as harmful as active smoking and causes death, disease and disability.[3]

Considering the harmful effects of tobacco, the WHO in 2003 negotiated the world's first public health treaty called "The Framework Convention on Tobacco Control" (FCTC), which mandates governments of all nations to take specific steps to reduce tobacco use. Article 8 of the FCTC binds governments to protect their citizens from exposure to tobacco smoke and requires them to adopt and implement effective legislative, executive, administrative and/or other measures for this purpose.[4]

In 2003, the Government of India enacted comprehensive legislation for tobacco control called the Cigarettes and Other Tobacco Products (Prohibition of Advertisement and Regulation of Trade and Commerce, Production, Supply and Distribution) Act (hereafter referred to as COTPA) – which prohibits smoking in public places and requires display of 'No smoking' signage with proper specifications at conspicuous points.[5]

Provisions under the Act prohibits smoking of tobacco in public places (Section-4), Advertisement of tobacco products including cigarettes is prohibited (Section-5), Tobacco products cannot be sold to person below the age of 18years (Section-6a) and in places within 100 meters radius from the outer boundary of an institution of education (Section-6b), Tobacco products must be sold, supplied or distributed in a package which shall contain an appropriate pictorial warning, its nicotine and tar contents (Section-7,8,9).[6]

Mere enactment of legislation is not enough to stop smoking in public places and it requires strong enforcement to ensure compliance to the law by the public. So the study was planned to know the extent of adherence to the regulations of Law by the community.

Methodology: A cross sectional survey was conducted to measure the level of compliance to COTPA-2003 in public places, at Points of sale, in Educational institutions and with regards to other regulations of Act in the Vijayapura district situated in North part Karnataka state in India in February & March 2019.

With 95% confidence level and margin of error of ±3%, a sample size of 1067 places allowed the study to determine the compliance of COPTA in all talukas of Vijayapura district. After round off the figure, recruitment target was set at 1080 places (216 places per taluka head quarters – that includes Public places, Point of sale & educational institutes together) Sample size was calculated by using the formula: $n=z^2p(1-p)/d^2$ Where Z= z statistic at 5% level of significance, d is margin of error and p is anticipated prevalence rate (50%).

The study was conducted in head quarters of all talukas present in the Vijayapura district. The district contains five talukas namely Vijayapura, Indi, Sindagi, BasavanBagewadi&Muddebihal. By keeping the main Bus stand as central point the team moved in all directions (preferably main roads) till the desired sample is covered for all the sections. If the desired sample is not achieved, next main roads or crowded places like markets were surveyed by using the checklist. Educational institute present on the way of survey were included and those which are situated in faraway places were visited by using private vehicle till desired sample was achieved. Purpose of the survey was explained at educational institutions & at point of sale before collection of information.

Study Units:

Section 4: Public places means any place to which the public have access and includes auditoriums, movie theatres, hospitals, public transport (aircraft, buses, trains, metros, monorails, taxis,) and their related facilities (bus stands/stations, railway stations), restaurants, hotels, bars, amusement centres, offices (government and private), libraries, courts, post offices, markets, shopping malls, canteens, refreshment rooms, banquet halls, coffee houses, educational institutions and parks.

Section 5: Points of sale where tobacco products are sold in each taluka headquarters were selected to observe the advertisement of tobacco products.

Section 6a: The points of sale where tobacco products are sold in each taluka headquarters were considered.

Section 6b: Educational Institutions is a place including any school/college/institution where education is imparted by an appropriate authority. The educational institutions present in taluka headquarters

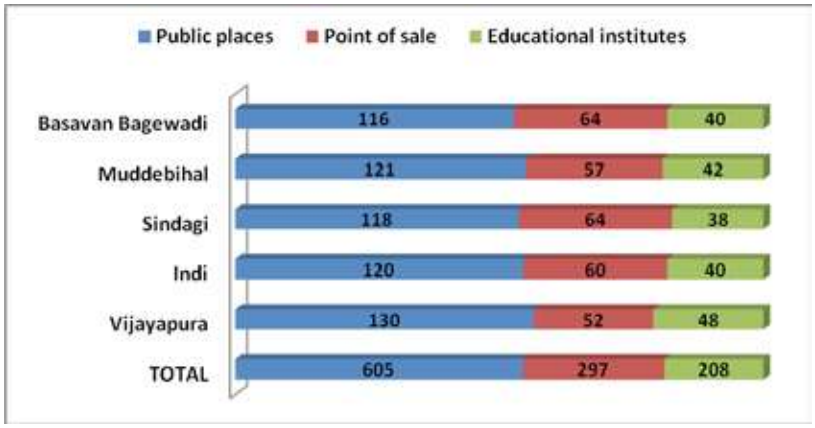
were considered for the study.

Section 7, 8, 9: The Packaged tobacco products were observed in each points of sale (POS) as identified under section 5 & 6a.

Statistical analysis of the information collected were summarized descriptively and presented diagrammatically.

Observations: Total around 240 to 250 visits were done to assess the compliance of COTPA-2003 in each taluka head quartersof Vijayapura district. Following were the observation made during the visits,

Figure 1: Taluka Wise Distribution of Visits Made During the Survey.



Nearly equal numbers of places were visited during the survey in all the taluka headquarters as shown in figure I.

Table 1:Compliance to COTPA-2003 regulationsin Vijayapura district

COTPA-2003	Regulations	Number	%
Section-4	People found smoking during visit	127	21
	'NO SMOKING' warning board NOT displayed according to the guidelines	423	70
	Smoking aids were present	17	03
	Used cigarettes / bidis found	42	07
Section-5	Tobacco product advertisement in POS- present	48	16
	Promotion of any brand name of tobacco product	14	05
Section-6a	Sale of tobacco to minors observed	17	06
	Sale of tobacco by minors observed	03	01
	Shopkeeper asking age of purchaser of tobacco products	00	00
	Tobacco products are easily visible	240	80
	Display of 'prohibition of sell of Tobacco products to minors' present	23	08
Section-6b	Sale of Tobacco products within 100 yards present	74	36
	Information regarding section 6b displayed	33	16
	Display NOT according to the guidelines	190	91
Section-7,8,9	Health warning present	100%	
	Nicotine content, Mentioned	00%	
	Health warning get damaged, while opening	55%	
	Helpline number to quit tobacco mentioned	100%	

About 70% public places not found following the rule of displaying **NOSMOKING** board according to the guidelines but among those who displayed only 12% were according to the guidelines. Among the boards of 'NO SMOKING' displayed in public places majority were in language Kannada (65%) followed by English (27%) and Hindi (08%). In few places smoking aids (3%) were present, which facilitates smoking in public places whereas in

7% of places used smoking buds were found during the visit.

Violation of Section-4 of COTPA is observed in public places with respect to open smoking in eating (13%) & accommodation facility (9%) followed by working places (10%) during the visits. Out of 30% public places where 'NO SMOKING' board was displayed, majority were eating (30) & accommodation facility (27%).

The violation of section-5 regarding displaying of advertisement of tobacco products was observed in 16% of Point of Sale and all of them were belonging to print type; illuminated & non-illuminated forms. Brand which is most commonly seen advertising is 'GOLD FLAKE' cigarette.

The sale of tobacco products was seen in Grocery shops also (19%) next to shops selling similar type products (65%). Sale of tobacco to minors (section-5) was observed in around 6% of point of sales during the visit whereas the shopkeeper was found not enquiring the age in any of the cases or in general also. In few shops (6%) of Vijayapura taluka, selling of tobacco by minors was found on observation but they were not accepting their age as less than 18 years during interview.

Awareness regarding asking the age of purchasers during selling tobacco by shopkeeper was found around 41% whereas displaying warning according to section-6a of COTPA was found only in 8% of point of sales. In 80% of point of sales, there was open exhibition of tobacco products, which was very easily visible and found attractive to the purchasers particularly adolescent age groups.

Sale of tobacco products was found in surrounding area of 36% of educational institutes and they were situated on an average 50 meters distance from them. Very less number of educational institutes (16%) followed the rule of displaying No Tobacco sale near the school premises & among them who followed around 50% was according to the guidelines of Section-6a of COTPA.

Display of health warning both textual & pictorial was found on all the tobacco products as per the guidelines of Section 7, 8, 9 of COTPA. Most common health warning present was 'Tobacco causes cancer' then 'Tobacco causes painful death'. No tobacco products mentioned Nicotine content on the packets whereas Helpline number to quit tobacco was mentioned in all the products including local made.

Discusion

Present study found compliance to the regulations of COTPA-2003 in the district was 30% for section-4, 84% for section-5, 92% for section-6a, for 64% section-6b and 99.9% for section-7,8,9.

Similar studies were conducted by Tripathy et al.[7] who found a mere 23% compliance of Section 4 of COTPA at a tertiary health-care institution in a smoke-free city of India. In study done by Goel et al.[8] found very high compliance rate of 92.3% for Section-4 of COTPA in a district of North India.

The COTPA Sections 4 and 5 violation was 134 (67%) and 94 (47%), respectively. A total of 124 (62%) of the educational institutions had tobacco vendors within 100 yards, and only 30 (15%) had signboard for the prohibition of tobacco use. Around 14 tobacco vendors had bidis without proper pictorial warning with them which violated Section 7 of COTPA.[9]

Among the 100 Educational Institutes surveyed (53 government, 47 private), tobacco products were sold at 43 outlets within a radius of 100 yards of 27 EIs. No outlet had a display board prohibiting sale of tobacco products to minors. One outlet sold tobacco products to minors during the period of observation, but sale of tobacco products by minors was not observed. Only 38% of EIs displayed board prohibiting tobacco sales; private EIs were significantly less likely to display signs prohibiting tobacco sales than government EIs.[10]

Signage indicating ban on smoking was seen at 71.9% places. Active smoking was absent at 77.2% places. About 25% shops around the institutes were found selling tobacco products. Signage displaying ban on sale within 100m of educational institution and sale to minors was not observed at any shop. Tobacco product vendor was seen around 80% of educational buildings. Tobacco free institution signage was seen at 60% of educational premises.[11]

The study found moderate to low compliance to the provisions of COTPA regarding the ban on sale of tobacco products, to and by the minors, and around educational institutions. Tobacco products were easily accessible to minors in 57.7% of tobacco shops. The mandatory signages under Section-6(b) of COTPA

were not displayed in less than half of the educational institutions. In nearly one fifth, tobacco products were being sold in and around 100yards of institute's boundary.[8]

Conclusion

COTPA includes measures that are intended to protect residents from exposure to secondhand smoke, to significantly restrict tobacco advertising and to eliminate easy access to tobacco products by youth. The Cigarette & Other Tobacco Products Act 2003 implementation in all the taluka headquarters of Vijayapura district is found less as expected. The main reason found behind this is low awareness regarding the act. Public places are the places where the crowd of the area stays most, is more susceptible for the side effects of second hand smoking if the Act is not effectively implemented. The educational institutes contain the more vulnerable groups of the community i.e. adolescent who are very easy targets for the tobacco sellers who are not following the guidelines of the act.

Recommendations: Increase the awareness regarding side effects of tobacco use and Second hand smoking among the population. Create awareness among the population regarding the rules & regulations of COTPA-2003. Regular inspection of the facilities followed by strict enforcement of law by the authorities on those who violet it. License of the point of sale should be held in suspension or canceled if the guidelines are not followed.

Acknowledgment: I extend my Gratitude to the stake holders at state level for allowing us to conduct survey in the district & also to the staff of Dept of Community Medicine department for their direct and indirect contribution for the survey.

Abstract

Context: The aim of this study is to compare the one year clinical performance of three bulk fill restorative materials in posterior class I occlusal restorations. 20 patients received three class I with one of three bulkfill restorative resins. Sonicfill, Tetric Evoceram and Filtek bulkfill. All restorations were evaluated at baseline, at three, six, nine months, and one year after placement. Two calibrated examiners other than the operator were evaluated each restoration. Modified USPHS criteria was used to evaluate the restorations. The results were statistically insignificant. More studies need to be carried out and for a long period of time.

Keywords: *Resin based composites, bulkfill composites, clinical performance.*

Introduction

With the increasing awareness among the patients there is a rise in the demand for aesthetic restorative materials even for the posterior teeth. So dental composites, have been an obvious choice for restorative material. But, the conventional layering or incremental technique used in dental composites is cumbersome and time consuming. This has led to the innovation of a new class of resin based composite (RBC) materials. They are an attempt to speed up the restoration process by enabling up to 4 or 5 mm thick increments (bulk fill) to be cured in one step, thus skipping the time consuming layering process.[1]

The main concern while using the bulk fill composites is potentially increased polymerization shrinkage stress at the tooth material interface.[2] The physical mismatch between the shrinkage prone restorative material and the stiffer tooth structure could result in micro leakage, marginal staining and post-operative sensitivity. This could lead to compromise in the physical and mechanical properties of the restoratives having a detrimental effect on their clinical performance.[3,4]

The aim of this study was to compare the one year clinical performance of three bulk fill restorative materials in posterior class I occlusal restorations.

Method & Material

Selection Criteria: Twenty three patients with ages ranging from 18 to 30 years and having at least three class I carious lesions were included in the study. The approval for this clinical study was obtained from

Corresponding Author:
Dr. Deepak Gupta
Reader, Dept. of Oral Medicine and Radiology, M.M. College of Dental Sciences and Research, Maharishi Markandeshwar (Deemed to be University), Mullana, Ambala, Haryana, India
e-mail: drdeepak_26@rediffmail.com
Phone: +91-9896671281

The Ethical committee, Maharshi Markandeshwar University, Ambala.

For the inclusion in the study the tooth to be restored were vital without pulpal or periodontal disease with at least one neighboring tooth present and an existing occlusal contact. The specific exclusion criteria included patients with poor oral hygiene, pulpal or periodontal disease, pain and preoperative sensitivity, serious health problems, heavy bruxism, known allergy to the substances used in the study. The patients were informed about the procedure and asked to sign the informed consent before the clinical procedures.

Restorative Procedure: All operative procedures were performed by same operator. Before starting with the cavity preparation bitewing radiographs were taken to evaluate the extent of caries. Class I cavity were prepared using a diamond abrasives with a high speed hand piece. The cavity design was restricted to eliminate carious tissues only. The grouping will be based on the resin based composites used. The details about these composites is summarized in table 2.

Group.1: Teeth restored with Sonic Fill bulk fill resin based composite. (Kerr Corporation)

Group.2: Teeth restored with Tetric Evoceram bulk fill resin based composite. (IvoclarVivadent, Inc.)

Group.3: Teeth restored with Filtek Bulkfill posterior restorative resin based composite.(3M ESPE, St. Paul, USA))

A standardised procedure was followed for etching and bonding for all the cavity preparation in all the three groups. Following which restorative resins were placed in bulk with help of filling instruments, additionally the dispensing gun was used for Filtek bulkfill and for placing the sonic fill bulkfill composite, sonic fill hand piece was used. It vibrated at 5 – 6 kHz, ejection force ranges between 0 to 170 N. After placement of composite, curing was done for 40 seconds. Then finishing was accomplished using finishing burs as per the protocol.

Clinical Evaluation: The restorations were evaluated by two calibrated examiners at Baseline (1 week after restoration), 3 months, 6months, 9 months and 1 year using mirrors and probes following the Modified USPHS (US Public Health Service)criteria described by Cvar and Ryge . The post operative evaluation was done by tactile method using probe and stream of compressed air for 5 seconds. The restorations were examined and labelled as Alpha (highest score of clinical acceptability), Bravo, Charlie and Delta to indicate the degree of clinical acceptability at every visit

Alpha: Perfect

Bravo: not perfect, but clinically acceptable

Charlie: restoration requires replacement

Delta: failure

Any discrepancy in evaluation between the two evaluators was immediately resolved at chair side. The three restorative materials for each criteria were compared using Chi-square test, Kruskal – wallis test at a significance level of 0.05.

Results

A total of 69 restorations were placed in 23 patients. There were three types of restoration in each patient. The recall rate was 100% at one year period.

The result of this study are summarized in tables (1-6). This presents the data for anatomic form, secondary caries, color match, retention, marginal adaptation, marginal discoloration, surface texture.

All the restorations were scored as alpha for **anatomic form** at the baseline. After one year one sonicfill restoration received a Bravo. There were no significant different among the restorative groups in terms of anatomic form.

In terms of **secondary caries**, all the teeth scored alpha. At the end of one year there were no loss of restorations, a 100% retention rate was recorded for all three restorative materials.

There were no significant differences among the restorative groups in terms of color match. Tetric evoceram shows all alpha scores at the end of one year. Sonic fill and Filtek restorations received one bravo score.

In the **marginal adaptation**, filtek bulkfill received the highest numbers of Bravo scores at the end of one year. Sonicfill received two bravo scores, but none of the restoration of tetric evoceram received a bravo score. There were no statistical differences among the restorations.

In terms of **marginal discoloration**, only one restoration from sonicfill and one from filtek bulkfill received bravo scores, whereas all restorations from tetric evoceram received alpha at the end of one year. No significant differences were observed in surface texture between the restorative materials. The results for intragroup comparison between baseline and each evaluation period were statistically insignificant. (P>0.05).

Discussion

The present study showed that all of the 3 tested materials are suitable and acceptable for restorations involving occlusal surfaces. Moreover, the bulk-fill technology has obvious advantages: 1) fewer voids may be present in the mass of the material, since all of it is placed at one time; 2) the technique would be faster than placing numerous increments if curing times were identical; 3) It may be easier than numerous increments.[5]

The reason for selecting patients with a minimum of three carious lesions, was so that all the three restoratives used in the study received similar oral environmental conditions.

Tetric Evo Ceram Bulk Fill (IvoclarVivadent) is a nanohybrid composite and contains in its composition an inhibitor of sensitivity to light and thus provides prolonged time for modeling of filling, an inhibitor of shrinkage stress in order to achieve optimal marginal seal, and Ivocerin, polymerization photoinitiator allowing curing of 4 mm layers of material.[6]

Filtek Bulk Fill posterior restorative (3M ESPE), a low-viscosity, visible-light activated flowable material for filling with bulk-fill technique, is manufactured in four shades (each of which may be polymerized in 4 mm increments according to international ISO standards).[6]

Oscillation energy has been proposed in as a new method to pack resin composite. The principle of this technique assumes that vibration lowers the viscosity of the resin, allowing the material to flow and easily adapt to the cavity walls in a similar way as a flowable resin composite.[1,4]

Shrinkage stress compensation mechanism in SonicFill system is obtained using a resin having low shrinkage properties and high filler content(84%).[6] The Sonicfill system composite used in this study is a combination of flowable and universal composites. As sonic energy is applied through the hand piece, the modifier causes the viscosity to drop (up to 87%), increasing the flowability of the composite. When the sonic energy is stopped, the composite returns to a more viscous, non-slumping state.[5,7] A study found that ultrasonic packing technique resulted in better but not statistically significant different interfacial adaptation values compared to application without ultrasonics of condensable composites.[4,8]

In this study, Modified USPHS (US Public Health Service) criteria described by Cvar and Ryge has been used. In terms of color match one restorative from all the 3 groups received bravo scores at the end of one year and group 1 and group 3 at the end of 9 months.

In terms of marginal adaptation three restoration from sonic fill and tetric evoceram and five from filtek received Bravo scores at the end of one year. The marginal adaptation is influenced mainly by the polymerization shrinkage of resin composite and the adhesive type, so both factors might have influenced the clinical results of this study.

A study conducted by Miroslaw orlowski et al showed that a higher marginal integrity and lower penetration of dye in fillings inserted using a sonic-activation condensing device was shown when compared with manual condensation. Statistically significant better marginal integrity of Sonic Fill, and Filtek Bulk Fill (compared to the composite Tetric Evo Ceram Bulk Fill), may be due to their flow consistency during application.[6,7]

Bulk-fill composite materials evaluated in the study by Bowski M. et al seem to meet satisfactorily the requirements of this type of materials in terms of marginal adaptation. The dye penetration test showed no microleakage for high percentage (73.33–93.33%) of tested restorations. Bulk-fill composites are more translucent than other restorations, which allow the light to get to much deeper layers.[6]

Post operative sensitivity is one of the most common complaints of patients with posterior resin restorative in this study. The cavities with class 1 resin composite restoration were more prone to marginal failure and post operative sensitivity due to of higher cavity configuration factor (C=5).[5,6] . In the present study tetric evoceram showed least post operative sensitivity.

It is most important to note that the modulus of elasticity is lower in the bulk-fill RBCs than in the nanohybrid and microhybrid RBCs. A material with a low modulus of elasticity, particularly when placed in load-bearing areas, will result in a higher deformability under masticatory stresses. This will cause, as a final consequence, catastrophic failures [1]. An exception is Tetric EvoCeram Bulk Fill, which shows moderate values for the modulus of elasticity, albeit having a high filler content. It must, however, be considered that Tetric Evo Ceram Bulk Fill also contains prepolymerized fillers, which is included in the total filler amount. Thus, the inorganic filler content, which in effect increases the modulus of elasticity, is consistently lower.[1] This could be the reason for the better performance of tetric evoceram, though not statistically significant, could be clinically significant.

Further clinical studies addressing different cavity types and longer duration should be conducted.

Conclusion

All the three bulkfill restorative resins showed similar clinical results statistically. Tetric evo-ceram showed a better performance in terms of marginal adaptation and sensitivity,which could be clinically significant and contribute to the clinicians while selecting restorative materials.

Abstract

Introduction: Diabetes as one of Non-communicable diseases has consumed a large share of money, material, time and human resources of health systems. Now, due to advancement in lifestyle and industrial process, prevalence of diabetes and its associated complications have been raised. Among these complications, diabetic foot considered as a common complication of diabetes.

Method: The present study was a quantitative quasi experimental two group pretest posttest design. The study was done at Amrita Hospital, Kochi. The main objective of the study was to evaluate the effectiveness of Burger Allen exercise on level of lower extremity perfusion among patients with type 2 Diabetes Mellitus. Totally 100 samples were taken in which 50 are in experimental and 50 in control group using convenience sampling technique.

Results: In the present study, majority were males with the average age among experimental group were 55.30 +- 4.58, 36(72%) and 55.30+- 4.58, 34 (68%) in the control group. The study result showed that mean and standard deviation of ABPI score among both groups on Day 1(0.07±0.01), day 2 (0.05±0.02) and day 3(0.19±0.01). There was statistical significance with the p value <0.01. There was also significant difference between the groups and within the groups in ABPI scores in 3 days among patients with type 2 DM which is significant at <0.05.

Conclusion: In the light of present study result, it depicted that the Buerger Allen exercise improve lower extremity perfusion among patient with type 2 diabetes mellitus.

Keywords: *Buerger Allen exercise, Lower extremity perfusion, Type 2 diabetes mellitus.*

Introduction

Diabetic mellitus is a group of metabolic disease in which defects in insulin secretion or action result in elevated blood glucose (hyperglycemia). In 2017, The WHO global report on diabetes demonstrates that the number of adults living with diabetes is 422 million adults.1.6 million deaths are directly attributed to diabetes each year. Type 2 DM accounts for around 90% of all diabetes worldwide.[1] Reports of type 2 diabetes in children have increased globally. Diabetes currently affects more than 62 million Indians, which is more than 7.1% of adult population. The average age of onset is 42 years. Nearly 1 million Indians die due to diabetes every year. Kerala is known as diabetes capital of India as prevalence of diabetes is high 20% which is double the national average of 8%. As compared the prevalence in Thiruvananthapuram was 17%, in Hyderabad and New Delhi 15%, in Nagpur 4% and in Dibrugarh 3%. [2]

Diabetic foot complication is a major cause of disability, reduced quality of life, prolonged

Lecturer, Amrita College of Nursing, Amrita VishwaVidyapeetham, Health Science Campus, Kochi.

hospitalization, financial loss, lower limb amputation and mortality rate. [3,4] People with diabetes develop foot ulcers because of neuropathy, vascular insufficiency and impaired wound healing. [5] Nearly 90% of diabetes relayed lower limb amputations were preceded by foot ulcers.[6] The value of these exercises had frequently been emphasized by Allen, many medical experts considered them as important adjuvant treatment and postoperative care for circulatory disturbances in the extremities. [7,8]The exercises involve the individual lying flat in bed with the legs elevated at 45 degrees until blanching occurs or for a maximum of 2 minutes. The patient then sits at the edge of the bed with the feet hanging down. Further exercises include dorsiflex, plantar flex, then inward and outward movement of the feet, followed by flexing and extending of the toes for 2 minutes. Finally the individual lies supine with the feet covered with a warm blanket lasting 5 minutes. The whole cycle is repeated 3 to 6 times each session, and the complete sequence is repeated 2- 4 times a day.[9]

The ankle brachial pressure index is a simple non-invasive and inexpensive diagnostic tool of choice for diagnosing peripheral artery disease in diabetic patients. The ABPI is the ratio of the systolic blood pressure in the angle to the systolic blood pressure in the arm. It is an objective indicator of arterial disease that allows the examiner to quantify the degree of stenosis. Doing exercise will help the patient to improve the vascularization and at the same time it will help to improve the wound healing process.

People with long standing Diabetes mellitus developcomplication of PAD, which leads to grave complications like gangrene in the lowerlimbs. The most common symptom is muscle pain in the lower limbs on exercise. Indiabetes, pain perception may be blunted by the presence of peripheral neuropathy.Therefore, a patient with diabetes ismore likely to present with an ischemic ulcer or gangrene. The use of ankle-brachial-pressure index in the clinic andbedside provide a measure of blood flow to the ankle. This could help early detection,initiate early therapy and may thus reduce the risk of critical limb ischemia and limbloss.

Buerger Allen Exercise is one of the intervention to stimulate the developmentof collateral circulation in the legs. Primary care providers should focus onprevention by early recognition and prevention of PAD to those at increased risk. An awareness of diagnostic and treatment strategies will enable primary care provide providers toeducate patients. This will help to improve both concordance with treatment anddisease outcome. Considering the above factors and review of literature, theinvestigator felt that all patients with diabetes mellitus should do the

Buerger Allen Exercise to improve lower extremity perfusion.

Methodology: The present study was a quantitative quasi experimental two group pretest posttest design. The study was done at Amrita Hospital, Kochi. The main objective of the study was to evaluate the effectiveness of Burger Allen exercise on level of lower extremity perfusion among patients with type 2 Diabetes Mellitus.

Selection Method of the Study Participants: The study included all patients between 45-60 years with Type 2 Diabetes Mellitus and whose ABPI score was 0.9 -0.4. The sample size was obtained using Master software based on previous article conducted by John J and Rathiga R on effectiveness of Buerger Allen Exercise to improve the lower extremity perfusion among patients with type 2 diabetes mellitus with -80% power, 95% Confidence interval minimum sample size 10 in each group. Totally 100 samples were taken in which 50 are in experimental and 50 in control group using convenience sampling technique. The study excluded patients who are unconscious, disoriented, critically ill, on anti-coagulant therapy, on treatment of deep vein thrombosis and also who are not willing to participate. The ABPI score was obtained by dividing the highest ankle systolic pressure to the highest brachial systolic pressure.After obtaining written informed consent, the ABPI was measured in each subjects and those subjects whose ABPI score was between 0.9 to 0.4 had been given the Buerger Allen Exercise for 12-13 minutes on three days. On the third day again the ankle brachial pressure index was calculated. Ethical clearance had been obtained from the Thesis review committee of AIMS and research Committee of Amrita College of Nursing.

Software Used for Data Entry, Compilation and Statistical Analysis: Microsoft Excel spread sheet was used for data entry and data analysis was done using the SPSS 20.0 version. In this study the quantitative data were expressed in terms of descriptive statistics. Paired t-test had been used for comparing statistical significant to compare the pre- test and post–test scores of ankle brachial pressure index among Type 2 Diabetic

Mellitus patients. Chi-Square test was used to find out the association between ABPI score and selected demographic variables.

Ethical Consideration: The project has been approved by theethics committee of the institution. Informed consent wasobtained from the participants before initiating the study.

Results

In the study, the average age of experimental group is 55.30 +- 4.58. 36 (72%) were males, almost 45 (90%) had education up to secondary level, 32 (64%) subjects were employed, 23 (46%) were doing sedentary and moderate work each, 46 (92%) were non- vegetarian diet, 29 (58%) had no ill habits and 33 (66%) had type2 DM for more than 11 years. Whereas in the control group, the average age is 55.30+- 4.58, 34 (68%) were males, 41 (82%) had education upto secondary level, 26 (52%) were unemployed, 31 (62%) were moderate workers, almost 45 (90%) were following non vegetarian diet, 34 (68%) had no ill habits.

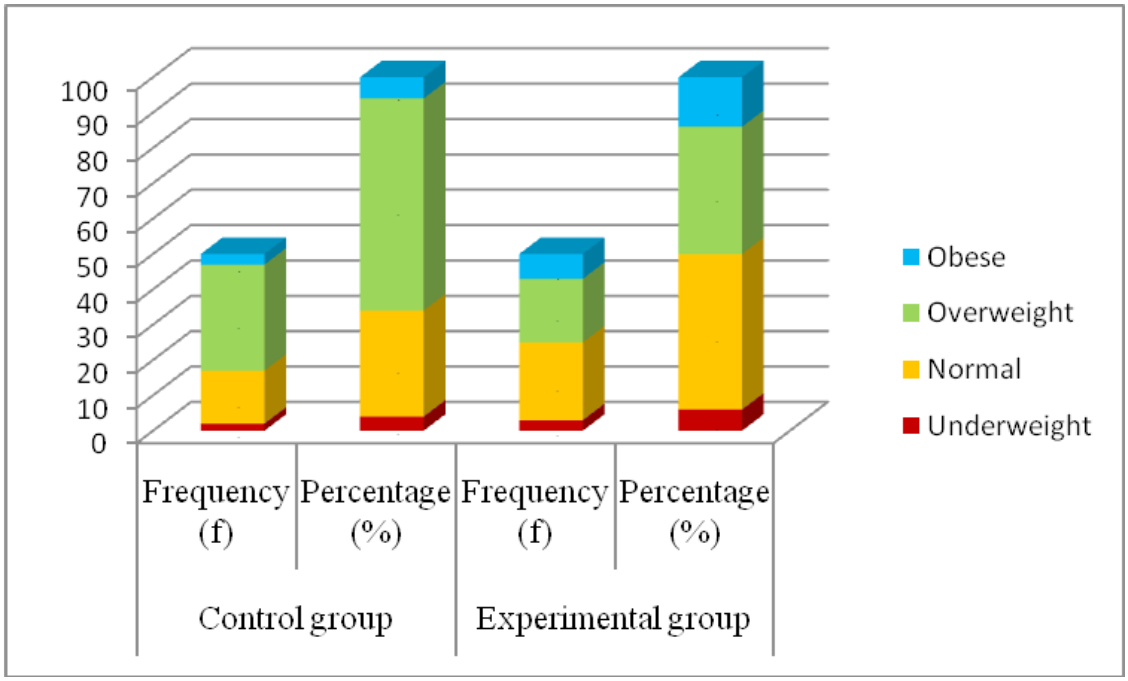

Figure 1: Frequency and percentages distribution of BMI among patients with Diabetes mellitus in control and experimental group.

In the present study, the result shows that BMI category in control group were 2(4%) underweight, 15(30%) normal, 30(60%) overweight and 3(6%) obese. In experimental group, 18(36%) were overweight and 7(14%) were obese.

Table 1: Comparison of mean, median and standard deviation of clinical variables among patients with diabetes mellitus in control and experimental group. N=100

Group	Clinical parameters	Mean	Median	Standard deviation (SD)
Control group	Height	159.24	158	6.14
	Weight	64.96	65	9.95
	BMI	25.56	25.8	3.10
Experimental group	Height	159.24	160	5.17
	Weight	64.48	60	11.71
	BMI	25.42	24.69	4.33

The above table shows that among the control group the mean and standard deviation of height, weight and BMI is (159.24± 6.14), (64.96± 9.95) and (25.56± 3.10) respectively. In the experimental group the mean and standard deviation of height, weight and BMI is (159.24± 5.17), (64.48± 11.71) and (25.42± 4.33) respectively.

Table 2: Mean and standard deviation of Ankle brachial pressure index among control and experimental group. N=100

ABPI Score	Mean	Standard Deviation	F	p- value
Day 1	0.07	0.01	4.44	0.00**
Day 2	0.05	0.02	2.88	0.01*
Day 3	0.19	0.01	0.60	0.00**

Data present in the table shows that mean and standard deviation of ABPI score among both groups on Day 1(o. o7±0.01), day 2 (0.05±0.02) and day 3(0.19±0.01). There was statistical significance with the p value <0.01.

Table 3: Comparison of ABPI scores among patient with diabetes mellitus in between and within the control and experimental groups. N=100

Variables	Days		Mean	Sum of square	df	F	p-value
ABPI score	Day 1	Between groups	0.135	0.13	1	45.55	0.000*
		Within groups	0.003	0.29	98		
	Day 2	Between groups	0.064	0.06	1	6.68	0.01*
		Within groups	0.009	0.93	98		
	Day 3	Between groups	0.984	0.98	1	349.92	0.000*
		Within groups	0.003	0.27	98		

The table 3 depicts the significant difference between the groups and within the groups in ABPI scores in 3 days among patients with type 2 DM which is significant at <0.05. There was no association between the demographic variables and the ABPI score

Discussion

Diabetes is a complex metabolic disease. A Non pharmacological natural approach is needed to overcome that problem. Burger's Allen exercise is a simple, which is easy to do, have no notable side effects and most acceptable one to reduce Diabetes mellitus.

In the present study, the average age of experimental group is 55.30 +- 4.58. 36 (72%) were males, almost 45 (90%) had education up to secondary level, 32 (64%) subjects were employed, 23 (46%) were doing sedentary and moderate work each, 46 (92%) were non- vegetarian diet, 29 (58%) had no ill habits and 33 (66%) had type2 DM for more than 11 years. Whereas in the control group, the average age is 55.30+- 4.58, 34 (68%) were males, 41 (82%) had education upto secondary level, 26 (52%) were unemployed, 31 (62%) were moderate workers, almost 45 (90%) were following non vegetarian diet, 34 (68%) had no ill habits.

Another study conducted by M. Vijayabarathi (2013) on effectiveness of buergerallen exercise on wound healing process among the diabetic foot ulcer patients admitted in diabetology department which results showed that in considering the age wise distribution, 36.7 % of subjects were in 50 to 60 years of age, in the experimental group. In the control group 33.3 % of subjects were more than 60 years of age. In the sex wise distribution, females were high in both experimental and control group as 80.0% and 83.3%.In Experimental group majority was educated up to primary education 50.0 % (15) and in Control group 63.3% (19) equally educated up to primary education and High School. When considering the type of family most of them belong to nuclear family in both the groups. In both the groups when considering the education status most of the subjects had only primary education.[10]

The present study shows that 30 (60%) subjects are overweight in control group whereas in the experimental group most of the subjects 22 (44%) have normal BMI.

Leelavathi. M (2015) conducted a study on

effectiveness buerger'sallen exercise on improving lower extremity perfusion among patients with diabetes mellitus which inferred that most of the patients with diabetes mellitus had B.M.I. of 25-29 (43.3%, 43.3%). Increased BMI was associated with increased prevalence of diabetes mellitus. An increase in body fat is generally associated with increased risk of metabolic diseases such as type II diabetes mellitus.[11]

Data present in the table shows that mean and standard deviation of ABPI score among both groups on Day 1(0.07±0.01), day 2 (0.05±0.02) and day 3(0.19±0.01). There was statistical significance with the p value <0.01.

Dr. Aruna S, Thenmozhi P (2015) conducted a study on effectiveness of allenbuerger exercise in preventing peripheral arterial disease among people with type 2diabetes mellitus.Experimental Research Design with 30 samples in experimental group and 30 samples in control group were selected by using random sampling technique at Kuthambakkam village. The findings of the study revealed that there is a significant improvement in Ankle-Brachial index Score in preventing peripheral arterial disease among people with Diabetes Mellitus in experimental group after receiving Allen Buerger exercise at the level of P<0.05. Independent t test revealed that there is significant difference between the experimental group and control group in preventing peripheral arterial disease among people with Diabetes Mellitus at the level of P<0.05.[12]

Anju Kumari, Kanika Rai, Vinay Kumari, Dr Jyoti Sarin conducted a study on effectiveness of buergerallen exercise on foot perfusion among patients with diabetes mellitus showed that (50%) patients were suffering from comorbid illness in which 56.6% were suffering from hypertension, 8/30 (26.6%) were suffering from Chronic Kidney Disease (CKD), 1/30 (3.33%) was suffering from CVA, 04/30 (13.3%) were suffering from CAD, and 30/60 (50%) of patients were not suffering from any comorbid illness.[13]

In the present study, the significant difference between the groups and within the groups in ABPI scores in 3 days among patients with type 2 DM which is significant at <0.05.

Jemcy John and A Rathinga conducted a research study showed a significant improvement in the lower extremity perfusion after the Buerger Allen exercise. Data depicts that the mean post- test ankle brachial index score was higher than the mean pre-test ankle brachial index score. The calculated t value was greater than the table value. The computed t value shows that there was a significant difference between the two mean ankle brachial index score.[14]

Mellisha MS conducted a study on effectiveness of buergerallen exercise on lower extremity perfusion and pain among patients with type 2 diabetes mellitus showed that in the experimental group, the mean score of level of lower extremity pain was reduced from 4.33 to 1.30. The reduction of pain was statistically significant difference at 1% level of significance (p=0.001). The mean score of level of lower extremity perfusion was increased from 44.50 to 52 and it showed a statistically significant difference at 1% level of significance (p=0.001).[15]

The above finding clearly indicates that the Buergerallen exercise was found to be an effective on lower extremity perfusion among patients with type 2 Diabetic Mellitus.

Conclusion

The study concluded that the study participants got benefited by Allen Buerger exercise in preventing Peripheral Arterial Disease among patients with type 2 Diabetic Mellitus. Nurses plays a significant role in preventing Peripheral Arterial Disease there by reducing the risk of amputation and restore normal function of the extremity by encouraging them to do the exercise which will help to improve the quality of life. It also suggests that Buerger's exercises could be an alternative procedure on improving peripheral circulation.

Conflict of Interest: There is no conflict of interest for the study.

Child Abuse: An Empirical Study Emphasizing on Child Health in Present Indian Socio-Economic Situation

Satakshi Chatterjee[1], Arunangshu Giri[2], Pradip Paul[3], Manigrib Bag[4], Swatee Biswas[5], Abanti Aich[6]

[1]Assistant Professor, Department of Pharmaceutical Management, Haldia Institute Management, Haldia, West Bengal, India, [2]Associate Professor, School of Management & Social Science, Haldia Institute of Technology, Haldia, West Bengal, India, [3]Senior Manager (Retail Sales), Haldia Divisional Office, Indian Oil Corporation Ltd., Haldia, West Bengal, India, [4]Assistant Professor, [5]Officer in Charge, Administration Department, Haldia Institute Management, Haldia, West Bengal, India, [6]Assistant Professor, Department of Science and Management, Haldia Institute of Health Sciences.

Abstract

Context: Child abuse is often neglected in the society. However, it should not be overlooked as this problem might become a major problem in the long run. Due to the hush-hush nature of this problem in the society, it is slowly creeping in as social stigma amongst the people which restricts the problem from being addressed directly. The main objective of the paper is to identify the health related factors of Child Abuse in present Indian socio-economic situation. The results of the study show that Child abuse is a growing peril in the Indian society and it must be addressed as soon as possible. Less research has been done in this field and there is a need to explore the various options in order to mitigate it. Adjusted odd ratios (OR) was used for the analysis of the data.

Keywords: *Child Abuse, Child Health, Indian Socio-economic Situation, Adjusted odd ratios (OR)*

Introduction

Child abuse, particularly sexual abuse, is often associated with the girls, however, it must be noticed that boys are also affected by this as much as the girls. Under these perilous circumstances wherein the children are exploited in an inhumane manner, some of the large epidemics like malaria, tuberculosis, HIV, etc. have adolescents fall under the highest risk group especially in the low income countries as they are subjected to large amount of stress by imbibing them into a background which is rich in violence, gender inequalities, health inequalities and low life expectancy (Fang, et al., 2016)[3]. This is especially so as these children are seen as commodities rather than human beings who are in need of nurturing and they are not kept under optimally hygienic conditions. This nurturing is proactively provided by the parents and guardians of the children and they are the best persons who can prevent child abuse by properly looking after their children (Gallo, et al., 2017)[4].

Literature Review: Lots of research has been done on the kinds of abuse committed against children. 44.4 per cent of the Indian population comprises of children below the age of 18 years and amongst this, half of the population are not provided with the most basic amenities required for surviving, that is, nutrition, health and basic education and from this we can say that these deficiencies make the children more vulnerable against the evil called child abuse(Carson, et al., 2014)[2]. Other factors that can be responsible for the increase in the rate of child abuse are insufficient income, domestic

violence, low socioeconomic status, other stresses like various socio-demographic factors, parental separation, illnesses, low maternal schooling, absence of mother's partner, parental death, maternal smoking, poor maternal mental health, unemployment, etc. (Metzler, et al., 2017)[7]. The various consequences of Child abuse can be broadly classified as physical and psychological (Malhotra & Biswas, 2006)[6]. A study has revealed that mothers, having intellectual disability run an increased risk of developing mental health problems, alcohol and drug addiction belonging from lower economic strata and their children have a higher prevalence rate of suffering from violence induced injuries and abuse in the long run (Wickstrom, et al., 2017)[10]. As a result, it is imperative that childhood abuse cases are detected as early as possible in order to lessen the adverse effects in the long term and as well as the short term and this can be made possible by developing an accurate screening process in the emergency departments of hospitals wherein the majority of the cases are first reported (Louwers, et al., 2014)[5]. A study was carried out in Saudi Arabia amongst the dental practitioners regarding the knowledge about Child abuse and neglect and it was found out that a majority of them (59 per cent) had experienced such a case in their career, however, only 10 per cent of the respondents reported the case for their lack of certainty about the diagnosis, the fear of reprisal from the family or their uncertainty over how to manage the case as only 20.9 per cent of them were knowledgeable about child protection policies (Mogaddam, et al., 2016)[9]. There has been instances when sexual abuse reaches its extremity as in the case of single perpetrator or multiple perpetrator rape, it was seen that alcohol was used as a common weapon against girls mostly at parties and as a result the girls had a hard time remembering the events leading up to their trauma and these victims require help in order to diagnose these physical findings, provide therapy for trauma, treatment of the Sexually Infected Diseases if infected and finally care and support. Thus, detecting child sexual abuse becomes notoriously difficult for investigative as well as for treatment purpose (Mitchell, et al., 2017)[8].

Socio-Geographical Context: India is a country with a population of about 1.2 billion and is rich in culture. India is the third largest democracy in the world and is a significant global player. Overall annual growth is expected to grow at an annual rate of 7.0 per cent for the fiscal year 17/18. It is roughly estimated that 10 per cent of the world's street children reside in India and the causes for this unusual development ranges from the fact that their parents hails from joint families who are illiterate to that of the children having to experience intra-familial physical abuse (Bonfim, et al., 2015)[1]. Following table describes the demographic profile of the respondents (Table 1).

Table 1: Demographic Profile of the Respondents

Serial No.	Variables	Participants included in the analysis	Participants included in the analysis %
1.	**Gender** Male Female	N=193 102 91	N = 193 52.85 47.15
2.	**Age of the Children** 10 to 14 years 14 to 18 years More than 18 years	N = 193 92 73 28	N = 193 47.67 37.82 14.51
3.	**Family income** Less than Rs. 2000 Rs. 2000 to Rs. 4000 Rs. 4000 to Rs. 6000 More than Rs. 6000	N = 193 92 26 58 17	N = 193 47.67 13.47 30.05 8.81
4.	**Education of the Child** Pursuing Primary Education Pursuing Secondary Education Not pursuing education	N = 193 58 07 128	N = 193 30.05 3.63 66.32
5.	**Employment of the Child** Employed Unemployed	N = 193 90 103	N = 193 46.63 53.37

Research Methodology: Here, our research model has been established with the help of both primary and secondary data. The primary data was collected from the parents and other various identified eye-witness of these issues where children had been abused. The target population were from the guardians of the street children, the caregivers or caretakers of the children belonging from the low economic background, the hawkers found in the busy market areas of major cities and also from the railway stations, bus stops, market areas who have working children, the shopkeepers who employ children for doing menial jobs, guardians of the children who do not live with their parents for earning a livelihood, etc. and the caretakers of the children found to be residing in the slums. For this study, samples were taken through convenience sampling technique only from these caregivers and caretakers and occasionally from the parents of those children who were capable of providing the complete data (N=193).

Analysis and Results: Each of the situational factors faced by children were taken and evaluated separately. Each affirmative answer would fetch one point (Yes=1 & No=0) for each of the situational factors. Thus, the total score can vary from 0 (no issues experienced) to 5 (all the issues experienced) for each respondent. The prevalence of each of these factors was also analyzed. Multinomial logistic regression was used to calculate the odds ratio (OR) and their respective 95% confidence intervals (95% CI) for the associations between the factors and their score which was generated. The OR was also calculated based on the kind of inter-relationships between the various types of factors. The analytical part of the study was carried out with the help of SPSS-21 and Microsoft Excel.

Table 2: Adjusted odd ratios (OR) and 95% confidence interval for pair wise relationships between different factors (N= 193).

Factors	Health Related Factors OR (95% CI)	Physical Abuse Related Factors OR (95% CI)	Education Related Factors OR (95% CI)	Income Related Factors OR (95% CI)	Family Related Factors OR (95% CI)
Health Related Factors		1.5 (0.5,2.6)**	2.9 (1.8, 3.7)*	4.3 (2, 6.7)*	1.6 (1.1, 2.2)
Physical Abuse Related Factors	1.5 (0.5,2.6)**		1.2 (0.2, 2.3)**	2.4 (1.6,3.3)**	1.9 (1.6,2.3)**
Education Related Factors	2.9 (1.8, 3.7)*	1.2 (0.2, 2.3)**		4.7 (3.5, 6)*	1.1 (0.7, 1.6)
Income Related Factors	4.3 (2, 6.7)*	2.4 (1.6,3.3)**	4.7 (3.5, 6)*		0.7 (0.3, 1.2)*
Family Related Factors	1.6 (1.1, 2.2)	1.9 (1.6,2.3)**	1.1 (0.7, 1.6)	0.7 (0.3, 1.2)*	

Adjusted for gender, age, family income, child education, child employment, area profile, * p-value <0.01 ** p-value < 0.05, Collected by the Researcher during the course of the Study

Table-2 shows the associations between the pairs of each of the factors experienced by the respondents. Five factors were taken for the mapping of the associations between the factors. These factors were Health Related factors, Physical Abuse Related Factors, Education Related Factors, Income Related Factors and Family Related Factors. p-value showcases the percentage of error. Both positive and negative associations have been showcased.Table-2also shows the associations between the pairs of each of the issues experienced by the respondents adjusted for the various demographic variables were gender, age, family income, child education and child employment.Strongest associations were seen between the Family Related Factors and Physical Abuse Related Factors. Highest positive associations were seen between Education Related factors and Health related factors and Income Related factors and Education Related factors. It was seen that a child experiencing undesirable situations due to Income Related factors were having 4.7 times higher incidences

of being affected by Education Related factors and vice versa. Similarly, a child experiencing adverse scenario due to Income Related factors was having 4.3 times higher incidences of experiencing Health related factors and vice versa. Negative associations could be found between Education Related factors and Health related factors and also between Educations related factors and Physical Abuse Related factors.

Discussion and Findings: Physical Abuse Related factors include intra familial physical abuse, domestic violence and Intimate Parental Violence. Intimate partner violence can be often found co-occurring with child abuse and it has a negative influence on the child. Also, it is clear that Intimate Partner Violence negatively influences the Overall Development of the Child. Furthermore, the families having low socio-economic status are more prone to physical abuse as well as neglect and neighborhood characteristics like housing instability, poverty, substance abuse, childcare burden, immigrant concentration, residential density, social impoverishment, etc., adversely affects the occurrence of Child maltreatment. Education is one of the most important aspects of the advancement of the civilization and it does have a major implication on the cause of child abuse. Education Related Factors include illiteracy, low maternal schooling, and higher rate of school dropouts and low levels of cognitive functioning. In reality, the rapid spread of Child sexual abuse in India is a complex mixture of socio-ecological, individual and situational factors of which factors such as lack of education and poverty are not only exclusive to the Indian context. Several factors like low family income, low maternal schooling, absence of the mother's partner, etc., are associated with a higher risk occurrence of Adverse child Experiences which further poses a negative effect on the overall child development by hampering their physical as well as their mental well-being. Family Related factors were seen as the most important factor related to child abuse in this study. Family Related Factors include neglect, housing instability, childcare burden, residential density, single parent's households and parental death under accidental circumstances. Poor living conditions and other issues can lead to child abuse which may develop various health related situations for the children as revealed from the inter-relationship between family related factors and health related factors. It was found out from the current study that housing instability and other family factors like childcare burden and neglect can be causal factors for domestic violence and other intra family physical abuse. The emotional burden on the parents can result in this which might further deteriorate the emotional growth and stability of the children. Income related factors include poverty and poor employability. There is a relationship between the income related factors and the health related factors as poverty situations lead a child to live a unhealthy lifestyle wherein basic amenities are not provided to them. It was seen that there is a strong co-relationship between insufficient incomes in the family with that of child maltreatment. Neglect and Housing instability can cause the children to develop certain habits which are not good for the physical as well as the emotional development of the children such as substance abuse, alcohol addiction, etc.

Managerial Implications: It is pretty evident that special care must be ensured so that the younger generation can feel safe in the Indian environment. This will motivate them to build a future for themselves in India itself and will prove a milestone in developing the country. The government needs to come up with certain laws and regulations to restrain this societal epidemic as much as possible. Otherwise, this will spiral forward drastically and then it will be very difficult to restrain it. The future of the nation is dependent on the youth. Thus, the youth should be provided with such an environment which will make them feel safe.

Conclusion

Child abuse is shaping itself into an epidemic and spreading to the various parts of India. It is becoming a growing nuisance in India. This problem must not be put aside. It must be addressed immediately and steps should be taken to control it to a certain extent. In order for the authorities to take certain steps, at first, it would be of great importance if the factors responsible for this crisis are found out. As discussed in the paper, there are a multitude of factors that are responsible for this societal disease; however, these factors can be closely monitored so that these kinds of activities can be prevented before they are caused. This will ultimately result to be of benefit to the society and humanity as a whole. The purpose of this study was to figure out the root cause of this evil polluting our society in present Indian socio-economic scenario and to find out the ways of removing this from its very root.

Ethical Clearance: Ethical approval for this study has been taken from selected Municipal Authorities from

selected states in India for executing the data collection process smoothly. Also respondents have been assured for keeping complete confidentiality of their responses regarding our research topic.

A Glimpse of Manual Scavanging in India

Shailla Cannie[1], Aasavri Cannie[2]

[1]Dean, Faculty of Nursing, Shri Mata Vaishno Devi University & Principal, Shri Mata Vaishno Devi College of Nursing, Kakryal, Katra, [2]Second Year MBBS Student, The University of Georgia, Tiblisi, Georgia

Abstract

Context: Across India, manual scavenging and its allied forms — the manual cleaning of dry latrines, sewers, manholes and septic tanks, abstraction of debris from sewage canals and any interaction with excreta — are openly prevalent, defined as a "cultural vocation". "In India, every five days, a manual scavenger dies in a sewer, septic tank or a manhole," the report verbally expressed. However, its scope was constrained as its primary source of data was statistics from NCSK, which has disarrayed information organised arbitrarily. The few key features of the Act Prohibits the expression or maintenance of insanitary toilets, Prohibits the engagement or employment of anyone as a manual scavenger, Violations could result in a years' imprisonment or a fine of INR 50,000 or both. The press Information Bureau, Government of India, Ministry of Social Justice and Empowerment has verbally expressed that a Task Force was constituted for carrying out a National Survey of manual scavengers in 2018 in 170 identified districts of 18 states. The right technology is considered as one of the solution to eradicate this scourge. In spite of that, the social and gender issues should be abolished by educating pupil about this ill.

Keywords: *manual scavengers, manholes, insanitary latrines, health issues*

Introduction

Across India, manual scavenging and its allied forms — the manual cleaning of dry latrines, sewers, manholes and septic tanks, abstraction of debris from sewage canals and any interaction with excreta — are openly prevalent, defined as a "cultural vocation" annexed to a few make-believe lower castes — Hindu Dalits, a few Dalit Muslims and some converted Dalit Christians. In India, this affair is hazardous, unsafe, unsanitary, degraded and above all, illicitly proscribed by Parliament a few years ago. The level of susceptibility increases as we peregrinate from rural to urban areas. However, reports designate that these days; there is incremented fatality in rural India, as well.[1]

The data from the National Commission for SafaiKarmacharis (NCSK) revealed appalling facts on the pattern of the deaths of manual scavengers from January 2017 to September 2018 and were widely shared by media houses and convivial media users. "In India, every five days, a manual scavenger dies in a sewer, septic tank or a manhole," the report verbally expressed. However, its scope was constrained as its primary source of data was statistics from NCSK, which has disarrayed information organised arbitrarily.

Manual Scavenger at work--- A bitter truth of reality

The two major Acts have been since 1993 by Parliament to ban and control manual scavenging. One of the Act passed by Narsimha Rao Government in 1993 created a history in the legislation banning manual scavenging altogether and aimed at rehabilitation of scavengers followed by passing of another Act in 2013 by UPA II after it was reported that manual scavenging still persists despite a slow progress.[2]

According to the India census of 2011, there are more than 2.6 million dry latrines in the country. Along with that toilets with human excreta flushed in drains is 13, 14,652 and 7, 94,390 dry latrines are cleaned manually. It has as well been identified that seventy three percent of these are in rural areas and twenty seven in urban areas.

The few key features of the Act are

Prohibits the expression or maintenance of insanitary toilets

Prohibits the engagement or employment of anyone as a manual scavenger

Violations could result in a years' imprisonment or a fine of INR 50,000 or both

Prohibits a person from being engaged or employed for hazardous cleaning of a sewer or a septic tank[3]

Offences under Act are cognizable and non-bailable calls for a survey of manual of scavengers in urban and rural areas within a time limit framework. While the Act is encouraging in that it focuses on the duty of official to ensure its implementation, it does not outline administrative measures beyond conduct rules that can be imposed if officials do not implement the Act.

The mundane accidents include falls/slips fire or explosion, oxygen depletion, heat stress, drowning, asphyxiation arising from gas, gas poisoning, vapour and entrapment by free flowing solids. Amongst these hazardous gases etc are facilely overlooked or neglected leading to earnest causalities.[4]

Definition: Manual scavenging refers to the unsafe and manual removal of raw (fresh and untreated) human excreta from buckets or other containers that are used as toilets or from the pits of simple pit latrines.

According to the Indian Law, 1993, Manual scavengers means a person engaged or employed at the commencement of this Act or any time thereafter, by an individual or a local authority or an agency or a contractor for manually cleaning carrying, disposing of or otherwise handling in any manner, human excreta in an insanitary latrine or in an open drain or pit into which the human excreta from the insanitary latrines is disposed of, or railway track or in such other spaces or premises, as the central government or a state government may notify, before the excreta fully decomposes in such manner as may be prescribed, and the expression 'manual scavenging' shall be construed accordingly.[5]

The prohibition of Employment of Manual Scavengers and their Rehabilitation Act, 2013, defines a manual scavenger as an individual employed by a local authority or agency for manually cleaning, carrying and disposing of human excreta from insanitary latrines.[2]

Categories of Sanitation Workers: A caste predicated and hereditary vocation, which is bequeathed, as a legacy from one generation to the next; "manual scavenging" has been an age-old routine for this community, which is untouched by technological advancement in sanitary practices.

i. **Sewer Cleaners:** These cleaners are involved in unblocking and cleaning of the permissive wastewater drains. The work is need based (pluvial season) and infrequently for preventive maintenance. The sewer gas is a complex amalgamation of toxic and non toxic flatulency engendered and accumulated in sewage system by the decomposition of organic home or industrial waste.

ii. **Latrine Cleaners:** They are involved in cleaning the process of evacuating dry/single-pit latrines preferably in rural areas. The process involves daily amassment and convey/evacuating of faecal matter.

iii. **Faecal Sludge Handling:** The scavengers muddled in faecal sludge by emptying, collecting and transporting human waste from septic tanks. The work is carried out on demand. The frequency of de-sludging ranges from six months to 10 years.

India does not even have categorical licit provisions cognate to the management of faecal sludge, additionally called septage in municipal parlance, albeit a number of laws cover sanitation accommodations and environmental regulations.[6]

iv. **Railway Cleaners:** These employees cleans the human excreta i.e. remains of a train that has ended its journey, leftover food, packets and paper boxesfrom the track as well as cleaning of the railway toilets. All these activities are carried out several times a day. These workers are employed by private contractors to whom the India Railways has outsourced. Most of the time when the water doesn't get the job done or the drains get clogged, the cleaners have to scoop up the excreta with ply boards using their bare hands without any precautions.[7]

v. Treatment Plant Workers: Treatment plant workers maintain and operate sewage and faecal sludge treatment plants on a quotidian footing. Workers are mostly in urban areas spread across India – working in the 527 STPs/FSTPs.[8]

vi. Community and Public Toilet Cleaners: These workers are engaged in maintaining the public toilets on daily basis. The workers belong to the rural and urban areas of slums and public convenience shelters. The task of these cleaners (halalkhors) is still the same as of colonial era.[9]

Statistics on Manual Scavengers in India: According to the findings of the socio-economic and caste census, 2011, the Ministry of Rural Development (Government of India) has revealed that that a paramount number of manual scavengers were analyzed in the state of Maharashtra followed by Madhya Pradesh at second position. The other states in the line of higher number are Jammu and Kashmir, Karnataka, Tripura, Punjab, Uttar Pradesh, Daman and Diu, Bihar. The census has as well acknowledged that Tamil Nadu, Kerela, Goa, Andhra Pradesh, Telengana, Gujrat, Assam and Manipur have no manual scavengers. These statistics are based on the number of households in the states. This survey communicates that India has 18.06 lakh manual scavengers in the country.[10]

The press Information Bureau, Government of India, Ministry of Social Justice and Empowerment has verbally expressed that a Task Force was constituted for carrying out a National Survey of manual scavengers in 2018 in 170 identified districts of 18 states. The national Survey concluded in 163 of the 170 identified districts. A total of 50,644 persons registered themselves in the survey camps. It was claimed that 20,596 persons have been accepted after identification with subsequent verification as manual scavengers. Data of the identified manual scavengers is being digitized in National Safaikaramcharis Finance and Development Corporation. Besides that the data of remaining 11,757 manual scavengers were digitized upto October 2018. Onetime cash assistance has been relinquished to 8438 identified manual scavengers.[11]

Schemes Available for Manual Scavengers: The National SafaiKaramcharis Finance and Development Corporation (A Government of India undertaking the Ministry of Social Justice and Empowerment) introduced Self Employment Scheme for Rehabilitation of Manual Scavengers (SRMS) and their dependents in alternative occupations by 2009. According to the updated number announced by States/UTs, 1.18 lakh manual scavengers and their dependents in 18 States/UTs were determined. One from each family of the identified manual scavenger is eligible for receiving cash assistance of Rs. 40000 immediately after their identification. The beneficiary is sanctioned to withdraw an amount of Rs. 7000 maximum in monthly instalments.

The quantum of loan upto a maximum cost of Rs. 10 lacs is permissible under this scheme and a sum of Rs. 15 lacs in case of sanitation related projects such as vaccum loader, suction machine with vehicle, garbage disposal vehicle etc. which are immensely compatible for target group with high success rate and income. The moratorium period is of two years. The repayment mode is of five years including the period of moratorium for the projects upto five years.[12]

Beneficiaries can as well avail the facility of subsequent loan from banks, if needed without capital and interest subsidy.

The training is administered to the beneficiaries for gaining new skills and entrepreneurship capabilities. The training is being provided by govt. agencies/Institutions along with the reputed specialized training agencies. The training is given as per their level of education and aptitude.[12]

Remedies: The solution, it seems, is a public-private partnership. Collaboration would work best because it would ravage the mafia of private cleaners, making them accountable

It was also found that some scavengers have endeavoured to challenge their social and economic status by transmuting their jobs. But determinately, they have to return to their pristine profession because of a social boycott and the lack of foothold from both private and governmental agencies. The law and order machinery has additionally proved inefficient.

Eradication of manual scavenging needs to be worked out on war footing. A mission for total eradication of manual scavenging and rehabilitation of manual scavengers needs to be set up and implemented by the government.

The right technology is considered as one of the solution to eradicate this scourge. In spite of that, the social and gender issues should be abolished by educating pupil about this ill.

The sewage handlers come across with multiple health issues such as respiratory and skin diseases, anaemia, jaundice, carbon monoxide poisoning and sometimes leads to death. The health issues should be taken care by the agency and safety equipments to be provided before handling. Vaccination against hepatitis A, E-Coli, Rotovirus, Norovirus must be administered to these workers to avoid deaths at young age of their life.

The construction of toilets under Swachh Bharat Mission on a large-scale was built under single pit toilets but the cleaning of these excreta is carried out by manual scavengers. Therefore, a technology based structure should be introduced to dispose of waste and reduce the figures of manual scavengers.

Knowledge of Primary School Teachers Regarding Learning Disorders among Children at Schools of Satara District

Shivaji H. Pawar[1], Durgawale P.M.[2], Kakade S.V.[3]

[1]Clinical Instructor Krishna Institute of Nursing Sciences, Karad, [2]Professor & Head, Department of Community Medicine, Krishna Institute of Medical Sciences, Karad, [3]Associate Professor, Department of Community Medicine, Krishna Institute of Medical, Sciences, Karad

Abstract

Introduction: "Learning disorder is a general term that refers to a group of disorders manifested by difficulty in the acquisition and use of listening, speaking, reading, writing, & mathematical abilities. These disorders are inherent to the person supposed to be because of central nervous system malfunction.

Most students who undergo from learning disorders will not be recognized before standard 3-4 of primary school since their teachers don't have adequate knowledge about learning disorder. Teachers are the child's first contact person in school and the perfect person to find out a learning difficulty. Unluckily, most either pay no attention to the problem or blame it on the child's personality.[2]

Methodology: The study was designed in the form of non-experimental descriptive type. Study comprised of 316 primary school teachers from conveniently selected schools at Satara district.

Result: Majority of the teachers was belongs to 41 to 58 age groups 203(64.24%), 199(62.97%) were females, 277(87.65) were Hindu, 301(95.25%) teachers was married, 214(67.72%) teachers were having educational qualification of D.Ed., 243(78.89%) teachers was having above 11 years of experience. 166(52.26%) of the subject had poor knowledge,146(46.20%) teachers had average knowledge & 04(1.26%) had good knowledge.

Conclusion: Present study showed the need for intensive training of primary school teachers on learning disorders.

Keywords: *Knowledge, Learning Disorders, Primary School Teachers, Primary School, children.*

Introduction

"Learning disorder is a general term that refers to a group of disorders manifested by difficulty in the acquisition and use of listening, speaking, reading, writing, &mathematical abilities. These disorders are inherent to the person supposed to be because of central nervous system malfunction[1]. The 4th version of Diagnostic and Statistical Manual (DSM-IV) refers these disabilities as learning disorders rather than academic skills disorders and mentioned under the section called "disorders first diagnosed in infancy, childhood or adolescence.[2]

Most students who undergo from learning disorders will not berecognized before standard 3-4 of primary school since their teachers don't have adequate knowledge about learning disorder [3].

Students who are suffering from learning disorders are very prone to get common social and emotional disorders and will have low motivation and incomplete learning from their lessons. Some time they are showing difficult behaviors also. It is supposed that, this problem is always probable to appear in students and if teachers

Corresponding Author:
Shivaji H.Pawar
Clinical Instructor Krishna Institute of Nursing Sciences, Karad

can't identify this problem, students are labeled: lazy, irresponsible, with no interest and motivation.[4]

Students suffering from learning disorders may become so disturbed with their academic performance in school they may feel like failure want to leave school or may develop behavior problems so learning disorders should be identified as early as possible during school years.

Teachers are the child's first contact person in school and the perfect person to find out a learning difficulty. Unluckily, most either pay no attention to the problem or blame it on the child's personality. Today our goal is all children's must learn in the school irrespective of their psychological and intellectual characteristics.

Due to difference in cognitive abilities of students, teaching should be based on teacher's knowledge means teachers should think about these learning disorders in students while teaching in class & finally, the best teaching- learning method should be selected.[5]

Lack of awareness about learning disorders is one of the major reasons for not identifying great talent in school children. Therefore, there is a need to create consciousness about the problem among teachers. Teachers should be given proper training to identify children with learning disorders so, easily they can find out these problems at school level.[6]

Methodology: The study was designed in the form of one group pre-test, post-test, design. With the objective of assessing the knowledge of primary school teachers regarding learning disorders among children. The study was conducted in selected schools of 11 talukas of satara district. The sample for the present study comprised of 316 primary school teachers from conveniently selected schools. For data collection, tool was used which consisted of two sections: Section I: Demographic data of primary school teachers. Section II Structured Knowledge Questionnaire related to learning disorders consist 30 questions. One mark was given to each correct answer & zero mark for incorrect answer.

A prior written permission was obtained from district education officer. After self-introduction, nature and objectives of study was explained to the participants to obtain maximum cooperation. Anonymity and confidentiality were assured to them. Written Consent was obtained from the participants and they were made comfortable.

Result

The data collected were analyzed according to the plan for data analysis which includes both descriptive and inferential statistics. Objective of the study was to assess the knowledge of primary school teachers regarding learning disorders among children.

Table 1: Description of demographic characteristics of teachers(N =316)

Demographic Variable	Frequency	Percentage
Age in Years		
20-40	114	36.07
41-58	202	63.92
Sex		
Male	113	35.75
Female	203	64.24
Religion		
Hindu	278	87.97
Muslim	38	12.02
Marital status		
Married	301	95.25
Un married	15	4.74
Educational status:		
D.Ed	215	68.03
B.Ed	97	30.69
M.Ed	4	1.26
Year of experience		
1 to 10yrs	73	23.10
Above 11	243	78.69
Tranning program attended related to learning disorders		
Yes	51	16.13
No	265	83.86
Previous Knowledge		
Yes	30	9.49
No	286	90.50
Residence area		
Urban	120	37.97
Rural	196	62.02

Distribution of demographic variable showed that majority of the teachers was belongs to 41 to 58 age groups 203(64.24%),199(62.97%) were females, 277(87.65) were Hindu, 301(95.25%) teachers was married, 214(67.72%) teachers were having educational qualification of D.Ed., 243(78.89%) teachers was having above 11 years of experience, 265(83.86%) teachers

were not attended any kind of training program related to learning disorders, 283 (89.55) teachers were not having previous knowledge related to learning disorders, 196(62.02%) teachers were residing in urban area.

Table 2: Assessment of pre test Knowledge of teachers regarding learning disorders. N=316

Sr.No.	Knowledge score	Pretest	
		Number	Percent
1.	Poor (0-10)	166	52.53
2.	Average (11-20)	146	46.20
3.	Good (21-30)	04	1.26

In above mentioned table represents total knowledge score of subject regarding knowledge of learning disorders in pre test 166(52.26%) of the subject had poor knowledge, 146(46.20%) teachers had average knowledge & 04(1.26%) had good knowledge.

Discussion

In present study 166(52.26%) of the subject had poor knowledge, 146(46.20%) teachers had average knowledge & 04(1.26%) had good knowledge. This study supported by study done by Karande S, Mehta V, S Ghimire 9 , Dr. Neena Sawhneya 10 , Syed Arifa, Nsreen A 11 & Poorna Shukla 12, Kulkarni M[7.] Other study done by Basim Ali C. T & *et.*[8]

In general, primary school teachers have very little knowledge about learning disorders. This may be due to the lack of teacher training programs related to learning disorders. Also, teachers are not interested for any further training that focuses on how to teach the children with learning disorders. The educational authorities should provide ongoing in-service training for teachers about teaching learners with special needs at school levels.[9]

Recommendation:

(a) Similar study can be conducted in a large group to generalize the study findings.

(b) Comparative study can be done between urban and rural areas.

(c) A study can be conducted in term of knowledge, attitude and practice of alternative learning method among school teachers of children with learning disabilities.

Conclusion

Present study showed the need for training of primary school teachers on Learning disorders it will help them to easily identify the student at early stage so,further Complications can be prevented.

Limitations: Due to time constraints, convenient sampling was adopted for data collection; and data are limited to Satara district, hence the findings cannot be generalized.

Acknowledgements: Authors would like to thank the teachers of the school involved in the study for their cooperation and support.

Conflict of Interest: None.

Source of Funding: None.

Ethical Clearance: Institutional ethical clearance was obtained prior to study

Efficacy of Cognitive Behaviour Therapy and SSRI in Treatment of Conversion Disorder

Shubhangni Jain[1], Nudrat Jahan[2], Dinesh Kataria[3]

[1]Research Scholar, Department of Clinical Psychology, SGT University, Gurugram, [2]Assistant Professor, [3]Professor, Department of Psychiatry, Lady Harding Medical College, New Delhi.

Abstract

Context: Current understanding of the phenomenon of conversion disorder implicates some role of the unconscious in the pathophysiology of this condition. It is therefore less likely to respond to treatment when the manifestations of the conversion are confronted directly as a unitary method of therapy. Many patients who experience a conversion disorder are unable to understand this inner conflict, which is perhaps occurring on an unconscious level. They may achieve resolution of the conflict, as well as their physical symptoms, once they are gently made aware of this connection. Once the patient is aware of this, the psychological currency of the symptom loses value, and the symptom may be allowed to improve. Efficacy of Cognitive Behaviour Therapy and SSRI in treatment of Conversion Disorder reveals that CBT combined with SSRI would be more efficacious to reduce the symptoms severity than SSRI alone for conversion disorder patients.

Keywords: *Conversion Disorder, Cognitive Behaviour Therapy, Selective Serotonin Reuptake Inhibitor, Psychosocial Dysfunction.*

Introduction

In Conversion disorder patients come with their symptoms such as numbness, paralysis, or seizures, where no medically evident explanations found[1]. Mostly these complications rise in reaction to problems which patient faces in their daily life. Both, ICD-10 as well as DSM-V (APA, 2013) considered that conversion is a psychiatric disorder[2][3]. According to ICD-10 "conversion" is usually useful to some complaints; it suggests that the unlikely distress, produced by the complications and clashes which the patient is not able to resolve, gets changed into the signs. According to ICD-10, dissociative (or conversion) disorders is an incomplete or comprehensive loss of the usual actions associated with the recalls of the past, consciousness of self, awareness of surroundings and controlled body activities. Usually, an important amount of controlled awareness on the recalls and senses can be chose for instant care and for the actions that has to be approved.

However, these complaints previously classified as "conversion hysteria", now, the term "hysteria" is seems to be avoided.

Diagnostic Criteria: Conversion symptoms, also described as pseudo-neurological symptoms, are abnormalities or deficits in voluntary motor or sensory function that are medically unexplained. Some of the most common pseudo-neurological symptoms are pseudo-seizures, pseudo-paralysis and psychogenic movement disorders. According to DSM-IV, conversion disorder is characterized by the presence of one or more pseudo-neurological symptoms that are distressing and/or disruptive and are associated with psychological stressor(s) or conflict(s). Also, the symptoms cannot be intentionally produced or feigned[8]. The onset and course of conversion disorder often take the form of an acute episode. Symptoms may remit within a few weeks of an initial episode and they may recur in the

Corresponding Author:
Shubhangni Jain
Research Scholar, Department of Clinical Psychology, SGT University, Gurugram

future. Some research indicates that a brief duration of symptoms prior to treatment is associated a better prognosis [9][10][11].

The aetiology of conversion disorder was always controversial. According to some researchers sexual categories, mental distress, family clashes, economical status, home stress, social surroundings are some of the important factors which plays an important role[12]. It was proved that the onset of this disorder in mid to late age range is due to the parental dysfunction and family psychopathology in younger age. The prevalence is highest in rural areas, uneducated and in the lesser socioeconomic classes

Treatment of Conversion Disorder: Although treating conversion disorder by psychoanalytic and behavioural method were emphasized in recent years with growing interest in using Cognitive Behavioural Therapy (CBT) in clinics worldwide, the efficacy of the method is found considerable. CBT has been declared as a successful treatment for the conditions grouped under the somatoform disorders, currently known as Somatic Symptom and Related Disorders. Randomized controlled clinical trials found that conversion disorder can be successfully treated with CBT which included the modification of catastrophic cognitions and inappropriate behaviours. A study conducted showed CBT to be effective in treating conversion disorder[13][14].

Studies report improvement with selective serotonin reuptake inhibitors (SSRIs), beta-blockers, analgesics, and benzodiazepines[15]. An open trial of antidepressants in patients with psychogenic movement disorder and recent or current depression also showed that class of medications to be effective in reducing conversion symptoms[16]. An ongoing randomized controlled study is evaluating the effectiveness of sertraline for patients with nonepileptic seizures and comorbid depression and anxiety[17].

Demographic and Clinical Characteristics: The demographic characteristics of conversion disorder have not been investigated extensively. Nevertheless, there is some evidence that conversion disorder is more common among women[6][18], non-whites and individuals from lower socioeconomic classes[19]. Co-morbid psychiatric distress in patients with pseudo-neurological symptoms is high; it has been estimated that 30% to 90% of patients seeking treatment for pseudo-neurological symptoms also meet criteria for at least one other psychiatric disorder, typically somatoform disorders, affective disorders, anxiety disorders, or personality disorders[20][10]. A co-morbid personality disorder diagnosis has been found to indicate poor prognosis of conversion disorder[21].

Psychosocial Dysfunction: Dysfunctions in conversion disorder patients refer to lowering of functioning irrespective of whether an adjustment is made with the circumstances or not, whether it is of permanent nature or not and whether it can be corrected in the treatment or not. Hence, after remission of the disease, the different level of dysfunction is a psychological concept, which is concerned with the present functioning of the individual at a particular point of time in comparison to particular reference point in the person's life, without changing one with adjustment, without categorizing it as permanent or temporary and without creating a personal view on curability. All the five areas of dysfunctions (i.e., social, personal, familial, vocational, and cognitive) are intrinsically correlated with each other to such an extent that a particular area cannot be advocated by excluding another area, but the cognitive dysfunction is the predominant area on which other functioning are mostly dependent[22][23].

Hypothesis:

1) There would be a significant difference on symptoms severity at Pre-post treatment level after SSRI in conversion disorder patients.
2) There would be a significant difference on symptoms severity at Pre-post level after CBT combined with SSRI in conversion disorder patients.
3) CBT combined with SSRI would be more efficacious than SSRI alone to reduce the symptoms severity of conversion disorder patients.
4) SSRI alone would be more efficacious than CBT combined with SSRIto reduce the symptoms severity of conversion disorder patients.

Methodology: To achieve the objectives of the study an appropriate design and methodology is an important step in any research. A research design encompasses the methodology and procedures employed to conduct scientific research.

Aim: of this study was to study the Efficacy of Cognitive Behaviour Therapy and SSRI in treatment of conversion disorder. Description of methodology is as following:

Design: Quasi- experimental research design.

Sampling: sample consisted of conversion diagnosed patients. A sample of 30 females (20-40 years) patients with conversion disorder selected from Lady Harding medical college hospital, Delhi. Patients suffering with any co-morbid disorder and with any serious physical illness were excluded from the study.

Measures:

Dysfunction Analysis Questionnaire (DAQ): (Pershad et al., 1985): The DAQ (Pershad et al., 1985) developed at PGIMER, Chandigarh, primarily for the measurement of the dysfunction in various areas of persons with psychiatric illnesses. This scale has 50 items grouped under 5 areas, viz., social, vocational, personal, family and cognitive. Each area which the scale assesses has 10 items and each item has 5 alternative answers indicating the same, better or worse level of functioning compared with the premorbid level of functioning. Rating of 1 indicates better than premorbid level of functioning and rating of 4 indicates rapid deterioration of functioning. Some items may not be applicable to a particular patient. This scale is used to assess various psychosocial dysfunctions of an individual. This scale has highly satisfied test-retest and split half reliabilities that ranged from 0.77 to 0.97.

Procedure: To conduct the present study, ethical considerations were taken care of. Official permission was sought from the administration of the selected departments for the data collection. Subject information sheet was given to the patient in his language to explain the research. The patient consent form was given to the participants to take permission for using data for research. The questionnaires were given to the participants to be filled by themselves. The duration of administration was of 10-15 minutes. After this, SSRI alone and cognitive behaviour therapy combined with SSRI treatment was planned for the patients by the trained professional. The 12-sessions of CBT sessions were considered to help patients disturb behavioural, physiological, and emotional reactions that happened at the time of onset of illness along with sertraline 50 mg. Patients were re-examined withDysfunction Analysis Questionnaire to examine the result and effectiveness of the treatment.

Results Analysis

The study was designed to examine the DAQ scores in the individual patient in all five domains of DAQ. The study subjects were divided into two groups 15 patients in SSRI group and 15 patients in CBT combined with SSRI Thus, in all 30 patients were recruited for this study.

Analysis of Treatment Effectiveness: Mean of Pre-Post treatment assessment of patient dysfunction level were compared by using *t.* test to see the difference between symptoms severities of conversion disorder after SSRI. Obtained result is mentioned below.

Table 1: Dysfunction level (Pre-post) of Conversion disorder after SSRI

Variable	Pre-Treatment Mean (S.D.)	Post-Treatment Mean (S.D.)	t. (d.f.=14)
Dysfunctioning level	66.6 (5.44)	51.2 (5.54)	14.3**

Note: **p<.01

The above results shows the pre-treatment mean score (M=66.6) and standard deviation (S.D. =5.44) of the dysfunctional level. As well as, the post-treatment mean score (M=51.2) and standard deviation (S.D. =5.54). Comparison between both the mean shows significant difference on dysfunction (*t.* =14.3, p<.01) which means that the symptoms severities of pre-post level of conversion disorder after SSRI is reduced.

Mean of Pre-Post treatment assessment of patient dysfunction level were compared by using *t.* test to see the difference between symptoms severities of conversion disorder after CBT combined with SSRI. Obtained result is mentioned below.

Table 2: Symptom severity (Pre-post) of Conversion disorder after CBT combined with SSRI

Variable	Pre-Treatment Mean(S.D.)	Post-Treatment Mean (S.D.)	t. (d.f.=14)
Dysfunctioning level	72.1 (7.3)	44.1 (7.89)	15.31**

Note: **p<.01

The above results shows the pre-treatment score of (M=72.1) and standard deviation (S.D=7.3) As well as, the post-treatment score (M=44.1) and standard deviation (S.D=7.89) of CBT combined with SSRI. Comparison between both the mean shows significant difference on dysfunction level (*t.* =15.31, *p*<0.1). The symptoms severities of pre-post level of conversion

disorder after SSRI are reduced.

To know whether all treatment combinations have produces similar reduction in symptom severity of conversion disorder, post treatment mean difference between different treatments combinations are calculated by using paired sample t-test. Obtained result is given in table no. 3

Table 3: Post treatment mean comparison between different treatment combinations

SSRI M (SD)	SSRI and CBT M (SD)	t.	Significance
51.26	44.13	2.70	.01
(5.54)	7.89		

Note **p<.01

As mentioned in table no. 3, paired sample t-test revealed that there is significant difference between the post treatment mean scores of conversion disorder patients treated by SSRI only, patients treated with combination of SSRI and Cognitive behaviour therapy (t.= 2.70, P<.01).

Above results shows that SSRI when combine with CBT found to be more effective than SSRI alone because when dysfunction level decreases the condition and symptoms of patient improves.

Discussion

Diagnosis and treatment of conversion disorder was controversial throughout the history of psychiatry. Even the form of its diagnosis sited on the basis of psychogenic model. In recent times, many researchers focused to determine the doubt related to aetiology and causal factors.

The most important cause for the diagnosis of disorder is a distortion or lack in neurological functioning without any organic injury. Conversion disorder is showed with pseudo-neurological symptoms in both classifications that must be well-known from true medical findings. In the past, hysteria was supposed as female disease. According to Early Egyptian physicians it was recognised as the symptoms of hysteria specifically related to women.

Psychosocial causes related to conversion disorders are reflected as conflicts in interpersonal relationship and social communication. As a result, it appear in avoidance from obligation, expression of emotion, symbolize a feeling or belief. Females were well thought-out as lesser then male and had no right to express their feeling as well as emotions willingly; so they were more likely to to develop hysterical symptoms. In Sub-continent, these let go thoughts are still prevailing. Personality features along with social, cultural and ethnic background may contribute in development of conversion disorder.

There is inadequate data on the treatment of conversion disorder or of pain disorder to make any conclusion. An evaluation of the empirical research on CBT for somatoform disorders suggests that in some respects it mirrors the literature on evaluating the efficacy of psychotherapy literature with various mental disorders. CBT has been shown to be superior to various control conditions, especially waiting lists or standard medical treatment. Effect sizes are respectable, relative to other medical or quasi-medical interventions.

According to some researches Selective serotonin reuptake inhibitors (SSRIs) may be helpful for somatization or dissociation. A pilot randomized controlled trial of sertraline in 38 patients with PNES revealed a 59.3% seizure reduction in the combined CBT and drug arm compared to the conventional treatment group.Neuroleptics and propranolol may be employed for severe dissociative disorders.

In this study, it was found that CBT combined with SSRI was proved to be more effective to improve the dysfunctions of conversion disorder patients whereas SSRI alone was not found to be that effective.

Conclusion

Most patients with functional Conversion Disorder will require an integrated multidisciplinary approach to treatment. The diagnosing clinician should communicate with the treating physical therapist and/or mental health clinician, and everyone should agree on the treatment plan. Other established health care providers should be informed of the functional Conversion Disorder diagnosis, as patients may present with other physical symptoms of uncertain origin, and there should be agreement on the message among all providers and minimization of unnecessary treatments. Functional Conversion Disorder are truly at the intersection of Conversion and psychiatry: patients present with neurological symptoms that are a manifestation of a neuropsychiatric disorder. Dualistic thinking is not helpful for these patients, as neurological symptoms and emotional functioning need to be viewed as influencing

each other. Integration of care is needed for this patient group.

Hence, according to this study CBT when combined with SSRI proved to be effective for conversion disorder patients

Conflict of Interest: Nil

Source of Funding: Study does not require any funding as this is part of Ph.D. project of SGT, University.

Ethical Clearance: Taken from SGT, University Ethical Committee.

In Vitro Study of Constitutive and Inducible Clindamycin Resistance in Staphylococcus Aureus with Reference to Methicillin Resistant Staphylococcus Aureus: Experience From Tertiary Care Hospital in Punjab

Sneh Lata[1], Rosy Bala[2], Neerja Jindal[3], Nitin Gupta[4]

[1]Senior Resident, Department of Microbiology, GGS Medical College, Faridkot (Punjab), [2]Assistant Professor, Department of Microbiology, Maharishi Markandeshwar Institute of Medical Sciences and Research, Mullana, Maharishi Markandeshwar (Deemed to be University), [3]Professor & Head, [4]Assistant Professor, Department of General Medicine,

Abstract

Backround: Serious infections due to methicillin resistant *Staphylococcus aureus* (MRSA) have become a major clinical challenge. Globally Macrolide-lincosamide streptogramin B family of antibiotics are commonly used to treat such infections as an alternative to vancomycin. The study was to conducted to find out the presence of inducible clindamycin resistance among *Staphylococcus aureus* and their association with methicillin resistance.

Method: The study conducted over one year (Jan 2016 - Dec 2016) in microbiology department of Guru Gobind Singh Medical College, Faridkot . Two hundred fifteen *S.aureus* isolates were included in the study. Methicillin resistance was detected by cefoxitin (30µg) disc diffusion method and inducible clindamycin resistance by erythromycin and clindamycin disc approximation test (D-Test).

Results: Of the 215 clinical isolates of *S.aureus*, 140 (65.11%) were MRSA. Erythromycin and clindamycin resistance was seen in 79.06%(170/215) and 49.30% (106/215) respectively. Resistance to erythromycin and clindamycin were higher in MRSA than MSSA (erythromycin resistance:100%v s 22.5% and Clindamycin resistance:70.1% vs 10.6%). Both iMLSB and cMLSBphenotypes are predominant in MRSA.

Conclusion: Detection of MRSA in our study shows the need to improve health care practices and to formulate new infection control policies to control MRSA infections. Inducible and constitutive resistance is comparatively higher in our study in MRSA .So It is necessary to perform D-test for detection of inducible clindamycin resistance among MRSA in routine antibiotic sensitivity testing so that therapeutic failures can be avoided.

Keywords: *Staphylococcus aureus, MRSA, Inducible Clindamycin resistance, D-test*

Introduction

Antimicrobial resistance in *Staphylococcus aureus* has become an ever-increasing problem. Methicillin resistant *S. aureus* (MRSA) which are often multiply resistant to other classes of antibiotics in addition to β–lactams, with increasingly high resistance to macrolides (erythromycin, clarithomycin) and lincosamides (clindamycin,lincomycin) leaving very

few therapeutic options[1].Newer antibiotics like vancomycin, linezolid and quinupristin-delfopristin have been advocated in treatment of such resistant isolates. Recent reports of resistance to these antibiotics raise real concerns about difficulties in therapy. The macrolide-lincosamide-streptogramin B (MLSB) family of antibiotics is commonly used in the treatment of staphylococcal infections. However, widespread use of MLSb antibiotics has led to an increase in number of staphylococcal strains acquiring resistance to MLS_B antibiotics.[2] Clindamycin, a lincosamide, represents an attractive option for treatment erythromycin resistant *Staphylococcus aureus* both in methicillin-resistant and susceptible staphylococcal infections, especially skin and soft tissue infections, for various reasons: available in both oral and intravenous formulations; excellent tissue penetration; less costly; inhibits productions of certain toxins and virulence factors in staphylococci[3]. However, possible presence of inducible clindamycin resistance among staphylococcal isolates is a major concern in use of clindamycin.[4]

Macrolide resistance arises either by an efflux mechanism or by target modification, the later resulting into resistance not only to macrolide but also to lincosamides and group B streptogramins[5]. An erm gene encodes methylation of the 23S rRNA- binding site that is shared by these drugs. Phenotypically, such resistance can be constitutive (MLSBc phenotype) or inducible (MLSBi phenotype)[6]. It is also possible for mutations to occur spontaneously that will transform MLSBi strains to MLSBc phenotype without the presence of a macrolide inducer, a concern being that this change might occur in the midst of therapy[7].

S. aureus isolates with constitutive resistance show resistance to erythromycin and clindamycin on in-vitro testing, whereas isolates with inducible resistance show resistance to erythromycin but appear sensitive to clindamycin on disc diffusion testing. Inducible clindamycin resistance in staphylococci can be detected by D test[8]. For erythromycin-resistant isolates, D test can help to determine whether clindamycin could be used as a therapeutic option. This study was undertaken to determine prevalence of inducible and constitutive clindamycin resistance among clinical *S. aureus* isolates and to study their association with MRSA.

Material and Method

This prospective study conducted over one year (January 2016 to December, 2016). A total of 215 S*taphylococcus aureus* (Catalase positive, coagulase positive)[9] were isolated from various clinical specimens like pus, blood, urine and catheter tips and drains. Methicillin resistance was detected by cefoxitin disc (30µg). The isolates which yielded zone diameter of <22mm around cefoxitin reported as MRSA.[8]

The erythromycin resistant strains were subjected to D –Test as per CLSI guidelines. Briefly, erythromycin (15µg) disc was placed at a distance of 15mm (edge to edge) from clindamycin (2µg) disc on a Mueller Hinton agar plate previously inoculated with 0.5 McFarland bacterial suspension. Following overnight incubation at 37^0C, flattening of zone (D-shaped) around clindamycin in the area between the two discs, indicated inducible clindamycin resistance.[10]

Three different phenotypes were appreciated after testing and interpreted as follows:

1. **MS Phenotype:** Staphylococcal isolates exhibiting resistance to erythromycin (zone size ≤13mm) while sensitive to clindamycin (zone size ≥21mm) and giving circular zone of inhibition around clindamycin.
2. **Inducible MLS_B Phenotype:** Staphylococcal isolates showing resistance to erythromycin (zone size ≤13mm) while being sensitive to clindamycin (zone size ≥21mm) and giving D shaped zone of inhibition around clindamycin with flattening towards erythromycin disc were labeled as having this phenotype .
3. **Constitutive MLSB Phenotype:** This phenotype was labeled for those Staphylococcal isolates which showed resistance to both erythromycin (zone size ≤13mm) and clindamycin (zone size ≤14mm) with circular shape of zone of inhibition if any around clindamycin.

Results

Of 215 *S.aureus* isolates 65.11% (140/215) were MRSA and 34.89% (75/215) were MSSA. Erythromycin and clindamycin resistance was seen in 79.06% (170/215) and 49.30% (106/215) isolates respectively. In this study erythromycin resistance (100%vs22.5%) and clindamycin resistance (70%vs10.6%) both were significantly higher in MRSA than among MSSA (p value=0.000). Similarly, constitutive as well inducible clindamycin resistance phenotypes were significantly

higher in MRSA (53% and 16.42%) than among MSSA (7.5% and 2.6%). In this study prevalence of iMLSB among *S.aureus* was found to be 13.48%.

