Emotional dysregulation is a central topic of interest in many clinical studies. It plays a vital role in making or breaking interpersonal and interpersonal relationships in clinical populations as well as healthy controls. This study seeks to investigate the nature, intensity and extensity patterns of emotional regulation in patients diagnosed as major depression (N: 254) and borderline personality disorder (N: 69). By using a one-shot cross sectional purposive sample survey design, this hospital-based study targeted a random sample of subjects from both gender between 18-30 years. Following clinical interviews and diagnosis as per the chosen inclusion and exclusion criteria, participants were recruited based on ICD-10 criteria and after they secured a minimum cut-off score on McLean's Screening Instrument for Borderline Personality Disorder and Hamilton Depression Rating Scale. The selected participants were administered Difficulties in Emotion Regulation Scale and Cognitive Emotion Regulation Questionnaire. Results show significantly high scores on emotion regulation in patients with borderline personality disorder than major depressive disorder ($p:<0.05$). These differences are maintained across all domains except for cognition mediated areas like 'awareness', 'self-blame', 'acceptance', 'rumination', and 'positive refocusing'. Associated variables like genderand marital status appear to influence only some aspects of non-cognitive emotional dysregulation. The findings are discussed along with their implications for therapy in the context of cultural factors unique to Indian settings.

Key Words*: Emotional dysregulation, Major Depression, Borderline Personality Disorder, Self-Blame, Rumination.*

Introduction

Emotional dysregulation is a term used in mental health settings to refer to emotional responses that are poorly modulated. It may manifest as anger outbursts, acts of aggression or destructiveness against self or others, and can result in a breakdown of interpersonal relationships. Emotional dysregulation is implicated as being at the core of major depressive disorder and borderline personality disorder. It is shown that in psychiatry disorders including anxiety, depression, eating disorderand substance-related disorders most commonly used strategy out of six strategies (problem solving, reappraisal, acceptance, suppression,avoidanceand rumination) was seen for rumination. Avoidance, problem solving and suppression were used with medium frequency where as reappraisal and acceptance used least. [1]

It is shown that individuals having major depressive disorder less differentiated emotional experiences than healthy controls but only for unhelpful emotions.[2] Further, emotion regulation difficulties in female patients with major depressive disorder are found to be greater in comparison to normal healthy controls [3]. Although there is extensive research exploring the relationships between these processes and depression, the research on other unhelpful emotions is sparse.

Based on self-report measures, investigators have identified a triad of emotional functioning-emotion

dysregulation, distress tolerance, and experiential avoidance in young adult out patients with borderline personality disorder [4]. Emotional reactivity to social rejection and negative evaluation in patients with borderline personality disorder was found to be higher than in comparable healthy controls [5]. Taking these facts in to account, our aim is to identify emotion dysregulation in major depressive disorder and borderline personality disorder, and compare emotion dysregulation in major depressive disorder and borderline personality disorder. Also we investigate emotion dysregulation in major depressive disorder and borderline personality disorder in relation to key socio-demographic correlates like gender, marital status, and occupation.

Material and Method

The clinical samples were recruited based on the [6]Diagnostic Criteria for Research-10 . 323 participants with the age range of 18-30 were recruited out of which 69 borderline personality disorder and 254 major depressive disorder. Those scored 7 are more on MSI-BPD[7] and HAM-D were included in the study.[8] Patients with intellectual disability, psychosis, bipolar disorder, substance dependence or abuse disorder and presence of any serious physical disease, head injury and neurological disorder. Personal details were collected using a socio-demographic data sheet. There were statements on assuring confidentiality, leaving choice of participation to the respondents, and acknowledging ones willingness or otherwise to participate in the study.

Self report questionnaires such as MSI-BPD and HAM-D were used to screen borderline personality disorder and measure depressive disorder patients [9,10] . Difficulties in Emotion Regulation Scale was used to measure difficulties in emotion regulation difficulties in the following six domains of emotion regulationNon-acceptance, Goals, Impulse, Awareness, Strategies and Clarity. [11] Similarly cognitive emotion regulation questionnaire was used to measure cognitive emotion regulation difficulties in nine dimensions present in the scale are self blame, blaming others, acceptance, refocus on planning, positive refocusing, rumination, positive reappraisal, putting into perspective and catastrophizing.[11]

Results

(i) **Emotion regulation in major depressive disorder and borderline personality disorder:**

Results of comparative overall scores on emotion dysregulation in persons with major depressive disorder and borderline personality disordershow gross difficulties in emotion regulation for both the clinical populations. If the patients with borderline personality disorder (N: 69; Mean: 103.48; SD: 7.72) score in 'moderate-severe' range of norms on DERS, the sample with major depressive disorder do not lag much behind (N: 254; Mean: 93.67; SD: 8.60). The same is true for the trends on cognitive emotion regulation between the two groups.

Table 1: **Distribution of Mean Scores and SD across Tests & Conditions**

Tools	Items	Score	BPD (N: 69)	MD (N: 254)	Probability
DERS	36	36-180	103.48 (7.72)	93.67 (8.60)	t: 8.5809; Df: 321; p: 0.0001
CERQ	36	36-180	100.99 (7.32)	95.70 (7.60)	t: 5.1670; Df: 321; p: 0.0001

(KEY: BPD: Borderline Personality Disorder; MD: Major Depression)

(ii) **Domain-wise profiles in emotion regulation between major depressive disorder and borderline personality disorder**

Wherein a domain-wise analysis of score profiles is undertaken on DERS, the patients with borderline personality disorder consistently score high across all areas except 'non-acceptance' (N: 69; Mean Score: 16.28; SD: 2.44) wherein those diagnosed as major depressive disorder score relatively lower (N: 254; Mean Score: 15.15; SD: 1.87).

Table 2 : Distribution of Mean Scores and SD across Domains on DERS

Sample	**N**	**NA (6)**	**G (5)**	**ID (6)**	**A (6)**	**S (8)**	**C (5)**	**Total (36)**	**Probability→**
BPD	69	16.28 (2.44)	14.93 (2.20)	20.26 (4.22)	15.14 (1.82)	24.03 (2.89)	13.35 (1.79)	103.48 (7.72)	<0.001; VHS;
MD	254	15.15 (1.87)	14.67 (2.18)	15.88 (3.60)	14.97 (2.20)	20.21 (2.31)	12.90 (1.86)	93.67 (8.60)	<0.001; VHS;

		VHS	VHS	VHS	NS	VHS	VHS		

[Key: NA: Non-Acceptance; G: Goals; ID: Impulsive Difficulty; A: Awareness; S: Strategies; C: Clarity][Number of items under each domain is given in parenthesis]

Domain-wise comparative analysis of scores on CERQ between the two clinical groups (Table 3) shows that the predominant aspects of cognition involved in emotion regulation that are affected is acceptance, rumination, self-blame, positive reinforcing and refocusing on planning, which are all mostly on the higher side for patients with borderline personality disorder than for those with major depressive disorder.

Table 3: Distribution of Mean and SD Scores across Domains on CERQ

Scales	**Items**	**BPD (N: 69)**	**MD (N: 254)**	**Probability →**
Self-blame	4	14.26 (2.54)	13.69 (2.13)	t: 1.90; p: 0.05; S;
Acceptance	4	16.94 (2.39)	15.98 (1.61)	t: 3.94; p: 0.001; VHS;
Rumination	4	13.41 (1.95)	11.44 (1.89)	t: 7.60; p: 0.001; VHS;
Positive Refocusing	4	13.65 (2.68)	10.66 (2.14)	t: 9.69; p:0.000; VHS;
Refocusing on Planning	4	9.46 (1.82)	9.96 (1.55)	t: 2.25; p: 0.03; S;
Positive reappraisal	4	8.58 (1.631)	8.84 (1.38)	t: 1.32; p: 0.19; NS;
Put into perspective	4	8.30 (1.49)	8.36 (1.55)	t: 0.27; p:0.78; NS;
Catastrophizing	4	9.22 (1.93)	9.33 (1.96)	t: 0.43; p: 0.67; NS;
Other-blame	4	7.49 (1.72)	7.61 (1.36)	t: 0.596; p: 0.55; NS
Probability↓				

(KEY: BPD: Borderline Personality Disorder; MD: Major Depression)

(iii) Distribution of profiles in emotion regulation between major depressive disorder and borderline personality disorder in relation to key socio-demographic variables

Gender wise differences within each clinical condition (p: <0.001). The males with borderline personality disorder score significantly high on the domain of 'Impulsive Difficulty' (N: 54; Mean: 20.77; SD: 4.20) than the females in the same group (N: 15; Mean: 18.40; SD: 3.88) (p: <0.001). A similar trend is seen also for the patients with major depressive disorder (p: <0.001).

Analysis of scores across domains on CERQ between the two clinical populations based on gender variable shows no statistically significant differences except for 'Other-blame' condition. There are statistically significant differences in all the domains on DERS for major depressive disorder as well as borderline personality disorderin relation to three categories of the occupational variable (p: <0.001).

On the CERQ, there is a clear pattern of nil significant differences across its nine different scales for patients with borderline personality disorder as compared to significant differences at least with respect to a few sub-scales for those with major depressive disorder in relation to occupational variable. Thus, respondents with major depressive disorder show significant elevation of emotion regulation scores on domains like positive reappraisal, catastrophizing, positive refocusing, refocusing on planning and other-blame tendencies for this variable (p: < 0.05). This means that clients with major depressive disorder still hold tendencies to think of pleasant things or experiences, or think of how best to cope with the situation.

The next series of test wise domain analysis was undertaken for the binomial marital variable: married vs. unmarried. There are statistically major differences for distribution of mean scores across all domains on DERS for both groups of sample with major depressive disorder as well as borderline personality disorder in relation to marital variable (p: < 0.001). On the CERQ, the distribution of scores across domains shows nil significant differences across all its nine different scales for patients with borderline personality disorder as compared to significant differences in all except one sub scale of catastrophizing sub-scales for those with major depressive disorder in relation to marital variable. Thus, the married respondents with major depressive disorder show significantly less elevation of scores on the domains of catastrophizing only (p: > 0.05). This means that married clients with major depressive disorder maybe receiving sufficient supports to buffer such attribution tendencies to cope with their predicament.

Discussion

Depression is found to be greatly associated with difficulties in cognitive control and, especially, with difficulties in inhibiting the processing of unhelpful material. Evidence appears to favour greater rumination in borderline personality disorder with also a different course or illness trajectory and treatment pathway as compared to major depressive disorder. It is noted that major depressive disorder can co-occur with borderline personality disorder. Many patients with borderline personality disorder often present depressive symptoms. It is postulated that depressed individuals are characterized by emotional inertia, while individuals with borderline personality disorder are characterised by emotional instability. Both groups have been found using more maladaptive affect regulation strategies than healthy controls [12]. The essential findings in the present study related to high scores on emotion regulation for patients with borderline personality disorder than those with major depressive disorder especially in cognitive related domains 'self-blame,' 'acceptance,' 'rumination,' 'positive refocusing,' and to a lesser extent on 'refocusing on planning' has critical implications for treatment.

Both the clinical conditions appear to be equally affected for emotion dysregulation in the domains of 'putting into perspective','positive reappraisal,'other-blameand 'catastrophizing',respectively. Similar trend are reported in previous studies [13,14,15] . Also, patients with borderline personality disorder are found to have poor social problem-solving skills that may disturb their emotion regulation [16] The high borderline personality disorder individuals demonstrated greater increase in unhelpful emotions, shame and ager in response to the social rejection/ compared with the annoying arithmetic task [17] .

Gender is most frequently discussed variable for emotion dysregulation in clinical conditions. Despite this lay conviction, empirical evidence on gender differences in emotional responding is mixed. A limitation of these studies is that they are all based on self-reports and is

vulnerable to the effects of gender stereotypes. Future studies must distinguish emotional reactivity and emotion regulation. There is also a cultural dimension to emotion regulation that is emerging in this study. Collectivistic cultures as in India, may recommend less expression of emotions for fear of upsetting social harmony [18,19]. Occupation has not emerged as a critical variable for emotion regulation in major depressive disorder and borderline personality disorderin this study. Being in relation or marriages in which one or both partners have borderline personality disorder can be tumultuous, conflict-laden, and dysfunctional. It is likely to be an everyday challenge for persons with major depressive disorder and borderline personality disorder to deal with negative emotions at work. However, more research is required to conclude emphatically on this variable of emotion regulation in these clinical conditions.

Conclusion

In conclusion, this study sought to inquire the nature, intensity and extensity patterns of emotion regulation in patients diagnosed as major depressive disorder and borderline personality disorder. By using a one-shot cross sectional purposive sample survey design, this hospital-based study targeting a random sample of subjects from both gender between 18-30 years has significantly high scores on emotion regulation in both the clinical populations with marked differences across specific cognition mediated domains and in relation to associated variables like gender and marital status appear to influence only some aspects of non-cognitive emotional dysregulation. These findings have implications for therapy in the context of cultural factors unique to Indian settings.

A Study on Stress Management and Health Impacts on Women Employees of it Sectors in Chennai City

Snigdha Preethi R.V[1], M. Valliappan[2]

[1]Research Scholar , Department of Management Studies, Sathyabama Institute of Science and Technology, Chennai, [2]Professor, Department of Management Studies, Jeppiaar Engineering College, Chennai

Abstract

Women are playing diverse roles in the family and in the work place. Women experience stress and many health impacts in both sides from psychological tension and physical harassment at workplaces, apart from the common job stress. Information Technology (IT) companies is one of the significant employee generating industry in the worldwide condition where the people are participating. In these companies women advanced into the corporate workforce, however without need of full improvement of their abilities and ascend for authority positions because of stress. Globalization of economy have constrained our IT workforce to concern more in winning the ability individual and India's informed IT proficient women are a noteworthy resource that should never again be underestimated and under-used. This paper depends on discoveries from research studies on Indian Information Technology Industry. It gives a diagram of the difficulties and stress observed by women who are working in IT companies associations. Here discussion is about what changes are required to manage stress among women and what is being done to get the prescribed procedures for Information Technology industry in India. The present paper features the adapting systems that can be chosen to additionally precede corporate journey to gender inclusion and the development of women in the society.

Keywords: *Stress management, IT companies, women, economy, health, employees*

Introduction

In the recent years the developments in the areas of communication, power and software developments is constantly increasing in India. Information technology industry has already established itself becoming a popular across the globe. In today's context the word stress we often listen everywhere in this globalized world, stress are often described as feelings of being under too much physical, emotional and mental resulting into tension.

Stress at work place is common aspect. Now a day jobs are more associated with stress. The working persons come under stress and suffer from its consequences. In reality the stress is faced by everyone in everyday life. Some people have high tolerance for stress and succeed well in the expression of numerous stressors in the environment. Stress is a wide phenomenon as it appears to exist in human beings, animals and even in metals.

However, this study is about women stress with unique focus on the work stress in IT companies. Numerous individuals think they comprehend stress, but actuality stress is perplexing and frequently misjudged. Our Information Technology industry has a name for it 'Burn out stress disorder', which is seen usually among women working in IT companies. Technological and administrative changes in the IT companies in India made a sharp and genuinely sudden increment in the interest for female laborers (Vijayakumar Bharathi, 2015)[1] Therefore stress among women employees in Information Technology industry is a contemporary issue to talk about and to hit upon on explanation of this issue.

Women Employees

In the modern world, women no longer wait behind in terms of career. The IT has been noticed that one of the industry, which has witnessed high development for women and helped them more. Though, still now women are expected to do multi tasking. The Nature has given

women too much supremacy but, the law gives them too little as there is no detach in support of women to fill the gap during their intrinsic responsibilities. Women themselves support the idea of men as a pioneer which cannot be broken by the women to make a position in the male-dominating corporate world.

Women in India is changing the view of them in the society, from just a housewife to CEO of an organization, she not only has acquired skills and abilities to being an ideal housewife but being at same time competition with life partner. Now, women are transforming themselves with their dream career and this is the new transmission of women but, women are suffering from numerous symptoms of stress those who are working. They have to fulfill the various demands at both workplace and home. Today, to create a balance with occupational life as well as their personal life at home with their children maximum married couples are working at equal level to live a stable life. But it is very difficult for the women as she has to perform various tasks right from a cooking, as a tutor to their children, a housemaid who take care and fulfill requirements of the home. So, a working woman is highly stressed and restless.

Health impact

Anxiety and depression are types of health impact that affects a mental status of a person. It can affect thoughts, feelings, behavior, and overall health. Normal feelings fall along a range from lower level to higher level. It is regular to react to suffering in life with sorrow and obscurity. But when these feelings create impact on a person from performing their everyday activities and the reality of a person's life, they are considered indications of Health impact (Eleni Kampanellou, 2016)[2].

Type of stress

Stress has often been misunderstood to be negative but, some people recognize the significance and effectiveness of positive stress. In daily life stress is everywhere and definitely unavoidable. So it is required to differentiate between positive stress and negative stress. Negative stress causes many physical and psychological problems. There are four main category of stress namely eustress, distress, hyper stress and hypo stress.