Table1: Clindamycin susceptibility patterns among MRSA and MSSA

Phenotype	MRSA N=140	MSSA N=75
E-S, Cl-S	Nil	45(60%)
E-R, CL-S (iMLS$_B$)	23(16.42%)	6(8%)
E-R, Cl-R (cMLS$_B$)	75(53%)	2(2.6%)
E-R, Cl-S (MS Phenotype)	42(30.17%)	22(29.33%)

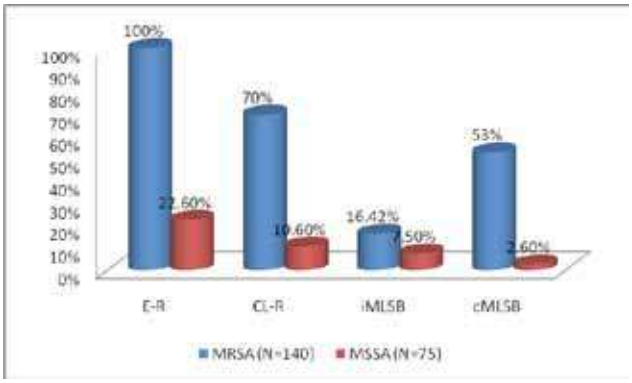

Fig 1: Comparison of erythromycin, clindamycin, iMLSBand cMLSB resistance among MRSA and MSSA

Table 2: Clindamycin susceptibility pattern among erythromycin resistant isolates: N=170

	MRSA	MSSA	TOTAL
iMLSB	23 (13.52%)	6 (3.5%)	29 (17.02%)
cMLSB	75 (44.11%)	2 (1.1%)	77 (45.21%)
MS phenotype	42 (24.70%)	22 (12.94%)	64 (37.64%)

Discussion

Improper infection prevention practices in hospital, indiscriminate use of antibiotics and hospitalization in ICUs has contributed to emergence of MRSA. Macrolide-Lincosamide-sterptograminB family of antibiotic are commonly used to treat MRSA infections. In the present study constitutive resistance to clindamycin was observed in 53% which is almost similar to the findings of Adhikari *et al*[11]but much higher than the studies of Baiu*et al*[12], Koppada*et al*[2]and Sah*et al*[1]. The reason for this could be selective pressure because of wide spread use of erythromycin and clindamycin for the treatment of even minor staphylococcal infections. Molecular studies have shown that some SCCmec elements on MRSA carry transposon Tn554 which contains the ermA gene mediating MLS resistance resulting in higher rate of resistance to MLS antimicrobial agents[13].

Inducible clindamycin resistance was found to be 16.42% in our study which is similar to that reported by Ansari *et al.*[11] *and Govindan et al*[14]. However higher iMLSB resistance of 37.5% from another study from India[15] and 91% from Japan[16] has also been reported.

In the present study, 30.17% of MRSA among the erythromycin resistant isolates were MS phenotype (E-R, Clin-S). This means that clindamycin could be used as a treatment option only for 30.17% of MRSA which are erythromycin resistant. So, there are only 30.17% chances of clinical efficacy of clindamycin while treating erythromycin resistant MRSA infections as an alternative to vancomycin. These findings further emphasize the need of performing D- test in routine to avoid clinical failure while using clindamycin as an alternative to anti-MRSA antibiotics like vancomycin and linezolid. Regular surveillance of hospital associated infections, monitoring of antibiotic sensitivity pattern of MRSA and formulation of definite antibiotic policies may be helpful in reducing the incidence of MRSA infections. This will guide clinicians to choose appropriate antibiotics to treat such infections without causing treatment failures.

A Study of Gender Based Knowledge Level on Risk and Cause of Obesity among Management Students of Urban, Rural, Semi Urban Areas of East Midnapore District

Sourav Gangopadhyay[1], Jayeeta Majumder[2], Susmi Biswas[3]

[1]Assistant Professor, Management Department, Haldia Institute of Management, Haldia, West Bengal, India, [2]Assistant Professor, [3]Assistant Professor

Abstract

Context: Obesity is becoming a huge burden for our society, it causes premature death and impairment of health some times for life long as it calls many diseases. The obesity is preventable. Awareness on obesity is a key of success of controlling that, but unfortunately our society is not showing aware of it. In this study we are trying to find out the knowledge level on risk and causes of obesity among different genders by using independent samples t test and to see the difference of knowledge level (both causes and risk of obesity) among rural, semi urban and urban, we have done ANOVA. We have used SPSS, 17th version. Total 138 students from those areas are included in the study. The study shows overall knowledge score is poor and there is gender inequality existing in semi urban and rural areas in respect of knowledge. Also the study showed knowledge level on obesity is statistically different among urban, rural and semi urban areas.

Keyword: *Obesity, urban, rural, semi urban, society, awareness, gender inequality.*

Introduction

Obesity is a metabolic disorders and it causes diseases like cardio vascular disease, diabetes, some cancer and many more (Schmidt, 2011)[14] and it is now a major cause of disability and pre mature death. Number of obesity increases about 50% during 1980 to 2013. The western life styles are assimilated by developing countries; rapid urbanization, fast and sedentary lifestyle, consumption of junk foods, and many unhealthy practice are the cause obesity (Gothankar, 2011)[6]. Health promotion is generally concentrated on the health education, and health knowledge (Chaponniere, 2013)[3]. Study shows the adult people who are lacking the formal education are more likely to have poor health (Lui C K, 2014)[9]. The Indian women are more involved in the household work which in turn to be sedentary life (Saikia, 2009)[13]. Not only urban areas but also rural women are slowly affected by unhealthy life style, the situation is worse as rural people are having poor educational background (Deying, 2011)[5]. Though few researchers showed that the urban girls are more prone to be obese than that of rural girls as the life style of urban and rural girl differs significantly (Hallal, 2006)[7], but now the rural life is slowly getting affected by modern life. The rural people is having poor health knowledge (Qiuzhuang, 2007)[12]. A study shows the rural women have higher total cholesterol level than rural male. Life style changed frequently in case of young population which is in most of the cases unhealthy. It is also seen that decrease physical activities, more time spending in television, engage in the social networking site are one of the major causes of obesity (Vohra, 2011)[17]. India is having gender discrimination in terms of education, health and even nutrition; in this regard education can play a vital role in it (Chaudhary, 1995)[4]. Few studies have made to

Mob No:9830601451.
e-mail:drsouravgangopadhyay@gmail.com,

assess the impact of obesity in the rural areas. Though the prevalence rate of obesity is more in case of urban areas than that of rural areas (Brahmbhatt, 2012)[2] but obesity is persistent in the both the areas. Study in the rural areas is becoming essential, as the rural areas are slowly influenced by modern life style (Shetty, 2002)[15] also poor level of awareness is existing (Ade, 2014)[1]. Desired level of awareness of obesity is still confined to those populations who are adhering with the health care field (Nyaruhucha, 2003)[11]. As there are few number of researches have done to show the difference of knowledge level on obesity among students of urban, rural and semi urban areas so it is necessary to do such research, also as many study showed there is existing level of gender inequality among students so it is became necessary to included in the study. So the objective of the study is

1. To see whether there is existence of any differences of knowledge level on risk and causes of obesity among the college goers from urban, rural and semi urban areas.
2. To see whether there is existence of gender inequality in respect of knowledge level on risk and causes of obesity among the college goers from urban, rural and semi urban areas.

Materials and Method

A cross sectional study has carried out in three different private management colleges located in East Midnapore. The Undergraduate students of the college, who are studying management, are included in the study and they are aged between 18 to 22 years. An informed consent is taken from the students and only those who are interested, are included in the study. Purpose of the study is also informed to the student before conducting the study. The study was also approved by the ethics committee. A questionnaire was developed which comprises two segments – first segment comprises 10 questions which are to assess the knowledge level of causes of obesity and second segment comprises 10 questions which are to assess the knowledge of risk associated with obesity or health hazard associated with obesity. Students are divided into three segments according to their locality – urban, rural and semi urban. From each segments 60 students were randomly selected. So total 180 students were included in the study, but 22 of them are rejected as they gave incomplete answer so at the end 43 students from urban, 44 students from semi urban and 52 from rural i.e. total 139 students are included in the study. To see the difference of knowledge level of risk and the causes of obesity among the students from urban areas, rural areas and the semi urban areas as well as the students of different gender, ANOVA and independent samples t test have run by the use of SPSS 17th version.

Results

Table 1: Characteristics of the respondents

According to Gender		
	Frequency	**Percentage**
Male	65	47.10%
Female	73	52.89%
According to Locality		
	Frequency	**Percentage**
Urban	42	30.43%
Rural	52	37.68%
Semi Urban	44	31.88%

The above table shows the distribution of the respondents by the gender. 65 i.e. 47.10% are male and 73 i.e. 52.89% of them are Female. The table is also showing the distribution of the respondents by their residence. 42 i.e. 30.43% of them are from Urban areas, 52 i.e. 37.68% of them are from Rural areas and 44 i.e. 31.88% of them are from Semi Urban areas. The knowledge level towards the risk and causes of obesity are collected and plotted in the SPSS and one way ANOVA performed and it gives the output below

Table 2: The Descriptive analysis

Knowledge level of Risk of Obesity		
	N	Mean
Rural Areas	52	21.38
Semi Urban Areas	44	25.75
Urban Areas	43	26.28
Total	139	24.47
Knowledge level of Causes of obesity		
	N	Mean
Rural Areas	52	23.73
Semi Urban Areas	44	29.82
Urban Areas	43	30.93
Total	139	28.15

From the above chart it can be concluded that the mean of knowledge level of risk of obesity in people of urban areas (26.28) followed by Semi Urban areas (25.75) and lastly the rural areas (21.38). Apart from that the mean of knowledge level of causes of obesity in

people of urban areas (30.93) followed by Semi Urban areas (29.82) and the Rural areas (23.73).The existing knowledge level of risk and causes of obesity is different in urban, rural and semi urban areas are collected and plotted in the SPSS and one way ANOVA was performed and it gives the output below

Table 3: ANOVA table

Knowledge level of Risk of Obesity					
	Sum of Squares	**Df**	**Mean Square**	**F**	**Significance**
Between Groups	702.849	2	351.424	41.444	< .001
Within Groups	1153.209	136	8.479		
Total	1856.058	138			

Knowledge level of Causes of Obesity					
	Sum of Squares	**Df**	**Mean Square**	**F**	**Significance**
Between Groups	1460.591	2	730.296	48.601	< .001
Within Groups	2043.567	136	15.026		
Total	3504.158	138			

From the first ANOVA table, it can be concluded that there is significant differences existing among Students from rural, urban and semi urban areas on existing level of knowledge of risk of obesity. F (2, 136) =41.444, and the P value is less than .001, also from the second ANOVA table it can be concluded that there are significant differences persisting among Students from rural, urban and semi urban areas on existing level of knowledge of causes of obesity. F (2, 136) =48.601 and the P value is less than .001.

Table 4: Multiple comparisons for knowledge level of risk of Obesity

Areas 1	**Area 2**	**Significance**
Rural	Semi Urban	< .001
	Urban	< .001
Semi Urban	Rural	< .001
	Urban	.601
Urban	Rural	< .001
	Semi Urban	.601

Table 5: Multiple comparisons for knowledge level of causes of Obesity

Areas 1	**Area 2**	**Significance**
Rural	Semi Urban	< .001
	Urban	< .001
Semi Urban	Rural	< .001
	Urban	.346
Urban	Rural	< .001
	Semi Urban	.346

The Games Howell method reveals that significant differences among Rural - Semi Urban, Rural-Urban and Semi Urban – rural are existing in respect to level of knowledge on risk of obesity. In case of rural - semi urban, rural-urban the p value is less than .001 but in case of semi urban – urban, no significant differences is found, p value is .601. Another comparison reveals - there are significant differences existing between Rural-Semi Urban, Rural-Urban and Semi Urban-rural in respect to level of knowledge on causes of obesity. In case of rural - semi urban, rural - urban the p value is less than .001 but in case of semi urban – urban there is no significant differences between them. The p value is .346.

Table 6: 2 tailed sample t test to see to see the gender and area wise knowledge gap

Urban Area					
Causes of Obesity		P value	Risk of Obesity		P value
Male	Female		Male	Female	
30.38	31.45	.196	26.19	26.36	.856
Rural Area					
Causes of Obesity		P value	Risk of Obesity		P value
Male	Female		Male	Female	
27.34	20.86	< .001	24.21	19.13	<.001
Semi Urban Area					
Causes of Obesity		P value	Risk of Obesity		P value
Male	Female		Male	Female	
32.90	26.72	< .001	27.18	24.31	<.001

The above table shows there is no gender inequality existing in case of urban students in terms of knowledge level of causes and risk of obesity, as the p value is .196 and .856 respectively, but in case of both the rural and semi urban areas the knowledge level of causes and risk associated with obesity is statistically different among genders. In both the cases the p value is less the .001.

Discussion

The overall level of knowledge score on risk and causes of obesity is poor among urban, rural and semi urban students, same types of research result was shown by Nyaruhucha[11] in the year 2003. Among them urban have scored highest followed by semi urban and lastly rural students. Same kinds of results can be found in many studies including Iloh[8] in the year 2011. The ANOVA analysis reveals that the students of urban and semi urban have statistically same level of knowledge score on causes and risks of obesity. In case of rural – semi urban and rural – urban the difference is statistically significant. That means the knowledge level on obesity of rural people is poorest. The study also has some other perspective i.e. gender. In case of urban area the knowledge level on risk and causes of obesity is same in both the gender i.e. difference of knowledge levels on obesity in both male urban and female urban have statistically insignificant. The p value is .196 and .856 respectively, but in case of both the genders of semi urban and rural the difference is huge and the differences are statistically significant and P value in both the cases is less than .001., same kind of results can be seen in research paper published by Mugo[10] in the year 2016. So there is gender inequality existing in case of rural and semi urban students in respect of knowledge level on risk and causes of obesity but it is not true in case of urban students. The study suggests an extensive awareness program on obesity is needed and same kind of suggestion is given by Tiwari[16] in the year 1998. Urban areas are well communicated with health care facilities and the people are more aware of many health problems but unfortunately it is not true in case of rural and semi urban areas. In those areas gender inequality can be seen too in terms of health awareness but it is not true in case of urban areas.

Implication: The study reveals two different and important aspects, first one is showing that knowledge regarding risk and causes of obesity is poorest among rural population and secondly the knowledge level regarding obesity differs in both the genders of rural population. Rural girls have poorer knowledge level on obesity than rural boys. It is not true in case of urban or semi urban population. So a clear discrimination can be seen in rural population in respect of existing knowledge level of obesity among two genders. So series of extensive surveys and continuous health educational programs are required to be conducted for the purpose of enhancement of knowledge level on health among rural girls. Also as the knowledge level of obesity is also poor in other groups they are also included in those programs too.

Conclusion

The study shows that the college goers are not satisfactorily aware of the risk and causes of obesity, also there is gender inequality existing in semi urban and rural areas in respect of level of knowledge on obesity. Also the study reveals though the urban and semi urban people have almost same level of knowledge on obesity but in case of rural people the knowledge level is poorest. So there is need of improvement of awareness among students of different areas, especially among rural people. Apart from that as there is existence of gender inequality among students of semi urban and rural areas so special emphasis on the implementation of process for up gradation of knowledge level among girl of those areas are needed.

Ethical Clearance: We got ethical clearance from Vice Chairman of different private colleges of Purba Midnapore district. Also the researchers have explained the purpose of the research and each respondent was assured by the researchers to maintain complete confidentiality.

Prevalence of Dengu Fever in India along with its Prevention and Treatment By Herbal Medicine

Srivastava Niraj[1], Saxena Varsha[2], Singh Amit[3]

[1]Associate Professor, Department of Kaumarbhritya, Bal-Roga, Sardar Patel Institute of Ayurvedic Medical Sciences & Research Centre. Lucknow, Uttar Pradesh, [2]Assistant Professor, Department of Shalya Tantra, Main campus Uttarakhand Ayurved University, Harrawala, Dehradun (Uttarakhand), India, [3]Associate Professor, Department of Dravyaguna, Apex institute of Ayurvedic medical sciences, Varanasi. India.

Abstract

Background: Dengue viruses are the causative organism of dengue fever (DF) and dengue hemorrhagic fever (DHF). Dengue virus belongs to family Flaviviridae. Dengue virus has four serotypes (DENV-1, DENV-2, DENV-3 and DENV-4) that spread by the bite of infected Aedes Aegypti mosquitoes. In Ayurvedic perspectives, Dengue fever comes under the group of Abhishangaja Jvara. Dengue fever can be controlled and prevented by the number of herbal drugs which is free from any side effects. Main aim of this article is to elaborate the dengue fever and its incidence in India along with review herbal drugs which is effective in prevention and treatment of dengue fever.

Materials and Method: This review work was carried out by using a widespread and planned data mining approach. To achieve significant literature author uses the key words"dengue fever " "dengue fever in India" and "herbal medicine for Dengue fever"searched in Google Scholar, web of science, Science direct, Scopus, Medline and PubMed Central journal literature.

Results: Seven publications were included in the final selection after systematic analysis.

Conclusion: Dengue is endemic in more than 128 countries; about half of the world's populations are at risk for infection. It is suggested that herbal plants could be used for prevention and treatment of dengue fever as potential anti-DENV agents and increasing the platelet (PLT) count, white blood cells (WBC) etc.Some herbal extracts have ovicidal activity against Ae. Aegypti.

Keywords: *Dengue fever, India, Herbal drugs, Abhishangaja Jvara.*

Introduction

Dengue fever and dengue hemorrhagic fever (DHF) are caused by infection due to any of the four serotypes of dengue viruses (DENV-1, DENV-2, DENV-3 and DENV-4)[1,2]. *Aedes aegypti* mosquito transmits the infection which breeds in clean water.[3] *Aedes albopictus* is another important competent vectors for dengue virus in India[4]. According to the World Health Organization (WHO) guideline 1997, dengue patients can be categorized into three categories including dengue fever, dengue hemorrhagic fever, and dengue shock syndrome.

Dengue hemorrhagic fevers (DHF) and dengue shock syndromes (DSS) are serious clinical manifestation of the dengue infection. Over the last 30 years, there has been increase in the frequency of dengue fever (DF), DHF and DSS and their epidemics. Dengue fever is also known

as break bone fever because of severe body and joint pains is main feature along with fever. The pathogenesis of DHF/DSS is not clear. It has been observed that sequential infection with any two of the four serotypes of dengue virus result in DHF/DSS in an endemic area.[5] In Ayurvedic perspectives, Dengue fever comes under the group of *Abhishangaja Jvara* predominantly *Pittaja* in pathological ground. The complications of this disease represent *Raktaja* and *Sannipataja Jvara.*

Dengue infection has become endemics in most of the South East Asian countries including India. In the last one decade several minor or major outbreaks have been reported from various parts of India[6]. Dengue hemorrhagic fever was first epidemic in 1954 in Philippines country after that quickly spread in another part of world because Dengue virus is transported from one place to another by infected travelers. It is estimated that during an outbreak of DHF, about 150-200 mild to silent infections occur in community for each case of DSS seen in hospital[7]. The first major epidemics of Dengue hemorrhagic fever in India is 1996 that involve mainly areas around Delhi and Lucknow and then it spread to all over the country. Delhi and other parts of North India experienced many number of cases of Dengue fever in 2003 and 2006. Mortality rate of this disease is more common in young child as compared to adults. In India during the period between 1996–2015, dengue cases reported more than 5 times due to increase global warming unplanned urbanization, changes in environmental factors, host–pathogen interactions and population immunological factors[8]. Now, Dengue is endemic in more than 128 countries, about half of the world's populations are at risk for infection and up to 50 million cases of dengue estimated each year[9]. In India monsoon usually starts in July and ends in September–October, this is common season for dengue fever also. Main endemic state for dengue in India is Assam, Bihar, Uttarakhand, Jharkhand, and Orissa. India experienced the highest dengue incidence in 2012 (about 41 per million population), 2013 (61 per million population) and 2014 (32 per million population).[10]

Dengue fever is spread by bites of *Aedes aegypti* or *Aedes albopictus* mosquitoes and these mosquitoes bite mostly during day time. In India this disease is commonly occurs during rainy season and immediately afterwards (July to October). If a person suffering from Dengue fever then Dengue virus is present in their blood. When Aedes mosquito bites dengue fever patients, then dengue virus enters into their body. The virus undergoes advance development in the body of the mosquito and when virus containing mosquito bites a normal human being, the virus is injected into the normal person's body and develop symptoms of dengue fever.[11]

The clinical manifestation of dengue virus infection varies from asymptomatic to severe life-threatening illness in the form of DHF/DSS. Most dengue infections in young children are mild and indistinguishable from other common cause is usually characterized by fever with chills, flushed face, headache, retro-orbital pain, bony and muscle pain, maculopapular skin rash and epistaxis.[12] The entire period of Classical Dengue fever lasts for about 5-7 days and after that symptoms subside. Some patients of dengue infections have varying degree of mucosal and cutaneous bleed with some degree of thrombocytopenia. Patients falling in this category may be seen in significant number in epidemics.[13-14-15]

Grading of severity of Dengue hemorrhagic fever (DHF): On the basis of clinical features DHF is classified into four grades of severity, wherein grades III and IV are considered to be DSS.

Grading	Clinical features
Grade-I	Fever accompanied by non-specific symptoms and only hemorrhagic manifestation is a positive tourniquet test.
Grade-II	In addition to the manifestation in grade I there may be spontaneous bleeding. But there is no hypotension.
Grade-III	Circulatory failure manifested by a rapid weak pulse and narrowing of pulse pressure (<20 mm Hg) or hypotension with presence of cold clammy skin and restlessness.
Grade-IV	Profound shock with undetectable blood pressure or peripheral pulses.

In mild and moderate condition of disease, supportive treatment is advised with either oral or intravenous rehydration[16] but for severe cases blood transfusion is indicated[17]. Aside from eliminating the mosquitoes, many researcher work for develop a vaccine and medicine that target the virus. World Health Organization mentions that about 70–80% of the world populations depend on non conventional medicines

mainly of herbal medicine for their healthcare. In modern medicine there are no particular medicines or antiviral or any vaccine to cure the dengue fever but you advised to rest and drink plenty of water. In this situation, many people are turning to some herbal medicines to control this dreaded disease.

The main aim of this review article is to review systematically the published research pertaining to dengue fever and use of medicinal plants in the management of dengue fever by using the PubMed and other database. Findings described in the literature, showed that it is hypothesized an antiviral activity against DENV of some medicinal plants.

Methodology: This review work was carried out by using a wide-ranging and organized data mining approach. To achieve significant literature author uses the key words "dengue fever in India" and "plants, herbal medicine for Dengue fever, Antiviral effect, Ayurveda" were parallel searched in Google Scholar, web of science, Science direct, Scopus, Medline and PubMed Central journal literature.

Inclusion criteria were literature sources such as peer reviewed journal articles, UGC care list journal, conference/ seminar proceedings book, refereed books and abstracts.

Herbal medicine used in prevention and treatment of Dengue fever: There are no specific antiviral drugs for dengue fever in any system of medicine; however, maintaining proper fluid balance and analgesics are important line of treatment. In this article author reviewed various plants and their preparations which have been reported for treatment of dengue and guideline given by CCRAS (*Central Council for Research in Ayurvedic Sciences*) for clinical management of Dengue. Various herbal formulations have also been tried and used in dengue fever and simultaneously been scientifically validated and documented by modern researchers.

A. Many researches showed *C. papaya* is very effective in human against dengue infection. In one study showed that *C. papaya* leaf juice have significant role in increase the platelet counts in the dengue virus infected patients within 24 h of treatment.[18]

B. Another study showed that *C. papaya* leaf extract (CPLE) have role in preventing the condition of thrombocytopenia by increase effect of Arachidonate 12-lipoxygenase and Platelet-Activating Factor Receptor gene which responsible for platelet production.[19-20]

C. Leaves extract of Neem (*Azadirachta indica) is effective in vitro* and *in vivo* action against dengue virus type-2 showed positive effect in reduction of virus.[21-22]

D. leave decoction of Tulsi (*Ocimum sanctum)is effective in prevention and treatment of Dengue fever.*[23]

E. Stem decoction of Guduchi (*Tinospora cordifolia) is effective in prevention of Dengue fever.*[24]

F. Whole plant of Patha (*Cissampelos pareira) extract* is effective *in vitro* and *in vivo* conditions and found effective against all four serotypes of Dengue fever.[25]

G. The herbal extracts had clinical evidence that using oil of Neem *(Azadirachta indica)* and Karanj *(Pongamia glabra)* showed 100% egg mortality against *Aedes* mosquito by ovicidal activity. While leaves of *Limonia acidissima* exhibited 83.2% ovicidal activity.[26]

H. CCRAS also advice a combination of herbal drugs which is effective in Dengue fever that is 2 gram *Shunthi* (Dry Ginger) powder twice daily with infusion prepared by adding 5 gram (one teaspoonful) of *Guduchi* (*Giloye*) powder in 100 ml (1/2 glass) of boiled water. Dose for children between 6 to 12 years of age will be half and for children below 6 years will be one fourth. One teaspoon of honey can be added to the infusion.

I. Guduchi ghana Vati, Amritadi Kwath and Tulsi Swarasaare effective in Dengue fever.

J. Green coconut water may be given in suitable quantity for maintain hydration and electrolyte.

Conclusion

Dengue fever is caused by four dengue virus (DENV) serotypesand this is transmitted by *Aedes aegypti (Ae.aegypti)* and *Aedes albopictus* mosquitoes. Dengue is a mosquito-borne viral infection. Dengue fever comes under the group of *Abhishangaja Jvara* predominantly *Pittaja* in pathological ground. The complications of this disease represent *Raktaja* and *Sannipataja Jvara.* The global incidence of dengue has grown dramatically in last 50 years to about half of the world's population is now at risk due unplanned

urbanization, changes in environmental factors. In India during the period between 1996–2015, dengue cases reported more than 5 times. In modern medicine there are no particular medicines or antiviral or any vaccine to cure the dengue fever but you advised to rest and drink plenty of water. In this situation, many people are turning to some herbal medicines to control this dreaded disease. Now herbal medicines have been considered as an important option for prevention and treatment of dengue fever. Very limited number of plants show efficacy against dengue virus. Aqueous extract of Neem leaves which have Azadirachtin compound have action against replication of dengue virus type-2 (DENV-2). *C. papaya* leaf extract (CPLE) have potential activity against DF by increasing the platelet (PLT) count, white blood cells (WBC) and neutrophils (NEUT). Tea, which is prepared by using *Ocimum sanctum* boiled leaves, acts as a preventive medicament against DF. Herbal extracts of Neem *(Azadirachta indica)* and Karanj *(Pongamia glabra)* showedovicidal activity against *Ae. Aegypti*. CCRAS also advice a combination of Shunthi (Dry Ginger) powder and Guduchi (*Giloye*) powder which is effective in Dengue fever.

Influence of Cardiorespiratory Fitness Protocol on Physical Function Performance in Geriatric Patients Undergoing Long Term Physiotherapy Treatment

Vishva D. Bhuva[1], Javid H. Sagar[2]

[1]Intern of Physiotherapy, Department of Cardio-Pulmonary sciences, Faculty of Physiotherapy, KIMS "Deemed To Be University" Karad, Maharashtra, India, [2]Professor,

Abstract

Background: The study aimed to find the effect of Structured Cardiorespiratory fitness protocol on Physical Function Performance in geriatric patients undergoing long term physiotherapy treatment.

Method: An Experimental Study was conducted among 45 Geriatric patients undergoing more than 2 month Physiotherapy treatment. The intervention were carried out daily for 6 weeks. All Patients received Structured Cardiorespiratory fitness Protocol. The interpretation of the study was done on the basis of comparing pre-test and post-test assessment of Peak Expiratory Flow Rate (PEFR), Respiratory Rate, Borg scale.

Result: pre and post-test Comparison result, respiratory rate (13.6±1.42 and 13.8±1.25; p=0.026) and PEFR (168.67±48.97 and 171.11±49.55; p=0.02) were found to be statistically significant and Borg scale were found to be extremely significant (15.73±1.42 and 15.02±0.23; p<0.0001).

Conclusion: A Structured Cardiorespiratory fitness protocol was improved the physical function performance in geriatric patient undergoing long term physiotherapy treatment.

Introduction

A consequence of aging is a degeneration in many physiological variable, with the most important being, sarcopenia and the subsequent loss of muscle strength. [1] Aging is associated with a decrease in lung function and respiratory muscle strength declining at a rate of 8 to 15% per decade of life after 50 year of age.[2, 3] The deficit in respiratory muscle strength affects physical performance leading to diminish in exercise tolerance, deterioration of gait, and decrease of quality of life with advancing age.[4] The reduction of respiratory muscle function in the elderly thus make this population more vulnerable to disease and disability.[5]

The respiratory muscle show a decrease in type II fibers with age, with a subsequent reduction in maximal respiratory pressures, maximal inspiratory and expiratory, which reflects the integrated function of all of the respiratory muscles.[6-8] These reductions associated with aging occur after 50 years of age and can interfere with coughing efficiency. These changes can also facilitate the occurrence of pathological processes, such as the accumulation of bronchial secretions and respiratory infections, which can interfere with the activities of daily living in elderly individuals.[9]

Both static and dynamic measures of lung function gradually deteriorate with age. Decreased elastic recoil capacity results in decreased vital capacity, reduced peak expiratory flow etc. With ageing results reduced alveolar support, increased rigidity of the rib cage, weakness of the respiratory muscles. Loss of efficient breathing is particularly noted with exercises with common complaints like shortness of breath while walking upstairs. The work of breathing increases as there is increase in the intensity of exercise. The older people hyperventilate for the same oxygen in comparison with young population.[10]

Cardiorespiratory fitness is the ability of circulatory and respiratory systems to provide oxygen to skeletal muscle, and thereby ability of the skeletal muscle to utilize the oxygen during prolonged moderate to vigorous physical activity.[11]

Physical function is defined as the ability to perform the basic actions essential for independence and carrying out complex activities.[12]

Physical fitness is the ability to carry out daily activities with strength and vigilance, without getting tired and with adequate energy to enjoy leisure-time pursuits and to compete with unanticipated emergencies. [13] It is a mixture of skill-related, health-related and physiologic components. Skilled components include agility, balance, co-ordination, speed, power and reaction time. Health components include cardio-respiratory endurance, muscular endurance, muscular strength, body composition and flexibility.[14] Geriatric population show various cardiorespiratory changes like;

Cardio-Vascular System: Degeneration of the heart muscle takes place, leaving room for fat and calcium deposits, Heart rate decreases and becomes more irregular but resting heart rate does not change much, Stroke volume decreases due to decreased myocardial contractility, The ageing heart is often in capable of increasing cardiac output during maximum exercise.

Respiratory System: In geriatric patient, lungs are only 56% efficient and maximum oxygen in take during exercise is only 40% when compared to a 30 year old person, Total lung capacity decreases, residual volume increases, and ventilatory capacity decreases, Forced expiratory volume (FEV_1) decreases, Altered pulmonary gas exchange: oxygen tension falls with age at a rate of 4mm Hg/decade. PO_2 is 75 at the age of 70, which is the 90 at 20 years, Decreased ciliary action to clear secretions, Strength of respiratory muscle decreases, Chest wall becomes rigid results in increased work of breathing.

The respiratory system is a vital route for gaining the elements essential to sustain life. Physical work capacity is declined with aging for multiple reasons. For example, structural and functional changes of the heart and blood vessels become more visible with advancing age. In general, aerobic work capacity is declined as with combined effects of lowered maximum target heart rate, reduced myocardial contraction, and consequently, stroke volume, in addition to reduce maximum oxygen consumption.[15] The reduction in maximum oxygen consumption noted with aging, however, is not exclusively caused by the altered physiologic functions, but also the physical deconditioning associated with increasing sedentary lifestyle.[16] Decreased alveolar capacity to diffuse air combine to reduce different parameters of ventilatory lung function, such as vital capacity, maximum voluntary ventilation, and forced expiratory capacity.[17,18] In a geriatric Population average respiratory rate is 12 – 28 breaths/min.[19]older adults have decreased sensation of dyspnea and diminished ventilatory response to hypoxia and hypercapnia, making them more vulnerable to ventilatory failure during high demand states and possible poor outcomes.[20]

Method

An approval for the Study was obtained from the Protocol committee and institutional Ethical committee of KIMSDU. Patients who fulfilled the inclusion and Exclusion Criteria were Informed consent was taken from each of the Patient prior to Participation. Instruction was given to the Patients about techniques performed. A total of 45 patients was treated. All Patients received Structured Cardiorespiratory fitness Protocol. Pre and post-test assessment was taken by using PEFR, Respiratory Rate and Borg scale to assess the patients.A total 45 patients both male and female Geriatric Patients Undergoing more than 2 month Physiotherapy treatment were included in the study. They were aged between 65-70 years, Patient who did not having previous history of cardiac surgery, Patient who are at least able to walk with Stick. Exclusion criteria were Patient who taken Physiotherapy treatment in last 6 month for improving Pulmonary functions, Patient who using Inhaler, Patient with Neurological or Psychiatric conditions.

Table 1: Structured Cardiorespiratory Fitness protocol

Cardio respiratory Fitness Protocol	
Exercises	**Dosage**
week 1	
1. Inspiratory Diaphragmatic Breathing Exercise.[21-23]	Combined Diaphragmatic breathing and Pursed lip breathing exercise given for 15 min at each session. 1 session daily.
2. Expiratory Pursed lip breathing exercise.[21, 23-24]	
week 2 – 3	
Continue above all exercises.	
1. Respiratory Muscle Training.[25-26]	Using Incentive respiratory spirometer For 15 min at each Session 1 session daily.
2. Balloon Blowing Exercise.[27]	Exs performed tow times at maximum Balloon blowing Over one min. The Exs Given One session daily.
3. Straw Breathing Exercise.[28]	Exs is performed five min breath only Through straw. Exs is repeat three times to complete one set. Exs given 1 session daily.
week 4 – 6	
Continue above all exercises.	
1. Treadmill exercise Training.[29]	All Exs given 15 min at each session. 1 session daily.
2. Static Cycling.[30]	
3. Walking.[31]	
4. Stair Climbing.[31]	

Results

Primary Outcome used for the result were Respiratory rate, Borg Scale and PEFR.

Gender Distribution:

Table 2: Gender Distributions.

Gender	Frequency	Percentage
Male	23	51%
Female	22	49%
Total	45	100%

Respiratory Rate: In this study there was significant difference in respiratory rate.

Borg Scale: In this study there was extremely significant difference in respiratory rate.

Pefr: In this study there was significant difference in respiratory rate.

Table 3: mean and SD of outcome measures

Parameters	Pre test	Post test	t value	p value
Respiratory rate	13.6 ± 1.42	13.8 ± 1.25	2.29	0.0267
Borg Scale	15.73 ± 1.42	15.02 ± 0.23	5.48	<0.0001
PEFR	168.67 ± 48.97	171.11 ± 49.55	2.41	0.02

Discussion

In Geriatric Population Cardiorespiratory Changes occur like Decreased lung Function, Lung Capacity, and Strength of respiratory muscle and it affects the normal physical function of the geriatric patients. This Study "Influence of Cardiorespiratory Fitness Protocol on Physical Function Performance in geriatric Patients Undergoing long term Physiotherapy treatment." Was conducted to find the effect of structured exercises protocol on geriatric patients undergoing long term physiotherapy treatment. If Cardiorespiratory Fitness improved it will directly improve the physical function among geriatric patients.

The Aim of the Study were to find the effect of Structured Cardiorespiratory fitness protocol on physical function performance in geriatric patients undergoing long term physiotherapy treatment.

The study was conducted with 45 patients. Prior consent was taken from them. The interventions were carried out daily for 6 weeks. The outcome measures for this study were PEFR, Respiratory Rate, and Borg Scale.

The patient in Structured Cardiorespiratory fitness Protocol received Breathing Exercises, Respiratory muscle training, Balloon Blowing Exercise, Straw Breathing Exercises, Treadmill exercise training, Static cycling, walking and Stair climbing.

Patil P. et al.[32] Effect of Abdominal Muscle Exercises on Peak Expiratory Flow Rate in Post-Menopausal Women. This study concluded that abdominal muscle exercise had significant improved clinically and statistically on PEFR in post-menopausal women.

Raquel RB. Britto et al.[33] Effect of the aging process on respiratory function. The identification on breathing patterns in healthy elderly individuals and changes in the respiratory system related to the normal aging process is important to detect and prevent respiratory dysfunction.

Bret D. et al.[34] Physiology considerations in the Geriatric patient. Respiratory changes with age related development of osteoporosis results in a reduction of height of the thoracic vertebrae causing further restriction. Reduction of respiratory muscle mass may contribute to a decrease in the force produced by the respiratory muscle activity.[35,36]

Sarawut J. et al.[24] Effects of Pursed-Lip breathing exercise Using windmill toy on lung function and respiratory Muscle Strength in the Elderly. Aging results in decline in lung function and reduction of respiratory muscle strength.

Sonia UM. Et al.[37] Effectiveness of shoulder and Thoracic Mobility Exercises on Chest Expansion and Dyspnoea in Moderate chronic obstructive pulmonary disease patient. This study concluded that shoulder and thoracic mobility exercises were more effective in improving chest expansion and reducing dyspnoea in COPD patients.

$J_{IN} - S_{EOP}$ K_{IM} et al.[27] Effect of balloon blowing exercise on lung function of young adult smokers. A study was done to clarify lung capacity when a balloon blowing exercise was used to increase Patients lung function. Balloon blowing exercise improves the physical functions in geriatric patients.

The result of this study showed that there was significant improved physical function in geriatric patients after 6 weeks of intervention. Within the group comparison was done by applying 'Wilcoxon rank sum test' to pre and post training values of same group for all outcome measures. Respiratory Rate Post training there was significant improvement($p = 0.0267$), Borg scale Post training there was extremely significant improvement ($p < 0.0001$), PEFR Post training there was significant improvement ($p = 0.02$) noted in geriatric patients undergoing long term physiotherapy treatment.

Therefor result of the present study showed that the structured cardiorespiratory fitness protocol was improved the physical function performance in geriatric patients undergoing long term physiotherapy treatment.

Conclusion

On the basis of the result of our study, It was concluded that the structured cardiorespiratory fitness protocol was improved the physical function performance in geriatric patients undergoing long term physiotherapy treatment.

Efficacy of Tele-Rehabilitation for the Management of Physical Impairments of the Children with Cerebral Palsy in the Inclusive Educational Settings: A Protocol for a Systematic Review

Pardeep K. Pahwa[1], Anshika Singh[2], Shobha Sharma[3], Suresh Mani[4]

[1]Lecturer in Physiotherapy,Composite Regional Centre (CRC) for Persons with Disabilities,UnderMinistry of Social Justice & Empowerment (Govt.of India) Sundernagar, Mandi (Himachal Pradesh), [2]Assistant Professor in Physiotherapy, Subharti College of Physiotherapy,Swami Vivekanand Subharti University, Meerut (U.P), [3]Senior Lecturer,Speech Sciences Program and Centre for Healthy Aging and Wellness, Faculty of Health Sciences, University, Kebangsaan, Kuala Lumpur (Malaysia), [4]Associate Professor, Department of Trans-Disciplinary Research (Physiotherapy), Lovely Professional University, Phagwara (Punjab)

Abstract

Introduction: Cerebral palsy (CP) elucidates a group of permanent disorders of movement and posture disorders caused by non-progressive damage to developing brain with a prevalence rate of about 2-2.5 per 1000 live births in the world. Despite the effectiveness of tele-rehabilitation in various physical ailments, there is a paucity of the literature of tele-rehabilitation for CP in inclusive educational settings. Therefore, the aim of the present review is to identify the efficacy of tele-rehabilitation in limiting down and managing these physical impairments of CP children in educational settings.

Method and Analysis: This protocol for a systematic review is based on principles of the preferred reporting items for systematic reviews & meta-analysis protocols (PRISMA-P). Published literature in the English language on the efficacy of tele-rehabilitation in improving physical impairment among CP children between ages 3-18 years will be included in the review. The *electronic databases such as PubMed, Scopus, Pedro, EMBASE, and MEDLINE (Ovid) will be used for literature search* between 2000 to 2018 years. The *Rev Man 5.3 software will be used to extract the data.* Down and Black critical appraisal checklist will be employed to evaluate the risk of bias. The guidelines for grading of Recommendations, Assessment, Development, and Evaluation (GRADE) will be used to assess the quality of research evidence.

Ethics & dissemination: This review does not inculpate the collection of primary data, so no ethical approval is required for the study. Findings of the review will be disseminated through peer-reviewed publication and conference presentation. Criteria for the review were set a priori and the present protocol got registration from PROSPERO (International Prospective Register of Ongoing Systematic Review) with ID: 42019130555.

Keywords: *Tele-rehabilitation, Information and communication technology, inclusive education setting, videoconferencing and physiotherapy.*

Introduction

Cerebral palsy (CP) is a group of non-progressive permanent movement and posture disorders caused by damage to developing the brain.[3] Globally, the prevalence of the CP is 2 to 2.5 per 1000 live births,

whereas the prevalence is much higher as 2-10 /1000 lives in developing countries with a clinical presentation of cerebrocortical and sub-cortical injury occurring in the very first year of life of child.[4] Since the CP requires long-term care and support for both CP children and their parents, the governments are committed to improve access to quality rehabilitation services and policies to reduce the discrimination, enhance access and inclusion in the society. The revised persons with disability act, 2016 clarifies that children with CP should not be denied for admission in a normal school as CP is the main disabling condition.[5,6] Being a heterogeneous group of disorder, children with CP experience various barriers and challenges in various activities due to deficient motor skills, altered muscle tone, poor balance, low cardiovascular endurance, postural deviations and poor hand functions as compared with normal children in an inclusive educational setting.[7,8] There is a paradigm shift in the focus of integrating the educational needs of CP children into the mainstream of education under the inclusive setting. In such settings, CP children often require help and assistance not only from parents and healthcare professionals but also from teachers and special educators for managing the physical impairments.[9] However, the management of physical impairments is not being addressed sufficiently in such inclusive setup due to lack of skills and resources especially for children studying in remote and rural areas.

The management of physical impairments of these children should be given high priority for enhancing learning and to achieve desired educational goals. The teachers and special educators should ensure the good positioning and posture of CP to maximize the physical efficiency in writing and reading process.[7] In an inclusive education setting, these teachers or special educators should be trained on fundamental management of physical impairments as a supportive service for improving muscular strength and mobility that may be incorporated into existing training programs delivered either via workshops.[8] This might assist these CP children in participating in mainstream schools activities with the guidance of physiotherapists emphasizing effective management of mobility, gross and fine motors skills.[10,11] However, CP children in an inclusive educational setting in rural and remote areas are unable to get physiotherapy services as these services are not available in those areas.

Tele-rehabilitation (TR) refers to the delivery of rehabilitation services via information and communication technology (ICT) services as a subset which includes assessment, treatment, and monitoring.[12] Literature reports that TR has been used for delivering speciality rehabilitation services by the various allied health professionals such as a physiotherapist, occupational therapist and speech therapist in clinics, schools or community settings.[13] TR covers a range of orthopaedics and neurological pathologies like traumatic brain injuries, spinal cord injuries, joint replacement, Parkinson's disease, Cerebral palsy and Multiple sclerosis.[14]

Despite the strong evidence of TR, authenticating that TR can improve the activity limitations of various physical disorders; there exist paucity of literature on the role of TR for CP children in educational settings. Further, there is yet no review published revealing the efficacy of TR in improving the physical impairments among CP children in inclusive school settings. Therefore, the objective of the present review is to identify the efficacy of TR in the management of physical impairments of CP children in educational settings.

Method and Analyses

Study Design: This protocol for a systematic review is based on principles of the preferred reporting items for systematic reviews and meta-analysis protocols (PRISMA-P).[1]

Study Registration: Criteria for the review were set a priori and the present protocol got the registration from PROSPERO (International Prospective Register of Ongoing Systematic Review,CRDUK) with ID: 42019130555.

Eligibility Criterion:

Types of Study: All the randomized controlled trials, quasi-randomized trials, case-control studies, cohort studies, case series & case studies, published and unpublished conference papers on inclusive tele-rehabilitation for cerebral palsy children in educational settings published between years 2000 to 2018 in the English language will be included. Articles other than English language and animal studies will be excluded.

Participants: CP children of any category/type as participants with a mean sample age between 3 -18 years will be included in the study. CP children with other associated problems such as hearing impairment, visual impairment, epilepsy and mental retardation will be included in the study.

Types of Interventions: Children receiving therapeutic services (tele-physiotherapy, tele-occupational therapy, tele-speech therapy or tele-rehabilitation) via information and communication technologyto improve the physical impairment of children with CP for any duration or intensity and frequency in school settings will be considered. Studies which reveal the interventions targeting upper and lower extremities and reporting gross or fine motor skills with activities of daily living (ADLs) will be included. The interventions via face-to-face method in a school setting will be excluded.

Comparisons or Control: The comparator of interest of the present study are no therapy, usual care, computer or video games, table games, conventional physiotherapy, and other exercise programs will be included in the study.

Outcome Measures: The outcome of interest will be TR feasibility, improvement in physical impairment and educational outcome within different levels of ICF models will be included.[15] Keeping in mind the possibility of TR and its effectiveness, following areas of the outcome will be applied revealing feasibility, cost-effectiveness, social and psychological aspects, child-related outcome within all levels of ICF models. All results will be reported in the form of both quantitative and qualitative.

Search strategies for the identification of data source: The electronic databases; PubMed (https://www.ncbi.nlm.nih.gov/pubmed), SCOPUS (https://www.scopus.com),PEDro (https://www.pedro.org.au) and EMBASE (https://www.embase.com), Ovid MEDLINE (http://www.ovid.com/product-details.901.html) will be employed for literature search. The published literature in English language reporting information and communication technology based rehabilitation/ physiotherapy will be included. Using MESH term including "Tele-rehabilitation or tele-physiotherapy, tele-therapy, and technology-based rehabilitation, tele-occupational therapy and tele-exercise" for the management of CP in inclusive educational settings will be used for the search. The reference section of each article will be reviewed for relevant more studies on the proposed topics. From each search database, the searches will be exported into Mendeley (https://www.mendeley.com) to make a consolidated file of all the studies.

Screening of Studies: The duplicity of literature will be rectified using the duplicate find function in Mendeley referencing. Further, the searched article's title and abstract will be evaluated for the eligibility based on the inclusion and exclusion criteria by PAHWA, a reviewer. These articles again will be counter checked by the other three reviewers (MANI, SHARMA, and SINGH). The final full articles will be received from two independent reviewers. Inter-rater agreements between the reviewers will be addressed in any phase of review. The difference of opinion between the reviewers shall be resolved through discussion in consent with another independent reviewer.

Data Extraction: Rev Man 5.3 software will be used to extract data from the included studies. To enhance the consistency between reviewers (PAHWA, MANI, SINGH & SHARMA), a data extraction form will be screened as a pilot study before starting the data collection. Two reviewers of the study will extract the data independently. During the data extraction, any disparity found between the authors will be rectified by the conversation with the fourth author, when needed.

Multiple records of single inquiry research subject area will be searched by comparing author name, interventions, sample sizes and outcome files of concerning eligible records. The data of study details (Author, year, country and funding), study design, sample characteristics, intervention characteristics, comparator, outcome measures, ICF domain, therapeutic and educational impact, and conclusion will be extracted. The data extracted will be summarised in tables and figures.

Risk of bias in Individual Research: Down and Black critical appraisal checklist will be employed to evaluate the quality of study for included quantitative research studies. It comprises of 27 questions items across five constructs that include study quality, external validity, study biases (in intervention and outcome), confounding and selection bias and power of the study.[16] Risk of bias of included qualitative studies will be assessed by JBI Critical appraisal checklist having 10 questions in Yes/No form.[17] Risk of bias for all the final included eligible studies will be assessed by two independent reviewers (PAHWA and MANI) without blinding. Results across the studies will be presented graphically. In case of the existence of substantial difference in risk of bias of included studies, results will be synthesized separately for studies which are at higher and lower risk of prejudice.

Strategy for Data Synthesis: For homogeneous studies in terms of interventions and outcomes, a meta-analysis will be carried out to by using strata V.14 to make consistency, size, and direction of feasible effects of available sufficient data. In case, the study showing poor established thresholds results for meaningful change of a given measure, the effect size (ES) thresholds as advised by Kohen[18] will be used revealing as trivial values (ES<0.20), small values (ES = 0.20 - 0.50) and moderate values (ES=0.50 - 0.80), indicating under or overestimation of magnitude of intervention-related change with course of time.[19] In situations where the meta-analysis is not possible due to substantial heterogeneity, a narrative synthesis of the findings from the included studies will be carried out and the heterogeneity will be quantified using the I^2statistics. This summary with related quality of evidence for each outcome will be synthesized to reveal the effectiveness of TR for children with CP in inclusive educational settings.

Quality of Evidence: The guidelines for grading of Recommendations, Assessment, Development, and Evaluation (GRADE) will be used to assess the quality of research evidence of included studies.[20]

Discussion

To the extent of our knowledge, this will be the first systematic review to investigate the efficacy of TR for the management of physical impairments in children with CP in inclusive educational settings. Previous studies reported that tele-rehabilitation could improve the physical impairment and activity limitation for CP,[21] and other neurological disabilities.[22] Furthermore, it has been noticed that CP children taking participation in activities shown significant improvement in performance indicating the need for rehabilitation and intervention programs in inclusive education settings.[23] The TR based skill practice and continuous delivery of rehabilitation services may give promising results to promote motor skills improvements in CP children. TR in educational settings has the potential for delivering training the special teachers for the management of disabilities in improving educational goals for CP children.[24] Each school under an inclusive educational setting should have access for a novel TR services to bring the physiotherapy, occupational therapy, and speech therapy services in their school premise via ICT. However, there is a scarcity of evidence on the feasibility and efficacy of TR in an educational settings.[14] Considering the poor availability of rehabilitation services in rural areas, it is imperative to analyze the role of TR in managing physical impairments of CP children in educational settings. The result of this study will provide the evidence regarding frequency, time and mode of delivery of TR services which are effective in managing the physical impairments in cerebral palsy child and will, in turn, inform the development of TR-based program for educational settings.

Ethics and Dissemination: The current research does not require primary data collection, so there is no ethical approval requirement. The author will disseminate the results by publishing them in the peer-reviewed journal & through the presentation at the conference. The findings will be recorded for systematic reviews and meta-analysis according to the latest edition of preferred reporting items (PRISMA).[1]

Protocol Amendments: Any change in systematic review protocol will be documented with the date along with the description of that changes with proper justifications.

Conflict of Interest: The authors state no conflict of interest to declare regarding the study.

Abstract

Context: Parkinson's disease (PD) is a neurodegenerative disease caused by degeneration of the dopamine-synthesizing cells of the mesostriatal-mesocortical neuronal pathway,which affects motor pathway in basal ganglia (BG). Neuropsychological studies showed that degeneration of dopamine neuroreceptor also affects nigrostriatal and mesocortical limbic system which is associated with emotional processing in PD. However, very few studies have identified deficit in selective attention in patients with PD patients except in patients with PD-MCI (PD-Mild Cognitive Impairment) or PD-D (PD-Dementia). Thus, the present study examined the effect of emotion on attentional processing in PD and matched control. Emotional flanker task was designed by using pictures selected from the International Affective Picture System (IAPS) based on their normative valence ratings. Results revealed that attentional processing of emotional images were slower in PD patients in comparison to matched healthy control.

Keywords: *attention, emotion, Parkinson.*

Introduction

Parkinson's disease (PD) is a neurodegenerative disorder caused by degeneration of the dopamine-synthesizing cells of the mesostriatal-mesocortical neuronal pathway in substantia nigra. Parkinson's disease (PD) is characterized by well-known motor symptoms, however the presence of non-motor symptoms, such as cognitive impairment, emotional disturbances and psychiatric symptoms are still underestimated. The important issues in PD research is that there has been a great progress in the management of motor symptoms however, very little attention has been given to emotional, cognitive and psychological impact of disease problem.

The impairment in affective processing in PD results in problem in recognition, regulation of emotions and emotion representations. In a previous study, PD patients demonstrated a recognition deficit for negative (sadness and anger) and positive faces[2]. Besides affective deficit, PD patients also exhibited problems in cognitive performance. The cognitive deterioration in PD encompasses impairment in performance related with executive function, working memory, visuospatial ability[3], whereas other cognitive processes like language are less affected[4]. Further, there is an intact attentional functioning in simple attention tasks like digit span and spatial span in patients with PD[5]. Furthermore, a study revealed that the attentional deficit at early stage of PD may be due to the reduced ability to resist interference revealed by flanker compatibility studies[6]. The interference in aged matched population of older adults was less impaired in congruent stimuli in comparison to incongruent stimuli on flanker compatibility task[7].

Furthermore, the effects of attention and emotion on face processing was examined by studies using fMRI to assess the effect of fearful and neutral faces in processing of spatial attention. The result revealed a differential impact of attention and emotion on face processing as

the interference produced by emotional distracters in the emotional processing in conflict resolution task is independent of attention i.e. it processed automatically[8]. However, a meta- analysison emotional influences on attention and perception showed that emotional stimuli compete for neural representation, require attentional resources i.e. processing of emotional stimuli is dependent on attention[9].

Thus, the studies suggested that the mechanism of attentional processing of emotional stimuli remains unclear. Studies showed discrepancies related to emotion processing in non- demented patients and hence further studies are needed to illuminate the emotional profile of patients with PD. Further, very few studies have done assessing the attentional processing with emotional stimuliin patients with PD. The studies in past had revealed the dysfunction in processing of negative stimuli, however, the attentional processing of positive stimuli is still unclear, which needs to be evaluated. Thus, the present study has attempted to clear the contradictory quest of deficit in emotional processing of stimuli and intact of attentional processing. The present research was an attempt to examine the processing of emotion stimuli on a stimulus- response compatibility flanker task. The study assess and compares the differences in the processing of different emotions under different target congruency conditions. The patients with PD-MCI (Mild Cognitive Impairment) and PD-D (Dementia) have been excluded from the study to remove any cognitive variability.

Methodology Participants: Participants were selected from the OPD of the Department of Neurology, I.M.S., B.H.U. and they were screened by using clock drawing test to exclude any cognitive impairment in PD patient. Seven PD patients and 7 age-matched healthy controls were recruited. The other parkinsonian disorders were excluded from the study.

Tools: Emotional Flanker task: The emotional flanker task has been designed and programmed in Superlab 4.0 version programming software. Emotional flanker task was designed using pictures selected from the International Affective Picture System (IAPS) [10].

Stimuli: The stimuli consisted of colored pictures that were selected from the International Affective Picture System (IAPS) based on their normative valence ('Valence' refers to the nature of emotion: positive, neutral or negative) ratings. The target congruency had two levels: congruent—when all the emotional stimuli are either positive, negative or neutral, and incongruent—when the center emotional stimuli are of different emotional valence than flanker emotional stimuli. The content of pleasant pictures included puppies, family, children etc. (IAPS no. 1710, 2340, 2347), whereas the unpleasant picture included hospital, stiches, explosion etc. (IAPS no. 2205, 3195, 9940). The neutral set included pictures of buttons, spoon, basket etc. (IAPS no. 7001, 7004, 7010).

Experimental paradigm: The paradigm consisted of three emotional conditions: 5 low valence negative, 5 high valence positive, and 5 neutral pictures. Selected negative pictures with a mean valence rating of 1.63 (SD 0.6) and a mean arousal rating of 6.07 (SD 0.5). Positive pictures with a mean valence rating of 8.34 (SD 0.5) and a mean arousal rating of 5.27 (SD 0.6). Neutral pictures with a mean valence rating of 5.01 (SD 0.3) and arousal rating of 6.96 (SD 0.4).

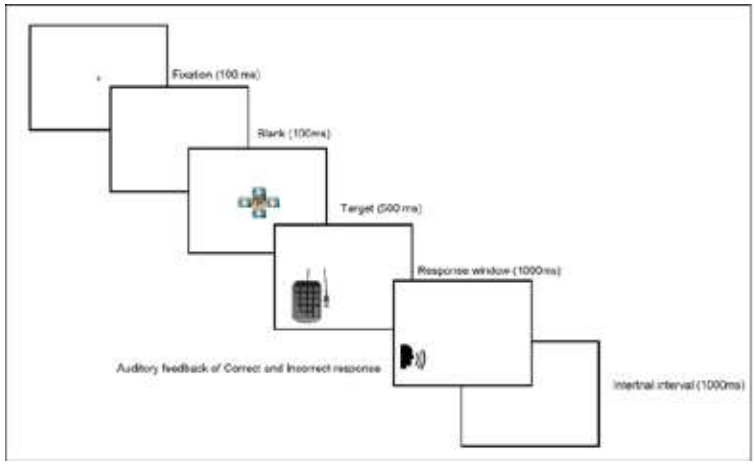

Figure 1: Schematic representation of trials in Emotional Attentional Task

Each trial consisted of six events. First, a fixation cross of 100ms duration was presented. A blank screen for 1000ms was presented before the appearance of target which lasts for 500ms. Patients were given 1000ms time for responding to the target. After the response, an auditory feedback was given about the correctness of response. The next trial of the experiment started after 1000ms of inter-trial interval(See Figure 1).

Experimental Design: A 2 (Group: PD patient & healthy control) x 3 (Valence: Positive, negative, neutral) x2 (Stimulus congruency: Congruent & incongruent) x mixed factorial design with repeated measures on last two factors was used.

Procedure: Diagnosed patients were taken from outpatient department of hospitals. Screening of non- demented PD patient and healthy control was done using Hindi Mental State Examination. Rapport was established and then consent and biographical information was taken. The patients with at least 6 months of dopaminergic treatment were taken to control the motor problem. Further, a separate numeric key pad was used for their convenience in pressing the key. Three keys were assigned indicated by color red, green and yellow to respond to positive, negative and neutral stimuli respectively. The participants were asked to attend and respond to the center stimulus and ignore the other four emotional stimuli. Participants were asked to discriminate emotions as happy, sad and neutral and instructed to attend the central image. There are 18 number of trials in demo condition with an auditory feedback in hindi language of "Sahi" and "Galat". In practice session of 32 trials, same auditory feedback was given. After the practice session, two experimental sessions of 54 trials were administered without any feedback.

Dependent Measures: The reaction time and accuracy was computed. The measures of flanker compatibility effect constitutes the difference between different congruency conditions.

Results

Neuropsychological Assessment: Patients with cognitive impairment were excluded using clock drawing test. The UPDRS and Hoehn and Yahr staging were also used to measure motor impairment and the severity of the disease.

Cognito-affective Assessment: Repeated-measures analysis on 2(Group: PD patients, HC)×3 (Emotion: Positive, Negative and Neutral)×2 (Target conditions: Congruent, Incongruent) was performed with group (PD patients, healthy controls) as a between-group factor and target, valence emotion as within-group factor.

Response Latency: The analysis of reaction time result showed a significant effect of group (F (1,12)= 71.10, p = 0.012) which revealed that patients with Parkinson disease performed poorer than healthy control. The main effect of target condition (F (1,12)= 214.47, p = 0.032) was significant indicating that the incongruency trials showed high reaction time. The attentional modulation of different emotional valence condition was also found significant, F (2,24)=23.93, p=0.001, which suggest differential effect of emotional valence on attention performance (see Figure 2).

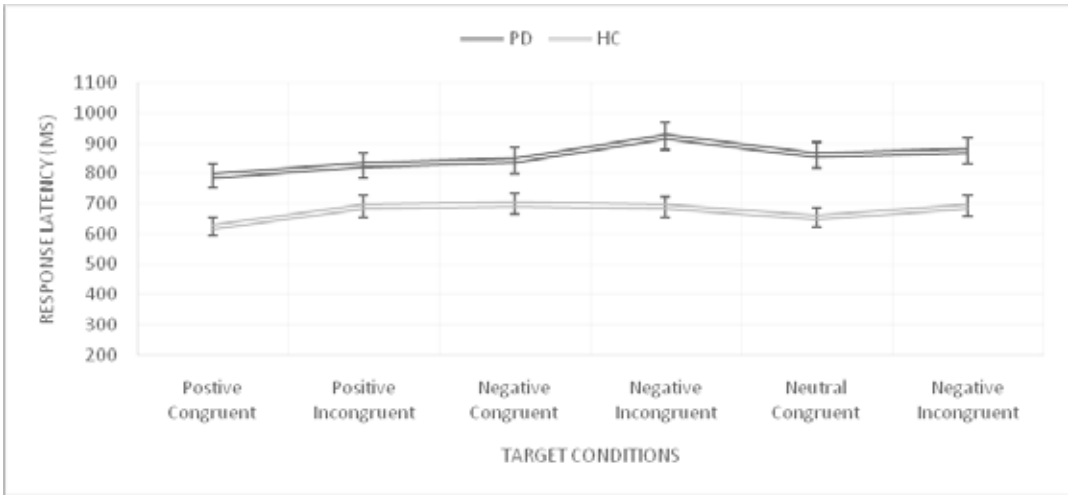

Figure 2: Graph showing mean reaction time of correct responses under different target conditions

The emotional stimuli of different valence state played an important role in attentional processing. The emotional stimuli with positive stimuli processed faster in comparison to negative and neutral valence stimuli as revealed by paired sample t test, $t(13)=4.207$, $p=0.001$. The paired sample t test between negative and neutral stimuli further revealed a significant difference, $t(13)=4.75$, p= 0.001, it was found that response time taken in processing neutral stimuli was significantly less than negative valence stimuli.

Furthermore, a significant interaction was found between group and target condition (F (1,12) =6.84, $p=0.040$), showed that groups under congruent target condition was found better than incongruent target conditions. The interaction between group and valence conditions (F (2,12)=8.21, $p=0.002$) was also found significant indicating that group performed significantly bettter in positive than, negative and neutral valence conditions. The trials with positive emotional stimuli (PD: M =746.14ms,HC: M =663.28ms) were processed faster and accurately as compared to negative (PD: M=829.00ms, HC: M =674.28ms) and neutral stimuli (PD: M = 837.57ms, HC: M = 696.57ms). However, the interaction between valence and target conditions (F (2, 12)=0.56, $p=0.57$) was not found significant, which indicates that the effect of congruent and incongruent condition do not affects the performance in processing positive, negative and neutral condition.

Accuracy Performance: The accuracy data analysis showed a significant difference in group, F (1,12)= 3.53, $p=0.085$ which revealed that patients with Parkinson committed more errors as compared to control. Further, the interaction between group and emotional valence were significantly different, F (1,12)= 0.369, p= 0.695 that revealed that trials with positive emotional stimuli (PD: M =75.14, HC: M =85.64) were processed more accurately as compared to negative (PD: M =79.07, HC: M= 86.85) and neutral stimuli (PD: M =79.05,HC: M =87.07). However, a non-significant interaction was found between emotional stimuli and target, F (1, 12)= 1.30, p= 0.29 which indicated that there was no difference in the effect of emotional stimuli on different congruency of target in patients with PD and healthy control (see Figure 3).

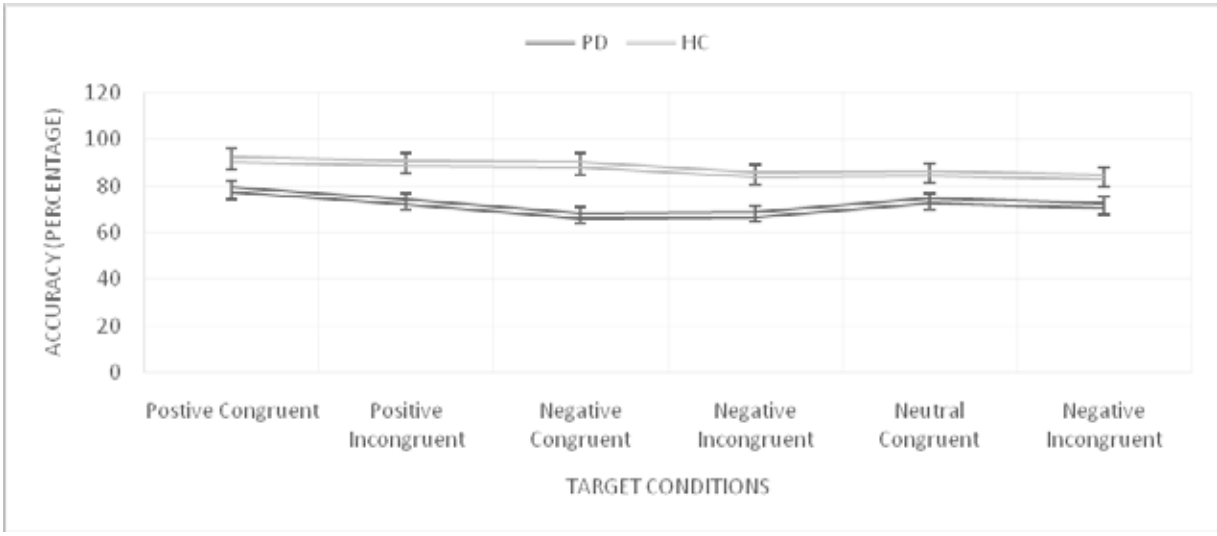

Figure 3: Graph showing mean reaction time of correct responses under different target conditions

Discussion

The study investigated the effect of emotional stimuli on a stimulus- response compatibility flanker task. In PD, an emotional symptom called facial amimia where patient's face becomes frozen and inexpressive due to the impairment in emotional processing which could relate with the problem in interpersonal relationship. In light of this, the primary results of the present study reveals that the patient group reported more problems in processing emotional stimuli with negative valence than healthy control. These deficits were possibly due to the deficit in the regulation of negative emotion which is consistent with findings of a study[11]. The findings of the present study further suggest that the response

processing to fear-eliciting stimuli is diminished, which is also consistent with aprevious studies[12]. Moreover, our study investigated cognitive aspect related to response inhibition processing related with emotions in non-demented PD patients. It was observed that response inhibition using flanker compatibility effect in PD and control did not differ in flanker effect which showed that there is no effect of congruency. One could argue that the deficits in emotional processing are an effect of general decline in cognitive functioning in PD. We excluded this possibility by not including PD-MCI (Mild Cognitive Impairment) and PD-D (Dementia) and only taken cognitively intact PD patients (PD-Non-cognitive Impairment (PD-NCI)). The finding of the present study agrees with the results of a study[13] which revealed that emotion processing impairment among PD patients was not related to the patients' cognitive status.

The findings are discussed in terms of accuracy and response latency. The results of the present study suggest that emotional stimuli impair the performance on attentional task. First, performance in tasks of emotional attentional processing was impaired in PD patients compared to controls in line with previous data[14,15] which means that performance on stimuli with different valence emotional stimuli under different target conditions was found different in healthy subjects and PD patients. The results are also consistent with[11] suggested that individuals with PD showed a lower attentional score for negative emotion than for relatively positive emotion. With regards to emotional deficit in processing emotional images in PD, our findings were relatively similar to a previous study[16].

Although the present study address the deficit of emotional processing in PD patients, however the study also exhibit a limitation of small sample size of the patient. Thus future study can be done on larger sample of Parkinson patient. Future study can also be done using emotional faces in place of IAPS pictures. The present study also gives a direction to future study corroborating with fMRI investigation which can be used to identify the brain area activation.

Conclusion

In sum, the present study infer that the attentional processing of emotional images were slower in PD patients in comparison to matched healthy control. Further, result yielded a difference in performance on congruent and incongruent emotional trials in PD patients, especially on negative incongruent conditions, however no such difference has been seen in matched healthy control. However, the analysis of accuracy results revealed no indication of diminished flanker compatibility effect on positive, negative and neutral stimuli which revealed that they recognized the emotional stimuli, however due to the differences in emotional valence and arousal the processing speed was affected as revealed by response latency measure.

Treatment Success Rate among Multidrug Resistant Tuberculosis Patients Registered Under Programmatic Management of Drug Resistant Tuberculosis Services in District Amritsar, Punjab, India

Pooja Sadana[1], Vishal Verma[2], Priyanka Devgun[3]

[1]Associate Professor, Department of Community Medicine, Sri Guru Ram Das Institute of Medical Sciences and Research, Sri Amritsar, [2]District TB Officer, Office of Civil Surgeon, Tarn Taran, Punjab, [3]Professor and Head Department of Community Medicine Sri Guru Ram Das Institute of Medical Sciences and Research, Sri Amritsar

Abstract

Background: MDR-TB has become an urgent public health problem worldwide, threatening the global TB control. The success rate of treating multi drug resistant remains very low.

Method: This cross-sectional study was conducted on all MDR-TB patients who were registered and being treated under PMDT services in Amritsar district from 1st January 2015 to 31st December 2016. The treatment outcome with their clinico-demographic determinants was ascertained. Data management and analysis was done by using Microsoft excel and SPSS.

Results: Out of 110 registered MDR-TB patients, 88 (80.0%) were males and 22 (20.0%) were females. The various treatment outcomes observed were- 36 (32.7%) cured, 20 (18.2%) treatment completed, 16 (14.5%) defaulted, 22 (20.0%) died, 11 (10.0%) regimen changed or shifted to XDR TB regime, 5(4.5%)transferred out. The success rate (cured+ treatment completed) was50.9%.

Conclusions: On statistical analysis, it was observed that age (p=0.012),weight band of patients under RNTCP (p=0.040) were significantly associated with the treatment outcome. Other factors like sex, residence, typeof tuberculosis and the HIV status of the patient did not affect the treatment outcome.

Keywords: *Multi-drug resistant TB, Treatment outcomes, success rate.*

Introduction

The emergence of Multidrug resistant TB (MDR TB) has created increasing constraints on effective tuberculosis control and has caused tremendous morbidity and mortality worldwide. Globally in 2017, there were an estimated 558 000 new cases of Rifampicin resistant TB (RR-TB), of which almost half were in three countries: India, China and the Russian Federation. Among RR-TB cases, an estimated 82% had multidrug resistant TB (MDR-TB). Globally, 3.5% of new TB cases and 18% of previously treated cases had MDR/RR-TB, with the maximum proportions (>50% in previously treated cases) in countries of the former Soviet Union.[1] The treatment of MDR-TB, is long,expensive and requires the use of toxic drugs and has substantially lower success rates than for drug-sensitive TB.[2]

Despite progress in tuberculosis (TB) control, the response to the multidrug resistant TB continues to be limited. Treatment success remains low, at 55% globally.[1] This is considered to be one of the major challenges to progress towards the country's targets to end TB by 2025. While prevention of development of

drug resistance is of paramount importance for ending TB, early detection and treatment completion are keys to interrupt on-going transmission.[3] Therefore, it is imperative to analyze the treatment outcomes of MDR-TB patients treated by standardized 2nd line chemotherapy. Hence the present study was planned to investigate the treatment outcomes and to assess the impact of different demographic and clinical conditions on the outcome among MDR-TB patients.

Method

The study was a cross-sectional study conducted on all MDR-TB patients registered and being treated with second line anti-tuberculosis drugs under Programmatic management of drug resistant tuberculosis services in Amritsar City.

Study Sample: All MDR-TB patients registered from 1st January 2015 to 31st December 2016.

Inclusion Criteria: All drug sensitivity tested (DST) confirmed MDR-TB cases who signed written informed consent.

Exclusion Criteria: Critically ill patients and pregnant females were excluded from the study.

Data Collection and Analysis: A total of 110 patients registered with District Tuberculosis Centre(DTC), Amritsar and being treated with second line anti TB drugs were included in the study. A pre-designed and pre-tested proforma was administered to the subjects after taking his/her consent. The consent of the caretaker or guardian/parent was sought on behalf of all child participants. Questionnaire included questions regarding the socio-demographic and clinical profile, of the patients. The possible outcomes of the MDR TB patients under DOTS can be: cured, treatment completed, died, failure, defaulted, regimen changed/ shifted to XDR and transferred out.[3]

Cured: Treatment completed as recommended by the national policy without evidence of failure and three or more consecutive cultures taken at least 30 days apart during CP are negative including culture at the end of treatment.

Treatment Completed: Treatment completed as recommended by the national policy without evidence of failure but no record that three or more consecutive cultures taken at least 30 days apart are negative after the intensive phase.

Failure: Treatment terminated or need for permanent regimen change of at least two or more anti-TB drugs in CP because of lack of microbiological conversion by the end of the extended intensive phase or microbiological reversion in the continuation phase after conversion to negative or evidence of additional acquired resistance to FQ or SLI drugs or adverse drug reactions .

Died: A patient who dies for any reason during the course of treatment.

Transfer Out: A patient who has been transferred to another reporting unit (DR-TB Centre in this case) and for whom the treatment outcome is not known.

Regimen Changed/shifted to XDR: A TB patients need for permanent regimen change of at least one or more anti-TB drugs prior to being declared as failed/A MDR-TB patient who is found to have XDR-TB by an RNTCP certified CDST laboratory and who has subsequently switched to a regimen for XDR-TB treatment initiation.

Outcomes were classified as Favourable outcome which includes cured and treatment completed patients and Unfavourable outcome that includes cases with outcome as defaulted, died, transferred out and those who were shifted to XDR TB or changed regime. Cured and treatment completed, these together define treatment success.

All the information so collected was compiled, analyzed statistically with help of SPSS version 20. Chi-square test was used to evaluate differences in categorical variables and $p<0.05$ was considered to be significant.

Ethics: The research proposal was approved by the college ethical committee at the time of commencement of the study.

Conflict of Interest: Nil

Results

A total of 110 patients with a diagnosis of MDR-TB were registered under PMDT services in Amritsar city during 2015–2016. The total sample comprised of, 88 (80.0%) males and 22 (20.0%) females. The mean age of the patient is 33.13 years (SD ±12.4 years), ranging 11 to 68 years. 84 (76.4%) cases were in the age group of 11-40 years. Most of the patients 88(80.0%) were males

and 67(60.9%) patients resided in urban areas. Almost all patients,107(97.3%) had pulmonary tuberculosis and only 3(2.7%) had extra-pulmonary tuberculosis. Maximum patients 58(52.7%) belonged to weight band of 46-70 kg .Only 4 (3.6%) patients were HIV positive. 7(6.3%)patients were resistant to both drugs Rifampicin and Isoniazid.

Table 1: shows the distribution of cases according to their treatment outcomes. Out of the total 110 patients, 36 (32.7%) were cured, 20 (18.2%) were categorized as treatment completed, 16 (14.5%) patients defaulted, 22 (20.0%) died, in 11(10.0%) patients regimen was changed or shifted to XDR TB regime and 5(4.5%) patients were transferred out. Treatment success rate (cured and treatment completed) was 50.9% in the present study.

Table 2: depicts the clinical and demographic factors affecting treatment outcome in MDR TB cases. It is evident from the above table that favourable outcome was seen in younger age group i.e. 11-25 yrs. Out of 110 patients,30 (69.8%) patients had favourable outcome. Unfavourable outcome was seen in 80.0% of patients of more than 55 yrs age. The results were found to be statistically significant (p=0.012). 43(48.9%) males and 13(59.1%) females had favourable outcome. The results were not found significant. Favourable outcome was significantly higher among patients with weight band 46-70 kg i.e 36(62.1%) as compared to patients belonging to other weight bands (p=0.040). Sex, residence, type of TB and HIV status of the patient were not significantly associated with treatment outcome.

Table 1: Treatment outcome of multidrug resistant TB patients

Outcome	Frequency	Percentage
Cured	36	32.7
Treatment completed	20	18.2
Defaulted	16	14.5
Died	22	20.0
Regimen changed/Shifted to XDR	11	10.0
Transferred out	5	4.5

Discussion

In the present study it was observed that out of the total 110 patients, 76.4 % of patients were in age group of 11-40 yrs. Similar study by Nair et al in Chennai showed that 70% were in the age group of 15-44 yrs.[4] The demographic profile of MDR-TB patients in our study was similar to other studies, with a majority of patients,62(56.4 %), in the economically productive age group (26-55 years) with male patient predominance.[5,6] Our study participants included 88 (80.0%) males and 22 (20.0%) females. The mean age of the patient was 33.13 years. A study conducted in Uttar Pradesh also revealed that more than 2/3rd of patients were male and the mean age was 32 years.[7] Similar male preponderance was observed in the study by a study on MDR-TB patients in Cairo, Egypt and in Indonesia showing that out of the total, 72.9% and 68.6% were males respectively. [8,9]

Table 1 revealed the outcome of the total 110 patients, 36 (32.7%) were cured, 20 (18.2%) completed treatment, 16 (14.5%) patients defaulted, 22 (20.0%) died, in 11 patients (10.0%) regimen was changed or shifted to XDR TB regime and 5 (4.5%) patients were transferred out. In the present study, treatment success rate,which consist of cured and treatment completed was 50.9%. The result is consistent with reported global (52%) and national (56%) MDR-TB treatment success rates.[10,11]

MDR-TB treatment success rate recorded in a study conducted in patients from Chinese referral hospitals also showed similar success rate.[12] Another study done in china showed success rate of 57 %.[13] A study undertaken to analyze the clinical profile and treatment outcome in pulmonary drug tuberculosis (TB) patients under programmatic management of multidrug resistant tuberculosis (PMDT) at a tertiary care center in Mumbai showed 48.4% of MDR-TB patients were successfully treated (cured + treatment completed), 43.47% were cured, 10.1% completed treatment, 13.04% died, 1.4% failed, 15.4% defaulted, 4.3% stopped treatment due to adverse drug reactions and 11.5% transferred.[14] Another study in Karnataka showed that at the end of treatment, 44.2% were cured, 12 defaulted, 9 died, 1 failure and 2 were under XDR TB evaluation.[15] Studies in Portugal and China showed the treatment success of 62% and 68.3% respectively.[16,17]

Table 2 shows the clinic-demographic determinants of treatment outcome. Our study observed that favourable outcome was significantly higher among the age group of 11-25 yrs. 30 (69.8%) patients had favourable outcome. Unfavourable outcome was seen in 80.0% of patients of more than 55 yrs age. Studies by Dengkui et al in Shanghai, Nair et al in Chennai and Gafar et al in South Africa on predictors of treatment outcome showed that unfavourable outcomes in MDR TB cases were significantly higher among cases >45 years.[18,4,19]

Favourable outcome was significantly higher among patients with weight band 46-70 kg i.e 36(62.1%) as compared to patients belonging to other weight bands (p=0.040).A study by Agarwalla, *et al* on outcome of MDR patients that majority of the patients in this study are oflow BMI (<18.5 kg/m^2) and their success rate is significantly less compared to patients having BMI more than 18.5 kg/m^2.[20]

Other factors like sex, residence, type of family and HIV status did not affect the treatment outcome.

Conclusion

Treatment of MDR-TB is major challenge due to the prolonged regimens, multiple drugs used and high incidence of drug toxicities. This is, in turn, contributes to poor treatment adherence and further exponential magnification of drug resistance which can have devastating consequences. The treatment success rate (cured and treatment completed) in the present study was 50.9% which is similar to global treatment success rates of a 55%. Favourable treatment outcome was

present in 50.9% cases. The predictors of unfavourable outcome were age ≥26 years and weight band of 26-45 under RNTCP

Denture Identification Method: A Review

Prabhjot Kaur[1], Anchal Arora[2], Navjot kaur[3]

[1]Former BDS student, Genesis Institute of Dental Sciences & Research, Ferozepur, Punjab, [2]Tutor, Genesis Institute of Dental Sciences & Research, Ferozepur, Punjab, [3]BDS Intern, Genesis Institute of Dental Sciences & Research, Ferozepur, Punjab.

Abstract

Context: Denture marking is accepted as a means of identifying dentures and persons in geriatric institutions, during war, crimes, and civil unrest, natural and mass disasters, post mortem and medico-legal investigations. This review highlighted the various method of denture marking and significance of placing identification marks on dentures.

Keywords: *Denture marking, Geriatric, Identification*

Introduction

Denture marking is accepted as a means of identifying dentures and persons in geriatric institutions, or post-mortem during war, crimes, civil unrest, natural and mass disasters. Due to the lack of a comprehensive fingerprint database, dental identification is growing as an essential part of forensic investigation. Prosthodontists are playing very important role in forensic dentistry as they are concerned with fabrication of various prostheses which can serve as an important tool for identification. The denture marking is important for the following reasons:[1]

a. It serves to identify an unknown denture wearer in cases involving amnesia or senility, loss of memory, psychiatric cases, homicide, suicide, victims of fire, explosion, floods, earthquake, plane crash, or war.

b. In cases of lost and found, the denture can be returned to the owner.

c. A rapid and accurate method other than finger printing is essential for identification of the individuals.

Prabhjot Kaur, Former BDS student, Genesis Institute of Dental Sciences & Research, Ferozepur, Punjab

d. In the laboratory, the dental technicians will find it easy to identify a denture, especially at the deflasking stage, if it is marked / labeled.

e. To ensure the correct denture delivery to the respective patient.

Medicolegal Importance of Denture Marking Systems[2]:

1. Identification of the dead or deceased when all other means have failed.
2. Identification of individuals for forensic, social and legal reasons.
3. Victim identification in case of mass disasters like terrorism, bombings, earthquakes, hurricanes, typhoons, air crashes and other transportation mishaps.
4. Identification of mutilated and decomposed bodies when all other parameters like scars, tattoos, and facial features have failed.

Method of Denture Identification: Various method of denture marking have been reported in the literature. However, there are two main method in marking dentures, namely the surface method and the inclusion method. As compared to surface method, inclusions method are permanent but require more skills and are time consuming.[3]

Surface Method:

Scribing or Engraving Method: In this method letters or numbers are engraved on the denture surface with the help of a small round dental bur.[4]

Disadvantage: Food entrapment occurs in the engraved grooves.

Embossing Method: In this technique name and other particulars of the patient are scratched on the master cast. After processing it produces stamped or embossed letters on the impression surface of dentures.[5]

Disadvantage: This technique has been associated with malignancy, possibly due to continued tissue irritation.

Invisible Ink Method: Harvey described a method wherein the patient's details are written with an invisible ink that is rendered visible by ultraviolet light. This is useful on acrylic resin dentures of those patients who object to normally visible identification marks.

Disadvantage: The mark is not readily visible and examination under special conditions is required to determine its presence.[6]

Fibre Tip Pen Method: Patient's details are written on the tissue-fitting surface or the polished surface of the denture with a fibre-tip pen. The patient's identification details are then covered by at least two thin coats of varnish in order to prolong the life of the marking.[7]

Disadvantage: This method resulted in an unesthetic denture.

Denture Bar Coding Method: A bar code consists of a machine-readable code of a series of bars and spaces printed in defined ratios. The technique described for denture bar coding involves printing a number code on paper, photographing the paper, making and transferring the negative to a piece of silk. An image of the bar code appeared on a prepared faience, by a machine that forced the paint through the silk, when heated to 860 degree C for 30 min in an industrial porcelain oven. The bar code is directly placed onto the denture surface and cyanoacrylate resin is painted to conceal the marking.[8]

Disadvantage: Incorporating the bar code into the curved denture flange is relatively cumbersome due to rigidity of the laminated strip.

Lenticular Card Method: In this technique a lenticular lens is used to produce images with an illusion of depth, morph, or the ability to change or move as the image is viewed from different angles. Lenticular printing is a multi-step process consisting of creating a lenticular image from at least two or more existing images, and combining it with a lenticular lens. Each image is sliced into strips, which are then interlaced with one or more of the other images. These are printed on the back of a synthetic paper and laminated on the lens The most common materials used for making lenticular images are polyvinyl chloride (PVC), amorphous polyethylene terephthalate (APET), acrylic, spectra, and polyethylene terephthalate glycol (PETG). The lens is incorporated in the channel cut on the denture and auto-polymerizing clear acrylic resin is added around and not on the identifier.[9]

Paper Strip Method: It utilizes onion skin paper. The acrylic resin fitting surface situated adjacent palatally between the ridge and the center of the palate is moistened with monomer on a small brush. The strip of typed paper is laid on this surface and the paper is moistened with the monomer. Clear resin is then placed over the paper before final closure of the denture flask.[10]

RFID Tags: RFID stands for radio-frequency identification, which is a wireless electronic communication technology. The radio-frequency identification (RFID) system consisted of a data carrier, or tag, and an electronic handheld reader that energizes the transponder by means of an electromagnetic field emitted via the reader's antenna. It then receives the coded signal returned by the transponder and converts it into readable data.[11]

Advantages: This method is a cosmetic, effective labeling method permitting rapid and reliable identification of the wearer.

b.) They are preferred because of their small size (8.5×2.2 mm).

c.) A large amount data can be stored in them.

d.) No special training is required to set the tag in the denture.

e.) The chip is resistant to disinfectants and solutions of 1% hypochlorite, 4% chlorhexidine, and 4% sodium perborate.

Photographic Method: In this technique patient's photograph is embedded in the denture with the help of clear acrylic resin.

The name, age and geographic location of the patient are written on the obverse of the photograph using a micro-tip graphite pencil. The marker is particularly useful in the countries with low literacy rate where a photograph is the easiest method of identification.[12]

Advantage: The identity is easily ascertained by lay persons with the unassisted eye.

Incorporation of Min. I. Dent: Patient's details are typed on Min. I. Dent denture identification strip and the strip is heated in an oven at 325 degree C for 30 s to 1 min. This allows shrinkage of lettering or numbers and the strip becomes a chip. The chip is trimmed to required size using carbide bur. A groove is cut into the denture and the chip is incorporated into the groove and sealed with orthodontic resin.[13]

Lead Foil: A piece of lead foil from a used IOPA radiographic film is cut and patient's details are engraved with a sharp pointed pen or instrument and is embedded in the denture with the help of clear acrylic resin.[14]

Advantage: This technique is easy to operate. b.) It is economical. c.) It is radiographically visible.

Ceramic Crown Engraving Method: After baking the opaque layer of porcelain, dentin porcelain is applied and initials of name of the patient or letters are carved with the brush. Stains are applied on carved initials followed by enamel porcelain application shaped with soft brush so that the initials are maintained. Few initials can be carved in crown and bridges due to lack of available space.[15]

Conclusion

Denture marking should be compulsorily carried out for hospitalized patients, unconscious patients and patients in geriatric institutions. There is a strong need to adopt an international policy for denture marking and international collaboration should be encouraged, with different opinions from the world-wide community of forensic odontologists discussed and with the aim of reaching some kind of consensus for the future.

Conflicts of Interest: The authors declare that there is no conflict of interest regarding the publication of this paper.

Repair of Cast Partial Denture Made Easy: An Alternative Approach

Pradeep. S[1]

[1]*Additional professor, Dept, of Prosthodontics, Manipal College of Dental Sciences.*

Abstract

Context: Patients wearing cast partial denture might face breakage of denture due to any reasons. The ideal approach for repair of broken cast partial is electrosoldering. This paper presents an alternative approach for repair of cast partial denture using heat cure acrylic resin.

Keywords: *Repair of denture, Electrosoldering, Cast Partial Denture.*

Introduction

Despite careful planning and competent construction with materials of good quality occasional breakage and distortion of Cast Partial Denture is seen.

Breakage can be either of the acrylic, major or minor connectors, clasps or the tooth. Need for repair may arise due to careless handling by the patient, inadequate mouth preparation, poor construction, metal fatigue,

loss of fit, careless handling in the laboratorary[(1)]. Ideally electro-soldering is used to repair cast partial denture which is a process of building up of a localized area with a filler metal or joining two or more metal components by heating them below their solidus temperature and filling the gap between them using a molten metal. [(2,3)]

This clinical report describes an alternative approach for repair of cast partial denture using heat cure acrylic resin.

Clinical Report: A 51-year-old male reported to the department of Prosthodontics with the chief complaint of broken maxillary cast partial denture. On examination, a fracture was observed on both ends of the longitudinal component (strap) of the major connector that was joining the anterior and posterior palatal strap (Fig.1). To repair this cast partial denture the ideal procedure was electro soldering, but an alternate approach was planned. This clinical report describes an alternate approach to repair the broken cast partial denture using heat cured acrylic resin.

Fig. 1: Broken cast partial denture Fig. 2: Broken Partial denture on cast

Fig. 3: Mechanical grooves for retention Fig. 4: Wax up

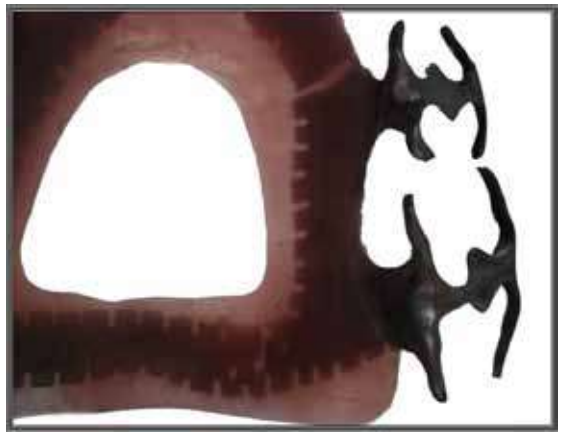

Fig. 5: After acrylization Fig.6: Through light

Fig. 7: Intraoral Placement of Cast Partial

Procedure: An impression of maxillary arch was made using alginate with the broken cast partial denture in place. After retrieving the impression, the cast partial denture was removed from the impression and impression poured in die stone. After the cast had set the fractured fragments of cast partial denture were approximated on the cast (Fig.2). Once approximated, mechanical grooves were made on both ends of the broken cast partial denture using a disc and a mandrel to enhance mechanical bonding between metal and acrylic resin (Fig.3). Wax up of the cast partial denture was completed and it was acrylized in usual manner (Fig.4). The final product was finished and polished to prevent affinity towards food debris (Fig.5). When seen through light the thickness of acrylic resin and the joint can be appreciated (Fig.6). The repaired cast partial denture was then placed intraorally and checked for the fit (Fig.7). Any difficulty in placement or any occlusal discrepancy was eliminated.

Advantages:

1. Comparatively easy to repair
2. Less technique sensitive
3. Economical
4. No complicated equipment required

Disadvantages:

1. Only major & minor connectors can be repaired
2. Can be bulky
3. Less thermal perception
4. Shrinkage can cause distortion
5. Less strength compared to metal
6. If not polished, then can cause irritation

Discussion

Breakage of cast partial denture is very uncommon which can be a result of careless handling by the patient, inadequate mouth preparation, poor construction, metal fatigue, loss of fit, careless handling in the laboratory. Electro soldering is the process by which broken cast partial dentures are repaired which involves the process of building up of a localized area with a filler metal joining two or more metal components by heating them below their solidus temperature and filling the gap between them using a molten metal. Advantages of this technique includes adequate strength in thin sections, less bulky, non-irritating and light weight, whereas disadvantages include technique sensitivity and is expensive.

The technique described in this paper uses heat cured acrylic resin for the repair of broken cast partial denture. The advantages include less technique sensitivity hence easy to repair, economical and less complicated equipments are required. The disadvantages include bulkiness to the cast partial denture, shrinkage of heat cure resin can cause distortion, less strength than metal and if not polished well can cause irritation.

Indigenous Healing Practices and Beneficiaries' Perception

Prakasha Amin[1], Mohan A.K.[2]

[1]Research Scholar, Department of Social Work, Central University of Kerala, [2]Associate Professor, Department of Social Work, Central University of Kerala, Kasaragod, Kerala.

Abstract

Context: For centuries, the concept of indigenous healing has been regarded as a non-invasive medical practice, and despite the development of clinical treatments, many people still depend on it for mental health. It is estimated that in developing countries, 80% of the population living in rural areas depend on indigenous healers for their healthcare needs (WHO, 2001). Despite the establishment of modern hospitals and educational institutions, people from the southern region of Karnataka believe that unnatural occurrences are due to Bhootas (Spirits) and a certain portion of the population attribute mental illness to witchcraft and supernatural causes. In order to overcome these obstacles,people approach healers for a miracle solution. Acknowledging the significant role of the belief system of people seeking the help of traditional healers for various problems, the present study was conducted to understand the perception of the beneficiaries regarding indigenous healing. Based on the findings, the study concluded that the belief system remains prominent in every aspect of the life of individuals who seek the help of healers, while indigenous healers need to be trained in order to provide better mental healthcare to the patients.

Keywords: *Mental illness, Traditional healers, Beliefs, Beneficiaries, and Patris*

Introduction

Beliefs and help-seekingbehaviours are highly correlated and greatly influenced by culture[1] as it significantly contributes in determining the different causes of mental illness, and shapes the treatment process accordingly.[2] It provides an explanation of the causes for the sufferings of the people and ways through which it can heal their problems.[3] It contributes to the manifestation of mental illness and attributes the cause of mental illness as a supernatural power, magical spirit, or possession by evil spirits.[4] More than two-thirds of people with mental illness and their family members have strong belief in the supernatural causation of mental illness, and this belief forces them to consult traditional healers before resorting to modern healthcare.

South India is a land of temples, where belief in the efficiency of 'pujas' and 'temple worship' is very strongly rooted.[5] The practice of traditional healing follows the belief that "various supernatural influences operating in the environment affect an individual's physical and mental health", and pursues treatment for health problems through rituals and spiritual healings performed by healers.[6] Traditional healing therefore, 'the sum total of all the knowledge and practices, used in diagnosis, prevention and elimination of physical, mental, and social imbalance and depending on practical experience and observation handed down from generation to generation'[7].

History of Traditional Healing Practices in India: Initially, traditional healing practice was an integral part of the semi-nomadic and agricultural tribal societies. As per archaeological evidence, the existence of traditional healing can be dated back to 6000 BC,

Corresponding Author:

where reference to evil spirits, possession, black magic, and traditional method of treatment can be found in the Vedas[8]. According to the Atharvaveda, committing of sin in the present or even past life, transgression from the normal divine prescribed course of life, disrespect of gods, witchcraft by enemies, and evil spirits of different types are some of the major factors that lead to different diseases.[9] Apart from the Atharvaveda, the Ashtanga Ayurveda, which builds on the idea that health and illnesses are determined by the balance of various elements, humours,and qualities in the body. Besides the gross physical body, a person is conceived as consisting of two other bodies, the subtle body and the causal body of which only the subtle body is relevant with respect to mental illness.[10]

Characteristics of Traditional Healing: Traditional healing has its own unique characteristics. As observed by Dala K., one of the distinguishing characteristic of the healing practices in rural India is the role of sacredness.[11] The whole weight of the community's religion, myths, and history enters the sacred therapy as the therapist proceeds to mobilize strong psychic energies inside and outside the patient. Traditional healing is considered to be holistic and aims at the overall well-being of the person and it takes the body, self, and society within a framework of dynamic equilibrium. The holistic approach takes into consideration the values, passions, beliefs, social interaction, and spiritual orientation of a person in its healing practices. Most of the healers act as mediators between the physical and the metaphysical. One can frequently find healers who are known for their ability to host a deity or spirit and under whose spell they acquire supernatural powers to control the minds of their visitors and heal them. The healer becomes the medium through which others can communicate with the deities and spirits. They get visions and can dispense favours at will. As diviners, they are presumed to be in direct communication with the supernatural and derive healing powers through divine grace. They are both feared and revered by the local community.[11]

Types of Traditional Healers: Generally,traditional healing can be grouped into two types, viz., 'Swasthik' and 'Tamasik'. They differ in the method and materials used in the healing. The Swasthik form of healing is commonly practiced by people belonging to a higher caste. They are well versed in Sanskrit and have knowledge about the Vedas. The Tamasik form of healing is practiced by the lower castes. They indulge in violent practices and conduct occult practices after midnight or on new moon days in a place of cremation.[12] The practice of traditional healing varies from region to region and is identified by various names. In Rajasthan, folk healers are called bhopas and mantarjanawals, wherein bhopas get possessed by a deity and speak directly to the supplicants. They are usually the attendants of a shrine. Mantarjanawals possess secret and powerful charms through which they treat their clients.[13] In central India, healers are called as Jankars and Barwas. The jankars treat through divination and are believed to be able to find the causes of various problems through divination. The barwas work with the assistance of a superhuman force and get into a self-induced trance by consuming liquor and inhaling camphor.[14] In Tamil Nadu, the devil dance is performed by the mistress of the community. This form of worship and healing is similar to the bhutharadana of Dakshina Kannada and Teyyam of Kerala, which propagates the belief that illnesses and misfortunes are caused 'Bhootas' or spirits.[12]

Rationale for the Study: The coastal region of Karnataka contains several cultural and religious sites, where apart from deities or God, Spirits or Bhootas are also propitiated, and it is believed that illnesses and misfortunes are caused by 'Bhootas'. Despite the establishment of modern hospitals and educational institutions, people of this region believe that unnatural occurrences are due to the Bhootas or devil spirits, and a certain portion of the population attribute mental illness to witchcraft, punishment for sins, and supernatural causes. So to overcome these obstacles,people approach traditional healers for solutions. The treatment is sometimes physically painful and expensive. Hence, this study has been undertaken to understand the factors responsible whereby people approach traditional healers and the type of treatment they receive thereof keeping in mind the significant role of the belief system.

Objectives of the Study: The study has been conducted with the following objectives:

1. To know the demographic details of the beneficiaries of traditional healing;
2. To determine the factors responsible whereby people approach traditional healers;
3. To know the opinion of the beneficiaries about the cause of their present problems; and
4. To find out the remedies as suggested by the healers.

Materials and Method

The present study has adopted the descriptive research design, which provides demographic details of the beneficiaries of traditional healing as well as their opinion about the causes for their problems and the solutions suggested by the healers. People from rural and urban areas of the two districts, i.e., Dakshina Kannada and Udupi, who have sought the help of traditional healers were considered as samples for the study and selected through purposive sampling technique. Altogether thirty beneficiaries, who had approached Mantravadis (Shamans), Naga Patri (Spirit Dancer for the Serpent), Kola and Dharshana cult artists (Spirit Dancer for the Demi-God), and an Astrologer for various problems, were interviewedvia a semi-structured interview schedule at the shrine of the healers.

Findings:

Demographic Profile of the Beneficiaries: The demographic variables of the beneficiaries who sought the help of traditional healer reveals that most of the respondents were male (63.33 percent), and 46.66 percent of the adults who sought the help of healers were self-employed (60 percent), 40 percent had solicited the help of DharshanaPatris, 23.33 percent had met an Astrologer, and 13.33 percent had sought for a solution from Kola cult artists. In order to know whether people seeking the help of traditional healers for their health problems was due to the unavailability of healthcare facilities, the distance between the respective houses of the beneficiaries to the hospital was assessed, and it was found that for 30 percent of the respondents, the distance was 20 km,for 16.66 percent of the respondents, the distance was only 10 km from their home, whereas 20 percent were unaware of the availability of healthcare facilities.

The demographic data of the present study denotes that, in spite of the availability of healthcare facilities nearby people depend on traditional forms of treatment. Similar results were found in an earlier study,[15] which denoted that a large number of people depended upon traditional and complementary healing for all sorts of problems and some portion of thepopulation specificallydepended on healers for psychological problems. This could be due to the broad use of traditional and complementary healing modalities and belief in spirituality and less faith in psychiatric treatments that people depend on traditional healing.

	Variables	Frequency	Percentage
Reasons	Job-related	15	50.00
	Curse of the Serpent	05	16.66
	Health Issues	16	53.33
	Future Prediction	02	6.66
	Addiction	13	43.33
	Possession	03	10.00
	No Hope in Life (Depression)	04	13.33
	Infertility	13	43.33
	Marriage Issues	10	33.33
	Problems with Relationship	02	6.66
	Foreign Visit	13	43.33

It was found in the study that people approached healers for various reasons, which were job-related (50 percent), the curse of the serpent (16.66 percent), marriage issues (33.33 percent), addiction (43.33 percent), health issues (53.33 percent), and depression (13.33 percent). Almost 10 percent of them opined that the major reason for their present problem was spirit possession, and this result was replicated in a similar other study,[16]which found that the respondents attributed possession as the cause for their problem. The result significantly contributes to understanding the cultural beliefs of the people living in the rural area.

Table 03: Opinion of Beneficiaries about the Cause of Present Problem

Opinions	Number of Respondents	Percentage
Unaware	15	50.00
Black magic	03	10.00
Dhosha (Curse)	05	16.66
Curse of the Serpent	03	10.00
Disturbed by the Soul	03	10.00
Uncertainty about Future	1	3.33
Total	30	100

Table 03 denotes shows that 50 percent were unaware of the causes of their problem, 10 percent believed that it was due to the curse of the serpent, few (10 percent) opined black magic (10 percent) as the reason for their sickness, whereas 16 percent felt the reason for their present problem as Dosha (Curse). The findings revealed that the respondents attributed to a supernatural cause (spirit possession and curse of the serpent) for their difficulties. Similar results were identified in other research works[17], where it was noted that most of the rural people (83.55 percent) had opined that black magic was the major cause for their health problems.

Table 04: Remedies Suggested by Healers

	Variables	Frequency	Percentage
Remedies	Herbs / Coconut/ Lemon/ Kumkum	18	60.00
	Homa (A ritual whereinreligious offerings are made to the fire)	03	10.00
	Prayer	06	20.00
	Visit to temples	12	40.00
	Talisman	03	10.00
	Serpent worship	15	50.00
	Consult doctor	03	10.00
	Exorcism	09	30.00
	Removal of black magic	06	20.00
	Solution for dosha (Curse)	09	30.00
	Animal sacrifice	06	20.00

The study attempted to understand the various mental health treatment method adopted by the healers and found that Herbs / Coconut/Lemon/ Kumkum was the common treatment method adopted by the healers (60 percent), exorcism was adopted for spirit possession (30 percent), 40 percent of the beneficiaries were asked to visit temples such as the Dharmastala and Subhramanya, and serpent worship was suggested for 50 percent of the respondents. The findings clearly show that the healers suggested treatments based on the cultural beliefs of the patient. In South India, serpent worship has its own significance in the treatment of mental illness. Even in the present study, most of the healers suggested this remedy to their clients, who presented complaints of possession.

A couple of studies[18,19] showed similar results, where the healers had prescribed remedies for problems based on the cultural beliefs of the patients. It is believed that the various cultural beliefs and practices associated with mental illness persuade the patient and his/her family members to delay seeking professional help. Apart from cultural beliefs, there are various other factors associated with the method of treatment suggested by the healers

such as the level of education of the healers, nature of the problem, and the financial status of the client.

Recommendations: This study reflects the influence of culture on the health-seekingbehaviour of the patient, who delays in seeking psychiatric care. So there is a need for sensitizing healers in early identification for optimum management of mental disorders and to ensure timely referral of the patients to psychiatrists. Mental health professionals need to comeforward to enhance the knowledge ofthe general public on mental health issues, and proper mental health policies need to be developed with due consideration towards the cultural beliefs and practices of the people and the healers. The indigenous forms of psychotherapy may effectively treat certain psychological diseases, and therefore, indigenous healers need to be trained in order to provide better mental healthcare to the patients.

Conclusion

The association between culture and mental illness is deep rooted in our country and will continue in the future. The present study denotes that strong cultural beliefs of rural people force them to depend on religious and spiritual healing. The study has covered a minimum population, so it would be difficult to generalize the result, but in spite of the availability of healthcare services in districts like Udupi and Dakshina Kannada, people depend on folk healing. So it is necessary to create awareness among people and orient them to follow modern mental health services.

Conflict of Interest: I declare no conflict of interest.

Effectiveness of Distraction Versus Cutaneous Stimulation on Venipuncture Pain Response among Children

Prini Varghese[1], Ahalya V [2], Aiswarya Kuriakose[3]

[1]Lecturer, Department of Child Health Nursing, Amrita College of Nursing, Amrita Vishwa Vidyapeetham, Kochi-41, Kerala, [2]IV Year B.Sc Nursing students, Amrita College of Nursing, Amrita Vishwa Vidyapeetham, Kochi-41, Kerala

Abstract

Introduction: Intravenous procedure is invariably painful for children. Non-pharmacological techniques such as distraction and cutaneous stimulation provide coping strategies that help to manage and reduce perception of pain and decrease anxiety without medications.

Aim: To compare the effectiveness of passive distraction (group I) versus cutaneous stimulation (group II) on venipuncture pain response among children.

Materials and Method: A quantitative two group post-test only single centered study was conducted among 100 children, between the age group of 3 to 7 years attending a selected hospital and undergoing venipuncture at a given time. OUCHER Scale (Asian Version- Male and Female) was used to assess pain responseto compare the effectiveness of passive distraction and cutaneous stimulation aimed at decreasing pain by applying ice pack over the site of procedure. The comparison of effectiveness of interventions wascomputed by using independent't' test.

Results: The result showed that the mean pain score of group I (passive distraction) and group II (cutaneous stimulation) was 4.68±2.66 and 3.48±2.16, which was statistically significant ($p = 0.01$).

There was a significant association between selected clinical aspects of children like being afraid of coming to hospital, being hospitalized and fear of needles with the pain score at $p< 0.05$ among children received distraction technique, whereas there was no association between the selected clinical aspects of children with the pain score in group received cutaneous stimulation.

Conclusion: In the present study cutaneous stimulation was found more effective pain relieve strategy than passive distraction during venipuncture.Hence, all the health care professionals should use optimal non-pharmacological pain management techniques in all aspects of paediatric practice and improve children outcomes to an extent as possible while maintaining high quality health care.

Keywords: *Passive distraction, Ice pack application, Non pharmacological techniques.*

Introduction

The experience of illness and hospitalisation is an unpleasant and stressful condition which often requires various examinations, investigations, treatment or procedures that are associated with pain, anxiety and fear in children. The International Association for the Study of Pain (IASP) defines pain as an unpleasant

sensory and emotional experience associated with actual or potential tissue damage. Children are vulnerable and under-served population and every child has different perception of pain, and the meaning of pain also differs from child to child[1].

The most frequently performed minor invasive procedures by nurse is venipuncture but for children the procedure-related pain can be worse than that of the illness itself [2]. Children requiring needle stick such as injections, IV cannulation and blood sampling view these procedures as frightening and painful. Since, children have little experience and understanding of the pain and disease process, unfamiliar and negative feelings can cause intimidation and considerable distress for them[3,4]. Hence, managing procedural anxiety and fear can provide both short term and long term benefits by increasing adherence and reducing avoidance behaviour in medical care[5].

Pediatric pain management entails the use of pharmacological and non-pharmacological interventions to control pain[6]. Non-pharmacological techniques such as distraction, relaxation, guided imagery, hypnosis, music therapy, acupuncture and cutaneous stimulation provide coping strategies that help to manage and reduce perception of pain and decrease anxiety without medications. Non-pharmacological procedures or techniques are generally less expensive and can be performed independently by a nurse. It also helps to avoid potential drug's side effects, decrease anxiety, provide a sense of control, enhance comfort and promote rest and sleep[7].

Focussing one's attention on pain makes the pain worse and getting the attention away from the pain reduces its severity. Distraction is a cognitive-behavioural intervention which draws attention or engaging a child in a wide variety of pleasant activities which helps children to focus attention on something other than pain and the anxiety. A narrative review was conducted by Vetri Buratti C, et al,[8] found that active and passive distraction techniques to be extremely effective in reducing distress and pain in children undergoing venipuncture.

In interactive distraction the child cognitively engages with the distracting stimulus whereas in passive distraction, child visually or auditory observes the distracting stimulus. The distraction activities such as listening to music, singing a song, blowing bubbles, playing a game, watching television or a video, focusing on a picture while counting, guided imagery and breathing techniques, helps to increase the tolerance for pain, facilitates coping and decrease the sensitivity for pain[9].

MacLaren J E, et al [10] and Bellieni C V, et al [11] conducted a study on comparison of distraction strategies for children receiving venipuncture and found passive distraction was more effective than active distraction, as the children's distress interfere with their ability to interact with the distractor.

Cutaneous stimulation is defined as stimulation of the skin and underlying tissues for the purpose of reducing pain impulses, muscle spasm or inflammation. Cutaneous stimulation is a physical intervention performed by several method such as simple rhythmic rubbing, use of pressure or electric vibrators, massage with hand and application of heat or cold at the site before injection. Cold application relieves pain by slowing the ability of pain fibers to transmit pain impulse and decrease the sensitivity of tissues and create a sensation of numbness, thus it can be used as a local anesthesia for short periods[12]. An experimental study was conducted by Ahmed Alalo F M, et al [13] in 2016 to examine pain intensity after an ice pack application prior tovenipuncture and the results revealed that the application of an ice pack was effective in reducing pain intensity among children.

Perception of pain in paediatrics is complex, and encompass physiological, psychological, behavioural, and developmental factors[14]. Even though non-pharmacological techniques are effective in reducing procedural pain in children but the professional practice of nursing within the Pediatric environment is challenging and it is often not being effectively applied[15].

The above review of literature emphasizes that non pharmacological techniques are effective in reducing procedural pain. Hence, the present study was undertaken with the aim to compare the effectiveness of passive distraction versus cutaneous stimulation on venipuncture pain response among children.

Materials and Method

A quantitative two group post-test only single centered study was conducted among 100 children between the age group of 3-7 years. Permission to conduct the study, ethical clearance certificate and a

written informed consent was obtained before starting data collection.

The study subjects,who met the inclusion criteria were selected by simple random sampling (lottery method) and assigned in two equal groups (group I- distraction technique group and group II- cutaneous stimulation group).

Hypothesis: $H_{1:}$ There is significant difference in pain response after intervention between group I and group II during venipuncture.

The Data Collection Instruments Included:

Tool I: Semi structured interview schedule for collecting demographic data of children and

Tool II: OUCHER Scale(Asian Version- Male and Female) [16]was used to assess pain responseto compare the effectiveness of passive distraction, by drawing attention of the child away from pain showing film video songs and cutaneous stimulation, that refers to the stimulation of the skin and underlying tissues aimed at decreasing pain by applying ice pack over the site of procedure for 3 minutes.

The comparison of effectiveness of interventions with distraction versus cutaneous stimulation was computed by using independent 't' test (Levene's Test for Equality of Variances) IBM SPSS Version- 20.0. The association between the pain score of subjects in group I and group II with the selected aspects of child was computed using chi-square test.

Result

In the present study the mean age of children of group I was 4.84 ±1.34 and of group II was 4.94 ±1.45. Majority (72%) of the children attended OPDs because of fever. Majority of the children (72%) accompanied their mothers, 21% with fathers and 7% with grandparents. Majority of the parents belonged to the age group of 20-30 years.

Table 1: Comparison of the effectiveness of distraction versus cutaneous stimulation on venipuncture pain response among children n=100

Groups	N	Mean	SD	T value	P value
Group I (Distraction technique)	50	4.68	2.66	2.47	0.01*
Group II (Cutaneous stimulation	50	3.48	2.16		

* Significant at 0.05 level.

Table 1 shows that there was a significant difference in pain response (P=0.01) after intervention between group I and group II during venipuncture. n=100

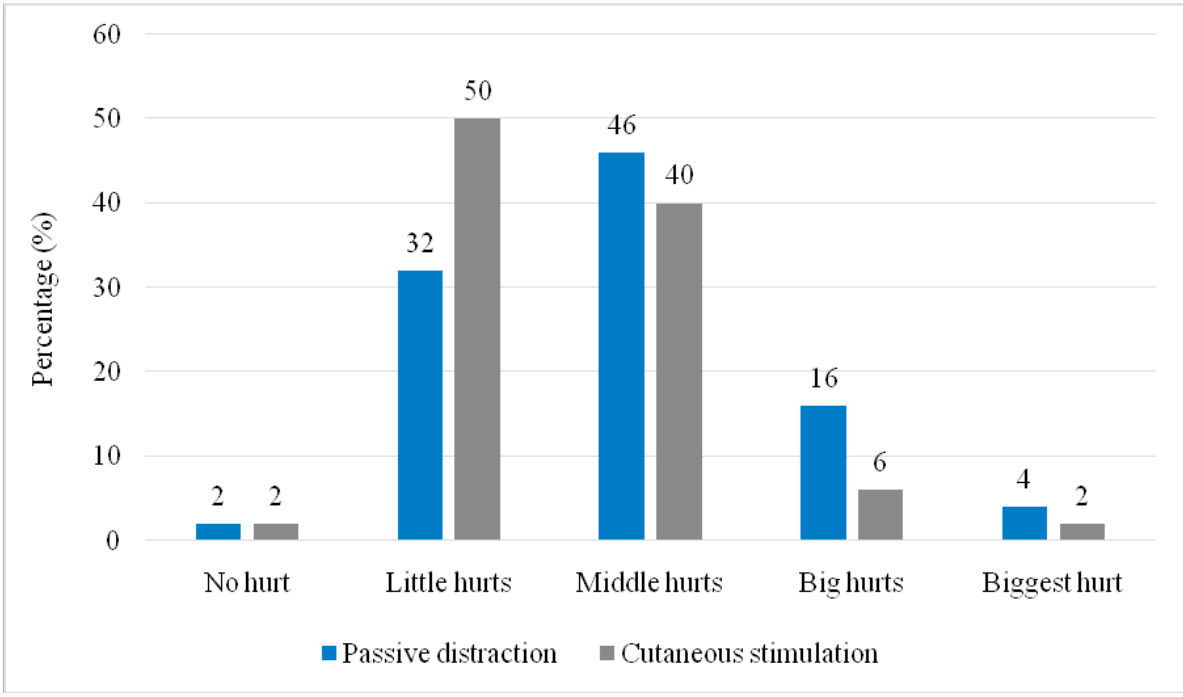

Figure 1: Percentage distribution of pain score of subjects of group I and group II during venipuncture

Discussion

The present study results shown that the mean pain score (4.68±2.66) of group received distraction therapy during venipuncture were comparatively more than that of group received cutaneous stimulation (3.48±2.16). The findings of the present study was supported by the study conducted by Kiran N et al[17]which revealed that icepack application significantly decreases pain during venipuncture. A study was carried out by Hasanpour M, et al[18]to evaluate the effect of local cold therapy and distraction in pain relief using penicillin intramuscular injection in children and found that thelocal cold therapy was effective in reducing IM injection related pain. This study findings were contradicted by Sahar Mahmoud El-Khedr Abd El-Gawad, et al[19] in which interactive distraction technique had a positive pain relive effect and was betterthan cutaneous stimulation in relieving children's pain during vein-puncture.

A quasi-experimental study was undertaken by James J, et al[20]revealed that use of animated cartoon as a distraction strategy has a significant effect on reducing the perception of pain among children at pre, during and post venipuncture. Whereas in a survey done by the researcher before the present study, revealed that more than watching cartoon videos, the children were more interested and get distracted by watching the film song videos. Hence, in the present study, children were distracted by showing the new film song videos.

Environmental and psychologic factors exert a powerful influence on children's pain perceptions. Children's reaction to pain are influenced by their developmental age, their previous experience with illness, separation, their innate and acquired skills and the support system available.

In the present study the association between the pain score of children with the selected demographic variables like age of the child, gender, area of residence, birth order of the child, parental age, number of children in the family, relationship of family member to the child, previous hospitalization, previous experience of venipuncture were not significant at $p < 0.05$ in both group I and group II. Whereas, few earlier studies noted and recognized that females suffer more pain than males. In a study conducted by Gaikwad N S, et al[21]to assess the effectiveness of ice application on pain response prior to intravenous procedures among children, revealed that there was significant association between pain scores with age of children ($\chi 2 = 8.816$), gender of children ($\chi 2 = 5$), and weight of children ($\chi 2 = 4.909$) in experimental group.

The findings of present study revealed that there was no influence of relationship of family member to the child on level of pain perception but the presence of parents during blood draw helped the children to remain more comfortable whereas, in a study conducted in Chandigarh by James J[20] reported that the perception of pain in children was significantly less when father was present with the child as compared to mother or grandparents. This may be due to the increased stress and anxiety among mother and grandparents compared to the father, which influenced the child.

In the present study there was a significant association between selected aspects of child like being afraid of coming to hospital, history of previous hospitalization, previous venipuncture and usual reaction of the child to the venipuncture with the pain score at $p < 0.05$ among children received distraction technique, whereas there was no association between the selected clinical aspects of children with the pain score in group received cutaneous stimulation.

Attending hospital itself is a stressful situation for children. In the present study, all children had previous experience of injections or blood draw, hence on entering the treatment room itself most of the children were distressed. Patient's expectations of how much pain they should have also influence how much pain they feel[22].

In the present study the researcher found implementing cutaneous stimulation was comparatively easier than distraction technique for children between the age group of 3-7 years. Ice is been used from long ago as a topical pain reliever but ice pack should not be applied for longer time as it can cause local vasoconstriction, which can delay the absorption of drug, thus should be avoided in cases requiring quick drug absorption.

Implementing non-pharmacological method in the hospital is an independent nursing intervention and children between the age group of 3-6 years use transductive reasoning as they lack understanding of cause and effect relationships. Therefore, unnecessary pain can harm the nurse-patient relationship, whereas proper knowledge and use of alternative techniques can improve patient care and satisfaction that will bring the best possible outcome for their patients in each unique scenario.

Limitation: The limitation of the present study was the fear and distress of the children from previous pain experience prior to the procedure which facilitated less cooperation during the procedure. Hence, a few cases, the researcher found difficult to distract and refocus the attention of a child away from pain and anxiety during venipuncture and they were excluded.

Conclusion

Non pharmacological techniques are easy to apply, safe, non-invasive, inexpensive and have a positive pain relief effect during venipuncture, which give the child a sense of control over the situation and their behaviour. There was significant difference in pain response after intervention between passive distraction and cutaneous stimulation. In the present study cutaneous stimulation was found more effective pain relieve strategy than passive distraction during venipuncture. Hence, allthe health care professionals should use optimal non-pharmacological pain management techniques in all aspects of paediatric practice and improve children outcomes to an extent as possible while maintaining high quality health care.

A Study on Customer Attitude and Shopping Intention Towards Health Care Products

R. Sharmila[1], .M. Kavitha[2]

[1]Ph.D Research Scholar, Vels University, Pallavaram Chennai, [2]PG Professor, & Research Supervisor, Department of Commerce, VISTAS, Pallavaraam, Chennai.

Abstract

Context: The study aims to identify various factors that influence purchase intention towards health care products. The study purpose of the paper is to recognize various purchase intention factors. A survey of 100 respondents was carried out with the help of the questionnaire. The researcher used Anova and Regressison analysis to check the hypothesis and to analyse the data. The result identified various attracting features that lead to purchase of health care product. Involvement and awareness towards healthy life style and time management played great impact over the customer shopping intention. This paper provide insights to the manufactures of health care products about the various determinants that the customer consider being most important and significant contributor in decision making process before making the purchase.

Keywords: *Health care products, Customer attitude, Shopping intention*

Introduction

Health care products are being purchased by lot of the customer. Health care products involves gym equipment's, fitness drinks, organic products, Blood pressure apparatus, Thermometer and weighing scale etc. People purchase these products irrespective of their profession. The customer in the urban areas increasingly showing interest to purchase more of the health care products. People in this era gain whole lot of information about health related issues from various sources. With the introduction social media application such as Facebook and other application are loaded with various influencers. Most of the influencers based on the experience without having professional degree influencing people to purchase health care products. The influencer are being followed by lot of the people. There are various factor that influence customer to purchase the health care products.

The study consist of four factors such as involvement and awareness towards healthy life style, increased beauty consciousness, Cost effective and time management. People are involved highly towards leading healthy life style because of the various information available over the various sources. The health care products customer showing constant interest towards beauty consciousness. Products like vitamin c capsule and biotin capsule are taken by the women for take care of their skin routine and also maintain healthy hair. The cost effective factors also influence customer purchase intention. Every time customer finds it difficult to get appointment to the doctors to their busy life. The customer try be to very rational on spending their each and every penny. They tend to monitor their health at the home with some basic knowledge. Most of the customer try to take treatment at their home trying to solve the health issue with natural remedy. The next factor is time management. The customer in the urban areas are busy on doing their chores. Instead of running to hospital people find it easy to monitor their health at the home. These factors are influenced by the customer attitude which in turn these attitude strongly make customer to affect shopping intention of the customer. The results designate that various factors have impact on the consumers while purchasing health care products. The

outcomes have very strong inferences tomanufacturers of health care products.

Review Of Literature: Moschis, (2008)The article points the inclinations and promotioninferences of the advanced customer division. The study focused only on health□care products and services. The article concluded with a huge deviation found inside the customer mature market division with respect to numerous marketing health□care offers. The study offered the suggestion to the marketers of health care products to produce products and the various services in accordance to the need of the established consumer division[5].

Paulus,(2000)The article paper focus on the theory of Pareto. The study analysed if the alteration attempted towards the united health care affects income distribution pattern. The article result shows that commencement of combined health care adds value to those who need care services, provider's givers of informal care[6].

Marshall(2009), The study article concentrates on the health care system that are prevailed around the USA, various plans that are listed on the insurance. The study also addresses the customer driven health care related plans andconvention regarding various service providers. The study objective is toexplore thesocial marketing needs of customer driven health care.The study concluded with a various suggestion on where and which part research must be conducted in the respective topic on the future study[3].

Yeon Kim (2011) This article is about the customer shopping behaviour towards the organic personal care products. The study addressed the diminishing effect on customer attitude and the shopping intention relationship. The article concludes that atmospheric awareness and exterior awareness influence customer attitude positively toward chemical free personal care products. The study came with suggestion on effectives strategies used in marketing to raise the shopping intention to buy chemical free products[8].

Srinivasan, R. (2016)The researcher analysed Himalaya Company in this study. The study focused on the various strategy that Himalaya face to stay concentrate on difference plan. The study concluded with the reason of focused differentiation to pay higher for competitor than its other competitor. The study also demonstrate on how Himalaya overcome such limits[7].

Guo, K. (2005), This study focus on the health care sector. The approach is made on the service management line. The study concluded with the suggestion to the managers of health care toapprehend and drill the 4 key points to focus effectively on how to become effective health care leaders. The study also give use full information on the health care in the service line management approach[2]

Moschis, (2013), The article focus on the preference of the customers for the data sources. The study showed innumerable approaches of shopping recommendation for medications and makeups items. The study pointed the specific explanation on why customer choose particular medication stores and people preference to rely on very particular brand and health related issues. The study on the article employed large date from the national level and study demanded various analytical procedures. The result of the article concluded with various plans to effectively appear to aged consumers on the whole and as well to the other specific lines on the areas[4].

Anthony. D. Ross (2009), The study focus on the problem related purchase on the area relating to health care. The studies focused on the new and second hand products on the emerging large health care providers. The study proposed a methodology for assessing research on large health care providers and in making decision. The study conclude with recommendation on various screening and choosing customers to be able to offer the new and second hand products[1].

Objectives of the Study:

1. To study the demographic profile of the customer who purchase health care products
2. To find the impact of health care products on customer attitude and shopping intention

Hypotheses of the Study:

1. There is no significant difference on demographic profile of the customers who purchase health care products
2. There is no significant impact of health care products on customer attitude and shopping attention

Result and Discussion

The researcher adopted opportunity sampling method to get the information from the respondents. The study was conducted around the Chennai city.

The Chennai city has variety of health care service providers and variety of income group of people which is one of the most vivacious metropolitan in South India. The Questionnaire circulated to 100 members. The questionnaire consist of three parts. The first part consist of demographic factors. The second part of the questionnaire consist shopping habits of the customer who purchase health care products. The third part of questionnaire are framed according to the Likert scale. The statistical data was done using SPSS. The researcher employed Anova test to check significance for the demographic factors and Regression test was used to find the Impact for the study.

Influence Of Monthly Income Of The Customer Perception Towards Shopping Intention Of Health Care Products.

Table 1: ANOVA

		Sum of Squares	df	Mean Square	F	Sig.
H1	Between Groups	401.361	1	401.361	81.035	.000
	Within Groups	485.389	98	4.953		
	Total	886.750	99			
H2	Between Groups	356.295	1	356.295	353.606	.000
	Within Groups	98.745	98	1.008		
	Total	455.040	99			
H3	Between Groups	409.417	1	409.417	138.673	.000
	Within Groups	289.333	98	2.952		
	Total	698.750	99			
H4	Between Groups	39.883	1	39.883	12.830	.001
	Within Groups	304.627	98	3.108		
	Total	344.510	99			

It was presented in the above table H1Involvement towards healthy life style (F= 81.035, P=.000) H2 Increased beauty conscious (F=353606, P=.000)H3 Cost-effectiveness (F=138.673, P=.000) H4 Time management (F= 12.830, P=.001) are statistically significant at 5% level.

Influence Of Employment Status Of The Customer Perception Towards Shopping Intention Of Health Care Products

Table 2: ANOVA

		Sum of Squares	df	Mean Square	F	Sig.
H1	Between Groups	710.529	3	236.843	129.026	.000
	Within Groups	176.221	96	1.836		
	Total	886.750	99			
H2	Between Groups	386.983	3	128.994	181.956	.000
	Within Groups	68.057	96	.709		
	Total	455.040	99			
H3	Between Groups	180.418	3	60.139	11.138	.000
	Within Groups	518.332	96	5.399		
	Total	698.750	99			
H4	Between Groups	113.296	3	37.765	15.680	.000
	Within Groups	231.214	96	2.408		
	Total	344.510	99			

It was presented in the above table H1 Involvement and awareness towards healthy life style (F= 129.026, P=.000) H2 Increased beauty conscious (F=181.956, P=.000) H3 Cost-effectiveness (F=11.138, P=.000) H4 Time management (F=15.680, P=.000) are statistically significant at 5% level.

Regression Analysis. 1: In this regression analysis table 1, table 2, table 3 Customer attitude acts as intermediate variable between the factors and shopping intention of the customer. So the customer attitude is treated as a dependent variable and the other factors are considered as independent variable for the analysis

Table 3: Model summary

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.749[a]	.561	.543	.881
b. Dependent Variable: att_sum				

From above table it is found that r = .749 r square = .561 and adjusted r square .543. This implies the factors create variance over the customer attitude. The cumulative influence of four variables of customer attitude is ascertained through the following one way analysis of variance.

Table 4: ANOVA[b]

Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	94.393	4	23.598	30.411	.000[a]
	Residual	73.717	95	.776		
	Total	168.110	99			
a. Predictors: (Constant), ss_sum, he_sum, fiv_sum, lbi_sum						
b. Dependent Variable: att_sum						

Table 2 presents that F= 30.411.107 p= .000 are statistically significant at 5 % level. This indicated all the four variable cumulatively responsible for customer attitude. The individual influence of all this four variables is clearly presented in the following co-efficient table.

Table 5: Coefficients[a]

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		B	Std. Error	Beta		
1	(Constant)	8.698	.898		9.685	.000
	H1	-.297	.054	-.683	-5.511	.000
	H2	-.168	.090	-.276	-1.863	.066
	H3	-.073	.059	-.104	-1.227	.223
	H4	.427	.048	.871	8.978	.000
a. Dependent Variable: att_sum						

From the above table it shows that H1 Involvement and awareness towards healthy life style (Beta=-.683, t=-5.511, p=.000), H2Increased beauty conscious (Beta= -.276, t=-1.863, p=.066), H3 cost –effectiveness (Beta=-.104, t=-1.227, p=.223), H4 Time management (Beta=.871, t=8.978, p=.000). The Involvement and awareness towards healthy life style and the Time management factor are significant statistically at 0.05. This indicates that the involvement and awareness towards healthy life style and time management factors affects attitude of the customer to purchase health care products.

Regression Analysis. 2: In this regression analysistable 1, table 2, table 3 Customer attitude acts as intermediate variable between the factors and shopping intention of the customer. Here in this part table 3,4,5 the customer attitude is treated as independent variable and the shopping intention factor are considered as dependent variable for the analysis.

Table 6: Model Summary[b]

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.923[a]	.853	.846	.902
a. Predictors: (Constant), si_sum				
b. Dependent Variable: att_sum				

From the above table it is found that r=.923r square= .853 and adjusted r square = .846. This implies the factors create variance over the shopping intention of the customer. The cumulative influence of purchase intention is ascertained through the following one way analysis of variance.

Testing of Hypotheses:

1. There is no significant difference among the demographic factors of the customers who purchase health care products - Rejected
2. There is no significant impact of health care products on customer shopping intention- Rejected

Findings and Conclusion

The present study had given information about various factors that influence customer attitude to purchase a health care products. This study gives insights to the manufacturers to look out the customer attitude that affect shopping intention towards health care products. The outcome of the paper suggests manufacturers to focus on all the other factors that affect the customer buying attitudes and shopping intention to purchase health care products. The study also has some limitation. The data collected are only in Chennai city. The sample was also restricted to 100 only. The questionnaire was issued to customer who purchase health care products. The opportunity method on sampling done for the study, thus inherently brings all limitation to it. Finally this finding may not be applicable to the other geographical areas.

- The factors determining customer shopping intention of health care products are Involvement and awarness towards healthy life style, Increased beauty consiousness, cost effectivness and time management.
- The following factors such as involvment and awarness towards healthy life style, Time management, Since urban areas peoples today are showing interest towards healthy life style as peoples life span of the are getting lower when compared to our before generations. And for the second factor time management, people these days are running out of their time in the busy bee life. People find it difficult to spend time even for the families so people considering time management they tend to purchase the health care products to monitior health realted issues.

Oral Health Literacy and its Relationship with Level of Education and Self: Efficacy among Patients Attending a Dental Rural Outreach Clinic in India

Shatakshi Srivastava[1], Shashidhar Acharya[2], Deepak Kumar Singhal[3], Abhishek Dutta[4], Kush Kalra[5], Nishu Singla[6]

[1]Lecturer, Dept. Of Public Health Dentistry, MGM Dental College and Hospital,Navi Mumbai, Maharashtra, [2]Professor, Dept. Of Public Health Dentistry, Manipal College of Dental Sciences, Manipal , Manipal Academy of Higher Education (MAHE), Karnataka, [3]Associate Professor, [4]Lecturer, [5]Senior Lecturer, [6]Associate Professor, Dept. of Public Health Dentistry, Santosh Dental College, Santosh University, Ghaziabad, U.P.

Abstract

Objective: To evaluate the relationship between Oral health literacy (OHL) with the level of education and self-efficacy among adults (age 18-77 years) patients attending a dental outreach clinic in Udupi Taluk.

Basic Research Design: A cross-sectional study of adult patients attending a dental outreach clinic by convenience sampling.

Method: Information was obtained about patient's sociodemographic factors along with the self-efficacy by using Dental Copings Belief's scale (DCBS) questionnaire and OHL was assessed by using a word recognition instrument Rapid Estimate of Adult Literacy in Dentistry (REALD-30).One way ANOVA and Pearson's χ^2 test were used for analysis.

Participants: 200adult patients age range of 18- 77 years who wanted to seek dental care in a dental outreach clinic.

Main Outcome Measures: Oral health literacy (OHL) and Self efficacy (DCBS).

Results: In this study the OHL was significantly associated with the level of education of patients.Among the 200 subjects who claimed to be able to read and write English language andhad completed education till class 10^{th}; more than 50% of the subjects had Low (≤21)OHL scores.Only 12.5% of the total study population had High OHL (≥26) and were clearly able to understand simple dental terminology. Moderate levels of literacy was recorded in 75.6% in graduate and postgraduates indicating that even these people partially understood dental terms. There was no significant association between oral health literacy and self-efficacy.

Conclusion: Ourstudy suggests level of education to be a strong indicator of the OHL in the Indian Population. Further research to develop new instruments to measure the OHL, in a culturally diverse country like India, which has people of different mother tongues should be encouraged.

Keywords: *Oral health; health literacy; self- efficacy; community outreach*

Introduction

The concept of Oral health literacy (OHL) has developed over several years and the existing literature is ever increasing in this field. Health literacy refers to the ability of individuals to obtain, understand and act upon health information and to make appropriate health decisions. [1-3]Oral health literacy (OHL) refers to the

degree to which individuals have the capacity to obtain, process and understand basic oral health information and services needed to make appropriate health decisions.[4] This concept has not yet gained sufficient weight age in regular dental practice.

Oral Health literacy is like a bridge between the dental care provider's instructions and the comprehension, thereby abiding of the patient to the same. This role of OHL makes it important for the dentist to ascertain the level of OHL of the patient before any procedure and then treat the patient according to the level of understanding of the patient. After identification of the level of OHL attention should be paid by the dentist to communicate with the public and remove literacy-related barriers to information, decision making, and healthful action.[5] A significant number of patients may have a low level of oral health literacy, which possibly interferes with their ability to process and understand oral health information. Providers should identify patients who are having difficulty understanding and using dental health information and address their needs. [6]

According to Paasche-Orlow and Wolf conceptual model of causal pathways between health literacy and health outcomes the effect of literacy on health outcomes is mediated by patient-level and extrinsic factors grouped as [1] access to and utilization of health care, [2] provider–patient interaction, and self-care.[7] Many factors are related to OHL but amongst the recent ones focus has been given to those that affect behavior because behavior is amenable to change. A successful dental practice is not only related to dental treatment provided, but also to the patient's attitude and behavior towards the treatment.[8] Individual health practices such as oral self-care are based on personal choices.[9] According to the model proposed by Lee et al., Personal characteristics such as self-efficacy mediate and/or modify the impact of literacy on oral health behaviors.[10]

Self-efficacy-Perceived self-efficacy is concerned with people's beliefs in their capabilities to produce given attainments.[11]Perceived self-efficacy is a judgment of capability to execute given types of performances and outcome expectations are judgments about the outcomes that are likely to flow from such performances. Perceived efficacy has a pivotal role because it affects behavior and its impact on other determinants such as goals and aspirations; outcome and expectations. Self-efficacy appraisals reflect the level of difficulty individuals believe they can surmount.[11]

The aim of the present study was to evaluate the relationship between Oral health literacy (OHL) by using Rapid Estimate of Adult Literacy in Dentistry (REALD-30)with the level of education and self-efficacy by using a questionnaire on Dental Coping Beliefs Scale (DCBS) among adult (age 18-77 years) patients attending a dental outreach clinic in Udupi Taluk.

Objectives:

1) To evaluate the Oral health literacy in adults visiting a dental outreach clinic in India by using word recognition instrument- Rapid Estimate of Adult Literacy in Dentistry (REALD-30).
2) To evaluate the Self-efficacy using Dental Coping Beliefs Scale (DCBS) questionnaire in the same subjects.
3) To evaluate the relationship between OHL with level of education.
4) To evaluate the relationship between OHL and self-efficacy.

Method

Sample and data collection- A convenience sample of participants (N=200) was recruited from patients presenting for an initial consultation to a dental rural clinic in Udupi. Written informed consent was obtained for all study participants. Study Design-A Cross-sectional questionnaire study. Inclusion Criteria were-subjects who claimed to be able to read English words, subjects more than 18 years of age but younger than 80 years, subjects who had completed education till a minimum of 10th class, subjects without cognitive impairment, subjects without vision or hearing problems and subjects without obvious signs of drug/alcohol intoxication. Exclusion Criteria: were subjects who are not able to read English words, subjects less than 18 years of age and more than 80 years, subjects who have completed education less than 10th class, subjects not willing to participate in the study, subjects with psychiatric disorders and subjects with other severe systemic illness. Ethical clearance was obtained from the Kasturba Hospital Ethics Committee, Manipal before commencement of the study(IEC 277/2014). Informed consent was obtained from all patients prior to the start of the study. The Oral Health Literacy Assessment was done using REALD-30 which is a word recognition instrument which has 30 dental related words arranged in order of increasing difficulty.[12] The words were read

aloud by the subject to the interviewer. The participants were asked not to phonetically deduce the words, but rather to skip a word if they did not know it. One point is given to each word pronounced correctly (zero point if incorrectly). The REALD-30 score was categorized as Low (≤21), Moderate (22 to 25) or High (≥26).[13]

In addition to the above, each patient completed a questionnaire regarding Self-efficacy. This questionnaire was a part of Dental Coping Beliefs scale (DCBS).[14] The participants were asked to mark only one response to each question. Total Self- efficacy was calculated by adding each of the responses. It had 9 questions and the responses were recorded on a Likert scale. The responses were-(1) Strongly agree, (2) Agree, (3) Neither, (4) Disagree and (5) Strongly disagree. Additionally, socio-demographic data was included in the questionnaire -Age, gender, education, occupation, monthly income.

Data Analysis: Statistical analysis was performed using SPSS (version 16.0).One way ANOVA was used to assess the relation between REALD-30(categorized-low, moderate, high)and self-efficacy (continuous variable). Pearson's $\chi 2$ test was used to assess association between education and REALD-30. The level of significance was set at 0.05.

Results

The study population consisted of 200 English speaking adults who visited the dental outpatient clinic. Questionnaire was administered to 200 adults and the response rate was 100.0%.The mean age of the respondents 38.33 years who were in the age range of 18 to 77 years. Among the respondents 41% were males and 59% were females. An individual's completion of the entire questionnaire was ensured by checking for it during the oral health examination. The respondents were asked to complete the incomplete forms. The demographic characteristics of the participants are presented in Table 1. The distribution of REALD-30 is presented in Table 2 of which 12.5% people have high OHL, 30.5% have moderate OHL and 57.0% have low OHL. Self-efficacy in results have been presented in Table 3. The self-efficacy range is 9-29 with a median of 18.0. The co-relation between REALD and Self efficacy was analyzed by One way ANOVA and presented in Table 4. There was no significant association between OHL and self-efficacy. Pearson's χ^2 test was used to test for association between Education and REALD has been presented in Table 5. The OHL was significantly associated with the level of education of patients. 6.0% of the participants completed high school education, 33.0%Intermediate/PUC, 58.5% Graduate/Post graduate and 2.5% Profession/ Honors.

Table 1: Distribution of study participants according to socio-demographic characteristics

Variables		Participants (%) N=200
Gender	Male	82 (41%)
	Female	118(59%)
Age (years)	Mean	38.33
	Range	18-77

Discussion

The aim of this study was to evaluate the oral health literacy (OHL) and its relationship with self-efficacy among adult patients attending a dental outreach clinic. To the best of our knowledge this is the second study done in India to assess the OHL using REALD-30 as the assessment tool and the first study done to look closely into the association between OHL and self-efficacy in an adult Indian population in an outreach dental clinic. In this study the OHL was significantly associated with the level of education of patients which is similar to the findings of another study on Health Literacy.[15]

The dental copings beliefs scale was used to assess self-efficacy. DCBS helps the oral health professional in understanding a patients' belief either in internal or external controls and also the ability to which patient perceives himself/herself to be able to perform given tasks.[14] In the present study, there was no significant association between oral health literacy and self-efficacy. The self-efficacy has been assessed using a self-reported questionnaire, thus this finding could be attributed to the social desirability bias.

Among the 200 study English speaking subjects who had completed education at least till 10th class, who participated in the study OHL scores were very low in more than 50% of the subjects (57%-low OHL). These subjects scored less than 21 which mean these patients are likely to struggle to understand simple dental terminology which is used by the dentists while communicating to the patients. Only 12.5% of the total study population had High OHL (≥26).This means only a little more than 10% of the whole of the study population is actually clearly able to understand the dental terms used by the dentists. Only moderate levels of literacy was recorded in 75.6% in graduate and postgraduates indicating that even these people understand only some of the dental terms and not all. The findings in the present study indicate that even in an Indian population with a basic level of education who are able to read and write in English have low levels of Oral health literacy. Similar findings are reported by M D'Cruz et al.,2014. [16]

Demands for reading, writing, and numeracy skills are intensified due to health-care systems' complexities, advancements in scientific discoveries, and new technologies. In this study there was no significant association between Oral health literacy and caries status and periodontal status. This could be attributed to the fact that the oral health literacy was taken by a word recognition instrument the REALD-30 which has several limitations.

This instrument is only a word recognition instrument and does not take into account whether the individual comprehends the dental words. Also, pronunciation of words vary in the Indian population due to a difference in dialect. It is possible that incorrect pronunciation may not necessarily mean that meaning of the word is also not known, more so among individuals with lower levels of education.[17] Therefore, the evaluation of oral health literacy via a word recognition instrument like REALD may be misleading. Due to these reasons, an association of oral health literacy with DMFT or CPI is difficult to assess.

Newer tools for assessing oral health literacy should be developed which test comprehension along with simple word recognition. Then the level of health literacy can be measured accurately and associated with oral health outcomes like caries status and periodontal status.

Conclusion

Demands for reading, writing, and numeracy skills are intensified due to health-care systems' complexities, advancements in scientific discoveries, and new technologies.[18] Poor health literacy has been described as a "silent epidemic" which needs to be taken care of by professionals and policy makers in order to improve quality of health care delivery, reduce costs and disparities. [18] The ''roots of health literacy problems have grown as health practitioners and health care system providers expect patients to assume more responsibility for self-care at a time when the health system is increasingly fragmented, complex, specialized, and technologically sophisticated". [19]Thus dentists should identify patients who are having difficulty understanding and using dental health information and address their needs.

Considering the importance of measuring oral health literacy and the numerous instruments available for the same, it becomes imperative to determine the applicability of the particular instrument to be used in the population under consideration.[15] Thus, for further research in the field of oral health literacy in a culturally diverse country like India with people of different mother tongues, other instruments which measure oral health literacy rapidly and also test comprehension of the participants should be developed.

There is no known conflict of interest for this study. There was no funding obtained for this study.

Perception and Prevalence of Substance Use among Undergraduate Medical Students in Mumbai

Priyanka Manghani [1], Nishtha Khatri [2], Ashish Vasava[3], Veena Mulgaonkar[4]

[1]Master's in Public Health Student, Prasanna School of Public Health, Manipal Academy of Higher Education, [2]Resident, Department of Pharmacology, Seth GS Medical College and KEM Hospital; [3]Graduate Student, Carnegie Mellon University, United States of America, [4]Consultant Obstetrician-Gynaecologist at Dr. Veena's Maternity Clinic.

Abstract

Introduction: Substance Use is a major public health concern due its potency to lead to long term addiction and its effects on an individual's health. Medical students follow general young adult patterns and are not exempt from the consequences of substance use, which may include injuries, work and social impairment, violence, risky sexual behaviour, cardiovascular disease, cancer, and death. In lieu of the same, it is crucial that the perception towards and prevalence of Substance Use in Undergraduate Medical Students be assessed.

Objectives: To study the Perception and Prevalence of Substance Use among Undergraduate Medical Students in Mumbai.

Method: This study was conducted among Undergraduate Medical Students in Mumbai with help of a pre-structured online questionnaire. A total of 250 participants were included in the study. The Data were entered and analysed using SPSS (Version 20). Descriptive statistics was done thereon.

Results: Majority (70.3%) agreed that substance abuse was a common problem in medical students and felt that Alcohol (71.8%) and Tobacco (20.9%) were the most commonly used substances.91.3 % perceived that substance use was most common in the age group 18-30 years and 52.9% felt that male gender had a tendency to lean towards substance use. Prevalence of substance use was 68.8%.

Conclusion: There is a high prevalence of substance use amongst medical students. An integrated approach involving multiple stakeholders is integral to target the same.

Keywords: *Substance Use, Undergraduate Medical Students, Perception, Prevalence.*

Introduction

Substance Use is a major public health concern due its potency to lead to long term addiction and its effects on an individual's health. Medical students follow general young adult patterns and are not exempt from the consequences of substance use, which may include injuries, work and social impairment, violence, risky sexual behaviour, cardiovascular disease, cancer and death. [1-3] Over the years, there has been an increase in the use of various substances such as alcohol, tobacco and cannabis by medical students. Studies from various countries reported the prevalence of excessive drinking among medical students ranging between 7% and 45%, and the prevalence of use of drugs such as cannabis and ecstasy ranging between 4% and 45% [4-8]. In India, alcohol use figures vary widely from 3.8% to 21.0%, with men 9.7 times more likely to regularly use alcohol

as compared to women. [9-11] Prevalence of smoking has been estimated as 26.0% in males and 4.0% in females.[12]A variety of factors can be attributed to the increasing prevalence of substance use in undergraduate medical students. Constant Academic Stress, Burnout, Depression, Peer Pressure etc. are some of the factors which facilitate substance use in Undergraduate Medical Students. Family and Social stressors can also lead to students feeling emotionally disturbed and not knowing how to cope with these constant stressors can further lead to substance use in them. Additionally, student perceptions regarding substance use and their potential benefits may also contribute to substance use .Young students who consume various such substances may easily get addicted to them in the future, thereby making them a high risk group. In lieu of the same, it is crucial that perceptions and prevalence of substance use in undergraduate medical students be assessed and measures to combat the same be taken. This study will thereby explore the perception and prevalence of Undergraduate Medical Students towards substance use.

Materials and Method

This study was conducted among Undergraduate Medical Students in Mumbai. It was a layered study of 250 participants. The study was conducted in compliance with all the ethical principles to be followed for medical research which involves human subjects.[13] Ethical approval for the study was obtained from DY Patil – School of Medicine, Navi Mumbai. An informed consent was obtained from all these participants and confidentiality of subjects was maintained. The first stage of the study was on their perception of substance use. In the second stage of the study, an online structured questionnaire was mailed to the students who participated in the first stage. This questionnaire was formulated by review of literature on the topic and discussion with experts. The questionnaire was validated by seven subject experts. The final content validity ratio – after the corrections suggested by the experts was more than 0.99 per item and hence all the changes done in questions were incorporated in the final questionnaire. The first part of the online questionnaire covered the demographic details of the participant while the second part covered questions to assess the perception related to substances commonly used, factors responsible for the same along with questions on individual use etc. The study duration was one year April 2017-March 2018. The data was entered and analysed using Statistical Package for Social Sciences (Version 20). For the purpose of statistical significance, a p –value of less than 0.05 was taken as the essential criteria for showing a significant association. Descriptive statistics was used thereon.

Results

A Total of 250 participants were included in the study. There were 111 males (44.4%) and 139 females (55.6%), thereby having a higher female participation. Mean age of the participants and Standard Deviation was 21.54 ± 4.95 years. Various other characteristics of the study participants are described in Table 1.

Table 1: Characteristics of Study Participants

Variable		Male	Female	Total	%
Year of Study	1st Year	10	21	31	12.4
	2nd Year	9	14	23	9.2
	3rd Year	33	45	78	31.2
	4th Year	33	22	55	22
	Intern	26	37	63	25.2
Age (in years)	18-20	41	44	85	34
	21-23	57	73	130	52
	24-26	13	22	35	14

	Localite	51	84	135	54
	Total	111	139	250	100

In this study, gender (X^2=1.44, p = 0.23) and age (X^2=0.2, p = 0.9) did not have a statistically significant association with ever use of substance. However, a statistically significant association was found between the year of study (X^2=9.87, p = 0.042) and substance use. It was seen that there was a higher prevalence of substance use in hostilities as compared to localites and this difference was statistically significant (X^2 = 5.92, p = 0.015). The prevalence of substance use amongst the participants was 68.8%. Table 2 illustrates the prevalence of substance use amongst both male and female participants.

Table 2: Association between substance use and gender, age, residence

	Variable	Use of substance		X^2	p-value

As depicted in Figure 1, 72 out of 111 males and 100 out of 139 females agreed to have consumed substance/s at some point in their lives. They were categorised as ever-users.

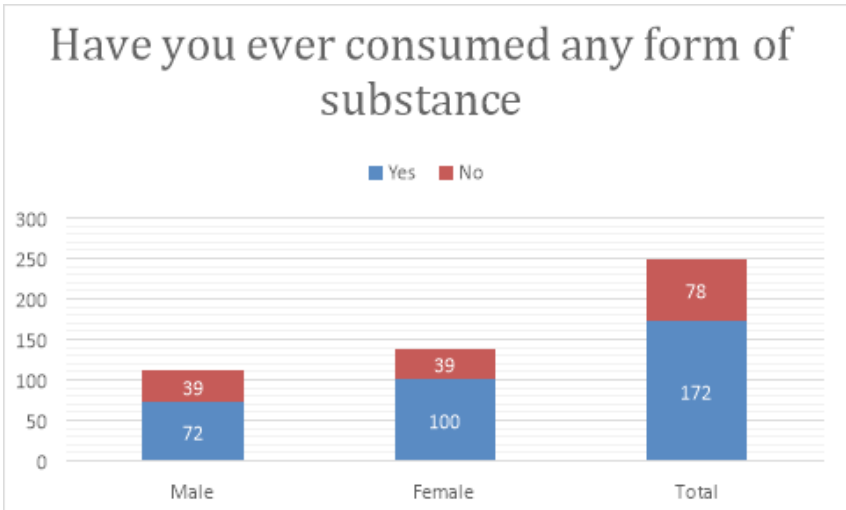

Figure 1: Prevalence of Substance Use

Majority of the participants (70.3%) agreed that substance use was a common problem in medical students while only 15.7% strongly agreed to the same. In contrast, 19.2% of the participants disagreed to the same and a mere 1.3% strongly disagreed. The perception difference of students (substance use: non-users and ever-users) towards substance use being a common problem is illustrated in Table 3.

Table 3: Perception Difference on Substance Use being a common problem in medical students (Non users v/s-Ever Users)

Response	Non-user						Ever-user					
	Male	%	Female	%	Total	%	Male	%	Female	%	Total	%
Agree	48	39.70%	73	60.30%	121	70.30%	22	43.10%	29	56.90%	51	65.40%
Strongly Agree	13	48.10%	14	51.90%	27	15.70%	7	63.60%	4	36.40%	11	14.10%
Disagree	11	47.80%	12	52.20%	23	13.40%	9	60.00%	6	40.00%	15	19.20%

Total	72		100		172		39		39		78	

Alcohol was the most common substance used (69.2%) followed by Tobacco (20.9%). In comparison, substances such as Cannabis (8.7%), Amphetamines (0.6%) and Heroin (0.6%) formed a minor proportion of the substances used by students. Table 4 illustrates the substances commonly consumed.

Table 4:Substances commonly consumed

Response	**Male**	**%**	**Female**	**%**	**Total**	**%**
Alcohol	46	38.7	73	61.3	119	69.2
Amphetamines	0	0.0	1	100.0	1	0.6
Cannabis	8	53.3	7	46.7	15	8.7
Heroin	1	100.0	0	0.0	1	0.6
Tobacco	17	47.2	19	52.8	36	20.9
Total	72		100		172	

Majority participants (91.3%) perceived that the age group of 18-30 years was most commonly affected by substance use. The perception difference of students (substance use: non-users and ever-users) towards age groups commonly affected is illustrated in Table 5.

Table 5: Perception Difference: Age group affected

Age	**Non-user**						**Ever-user**					
	Male	%	Female	%	Total	%	Male	%	Female	%	Total	%
18-30	34	49.3	35	50.7	69	88.5	66	42	91	58.0	157	91.3
30-45	1	50.0	1	50.0	2	2.6	4	80.0	1	20.0	5	2.9
45+	Nil	Nil	Nil	Nil	Nil	Nil	1	100.0	Nil	Nil	1	0.6
Not stated	4	57.1	3	42.9	7	9.0	1	11.1	8	88.9	9	5.2

91 participants (52.9%) felt that males had a higher tendency to lean towards substance use while 10 (5.8%) felt that females had a tendency to lean towards substance use. In contrast, 31 (39.7%) felt that gender didn't matter with regards to substance use; while a mere 3 (3.8%) didn't know if gender impacted substance use. Peer Pressure was the major factor participants believed to have been responsible for substance use followed by curiosity and depression. The factors presumed to be responsible for substance use as per consumers and non-consumers is shown in Figure 2.

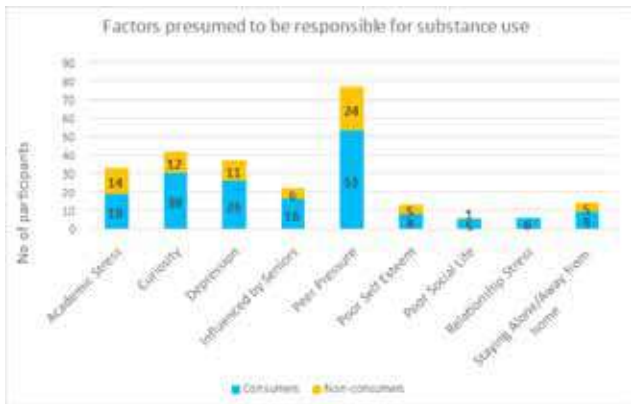

Figure 2: Factors presumed to be responsible for substance use as per non- users and ever-users

Majority (62.8%) claimed that they did not expose themselves to substance use due to fear of addiction, followed by a mere 12.8% claiming they were just not keen and 10.3% claiming that they opted not to due to fear of cancer. Additionally out of substance users, 33.1% claimed that the substances were available on campus while 66.9% denied the same. In comparison, 37.2% of non – users agreed that the substances were available on campus while 62.8% disagreed. With regards to potential benefits of substance use, majority substance users (71.5%) felt that it did not have any benefits. Table 6 illustrates the perception of substance users towards potential benefits of taking various substances.

Table 6: Perception of Substance Users towards potential benefits of various substances

Response	Male	%	Female	%	Total	%
Yes	7	77.8	2	22.2	9	5.2
No	53	43.1	70	56.9	123	71.5
May be	8	34.8	15	65.2	23	13.4
I don't know	4	23.5	13	76.5	17	9.9

Out of 172 participants who were substance users, 34.3% claimed that they did try quitting substance use, 41.9% said they didn't while 23.8% claimed they would not do that. Figure 3 illustrates the proportion of substance users who tried quitting v/s those who did not.

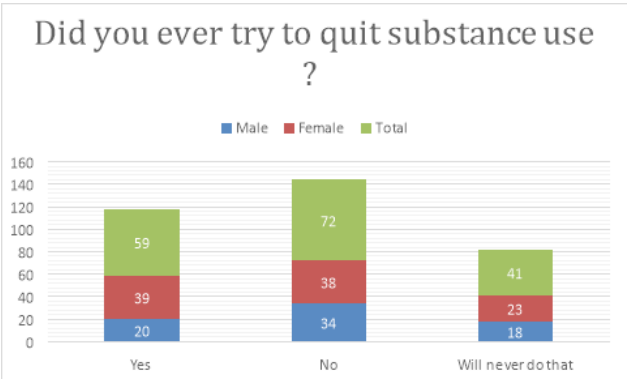

Figure 3: Proportion of Substance Users who tried to quit Substance Use

Discussion

Substance use is a growing concern in medical students. The prevalence of substance use amongst undergraduate medical students in our study was 68.8%. There is a vide variation in the reporting of substance use prevalence among Indian medical students. The prevalence has been known to be reported from 32.5 % to as high as 81%.[14] A higher prevalence was witnessed among female participants – 58.1% while male participants had a prevalence rate of 41.9%. Similarly, Boland M et al found an increase in alcohol use rates in females.[15] However, the difference in our study was not statistically significant. Previous studies have shown substance use to be more common in males.[16, 17] Majority students who consumed substances were in the age group of 21-23 years. Similar results were obtained by Mir AR et al, who found that substance abuse was initiated majorly by students in the age group of 20-23 years.[18] However, the association between age and substance use was not statistically significant in our study. A statistically significant association was found between the year of study (X^2=9.87, p = 0.042) and substance use. Pre-Final Year students (3rd Year) students had a higher prevalence of substance use followed by Interns. One of the reasons for the same could be attributed to the fact that the leisure time is more is more in third professional year as compared to first and final year while in internship the student is in a constant stress of post-graduate entrance exams. Likewise, in the study done by Mir AR et al, substance abuse was highest amongst 3rd year medical students.[18] It was seen that there was a higher prevalence of substance use in hostelities as compared to localites and this difference was statistically significant (X^2=5.92, p = 0.015). Similarly, Kumar P et al found that more hostellers were found to be drug consumers than non-hostellers.[19] Majority of the participants (70.3%) also agreed that substance use was a common problem in medical students, thereby highlighting the fact that it is an issue and needs to be addressed. Alcohol (69.2%) was the most commonly used substance followed by Tobacco (20.9%). In comparison, substances such as Cannabis (8.7%), Amphetamines (0.6%) and Heroin (0.6%) formed a minor proportion of the substances used by students. Similar results were obtained in a study done by Jaiswal HS et al wherein alcohol and tobacco were found to be the most commonly used substances.[20] Likewise, Tockus D et al showed that with respect to the drugs most commonly used by medical students,alcohol use was more prevalent (70.45%) followed by cigarette (27.3%) and marijuana (10.2%).[21]The reason why alcohol and tobacco could be the most commonly used substance amongst a variety of studies is their easy availability and lack of stringent legal regulations regarding their consumption by adults and alike. Majority participants (91.3%) perceived that the age group of 18-30 years was most commonly affected by substance use. This highlights the fact that not only first year students

but also professionals form a vulnerable group for substance use. With regards to gender and substance use, 52.9% of the participants felt that males had a higher tendency to lean towards substance use. Similar results were obtained in a study done by Shafiq M et al, wherein male gender was found to be a predisposing factor for drug use as perceived by the students.[22] Peer Pressure was the major factor participants believed to have been responsible for substance use followed by curiosity and depression. Likewise, Deressa W et al found that peer's influence was one of the important factors for students to practice substance use.[23]Additionally, Chatterjje et al and Boniatti et al. observed that curiosity was one of the factors for substance use.[24, 25] Mesquita EM et al stated the stressful nature of the medical program as an initial cause and motivator for drug consumption.[26] Majority (62.8%) claimed that they did not expose themselves to substance use due to fear of addiction, followed by a mere 12.8% claiming they were just not keen and 10.3% claiming that they opted not to due to fear of cancer. These findings could have been synonymous with the fact that medical students are comparatively more aware about the health hazards of substance use and long term chemical dependency, which could have influenced their choice to not opt for the same. Additionally out of substance users, 33.1% claimed that the substances were available on campus while 66.9% denied the same. In comparison, 37.2% of non – users agreed that the substances were available on campus while 62.8% disagreed. Though the proportion of participants who claimed substances were available on/near the campus is comparatively lesser than those who denied it, the easy availability and proximity to college area could be a factor for a higher prevalence as well. With regards to potential benefits of substance use, majority substance users (71.5%) felt that it did not have any benefits. This is contrary to the high prevalence and leaves room for a further research into driving factors for substance use since despite being aware that there are no benefits of the same, the prevalence is still high. In contrast, the proportion of students (5.2%) who claimed substance use did have potential benefits was very minor and additionally 13.4% claimed that maybe the substances have benefits while 9.9% didn't know. Out of 172 participants who were substance users, 34.3% claimed that they did try quitting substance use, 41.9% said they didn't while 23.8% claimed they would not do that. This also highlights the high burden of substance use in correlation with the small proportion of students who tried to quit substance use.

Limitations: Owing to the fact that a convenient sample size was taken, the study results cannot be generalized. Additionally, the fact that a proportion of students belonged to affluent private medical colleges; this could have also impacted the prevalence figures and was also a contributing factor for selection bias. Lastly, since the study design was cross-sectional in nature – no causal inference could be determined.

Recommendations: Substance use is a major public health issue. There are comparatively few studies done in India on perception of medical students towards substance abuse. Counselling sessions should be conducted in various medical colleges to sensitize students to deal with stress and coping mechanisms so as to avoid long term chemical dependency. Media coverage regarding substance use and its hazards can impact students on a large scale. Media and its various resources as well campaigns can be an effective mode of behaviour change communication for students. Mere reporting of the increasing prevalence is not enough; there is a cumbersome need for targeted intervention programs to target the same through a variety of channels including involving medical school authorities, students and media portals. Additionally, there is scope for future research to get a more detailed understanding of the issue through qualitative studies.

Conclusion

There is a high prevalence of substance use amongst medical students. A variety of factors influence substance use in medical students and each of these needs to be addressed. Thereby to combat this issue on a large scale, a series of interventions with a variety of modules are required.

An Assessment of Trust in Medical Profession amongst People Residing in a Semi: Urban Area,Tamil Nadu

Taseen Sida.A.S[1], Alice Matilda Mendez[2], Nisha B[2], Timsi Jain[3]

[1]3rd year MBBS, Saveetha Medical College and Hospital, Thandalam, TamilNadu, [2]Assistant professor, Department of Community Medicine, Saveetha Medical College and Hospital, Thandalam, Tamil Nadu, [3]Professor and Head.

Abstract

Introduction: The fundamental basis in health care system and relationship is Trust. Trust is a set of expectations that the health care provider will do the best for the patient. The word "Trust" has been in a state of crisis over the last decade in India particularly in medical profession. Unlimited and implicit access to health care system and medical information from a varied range of source helps patients in one way and in contrary to that it may also misinform and adversely affect "Trust" in medical profession.

Objectives:

- To assess trust in medical profession among people (>18 years) residing in a semi urban area of Tamil Nadu.
- To assess the factors affecting Trust in medical profession.

Methodology: A community based cross-sectional study was conducted during February 2019 in Thirumazhisai, a semi-urban township in Chennai. 150 Men and Women above 18 years were included in the study. Data Collection was done using semi structured questionnaire. TMP (Trust in Medical Profession) scale was used to measure trust in medical profession.

Result: 56.4% have good trust on Doctors and 44.33% have trust lower than the expected score based on TMP scale. Trust was higher among unemployed, women, people below poverty line, those not suffering from chronic illness though statistical association could be established only with socio economic status(p 0.04) and system of medicine followed (p 0.01).

Conclusion: The trust in doctors have largely been reduced and hence understanding this would lead to better ways of responding to patients requests that preserve or enhance patients trust, leading to better outcomes.

Keywords: *trust in medical profession, TMP scale, semi urban area.*

Introduction

The fundamental basis in health care system and relationship is **Trust.** Trust is a set of expectations that the health care provider will do the best for the patient. Research shows that the number of hospital jobs increased by 306% in 2015 and hence it's the high time that we focus on the basis "TRUST "[(1)]. The word "Trust"

has been in a state of crisis over the last decade in India particularly in medical profession. Generally public in today's world have unlimited and implicit access to health care system and medical information from a varied range of source, this access helps patients in a way and in contrary to that it may also misinform and adversely affect "Trust" in medical profession. Views also varied by sex, age, health, education, income, number of visits/ years with physician, past dispute with a physician, and satisfaction with care [2]. Trust also depends on patients willingness to seek care, reveal sensitive information, submit to treatment and follow physician. Measurement of trust also suggest an important tool for monitoring performance of individual providers and health

plans [3]. Trust in doctors is found to have five main domains: Fidelity, competence, honesty, confidentiality and global trust [4]. Importance of studying Trust is twofold – at macro-level, Trust is an indicator of support for the health system and changes in the health system and at micro-level, there is relationship between trust and peoples' behaviour in real choice situations.

Methodology: A community based cross-sectional study was conducted in Thirumazhisai, a semi-urban area of Chennai during February 2019. Thirumazhisai is the urban field practice area under department of Community Medicine, Saveetha Medical College and hospital. The study population included men and women who have completed 18 years of age residing in Thirumazhisai for more than 6 months. Sample size was calculated to be 150 using formula for cross sectional study with an anticipated population proportion of 40 % [5] , confidence level of 95% at 5% significance level and allowable relative error of 20%. A two stage sampling technique was used to enrol individuals to the study. There are 15 municipal wards in Thirumazhisai and each ward has 10 to 15 streets. At the first stage simple random sampling was done to select one street from each ward. A ward wise list of all the streets was prepared. One street was selected by lot method from each of the 15 wards . Systematic random sampling was done to select 10 households from each ward . The first family was selected randomly from street wise list of family folders maintained in Urban Health Centre of Saveetha Medical College at Thirumazhisai using random number tables. Every third house was visited starting from the randomly selected house till 10 houses were covered . Only one member (above 18 years) per household was chosen to avoid cluster bias.

Data was collected orally by interview method using structured questionnaire which included sociodemographic profile and TMP(TRUST IN MEDICAL PROFESSION) scale[2] to measure trust in Medical Profession. TMP scale is a validated 11-item 4 point likert scale

(Table 1) with responses grading from Strongly agree, Agree, Disagree, Strongly disagree.Here maximum score is 1 for strongly agree and 2,3 and 4 for agree, disagree and strongly disagree respectively. In the questionnaire the negative format question is also changed and recoded according to the format above. Total TMP score was calculated for each individual by adding the scores of the 11 questions. The maximum possible score would be 44 (least trust) and minimum score will be 11 (maximum trust) Mean score was taken as the cut off for categorising into good trust(a score less than mean) and reduced trust (score more than mean).

The study was initiated after obtaining approval from institutional ethical committee of Saveetha Medical College. Informed consent was obtained from the study participants and confidentiality of data was assured and maintained throughout the study. Data was entered in Microsoft Excel and analysed using SPSS software. Qualitative data is expressed as frequencies and proportions, quantitative data were summarised as mean (standard deviation). Chi-square test was applied for bivariate analysis to find association between Trust and qualitative factors like age category, gender, occupation, education, socio economic status (APL/BPL), presence of chronic disease and system of medication followed. Logistic Regression was done for multivariate analysis.

Results

A total sample of 150 people of both men and women above 18 years of age were interviewed. Analysis of the demographic data revealed that there were more number of women about 60.66% and males about 39.33%. Mean (SD) age of the study population was 43.3 (15.6). Majority of people interviewed were in the age group of 18-40 years of age(51.33%) . 38 % of the study population were unemployed followed by 23.3 % unskilled workers. 82% were educated till High school or above. 18 % were Below Poverty Line (BPL) with respect to the ration card that was possessed.

The mean(SD) TMP score of the study population was 21.3 (6.214). The maximum score obtained was 37 and minimum was 14. A score below mean (21.3)was

considered as "Good Trust" for comparison purpose in our study . Among the study population 85(56.7%) individuals were found to have "good" trust in medical profession while 65 (43.3%) had reduced trust. When 61% of the males in our study population was found to have good trust, only lesser number of females (53.84%) had good trust in Medical profession . While all the four participants above 80 years had good trust in Medical profession, 62.5% of those in the middle age group (40-60) had good trust. Trust did not vary significantly among the various occupational groups. Trust is higher amongst those belonging to below poverty line (74.1%) while only 52.8% of APL card holders were found to have good trust. Other factors influencing trust also were analysed and showed that trust has been slightly lower(51.1%) amongst people having at least one of the chronic diseases(hypertension, Diabetes Mellitus, cardiovascular disease, bronchial asthma) and it is 59.2% amongst people without any chronic disease .Trust also varied according to the system of medicine followed by the individuals as shown in Table 2.

Bivariate analysis was done using chi-square to test the statistical association between the various factors and trust in medical profession (table 2). Socioeconomic status (p value - 0.04) and system of medicine followed by the participants (p value- 0.010) had a significant association with Trust. Multivariate analysis by logistic regression with "good trust" as the dependant variable did not reveal significant association with any of the independent variables.

The most important quality of a doctor that can influence the trust in medical profession as perceived by the study participants were as follows: 44% of the participants perceived verbal communication as most important followed by behavioural competence(25%), comfort level(16%) and simple elegant appearance(15%). Question number 11 in TMP (table 1) which individually measures the over all trust showed that 74% of the study participants agreed that they "trusted their doctor completely".

Table 1: 11-item Trust in Medical Profession(TMP scale)

1.	Doctors care their patients health more than or as similar to their parents
2.	Doctors care more about their convenience than their patients medical need
3.	Doctors are thorough and careful
4.	Completely trust Doctors about which medical treatments are best
5.	Doctors are honest in telling their patients about different treatment option available
6.	Doctors think about what is best for their patients
7.	Doctors do not pay full attention to what patient tells
8.	Doctors use their best skills and efforts
9.	You have no worries on putting your life in Doctors hand
10.	Doctors would never mislead you about anything
11.	You trust your doctor completely

Figure 1: Distribution of trust in medical profession

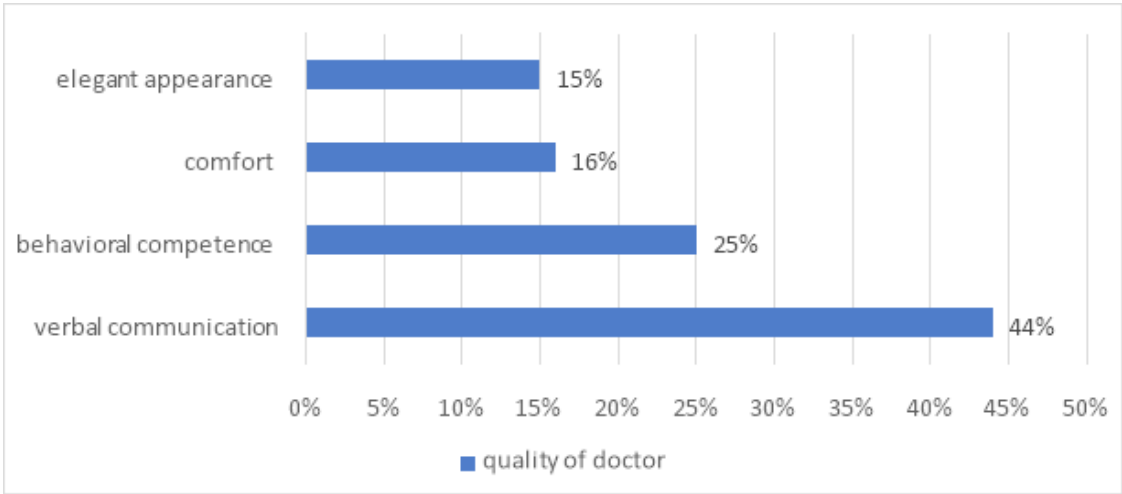

Figure 2: Perceived quality of a doctor that influence trust

Discussion

A cross sectional study was done to assess "trust in medical profession" among adults population in a semi-urban township of Chennai, TamilNadu. Proportion of females and unemployed persons were more in our study population when compared to census figures of Tamil Nadu.[6] This may be due to the reason that the data collection was done during day time when males who were engaged at their occupation were not available at household . In this study based on the score calculated trust in medical profession is found to be 56.7% have good trust and about 43.3% have reduced trust and which is similar to study conducted in China by Da-Hai Zhao et al showed that the 67% has strongly trusted and about 33% had reduced trust.[7] Since this is a cross sectional study, deducing a continuous trend in long term was not possible. Mean score in this study is 21.3 out of 44 and in the previous study by Da-Hai Zhao et al the mean score is 35.4 out of 50 (5 point likert 10 item scale)[8] . Here it's important to note that level of trust is good in middle age group (40-60) in this study and is compared to study conducted in north-east Poland by Marcinowicz et al[9] . Based on the Table- 1,question number 3 " Doctors are thorough and careful " scored the highest about 68% and shows that the public is confident with Doctors knowledge and which is one of the factor influences trust in medical profession. Question number 8 in Table 1 "Doctors use their best skills and efforts" scored the least about 42% and shows that public has less confidence in transparency and skills in medical profession. During interrogations some people have lower Trust but were reluctant to express to medical students. Here the reduced trust may be due to recent media coverage of unethical practices by the doctors.

Factors affecting trust was studied and there is statistical significance obtained between two independent variables,socio economic status and the system of medications followed and Trust. Economic factors were found to be determinant of trust in doctors by studies done by Birkha et al and Gopichandran [10,11] . Another study done in older population by Guerrero et al also showed similar result [12]. Consistent results with association of trust in medical profession and system of medicine were not available. In this study participants perceived verbal communication and behavioural competence as more important and physical appearance as less important factor in influencing trust. Similar results were seen in another study done in rural and urban setting of Tamil Nadu[13] .

One of the limitations of this study is that it was conducted in a single geographic area . The representativeness of study population was not adequate as the data collection was done during day time and hence the responses of males and working group could not be captured fully.

Conclusion

The final outcome from this study is that 56.7% has good trust and 43.3% have reduced trust in medical profession. Trust have been higher among unemployed, women, people below poverty line, those following alternate systems of medicine and those not suffering from chronic illness though statistical association could be established only with socio economic status(p 0.04) and system of medicine followed (p 0.01). Doctor's verbal communication skills was perceived by majority(44%) of the study participants as the most important quality that would determine trust in medical profession which should be focused on . The study would recommend the medical professionals to build up a close relationship with their patients and be still more transparent to avoid unethical issues. The trust in doctors have largely been reduced and hence understanding this would lead to better ways of responding to patients requests that preserve or enhance patients trust, leading to better outcomes.

Li-Fi Based Automated Patient Healthcare Monitoring System

B.Srimathi[1], T. Ananthkumar[2]

[1]*PG Scholar, Dept. of ECE, IFET College of Engineering,* [2]*Assistant Professor, Dept. of CSE, IFET College of Engineering*

Abstract

Context: Now a days, patient healthcare monitoring systems have realized lots of consideration. This monitoring system repeatedly peer the patient health for the earlier recognition of any physical fall in health. In previous days, Wi-Fi technology was used to transmit the data regarding patient health which cause some health disorders due to its harmful radio waves. To overcome this hazardous problem, Li-Fi (Light Fidelity) is proposed which has no harmful radiation effect with fast and secure communication than Wi-Fi. For more secure, bastion algorithm is used to make the data more immune to attacks by the encryption of data using block cipher encryption and proficient linear post processing to the ciphertext. In the proposed work, the data's are obtained using Arduino and then the statistical data's are manipulated using deep learning algorithms for sending the emergency alert to the doctor.

Keywords: *Patient monitoring; Li-Fi; Bastion algorithm; Secure Li-Fi; Healthcare VLC.*

Introduction

The goal of Patient Monitoring is to provide an early detection of any health deterioration with reliability and accuracy and to provide warning or alarm. At present, the healthcare monitoring system attains more importance because patients were continuously monitored and examined without any human interventions. This monitoring system is also helpful to the home dwelling chronic or elderly patients. The health status details of a patient such as temperature, ECG, and heart rate were observed using temperature sensor, ECG sensor and Heart rate sensor. The rapid growth of wireless communication led to the problem of efficient use of an electromagnetic spectrum. The most standard wireless technologies use the lowest part of the electromagnetic spectrum in the range of 3KHz-300GHz namely Radio waves. The details collected were transmitted to the receiver using Wi-Fi technology which uses Radio frequency band of an electromagnetic spectrum. This radio signal transmitted form Wi-Fi antenna will be received by the Wi-Fi receiver like mobile phones and computers equipped with a Wi-Fi card. It causes some health problems like development of insomnia, affect cell growth, cardiac stress and reduce brain activity. Hence, it was not allowed in Operation theatre due to the radiation consequences because Wi-Fi blocks the signal from monitoring equipment and affect the medical equipment.

Li-Fi, a wireless technology that make use of visible light communication or infrared and near UV spectrum waves to resolve the problem of radio waves. The household LED bulbs also utilized for data transmission at a rate of 224 gigabits per second. In medical,Li-Fi was allowed in operation theatres rather than Wi-Fi to use internet and to regulate medical equipments. Hence, it is favourable for robotic surgeries in hospitals and for automated strategies.

Related Work: Nowadays, a patient health monitoring system attains more importance to observe patients remotely using Wireless Sensor Network (WSN)[1-4]. It also helpful for an home dwelling patients who are aged persons[5-6]or affected by chronic diseases includes hypertension[7-9].

Along with ECG, monitoring heart rate was necessary to measure frequency at what rate the blood

Corresponding Author:
B. Srimathi:
PG Scholar,Dept. of ECE, IFET College of Engineering.
e-mail: srimathibaskaran96@gmail.com

was pumping[10-11] and respiration also essential to measure the breathing rate of a patient while sitting, sleeping, lying down or standing[12]. Some techniques observe both breathing and heart rate using a Vital-Radio by inhalation and exhalation[13] and a Dynamic Time Warping algorithm[14].Real time monitoring systems also were implemented for both hospitalized or leading regular life activities[15] and also monitored using wearable sensors[16].Pervasive patients also observed with a sensor based healthcare system[17].Through this monitoring system, doctor stress and medical errors were reduced and overall flexibilityalso improved in observing the patients [18].

Later, a mobile patient monitoring system uses Visible Light Communication system to pass on the ECG and PPG (blood pressure) details to doctors through high illumination LED. This LED transmits the details by switching between on and off condition as the light signal and received by photodetecter[19]. This technology was also used in automated billing system to reduce human effort and to avoid standing in queues for billing things through mobile application using Li-Fi module and payment was done by mobile banking [20].

Due to radiation effect, Wi-Fi was restricted in hospitals. The problem in Li-Fi was, during transmission it is necessary to make sure that it ensures confidentiality. Hence, Elliptic Curve Diffie Hellman and Secure Hash Algorithms were used to provide security which use key and authentication to make it difficult to hack data in hospitals[21]. If the key used for encrypting the data is exposed, the confidentiality must be maintained. To ensure confidentiality of an encrypted data, Bastion algorithm was used even when the key was opened. In bastion, the cipher text blocks were stored in multiple storage systems, so the adversary has to gain the encryption key, and to compromise all systems to win back the plaintext[22].

Proposed System: The proposed system uses Li-Fi to transmit data using visible light communication and requires Line of sight condition. It is an optical communication technology that utilizes visible light rays between the frequency range of 400-800 THz, as an optical carrier for data transmission for a short range wireless communication system. Li-Fi transmits data in binary form as shown in fig 1.

Fig 1: Data transmission

. The principleof Li-Fi technology is based on amplitude modulation, the light source in a standardized way. LEDs were switched on and off much faster with the operating speed of less than 1 microsecond and achieves speeds of up to1Gbps, so which cannot be detected by human eyes. Fig 2 shows the patient monitoring system using Li-Fi.

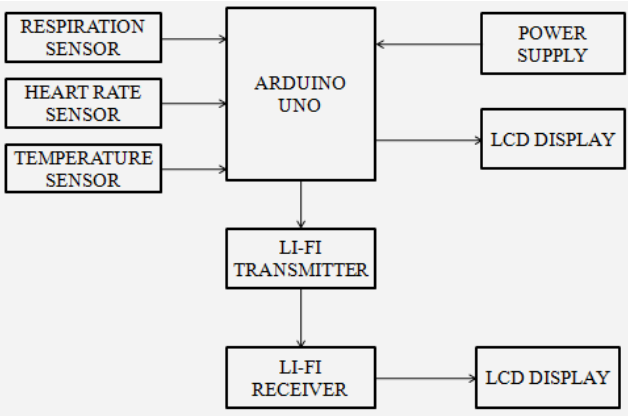

Fig 2: Block diagram

Transmitter Section: In Li-Fi, data was transmitted using LED bulb through a LED driver circuit which controls LED on and off. If the LED is on, binary value 1 will be transmitted and if is off, binary value 0 will be transmitted. LED can be flickers on and off in a rapid manner that provide good chance to transmit the data. It is feasible to encode the data by changing the rate of LEDs flicker to give different strings of 0's and 1's. The intensity of LED was regulated rapidly hence, on and off conditionof LED cannot be noticeable by human eye, so the output appears constant. The data rate of Li-Fi can become greater by using an array of LEDtotransmit different data streams to achieve parallelcommunication. The data from respiration sensor, heart rate sensor and temperature sensor were fed to Arduinouno that convert an analog signal into digital output because Li-Fi transmits data as a binary stream by switching the LED on and off quickly. The Li-Fi transmitter encodesthe signal using on off keying technique and encrypt the signal using secret key cryptography before transmission. Fig.3 shows the transmitter side of proposed system.