Positive Stress

Stress is said to be positive when the circumstance offers an opportunity for one to gain something. Eustress implies useful stress-either mental, physical or biochemical, radiological. Eustress is frequently seen as an inspiration since in its nonappearance the individual. Positive stress gives the sprit to accomplish and actuates us to succeed are achieve the following dimension of vocation openings and to get more money related advantages, these positive stress helps women.

Negative Stress

Stress influences individual physiologically and typically and it is connected to a few medical issues, the procedure of physiological stress reaction begins from the minute the body understands the stressor, viewed by the sending of signs to the cerebrum, and to the particular thoughtful and hormonal reactions to take out, decrease or adapt to the stress Sympathetic Response things to go immediately with stress and the synapse is discharged by the nerve endings and is sent to the SNS Enhance the quality of your skeletal muscles.

Nature of stress

The main cause of stress among the work force has become part of human life, due to development, whether it is supposed as a negative or positive experience. There various reasons for stress in workplace conditions are associated with the work pressure, physical and mental-illness. Some of stresses are identified as Job related stress and they are workload, organizational and physical work environment, long working hours, culture and politics of the organization, the restrictions compulsory on behavior, etc. Relationship related stress which is identified outside the workplace. Change in living conditions also plays important role in creating stress (Schneiderman et al, 2016)[3]. Stress linked with the home and workplace interface and it includes conflicts of allegiance, life style and life crisis.

REVIEW OF LITERATURE

Sudha Tiwari (2015)[4] stated that the stress originates from two sources, namely organization and the family. The factors recognized for the stress include anxiety about the replacement and insecurity, future of their children and financial inference. The percentages of women being affected by these in two companies are equivalent. The stress can be managed by maintaining balance between the proficient and the individual responsibility.

Thirumaleswari (2013)[5] has conducted a study on job stress among employees of IT industries in Chennai. She has found that employee becomes stressed when they are allotted with unachievable targets and are unable to manage the given situation. The researcher acknowledged few steps for effectively handling stress. The result from the study stated that the employees should to be avoided by providing overload of work; proper rewards should be giving for their excellent performances of the employee.

Janani (2016)[6] stated in her study that the stress refers to a physical function that is mainly caused by some form of emotional or psychological, it could be a mild depression, work-related pressure and even tremendous behavior qualities that can produce severe stress. However, these problems are considered to run in families and workplaces. Working women suffers from stress issues; it may also be at a risk of making tragedy in their family, work and their life.

Rao N (2017)[7] conducted a study on the effect of stress on women health. Results show that working women are facing higher level of stress than that of the non- working women. It has been determined that stress level of working women were higher when compared to non- working women and that there was a significant difference between women's working status and their stress level. Working women had higher level of stress than unemployed women.

Chaudhari et al. (2014)[8] studied that raise in stress levels are found in female health care professionals in the India due to shortage of manpower, lack of infrastructure, extended working hours and inadequate remuneration for their work. Enthusiastic relaxation exercises had decreased not only the stress levels but also increased the quality of their life and most important patient care.

OBJECTIVES

- To study stress management among women employees of IT industries in Chennai.
- To study the effects of stress on women employees.
- To analyze the level of stress and health impact experienced by women employees.
- To provide suggestions for the women employees to overcome stress.

Research Methodology

Details regarding the research design, data collection questionnaire, sampling plan, area of the study and statistical tools used have also been given. Finally, the limitations of the study have also been briefed.

Research Design

The research design is purely and simply the framework or plan for a study that guides the collection and analysis of the data. The research design indicates the methods of research that is the method of gathering information and the method of sampling study is descriptive in nature.

Sampling Plan

The sampling plan is to be decided about the sampling unit, sample size and sampling method.

Sampling Method

For this study, the samples were drawn using random sample method.

Statistical Tools Applied for the present paper

The following tools and techniques have been used for the analysis of the data.

i. One- way ANOVA

ii. Chi-square

iii. SEM (Structural Equation Modeling)

ANALYSIS OF THE DATA

The data collected through questionnaires have been tabulated. By using the above mentioned statistical tools, the data have been analyzed. Interpretations have been drawn based on the analysis. The findings and observations are the result and outcome of the interpretations made during the course of analysis.

ONE WAY ANOVA

H_{01}There is no significant difference between age with respect to perception about Work Performance, Occupational stress, Organizational stress, Behavioral stress and Stress management.

Table 1: One Way ANOVA

		Sum of Squares	df	Mean Square	F	Sig.
Work Performance	Between Groups	28.902	4	7.225	.469	.758
	Within Groups	3016.571	196	15.391		
	Total	3045.473	200			
Occupational stress	Between Groups	53.345	4	13.336	1.148	.335
	Within Groups	2277.023	196	11.617		
	Total	2330.368	200			
Organizational stress	Between Groups	34.181	4	8.545	1.222	.303
	Within Groups	1370.416	196	6.992		
	Total	1404.597	200			
Behavioral stress	Between Groups	32.534	4	8.133	.747	.561
	Within Groups	2132.750	196	10.881		
	Total	2165.284	200			
Stress management	Between Groups	56.259	4	14.065	1.503	.203
	Within Groups	1834.637	196	9.360		
	Total	1890.896	200			
Health Impact	Between Groups	99.393	4	24.848	2.024	.093
	Within Groups	2406.696	196	12.279		
	Total	2506.090	200			

**Significant at 0.05% level

Analysis: It can be seen from Table 1.1 that the p-value is significant at 0.05% level for Stress management of women employee in IT companies. Therefore, the null hypothesis is rejected in such cases.

Discussion: There is no significant difference between age with respect to perception about Work Performance, Occupational stress, Organizational stress, Behavioral stress and Stress management

*Significant at 5% level

Analysis

Since the P value is lesser than our chosen Significance at =0.05, we can reject the null hypothesis, and conclude that there is an association age and experience.

Discussion:

There is no significant association between age and experience in relation to the variables such as Work Performance, Occupational stress, Organizational stress, Behavioral stress and Stress management.

Model Fit Indices Summary: The important fit indices are presented in the Table below.

Table 3: Major Model Fit Indices Summary

Parameters	Acceptable values for Good Fit	Research Model Values
GFI	>0.9	0.932
AGFI	>0.9	0.900
CFI	>0.9	0.958
RMSEA	<0.06	0.027
RMR	<0.02	0.008

Source: Primary Data, SPSS AMOS output, Haier et al. (2009); Hooper et al. (2008); Steiger (2007); Hu and Bentler (1999).

Interpretation:

The Goodness of Fit Index (GFI) value was 0.932, Adjusted Goodness of Fit Index (AGFI) value was 0.900 and Comparative Fit Index (CFI) value was 0.958. All these values are (greater than 0.9) indicating a very good fit. It was found that Root Mean Score Error of Approximation (RMSEA) value was 0.027 (lesser than 0.06) and Root Mean Square Residual (RMR) value was 0.008 (lesser than 0.02).

Findings

- The respondents are only women employees from IT companies in Chennai city
- The majority of the respondents are employed and below the age of 30
- The result is showing that the stress management and health impact playing a significant role in work performance of working women.
- It is observed from the study that the women employee of IT perceive high level of stress

Suggestions

- Though the stress is common for everyone, the solution for managing stress should be done. Hence, it is suggested that expert can be appointed to identify the problems faced by the women employees working in the IT companies which could help in managing such stress.
- Proper practice relaxation techniques like meditation and yoga should be implemented and awareness should to be created in every IT companies to reduce the level of stress
- It is further suggested that promotions based time bound also be introduced and which will help the employees to get promotion occasionally.
- The stress can be managed by keeping a fine balance between work life and family life. It is advisable to avoid unnecessary concern about the work-place anxiety there itself before coming home.

CONCLUSION

Women working in the IT sectors feel stress due to various professional and family factors, prominent of which being relocation and uncertainty, anxiety about the future of their children and financial implications. Job-related stress is a major issue for working women. Women are being the mainly affected by stress therefore their stress management is essential for both family and work life. Companies have to understand the needs of the women employees and they have to provide relaxation techniques and counseling sessions and to provide good opportunities for their career development. The development of an independent woman's health program that takes a life-course approach to improving their access to healthcare is needed to enable management of all issues that affect women's health. This requires behavioral change communication in the health system to primary-level health workers and through them to the communities. Any people with stress cannot precede their work life balance properly. The human life and stress common and nobody are free from stress. It is not that only people with higher position will have only stressed even the low position people also has stress. If our attitude is positive and its outcome will be also positive. It is also found that in case of IT companies the level of stress is high.

Ethical Clearance: This research was approved by Head of the Department of Management Studies, Sathyabama Institute of Science and Technology, Chennai. The research was reviewed and discussed under the guidance of Research Supervisor of Department of Management Studies, Jeppiaar Engineering College, and Chennai.

Source of Funding: The research was self funded. This research obtained no specific grant from any funding agency in the public, commercial, or not-for-profit companies.

Superbrain Yoga Enhances Well-Being among School Students

Srikanth N Jois [1],K. Nagendra Prasad[2], Lancy D'Souza[3]

[1]Research Head, World Pranic Healing Foundation, India, Research Centre, Mysore, India, [2]Senior Research Consultant, World Pranic Healing Foundation, India, Research Centre, Mysore, India, [3]Associate Professor, Maharaja's College, University of Mysore, Mysore, Karnataka, India

Abstract

Background: Superbrain Yoga (SBY) boosts pranic energy in the brain. It is based on ear acupuncture and the movement of subtle energy in the body.

Aim: The aim of this study is to improve the well-being of school students by practicing SBY.

Setting and Design: The study involves 1,945 school students from Mysore district, India. SBY was practiced by the students for a period of three months thought by their teachers.

Method: Responses with a questionnaire from the students and their teacher were collected and examined. The questionnaire was on health, relationship with their family and friends, time consciousness, communication skills and activeness of students.

Statistical Analysis: The data collected were analyzed with Chi-square test and contingency coefficient analysis.

Results: Responses of the students were analyzed and they reported that their health has often improved by 78%, sometimes improved (16.3%) and rarely improved (5.6%). Similarly, responses in the relationship with family and friends were found to be drastically improved (81.3%), moderately improved (14.6%) and hardly improved (4.1%). Both the results were found to be significant (p<0.001). Teachers also reported that students improved in their time consciousness, communication skills, and activeness.

Conclusion: SBY has improved the overall well-being of school students.

Keywords: *Brain, family, health, prana, school, yoga*

Introduction

The human brain being more powerful and sophisticated, it becomes essential to maximise its potential for better work output and holistic wellbeing. Many techniques to optimize brain wellness are described in literature. Among them Yoga is most popular. Yoga changes the physiology of the body through breathing techniques, physical postures (asanas), and cognitive control (relaxation and meditation).[1,2] Superbrain Yoga (SBY) is a yogic exercise that cleanses and energies the chakras needed for the brain to function efficiently. The chakras are actually the main acupuncture points. SBY is done by squeezing earlobes with forefinger and thumb in a specific position followed by fourteen squats with controlled breathing technique. By doing this, the ear produces the necessary energy or *prana* connection to the right and the left brain. This causes the left and right brain to become activated and energized.[3]

Crown chakra is located at the crown of the head and has the task of controlling and energizing the brain. The sex chakra is located in the coccyx area. It controls the energy of the gonads and gives them energy. Basic chakra is a dynamic activity center. This is the center of action and operation. If basic chakra is imbalanced, it

Corresponding author:

Email: research@pranichealing.co.in

will be very overactive and could lead to several health complications for humans. By doing SBY energy is transferred from the lower centers to the upper centers mainly the crown centre, which control the pineal gland and overall brain health. Hence, SBY could enhance the Pranic energy in the brain. This technique was practiced and developed long ago by Indian rishis to increase the intelligence of people.[4] Earlier studies showed when school childrens practiced SBY it could help in enhancing concentration, confidence,[5] memory, selective attention,[6] academic performance and visuospatial ability [7]. When SBY is practiced for one minute, Alfa wave activity in the brain is increased.[8] It also helps children with Attention Deficit Hyperactivity Disorder (ADHD).[9] SBY is easy to learn technique, cheap and could be practiced daily by school students to improve their overall performance. The present study aims to find the effectiveness of SBY on well-being of school students.

Method

Sample

Thirty eight teachers from many schools in Mysore district, India randomly participated in this study. They were trained about SBY technique. Among them 997 were girls and 948 were boys totalling to 1,945 in number, with their average age of 12.5 yrs. The subjects (teachers and students) were informed about the purpose and method of the study and their consent was obtained. They were guaranteed that they could withdraw from the study at any time.

Study Design

Cross sectional study design was used.

Phases of the study

The study was performed in three phases.

Ist phase

A workshop was performed for the selected school teachers about SBY as hypothesised by Master Choa Kok Sui. They were provided with SBY trainers manual, which contained detailed information about SBY and its procedure

IInd phase

These teachers in turn trained their students who participated in this study about SBY and was practiced for a period of three months. Daily before the school began, teachers guided students to practice SBY except on Sundays and hoildays.

IIIrd phase

Teachers and students responses were collected with a questionnaire and analysed after completion of second phase.

Superbrain Yoga procedure

Stand facing the east, Connect the tongue to the roof of your mouth i.e..palate; Press the right earlobe by the thumb and index finger of the left hand and left earlobe by the thumb and index finger of the right hand; The right hand should overlap the left hand; While sitting, simultaneously inhale and while standing, simultaneously exhale; Repeat the last step for 14 times. [3]

Tools employed for the study

Two questionnaires were used as tools in the present study.

- *Superbrain Yoga Questionnaire for school teachers.*
- *Superbrain Yoga Questionnaire for students*.

Permission

Permission to conduct this study was obtained from Deputy Director of Public Instructions office (DDPI) and from District AYUSH Officer, to conduct the study.

Statistical methods applied

The data collected have been analyzed under Chi-Square test and Contingency Coefficient analysis and the results obtained have been tabulated and interpreted.

Results and Discussion

Improvement in overall health

Table I denoted that 78 % of the students have opined that they have often felt an improvement in their overall health after the practice of SBY. Only 16.3 % of them felt that sometimes they observed improvement and 5.6 % felt that practicing SBY has helped them rarely in improving their health. Chi-square test revealed a significant difference in student's health after SBY (X^2 = 1783.528, P < .001). Among 78 % of the students who

have experienced significant improvement in their health 93.8 % of them are studying in the lower grade (1st to 5th standard), 71 % in the middle grade (6th to 8th standard) and only 66.3 % in the higher grades (9- 10th standard) and the results were found to be signifncant (P<0.001).

Relationship with friends and family members

Both urban and rural area students have found to have experienced improvement in relation to their family and friends. Practice of SBY has helped the students from urban areas to improve the relationship with their friends and family members by 85.1 % than the rural students (78.1 %) and the resuts were significant (P<0.001). The effect of SBY is the same for both boys and girls of all age group (Table II). Chi-square test revealed a significant difference in student's relationship after SBY practice (X^2 = 2049.247, P < .001).

Teachers feedback

To study the impact of SBY on students, 14 teachers were randomly selected and given a questionnaire. There were 11 male and 3 female teachers within age 30 to 55 yrs. Data from teachers were elicited questioned through a questionnaire regarding the effects of SBY on student's time consciousness, discipline, communication skills, memory and activeness of students. It is very encouraging to know that 92.9 % of the teachers opined that they have observed improvement in the time consciousness among students after the practice of SBY and it was found to be significant. As shown in Table III, a majority of the teacher's (85.7 %) of them observed a better discipline in students after the practice of SBY. Majority of the teachers (71.4 %) have opined that they have noticed signs of memory enhancement of the students after the practice of SBY.

	%	0	7.1	92.9	

Discussion

The relationship of students with their family and friends have improved along with the physical health indicating overall improvement among students after the practice of SBY. SBY being practiced on a regular basis becomes a physical activity contributing towards the brain wellness of the child. Examinations of SBY practitioners with EEG and Brain Maps show that their brain are fully synchronized and balanced. Even the Alpha waves activity is increased over Frontal, Parietal and Occipital regions of the brain.[8] Elevations in alpha wave activity have been associated with an increased perception of calmness, memory enhancement and pain reduction. Aplha waves are also known to strengethen the immune system, which makes the person healthy.[10] Yoga claims to relax the sympathetic nervous system by activating parasympathetic–limbic pathways that relax body and mind.[11] This helps to enhance children's performance at school. According to studies of Wheeler & Wilkin, [12] yoga improves focus, concentration and learning readiness as well as enhances health and fitness. A positive correlation with yoga in improving physiological and pychological performance of healthy subjects was studied by Mariappan and Subramanium. [13] By performing Yoga, children reported that they felt calmer, could sleep better, less panicky and more relaxed.[14] Child self-esteem showed significant improvements in children's confidence, social abilities and involvement. Child–parent relationship quality also improved.[15]

Earlier studies on SBY revealed that it is a very simple exercise, being performed in less than two minutes can transform and help the students to remain active mentally and intellectually.[16] SBY can play an efficient role in the enhancement of mental activity among college-going adolescence.[17] It exercises the brain and balances energy in the left and right hemisphere of the brain. This balance of energy in the brain contributes to the enhancement of well-being of a person. SBY is an technique that needs no special technology and equipment, no particular time and place to practice as a result, the independence of the practicioner is preserved.