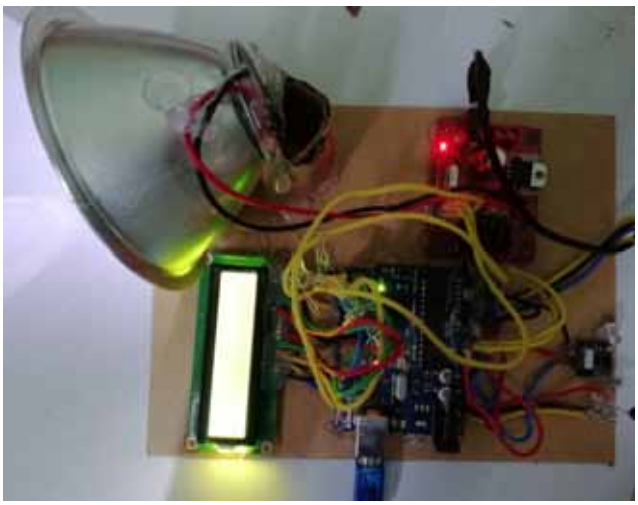

Fig 3: Li-Fi transmitter

Receiver Section: The photodetector at the receiver section receives the light signal and retrieves back into an electrical signal, then fed to a Li-Fi receiverwhere it decodes and decrypt the signal and removed the noise in the signal. This signal then fed to Arduinouno and viewed in the LCD display. Fig. 4 shows the receiver section on Li-Fi unit.

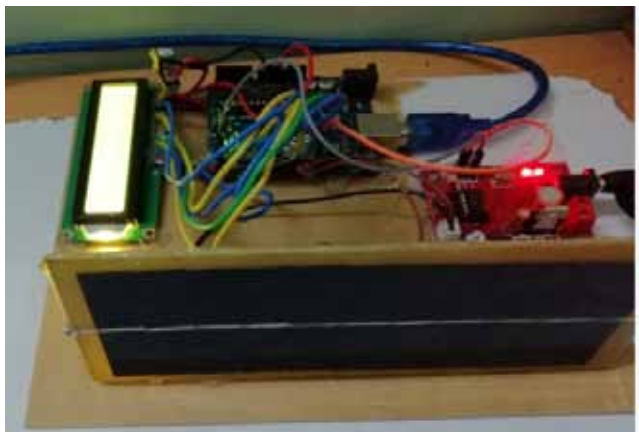

Fig 4: Li-Fi receiver

Security: Bastion Algorithm In patient monitoring, health details of the patient or any medical data or report were transmitted to the doctor or medical man. In that case, the data must be transmitted more securely. Hence the data were encrypted and decrypted. The process of converting a information or data by an algorithm into an unreadable or unusable form using key is called encryption. The encrypted data is called ciphertext and the original data is called plaintext. Decryption is the reverse process of encryption to recover the original data from ciphertext using the same key.

The data will be encrypted using some standard encryption techniques. If the encryption key is leaked, for assuringdata confidentiality, the only way is to restrict the access of an adversary (opponent) to the ciphertext(example, distributing the ciphertext to multiple domains). Even though, the data is encrypted and distributed over multiple domains, adversary with an suitable key can compromise a server in a domain and decrypt ciphertext block stored therein. To counter such adversary, an efficient scheme Bastion, proposed to guarantee confidentiality even the key is revealed, ensures that an original data cannot be reclaimeduntil the adversary access at most all but two ciphertext blocks. Bastion pulled off this by combining the standard encryption function and efficient linear transform in similarities withAONT(all-or-nothing transform). AONT is not an encoding technique but utilizedbefore

encryptionas a pre-processing step in Li-Fi based systems.Bastion departs from existing AON encryption technique requires a pre-processing step of block cipher encryption for the AONT which is followed by another round of block cipher encryption. ButBastion first complete the encryption of data using one round of block cipher encryption followed by efficient linear post-processing to the ciphertext. Bastion relaxes the conception of all-or-nothing encryption with improved performance. In bastion, for an input with a security parameter k, the key generation algorithm of Bastion gives an output key K ∈ {0,1}k for the block-cipher which is used to encrypt the set of input blocks that results ciphertext q′ = q′[1],...,q′[p+1]. Then, Bastion follows a linear transform to q′ as follows. Let n = p + 1 and assume A to be an n x n matrix where element $a_{i,j}$ = 0^l if i = j or $a_{i,j}$ = 1^l,.Bastion computes q′ = q • A−1 and decrypt q′ using K where matrix A is invertible and A = A−1.

Results

To overwhelm the drawback of radiation concern in Wi-Fi technology data observed from patients will be transmitted using Li-Fi. It uses visible light part of the electromagnetic spectrum for data transmission. It supports data rate from 100 kbps -100 Mbps for various modulation scheme. The data observed from a patient was first fed to an Arduino that convertsanalog data to digital data. This data was encrypted into unreadable form using bastion algorithm and then transmitted as light using Li-Fi transmitter by flickering LED. The photodetector in receiver convertlight to a digital signal and decrypt the signal which is again fed to another Arduino in receiver that recovered the transmitted data from the digital signal. This will be viewed using LCD. The bastion algorithm ensures that data confidentiality that only receiver can access the data sent, no other adversaries cannot access the data even the key was known.

The fig.4. Shows the respiration rate i.e. count of number of breaths per minute. The conventional respiration rate is 12 to 20 breaths per minute. The rate below 12 or above 25 breaths are considered abnormal. It is necessary to measure respiratory rate because patients affected by asthma, anxiety, pneumonia, congestive heart failure, lung disease or drug overdose may vary from normal rate.

Fig 4: Respiration value

Fig :5 shows the temperature value. The normal body temperature is 98.6˚F. Above that is considered as fever and below that is hypothermia. Hence it is necessary to measure body temperature because it reveals our health information like hormonal health, metabolic rate etc.

Fig 5: Temperature value

Fig. 6 shows the heart rate of a patient which measures the cardiovascular fitness assessment. The normal heart rate is 60 to 100 bpm. When it is less than 60 bpm, considered as bradycardia and more than 100 bpm is considered as tachycardia.

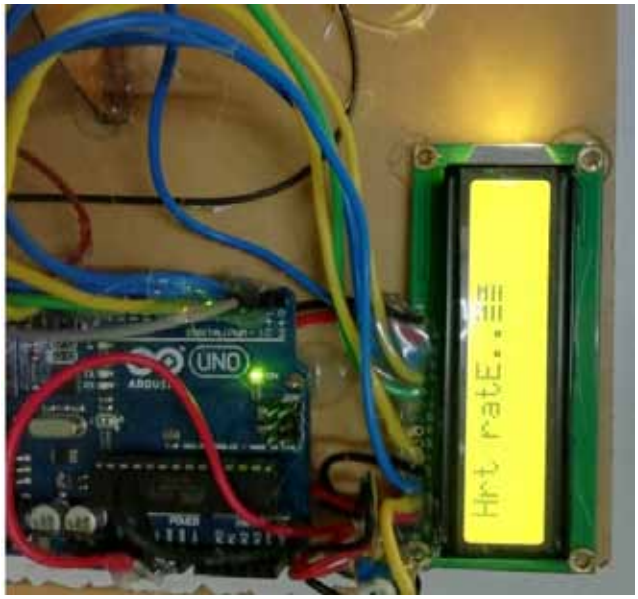

Fig 6: Heart rate

These measured data will be transmitted to receiver using Li-Fi which has some advantages and better throughput over other wireless communication that shows graphicallyin fig.7.

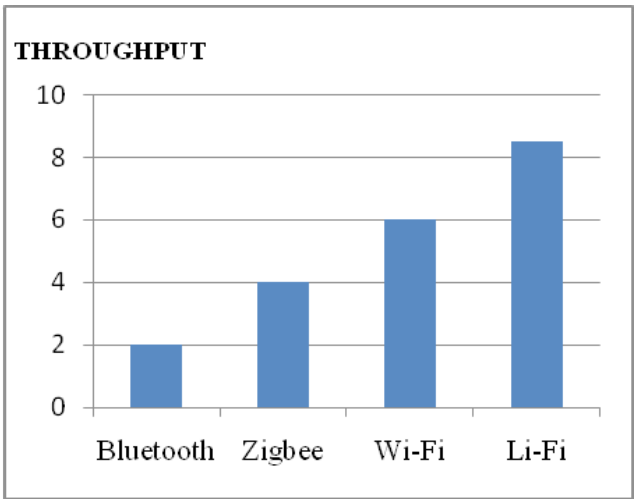

Fig 7: Li-Fi vs other technologies

Here, the data obtained from various sensors by placing the sensors on the patient's body were converted to a digital form using analog to digital convertor present in the Arduino UNO. It regulates this digital signal to the 5V level. Then the signal was fed to the transmitter where it was transmitted as optic pulses using LED driver circuit which control the LED's on and off condition to transmit data in a rapid manner.Then it was received by the solar panel to convert this light into electrical signal and then given to the Arduino. Based on the signal voltage level and health data, which is referred with predefined vales, the abnormal or any deviation from normal value was detected. The alert through SMS or alarm will be sent automatically to the doctor using Li-Fi technology.

Conclusion

In this paper, healthcare monitoring system using Li-Fi technology was proposed which has certain advantages over Wi-Fi technology. Because of the radiation effect exist in Wi-Fi, it was restricted in some areas like aircraft, hospitals, nuclear power plant etc. In hospital, the radio waves may affect the patient health and also the medical equipments. Hence it was not allowed during operation. But Li-Fi provide safe, fast and secure data transmission on low power because it uses visible light spectrum instead of radio waves which never cause any harmful effect on humans. For security during transmission, data will be encrypted using standard encryption techniques. If the encryption key is exposed, data confidentiality will be guaranteed using an efficient algorithm called Bastion. It ensures confidentiality by distributing the encrypted data across multiple storage systems. It limits theopponent to access the encrypted data because the data was distributed to multiple systems, hence the adversary cannot compromise all system to access the data stored therein.

A Low Cost Hardware Based Fall Detection and Call for Help System for Elderly Person

K. Suganya[1], M. Saravanan[2]

[1]PG Scholar, Dept. of ECE, IFET College of Engineering, Villupuram, Tamil Nadu, India, [2]Associate Professor, Dept. of ECE, IFET College of Engineering, Villupuram, Tamil Nadu, India

Abstract

Context: Aging is common for a Human being. Especially an old aged person needs attention due to weakening in their physical capability. Fall is one of the major problems faced by elderly persons during their daily day activities. Falls are caused due to accident, loss of consciousness. Fall poses a serious impact on health issues of an elderly person. Fall detection is one of the necessary actions to be taken. So the fall detection system is needed. Thereby here the development of the system includes methodology based on sensor-video integration technology. The event of fall occurrence can be detected using the sensor as well as the camera and the acquired information is sent as messages and live video feed to the user in case of emergency through making use of Wi-Fi technology.

Keywords: *Accelerometer Sensor, camera, video, emergency, Wi-Fi, message, fall detection.*

Introduction

With the increase in population, concerning the persons around the age groups of 60 years and above needs help in one way or another who are living independently in a home environment after the family members left for their work. The following figure shows the causes of fall.

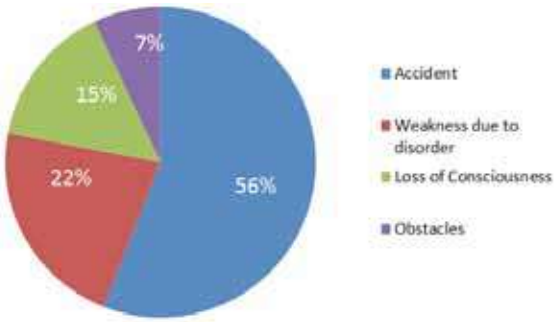

Fig 1: Causes offall

Corresponding Author:
K. Suganya:
PG Scholar, Dept. of ECE, IFET College of Engineering, Villupuram, Tamil Nadu, India.
e-mail: ksuganyav@gmail.com.

According to World Health Organization[1], the old aged group increases quickly in population, the percentage of fatal fall rates increase gradually in age groups from 65 to 85 and above shows the detail about the fall risk of old aged person. Many accidental falls occurs and causes injuries and health issues lead to long term among them. Considering as the main issue the system should be developed in order to help old aged people in best way, detecting the fall occurrence especially will assist them during that crisis. On the account of the importance of detecting the fall occurrence, the risk of falling can be avoided. The major challenge and problem among older person is falling. Fall may lead to extend of death among them if it is handled. Various fall detection systems were designed in order to bring at low cost and better efficient one. Many systems include methodology based automatically detect the fall event using acoustic sensors[2] and also the system involves creating signatures for each activity and classifying the fall event using Doppler radar and analyzing the difference in time of signatures and representing in time frequency signals[3,8] and taking the features of each posture of body and segmenting them to detect the fall event[5]. The system used in identifying the fall event based on which uses, namely infrared[14], Tri axial accelerometer sensors[12], fibers optic[15], ultrasonic sensor[16], floor

pressure sensing sensors[18],wearable cameras[9-11,21]and using smartphone.

Proposed Model: Here the fall detection system is developed and implemented with the aim to achieve low cost, reliable and efficient one to serve as useful one. In addition to that a web camera separately connected to them to record the video automatically if the event is to befall occurrence. Firstly the prototype is developed by a Raspberry Pi board for sending message.

Now nextly this system is developed based on raspberry Pi 3 model B+ board, for storage as well as it has built in Wi-Fi chip for accessing internet connection and subsequently to reduce the cost.

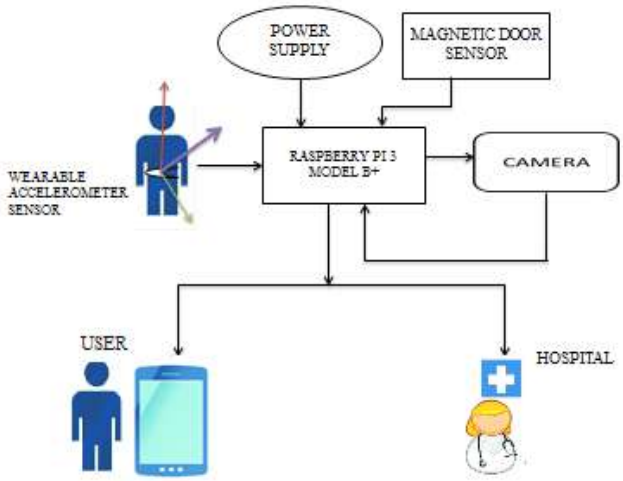

Fig 2: Proposed Model

And there are many visions based devices available for fall detection these days. The implemented fall detection system will notify the rescuers with the message as well as live video feed in order to provide assistance. The system can be easily be installed and established with wireless communication.

Proposed Fall Detection System: The fall detection system consists of tri axis accelerometer sensor and web camera for capturing the fall event. This sensor will sense the acceleration, velocity and position of the person. Thereby with the acceleration values obtained from the sensor will be compared with the fixed threshold value. Using this data the fall event occurrence can be detected and a message will be send as alert to the rescuers to assist them. By means of the Wi-Fi technology, communication can be made easier. A web camera is used for capturing image of the fall event. Here both the sensor and video technology has been used. Additionally, magnetic door sensor is used as for detecting the door activities such as door open and the door close.

The main aim is to detect fall and handle the emergency situation in correct manner without any delay. The timing plays an important part in this system. Based on the occurrence, Fall can be fatal or not but causes some serious impact in the health of the aged person. Health of the person can be seriously damaged due to their natural weakness. This fall detection system will probably provide immediate action in the way of message form to respective hospital and member of the family utilizing the python programming language. Elderly person who lives independently in home environment after the family members left for daily activities outside. Here the following fig 3 and fig 4 shows the proposed fall detection system and python programming setup.

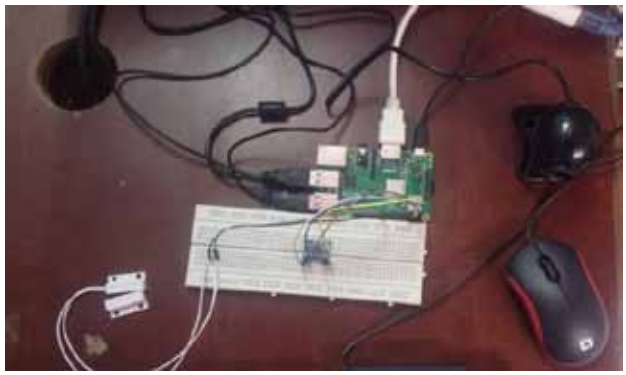

Fig 3: Proposed Fall Detection System

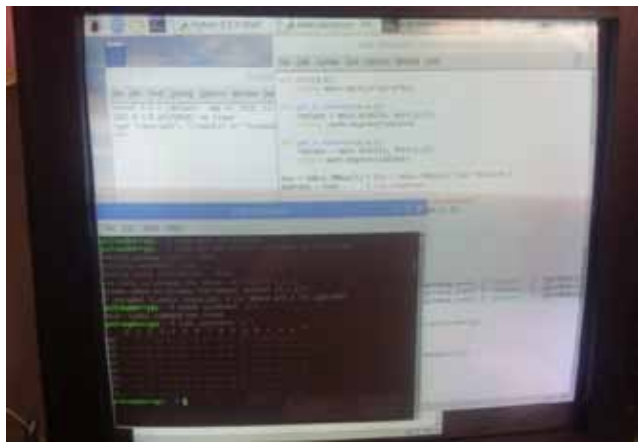

Fig 4: Python Programming Setup

In the python programming setup, utilizing the GPIO library the coding is done. Programming language plays an vital role in the software part. The types of fall are shown in the following table 1.

Table 1:

S.No.	Types of Fall
1	Normal fall
2	Falling forward
3	Falling right
4	Falling left
5	Falling backward
6	Falling due to loss of conscious state
7	Falling due to obstacles (furniture).
8	Accidental fall

Algorithm Description: The algorithm used for fall detection system is as follows. The First step of the algorithm involves the acquiring the raw data from the 3 axis of the accelerometer sensor namely X, Y, Z axis. This axis, which gives the details of roll andpitch .This accelerometer sensor value will be higher compared with the normal acceleration value.

Normally the movement of older person will have low acceleration values. But when fall occurrence takes place means the acceleration value of the person will be higher than the normal acceleration. These acceleration values can be compared with the threshold values. The values from the 3 axis of the accelerometer can be calculated as follows

$$\|F_A\| = \sqrt{F_{AX}^2 + F_{AY}^2 + F_{AZ}^2} \quad (1)$$

From the above equation (1), the data from each axis can be calculated and compared with threshold value. The algorithm is based on threshold based method. Now the steps involved for the fall event and door event are tracked one by one.

The steps how the proposed fall detection system will work are given as

The variables are used for assignment as the accelerometer sensor is a digital one. So the values will be 0 and 1.

Input: ox; fall detection x, y, z axis values are detected by the sensor.

Input: m; magnetic force value detected by the sensor.

Output P, K; P=1 if fall detection, K=1 if door opened, P=0, K=0 if it is off state.

1: Start.

2: Set the ox threshold value, x, y, z axis.

3: Set the m distance and time.

4: Connect fall detection sensor and magnetic door sensor to Raspberry Pi.

5: Repeat

6: Read ox from sensor.

7: Read m from sensor.

8: If ox<=x then P=1

{Send SMS for registered mobile number, Trigger camera to ON state, Ask request for video Send video same number}.

9: If m. distance > distance & m. time<=time then

K=1

{Send SMS for registered mobile number}.

10: Else Set P=0, K=0 and go to step 4.

11: Until 1000ms.

12: End.

Now, the working of the proposed fall detection system is as follows will clearly give the idea of the system how it detects falls and proceed with the information to the next stage. The accelerometer sensor is fixed to the body as in the belt part so that the acceleration value varies for each activity. But the obtained value can be compared with the predefined value.

This whole system will provide only the detail of the fall event and the other activities of the person. Time delay is set in order to determine the duration. The advantage of this system is monitoring of 24 hours is not needed.

The condition of the person can be judged from this kind of system to provide assistance without any delay. Taking the health as the main concerns the fall detection system will be helpful.

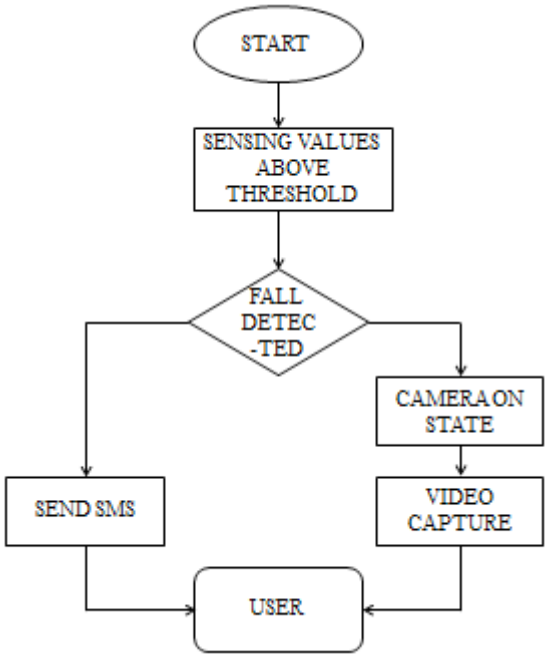

Fig4: Flowchart of the Proposed System

The fall detection system works based on the methodology of accelerometer sensor which plays a vital part of the system. The sensed value of the sensor from the axis based on the calculation exceeds the value of threshold value means the system works continues the process as given in the flowchart otherwise it stays away. This system mainly focuses on detecting the fall not just only intimating by message. Video feed brings the rescuers to handle the situation correctly. Health issue caused due to fall event can be serious or minor problem to the affected elderly person but needs some attention to them.

Alert System: The real time monitoring system includes the live video feed with the every movement of the person [19].Here the alert system is developed using Raspberry Pi 3 model b+ has built-in Wi-Fi chip to access internet connection where wireless communication is established in which the message is sent to family members and hospital for providing assistance in emergency situations. The alert is made through SMS and MMS to user mobility.

This important feature can be added to the alert system in future based on pre-set time and the time taken by the system to send the message and video to the user without the false alarm rate it. The time delay is set as 2 mins it is enough for the fallen person to recover from the fallen state to normal state. Directly the image of the fall event is provided visually to the user to take action for the event .communication are made easily to the nearest hospital and member of the family

Here magnetic door sensor is utilized to monitor the door is closed or in open state with the addition to detecting the fall event. When the person does not recover for a long period of time, the fall detection system will come to the state that the assistance is needed for the person immediately from the video.

Here the video captured by the camera will be sent to the user or care unit to know the status of the fall event as well as recovery. The condition of the person can be severe or less .This fall detection will continuously check for the fall event whereas the privacy of the person is protected. Privacy of the person is also considered as the vital aspect of the fall detection system. This alert system will provide information about the status of the person in home environment who lives independently thereby helpful for family member and hospital The following figure 5 shows the fall detected scenario.

Fig 5: Fall Detected Scenario

Based on the fall event occurrence the message is sent to the user as alert to make a call for help immediately in order to avoid the condition of the person severe. The false rate of the fall occurrence will be less compared to other fall detection system. The size of the video sent to user mobile has some limitations. The size of the file plays an important role so that the captured image can be sent as alert to the user. The video consists of continuous frames. Here web camera is used with high resolution so that the picture quality will be high. The following fig 6 shows the alert message and fig. 7 shows the video sent to user‘s mobile for notification.

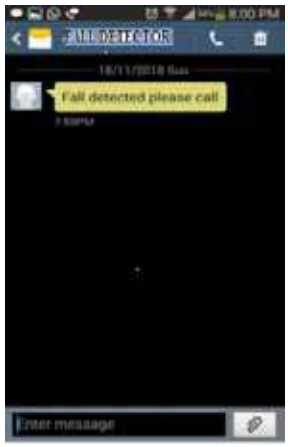

Fig 6: Alert message

Fig 7: image of the fall event

Here SMS message and video message to 2 different users is shown in the above figures.

Results and Discussions

A. Parameters: The parameters needed for calculations are in order to measure the performance of the system as follows .They are

- Sensitivity
- Specificity
- Accuracy

And it is defined as Sensitivity=TP/TOT P.

Specificity=TN/TOT N.

Accuracy= (TP+TN)/TOT Event.

Where TP= True Positive.

TN=True Negative.

TOT P = Total Positive.

TOT N= Total Negative.

Based on the proposed fall detection system, performance of the system is desirable. The fall rate occurs due to some above mentioned reasons. Hence the false rate of falls can occurs sometime due to the increase in the acceleration value so based on the calculation., it can be analyzed but using the web camera which gives an advantage of viewing the event whether the fall occurs or not and also the recovery status. Capturing the fall event is an additional feature added to the system. Therefore the fall detection system has provided satisfactory for the user with the capability of visually analyzing the situation. Compared to other fall detection system monitoring the other activities is evaded. And the only fall event is needed so this system is suitable for fall detection. The following table shows the result in terms of percentage

Table 2:

PARAMETERS	PERCENTAGE
Accuracy	96%
Sensitivity	96.6%
Specificity	97%

Conclusion

Here we designed a fall detection system using

Sensor-video integration technology. Our work offers a way in protecting the privacy of the person during the detection of fall occurrence. This system gives a novel approach to send the information in the form of video as MMS messageas well as SMS. An Experiment carried out shows the results obtained for detecting the fall occurrence in the independent home environment gives an accuracy of high level which is desirable for fall detection system.

In future work, the improvement of the system will be based on how to reduce the false alarm rate to some extent.

This fall detection system is very efficient, low cost and reliable one.

Real Time Dengue Prediction Using Machine Learning

A. Divya[1], S. Lavanya[2]

[1]*Assistant Professor, Department of CSE, IFET College of Engineering, Villupuram, India,*
[2]*UG Scholar, Department of CSE, IFET College of Engineering, Villupuram, India*

Abstract

Context: Dengue is generally spreading the endemic zones for atmosphere zones. In a whole world, transmitted to an individual by an Aedes Aegyptus mosquito, dengue load in India is expanding at an upsetting rate. The commitments of expanded versatility, both vector and human populaces, urbanization and atmosphere changes are the most critical factors to clarify the expanding episode of dengue. Generally, the different calculations looked at, it was wasteful to evaluate the exactness for early dengue illness expectation. The recommended framework is to build up an application for Smart Prognosis Dengue (SPD) Model for AI development to foresee constant Dengue illness. It will continue with unmistakable AI approaches going from basic classifiers like Decision Tree, Logistic Regression. Thus, the Logistic Regression Algorithm gives the most extreme exactness precision will analyse for the dengue expectation. By utilizing both the equipment and programming setup, it joins the AI ideas with the expectation calculation and furthermore gives the framework can be altered to produce risk alert and area explicit forecasts.

Keywords: *Machine Learning, Logistics Regression Algorithm, Raspberry Pi 3, GSM Module, GPS Module*

Introduction

Dengue Disease & Dengue Hemorrhagic Disease is a critical significant ailment in both metropolitan and country regions of the nature. Aedes mosquito's family including Aedes Aegyptus mosquitoes, Aedes Albopictus mosquitoes, convey as the superior transmittal method for dengue irresistible infection. Essential dengue infection in people frequently realize a scope of expository manifestations, of fever to potentially pernicious dengue disorder, and powerful antiviral specialists equipped for treating dengue disease are not accessible at present.

The most demanding reason for this task is dengue infection forecast utilizing different spaces like AI calculations. At first, recognize the appearances of dengue experiences patients and forecast starts this distinguishing proof. The informational collections are utilized for pre-preparing and to estimate exactness precision. The different AI calculations are examined in the approaching areas.

Accordance with the World Health's Organizations (WHO), dengue infection has bent over worldwide over hasty quintet decades. Around 200 to 750 million new infectious illnesses happen once per year alongside 70 nations. Numerous analysts are chasing away at part to anticipate and control the spread. In the advanced years, expanded research has concentrated on a scene the study of disease transmission utilizing machine learning approaches for better infection forecast.

In this desire significant to determine the appropriate of data acquired by various hospitals and health care units for the early detection along with controlling of dengue. Most patients recuperate inside around multi-week. Nonetheless, a few patients turn out to be more awful and create extreme stomach torment, tireless retching, discharge (gums, nose, under the skin, gastrointestinal), and inconveniences including the heart, liver, and lungs. Presently, treatment is strong and antibodies proceed a work in progress. In spite of the evidence that dengue is regional in no below than 100 nations in the tropical

Assistant Professor, Department of CSE, IFET College of Engineering, Villupuram, India
e-mail: div.anandan88@gmail.com

zone and subtropical zone, these territories occasionally experience expanded hazard when mosquito populaces increment in vicinity to powerless human residence. Natural variables are known to impact the commonness of mosquito vectors and the dangers of people getting to be tainted with dengue.

By cause of the likelihood of serious effects and demise, there is incredible enthusiasm for anticipating these ailment flare-ups. Because of general wellbeing worries about the spread and expanding degree of dengue, the US Centered for Disease Prediction and Control, the US Departments of Defense, the US Departments of Health's and Human Service, the US Departments of Homeland's Security, and different US government organizations combined to support a Dengue Prediction Challenge venture in 2015. The central point of the venture was on foreseeing key measurements for verifiable dengue seasons utilizing just information from timeframes before those seasons.

Related Study: In order to state that, in this exploration displays the examination about the expectation of DHF in Bandung authorization utilizing K-Means Clustering as pre-handling strategy and Support Vectors Machines (SVM) calculations as order technique as indicated by authentic information of DHF and climate information. The most impact situation is marking class situation since K Means Clustering name technique demonstrates exactness [1].

In this paper clearly explained, in this exploration we consultation about Naive Bayer's algorithm for classification that describes utilization for dengue disease prediction. The preeminent aspiration of this related survey is, to resolve proper prediction system for dengue. The methodology used to diagnose a patient is modified NB predictor algorithm [2].

In this proposed paper, the dengue representation for the vulnerability map for nation Malaysia in the area of state Selangor and its areas, which is observed to be most astounding dengue episodes happened in 2014, as the ascent of rates were impelled from month of May till June the greatest number of occurrences can be restricted for the specific directions [3].

It offers a method to classify mosquitoes using SVM with the feature of MFCC. From the test results, they so that the conclusion obtained SVM using Kernel is better than previous research using back-propagation. This research may also be improved by classification using the Neural Networks, as well as other data retrieval method to get higher accuracy [4].

In proposed paper, the fundamental inspiration of this procedure is to characterize information and give appropriate route to the applicants for removing valuable data from information. It effectively recognizes a reasonable calculation for the exact present calculation result from it. They distinguish calculation based on their outcome investigation and the preciseness of the forecast [5].

In the proposed methodology, household clustering of dengue is to be done by using dengue serotypes depending upon the age group through applying K-means Clustering Algorithm is increasing the proficiency of the output[6].

Proposed System: In a proposed system, the "Smart Prognosis Dengue Model" is to prediction of dengue that adopts the Logistics Regression Algorithm, as it supports heterogeneous data types and provides statistical measures with a better predictive power. Traditionally, various algorithms are used to predict the dengue cases. It is not sufficient method to give a correct accuracy, when compared to Gradient Boosting Algorithm. The Gradient Boosting Regression (GBR) calculations are fundamentally utilized for foreseeing the information, and in GBR are utilizing Ensemble Technique. When endeavour to foresee the objective variable utilizing any AI strategy, the primary driver of distinction in real and anticipated qualities are noise, difference, and bias. Group decreases these components (with the exception of commotion, which is an unchangeable mistake). A gathering is only an accumulation of indicators which meet up (for example mean everything being equal) to give the last expectation.

The final product of a fitted relapse examination is that known highlights and can foresee the obscure yield esteem. Here is the procedure that boosting relapse pursues,

1. Predict an underlying assessment of 0.0
2. Use the genuine qualities to ascertain the blunder in the underlying forecast.
3. Split the information into gatherings utilizing the highlights of the information, with the objective of putting information with comparative mistake into a similar gathering. For each gathering, locate the normal blunder

4. For each datum point in that gathering, add the normal blunder to the present forecast
5. Calculate the new mistake for each point for the new expectation
6. Then recurrent the cycle over again beginning at stage 3 the same number of times as wanted. For anticipating the information, the Gradient.

Boosting Regression (GBR) calculation is utilized, and in GBR are utilizing Ensemble Technique. When the attempt to anticipate the objective variable utilizing any AI strategy, the primary driver of contrast in genuine and anticipated qualities are commotion, fluctuation, and predisposition. Gathering lessens these variables (with the exception of commotion, which is a final mistake). A gathering is only an accumulation of indicators which meet up (for example mean all things considered) to give the last expectation. The takeaway is that powerless students are best joined in a way that enables everyone to solve a constrained segment of the issue.

Any machine learning routine can be utilized as a weak learner student. Neural nets, support vector machines or some other would work, yet the most generally utilized weak learner is the decision tree.

Generally, Its incorporated with Mean Square Error for improving the levels of performance as it's a part of measure, how close a fitted line is to the data points. It can use a new configuration computer called Raspberry PI with GSM and GPS module. This application can also contribute and generates the risk maps and its location-specific predictions.

Methodology

A.Data Pre-Processing: The dataset contains all the data which the learning model should learn for making the right forecasts. The crude information may have many varieties in the estimations of each element which may prompt off base outcomes. Thus the learning procedure will pre-process the dataset.

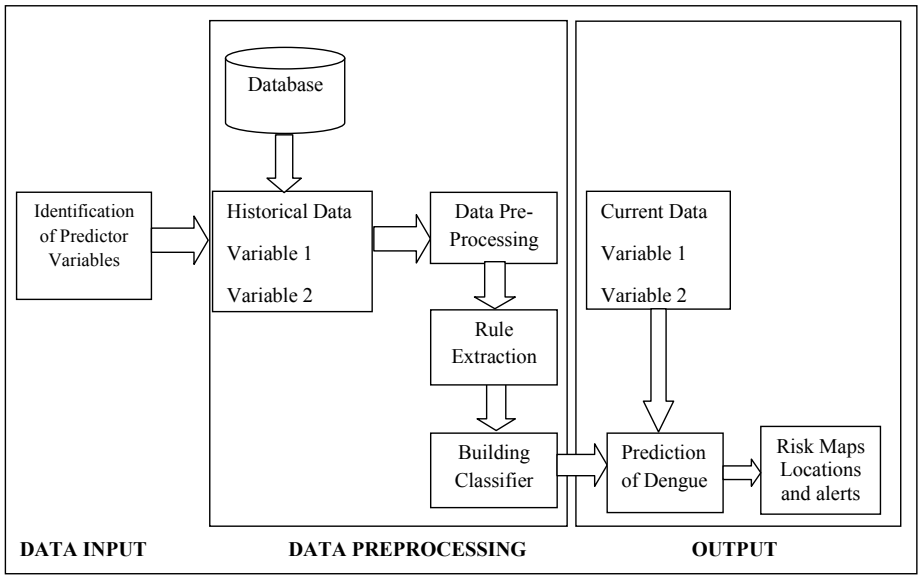

Fig 1: Smart Prognosis Dengue (Spd) Model

B. Prediction of Missing Values:

- **Removal of Data Occurrences:** The information occasion which has a missing an incentive for any element was evacuated. On these lines expelled the untrustworthy information point from the preparation set and yet, it has decreased the dataset estimate from 5000 to 1000
- **Filling the Missing Values:** The missing qualities in the datasets were doled out the most much of the time happening an incentive for that include. By utilizing the bundle "Pre-processing" and the usefulness "Imputer()" from scikits.learn.
- By seeing that utilizing the second methodology (for example Imputer) the outcomes were progressively exact

C. Segregating the Dataset Into Standardization: They can be an enormous variety in the measures of a component over the sufficient dataset. This

will make it troublesome for the model to gain proficiency with the information legitimately. It makes vital to institutionalize the info. It very well may be actualized by taking out the mean from the rate of each credit and scaling to unit changes. For this occurrence, utilizing the usefulness of "Standardscalar()" to decide from the preparing package.

D. Conversion of Array To Nominal Values: The component "states" in the dataset incorporates the names of three states. Its need to change over character esteems to numerical esteem. By applying the equivalent by utilizing LabelEncoder() usefulness of the pre-handling bundle.

E. Integration of Raspberry Pi With Generates the Alert Maps: At long last, to execute the content in Raspberry Pi 3, to foresee the dengue is there or not with given side effects. On the off chance that dengue ailment is found for the individual, raspberry pi coordinating with machine learning concepts to intimate the dengue sickness is found or not. It can likewise send and advise the cautions to influenced individual or specialist. Alongside that, it very well may likewise create risk map areas utilizing GPS and GSM modules.

Algorithm: In Dengue Prediction Model are mainly using two algorithms and they are;

1. Logistic Regression Algorithm(LRA)
2. Mean Square Error (MSE)

Logistic Regression Algorithm: Logistic Regression is an exceptional among the most utilized Machine Learning calculations for parallel grouping. Logistic Regression is go-to technique for double order. It gives you a discrete paired result among 0 and 1. Calculated Regression estimates the connection among the needy variable and the at least one determining factors, by assessing probabilities utilizing its natural strategic function. These desires should then be changed over into a paired number that one numerous really make a forecast. This work of Logistical Regression Algorithm likewise called a sigmoid capacity. The strategic capacity, additionally called the sigmoid capacity was created by analysts to portray properties of populace development in nature, rising rapidly and maximizing at the conveying limit of the earth. It's an S-shaped bend that can take any genuine esteemed number and guide it into an incentive somewhere in the range of 0 and 1, however never precisely at those points of confinement.

The key limit, also called the sigmoid capacity was made by examiners to depict properties of masses improvement in nature, rising quickly and boosting at the passing on farthest point of the earth. It's a S-shaped twist that can take any certifiable regarded number and guide it into a motivating force some place in the scope of 0 and 1, yet never correctly at those purposes of restriction. 1/ (1 + a^-esteem)

Where a is the base of the typical logarithms (Euler's number or the EXP () work in your spreadsheet) and regard is the genuine numerical regard. It is used to predict twofold outcomes for a given course of action of self-sufficient components. The yield of Logistical Regression is a sigmoid twist (or even more broadly known as S-twist). In vital regression, there are two achievable event 0 & 1. That object occurs, or it doesn't. It uses a cut-off a motivating force to make our desire more straightforward. Self-sufficient segments or factors can be hard and fast or numerical elements. Logistical Regression is used to check discrete characteristics (regularly twofold characteristics like 0/1) from many free factors. It anticipate the probability of an appearance by capable data to a logit work. It is similarly called logit regression. These techniques recorded underneath are every now and again used to help improve determined to backslide models join coordinated effort terms, take out features, regularize frameworks, using a non-straight model.

Mean Square Error: The Mean Square Error (MSE) is an estimating capacity the regular even of the errors- that is, the normal squared contrast between the assessed qualities and what is assessed. MSE is a hazard work, relating to the normal estimation of the squared blunder misfortune. The way that MSE is quite often entirely positive (and not zero) is a direct result of arbitrariness or in light of the fact that the estimator does not represent data that could create progressively exact assessments. The MSE is a proportion of the nature of an estimating - it is dependably non-active, and qualities more like zero are better. MSE can speak to the contradiction between the real perceptions and the perception esteems anticipated by the model. In this unique circumstance, it is utilized to decide the degree to which the model fits the information just as in the case of expelling some illustrative factors are conceivable without altogether the model's prescient capacity.

VI. Experimental Setup Testing Results:

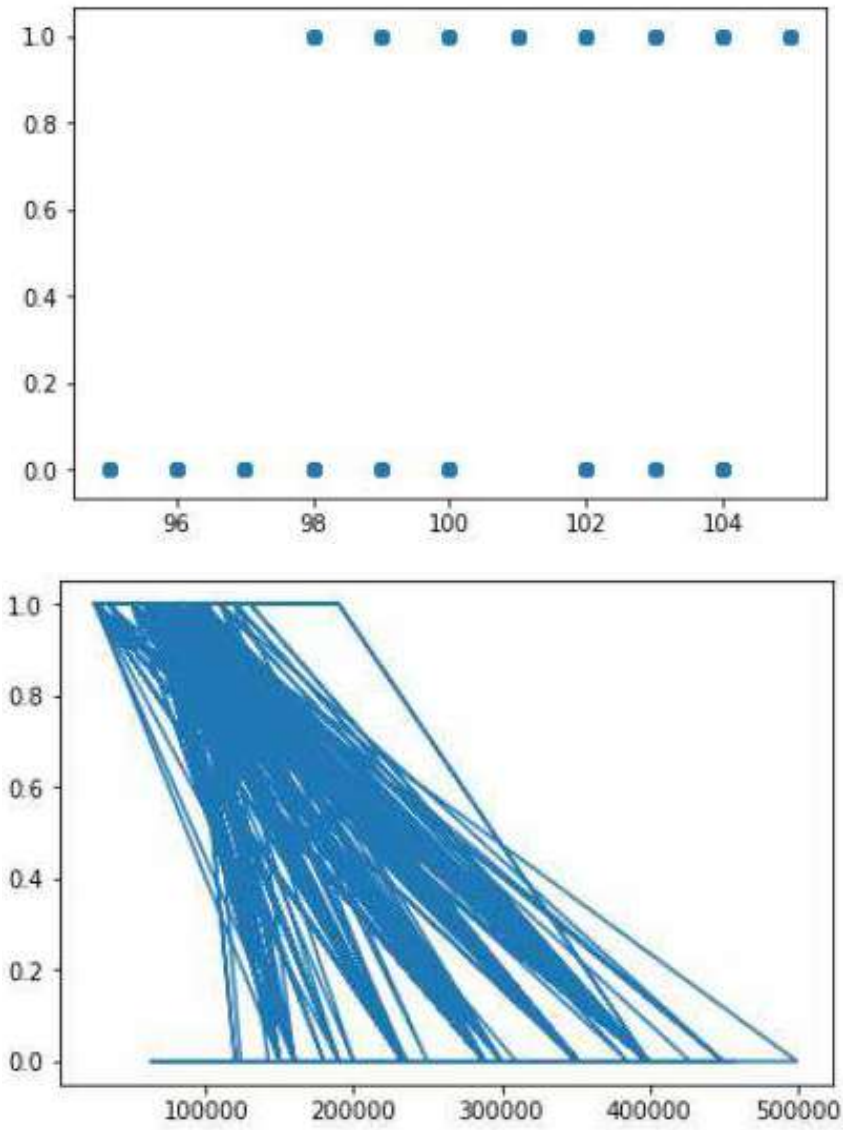

Fig 2: Matplots Representation

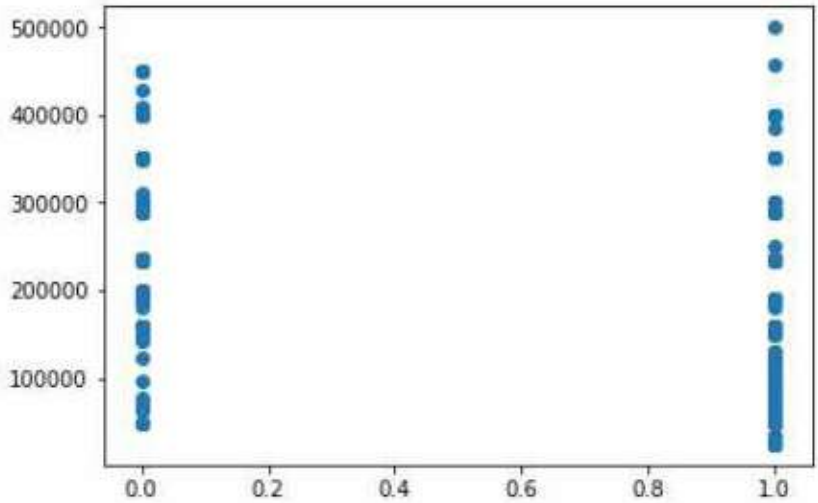

Fig 3: Software Configuration

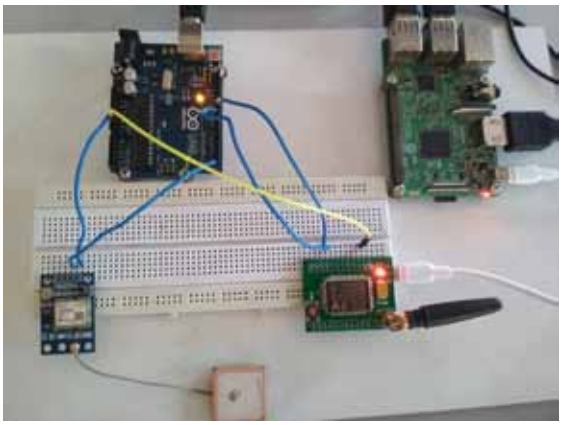

Fig 4: Hardware Configuration Notify When Dengue Is Found

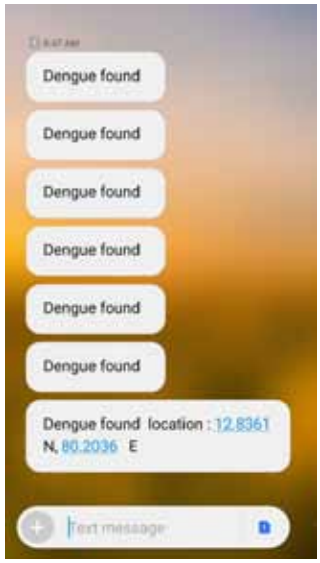

Fig 5: Alert Message and Locations

Conclusion

The proposed conceptual smart prognosis dengue (SPD) recommend advanced method of predetermine and early detection of dengue cases. A standard for predicting the forthcoming dengue outbreaks incorporating Logistic Regression Algorithm. From the undertaken experiments, it shows that Logistical Regression Algorithm capable to obtain good generalization ability compared to Gradient Boost Algorithm, thus enhance the forecast accuracy and Mean Square Error. In the substantial foresight scenario, there are several numbers of factors having their influence on dengue outbreak such as Fever, Platelets, Temperature, Vomiting and Fatigue, etc. The suggested model will useful to governance, specifically Ministry of Health Sector in arranging plans and identifying initiatives needed for the purpose to strengthen dengue control. Besides, it will also give precedence to the people in understanding and taking precaution steps in preventing dengue epidemic from becoming pervasive.

An Survey on Breast Cancer in Machine Learning

Martina Jose Mary M[1], Umadevi .S[2]

[1]PG Scholar, [2]Associate Professor, Department of Computer Science and Engineering, IFET College of Engineering, Villupuram

Abstract

Context: With the fast development of information in biomedical and social insurance networks, it has been a troublesome assignment to separate learning rapidly from accessible information. Breast cancer ahead of time can diminish the hazard rate of life; numerous investigations have demonstrated the relationship of AI calculations in various malady expectation. As health care needs timely and accurate performance for diagnosis, we are making use of data for better understanding about stage of cancer, prediction, effective decision making, maintenance of breast cancer record, organizing structured and unstructured data to give accurate results. This paper summarizes a traditional survey and the importance of dataset in health care machine learning can be implied.

Keywords: *Health care, prediction, diagnosis.*

Introduction

Breast cancer was the most hazardous disease after lung disease. Early discovery can endure the general population lives since it is simpler to treat and keep the tumor from extended. Tumor is the irregular development of cells. Enduring, the X-beam was the main technique that was utilized to distinguish the bosom malignant growth. In any case, numerous another strategies have been produced and proposed for distinguishing process that are more proficient than x-beam technique, for example, neural systems, artificial consciousness, and information mining.

Health care communities have advanced in achieving the accuracy using big data analytics. The main potential of Big-data lies in the delivery of the proper medicine, using an accurate decision support system for clinical results like extracting literature, changing times, growing voluminous amount of data continuously with speed and yield better models with high precision results. The four main characteristics of big data are high Volume of data, Variety forms of data, Velocity of streaming data, Veracity of data. Now-a-day‟s, Big-data gaining importance in terms of precision medicine, which is mainly targeted activities like analyzing daily activities, the patient‟s genetics, and the environment etc., Analyzing human genome is one of the keys to human health. Large data storage and digitization of records also needs Big-data.

AI has made an extreme improvement throughout the years to help redemption of precise outcomes without human intercession and for better comprehension of crafted by human. It gives sorts of Artificial Intelligence (AI) that helps a framework with the capacity to learn independent from anyone else without being modified unequivocal. It involves six steps for complete process are collecting the data,cleaning the data, analyzing the data, training the data,testing the data and obtaining their result. An AI calculation is managed supervised and unsupervised algorithm. Supervised Learning is a technique, which uses labelled data for learning and then making predictions. The algorithm is trained with a specific task driven ability to map the output with the input given. The sort of supervised learning algorithms are called classification, and prediction. Examples

Corresponding Author:
Umadevi .S
Associate Professor, Department of Computer Science and Engineering, IFET College of Engineering, Villupuram.
e-mail: mamahima@gmail.com

of supervised learning types are SVM, K-NN, Naïve Bayes, Neural Networks, Ensembling method, and Decisiontrees. Labels are not required in unsupervised Learning, This technique involves in finding out the similarities among the input and based on similarities, it groups the data. Clustering is one of the best examples for unsupervised Learning. On clustering technique, the clusters are divided based on their similarities that lie among clusters. K- Means and Hierarchal are types of clustering techniques.

Literature Survey:

A. A Hybrid Model to Support the Early Diagnosis of Breast Cancer: Davi Carvalho, Plácido Rogerio Pinheiro, Mirian Calíope Dantas Pinheiro[1] have proposed the Hybrid Model to help the early finding of Breast Cancer, which is utilized as a help in diagnosing. Hybrid model is more accuracy than Bayesian Network .The main objective of the Multi-Criteria Decision Analysis is accomplished an ideal to recognize the most persuasive characteristics of breast cancer. It can be used to obtain accuracy as 95.7% of success, 1.7% of doubt and 2.8% of failure.Given a sufficiently vast database this device will most likely gone through a great many cases in almost no time and alarm the cases with high shot of having breast cancer.Besides with a bigger database, the outcomes will be progressively steady and precise. We will keep on attempting to improve the outcomes and lessen the quantity of individuals who have a late analysis or a superfluous horrendous medical procedure.

B. An Application of Classification Techniques on Breast Cancer Prognosis: andeep Chaurasia, Prasu Chakrabarti, Neha Chourasia[2] have proposed the Supervised learning is a strategy in which a lot of delegate input-yield sets is displayed to the system. The test has been performed on the Breast cancer malignant growth dataset utilizing three grouping procedures: Navies Bayes, Decision Tree, and Neural Network. The author can be compared their overall results for benign class is highest in Naïve Bayes classification with 98.65% with 437 true and 6 false predictions in contrast with Neural Network having 94.09% class prediction with 446 true and 28 false predictions and for Decision tree with 96.87% with 433 true and 14 false predictions. The prediction class for malignant class is highest in Neural Network classification with 94.67% with 12 true and 213 false prediction a compared to Naive Bayes algorithm with 91.8% class precision with 21 true and 235 false predictions and in Decision Tree with 90.08% precision with 25 true and 227 false predictions. So the efficiency of Neural Network is highest to predict the malignancy in breast cancer with +2.87% more than Bayesian classification and +4.59% more than Decision Tree.

C. Interpretability of Artificial Hydrocarbon Networks for Breast Cancer Classification: Hiram Ponce et al.[3] have proposed an Interpretability of Artificial Hydrocarbon Networks for Breast Cancer Classification, in which counterfeit hydrocarbon organizes, an AI calculation is changed over into the standard based and tree-based model with high exactness. The proposed methodologies comprised of two stages are data similitude and bunch ID, to assemble a tree-model of the hidden conduct of fake hydrocarbon systems. Diverse atomic parameters of the technique were recognized for interpretability. At that point, we investigated this strategy in the bosom disease characterization utilizing an outstanding open dataset. It can be used for tools are 10 cross fold validation .For the most part, AHN portrays about the component of synthetic inside a natural particle of tumor advancement in the Breast. Information likeness and group arrangement are the two fundamental techniques utilized in AHN classifier. The exactness acquired is 97.85%.

D. Using Machine Learning Algorithms for Breast Cancer Risk Prediction and Diagnosis: Hiba Asri, Hajar Mousannif, Hassan Al Moatassime, Thomas Noel[4] have proposed the performance comparison between different machine learning algorithms are support Vector Machine (SVM), Decision Tree, Naive Bayes and k-Nearest Neighbors on the Wisconsin Breast Cancer datasets. The tools used for 10 cross folds validation with Wisconsin dataset has 699 instances with two classes of Malignant (65.5%) and Benign (34.5%). The highest accuracy with the lowest error rate by SVM is 97.13%.

E. Prediction of Breast Cancer using Voting Classifier Technique: U. Karthik Kumar, M.B. Sai Nikhil and K. Sumanga li[5] have proposed the prediction of breast cancer by using the voting classifier technique in which they have included the algorithms are Decision tree, SVM, and Naive Bayes. Voting is one of the method of ensemble learning. The properties

which contribute less in exactness and in the forecast of disease are expelled utilizing the positioning calculation. The attributes which contribute less in accuracy and in the prediction of cancer is removed using the ranking algorithm and used 10 Cross-fold validations for avoiding missing values and over fitting in the subsets. Out of all algorithms, Naive Bayes has yielded high accuracy.

F. Automated annotation and classification of BI-RADS assessment from radiology reports: Sergio M.Castro, EugeneTseytlin, OlgaMedvedeva, KevinMitchell, ShyamVisweswaran, TanjaBekhuis, Rebecca S.Jacobso [6] have developed a technique which improves the quality assurance of healthcare. It manually analyzes the radiology data reports of mammography. It used the methodology of NLP along with PART. The evaluation is performed on 2159 radiology reports. Selections of the type of radiology documents are made using an output of a rule-based approach called BROK algorithm. The accuracy obtained using PART is 93%, better when compared with Naïve, and SVM. Limitations in this approach are Brooks is ambiguous due to multiple BI-RADS.

G. Breast Cancer Detection using K-nearest Neighbor Machine Learning Algorithm: Moh'd Rasoul Al-hadidi, AbdulsalamAlarabeyyat, Mohannad Alhanahna [7] have discussed about two techniques in which, first using an imaging technique for pattern extraction and feature process (noise of the image is eliminated using a Wiener filter), second is to predict the breast cancer using ANN and logistic regression.It used 209 images that were extracted from 50 patient's cases. These images were used for training, testing, and validating processes. In ANN and logistic regression model yielded with 93% accuracy for 209 images.

H. Neural Network Techniques for Cancer Prediction: A Survey: Shikha Agrawal, Jitendra Agrawal [8] have discussed a survey on Cancer Prediction. By Using multilayer perceptrons accuracy gained was 97.1% and PNN yields accuracy of 96%. Future enhancement of the work can be improved using numerous neurons in the hidden layer.

I. Identification and analysis of novel microRNAs Proceeding from fragile sites of human cervical cancer: Computational and experimental approach: G. Reshmi a, S.S. Vinod Chandra b, V. Janki Mohan Babu [9] have described a novel approach 'Mphred' which first recognizes initial-microns and then post-microns. Zuker"s Energy minimization method was used for validation; the validity of 95.60% is gained along with 98.5% specificity and 92.4% sensitivity.

J. Prediction of Cancer Class with Majority Voting Genetic Programming Classifier Using Gene Expression Data: Topon Kumar Paul et al [10] have proposed an approach, in which different type of cancer and machine learning applications over patient"s gene expression data is addressed. As the samples for training the genetic data are limited, most of the method cannot overcome over fitting problem so majority voting genetic programming classifier is proposed for classifying microarray data. The experiment is performed mainly on four data sets, using the proposed model and yielded the best accuracy on prostate cancer with 90.59% and lung carcinoma with 95.50%.

K. Using automatically extracted information from mammography reports for decision-support: SelenBozkurtet al [11] have introduced a system for decision-support to identify the lesions, that are malignant in nature among mammography reports. It used algorithm are NLP, Bayesian Neural network . The reports of free depicted objects are taken as an input and then using these two approaches, the probabilities of malignancy to each injury in mammography is given as output. The accuracy obtained is 97.58% (precision -98.3%, and recall-98.8%).

L. Fully automatic classification of breast cancer microarray images: Nastaran Dehghan Khalilabad et.al [12] discussed about a strategy called Microarray picture that is utilized for conclusion of destructive cells in the completely programmed characterization of bosom disease microarray pictures. The small scale exhibit imaging strategy helpful for extricating genome datasets (which is taken for DNA); the way toward removing the genome includes three stages called granulating, quality choice from DNA and characterization. A choice tree calculation is utilized continuing and 95.23% exactness is gotten in the visualization of sorts of bosom malignant growths.

Proposed System: The proposed framework aims to utilizing the health care record results as section to

help even advances the analysis of Breast Cancer. It can be used to predict and analysis a breast cancer in a difficult situations. It used to obtain their better accuracy in a breast cancer. Obtained result which used to make decision in a early stage of the breast cancer by using machine learning algorithm.

Conclusion

This paper condenses the examination usefulness in setting up enormous systems in human services utilizing huge information and the utilization of various AI calculations for guess of the malady. The commitment made by numerous specialists for the use of various machine calculations alongside precision is similarly appeared.

Health of the Elderly in India: A Socio-Legal Study

Arti[1], J.K. Mittal[2]

[1]Ph.D. Research Scholar under the supervision of Professor. J.K Mittal, Professor Emeritus, Amity Law School, Amity University, Uttar Pradesh, [2]Professor. J.K. Mittal, Professor Emeritus, Amity Law School, Amity University, Uttar Pradesh

Abstract

Context: To study the health and social problems of the elderly and their attitude towards life. Materials and Method: Descriptive study carried out in the Field practice area of the Department of Community Medicine in South India. A total of 213 elderly patients (60 years old and above) who attended the outreach clinics were interviewed using a pre-tested schedule. Findings were described in terms of proportions and percentages to study the socio-economic status of the samples and its correlation to social problems. Results: Around 73% of the patients belonged to the age group of 60-69 years old. Nearly half of the respondents were illiterate. Around 48% felt they were not happy in life. A majority of them had health problems such as hypertension followed by Arthritis, Diabetes, Asthma, Cataract, and Anemia. About 68% of the patients said that the attitude of people towards the elderly was that of neglect.

"It is not sufficient to add years to life but the more important objectiveis to add life to years"-

WHO Slogan. S: The popular saying, *"old* is *Gold'* which implies the gravity of aged on the earth. All the things get aged. The things around us both animate and inanimate go through this aging process. The things which don't have life earn currency and given a due place and reverence on account of aged.

The thing such as old swords, old Icon, old buildings, Cars and so forth. Are revered due to their aged. On contrary, the objects which have life such as animals, human beings are thrown useless things. The old people are not treated well and they need special care and policies for their autumn days. The increasing number of aged population, due to advancement in medical sciences, health care etc, amount a problem on both developed as well as developing countries[1]. The policy makers and social scientists focus their attention to abate the seriousness of the problem, which pose before countries, particularly third world countries. For understanding the problem of these aged, we have to know the basic concepts like aging.

Aging is natural, inevitable and ubiquitous phenomenon. Everyone should confront this process,

if he/she lives. It is irreversible one. Literally it refers to the effects of age. Commonly speaking, it means the various effects or manifestation of old age. In this sense, it refers to various deterioration in the organisms. Aging has been viewed differently by different persons. To politicians and Industrialists, it means power and wealth whereas to a middle class employee, it amounts to a forced retirement. To biologists and social scientists, it is a field of research on biological cells and problems on individual respectively. Handler defined "Aging is the deterioration of nature organism resulting from the dependent essentially irreversible changes intrinsic to all members of a species such that, with the passage of time. They become increasingly unable to cope with the stresses of the environment thereby increasing the probability of death"[2]. Beckar defines aging in the broader sense as "Changes coursing in an individual as the result of the passage of time". He adds "Aging consists of two simultaneous components of anabolic building up and catabolic breaking down". Comfort regards it as "the total effect of all changes which occur in a living being with increasing chronological age and which render it more vulnerable or less viable". Birren and Renner define "aging refers to the regular changes that occur in mature genetically representative organisms living under representative environmental conditions as they advance in chronological age". According to Hurlock, old age is the closing period in the life span. It is a period when people move away from previous, more desirable periods or times of usefulness. Stieglitz has rightly observed that "aging is a part of living.

Aging begins with conception and terminates with death. It cannot be arrested unless we arrest life. We may retire aging or accelerate it but we cannot arrest while life goes on, because it is essentially an element in living"[3]

Demographic Profile of Elderly in India: India, the world's second most crowded nation, has encountered a sensational statistic progress in the previous 50 years, involving very nearly a significantly increasing of the populace beyond 60 years old years. This example is ready to proceed. It is anticipated that the extent of Indians matured 60 and more seasoned will ascend from 7.5% in 2010 to 11.1% in 2025 UNDESA (United Nations Department of Economic And Social Affairs, 2008)[4]. This is a little rate point increment, yet a surprising figure in supreme terms. As per UNDESA information on anticipated age structure of the populace (2008), India had more than 91.6 million older in 2010 with a yearly expansion of 2.5 million old somewhere in the range of 2005 and 2010. The quantity of old in India is anticipated to arrive at 173 million out of 2026 and the share of older persons, above 60 years, in 2050, in India's population is projected to increase drastically by 20 percent.

Rundown figures veil the unevenness and complexities of the statistic progress inside India crosswise over Indian states with various degrees of financial improvement, social standards, and political settings. Anticipated appraisals of populace structure in 2025 for North India hold a "pyramidal" shape, while for south India, the portion of the older populace is required to grow significantly. Straight development in the number of inhabitants in the older is normal in the following 100 years, with more extreme slopes of increment in focal and east India and leveling off of supreme quantities of old in the north, south, west, and upper east .

A few important characteristics of the elderly population in India are noteworthy. of the 8.5% of the population who are elderly, two-thirds live in villages and nearly half are of poor socioeconomic status (2016 report by the ministry for statistics and programme implementation). Half of the Indian elderly are dependents, often due to widowhood, divorce, or separation, and a majority of the elderly are women (70%). of the minority (2.4%) of the elderly living alone, more are women (3.49%) than men (1.42%). Thus, the majority of elderly resides in rural areas, belongs to low SES, and is dependent upon their families.

While the southern states (Andhra Pradesh, Karnataka, Kerala, and Tamil Nadu) might be viewed as the greatest drivers of maturing in India, other Indian states (quite Haryana, Himachal Pradesh, Maharashtra, Orissa, and Punjab) are likewise encountering an old populace blast, to a great extent in provincial regions. Enormous scale investigations of the wellbeing practices of this developing old Indian populace are rare. In any case, data assembled from various overviews and provincial and neighborhood studies point to the high commonness of a few dangerous practices, for example, tobacco and liquor use, and physical dormancy. With these stressors, typically, total information contrasting the 52nd (1995–1996) and 60th Rounds (2004) of the National Sample Survey (NSS) propose a general increment in the reports of infirmities and usage of human services administrations among the old. Access

to administrations, be that as it may, is uneven the nation over.

An analysis of morbidity patterns by age clearly indicates that the elderly experience a greater burden of ailments (which the National Sample Survey Organisation defines as illness, sickness, injury, and poisoning) compared to other age groups (see National Sample Survey Organisation, 2006, Fig. 1), across genders and residential locations. The elderly most frequently suffer from cardiovascular illness, circulatory diseases, and cancers, while the non-elderly face a higher risk of mortality from infectious and parasitic diseases. In developed countries advancing through demographic transition, there have been emerging epidemics of chronic non-communicable diseases (NCDs), most of which are lifestyle-based diseases and disabilities In contrast, India's accelerated demographic transition has not been accompanied by a corresponding epidemiological transition from communicable diseases to NCDs. As indicated in Figure 15-1, the Indian elderly are more likely to suffer from chronic than acute illness. There is a rise in NCDs, particularly cardiovascular, metabolic, and degenerative disorders, as well as communicable diseases. While cardiovascular disease is the leading cause of death among the elderly, multiple chronic diseases afflict them: chronic bronchitis, anemia, high blood pressure, chest pain, kidney problems, digestive disorders, vision problems, diabetes, rheumatism, and depression. Concurrently, the prevalence of morbidity among the elderly due to re-emerging infectious diseases is quite high, with considerable variations across genders, areas of residence, and socioeconomic status. It is projected that NCD-related disability will increase and contribute to a higher proportion of overall national disability, in step with the graying of the population. However, a very significant shortcoming of most of the above studies is the use of self-reported data, which, in the absence of autopsies and physician examinations of patients, represents enormous lacunae in data on the conditions affecting the elderly. More detailed studies are needed, other than surveys, to extract information on the epidemiology of health conditions experienced by the elderly.

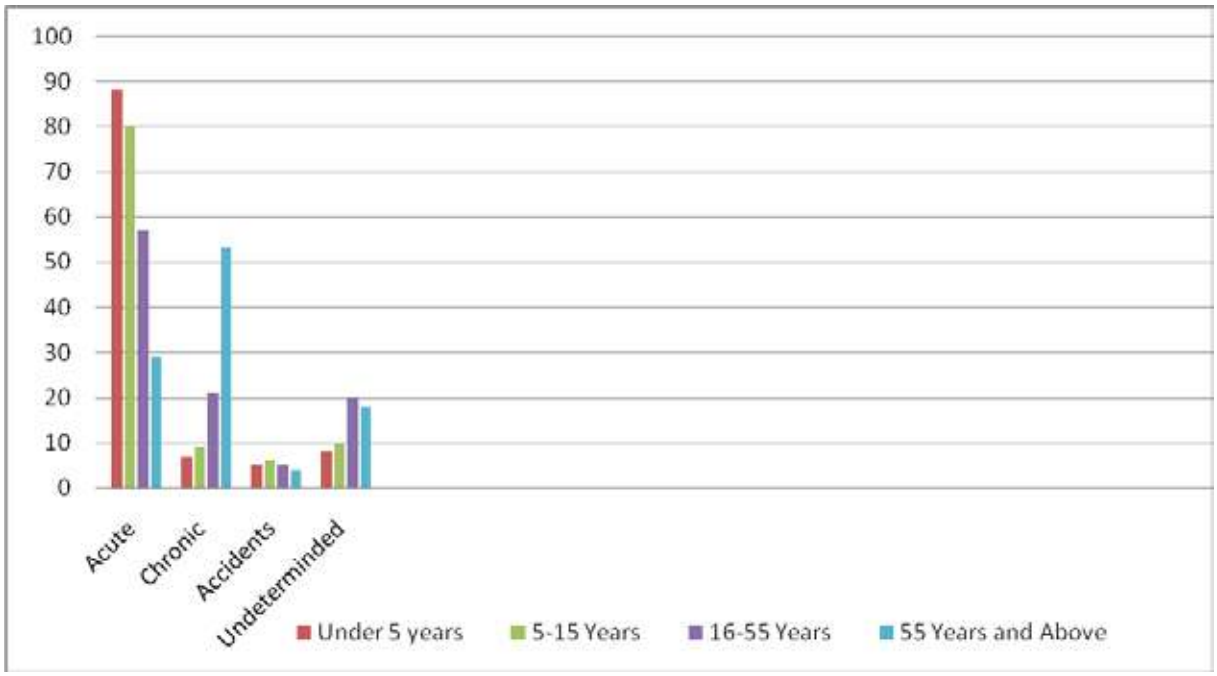

Figure 1: Burden of Illness Type Among Indians. Source: Dror, Putten-Rademaker, and Koren (2008).

Social Factors: A more intensive take a gander at the writing on access to human services uncovers variety over an age angle. More established Indians have revealed higher paces of out-patient and inpatient visi. The age angle in older wellbeing access is overlaid by social determinants of wellbeing[5]. For one, there is a feminization of the old populace; as indicated by the 2001 registration, the sexual orientation proportion

among the Indian old matured 60 years and more seasoned is 1,028 females for 1,000 guys. It is normal that by 2016, 51% of India's old will be ladies (in provincial regions, this extent will be a lot higher). More ladies report weakness status when contrasted with guys, but a far more noteworthy extent of men is hospitalized when contrasted with females (87 versus 67 for each 1,000 matured people).

Neglected well being needs are progressively articulated among the 33.1% of the old in India who in 2001 were accounted for to have lost their mates, of whom a bigger relative extent is female (half of female old are widows versus just 15% of male older who are single men). Studies have demonstrated that widows are lopsidedly helpless against incapacity, ailment, and poor medicinal services use because of various portability, business, property, and monetary limitations.

Notwithstanding sexual orientation and conjugal status, religion, standing, instruction, financial autonomy, and sanitation have bearing on older wellbeing. Tally displaying of information from the 52nd Round of the NSS shows that the quantity of infections endured by an old individual, determined freely for rustic (Poisson Model) and urban populaces (Negative Binomial Model), incorporate age, sexual orientation, education, accessibility of drinking water and a latrine office, and family unit month to month utilization use. Another investigation of Uttar Pradesh (UP) and Maharashtra found that the older elderly (70 years and more seasoned) were altogether more averse to look for treatment contrasted with the 60–69 age classification, while Muslims were somewhere in the range of 62% and 49% bound to look for treatment in UP and Maharashtra, separately, contrasted with Hindus. This investigation found that old in booked clan/planned standing (SC/ST) classifications were 54% more uncertain and other in reverse classes (OBC) 35% more averse to look for treatment for existing diseases in Maharashtra contrasted with different ranks. At long last, secondary school graduates were twice as likely in UP and multiple times as likely in Maharashtra to look for treatment contrasted with the uneducated gathering. Be that as it may, in the previously mentioned examination, a greater part of the older experienced various bleakness conditions, which makes translating the exhibited outcomes troublesome. The nonattendance of thoroughly structured examinations that evaluate the sorts and seriousness of different sickness conditions in the old further features this reality utilizing information from a similar review, inferred that 9.5% of provincial occupants and 4.2% of urban occupants report absence of access to everyday necessities of drug, near twofold that of apparel and sustenance.

Broad Health Coverage: Planning and Needs A pathway to national wellbeing change has been imagined by the Planning Commission in the number one spot up to the twelfth Five-Year Plan for India. In October 2010, a High-Level Expert Group (HLEG) was gathered by the Planning Commission to prescribe changes in wellbeing financing, medicate obtainment, network cooperation in wellbeing, wellbeing the executives, and physical and money related standards for wellbeing and HR. Arranging older wellbeing in a more extensive system of all inclusive access and moderateness of Universal Health Coverage (UHC) can possibly change the auxiliary conditions that hamper the prosperity of the matured. We abridge a portion of the manners by which UHC may serve these capacities, all through showing the proof holes that will be required for these capacities to be met.

Key UHC changes relevant to access incorporate the arrangement of extra HR at the Sub-Health Center level (per 5,000 populace), just as the presentation of an extra Community Health Worker (like an Accredited Social Health Activist) in rustic and low-salary urban regions[6]. These changes would guarantee that notwithstanding existing needs of maternal and youngster wellbeing, rising needs in NCD control, just as activity on social and physical hindrances to get to, can be tended to locally (i.e., pair with Village Health and Sanitation Committees and their urban identical). Future research may help decide the extent of consideration at the Sub-Health Center level and the scope of promotive administrations gave at the town/network so as to take into account the necessities of India's older.

It has been proposed by the HLEG, additionally, that a fundamental bundle of consideration (including essential, optional, and tertiary-level administrations) be cashless at purpose of administration using a National Health Entitlement Card (which would likewise fill in as an identifier for Electronic Medical Records, conveying quiet chronicles and care-chasing profiles). This arrangement will be especially valuable for the older poor, and will require advancement and a far reaching exercise in information accumulation and assemblage on both the client and supplier sides. To this end, methodological commitments from progressing

associate examinations, for example, the Longitudinal Study on Aging in India (LASI) and parallel endeavors universally will be very significant.

Various administrative instruments under the aegis of a recently proposed National Health Regulatory and Development Authority will guarantee wellbeing framework backing, accreditation, and nonstop wellbeing frameworks assessment. This procedure may profit, once more, from the developing base of research on old clients of the wellbeing framework, who may have a more drawn out length of collaborations with the framework just as incredible variety regarding need and weight, affected by changing social determinants. Wellbeing frameworks assessment will also need to reflect age-explicit horribleness and mortality designs, just as that of intersectional older gatherings (the bereaved old, matured of religious minority status, and others).

Conclusion:

The development of the older populace in the coming decades will carry with it exceptional weights of horribleness and mortality the nation over. As we have laid out, key difficulties to access to wellbeing for the Indian old incorporate social hindrances molded by sexual orientation and different tomahawks of social disparity (religion, position, financial status, shame). Physical obstructions incorporate diminished versatility, declining social commitment, and the constrained reach of the wellbeing framework. Wellbeing moderateness requirements incorporate restrictions in pay, business, and resources, just as the confinements of money related insurance offered for wellbeing consumptions in the Indian wellbeing framework.

Among the most critical discoveries that rose in building up this audit was the inadequacy of information on the weights of access and moderateness among older populaces in India. A noteworthy purpose behind this is standard wellbeing information gathering in India isn't intended to reflect or describe neurotic movement: a procedure wherein, by goodness of being alive longer than others, the older are bound to encounter a pathology, prompting impedance, practical impediments, and at last incapacity. Numerous standard information accumulation strategies (National Sample Surveys, Census information, or passing endorsements) in India don't catch neurotic movement nor do they disaggregate dreariness and inability results among the older.

Effectiveness of Rhythmic Chopping & Lifting Pattern on Shoulder Range of Motion and Upper Extremity Functional Index in Post: Mastectomy Patients

Aishwarya Bulbule[1], T. Poovishnu devi[2]

[1]Intern, Faculty of Physiotherapy, Krishna Institute of Medical Sciences Deemed To Be University, Karad, Maharashtra, India, [2]Associate professor, Department of Oncolgy, Faculty of Physiotherapy, Krishna Institute of Medical Sciences Deemed To Be University, Karad, Maharashtra, India

Abstract

Objective: T o determine the effect of Rhythmic chopping & lifting pattern on shoulder range of motion in Post-mastectomy patients.

Method: A total 40 subjects were taken according to inclusion and exclusion criteria. Each subject was assessed by using Shoulder goniometry and UEFI questionnaire.

Result: A statistical analysis showed that Rhythmic chopping and lifting PNF exercises showed significant improvement in the outcome variables concluding that it improves shoulder ROM and functional activities.

Conclusion: Analysis of all the data obtained through the outcome measures (UEFI Questionnaire and shoulder ROM) shows that Rhythmic chopping and lifting PNF exercises showed significant improvement in the outcome variables concluding that it improves shoulder ROM and functional activities.

Introduction

Breast cancer is an abnormal growth of cells that normally line the ducts and lobules.[1] Breast cancer is the most common female cancer worldwide representing nearly a quarter (25%) of all cancers.[2] In present scenario, breast cancer is reflected as an important public health problem for adult women residing in developing countries and showing prevalence is estimated around 2.5 million, with over 0.8 million new cases & 0.5 million deaths occurring each year. [3]

Changes in reproductive risk factors, dietary habits & increasing life expectancy it is causative factor of rising incidence of breast cancer in India. Study suggests that approximately 75,000 new cases occur in Indian women every year. Breast cancer can be invasive carcinoma or non-invasive carcinoma.

Treatment of breast cancer is classified into two types- Local therapy (surgery and radiotherapy) or Systemic treatment (chemo, hormone and targeted therapy).

Mastectomy: Mastectomy is removal of the entire breast, including the nipple, but no lymph nodes from under the arm or muscle tissue from beneath the breast is removed.

In a Modified radical mastectomy consists of removal of entire breast with lymph nodes in the axilla. The extent of lymph node dissection may vary from complete

clearance to less extensive procedure. Mastectomy and adjuvant radiotherapy given to the mastectomy site and axilla increases the risk of impairment of shoulder function.[4]

Radiotherapy leads to release of reactive oxygen species cuases vascular damage leads to hypoxia,while the alteration in LDH (lactate dehydrogenase) levels secondary to hypoxia enhances fibrosis and worsen it.[5]

Lennart Blomqvist et,al established that radiotherapy will cause fibrosis that results into reduction of ROM of shoulder joint in mastectomy patients .[6]

Pectoralis major, serratus anterior, upper trapezius, rhomboid are affected which causes reduction in flexion, external rotation,scapular elevation and retraction. Biceps, triceps,deltoid, latissimus dorsi are also affected.[7]

Complications: Estrogen withdrawal symptoms, arthralgias, fatigue,mood swings, anxiety, weight gain, peripheral neuropathy, reduced mechanical strength of bone,discomfort pain,decreased range of motion and weakness in the muscles of the shoulders and arms lymphedema may affect the daily operational activity and the overall functional abilty associated with health and quality of life. [8]

Rhythmic Chopping & Lifting Method: Proprioceptive neuromuscular facilitation technique (PNF) is stretching technique. It has positive effect on active and passive ROM.It helps to improve functional movement through facilitation, inhibition, strengthening & relaxation of muscle group.[9]

Chopping & Lifting is one of the pattern of PNF in which combination patterns of bilateral asymmetrical thorax, upper extremity combined with neck along with contract relax technique.

In this technique the muscle is strectched isometrically,contracted for 7-15 seconds,briefly relaxed for 2-3 seconds, and then immediately subjected to a passive stretch that stretches the muscle even further than initial passive stretch. This final passive stretch is held for 10-15 seconds. The muscle is then relaxed for 20 seconds before the PNF technique is performed.[10]

Study conducted by Cochrane states that scapulohumeral rhythm can be initiated with active assisted ROM, PROM, Soft tissue scar mobilization and proprioception neuromuscular facilitation (PNF) exercises.[13]

Studies conducted previously by Neuromuscluar Facilitation (PNF) techniques help in improving range of motion as it elongates the Golgi tendon organ that facilitates relaxation of the antagonist muscle. .

As PNF Technique is known to show significant effect in terms of pain reduction,correcting scapular dyskinesis and improving shoulder ROM,no study till date has cheaked the efficiency of Rhythmic Chopping & Lifting pattern in mastectomy patients. So the need of the present study is to cheak the effectiveness of single PNF technique i.e. Rhythmic Chopping & Lifting technique on shoulder range of motion and upper extremity functional index in Post-Mastectomy patients.[14]

Materials and Methodology

Subjects were selected from Krishna Hospital karad:

Inclusion Criteria:

- Unilateral carcinoma of breast.
- Subjects who underwent mastectomy procedure alone or along with radiation for breast carcinoma.
- Not involved in any other type of exercise protocol.
- Subjects who are interested to participate in the study

Exclusion Criteria:

- Infection in axillary area.
- Open wounds
- Plan or infection to undergo a reconstructive surgery with in intervention period.
- Previous history of trauma to shoulder, surgery, untreated patholgy or dysfunction.
- Current or previous cervical Neuropathy.

Methodolgy: Study was conducted among post mastectomy patients in Krishna hospital karad. A total 40 subjects were taken according to inclusion and exclusion criteria. After taking ethical clearance from instituitional ethics committee consents forms were given and taken consents from participants. The subjects were assessed by using shoulder goniometry and UEFI Questionnaire. The scores were according to the answers given by the subjects with the help of same Questionnaire and . Statistical analysis of collected data was done accordingly and hence result was obtained.

Result

1 Within the group comparison:

Group A:

1. UEFI:

Parameter (Group A)	Pre	Post	Mean diff	t value	p value	Remark
UEFI	4.0±1.182	4.3±1.081	-0.3000	2.854	0.0102	Significant

The above table and graph shows pre and post comparison within the group. Post treatment there was significant improvement noted in shoulder and arm mobility.

2. Shoulder ROM:

Parameter (Group A)	Pre	Post	Mean diff	t value	p value	Remark
FLEXION	70.9±7.210	80±6.287	-9.550	12.698	<0.0001	Sig

EXTERNAL ROTATION	57.4±8.858	55.7±1.841	1.300	0.4914	0.6259	N.S

The above table and graph shows post comparison between the groups. Post treatment there was significant improvement noted in group B as compared to group A according to the p values.

Discussion

This study "Effectiveness of Rhythmic chopping & Lifting Pattern on Shoulder Range of Motion and upper extremity functional index in Post- Mastectomy Patients" was conducted to compare the effectiveness of conventional shoulder and thoracic mobility exercises and Rhythmic chopping and lifting PNF Pattern, and find out the effective technique that improves shoulder ROM and upper extremity functional index in post-mastectomy patients.

There is rapid increase in incidence of breast cancer, hence surgery along with chemotherapy is mandatory for treatment of cancer. Surgery leads to dissection of muscles and soft tissue structures and chemotherapy causes decreased joint mobility and muscle strength, pain,impairment in functions and disabilty in gross fine motor skills leading to limitations in acivities of daily living.

The study was conducted with 40 subjects. The subjects were divided into two groups. Prior consent was taken from them. The subjects in first group received conventional shoulder and thoracic mobility exercises and in the second group received rhythmic chopping & lifting PNF Pattern. The interventions were carried out for alternate days per week for 4 weeks. The outcome measures for this study were ROM assessment and UEFI Questionnaire.

Previous studies state that therapeutic exercises that is AROM, PROM, AAROM, Stretching,strengthening are been used till date as a part of conventional treatment

Previous studies conducted by Kayla B. Hindle, Whitcomb, Wyatt O. Briggs, Junggi Hong concluded that PNF technique increases ROM by increasing the length of the muscle and neuromuscular efficiency.

Studies conducted previously by Dr .Kayinat Hassan, Dr. Danish Nouman, Dr. Surandar Kumar concluded that Proprioceptive Neuromuscluar Facilitation (PNF) techniques help in improving range of motion as it elongates the Golgi tendon organ that facilitates relaxation of the antagonist muscle.

Study conducted by Cochrane states that scapulohumeral rhythm can be initiated with active assisted ROM, PROM, Soft tissue scar mobilization,and proprioception neuromuscular facilitation (PNF) exercises .

Study conducted by Nicolaou Valentina, Stasinopoulos Dimitrios, Lamnisos Dimitrios states that PNF helps to improve quality of motion in various musculoskeletal diseases and in women with breast cancer.

Within the group comparison:

1. **Conventional Exercises:** Post training there was significant improvement noted with conventional exercises in UEFI (p = 0.0102). Post training there was significant improvement in ROM for Shoulder flexion (p=<0.0001) and internal rotation(p=<0.0001),In abduction (p=0.1263),external rotation (p=0.1036), and Extension(0.10360 following p values showed that there was no significant difference in the outcome variables.
2. **Rhythmic chopping and lifting Method:** ost training there was significant improvement noted with PNF rhythmic chopping and lifting exercises in UEFI (p=0.0421).There was significant improvement in Shoulder flexion (p=<0.0001), and internal rotation (p=<0.0001). And no significant difference was noted within the outcome variables in abduction (p=0.1542) and external rotation (p=0.6954) and extension (0.3786).

Between the Group Comparison: Post test there was significant difference between outcome variables in UEFI (p=0.0421). Following are the p values which led to analysis of improvement in flexion(p=0.0014), internal rotation(p=0.0046).And no significant difference was noted between the outcome variables in abduction(p =0.7760),external rotation(p=0.6259) and extension (0.1647).

This study shows that Rhythmic chopping and lifting method showed significant improvement in the outcome variables concluding that it improves shoulder ROM and arm mobility.

Conclusion

Analysis of all the data obtained through the outcome measures (UEFI Questionnaire and shoulder ROM) shows that Rhythmic chopping and lifting PNF exercises showed significant improvement in the outcome variables concluding that it improves shoulder ROM and functional activities

Conflict of Interest: Do not have any conflicts of interest to declare.

Source of Funding: This study was funded by Krishna Institute of medical sciences deemed to be university, Karad.

Ethical Clearance: The institutional Ethics Committee has given permission to initiate the research project entitled EFFECTIVENESS OF RHYTHMIC CHOPPING & LIFTING PATTERN ON SHOULDER RANGE OF MOTION AND UPPER EXTREMITY FUNCTIONAL INDEX IN POST- MASTECTOMY PATIENTS

Abstract

Background: Alzheimer's disease (AD), a category of neurological degeneration generally seen in elderly people which is reflected by memory loss and affecting daily living activities.

Method: The data has been accessed from scopus, pubmed, science-direct and google-scholar which is included in this article.

The literature provide the information about pathological alterations of Alzheimer disease emphasizing on formation of neuritic plaques, beta amyloid protein, neurofibrillary tangle and also updates therapeutics used in Alzheimer's disease including cholinesterase inhibitors, ACE inhibitors, NMDA receptor antagonists, secretase inhibitors and anti-inflammatory drugs, herbal drugs and other naturals.

Results: The research on neuropathology and diagnosis of Alzheimer's disease are determinants of this study. The pathophysiology, diagnosis using biomarkers and therapeutics of disease has been summarized.

Conclusion: The aim of this review paper is to focus on how diagnosis and pharmacotherapy of Alzheimer's disease useful for researchers engaged in the experimental research.

Keywords: *Alzheimer's disease, β-amyloid precursor protein, neurofibrillary tangles, Acetylcholinesterase inhibitors, Secretase inhibitors, biomarkers.*

Introduction

Alzheimer's disease (AD) is approved as a chronic, irreversible neurodegenerative disorder in many countries which produces various cognitive impairments in old people. Alzheimer's disease (AD) is indicated by memory loss and cognitive impairment which affect daily living activities. With an increase in the geriatric population in India, quantities of AD patients are increasing step by step[(1)]. The neuropathologists had distinguished 64 instances of amyloid plaques and NFTs, a cause of disease, at the time of Dr. Alois Alzheimer, in autopsied brains of AD individuals[(2)]. The extracellular deposition of Ab called Amyloid plaques; saw in parenchymatous cells of brain and furthermore in cerebral blood vessels called cerebral amyloid angiopathy (CAA) [(3)].

Currently such medications are approved by USFDA (US Food and Drug Administration), including five medications those are utilized for the treatment

Corresponding Author:

of cognitive manifestations of AD. NMDA receptor antagonist–memantine (Namenda) donepezil (Aricept), AChEIs –rivastigmine (Exelon), tacrine (Cognex) and galantamine (Razadyne, Reminyl) are drug of choice as per indications [4].

Pathophysiology of Alzheimer's Disease: In 1907, AD is known to treat subsequent to recognizing the pathophysiology of AD when neuropathological features of this disease observed and described by amyloidal plaques and hyperphophorylated NFTs and different hypotheses have been proposed [5] (Fig.-1). In last decade, it has been suggested that commonly used Ab hypotheses is responsible for complex pathophysiology of growing disease [6].

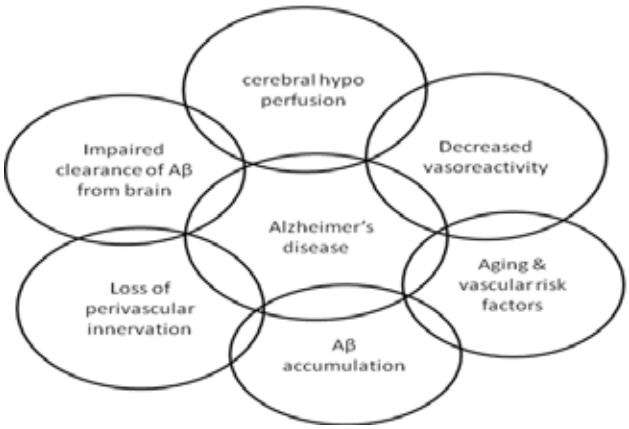

Fig 1: Various pathophysiological processes causing Alzheimer's disease (AD)

In late stage, development of amyloid plaques is appeared in the older age of patients [7]. The breakdown of APP is occurred by α-secretase which is further by action of β-and γ-secretases in amyloid cascade hypothesis [8]. The activities of neurons and their related astrocytes are responsible for production of Ab42 oligomers. The cytokines like IL-1b, TNF-a, and IFN-g stimulate neighbour astrocyte-neuron which produces Ab42 oligomer [9]. Working of neuron–astrocyte complex is affected by oligodendroglia (OLGs) which are destroyed by Ab oligomers [10]. The aggregation of Ab oligomers also induces degeneration in neurons of AD patients [11]. It was proposed that receptor pharmacology of Ab activates neuroprotectiion mediating Ab42 monomers through signaling pathways of mediating receptors [12].

Use of Biomarkers In Alzheimer's Disease: The cholinergic hypothesis of AD mechanism stipulates that most of cognitive manifestations are a result of cholinergic dysfunction [13].

Early Detection Strategies via Biomarkers: The magnetic resonance imaging and fluorodeoxy-glucose positron emission tomography determine hippocampus atrophy and cortical hypo-metabolism in AD progression. Advancements in science, radiology and system biology promotes use of biomarkers in AD research [14].

Biomarkers Using Cerebrospinal Fluid: Scientists have determined levels of Ab-42 peptide by knowing and total phosphorylated Tau protein (t-tau and p-Tau) and by estimating cerebrospinal liquid (CSF) which is responsible for neurodegeneration in AD. All three parameters have been proposed as one of the prevailing biomarkers for this disease which is independent of the apo-lipoprotein E (APOE) genotype [15]. The accuracy in AD symptoms and combining CSF Ab with either t-tau or p-tau level [16].

Biomarkers Using Imaging Techniques: Beta-amyloid load in the brain can be estimated through positron emission tomography (PET) using amyloid ligands such as Pittsburgh compound B (PiB), florbetapir (AV-45). Amyloid PET is considered a strong biomarker which was incorporated in 2011 and re-evaluated by National Institute on Aging-Alzheimer's Association diagnostic criteria for AD. In spite of being an amazing screening instrument in clinical trials, there is as yet limited evidence as a diagnostic tool for AD in clinical practice [17].

Biomarkers Using Genetic Screening: Early AD was related with special autosomal dominant mutations in amyloid precursor protein (APP), and/ or presenilin 1 (PSEN1), or presenilin 2 (PSEN2). At present, genetic testing for both PSEN1 and PSEN2 lay down in one family member with early-beginning of AD[18]. Lanoisele´e et al. observed the occurrence of AD, proposing potential advantage of screening non-familial cases of AD for these mutations[19]. Late-onset AD is most normally connected with APOE4 allele which is situated on chromosome 19q13.2 including regulation of Ab aggregation and clearance [20]. Besides, carriers of this allele have a lower onset of disease and more hippocampal atrophy in dose-dependent manner [21].

Strategies Used For Treatment of Ad: Currently available medications N-methyl d-aspartate receptor antagonist (Memantine), acetylcholinesterase inhibitors (Rivastigmine, Galantamine, Donepezil) in the various stages of disease [22]. In AD, deletion of amyloid beta protein deposition is one of the most favorable targets for treatment.

Anticholinesterases:

The drugs can change cholinergic neurotransmission, have been approved from regulatory authorities for Alzheimer's therapy [23]. Three ChEIs like Donepezil, Rivastigmine and Galantamine. Donepezil and Galantamine are usually used to get patients with mild to moderate AD. Rivastigmine inhibits both Acetyl cholinesterase and Butyryl cholinesterase associating the degradation of Acetyl choline [24]

NMDA Receptor Antagonist (Memantine): Memantine is a newer medication used in treatment of moderate to severe dementia. Its mechanism of action is a voltage-dependent, low-moderate affinity, uncompetitive NMDA receptor antagonism[25]. Memantine blocks abnormal glutamate activity which causes neuronal cell death and cognitive dysfunction[26].

Angiotensin-converting enzyme (ACE) inhibitors: It has been seen that ACE inhibitors decrease aggravation in brains of AD patients [27]. The mechanism includes transformation angiotensin I to angiotensin II. Another possibility is that angiotensin II is converted to angiotensin III after that to angiotensin IV. Angiotensin IV binds at AT_4 receptor sites, which are most predominant in the neocortex, hippocampus, and other areas and improves learning and memory [28].

Nonsteroidal Anti-inflammatory Drugs: Most researches on nonsteroidal anti-inflammatory drugs have concentrated on prevention instead of treatment of AD[29]. Animal models have exhibited that anti-inflammatory cyclooxygenase-2 (COX-2) inhibitors (Rofecoxib) reduced oxidative stress yet nonspecific COX inhibitors (Flurbiprofen and Ibuprofen) [30].

Secretase Inhibitors: Secretases are enzymes forms plaques by breaking APP of cell membranes into βA fragment. Memoquin, an example of β-secretase inhibitors reduce βA production by inhibiting AChE and limits tau hyperphosphorylation in early developmental stage [31].

Herbal Drug Treatment:

Polyphenols: e.g. Resveratrol found in red wine, peanuts and other plants, has been used to reduce oxidative stress, inflammation, βA and protect DNA thus, decrease in cell death. A moderate utilization of red wine decreases the danger of growing AD [32].

Curcumin: obtained from turmeric is used in AD treatment. Curcumin has neuroprotective, anti-inflammatory, antioxidant activities and cause inhibition of βA formation and clearance of existing βA [33].

Ashwagandha: (also known as Withania somnifera) proposed to have neuroprotective, anti-inflammatory, antioxidant, AChE inhibitoy, βA inhibitory activities which decrease in cell death[34]. It has been found that its oral use reversed damage to hippocampus and brain cortex by diminishing neurite atrophy, restoring synapses and improving memory in mice[35].

Nutrients and Hormones: Alpha-lipoic acid acts as a prevailing micronutrient with various pharmacological and antioxidant properties[36]. LA has been proposed to have anti-dementia in AD by altering antioxidant protective enzymes[37].

Polyunsaturated fatty acids: like omega 3-fatty acids (FAs), docosahexaenoic acid (DHA) found in high levels in the mammalian brain, neuronal membranes and myelin sheath. Their actions were observed by enhanced receptor binding and function of ion channels [38]. The cognitive impairment occurs due to diminished serum DHA levels which obstruct learning and memory [39]. As a result, the scientists have explored possibility of DHA supplement utilization may decrease risk of progression of AD [40].

Vitamin B_{12} and folate: in low levels are shown to result into cognitive decline. AD patients have high levels of homocysteine which need to become low. Homocysteine levels seem to relate with aging but not with cognition. A combination of vitamins B_{12} and B_6 and folate brought down homocysteine in people with mild to moderate AD [41].

Retinol: commonly known as Vitamin A is essential for learning, memory and cognition. Vitamin A levels in the brain decline in AD people, therefore its need to improve. A metabolite of vitamin A, retinoic acid is known to slow cell death and protect from βA [42].

Lithium Compounds:

Are prescribed for some neurodegenerative disorders. Enhancement of bcl-2 levels (neuroprotective protein) in hippocampus and frontal cortex of the rat has been observed. It also inhibits GSK-3, which is involved in increasing levels of phosphorylated tau and believed to be a factor prompting βA plaques and cell death [43].

Melatonin: has antioxidant, anticancer properties

and also protects mitochondria against tau tangles and also reduces βA toxic effects [44].

Conclusion

The evidences have been proposed to suggest that Aβ has pivotal role in the pathogenesis of AD, which involves many complex secondary events in the disease. Novel developments like radiology, chemistry and system biology involved use of biomarkers to identify mechanism. Enormous development has proposed to make various strategies for AD treatment including anti-inflammatory, antiamyloid, secretase inhibitor, antihypertensive, cholinesterase inhibitor, and some natural nutrients and hormones.

In this paper, authors have discussed the current research on diagnosis and pharmacotherapy of Alzheimer's disease which may be fruitful for researchers engaged in the experimental research.

Abbreviations: AD, Alzheimer's disease; ACh, acetylcholine; AChRs, acetylcholine receptors; AChEs, acetylcholinesterase; AChEIs, acetylcholinesterase inhibitor; ApoE, apolipoprotein-E; βA, beta amyloid; β-APP, β-amyloid precursor protein; NMDA, N-methyl d-aspartate.

Prevalence of Thalassemia among Reproductive Age Group Women of Central Gujarat

Anil Sharma[1], Vipin Vageriya[2]

[1]Associate Professor, Manikaka Topawala Institute of Nursing, [2]Assistant Professor, Manikaka Topawala Institute of Nursing, a constituent of Charotar University of Science & Technology, Changa, Dist. Anand, Gujarat, India

Abstract

Background: thalassemia is one of serious genetic blood disorder. To know about its suffering during or before child bearing to female will be great help to manage married life and can avoid children morbidity or disability.

Objective: study aimed to now prevalence of thalassemia among reproductive age group of females.

Method: Cross-sectional research design used to follow this prevalence from September 2018 to December 2018 among reproductive age group females of central part of Gujarat. House to house survey conducted by using predesigned, validated questionnaire to collect base-line information and blood sample collected and analyzed to know presence of thalassemia. Data was analyzed by using SPSS version 20 (Trial). Proportion, chi-square statistical tests used to know finding and interpret it.

Result: the overall prevalence of thalassemia among reproductive age group female is 3.679% which is almost nearer to India's prevalence of thalassemia.

Conclusion: Prevalence of thalassemia is higher in India especially in rural area where people having lack of knowledge about diseases

Keywords: *HPCL, thalassemia, reproductive age, prevalence*

Introduction

Thalassemia is a term derived from Greek word. Thalassemia is an autosomal recessive blood disease which lead to decreasing hemoglobin level through genetic defects in globin chain synthesis.

Thalassemia is one of serious genetic inherited disorder. It alters physiology of individual by loosing oxygen carrying capacity of Hb because of producing abnormal forms of Hemoglobin. Inability to carry oxygen leads to anemia which will be more serious in form of thalassemia because of excessive destruction of RBC's. It is a genetic autosomal recessive disorder which cause genetic defect and leads to decreased synthesis of globin chains of Hb. Further based on abnormal chain sequence alpha and beta thalassemia exist. As it is inherited disease so parent carries this recessive gene.

Autosomalrecessive disease happen inheritantly, where both parent bring equal amount of receive gene and in thalassemia this defect lead reduced level of hemoglobin. Persons carrying only one of these genes are called 'carriers' as they do not suffer from any disease but carry the abnormal gene and transmit it to the next generation. Carriers cannot be recognized clinically but only by performing special blood tests. Where both mother and father are 'carriers', there is a chance that their children may inherit the abnormal gene from both parents and thus suffer from a severe thalassemia

syndrome or a Sickle Cell syndrome or may be normal without any abnormal gene or carriers like their parents[1].

The present prevalence of thalassemia stated by WHO is 4.5% at world level while in India it varies from 0-17% but average can be counted as 3.5, where in Gujarat the prevalence rate is high[2].As per available statistic the highest prevalence of thalassemia remain at Gujarat (10 to 15%), which will further followed by other states in row as West Bangal (10.20%), Punjab (6.50%), Delhi (5.50%), Tamil Nadu (4%), Maharastra (1 to 2%) and Kerala (less than 1%)[3]. As prevalence is higher in Gujarat, so researcher took interest to find prevalence of thalassemia among reproductive age group females at Anand district of central Gujarat.

Estimation of prevalence will be informed to state government to take necessary action to handle the prevalence rate of thalassemia.

To support the significance of the research, researcher reviewed few studies result, few are like one study recommended that a routine premarital screening should be began so that high-risk marriage can be identified and prevent. Such step will further prevent happing of child suffering due to transfusion-dependency. These recommendations given by study after estimated higher prevalence of hemoglobinopathy[4].

A cross section study conducted in Bhopal of India also shown all most similar recommendation with some of additional points to suggest public awareness about thalassemia kind of disease and complete facts should be known to all healthcare professionals working in community services and it's their duty to aware public about these diseases through periodic meeting[5].

Material and Method:

Researchers used cross-sectional research design to achieve objective of study, and it covered in rural area of Anand Gujarat-North India. The data were collected from September 2018 to March 2019. A total of 958 female of reproductive age group were screened for thalassemia. The blood was collected by trained nursing staff. This study participants were combination or mixture of rural population involving them without discrimination with caste, religion. The sampling method used to recruit the sample were selected village randomly by lottery method.

Educational talks and audiovisual presentations were delivered to create awareness prior to get blood sample for investigation. Informed consent was filled by participants prior to study.

Structured Performa used to gather base-line information which included age, income, marital status, kind of family, food habits, occupation, caste, religion, family history of blood disorders.

Blood samples of 5 ml were collected in ethylene diamine tetrachloride acetate (EDTA) vaccute. Laboratory findings were measured after as all investigations held in NABL accredited laboratory. To know the high-risk sample and selecting sample for hemoglobin electrophoresis the HbA_2 level identified and all participants having less than 4.0 % Hb asked to go for Hb electrophoresis for disease confirmation. The entire participants who fulfil inclusion criteria are included in study. The females those were suffer with communicable and life threaten conditions are excluded from the study.

Participants those were between 18-35 year, willing to go for phase II(if screen in phase I) and residing in rural area of Anand district were recruited. The subject those were belongs to 18-35 year of age.Women those were diagnosed with any blood related disorder like anaemia and sickle cell anaemia, pregnant or breast feeded and suffering with any communicable disease were excluded from study.

About Anand District: Anand District Panchayat have 8 taluka's(Tehsil) which having 351 gram Panchayat. The total population of Anand district is 18,56,872.

The sample size calculated with the prevelance of 5% and precision of 5% by using formula

N=Z2 PQ/L2 and calculated sample size is 850 by calculating 10%of drop out rate we finalised the sample size of 958.

Anand district have total 8 talukas and samples are recruited from each talukas in equally weight age manner. The researcher collected base line information before collection of blood sample. It was completely assumed that collected blood sample should reach to laboratory for testing within 2 hours of collection. All universal precaution taken for collecting, storing, and transporting the simple. Data were collected by house to house survey. All samples are tested at lab of NABH accredited hospital.

Counseling done

Finding: Study estimated prevalence of thalassemia as per identified objective and it calculated 3.697. It means out of 1000 women, 3 to 4 females are vulnerable to become thalaasemic.

Table 1: shows prevalence of thalassemia

Count		
Normal	924	Prevalence of Thalassemia = 3.679%
Thalassemia	34	

The data related to marital status, educational qualification, having blood disorder, type of family, diet pattern and feeling of tiredness were collected.

Total 958 females were recruited for blood collection. Out of which 924(96.45) had not shown trait for thalassemia while 34 females (3.55) were considered as thalassemia trait. The mean MI value of thalassemia women were 10.92, mean HGB 9.66, mean MCV 62.08 and mean RBC value is 5.53 which is lesser than non thalassemia women.

Table 2: Frequency distribution of samples

N=958		
Marital status	**Frequency**	**Percentage**
No	140	14.6
Yes	818	85.4
Education		
Illiterate	124	14.45
Primary	544	56.78
Secondary	205	21.39

Every week	333	34.76
Every 3 month	111	11.59
Never	193	20.15

Table 3; shows complete sample descriptive statistic

Descriptive Statistics N-958		
	Mean	Std. Deviation
MI Value	18.0614	4.34781
HGB	11.1910	5.09125
MCV	78.3230	11.56269
RBC	5.2413	18.01294

Table 4: shows descriptive statistic of Normal female and thalassemia female

		N	**MEAN**	**SD**
Normal Women	MI VALUE	924	18.32	4.20
	HGB		11.25	5.15
	MCV		78.92	11.25
	RBC		5.23	18.34
Thalassemia Women		N	MEAN	SD
	MI VALUE	34	10.92	0.77
	HGB		9.66	2.68
	MCV		62.08	7.51
	RBC		5.53	0.65

Blood investigation also revealed about level of hemoglobin among reproductive age group, it's surprised to know that 26.51% (254 sample) of whole samples having less than 10 gm hemoglobin.

Ethical Consideration: Researchers obtained ethical committee approval and written informed consent also taken on voluntary basis from each participants before enrolling them in study. Informed consent covers all possible risk and benefits of present study and further each participant informed that any point of time they can withdraw from study.

Conclusion

This study concluded with a clearly estimated prevalence of thalassemia among reproductive age group of females in rural part of Anand district is 3.69 which almost nearer to national prevalence. As a secondary data researcher also find out that 26.59% prevalence of mild anemic cases with less than 10 gm of Hb.

Researcher took this opportunity to suggest premarital counselling or genetic counselling to avoid future complications of thalassemia.

Acknowledgement: Researcher acknowledge immense support of Charusat university for proving funding and local health professionals who helped us to gather all relevant informations.

Financial Support and Sponsorship: The study was supported by CHARUSAT University.

Conflict of Interest: there is no conflict of interest

Prevalence and Risk Factors of Obesity among Women

Anju Kayathri S.[1], Lucyamma C.V.[2]

[1]Lecturer, Department of Community Health Nursing, Amrita College of Nursing, Amrita Vishwa Vidyapeetham, Kochi, Kerala, [2]Associate Professor, Department of Community Health Nursing, Government College of Nursing, Kottayam, Kerala

Abstract

Background: Obesity is a state throughout that there's a generalized buildup of humoring fat among the body, leading to a weight of quite two hundredth of the essential weight. Fatness invites disability, disease and premature death.[1] Women are vulnerable to becoming overweight because of inadequate resources for physical activity, healthy food choices and family demands.

Objective:

1. To review the prevalence of obesity among women.
2. To determine risk factors of obesity among women.

Material and Method: A Quantitative approach with descriptive survey design was adopted for this present study. It was conducted among 300 adult women aged 20-60 years of selected wards of Athirampuzha Panchayat using simple random sampling method. BMI was calculated by WHO Asian classification and risk assessment check list was used to identify risk factors. Odd's ratio was used to examine association between obesity and risk factors.

Results: Prevalence of obesity was 24.3%.It was found that 66.2% of women were housewives. Common risk factors of obesity identified among women were consumption of bakery items (40%), family history and history of hypothyroidism (23.3%), excessive intake of fried item (35%), lack of exercise (34%), retained weight gain in relation to pregnancy (26.6%). Odds ratio shows significant positive association between obesity and risk factors [OR> 1].

Conclusion: Enhancing knowledge regarding regular physical activity and healthy dietary practices would obviously decrease the risk factors of obesity which would turn improve the health status of the women.

Keywords: *Obesity,Prevalence, Risk factor, BMI, Women*

Introduction

Obesity is promisingsober health problem increasing hastily worldwide. Obesity is a state throughout that there's generalized buildup of humoring fat among the body leading to a weight of quite two hundredth of the essential weight.[1] Fatness invites disability, disease and premature death.[2]

Obesity is considered as a 'hired gun lifestyle' disease. It is one of the leading preventable cause of death worldwide with increasing prevalence in both adults and children.[3] Childhood obesity is a known precursor to adult obesity and other lifestyle diseases in adulthood.[4] Adult hood obesity is the one of the most serious public health challenge of 21st century. According to World Health Organization, 1.2 billion people worldwide are formally classified as overweight. In the Indian setting, even with the increasing consciousness about health and

fitness, more than 3% of the populations are obese. This is probably due to sedentary lifestyle of people. So there is an insistent need to create public awareness about the mechanisms of detection, prevention and treatment of obesity than ever before.[5]

NFHS-3 has reported that more than 20% of urban Indians are overweight or obese. And in the northwestern Punjab, nearly 40% of all women are overweight or obese. Kerala is a second most state in obesity next to Punjab. That is 28% women and 18% of men aged 15 years to 49 years in Kerala were overweight or obese. The review also reported that 52.2% abdominal obesity was additional prevalent among women.[6]

Obesity is a multi factorial phenomena and associates with age, sex, economical status, marital status, smoking, physical activity, education, traditions, levels of leisure time, parity, family history of obesity, alcohol consumption and dietary habits. In comparing to men, such determinant factors of obesity were normally accumulated in women. Women are vulnerable to becoming overweight because of inadequate resources for physical activity, healthy food choices and family demands.

. The findings of many studies have shown that the incidence and the prevalence of obesity in women is higher in many countries compared to men and surprisingly the ratio is higher by 10–15% in women than in men and it is associated with socio economic status and lifestyle.[7]

Women have more frequently opportunities to consume food and more likely to have greater volume of food available because they traditionally prepare meals for their families however more women are eating outside their home now a days on well as buying home food from restaurant food stall, fast food centers for their families[8].Among women of childbearing age, one potential pathway for the development of obesity has been through the retention of gestational weight gain.[9]

In Kerala, life style diseases are common among women associated with multiple risk factors. Researcher experiences the fact that women are more conscious about their weight,but are unaware of healthy practices,it was necessary to have an accurate data to assess prevalence and risk factors of obesity among women in order to reduce future obesity burden.

Material and Method:

The present study was conducted in selected ward of Athirampuzha Panchayat, Kottayam among the women between the age group of 20-60 years during 2016. Sample consists of 300 was calculated on the basis of NFHS-3 data reported that prevalence of obesity among adult women in Kerala was 28% using $4PQ/D^2$ formula. [P=prevalence, Q=100-P,D=Allowable error]

Institutional ethics committee permission was obtained. And written informed consent of the study subjects was taken. Data for the present study was collected from women residing in 8, 9 and 10 wards of Athirampuzha Panchayat, Kottayam between the age group of 20-60 years. Wards were selected by lot method. A list of women in the age group of 20-60 years was obtained from the family survey register of JPHN. Samples were selected using tables of random numbers. Baseline information was collected using socio personal data sheet. Their height and weight were measured by measuring tape and standardized weighing scale. BMI was calculated with this measurement. BMI > 30 will be considered as obese based on WHO classification. The risk assessment checklist was used to identify the risk factors of obesity. Analysis was done using SPSS 16.0. Information Booklet regarding obesity, its prevention and management was prepared and given to the women after the data collection procedure. The content of the booklet was explained to each women and doubts were clarified.

Results

Table 1: Frequency distribution and percentage of women based on BMI (n=300)

Prevalence of obesity	**f**	**%**
BMI		
Under weight (<18.5)	18	6
Normal weight (18.5-24.9)	151	50.3
Over weight (25-29.9)	58	19.4
Obese (30 and above)	73	24.3

Table 1 depicts that 50.3% of the women were with normal (18.5-24.9) BMI. 24.3% were obesity,19.4% were with overweight and only 6% were with underweight. Based on BMI table shows that prevalence of obesity (BMI > 30 and above) among women were 24.3%.

Table 2: Frequency distribution and percentage of women based on risk factors (n= 300)

Risk factors	Yes		No	
	f	%	f	%
Family history	70	23.3	230	76.6
History of PCOD	68	22.6	232	77.3
History of hypothyroidism	70	23.3	230	76.6
Excess intake of food	29	9.6	271	90.3
Consumption of ghee > three times/week	43	14.3	257	85.6
Consumption of fried items> three times /week	105	35	195	65
Consumption of egg with yolk > three times /week	58	19.3	242	80.6
Consumption of meat > three times/week	85	28.3	215	71.6
Consumption of bakery items/ ice cream / chocolate > three times/week	120	40	180	60
Lack of exercise	102	34	198	66
Stress in daily life	59	19.6	241	80.3
Excessive sleep	55	18.3	245	81.6
Retained weight during Pregnancy and postpartum care	80	26.6	220	73.3
Intake of steroids > three months	34	11.3	266	88.6
Intake of antipsychotics > three months	4	1.3	296	98.6
Intake of antiepileptics > three months	3	1	297	99

Table 5 shows the risk factors of obesity and findings reveals that 40% of the women were consuming bakery items, ice cream,and chocolate more than 3 times/week. 35% of the women were consuming fried items more than 3 times/week. 34% of the women had lack of exercise in their routine 28.3% of the women were consuming meat more than 3 times/week. 26.6% of women had weight gain during pregnancy and post partum care. 22.6% of the women had a history of PCOD, 23.3% of the women had a family history of obesity and history of hypothyroidism. Table also shows that. 19.3% of the women were consuming egg with yolk more than 3 times /week. 14.3% of the women consuming ghee more than 3 times /week. 19.6% of the women were experiencing excessive stress in their life and also 18.3% of women had excessive sleep more than 8 hours per day and 11.3 % of the women were using steroid medication more than three months.

Table 3: Frequency distribution, and Odd's ratio of women based on dietary habits (n=300)

Risk factor	Obese	Non obese	Odds ratio	CI Lower limit	CI Upper limit
	f	f			
Excess intake of food	19	10	7.46*	3.28	16.95
Consumption of ghee > three times/ week	24	19	5.22*	2.65	10.52
Consumption of fried items> three times /week	54	51	9.26*	5.08	16.88
Consumption of egg with yolk> three times /week	36	22	8.78*	4.66	16.55
Consumption of meat >three times/week	43	42	6.07*	3.43	10.75
Consumption of bakery items/ ice cream / chocolate > three times/week	56	64	8.38*	4.53	15.51

Table 3 depicts that Odd ratio is significant at 95% confidence interval[OR>1] and it shows that there is a positive association between obesity and dietary habits.

Table 4: Frequency distribution and Odd's ratio of women based on lack of exercise, stress in daily life, excessive sleep, retained weight during pregnancy and post partum care (n=300)

Risk factor	Obese	Non obese	Odds ratio	CI Lower limit	CI Upper limit
	f	f			
Lack of exercise	54	48	10.01*	5.47	18.31
Stress in daily life	24	35	2.61*	1.43	4.80
Excessive sleep	33	22	7.46*	3.95	14.08
Retained weight during Pregnancy and postpartum care					
	55	25	23.27*	11.94	45.34

Table 4 depicts that Odds ratio is significant at 95% confidence interval [OR>1] and it shows that there is a positive association between obesity and lack of exercise, stress in daily life, excessive sleep, retained weight during pregnancy and postpartum care

Table 5: Frequency distribution and Odd's ratio of women based on family history of obesity, history of PCOD, history of hypothyroidism (n=300)

Risk factor	Obese	Non obese	Odds ratio	CILower limit	CIUpper limit
	f	f			
Family history	40	30	7.68*	4.23	13.96
History of PCOD	27	41	2.57*	1.44	4.61
History of hypothyroidism	34	36	4.48*	2.51	8.00

Table 5 depicts that Odds ratio is significant at 95% confidence interval [OR>1] and it shows that there is a positive association between obesity and family history of obesity, history of PCOD, history of hypothyroidism

Discussion

The present study was carried out in the selected ward of Athirampuzha Panchayat among 300 adult women aged 20-60 years.

The first objective of the study: was to assess prevalence of obesity among women. The findings of the present study shows that prevalence of obesity was 24.3% and it is congruent with the findings of a cross-sectional study carried out on prevalence of overweight and obesity among adult population at Malaysia population aged 18-59 years old and it reveals that the prevalence of obesity among women was 22.9%.[10] A study was undertaken in an urban slum in Chennai cityto find out the prevalence of overweight and obesity among women aged 20 years and above revealed that prevalence of obesity was 19.8%.[11] Another cross sectional study was conducted among 300 adults in Nellanadu Panchayath, a rural area in Trivandrum, Kerala shows that prevalence of obesity was 40.7% in women.[12]

The second objective: was to identify the risk factors of obesity among women and findings revealed that majority of women (40%) were consuming of bakery items/ ice cream / chocolate more than 3 times/ week. 35% of the women were consuming fried items more than 3 times/week. 34% of the women had lack of exercise in their routine 28.3% of the women were consuming meat more than 3 times/week. 26.6% of women had weight gain during pregnancy and post partum care. 22.6% of the women had a history of PCOD, 23.3% of the women had a family history of obesity and history of hypothyroidism.

The study findings are congruent with the findings of another study to review causes of obesity among adult at UK London, findings shows that risk factors for obesity were sedentary lifestyles,a high intake of energy-dense, micronutrient-poor foods,heavy marketing of energy-dense foods and fast food outlets, sugar-sweetened soft drinks and fruit juices,adverse social and economic conditions developed countries, especially in women.[13]

The third objective of the study: was to find out association of obesity and risk factors. And findings reveals that [OR>1] there is a positive association was

found between obesity and all mentioned risk factors. The study findings are congruent with the descriptive epidemiological study was carried out among seven thirty adults of 15-64 yr age group in a village of West Bengal revealed that there is a significant association was found with age group, per capita income, tobacco use, alcohol consumption, physical activity, salt intake with food and intake of oils.[49]

Conclusion

The major conclusion drawn from this study is that low levels of physical activity, intake of bakery items,stress in daily life, excessive sleep,retain weight after pregnancy were associated with a higher prevalence of obesity. Thus, participation in household activities and regular physical exercise could help in lowering the prevalence of overweight. And also educate adult women on the aspects of healthy dietary habits and desired lifestyles to prevent overweight/obesity and its associated ill effects.

Ethical Clearance: Taken from Institutional ethical committee. IEC no:86/2016

Assess the Knowledge and Risk Factors among Pregnancy Induced Hypertension among Antenatal Mothers

Aswathy Krishnan .S[1], Anju Philip .T[2], Syama Mohan[3], Reshma Saji[4]

[1]Lecturer, [2]Associate Professor, Dept. of Obstetric And Gynecologic Nursing, Amrita College of Nursing, Amrita Vishwa Vidyapeetham, Kochi, Kerala, India, [3&4]IV Year Nursing Students

Abstract

Background of the Study: Hypertension, complicating 5-10% of all pregnancies worldwide, is a leading cause of maternal and fetal morbidity. The control of pregnancy-induced hypertension (PIH) appears difficult to achieve. Part of the reason for poor control of hypertension in these women might be limited PIH self-care knowledge.

Objective: to assess the knowledge and risk factors of PIH among antenatal mothers and to find out the association between knowledge and risk factors with selected demographic variables.

Materials and Method: Study was conducted on 110 antenatal mothers attending in Gynecologic OPD, AIMS, Kochi, Kerala. The research design used was non experimental descriptive design.

Result: The present study reveals that more than half of the mothers (63.6%) had average knowledge regarding PIH. Half of the mothers had the risk factors of family history of hypertension (50%) and followed by 32.7% had the habit of high non vegetarian food intake. A statistically significant association was observed for education and knowledge and comorbidities and knowledge of antenatal mothers. Significant association was found in risk factors and comorbidities of antenatal mothers.

Conclusion: The finding of the study shows that antenatal mothers had average knowledge related to PIH. Health care providers should implement the focused health education programme during antenatal visit

Keywords: *Knowledge, Pregnancy Induced Hypertension, antenatal mothers, risk factors, Pregnancy.*

Introduction

Pregnancy is a kind of miracle by the god and a mother`s joy begins when new life is stirring inside and a tiny heartbeat is heard for the very first time. Pregnancy is the unique and exciting time in woman`s life, as it highlights the woman`s amazing creative and nurturing powers while providing a bridge to the future[1.] Hypertensive conditions during pregnancy contribute greatly to maternal mortality and morbidity around the world. It is the most common medical problem encountered during pregnancy, complicating 2-3% pregnancies. Approximately 1, 00,000 women die worldwide per annum because of Pregnancy Induced Hypertension (PIH). Although prompt recognition and treatment can greatly reduce the morbidity and mortality associated with pregnancy-induced hypertension and preeclampsia, the only known resolution is delivery of the fetus and placenta[1].

Pregnancy induced hypertension is a common medical disorder seen associated with pregnancy, and it leads more complication when it unregistered. Maternal and fetal morbidity and mortality can be reduced by early recognition and institutional management.[2] Darling B Jiji conducted a study regarding a study to assess the

knowledge of risk factors about pregnancy induced hypertension and availability of supplies among health care workers in the selected health care facilities in Sebha, Libya. Finding of the study showed that majority of 76(55.1%) had adequate knowledge about pregnancy induced hypertension and 62(44.9) had inadequate knowledge about pregnancy induced hypertension .[3]

Maternal mortality in PIH is primarily due to low standard of care and delay in referral services. One of the most important functions of antenatal care is to detect high risk pregnancies and give them the necessary care .Early detection of pre-eclampsia and eclampsia is important in reducing the maternal and neonatal mortality and morbidity.[4]

Pregnancy-induced hypertension occurs in about 5-8% of all pregnancies. Although the cause of PIH is unknown, certain factors are known to increase the risk of PIH, such risk factors include that PIH mostly affects young women with a first pregnancy, pregnant women younger than 20 years and those older than 40 years, women with multiple fetuses, pregnant diabetics, pregnant women with preexisting hypertension or previous episodes of preeclampsia or PIH and pregnant women with preexisting renal disease.[5]

The present study is an attempt to assess the level of knowledge and risk factors regarding pregnancy induced hypertension. It also aims to find out the association between the level of knowledge and selected demographic variables.

Materials and Method

The Study was conducted on 110 antenatal mothers[6] and the research design used was non experimental descriptive design. The subjects were selected by Convenience sampling technique based on inclusion criteria and a rapport was established with them. The researcher explained the purpose of the study and obtained an informed consent from them and the tools were administered. The demographic data and clinical data were obtained from the subject themselves. The data regarding knowledge and risk factors of pregnancy induced hypertension was obtained using self-prepared questionnaire and checklist. Each sample took 15 minutes to fill the questionnaire. The data obtained was analyzed using descriptive and inferential statistics and association using Chi Square.

Results

Out of 110 antenatal mothers majority of the subjects were belongs in the age group of below 25 years (44.5%), most of them were graduate (42.7%) and 76.4% women were unemployed. About (60.0%) were resided in city with in that (68.2%) are primi mothers and (69.1%) not had any history of co morbidities like GDM, thyroid dysfunction, heart diseases etc.

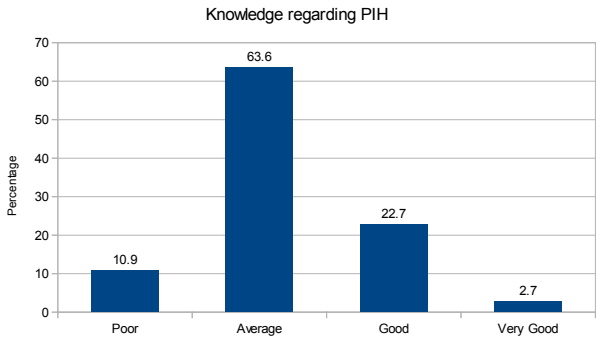

Figure 1: Distribution of subjects based on knowledge regarding pregnancy induced hypertension.

About 63.6% had average knowledge regarding pregnancy induced hypertension and 22.7% had good knowledge.

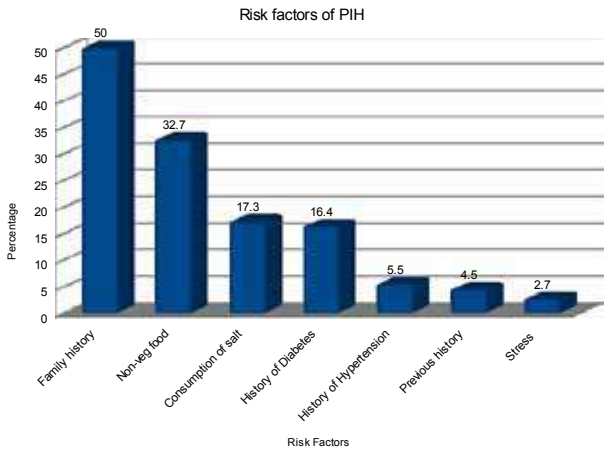

Figure 2: Assess the risk factors of PIH among antenatal mothers.

Risk factors of pregnancy induced hypertension are only 4.5% in women with previous history. 50% had family history of hypertension and no relevant history of twin pregnancy. 16.4% of mothers had history of diabetes, 5.5% had history of hypertension and there was no relevant history of renal disease. 17.3% mothers **had** habit of high salt intake, 2.7% had stress and about 32.7% had habit of high non veg food intake

Table 1: Association of level of knowledge among antenatal mothers and selected demographic variables

n=11

Variable	Category	Knowledge				Chi square	df	P value
		Average		Good				
		F	%	F	%			
Age	<= 25	39	79.6	10	20.4	1.186	2	.553
	25-30	31	70.5	13	29.5			
	>30	12	70.6	5	29.4			
Education	Below degree	50	84.7	9	15.3	6.978	1	.008
	Above degree	32	62.7	19	37.3			
Occupation	Unemployed	66	78.6	18	21.4	3.036	1	.081
	Employed	16	61.5	10	38.5			
Residence	Village	34	77.3	10	22.7	.287	1	.592
	City	48	72.7	18	27.3			
Parity	Primi	59	78.7	16	21.3	2.110	1	.146
	Multi	23	65.7	12	34.3			
Comorbidities	Yes	20	58.8	14	41.2	6.410	1	.011
	No	62	81.6	14	18.4			

Data in table 2 shows that there was significant association found in knowledge of antenatal mothers and education (p= .008) and level of knowledge with comorbidities (p=.011) among antenatal mothers. However no association was found between antenatal knowledge and selected variables like age, occupation, parity and residence.

Table 2: Association between risk factors of PIH and selected demographic variables

Variable	Category	Knowledge				Chi square	df	P value
		Average		Good				
		F	%	f	%			
Age	<= 25	11	22.4	38	77.6	1.479	2	.477
	25-30	7	15.9	37	84.1			
	>30	5	29.4	12	70.6			
Education	Below degree	12	20.3	47	79.7	0.25	1	.874
	Above degree	11	21.6	40	78.4			
Occupation	Unemployed	19	22.6	65	77.4	.628	1	.428
	Employed	4	15.4	22	84.6			
Residence	Village	11	25.0	33	75.0	.742	1	.389
	City	12	18.2	54	81.8			
Parity	Primi	19	25.3	56	74.7	2.790	1	.095
	Multi	4	11.4	31	88.6			
Comorbidities	Yes	2	5.9	32	94.1	6.719	1	.010
	No	21	27.6	55	75.4			

Data in table 3 shows that there was a significant association found in risk factors of antenatal mothers comorbidities. However no association found between age, education, occupation, residence and parity.

Discussion

Hypertension during pregnancy may lead to several problems to the mother and child. It was a major pregnancy complication, causing premature delivery, fetal growth retardation, abruption placenta, and fetal death, as well as maternal morbidity and mortality. The present study revealed that 63.6% had average and 22.7% had good knowledge regarding PIH. Another study conducted by Darling B Jiji to assess the knowledge of risk factors about pregnancy induced hypertension among 138 antenatal mothers revealed that majority 76(55.1%) had adequate knowledge about pregnancy induced hypertension and 62(44.9%) had inadequate knowledge about pregnancy induced hypertension.

In the present study explored risk factors of pregnancy induced hypertension were 4.5% of women with previous history of PIH. 50% of mothers had family history of hypertension. About 16.4% of mothers having history of diabetes, 6% having history of hypertension .17.3% mothers are having habit of high salt intake, 2.7% are in stress and about 32.7% having habit of non-veg food intake. Another study conducted by Leanne Bellamy to investigate pre-eclampsia and risk of cardiovascular disease and cancer in later life among 3488160 women revealed that after pre-eclampsia women have an increased risk of vascular disease. The relative risks for hypertension were 3.70 after 14.1 years weighted mean follow-up, for ischemic heart disease 2.16 after 11.7 years, for stroke 1.81 after 10.4 years, and for venous thromboembolism 1.79 after 4.7years[7].

It was also identified in the present study, that there is a significant association between pregnancies induced hypertension and mother's educational status and comorbidities (previous history, family history, history of diabetes, history of hypertension, stress etc.). The finding was consistent with the study conducted by LA Rahman, NN Hari, N Salleh to investigate the association between PIH and low birth weight. This study revealed that there was a significant association of pregnancy induced hypertension with low birth weight[8].

Conclusion

Pregnancy-induced hypertension is a common medical disorder seen associated with pregnancy, and it leads more complication when it unregistered. Maternal and fetal morbidity and mortality can be reduced by early recognition and institutional management. Early diagnosis and treatment through regular antenatal check-up is a key factor to prevent hypertensive disorders of pregnancy and its complications.

Abstract

Background: Many diabetic patients are affected by diabetic foot, a devastating and potentially fatal condition mostly due to lack of knowledge of foot care. Aim of the study: to evaluate the effectiveness of nursing intervention program on patient's knowledge about diabetes and foot care.

Subjects and Method: This quasi-experimental study was carried out at the Diabetes and outpatient clinics of Beni-Suef University hospitals on a convenience sample of 158 adult diabetic patients. An interview questionnaire was used to collect data on patient's socio-demographic and diabetes characteristics and patient's health habits, in addition to, knowledge questionnaire and diabetic foot screening format which used to assess foot condition.

Results: The sample had an equal gender distribution, and mostly had intermediate education (41.1%), with 52.5% having their diabetes for less than five years, 77.2% had one or more abnormal physical finding in foot assessment. Overall, 32.9% had satisfactory knowledge before the intervention, and this significantly increased to 90.5% after the intervention ($p<0.001$). In multivariate analysis, the study intervention was the main positive predictor of the knowledge score change.

Conclusion and Recommendations: A patient's education program is effective in improving patients' knowledge about diabetes and diabetic foot. It should be widely used in educating diabetic patients. A longer term study is proposed to investigate the impact of knowledge improvement on prevention of diabetic foot.

Keywords: *Diabetic foot, Knowledge, Health education*

Introduction

Diabetes mellitus (DM) is one of the chronic diseases which need active participation from patients to achieve good control and avoid complications [1]. According to the World Health Organization (WHO), the worldwide prevalence of diabetes in adults in the year 2014 amounted to 8.5%, with higher rates in developing countries, including Egypt. The related mortality is expected to have a twofold increase from 2005 and 2030, with diabetic foot having a major contribution as a death cause [2].

As many as 8-17% of diabetic patients are affected by diabetic foot, and one in five of diabetic patients attending hospitals present with foot problems [3]. Although diabetic foot is an ominous complication of diabetes, it is one of the most amenable to prevention [4]. The condition presents with infection, ulcer formation, with possible deep tissue destruction leading to vascular and neurological disorders in the foot and lower extremity which leading to amputation of the lower limb

e-mail: draziza55@gmail.com

with a rate reaching the double in comparison with non-diabetic people [5,6,7].

According to [8] the lack of knowledge of foot care and related deficient practices are significant risk factors for diabetic foot in diabetic patients. Thus, good patient education for those with high risk may prevent this deleterious complication. Moreover, a correct management of diabetic foot can prevent complications as gangrene and amputation. Nevertheless, diabetic patients often neglect proper foot care practice so long they do not have complications; additionally, patient education often starts after foot complications have already started. So, patient education is urgent, prominent and activities should give more focus to patient responsibility for own health [9.10].

Diabetes mellitus (DM) is a public health problem in Egypt, with high prevalence especially in rural communities. The risk factors for diabetic foot and related complications are also higher and are related to patients' socioeconomic status, especially education. These patients need to be educated regarding proper foot care, which would have a positive influence on their practices.

Aim of the Study: The aim of this study was to evaluate the effectiveness of nursing intervention program on patient's knowledge about diabetes and foot care.

Research Hypothesis: The percentage of patients with satisfactory knowledge will significantly increase after implementation of the educational program.

Subjects and Method

Design and setting: quasi-experimental design with pre-post assessment was used in carrying out this study at Diabetes and outpatient clinics at Beni-Suef University hospitals.

Subjects: A convenience sampling technique was used and all patients attending aforementioned settings during the time of study was eligible for the study upon fulfilling the inclusion criteria of being adult, diagnosed as having diabetes at least three months before, and have early signs of diabetic foot were participated in the intervention. Patients with any physical or mental disablement were excluded. The sample size was calculated to demonstrate an improvement of the percentage of participants with satisfactory knowledge from a pre-intervention level of 50% by an Odds Ratio of 2.0 at 95% level of confidence and 80% power. Accordingly, using the Open-Epi software package, the required sample size was 137. This was increased to 158 to compensate for an expected dropout rate around 10%.

Data Collection Tool: The researchers used an interview questionnaire form and a diabetic foot screening format to collect required data

The interview questionnaire comprised four sections the first is patient's socio-demographic characteristics including age, gender, level of education, residence, marital status and job. A second section covered the characteristics of diabetes as the duration and mode of discovery, as well as the history of other chronic diseases, and perception of health. These two sections were developed by the researchers based on review literature. A third section, based on [11] addressed patient's health habits such as dietary regimen, physical activity, smoking, eye, dental, and foot care. It also comprised the habits of testing urine and blood, follow-up, as well as having DM card. The sum of healthy practices reported to be done was calculated and divided by the total number of practices and presented as a percent score; a higher percent score indicated healthier practices.

The last section was developed by researchers based on review literature the questionnaire consisted of knowledge test for pre-post assessment. It consisted to a series of True/False questions covering the definition, symptoms, complications, prevention, and treatment of diabetes, as well as questions on suitable diet, insulin injection, travel arrangement, foot care, and selection of suitable footwear. For scoring, the correct response for each item was scored 1 and the incorrect zero. Knowledge was considered satisfactory if the percent score was 50% or more and unsatisfactory if less than 50%.

The diabetic foot screening format: This was developed by the National Foot Treatment Center (1990), and was modified by the researchers to suit the aim of the study. It covered foot anomalies as Charcot, callous, dryness/cracks, etc.; foot infections as interdigital fungus and interdigital wounds; foot sensation as hypoesthesia, anesthesia, no sweating, etc. and atherosclerosis as inability to walk due to pain, cold extremities, absence of pulse, etc. The sum of the number of anomalies found by foot examination was calculated and divided by the

total number of possible anomalies and presented as a percent score; a higher percent score indicated more physical examination anomalies. The patient height and weight was also recorded to calculate Body Mass Index (BMI).

Pilot Study: The tools were rigorously revised by a panel of experts in nursing and medicine for validity, reliability, and modified according to their recommendations. Then, they were pilot-tested on a sample representing about 10% of the sample size. The tools were finalized in view of the pilot results. The pilot sample was not included in the main study sample.

Fieldwork: The study was carried out from October 2017 to April 2018. It was conducted through assessment, planning, intervention, and evaluation phases. The assessment phase was started after securing all needed permissions. The researcher met individually with the diabetic patients in the settings, explained the aim of the study and its process. After they were giving their consent they interviewed to fill the first tool. Then, foot examination was done using the second tool. In the planning phase, the researchers used the assessment data to develop an educational program that meets the identified diabetic patients' needs and to fill their knowledge gaps. The program covered various areas of diabetes disease. The researchers developed an illustrated booklet in simple Arabic language to help participants to retain knowledge.

The implementation phase involved application of the program to participants. This was done in small group sessions of 9-10 patients in the study settings while patients were waiting for service or after obtaining it. Each session lasted 45-60 minutes. The sessions were interactive with ample time given for questioning and discussions. Audiovisual aids were used in short presentations with demonstrations and brain storming. The program involved a theoretical part for diabetes knowledge, and a practical part including foot care practices such as skin care, proper nail cutting, selection of footwear, etc. By end of the program, its effectiveness in improving participants' knowledge was measured through a posttest using the knowledge section of 1st tool.

Administrative and ethical considerations: The data collection took place in collaboration with two Non-Governmental Organizations (NGOs), namely Women`s Health and Resala company. Before starting any data collection, official permissions to conduct the study were obtained from the medical and nursing directors of the study setting. The researcher explained the aim of the study and its procedures to eligible patients in simple terms to get their oral informed consent. They were informed about the rights to refuse participation or withdraw at any time and about the confidentiality of the study.

Statistical Analysis: Data entry and statistical analysis were done using SPSS version 20.0. Data were presented using descriptive statistics in the form of frequencies and percentages for qualitative variables, and means, standard deviations and medians for quantitative variables. Spearman rank correlation was used for assessment of the inter-relationships among quantitative variables and ranked ones. In order to identify the independent predictors of the knowledge score, multiple linear regression analysis was used.

Results

As presented in **Table 1**, more than half of the study sample had diabetes for less than five years (52.5%), and it was mostly discovered by chance (57.4%). One half of them experienced hypoglycemia (50.0%). The majority were overweight to obese (38.9%, 34.8%).

Regarding practices, **Table 2** demonstrates a wide variation as, some healthy practices were reported to be done by majority of patients including proper wound care (89.2%), & eye care (85.4%). Minority of them reported visiting dentist (3.2%), testing urine daily (7.0%), having DM card (22.2%), brushing teeth (24.7%) and foot care was reported by 72.2% of them. The median percent of total healthy practices was 47.1%.

Table 3 demonstrates that the most common abnormal findings of feet examination were dryness and cracks (49.4%), hypoesthesia (48.1%), leg/thigh pain (29.9%), and delayed wound healing (29.1%). In total, the majority (77.2%) had one or more abnormal physical finding.

As shown in **Table 4,** patients' knowledge about DM was variable before the study intervention. The majority had correct knowledge of the DM definition, symptoms, and prevention, as well as insulin injection and none of them had correct knowledge of foot care or suitable footwear. The implementation of the intervention led to significant improvements in all knowledge areas. Only 32.9% of the patients had satisfactory knowledge before

the intervention, which significantly increased to 90.5% after the intervention (p<0.001).

Table 5, points to significant positive correlation between patients' knowledge scores and healthy habits practice (r=0.252). It also shows positive correlations between knowledge and practice scores which negatively correlated with age. The duration of diabetes also correlated negatively with knowledge score in pre-test (r=-0.241).

The multivariate analysis (Table, 6) identified the study intervention as the main positive predictor of the knowledge score change, in addition to having DM card. On the other hand, having a lower health perception was a negative predictor of this score. The model explains 52% of the variation in the knowledge score.

Table 1: Describe disease and medical characteristics of patients in the study sample (n=158)

Items	Frequency	Percent
Duration of diabetes (years):		
<5	83	52.5
5+	75	47.5
Mode of discovery of DM:		
By chance	59	57.4
Symptoms/signs	85	53.8
Coma	14	8.9

Discussion

The study findings indicate that only one-third of the diabetic patients in the study sample had satisfactory knowledge before the intervention. This increased significantly after implementation of the educational program, which leads to acceptance of the set research hypothesis.

The present study was carried out on a sample representing the population of diabetic patients in the fourth to fifth decades of their age. The diabetic state was mostly discovered by chance among these participants which is a commonly reported finding in previous research. It indicates low health awareness and health behavior among them. This result is in agreement with a study in Italy which revealed that about two-thirds of the diabetic patients discovered their disease just by mere chance [12].

Moreover, one half of participants in the current study reported having had hypoglycemia; additionally, more than one-fourth of them had previously experienced an attack of diabetic coma. This further indicates poor diabetic control among them, which is explained by the low practice scores as the study findings revealed, particularly regarding regular testing of urine for glucose. The reported rate of hypoglycemia is very high compared with the rates reported by [13]. In a study at the United States. Thus, the risk of hypoglycemic attacks is one of the most important indicators of good diabetic control as recommended by [14].

Majority of patients in the present study were overweight or obese. This result corroborates the poor control of diabetes among them as it reveals lack of strict following a DM dietary regimen. The importance of weight reduction and compliance with a dietary regimen was outlined in a systematic review [15]. However, to be effective in achieving good glycemic control, this regimen should lead to >5% weight loss. Thus, bariatric surgery could have an important preventive role in the management of recent onset diabetes [16].

Concerning foot care, the current study results showed that more than one-fourth of participants do not practice good foot care. It might indicate lack of proper patient education since only less than one-third of the patients reported having had instructions for DM care. Similarly, a low level of practice of diabetic foot care was demonstrated among Iraqi diabetic patients [17]. Hence, a study in Brazil underscored the importance of patient education to improve their practice of good diabetic foot care [18].

The lack of good health habits practices among study sample was reflected on the prevalence of abnormal physical findings identified among them. The most common of these problems include dryness and cracks, hypoesthesia, pain, and delayed wound healing. The median number of abnormal findings was 4, indicating that at least one-half of the sample had four or more of these abnormal findings. In congruence with this, a study in Japan among diabetic patients found that calluses and cracks were the most prevalent signs of non-ulcerative diabetic foot **[19].**

Although patients' knowledge about DM was generally acceptable before the study intervention, but none of them had correct knowledge of proper foot care or suitable footwear. This might explain the high prevalence of abnormal physical findings among them in feet examination. In fact, the multivariate analysis revealed a negative relation between the knowledge score and the number of abnormal physical findings. Thus, a better knowledge score is associated with a lower number of abnormal findings. In agreement with this, a study in Malaysia by **[20].** found poor knowledge of diabetic foot care among participants. Also in congruence with the present study results, **[21].**in a study in Saudi Arabia reported that the majority of diabetic patients lacked correct knowledge of how to choose appropriate footwear.

Regarding the factors influencing patients' knowledge scores, the bivariate analyses revealed positive associations with the educational level, and negative associations with patients' age and duration of diabetes. The positive correlation with education is quite conceivable given the relation between the level of educational attainment and the general health behavior. The findings are in agreement with those of **[22].** whose study in China demonstrated that diabetic patients' knowledge increased with their level of education and decreased by age.

Nevertheless, the negative correlations with age and duration of diabetes revealed in the present study might be confounded by education given that the educational level of older age patients with longer duration of the illness might be lower compared with those from younger generations. None of these factors was found to have an independent influence on the knowledge score.

Meanwhile, having a DM card was identified as a positive predictor of the knowledge score, which indicates the importance of this as it reflects a positive health behavior. In line with this, the importance of carrying a wallet diabetes care card to protect the diabetic patient in case of any emergency was highlighted by United States department of Health and Human Affairs [23].

The implementation of the current intervention study was effective in improving patients' knowledge of DM in all of its areas. Moreover, the intervention was identified as the main positive predictor of the knowledge score in multivariate analysis, thus confirming its independent and significant positive effect. This success could be attributed to the fact that the program was tailored to their findings, and its content had direct applications to their care practices. A similar successful educational program was reported by [24]. in an intervention study in Slovakia. On the same line, a pre-post intervention study in Brazil demonstrated significant improvements in diabetic patients' knowledge [25].

Conclusion and Recommendations

In conclusion, education program for diabetic patients proved to be effective in improving their knowledge of diabetes and diabetic foot. The program should be widely used in educating diabetic patients, particularly those at risk for diabetic foot. The developed booklet should be made available in diabetes care settings. The study could not assess the effect of the knowledge improvement on patients' practices, which is a limitation of the present study since these practices needed more time to be changed. Hence, a longer term study is proposed to investigate the impact of knowledge improvement on diabetic foot care.

Ethical Clearance: Taken before starting the research process from the research ethics committee at Faculty of nursing Beni-Suef University.

Source of Funding: This study is part of a project of Beni-Suef University Scientific Research Development Unit and the Support and Project Finance Office, funded by the United Nation Programs to fight poverty in developing countries.

Conflict of Interest: All authors shared substantially in fulfilling study & approved the final version to be published.

The Empowerment among Type 2 Diabetes Mellitus Patients

Bency Bhasy[1], Linda Varghese[2], SreekuttyC S[3], Sreepadma P K[4]

[1]Lecturer, [2]Assistant professor, IV year B.S Nursing[3 & 4], Amrita College of Nursing, Amrita Institute of Medical Science, Amrita Vishwa Vidyapeetham University, Health Science Campus, Kochi

Abstract

Context: TYPE 2 DIABETES MELLITUS is one of the most serious health concerns and policy agendas around the world. Diabetes is strongly associated with the patients' unhealthy lifestyle and behavioural patterns and socio-economic changes. New model of thinking is required to recognize whether the patients are in control of and responsible for the daily self-management of Type 2 Diabetes Mellitus. A descriptive study was conducted for a period of 4 weeks in 2018 in AIMS hospital. Objective is to assess the level empowerment among Type 2 Diabetes Mellitus, to find the association between Diabetes Empowerment Scale and selected variable. Method Data were collected by using Diabetes Empowerment Scale(DES). Collected data was analysed by using IBS SPSS software version 20.

Methodology: A quantitative research approach with convenience sampling technique was used for study the setting of the study was the sample size of Type 2 Diabetes Mellitus patient selected. A semistructured questionnaire used to assess demographic data and diabetes empowerment scale used to assess empowerment among type 2 Diabetic Patient.

Result: A sample size of 150 was available for analysis, ranging from 20 years to above with 43% of the subjects belongs to the age group above 65 years and majority are females. Using, diabetes empowerment scale, each domains of 'managing the psychosocial aspects of diabetes, assessing dissatisfaction and readiness to change and setting and achieving diabetes goal were measured and scored for each patient. The Data analysis revealed a statistical significance in age.

Conclusion: Using the empowerment approach, healthcare professional would help patients make informed decision in accordance with their particular circumstance.

Keywords: *Diabetes Empowerment Scale (DES),Type 2 Diabetes Mellitus(DM)*

Introduction

TYPE 2 DM is one of the most serious health concerns and policy agendas around the world. Diabetes is strongly associated with the patients' unhealthy lifestyle and behavioural patterns and socio-economic changes. Diabetes is the fifth leading cause of death in most countries. According to National Diabetes Statistic Report, 2017 found that, India is the diabetes capital of the world with a projected 109 million individuals with diabetes by 2035. The disease currently affects more than 62 million Indians, which is more than 7.1% of India's adult Population. An estimate shows that nearly 1 million Indians die due to Diabetes every year and the average age of onset is 42.5 years. [1]

New model of thinking is required to recognize whether the patients are in control of and responsible for the daily self-management of Type 2 DM. Such a new approach should be based on 'empowerment and involvement' to be more applicable to daily activities in diabetic patients. Rapid changes toward patient empowerment and increasing involvement of patients

in their care plan indicate more emphasis on disease prevention and health promotion and education than on mere disease and its treatment. Such changes make a step toward pervasive sense of responsibility among patients about their illness for their daily activities. Using the empowerment approach, healthcare professionals would help patients make informed decisions in accordance with their particulacircumstances.[2]

Patient empowerment implies a patient-centred, collaborative approach that helps patients determine and develop the inherent capacity to be responsible for their own life. Empowerment is something more than certain health behaviours. Empowerment is more than an intervention, technique or strategy. It is rather a vision that helps people change their behaviour and make decisions about their health care. It has the potential to improve the overall health and well-being of individuals and communities, and to change the socio-environmental factors that cause poor health conditions. The main concept of this change is the tendency to change.[3]

Materials and Method

A descriptive study is conducted Amrita Institute of Medical Science, 2018 among 150 Type 2 DM patient. Patients selected according to the inclusion criteria for study were patient diagnosed Type 2 DM, who were able to read and write English/Malayalam. People with mentally challenge were excluded from the study. Allpatientinformedabout the aim of the study.

Data was collected by using DES, standard questionnaire developed by Michigan Diabetes Research Centre.Patient empowerment was measured by DES self reported scale with subscale reflecting three areas including managing psychosocial aspect of diabetes(9items), Assessing dissatisfaction and setting and readiness to change(9 items), and setting and achieving diabetes goal(10 items). Each item have 5 response categories ranging 1 to 5(1=strongly disagree,2=somewhat disagree,3=neutral,4=somewhat agree and 5=strongly agree). Accordingly, the minimum and maximum scale values were 28 and 140, respectively.

Result

Tool 1: Section A: Demographic variable

Table 1: Distribution of subjects based on Socio-Demographic variable

Sl. no	Variables		Frequency	Percentage
1	Age (Years)	20-49	23	15
		50-64	62	42
		>65	65	44
2	Gender	Male	66	44
		Female	84	56
3	Education Status	Primary	23	15
		Secondary	73	49
		Higher secondary	23	15
		Graduation	31	21
4	Marital Status	Married	125	83
		Unmarried	25	17
5	Occupation	Home Maker	67	45
		Govt. Employee	27	18
		Private Sector	32	21
		Others	24	16
6	Income	Below 10,000	83	55
		Above 10,000	67	45
7	Place of residence	Rural	102	68
		Urban	48	32

Figure 1: Pie diagram showing distribution of subjects based on age

Table 1 show that, among the 150 subjects, majority 65 (44%) of the subjects were above 65 years and 84(56%) were female .Among the samples73(49%) of them have secondary education. In case of Marital status 125(83%) were married and 67(45%) are home makers. Most of them 83(55%) have income below 10,000 and 102(68%) were living in Rural areas.

Section B: Clinical Variable

Table 2: Distribution of subjects based on clinical variable

Sl. no	Variables	Frequency	Percentage
1	Family history of DM a)yes b)no	51 99	34 66
2	Duration a)<6 years b)>6 ears	45 105	30 70
3	Treatment a)diet b)drugs c) insulin d)both a & b e)both b & c f)a, b & c g)both a & c	4 20 26 46 19 17 18	3 13 17 31 13 11 12
4	Medical history a)no b)yes	35 115	23 77
5	Habit a)smoking b)alcoholism c)both a & c d) none of these	5 17 7 121	3 11 5 81
6	Complication a)diabetic neuropathy b)others c)nil	30 19 101	20 13 67

Table 2 represents the data regarding clinical variable shows that 60% have no family history of DM, 70% have duration DM is greater than 6 years, 37% have treatment is diet and drugs, 77% have other medical problem, 81% have no habit, 67% have no complication**.**

Tool 2: Diabetes Empowerment Scale

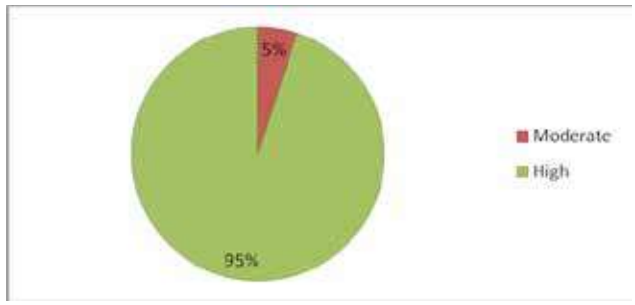

Figure 1: Pie diagram explain distribution of subjects based on total diabetes empowerment scale

Figure 1 represent that most of the subject 142(95%) have high DES score.

Table 3: Frequency distribution of subscales

Sub scale	Level	Frequency	Percentage
Subscale a	Moderate High	9 141	6 94
Subscale b	Moderate High	4 146	3 97
Subscale c	Moderate High	9 141	6 94

Table 3 illustrate 3 subscale distributions, Subscale A(managing psychosocial aspect of diabetes) most of subjects 141(94%) have high score. Subscale B (assessing dissatisfaction and readiness to changemost of the subjects 146(97%) have high score. Subscale C (setting and achieving diabetes goal) most of subjects 141(94%) have high score.

Discussion

The present study was undertaken to assess the empowerment among patient with Type 2 Diabetes Mellitus. The study was formulated with the following objectives.

The first objective of the study was determine the level of empowerment among Type 2 Diabetes Mellitus patients.

In the present study out of 150 subjects 142(95%) had high empowerment score and only 8(5%) had moderate empowerment score, that is majority had high empowerment among Type 2 Diabetes Mellitus.

Similar empowerment assessment study conducted by Anna Ninan in 2014shows that the better /high empowerment level. Effective patient empowerment is not achieved unless patient can receive the necessary

information and are educated about their health condition.[4]This, proves that patient with diabetes can be empowered to manage their chronic disease if they are adequately informed and educated..[5]

To summaries the discussion based on first objective it is markedly clear of empowerment of the participants was moderate to high.

The second objective of the study to find the association between diabetes empowerment score and selected demographic variables among patients with Type 2 Diabetes Mellitus.

Association between the total DES score and selected demographic variable like age, sex, education, marital status, occupation, income, place of residence and clinical variable like family history of DM, duration of DM, treatment, medical problems, habit, complications was done using chi- square.

In the present study, statistically association exist between total DES score and demographic variable age.

AzarTolconducted a study to determination of empowerment score in Type 2 diabetes patient and its related factors and there is an association between total empowerment score and age. Diabetes empowerment scale showed significant relationship between variables such as educational level($p<0.001$), gender (0.007), age ($p<0.001$) and duration of diabetes ($p<0.001$). Persons correlation coefficient also revealed that empowerment of Type 2 diabetes patient has a reverse relationship with HbA1c(r= -0.75,p0.001). Furthermore ordinal regression test that having diploma and higher education($p =0.005$), and optimal and borderline HbA1c($p<0.001$)were effective factors in empowering patient.[6]

Conclusion

Patients with Type 2 Diabetes Mellitus can be empowered so that they canreduce the complications and able to improve their self esteem and self actualization.

Ethical Consieration: Study was presented in the research committee of Amrita College of Nursing for approval. The permission was obtained from head of the Department of Podiatry at AIMS, Kochi. Ethical clearance was obtained from thesis Review committee of AIMS.

Assessments of Pre: Competetitive Psychological Variables Between South Zone Volleyball Players and Baskertball Male Players

C.P. Ampili[1], M. Rajashekaran[2], M.Senthilkumar[3]

[1]Ph.D. Research Scholar, Dept of Physical Education & Sports Sciences, Annamalai University, [2]Professor, Dept of Physical Education & Sports Sciences, Annamalai University, [3]Asst. Prof, Dept of Physical Education & Sports Sciences, Srmist

Abstract

Context: The purpose of the study was to find out assessments of pre-competitive anxiety between volleyball players and basketball south zone male players. To achieve the purpose forty subjects were selected SRM IST Chennai. The age ranged between 18 to 25 years male players. The competitive state anxiety inventory II Burton (1990) questionnaire was used. The questionnaire consisted of III dimension, Cognitive anxiety, stress and self-confidence. This study showed that anxiety is required to measure the performance during competition. To compare pre-competitive anxiety between volleyball players and basketball south zone male players. Unpairedt-test was employed with the help of statistical packages of SPSS. To test the significant level was set as 0.05 level. The results showed that there was insignificance difference on Cognitive anxiety, stress and self-confidence between volleyball players and basketball players.

Keywords: *Cognitive anxiety, stress, self-confidence, volleyball, basketball*

Introduction

Pre competitive anxiety is considered as one of the most vital problems in the area of modern sports psychology. It has been noted for many years as one of the psychological factors. Specifically anxiety plays a central role in the sports competitions where every athlete undergo fear before, during and also after events.[1] Anxiety makes even the world most victorious athlete to experience nervousness. Factors such as fear of losing the game and be short of confidence provoke anxiety in the athletes. Anxiety is similar to worry and it is an unpleasant feeling that most face often when they are put to challenges.

Anxiety is considered to be normal and it is usually related to healthy emotions. But, if a person regularly suffers inconsistent degree of *anxiety*, it might result in medical related disorders.[2] Disorders pertaining to anxiety form a group of mental health identify that result in extreme nervousness, high fear, apprehension, and lot of worry. Anxiety is often distinguished from fear, which is suitable to cognitive and emotional linked responses to a supposed threat. Anxiety is related to the exact behaviors of fight-or-flight responses, protective behavior or break out.[3] It happens in circumstances only perceived as unmanageable or inevitable, but not realistically so defines anxiety as "a future-oriented mood state in which one is not ready or prepared to challenge to cope with future negative actions and that it is a division between the dangers of future and present which helps in the division of anxiety and fear.[4] Additional description of anxiety is pain, terror, fright and also uneasiness. In constructive psychology, anxiety is expressed as the intellectual state that leads from a difficult challenge for which the subject has deficient surviving skills.[5]

Fear and anxiety can be made with a distinction in four areas in the period of emotional experience, sequential center, specificity of the threat, and forced direction.[6]Fear is little lived, near focused, thrusted towards a particular threat, and made easy free from threat; anxiety, additionally it is long-acting, potential focused, generally focused towards a disperse threat, and supporting excessiveness.

Statement of the Problem: The purpose of the study was to evaluatetheassessments of pre-competitive anxiety between volleyball players and basketball south zone male players.

Methodology: The present research was "assessments of pre-competitive anxiety between volleyball players and basketball south zone male players". To achieve the purpose 40 south zone men players (20volleyball players and 20basketball players) were recruited as subject. The age ranged was 18 to 25years. To check pre-competitive anxiety of recruited subjects (CSAI -2) questionnaire was used.

The competitive state anxiety inventory 2 (CSAI -2) is a 27 item questionnaire consisted of 3 dimensions. Cognitive anxiety, stress and self-confidence. To score the CSAI-2 take all the scores for each item at face value with the exception of item 14, where you reveres the score.

Test Administration: After collection data it was proceed and analyzed with statistics to compare the subjects mean, standard deviation and unpaired t-test was employed with the help of statistical package of SPSS. The significance level was set at 0.05 level. Cognitive anxiety had the sum items as 1,4,7,10,13,16,19,22 & 25. Stress had the sum items as 2,5,8,11,14,17,20,23 & 26 and Self Confidence had the sum items as 3,6,9,12,15,18,21,24 & 27.

Table 1: Mean and Standard Deviation of Cognitive anxiety between volleyball players and basketball player's south zone male players

Group	N	Mean	Standard Deviation	Standard Error of mean	t
volleyball players	20	22.60	4.29	0.89	1.2423
basketball players	20	21.40	6.96	1.50	

Significant at 0.05 level of confidence

Table 1 presents the mean and standard deviation with regards to south zone volleyball men players 22.60 and 4.29 whereas case of south zone basketball players 21.40 and 6.96 respectively. The value of t – value 1.2423 which is less than table value 2.048 at 0.05 levels. There is insignificant difference between cognitive state anxiety variables volleyball players and basketball players south zone male players.

Table 2: Mean and Standard Deviation of stress between volleyball players and basketball player's south zone male players

Group	N	Mean	Standard Deviation	Standard Error of mean	t
volleyball players	20	22.25	3.25	0.69	1.0266
basketball players	20	21.24	3.47	0.81	

Significant at 0.05 level of confidence

Table 2 shows the mean and standard deviation with regards to south zone volleyball men players 22.25 and 3.25 whereas case of south zone basketball players 21.24 and 3.47 respectively. The value of t – value 1.0266 which is less than table value 2.048 at 0.05 levels. There is insignificant difference between cognitive state anxiety variables volleyball players and basketball players south zone male players.

Table 3: Mean and Standard Deviation of self-confidence between volleyball players and basketball player's south zone male players

Group	N	Mean	Standard Deviation	Standard Error of mean	t
volleyball players	20	21.90	3.98	1.03	0.9963
basketball players	20	23.14	3.63	0.92	

Significant at 0.05 level of confidence

Table 3 presents the mean and standard deviation with regards to southzone volleyball men players 21.90 and 3.98 whereas case of southzone basketball players 23.14 and 3.63 respectively. The value of t – value 0.9963 which is less than table value 2.048 at 0.05 levels. There is insignificant difference between cognitive state anxiety variables volleyball players and basketball players southzone male players.

Discussing on Findings: The insignificant differences of cognitive anxiety, stress and self confidence between volleyball players and basketball players south zone male players. Analysis of student t-test showed the insignificant difference. Both a team players have high experience participation and won so many trophies and number of time they mentally well prepared for tournament.

Discussion on Hypotheses: It was hypothesized at the beginning of the study that there would be insignificance difference Cognitive anxiety, stress and self-confidence between of volleyball players and basketball players.The present study produced similar results. Hence, the first research hypothesis of the investigator was held true.

Conclusions

The results showed that there was insignificance difference Cognitive anxiety, stress and self-confidence between of volleyball players and basketball players.

A Study to Find the Prevalence of Breast Engorgement among Lactating Mothers

D. Indrani[1], M.V. Sowmya[2]

[1]MPT-1st year, Urology and Obstetrics Physiotherapy, Saveetha College of Physiotherapy,Saveetha Institute of Medical and Technical Sciences,Chennai, [2]MPT.,(Ph.D),Assistant professor, Saveetha College of physiotherapy, Saveetha Institute of Medical and Technical Sciences, Chennai.

Abstract

Introduction: Breast engorgement problem was common in early days and also after weeks of breast feeding. This frequent problem can happen to lactating mother who don't or can't breast feed as well as those who do. It is usually caused by an imbalance between milk supply and infant demand, if engorgement left untreated it can lead to potentially serious issues including painful blebs, plugged milk ducts or mastitis.

Aim: The study aimed to find out the prevalence of breast engorgement among lactating mothers with vaginal delivery, Lower segmental caesarean section.

Materials and Method: A total of 90 women were selected from SaveethaHospital and Saveetha Rural Health Centre, based on the inclusion criteria Saveetha Hospital and Saveetha Rural Health Centre, based on the inclusion criteria of Lactating mothers with Breast Engorgement and pain for atleast 2-3days who underwent vaginal delivery or lower segmental caesarean section. Exclusion criteria were lactating mothers with soft breast and non lactating mothers and other breast problems. After getting the consent from mothers and after explaining the Six Point Self-rated Engorgement Scale(SPES) and Visual Analogue Scale(VAS). They were asked to rate their level of engorgement and pain .The materials used were VAS and SPES.

Results: The study showed that the prevalence of breast engorgement among lactating mothers was 65%-75%.

Conclusion: The study concluded that the prevalence of breast engorgement among lactating mothers was 65%-75%.Breast engorgement is a major issue in the lactating mothers can leads to many problems like blocked milk ducts, feeding difficulties, a depressed milk ejection reflex, infection, inflammation of the breast and sore/cracked nipples.

Keywords: *Breast engorgement, Vaginal delivery, Cesarean delivery, Breastfeeding, Visual Analogue Scale, Six Point Self -rated Engorgement Scale,*

Introduction

Breastfeeding is a mother's gift to herself, her baby and the earth,there is no substitute for mother's milk. Colostrum is a yellowish liquid that contains important nutrients and antibodies that a baby needs right after birth [1].During initial stages of Breastfeeding, mother breasts produce colostrum in small amounts. But after making a couple of days, they're going to increase in milk production. So breast becomes fuller and firmer.

Correspondence Author:

Mob No: 7731852852.
e-mail: indranidasarapu@gmail.com,

This swelling is not only caused by the greater amount of milk, but also by increased blood flow and extra lymph fluids[2] in breast tissue. For most new mothers, these feelings of heaviness pass without problems when their baby feeding well and frequently. But some produce more milk than their breast can hold which makes them feel rock hard and uncomfortably full - a condition called engorgement. Breast engorgement is a problem[3] that is commonly encountered in breast feeding mothers and it can lead to potentially serious issues[4] including painful blebs, plugged milk ducts or mastitis. There are many lactating mothers suffering with breast engorgement[5]. Severe engorgement can make it difficult to baby to latch on to the breast properly and feed well. Engorgement may even cause body temperature to rise around 99-100 degree F, it is also known as milk fever. . According to Academy of Breastfeeding Medicine Protocol Committee, breast engorgement is defined as "the swelling and distension of the breasts[6]. Usually in the early days of initiation of lactation caused by vascular dilation as well as the arrival of the early milk. Breast engorgement during the first week of breast feeding and can also occurs as a result of delayed,infrequent or interrupted removal of milk from the breast[7,8,].The factors which may place a mother at a higher risk of engorgement are failure to prevent or resolve milk stasis resulting from infrequent or inadequate drainage of the breasts[9,10,]. The main aim of the study is to find the prevalence of breast engorgement among lactating mothers with vaginal delivery, Lower segmental caesarean section in rural population.

Materials and Method

This was an observational study conducted in Saveetha Hospital and Saveetha Rural Health Centre and took nearly 3months to complete the study. A total of 90 lactating mothers belongs to rural areas who complains of engorgement and pain for atleast 2-3days were selected. Samples collected by convenient sampling with the inclusion criteria of lactating mothers with breast engorgement and pain for atleast 2-3days who underwent vaginal delivery or lower segmental caesarean section. Exclusion criteria were lactating mothers with soft breast, non lactating mothers, nipple problems such as nipple sore, nipple cracks, inverted nipple or postnatal complications in previous her vaginal delivery or lower segmental caesarean section.The patients were fully explained about the study and after getting consent from the mothers. They were also given a detailed explanation about the Six Point Self-rated Engorgement Scale(SPES)[11] and Visual Analogue Scale(VAS)[12].They were asked to rate their level of engorgement and pain. The outcome measures used were SPES and VAS.

Engorgement was assessed using Six Point Self Rated Engorgement Scale from 1 to 6

1- being soft, no change

2- being slight change

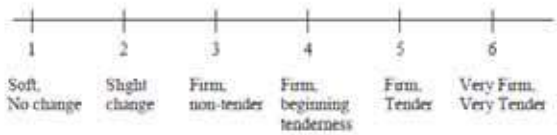
3- being firm, non-tender

4- being firm, beginning tenderness

5- being firm, tender

6- being very firm, very tender,[Any measure of 3- firm, no tender or more after baseline was the threshold for this subjective rating.]

Figure 1. Six Point Self Rated Engorgement Scale



Pain was assessed subjectively by using the visual analogue scale, a subjective measure of self-rated pain on a numerical scale of 1-10

0-Being no pain

1-3 being mild pain

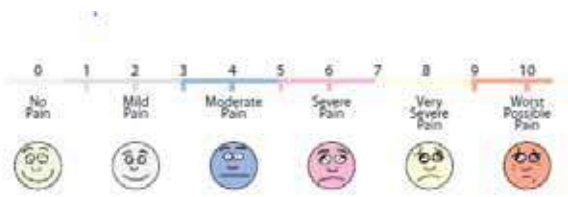
3-5 being moderate pain

5-7 being sever pain

7-9 being very severe pain

9-10 being worst possible pain [10 being the worst possible pain,5 moderate pain, 0 no pain] . The threshold for pain was having atleast one subsequent pain measure 3points or more above baseline.

Figure 2. Visual Analogue Scale

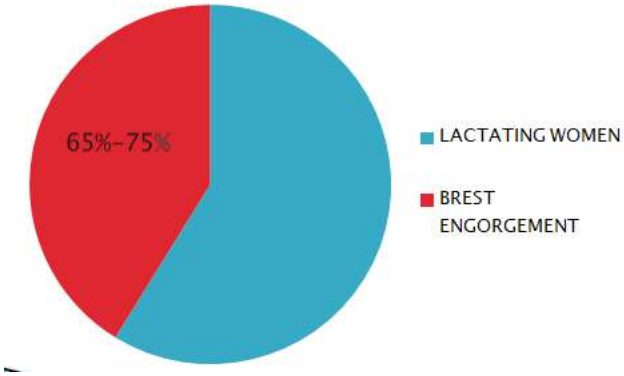


The participants in this study belongs to lower socio economic status and had no idea about breast feeding positions, breast care, breast engorgement and problems related to breast.

Results

Total samples of 90 belongs torural population were randomly selected as a part of the study. Lactating mothers were asked to rate their level of breast engorgement in their breast, according to SPES and also asked to rate their level of pain according to VAS. This study shows that 59-68 lactating mothers complained engorgement and pain in their breast. The result of the study was 65%-75%

Figure 3. Percentage of Breast Engorgement among Lactating Mothers.



Discussion

In this study breast engorgement was self-reported and diagnosed on the answers given by the lactating mothers. This study provides an opportunity to analyse the prevalence of breast engorgement among lactating mothers with vaginal delivery, lower segmental caesarean section. The samples were selected to find the prevalence with the help of Six Point Self-rated Engorgement Scale and Visual Analogue Scale. It is proven that SPES and VAS have their own validity and reliability. The SPES and VAS are valid diagnostic tools used for measuring breast engorgement and pain. SPES and VAS appears to be valid and reliable measures to assess breast engorgement and pain. Among 90 lactating mothers, this study showed that 59-68 lactating mothers complained engorgement and pain. Results showed that 65%-75% lactating mothers suffering with breast engorgement. Clearly health professionals should educate the mother who intends to breast feed that she is most likely to experience some degree of engorgement during the first two weeks post partum and perhaps for a longer duration.The health professional should not assume that the degree of engorgement or pattern is the same for every breast feeding mother.According to Lawrence[13], it is important that back pressure in the milk should be prevented from developing and eventually inhibiting milk production uncomfortable engorgement is best prevented by frequent breast feeding around the clock, since the infant is the most effective mechanism for removal of milk. Applebaum[14] suggest that if the infant is sleepy or sucking is impaired temporarily, the mother's residual milk and high milk tension may be relieved by breast massage and manual expression.

Conclusion

The study concluded that the prevalence of breast engorgement among lactating mothers were 65%-75% in rural population. At present there is no approved medicine to 'dry up' milk supply and prevent engorgement.We need to identify effective preventive and treatment measures for engorgement with no side effects to mothers and the baby,which not only helps to relieve the discomforts of lactating mother but also helps to promote proper milk to thebaby.

Depression & Diabetes Has No Relation: A Cross Sectional Study in Tertiary Care Hospital of Eastern India

Datta Subhendu[1], Chattopadhyay Somsubhra[2], Gayen Rumi[3], Debnath Sharmistha[4]

[1]Resident Medical Officer, Department of Psychiatry, College of Medicine and Sagore Dutta Hospital, Kolkata. [2]Assistant Professor, [3]Assistant Professor, Department of Biochemistry, College of Medicine and Sagore Dutta Hospital, Kolkata, [4]Associate Professor, Department of Laboratory Oncology (Oncopathology), Medical College, Kolkata

Abstract

Background: Diabetes and depression is a growing concern now a day. Both have bidirectional relation. But few studies showed no association between two. Here we tried to find out whether there is any association between two.

Method : 96 patients were recruited in the study. They were assessed by structured interview by trained psychiatrist and diagnosed by ICD 10 diagnostic criteria. Severity of disease was assessed by Beck depression inventory (BDI).

Blood sugar was assessed by Fasting and Postprandial blood sugar and glycosylated haemoglobin (HbA1c).

Result: The p value of FBS, PPBS and HbA1c was 0.91, 0.957, 0.957 respectively. It signifies that in our study the two diseases have no association. Most of the patients were female and male to female ratio was 1 : 2. Mean age of the patients were 40.9±12.2 .30 patients were single which suggest that in our study depressive disorder were more common in married population. And most of the patients were unemployed about 54.167 percent people had no job.

Conclusion: In our cross sectional study we did not find any significant association between depression and diabetes.

Keywords: *Diabetes, Depression, Glycosylated haemoglobin (HbA1c).*

Introduction

Diabetes as well as depression is becoming an epidemic in India.(1)As per projection of World Health Organisation the number of diabetes will increase by 122 percent in 20 yrs from 1995 to 2025.(1)There will be 42 percent increase in developed countries and 170 percent increase in developing countries.The maximum increase will occur in India about 195 percent.(1)

And depression which is characterized by depressed mood,decreased energy,anhedonia,early morning awakening,lack of concentration, decreased appetite and suicidal ideation (ICD 10 diagnostic criteria), is on rise. According to world Health Organization Depression is responsible for great burden and 12 percent total year lived with disability.(2)

Depressive disorder is becoming a social burden and cause for increased mortality as a result of poor self care, higher incidence of noncompliance or treatment non adherence,decreased quality of life.(3)

Depression or Major depressive episode as per WHO is a major public health problem,that costs substantial sufferings,loss of productivity,higher rates

of morbidity and mortality and at last but not the least impaired quality of life. [4,5]Among the various causative factors depression is very much common in any chronic illness such as diabetes,cancer etc.[6]Low grade symptoms of depression in diabetes frequently missed.[7]Approximately half of diabetes patients use to experience low grade to sub threshold depression in their lifetime.[7]

The relationship of depression and diabetes is bidirectional.[8]Depression increases the risk of diabetes both by biological and behavioural factors.[9]The relationship of depression and diabetes described by a British Physician Thomas Willis.[10]As per his view diabetes is consequences of depression.And now this is widely discussed topic as chicken egg dilemma.

Co morbid diabetes and depression impairs the course and prognosis of both the disorders and utilises great public health and social resources.[11]

Depression is associated with both the types of diabetes,but there are some researchers who are strongly in favour of type 2 variant.[12]

Apart from the biological factors including activation of HPA axis,Sympathoadrenal system,diabetes is associated with poor health related behaviours of depression.[13]Obesity,physical inactivity is the risk factor of diabetes.[14]Another study found that glycemic control measured by glycosylated haemoglobin is directly proportional to the number of depressive episodes.[15]And severity of diabetic complication is also predicted by depression.[16]

Mezuk et al., 2008 stated that depression is correlated with 60% increase in type2 DM and type 2 DM has only 15% correlation with depression.[17]

Current study aims at prevalence of diabetes in patients of depression who never had been treated with antidepressants for their depressive episodes.

Methodology: The study was conducted by Department of Psychiatry and Department of Biochemistry of College of Medicine & Sagore Dutta Hospital, Kamarhati, Kolkata, WestBengal, after obtaining ethical clearance from institutional ethical committee.Informed consent was taken from patients before entering into the study.Biochemical tests were done at the Department of Biochemistry of the same institution.

Study Population: The study group comprised of patients having the diagnosis of depressive disorder .First episode depression was included in the study.

Study Design: This cross sectional was designed assess prevalence of DM in patients of depression in a tertiary care hospital of eastern zone of India .During the period of four months we recruited the patients having MDE as per our inclusion criteria.1) age more than 18 yrs 2) Drug naïve (those did not receive any antidepressants in past) 3)Free from any psychiatric and medical co morbidities which can influence the metabolic profile and thus glycemic control.

Socio-demographic and clinical information was collected on a semi structured proforma designed for the study.Physical evaluation included measurements of body weight in kilogram (KG), height in centimeters (cm) and waist circumference (in cm) by a calibrated scale and recording of blood pressure (BP). Waist circumference was measured in cm using a measuring tape in the horizontal plane midway between the inferior margin of the ribs and the superior border of the iliac crest; measurement being recorded at the end of normal expiration in the standing position.Fasting blood sugar and PPBS were measured at Biochemistry laboratory of the institution.The venous blood samples were collected after 8 hrs of fasting incase of Fasting blood sugar (FBS) and 2hrs after having 75 gms of glucose in case of Postprandial blood sugar(PPBS) and glycosylated haemoglobin (HbA1c)..

Severity of depression was assessed among patients using Beck depression inventory (BDI).

Result

Table 1:Depression level * FBS level Cross tabulation

		FBS level		Total
		X	Y	
Depression level	Mild	28	6	34
	Moderate	47	7	54
	Severe	6	1	7
	Very severe	1	0	1
Total		82	14	96

X ≤ 126, Y >126 Chi square value= 0.541, df= 3, p value= 0.91

In our data patients were grouped into two,those having fasting sugar more than 126 mg/dl and those having less than and equals to 126 mg/dl.

Here among the patients with mild depression 6 were having fasting blood sugar more than 126 mg/dl.And 7 among Moderate,1 among severe and nil having very severe having FBS level more than 126 mg/dl.And it shows that there were no association between the variables.

Table 2:Depression level * PPBS level Cross tabulation

		PPBS level		Total
		M	N	
Depression level	Mild	31	3	34
	Moderate	49	5	54
	Severe	6	1	7
	Very severe	1	0	1
Total		87	9	96

M ≤ 200, N>200 Chi square value= 0.315, df=3, p value = 0.957

Table 3:Depression level * HbA1c level Cross tabulation

		HbA1c level		Total
		A	B	
Depression level	Mild	31	3	34
	Moderate	49	5	54
	Severe	6	1	7
	Very severe	1	0	1
Total		87	9	96

A ≤ 7.0, B > 7.0 Chi-squares value = 0.315, df= 3, p value = 0.957

200 mg/dl was taken as PPBS standard.And similarly fewer patients were having blood sugar more than reference value.And p value is 0.957 which is not significant.

Regarding HbA1c,7 was taken as standard.And only 9 patients have HbA1c level more than 7 and p value is 0.957 which is not significant.

Most of the patients were female and male to female ratio was 1 : 2.Mean age of the patients were 40.9±12.2 .

Table 4: Sex distribution

		Frequency	Percent
Valid	F	64	66.7
	M	32	33.3
	Total	96	100.0

30 patients were single which suggest that in our study depressive disorder were more common in married population.

Table 5: Marital status

		Frequency	Percent
Valid	Single	30	31.25
	Married	66	68.75
	Total	96	100.0

And most of the patients were unemployed about 54.167 percent people had no job.

Table 6: Employment status

		Frequency	Percent
Valid	Employed	44	45.833
	Unemployed	52	54.167
	Total	96	100.0

Discussion

Here we tried to find out the relationship between depression and diabetes in a cross sectional study but we did not find any significant association between two.The previous studies stated that depression and diabetes were related bidirectional.[18]Among 96 depressed patients of various grade we did not find any relation between two. This study is contradiction of previous studies.But one study was in our favour which stated that diabetes and depression has no association in clinical and genetic level.[19]

In current study we used structured interview and diagnostic criteria of ICD 10 to diagnose depression of varying severity.And blood sugar was assessed by fasting blood sugar,PP sugar after 2 hrs of meal,and HbA1c.But none of them shows any significant association with depressive disorder.

Previous studies had got several limitations.In these studies varying method were used to diagnose depression like diagnosis by physician,self reported questionnaire etc. [20,21]But in our study we used structured diagnostic criteria of ICD 10.

In our study depression is more common in woman and unemployed persons which supports the previous studies.[18,22]

And also married persons were affected by the disease process twice as common as single person which also contradiction of previous studies.[23]

Married and unemployed persons were affected much more common which probably suggest the chronic

stress of a family man ends with the disorder which also costs the productivity and thus the vicious cycle runs.

But our study has got several limitations.It was a cross sectional study in a hospital based population which does not reflect the entire community as only a fewer patients with symptoms come to the hospital.And the study lacks the comparison group which could be used to assess comparison between the prevalence of depression among diabetes and non diabetic individuals.

Conclusion : We have studied in a tertiary care hospital of North Kolkata,which was not representative of whole community. Multicentric study using larger population sample and probably the genetic analysis will give better insight into the problem.

Prevalence of Psychiatric Morbidities in Migraine: An Observational Study

Datta Subhendu[1], Chattopadhyay Somsubhra[2]

[1]Resident Medical Officer, Department of psychiatry,College of Medicine and Sagore Dutta Hospital, Kolkata. [2]Assistant professor

Abstract

Background: Migraine is a chronic episodic moderate to severe throbbing headache having many psychiatric co morbidities. Current study aims to detect epidemiology of psychiatric co morbidities in migraine.

Method: Patient aged 11-65 years selected by International classification of headache 3rd edition to have migraine. SRQ-24 and ICD-10 criteria was applied to detect psychiatric co morbidities.

Result: Anxiety was found to be prime co morbidity followed by depression.

Conclusion: Treating co morbidities may improve disease condition.

Keywords: *Migraine, Co morbidity, Anxiety.*

Introduction

As per International classification of headache disorder 3 rd edition, migraineis characterized by chronic or episodic headache, pulsatile in nature associated with photophobia or phonophobia, aggravated by routine physical activity which causes avoidance of that situation.

Among the various types of headache the prevalence of tension type of headache is 38 percent and of migraine is 10 percent(1). And it is one of the debilitating disorder which causes functional (2), cognitive(3) and social impairment. It has become a social burden in terms of increased utilisation of health care cost by visiting the physician regularly or by consuming the drugs.(4)

Though migraine is second most common in primary headache disorder after tension type headache,but the disability comes first(5).Social burden of disease ranges from mild impairment to severe disability that limits the work like study,regular official job and routine household work. Migraine is associated with various comorbid conditions like impaired interpersonal relationship,psychosocial problem,cognitive impairme nt,neurological,gastrointestinal,autoimmune diseases, cardiovascular diseases.(6)

In most of the cases the headache is underestimated(7) and also its comorbid conditions leading to loss of productivity for the society as it is mostly affecting the economically productive age groups. And the quality of life is also impaired in migraineurs(8) and it use to severely impaired in associated psychiatric, neurological or medical disorders among the various psychiatric comobidities Depressive disorder is one of most common in migraine patients(9). In previous studies it estimated that anxiety and depressive disorders are ten times more common than general population. Substance abuse disorder,Panic disorder, phobia,Personality disorders are significantly associated with migraineurs. Significant percentage of people attempt suicide in very severe debilitating condition(9). Among neurological symptoms epilepsy, allodynia, visual symptoms,vertigo and gait instability and impaired higher cognitive functions is

Assistant professor, Department of psychiatry, College of Medicine and Sagore Dutta Hospital, Kolkata.
Mob No**:** 9836145175.
e-mail**:** somsubhra.chatterjee@gmail.com

important[10]. Apathy, impaired attention,executive functions use to get impaired[3]. It also decrease the school performances in school going children. Cognitive function is affected by age, frequency of attack,duration of headache.[3] In studies it shows that cognitive decline is mostly associated with migraine with aura[3].