Conclusion

SBY helps in increasing their health and enhanced relationship with family and friends of students. Schools can implement SBY regularly to students to improve their well-beign.

Impact of Kinship on the Chosen Autosomal Anomalies in Sivagangai, Tamil Nadu, India

Subalakshmi T[1], Jepa Chandra Mohan[2]

[1]Research Department of Zoology, [2]Assistant Professor, Research Department of Zoology, Raja Doraisingam Government Art College, Sivagangai, Tamilnadu, India

Abstract

Significance of study: Prevalence of consanguinity and their impact on the autosomal recessive anomalies such as diabetes mellitus, hearing impairments, epilepsy, limb defect and eye defect among Sivagangai population was studied. The present investigation provides a new plat form for pinpointing out the genetic causes leading to congenital autosomal recessive disorder, so that in future newer gene therapy approaches can be developed to treat such anomalies. In our study, an attempt has been made to evaluate the association of the most common causes of autosomal recessive impairment among heterogeneous Sivagangai population.

Objective: To determine the effect of endogamy on the hereditary anomalies of Sivagangai population.

Study design: Human health survey.

Method: The impacts of kinship against autosomal recessive disorder among the selected population of Sivagangai were studied. In this study, 2376 families were taken for assessment by face-to-face interviewed in the local language according to the standard procedures.

Result: Consanguineous marriage was significantly higher in current generations (29.62%) than the previous generations (37.94%). The occurrences of abnormality were higher among inter breeding populations (67.34%) than non consanguineous population (32.65%). The highest Odd ratio was recorded in epilepsy, followed by hearing impairment, limb defect and eye defects, while, the lowest value was observed in diabetic population. The highest P value, odd ratio and 95% Class Interval recorded were 0.001, 26.48 and 18.63-37.63 respectively. The highest degree of consanguinity reported in the study was 2nd degree in epilepsy.

Conclusion: The present study showed that the hereditary anomalies were higher among cognate population than out breeding population. The children of such con sanguineous couples have higher risk of expressing recessive gene disorders.

Keyword*: Endogamy, Lethality, **e**pilepsy, hearing impairment, limb defect, diabetics and eye defect.*

Introduction

Kinship refers to the culturally defined relationships between two people who share a common ancestor or blood. Consanguineous marriages have been practiced for hundreds of years in many communities throughout the world[1]. Historically, the prevalence of consanguineous marriages is very high in south India. However, marriages between biological relatives are quiet common not only in developed countries but also in developing countries. More than one billion peoples around world are consanguineous [2 and 3]. In India, cognate marriage is a customary practice in some communities. They won't prefer non-consanguineous marriage because of their cultural differences between families. This is based on either matrilineal or patrilineal. The

endogamous population increases the level of autosomal recessive homozygosity, which leads to biological unfitness of population. This phenomenon is known as inbreeding depression[4]. The children of consanguineous unions have the highest chance for expression of single-gene disorders inherited from their recessive parents. The risk of autosonal anomalies increases with degree of genetic relationship between the parents. In the present study, an attempt has been made to assess the prevalence of consanguinity and their impact on the autosomal recessive anomalies such as diabetes mellitus, hearing impairments, epilepsy, limb defect and eye defect among Sivagangai population. The present investigation provides a new plat form for pinpointing out the genetic causes leading to congenital autosomal recessive disorder, so that in future newer gene therapy approaches can be developed to treat such anomalies.

Autosomal recessive defect selected for the present study

Diabetes mellitus

It is a type of heterogenous metabolic disorder causes high blood sugar level for a prolong period of life. Hence it is called as hyperglycemia. It is due to either the disinfection of beta cells of pancreases to secrete insulin or irresponsiveness of body cells to insulin hormone. Based on this, diabetes can be classified into Type 1 and Type 2 diabetes.Type1 diabets is caused by insufficient production of insulin by pancreas and also called as Insulin dependent diabetes mellitus (IDDM) or juvenile diabetes. Type 2 is caused by insulin resistance power of the cells in our body and also known as non-insulin dependent diabetes mellitus (NIDDM) or adult onset diabetes. Any defective 3 genes for type I and 20 genes for II diabetes are responsible for these anomalies. These genes are localized in 2,3,4,5,6,7,8,10,11,12,13,15,17,19, and 20th chromosomes[5].

Epilepsy

It is a clinically heterogeneous neurological disorder, commonly called as seizures. Seizures are caused by a disturbance in the electrical activity of the brain. Thus the nerve cell produce excessive and abnormal activity at the cortex region of the brain. Epilepsy may occur as a result of genetic disorder and acquired brain injury such as a trauma or stroke. During a seizure, a person experiences abnormal behaviour, symptoms and sensations leads to the loss of consciousness. There are various types of seizures, but all are not involve in convulsion, unconsciousness and shaking. Some of them are caused by single gene defect and many of them were caused by multiple gene defect. Epilepsy is usually treated by medication and in some cases by surgery, devices or dietary changes.

Limb Defect

Congenital Limb defect is the most common complex disorders among human population. This disorder occurs during the specification of upper or lower limb development. This defect is a common congenital disorder next to cardiac anomalies. The impact of congenital limb malformations are reduction of limb size, direction of bone angle, polydactyly and syndactyly. These are genetic syndromes produced by number of point mutations during cell fate determination and regulation during embryogenesis.

Eye Defect

The development of eye is specified through a complex program during the embryonic development. Any anomalies in this specification of eye cause profound defects in the eye. The most common congenital inborn errors in eyes are **anophthalmia, microphthalmia, coloboma, aniridia** and **optic nerve hypoplasia.** The other minor defects are myopia, hypermetropia, presbyopia, astigmatism and cataract.

Ear defect

The ear defect is a problem in recognizing different types of sound from the birth. It is a hereditary disorder due to the loss of certain factors in the uterus during development. More than 50% of the ear defect is caused by genetic factors. The hearing loss is an autosomal dominant or autosomal recessive or X-linked pattern of inheritance. Approximately, about 5% of the population has some sort of such ear malformation. The frequently encountered congenital ear problems are protruding ear and external ear microtia.

The characteristics of nonsyndromic hearing loss vary among the different types.Hearing loss can affect one ear (unilateral) or both ears (bilateral). Degrees of hearing loss range from mild (difficulty understanding soft speech) to profound (inability to hear even very loud noises). The term "deafness" is often used to describe severeto-profound hearing loss. Hearing loss can be stable, or it may be progressive, becoming more severe as a person gets older. Particular types of nonsyndromic

hearing loss show distinctive patterns of hearing loss. For example, the loss may be more pronounced at high, middle, or low tones. Most forms of nonsyndromic hearing loss are described as sensorineural, which means they are associated with a permanent loss of hearing caused by damage to structures in the inner ear. The inner ear processes sound and sends the information to the brain in the form of electrical nerve impulses. Less commonly, nonsyndromic hearing loss is described as conductive, meaning it results from changes in the middle ear. The middle ear contains three tiny bones that help transfer sound from the eardrum to the inner ear. Some forms of nonsyndromic hearing loss, particularly a type called DFNX2, involve changes in both the inner ear and the middle ear. This combination is called mixed hearing loss. Depending on the type, nonsyndromic hearing loss can become apparent at any time from infancy to old age. Hearing loss that is present before a child learns to speak is classified as prelingual or congenital. Hearing loss that occurs after the development of speech is classified as postlingual.[5]

Methodology

The present study was a cross sectional based population investigation, carried out in Sivagangai thaluk, which have many native populations. A total number of 2376 families were investigated. These families were selected by simple random sampling. The details about their subjects in terms of history, clinical features, consanguinity, disorder and pregnancy outcomes in the present generation as well as the previous generation by face-to-face interview in the local language according to the standard procedure[6 and 7]. The maximum care was taken to avoid any wrong interpretation by the respondents. Information was collected through personal visit to the selected families. The collected data were then processed to get the prevalence of consanguinity and defects. The types of disorder were then classified.

Odds ratios were calculated based on the influence of endogamy on autosomal recessive anomalies status in the current generation as well as the respondent's children. For the current generation, cases of respondent's offspring of consanguineous union and non-consanguineous union were experimental and control respectively. Chi-square test was used to ascertain the associated between two or more categorical variables. Since the sample size was small (2x2 tables), the Fisher exact test (two-tailed) was applied. Mantel-Haenszel method was used to calculate Relative risk and confidence level at 95% interval. All statistics test were two-sided and $p<0.05$ was considered statistically significant.

Result

The 2376 families were selected for the cross sectional studied. A total of 704 consanguineous (29.62%) and 1672 non consanguineous (70.38%) union in parental generation were observed. The maternal grand parents of 916 were consanguineous and 1460 non - consanguineous and the paternal grand parents were 887 consanguineous and 1489 non-consanguineous (Figure 1). The overall prevalence of consanguinity among parents was 29.62% and grandparental generation was 37.94%. This showed that th econsanguinity was higher among the grandparent generation than the current generation.

Figure 2 depicts various types of abnormalities among the consanguineous and non consanguineous population. The highest number of anomalies were recorded among consanguineous population. The total number of abnormalities among consanguineous population was 67.34%. The maximum number of degree of consanguinity recorded in 2nd degree.

The P value, odd ratio and 95% CI for diabetes mellitus were 0.02, 8.75 and 6.34-12.09 respectively, for hearing impairment were 0.0006, 22.53 and 15.17-33.47, epilepsy were 0.001, 26.48 and 18.63-37.63 respectively. In the case of Limb defects and eye defects, the P value, odd ratio and 95% CI were 0.0108, 18.24 and 10.99-30.26, and 0.319, 14.44 and 9.53-21.87 respectively (Table 1).

Table1: Odd ratio and P value of consanguineous and non-consanguineous population.

	Consanguineous		Non consanguineous		Odd Ratio	95% Confidence Interval	P value
	Affected individuals	%	Affected individuals	%			
Diabetes	96	60	64	40	8.75	6.34-12.09	0.02
Hearing impairment	120	78.94	32	21.06	22.53	15.17-33.47	0.0006
Epilepsy	168	60	112	40	26.48	18.63-37.63	0.001
Limb	64	80	16	20	18.24	10.99-30.26	0.010
Eye	80	71.42	32	28.58	14.44	9.53-21.87	0.319

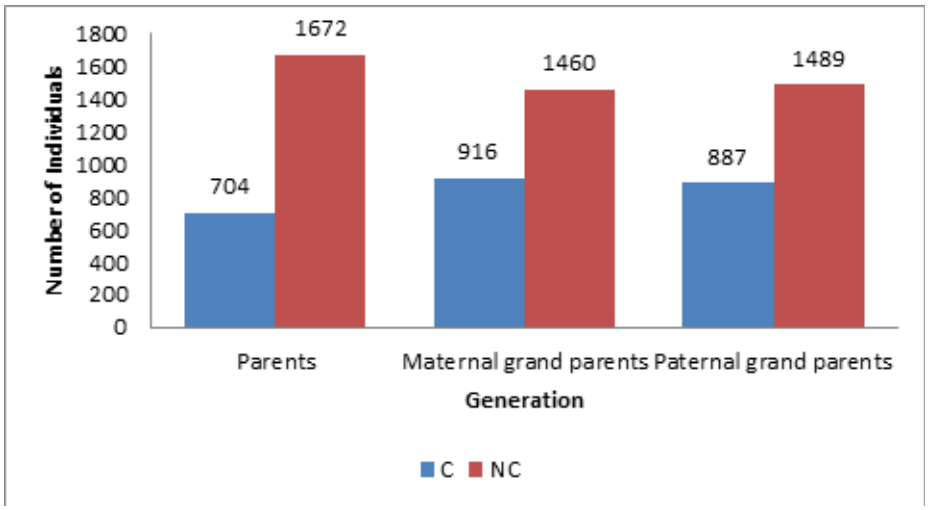

Figure 1: Prevalance of consanguineous and non consanguineous marriages

C: Consanguineous NC: Non Consanguineous

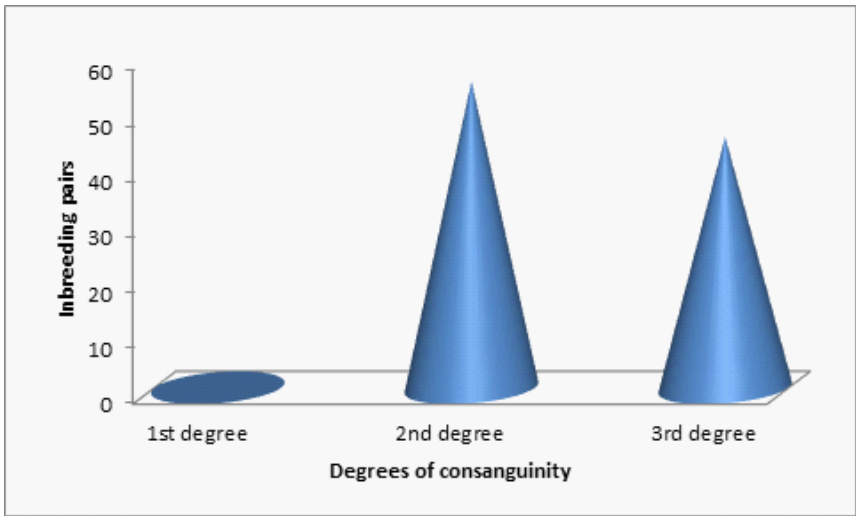

Figure 2: Degrees of endogamy in current generation and parental generation

Discussion

Consanguinity is a couple of biologically blood related individuals of second cousins or more closer to one another[8]. It promotes family stability with significant social and economic advantages[9 and 10]. Kuntla *et al.,* (2013)[11] estimated that the prevalence of consanguineous marriage among Indian population was 38.2%. In this study, consanguineous marriage was higher among grand parents generation (37.94%) than the current generation (29.62%). Among the selected population, 704 couples were consanguineous and 1672 were non-consanguineous of current generation, where as 916 and 1460 of maternal grandparents and 887 and 1489 of paternal grand parents were consanguineous non-consanguineous respectively. The calculated P value was statistically significant. The highest Odd ratio was recorded in epilepsy, followed by hearing impairment, limb defect and eye defects, while, the lowest value was observe eye defectd in diabetic population. The highest degree of consanguinity reported in the study was 2nd degree. The reported marriages were first cousin type. According to the study of Roychoudhury (1976)[12] and Badaruddoza (1998)[13] that the frequency of first cousin marriages in different parts of South India varied from 5 to 57 %. The intra familial marriages have the possibilities of transmitting recessive identical lethal genes from parents to offspring. Such lethal genes cause number of anomalies in children. Congenital malformations are the major reasons for prenatal mortality during gestation in developing countries like India [14 and 15]. In the present study, the prevalence of abnormalities were higher in consanguineous population (64.5%) than the non consanguineous population (34.5%). The studies of Verma *et al.* (1992)[16] and Becker *et al* (2015)[17] had recorded the significant number of congenital malformations among the children of consanguineous couples than the non-consanguineous one. The babies born with congenital anomalies were found to be 3.4 times more from consanguineous parents than non-consanguineous. In the present investigation, the risk of deleterious anomalies was found to be statistically significant.

Diabetics are a most common defect in India. It may be heritable. It may be due to insufficient secretion of insulin by pancreas. Epilepsy is also called as seizure. It is due to any disturbance in the electrical activity of brain. The limb defect is a type of autosomal dominant or autosomal recessive or x-linked anomalies. These genetic defects are caused by primary intrauterine inhibition or intrauterine destruction of normal embryonic tissues. It can also occur with various syndromes in offspring. Teratogenic agents (eg, thalidomide, vitamin A) are known causes of hypoplastic or absent limbs. The other congenital limb anomaly is amniotic band-related limb deficiency, which loose strands of amnion entangle or fuse with fetal tissue. Hereditary hearing loss is an autosomal recessive or X-linked recessive as well as by mitochondrial inheritance. The defective genes cause syndromic or non-syndromic with dominant or recessive genes hereditary hearing loss. The syndromic hearing loss is a hearing impairment associated with specific traits. The dominant deafness is caused by only one faulty gene from the mother or father with hearing impairment. The recessive deafness is because of faulty gene from both the mother and father. There are more than 200 forms of such syndromic hereditary hearing impairment. The human eye is programmed by a complex system of specification during embryonic development. The common congenital eye malformations are anophthalmia, microphthalmia, coloboma, aniridia, and optic nerve hypoplasia. The eye is completely developed in the first trimester of pregnancy. Many genes have been found to have a role in this complicated process. Any alternation in these genes due to point mutations can cause abnormal development in eyes.

Considering the above, the practice of consanguinity should be avoided by educating the public about the adverse effect of blood related marriages. The present investigation provides a new plat form for providing proper health care to public regarding the transmission of lethal endogamic disorders.

Author statement section

Ethical approval – Ethical approval is not required for this study, because we had not used any experimental samples (Blood/ saliva) from the individuals. Before sampling, consent certificate had been received from each individual. We collected data by individual face to face interview.