Helicobacter pylori infection,irritable bowel syndrome,unexplained right upper abdominal pain,celiac disease cyclic vomiting syndrome are associated with migraine significantly.[11]

In the current study we tried to find out psychiatric disease burden in migraine patients so that in future modifying the associated risk and comorbid condition disease course will be modified.

Methodology: The study conducted in department of psychiatry in College of medicine and sagore Dutta Hospital. It took about 6 months to collect the data. Ethical permission was obtained from institutional ethical committee. Informed consent was taken from all the patient before entering the study. In case of minors consents were taken from parents.

Inclusion Criteria:

1. Age 11 yrs to 65 yrs
2. With sound mental activity
3. Can give informed consent
4. Willing to participate in study

Exclusion Criteria:

1. Patients with mixed headache
2. Unsound mind
3. Not willing to take part in study
4. Those having organic brain lesion
5. Those having anatomical lesion in either CT scan or MRI

Patients were selected as per inclusion and exclusion criteria. They were diagnosed as per diagnostic guidelines in International classification of headache disorder 3 rd editions. Semi structured proforma was used to record the socio demographic data and to record the associated symptoms. Then SRQ 24 was administered to assess whether they have any psychiatric disturbances. SRQ is self reported questionnaire with N and P score. N score more than 6 and P score more than 2 was considered positive. After that they were diagnosed by ICD 10 diagnostic criteria. Anatomical lesions in CT scan or MRI were excluded from study.

Result

Table 1: Sociodemographic profile in migraine (n = 173)

Mean Age	32.9±10.4yrs (11 to 65 yrs, n=173)
Sex	Female-138(79.8%), Male-35 (20.2%) F:M = 3.94 : 1
Religion	Hindu – 48 (27.7%); Muslim – 121 (69.9%); Christian -4 (2.3%)
Marital Status	Married – 124 (71.7%), Unmarried-34 (19.7%), Divorced – 15 (8.7%)
Family history	Present – 37 (21.4 %), Absent- 136 (78.6%)
Occupation	Employed-63 (36.4%), Unemployed -110 (63.6%)
Education	Graduate 2(1.2%), Higher secondary 16 (9.2%), Secondary -39 (22.5%), Middle School – 75 (43.4%), Primary 41 (23.7%)
Aura	Present – 16 (9.2%), Absent – 157(90.8%)

Our population was mainly middle aged females with mean age 32.9±10.4yrs and female to male ratio was 3.94 : 1.As the local community around the hospital is predominantly Muslim,our study reflects disease affection mostly in Muslim,married (124)patients. Most of them did not have family history of migraine headache. Most of people were educated upto middle school (upto class VIII) and were unemployed. Aura was present in small number of patients.

Table 2: Psychiatry Diagnosis (n =173)

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	No illness	88	50.9	50.9	50.9
	Alcohol Dependance	3	1.7	1.7	52.6
	Bipolar Disorder	9	5.2	5.2	57.8
	GAD	41	23.7	23.7	81.5
	MDE	19	11.0	11.0	92.5
	OCD	2	1.2	1.2	93.6
	Panic Dis	11	6.4	6.4	100.0
	Total	173	100.0	100.0	

50.9% patients did not have any psychiatric illness. So almost half of patients had various comorbid psychiatric illnesses. Most of the patients had generalized anxiety disorder (23.7%). And moderate depressive episode, panic disorder, bipolar disorder, alcohol dependence and obsessive compulsive disorder were psychiatric comorbid illness they have.

Table 3: Smoking

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	No	145	83.8	83.8	83.8
	Yes	28	16.2	16.2	100.0
	Total	173	100.0	100.0	

Table 4: Suicide attempt

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	No	154	89.0	89.0	89.0
	Yes	19	11.0	11.0	100.0
	Total	173	100.0	100.0	

Most of the patients were non smoker (83.8 %) and few patient (11%) attempted suicide in past.

Discussion

We studied in tertiary care hospital which crater predominantly Muslim population in urban area. Middle aged female population were affected mostly. Most of Indian population were villagers. Our study conducted to assess prevalence of migraine in urban area. The prevalence varies in different countries. One year prevalence rate 25.2% in one study from Karnataka[12] The mean prevalence in European country 14.7%[13]. In one previous study occurrence of migraine higher in females than in males[14].

Most of the patients did not have family history of migraine in our study which is consistent with the previous studies[15].Large number of patients were married as it is explained by that the disease mostly affects the reproductive age group[15].

Aura was present in small number of patients (9.2%) which is also consistent with previous studies.[15]

About 50% patients had various psychiatric illnesses. Among them most prevalent was generalized anxiety disorder (23.7%). Next in the list were moderate depressive episode, panic disorder, bipolar disorder, alcohol dependence and obsessive compulsive disorder. [16]The causes of psychiatric comobidity is recurrent attack of pain which causes agony and anxiety,and depressive disorder[17]. Epidemiological studies found that there are same pathophysiology underlying migraine and anxiety and depressive disorders[17].But this is not the sole cause of the comorbidities as many patients with migraine did not have any psychopathology.

In the previous study percentage of suicide attempt in migraine headache is close to our finding[18].But it

did not tell us whether there is actual increase of suicide rate than the general population as we did not have comparison group.

And another limitation of our study was we studied in a centre which was not representative of entire community.

Conclusion

The comorbid conditions adversely affect the prognosis and treatment responses in migraine headache. It is necessary for the therapist to assess the comorbid conditions and treat them accordingly so that disease course can be modified. To get the exact picture of disease comorbidity multicentric trial with large sample may be required.

Economic Slow Down and it's Impact on Disease Burden in India

Divya A Reddy[1], Siddharth Misra[2], Subin Koshy, Sudhakar A[3]

[1]Assistant Professor, [2]Research Mentor, Accendere Knowledge Management Services,
[3]Student, MBA, Krupanidhi Group of Institutions, Bangalore, India

Abstract

Context: Fall in employment, growth, incomes and investments are the more visible and obvious ill effects of an economic slowdown but there are far reaching impacts of an economic slowdown that aren't so immediate and visible. The aim of this study is to assess how these economic downturns have dented the health outcomes in India since 1990. We assess the non-fatal outcomes of public health using the morbidity measure DALY(Disability adjusted life years) caused by economic slowdown. We find that rise in income led to reduction in communicable, maternal, neo natal and nutrition diseases (CMNNDs) while it led to an increase in injuries and non-communicable diseases. An increase in unemployment was associated with an increase in disease burden for CMNNDs, non-communicable disease and injuries. Economic slowdown puts the people in a vulnerable position as loss of income and employment lead to increase in disease burden. The public health policy especially in developing nations must focus on social security protection to prevent such negative health outcomes during an economic slowdown.

Keywords: *Disease burden, DALY, Morbidity Measures, Economic Slowdown*

Introduction

A healthy population is a productive one. Achieving better public health not only has positive outcomes on the society but also makes economic sense as expenditure and economic loss from ill health can be prevented. While a growing economy creates opportunities for better health outcomes, the contrary can also be true. Public health deteriorates during an economic slowdown or during an economic crisis.

In today's globalized world, contagion of financial distress in one part of the world to the entire global economy is an expected effect. The 2008 global economic crisis led to the increase of mortality rates in every affected country.[1] Irrespective of the wealth of a nation, the poor and those who fell in to poverty because of loss of Income or housing were hit the hardest.Developing countries with huge percentage of population living in poverty are particularly vulnerable. During an economic crisis there is huge financial stress on the poor as they suffer from lower incomes, they reduce the spending on both quantity and quality of nutrition which can have irreparable impact of their physical and psychological being and productivity.[2]

India's economy since 1990 has transformed dramatically due its trade openness. The Gross domestic product has been out on a growth trajectory since the New Economic policy in 1991.[7] Increasing per capita incomes supported by steady economic growth leads to improvement in the nation's capacity to consume goods and services that promote public health.[8]Post reforms, unemployment grew gradually due to increasing rural unemployment and predominance of casual workers. Spike in number of student population due to expansion in higher education, is another reasons attributes slow growth in the workforce.[9,10] Temporary unemployment and unemployment in long term affects physical and mental health of the population.[10,11]

Earlier studies have studied public health by analyzing mortality rates and Public health expenditure.[1,13-14]Mortality measures don't provide adequate information with respect ill health of a population. DALY(Disability adjusted life years) is becoming the commonly accepted measure to assess status of public health as it a comprehensive indicator comprising of both morbidity and mortality giving a picture about the healthy life expectancy lost due to ill health.[11]Therefore, present study gives a macro perspective and tries a new approach to assess the impact of an economic slowdown on public health by studying the Disease Burden.

Literature Review: Globalization has increased the potency of economic crisis by having a cascading effect on global economy. However, according to the decoupling theories, the emerging economies do not reflect the patterns exhibited by the developed nations during the rise and fall in the business cycle, as it is believed that the emerging economies are largely independent of each other.[3, 4] However, the aftermath of an economic crisis characterized by capital flow reversal, pressure on the fiscal deficit due to stimulus packages provided by the government, corporate debt and currency depreciations was witnessed in India post 2008.[14]

Economic slowdown harmfully heightens the impact on mental health of the public. The stresses of unemployment and mortgages adds pressure to the primary attendees increasing depression, anxiety and alcoholism.[5] Financial crisis can have a rapid impact on mortality related to suicide amidst the tumult in banking sector.Anticipation of job loss and social security aggravates the suicide prevalence.[1] Studies in developed countries which have well-functioning social security systems, have confirmed the immediate rise in suicides following a financial crisis.[14]

Demand for the public health care increases during economic slowdown as the incomes contract and public expenditure on private health care decreases.[26,27] This can create increased pressure on the public health systems in the light of austerity measures and cuts in government spending thus leading to damaging effects on public health such as sharp increase in people report worsening health, suicides, drug abuse, violence and infectious disease burden.[5] An immense pressure will be put on public health sectors as more people shift from private health services to public health service providers due to affordability issues. Poor health equity in regions can decrease access to the needy in such situations as the non-poor grab the services.[4] There is immense need to recognize the fragile nature of Public health in relation to turmoil in the business cycle. Due to the efforts of the Global Disease burden Initiative 2017, it has become feasible to study morbidity in India on multiple dimensions.

Data: The data on Public health for the period 1990 to 2016 is obtained from the broad study conducted as part of the Global Disease burden Initiative, 2017 by Indian Council of Medical Research, Public Health Foundation of India, and Institute for Health Metrics and Evaluation. The findings of this study are first of its kind on the basis of scale completed with the collaboration of 103 institutions and over 200 health scientists. The study provides estimates of all India and state level metrics for DALYs (Disability adjusted life years) for 333 disease conditions and injuries and 84 risk factors for each state of India from 1990 to 2016. The study uses the aggregates of DALY's for three broad categories namely, communicable, maternal, neonatal, and nutritional diseases (CMNNDs); non-communicable diseases (NCDs); and injuries. Disease burden is given by DALY gives relatively a deeper understanding on status of health when compared to mortality measures as is takes in to account the years of health life expectancy lost due to injury, disease and premature death.[11]

Studies previously conducted on this topic have used unemployment rate as the primary measure of macro economy.[1,13-14]The present study uses unemployment rate and Per capita income at constant prices as they comprise of two key determinants linking macro economy and health.[2] The unemployment rate has been sourced from International Labour Organisation and the per capita national income at constant prices has been sourced from World Bank Open data source.

Method

Linear regression technique is employed in the study to establish the impact of change in per capita income and unemployment on disease burden in India. We have used Gross National per capita income at constant prices which is adjusted for inflation. Unemployment rate captures the number of people actively seeking employed upon total number of people in the labour force. Per capita income and unemployment are the explanatory variables. Our predictor is DALY (Disability adjusted life years) which captures the disease burden that is the

healthy life expectancy years lost due injuries, disease and premature death with is the summation of YLL (Years of life lost) and YLD (years lived with disability) for a total of 333 disease conditions. Log transformation technique has been used to standardise the data as the values are non-negative. Linear regression is performed initially to analyse the impact of per capita income and unemployment of DALY for aggregate of all causes. Later the regression estimation will be performed to assess the impact of the independent variables on three categories namely communicable, maternal, neonatal, and nutritional diseases (CMNNDs); non-communicable diseases (NCDs); and injuries.

Results and Interpretations

Results of 42 linear regression models were computed to establish relationship between disease burden, Per-capita income and Unemployment for the time period 1990 to 2016 in India. It was noted that a percentage increase in per-capita income was associated with a 0.843 percent fall in disease burden for all causes across all ages. Similar effect was noted for the aggregate disease burden for communicable, maternal, neonatal and nutritional diseases (CMNNDs).A percentage rise in per capita income was associated with a 0.914 percent fall in disease burden for CMNNDs. By contrast, it was noted that the association was inverse for Non- communicable diseases and injuries. A percentage increase in per-capita income was associated with a 1.019 percent rise in non-communicable diseases and with a 1.049 rise in injuries.

A rise in per- capita income had varying effects on disease burden for different age groups. While increase in per-capita income led the decrease in disease burden for the age group under 5 and for 5 years to 14 years, an opposite relationship was observed for age groups 15 years and above. Relatively higher increase in disease burden was observed in Age group 15 to 49 years (with co-efficient 1.055) when per-capita income increased.

The effect of rise in per-capita income on disease burden was more distinct in female population with beta co-efficient of -0.905 when compared to the male population -0.68. For both female and male population increase in per-capita income was associated with a reduction in disease burden for age groups below 14 years and for age groups above 15 years the effect was reversed, where an increase in per-capita income was associated with an increase in disease burden.

The study attempts to associate another independent variable with disease burden i.e. Unemployment. The results indicated a significant association between unemployment and disease burden. However, the beta coefficients of the linear regression models were lesser across disease categories, gender and age groups in comparison with per-capita income. An increase in unemployment was associated with an increase in disease burden for CMNNDs, non-communicable disease and injuries. The effect of unemployment was negligible with a beta coefficient of 0.06 on disease burden due to Non- communicable diseases. A positive relation between unemployment and disease burden was detected across age groups except for population in age group 50 to 69 years for both female and male populations, where an increase unemployment was negatively related to disease burden.

Discussion and Conclusion

Our results have shown that Economic slowdown leads to negative health outcomes on a nation. These results are consistent with the previous studies which have confirmed the negative health effects loss of income and employment can have on the population health.[1,4] Increase in income is observed to be positively related to decrease in disease burden from communicable, maternal, neonatal and nutritional diseases. Increase in income can lead to better access to clean water, sanitation, quality health care, vaccinations, nutrition and insurance. India is also undergoing an epidemiological transition where there is shift in disease burden from CMMNDS as major contributor to NCDs and injuries. The epidemiological transition can be attributed to demographic transition (decreasing mortality and fertility) and social transition (increasing awareness and expectations about the health system) happening in a developing nation like India.[3] These transitions seem to be affected by an economic slowdown as the disease burden among all these classifications showed a significant relation with change in income and employment.

Some of the previous studies have argued that road accidents increase with decrease in Unemployment. However, India witnessed a 65.1 percent rise road accidents 29.8 percent rise in cases of self-harm and 41.3 percent rise in falls from 1990 to 2016.[3] According the results obtained by us an increase in unemployment and per capita income led increase in injuries. In India about 82.2 percent are employed in informal sector with little or no social security protection, which means that when joblessness goes up people take up hazardous jobs

which can increase the incidence of injuries due to poor working conditions.

Positive health effects of increase in per-capita income were observed only in very young population aged below 14 years. For the age groups above 14 years disease burden increased as income and employment increased. The working populations belonging to these age groups are exposed to many external environmental hazards which are the leading cause for increase in disease burden. Some of top risk contributors to disease burden with highest change since 1990 were High body-mass index (+281%), unsafe sex (+214%),High fasting plasma glucose (+127%), High total cholesterol (+106.2%), High systolic blood pressure (+89.3%)and low physical activity (+109%). These are the risk factors associated with rise non-communicable diseases which steadily become the top contributor for India's disease burden since last decade. Rise in non-communicable diseases is an issue that is plaguing middle and lower income nations like India. Increasing urbanization, over nutrition, sedentary lifestyles, pollution, shift in dietary habits and addictions are some of the causes of increase in non-communicable diseases in developing countries in spite of a steady increase in incomes and our results were in conformity with this view.[6, 8]

The study relies entirely upon the morbidity estimates and its relation to the changes in income and employment. This can be a limitation as earlier studies on morbidity in India have indicated that the there exists a problem of under self-reporting and underestimation of morbidity due its subjective nature. Accurate reporting morbidity depends upon awareness about general health conditions among populations. Many social, community and individual factors influence the reporting of morbidity, therefore collective morbidity reports may not entirely be representative of the actual morbidity figures among various sections of the nations. It is observed that this may be more valid for poorer populations and women.[4]There exists immense scope for future research in the light of the findings of our study. India is a nation with huge population with immense diversity among its states. The associations established in the study can be extended to various states in India and the further addition of other socio economic determinants of health can provide deep insights on factors affecting morbidity in India.

The effects of economic fluctuations on public health is more potent in less developed countries with a week social security net especially in terms of unemployment insurance.[42] The findings of the present study are also in line with the National health policy 2017, which aims to work towards strengthening the social security protection. The results obtained by this study attempts to throw some light on this issue and indicate a direction for National health policy decisions. India's state of public health is often linked to the quantum of public expenditure on health which is way below the world average. The findings of the study indicate along with increasing public expenditure on health, the government should focus on improving working conditions of unorganized workforce, social security protection in the event of unemployment and widen the scope of public health insurance to cover variety of diseases.

Effect of Self Myofascial Release Using Foam Roller Versus Tennis Ball in Subjects with Plantar Fasciitis: A Comparative Study

Fahad Shahul Hameed[1], Saumya Srivastava[2]

[1]Post Graduate Student, [2]Assistant Professor, Nitte Institute of Physiotherapy, Derlakatte, Mangalore, Karnataka, India

Abstract

Background: Plantar fasciitis is a repetitive micro trauma overloaded injury of the attachment of plantar fascia at the inferior aspect of the calcaneum. It results into inflammation and thickening of the fascia causing heel pain. Myofascial release (MFR)is a manual therapy technique which can be used to release the tension developed in the thickened fascia. Self-Myofascial Release (SMFR) can be given with a variety of tools such as foam rollers and tennis ball. They are easy, harmless and cost effective method of giving SMFR. However, the efficacy of the technique in plantar fasciitis is not yet clear.

Objective: To compare the effect of SMFR technique using foam roller and tennis ball in subjects with plantar fasciitis.

Method: Thirty-twoeligible patients were recruited for the study. They were allocated into either group A (n = 16) and group B (n=16). Group A was given SMFR with Foam roller and group B was given SMFR with tennis ball. The intervention was given for 2 weeks (5 days/week). Visual analogue scale (VAS) and Foot and Ankle Disability Index (FADI) outcome measures were taken both at baseline and after 2 weeks of intervention.

Results: Both group A and group B showed significant improvement in VAS and FADI after two weeks of interventions (p value <0.05). However between groups comparison were statistically insignificant (p value>0.05) for both the outcome measures.

Conclusion: This study concludes that SMFR with both foam roller and tennis ball showed improvement in pain and muscle function i.e. both interventions were equally effective. Neither of the method was found superior than the other.

Keywords: *Heel pain, Plantar Fasciitis, Foam Roller, Tennis Ball, Self-Myofascial Release, Manual Therapy.*

Introduction

Plantar fasciitis is a degeneration of the plantar fascia as a result of repetitive micro tears of the fascia that lead to an inflammatory reaction.[1] Inflammation of the plantar fascia and other fascial structures is characteristic feature of plantar fasciitis.[2]

Plantar fasciitis or plantar heel pain is most commonly reported cause of inferior heel pain. In a course of a lifetime, it has been estimated that approximately 10% of general population are afflicted with plantar heel pain.[3]

Plantar fasciitis prevails in both athletic and non

athletic populations and about 15% of adult foot complaints need clinical help. [4]It is found to be more common in females when compared to males.[5]

Risk factors for plantar fasciitis are work related weight bearing, sudden gain in body weight, shoes with poor cushioning, athletic population, increased age, decreased ankle dorsiflexion, occupation involving prolonged standing and tightness of Achilles tendon.[6]

Heel pain is mostly noticed in morning, during initial steps of walking or after a short interval of inactivity. Pain gradually decreases with activity but tends to worsen by end of the day. Antalgic gait may be observed if the pain is severe.[7]

Therapists use various manual Myofascial therapies over the soft tissue to produce therapeutic changes in these tissues. A variety of interventions including structural integration, osteopathic soft- tissue techniques massage including connective tissue massage (CTM), myofascial trigger joint therapy and instrument assisted fascial release have been utilized.[8]Also, treatment method like Orthosis (heel pads and arch supports), Non-steroidal anti-inflammatory drugs, local steroid injection, exercise for stretching the Achilles tendon, night splints, below knee cast are used commonly.[9]

SMFR is a technique used to treat myofascial restrictions and restore the normal soft - tissue extensibility. To increase myofascial mobility, foam roll and roller massager are commonly used tools. The clients use their body weight to apply pressure to the soft- tissues during the rolling motion with foam roller.[10]

Tennis ball is amongst the most resourceful aid used for self-massage. The ball can be placed on the floor or a wall or any other body part to apply definite pressure on the tight or aching site of the muscle. The main aim is to reach the area of the body which cannot be reached with the individual's own hands. The pressure applies by tennis ball should be large enough to release the tightness without irritating the nervous system. The resultant pain sensation should be considered as "good pain". [11]

Heel pain associated with plantar fasciitis is common in both sedentary as well as in active individuals. Investigation regarding method used to treat plantar fasciitis is scarce, however, different interventions have shown to be beneficial but there ispaucity in the literature regarding the effect of SMFR using a foam roller or tennis ball. Thus, the need of this study is to find out the effect of plantar SMFR using foam roller and tennis ball in subjects with plantar fasciitis.

Methodology: The study was conducted between May 2018 to April 2019 in the department of physiotherapy,in a tertiary hospital of Mangalore, India.Obtaining ethical clearance from the institutional ethical committee from theuniversity,participantsdiagnosed with plantar fasciitis by specialized physicianwere recruited.The participants of both the genders were included if they presented with clinical diagnosis of acute plantar fasciitis andwere of age above 18 years,and they were excluded if they reported with calcaneal spur, fracture of foot and loss of plantar foot sensation. The participants were randomized by using chit method into two groups. Outcome measures were recorded by the therapistwho was not a part of the study and was blinded to the interventions. Written informed consent was obtained from all the eligible participants.

Along with SMFR both groups also received ultrasound therapy over the entire length of the plantar fascia.Outcome measures VAS (Visual Analogue Scale) and FADI (Foot and Ankle Disability Index) were taken before and after the treatment sessions. Treatment was given for10 sessions over a period of 2weeks.

Group A: Smfr With Foam Roller: Participants were instructed to be in standing position and foam roller was given to roll under the affected sole starting from behind the head of metatarsals towards the heel focusing on medial arch for 2 minutes. They were asked to exert maximum pressure, till a point of discomfort but not pain (Figure 1) and Ultra sound therapy was given over the affected plantar surface of the foot with Intensity 1.0 $W/cm^{2,}$ continuous mode and $3MH_z$ depth for 7 minutes.

Group B: Smfr With Tennis Ball: Participants were instructed to be in standing position and tennis ball was given to roll under the affected sole starting from behind the head of metatarsals towards the heel focusing on medial arch for 2 minutes. They were asked to exert maximum pressure, till a point of discomfort but not pain (Figure 2) and Ultra sound therapy was given over the affected plantar surface of the foot with Intensity 1.0 $W/cm^{2,}$ continuous mode and $3MH_z$ depth for 7 minutes.

Statistical Analysis: SPSS software 16.0 was used to assess the data obtained. Independent sample t test was used for Group A and Group B to compare the pre and post measurements for VAS and FADI, within the group comparison was analysed by using paired t test.

The p-value less than 0.05, was considered significant for the study.

Results

The study consisted of 7 males and 9 females in group A and 4 males and 12 females in group B. The meanage in group A and B was 25.5±7.37 and26±8.9 respectively. There was no significant difference seen between both the groups with respect to age and gender ($p>0.05$). Within the group analysis for the outcome measures VAS and FADI was done using paired t test (Table 1).A statistical significant difference was obtained within the group analysis ($p<0.001$) for both the outcome measures in both the groups. However, no significant difference was seen between the groups analysis ($p>0.05$),(Table 2 and 3).

Discussion

The purpose of this study was to compare the effect of SMFR using foam roller versus tennis ball in subjects with plantar fasciitis. The results of the present study indicated that SMFR with both foam roller and tennis ball showed improvement in pain and muscle function i.e. both intervention were equally effective. Neither of the method was found superior than the other.

The exact mechanism behind the role of SMFR in improving plantar fasciitis is still not clear. Meltzer et al demonstrated that MFR causes apoptotic rate normalization, changes in cell morphology and reorientation of fibroblasts. This facilitates the healing processes by halting degeneration of plantar fascia which may possibly decrease the pain.[12] Also a study suggests that MFR helps to return the shortened fascial tissues to its normal length by collagen reorganization.[13] MFR stimulates the afferent A delta fibers which causes segmental pain modulation, supporting the analgesic effect of MFR.[3]

A study suggested that SFMR using a foam roller can be used as an alternative to reduce pressure pain of latent muscle trigger points on gastrocnemius muscle.[14]It has been proved by Le GAL J et al, SMFR using tennis ball on infraspinatus and pectoralis muscle of tennis players reduced pain and improved ROM (Range of Motion) of glenohumeral joint. The findings of the current study favored the above studies.[15]

Branca Romero et al conducted a study to compare the effects of vibration and non-vibration foam roller and proved that both protocols were effective in improving pain and joint ROM, but VFR (Vibrating Foam Roller) achieved greater short-term effects on pain perception and ROM.[16] so, further studies are required to evaluate the effectiveness of foam roller to reduce pain.

A systematic review in 2015 showed that ROM of joints; muscle performance and pain can be effectively improved by foam rolling or roller massage. But as the method used in the studies were highly heterogeneous, no appropriate consensus has been developed on an optimal SMR program.[17]

However, a narrative review of 2016 by Kalichman L et al concluded that joint ROM increased significantly after using SMFR. The muscle force and performance didn't change. But there is scarcity of studies investigating the role of SMFR in lowering the myofascial pain.[18]

Conclusion

The present study shows that SMFR given with both tennis ball and foam roller reduced pain and improved function in patients with plantar fasciitis. However, on comparing the mean difference of both the groups foam roller SMFR was superior to tennis ball SMFR, although this difference was not statistically significant. Hence it can be inferred that foam roller SMFR and tennis ball SMFR both were equally effective in improving pain and function in patients with plantar fasciitis. The limitations of the study are the small sample size, short-duration of intervention, no control group and no long term follow up was taken.

A Study on the Impact of Demonetization on Utilisation of Private Health Care Services in a South Indian City

Vijay K. Yalamanchili[1], N. Partha Sarathy[2], U. Vijaya Kumar[3], M. Ravi Kiran[4], Kalapala Abhilash[1]

[1]Postgraduate Student in Community Medicine, [2]Professor & Head, [3]Professor, [4]Assistant Professor, Department of Community Medicine, Alluri Sitarama Raju Academy of Medical Sciences, Eluru, Andhra Pradesh

Abstract

Background: Private sector plays a key role in India's healthcare system. The demonetization of Rs.500 and Rs.2000 currency notes on 8th November 2016 had a great effect on the Indian economy as well as day-to day lives. Hence this study was aimed at assessing the impact of demonetization on utilization of private healthcare services in Eluru, Andhra Pradesh.

Material and Method: This was a health-facility based cross-sectional study. Ten health facilities were involved and 200 study subjects from these facilities were interviewed using a pre-designed and validated questionnaire. The respondents' characteristics, their utilization of health services and overall experience with regard to healthcare was included in the questionnaire.

Results: When asked about the overall experience, 27pc of respondents said they were not affected, 49.5pc said they were affected but felt it tolerable, and 23pc said they were severely affected and suffered. 33.5pc of the respondents have postponed their visits to the health facility due to cash shortage. This was mostly seen in low income groups. Only 35pc of the respondents were willing to use credit/debit cards for cashless transactions.

Conclusion: Majority of respondents felt their healthcare was affected by demonetization but it was tolerable. The low income groups had highest impact. The penetration of cashless payments in private healthcare was very poor.

Keywords: *Andhra Pradesh, Demonetization, Healthcare, Private, Utilization.*

Introduction

Healthcare is one of the most vulnerable sectors which is adversely affected by economic policies and crisis[1]. In India private sector plays a key role in healthcare. Today it accounts for 82% of outpatient visits, 58% of inpatient expenditure, and 40% of births in institutions. India ranks among the top 20 of the world's countries in its private spending, at 4.2% of GDP[2]. At least 7% of the population in India fall below poverty line each year due to Out of Pocket Health Expenditure[3].

The Government of India has enacted demonetization of Rs.500 and Rs.1000 currency on 08-11-2016. The total value of these notes in the economy at that time was Rs.15.41 lakh crores. New notes of Rs.2000 first and Rs.500 later were introduced in their place[4].

There has been a widely varied response to demonetization. The academicians were skeptical about the role of this exercise in achieving its intended purpose[5]. It was reported that there was a decline in the outpatients of around one-third in peripheral hospitals. The media cited that persons on daily wages had difficulty in obtaining money for their treatment. Apparently

Professor & HOD, Department of Community Medicine, ASRAMS, Eluru-534005, Andhra Pradesh
e-mail: sarathynp1@gmail.com

several hospitals refused treatment in exchange for the demonetized INR 500 and INR 1000 currencies. Reports of people suffering due to cash shortage and long queues in banks and ATMs[6, 7].

However public welcomed this move and were patient enough to endure the hardships for the sake of perceived overall benefit. There were no reports of widespread unrest[8, 9]. In wake of this, the present study was undertaken to study the impact of demonetization on utilization of private healthcare services in Eluru city, the district headquarters of West Godavari, Andhra Pradesh.

Objectives:

1. To understand the overall experience of the patients regarding health care, in wake of demonetisation.
2. To see the effect on different socio-economic groups and their utilization of health services.
3. To study the implementation of cashless economy in private health care in wake of demonetisation.

Method

Study Setting: The study was done among patients attending various private health facilities in Eluru city, West Godavari.

Study Period: The study was done for a period of two weeks, beginning one month after demonetization (10^{th} to 25^{th} December 2016).

Study Sample: All the private health facilities in Eluru town were approached for permission to do the study. Among them the facilities who have given consent were included. One medical college hospital, four clinics, two nursing homes, and one each of dental, physiotherapy and RMP (registered medical practitioner) clinics have consented to be involved in this study.

Sample Size: At the time of study, to the best of our knowledge, there was no quantitative evidence on the effect of demonetization on utilization of healthcare services in private sector. Hence it was assumed that the proportion affected is 50. Taking p=50 and an absolute precision (d) of 7, the sample size was calculated using the formula, $n= (Z_{\alpha/2})^2 \times p \times (1-p) / d^2$. Since the confidence level of this two-tailed study was set at 95pc, the $Z_{\alpha/2}$ was taken as 1.96. Thus a sample size of 196 was obtained, which was rounded to 200. Since a total of ten health facilities were involved in the study, the total sample was divided by ten, and from each health facility twenty patients were involved.

Interview of study subjects: Each of the health facility was visited either during 10 AM-1PM slot or from 6 PM-9PM slot. The doctor running the facility was met the previous day and briefed about the study. The study subjects were selected from all the people present in the health facility during that particular slot. Patients in out-patient division, wards and casualty were uniformly included. In case the patients were financially dependent, i.e., children, students, elderly or housewives, their attendants who take care of their expenses were interviewed.

Study Tools: A semi-structured questionnaire was designed to interview the patients. It was tested and validated before the actual study. The patients were interviewed in Telugu as per the questionnaire.

Components of the Questionnaire: The general data comprised of the patient's income, occupation, nature of visit to hospital and their health insurance status.

Next set of questions were about the patient's healthcare related experience. They included the number of visits made to health facility in last one month, and whether they have postponed any visits to health facility due to shortage of cash. They were asked whether they had postponed getting routine laboratory investigations done or procuring routine medications due to shortage of cash. Impact on health due to waiting in queues in banks and ATMs was also assessed.

To understand the spending priorities of the respondents, they were asked how much of the newly withdrawn money was spent on health-related expenses, and if they had any other priorities in spending over health-related expenses. To understand the penetration of banking system and cashless payments, the subjects were asked if they were ready to make health-care related payments through digital transactions.

The last component of the study was about the direct effect of cash shortage on their healthcare utilization. The subjects were asked which part of healthcare did they have the biggest difficulty with, namely, billing, consultation, pharmacy, laboratory, transportation. To assess the adverse impact, the subjects were asked if there was any death or aggravation of illness among their family or friends due to shortage of cash and waiting

in queues. Finally the subjects were asked to grade their overall experience in healthcare utilization after demonetization as "no effect" or "effected but tolerable" or "severely affected".

Data Entry & Analysis: The data from the questionnaires was compiled in Microsoft Excel 13 and analyzed in SPSS Version 20.

The frequencies of various input characteristics were tabulated and expressed as percentages. The patients' income and amount of money spent were expressed as medians, to avoid getting affected by extreme values. Since the study was limited to private health facilities, all the sections of population were not likely to be covered. So to avoid bias, instead of taking standard classifications for socio-economic status, the patients were divided into four income-groups based on the inter-quartile ranges. The lowest income group was Category 1 and highest was Category 4.

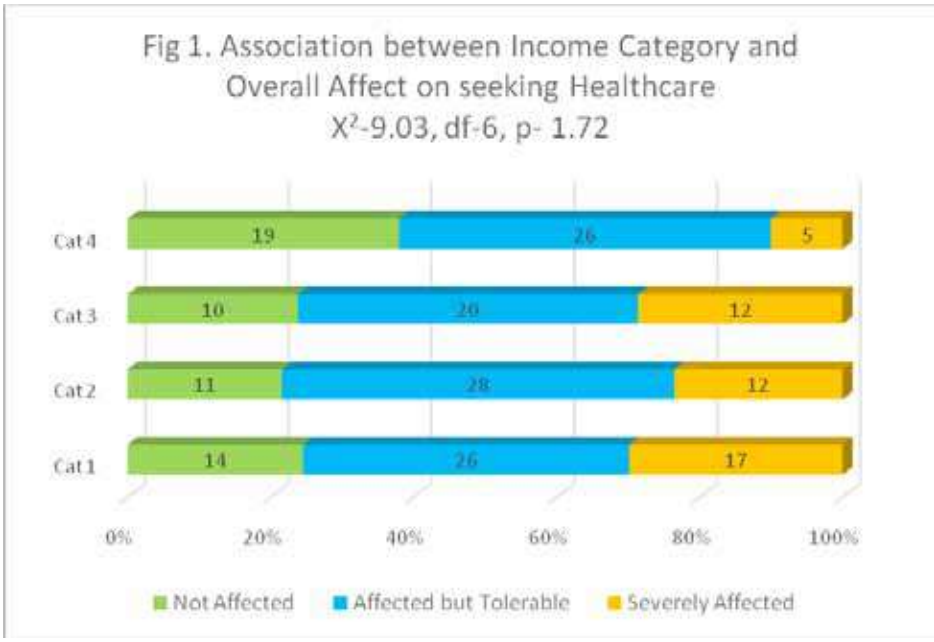
The internal consistency of the questionnaire was checked using Cronbach's alpha. The output variables were the subjects' overall experience, the healthcare component where they had the biggest difficulty, and postponement of visit due to cash shortage. The study subjects' characteristics and experiences were seen for any significant association with the outcome variables using chi-square test. If there was any significant association, the influence of that factor would be measured by logistic regression.

Results

Data of the Respondents: Out of a total of 200 respondents, 88 (44pc) were patients and 112 (56pc) were attendants. Among the respondents, 79(38.5pc) were daily wagers, 72(36pc) were salaried, 38(19pc) were businessmen and land-owners and 11(5.5pc) were pensioners. Regarding the nature of visit, 117 (58.5pc) were out-patients, 29(14.5pc) were admitted on advice, 23(11.5pc) were admitted for elective surgery and 31(15.5pc) presented as an emergency. Regarding the number of visits, 71(35.5pc) respondents are on their first visit to a health facility, whereas 79(39.5pc) have visited more than 3 times in the last one month. Only 52(26pc) of the patients had their visits covered under insurance. The median monthly income was Rs 12000 (95pc CI 10000-15000).

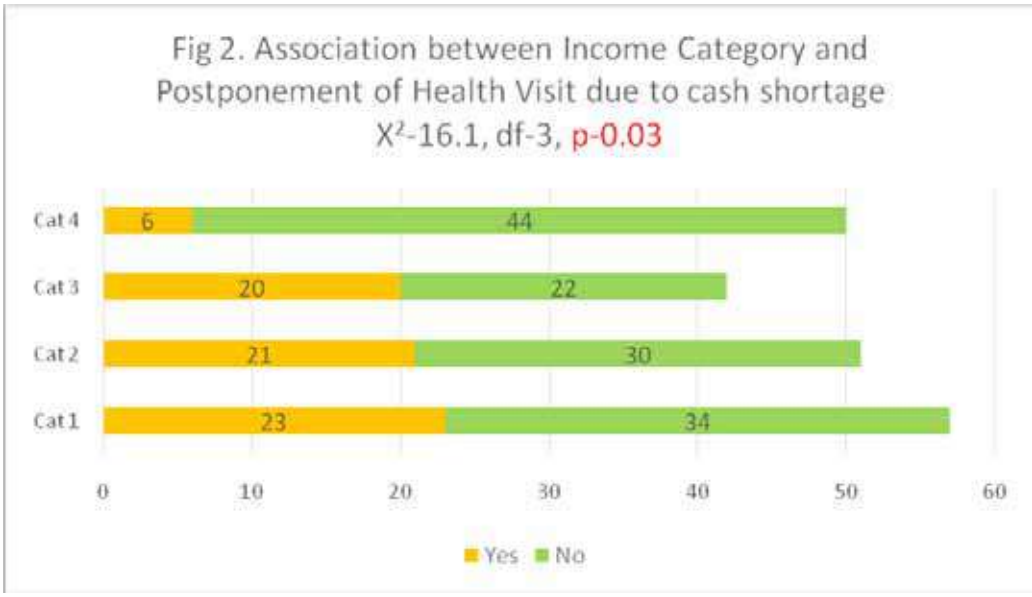
Findings of the Study: When asked about overall experience regarding health care due to demonetization, 27pc of respondents said they were not affected, 49.5pc said they were affected but felt this tolerable, and 23pc said they were severely affected and suffered. There was no statistically significant difference among various income groups, type of visit or insurance status.

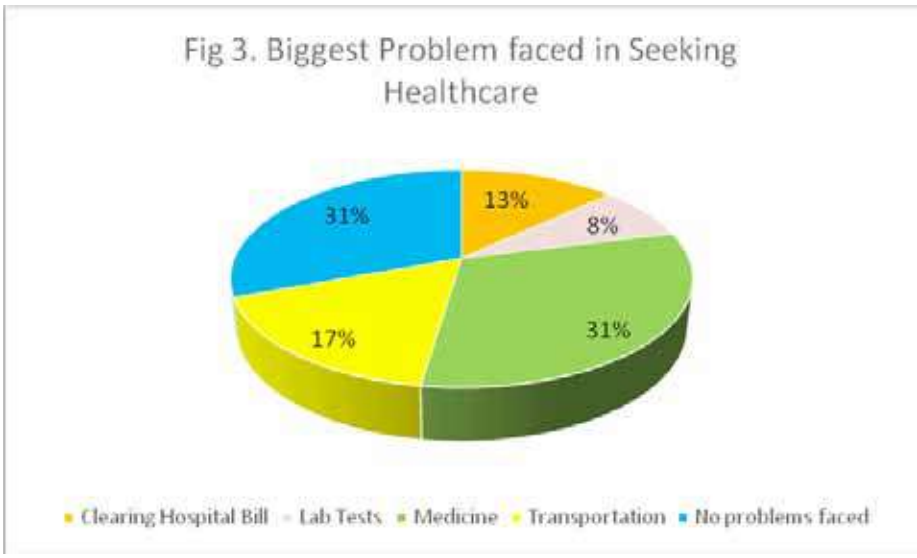
There was reluctance to use cards for payment in 64pc of the respondents. This is significantly higher in low income groups. The reasons for this reluctance ranged from ignorance to mistrust. Out of the 36pc ready to use cards, only 2pc could use them for payment as many health facilities were not accepting payments through cards.



Regarding the visits to healthcare facility, 33.5pc had postponed their visit if it was not urgent, particularly due to cash shortage. This was significantly lower in high income groups. This is the only significant statistical association found in the study. 15pc reported their relatives or neighbors had to postpone visits. About 4.5pc reported aggravation in health issues due to postponement. This did not have any significant association with the income category or nature of visit.

The median amount of money spent on healthcare post-demonetization was Rs 4000 (95pc CI 3000-5000). Majority of the people had problem with buying medicines (33.5pc), followed by transportation (15.5pc) and billing (14.5pc).55pc had difficulty in changing old notes and 46pc with new notes. 15pc postponed buying medicines or getting routine investigations done, due to lack of change. One third (33.5pc) of the respondents felt their plans to visit health-care facilities were affected by waiting for cash in banks and ATMs.





Discussion

Almost half (49.5pc) of the respondents felt their healthcare utilization was impacted by demonetization, but it was tolerable. This was in tune with the findings of the PHD Bureau, which found that 58% of the population were stressed due to demonetization[10].

In the present study, 33.5pc of the respondents stated that they have postponed their visits to health facilities

if it was not urgent. This is consistent with the findings of Kumar et al that there was one-third reduction in out-patients across the country[6]. However the doctors running the health facilities stated that it was because the period from late November, leading up to Christmas and Sankranthi was "off-season".

Over half of the respondents had difficulty in changing demonetized notes at healthcare facilities. This was in spite of the government allowing essential services to accept demonetized notes for a certain period. Similarly using the newly issues Rs 2000 notes proved difficult as it was difficult to obtain change. It was during the time of study that new Rs 500 notes were announced to tide over this problem. This was in contrast with the findings of Hariharan et al where over 64pc of respondents were satisfied with the flow of new currency after demonetisation[9]. In the present study, 4.5pc of respondents have mentioned aggravation of health issues due to waiting in queues for cash in banks and ATMs.

The government's intention to boost cashless transactions did not find much takers in the present study. Only 36pc of the respondents were ready to use cards for swiping. This was similar to the findings of Hariharan et al, where 30pc of the respondents were using debit cards and online transactions. Unfortunately, at the time of the study, none of the health facilities were accepting cashless payments. The lone medical college hospital in the city started card swiping six weeks after demonetization. This was in contrast to the study by Rao et al in Lucknow where there was significant use of cashless payments at hospitals[11]. This calls for a serious re-look on peoples' attitude about using banking sector and cashless economy in smaller towns and cities.

Conclusion

Most of the people felt their health care was affected due to demonetisation, but it was tolerable. Nearly a third of the respondents have postponed seeking health care if it was not urgent.

Though the health care facilities were asked to accept old notes for an extended period, it could not be done. This was due to the overall difficulty in providing change to the higher notes.

Another crucial finding is the near-total absence of cashless payments in private health care in the study field. This is lacking on both sides. Majority of the patients are not willing to use cards or operate bank accounts on a regular basis, in spite of having Jan Dhan accounts. Similarly, many health care facilities are not encouraging cashless payments. Since the government is pushing for digital economy, private health care is one crucial area it should focus on, in this endeavor.

It is hoped that the cash crunch subsides soon enough to restore the normality in utilization of private health care facilities.

Conflict of Interest: The authors belong to the medical college, which was one of the ten health facilities included in this study.

Source of Funding: Self

Ethical Issues: The respondents and health facilities were assured of complete confidentiality. Informed consent was taken from all the respondents. This study was approved by Institutional Ethical Committee.

Impact of Learning Opportunities in Preparing Dental Students for Their Profession

Asha Vashe[1], Vasudha Devi[2], Raghavendra Rao[3], Reem Rachel Abraham[4]

[1]Assistant Professor, Department of Physiology, Melaka Manipal Medical College, Manipal Campus, [2]Professor, Department of Pharmacology, Melaka Manipal Medical College, Manipal Campus, [3]Professor, Department of Physiology, Kasturba Medical College, Manipal, Manipal Academy of Higher Education, Manipal, Karnataka, India, [4]Professor, Department of Physiology, College of Applied Medical Sciences, Jubail, Imam Abdulrahman Bin Faisal University, (formerly University of Dammam), Kingdom of Saudi Arabia

Abstract

Introduction: The emphasis in outcome-based education is on the outcomes or the products, and in the context of a medical or dental school, the kind of doctors and dentists it produces becomes the outcome. The young doctors and dentists coming out of these schools need to possess the competencies to practice in an increasingly complex healthcare scenario with changing patient and public expectations. The choice of learning opportunities (teaching-learning method) should be aligned and oriented towards achieving the expected learning outcomes. The current study established the links between learning opportunities and the expected learning outcomes in dental physiology curriculum through curriculum mapping.

Method: Learning opportunities were linked to expected learning outcomes by examining the conduct of each of them. Moreover, students' and teachers' views were obtained through focus group discussions and interviews.

Results: It was found that learning opportunities provided to students in the form of lectures, problem-based learning and practical sessions served its purpose of achievement of expected learning outcomes. Furthermore, valuable suggestions on the improvement of the existing learning opportunities were obtained.

Conclusions: The study, therefore, confirmed the link between the learning opportunities and expected learning outcomes.

Keywords: *Learning opportunity; dental physiology curriculum; expected learning outcomes; curriculum mapping.*

Introduction

Reforms in education have led to the advent of outcome-based education (OBE), with the focus shifting from inputs and processes to outcomes. The emphasis in OBE is on the outcomes or the products, and in the context of a medical or dental school, the kind of doctors and dentists it produces becomes the outcome[1-3]. The young doctors and dentists coming out of these schools need to possess the competencies to practice in an increasingly complex healthcare scenario with changing patient and public expectations[2,3]. This being the primary objective, the expected learning outcomes (ELOs) will have to be defined accordingly. ELOs are the culminating demonstration of abilities the learner will be able to do at the end of the learning period[3,4]. OBE in its structure and composition, has to facilitate achievement of these outcomes by students

and hence need to be equipped with appropriate content, learning opportunities (teaching-learning method), and assessments, which are selected based on the outcomes chosen[3-5]. The choice of teaching method, including lectures, small group work, and independent study, should be aligned and oriented towards achieving the learning outcomes[5]. This requires use of suitable tools to find out the links between learning opportunities and ELOs.

Curriculum mapping is a method employed to know the links between the curricular components, such as learning opportunities, assessments, content, ELOs, etc., and thereby making the curriculum transparent. Or in other words, curriculum map displays the components of the curriculum and relations between them. Curriculum mapping enables the researchers to find out the gaps in the curriculum by assessing the extent to which the curricular components are linked among themselves[6].

Researchers have used curriculum map to determine contribution of learning events to the medical school's core competencies[7], coverage of competencies in a dental curriculum[8], and to explore alignment between the components of the curriculum[9]. Links or relations between the components are the very essence of a curriculum map, as reported by Harden[6]. However, there is a lack of literature from India on curriculum mapping. Moreover, studies from India seldom attempted to find any influence of curricular components on attainment of the ELOs in students. Hence, the current study was conducted to establish links between learning opportunities and ELOs in physiology through curriculum mapping.

The research question formulated was

- Are the various learning opportunities facilitating students to achieve the ELOs?

Method

The undergraduate Bachelor of Dental Surgery (BDS) program at Melaka Manipal Medical College (MMMC), Manipal Campus, Manipal Academy of Higher Education, Manipal, India, is a five year academic program in twin campuses. The first two years of study are done at Manipal, India, and the latter three years at Melaka, Malaysia. During the first year, students learn anatomy, physiology, biochemistry and oral biology. The current study was conducted in the department of physiology, MMMC, Manipal Campus. The study subjects were students of BDS batches 4, 5, and 6 (September 2012, September 2013, October 2014 admissions) of MMMC and physiology teachers of MMMC.

The ELOs of the physiology curriculum which students must attain at the end of the year are knowledge of basic physiological principles and mechanisms, critical thinking skills, self-directed learning (SDL) skills, collaborative learning skills, communication skills, and practical skills. These ELOs were derived from the BDS program outcomes.

MMMC follows a hybrid curriculum where the learning opportunities available for students are didactic lectures, problem-based learning (PBL) sessions, and practical sessions. Every week, two didactic lectures are conducted. Practical sessions are scheduled for three weeks per block (one slot of two hours duration), which includes both demonstration and hands-on experiments. One PBL session is conducted in each block in the traditional way, consisting of brainstorming and presentation sessions. During the study period in between brainstorming and presentation sessions, students are encouraged to involve in collaborative learning.

Lectures, PBL, and practical sessions were linked to ELOs by examining the conduct of each of them. In addition, students' and teachers' views were obtained through focus group discussions (FGD), and interviews to establish the link between learning opportunities and ELOs.

Two FGDs were conducted with every batch of students at the end of first year to explore the effectiveness of learning opportunities in attaining ELOs. The teachers of the physiology department at MMMC were interviewed individually at the end of the year to explore how useful the learning opportunities were in achieving ELOs. Qualitative data analysis was done using constant comparative analysis[10].

Results

It was found that appropriate learning opportunities were provided in the curriculum for the attainment of ELOs by the students (Table 1). Analysis of qualitative data revealed that lectures helped in acquiring knowledge, critical thinking, and SDL skills; PBL helped to achieve knowledge, critical thinking, SDL, collaborative learning, and communication skills; practical session helped in attaining knowledge, critical

thinking, collaborative learning, communication, and practical skills. The themes that emerged from the qualitative data analysis were a) reasons for achieving ELOs through learning opportunities and b) reasons for not achieving the ELOs through learning opportunities c) suggestions to improve the learning opportunities.

Lectures:

Reasons for achieving ELOs: Students and teachers opined that the scope for increased student-teacher interaction in class, explaining concepts effectively, and teaching using relevant multimedia helped in achieving the required knowledge.

Please change the following sentence 'We guide students in learning by explaining the concepts in an easy way' (Teacher)

Students mentioned that discussion of sample questions also benefited them to develop knowledge. The participants expressed that teaching with case scenarios and teachers asking thought provoking questions made students think critically. Also, students opined that lectures incorporated discussion of content by students and teachers, which made lectures interesting and encouraged students to search for additional information. This, in turn, helped them to attain SDL skills.

Reasons for not achieving the ELOs/suggestions for improvement: Students felt that lectures of some teachers could be improved by providing scope for more interaction with students, improving teachers' communication skills, and in some cases, presentation slides. Students mentioned that lecture handouts could be provided to them so that during the class, they need not have to spend time in noting down the content; instead they could focus more on listening in the class. Students opined that they require more time to take down the notes if handouts are not provided to them. Teachers suggested that to facilitate achievement of learning outcomes through lectures; active learning strategies could be used; students could ask more questions and interact with the teacher during class.

PBL sessions:

Reasons for achieving ELOs: The study participants felt that the thought provoking and interesting PBL cases, assessment during the PBL, and peer interaction during the sessions helped them to attain the knowledge and skills.

'Because we have to present and it is assessed, we search for information, and we understand the topic' (Student)

Also, the mandatory presentation included in PBL, helped them to hone their communication skills besides acquiring additional knowledge in the topic as they had to prepare for their presentation. The challenge involved in arriving at the relevant learning objectives helped them to improve their critical thinking skills. Moreover, students also felt that they could integrate the topics in a better way through PBL.

Reasons for not achieving the ELOs/suggestions for improvement: The respondents commented that in some groups, collaborative learning was less, which was a hindering factor in acquiring knowledge and skills.

'Less group interaction was observed in some groups' (Teacher)

Time constraints, students' preference for studying individually instead of collaboratively, were the reasons given by the participants.

Practical sessions:

Reasons for achieving ELOs: Students and teachers opined that practical sessions were interesting and relevant to the students, which made them acquire knowledge, critical thinking, collaborative learning, communication, and practical skills. They felt that as the practicals were related to theory, it improved their understanding of the theory topics as well.

'Understood some of the theory through practicals' (Student)

The respondents opined that teachers facilitated students in developing practical skills through demonstrations as well as encouraging them to practice. Furthermore, students were made to collaborate with their friends and learn practical skills, as expressed by the participants. Moreover, during clinical examinations, students were taught how to take informed consent from the subjects, which helped them to improve their communication skills. The participants revealed that during practical sessions discussion of renal problems, cases about endocrine disorders helped them to promote their critical thinking skills.

Reasons for not achieving the ELOs/suggestions for improvement: Some students expressed their desire

to learn more about clinical examination practical topics like detailed examination of the cardiovascular system instead of limiting it to auscultation of heart sounds, as per the existing learning objective.

'I feel we need more practicals like palpation of cardiovascular system like MBBS. In future if patient comes to my clinic, I should know' (Student)

Table 1: Links between learning opportunities and expected learning outcomes

Learning opportunities	Expected learning outcomes
Lectures	Knowledge
PBL sessions	Knowledge, critical thinking skills, self-directed learning skills, collaborative learning skills, communication skills
Practical sessions	Knowledge, critical thinking skills, collaborative learning skills, communication skills, practical skills

Discussion

In OBE, the given learning opportunities should facilitate the attainment of the outcomes, and hence selection of proper learning opportunities is crucial[5]. The current study aimed at finding out whether the learning opportunities facilitated achievement of learning outcomes or not, culminated in affirmative results. It is evident from the opinions of majority of the respondents that the learning opportunities helped students to achieve the outcomes.

Lecture is a widely used instructional method in higher education and is one of the key learning opportunities. Lectures continue to play an important role in student learning[11] and will be effective, provided, the lecture is planned as per suitable pedagogy,and delivered appropriately[12]. It is also necessary that lecture-based teaching employs effective method, such as the active engagement of participants[13]. At MMMC, lectures are used as the main mode of learning opportunity, and it was found that lectures helped in attaining knowledge, critical thinking, and SDL skills. Students mentioned that the use of videos and the interactive mode of teaching helped them to acquire the outcomes and teachers endorsed this opinion. Explaining and questioning are the two important skills in lecturing[14]. At MMMC, these techniques were effectively used by teachers to facilitate student learning, as expressed by both teachers and students. Brown[14] pointed out that students value the lectures more if it is well structured, interesting and has clarity of presentation. Students' opinions obtained in the present study endorses the above fact. Students felt that the interactive sessions, non-monotonous and interesting lectures with appropriate explanations of the topics greatly helped in learning. A lecture could be used to provoke thought, to deepen understanding and to enhance scientific and clinical thinking[14]. Students mentioned that thought provoking questions during lecture classes made them think critically. The most important aspect of lecturing appears to be the stimulation of students to become active learners[15]. At MMMC, through active learning strategies like conducting quizzes, role-plays, etc., teachers facilitated student learning during the lectures. Students and teachers mentioned that lectures helped to improve SDL skills also. It was reported that students' views about poor lecturing include poor use of audio-visual aids, inaudibility, incoherence, talking too fast, and too much information[14]. In the present study also, students mentioned poor use of audio-visual aids, in some cases as one of the reasons for ineffective lecturing.

One must know lectures alone will not be able to nurture the relevant skills needed for dental practitioners. PBL helps facilitate higher order thinking as it is a student-driven process. Moreover, PBL helps arousing curiosity of students, which in turn motivates them to learn even the basics during the process of analyzing cases[16]. The success of the PBL depends on the case or problem given to the students, and hence development of an effective case is very important. At MMMC, the case designed is validated at multiple levels. The faculty member in charge of developing the case will design the case, which will be discussed among the members involved in the block for the accuracy and relevance of content. Later it will be scrutinized by heads of departments of first year. The present study revealed that PBL helped students in attaining critical thinking, SDL, collaboration, and communication skills.

Earlier studies reported that medical and biology students found practical sessions in physiology were interesting and also helpful in understanding the theory concepts[17,18]. The outcome of the current study was also in line with the above observation. Teaching theoretical concepts before practical sessions, practice sessions facilitated by the teacher, and provision of enough time for practicing the skills during routine practical sessions as well as provision of revision classes could have evoked the positive response from students.

Conclusions

Professional education, such as dental education, requires a specific set of competencies to be acquired by the students by the end of their study period. Learning opportunities provided to students in the form of lectures, PBL, and practical sessions served its purpose of acquirement of knowledge as well as practical skills in physiology, facilitation of SDL, critical thinking, and other generic skills in students, as evident from the qualitative data. Some perceptions were found to be similar among students and teachers, which substantiates and reaffirms the authenticity of the responses. The study, therefore, confirmed the links between learning opportunities and ELOs in the dental physiology curriculum at our institution and thereby helping the students to be prepared for their profession. Furthermore, through the study, we obtained valuable suggestions pertaining to the existing learning opportunities from the stakeholders, which helps for continuous quality improvement.

Home Remedies and Health Care Seeking Behavior among Care Takers of Under-5 Children in Rural Field Practice area of a Medical College: Focus Group Discussion

Cheluve Gowda G.K.[1], Savitha Rani B.B.[1], Krishna Iyengar[2], Venkatesh P.[3]

[1]Assistant Professor, [2]Professor & Head, [3]Associate Professor, Department of Community Medicine, Sri Siddhartha Medical College, Tumkur, Karnataka

Abstract

Background: The health of children has historically been of vital importance to all societies because children are the future of mankind. In developing countries, home remedies are often the only accessible and affordable treatment available.

Materials and Method: The study was conducted in Nagavalli, the rural field practice area of Sri Siddhartha Medical College Tumkur, during January 2019 - March 2019. After getting the clearance from Ethics Committee the data was collected using focus group discussions (FGDs) with purposively selected care takers who were willing to participate and talk freely.

Results: The common home-remedies used for these ailments by majority of the care takers wereTulasi for fever, cough and cold, Garlic forcough and cold, Ginger forcough and cold, Black pepper for cough and cold, Honey for cough, Amulet for bala graha, falls, evil's eye, Crushed pomegranate for diarrhea, Tea decoction for diarrhea, Turmeric for cough and cold, Coffee powder for cuts and injuries, Branding with hot iron rodfor pain abdomen and inability to pass stools(Constipation), Hot broken bangle piece: head ache and fever, Hot Castor oil: For earache and for constipation.

Conclusion: Rural population preferred home-remedies for treatment of common ailments in under-5 sick children in the initial phase of the illness. Some of the practices followed by care takers were harmful.

Keywords: *Home remedies, Under-five children, Honey, Turmeric, Focal group discussion.*

Introduction

The health of children has historically been of vital importance to all societies because children are the future of mankind. Therefore, at each stage of child's growth and development appropriate care is very essential.[1] Minor ailments present in the under-five children such as fever, diarrhoea and vomiting, ear ache, head ache, nose bleed, sore throat, and common cold etc. can be treated at home with home remedies.

In developing countries, home remedies are often the only accessible and affordable treatment available. Non-availability of doctors and high medicine cost make health care inaccessible to the rural population and consequently home remedies serve as one of the options for immediate care.

Indian Council for Medical Research task force has reported that still in rural parts of India, people follow some home remedies or seek traditional medicine practitioners to get rid of various ailments because they feel that these therapies are time tested and mainly they have no side effects like modern medicine.[2]

In focus group discussions there is a tendency that the attitudes and perceptions are developed through interaction withothers in the groups.[3] Instead of the moderator asking questions, the group members are encouraged to communicate with one another, exchanging ideas and comments on each other's experiences or points of view.[4]In this sense, focus groups showeddimensions of understanding that often remain untappedor inaccessible by other forms of data collection.[5]In the context of healthcare and medical research, focusgroups are particularly apt due to the fact that most healthrelatedconditions are created by social environments andmade within the social context.[6] Thus, focus groups area popular method for assessing public experience andunderstanding of illness,[7,8] identifying ideas concerninghealth-risk behaviours and danger,[8,9] and discovering thepublic's perception of causes of diseases.[10]Theycan also be used to gain insights into people's experiencesof ill health and health services,[11,12] and explore theattitudes and needs of healthcare providers.[13]

Objectives:

- To study the use of homeremedies during episodes of illnesses among under-5 children.
- To assess health care seeking behaviour among caretakers of under- 5 children.

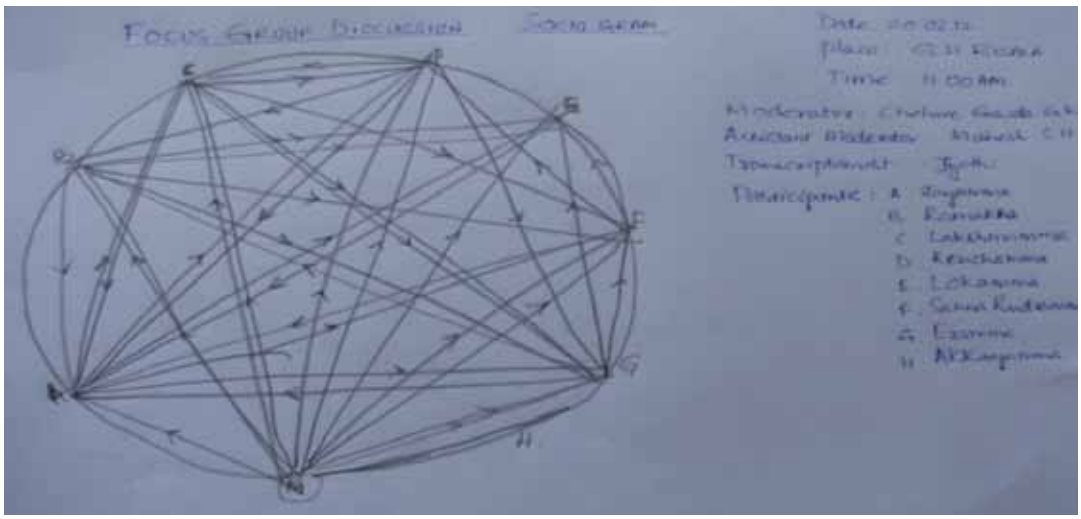
Materials and Method

The study was conducted in Nagavalli, the rural field practice area of Sri Siddhartha Medical College Tumkur, during January 2019 - March 2019. After getting the clearance from Ethics Committee, the data was collected using focus group discussions (FGDs) with purposively selected care takers, who were willing to participate and talk freely.

Focus Group Discussions: Focus Group Discussions (FGDs) were conducted in 19different villages of field practice area of Sri Siddhartha Medical College. A total of 19 FGDs, each with 8-12 participants, were conducted in the local language Kannada and were recorded on audio. A trained facilitator ledeach discussion while another person took notes, which werelater were translated into English. The care takers included mothers and grandparents who were purposively selected from rural field practice area covering different socio-economic strata. The FGDs addressed thevarious illnesses among under-five children, home remedies for those illnesses and health care seeking behaviour.

The number of FGDs was decided by a saturation point where it stopped yielding new information and after 19 FGDs, saturation point was reached. Statistical analysis was done by Coded key word approach.[14] Coded key word technique allows more precision in identifying comments and does not risk 'losing' a comment merely. The coded key word approach involves reading the focus group notes thoroughly and assigning a code/key word to each comment in order to identify themes or categories within the text. The group (rather than the individual) is the unit of analysis. When constructing tables to classify data or identify themes, a disease is listed in the table, if it is mentioned by a group; however, it is listed only once, no matter how many times respondents in a particular group mention it. The number of groups, not the number of individuals, is used as the denominator.

Sociogram:



The participants were made to sit in a circle, so that each participant is fully visible to all others. The moderator initiated the conversations on the subject and encouraged everyone participate in the discussion and one investigator made notes while the other recorded the conversations. The discussions were continued till all the participants agreed to the relevant and specific home remedy for that particular ailment.

Results

Table 1: Distribution of participants according to religion

Religion	Frequency	Percent
Hindu	186	93.00%
Muslim	14	7.00%
Total	200	100.00%

In the study there were 200 participants of whom 186 were Hindus and 14 were Muslims.

Table 2: Distribution of participants according to Education status

Education	Frequency	Percent
7th standard	36	18.00%
SSLC	113	56.50%
2nd PUC	46	23.00%
BA	5	2.50%
Total	**200**	**100.00%**

Majority of the participants (113) had studied till SSLC and some of the participants till 2nd PUC (46). Very few (5) had degree qualification.

Table 3: Distribution of participants according to Socio-Economic status

Socio-Economic Status	Frequency	Percent
Lower class	89	44.50%
Lower middle class	98	49.00%
Middle class	8	4.00%
Upper middle class	5	2.50%
Total	**200**	**100.00%**

Majority of the participants belonged to lower middle class and lower class according to modified B.G.Prasad's socio-economic status.

Majority of the participants agreed that the most common symptoms among under-5 children were cough, cold, fever, loose stools, pain abdomen, constipation, cuts and "balagraha" (excessive crying and irritability).A few also mentioned other symptoms like headache, problems of feeding, falls and injuries, difficulty in breathing, ear pain and discharge from ear. The common homeremedies used for these ailments by majority of the care takers were

Tulasi, Garlic,Ginger, Black pepper,Honey, Amulet, Crushed pomegranate, Tea decoction, Turmeric, Coffee powder, Branding with hot iron rod, Hot broken bangle piece, Hot Castor oil.

Discussion

The common home-remedies used for these ailments by majority of the care takers were

Tulasi : Fever, cough and cold, Garlic : Cough and cold, Ginger : Cough and cold, Black pepper : Cough and cold, Honey : Cough, Amulet : Bala graha, fall, evil's eye, Crushed pomegranate: diarrhea, Tea decoction: diarrhea, Turmeric; cough and cold, Coffee powder: Injuries, Branding with hot iron rod: for pain abdomen and inability to pass stools(Constipation), Hot broken bangle piece: head ache and fever, Hot Castor oil: For earache and for constipation.

A study conducted by sandy cove et.al showed Comparison of honey with Dexamethasone revealed no significant differences. Honey may be preferable for the treatment for cough and sleep difficulty associated with childhood respiratory tract infection.[15]

A quasi experimental study was conducted with 100 parents (27 men, 73 women) enrolled in a prepaid medical health plan to investigate their use of home remedies. A remedy was reported for almost every health problem listed. Substances most frequently used were aloe vera, honey, peppermint, garlic, eucalyptus, and rose hips; health problems most frequently treated were burns, colds, fever,diarrhoea, vomiting, indigestion, insect bites, insomnia and rashes.[16]

A study conducted by Cevit Karkaset.al showed honey (25%) and ginger (27%) were the most common home remedies used for the relief of cough. Self-advised medications were used by 24% mothers and majority 58.4% gained knowledge from mass media.[17]

It was noticed that majority of the participants preferred home-remedies due to low cost, easy availability and in emergency situations. Few also mentioned that it was recommended by the grand

parents and their neighbors. Majority of them preferred home remedies in the initial phase (i.e. on day 1 and day 2) of the illness irrespective of the availability of health care facilities. Some of the female respondents said they do not use allopathic medicines because of fear of side effects. There was no sex discrimination regarding the use of home-remedies.

When there was no improvement or if the problem aggravated, then majority of the care takers approached clinics or private practitioners in the village or nearby health facility in that area, irrespective of provider's qualification. The reasons for delay in seeking health care by majority of participants were lack of money, faith in home remedies, non-availability of transport, non-availability of doctor and absence of responsible person at home. The socio-economic status of the family played major role in deciding the type of provider to be approached for seeking treatment. Poor families generally approached local practitioners or registered medical practitioners of the area, who provide treatment at low cost. A few care takers approached government health facilities, where treatment is provided at relatively lesser cost.

Bhandari *et al* also reported that 40% of sick neonates did not get medical care in periurban area of Delhi. Various barriers which interfered with the translation of knowledge into action in our respondents in terms of access to medical care were ignorance of parents, lack of money, faith in supernatural causes, non-availability of transport, home remedy, non-availability of doctor and responsible person not at home in descending order.[18]

As revealed from many quantitative and qualitative data, there was relatively more preference for government health care services. Hence, improvement in capacity, quality and reach of government health care services and national health programs is crucial for ensuring optimal newborn care in rural area. Kaushal *et al* and Awasthi *et al* also reported similar health seeking behavior for sick children in North India.[19]

Health seeking behavior among different populations, particularly in the rural communities, is a complex outcome of many factors operating at individual, family and community level including their bio-social profile, their past experiences with the health services, availability of alternative health care providers including indigenous practitioners and last but not the least their perceptions regarding efficiency and quality of the services.

Conclusion

Rural population preferred home remedies for treatment of common ailments in under-5 sick children in the initial phase of the illness. Some of the practices followed by care takers were harmful. Traditional medicine can contribute and has contributed in various ways to the development and dissemination of good practice. With its centuries-old knowledge of herbal medicines, it hasbeen used to treat or palliate numerous illnesses and has paved the way for discovery of new drugs.

Recommendations: Care takers need to be educated about harmful practices. Improved living conditions, better nutrition, provision of Maternal and Child Health care, immunization and community support will decrease the disease burden. Caretakers should be made to appreciate the need for early diagnosis and start prompt treatment.

Acknowledgement: We would like to extend our heartfelt thanks to all the participants.

Breast Cancer Screening: Are 'At Risk Population' Known by Public Health Nurse Practitioners?

G.M. Venkatesh[1], M. Sundar[2]

[1]Assosicate Professor, [2]Professor and Head, Department of Community Medicine, Hassan Institute of Medical Sciences, Hassan

Abstract

Introduction: Health care providers, especially Public Health Nurse who come in regular contact with women, can play an important role in providing the information regarding breast cancer. Hence this study is undertaken to assess the knowledge of risk factors associated with breast cancer and screening for breast cancer among Public Health nurse practitioners.

Method: This is a cross-sectional study designed to assess the Knowledge of risk factors associated with breast cancer and screening for breast cancer among Public Health nurse practitioners working in the Health centres of Dept of Community Medicine of Hassan Institute of Medical Sciences. All (30) Public Health nurse practitioners in the Seven Primary care facilities participated in the study.

Results: Fourteen percent of Public Health Nurse knew that most common cancer among women was breast cancer. However, 43% were aware that the obesity increased the risk of developing breast cancer. Whereas 60% were aware that nulliparity was a risk factor for developing breast cancer and 43% said having 2 or more children decreased the risk of developing breast cancer. However, 33% knew breast feeding was protective against breast cancer. Moreover, early menstruation and late menarche were known to be risk factors by 20% each, and 33% knew physical activity could be a preventive factor for Breast cancer. 96% were aware that a lump in the breast was a sign of breast cancer and 56% said discharge from the nipple was also a sign of cancer in the breast. All 100% knew that Breast Self-Examination was a screening method and only 20% were aware that clinical examination was also a method for identification of breast cancer.

Conclusion: District Health Authorities should periodically train public health nurses to improve their knowledge regarding risk factors, early signs and symptoms of breast cancer and method of cancer screening. This intern would help them to educate, suspect, and detect the breast cancer among the risk population at the earliest.

Keywords: *Breast Cancer, Risk factors, Public Health Nurse.*

Introduction

Breast cancer is the most common female cancer in the world with an estimated 2.08 million (24.2%) new cancer cases diagnosed in 2018. With age standardised incidence rate of 46.3/100000 women and age standardised mortality rate of 13/100000 women. While in India also it has now become the most common female cancer with 162 468 (27.7%) new cases reported in 2018. Whereas the age standardised incidence rate was 24/100000 women, 87090 women died from breast cancer in 2018 giving an age adjusted mortality rate of 13 per 100000 of population. And is estimated to increase to 261850 by 2040.[1]

Breast cancer risk factors include increased age, early menstrual period, late or no pregnancy, starting

Corresponding Author:
Dr G.M. Venkatesh
Associate Professor, # 66 Doctors Quarters, Hassan Institute of Medical Sciences, Hassan
e-mail: drvenkateshgm@gmail.com

menopause after age 55, not being physically active, being overweight or obese after menopause, having dense breast, using combination hormone therapy, taking oral contraceptives, personal history of breast cancer, family history of breast cancer, previous treatment using radiation therapy and alcohol consumption. [2-8]

Adequate knowledge about the signs and symptoms and early breast cancer detection through breast self-examination (BSE) or clinical breast examination (CBE) or mammogram, is crucial to reducing breast cancer-related morbidity and mortality.[9] Screening asymptomatic women by means of breast self-examination, clinical examination or mammography can play a significant role in decreasing breast-cancer mortality in developing countries.[10] The Breast Health Global Initiative developed appropriate guidelines that can be used in nations with limited health care resources to improve breast cancer outcomes.[11]

Health care providers, especially Public Health Nurse who come in regular contact with women, can play an important role in providing the information regarding breast cancer.[12] Empowering nurses with information about early detection method and their related benefits could help in advancing their skills in performing breast self-examination and expanding their role as client educators.[13] Education and awareness need to be culturally appropriate and targeted towards the relevant risk population, because this may contribute towards an increase in early presentation so that highest benefit can be gained.[14] The information obtained could help to initiate interventions to address the gaps in knowledge of Public Health Nurses towards breast cancer-related risk factors, signs and symptoms and early breast cancer detection through breast self-examination (BSE) or clinical breast examination (CBE). Hence this study is undertaken to assess the knowledge of risk factors associated with breast cancer and screening for breast cancer among Public Health nurse practitioners.

Methodology

This is a cross-sectional study designed to assess the knowledge of, risk factors associated with breast cancer and screening for breast cancer among Public Health nurse practitioner in the Health centres of Dept of Community Medicine of Hassan Institute of Medical Sciences. We have seven Health Centre with following number of Public Health Nurse Practitioners (Salagame PHC (7), Krishna Urban PHC (5), Shantigrama CHC (5), Masalehosahalli CHC (3), Nitturu PHC (4), Dudda CHC (3), Konanuru PHC (3)). All (30) Public Health nurse practitioners in the selected health facilities participate in the study over a period of 2 months. A pretested questionnaire was used to collect the data. The questionnaire included information on sociodemographic profile of the study subjects, knowledge of breast cancer risk factors, knowledge of breast cancer signs and symptoms, knowledge of Breast Self-Examination, Clinical Examination and Mammography. Data collection on Knowledge of breast cancer among the participants was assessed based on knowledge on risk factors of breast cancer, signs and symptoms of breast cancer and knowledge on BSE and CBE. The assessment is done by scoring breast cancer knowledge computed by giving "1" to the correct answer, and "0" for the wrong and 'do not know' answers. The data obtained was entered excel and analysed using epi info software. The data is display using tables and graphs.

Results

Knowledge about the risk factors for breast cancer among the study participants: Thirteen percent of Public health nurse knew that most common cancer among women was breast cancer and 36% said this cancer was inherited. However, 43% were aware that the obesity increased the risk of developing breast cancer and 30% were aware that the large breast increases the risk of developing breast cancer. Whereas 60% were aware that nulliparity was a risk factor for developing breast cancer and 43% said having 2 or more children decreased the risk of developing breast cancer. However, 33% knew breast feeding was protective against breast cancer. Moreover, early menstruation and late menarche were known to be risk factors by 20% each. However, 60% knew that advancing age was a risk factor for Breast cancer and 66% knew consumption of alcohol can be a risk factor for developing breast cancer but only 33% knew that physical activity could be a preventive factor for Breast cancer. (Table -1)

Knowledge about signs and symptoms of Breast Cancer: 96% were aware that a lump in the breast was a sign of breast cancer and 56% said discharge from the nipple was also a sign of cancer in the breast, whereas 80% of the Public health nurse said pain and swelling in the breast was also a sign of Breast Cancer. Dimpling in the breast was understood to be a sign cancer among 50% of Public health nurse and 46% were aware that ulceration in the breast can be a sign of cancer. Only

30% knew that weight loss can also be a symptom of cancer whereas a majority 63% were aware that the change in the shape of the breast tissue can be a sign of cancer. A minimal 16% of Public health nurse had known that inversion of nipple can be a sign of cancer but 46% were aware that a lump in the arm pit could be a sign of breast cancer. But very few 16% knew that the dry skin on the nipple region can be a symptom of breast cancer. (Table 2).

Knowledge about Screening Method: A large majority 100% knew that Breast Self-Examination was a screening method to appreciate sign of cancer and only 20% were aware that clinical examination was also a method for identification of breast cancer and none of them knew about mammography as a screening method for identification of breast cancer. (Table 3).

Table 1: Knowledge about risk factors of breast cancer among the study Participants

		No (30)	%	Sd
1	Breast cancer is the most common cancers among women	4	13	1.4
2	Breast Cancer is an Inherited Disease	11	36	3.5
3	Being Overweight and Obese increase the risk of developing Breast Cancer	13	43	4.4
4	Breast cancer is more common among Nulliparity increased the risk of developing Breast cancer	18	60	5.9
5	Large Breast increased the risk of Breast Cancer	9	30	2.9
6	Breastfeeding may decrease the risk of breast cancer development	10	33	3.5
7	Bearing two or more children decreases the risk of breast cancer	13	43	4.3
8	Early Menarche may increase the risk of breast cancer	6	20	2.1
9	Late menopause may increase the risk of breast cancer	6	20	2.1
10	Breast cancer risk increase with advancing age	18	60	5.9
11	Smoking and Alcohol consumption increase the risk of breast cancer	20	66	6.8

Discussion

Breast cancer is the most common female cancer in the world as well as in India. Panieri E et al 2012.[15] Opined that screening asymptomatic women by means of breast self-examination, clinical examination or mammography can play a significant role in early detection of breast cancer.[13].

Knowledge about the risk factors for breast cancer among the study participants: Only thirteen percent of Public health nurses knew that most common cancer among women was breast cancer. The study shows that our public health nurses are not oriented to the problem of Cancer in their population and women cancer in particular. However, factors like multiparity, breast feeding and physical activity as protective factors was not known by many. This shows that the respondents are not informed of the protective factors. Shuyuasa et al[16] in their study found that the risk for breast cancer development among single was 49% more as compared to the married women and also nulliparous woman had 38% more risk as compared to women with 5 or more children. A recent meta-analysis by Zhou Y et al [17] in 2015 involving twenty-four articles with 13,907 breast cancer cases showed that breastfeeding was inversely associated with the risk of breast cancer. Wherein the relative risk of breast cancer for the ever breastfeeding compared with never was 0.613 and an inverse association was found for the longest as compared with the shortest duration of breastfeeding with the relative risk of 0.471. Also, Pettapiece-Phillips R et al (2015) [18] in their study reported that physical activity increases the expression of normal BRCA1 or BRCA2 gene and their by mitigating inherited BRCA mutation. Our study shows that the study population are poorly informed about the association of mensuration on breast cancer. This has been documented by shuyuasa et al[16], that relative risks of breast cancer for women reporting menarche prior to the age of 13 years was twice as high as that for those with menarche occurring after 16 years of age. The author also recorded relative risk of 1.40 for women reporting menopause at 50 years of age or over, as compared to those reporting it prior to 50 years. Also 66% knew consumption of alcohol can be a risk factor for developing breast cancer. This association was recorded by Romieu et al 2015 [19] in their study, wherein it was estimated that, for each 10 g/day increase in alcohol intake the risk increased by 4.2%.

Knowledge about signs and symptoms of Breast Cancer: 96% were aware that a lump in the breast was a sign of breast cancer, which is better than that of a finding reported by Negalign Getahun et al [20] from china where breast lump was the most commonly known symptom of cancer by 61.7% of the respondents. This may be because of the recent experience of the public health nurses with the cases in their field practice areas. Dimpling in the breast was understood to be a sign of cancer among 50% of public health nurse and 46% were aware that ulceration in the breast can be a sign of cancer. Similar observations were reported by Andegiorgish et al [21] in their study, where more than 85% of the respondents stated that a lump in the breast, change in the size of the breast and discoloration/dimpling of the breasts are the major signs of breast cancer.

Knowledge about Screening Method: All 100% knew that Breast Self-Examination was a screening method to appreciate sign of cancer and only few were aware that clinical examination was also a method for identification of breast cancer, Santhana krishnan et al[22] in their study among nursing staff reported that 73.2% mentioned BSE as a screening test and only 20% mentioned CBE as a diagnostic test. This observation is likely because of the training under non communicable disease programme initiative where predominantly teaching is about the signs and symptoms of breast cancer and about breast self-examination.

Conclusion

Our study revealed minimal awareness of risk factors associated with breast cancer among respondents. The study found that majority of the respondents answered the most common symptom of breast cancer and were aware of breast-self-examination. So, we recommend that District Health Authorities to periodically train public health nurses to improve their knowledge regarding risk factors, early signs and symptoms of breast cancer and method of cancer screening. This intern would help them to educate, examine and detect the breast cancer among the risk population at the earliest.

Efficacy and Feasibility of Proprioceptive Neuromuscular Facilitation on Hand Opening in Stroke Individuals: A Case Series

Maitri Rajyaguru[1], Sukumar S.[2]

[1]Post Graduate, Nitte Institute of Physiotherapy, Nitte (Deemed to be University), [2]Assistant Professor, Nitte Institute of Physiotherapy Nitte (Deemed to be University)

Abstract

Introduction: Stroke is a leading cause of death all across the globe, and hand impairment after the stroke is inevitable. The hand dysfunctions are the primary cause of disability, and dependency is stroke patients. Thus it is very imperative to address the condition. PNF is a proved treatment to be useful for the weakened muscles and even for the stroke.

Aim/Objective: The purpose of the study was to evaluate the efficacy and feasibility of PNF techniques on hand opening in stroke patients.

Method: Three patients were treated with stroke and inability to open hands, were treated with PNF techniques for four weeks. All three patients recovered with the treatment, and they were able to open their hands fully or partially.

Conclusion: This study concludes that PNF techniques are effective for hand opening in stroke individuals.

Keywords: *Stroke, PNF, Hand opening, Hand function.*

Introduction

World health organization (WHO) has defined a stroke as rapidly developing clinical signs of focal disturbance of cerebral function lasting more than 24 hours or leading to death with no apparent cause other than a vascular origin.[1] The incidence rate in India is 84-262/100,000 in the countryside and 334-424/100,000 in metropolitan areas.[2]

Patients suffering from a stroke might have numerous impairments such as weakness, sensory dysfunction, spasticity, balance issues, in-coordination, gait deviations, perceptual disorders, cognitive deficits, attention deficits, and behavioral changes. The most common impairment following stroke is of the upper limb that is arm, hand, and finger. It is often reported to be incomplete in functional recovery and to regain the motor activities.[3]

Evidence shows that chronic deficits are very prevalent observant in hand. Finger extension is the motor function very likely to be affected. This distal limb impairment is especially very problematic because proper hand control and hand function are very crucial for manual exploration and manipulation of the environment.[4]

A hand is the last part to be recovered after stroke, and importantly hand opening and wrist extension are very crucial to carry out activities of daily living it becomes very depressing for the patient with this hand impairment.

Physiotherapy can help immensely for the rehabilitation of the hand with the help of interventions like task-oriented therapy, constraint-induced movement therapy, bio-feedback and robot-assisted therapy, neuromuscular electrical stimulation, functional electrical stimulation.

Even though hand opening is very crucial and essential to carry out hand functions and for the execution the daily activities there is no study done for improving facilitating the hand opening or wrist extension in the stroke population.

PNF is a facilitatory technique which is used to stimulate weakened muscles; weakened muscles will work more efficiently with the enhancement of antagonistic muscle compared to when they operate individually.

PNF patterns are proved to be effective in strengthening the muscles of lower limbs.[5] PNF techniques such as- rhythmic initiation, repeated stretch, combination of isotonics and percussions are proved to be beneficial for facial palsy patients.[6] PNF is determined to be helpful for motor recovery on patients with chronic stroke and is useful in restoring functions of stroke survivors.[7] PNF influences the functional ambulation in stroke individuals.[8] PNF can decrease the tone abnormality, and muscle stiffness in the lower extremity of chronic stroke patients.[9] Aquatic PNF patterns is known to improve balance and ADL of stroke patients.[10]

Hence, PNF is proved to be useful for facilitating the weakened muscles as well as to gain control for the muscle function. PNF is even proved to be effective for stroke patients when given for facial palsy and lower limbs. Since there is no evidence found to evaluate the effectiveness of proprioceptive neuromuscular facilitation on hand opening in stroke individuals. Therefore, this study was undertaken to evidence the effectiveness of proprioceptive neuromuscular facilitation on hand opening in stroke individuals.

Case Report: There were three participants with hemiparetic stroke aged between 45 and 65 years referred to the physical therapy department. All participants had complained regarding carrying out their daily activities with their affected hands for seven days to 2 months. These participants were screened using inclusion criteria, and the screened participants were given a consent form. Inclusion criteria were having the first episode of stroke, duration of fewer than three months since onset, age 40-65 years, no significant cognitive deficit (a score >25 points in mini-mental status examination). The participants were not having any deformities of hand, any surgeries of hand affecting hand functions, or diabetic neuropathy.

Case 1: A 63 years old male, who was a retired shopkeeper by profession with a BMI of 22.65. He was suffering from systemic hypertension for around 15 years; he used to have frequent episodes of giddiness and headaches due to hypertension. He experienced weakness of right side of body two months back and was admitted. The participant was great difficulty in doing daily activities as the dominant side of the body was affected by stroke. The physiotherapy examination revealed high blood pressure of 140/90 mm Hg at time of assessment, the higher mental evaluation was normal 30/30 as assessed by mini-mental examination, and reflexes on the right side showed a normal response that is 2+.

The outcome measures used to evaluate the hand opening functionally was BAB and ARAT. The baseline values for BAB was 12, and for ARAT was 2. For assessing the hand opening quantitatively, wrist extension range was taken, which showed 30 degrees at baseline. To evaluate the disability of the participant, the modified Rankin scale was taken, which showed four at baseline. To check the recovery based on Brunnstrom stages, Brunnstrom recovery stages were used, which showed stage 4 when assessing.

Case 2: This was a 57 years old female participant who was a housewife with a BMI of 26.85. She suddenly felt a weakness towards the right side of the body. The participant had difficulty when performing the daily task for seven days as the dominant hand was affected by stroke. When examined physically, the blood pressure came as 138/86 mm Hg, MMSE as normal that is 26/30 and reflexes as exaggerated that is 3+.

The outcome measures at baseline for BAB showed 20, for ARAT showed 16, wrist ROM was 15 degrees, modified Rankin scale was 4, and the stage for Brunnstrom recovery was noted to be 3.

Case 3: This was a 45 years old male participant who was a construction worker with a BMI of 23.82. The participant started experiencing severe headache, and difficulty of speech suddenly one day while working and lost his consciousness and fell. Then he started

experiencing weakness of the left side of the body for 11 days. The participant was right side dominant, and the weakness was on the left side, so the deterioration of hand function was less. The physical examination of the patient depicted the blood pressure of 124/84 mm Hg, the mental examination as normal(30/30) and the reflexes also as normal (2+).

The outcome measures evaluated at the baseline showed the following results, for BAB was 31, for ARAT was 13, active wrist extension was 20 degrees, modified Rankin scale was 3, and the Brunnstrom recovery stage was 4.

Table 1: Characteristics of three patients with hemiparetic stroke having difficulty in hand opening

Characteristics	Case 1	Case 2	Case 3
Age	63	57	45
Gender	Male	Female	Male
Side affected	Right	Right	Left
Hand dominance	Right	Right	Right
SBP	140	138	124
DBP	90	86	84
Duration	2 months	7 days	11 days
MMSE	30/30	26/30	30/30
Reflexes	2+	3+	2+
BMI	22.65	26.85	23.82

Table 2: Descriptions of baseline and post intervention variables

Variables	Case 1		Case 2		Case 3	
	Pre	Post	Pre	post	pre	Post
BAB	12	18	20	24	31	34
ARAT	2	10	16	22	13	19
MRS	4	3	4	4	3	3
Wrist Extention	30 degree	45 degree	15 degree	35 degree	20 degree	33 degree
Brunnstorm Stage	4	5	3	4	4	4

Treatment: The same treatment was given to these three participants. The participants were given conventional physiotherapy as well as two patterns of PNF for the upper limb. The patterns used were facilitating for hand opening that is: flexion-abduction-external rotation and extension-abduction-internal rotation patterns. These patterns were chosen because the end position of these patterns promotes the wrist extension. The techniques used were a combination of isotonics, dynamic reversals, and stabilizing reversals. The participants were made to be supine lying position and fist they were shown the PNF patterns used by passive movement, then they were taught to practice these patterns. For combination of isotonics, they were told to concentric, eccentric and stabilizing contraction of agonist muscle group without relaxation. For dynamic reversals, they were told to do the contraction of agonist and antagonist without pause. For stabilizing reversals, they were told to do alternating isotonic contraction opposed by therapist's resistance. Each one of this technique was given for 10 minutes, 5 minutes using flexion-abduction-external rotation pattern and 5 minutes using extension-abduction-internal rotation pattern. The total duration of the PNF treatment was 30 minutes. The conventional treatment given was- passive movement of all joints of upper limb 10 repetitions for each joint, stretching of supinators and wrist flexors 3 repetitions for each, weight bearing on the affected extremity in sitting position for 10 minutes, giving reach outs to the affected extremity in sitting or standing position for 10 minutes, and grip strengthening exercises for 10 minutes. The conventional treatment was given for 45 minutes. The participants were being treated for 4 weeks, for 5 days in a week. Another treatment was given to the participant according to the need of the patient, as strengthening exercises for lower limb, standing, weight shifting, sit to stand, gait training, co-ordination activities.

Figure 1. Treatment given PNF flexion-abduction-external rotation pattern with dynamic reversals

Figure 2. Treatment is given PNF extension-abduction-internal rotation pattern with dynamic reversals

Outcome Measures: The post values were taken after the treatment of affected upper extremity after providing the four weeks of conventional and PNF therapy. The outcome measures used were BAB, ARAT, MRS, active range of wrist extension, Brunnstrom recovery stages. The post values of all the outcome measures except MRS showed a clinically significant difference. The difference in the pre and post values of BAB in case 1 is 6, case 2 is 4, and in case 3 it is 3. The difference between ARAT scores pre and post was noted to be 8 in case 1, 6 in case 2 and case 3. Wrist extension showed a difference of 15in case 1, 20 in case 2 and 13 in case 3. Brunnstrom recovery stages also showed an improved response from stage 4 to 5 in case 1. From stage 3 to 4 in case 2, but it didn't show the difference in case 3 where it remained in stage 4 after the treatment. MRS didn't much significant difference in cases 2 and 3, but in case 1 it progressed from 4 to 3.

Discussion

This study was conducted to evaluate the added effects of proprioceptive neuromuscular facilitation on hand opening in hemiparetic stroke individuals to conventional treatment. The conventional treatment for hand opening is passive exercises, stretching exercises, weight-bearing exercises, reach outs, and grip strengthening exercises. These exercises may actively help in gripping activities of hand, but hand opening remains passive in these exercises. So even though the hand gripping will be improved, the hand will remain non-functional as the hand opening is compromised. For the daily activities and the smooth activities of hand, the opening of hand is very imperative. Thus, to evaluate this hand opening with the help of PNF, we selected three patients with hemiparetic stroke. The baseline data of the three patients clearly stated that there was a deterioration in the hand function due to hemiparesis. At the end of the treatment of four weeks, the participants witnessed the improvement in the hand function as assessed by the outcome measures

Our results are in support of Honghun Kim et al. (2011), who suggested that PNF enhances muscle activity. The study proved to be effective in patients with stroke when treated with PNF in improving the functional reach test and muscle activity of lower limb muscles.[11] The possible mechanism of PNF affecting the movement of the hand and improving the motor control can be as suggested by K Shimura et al. in 2002, PNF position enhances the range of motion, reduces the time of EMG-RT, and increases the efficiency of muscle contraction.[12]

Conclusion

The objective of this study was to evaluate the efficacy and feasibility of PNF techniques so that this protocol can be used for the rehabilitation of hand opening in stroke individuals. The results show that PNF and conventional therapy is given to all three patients have shown improvement in all the outcome measures compared to the baseline. Also clinically, the patient's hand function is seen to be enhanced after the four weeks of treatment.

Scope of Future Work:

- A randomized controlled trial can be conducted with a larger sample size so that the result can be generalized.
- Long-follow ups can be taken to determine the long term effect of the treatment
- A similar type of study can be done with the combination of other treatment techniques
- Surveys can be done to evaluate the quality of life with the PNF treatment

Conflict of Interest: The authors declare that there is no conflict of interest.

Source of Funding: The project is self-funded.

Ethical Clearance: The study has been approved by the institutional ethics committee.

Knowledge and Perception Regarding Menopause among Married Women

Amitha[1], Malathi G. Nayak[2], Pratibha[3]

[1]M.Sc. Nursing Student, [2]Associate Professor in Community Health Nursing, Department, [3]Assistant Professor in Obstetrics and Gynaecological Nursing Department, Manipal College of Nursing, Manipal Academy of Higher Education, Manipal, Karnataka, India

Abstract

Introduction: Menopause is one of the mile stones in women's life that all women at midlife are expected to experience. **Objectives:** To assess the knowledge and perception of married women regarding menopause, and to find out the association between the knowledge and perception of married women regarding menopause with selected demographic variables.

Methodology: A cross sectional descriptive study was conducted among 140 married women between the age group of 45 – 55 years. The study was conducted in two villages which were selected by simple random sampling from Udupi Taluk, Karnataka. Data were collected by using structured knowledge questionnaire and perception scale towards menopause. Data were analysed by using inferential and descriptive statistics.

Results: Out of 140 married women the data shows that majority of women belongs to the age group of 45-50 years and their mean age was 48.26 years and SD 2.359. Most 106(76.4%) of the women had a history of regular menstrual cycle and 138(98.6%) had no history of any gynaecological illness during the data collection. Majority of the married women 120(85.7%)had average knowledge on menopause. Among 140 married women most 111(79.3%) of them had good perception. There is significant association between knowledge score and education ($\chi 2$ =25.680, p =0.008) and income (χ^2 =11.071, p =0.027).There is weak positive correlation between the knowledge and perception was observed (r =0.212, p = 0.010).

Conclusion: Awareness regarding menopause is very essential and should not be neglected. Assessing the knowledge and perception regarding menopause will help them to cope up with the changes that take place during this stage.

Keywords: *Menopause, knowledge, perception, married women.*

Introduction

The menopause refers to the time in every woman's life when menstruation stop and ovaries loss their reproductive function. It is essential to ensure that a woman understands that the menopause represent a change of life and not an end of life, and that, unless women allows it to do so, it will not result in women suddenly becoming aged and unattractive. Menopause is one of the essential stage in women's life. It is characterized by major physical, psychological and social changes and is currently considered as important public health problem associated with a worse health related to quality of life and it is also very important that all family members should understand and support her during menopausal stage.

Menopause may result many alterations in women's physiological functioning and cause anxiety. It is

Corresponding Author:
Dr. Malathi G. Nayak
Associate Professor, Community Health Nursing Department, Manipal College of Nursing, Manipal Academy of Higher Education, Manipal, Karnatak, India-576104
Mobile Number: 9449586431

important that women during menopausal period should have adequate knowledge and positive perception regarding menopausal transition that may help them to cope up with the changes in their life and improves the quality of life[1].

Menopause is not the end of life, but during the menopausal stage women may experience various symptoms. These symptoms may affect their physical as well as psychological activities. Post-menopausal women need better understanding and support from family members especially husband so that they can easily cope up with the postmenopausal life. Study suggested that public health system should continue to educate, counsel and aware about menopause among premenopausal women and their spouses so that they can spend their future life in a better way[2].

There is a need to identify the problem and create health care facilities for women. With decreased level of oestrogen, the transition tomenopauseis quite a challenging phase for life of every women. Some women experiencing hot flushes, tiredness and some are experiencing it as losing their energy. Menopausal period of women's life is very crucial where she needs most emotional support and expert guidance. The women's physiological, biochemical and psychological environment altered due to menopause. Thus knowledge and perception of its symptomatology is important to adjust to the normal occurrence. Family members also should awarethe changes occur in the women during menopausal stage. Hence the researcher felt to conduct a descriptive study to assess the level of knowledge and perception towards menopause among married women.

Materials and Method

The descriptive survey was carried out in the selected villages of Udupi Taluk among married women. The sample size was calculated as 140 based on the findings of previous study. The Villages were selected by simple random sampling method; subjects were selected by convenient sampling method. Data were collected from the married women aged between 45 – 55y ears who did not attained menopause and living with their spouses. The data were collected byadministering the demographic proforma, structured knowledge questionnaire and perception scale on menopause to the participants. The tools were validated by 9experts and the reliability of the tools were, for knowledge questionnaire was 0.71, perception scale was 0.88.

Ethical consideration: Ethical Clearance and administrative permission were obtained before data collection. The data were collected from married women after obtained the consent from the participants who met the inclusion criteria by using structured questionnaire.

Statistical Analysis

The data were analysed by using Statistical Package for the Social Sciences (SPSS) version 16.0. The statistics used for data analysis were, frequency and percentage for distribution of demographic variables, knowledge on menopause, perception towards menopause. The Chi-Square test was performed to find the association between knowledge and perception on menopause with selected demographic variables. Spearman correlation co-efficient was used to analyse the relationship between knowledge and perception regarding menopause. A p-value of < 0.05 was considered to establish the statistical significance.

Results

Result shows that out of 140 participants majority of the married women were belongs to the age group of 45-50 years 118(84.3%), 113(80.7%) were from nuclear family, 130(92.9%) were belongs to Hindu religion, 80(57.1%) of them had their education upto higher secondary and 96(68.6%) of them were house wives. Majority 138(98.6%) of married women had more than 15 years of married life, 49(35%) of them had information from more than one source and 84(60%) of them were having two children. 77(55%)of married women had their monthly income between Rs. 5001 -10000, 107(76.4%) of them had their regular menstrual cycle, 12(8.6%) of them had history of diabetes and 15(10.7%) of them had history of hypertension and 138(98.6%) had no history of any gynec illness at the time of data collection [Table 1,2 & 3].

With regard to knowledge majority of the married women i.e 120(85.7%) had average knowledge, 11(7.9%) of them had poor knowledge and only 9(6%) of them had good knowledge [Fig. 1]. Result further shows that women were know the meaning of menopause [mean 6.30, SD 1.79], they had least knowledge on signs and symptoms present during menopause [mean 3.96, SD 1.351] and women had average knowledge on management [mean 6.34, SD 1.86]and overall maximum knowledge score was 27 and minimum score was 7 and mean and standard deviation was 15.98 and 3.364 respectively [Table 4]. With regard to the

perception on menopause, 111(79.3%) of the married women had good perception, 29(20.7%) of them had average perception[Table 5]. Result also shows that there is significant association between knowledge score and education ($\chi 2$ =25.680, p =0.008) and monthly income of the family($\chi 2$ =11.071, p =0.027). The finding inferred that women those who had good education and socioeconomic background have good knowledge on menopause [Table 6]. Further data shows that there is weak positive correlation between the knowledge and perception on menopause of married women (r = 0.212, p = 0.010).

Discussion

In the present study majority 118(84.3%)of the married women were belongs to the age group of 45-50 years, 80(57.1%) of them had their education upto higher secondary, and 49(35%) of them had received information from more than one source. Similar findings obtained by Shabana Sultan et al & Neha Mehta et al found that majority 122(81%) of the women were 46-55 years old, 70% had completed their education and 93(62%) of the women received information regarding menopause from friends and relatives [3, 4].

In the present study majority 120(85.7%) of the married women had average knowledge, 11(7.9%) of them had poor knowledge and only 9(6%) of them had good knowledge. Similar findings obtained by a study conducted by Ensieh Noroozirevealed that 32(8%) of the participants had poor knowledge, 272(68%) had moderate knowledge and 154(38.5%) had good

knowledge[5]. The present study also contradicted by a study done by Prabathi Nepal revealed that majority of the women 90(63.4%) of the respondents had poor level of knowledge, more than one quarter 48(33.8%) had fair and only 4(2.8%) had good level of knowledge on peri-menopausal women [6]. Similar findings of the study also found by a study done by Marie E Pintoshown that majority of the women 78% in rural area had average knowledge and majority of the women in urban area 62% had satisfactory knowledge [1]. The present study shows that the mean + SD score on knowledge was 15.98 + 3.36 and similar findings identified by Kwak et al the mean score on knowledge was 17.93 ± 2.39[13].

The present study identified that 111(79.3%) of the married women had good perception, 29(20.7%) had average perception on menopause. The study was supported by a cross sectional observational study was conducted among 100 postmenopausal women who visited the outpatient department of Obstetrics and Gynecology, Government Medical College Idukki revealed that 77(77%) had positive perceptions [2].

The present study found that majority of the women 96(68.6%) perceived menopause as a normal event in life just as pregnancy and child birth. Similar findings obtained by a study conducted by Sabir GNrevealed that 427 (85.4%) of women perceived menopause as a natural condition[7]. It also supported by a study done by Nisar Nusratidentified that 680 (78.79%) women considered menopause as a natural process[8].

The present study revealed that most 63(45%) of the women perceived that they should not discuss their experience of menopause to their family members and friends. This was supported by a study conducted by Ibraheem O.M, Oyewole O.E and Olaseha I.O (2015) revealed that women should not discuss about their menopausal experiences with others i.e by 146(60.8%) [9].Women in eastern societies view menopause as a natural process and hold a positive attitude [10]. Chen et al[11] reported that 95.7% midlife Chinese women in Taiwan perceive menopause a natural phenomenon and most of these women could deal with menopause in a positive way. Another population based cross sectional study from south India showed similar results that 57% of women perceive menopause as convenient [12]. Majority of women were aware about menopause and most of them were bothered by menopausal symptoms, but very few consulted doctor[14].

Limitations of the Study: In present study sample size restricts generalization of the study findings and the study finding was limited to married women who did not attained the menopause.

Conclusion

The study concluded that the married women had average knowledge and perceptionon menopause. So the researcher felt that there is a need to conduct awareness program on menopausal symptoms management. It will help them to cope up with the changes and improve the quality of life of married women during the menopausal period.

Prosthetic Status and Demand for Services in an Adult Rural Population in Relation to Dental Service Infrastructure in Mangalore Taluk, South India

Mallika S. Shetty[1], Uma Mayoor Prabhu[1], Prakyath Malli[2], Rekha Shenoy[3]

[1]Reader, [2]Assistant Professor, Department of Prosthodontics, [3]Professor and Head, Department of Public Health Dentistry, Yenepoya Dental College

Abstract

Context: Oral health can be considered as an indicator of general health and quality of life. Planning dental services is therefore the collection of up to date information on the prevalence of oral health status in a given population.

Aims: This study was conducted to assess prosthetic status and demands for services among the rural population in Mangalore Taluk.

Method and Material: A cross sectional survey was carried out on 1312 participants aged 18 years and above. Sixteen gram panchayats were selected and asurvey was conducted to determine the prosthetic status and prosthetic need.

Results: Complete denture prosthesis was predominantly high among the age groups above 61. Removable partial denture was predominantly high among the age groups 31-45. Fixed partial denture was high among age groups 46-60.

Conclusions: Irrespective of the age, gender and education the need for Multi unit prosthesis was found to be significantly high.

Keywords: *Prosthetic status, prosthetic needs, treatment facilities.*

Introduction

Mangalore is one among the five taluks/subdivisions of Dakshina Kannada District of Karnataka State. Mangalore has the highest population of 1048 persons per square kilometer among the taluks of Dakshina Kannada. It is a reputed centre for medical education and health care with five dental schools and a multitude of private dental clinics.[1]

Studies reporting the dental prosthetic status and treatment needs of people give an indication of the poor prosthetic status and burden of unmet treatment needs.[2,3]

Most of the studies done in India to estimate prosthodontic treatment needs are institution based in urban areas in the age groups of 35 years and above and on smaller sample size. Statistics shows a paucity in dental health infrastructure in the rural areas of Mangalore taluk.[1]Therefore this study was conducted to assess prosthetic status and demands for services in Mangalore Taluk.

Subjects and Method:

A cross sectional survey was carried out to determine the prosthetic status and prosthetic need among the rural population of Mangalore taluk, on 1312 participants.

The sample size was determined based on the prevalence of prosthetic status (22.7%) as determined by the national health survey and fluoride mapping which was carried out in 2002-2003[4].

The map of Mangalore taluk was divided into North and South zone. Eight gram panchayats each were randomly selected from both zones. Among sixteen gram panchayats selected ahouse-to-house survey was carried out till a target of 82 individuals were examined in each panchayat. The individuals were interviewed and examined.

Before beginning the data collection, permission was obtained from the Institutional Ethics Committee.

Inclusion criteria: (i) The individual should be a resident of the area (ii) All the population in the age range of 18 years and above.

Patients, who refused for the dental check-up and those with full complement of teeth, were excluded from the study.

A pretested proforma was used for data collection. It consisted of two parts—the 1st part recorded data on sociodemographic factors, while the 2nd part contained a section of the World Health Organization (WHO) Oral Health Assessment Form (1997)[5] to record the prosthetic status and prosthetic need of the population.

Data collected were analyzed using SPSS version 17.0 and the Chi- squared test. $P<0.05$ was considered as significant.

Results

This study comprised of 520(40%) males and 792(60%) females.The age and gender distribution as shown in Table:1shows that among all the age groups females outnumbered males.

Table 2 and 3 revealed that prosthetic status in maxillary arch, complete denture was predominantly high among the age groups above 61 years (58.5%) which was highly expected due to tooth loss. Removable partial denture was predominantly high among the age groups 31-45 years (23.4%). Fixed partial denture was high among age groups 46-60 years (3.8%). Crown was predominantly high among the age groups 18-30 years (8.5%).

Mandibular arch revealed that complete denture was high among age groups above 61 years (57.4%). Removable partial denture washigh among age groups 31-45 years (22.6%). Fixed partial denture was high among age group 31-45 years (1.4%). Crown was high among age group 18-30 years (2.1%).

To quantify based on educational status graduates and post graduates were combined into one group as group A, while those with less qualification formed group B.

Prosthetic status and education in both the arches in Table 4 and 5 showed that, significantly higher number of participants in group B were prosthetic wearers. As the level of education increased the number of prosthesis also increased which infers that influence of education, knowledge and income may have led to an improved prosthetic status.

Distribution of study subjects according to prosthetic status and gender showed that 718(54.7%) in the maxillary arch and 779(59.4%) in the mandibular arch did not present with any prosthesis, 306 (23.3%) in the maxillary arch and 294 (22.4%) in the mandibular arch presented with complete denture prosthesis, in which males presented more than females. 209 (15.9%) in the maxillary arch and 294 (22.4%) in the mandibular arch presented with removable partial denture prosthesis in which females presented more than males. 34(2.6%) and 14(2.6%) presented with fixed prosthesis and crown respectively in the maxillary arch and 13(1.0%) and 14(1.1%) presented with fixed prosthesis and crown respectively in the mandibular arch in which males presented more than females.

Prosthetic need in both arches reveals that majority of the rural adult population required multi unit prosthesis (maxillary35%, mandibular 46%) followed by full prosthesis(maxillary 26%, mandibular 25%).

Distribution of study subjects according to prosthetic need and age group: while the need for multi unit prosthesis was high among all age groups, the need was alarming among those in the 18-30(57%) and 31-45 year age group (54%). This is an indication of the failure of the health care system where people in productive age group have lost multiple teeth and also have not been able to replace them.

It was found that females had a higher requirement for multi unit prosthesis in both the arches, although the difference was not significant in both genders.

The education level of the population seemed to influence the prosthetic need. Among those with no education and lower levels of literacy the need for multi unit prosthesis was highest, this shows lack of awareness or poor attitude towards oral health resulting in loss of multiple teeth with no replacement.

Discussion

Data on prosthetic status and need in rural population aged 18 years and above is very scanty. Thereby an attempt was made. In rural areas the standard of living and economic status is low and no importance was given to women's education. Dental treatment is therefore obviously neglected till tooth loss is the final result.[6] Dentists too are responsible for this state of affairs as for the same population ratio, there are 10 times more dentists in cities than in villages in India.[1]

According to the data obtained by Shenoy R (2015)[1] it was found that dental services were not available at any of the 21 PHCs (five urban and 16 rural) in Mangalore taluk. Dental surgeons were posted at both the CHCs and they provided basic dental services such as extractions, minor restorative care and oral prophylaxis to those seeking dental care. Two dentists were rendering services at the District Government Hospital in Mangalore City. They too were providing only basic dental care to patients due to lack of resources.[1]

Among private dental clinics 189, were registered with the office of the DHO and the IDA of which 91% (172/189) were located in urban and 9% (17/189) in

rural areas of the taluk. This study found 91% of dental clinics clustered in urban areas. It clearly shows that urban bias exists, with 75% dentists practising in urban areas. Although dental clinics provide a major share of the dental care delivered in India, their inaccessibility forces many rural patients to forgo or delay essential dental treatment. Therefore, although oral health care is accessible in urban areas, it is difficult to obtain in rural areas.[1]

Preventive dental care is almost non-existent in rural India[7]. In the present study, when the prosthetic status and age group was evaluated it was found that complete denture was predominantly high among the age groups above 61 in the maxillary (58.5%) and mandibular arches (57.4%). The present study reveals that prosthetic status increased with age, similar results were obtained by Florian, (2003)[8]showing 23% in 55-64 age group and 69% in 75-79 age group.

In the present study the removable partial denture was predominantly high among the age groups 31-45 in both arches. The prevalence of partial denture decreased with increase in age in the mandibular arch and increased with increase in age in the maxillary arch. According to Shah, (2004)[9] prevalence of partial denture decreased with age in both arches.

Fixed partial denture was high among age groups 46-60 (3.8%) in the maxillary arch and among 31-45 (1.4%) in the mandibular arch, whereas results obtained by Mojon,(1995)[10]showed 14.4(28.8%) and Prasad,(2001)[11]showed (0.89%) of prevalence. Crown was predominantly high among the age groups 18-30 in both arches.

When prosthetic status and gender was evaluated in the maxillary arch, complete denture was predominantly high in both males (26.6%) and females (21.0%) followed by removable partial denture among males (15.1%) and females (16.5%). Similar results were obtained by Galon *et al.,* (1993).[12] In the present study female prosthetic wearers were found to be less than males, the probable reason was that female members usually depend on male members to take them for treatment, which is in agreement with a study by Shah *et al.,* (2012).[3]

When prosthetic status and education was evaluated in themaxillary arch, majority of the subjects with higher educational level wore fixed prosthesis. Similar results obtained by Florian *et al.,* (2003).[8] Surprisingly removable partial denture was predominantly high among graduates and post graduates. The reason was that, they did not want their tooth to be cut in order to fix fixed partial denture.

When Prosthetic Need was evaluated, it was found that among all age groups multi unit prosthesis was needed predominantly in both arches. Study by Prateek *et al.,* (2001)[13]showed need for removable partial denture among 35-44year olds for both arches.

In the present study the need for full prosthesis was found to increase as the age increased. The need for Full prosthesis was slightly more in males than females as stated by, Goel *et al.,* (2006)[14]and Shah *et al.,* (2012)[3] This may be due to tobacco related habits among males which results in extraction of teeth.

Need for Multi unit prosthesis in mandibular arch was seen most often in subjects of 18-30 years which was in accordance with the study by Prateek *et al.,* (2001)[13](18.8%), but in maxillary arch it is seen among subjects of 46-60 years which was contradicting with the results of Prateek *et al.,* (2001)[13],wherein subjects 25-34 years(12.1%) needed prosthesis.

Need for Multi unit prosthesis was high among females in both the arches whereas according to Shah *et al.,* (2012)[3]the need was high among both the genders and according to Prateek *et al.,* (2001)[13] need was higher among males in maxillary arch and higher among females in mandibular arch.Full and Multi unit prosthesis were needed among all the education levels.

In the present study, the need for multiunit prosthesis was more than the need for single-unit prostheses,but in contrast to this a study by Srivastav A *et al.,(*2011)[15]showed that the need for single-unit prostheses (35%) was more than the need for multi-unit prostheses. Study has evaluated that in comparison with the dental prosthesis used, 45.2% in maxillary and 40.6% in mandibular arch, the need for prosthesis was high, and it was 70.4% in maxillaryand 79.2% in mandibular arch. This may be because of low education levels, poor awareness, unavailability of services in rural areas and financial constraints.

Therefore, to improve the prosthetic status and reduce need, it is important to educate and motivate the patients regarding oral health care and provide free dental treatment camps. This is in agreement with Pallegedara and Ekanayake, (2005)[16] who reported that the prevalence of wearing of dentures was low despite

the fact that there was a high prevalence of missing teeth. Lack of perceived need for dentures seemed to be the main reason for this finding.

Conclusion

A large population was found to have complete denture among the study population. Irrespective of the age, gender and education the need for Multi unit prosthesis was found to be significantly high.

Evaluation of Intrusive Forces Created by 'V' Bend, Intrusion Arches at Various Deflections: An Invitro Study

Manikandan S.[1], Deepak Chandra[2], Gnanashanmugam K.[2], Sasidharan Sivakumar[3]

[1]Associate Professor, [2]Professor, Department of Orthodontics,Sree Balaji Dental College & Hospital, BIHER, Chennai, [3]Post Graduate Student, Department of Public Health Dentistry, Best Dental College, Madurai

Abstract

Aim: To evaluate of intrusive forces created by 'v' bend, intrusion arches at various deflections- an invitro study.

Objective: The present study is to consider the importance of alloy used as intrusion arches.

Material and Method: We used stainless steel wires, timolium wires, CNA Beta 3. Wires (Libral,USA), blue elgiloy all with rectangular section of dimension 0.017 x 0.025 inch, 15 numbers each. Arch forms are standardized with the help of arch form selector guide. Three distances from vestibule to bracket slot in upper anteriors were marked. Trials were conducted at the CIPET (Central Institute Of Plastic Engineering and Technology, Chennai) and a dynamometer (Autograph, U.K) with 1kgf load cell at 0.01kgf resolution and speed of 10mm/min7. The load magnitude at various displacements (5, 10, 15 mm) were recorded.

Statistical Method: The significance level of 5% was taken. ANOVA was used for assessing the force of all the alloys and Tukey test was used for multiple comparisons.

Results: The forces recorded at 5, 10, and 15 mm were all significant between the four alloys when compared except for CNA and timolium between 5 mm and 10 mm and for blue elgiloy between 10 mm and 15 mm were not statistically significant.

Conclusion: The load increments tends to decrease from the first to last increment, and the differences is being more significant from the first increment to the second increment for all the alloys, and more significant in stainless steel and the blue elgiloy. CNA produced the least force.

Keywords: *Intrusion, v-bend, load deflection rate.*

Introduction

Deep bite correction depends on the diagnosis and treatment planning. Orthodontically it can be done either by intrusion of maxillary/mandibular incisors, extrusion of posterior teeth or by a combination of intrusion and extrusion.

Intrusion is the most needed and difficult movement, as it needs a very light and constant force. Forces exceeding the biological limit can damage the supporting tissues. To achieve this proper mechanics is essential.

According to Consolaro(2005) the optimum force established by Schwarz in 1932 was conceptual, because technology for such measurement was not available then.

Force system is determined both by the design and material used in the appliance. Orthodontist must know the role of the wire used including its size and composition.

To achieve intrusion the constancy of the force has

to be in control. The wire which is more resistant to deflection will release the acquired force at a faster rate. So the wire with low load deflection rate will tend to release the force slower at constant rate.

Due to the recent advancements in metallurgy, the clinician is facing a challenge in selecting an arch wire from a wide range of alloys which are available in a variety of cross sections.

Mulligan prefers constant bends because they are easy to do, readily reproducible, and offer low force ranges when the orthodontist is familiar with the "by - pass" approach to force control.

This study tends to compare intrusive forces in stainless steel, timolium, blue elgiloy and CNA, 'V' bend intrusion arches with different magnitudes of deflection. In other words the study tends to identify an alloy at a particular bending magnitude which deliver near ideal force favourable for intrusion.

Aim: To evaluateof intrusive forces created by 'v' bend, intrusion arches at various deflections.

Objective: The present study is to consider the importance of alloy used as intrusion arches.

Materials and Method

This study considers Stainless steel wires, timolium wires, CNA Beta 3 wires, Blue elgiloy alloy with rectangular section of dimension 0.017 x 0.025 inch, 15 numbers each. Arch forms are standardized with the help of a arch form selector guide (TP Orthodontic, La Porte, Indiana, USA). Bio-arch IV is selected as the standard arch form, as the arch form of the typhodont coincides with that arch form. Straight length of Blue Elgiloy wire is bent in to arch form with the help of a turret (Morelli, Sorocaba, Sao Paulo, Brazil).

Intraoral rulers are fixed in the phantom upper jaw to record the displacements. Buccal tube(0.22slot) is fixed in the first molar. Stainless steel wire is placed in the centre of upper anteriors to represent bracket slot line, as presence of brackets may interfere during force measurement[7]. A V-bend of 45 degrees for intrusion is made in the second premolar-molar region of the arch wire[7,22,23,24]. This produced a deflection of 40 mm from the bracket slot line.

Trials were conducted at the CIPET (Central Institute Of Plastic Engineering and Technology, Chennai) and a dynamometer (Autograph, U. K) was used with 1 kgf load and 0.01 kgf resolution. The arch wire was inserted in the auxillary tube and the load is connected to the arch wire in the midline. Trial speed was set at 10 mm/ min[7]. The magnitude of the load at 5, 10, 15 mm were recorded.

Statistical Analysis: The significance level of 5% was taken. ANOVA was used for assessing the force of all the alloys and Tukey test (table 3) was used for multiple comparisons.

Table-E enlist the Force values of different alloys at different magnitudes of deflection. On comparing the forces registered at 5, 10, and 15 mm the differences between all the alloys were statistically significant except for CNA and timolium between 5 mm and 10 mm and for blue elgiloy between 10 mm and 15 mm were not statistically not significant as shown by the figures presented in (Table 2).

Result: The Kolmogorov-Smirnoff test identified a normal distribution.

Comparison between the load increments necessary to deflect the arch at every 5 mm (Table 1) identified different forces between nearly all the intervals for stainless steel, CNA, blue elgiloy, timolium.

Table 1: Force Values of different alloys at different magnitudes of deflection

Distance	F	P	Stainless steel		CNA		Blue elgiloy		timolium

Discussion

At times orthodontist simply placed a V bend in the posterior region for intrusion neglecting proper force measurement. There is no constant angulation which can be placed for all the patients because there are variations in patient's dental arch length, height of the buccal vestibule, crown height and its angulation. Method error evaluation was not done since the repeatability characteristic could not be assured as the same arch would possibly present some change upon being newly measured.

The observed forces of 227.83 gf for stainless steel, 137. 87 gf for CNA, 197. 46 gf for blue elgiloy, 186. 16 gf for timolium at the same distance of 15mm were different with those of Cristiane Aparecida de Assis Claro et al (2007)[7], because the arch perimeter of the typhodont used is small and produced only 15mm deflection with a 45 degree V bend.

The CNA wire produced lesser force than stainless steel, blue elgiloy, and timolium when deflected from 15 mm, and presented better spring back than the others. Timolium presented intermediary characteristics between blue elgiloy and CNA. Blue elgiloy presented intermediary characteristics between stainless steel and timolium.

By comparing the load increment at each registered distance of 5 mm, it was possible to identify a higher regularity in the loads necessary to deflect the CNA and Timolium arches, and a higher irregularity in the loads necessary to deflect the stainless steel and blue elgiloy arches. These are concordant with those of Cristiane Aparecida de Assis Claro et al (2007)[7] for timolium and stainless steel. Moreover, it was determined that there was a decreasing tendency in load quantity from the first to the last interval.

The load increments necessary to deflect the arches tended to decrease from the first to the last interval, these differences being more significant from the first increment to the second increment for all the alloys. In other words the majority of the load required to deflect the arch wire is spent in the first segment (15-10mm). This is a very important point in a clinical situation, mostly when constant angulation for 'V' bends is used. Also, as the tooth starts intruding, the loss of force is minimal as the teeth can never cross the last two segments.

The forces observed in this should not be used as reference and has to be measured when an intrusion arch is tied as the geometry of the teeth and the distance between the point of force application varies from patient to patient.

Conclusion

Based on the analyses conducted in the present study, it was concluded that:

1. The CNA intrusion arches produced the least amount of force followed by timolium, blue elgiloy and stainless steel arches in increasing order at 5,10,15mm of deflection.

2. In all the alloys, an increase in distance of every 5mm entailed a significant increase in force between all registered values.
3. The load increments necessary to deflect the arches tended to decrease from the first to the last interval, these differences being more significant from the first increment to the second increment for all the alloys, more significantly in stainless steel and blue elgiloy.

Conflict of Interest: None.

Autistic Spectrum Disorder- Contextual Paediatric Global Updates

Manmeet Kaur[1], Harmeet Kaur[2]

[1]Assistant Professor, [2]Principal, Chitkara School of Health Sciences, Chitkara University, Rajpura, Punjab

Abstract

Autistic spectrum disorders are the complex neurological conditions resulting in impaired social interaction, difficulty in understanding verbal and non-verbal communication. Caring for children with autism spectrum disorders (ASDs) is challenging for both children and their caregivers. Paediatric autistic population have restricted stereotyped behavioural conditions thus resulting in psychological distress, depression, anxiety and other physical health problems among caregivers. The Autistic spectrum disorder uplifts its effect in the early 2.5-3years and continues thereafter till the child turns to an adult. Moreover, many caregivers face severe financial crises, given high out-of-pocket health care expenses, unemployment. Certain set of researches conducted reported plethora of psychosocial problems affecting caregivers of children with autism, ranging from stress, depression, anxiety, restrictions of activities, strain in marital relationships and diminished physical health. The paper aims to discuss the prevalence of autistic spectrum disorder that is increasing due to altered environmental changes, genetic pre-disposition and inability to maintain regularity in antenatal services. Further more, altered quality of life of the caregivers will also be discussed along with exploration of their concerns while dealing with special children.

Keywords: *Child Development Disorders, Prevalence, Health Related Quality of Life, Caregivers concerns.*

Introduction

Developmental disorder" or "developmental disability" means a severe, chronic disability of the child that is an attribute to a mental or physical impairment, or combination of both which is manifested and is likely to continue indefinitely. Developmental deficits occur in new-borns due to genetic or chromosome abnormalities, exposure to teratogenic substances, alcohol consumption and certain viral infections during the prenatal period.[1] These abnormalities pose a serious threat to the new-born for the coming ages to develop into a normal child who can be able to co-ordinate between his cognitive and affective area of implementation. The child is self-insufficient which presents with the inability to be receptive and unable to reflect the need for a combination and sequence of self-care activities and capacity for independent living.[2] Common developmental disorders in paediatric population are namely Conduct disorders, Autism Spectrum Disorders,Attention Deficit Hyperactive disorder(ADHD) and Expressive language disorder. In pace of Attention Deficit Hyperactive disorder (ADHD), Autism Spectrum disorder is one such developmental condition whose incidence is increasing rapidly across the globe[3].

A study regarding Autism Spectrum Disorders funded by the Center for Disease Control and Prevention (CDC) determined the prevalence of ASD in the United States estimated to be about 11.3 per 1,000 (1 in 88) children. Autism Spectrum Disordersamong all have an increased prevalence among all developmental disorders which affects nearly 20% paediatric population. It is one of the severe form of developmental disabilities which appear in the first three years of life.Autism spectrum disorder is characterized by the persistent deficits in social communication along with social interaction and nonverbal communication behaviour. Caring for the children suffering with autism is challenging and affects the life of the caregivers. Psychological distress, depression, anxiety and other mental or physical health problems are the common symptoms that the caregivers face while caring for an autistic child.In relation to managing the intellectual inabilities and communicational deficits majority of the caregivers face financial issues during the course of treatment[9].

Therefore,parenting in the children suffering with Autistic Spectrum Disorder is different and requires necessary structural or technical modifications in both domestic and social environment. Weiss mentioned that the general experiences of the caregivers of the children suffering with Autistic Spectrum Disorders (developmental disabilities) can be either positive (e.g. joyful and happy feelings) or negative (e.g. stress, burden, sorrow, physical exhaustion, etc.) or could be a combination of both, depending on the severity of autistic cases.

Getting insight to the factors causing stress it is necessary to implement corrective measures to enhance the health related quality of life and will idealize the researcher's concept to explore the caregivers concerns among the children diagnosed with autistic spectrum disorder. Since, caregivers are the first point of contact for the children it is necessary to maintain positivity and self-confidence among them to make them resile through the challenging phase of learning, sensory processing problems, speech disabilities, social interaction and repetitive behaviour as well. It is also important to explore the caregivers concerns that can help the researcher to modify the ways the autistic children gain self-esteem and self-confidence to walk in pace with the society.[14,15]

Need: Autistic spectrum disorder is a developmental disorder characterized by difficulties in social interaction and communication and by restricted or repetitive patterns of thought and behaviour. This restriction in behaviour and thought process of the child poses an emotional threat to the caregivers involved in rendering care and support. Meeting the high care demands of affected children requires much time, effort and patience. This often results in psychological distress, depression, anxiety and other mental or physical health problems among the caregivers.[16]The Autistic spectrum disorder uplifts its effect in the early age of 2.5-3years and continues thereafter till the child turns to an adult. Specific age for the child to promise better way to face the community with confidence is to start the interventions at the age of three years till the child attains specificity in following the commands. Interventions for children with Autistic spectrum disorder require caregivers involvement thus increasing skills, self-efficacy, knowledge of the disorder, and hence reducing family stress. Assessment of health related quality of life can help gain access to the psychological abilities of the caregivers to provide with necessary required interventions and promote on-going learning to the child.[17] Furthermore; it is necessary to maintain well-being of the caregivers as it could positively influence the effect the interventions have on children with Autistic spectrum disorder.[19]

Caregivers involved in parenting children with Autistic spectrum disorder, usually present themselves with feelings of intense anger, guilt, depression or anxiety most of the time.The lower self-esteem among the caregivers deteriorates the spirit and confidence that is essential for the child to uplift self through the deficits of behavioural, psychological and learning capabilities[20].

Review Components:

Prevalence of Autustic Spectrum Disorders and Associated Factors: Supporting an evidence stated by centre for Disease Control and Prevention (CDC) autistic spectrum disorders have jumped a higher prevalence rate since 2014 About 1 in 59 children in the United States have ASD, CDC also generalize the fact that the disorder occur four times more likely in boys than in girls due to genetic related factors.[8] Earlier, autism was considered to be a rare condition with a prevalence of around 2–4 per 10,000 children. Whereas, in the late 90s and continuing the fact upto present 21st century, an annual rise in incidence of autism in pre-school children is based upon the age of diagnosis and increases in the age-specific prevalence rates in children. Centre of disease prevention and control also reported that at present the prevalence rates have a rise of up to 60 per 10,000.[9]

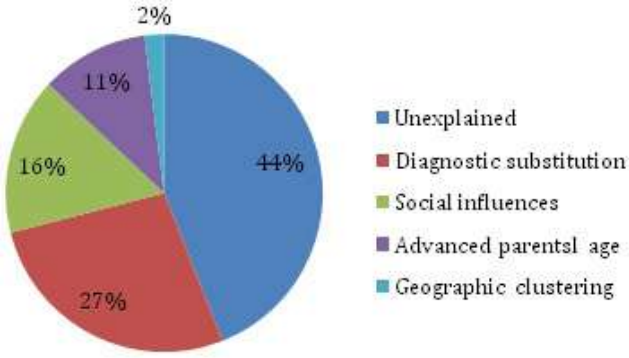

Figure 1: Factors explaining increase in Autistic spectrum disorder prevalence.(Source: Dr. Peter Bearman)[21]

Figure 1 explains the certain factors that have jumped the prevalence rates are changes in the diagnostic criteria, development of the concept of the wide autistic spectrum, different method used in studies, growing awareness and knowledge among parents and

professional workers and the development of specialist services.

Upon a household survey conducted by LR French and KL.Hyde in 2011 it was found that more than 10 million children in India suffer from autism, [11]Moreover, it was found that in India about 1 to 1.5 per cent autistic children are between age group from two and nine years. In order to combat the rising prevalence rates it is the prime responsibility of the health care workers to find out an effective way to impart knowledge to practice monthly ante-natal check-ups till last trimester. In addition to it, L.Wing and D Potter focussed on the need of specific care to be undertaken to strengthen the area of diagnostic investigations and hence management of the disorders based upon speech, behaviour and communication strategies. Strong treatment modalities and health care team can help manage an autistic child effectively and can help him/her to gain livelihood and occupational choices. [12]

Quality of Life- Caregivers: Research evidences from the recent years have reported that the parents of the children suffering with an autistic spectrum disorder usually experience heightened stress, overburden and a sense of self blaming. Getting insight to certain factors causing stress it is necessary to measure the health related quality of life .Since, caregivers are the first point of contact for the children, it is necessary to maintain the feeling of positivity and self-confidence among them. Caring for an autistic child is challenging and needs the devotion to balance learning with the practical aspects form the side of the child.[13]

Sharpley, et al. commented on the three most stressful factors among mothers of autistic child namely (a)concern over the permanency of the condition; (b)poor acceptance of autistic behaviours by society and, often, by other family members; and (c) the very low levels of social support received by parents." Study conducted by KL Hyde revealed the fact that majority of parents of children with autism worry about everything from lifetime dependency to family disharmony.Ciara Padden & Jack E. James in the early 2017 conducted a research study to compare the stress involving Physiological Indicators and Parental Self-Reports. Concludingwith the findings, caregivers of the autistic children reported to experience higher levels of stress and poor physical and psychological health than parents of the normally developing child.

Interesting fact emerged from a research conducted by Ewa pistula and Rafal Kawa in 2015. The study concluded that the parents of children with ASD reported significantly higher levels of parental distress, anxiety, and depression. With the exception that parents of children with ASD had significantly lower cortisol levels 30 min after waking, no other significant group differences were found for physiological measures. Parents of children with ASD reported significantly higher use of a number of adaptive coping strategies (e.g., emotional support) in comparison to parents of the normal children.[15]

After concluding the fact that, Quality of life among the caregivers of an autistic child is low based upon the social, physical and physiological roles, Larsson quoted a prime need to assess the quality of life at the care centres in order to resile the caregivers and hence assure the effective care for the special children thereafter. So, talking about World Health Recommendations, the psycho-educational interventions must be inculcated among caregivers to be capable of handling stress and emotions and hence modifying false beliefs and solving daily problems.[19]

Caregivers Concerns Involved in Management of Autistic Children: Caregivers are the first point of contact involved in care and management of the autistic child. World Health Organization census denotes the fact that about 94% of the caregivers suffer from physical and psychological distress. Various researchers concluded the related fact that the major concerns evolved while caring for an autistic child are inability to compensate the communication loss and social discrimination. The Primary objective of one of the research conducted by Silvia von Kluge was to identify the cognitive and behavioural profiles that actually affected adjustment, among parents of autistic children. Findings of the study revealed that emotion focussed strategies among caregivers experienced the feeling of guilt and false beliefs. Moreover, Caregivers concerns are often described as the areas involved as the challenges during provisional care in managing significant proportion of children with autism spectrum disorder (ASD). Due to the challenging behaviours in children and adolescents suffering with Autistic spectrum disorder often result to underlying social and communication difficulties and comorbid anxiety. Furthermore, the significant difference can be brought if the families of the children with special needs determine the triggers of behavioural problems and then find out the appropriate interventions

to prevent the identified triggers, before the behaviour becomes habitual.[16]

Various researchers qualitatively evolved the basic concerns during the talk exploration with the parents/ caregivers of the autistic children. A research conducted by Fletcher-Watson et al in 2015 concluded that the caregivers also experience repetitive behaviour, difficulty in controlling emotional perspectives, performing group activities and activities of daily living. He also quoted that inability towards brain enhancing activities through continuous efforts are also considered as a major factor of worry for the caregivers. Boyd et al. in 2015 did a research study on exploration of the concerned factors and concluded that the caregivers involved in parenting children with Autistic spectrum disorder, usually present themselves with feelings of intense anger, guilt, depression or anxiety most of the time. Researchers from the health and family welfare highlighted that lower self-esteem among the caregivers deteriorates the spirit and confidence that is essential for the child to uplift self through the deficits of behavioural, psychological and learning capabilities.

Effective Management of an Autistic Child: In various areas of developing countries such as India, the prevalence rates are rising due to lack of appropriate resources and health-care related manpower. Moreover, main drawback stands on the part that India as a whole is not practising the interventions on a daily routine, but implementation is done mainly on Out Patient basis. This stands no longer useful for the child because repetitions in the form of therapies can only be effective if they are given daily on the desired routine. In order to gain effective outcome of the interventions the following process should be followed.[17]The findings laid down by Luke T. Curtis and Kalpana Patelindicated that the maintenance of optimum nutrition during ante-natal period can combat the congenital risk of developing Autistic spectrum disorders and ADHD as the nutritional and environmental factors play major roles in disease occurrence.

Recent research focus on the fact that despite having a diagnostic guideline, still the census falls below the normal in order to follow the appropriate diagnostic criteria. The American Academy of Pediatricsand American Psychological Association recommended an approach to the identification of ASD that involves systematic analysis. Besides routine appointments, the approach calls for formal screening in case thebehaviours of concern are noted during surveillance. If screening, including any caregiver concern, indicates cause for an attention, this is to be followed by the formal diagnostic assessment thereafter. Lack of appropriate manpower, resources and standardized cognitive and developmental testing are leading to slower management process related to autistic spectrum disorder. As per the American Academy of Pediatrcs guidelines following steps need to be undertaken to ensure the early diagnostics of Autism:

- Strengthening areas of Genetic counselling.
- Systematic diagnostic evaluation to rule out the cause of autistic spectrum disorder.
- Start the occupational therapy (Speech+behaviour+symptomatic) by the age of 3 years.
- Routine follow-up visits as per psychologist's advice.
- Evaluation of every visit.
- Assessment of risk factors- Genetic predisposition.

Conclusion

Autistic Spectrum Disorder ranges in severity from a handicap that somewhat limits an otherwise normal life to a devastating disability that may require an appropriate institutional care. It involves various impairments such as social interactions, verbal and nonverbal communication.[18] Children with an Autistic spectrum disorder have certain restricted behavioural functions, such as stereotype behaviour, inability to adjust to new situations and experience severe tantrums or sleep problems.[20] A research study carried out by AP Hill,K P. Zuckerman supported the evidence that about 47%

of the parents deny about being their child to be autistic. Furthermore, parents of children with autistic spectrum disorder experience heightened stress, overburden and sense of self blame. Since, caregivers are the first point of contact for the children getting insight to the factors that are causing stress is of utmost necessity to measure the health related quality of life Thus,conclusion can be made out by improvising strategies towards the management of developmental deficits necessarily to strengthen the child's capabilities and parental coping comprehensively.[21]

Effectiveness of a Comprehensive Nurse-Patient Strategy in Care of Patients with PIVC and its Clinical Outcomes

Mathew Romeo[1], B. Sulochana[2], Nayak Malathi G.[3]

[1]M.Sc. Nursing Student, [2]Associate Professor, Fundamental Nursing Department, [3]Associate Professor in Community Health Nursing, Department, Manipal College of Nursing, Manipal Academy of Higher Education, Manipal, Karnataka, India

Abstract

Introduction: Peripheral Intra-Venous Cannulation (PIVC) is the second most common invasive procedure performed on in-patients, with an estimated 80% of patients requiring a peripheral cannula and about 69% of PIVC insertions were failed due to occlusion, infiltration, phlebitis and dislodgement.

Aims: To assess the effectiveness of a comprehensive nurse-patient strategy in the care of PIVCs on clinical outcome.

Materials and Method: A quasi-experimental, post-test-only design was used. 30 subjects from each groups, i.e experimental and control group, were observed for development of PIVC complications. Education was provided to nurses and patients in the experimental group regarding how to prevent the early removal of PIVCs. The obtained data were analyzed and interpreted using descriptive and inferential statistics to compare the clinical outcomes among the groups.

Result: The results shows that there is significant difference was observed in duration of PIVCs. Among the experimental group, after implementation of the Nurse-Patient Strategy, 66.66% of the PIVCs stayed more than three days (72 hours) whereas in the control group it was 40%. The pain and swelling were mostly observed complications in PIVC.

Conclusion: A comprehensive nurse-patient strategy has proved effective to increase the practice of flushing PIVCs, which in turn improves their indwelling period.

Keywords: *Infusion, education, thrombosis, duration.*

Introduction

Peripheral Intra - Venous Cannulation (PIVC) is the most common invasive procedure performed on patients who are admitted to hospital, which is the second most requiring procedure during their hospital stay[1]. PIVCs increasingly used to save the life of the patients during emergency conditions[2]. These devices may need to be left in place for days or even weeks; however, it can be associated with complications. Mechanical complications include phlebitis, occlusion, thrombosis, dislodgement, leakage, infiltration, pain and scar formation[3,4,5,6,7]. PIVC failure rates have been reported as high as 69% and occlusion was observed as the least common complication (0.5%)[8].

The identified predictors of phlebitis were females, insertion in the forearm and infusion of medication[9]. Even though it is an invasive procedure, technically difficult, more prevalent; the most nursing professionals in developing country are not been skilled and receive

little education and opportunity to practice skills until competent [10]. There is very scare and little evidence of PIVC insertion, maintenance and removal in country like India.

Methodology

A quasi-experimental, post-test-only design was used to assess the effectiveness of a comprehensive nurse-patient strategy in the care of Peripheral Intra-Venous Catheters (PIVCs) in terms of duration and insertion of I V Catheters at a tertiary care hospital. A total of thirty patients from each of two groups, i.e the experimental and the control group, were observed for development of PIVC complications. Education was provided to nurses and the patients in the experimental group regarding how to prevent the early removal of PIVCs. Sample size was calculated based on the pilot study by using formula: $N = 2*(Z\ 1- \alpha/2+Z1-\beta)2*\sigma2/d2$ (Comparing two means) [11] and it was found 30 in each group. Afterinstitutional ethics approval data collection was done through observation which began after the implementation of the comprehensive nurse-patient strategy among the experimental group. Thirty patients from the surgical and medical ward were taken by simple random sampling technique for each control and experimental group. Patients who were undergoing PIVC insertion on the upper extremities, between 18 and 65 years of age were included in the study. The patients who receive blood transfusion, parenteral nutrition, chemotherapy; or contrast media (dye); diagnosed with peripheral vascular diseases and already inserted PIVC patients were excluded.

The nurses were assessed for their existing practices through a checklist which covers the areas on IV insertion, maintenance and removal of PIVC. The comprehensive nurse-patient strategy was employed to nurses who were in the experimental group and were as control group received the standard care. The recruited patients who had undergone PIVC procedure were educated in the patient strategy before undergoing PIVC insertion. The event of insertion and removal of PIVC in every participantwere observed. The indwelling period was calculated in hours from the time of PIVC insertion until removal. Care of the PIVC (flushing practice) was observed during drug administration through the PIVC. Flushing before and after drug administration was observed and documented with additional details of the solution used for flushing, the reason for not flushing and visible contamination of the PIVC insertion site.

The description of the comprehensive nurse - patient strategy intervention is given below:

Comprehensive nurse-patient strategy was operationally defined as education including practice skills in PIVC insertion, maintenance and removal to nurses and instruction on PIVC maintenance practices to the patients who require venepuncture with cannula placement. Comprehensive nurse-patient strategy was developed based on literature review [2,4,10] and suggestions from experts; which consisted strategy for nurses and patients. A strategy was accomplished in the form of educational intervention to the nurses in the clinical setting as group discussion and demonstration of practice skills in the skill lab and at the clinical area in real time. Prior to the intervention a need assessment was carried out to understand the context, the need for improvement and existing information on PIVC care. Regarding patient strategy, the practices considered were movement and position of the limb, cleanliness, care of the extension line and complications and at the end a pamphlet was provided to the patients after the instructions.

The obtained data were analysed by using the SPSS package version 16 and were interpreted by using descriptive and inferential statistics on the basis of the objectives and hypotheses of the study.

Results

The data were collected from 60 subjects (30 in the control and 30 in the experimental group). The data shows that 17 (57%) of the patients were in the 51-65 age group in both the control and the experimental group. Males predominated in both groups, with 27 (90%) in the control group and 22 (73%) in experimental group. Most of the patients, i.e., 12 (40%) in the experimental group and 17 (57%) in the control group, had an education up to high school. The data obtained by observation during the insertion of the PIVC show that the majority of the PIVC insertions in the experimental 29 (97%) and the control group 27 (90%) were performed with a 20G cannula. The vein selected among the experimental group was mostly the cephalic vein 14 (47%), whereas 40% in the control group. The type of adhesive used to secure the PIVC was mostly non-transparent in both the experimental 29 (97%) and the control 30 (100%) group. The connectors used among the experimental were mostly 3-way i.e by19 (63%), whereas 80% of them used in the control group (Table 1).

PIVC maintenance practices were observed, specifically flushing practices during and after drug administration. In the experimental group 16 (53%) and in control group only 3 (10%) IV cannula flushing practices were observed. Coming to noncompliance to the practice of IV cannula flashing before 14 (47%), after 18 (60%) in experimental group and in control group majority 27(80%) were not complaint with flashing practises. The main reason reported for non-compliance in flushing before and after drug administration was ignorance 27(80%) by the groups. (Table 2). Clinical outcomes were reported by the patients were pain and swelling in both the experimental and the control group (Fig.1). The duration of the time of IV cannula insitu was observed in 20 (67%) patients and it was in place longer than 3 days (72 hours), whereas in the control group for 12(40%) remained longer than 3 days. Further to this a statistically significant difference between the groups ($t_{(58)}$=4.245, P<0.05) was observed on indwelling period. Comparison of flushing practices among the groups was statistically shown difference in flushing practices before drug administration between the groups (χ^2=13.01, P<0.05)and after drug administration between the groups (χ^2=19.20, P<0.05). (Table 3).

Discussion

In the present study, patients who underwent PIVC insertion in the cephalicvein were observed to have a longer indwelling period with a 10-cm extension than those who underwent PIVC insertion in the dorsal venous arch. No other studies could be identified that compared a 10-cm extension with a 3-way connector for PIVCs. The complications observed in the study at the time of PIVC removal were pain and swelling and the appropriate selection of vein is one of the key indicator for longer indwelling period and which supplemented by implementation of nurse patient strategy.

These findings were supported by an experimental study conducted in Queens land, Australia, which found that phlebitis occurred in 7% of patients from each group, while occlusion, accidental removal and other

complications were equivalent between the routine and clinically indicated PIVC removal groups [12]. Other few studies were done to assess the incidence and predictors of PIVC-induced complications. The top observed complication were phlebitis (17.6%) followed by pain (7.6%), and occlusion among all patients (0.5%) [13,14,15,16].

In the present study, the onset of phlebitis was found to be deferred in the experimental group (36.66% within 72 hours and 63.3% after 72 hours of PIVC insertion) compared to the control group (76.6% within 72 hours and 23.3% after 72 hours of PIVC insertion). These findings were supported by a study results, where the incidence of phlebitis was 11.09% and patients who had PIVCs in an upper limb were at high risk of phlebitis. Further study results recommended that the correct selection of PIVC sites is an important factor in the prevention of phlebitis [17,18,19].

When considering the study limitation the researcher could not ensure the use of transparent dressings to secure PIVCs, though it was part of the nurse education strategy, owing to non-availability due to the cost in the pharmacy stores. This study sheds light on infusion safety and the routine PIVC changing protocols that exist in various hospitals around the world. It shows that a combined educational strategy can improve the indwelling period and care of PIVCs. Thus, it is recommended that the nurse-patient strategy be implemented for PIVCs to ensure fewer complications and longer indwelling periods. The developed strategy should be used by nurses in general and specifically with the selected patients for better outcomes of PIVC. It reinforces the knowledge acquired by nurses during their training and adds to the weight of a continuous nursing education. Nurse administrators can arrange training similar to this strategy where PIVC-related problems are prevalent and can update policies related to PIVC removal and replacement.

The study results recommended improved insertion techniques to reduce the incidence of PIVC associated complications, thus extending the onset of such complications beyond 72 hours[6]. The predictors for PIVC failure are studied in greater perspective [2,5,20,21]. The practices related to the periodic replacement of PIVCs are still not clear and there is a weak evidence from developing country. There is a need to train the nurses to improve the practices [10,17, 22].This study demonstrated improvement in skill of nurses and patient outcome from putting into practice the comprehensive nurse-patient strategy in clinical nursing care. The Peripheral Intra-Venous Catheter (PIVC) insertion poses a challenge for nurses in clinical practice. The evidence contributes the literature which should be considered to improve the patient care outcome on PIVC maintenance. Comprehensive nurse – patient strategy will facilitate nurses abilities in PIVC management and further improves clinical outcomes and patient satisfaction. Ongoing education to the clinical nurse, patient/family will enhance the standard of care and improve the outcome.

Conclusion

Pain associated with PIVCs is a common problem in hospitals around the world. A comprehensive nurse-patient strategy has proved effective to increase the practice of flushing PIVCs, which in turn improves their indwelling period. This study suggests that the selection of the cephalic vein for PIVC insertion also may increase the indwelling period.

Healthcare Rights of the Mentally Ill: Awareness among Healthcare Providers

Melisha Nichol Lobo[1], Sweta D'Cunha[2], Sucharitha Suresh[2]

[1]PG Student, [2]Professor, Department of Hospital Administration, Father Muller Medical College, Mangalore

Abstract

Background: Enjoyment of the human right to health is vital to all aspects of a person's life and well-being. Since the origin of human civilization, mentally ill patients have received the scant amount of care and concern for the community. For centuries, as a result of this, the rights of mentally ill have been abused and ignored. Psychiatric hospitals, informal healing centre and family homes reported that low- income countries neglect the mentally ill patient. Various initiatives exemplify a top down approach to promoting human rights which historically has had limited impact at the level of those living with mental illness and their families. Human rights are an important component for effectiveness in care. The health caregivers and the medical and nursing interns must know the rights of a mentally ill person; and should support, protect and meet their health needs. So, there is need to know whether the health caregivers are aware of the human rights of the patients who are mentally ill.

Objectives: To assess the awareness regarding the Healthcare Rights and General rights of the mentally ill among health care providers.

Method: The study was conducted in a medical college and hospital in Mangalore. The Survey method was used to collect the data. The study population was professionals and medical and nursing interns taking care of mentally ill. The Sample size was 154. Purposive sampling technique was used. The data were collected using structured questionnaires after which it was analysed using frequency, percentage, chi-square test, fishers exact test.

Result and Conclusions: Results show moderate awareness. Hence, it is recommended that the health care providers should be given more awareness regarding the human rights of the mentally ill.

Keywords: *Healthcare rights, healthcare providers, mentally ill, awareness.*

Introduction

Mental disorders represent four of the ten leading causes of disability worldwide[1]. People with mental illness may be experiencing a wide range of human rights violations[2]. The majority of the mentally ill may be excluded from community life and denied basic rights such as shelter, food and clothing. This could be due to stigma and misconceptions associated with mental illness[3]. Mentally ill are also discriminated against in the field of employment, education and housing[4].

The United Nations has defined Human Rights as "Those rights which are inherent in our nature and without which we cannot live as human beings"[5]. People with mental disorders are particularly vulnerable to abuse and violation of their rights. If a protective mechanism is not in place, they are susceptible to abuse by society, which includes family members, caregivers, professionals, friends, fellow citizen etc.[6]. Human rights are also connected to mental health in two distinct ways as mental health policy affects human rights

and human rights violations affects mental health[7]. Therefore, positive promotion of mental health laws and human rights are an essential means of promoting and protecting their rights. Despite this, countries all over the world fail to legislate effectively[8]. Indeed, it is important to improve the quality of life and mutually reinforce one on another.

The Constitution of India assures equal treatment and equality of opportunity and status to all the citizens. Every person with a mental illness has the same basic rights as every other person, specifically including the rights set out in the International Covenant on Civil and Political Rights (ICCPR) and the rights recognized in the Declaration on the Rights of Disabled Persons; that discrimination on the basis of mental illness is not permitted and that people being treated for a mental illness must be accorded the right to recognition as a person before the law[9]. Despite the adequate legislations, we often come across horrendous stories about the way people with mental illness are treated in the community and various psychiatric institutions[10]. As evident by the National Human Rights Commission report[11]which highlighted the gross inadequacies and subhuman living conditions in mental hospitals. Furthermore, India's dismal record of rights violations of the mentally ill was glaringly exposed with the grotesque death of 25 patients at an "asylum" in Tamil Nadu[12]. The lack of human rights or their violations, as seen in the Erwadi tragedy and similar cases, does not stem from a shortcoming in existing Indian or international law per se; but is the result of social stigma, prejudice, and other social and economic factors linked with mental illness[13].

Many countries are facing challenges regarding the adequacy of human resource which is needed in delivering evidenced based care for mentally ill.At present, human resources for mental health in countries of low and middle income show a serious shortfall that is likely to grow unless effective steps are taken. It proved that through primary health care setting, community-based protocols and task based approaches stand the best way in delivering mental health care.Non-specialist health professionals, lay workers, affected individuals, and caregivers with brief training and appropriate supervision by mental health specialists are able to detect, diagnose, treat, and monitor individuals with mental disorders and reduce caregiver burden [14].

Lack of knowledge and awareness among the students is associated with the negative attitudes towards mental illness in the community. Medical health professionals have to conduct awareness camps at initiative levels like schools, universities. Educating the students at the training level leads to the change in the attitude of the students towards the mental patients[15]. A study assessing the students attitude on stigma towards the mentally ill showed that the attitude was poor towards the mentally ill. They suggested that the improvement in the role of teachers in educating their students regarding the mental health is important in building up the attitude of students towards the mentally ill[16]. Information regarding the rights of the mentally ill is disseminated by mental health professionals and mass media. The society can be misguided when the information delivered to them through the healthcare professionals and the mass media is inadequate. Supporting this fact, a study was conducted to assess the knowledge about human rights of the mentally ill among the mental health professionals and the health journalists, which showed through both the groups have good knowledge about the human right of persons with mental illness (approximately 86.3% right responses); there was a trend towards Mental Health Professionals(MHP) having better knowledge compared to Health journalists(HJ)[17].

The human right frameworks have both normative and legal backing and have substantial overlapping with medical ethics. Being inclusive in all the aspects of mental health care, human rights have provided a base to the guidance in the care of mentally ill patients eliminating the past indifferences regarding the worth and dignity of the mentally ill patients[18]. There has been a dynamic relationship between the concept of mental illness, the treatment of the mentally ill and the law. The mental health professional especially nurses should know the basic legal and ethical aspects of psychiatry. The descriptive study was thus undertaken with the objective to identify the knowledge of the staff nurses regarding legal and ethical responsibilities in the field of psychiatric nursing at selected psychiatric centre. The findings of the study revealed that majority (90%) of the nurses possess a moderate level of knowledge[19].

Therefore, it is an urgent need to take necessary steps to protect, promote and fulfil human rights of people with mental illness through providing care, education to the community and strengthening the legislations. Hence this study was conducted with a twofold objective ofassessing the awareness regarding healthcare rights of mentally ill and general rights of the mentally ill among healthcare providers.

Methodology

The present study was a cross sectional based descriptive study. All the professionals taking care of mentally ill and medical and nursing interns who were undergoing training to care for mentally ill were taken as the subjects for the study from a medical college and hospital in Mangalore for a period of One-month study. Data from the subjects was obtained by a structured questionnaire in a medical college and hospital Mangalore. The sample size included the doctors, staff nurses, medical interns, nursing interns and clinical counsellors from the medical college and hospital. A total of 154 samples were included in the study, ethical clearance was taken from the institutional ethics committee before starting the study. After obtaining the consent from the subjects, the data was collected using a structured questionnaire, the questionnaire was adapted and modified from the study of Yang, 2013[20] which included the demographic factors, awareness and human rights of mentally ill. The data thus obtained was compiled and tabulated using frequency, percentage along with the use of SPSS software.

Results and Discussion

The questionnaire was distributed among the 154 selected samples of the study. Those consenting to participate were taken for the data collection. The questionnaire was administered in an anonymous form and no identifiable information was collected from the participants. Conditions of anonymity and confidentiality were observed throughout the course of the study.

The majority of the sample were females than males with an age <30 years. Educational background was also considered in the study in which it was found that the medical and nursing interns were in the majority of 67.5% and also it was observed that they didn't have much experience in the care of the mentally ill. The respondents being in the early stage of their healthcare profession and working in a general hospital with psychiatric set up emphasise on the need for inclusion of mental health in their curriculum and training.

Insert Fig 1: Section 1: This section was about the awareness regarding the healthcare rights of mentally ill. The association between demographics and healthcare rights is also presented below.

Healthcare professionals have high awareness regarding seclusion and restraint (87.2%) followed by treatment and planning (82.6%) and moderate awareness regarding occupational therapy (78.1%) followed by social responsibility (74.6%) and admission and discharge (51.3%) and have low awareness regarding privacy (37.65%). The findings are not in accordance to a study in Bangalore[21] which revealed that awareness regarding seclusion and restraint was 70% (less than present study)and privacy was 44% (more than present study).

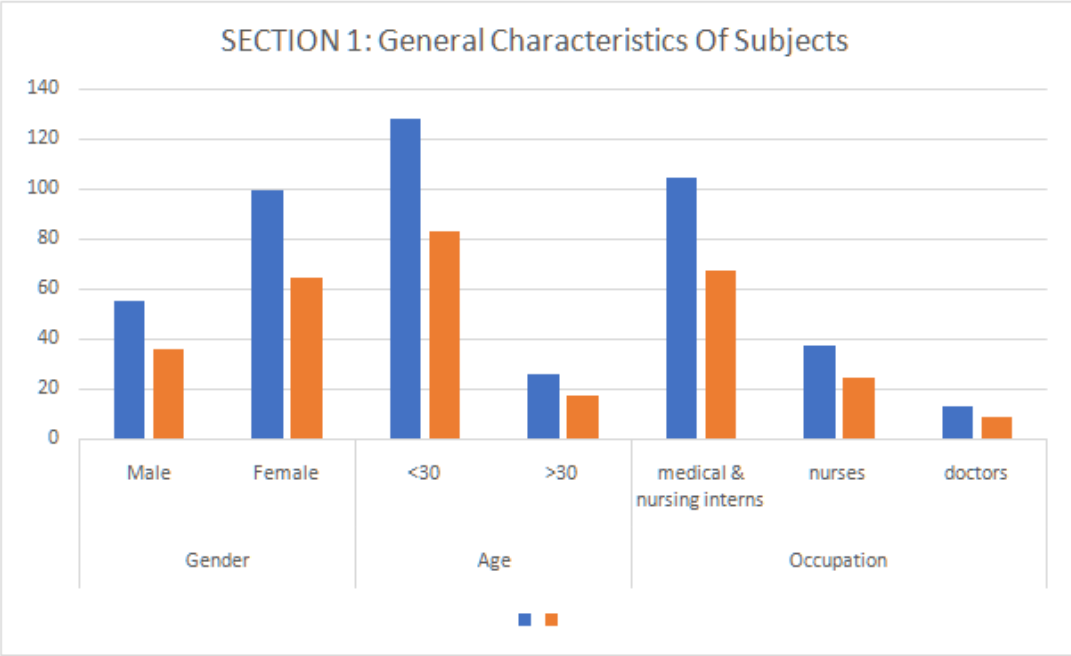
Insert Table 1: Table 1 shows that there is no significant difference between occupation and awareness of healthcare rights ($p=0.3 >0.05$). There is a significant difference between age and awareness ($p=0.004<0.05$). This indicates that the awareness among age <30 was good (65.6%) than above 30years. Younger individuals had more awareness and it could be due to more media exposure by the younger generation. There is a significant difference between gender and awareness of healthcare rights ($p=0.18 <0.05$). This indicates that the awareness among female (65.7%) was good compared to males. These findings do not coincide with the study by Ananthapriya, 2014 where results revealed that male caregivers had relatively more awareness than the female caregivers. The findings of this study coincide with study conducted among the ayurvedic doctors revealed that among 30, majority of participants i.e. 25 were not aware of the rights of mentally ill person only 2 of them are having highly adequate level of knowledge (Nagarajaiah & Vijiayarani, 2009)[22].

Section 2: The respondents were assessed on their awareness regarding the general rights of the mentally ill. The association between demographics and awareness is also presented below.

The respondents had 65.09% of awareness of the existing human rights for the mentally ill in place and this also is seen in contrast with the studies by Jagannathan and Rao, 2015 whose results showed though knowledge was satisfactory, it was not comprehensive enough to propagate it to others. Mainly in the domains like personal needs, communication, hospital stay and violation practices needed to be improved.

Insert Table 2: The above table shows that there is no significant difference between age and awareness of general rights ($p=0.5 >0.05$); gender and awareness of general rights ($p=0.1 >0.05$). There is a significant difference between occupation and awareness ($p=0.00 <0.05$). This indicates that the awareness among doctors

was good (84.6%) than nurses, medical and nursing interns. In relation to this finding a study conducted on nurses in Karad, by Chendake et.al,[23] showed that 85% of the nursing students had average knowledge and 15% had poor knowledge regarding the human rights of mentally ill.



(blue: count, red: %)

Fig 1: General Characteristics of Subjects

Table 1: Association of demographics with awareness of healthcare rights of mentally ill

Demographic variables		Awareness of healthcare rights of mentally ill			
		Poor	Moderate	Good	
Occupation	Medical & Nursing interns	6.7%	31.7%	61.5%	Fisher's Exact test p=0.300
	Nurses	0.0%	35.1%	64.9%	
	Doctors	0.0%	53.8%	46.2%	
Age	<30	5.5%	28.9%	65.6%	Chi square test p=0.004
	>30	0.0%	61.5%	38.5%	
Gender	Male	10.9%	36.4%	52.7%	Fisher's Exact test p=0.018
	Female	1.0%	33.3%	65.7%	

Table 2: Association between demographics & awareness of general rights of mentally ill

Demographic variables		Awareness of rights of mentally ill			
		Poor	Moderate	Good	
Occupation	Medical & Nursing interns	7.7%	57.7%	34.6%	Fisher's Exact test p=0.00
	Nurses	13.5%	78.4%	8.1%	
	Doctors	0.0%	15.4%	84.6%	
Age	<30	8.6%	60.9%	30.5%	Chi square test p=0.532
	>30	7.7%	50.0%	42.3%	
Gender	Male	9.1%	49.1%	41.8%	Chi square test p=0.149
	Female	8.1%	64.6%	27.3%	

Conclusion

This study emphasis on educating the healthcare providers about human rights of mentally ill by investigating the awareness of human rights among them. As per the study findings. the level of awareness of the different aspects pertaining to the human rights of mentally ill was less than 80%. Indeed, there is a strong need to educate the healthcare professionals by conducting training programs about the human rights of mentally ill and their protection. So, that the stigma towards the mentally ill from the society can be removed with making it even more imperative to treat all humans equally regardless of the disease condition.

Added Effect of Deep Breathing and Diaphragmatic Breathing Exercise in Upper Abdominal Surgery Patients: A Randomised Clinical Trial

Mistry Nirali[1], Saumya Srivastava[2]

[1]Post Graduate Student, [2]Assistant Professor, NITTE Institute of Physiotherapy, Derlakatte, Mangalore, Karnataka, India

Abstract

"Added Effect of Deep Breathing and Diaphragmatic Breathing Exercise in Upper Abdominal Surgery Patients: A Randomised Clinical Trial"

Background: PPC complication like at elect as is, reduced lung capacity, secretions, etc. are the most common complications seen in the patients undergoing upper abdominal surgery patients. Literature suggests that deep breathing and diaphragmatic breathing exercise is effective in reducing these complications.

Aim: To evaluate the added effect of deep breathing and diaphragmatic breathing exercise in upper abdominal surgery patients.

Method/Design: Thirty six patients with upper abdominal surgery were randomised into 3 groups by block randomization opaque sealed envelope method. Group A, B and C were given diaphragmatic breathing, deep breathing and combined deep and diaphragmatic breathing exercises respectively. Outcomes were taken on post-operative day 2 and day 7 for pulmonary function test (FVC, FEV1), chest expansion measurement with inch tape, and AMPAC6-click scale.

Results: Between the groups analysis using ANOVA showed that there was no significant difference between the groups in pre-and post-values (>0.05). Within the group analysis using paired t- test showed a significant difference ($p<0.05$) in the pre-and post-vales of chest expansion measurement and AMPAC scale but not in pulmonary function test.

Conclusion: We concluded that combine application of diaphragmatic breathing and deep breathing exercise did not yield a statistically significant improvement but diaphragmatic breathing and the deep breathing exercise can be given individually. This gave a significant improvement in the post-operative pulmonary complication in the upper abdominal surgery.

Introduction

Globally 234 million patients undergo surgery yearly. [1-3] The world bank in 2002 reported 164 million disability-adjusted life years, out of which 11% disease has to be treated surgically. Surgery is performed in all aspects of the body. [2,4] "Surgical removal of mass or masses from the abdomen by the abdominal incision is called as laparotomy." [1] Exploratory laparotomy is a method of opening of the abdominal cavity and

examining of its contents, for example, to obtain a source of bleeding or injury, etc.[1]

Post- operative pulmonary complication (PPCs) can be defined as "pulmonary abnormalities occurring in the post- operative period, producing clinically significant identifiable disease and dysfunction that adversely affect the clinical course." [1,5]Incidence of PPC is 35%. General anaesthesia directly affect the respiratory system causing PPC.[6-8]Itcauses temporary Phrenic nerve dysfunctions[9] and shallow monotonous breathing pattern.Which will decrease in ventilation in the lower zone of the lungs. [5]The incision pain further reduces the ventilation.[4] All these factors will contribute to impaired respiratory function, exacerbate mucociliary clearance, depresses cough reflexes thus causing secretion retention resulting in atelectasis, which will lead to reduced lung functions and lung volumes.[7,8,10]

Breathing exercise is defined as "the therapeutic intervention by which purposeful alteration of a given breathing pattern is categorized as breathing exercises outcomes." Different techniques of treatments were percussion, clapping, vibration, diaphragmatic breathing exercise, incentive spirometry and so on. They include different forms of breathing exercise like diaphragmatic breathing exercise, deep breathing exercise (DBE), ACBT, etc. [9-13]

Anaesthesia will significantly reduce vital capacity, the expiratory flow rate which will lead to decrease pulmonary reserve. Thus, Diaphragmatic breathing is used to regulate the movement of the diaphragm while inhalation and exhalation [14]causing reduction in work of breathing, improve alveolar ventilation, improve airway clearance by improving cough and also improves the strength of the respiratory muscle. An RCT study done by Alaparthi GK et al. found that volume IS and diaphragmatic breathing exercise can be given as an intervention for all patients in the management of laparoscopic abdominal surgery. [11]

Thoren et al. conducted the first study showing the effects of DBE on PPC in abdominal surgery patients. DBE with end-inspiration hold concentrates on reducing atelectasis, increases lung volume and facilitates secretion elimination and improving the gaseous exchange.[15] Slow inspiration helps in improving basal ventilation by proper distributions of air to the lower lobes of the lungs, end inspiration hold for 2-6 sec may help to reduce airway collapse and revert atelectasis.[16,17]

From the literature, as mentioned earlier, it is clear that the conclusion of these studies has been conflicting, and this may contribute to a varied pattern of practices and the use of breathing exercise for the patient with upper abdominal surgery. Hence there is a scarcity of literature on the combined effect of diaphragmatic breathing and DBE. Therefore, this study has been taken up to find out the combined effect of diaphragmatic breathing and DBE on upper abdominal surgery patients.

Materials and Method

Current study was a prospective randomised clinical trial carried out in the Surgery department of Tertiary Hospital of India between May 2018 to April 2019. Thirty-six patients, 23 males and 13 females undergone upper abdominal surgery were recruited. After obtaining the ethical clearance from the Institutional Ethical Committee (figure 1), the trial was registered in the Clinical Trial Registry of India (CTRI/2018/06/014443) and an informed consent was taken from the patients. Patients who were above the age of 18 years, undergoing any upper abdominal surgery were included with VAS score <5**,** no previous history of cardiac and pulmonary complications and non-obese individual (body mass index > 27 kg/m^2). The patients were excluded if they have hemodynamic instability, required ICU care for more than 48 hours**,** require mechanical ventilation.

Procedure: The patient allotment was done by block randomisation with opaque sealed envelope method into 3 groups Group A, Group B, Group C.

- **Group A** was given diaphragmatic breathing
- **Group B** was given DBE
- **Group C** was given the combine of both

All the groups were given 4-6 cycles of the breathing exercise per hourly for 8 working hours a day for 7 days of the week and early mobilisation exercises which included ankle toe movements, heel slides, bed side sitting, ambulation and stair climbing. [11]

Outcome: Blinded assessor took the outcome measures pre-treatment on POD 2 and post treatment on POD 7. The outcome measures were pulmonary function test (PFT) values forced vital capacity (FVC) and forced expiratory volume at first sec (FEV1). The FVC evaluate the vital capacity of the lungs on forceful expiration and FEV1 will help to evaluate the volume of air breath out during the first second of the expiration, [18] chest

expansion measurement with inch tape for upper lobe at axillary level, middle lobe at 4th intercostal and xiphoid process for lower lobe, [1] Activity Measure for Post-Acute Care (AM-PAC) "6-Clicks". It has 2 short forms

- Inpatient Daily Activity Short Form
- Inpatient Basic Mobility Short Forms.

It measures 2 functional domains that are essential mobility, daily activities. [19]

Statistical Analysis: Statistical analyses were performed using SPSS version 16.0. The test of ANOVA was used to compare pre-test and post-test values of the outcome measures for between the group analysis. Within the group analysis was performed using paired t-test. The p value < 0.05 was considered to be statistically significant.

Results

There was no significant difference ($p > 0.05$) seen in all three groups when they were analysed for the baseline data (Table 1) which showed that the groups were homogeneous.

When all the three outcome measures pre-and post-values were compared for between the groups analysis, there was no significant improvement seen between the groups. All the groups showed equally better improvement which was observed when intergroup comparison was performed (Table 2).

On comparison of within the group analysis of each group showed statistically significant improvement in the chest expansion measurement and the AMPAC scale ($p<0.05$). But there was no improvement observed in the pulmonary function test outcome (Table 3).

Discussion

This randomised clinical trial was designed to evaluate the added effect of deep breathing and diaphragmatic breathing exercise in the upper abdominal surgery patients. Between the group analysis showed no significant difference. These findings were rationalised by a systematic review and meta-analysis done by T. Samantha et al.[8] Different studies evaluated the outcome measures which included pulmonary function test values. On analysing their between the group comparison showed no difference in 3 studies, 2 studies showed improvement in only few of the parameters out of 6. The FVC values only showed significant improvement. The possible reason given by the author is the methodological limitation, lack of well-defined studies which hindered their results. Another systematic review by Pasquina P. et al. [9] included 35 trials, out of which 13 trials gave no intervention to the control group from which 9 studies did not show significant difference between the groups in PFT. This study states an unclear use of PFT and also no evidence of improvement in their parameters with any of the tested physiotherapy treatment.

In the present study, there was no significant improvement found in the PFT when within the group analysis was done. This finding correlates with the findings of the Manzano RM. et al.[7] who evaluated the PFT values and found no significant difference in the groups suggesting that the results were not achieving because the patients were not able to produce the best or even moderate efforts to fulfil their pulmonary capacity and produce maximum forced expiration and the post-operative pain in the suture site which hinders them to breathe to their maximum capacity.

A RCT done by Alaparthi GK.et al.[11] proved controversial where 260 patients were randomised into 4 groups. The outcome measures used were PFT, diaphragm excursion with ultrasound. The FVC, FEV1, PEFR and diaphragm excursion within the groups showed a significant improvement in all the groups and on between the group comparison, diaphragm excursion and FVC showed less significant difference than the control group. The possible reason for the decrease is the post-operative pain, the anaesthesia and analgesic usage. This improvement was visible in the present study when diaphragmatic breathing exercise was given individually to the patients.

Another study done by Tripathi S. et al. [17] showed a significant improvement in the respiratory rate and values of the PFT. The practice of the deep breathing exercise increases the lungs capacity which was depicted by the results in the study. The result of the current study is in accordance with the study stated above when individual DBE was given and showed significant improvement.

Conclusion

From the study conducted we draw a conclusion that the breathing exercise like diaphragmatic breathing and DBE can be given individually with the conventional early mobilisation technique. This will yield a significant improvement in the post-operative pulmonary complication following the upper abdominal surgery.

A Review Study on Pharmaceutical Inventory Management & Store Keeping Practices of Pharmacy in Rural Hospitals

Monalisa Debbarma[1], Usha Rani[2]

[1]MHA Student, [2]Assistant Professor, MHA Program, PSPH, Manipal Academy of Higher, Education, Udupi, Karnataka, India

Abstract

Background: In pharmacy operations, inventory is referred to as the stock of pharmaceutical products retained to meet future demand. Inventory represents the largest asset in pharmacy practice, and its value continues to rise because of the growth in variety and cost pharmaceutical products. From both financial and operational perspectives, efficient inventory management plays a great role in pharmacy practice.

Ensuring medicines availability is an important goal for health system as medicines are an important building block in the health system. Essential medicines are defined by the WHO as those medicines which respond to the most pertinent health needs of a population. These medicines are the foundation for most public health programmes that are aimed at reducing morbidity and mortality. WHO states that essential medicines should be available at all times. The consequences of medicine unavailability are widespread and can have detrimental effects on individual and public. Unplanned treatment interruptions could lead to an increase in resistance for example to antimicrobials and antivirals which can have the ripple effect of switching to more costly treatment and interventions. Patients may have to travel to alternative facilities including the private sector facilities to source medicines. This may be costly and becomes a barrier to accessing medicines. Therefore to ensure uninterrupted availability of medicines, inventory management system of medicines has been upgraded from paper based to computer and web-based system.

Keywords: *Inventory control, Pharmacy security, Drug procurement, Inventory management, Drug tracking, Drug storage, ABC and VED.*

Introduction

Pharmacy inventory management is a complex but critical process within the healthcare delivery system. Without adequate pharmacy inventory management practices, hospitals run the risk of not being able to provide patients with the most appropriate medication when it is most needed. Additionally, pharmacies dispensing patterns and drug selection choices may have a direct effect on the affordability of care[1]. In addition to patient safety & financial considerations, stringent regulatory requirements pertaining to drug traceability, inventory management elevate the importance of maintaining effective control over drug inventories in today's ever expanding healthcare compliance environment. Pharmacies can control a number of factors within the pharmacy inventory management & pharmacy revenue cycles that can support better outcomes for patients and enhance the bottom line for facilities. This provides perspectives on leading practices & internal controls pertaining to :- procurement, tracking system, traceability, storage, disposal of drugs etc.[3]. These control mechanisms can provide a basis for consistent quality,better financial performance & improved regulatory compliance when implemented appropriately and adhered to during day-to-day operations.

Pharmacy Revenue Cycle: It typically includes the following areas: pharmacy purchasing data, dispensing transactions, charge description master(CDM), pharmacy charges & patient billing. The amount of inventory a pharmacy carries may have a significant financial impact given that a drug resting in inventory has minimal payment(reimbursement value until it is dispensed. Mismanagement & discarding of expired medications has a potentially costly impact . An inventory tracking system that interfaces appropriately with the billing system facilitates an effective pharmacy revenue cycle & revenue integrity program[5].

Pharmacy Security: A pharmacological as well as the location of the drugs it houses should be restricted through physical access controls.Entrances to pharmacies should now be restricted by either badge access readers or biometric readers. Individuals who are able to enter the pharmacy should be limited to only licensed professionals who acquire access such as pharmacists, technicians, pharmacy & pharmacy director. Cameras & alarm system should exist in order to monitor the access in & out of the pharmacy on a continual basis[8].

Drug Procurement:- Drug costs make up an increasing percentage of healthcare expenses. Proper management of drug procurement is essential for addressing cost & promoting patient safety & quality care.To ensure pharmacy procurement activities are operating appropriately, formal procurement procedures are to be followed. They should be designed to promote safety & efficacy for drug purchases & should include cost containment techniques such as practicing competitive bidding to secure optimal drug pricing[4].

Drug receipt & storage:- Drugs received & stored in a pharmacy can be placed in inventory through a no. of avenues when drugs are received, before placing them in to inventory. Pharmacy personnel should perform appropriate receipt procedures such as reconciling drugs received to drugs ordered, to ensure that discrepencies between quantity & drug type don't exist. Once the drugs received have been verified, they should be physically maintained in secure storage areas or active dispensing areas of the pharmacy. Drug storage should include the use of automated dispensing devices. Controlled substances require additional storage security to prevent any unauthorized access. Temperature can be important factor in maintaining & storing drugs to ensure their quality & integrity. Many drugs (eg.vaccines) require storage in climate controlled environments such as a refrigerator with specific temperature ranges[29].

Drug tracking & inventory management:- Effective & tracking systems that allow pharmacies to accurately record inventory components such as medication expiration dates & physical quantities also have the potential to reduce adverse patient outcomes. The "real time" tracking ability offered through these systems includes recommending items & quantities to be ordered based on par levels set by the pharmacy in the system, providing limits on excessive orders & electronically placing orders after a manual authorization when setting the par levels for the automated ordering, it is important to set appropriate levels to maximize the ordering process & minimize excessive supplies[8].

A pharmacy's inventory represents its single,largest investment .Consequently no other asset has the potential to devastate a pharmacy as much as poorly controlled inventory .In an average pharmacy, cost of goods sold account for approximately 68% of total expenditures .For every 1% change in an average pharmacy's cost of goods, profits may increase or decrease by slightly more than 20%. Thus, the inventory control matters of great importance to both cashflow & profitability[6].

The objective of inventory control system is to make inventory decisions that minimize the total cost of inventory. This is not to beconfusive with minimizing inventory. It is often more expensive in a pharmacy to run out of an item than to simply keep more units in stock.

For example, in a retail pharmacy if a customer is unable to obtain their medication, they may go somewhere else and the pharmacy may lose future purchases. In a hospital pharmacy if we run out of an item, we might be required to obtain it by a more expensive method (over-night deliverey). Most pharmacy inventory decisions involve replenishment system i.e. how much to order & when to order. In this course, we will look at several models for minimizing the total cost of inventory,including the popular method of Economic Order Quantity(EOQ). This particular method attempts to balance the carrying cost inventory with the cost of running out[28].

Purchasing Concepts:

ABC classification system: The ABC classification system group items according to annual sales volume, in an attempt to identify the small number of items that

will account for most of the sales volume & that are the most important ones to control for effective inventory management[32].

VED Analysis: It stands for Vital Essential Desirable, takes a qualitative approach.VED analysis encourages us to divide inventory in to three groups: vital items,essential items are those without which healthcare set-up can function but the quality, speed or cost of service will be damaged.Unavailibility of desirable items will not affect the functioning of the healthcare set-up but may incur minor costs or short-term disruption[20].

Five steps to do VED Analysis:

i. First draw up a list of every non-trivial item our healthcare centre has ordered multiple times in the past 1-5 year.

ii. Assemble a panel of experts from the healthcare centre. It's absolutely critical that this panel is representative of every area and every level of your organization. Which inventory is vital is dependent on perspective, so there needs to be someone present who can make a fair case for each department.

iii. Set an agreement threshold -50% is generally a good starting point. That means if 50% of votes agree, the item is placed in that.

iv. Have the panel discussion and vote on a category for each item.

v. If any items fail to reach the 50% threshold then they will require further discussion until an agreement is reached. We might also want to define a failure option, which will usually be an executive decision by senior management, if a category simply can't be agreed upon[5].

Method

Peer reviewed articles published in English were searched for on the availibilty & inventory control techniques of medicines and medicine stock management common used databases for public health and medicine which include PubMed, EBSCOHost, Google Scholar, Scopus and Cochrane. Articles from the past three decades were considered.The identified articles were analysed for relevance. This was identified by searching through websites WHO, IPHS and google. A review template was developed to extract information from the literature identified for the structured literature review.

Discussion

Compared to the set-up of the health-care located at the urban areas,the condition of PHCs in the rural areas are compromised. Every PHC should have a separate location for storing drugs & other medical supplies and it is called the main drug store. The main purpose of managing a store is to cater the needs of receiving, holding & dispatch stock. With the advent of eesential drug concepts, essential medicines defined by WHO as well as by IPHS need to be dispensable at the PHCs. Therefore, drugs need to be available and accessible whenever required in all appropriate dosage forms. Medicine supply management in health systems occur at more than one level and the factors that influence this at the health facility may not always stem from the health facility itself. However, studies have reported that some health facilities may have medicine shortages even though the stock is available at the central level which supplies them with medicines. There is a lack of research that has been carried out at health facility levels such as PHC clinics exploring the processes at the facility and how these may be linked to the occurance of medicine stock outs levels especially in the lower income settings. The absence of medicines i.e. stock-outs at these levels should be prioritized. The factors that contribute the most of the occurance of stock-outs of medicines at the facility level include inadequate health workforce particularly pharmacy personnel. Poor medicine stock management and inefficient communication between suppliers, depots and health facilities.

Conclusion

A considerable amount of research has been conducted in the area of medicines availability particularly to determine what the likely causes of unavailability are. It is known that the causes of medicines unavailability are mostly embedded in the medical supply systems, particularly in the procurement and distribution of medicines. Non-existent or poor stock control including poor forecasting are the major causes of stock-outs and shortages reported in literature at the health facility level when stock is available at the central or depot level and it is very important to continually assess and improve medicine stock management at the health facility level to ensure uninterrupted access medicines for patients at these facilities. This involves incorporation of standardized strategic methodology with Information and Communication Technology interventions in processes dealing with pharmaceutical purchasing,

selection, quantification, distribution, management of human resource and inventory management.

The Effect of Circuit Training and Weight Training on Selected Physiological Variables and Running Performances among University Athletes

N. Kalaiarasan[1], N.C. Jesus Rajkumar[2]

[1]M.Phil. Research Scholar, [2]Asst. Professor, Dept. of Physical Education and Sports Sciences, SRM IST, Kattankulathur

Abstract

The purpose of the study was to find out the effect of circuit training and weight training on selected physiological variable among university athletes. To achieve the purpose of the present study, forty five (n=45) University athletes from Chennai, Tamilnadu, India were selected as subjects at random and their ages ranged from 18 to 21 years. The experimental group endured the training activities for 12 weeks with a schedule of six days whereas the control group remained with no activities. The subjects were tested prior to and after the experimentation on vo2 max The obtained data from the experimental and control groups of initial and final readings were statistically analyzed with analysis of covariance (ANCOVA). To find out difference between experimental and control group at the level of significance was set at 0.05. It was proved that there was a significant difference existing on circuit training group on selected physiological variable among university athletes.