Preliminary Phytochemical Screening and FTIR analysis of an Indian Medicinal Herb: Paederia Foetida (Prasarini)

Subhashree Satapathy[1], Gurudutta Pattnaik[2]

[1]M. Phil Scholar, School of Pharmacy and Life Sciences, Centurion University, Jatni, Bhubaneswar 752050, Odisha, India. [2]Principal, School of Pharmacy and Life Sciences, Centurion University Jatni, Bhubaneswar, Odisha, India

Abstract

Aim: To carry out the preliminary qualitative phytochemical screening of leaf extract of an Indian herb. *P. foetida* and Fourier Transform Infra-red Spectroscopy (FTIR) analysis of the extract containing the highest number of phytochemicals.

Method: The leaf extracts were prepared using, water, methanol, ethyl acetate and acetone. Several *in vitro* phytochemical analyses were carried to check for the presence various secondary metabolites. FTIR analysis of all the 4 extracts were carried out of the for identifying organic secondary metabolites.

Results: Ethyl acetate extract was found to be positive for most of the qualitative phytochemical screening test containing almost all the phytochemicals. The FTIR analysis revealed, that the leaf-extracts of *P. foetida* had phytochemicals of different functional groups such as alkanes, aromatic compounds, aldehydes, saturated fatty acids, alcohols, carboxylic acids, esters, ethers and alkyl halides

Conclusion: The study concluded that, the Indian herb *P. foetida* is rich secondary metabolites and it can be used in the production alternative and complementary drugs, that can be against various human diseases.

Keywords: *Medicinal plants; Paederia foetida; Phytochemical screening; FTIR analysis; Secondary metabolites*

Introduction

Medicinal plants refer to plants having medicinal or therapeutic values. These medicinal plants are a rich resource of biochemicals which can be used in development of natural drugs against several health ailments. They are also a rich source of nutrition, hence can be used as preventive too.[1] Plants their by-products are also used in various daily use products such toothpaste and oils. The use of complementary alternative medicine has become quite popular across various societies of the world.[2] However, the modern health care system is still heavily dependent on chemical based drugs, which has mild to severe side effects and some of them are slowly becoming ineffective, e.g. antibiotics. Hence, medicinal plants are the best alternative to solve the worldwide problems arising due to synthetic drugs.[3]

Treatment with medicinal plants is an ancient process, as old as human origin itself. The relationship between mankind and their search for drugs is recorded and documented in all civilization, across the world. [4] Knowledge of medicinal plants and their usage is an outcome of years of research and trials by various ancient health care workers to modern day doctors and researchers. Modern day science has also approved and accepted plant based drugs.[5] The knowledge of the development of ideas related to the usage of medicinal plants with awareness has increased the ability of pharmacists and physicians to respond to the challenges that have emerged with the spreading of professional services in facilitation of man's life.[6]

Paederia foetida is an Indian edible herb that has traditionally been used against gastrointestinal and male infertility problems. *P. foetida* is a promising antioxidant, anti-inflammatory antimicrobial, anthelmintic and anticancer agent.[7, 8] Its efficacy encourages the need of proper scientific evaluation so that it can be considered for development of new drugs. Some studies also validate in erotogenic and aphrodisiac properties.[9] The medicinal properties are majorly due to presence of phytochemicals present in this herb, which acts in combinations or in solitary mode against various human ailments.[7,8] Hence, this study was conducted to know the phytochemicals present in the 4 solvent extracts of the plant and further the best extract is was subjected FTIR analysis for the identification of different functional groups in each extract of *P. foetida* leaves.

Material and Method

Processing of plant material

Fresh young leaves of *P. foetida* plant were collected from the Chandaka forest region, Bhubaneswar, Odisha. The fresh leaves were washed properly, shed-dried and powdered and were stored in airtight polybags for future use.

Extraction

A total of 15-gram sample of powdered leaf samples was taken and extraction was carried out with the help of a Soxhlet apparatus by using different solvent like ethyl acetate, acetone, methanol and water on their polarity basis. After extraction, the extracts were concentrated using a rotary-evaporator. The final crude extracts were stored in a glass air tight container at 4°C until further use.

Primary screening of phytochemicals

Test for Alkaloids

1. **Mayer's test**: To 5 ml of each extract 0.5 ml of Mayer's reagent were added separately and it was observed for precipitation.

2. **Dragendroff's Reagent**: 0.5 ml of Dragendroff's reagent was added separately to each filtrate and observed for orange yellow precipitation.[11]

Test for Carbohydrates

1. **Molisch's Test**: An aliquot of 3 ml of each extract was dissolved in ethanol and two drops of a 20% w/v solution of α-napthol in ethanol were added to it. Further, 1 ml of concentrated H_2SO_4 was added. Appearance of red-purple ring at the interface of the two layers indicated the occurrence of carbohydrates.

2. **Fehling's Test**: An aliquot of 2 ml each solvent extract was dissolved in about 2 ml of distilled water and filtered. An equal amount of Fehling's solution A and B was added to the filtrate and the contents were boiled. Advent of brick red precipitates indicated the presence of reducing sugars.

Test for Cardiac glycosides

1. **Keller killiani's test** (Cardiac glycosides): In a mixture of glacial acetic acid, one drop 5% $FeCl_3$, concentrated H_2SO_4, 2ml of each extract were added. Further at the junction of the 2-layer Reddish brown colour was observed & bluish green colour were observed at the upper layer of the mixture.

2. **Raymond's test**: Few drops of test solution were mixed with hot methanol alkali Further violet colour precipitation was observed.

Test for Anthraquinones

1. **Modified Borntrager' Test**: To 5ml extract, 5 ml 5% $FeCl_3$ & 5ml dilute HCL was added and the mixture was heated for 5min. in boiling water bath. Further it was cooled, and benzene was added to the mixture. Organic layer was separated, Equal volume of dilute Ammonia was added to observe ammonia layer shows pinkish red colour, which indicated the presence of anthraquinones.[11]

Test for Saponin

1. Foam test: Plant extracts were thoroughly mixed with distilled water and stirred well. The formation of foam indicated the presence of saponins.

Test for Coumarins

1. The moistened dry leaf powder in test tube was covered with filter paper pre-soaked in dilute NaOH. The tube was heated in water bath. After some time, filter paper was exposed to Ultraviolet light. The formation light yellowish-green florescence was observed, which indicated the presences of coumarins

Test for Proteins

1. **Biuret test**: To 3 ml leaf extract, 1 ml of 4%

NaOH and few drops of 1% $CuSO_4$ solution was added. Further the formation of violet or pink colour indicated the presence of proteins.

2. **Million's test:** To 3ml leaf extract, 5 ml of millions reagent was added, and it was heated in boiling water bath, Appearance of brick red and pink colours indicated the presence of proteins.

3. **Xanthoprotein test**: To 3ml of leaf extract, 1 ml conc.H_2SO_4 was added. white precipitation indicated the presence of proteins.

Test for Amino acids

1. **Ninhydrin test:** To 3 ml test solution 3 drops 5% ninhydrin solution was added and the mixture was heated in a boiling water bath for 10 min to observe the Purple or bluish colour change, which indicated the presence of amino acids.

Test for Steroids

1. **Salkwoski reaction**: To 2ml of extract, 2ml of chloroform and 2 ml con. HCL was added. Appearance of red colour in the chloroform layer and greenish yellow fluorescence colour in acid layers indicated the presence of steroids.

Test for Flavonoids

1. **Addition of lead acetate:** Small quantity of extract was added to the lead acetate; yellow colour precipitate indicated the presence of flavonoids.

2. **Addition of Sulphuric acid**: By addition of sulphuric acid (66%-80%) to extract yellow colour was observed, which indicated the presence of flavonoids

3. **Addition of Sodium hydroxide:** Addition of increasing amount of sodium hydroxide to the extract showed colorations and decoloured by adding acid, indicated the presence of flavonoids. [11]

Test for Fat and Oil

1. **Solubility test**: Extracts were mixed with the ether, benzene, and chloroform totally mixing of extract shows the presence of oil in the extracts, stains on filter paper shows the presence of the oil in the extracts.

2. **Addition of $CuSO_4$ and NaOH**: Addition of the CuSO4 and NaOH in extract shows the clear blue coloration.[11]

Total phenolics content

The **t**otal phenolic content was evaluated using Folin–Ciocalteu reagent, a method described by Alhakmani et al in 2013.[12]

Total flavonoid content

An aliquot of 0.5 ml of sample solution was mixed with 0.1 ml of 10% aluminium nitrate, 0.1 ml of 1mol.L^{-1} potassium acetate and 4.3 ml of 80% methanol. The mixture was thoroughly mixed and was incubated at room temperature. The absorbance was measured at 415nm. Quercetin was used as standard compound for the quantification of flavonoids content. Results were expressed in milligram of Quercetin equivalents per gram of dried extract. [13]

FTIR analysis

FTIR technique was used for the identification of different functional groups in each extract of *P. foetida* leaves as described in Sravan et al 2015. The infrared spectroscopy spectrum (IR) was obtained using FTIR Shimadzu Japan [14]

Results

Methanol extract of *P. foetida* leaves was recorded for the presence of a maximum number of polar compounds in the crude drug followed by the aqueous extract (Table 1).

Table 1. Extractive values of P. *foetida* leaves

Solvent Used	Extractive Value (% wt/wt)
Ethyl acetate	5.160 ± 0.32
Acetone	11.133 ± 0.4
Methanol	46.306 ± 0.26
Water	22.00 ± 0.12

Preliminary phytochemical screening of *P. foetida* leaf extracts

In the ethyl acetate extract, carbohydrate, glycosides, alkaloids, tannins & phenolic compounds, flavonoids and amino acids were present as recorded (Table 2). Out of which, carbohydrate is richly present in the extract. Other phytochemicals are present moderately. Steroid content was found very low. Carbohydrates, glycosides, alkaloids, tannins & phenolic compounds, flavonoids,

proteins and amino acids were present in the acetone extract. Among of all these phytochemicals, carbohydrate is abundantly present. Others were moderately present. However, proteins, amino acids and steroids content was low. Lastly methanol and aqueous extract show similar results. High amount of carbohydrates, glycosides, alkaloids, tannins & phenolic compounds, flavonoids presence was recorded. The preliminary phytochemical screening of *P. foetida* leaves concluded that, that there was a high number of polar compounds present in the crude extract.

Determination of total phenolic content

The anti-oxidative effectiveness of this plant has been reported due to presence of phenolic compounds. Acetone extract had the highest phenolic content (789.70mg GAE/gm), followed by methanol, aqueous and ethyl acetate (Table 2, Figure 1)

Table 2. Phenolic content in different solvent extracts

Extracts	Phenolics content (mg GAE/gm)
Ethyl acetate	449.1176
Acetone	789.7059
Methanol	652.647
Aqueous	533.529

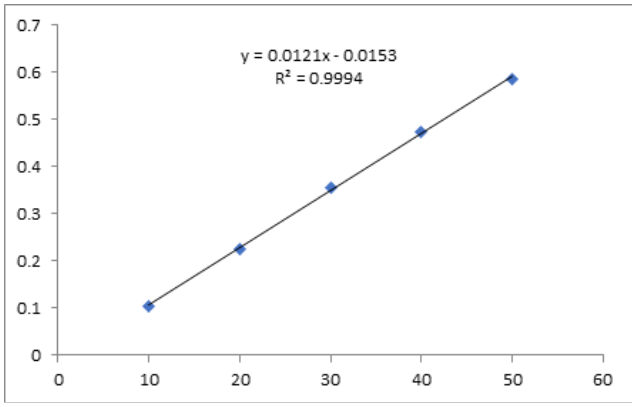

Figure 1. Standard Curve of Gallic acid

Determination of total flavonoid content

Flavonoids are a large group of ubiquitous molecules and possess antioxidant activities. Methanol extract contained highest flavonoid content (44.558 mg QUE/ gm), followed by aqueous, ethyl acetate and acetone (Table 3, Figure 2).

Table 3. Flavonoid content in different solvent extracts

Extracts	flavonoid content (mg QUE/gm)
Ethyl acetate	35.44118
Acetone	25.58824
Methanol	44.55882
Aqueous	43.08824

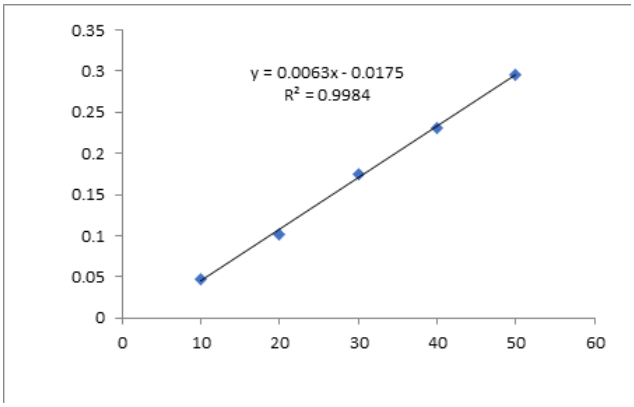

Figure 2. Standard Curve of Quercetin

FTIR Analysis

The FTIR spectral analysis was utilised to identify the functional group of the active ingredients based on peak value in the vicinity of infrared radiation. The results of FTIR peak values and functional groups of aqueous extract are represented in the graph. IR spectrum shows strong absorption peaks at 2850.79cm^{-1}(weak band), 1724.36cm^{-1} (wide), 1600.91cm^{-1} (sharp), 1444.68cm^{-1}(weak), 1049.27cm^{-1}(wide), 831.39cm^{-1}(sharp), which corresponds to the presence of small amount of alkanes (C-H stretch band), aldehydes, saturated aliphatic or α-β-unsaturated esters, aromatics (C-C stretch ring), aromatics, alcohols, carboxylic acids, esters, ethers (wide), alkyl halides respectively. Methanolic extracts showed peak values 2918.29cm^{-1}(sharp), 2850.79cm-1(weak), 1724.36cm-1(sharp), 1600.91cm-1(wide), 819.74cm-1(small) which could be attributed to the existence of functional groups alkane(medium), small amount of alkanes, aldehydes and saturated fatty acids(c=o stretch), aromatics, aromatics respectively. The graph (Figure 3), shows that the peak data of acetone and ethyl-acetate extract are quite same with the methanolic extract. Both,

ethyl acetate and acetone extracts showed peak values 2850.79cm-1(strong band), 1724.36cm-1(strong), 1600.91cm-1(strong), 1444.68(sharp), 1049.27cm-1(small),831.39cm-1(sharp),which corresponds to the presence of alkanes, aldehydes and saturated fatty acids, aromatics, alcohols, carboxylic acids, esters, ethers and alkyl halides, respectively.

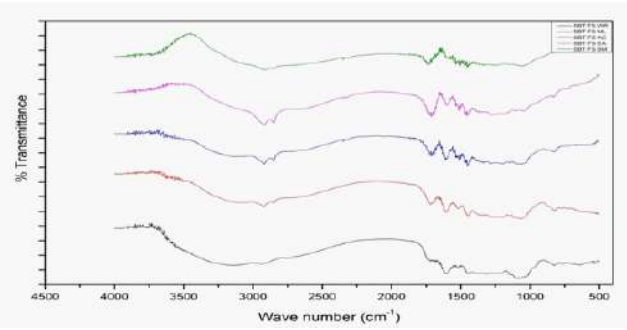

Figure 3: Transmittance of *P. foetida* leaf extracts by [FTIR].

Discussion

As part of the traditional therapy, population of different regions of the world use medicinal plants. Not only whole plant but also some specific parts (such as leaves, bark, etc.) of the plant are used as the herbal therapy.[15] As a part of traditional use, leaves of *P. foetida* is used for the treatment of many human ailments in Indian and other countries. It was confirmed preliminary phytochemical screening that both methanol and ethyl acetate extract of *P. foetida* possess some compounds like alkaloid, tannin, flavonoids, steroids, saponin etc. which may be responsible for amelioration of diarrhoea.[16]

Chemical diversity in natural product is an advantage for human civilization and they are a rich source of new pharmaceuticals, cosmetics, agrochemicals and other economically important chemicals. Therapeutic potentials of plant-based drugs ranges from simple parts of plants, to simple extracts to isolated active constituents.[17] Plants may be considered as biosynthetic laboratories in which various kinds of organic compounds are synthesized such as carbohydrates, proteins, lipids, flavonoids, glycosides, alkaloids, volatile oils, and tannins etc., which exert a physiological effect and are utilized as biologically active components by man since time immemorial.[18,19] The therapeutic value of any plant drug, however, depends on the nature of chemical constituents present in it and is referred to as active principle. Phytochemical screening comprises of different chemical tests and chemical assay. The isolation, purification and identification of active constituents are chemical methods of evaluation. The phytochemical evaluation helps in establishing chemical profile of crude drugs.[19] The purity of crude drugs is ascertained by quantitative estimation of the active chemical constituents present in them. The method may be useful in determining single active constituents or the group of related constituents present in the same drug. [20]

Conclusion

Ethyl acetate extract was found to be positive for most of the qualitative phytochemical screening test containing almost all the phytochemicals. The FTIR analysis revealed, that the extracts of *P. foetida* leaves had phytochemicals of different functional groups such as alkanes, aromatic compounds, aldehydes, saturated fatty acids, alcohols, carboxylic acids, esters, ethers and alkyl halides. The study concluded that, *P. foetida* is rich secondary metabolites and it can be used in the production alternative and complementary drugs.