Keywords: *Circuit training, Weight training, Physiological, Experimental group, Control group.*

Introduction

Athletics is mostly an individual sport, with the exception of relay races and competitions which combine athletes performances for ateam score, such as cross country. Organized athletics are traced back tothe Ancient Olympic Games from 776 BC. The rules and format of the modern events in athletics were defined in Western Europe and North Americain the 19th and early 20th century, and were then spread to other parts of the world. Most modern top level meetings are conducted by the International. Association of Athletics Federations and its member federations. A variety of running events are held on the track which fall into three broad distance categories: sprints, middle-distance, and long-distance track events.[1] Relay races feature teams comprising four runners each,who must pass a baton to their teammate after a specified distance with the aim of being the first team to finish. Hurdling events and the steeplechase are avariation upon the flat running theme in that athletes must clear obstacles on the track during the race. The field events come in two types jumping and throwing competitions. In throwing events, athletes are measured by how farthey hurl an implement, with the common events being the shot put, discus, javelin, and hammer throw.[2] There are four common jumping events: the long jump and triple jump are contests measuring the horizontal distance an athlete can jump, while the high jump and pole vault are decided on the height achieved. [3]

Circuit training is a practical method entailing some preliminary planning, but beyond that, it needs co-ordination. Athletes find it motivating since it makes conditioning fun and challenging through competition against team mates.[4] Circuit training is a continuous series of exercises attempting to improve as many components of physical fitness as possible especially endurance.

Weight training improves the muscle strength, power and endurance. Weight training mostly increases the size of muscle fibers. During this training the muscle protein content increases rapidly which involves in metabolic reactions. Strength training can be resulted in

hypertrophy of the muscle, partly through an enlargement of muscle fibers. In addition, training with high weight can change the fiber type distribution in the direction of faster twitch fibers. An improvement in muscular strength training through isolated movements seems closely related to training speeds.[5] It was well established that weight training can enhance the force production capabilities of an older adult by increasing muscle mass or improving muscle quality (i.e., the force-generating capacity of individual muscle fibers). It was recommend that beginners starts with 8 to 10 exercises for the major muscle groups with more repetitions thrice in a week. Before the weight training the doctor's suggestion for people who have overweight. This type of training needs the selection of right equipment and must be conditioned before the weights. Weight training can be used without recourse to the devices.[6]

Muscle strengthening is critically important for injury prevention,rehabilitation, and performance enhancement. Strength is the ability of thebody, to withstand force. The development of strength involves exercising atvarious loads, modes, speeds, angles and frequencies. The combination of these variables dictates the outcome of the weight training programme.

Statement of the problem: The purpose of the study was to find out the effect of circuit training and weight training on selected physiological variables among university athletes.

Methodology

The purpose of the study was to find out the effect of circuit training and weight training on selected physiological variables among university athletes. To achieve the purpose of the present study, forty five University athletes from Chennai, Tamilnadu, India were selected as subjects at random and their ages ranged from 18 to 21 years. The experimental groups endured the training activities for 12 weeks with a schedule of six days whereas the control group remained with no activities.

Test Administration of VO2 max

VO2 Max

Purpose: To measure the VO2 max level of the university athletes.

Equipment Required: Flat, non-slip surface, marking cones, 20m measuring tape, beep test audio, music player, recording sheets.

Procedure: This test involves continuous running between two lines 20m apart inti me to recorded beeps. For this reason, the test is also often called the & #39;beep & #39; or & #39;bleep & #39; test. The participants stand behind one of the lines facing the second line, and begin running when instructed by the recording. The speed at the startis quite slow. The subject continues running between the two lines, turning when signaled by the recorded beeps. After about one minute, a sound indicates an increase in speed, and the beeps will be closer together. This continues each minute (level). If the line is reached before the beep sounds, the subject must wait until the beep sounds before continuing. If the line is not reached before the beep sounds, the subject is given a warning and must continue to run to the line, then turn and try to catch up with the pace within two more 'beeps'. The test is stopped if the subject fails to reach the line (within 2 meters) for two consecutive ends after a warning.

Scoring: The athelete's score is the level and number of shuttles (20m) reached before they were unable to keep up with the recording.

Results and Discussions

Table 1: computation of mean and analysis of covariance of VO2 max of circuit training, weight training and control groups

Tests	CTG	WTG	Control Group	Source of Variance	Sum of Squares	df	Mean Square	F
Pre Test Mean	47.00	46.66	46.13	BG	5.733	2	2.867	0.89
				WG	135.067	42	3.216	
Post Test Mean	52.93	54.06	46.80	BG	458.533	2	229.267	69.64*
				WG	138.267	42	3.292	
Adjusted Post Test Mean	52.97	54.07	46.75	BG	453.099	2	226.549	67.81*

* Significant at 0.05 level Table value for df 2, 42 was 3.21 and 2, 41 was 3.22

The above table 1 indicates the adjusted mean value of vo2 max of circuit training group, weight training group and control groups were 52.97, 54.07 and 46.75 respectively. The obtained F-ratio of 67.81 for adjusted mean was greater than the table value 3.22 for the degrees of freedom 2 and 41 required for significance at 0.05 level of confidence. The result of the study indicates that there was a significant difference among experimental and control groups on vo2 max. The above table also indicates that both pre and post test means of experimental and control groups differ significantly.

Table 2: Adjusted mean and differences between the means of circuit training, weight training and control groups on VO2 max

CTG	WTG	Control Group	Mean Difference	CI value
52.97	54.07	---	1.10	1.69
52.97	---	46.75	6.22*	
---	54.07	46.75	7.32*	

Table 2 shows the adjusted means on vo2 max and difference between the means of the circuit training group, weight training group and control group. The mean differences of circuit training group and control group, weight training group and control group were 6.22 and 7.32 respectively was greater than the CI value 1.69. Hence there exists significant difference.

The mean difference between circuit training group and weight training group was 1.10 lesser than the CI value 1.69. Hence there exists no significant difference.

Discussing on Findings: The result of the study reveals that the experimental groups produced significant improvement on selected physiological variables when compared to the control group after the completion of twelve weeks of circuit training and weight training.

Discussion on Hypotheses: The hypothesis stated the circuit training programme would show significant difference on selected physiological variables and running performances among university athletes. From the analysis of data it was proved that there was a significant difference existing on circuit training group on selected physiological variables among university athletes. Hence the formulated hypothesis was accepted at 0.05 level of confidence.

Conclusions

From the analysis of data it was proved that there was a significant difference existing on circuit training group on selected physiological variables among university athletes.

The Assessment of Suppression in Anisometropia

Namrata Pandey[1], Renu Thakur[2]

[1]Chitkara School of Health Science, Chitkara University, Punjab, [2]Sankara Academy of Vision, Sankara Eye Hospital, Ludhiana, Punjab

ABSTRACT

Anisometropia is dissimilarity between the power between the two eyes that occurs in one or both principal meridian.[1] This becomes clinically significant when its magnitude reaches approximately 1D in either or both of the principal meridians.[3] When two eyes forms two non uniform images due to differences in power of both eye which leads to retinal rivalry. Suppression is an active inhibitory mechanism from the brain to reduce retinal rivalry.[18] Total 50 subjects of age groups 5-19 yrs were undergone both objective and subjective refraction with anterior and posterior segment evaluation. After that worth four dot test was done on each patient from near to far. (40cm- 4m). For evaluation Log Marchart, Heine retinoscope, worth four- dot torch,slit-lamp was used. Analysis of subjects showed that suppression is lesser in myopic group than hyperopic. The degree of suppression in anisometropia, their mean and SD in NA(0.57±0.62) and AA(1.2±1.18) respectively (P<0.01) be statistically significant .The mean and SD of angle of suppression in hyperopia (1±0.9), myopia (1.02±1.25) degree respectively(p>0.001) was statistically non significant. The mean and SD of differences in refractive error (DRE) in hyperopia (3.1±1.23),myopia (-2.72±1.03) and angle of suppression in each groups hyperopic(0.99±.91) and myopic groups (1.04±1.24) respectively (p<0.001) was statistically significant. However suppression is found in Amblyopia cases with greater visual acuity than refractive error. Difference in refractive power show Statistical significance in suppression as their degree of anisometropia increases.

Keywords: *Non amblyopia (NA), amblyopia (AA), Difference in refractive power of both eye (DRE), refractive error (RE), angle of suppression (AOS).*

Introduction:

The prevalence rate of anisometropia in children is 7%[7] which also make it considerable factor for refractive error management in optometric field. "Anisometropia is inter eye asymmetry of refractive status of an individual's".[3] To some extent changes in size and shape of objects causes asymmetric astigmatism, asymmetric hyperopia and asymmetric myopia.[1] Due to difference in images of both eye brain is unable to fuse both image to form a binocular single image to perceive which leads confusion in the brain. Due to conflict & confusion created by dissimilar stimuli on corresponding points, the phenomenon of retinal rivalry takes place.[9,10] The dominance of the eye rather than the attention value of the stimulus is responsible for it. To maintain the uniformity of viewing single image from both eye brain starts to suppress the one eye image also known as neurophysiological process.[8,17] The suppression of eye leads to deprivation of growth of that eye development in binocular skills like accommodation and vegences. Children mostly develop unilateral amblyopia or sometime bilateral amblyopia due to suppression.[18] in some cases often strabismus is also found due to suppression of one eye.[5,6]

Effects of Suppression in Anisometropic Groups: The level of suppression in anisometropia,strabismus and mixed amblyopia was evaluate in study done by shows that the most important role of suppression is in amblyopia and its impact while treating amblyopia.[2] To assess the depth of stereopsis and fusion in patients with anisometropia with presence of amblyopia study done by Hyun Sun Jeo et,.al shows that depth of stereopsis and fusion were significantly lower in case of non amblyopic anisometropia (NA) than amblyopic amblyopia (AA).

There were no statistical significance in comparison of NA and isometropic groups.[4] The level of stereopsis in the NA group, however, did not differ significantly from that in the isometropic control, while the rate of fusion was significantly lower. Dadeya S study on the effect of anisometropia in binocular vision shows that small amount of anisometropes shows fusion whereas greater power was unable to fuse. While prescribing glasses to anisometropia with binocular vision, the most considered factor is amblyopia.[3]

Material and Methodology

50 subjects were undergone comphrensive eye evaluation in which vision with Log Marchart, refraction both objective and subjective with Heine retinoscope[19] Topcon autorefractometer. Anterior segments and posterior segment were evaluated with sit lamp (Topcon) and direct ophthalmoscopes(Heine).[12,20] After that worth four dot test was done on each patient using worth four dot torch and red green filter at room illumination from 40cm to 4m with increasing steps. Subjects with BCVA with refractive power were added filters,red filter in OD(right eye) and left filter in OS (left eye). After that subject were asking to look straight ahead at the torch from 40cm. First right eye is covered and ask "how many lights do you see?" Now the left eye is cover and asks, "How many lights do you see?" After that both eyes open asked, "How many lights do you see?" This process is repeated each step in increasing way till 4m.[11]

Results

The statistical analysis was done by qimacros andquick pad calculator using t test to compare two groups mean values. Worth four -dots test was obtained on 50 children in age from 5 to 19 from near to distance (40 cm to 4m). Total subjects of age groups of 5 to 19 (12.16±4.08) were participated in study inwhich mean values of hyperopia (4.5±1.67), myopia (-5.8±3.36), amblyopia(-0.7±6.5) and non amblyopia(0.8±.8). 26% of the participants had no suppression, 8%of the participants had suppression from 4ocm, 32% had suppression from 1m, 16%had suppression from 2m, and 18% had suppression from 3m. The mean values of refractive error with angle of suppression shows statistically significance in bothamblyopic, non amblyopic groups(p=0.05)and myopic and hyperopic groups are not statistically significant.(p>0.0001). Differences of refractive error in both eye shows statistically significant compare to angle of suppression. (p=0.0001) in both myopic and hyperopic groups.

Discussion

The principle of our study was to evaluate the suppression in anisometropic children between two groups myopia, hyperopia and amblyopic, non amblyopic patient in age group of 0-19 yrs. Initial result ahow that myopic groups had less suppression compare to hyperopic groups. 23% of the participants had no suppression, 4% of the participants had suppression from 4ocm, 37% had suppression from 1m, 17% had suppression from 2m, 19% had suppression from 3m. 52% of participants were hyperopic and 24% were myopic. The primary finding is that the majority of myopic patient having less suppression compare to hyperopic patient. Non amblyopic patient were having less suppression compare to amblyopic groups. As vision decreases suppression of group's increases shows statistically significant result. But difference of refractive error as increases doesn't show statistically significant result comparing to suppression. Our study shows similar result as Hyun Sun Jeo et, .al study depth of suppression in steropsis and fusion in presence of amblyopic in anisometropia shows that depth of stereopsis and fusion were significantly lower in case of non amblyopic anisometropia (NA) than amblyopic amblyopia (AA).there were no statistical significance in comparison of NA and isometropic groups. S dadeya et,. al,the effect of anisometropia on binocular visual function shows that small amount of anisometropes shows fusion whereas greater power were unable to fuse similar to our study lower groups of myopia and hyperopia shows no suppression,with increases of re suppression increases.

Conclusion

Our goals of the study were to find out the suppression in anisometropic children. Hence in our study, weconcluded that suppression presence in anisometropia is more significant with decreased of vision. However differences of refractive error in both eye compare to suppression doesn't show any significant results. In amblyopic and non amblyopic groups as the refractive error increases, suppression increases. However most of participant had suppression from 1m despite of different ranges of refractive error.This should be taken in consideration while prescribing or evaluating any anisometropic children to control their suppression.

Conflicts of Interest: No

Ethical Clearance: Non-invasive study that's why ethical clearance was not required.

Funding: No as study used the instruments and procedure which is done regularly on clinical basis.

Proficiency, Perspective and Practice Regarding Plagiarism among Dental Professionals of Three Dental Colleges of Western Chhattisgarh: A Cross Sectional Study

Naveen N.[1], Sudha Suman[2], Yunus G.Y.[3], Ram Tiwari[4], Abhinav Patel[5], Heena Sahni[5]

[1]Professor and Head, [2]Post-graduate Student, [3]Reader, [4]Senior Lecturer, [5]Post-graduate Student, Department of Public Health Dentistry, Rungta College of Dental Sciences & Research. Bhilai, Chhattisgarh

Abstract

Aim & Objectives: To determine and compare knowledge, attitude and practice regarding plagiarism among faculties and postgraduates of dental colleges of Western Chhattisgarh.

Material and Method: A descriptive cross-sectional questionnaire study was conducted among 198 dental professionals of 3 dental colleges in Western Chhattisgarh. The study was conducted for a duration of 1 month using self- structured close ended questionnaire consisting 43 items, assessing knowledge, attitude and practice to collect data regarding plagiarism. Descriptive statistics, ANOVA and Kruskawallis test were applied to analyse data.

Results: In the present study out of 198 study participants 87 were males and 111 were females. The Mean knowledge of postgraduates, BDS and MDS faculties were 9.38 ± 3.9, 9.64 ± 3.9 and 12.8 ± 3.6 respectively. The mean attitude of postgraduates, BDS and MDS faculties were 0.95 ± 2.0, 1.78 ± 3.2 and 1.91 ± 3.0 while mean practice of postgraduates, BDS and MDS faculties were 3.9 ± 1.6, 4.9 ± 0.9 and 4.91 ± 1.3 respectively. Intergroup comparison of knowledge among faculties in different specialities was found to be significant ($p \leq 0.05$).

Conclusion: This study concluded that knowledge, attitude and practices regarding plagiarism among the postgraduates was found to be less as compared to faculties.

Keywords: *Dental professionals, Plagiarism, Western Chhattisgarh.*

Introduction

Scientific research work is as important as taking good care of the patients.[1] High standards of scientific and medical research practice is expected from the researchers. To bag the confidence of the public, it is essential to maintain the probity, uprightness, prowess and truthfulness of the scientific researches.[2] There is a rising concern in academia regarding the increase in scientific misconduct that is occurring among the students.[3] Plagiarism constitute a severe educational challenge which is intensely faced by universities, research institutions and even schools.[4] Scientific misconduct includes fabrication, falsification, plagiarism and other unethical behaviour in scientific researches.[5] Plagiarism is a form of academic misconduct which is derived from the Latin word plagiare or kidnapper; which refers to presenting the ideas of somebody else without acknowledging or giving credit to the original.[6] Self-plagiarism is defined as the inappropriate presentation of one's own published data or text as new and original.[7] There are various types of plagiarism including taking data, tables or figures from previous publications and using it without citation, publish similar documents

e-mail: naveen.drn@gmail.com

repeatedly, publish similar article in a local and also in an international journal with different or same authorship.[8] Plagiarism may be intentional or unintentional. The first and leading reason is the accessibility of elephantine information at our fingertips through the internet facility.[9] Internet facilitates with the plagiarism detection software; an initiative to terminate the degradation of the scientific writing. The main consequences of plagiarism are penalties that can range from warnings to various forms of legal actions.[10] Since the dental postgraduates and faculties are always under pressure for the publication for which certain ethics should be followed for the scientific writings; they neglect the consequences of such academic theft. Previous studies indicate lack of knowledge about plagiarism, students aptness towards such behaviour and not understanding the seriousness of such violations increase plagiarism frequency especially when the internet is the source of plagiarism.[11,12,13] Thus this study was conducted with an aim to assess knowledge, attitude and practice regarding plagiarism among postgraduates and faculties of dental colleges of Western Chhattisgarh.

Methodology

This present cross- sectional questionnaire study was carried out on 275 participants (faculties and postgraduates) enrolled in 3 dental colleges of Western Chhattisgarh.[14, 15] The close- ended questionnaire containing 24 knowledge, 10 attitude and 9 practice related questions was developed by modifying the questions from previous similar studies[16-19.] Only those subjects who gave the written consent were considered to be the part of the study.

Pilot Study: A self stuructured, close-ended questionnaire was prepared in English language. The questionnaire content and face validation were carried out among 10 experts in the subject of Public Health Dentistry. The reliability of the questionnaire was assessed in a pilot study conducted among 30 participants who were not included in the main study. The reliability of the questionnaire was 0.76 (Cronbach's alpha) which was considered good. The knowledge questions were assigned score of one for the correct answer and zero for the wrong answer. The partially filled or incomplete questionnaires were excluded. Similarly for attitude score one was assigned for the correct answer and zero for incorrect answer. The option of don't know was assigned zero score.

Questionnaire: The questionnaire was divided into 4 parts with close ended questions.

1. First part of the questionnaire recorded the demographic details.
2. The second part included 24 questions for the assessment of the knowledge towards plagiarism.
3. The third part constituted of 10 questions to assess the attitude of the participants.
4. The fourth part comprised of 9 questions to assess the practice of the study participants.

Total 239 questionnaires were distributed (68 MDS faculties, 26 BDS faculties and 145 P.G students). Six dental professionals were excluded from the study as they expressed inability to spare time and didn't provide consent. One ninety eight study participants returned the filled questionnaire. Questionnaire were distributed among all the dental professionals in all specialities. On the day of data collection, the study subjects were explained verbally about the study before filling of the questionnaire. The filled questionnaire was collected on the next day.

Statistical Analysis: The data was entered in Microsoft Excel sheet and the data analysis was done using statistical software SPSS version 19.0 (IBM Corporation, SPSS Inc, Chicago, IL, USA). Descriptive statistics were derived. ANOVA test was used for the comparison of knowledge and practice between dental professionals in different subject specialities, whereas Kruskal Wallis test was used for the comparison of attitude between them. $P \leq 0.05$ was considered to be statistically significant. Kolmogorov- smirnov test was used to check the normality of the data.

Results

This cross sectional questionnaire study was conducted to assess the knowledge, attitude and practice regarding plagiarism among the postgraduate students and faculties of dental colleges of Western Chhattisgarh. The response rate was 82% with the total of 198 dental professionals returning the filled questionnaire. The mean age of 198 study participants was 30.57 ± 6.02. Out of total participants 122 were post graduate students, 62 and 14 were MDS and BDS faculties respectively.

Table 1: Distribution of study participants according to their knowledge, attitude and practice.

Designation	Knowledge (Mean±SD)	Attitude (Mean±SD)	Practice (Mean±SD)
BDS Faculty	9.64 ± 3.97	1.78 ± 3.21	4.9± 0.92
Postgraduates	9.38 ± 3.90	0.95 ± 2.10	3.9 ± 1.61
1st Year	9.25±2.51	0.8±2.12	4.5±1.25
2nd Year	9.46±3.96	1.05±2.04	3.6±1.73
3rd Year	9.37±4.52	0.88±2.12	4.0±1.64
MDS Faculty	12.81 ± 3.67	1.91 ± 3.06	4.9 ± 1.34

Table 1 showed higher mean score of knowledge among MDS faculties as compared to others. A statistical significant difference was present between the knowledge of the dental professionals of different specialties (p □ 0.001).

Practice when assessed among the dental professionals, BDS faculties had a mean practice of 4.9 ± 0.92, postgraduates had 3.9 ± 1.61 whereas MDS faculties had a mean practice of 4.9 ± 1.34. Out of total participants, 55% of dental professionals have sometimes plagiarised, 52.5% of study participants believe that a person can always write a scientific paper without plagiarizing, 73.7% of study participants answered that they sometimes copy a sentence or just two to take an inspiration for further writing,

There was a highly statistically significance found in knowledge between BDS and MDS faculties (p- 0.006) & MDS and postgraduate students (p-0.000). (Table 2).

Table 2: Comparison of knowledge and practice regarding plagiarism between BDS faculty, MDS faculty & postgraduate students.

	Designation		Mean Difference	f-Value	p-Value
Knowledge	BDS Faculty	MDS Faculty	-3.16	16.73	0.001***
	P.G. Students	BDS Faculty	-0.25		
	MDS Faculty	P.G Students	3.42		
Practice	BDS Faculty	P.G Students	-0.93	2.41	0.09
	P.G. Students	MDS Faculty	-0.95		
	MDS Faculty	BDS Faculty	-0.23		

Statistical test – ANOVA. $p \leq 0.05$

Attitude when assessed among the study participants, it was found that 32.7% had uncertain attitude followed by 40.15% with positive attitude and 27.0% with negative attitude. The mean attitude among the BDS faculties were 1.78 ± 3.21, among postgraduates were 0.95 ± 2.10 whereas MDS faculties had a mean attitude 1.91 ± 3.06. (Table 3).

Table 3: Comparison of attitude regarding plagiarism between BDS faculty, MDS faculty & postgraduate students.

	Designation	N	Mean±S.D.	X^2-Value	P-Value
Attitude	BDS Faculty	14	1.78 ± 3.2	4.80	0.90
	Postgraduates	122	0.95 ± 2.0		
	MDS Faculty	62	1.91 ± 3.0		

Test applied- kruskal-wallis H test, $p \leq 0.05$

There was no statistically significant difference found in knowledge, attitude and practice regarding plagiarism between the study years of postgraduate students. (Table. 4 & 5).

Table 4: Comparison of knowledge and practice regarding plagiarism between the study years of the postgraduate students.

	Study Year		Mean Difference	f-value	p-value
Knowledge	First Year	Second Year	-0.03	6.56	0.001***
	Second Year	Third Year	0.11		
	Third Year	First Year	-0.08		
Practice	First Year	Second Year	1.66	2.37	0.07
	Second Year	Third Year	-0.41		
	Third Year	First Year	-0.44		

Statistical test – ANOVA. $p \leq 0.05$

Table 5: Comparison of attitude regarding plagiarism between the study years of the postgraduate students.

	Designation	N	Mean±S.D.	X^2 Value	p-value
Attitude	1st year postgraduate	27	0.8±2.1	1.26	0.53*
	2nd year postgraduate	52	1.05±2.04		
	3rd year postgraduate	43	0.88±2.12		

Test applied- kruskal-wallis H test, $p \leq 0.05$

There was statistically significance found in knowledge between the faculties with a teaching experience of 10 years and above and less than 4 years with a mean difference of 2.52 (p- 0.04) whereas no statistically significance found in attitude and practice.

Discussion

In the present study, the mean knowledge regarding plagiarism was categorized as below average<10, average = 10.1-15, good = 15.1- 20 and excellent = 20.1-24. The mean knowledge of the postgraduate is 9.38± 3.90, which was lesser than the mean knowledge score of the faculty (12.81± 3.61). The reason could be that the MDS faculties are more updated with plagiarism in their due course as faculty. Similar results was found in the studies conducted by Poorolajal et al.[20]

Our study found that overall (93.9%) dental professionals knew what plagiarism is which was in accordance with the study conducted by Singh et al[21]. The study population of the present study stated that the reason for indulging in plagiarism was mainly due to pressure to complete the task in short time and easy to cut and paste. This was in accordance with study conducted by Zulle et al [22]. The reason for this could be that the pressure of appraisal and promotions were dependent on their research work and publication, hence they could have indulged into plagiarism. Thirty two percent of the study subjects knew that plagiarism was a punishable offence. Surprisingly a study conducted by Singh et al [21], only 5% of the population were aware for that. As per the section 57 of the Indian copyright Act (ICA), 1957 [23] has stated that plagiarism attracts punishment in the form of warning and penalty. This striking difference in the awareness could be lack of noteworthiness of the consequences of plagiarism among researchers and also the due prominence towards learning of such ethical issues in the under graduate curriculum is not asserted.

In the present study 40.15% had positive attitude, 32.7% with uncertain attitude followed by 27.0% with negative attitude. The reason may be because of the ignorance regarding the impact of plagiarism in research and plagiarism is not been a part of undergraduate curriculum. Our study showed that (58.2%) postgraduates and (80.6%) faculties agreed that plagiarism is an ethical issue in scientific writing which was in accordance with study conducted by Kirthiet al[17]. This study result showed that (48.4%) postgraduate students and (69.4%) faculty members agreed that plagiarized paper does

harm to science. As per the study conducted by Gomez et al [2] (3.5%) postgraduate students and (9.8%) faculties, as per Jain et al [7](22.6%) dental professionals disagreed to the statement that plagiarized paper does no harm to science.

In our study 40.15% of dental professionals showed positive attitude towards question related to plagiarism. This was in accordance with the study conducted by Rathore et al [23] which had high ATPQ (attitude towards plagiarism questions) 51.6%.

In the present study (48.4%) faculties agreed that it is necessary to plagiarize sometimes which was contradicting to the study conducted by Gomez et al [2](27.4%) and Kirthi et al [17] (15.9%) agreed to the statement sometimes it is necessary to plagiarize. This is a highly concern raising issue as most of the study subjects don't find it wrong to copy a sentence. Cognizance regarding the ICA 1957 needs to be ameliorated. In the present study (23.8%) postgraduate students and (43.5%) faculties always have made an attempt to write an article without plagiarizing. This kind of practices need to be encouraged and highlighted among all the researchers as it increases the quality of scientific writing.

Conclusion

Though the postgraduate students are the rising buds as a future professionals, they need a proper guidance from their faculty members while writing the scientific paper for the first time, then only the chances of plagiarizing of a paper will be carved out. To maintain the originality of the scientific writing, scientific writing courses program should be carried out among the postgraduate students as they are in the budding stage as our future professionals.

Ethical Clearance: It was obtained from the institutional ethical committee of Rungta College of Dental Sciences & Research, Bhilai, Chhattisgarh.

Palateless Complete Denture: A Minimally Invasive Approach to Preventive Case

Neha Chugh[1], Pradeep Sheriger[2], Aparna Ichalangod Narayan[3], Dhanasekar Balakrishnan[4]

[1]Post Graduate Student, [2]Additional Professor, [3]Professor, [4]Professor and Head, Department of Prosthodontics and Crown and Bridge, Manipal College of Dental sciences, Manipal

Abstract

Background: Tooth loss due to caries and various other consequences, can cause simple loss of function to long term deleterious effects on the remaining residual bone, oral proprioception, temporomandibular joints and facial appearance.

Case Description: A 33 year old female patient with Kennedy's class I edentulism in both the arches with just three teeth remaining in maxilla has been treated with attachment retained maxillary palateless overdenture and mandibular removable partial denture. The maxillary teeth 11 21 23 were endodontically treated and a short coping with rhein 83 attachment were cemented and a maxillary overdenture over this was fabricated. This was opposed by mandibular partial denture. This case report attempts to prevent the remaining teeth in the oral cavity and gives a cost effective treatment option to the patient considering her financial status.

Conclusion: This case report emphasizes the use of preventive prosthodontics helping enhance the quality of life of patient

Keywords: *Overdenture, Tooth-supported overdenture, Attachments, combination syndrome, preventive prosthodontics.*

Introduction

Overdentures have always offered a prudent appeal and sensible approach to prosthodontists and numerous patients have been benefitted by it. The applied ingenuity of this technique has mitigated much time dependent risk inherent in complete denture service. It has been successfully used for ages, however the emphasis on preventive dentistry has popularized its use. This case report presents a similar case of preventive prosthodontics.[1]

Case Report: Patient details: A 33 year old female patient reported to Department of Prosthodontics, Manipal College of Dental Sciences, Manipal with a chief complaint of missing teeth in upper and lower arches and wanted them to be replaced. The patient reported with a history of uneventful extractions of maxillary and mandibular posterior teeth. The medical and family history were not relevant.

Examination: Extra oral examination exhibited apparently bilaterally symmetrical face and normal temporomandibular joints.

Intra oral examination revealed partially edentulous arches with only three teeth in maxilla. 11, 21 23. The Retained teeth were having good periodontal support. The mandibular arch had Kennedy's class 1 partial edentulism with 32, 32 41, 42, 43 present. Oral mucosa and tongue were normal (Figure 1). The residual alveolar ridges were high well rounded.

Figure 1: Pre Treatment

Diagnostic mounting: After diagnostic mounting, various treatment options available were discussed and the treatment plan was decided. The available treatment options were either extraction of remaining maxillary teeth and fabrication of conventional complete denture or implant supported overdenture, or to retain the maxillary teeth and fabrication of tooth supported overdenture. The patient rejected the option of implants due to additional surgery involved, more expenditure and prolonged duration of treatment. So, tooth supported overdenture was chosen as treatment option. All the maxillary teeth were chosen as Overdenture abutments and they were endodontically treated. The diagnostic mounting helped us evaluate the interarch space and it was found adequate for overdentures with short copings.

Treatment: The Overdenture abutments were then prepared to fabricate copings with attachments. A post space of 5mm length was prepared [Mani peeso reamers #1, #2, 28 mm]and a definite chamfer finish line [Shofu Inc. crown and bridge preparation kit] around the abutments (Figure 2).

Figure 2: Abutment preparation

Polyvinyl silicone elastomeric impression [Reprosil® heavy body and light body Dentsply caulk, Germany] was made using a J shaped wire loop snuggly fitting the post space (Figure 3).

Figure 3: Polyvinylsiloxane impression

Indirect method was used to fabricate the post and wire was coated with tray adhesive [Caulk tray adhesive, Dentsply, Germany] to make impression of the post space andMaster cast was poured [Type IV die stone, Ultrarock, Kalabhai Karson Pvt. Ltd., Mumbai, India] and custom cast copings were fabricated with male component of Rhein 83 attachments (Figure 4).

Figure 4: Wax pattern

The parallelism of all the three attachments was maintained and they were casted using co-cr alloys. The

finished and polished copings with male component of attachments were tried in the patient's oral cavity and cemented (Figure 5) with GIC [GC Fuji PLUS™ GC America].

Figure 5: Copings cemented

An irreversible hydrocolloid impression [Zelgan 2002 Dentsply] was made and a stone cast [Type III dental stone, Kalstone, Kalabhai Karson Pvt. Ltd., Mumbai, India] was poured. A custom tray was fabricated using self cure acrylic resin [Trevalon, Dentsply India Private Limited. Gurgaon Haryana], and was used for border molding light body polyvinyl siloxane was used for final impression (figure 6).

Figure 6: Wash impression

The cast was then poured and trial denture bases were fabricated. Jaw relations were recorded and teeth arrangement was done using Acryrock teeth (Acryrock Ruthinium dental products). After a satisfactory try in, the dentures were fabricated using Trevalon HI heat cure denture base resin with palateless maxillary denture reinforced with metal mesh and female components of the attachments incorporated in it during denture curing using lab analogue, and mandibular removable partial denture with wrought wire clasps. The dentures were inserted (Figure 7) and patient was instructed about the care and maintenance of the denture and the abutments. The periodic recall of the patient (Figure 8) and periodontal health of the abutments and remaining natural teeth was taken care.

Figure 7: Maxillary and Mandibular Dentures in place

Figure 8: Pre and post treatment views

Discussion

Various treatment options were given to patient including implants, overdentures, partial denture or complete denture. Financial constraints of the patient excluded the option for implants. The treatment of choice for the patient was overdenture for maxilla and removable partial denture for mandible. A reasonably right choice due to various reasons explained here. Complete dentures present many problems related to mastication and phonation, which may be eluded byretention of some natural teeth, and their supporting structures, which serve useful function for long periods of time. The biologic maintenance oftemporomandibular articulation, neuromuscular mechanism, and thesupporting structures of a denture can be accomplished by teeth than the mucoperiosteum. In this case the preservation of the remaining teeth prevented the impending complications of an edentulous maxilla opposed by a partially edentulous mandible which could have led to a classic case of combination syndrome.[3, 4] The preservation of anterior teeth helps preventing the proprioception[5], dimensional perception[6] and directional sensitivity.[7]Retention of these teeth made

possible a denture which provided support, retention, stability, ability to bear more occlusal load and comfort superior to that of a conventional complete denture. Various advantages such as the preservation of alveolar bone and the maintenance of occlusal verticaldimension and centric relation. It increases patients' manipulative skills in handling the denture. Facial and lip changes areminimized and the masticatory performance is maximized. The teeth selected as abutments were based on the number of teeth remaining, leading to one tooth per quadrant and a tripod approach for the support due to position of teeth in the arch gave us the mechanical advantage. Canine being the best abutment due to longest root, more surface area, strategic position in the arch and more proprioceptive nerve endings around it gives us the best choice for the abutment.[1]The use of short copings was decided according to the amount of inter arch space available and to increase the retention and support from the natural tooth, the radicular extension of 5mm was decided. Among the various options available for Overdentures the attachment retained have proven to be the best and provide better retention and stability when compared to Overdentures with only copings. This type of stud attachments are easier for the patient to maintain his hygiene. Since there was adequate retention and stability with the maxillary denture a decision for palateless denture was made considering patient's concern regarding discomfort caused by the palatal coverage and the denture was reinforced with metal mesh to combat flexural fatigue likely to develop in this type of denture. The patient benefits psychological, functional as well as biologic advantages.

Conclusion

The old age concept of over dentures helps prevent the vicious cycle of residual ridge resorption and combination syndrome to a great extent. With innovative approaches, and identifying possibilities rather than limitations, it has enthralled the field of preventive prosthodontics. Doing justice to every minute detail of treatment can be the only key to achieve success in prosthetic rehabilitation of patients.

Effectiveness of Pelvic Proprioceptive Neuromuscular Facilitation on Trunk Control in Children with Spastic Diplegia: A Randomized Controlled Trial

Nimmy A.[1], Sukumar Shanmugam[2], Shilna Rani P.[2]

[1]Post Graduate Student, [2]Assistant professor, College of Health Sciences, Gulf Medical University, Ajman, UAE

Abstract

Background: One of the most prevalent neurodevelopmental disorder seen in children is Cerebral palsy and it is associated with lifelong disability. Impaired trunk control effects performances of daily life such as sitting, reaching and walking. It is evidenced from studies that pelvic asymmetry is common in children with CP. The PNF patterns of pelvis not only exercises the pelvic motion and stability, but also facilitates trunk motion and stability.

Objective: To investigate the effectiveness of pelvic PNF techniques on trunk control in children with spastic diplegia.

Method/Design: 36 diplegic children irrespective of gender, age group between 8-15 years were recruited for the study. The intervention group received pelvic PNF along with the conventional therapy for 4 weeks. The control group received conventional physiotherapy in form of truncal exercises for 4 weeks. The primary outcomes used were TCMS and PALM.

Results: The results showed that there is an improvement in the TCMS score after the application of pelvic PNF techniques on children with spastic diplegia.

Conclusion: Application of PNF along with conventional therapy helps in improving trunk control and reducing disability in children with spastic diplegia.

Keywords: *Cerebral palsy, Pelvic asymmetry, PNF, Trunk impairment.*

Introduction

Spastic diplegia is the predominant type of cerebral palsy (CP), in which both lower limb is manifested with spastic muscle weakness[1]. It is commonly seen among 64% to 75% of preterm infants, especially those children's birth weights below 1000gm[2]. In India 3 (out of 1000) in every live birth manifest CP which is considered to be a higher incidence rate than the incidence rate of developed countries (2/1000)[3].

Apart from perceptual, cognitive and special sensory deficits, children with spastic diplegia develops impaired trunk control, pelvic asymmetry, balance and gait abnormality etc[4,5,6]. Further, mal-adaptation of neuromusculoskeletal structural components can lead to abnormal pelvic tilts which causes a reduction in the trunk control and normal functioning of the lower limb[5].

Evidence shows that children with CP frequently show impaired trunk control, which can affect performances of daily life such as sitting, reaching and walking etc[7]. It is also proved that pelvic asymmetry is

+91-9611839013 (India)

common and it influence the functions of trunk and lower limb[8]. Pelvis is anintegral part of trunk that supports lower extremity and provide base for the lower limb motions. Since the trunk muscles helps in the motion of pelvis, the range of motion in pelvisdepends on the quality and quantity of motion in the lower spine.

The relationship among the movements of pelvis, trunk and lower limb is evidenced, where the altered pelvic symmetry reduce the effective functioning of trunk and lower limb. In order to address the all three components collectively or individually various rehabilitation protocols are used. In the treatment of cerebral palsy especially in the case of spastic diplegia, the clinicians focusses on training the muscle strength, task manipulation, sensory-motor integration, balance, core muscle strength, muscle flexibility, trunk stability, postural control, co-ordination and gaitpattern to improve the quality of life[9].

Since the pelvis is a prime structural and functional component, and its influence on trunk control during static and dynamic activities, it is important to focus on trunk control by treating the pelvic asymmetry if it is identified. Evidence also strongly supports the positive relationship between the pelvic asymmetry and its associated dysfunctions such as poor trunk control and gait pattern manifested in spastic diplegic children[9]. The impaired trunk proprioception can also be considered as a contributing factor for the poor trunk control and pelvic mal-alignment.

Even though there are various interventions applied for the management of pelvic asymmetry, there is no study been done focusing on the training of multi segmental sensory motor integration in order to improve the pelvic symmetry and trunk control in children with spastic diplegia. According to the physiological mechanisms of proprioceptive neuromuscular facilitation, it can facilitate the normal functional movement pattern by activating the muscles of pelvis, trunk and lower limb when applied over the pelvic segment. Therefore collaborating PNF with conventional physiotherapy can help in improving the trunk control as well as to correct the pelvic malalignment in children with spastic diplegia.

PNF is a technique used to facilitate the response of neuromuscular processing through a proprioceptive stimuli. PNF deploys a distinctive diagonal pattern which in turn stimulates the proprioceptive sensation[8].

This technique not only stimulates the proprioceptors (muscle spindle and golgi tendon organ) and it also stimulates other deep sensory receptors for vibration, pressure, tactile discrimination and kinaesthetic sensation[10]. So it may collectively improve muscle strength, flexibility, inter and intramuscular coordination, balance and other functional activities. The principles and techniques of PNF are predominantly beneficial when consolidated along with the proper selection and implementation of joint and soft tissue mobilization techniques[10]. Since there is a no study evidenced the effectiveness of pelvic PNF on trunk control in children with spastic diplegia,this study was conducted to evaluate the effectiveness of pelvic proprioceptive neuromuscular facilitation on Trunk control in children with spastic diplegia.

Methodology

Trial Setting: A prospective, parallel group and assessor blinded randomized controlled trial was conducted during the period between March 2018 to March 2019 in the Department of Paediatric Physiotherapy of Justice K.S. Hegde Charitable Hospital, Mangalore, Karnataka state of India.

The ethical approval was attained from the Institutional Ethics Committee of Nitte Institute of Physiotherapy, and trial was registered in CTRI. This trial followed the ethics of research in humans (Helsinki convention norms) and prior to the participation, all the participants and their parents were informed about the study and consent was obtained. The participants were also made known about their rights to withdraw their participation during the study.

Participants: The participants diagnosed with spastic diplegia by the Paediatrician and Neurologist of the Justice K. S. Hegde Charitable Hospital, According to the selection criteria, an independent Physiotherapist assessed the patient and included the participant to undergo the study interventions. Inclusion criteria were, either Gender between 8 to 15 years, children diagnosed with spastic diplegia, children having pelvic asymmetry, children who can sit independently, children who are able to follow commands (Paediatric MMSE greater than or equal to 22) and children with GMFCS level 1 to 3. Exclusion criteria's were, children undertaking Botox injection since 6 months, children who underwent any surgery involving spine and lower limb in past 6 months, children having uncontrolled seizure since past 6 months. Children with fixed deformities in spine,

children with any fractures and dislocation of spine and lower extremity.

These participants once screened by inclusion criteria, were given consent and assent forms, and were divided into 2 groups, experimental and control group. Both group participants pre-post pelvic tilt was assessed using PALM device and trunk control was assessed using TCMS by the blinded assessor.

Interventions: The experimental group received both conventional and Pelvic PNF for 30 minutes each, once in a day, 5 days per week for 4 weeks. The experimental received anterior elevation-Posterior depression pattern with the techniques of Rhythmic initiation, Slow reversal and Stabilising reversal[17]. Each side of the pelvis were given these techniques for 15 minute each, and total 30 minutes of pelvic PNF in one session with rest periods in between.Participants were positioned into side lying with both hip flexion 100^0 and knee flexion 45^0, neck supported by a pillow with flexion of 30^0. The position of the therapist was behind the child to face the direction of the pelvic movement, the hand of the therapist placement for anterior elevation over the crest of the ilium one hand overlaps other for posterior depression heel of the one hand hold with other hand on the ischial tuberosity. "Pull up" and "Push down" command were given along with the techniques of rhythmic initiation, slow reversal and stabilizing reversal[11].

Control group received conventional physiotherapy in form of truncal exercises, which consist of upper and lower part of trunk for total 30 minutes including rest periods in between, once in a day for 5 days for 4 week duration.

Results

Baseline Outcome: 36 children diagnosed of spastic diplegia (72.2 % male and 27.7 % females) with a mean age of 11 years homogeneously distributed among the two groups in this study. We found that there is no statistically significant difference between the baselines mean scores of PALM device and TCMS. This also indicate that there is indication for abnormal pelvic alignment and trunk control ability among the children with spastic diplegia who are participated in this study.

Table 1: Baseline characteristics (PALM: Palpation Meter Device, TCMS: Trunk Control Measurement Scale)

Variables		Experimental group	Control group	p.value
Age (Years)		10.56 ± 2.45	11.44± 2.28	0.268
Gender	Male	83%	61%	0.137
	Female	17%	39%	
PALM score		2.21± 0.95	2.34± 0.89	0.684
TCMS score		25.39 ± 8.69	26.44± 10.12	0.739

Table 2. Within group comparison of TCMS and PALM

Groups	Outcome measures		Mean± S.D	p.value
Experimental	PALM	Pre	2.15 ± 0.87	<0.001
		Post	1.75 ± 0.72	
	TCMS	Pre	24.79 ± 9.33	<0.001
		Post	31.50 ± 8.84	
Control	PALM	Pre	2.46 ± 0.76	<0.001
		Post	2.15 ± 0.75	
	TCMS	Pre	25.54 ± 10.30	<0.001
		Post	27.77 ± 10.58	

Table 3. Between group comparison

Outcome measure		Mean± S.D	p. value
PALM	Experimental	.40 ±0.25	0.323
	Control	.31 ±0.23	
TCMS	Experimental	-6.71 ±4.94	0.004
	Control	-2.23 ±1.42	

Pelvic Symmetry: After the 4 weeks of pelvic PNF with conventional treatment among the 18 patients of intervention group and 18 patients of control group which was treated with conventional treatment alone proved to be effective in reducing the pelvic asymmetry. Similarly, the mean difference between the change score of PALM device indicate the addition of pelvic PNF into the conventional treatment have not produced any significant effect on pelvic asymmetry among the children with spastic diplegia.

Trunk Control: In the case of trunk control the children treated with pelvic PNF along with conventional treatment and standalone conventional treatment have significantly improved after the 4 weeks of treatment. However, the children who received Pelvic PNF in addition improved better (meandifference = -4.48) compared to conventional treatment which was applied in the control group.

Dropout: During the first two weeks of intervention there were 3 subjects in the experimental group and 2 subjects in the control discontinued (overall dropout percentage = 13.88%) the treatment due to the long travel distance and other personal reasons.

Figure 1: The patient receiving Pelvic PNF.

Figure 2: The patient receiving conventional treatment.

Discussion

According to the data basis searched, this would be the first study addressing the effect of Pelvic PNF for improving trunk control in cerebral palsy children. This study was used to evaluate the effectiveness of Pelvic Proprioceptive Neuromuscular Facilitation on Trunk control in children with spastic diplegia. The primary outcome measure TCMS showed a significant improvement in comparison with the control group. That is the group treated with PNF combined with conventional treatment has improved better in TCMS score compared to conventional treatment.

In a study conducted by Khanal D et.al to find out the effect of Pelvic PNF techniques on facilitating trunk movement in stroke population, the study came with a conclusion that both the control and intervention group showed improvement on trunk performance, range of motion, balance and gait after the intervention[10].

PNF deploys a distinctive helical or diagonal pattern which in turn stimulates the proprioceptive sensation and promotes nerve root response, thus enhancing functional movements, and stimulating weakened muscles. The weakened muscles, thus functions more constructively and beneficially with the action of the antagonistic muscle when compared to their individual action alone. PNF

also stimulates proprioceptors within the tendons and muscle, thus improving strength of muscle, flexibility, function and balance. Hence improving proprioceptive sensation is a key component for trunk stability and thus PNF exercises helps in improving trunk stability[10,11].

There are few studies quoting the need of focusing on pelvic asymmetry in children with cerebral palsy. In a study done by De Morais Filho et.al on identifying the factors affecting pelvic asymmetry during gait in children with cerebral palsy, it was observed that pelvic retraction and internal hip rotation are the strongest contributors for asymmetric pelvic tilt. Since the trunk muscles helps in the motion of pelvis, the range of motion in pelvic pattern depends on the amount of motion in lower spine[12].

Another study conducted by Sebastian Wolf et.al, it was found out that anterior pelvic tilt is the main factor for the functional impairment in spastic diplegic children[13].

Hence, from the retrieved literature, it can be shown that, correcting the pelvic malalignment, and thus improving trunk control can help in making a child with poor trunk control functionally independent.

In a systematic review done by Anttila et.al to find out the effectiveness of Physical therapy interventions for children with cerebral palsy, they focused on interventions such as Neuro Developmental Therapy (NDT), strength training, conductive education, and various Physical therapy interventions such as Constrained Induced Movement Therapy (CIMT), postural control, passive stretching, hydrotherapy and orthotic devices[9].

Though many studies have addressed various such therapeutic interventions, there are no studies done in cerebral palsy children focusing on correcting the pelvic asymmetry and thus improving trunk control. Since pelvis is the framework which connects the trunk and lower extremity, correcting the pelvic malalignment by means of giving pelvic PNF could improve trunk control[12,13,14,15]. Once the trunk control is improved, it can also act as a contributing factor for improving gait as well as balance.

Hence incorporating pelvic PNF along with the conventional physical therapy can also benefit in improving trunk control and thus making a child functionally independent.

Conclusion

The conclusion of this study is that use of proprioceptive neuromuscular facilitation technique for the pelvis has shown an improvement in trunk control among children with spastic diplegia. The four week intervention programme shows an improvement in trunk control as seen in the TCMS outcome measure thereby reducing disability among children with spastic diplegia. Hence, incorporating pelvic PNF along with conventional physical therapy can also benefit in improving trunk control thus making the child functionally independent.

Limitations and future scope: Small sample size were included and there was no follow up present. Hence similar type of study can be conducted in a larger population and in future studies could include certain other components such as the effect of PNF on balance, gait, functional independence, quality of life and caregiver burden.

Conflict of Interest: The authors had declared that there is no conflict of interest

A Quasi Experimental Study to Evaluate the Effectiveness of Revised Nursing Care Standard Operative Procedures on Knowledge & Practice Regarding Infant Feeding among Students of Selected Nursing College, Vadodara

Nirmal Raj[1], Bhumika P. Parmar[2], Rajesh Joseph[3]

[1]HOD of Child Health Nursing, [2]M.Sc. Nursing, [3]Associate Professor,
Sumandeep Nursing College, Sumndeep Vidhyapeeth University, Vadodara, Gujarat, India

Abstract

Background: Malnutrition has been responsible, directly or indirectly, for 60% of the 10.9 million deaths annually among children under 5. Well over two-thirds of these deaths, which are often associated with inappropriate feeding practices, occur during the first year of life. No more than 35% of infants worldwide are exclusively breastfed during the first four months of life; complementary feeding frequently begins too early or too late, and foods are often nutritionally inadequate and unsafe. Malnourished children who survive are more frequently sick and suffer the life-long consequences of impaired development.

Method and Materials: Quantitative evaluatory approach with quasi experimental non randomized control group design including 40 students from BSc nursing in which 20 experimental and 20 control were selected as a sample with use of purposive sampling technique. To collect data self-structured questionnaire and practice checklist were administered.

Results: The pre-test score of the experimental group the knowledge score mean % is 34.60% and the practice score mean % is 34.03% & that in control group the knowledge score mean % is 38.33% and practice score mean % is 30.57%. In respondents 45% were having inadequate knowledge, 55% were having adequate knowledge & no one were having excellent knowledge while in practice 80% were having poor practice, 20% were having adequate practice & no one having good practice in providing infant feeding. The post test score of the experimental group the knowledge score mean percentage is 85.19% and the practice score mean % is 88.46% & that in control group the knowledge score mean % is 36.91% and practice score mean % is 37.5. In respondents 27.5% were having inadequate knowledge, 22.5% were having adequate knowledge & 55% were having excellent knowledge. And in practice 32.5% were having poor practice, 17.5% were having adequate practice & 50% were having good practice in providing infant feeding. **Conclusion:** Administration of procedure regarding Standard operative procedure on infant feeding was effective as there is a significant difference in pre-test and post-test knowledge & practice score.

Keywords: *Infant Feeding, Standard Operative Procedure.*

Introduction

"Formula feeding is the longest lasting uncontrolled experiment lacking informed consent in the history of society"

Infant means age between 0 and <12 months (and also sometimes referred to as 0-11 months) that is 12 completed months of life. A young infant is referred as an infant aged between 0 and <6 months, that is six completed months of life. A very young infant is defined as an infant aged between 0 and <2 months (sometimes referred to as 0-1 months) that is two completed months of life.[1]

Infant feeding plays a major role in promotion of infant health by reducing and preventing malnutrition.

Breastfeeding, especially if given exclusively up to first six months of life can make a major contribution to an infant's development and health and also associated with mother's better health. Infant feeding is also associated with reducing healthcare costs as well as having a positive impact on health of an infant in the society.[2]

Feeding baby with Katori spoon plays a specific & useful role. It helps Babies for better lip development, control and movement as they suck feed off a spoon. And also helps to limits the amount of food so baby will spit out and gets more food into baby's stomach. However, probably persons (i.e. nurses, parents) place the spoon in child's mouth and then scrape the food off on the top of infants lip as they remove the spoon. Instead of these they have to teach infant to suck the food off the spoon.[4]

Bottle feeding is a way to provide breast milk or formula feed to a baby who is not willing or not able to breastfeed directly from the breast. Bottle feeding is best alternative used for mother who is not able to breastfeed via breast or in the absence of breastfeeding.[4]

Need for the study: Directly or indirectly, 60% of the 10.9 million deaths occur annually among children under five due to Malnutrition. And two-thirds of these deaths are often related with inappropriate feeding practices; occur during the first year of life. Worldwide Only 35% of infants are exclusively breastfed during the first 4 months of their life. And also provides complementary feeding either too early or too late. Foods which are provided in weaning are frequently nutritionally unsafe & inadequate. The children who survive in malnutrition are more frequently suffer from the life-long consequences of impaired development.[6]

Appropriate feeding practices for infants and young children can increase their survival chances. It also helps to promote optimal growth and development, especially from birth to 2 years of age in the critical window. As per recommendation, breastfeed should be started within one hour of birth in infants, and continue breastfeed exclusively up to first six months of life. After six months continue to be breastfed up to 2 years of age with appropriate complementary feeding (age-appropriate feeding can be solid, semi-solid and soft foods.)

As infants growing, their nutrient needs also grown up with them. An infant's nutrient demands start to exceed after the first six months of life, what breast milk alone can provide. To satisfied these growing demands, WHO recommends to begin eating solid, semi-solid or soft foods at age after 6 months to make sure that infants nutrient intake is sufficient to fuel their developing brains and bodies and thus it become increasingly important to track indicators related to consumption of solid, semi-solid and soft foods.[8]

Thus, adequate, appropriate knowledge & true knowledge along with the good skill practices are required to be imparted among the nursing students & nurses & the community should be made aware of providing infant feeding.

Material and Method

Research Design: In this study, the research design was studywas Quasi experimental research (Non-randomized control group) design.

Setting: The study was conducted in the Sumandeep Nursing College, Piparia, Vadodara.

Sample: 40 Students of 3rd year B.Sc. Nursing of Sumandeep Nursing College, Piparia, Vadodara.

Inclusion criteria:

1. Nursing students studying in 3rd year BSC. Nursing of Sumandeep Nursing College.
2. Nursing students who are willing to participate in the study.

Exclusion Criteria:

1. Nursing students who are not available during the time of data collection

Tool for data collection:

This consists of two parts:

Section 1: Self-Structured questionnaire to assess the knowledge regarding procedure of infant feeding.

Section 2: Check list to assess the practice of infant feeding.

Scoring procedure: For knowledge assessment

If answer is right then give 1

If the answer is wrong then give 0.

Scoring interpretation:

Category	Knowledge Score
Inadequate knowledge	0-8
Adequate knowledge	9-17
Excellent knowledge	18 – 25

For practice checklist 1 mark given for each correct step and 0 mark was given for wrong practice and partial step Scoring interpretation:

Category	Practice Score
Poor practice	0-10
Adequate practice	11-18
Good practice	19 – 26

Reliability: The reliability of tool established by using split half method Spearman Brown Prophecy formula (r=0.87) reliability test.

Data collection procedure:

1st & 2nd Day: Study subjects were selected from the population of the Study with use of purposive sampling technique and the purpose of the study was explained to the study subjects and the necessary information was provided to them regarding the research and the collection of the information. Thereafter, Informed consent was taken from each subject before implementing the data collection process, The subjects were explained about the tool and then pre-test was conducted for all the 40 subjects. After the pre-test whole sample were divided into two groups i.e. experimental (20) and control (20) group respectively using non-randomization process. Then, administered an infant feeding procedure to the experimental group by keeping control group blind.

8th and 9th day: The post test was conducted for all 40 selected study samples by administering same knowledge questionnaire and practice checklist to test hypothesis.

Statistical Design: Data were verified prior to computerized entry. The Statistical Package for Social Sciences (SPSS version 20.0) was used. Descriptive statistics were applied (e.g., mean, standard deviation, frequency and percentages). Test of significance (unpaired t test) was applied to test the study hypothesis.

Findings:

Section-I: Overall Distribution Of Respondent To Knowledge Level In Pre-Test

Table:1 Overall distribution of knowledge level in pre-test

Category	Knowledge	
	Frequency	%
Inadequate	18	45
Adequate	22	55
Excellent	00	00

Above table reveals that out of 40, total numbers of 18 with 45% of respondents were having inadequate knowledge, total number of 22 with 55% were having adequate knowledge but no one were having excellent knowledge regarding standard operative procedure on infant feeding.

Overall Distribution Of Respondent To Knowledge Level In Post-Test

Table:2 Overall distribution of knowledge in post-test

Category	Knowledge	
	Frequency	%
Inadequate	11	27.5
Adequate	9	22.5
Excellent	20	50

Above table reveals that out of 40, total numbers of 11 with 27.5% of respondents were having inadequate knowledge, total number of 9 with 22.5% were having adequate knowledge and total number of 20 with 50% were having excellent knowledge regarding standard operative procedure on infant feeding.

Section-II: Overall Distribution of Respondent to Practice in Pre- Test

Table:3 Overall distribution of practice score in pre-test

Category	Practice	
	Frequency	%
Poor Practice	32	80
Adequate Practice	8	20
Good Practice	00	00

Above table reveals that out of 40, total numbers of 32 with 80% of respondents were having poor practice, total numbers of 8 with 20% were having adequate practice and 00% were having good practice regarding standard operative procedures on infant feeding.

Overall Distribution Of Respondent To Practice In Post-Test

Table: 4 Overall distribution of practice score in post-test

Category	Practice	
	Frequency	%
Poor Practice	13	32.5
Adequate Practice	7	17.5
Good Practice	20	50

Above table reveals that out of total 40, 13 numbers with 32.5% of respondents were having poor practice, 7 numbers with 17.5% were having adequate practice and 20 numbers with 50% were having good practice regarding standard operative procedure on infant feeding

Section-III: Effectiveness Of The Knowledge Level In The Post Test Score

Distribution of mean percentage and "t" – value of post test knowledge score in experimental and control group.

Table 5:Mean % and t value of post-test knowledge score in both group

Post- Test Knowledge	Mean %	Mean Difference	t- Value	Significance
Experimental	85.19	48.28	15.18	S
Control	36.91			

At df = 38 and significant level 0.05 the obtained p value =15.18 is found to be more than the table value (2.02) which suggest the significant difference between experimental and control post-test knowledge score.

Effectiveness Of The Practice In The Post Test Score: Distribution of mean percentage and "t" – value of post test practice score in experimental and control group

Table 6: Mean % and t value of post-test practice score in both group

Post- Test Practice	Mean %	Mean Difference	t- Value	Significance
Experimental	88.46	50.96	14.31	S
Control	37.5			

At df= 38 and significant level 0.05 the obtained p value =14.31 is found to be more than the table value(2.02) which suggest the significant difference between experimental and control post-test knowledge score.

Thus, here the H1 is tested and as the above analysis reveals that there is a significant difference between post test score of knowledge and practice in the experimental and control group H1 IS ACCEPTED.

Section-IV: Correlation Between The Knowledge And Practice Regarding The Revised Standard Operative Procedureon Infant Feeding

The correlation co-efficient value(r) obtained by using Karl Pearson's correlation co-efficient is -0.04 so there is no correlation between the knowledge and practice.

Discussion

The aim of the study was conducted to evaluate the effectiveness of SOP on knowledge and practice regarding infant feeding among nursing students. It was found that nursing students had inadequate knowledge and practice regarding infant feeding and sop is effective to improve the knowledge and bring a good practice related to infant feeding.

Various evidences how the effectiveness of SOP in improving knowledge and practice regarding infant feeding. The B.Sc. nursing students are having lack of knowledge regarding infant feeding, so it is important

that health care provider should provide the knowledge related to infant feeding.

Conclusion

The analysis shows that the total mean of post-test knowledge and practice score was observed to be significantly higher than the total mean of pretest knowledge and practice score after providing SOP to the nursing students regarding infant feeding Hence, it is concluded that the SOP was effective to increase the knowledge regarding the infant feeding among nursing students. Demonstration regarding infant feeding should be given to all nursing students to improve their knowledge and practice of procedure which may aid in reducing rate of malnutrition and feeding problems.

Conflicts of Interest: The authors declare that there is no conflict of interest statement

Source of Funding: Fund for this research is researcher own.

Ethical Clearance: Ethical Clearance for this dissertation was obtained from the ethical committee SVIEC of Sumandeep Vidyapeeth University.

Knowledge, Attitude and Practice of Biomedical Waste Management in Nursing Staff of a Private and a Government Tertiary Care Teaching Hospital: A Comparative Study

Nishitha K.[1], Alice Matilda Mendez[2], Nisha B.[2], Timsi Jain[3]

[1]3rd Year MBBS, [2]Reader, Department of Community Medicine, [3]Professor and Head, Department of Community Medicine, Saveetha Medical College and Hospital, Thandalam, Tamil Nadu

Abstract

Introduction: Biomedical waste is "Any waste which is generated in the diagnosis, treatment or immunization of human beings or animals or during research" in a hospital. Improper disposal of hospital waste poses a major threat to the environment. Lack of proper management, awareness, insufficient resources and poor control of disposal of waste are the most pressing problems faced.

Objective: To compare the knowledge, attitude and practice of hospital waste management in nursing staffs and nursing assistants of a private and government tertiary care hospital in Chennai, Tamil Nadu.

Methodology: This is a cross sectional study done in a private and a government tertiary care teaching institute on 300 nursing staff (150 from each) using an orally administered structured questionnaire. The data were entered into excel and analysis was done.

Result: Of the 150 participants from government hospital 71% had training in BMW management,82% knew where to report in case of a needle stick injury,61% perceived that they have adequate knowledge regarding BMW management,98% were willing to attend programmes regarding BMW. 73% had good knowledge regarding BMW management. 90% practice good management of BMW.

Of the 150 participants from private hospital 81%had training in BMW management, 79%knew where to report in case of needle stick injury, 67% perceived that they have adequate knowledge regarding BMW management, 95% were willing to attend programs regarding BMW management. 74% had good knowledge. 85% practice good management of BMW.

Conclusion: The knowledge, attitude and practice of BMW management among nurses and nursing assistants of the private and the government hospital are found to be satisfactory. There is no significant difference (at $p<0.05$) in the knowledge, attitude and practice of BMW management among the nurses and nursing assistants of both the hospitals.

Keywords: *Biomedical waste management, knowledge, attitude, practice, nursing staff.*

Introduction:

Biomedical waste (BMW) is the waste that is generated in hospitals and health care centres during diagnosis, treatment or immunisation of human beings, mainly consists of needles, syringes, ampoules, dressing materials, disposable plastics and microbiological wastes[(1)]. With the aim of reducing health problems and

Corresponding Author:
Dr. Alice Matilda Mendez
Assistant Professor, Department of Community Medicine, Saveetha Medical College and Hospital, Thandalam, Tamil Nadu

treating the sick, health care services inevitably produce wastes that may be hazardous to health. According to the World Health Organisation (WHO), 10-25% of the biomedical waste are estimated to be hazardous[2]. Improper handling of biomedical waste increases the airborne pathogenic microbes, adversely affecting the hospital environment and community at large. Apart from polluting water, air & soil, it also has considerable impact on human health due to aesthetic effects.

BMW management (BMWM) means the management of waste produced by hospitals using techniques that will check the spread of diseases. The objectives of biomedical waste management are toreduce waste generation, to ensure its efficient collection, handling, as well as safe disposal in such a way that it controls infection as these wastes need a special attention for their proper disposal. Adequate knowledge, attitude and practices regarding biomedical waste management is lacking in developing countries[3]. The volume of the health care wastes have also increased over the last 30 years. The World Health Organisation has hence prepared biomedical waste management guidelines to ensure proper handling of these wastes.

This study was done to assess and compare the knowledge, attitude and practice of biomedical waste management among the nursing staff working in a private tertiary care hospital and a government tertiary care hospital in Chennai.

Materials and Method

This was an observational cross-sectional study done from January 2019 to May 2019. This study was conducted in a private tertiary care hospital and in a government tertiary care hospital situated in Chennai, capital city of Tamil Nadu in South India. The study included the nurses and nursing assistants working in the above mentioned institutions.

The sample size of the study is n=300, 150 from each of the above mentioned institutions. The sample size was measured using the formula {(Za-Z1-b)^2*[P1(100-P1)+P2(100-P2)]}/(P1-P2)^2, where P1 = 35%, P2=20%[4], expected difference of 15%, alpha error of 5% at 95% confidence interval.

After obtaining permission from the human resource department, a list of all the nurses and nursing assistants working in the above mentioned institutions was obtained and the participants were selected randomly using random numbers table. Nurses and nursing assistants not willing to participate in the study were excluded.

The study tool used was an orally administered structured questionnaire containing questions regarding the knowledge, attitude and practice of Biomedical waste management (BMWM) respectively. Questions related to demographic details like the participants name, age, sex,department they are currently working in, total years of experience, years worked in the current hospital,their training in biomedical waste management, years of experience, vaccination against Hepatitis, needle stick injury were also included. It included eleven questions to assess their knowledge, which included questions regarding where they would dispose certain wastes like anatomical wastes, contaminated gauze, disposable intravenous tubes and catheters, broken glass vials, discarded disinfectants, contaminated mattresses and linens . The six attitude questions were regarding whether they thought biomedical waste management as a financial burden on the setup, do they find it as a burden to report a needle stick injury, whether they are interested in attending programs to enhance and upgrade their knowledge on biomedical waste management and if they think it is important to dispose health care wastes in a proper manner. Six questions regarding their practice of biomedical waste management was also included (Table 2). One point was awarded to each correct answer and the wrong answers weren't given any point. Each of the three aspects were assessed separately and a score of more than 60% was considered that the participant had good knowledge, attitude and practice of biomedical waste management. The data was entered in MS-Excel spreadsheet and analysis was done using SPSS software. Qualitative data was expressed as frequencies and proportions, quantitative data were summarised as mean (standard deviation). Bivariate analysis was done using chi square.

Results

A total of 300 nurses and nursing assistants took part in this study, of which 150 were from the private institute and 150 were from the government institute.

The mean age of the participants from the government institute was 32.9 years whereas the that of participants from the private institute was 25.17 years. Of the participants,81% from the government institute and 75% from the private institute were nurses. The mean years of experience was higher in the government,

which is 8.29 years compared to 3.06 mean years in the private institute (Table 1).

Significantly more percent of the participants (90%) from the government institute separate biomedical waste during collection and they also collect liquid waste in leakage proof bags (77%)when compared to the participants from the private institute. Significantly more participants from the private institute collect liquid and other wastes together(43%) whereas more percent (23%) of participants from the government institute store infectious waste together with the other wastes. 83% of the participants from the government institute use personal protection while handling biomedical waste whereas only 77% of the participants from the private institute do so which is significantly less when compared.(Table 2)

Only 71% of the participants from the government institute and 81% of the participants from the private institute have had training in biomedical waste management.(figure 1).

Although the difference is not statistically significant, it was found out that increased percentage of the participants from the government institute had a good knowledge, attitude regarding biomedical waste management and a good practice of biomedical waste management when compared with the participants from the private institute (Table 3).

All the participants from the private institute had been vaccinated against Hepatitis B compared to the 73% from the government institute and 82% of the government institute participants knew to whom they were supposed to report an incident of needle stick injury compared to the 79% from the private institute. 25% of the participants from the private institute have had a needle stick injury in the past and 90% of them had reported the incident to appropriate authority, whereas 33% of the participants from the government institute have had a needle stick injury and all of them had reported the incident to the authority.

61% of the participants from the government institute showed a positive attitude towards biomedical waste managementbut only 48% of the private institute participants showed positive attitude. 98% of the participants from the government institute and 95% of the participants from the private institute were willing to attend programs regarding biomedical waste management.

70% of the participants from the private institute and 62% of the participants from the government institute think that there is an increased risk of injury if the health care waste is segregated at the source. 45% of the participants from the private institute and 33% of the participants from the government institute think BMWM setup as a financial burden on the institute. 31% of the total study population consider it as a burden to report needle stick injury .

Table 1: General profile of the participants

General Profile	Government	Private
Mean age	32.89 years	25.17 years
Mean years of experience	8.29 years	3.06 years
Nurses	122 (81%)	112(75%)
Nursing assistants	28 (19%)	38 (25%)

Table 2: Comparison between the various practice habits of the participants from the two institutes .

Practice Habits	Government	Private	P-Value
Sort BMW during collection	135(90%)	120(80%)	0.015293*
Separate sharps from blunt waste	140(93%)	137(91%)	0.515049
Use personal protection tools while handling BMW	125(83%)	116(77%)	0.191118
Collect liquid waste in leakage proof bags	115(77%)	91(61%)	0.002815*
Collect liquid and other wastes together	44(29%)	64(43%)	0.016145*
Store infectious wastes together with other wastes	35(23%)	14(9%)	0.001039*

(*- Significant at $P < 0.05$)

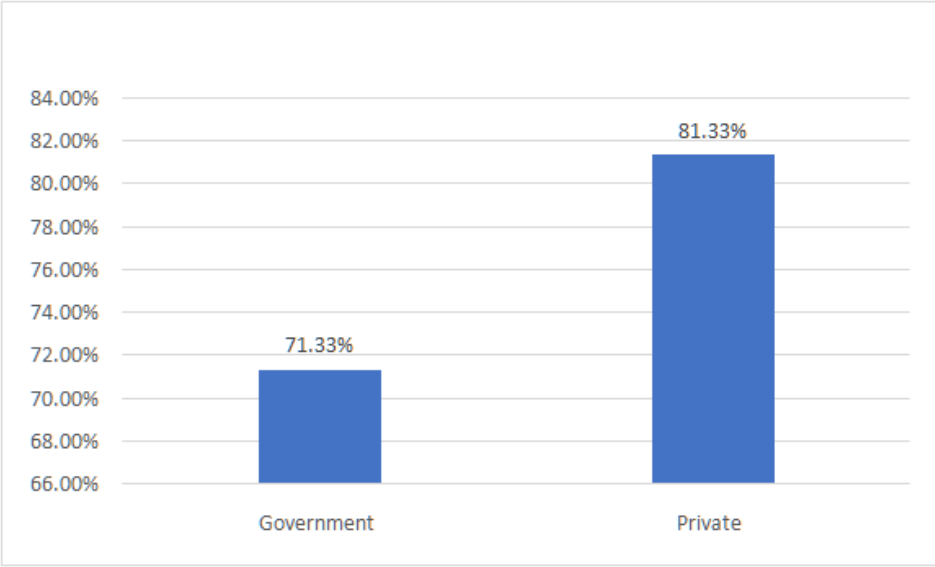

Figure 1: Participants with training in BMWM.

Table 3 Comparison between the percentage of participants having good knowledge, practicing good management of BMW and having a good attitude regarding the same

	Government	Private	P- Value
Good knowledge	73.33%	74%	0.872707
Good attitude	61.33%	48.33%	0.076136
Good practice	90%	85.33%	0.285049

Discussion

This is a cross sectional study conducted in a private and a government tertiary care hospitals regarding the knowledge, attitude and practice of BMW among their nurses and nursing assistants.

In this study it was found that 71% of the participants from the government institute and 81% of the participants from the private institute had training in biomedical waste management, compared to 68% of the nurses who participated in a study done by Lohani N et al[5].

All the participants from the private institute had been vaccinated against Hepatitis B compared to the seventy three percent (73%) from the government institute. Only 20% of the nurses who participated in the study done by Soyam GC et al[6] had been vaccinated against Hepatitis. Reporting of an incident of needle stick injury was high in both the study groups (100% in the government and 90 % in the private institutions) when compared to a study done by Stein et al[7]which showed only 37% reporting .

83% of the participants from the government institute use personal protection while handling biomedical waste whereas only 77% of the participants from the private institute do so. In a study by Madhu Kumar et al[8] all the participants wore personal protective equipments while handling biomedical waste

98% of the study population knew about the different biomedical waste categories compared to 56% of the participants in a study done by Basu et al[9], 45% of nurses of a study by Anand P et al[10]and 90% of the study population consisting of doctors and nursesin a study conducted by Mathur et al[11].

Sixty one percent (61%) of the participants from the government institute and only forty eight percent (48%) of the private institute participants showed a positive attitude towards biomedical waste management. In a study done by AdekunleOlalfa et al[12] 54% of the staff who participated showed a positive attitude towards biomedical waste management.

70% of the participants from the private institute and 62% of the participants from the government institute

think that there is an increased risk of injury if the health care waste is segregated at the source, whereas in a study by Adekunle Olalfa[12]et al 24% of the participants had the same idea. 31% of the participants consider it as a burden to report needle stick injury, while 44% of the nurses who participated in a study by Anand P et al[10] thought the same. But in a study by Malini et al[13], the participants did not consider it as a burden to report an incident of needle stick injury. 45% of the participants from the private institute and 33% of the participants from the government institute think biomedical waste management setup as a financial burden on the institute. In a study done by Khan MJ et al[14], 53% of the physicians who took part thought BMWM setup as a financial burden on the institute.

Conclusion

In this study it has been found that the difference in the knowledge, attitude and practice of biomedical waste management was not significant. But certain aspects in the practice of biomedical waste managementlike segregation of waste during collection and collection of liquid and other wastes separately were better among the participants from the government institute, whereas more percent of participants from the private institute stored infective and other wastes separately. The attitude regarding biomedical waste management was better in the participants from the government institute than that of the participants from the private institute and more participants from the government institute were willing to attend programs to improve their knowledge and practice of biomedical waste management .

Even though the knowledge, attitude and practice of biomedical waste management are not poor among the participants of this study, it can be further improved by conducting programs stressing not only on the knowledge and practice but also should stress about the attitude of the workers towards biomedical waste management by educating them about the importance of it and by enlightening them about the hazardous effects of improper management of biomedical waste management on the environment, public health and also on health of the health care workers themselves.

A Study to Find Out Strongest Predictive Factor for Functional Outcome After Stroke: An Exploratory Study

Ashish Dhirajlal Kakkad[1], Priyanshu V. Rathod[2]

[1]Ph.D. Scholar,School of Physiotherapy, RK University, Rajkot, Gujarat, India,
[2]Ph.D., Guide & Dean, Faculty of Medicine; School of Physiotherapy, RK University, Rajkot, Gujarat, India

Abstract

Background: Stroke is second commonest cause of death and fourth leading cause of disability worldwide. Its recovery makes an important concern not only for the physiotherapists but for the entire rehabilitation team.

Aim/Purpose: Stroke affects each patient variably and differently. All stroke patients who receive physiotherapy services may improve in function, rate and quality may vary. At present, there is no any objective method which tells expected prediction for recovery after stroke. So it becomes very important that there should be identification of different factors to predict recovery after stroke.

Objective: To find out strength of association between different predictive factors and functional outcome of stroke patients.

Setting: Different physiotherapy centres of Surat city.

Method: Exploratory study was done in Surat city. Selection of stroke patients was done as per selection criteria. After ethical clearance, subjects were explained about the study. Informed consent forms were signed by the patient and/or relatives. Subjects selected by convenient sampling were assessed for different 21 factors and functional outcome by Modified Barthel Index Score was recorded for all patients.

Participants: Total 125 male and female stroke patients.

Main Outcome Measure: Modified Barthel Index Score.

Results: Linear regression at confidence interval 95% was applied to find out strength of association between different predictive factors and post stroke functional outcome. Length of hospitalization was found as strongest predictive factor for functional outcome.

Conclusion: These findings may suggest that length of hospitalization is strongest factor for prediction of post stroke recovery.

Keywords: *Stroke, Predictive factors, Modified Barthel Index, Post stroke functional outcome, Length of hospitalization.*

Introduction

World Health Organization (WHO) defines stroke as a clinical syndrome characterized by rapidly developing clinical symptoms and/or signs of focal and at times global loss of cerebral function, with symptoms lasting more than 24 hours or leading to death, with no apparent cause other than that of vascular origin.[1,2]

Stroke is classified into two types. Ischemic stroke is the most common type affecting about 67-80% of individuals with stroke.[2,3] and results when a clot or block impairs blood flow, depriving the brain of essential oxygen and nutrients, leading to disruption of cellular metabolism, injury and death of tissues. Hemorrhagic stroke occurs when blood vessels rupture, causing

leakage of blood in and around brain. It may occur due to increase in intracranial pressure or restriction of distal blood flow.[1] Stroke is a global health problem. It is second commonest cause of death and fourth leading cause of disability worldwide.[4]

The incidence of stroke rises rapidly with increasing age. In India, the overall prevalence rate for stroke lies between 84 – 262 per 100,000 in rural area[5] and between 334 – 424 per 100,000 in urban areas.[5] After the age of 55 years, the risk of stroke doubles every 10 years; two thirds of all strokes occurring in people older than the age of 65 years.[6] The incidence of stroke is about 1.25 times greater for males than female.[7]

Major risk factors for stroke are hypertension, heart disease, atherosclerosis, diabetes and elevated total blood cholesterol level. All these factors are not only responsible for occurrence of stroke but they are also affecting post stroke recovery. Recovery from stroke is generally fastest in the first weeks after onset, with measurable neurological and functional recovery occurring in the first month after stroke. Much of early recovery can be attributed to the resolution of diachesis, or transient inhibition of function, that accompanies acute stroke. Thus the reduction of edema, absorption of damaged tissue, and improved local circulation and cellular metabolism allows intact neurons that were previously inhibited to regain function.[8] Patients can continue to make measurable functional gains generally at a reduced rate for months or years after insult. Late recovery of function has been demonstrated for patients with chronic stroke (defined as greater than 1 year post-stroke) who undergo extensive functional training.[9-14] These changes are due largely to function-induced plasticity. A functional training approach that emphasizes use of the more involved extremities and an enriched environment effectively stimulates neural reorganization of the brain. Prolonged recovery with improvements occurring over a period of years is especially apparent in the areas of language and visuospatial function.[15] Predictor on activity limitation and participation restriction are found the effect of age, gender, stroke type, stroke severity, pre stroke disability and post stroke disability remains highly prevalent on activity limitation and participation restriction after 4 years of stroke[16]

Stroke affects each patient variably and differently.[17] All stroke patients who receive physiotherapy services may improve in function, rate and quality of improvement may vary.[18] Some stroke patients may show very good recovery in short period where some may show minimal improvement. This leads to variation in financial cost of treatment.[19] In this fast growing world of health science at present, there is no formula or scale which tells time prediction for recovery after stroke. Era of evidence based practice and clinical reasoning is emerging day by day. Health insurance coverage also needs some objective data for prediction for recovery after stroke. So it becomes of utmost importance that there should be some objective criteria to predict recovery of stroke. Information of factor responsible for good recovery after stroke is mandatory for patient evaluation, treatment planning, guidance to patient and relatives and also for searching new therapeutic regime.[20] For the same, association should be found between different predictive factors and functional recovery in stroke patients. So objective of study is to find out strength of association of different predictive factors with post stroke functional outcome.

Materials and Method

The present study is an exploratory study which is a cross-sectional observational design; where each subject was assessed one time only for physical assessment and was assessed for past history, records of hospitalization and demographic data etc. The Ethical Committee recognized by the Central Drug Standard Control Organization (CDSCO), Govt. of India had approved this search protocol. The patients of Surat, those coming to different Physiotherapy clinics with a clinical diagnosis of stroke by general physician or neurophysician and who are discharged from hospital due to stable medical condition and having less than 6 months post stroke duration, during the period of September 2017 to October 2018 were considered as the study population.

Few different hospitals and physiotherapy centres of Surat city were visited frequently, at least once a week, to reach to new stroke patients. In the present research, a Convenient Sampling was used to select stroke patients. The purpose of this study was explained and a written informed consent was taken from all the patients &/or relatives. Patients were preliminary screened based on the inclusion and exclusion criteria.

Inclusion Criteria:

1. All stroke patients who are willing to participate
2. Both male & female stroke patients

3. Mini mental scale examination score ≥ 24[21]
4. Duration of stroke varies from discharge from hospital up to 6 months[22]
5. Patients who are taking medical treatment as per guidelines of Neurophysician or General Physician & physiotherapy treatment as per guidelines of Physiotherapist.

Exclusion Criteria:

1. Stroke patients who are not cooperative.
2. Stroke patients who have auditory &/or visual deficits.
3. Stroke patients who do not have proper medical records.
4. Patients having another neurological deficit with stroke.
5. Patients who have been Discharged Against Medical Advice (DAMA) from initial hospitalization due to request of patients &/or relatives or extended hospitalization due to any other medical &/or surgical condition with stroke or who are not hospitalized.

Patients were assessed as per assessment form which includes patient's demographic data, stroke history, addiction history, family history and presence of co-morbidities etc. List of the factors are as follows:

1. Age
2. Gender: Male/Female
3. Hand dominancy: Right/Left
4. Body Mass Index (BMI)
5. Side affected: Right/Left
6. Type of Stroke: Hemorrhagic/Ischemic
7. Length of Coma (LOC)
8. Length of Stay in Hospital (LOS)
9. Family History: Present/Absent
10. Duration of Smoking History
11. Duration of Alcohol History
12. Duration of Tobacco History
13. Transient Ischemic Attack/Stroke History: Present/ Absent
14. Duration of Hypertension
15. Duration of Diabetes
16. Duration of Atrial Fibrillation
17. Duration of Cardiomyopathy
18. Duration of Renal dysfunction
19. Socioeconomic condition
20. Education
21. Post Stroke Duration

All these factors were decided by review of literature and consensus among eleven subject experts who are dealing with stroke patients with experience of more than five years which included one neurophysician and ten senior physiotherapists and neurophysiotherapists.

Additionally all the patients were assessed by Modified Barthel Index for post stroke recovery and by Revised Kuppuswami Scale for socio economic status of them.

All the subjects passed for assessment for demographic details and physical examination performed by there searcher. On the day of the study, all subjects underwent a baseline assessment using Mini Mental Examination Scale Examination. All the measurements were taken by there searcher of the study. All the patients included in study were under Physiotherapy treatment. Goal of Physiotherapy treatment was an attempt to meet the individual needs of the patients, incorporating re-education of lost movement, facilitation method and was aimed at enhancing patient's independence for activity of daily life. Patients were allowed to speech therapy requiring their services.[23]

Outcome Measure: The Mini-Mental Status Examination (MMSE) provides a valid and reliable quick screen of cognitive function.[18] Functional outcome was assessed by means of the Modified Barthel Index (MBI).[24]

Human and Animal Research: This study is approved and registered in Clinical Trial Registry of India with registration number CTRI/2018/10/015992

Statistical Analysis: In 125 stroke patients, from discharge to upto 6 months, Modified Barthel Index (for post stroke recovery as dependent variable) was checked for multivariate linear regression with all predictive factors (as independent variables)with confidence interval set at 95% by SPSS version 20 for Microsoft Windows.

Result

Results by for multivariate linear regression with all predictive factors is shown in following table 1.

Table 1: Strength of association of different predictive factors on post stroke recovery

Sr. No.	Factor	R Square	Adjusted R Square	Strength of Association
1	Side of body	0	-0.008	0.8
2	Age	0.023	0.015	1.5
3	Gender	0.035	0.027	2.7
4	Hand dominancy	0.005	-0.003	0.3
5	Type of stroke	0	-0.008	0.8
6	Length of coma	0.092	0.085	8.5
7	Length of hospitalization	0.146	0.139	13.9
8	Body Mass Index	0.042	0.031	3.1
9	Family History	0.005	-0.003	0.3
10	Smoking history	0	-0.008	0.8
11	Alcohol history	0	-0.008	0.8
12	Tobacco	0.004	-0.004	0.4
13	TIA	0.02	0.012	1.2
14	Diabetes	0.002	-0.006	0.6
15	Hypertension	0.006	-0.003	0.3
16	Atrial fibrillation	0.003	-0.005	0.5
17	Cardiomyopathy	0.003	-0.005	0.5
18	Renal dysfunction*	-	-	-
19	Socioeconomic condition	0.007	-0.001	0.1
20	Education	0.037	0.029	2.9
21	Post stroke duration	0.023	0.015	1.5

*In study, no patient with renal dysfunction was found.

Bar diagram showing strength of association of different predictive factors in post stroke functional outcome

Discussion

From the results, it is seen that different factors affect post stroke functional outcome variably. Out of all these factors, length of hospital stay is most significant as well as strongest predictive factor. Literature has found more than 60 predictors those affect post stroke recovery. Length of hospitalization is contributing 13.9% alone in predicting post stroke functional outcome. Length of hospitalization shows time taken by physician to make vitals stable. Many studies aimed to see the outcome/recovery of patient with respect to all factors (age, gender, body mass index, diabetes, hypertension, smoking addiction, tobacco addiction, alcohol addiction, family history of stroke, previous history of transient ischemic attack) on recovery after stroke.

Other studies of Simic-Panic S Dusica et al. (2015) also showed that length of stay in hospital is also considered predictive factors which are decided by functional status at the time of admission in hospital and it shows time taken for vitals to be stable.[25, 26]Jon Erik Ween et al (2000) concluded that length of stay was significantly prolonged in patients with poor outcomes.[27] Stephen Bagg (2002) concluded that it is one of the strongest predictor for stroke outcome.[25]All these studies support findings of present study.

Additionally it was found during study that few patients had taken discharge against medical advice and few patients have not hospitalised themselves and taken treatment at home by frequent visit of doctor to avoid financial burden of hospital stay. These types of patients were not included in study. So for these types of patients, significant factor for recovery is questionable.

Limitations of present study were small sample size, un-cooperative patients may not respond well for some examination, weight of patient cannot be measured accurately in few patients for those who are not able to stand without assistance and undiagnosed co-morbidities like hypertension and diabetes etc may affect the results.

Future studies can be done with more sample size as per prevalence rate and follow-up for more than 6 months.

Conclusion

Length of hospital stay is the strongest factor to predict post stroke functional outcome. So it should be considered for prognosis of stroke recovery.

Impact of Demographic Factors on the Ethical Conduct of Physicians in India

Bishal Bhuyan[1], Shailendra Kumar[2], Sanghamitra Choudhury[2], Kinnori Kashyap[3]

[1]Research Scholar, [2]Assistant Professor, [3]Research Scholar, Sikkim University

Abstract

The study focus on the various demographic characteristics related to physician's practice related code of ethics in the healthcare sector which might help in upgrading the ethical standards to promote healthy medical care. The demographic characteristics of the physicians includes gender, age groups, work experience and education qualification. The target population was full time physicians from the with a sample size of 114, comprising of 56 male and 58 female respondents with age group 25-29 years, 30-34 years and above 34 years. To accomplish the objectives stratified random sampling technique was used. A standardized questionnaire was used to identify the practice related code of ethics of the physicians. The results revealed that there was a significant difference among various work experience and education qualification. Whereas, age and gender were found to have no significant difference regarding practice code of ethics. Therefore it is vital to change the attitude of physicians and have adequate knowledge and awareness about the ethical codes among all the stage of the medical process.

Introduction

Health care sector is one of the largest growing sectors in India. According to Indian Brand Equity Foundation, 2017 Indian health care sectors became the fifth largest employer with a total of 4,713,061 employers[1]. To cater the various requests of the patients in the medical field, the physicians are expected not only to have the skills and knowledge relevant to their particular field but also with the ethical and legal perspective which needs to be followed on the regular practices[2].

But what does ethics means? The word *Ethics* originally is derived from the Greek word *ethikos* or *ethos*-meaning *custom, habit or character.* However, ethics has been defined in a range of diverse forms[3]. Medical ethics has been framed into four moral principles: a. Autonomy, is the respect for the patient's decision making capacity b. Beneficence, is the obligation to remove harm and contribute for the welfare of others c. Non malfeasance, is not to impose adverse effects on the patients d. Justice, implies equitable and fair distribution of benefits, risk, cost and resources[4]. Conversely in the recent years, there has been increasing concern regarding the ethical behavior of the health care professionals. This is frequently indicated as complains against the physicians for the illegal medical practices such as re-using syringe, unnecessary prescription and health care fraud[5,6,7].

Gender, Age, Work experience and Education on ethical practice at workplace: Gender differences in the work environment are initiated from psychological, social or physical features[8]. According to the social role theory, men and women hold different place in workplace as well as in the family[9]. Furthermore, men and women are genetically programmed differently to behave since birth[10]. Therefore gender role attitudes may lead to differences in the perception of unethical behaviour among the men and women.

Age can be a factor related with practice code of ethics among the physicians. A study was conducted regarding practice code of ethics among 500 medical doctors, revealing that the doctors of age group 25-29 follow strict ethical behaviour than the senior doctors[11]. Another study tried to understand the knowledge of medical ethics among the senior and junior doctors[12].

Practice code of ethics is influenced by the work experience of the doctors in their particular field. A study conducted on medical professionals of Rajasthan showed that best practice was found among those with 10-20 years of work experience[13]. Moreover, medical doctors with work experience more than 8 years were likely to have favorable attitude towards code of ethics as they might recognize the importance of code of ethics[14] .

Doctors working in government health sector showed healthy practice of ethical principles than those of the private health facilities. This might be because government health facilities have ethical committee that oversees the medical doctors working according to the ethical codes[15]. For medical doctors to practice health ethics, a proper training and education qualification with respect to clinical expertise and knowledge about the subject matter is necessary[16].

Need of the Study:

1. The study aims to give an insight about the various medical care practices which are being adopted in hospitals by the physicians.
2. The study aims to offer a valuable framework for establishing standard ethical norms for medical care.
3. The study will help in finding out the differences regarding the demographic factors of the physicians.

Objectives:

1. To find out the significant differences between male and female physicians on practice code of ethics.
2. To find out the significant differences between the three age groups (25-29), (30-34) (34 and above) of the physicians on practice code of ethics.
3. To find out the significant differences between work experience of physicians on practice code of ethics.
4. To find out the significant differences between general practitioner and specialist on practice code of ethics.