Clinical and Biochemical Profile of Indians with type 2 Diabetes Mellitus: A Study from a Tertiary Care Hospital in Greater Noida

Suresh Babu[1], Payal Jain[2], Saurabh Srivastava[3], Parwinder Kour[4], HM Kansal[5]

[1]Senior Consultant, [2]Associate Professor, [3]Professor, Department of Medicine, Government Institute of Medical Sciences, Greater Noida,Gautam BuddhNagar,UP, [4]GDMO, 15th battalion, ITBP, Udhampur, [5]Ex Professor, Department of Medicine, SMS&R, Sharda University, Greater Noida

Abstract

Objective: To study the clinical and biochemical profile of newly detected type 2 diabetes mellitus patients from a tertiary care hospital in Greater Noida,Gautam Buddh Nagar.

Method: At total of 100 newly diagnosed type 2 diabetes mellitus patients presenting in the Department of Medicine were included and studied. A detailed clinical history, examination and investigations were recorded.The presence of microvascular and macrovascular complications of diabetes mellitus was assessed using this clinical and laboratory data.

Results: There were 52 males and 48 females. Maximum patients belonged to fourth decade and upper-lower socioeconomic status.20% patients had obesity and 50% people were overweight. Polyuria was the chief presenting complaint in 51% cases with polydipsia,weight loss and weakness being the other common symptoms. 62 % of the diabetics had hypertension. Increased cholesterol was reported in 44% and 53 %patients had altered triglyceride. The prevalence of neuropathy, retinopathy and nephropathy was 33%, 28% and21 % respectively.

Conclusion: Type 2 diabetes mellitus patients present with comorbidities and complications frequently. Significant proportion of patients in this study had poor glycemic control as well as microvascular complications at the very time of diagnosis.A vast majority were overweight with high waist circumference. Commonest observed comorbidities with diabetes were that of hypertensionand dyslipidemia.

Keywords:*type 2 diabetes mellitus,Neuropathy, Retinopathy, Nephropathy.*

Introduction

Diabetes Mellitus is a chronic, progressive disease characterized by elevated levels of blood glucose. It is a non-communicable disease due to either genetic or acquired deficiency in production of insulin (type 1 diabetes mellitus)or a lack of action of insulin (type 2 diabetes mellitus).Raised blood glucose, a common effect of uncontrolled diabetes, may lead to serious damage to the heart, blood vessels, eyes, kidneys and nerves. Eventually, diabetics are further affected by various diseases including obesity, hypertension, microangiopathy and metabolic syndrome.

Diabetes is the cardinal cause of death globally with an estimated 3.7 million deaths in 2012. This number includes 1.5 million deaths as direct cause, and an additional 2.2 million deaths from cardiovascular diseases, chronic kidney disease, and tuberculosis due to hyperglycemia. After 50 years of age, middle income countries have the highest proportion of deaths attributed to diabetes.The prevalence of diabetes mellitus is on

Greater Noida,Gautam BuddhNagar,UP
email: drpayaljainn@gmail.com

rise, particularly in developing countries. It has been predicted that India along with China will harbour more than 75%of global diabetic load by 2025.[1,2]

The starting point of management in diabetes is an early diagnosis – the longer a person suffers with undiagnosed and untreated diabetes, the worse their outcomes are meant to be. The disease may go undiagnosed for several years, until complications have already arisen. To facilitate early diagnosis and suggest lifestyle modifications to curb the onward progression of the disease,it is vital to describe and understand the clinical and biochemical profile of diabetes population. Hence the current research was carried out with an objective to study the socio-demographic and biochemical profile of diabetes patients attending diabetes clinic in a tertiary care hospital in GautambudhNagar,Greater Noida,Uttar Pradesh.

Materials and Method

This retrospective study was carried out in the department of Medicine, Government Institute of Medical Sciences, Gautam budh Nagar. Case records of 100 newly diagnosed type 2 diabetes mellitus patients of both genders were enrolled randomly for the study.

Inclusion criteria

The American Diabetes Association criteria were used for selecting the newly diagnosed type-2 diabetes mellitus patients. i.e. a fasting plasma glucose (FPG) level of >7.0 mmol/L or ≥126 mg/dL after a minimum 12-hour fasting, or two-hour post glucose level (oral glucose tolerance test) of >11.1 mmol/L or ≥200 mg/dL on more than one occasion, with symptoms of diabetes.

Exclusion criteria

The case records of patients having the following features were excluded from this study

1. Type-1 Diabetes mellitus or established diabetes mellitus on treatment for more than 6 months.

2. Patients with pregnancy/ gestational diabetes.

Case records of the patients from diabetic clinic of our hospital having thorough work up and comprehensive case history including details of age, presenting complaints, diet, smoking, alcohol consumption, physical activity, socioeconomic statuswere included. The findings ofgeneral physical examination,history of hypertension and other co-morbid conditions was assessed from case records. Socio-economic status of the study subjects was divided according to Kuppuswamy classification.[4] The American Heart Association criteria was referred to define and diagnose hypertension.[5]

Anthropometric data measured using standardized procedures was recorded from case sheets. Results of clinicaland biochemical tests, such as urinalysis (first-morning sample for micro-albuminuria), complete haemogram, plasma glucose, glycosylated haemoglobin (HbA1c), renal function tests, and lipid levels including total cholesterol (TC), triglycerides (TG), and high-density lipoprotein-cholesterol (HDL) levels and Low-density lipoprotein-cholesterol (LDL-C) were recorded from the case records andanalysed. Dyslipidemia was defined when one of the following was present: Triglyceride (TG) concentration more than 150 mg/dl or Cholesterol concentration more than 200 mg/dl or HDL cholesterol less than 50 mg/dl in females and less than 40 mg/dl in males or LDL more than 100 mg/dl. This classification was conforming to ATP III (Adult Treatment Panel III) guidelines.[6]

The nervous system examination at the time of initial evaluation for touch, pain, vibration and reflexes was recorded from thecase sheets and analysed. 128 Hz tuning fork was used to examine vibration sense and 10 g monofilament for light touch perception in diabetic clinic.

Records of fundus examination for assessment of retinawere interpreted and 24hour urinary albumin estimationdone was used to diagnose nephropathy. Coronary artery disease (CAD) was reported on the basis of electrocardiograph (ECG) changes, treadmill test and echocardiography reports. Patient was reported to be having stroke if supported byclinical history, examination,and non-contrast CT scan. Data of peripheral arterial disease,which was diagnosed by history of claudication, absence of pulses or Doppler study wherever required,was recorded and analysed.

Data Analysis: Data were compiled, tabulated and analysedby using standard appropriate statistical technique, which includes numbers and percentages. The mean and standard deviation was obtained for summarizing the quantitative variables.

Results

In this study, data of 100 patients with newly diagnosed type 2 diabetes mellitus who presented in diabetes clinic of our hospital were studied.Out of these cases, 58 were females and 42 were male.Maximum incident cases wereseen in the fifth decade of life with a mean age of subjects being 54.6 years.The maximum number of patients,around 35% belonged to upper- lower socioeconomic status.The education status showed that majority of subjects in our study,around 68%,were either had no formal education or educated only upto primary level (table 1).

Table 1: **Demographic variables of the Patients**

Gender	Number of patients(%)
Male	42(42)
Female	58(58)
Age (years)	
≤ 35	2(2)
36-50	29(29)
51-65	49(49)
>65	20(20)
Socioeconomic status	
Upper	6(6)
Upper middle	10(10)
Lower middle	25(25)
Upper lower	35(35)
Lower	24(24)
Education level	
No formal education	28(28)
Primary	40(40)
Secondary	27(27)
Tertiary	5(5)

It was observed that BMI was significantly high,with 50% patients being overweight and 20% obese.70% patients had high waist circumference (table 2)

Table 2: BMI and Waist circumferenceof the study subjects

Variables Number of patients(%)
BMI ≤ 18.5 (Underweight) 2(2) 18.5 - 22.9 (Normal) 28 (28) 23 - 24.9 (Overweight) 50 (50) ≥ 25 (Obese) 20(20)
Waist circumference Female(58) >80 cm 50(82.7) Male (42) >90 cm 20(47.6)

Table 3:Biochemical profile of study subjects

Variables	Number of patients(%)
Glycaemic status (HbA1c%) <7 (good control) 7-8 (sub-optimal control) 8-9 (sub-optimal control) >9 (uncontrolled)	 3(3) 19(19) 34(34) 44(44)
Microalbuminuria	21(21)
Hypercholesterolemia (>200mg/dl)	44(44)
Hypertriglyceridemia (>150mg/dl)	53(53)
High density lipoprotein cholesterol(<35mg/dl)	39(39)
Low density lipoprotein cholesterol(>130mg/dl)	33(33)
Normal Blood pressure	38(38)
High blood pressure	62(62)

44%of the patients had uncontrolled diabetes with a high glycated haemoglobin greater than 9%. In our study 44 patients had increased cholesterol and 53 patients had hypertriglyceridemia. 62% were hypertensive and 38 %were normotensive among diabetics (table 3).

Mostcommon presenting symptom in our study was polyuria(51%),with polydipsia(32%),weight loss (35%) and weakness (38%)being other common ones.Among

microvascular complications,neuropathy,retinopathy and nephropathy was reported in 33%,21% and 28% of our subjects respectively. The prevalence of coronary artery disease,peripheral vascular disease and stroke was found to be 13%,6% and 3% respectively(table 4).

Table 4:**Presenting symptoms and complications**.

Presenting symptoms	Number of patients(%)
Polyuria	51(51)
polydipsia	32(32)
polyphagia	18(18)
Weight loss	35(35)

Weakness	38(38)
Blurred vision	15(15)
Skin manifestation	8(8)
Urinary tract infection	16(16)
Altered sleep	10(10)
Microvascular complications	
Neuropathy	33(33)
Nephropathy	21(21)
Retinopathy	28(28)
Macrovascular complications	
Coronary heart disease	13(13)
Peripheral artery disease	6(6)
Stroke	3(3)

Discussion

The prevalence of diabetes mellitus is on a rise,particularly in developing world.In near future,India shall become the diabetes capital of the world. Our main concern through this study was to assess the profile of diabetic patients in this part of Uttar Pradesh so that we can prevent or decrease the burden of complications by early diagnosis and intervention.

In this study maximum incident cases of diabetes mellitus occurred in fifth decade,followed by fourthdecade.The risk of developing diabetes, especially type 2 diabetes mellitus, greatly increases with age, where the most affected age group is that of 40–59 years.[7] This finding is in accordance with other Indian studies which also report the highest incidence in fourth and early fifth decade.[8,9]

Maximum number of patients in our study were from low socio-economic status. This may be due to a greater number of poor people in the vicinity of our institute where study was conducted. The demographic profile of the study participants can be explained by the fact that the hospital where this study was conducted is a government hospital. In a study Mudhaliar MR et al,similar results were reported.[10]

With regard to gender, while our study had 58% females as compared to 42% of males, a study from Gujarat found males to be 62% of the total.[11]

In our study majority of the patients were either educated upto primary or had no formal education while few studies observe a high literacy rate with illiterates forming a mere one percent in their study.[11]

In the present study, the majority (70%) of the subjects were either overweight or obese. This is consistent with the findings of various other studies.[11,12] Ideal normal BMI was observed in only 28% patients which could be because of poor awareness about weight management as a measure to control diabetes. The was similar to a study in Brazil where normal BMI has been reported in 24% patients.[12]

Another noteworthy finding in our study was that diabetic females overpower males in the proportion of being having high BMI with a higher waist circumference seen in almost 50%of females. High mean of BMI in females though being significantly low weight and short statured when compared to the males could be explained from a sedentary lifestyle of females. A high proportion of abnormal waist circumference and a high mean of BMI in the female subjects forecasts higher insulin resistance in them due to decreased insulin sensitivity.[14]

The main presenting symptom in our study was polyuria. Similar presentation of a classic symptom in newly diagnosed diabetics was reported in few other studies.[15]

In the present study, only 3% of the subjects had good glycaemic control while 44% had uncontrolled diabetes. This was similar to a study from Gujarat who reported only 7% of their participants with controlled diabetes whereas 41% with uncontrolled diabetes.[11]

A Swedish study reported that 34% of type 2 diabetes subjects had good glycaemic control.[16] Again a few other studies reported good control of glycemia in more than 30%.[17,18]

Awareness and intervention programs targeting the measures at glycemic control among diabetics are the need of hour. Our study showed around 62% diabetic patients to be hypertensive. Basavegowda M et al from urban slums of city of Mysore also showed the prevalence of hypertension to be around 65% in diabetics.[19] Some showed almost 50%hypertension prevelance in diabetic population.[11]

The lipid profile was significantly deranged in our diabetic study subjects. The most prevalent form of dyslipidemia in this study was Hypertriglyceridemia which was seen in 53% of diabetics. The pattern of dyslipidemia in our study more or less matched the typical diabetic dylipidemia,that is high TG and low HDL as reported in many studies.[22]

Our study reported a high prevalence of microvascular complications with retinopathy (21%), peripheral neuropathy (33%) and nephropathy (28%). This was similar to a study from cenral India which showed a prevalence of retinopathy (26%),peripheral neuropathy (26%) and nephropathy (22%).[9] Another study from south India also reported a high prevalence of retinopathy.[20] The diabetics with retinopathy had poor glycemic control, a significantly high fasting plasma glucose and were mostly dyslipidemic. These findings were in accordance with other studies from India.[9,20] A close prevalence of nephropathy to retinopathy might be used in the prediction of a high-risk of concomitant diabetic neuropathy in patients with retinopathy,though some earlier studies did not show this pattern.

The prevalence of coronary artery disease,peripheral vascular disease and stroke in our study was found to be 13%,6% and 3% respectively. A similar study in South India on new onset type 2 diabetics showed prevalence of coronary artery disease(25%), peripheral vascular disease (11%) and stroke (8%).[23] These results suggest that complications in diabetes mellitus begin before overt hyperglycemia is seen.

Conclusion

Most of the patients were not obese in our study but were overweight and had high waist circumference. Hypertension was the commonest observed comorbidity. Significant percentage of our patients had microvascular complications at the time of diagnosis of diabetes mellitus.Hence blood sugars and lipid profile should be aggressively managed early in the course of disease to prevent life threatening complications. The demographic profile of the diabetic patients attending our hospital comprises mainly of lower socioeconomic class and has poor literacy rate.Therefore, educating the masses with increased awareness about the disease and its management is of prime importance.More population-based studies on a larger scale are required further to increase our understanding and better identification of the magnitude of the problem.

Effect of Proprioceptive Neuromuscular Facilitation (PNF) Pattern on Respiratory Parameters in Chronic Bronchitis

Sushma Singh[1], Javid H. Sagar[2], G. Varadharajulu[3]

[1]MPTh (Cardio-pulmonary), [2]Professor/ Unit Head (Cardio-pulmonary), [3]Dean/ Professor/ HOD, Krishna College of Physiotherapy, Krishna Institute of Medical Science Deemed to be University, Karad, Maharashtra, India

Aim: To study the effect of PNF pattern on respiratory parameters in chronic bronchitis.

Objectives: To find the effect of PNF pattern on respiratory parameters and to compare the effects of pursed lip breathing and PNF pattern in chronic bronchitis.

Materials and Method: 60 patients were included according to inclusion and exclusion criteria by consecutive random sampling and were divided into two groups, group A (Conventional-PLB) and group B (D1 & D2 flexion and extension) - with 30 patients in each group. The treatment was given for 2 weeks thrice a day. After 2 weeks effect of interventions were assessed by taking Respiratory Rate (R.R), Oxygen Saturation ($SpO_{2)}$ and FEV_1/FVC.

Results:. There was significant difference in R.R, SpO_2 and FEV_1/FVC seen with PNF pattern exercises. The intra group comparison showed significant improvement in R.R, SpO_2 and FEV_1/FVC. The inter group comparison showed no significant improvement in SpO_2 and FEV_1/FVC except R.R

Conclusion: PNF pattern has shown significant improvement in SpO_2, R.R and FEV_1/FVC

Key words: *Chronic Bronchitis, PNF, PLB, PFT.*

Introduction

Chronic bronchitis is a term that describes inflammation of the bronchial tubes (i.e. bronchi and smaller branches termed bronchioles) that results in excessive secretions of mucus into the tubes, which leads to tissue swelling that can narrow or close off bronchial tubes.

One of the major disease includes COPD, the significance of which is difficult to overestimate. According to the GOLD (2013), guidelines states that chronic bronchitis is a completely independent disease but one which can precede the development of airflow limitation as well as cause or aggravate the persistent airflow limitation. The primary risk factor for majority of patients is smoking. [1]

Chronic bronchitis is defined as a productive cough that lasts for three months for at least two consecutive years. Most people with chronic bronchitis have chronic obstructive pulmonary disease (COPD). [1,2]

The common characteristic of the disease is obstruction to airflow out of the lungs which leads to poor gas exchange and difficulty in breathing. [2]

Symptoms include dyspnea, cough with mucus (sputum) production, wheezing are generally seen. [15] Other features are: constriction in the chest, tachypnoea, tachycardia, adventitial breath sounds, accessory muscles becomes active, thick and stringy mucus.

The other causes are long term exposure to irritating gases or particulate matter, respiratory infection and most often from cigarette smoke.

The pathological foundation for chronic bronchitis is due to the over production of mucus in response to the inflammatory signals, this is known as mucus metaplasia. The overproduction and hypersecretion is due to the presence of goblet cells and reduced elimination of mucus.

The mechanisms responsible for mucus metaplasia is associated with the function of the T cells, this mechanism is still poorly understood but it is believed to

be linked to end production of the cells called as Th2 cells which are inflammatory cells while the cellular response is thought to be attributed to the Th1 inflammatory cells, cytokine substance is produced by both the cells that have an influence on mucus production associated with chronic bronchitis. [2]

Airflow obstruction is caused due to mucus metaplasia through several mechanisms and they causes luminal occlusion, thickening of the epithelial layer which intrudes on the airway lumen and the mucus alters the airway surface tension. [2]

Due to this, the airway has high tendency for collapse and also decreases the capacity for airflow and exchange of gas. [2]

Mucus hypersecretion is one of the risk which is associated with cigarette smoking, viral infections, bacterial infections or inflammatory cell activation.

When combined with poor ciliary function, distal airway occlusion, ineffective cough, respiratory muscle weakness and reduced peak expiratory flow rate clearing secretions becomes difficult and requires high energy expenditure. [2]

Chronic bronchitis is a condition in which an obstructive ventilation disturbance of the respiratory passages evokes a feeling of shortness of breath. Respiratory rate, oxygen saturation, chest mobility, expiration are all affected. [2]

Furthermore, the amount of air exhaled during initial one second (FEV1) is reduced and is reduced to a greater degree than the entire Forced Vital Capacity and FEV_1/FVC ratio is affected. [10]

PFT is used to measure the lung volumes and capacities which shows decreased FEV_1/FVC ratio . It is an investigation tool for monitoring of patients with respiratory pathology. It also provides information about large and small airways, the pulmonary parenchyma and the size and integrity of the pulmonary capillary bed. [10]

As this is progressive condition and can worsen the quality of life, the physiotherapy plays an important role for promoting good health by reducing breathlessness, improves chest mobility by various breathing exercises.

Breathing exercise and other ventilatory techniques also have a vital role in influencing the rate, depth and distribution of ventilation. [10]

Pursed lip breathing is used as a conventional treatment in chronic bronchitis which showed improvement on respiratory parameters and also in reducing dyspnea. [10]

PNF i.e. D1 and D2 flexion and extension used as an advance technique which has also some improvement.

PNF pattern and methods of treatment were used to obtain the maximum quantity of activity, which can be achieved at each voluntary effort and the maximum possible number of repetition of the activity to facilitate the response.

In the development of PNF techniques, greater emphasis was placed on the application of maximal resistance throughout the range of motion, using many combinations of motion that were related to primitive patterns and the employment of postural and righting reflexes.

In the modern field, the advanced physiotherapy techniques of PNF are being applied as a means of stimulating response and strengthening muscles related to respiration.

PNF mobility exercise aims in improving the pulmonary functions and the mobility of chest wall, trunk and shoulder. [11]

As D1 and D2 flexion extension involves movement of shoulder which improves chest mobility and also shows improvement in chest expansion and mobilizing secretions.

This study is basically done to find the effects of PNF pattern on respiratory parameters and also to compare the effects of PLB and PNF as there are very few literatures available on it. This technique is rarely used in hospital setup so after the study, based on the findings we can prescribe the more effective treatment to the patients for prevention of chronic bronchitis complications and symptoms and thus enhance the patient's recovery which can also improve the quality of life.

Method

Study type: Experimental study

Study design: pre test or post test

Sample size: 60 (30 + 30)

Place of study: Krishna Hospital, Karad

Criterion for Study

Inclusion criteria:

- Both male and female
- Patient diagnosed with chronic bronchitis
- Patients with reduced chest wall movements and reduced air entry
- Haemodynamically stable patients who are willing to participate in the study.

Exclusion criteria

- Any recent thoracic surgeries and abdominal surgeries
- Any musculoskeletal abnormalities limiting the shoulder girdle functions.
- Neuromuscular weakness of upper limb
- Patients with grade IV dyspnea (according to MMRC grading).

Procedure

The subjects who were admitted in wards and those falling in inclusion criteria were selected. Each subject was screened as per inclusion and exclusion criteria and was informed about the study and a written consent was taken from them.

By using consecutive random sampling method the participants were divided into two groups.

Group A and Group B and was named as Conventional and Experimental group. PLB exercise was given as a conventional exercise and PNF was given to the experimental group.

The intervention was given for 2 weeks and thrice a day for both the groups.

Pre test and post test evaluation was taken, which includes: R.R, SpO_2 and FEV_1/FVC

Intervention :

GROUP A : PLB was given in this group. Patient was positioned in semi fowler position with relaxed shoulders and slowed expiration was done by pursing the lips. It was performed 10 times and was given for 2 weeks thrice a day.

GROUP B : In this group, PNF pattern was given: D1 flexion and D1 extension, D2 flexion and D2 extension. It was performed with 10 repetitions for 2 weeks thrice a day. After two weeks of session post test and statistical analysis was done.

Outcome Measure

- SpO_2 / R.R
- PFT: FEV_1/FVC

Results

Table 1: Comparison of pre and post R.R, SpO_2 and FEV_1/FVC within the group

	MEAN ± SD	MEDIAN	P VALUE	t VALUE	df
GROUP A PRE R.R	17.7±3.800	17.000	0.0004	3.096	29

Statistics

The outcomes were assessed at the 1st day prior to treatment and at the end of 2nd week post treatment. Inter group analysis was done by unpaired 't' test and intra group analysis was done by using paired 't' test. The inter and intra group analysis was done by using Instat 3.

Discussion

Chronic Bronchitis is common but a variable phenomenon on COPD with numerous clinical consequences and reduced lung function with increase in airflow obstruction[1]

The therapeutic role of PNF pattern based on stretch-reflex theory in altering pulmonary functions. E.Dean, Donna Frownfelter stated that ventilation has been improved, chest wall muscles are being maximally stretched and ribs are naturally opening up in butterfly technique where the inspiration with trunk extension, shoulder flexion, abduction and external rotation (D2 flexion) and the expiration with trunk flexion, shoulder extension, adduction and internal rotation (D2 extension) . [4]

Vanessa Resqueti stated that pursed lip breathing is used conventionally which has been showed in reducing the dyspnoea and has greater effect on improving pulmonary function. [10]

The main objective of the study was to find the effect of PNF on improving the pulmonary function in chronic bronchitis.

In the present study, the sample size was 60 and they were divided into two groups: group A (conventional group) and group B (experimental group) which consisted of 30 participants in each group. The participants were selected on the basis of inclusion and exclusion criteria.

In this, the efficacy of D1 and D2 flexion and extension pattern on respiratory rate, oxygen saturation and FEV_1/FVC were investigated. They were investigated using Pulmonary Function Test. The intervention was given for 2 weeks thrice a day.

After the intervention statistical analysis was done where; Respiratory Rate, SpO_2 and FEV_1/FVC ratio of pre and post were compared by paired 't' test of within the groups. Whereas, the comparison between the groups were also done by comparing pre and post R.R, SpO_2, FEV_1/FVC of group A with group B by unpaired 't' test.

Post intervention it was found that there was significant improvement within the group A and group B and in comparison of both the groups there was no significant improvement may be because the shoulder movement didn't had effect on improving lung volumes and capacity and thus FEV_1/FVC ratio and oxygen saturation was not improved.

And also, during intervention patient had difficulty in performing shoulder flexion and extension repeatedly due to dyspnoea where some of the participants were performing trick movements.

Therefore, various dyspnoea relieving techniques were given to the patient like pursed lip breathing, forward leaning position and rest which helped in relieving dyspnea.

It was difficult to treat dyspnoea in grade 3 patients, as some patients were non –co-operative and some didn't do exercises independently once the therapist is taught how to do the exercise and instructed to do number of times in a day, which hampered the results of the study

and recovery in the patients.

But there was significant improvement in respiratory rate post intervention may be due to chest wall muscles are being maximally stretched and the inspiration with trunk extension, shoulder flexion, abduction and external rotation (D2 flexion) and the expiration with trunk flexion, shoulder extension, adduction and internal rotation (D2 extension).

As the intercostals muscle and diaphragm contains sensory muscle spindles that respond to elongation. A signal is sent to spinal cord and anterior horn cells. These neurons signal make more muscle fibers to contract (recruitment) and thus increase the strength. Stretching the ribs and diaphragm activate the stretch reflex and help the patients to take a deep breath which helps in improving the quality of breathing and thus improves the respiratory rate.

Few studies like D.Anandhi, P.Deekshitha - PNF shows an immediate improvement in FVC and IC thus shows an enhanced lung function among collegiate students.

Leandro Ferracini - concluded that pursed lip breathing reduces dynamic hyperinflation and improves exercise tolerance, breathing pattern and arterial oxygenation at submaximal intensity exercise.

Gopi Parth Mehta - shows significant improvement in chest expansion and pulmonary function test such as forced expiratory volume and forced vital capacity than only active assisted exercise program for elderly subjects.

After comparing with the above study, PNF exercise has important role on pulmonary function as the therapeutic role of PNF pattern is based on stretch reflex theory in altering pulmonary functions with D1 and D2 extension it showed improvement in oxygen saturation, respiratory rate and FEV_1/FVC ratio.

But in comparison it had no significant improvement except respiratory rate which may be due to short intervention duration and small sample size may be responsible for the baseline differences that appeared to exist in the groups for PLB and PNF.

Conclusion

Based on the statistical presentation, analysis and interpretation it can be concluded that Proprioceptive Neuromuscular Facilitation pattern has shown significant improvement in SpO_2, R.R and FEV_1/FVC.

The present study provided the evidence to support that both the techniques are effective on SpO_2, R.R and FEV_1/FVC individually in chronic bronchitis patients.

However, the techniques when compared with each other were equally effective and there were no significant difference between each other but had shown significant improvement in R.R.is study

Conflict of interest: Short intervention duration as patients did not stay in wards for more than 2 weeks.

Funding: This study was funded by Krishna Institute of Medical Science Deemed to be University, Karad.

Ethical Clearance: The study was approved by the institutional ethics committee of KIMSDU.

Impact of Thera-Pep and Forced Expiratory Technique in Chronic Bronchitis Patients

Sushmita Goswami[1], Javid H Sagar[2], G. Varadharajulu[3]

[1]MPTh (Cardio-pulmonary), [2]Professor/ Unit Head, [3]Dean/ Professor/ HOD, Krishna College of Physiotherapy, Krishna Institute of Medical Science Deemed to be University, Karad, Maharashtra, India.

Aim: To study the impact of Thera-Pep and Forced Expiratory Technique in Chronic Bronchitis patients.

Objectives: To find the effect of Thera-pep device in mobilizing secretion. To find the effect of forced expiratory technique in mobilizing secretion and To compare the effect of Thera-pep and forced expiratory technique in chronic bronchitis patients.

Materials and Method: 54 patients were included according to inclusion and exclusion criteria, were randomized by chit method into two groups. Group A (Forced Expiratory technique with coughing) and Group B (Thera-PEP device with coughing) - with 27 patients in each group. All the patients were assessed with Six Minute Walk Test (6MWT) and Peak Expiratory Flow Rate (PEFR). The treatment was given for twice a day for 6 days a week for 2 weeks. After 2 weeks, effect of interventions were assessed by 6MWT and PEFR.

Results: There was no significant difference in 6MWT and PEFR score in comparison of both experimental and conventional intervention. The inter group values of 6MWT and PEFR showed significant improvement in chronic bronchitis patients. The intra group values of 6MWT and PEFR showed no significant improvement in comparison of the techniques in chronic bronchitis patients.

Conclusion: Both the techniques are effective on removal and mobilizing of secretion individually in chronic bronchitis patients. However, the techniques when compared with each other were equally effective and there was no significant difference between each other.

Key words: *FET, 6MWT, Chronic Bronchitis, PEFR, Thera-PEP device.*

Introduction

Chronic obstructive pulmonary disease (COPD) is an illness which progresses in severity and needs lifelong treatment.[1] The signs and symptoms are observed over 40 years of age and in 10% of general population.[1] There occurs partial reversible flow restriction in the airways in pulmonary pathology.[2] Patient condition and disease prognosis depends on the severity of pathology and physiological changes, intensity of symptoms(chronic cough, sputum production, resting dyspnea and reduced working capacity), presence of non-pulmonary general pathologies (body mass loss and dysfunction of the musculoskeletal system with nutritional abnormalities) and co-morbid factors (osteoporosis, bone fractures, diabetes, chronic anemia, cardiovascular diseases, depression).[2] Inflammation of large and medium sized airway bronchi in the lungs is known as bronchitis.[2] The symptoms includes coughing up mucus, wheezing, shortness of breath, and chest discomfort.[3] Bronchitis is classified into two types: acute bronchitis and chronic bronchitis.[3] Chronic bronchitis (CB) is very common but changeable phenomenon in chronic obstructive pulmonary disease (COPD).[4] Chronic bronchitis is defined as a productive cough lasting for minimum of three months or more per year and consistent for at least two years.[4] It affects about a third of patients with COPD, but also occurs in individuals with normal lung function, with prevalence estimates varying widely both in population based studies (2.6-16%) and among COPD patients (7.4-53%).[5] Cigarette smoking is the most probable cause, with many other factors such as air pollution and genetics playing a smaller role. [5] The conventional treatments used include cessation of smoking, vaccinations, rehabilitation, and

inhaled bronchodilators and steroids via nebulizers. Also long-term oxygen therapy or lung transplantation may help in prognosis of the condition.[6] Positive expiratory pressure Thera-Pep device allows the entry of air to peripheral airways via collateral airways which creates pressure air to go behind the secretions. This will move the secretion towards the larger airways and expel out easily to prevent collapse of alveoli.[6] It is a portable device with easy to use technique so that patient with Cystic Fibrosis (CF), lung diseases with secretory problems, atelectasis, and patients recovering from surgery can use for mobilizing their secretions.[7] Forced Expiratory Technique (FET) with correct procedure and learning, this technique is most practiced and effective airway clearance technique.[7] This technique can be used as an individual technique or with different airway clearance techniques for mobilizing secretions.[8] It can be used as a stand-alone technique and also can be included in any airway clearance routine.[8] Huff is also known as forced expiratory technique with breathing control and mobilizes the secretions from lower to upper airways and expectorates them through mouth by coughing out.[9] FET is effective than coughing as it is less painful, less tiring, and creates less intracranial pressure inside skull.[9] Peak expiratory flow rate is the outcome measurement tool used to evaluate the maximum flow rate generated during forceful exhalation starting from full lung inflation.[10] It depends on the voluntary effort and muscular strength of the patient reflecting large airway flow.[10] The 6mwt is a submaximal exercise test used to evaluate the functional capacity of the patient. It measures the distance walked over a span of 6 minutes with various cardiopulmonary responses in the body. [10] It measures the response to therapy and prognosis of various cardiopulmonary conditions.[10]

This study examined the effect of Thera-PEP device in mobilizing secretion in chronic bronchitis patients. We also investigated the effect of Forced Expiratory Technique in mobilizing secretion in chronic bronchitis patients. As Chronic Bronchitis is a very common condition with progressive worsening of its symptoms. It needs effective treatment to control the symptoms and its complications which hampers the quality of life of the patient. Easy and beneficial technique may be effective in improving the quality and functional life of the patient. Therefore comparison of both the techniques has been done and given to patients respectively to check for the improvement in the functional capacity and quality of life of patient.

Method

Study type: Experimental study

Study design: Comparative

Sample size: 54 (27+ 27)

Place of study: Krishna Hospital , Karad

Criterion for Study

Inclusion criteria:

1. Confirmed patient diagnosis of chronic bronchitis.
2. Male and female patients.
3. Patients who can complete stage I of Bruce protocol.
4. Patients Haemodynamically stable and who are willing to participate in my study.

Exclusion criteria:

1. Patients who are in ICU with mechanical ventillatory support.
2. Unconscious, uncooperative patients.
3. Patients having grade IV dyspnea.
4. Patients having other respiratory complications secondary to chronic bronchitis.
5. Bedridden patients.
6. Recent facial, skull surgery or trauma.

Procedure

By using random sampling method the participants had been divided into 2 groups by chit method; Group A, Group B. subjects with confirmed diagnosis of Chronic Bronchitis with secretions and who are able to complete stage I of Bruce Protocol had been assessed by 6MWT and PEFR.

The intervention had been given for Twice a day for 2 weeks and treatment was given 6 times a week.

Intervention protocol for group A and group B

<u>GROUP A: Forced expiratory technique with coughing:</u>

Before starting the session, the technique and its physiology with diagrams which will help the patient to understand the need for monitoring the expiratory force were taught to the patient. Technique was taught in sitting position. Technique involved using 1 or 2 huffs from middle to low lung volumes, with the glottis open, followed by a period of relaxed-controlled diaphragmatic breathing with slow deep breaths. The patient then breathes quietly, at their own pace, for as long as is required and then coughing followed by huffing were performed. The session was carried out for (15-20 mins).

Group B: Thera-pep and coughing:

Patient is seated in upright or sitting position. The patient was instructed to slowly inspire to vital capacity and then hold the breath for about 3 seconds and then slowly exhales through the mouthpiece with the fixed orifice resister that creates an expiratory pressure resistance between 10–20 cm H_2O. The resistance can be increased or decreased according to the patient's condition. Then the patient performs slow deep breathing which was repeated anywhere from 10 to 20 times. Then a "cough" technique was done to clear secretions that have been mobilized from larger airways to central airways. Rest intervals for relaxation and breathing control for about 1–2 minutes were provided. Full expiration was explained to be avoided. Treatment session was given for about 15–20 minutes and this therapy duration and frequency were adjusted according to patient's condition. Sterilisation process after the use of Thera-PEP device was done in autoclave machine.

Outcome Measure:

1. **Peak Expiratory Flow Rate(PEFR):**

Peak Expiratory Flow Rate is the maximum flow rate generated during a forceful exhalation, starting from full lung inflation. PEFR primarily reflects large airway flow and depends on the voluntary effort and muscular strength of the patient. It is a portable flow gauge device (PFM). The PEFR measurement depends significantly on patient effort and technique. Clear instructions, accurate demonstrations, and frequent review of technique are essential. The position of patient while measuring PEFR is seated upright on chair.

2. **Six Minute Walk Test (6MWT):**

6MWT is a simple evaluative tool to asses functional exercise capacity that is the capacity of the individual to perform activities of daily living. 6MWT is a self paced test, which depends on various external factors like energy expenditure, encouragement of the therapist and motivation. It varies with age, gender, body weight, height. The patient is instructed to walk 60m yard (i.e; 30 m each lap) for 6 minutes without any symptoms or episodes of breathlessness. 6 MWT measures the heart rate, respiratory rate, oxygen saturation, blood pressure and distance walked before and after the treatment.

Results

Table 1: Comparison of PRE and POST intervention showing Mean, Median, p Value of PEFR and 6MWT of Group A and Group B respectively.

Statistics

The outcomes were assessed at the 1st day prior to treatment and at the end of 2nd week post treatment. Intra group analysis was done by paired t test and Inter group analysis was done by using unpaired t test. The inter and intra group analysis was done by using Instat 3 application.

Discussion

Chronic Bronchitis patients experience a progressive deterioration and disability leading to worsening of their health related quality of life. Chronic Bronchitis is common but a variable phenomenon of COPD with numerous clinical consequences and reduced lung function with increase in airflow obstruction [1]

Forced Expiratory technique (FET) is a technique including huffs with controlled diaphragmatic breathing. In this technique mucus is separated from the bronchial wall and moved to upper airways where expectoration occurs with cough [2]. Thera-PEP device is an advance PEP device used in urban multi- Specialty Hospitals for airway clearance {2}.

The main purpose of the study was to examine the effect of FET and Thera-PEP device in chronic bronchitis patients. The objective of this study was to determine the effect of FET and Thera-PEP device individually in mobilizing secretion and to compare both the techniques in chronic bronchitis patients.

In the present study, there were 15 males and 12 females in group A whereas, 22 males and 5 females in group B. The mean age of group A and group B were 63.77 and 62.77 respectively.

In this, the effect of FET and Thera-PEP device in chronic bronchitis patients were investigated. They were investigated using PEFR and 6MWT. The intervention was given for 6 days a week, twice daily for 2 weeks. In group A FET with coughing was given and in group B the Thera-PEP device with coughing was given. Both the techniques were given in sitting erect position.

Post intervention it was found that there was significant improvement in both PEFR and 6MWT in both the groups individually. But when both the groups were compared, it showed no significant differences in PEFR and 6MWT between group A and group B. This may be because of both the techniques having final outcome by coughing out mechanism and another reason may be due to patients getting nebulizers and other medications which may have hampered the outcomes of PEFR and 6MWT.[3]

Also during intervention, patient had initially difficulty in coughing out due to dyspnea leading to changes in the baseline differences in the pre PEFR and 6MWT values. Patients were taught with instructions about the device and its usage in patients own language i.e; Marathi.[4]

Also while teaching the patients in rural area 'Karad' the patients initially did not understand the technique to use and apply Thera-PEP device with the breath hold mechanism. This lead to reduced differences in the PEFR and 6MWT values. So the patients were shown video clips of the Thera-PEP position and use to get a biofeedback of the Thera-PEP device.[5]

Patients were taught with instructions about the mechanism of the device in helping to mobilize the secretion and thus reducing the symptoms.[6]

It was difficult to treat dyspnea in grade 3 patients as it includes breath hold mechanism of 3 secs, and some patients were non –co-operative and some didn't do the intervention given independently, so once the therapist has taught how to do the conventional as well as the device usage prior intervention then the patient can effectively utilize the Thera-PEP device. Also some patients did not follow the instructions and protocol of the intervention i.e.; to do number of times in a day, which hampered the results of the study and recovery in the patients.[7]

The adaptation and independency of Thera-PEP device in rural population was good and can be advised for home care management for chronic bronchitis. Using Thera-PEP device gives a biofeedback to the patient and thus helps the patient recovery and independency.[8]

Utilizing Thera-PEP device in rural area "Karad" can be further studied considering the durability, feasibility and cost of the device.[8]

6 MWT and PEFR depends on various nutritional, psychological and comorbid factors which may be also the reason for no improvement. Also the intervention duration was for two weeks as patients in wards do not stay for more than two weeks, which may be a short duration for effectiveness of the Thera-PEP device.[9]

Thera-PEP device is commonly used in urban multispecialty hospitals and the awareness and usage of Thera-PEP device in rural population and the effectiveness of the device with conventional techniques was the purpose of the study

Elkins, Jones et al had also reported such a preference in favour of treatments that allow greater independence of using Thera-PEP device. It is of great importance that the effectiveness of the Thera-PEP for home physiotherapy is evaluated. Adherence over longer periods of time is important, but it is unknown that the Thera-PEP is more acceptable device for sustained use. Other factors to consider which could have impact on the uptake of Thera-PEP were its relative cost, durability, and ease of maintenance [10].

The small sample size and the short duration intervention may be responsible for the baseline differences that appeared to exist in the groups for PEFR and 6 MWT.[10]

In the present study, after comparing the results with the previous studies it suggests that both the techniques are equally effective for chronic bronchitis patients and on comparing there is no significant difference in both the groups.

Conclusion

Based on the statistical presentation, analysis and interpretation it can be concluded that both the techniques are effective on removal and mobilizing of secretion individually in chronic bronchitis patients.

The present study provided the evidence to support that both the techniques are effective on removal and mobilizing of secretion individually in chronic bronchitis patients.

However, the techniques when compared with each other were equally effective and there was no significant difference between each other.

Conflict of Interest: Short Intervention duration as patients did not stay in wards for more than two weeks.

Funding: This study was funded by Krishna Institute of Medical science Deemed to be University, Karad.

Ethical Clearance: The study was approved by the institutional ethics committee of KIMSDU.

Critically Appraisal of Tools to Measure Using the COSMIN Checklist

Suvi Kanchan[1], Anitha. R. Sagarkar[2], Ranadheer. R[3]

[1]Post graduate, [2]Reader, [3]Associate Professor, Public Health Dentistry, Faculty of Dental Sciences, M.S. Ramaiah University of Applied Sciences

Abstract

Purpose: Oral health literacy tools are important for assessing a population's oral health knowledge and awareness. The objective of this study was to critically appraise the methodology used for developing all the existing oral health literacy assessment tools, by systematically reviewing the available evidence.

Materials & Method: Databases used for the search were Wiley, BMJ open, Pub Med/Medline and Science Direct. We identified 10 studies, published in English during 2006 – 2016, that focused on the development and validation of oral health literacy tools. We then assessed these studies using the COSMIN checklist, which evaluates the methodological quality of studies on measurement properties**.**

Results: Most of the tools were adapted from the general health literacy tool. All the 10 tools had measured validity and reliability, but lacked cross-cultural validity.

Conclusion: Findings from this review confirm that majority of the tools focus towards assessment of word recognition, numeracy and reading skills, rather than indicative of aspects such as health behaviors and service utilization. Developing tools that are adapted for specific populations will require further work, such as incorporating tests to ensure their acceptability and cultural competence.

Key-words: *Oral, health literacy, COSMIN checklist, tools, review*

Introduction

Oral health literacy (OHL) is defined as the 'degree to which individuals have the capacity to obtain, process and understand basic oral health information and services needed to make appropriate health decisions' [1] [2]. This ability to access and leverage oral health-related information and services serves as the most reliable indicator of oral health levels, since a high degree of OHL would correspond to a higher likelihood of good oral health being maintained. Being able to measure such an important indicator would prove to be extremely valuable in assessing overall oral health levels of a given population.

A number of tools have been developed to assess OHL levels of populations, of which the most widely used is the Rapid Estimate of Adult Literacy in Dentistry (REALD-99) [3], several variants of which were subsequently developed. Other popular tools, such as the Test of Functional Health Literacy in Dentistry (ToFHLiD)[4], the Comprehensive Measure of Oral Health Knowledge (CMOHK) [5] and the Health Literacy in Dentistry scale (HeLD) [6], have also been greatly successful.

A few reviews have been conducted for assessing OHL tools, including those by Dickson-Swift et al. (2014), and Navdeep Kaur and Daniel Kandelman (2015), which focus on what the different tools measure. However, no review has so far been conducted to evaluate the methodology used for developing these tools, which

Corresponding Author:

Faculty of Dental Sciences, M.S Ramaiah University of Applied, M S R Nagar, New Bel Road, Bangalore, Karnataka, India 560054

could help the researchers in understanding the critical points that are to be considered while planning the development of new tools.

This systematic review, hence, analyses, assesses and benchmarks all the currently available tools. The aim of this study is to critically appraise the methodology used for developing all the existing oral health literacy assessment tools, using the COSMIN checklist.

Materials and Method

This systematic review was conducted based on the five steps mentioned by [7]. The studies which emphasize on methodology of development and validation of different oral health literacy tools were included in the review. All other studies were excluded from the review during the step of screening. The final study selection was based on the inclusion and exclusion criteria mentioned in Table 1.

Table 1: Inclusion and exclusion criteria for the studies

Inclusion Criteria	Exclusion Criteria
1. Time period of studies from 2006- 2016. 2. The tools developed in different languages but published studies available in English language. 3. Studies based on development of Oral Health Literacy tools.	1. Tools adapted from an original tool. 2. Commentary articles/conference reports/theses/ workshop summaries

The research for the review was started with Google Scholar search and was completed with the help of Wiley, BMJ open and Pub Med/Medline databases. The key words used for the following search were 'health literacy', 'oral', 'development' and 'tool' with Boolean search strategy. MeSH term used was 'health literacy'. The time period selected for the review was 10 years. The search time frame was January 2006- April 2016.

Study selection

Using the search items selected for this review, 12585 turned up in the initial search. Then after applying various filters and removing duplicate studies, finally 10 studies were selected.

The quality of the studies selected were assessed based on the methodology used for the development of the oral health literacy tool in the particular study.

The Consensus-based Standards for the Selection of Health Measurement Instruments (COSMIN) checklist was used to evaluate the methodological quality of studies on measurement properties [8]. It is a valid and reliable tool for evaluating the methodological quality of health measurement instruments. The COSMIN uses a quality-rating system of nine domains including internal consistency, reliability, measurement error, content validity, structural validity, hypotheses testing, cross-cultural validity, criterion validity and responsiveness. Each domain is assessed with a series of questions that are scored on a 4-point scale from excellent to poor. For this review, studies that met the inclusion criteria were scored.

Results

In this review we identified all the original oral health literacy tools and analyzed the methodologies adopted to develop and validate such tools. We observed that the first tool developed was the REALD- 30 in 2007 as shown in Table 2, which was adapted from Rapid Estimate of Adult Literacy in Medicine (REALM). REALM was the commonly used tool for assessing general health literacy. REALD- 30 was based on word recognition tests that helped in merely assessing the reading ability of the population.

Other recently developed tools such as the Adult Health Literacy Instrument for Dentistry (AHLID) [9], Oral Health Literacy Adults Questionnaire (OHL-AQ) [10]including new measures of literacy skills (OHL Adults Questionnaire: OHL-AQ, etc. were also based on parameters such as reading comprehension, numeracy, literacy and decision-making (factual, procedural, and conceptual). Apart from these, population-specific tools such as the Hong Kong Oral Health Literacy Assessment Task for Pediatric Dentistry (HKOHLAT-P) [11] and Oral Health Literacy Inventory for Parents (OH-LIP) [12] were also developed, which helped in assessing the oral health literacy of parents/ children with respect to word recognition, vocabulary knowledge and comprehension. It did not measure the comprehensive skills.

Table 2: Overview of oral health literacy tools

Name of tool	Year	Authors	Type of tool
Multi-site assessment of oral health literacy	2016	Macek et al.	Conceptual model with 3 domains
Health Literacy in Dentistry (HeLD)	2014	Jones et al.	29 item- Modelled on the HeLMS
Adult Health Literacy Instrument for Dentistry (AHLID)	2015	Stein et al.	Based on an OECD instrument
Oral Health Literacy Adults Questionnaire (OHL-AQ)	2014	Sistani et al.	17 items in 4 sections, reading comprehension, numeracy, literacy and decision making
Hong Kong Oral Health Literacy Assessment Task for Paediatric Dentistry (HKOHLAT-P)	2013	Wong et al.	Literacy and numeracy tasks across three kinds of knowledge (factual, procedural, and conceptual)
Oral Health Literacy Inventory for Parents (OH-LIP)	2011	Richman	3 parts- word recognition, vocabulary knowledge, and comprehension of 35 terms used in paediatric dentistry
Oral Health Literacy Assessment-Spanish (OHLA-S)	2012	Lee et al.	24 items- word recognition and a comprehension section
Oral Health Literacy Instrument (OHLI)	2009	Sabbahi et al.	38 item- reading comprehension and 19 item-numeracy sections
Test of Functional Health Literacy in Dentistry (ToFHLiD)	2007	Gong et al.	Reading comprehension and numeracy 68 item reading comprehension and 12 item numeracy
Rapid Estimate of Adult Literacy in Dentistry −30 (REALD-30)	2007	Lee et al.	30 item word recognition common dental words

Discussion

The present review focused on how over the years, various oral health literacy tools have been developed/adapted from original tools. For instance, the REALMD-20 [17] has been adapted from the REALD-30. But unlike such adapted tools, most of the original tools which were developed later included different domains for assessing oral health literacy such as comprehension, knowledge, numeracy and vocabulary. In 2007, another tool was developed, namely the Test of Functional Health Literacy in Dentistry (ToFHLiD), which assessed the comprehensive and numeric ability of a population. The tool showed satisfactory levels of reliability and convergent validity. However, the ToFHLiD lacked test-retest reliability.

Also, there were no proper measures followed for assessing the psychometric properties of the tool. As a consequence, the results obtained from the REALD-30 and the inferences drawn from them would include a significant level of inaccuracy, and would not be a reliable indicator of the true extent of oral health literacy in the given population.

A study done by Mark D. Macek and his colleagues in 2016 was based on a multi-site investigation which included a conceptual model with three domains: Health Literacy (Domain #1), Behaviors/decisions (Domain #2), and Health Outcomes (Domain #3), influenced by selected oral health-related and socioeconomic status

(SES) covariates.

Most of these tools were adapted from existing tools which were originally developed for measuring general health literacy. For instance, the Health Literacy in Dentistry (HeLD) [6] was adapted from a general health literacy measure, the Health Literacy Management (HeLM) scale. Similarly, REALD was based on the Rapid Estimate of Adult Literacy in Medicine (REALM).

Despite successful adaptions of these original tools, however, it was observed in the review that all of the tools that were reviewed lacked cross-cultural adaptation. But there were a few tools which considered the importance of language in assessing the literacy of a population. The tools that were developed by [11] and [14], for instance, were translated into Mandarin and Spanish languages respectively.

In the past, there have not been many reviews for assessing oral health literacy tools. The results we obtained by means of this study were similar to those obtained from reviews done by [18] and [19], the latter of which states that none of the current tools offer an accurate assessment of oral health literacy level of a given population.

With this review we observed that there is a need of oral health literacy tools which are not only disease specific but consider all the domains of health literacy such as word recognition, comprehension, decision making etc. the tools should also be cross-culturally adapted for specific population.

One of the limitations of this review was that only original studies were considered for the purpose of the review. The various tools adapted from original tools were not considered.

Conclusion

Findings from this review confirm that majority of the tools focus towards assessment of word recognition, numeracy and reading skills, rather than indicative of aspects such as health behaviors and service utilization. Of late, attempts have also been made to incorporate other parameters into the development phase of the tool, which include parameters that are considered important, including decision making and possibly service navigation. The incorporation of these parameters should increase the validity of these tools as a measure of oral health literacy on a larger scale, as they are more capable of incorporating communicative/ interactional and critical nuances of oral health awareness. Efforts in the area of formal validation, however, are still required. In addition, further work would be required to develop tools that are adapted for specific populations, by incorporating tests to ensure their acceptability and cultural competence.

Abstract

Background: Mental toughness is one of the psychological dimensions considered essential for performance in sports. In this study, the Psychometric validation of the Psychological Performance Inventory (PPI) was validated for the measurement of mental toughness in elite athletes. *Materials and method:* A sample of 76 elite athletes was selected via purposive sampling. To assess mental toughness, we used the Psychological Performance Inventory, by Loehr (1986). A confirmatory factor analysis was conducted to confirm the factor structure of the Psychological Performance Inventory in an Indian context. *Results*: The mean scores for negative energy control, positive energy control, attention control, and attitude control were 3.41 (SD = .18), 3.88 (SD = .23), 3.68 (SD = .15), and 3.86 (SD = .23), respectively. Only 29 items were adequately internally consistent in assessing mental toughness for Indian elite athletes. In composite reliability (CR), all factors had values above .85, indicating good reliability.

Conclusion: The lack of success among elite Indian athletes is their excessive focus on affective skills, neglect of cognitive skills. Balancing affective and cognitive skills is the way to improve mental toughness,

Keywords: *Affective, cognitive, Indian elite athletes, mental toughness, skill*

Introduction

In today's increasingly competitive games, the already thin margin between winning and losing (i.e., performance) is becoming progressively thinner. These decreasing margins are causing immense stress for athletes, as achieving the highest level of success requires a blend of complex technical skills, self-efficacy, and understanding the dynamic mental and physical environmental constraints.

Performance in competitive sports comprises three domains: technical movement or mechanics (skill), cognitive skills (ability to deal with the environment), and affective skills (an emotional component).[1,2]. An Aoyagi and Portenga have noted, 'successful performance requires both the development and mastery of knowledge, skills, and abilities and the capability to consistently and reliably deliver (i.e. perform) at the time of performance'. [3]

Contesting every athletic should have ability to manage the delicate mind–body connection, which becomes dramatically clear within the competitive arena.[4]

Sugarman reported that athletes often spend so much time on physical practice in order to gain an edge in competition that they end up ignoring another essential aspect of sports performance, namely, mental skills. A trained mind is essential to achieve this skill.[5]

Mental toughness is considered as an important psychological dimension for performance excellence. Mental toughness is used as a measure of the specific cognitive and affective skills that athletes must possess for good sports performance.[6-10]. Broadly, mental toughness has been denoted as the quality necessary to perform better than others in a competition or to perform well in a competition. [11,12,13]

The cognitive aspect of mental toughness refers to the ability to deal with problems on and off the field [12] and deal with the pressure, negativity, and adversity [13-14] by staying calm and focused and maintaining belief in one's own plans and actions [6]. The affective aspect, on the other hand, refers to athletes' ability to remain motivated and confident[11] despite numerous failures on a daily basis, both during and after competitions.

Presently, most studies on mental toughness in Indian athletes focused on comparing mental toughness among various competitive levels of a single sport, such as the school, university, and national levels.[15-18] Few studies have examined how mental toughness correlation with other factors like win to win, winners to losers, anxiety state across various sports, such as badminton, gymnastics, athletics, and cricket[19,20]. There is no reported study on mental toughness and its correlations with various components of mental toughness.

This study was conducted to validate the PPI in the Indian context for elite athletes and to measure mental toughness and assess the psychological reasons for the poor performance of Indian athletes at the international level.

Materials and Method

The purposive sample of 76 elite Indian athletes competing at the national and international levels, in golf (n = 20), shooting (n = 15), track and field (n = 17), tennis (n = 5), squash (n = 2), wrestling (n = 4), swimming (n = 2), and boxing (n = 3) were included in the study. The sample was collected at various international competition events in India, such as the Indian Open golf tournament, the Women's Indian Open, the International Shooting Sport Federation (ISSF) World Cup, the Asian Athletics Championship, and various camps held for national players in competition at the international level.

The Psychological Performance Inventory (PPI; Loehr 1986) [21] was used to measure mental toughness. This 42-item scale yields a total mental toughness score, as well as seven 6-item subscale scores: (a) self-confidence; (b) negative energy control; (c) attention control; (d) visualization and imagery control; (e) motivation; (f) positive energy control; and (g) attitude control. Each item is rated on a five-point Likert scale anchored by 'almost always' and 'almost never'. The subscale scores range from 6 to 30 (with higher scores indicating more desirable levels), with total scores ranging from 42 to 210. The PPI has been found to be internally consistent, with Cronbach's alphas for the seven subscales indicating high reliability (self-confidence = 0.69; negative energy control = 0.42; attention control = 0.75; visualization and imagery control = 0.82; motivation = 0.70; positive energy control = 0.71; attitude control = 0.71). The PPI demonstrated acceptable psychometric properties when used on athletes performing at a National or international level [22,23]. PPI was selected because its subscales allow easy breakdown of items into affective and cognitive skills.

Procedure

Structural equation modelling (SEM) was employed to test the validity of the PPI using confirmatory factor analysis, which involves confirming how well the scale items fit the subscales (self-confidence, visualization and imagery control, motivation, positive energy control, negative energy control, attention control, and attitude control) forming the construct of mental toughness. First, the internal consistency was examined and maximized using Wille's stepwise procedure, which was repeated until removal of any of the remaining items in the scale did not lead to an increase in the corresponding subscale's alpha. Second, a partial least squares SEM (PLS-SEM) approach was used to determine whether the factor loadings of all remaining items in the final model of mental toughness were more than[5] which would indicate the presence of convergent and factorial validity. High internal consistency and reliability further serve as proof of construct validity.

Results

The obtained data was statistically evaluated with IBM SPSS Statistics for Windows, Version 21.0. Armonk, NY: IBM Corp using *t*-test, Cronbach's alpha coefficient Regression (β) path coefficients, at p value 0.05. The mean scores of self-confidence, visualization and imagery control, and motivation were 4.33 (SD = .16), 4.13 (SD = .20), and 4.56 (SD = .04), respectively. The mean scores for negative energy control, positive energy control, attention control, and attitude control were 3.41 (SD = .18), 3.88 (SD = .23), 3.68 (SD = .15), and 3.86 (SD = .23), respectively. Subscales of the PPI were significantly correlated ($p < 0.05$, Table 1).

Table 2 indicates the significance of reliability and validity of Psychological Performance. The internal consistency reliability of each of the seven subscales was good. Using Wille's method, we found that only 29 items were adequately internally consistent in assessing

mental toughness for Indian elite athletes. Regarding the composite reliability (CR), all factors had values above .85, indicating good reliability All subscales also had average variance extracted (AVE) values of greater than 59, indicating good convergent validity. To assess the common method bias, we used Harman's one factor test (based on a principal component analysis) to see if all the items loaded onto one factor. We found no common variance or a common latent factor (Table-3, 4).

Discussion

Mental toughness is a key quality for athletes, especially the elite level, where the margin for victory can be millimetres or milliseconds.

The PPI has been used in a number of empirical studies and is recommended as a useful instrument for assessing mental toughness. [21,22] We found that only 29 of the original 42 items of the PPI were relevant to measuring mental toughness in Indian elite athletes. Following removal of the other 13 items, we were able to confirm the convergent and discriminant validity of the seven factors through an examination of the individual parameter estimates. Furthermore, the internal

consistency coefficients of the seven factors were satisfactory, indicating that all subscales were internally consistent. Taken together, the scale items appeared to be suited to assessing mental toughness.

Affective skills help athletes maintain a strong faith in their ability to achieve a set goal, despite the low odds and lack of success [6]. This faith does not appear to fade even in the face of self-doubt about their performance or questions posed by others about their poor performance. These athletes remain in a state of optimal motivation, confidence, and control. [23] which helps them overcome and rebound from adversities and failure. In the present study, the subscales corresponding to the affective skills—motivational, visualization and imagery control, and self-confidence—made strong contributions to the construct of mental toughness among elite Indian athletes. Of these, self-confidence and visualization and imagery control were dominant, although motivation still had a high and significant contribution. By contrast, the cognitive skills of attitude control, positive energy control, and negative energy control did not have significant contributions; attention control did have a significant contribution, but it was somewhat weak. These findings show that the Indian athletes are continuously trying and motivated to achieve success via affective skills, rather than by relying on their cognitive skills.

However, during competition, the difference between winners and losers at the elite level is not a matter of motivation rather, it is down to their level of cognitive skills. Such skills allow athletes to assess and understand the situation, and then act accordingly. Numerous researchers have shown that successful athletes utilize cognitive skills to effectively deal with challenges, stressors, and pressure, irrespective of the prevailing circumstances [13]. Studies have also shown that reliance on affective skills particularly a higher motivational intensity can weaken cognitive skills and lead to poor decision making [24]. Higher-than-optimal motivational levels can make a person act hastily and hurry without analysing the situation; this makes them more result-oriented in their approach, as opposed to process-oriented. [25]

The results of this study might be useful for facilitating athletes' reflection on their lack of specific cognitive skills, which may be a reason for their limited success in international competitions. Athletes must be able to identify the most information-rich areas of their display, direct their attention appropriately, and extract meaning from these areas efficiently and effectively.

The psychometric support found for the PPI after item reduction in an Indian context can increase researchers' confidence in the instrument's usability to evaluate elite athletes in India in both future research and professional practice. It could be used in developing mental training programmes that place emphasis on assessing and training cognitive skill, in addition to affective skills.

The results of our study suggest that a probable cause of the lack of success among elite Indian athletes is their excessive focus on affective skills, neglect of cognitive skills, when they are developing mental toughness. Balancing affective and cognitive skills is the way to improve mental toughness, and may help to bring consistent success for Indian athletes at the international level.

Conclusion

The lack of success among elite Indian athletes is their excessive focus on affective skills, to the neglect of cognitive skills. Balancing affective and cognitive skills is the way to improve mental toughness,

An Assessment of Trust in Medical Profession amongst People Residing in a Semi-Urban Area, Tamil Nadu

Taseen Sida.A.S[1], Alice Matilda Mendez[2], Nisha B[2], Timsi Jain[3]

[1]3rd year MBBS, Saveetha Medical College and Hospital, Thandalam, TamilNadu, [2]Assistant Professor, [3]Professor and Head , Department of Community Medicine , Saveetha Medical College and Hospital, Thandalam, Tamil Nadu

Abstract

Introduction: The fundamental basis in health care system and relationship is **Trust.** Trust is a set of expectations that the health care provider will do the best for the patient.The word "Trust" has been in a state of crisis over the last decade in India particularly in medical profession. Unlimited and implicit access to health care system and medical information from a varied range of source helps patients in one way and in contrary to that it may also misinform and adversely affect "Trust" in medical profession.

Objectives

- To assess trust in medical profession among people (>18years) residing in a semi urban area of TamilNadu.
- To assess the factors affecting Trust in medical profession.

Methodology: A community based cross-sectional study was conducted during February 2019 in Thirumazhisai , a semi-urban township in Chennai. 150 Men and Women above 18 years were included in the study. Data Collection was done using semi structured questionnaire. TMP(Trust in Medical Profession) scale was used to measure trust in medical profession.

Result: 56.4% have good trust on Doctors and 44.33% have trust lower than the expected score based on TMP scale. Trust was higher among unemployed, women , people below poverty line , those not suffering from chronic illness though statistical association could be established only with socio economic status(p 0.04) and system of medicine followed (p 0.01).

Conclusion: The trust in doctors have largely been reduced and hence understanding this would lead to better ways of responding to patients requests that preserve or enhance patients trust, leading to better outcomes.

Key words*: trust in medical profession, TMP scale, semi urban area.*

Introduction

The fundamental basis in health care system and relationship is **Trust.** Trust is a set of expectations that the health care provider will do the best for the patient. Research shows that the number of hospital jobs increased by 306% in 2015 and hence it's the high time that we focus on the basis "TRUST "[(1)]. The word "Trust" has been in a state of crisis over the last decade in India particularly in medical profession. Generally public in today's world have unlimited and implicit access to health care system and medical information from a varied range of source, this access helps patients in a way and in contrary to that it may also misinform and adversely

Assistant Professor, Department of Community Medicine, Saveetha Medical College and Hospital, Thandalam, Tamil Nadu

affect "Trust" in medical profession. Views also varied by sex, age, health, education, income, number of visits/ years with physician, past dispute with a physician, and satisfaction with care [(2)]. Trust also depends on patients willingness to seek care , reveal sensitive information , submit to treatment and follow physician. Measurement of trust also suggest an important tool for monitoring performance of individual providers and health plans [(3)]. Trust in doctors is found to have five main domains: Fidelity, competence, honesty , confidentiality and global trust [(4)]. Importance of studying Trust is twofold – at macro-level , Trust is an indicator of support for the health system and changes in the health system and at micro-level, there is relationship between trust and peoples' behaviour in real choice situations.

Methodology

A community based cross-sectional study was conducted in Thirumazhisai, a semi-urban area of Chennai during February 2019. Thirumazhisai is the urban field practice area under department of Community Medicine , Saveetha Medical College and hospital. The study population included men and women who have completed 18 years of age residing in Thirumazhisai for more than 6 months. Sample size was calculated to be 150 using formula for cross sectional study with an anticipated population proportion of 40 % [(5)] , confidence level of 95% at 5% significance level and allowable relative error of 20%. A two stage sampling technique was used to enrol individuals to the study. There are 15 municipal wards in Thirumazhisai and each ward has 10 to 15 streets. At the first stage simple random sampling was done to select one street from each ward. A ward wise list of all the streets was prepared. One street was selected by lot method from each of the 15 wards . Systematic random sampling was done to select 10 households from each ward . The first family was selected randomly from street wise list of family folders maintained in Urban Health Centre of Saveetha Medical College at Thirumazhisai using random number tables. Every third house was visited starting from the randomly selected house till 10 houses were covered . Only one member (above 18 years) per household was chosen to avoid cluster bias.

Data was collected orally by interview method using structured questionnaire which included sociodemographic profile and TMP(TRUST IN MEDICAL PROFESSION) scale[(2)] to measure trust in Medical Profession. TMP scale is a validated 11-item 4 point likert scale

(Table 1) with responses grading from S*trongly agree, Agree, Disagree, Strongly disagree*. Here maximum score is 1 for strongly agree and 2,3 and 4 for agree, disagree and strongly disagree respectively. In the questionnaire the negative format question is also changed and recoded according to the format above. Total TMP score was calculated for each individual by adding the scores of the 11 questions. The maximum possible score would be 44 (least trust) and minimum score will be 11 (maximum trust) Mean score was taken as the cut off for categorising into good trust(a score less than mean) and reduced trust (score more than mean).

The study was initiated after obtaining approval from institutional ethical committee of Saveetha Medical College. Informed consent was obtained from the study participants and confidentiality of data was assured and maintained throughout the study. Data was entered in Microsoft Excel and analysed using SPSS software. Qualitative data is expressed as frequencies and proportions, quantitative data were summarised as mean (standard deviation). Chi-square test was applied for bivariate analysis to find association between Trust and qualitative factors like age category, gender, occupation, education, socio economic status (APL/BPL), presence of chronic disease and system of medication followed. Logistic Regression was done for multivariate analysis.

Results

A total sample of 150 people of both men and women above 18 years of age were interviewed. Analysis of the demographic data revealed that there were more number of women about 60.66% and males about 39.33%. Mean (SD) age of the study population was 43.3 (15.6). Majority of people interviewed were in the age group of 18-40 years of age(51.33%) . 38 % of the study population were unemployed followed by 23.3 % unskilled workers. 82% were educated till High school or above. 18 % were Below Poverty Line (BPL) with respect to the ration card that was possessed.

The mean(SD) TMP score of the study population was 21.3 (6.214). The maximum score obtained was 37 and minimum was 14. A score below mean (21.3)was considered as "Good Trust" for comparison purpose in our study . Among the study population 85(56.7%) individuals were found to have "good" trust in medical profession while 65 (43.3%) had reduced trust. When 61% of the males in our study population was found to

have good trust , only lesser number of females (53.84%) had good trust in Medical profession . While all the four participants above 80 years had good trust in Medical profession, 62.5% of those in the middle age group (40-60) had good trust. Trust did not vary significantly among the various occupational groups. Trust is higher amongst those belonging to below poverty line (74.1%) while only 52.8% of APL card holders were found to have good trust. Other factors influencing trust also were analysed and showed that trust has been slightly lower(51.1%) amongst people having at least one of the chronic diseases(hypertension, Diabetes Mellitus, cardiovascular disease, bronchial asthma) and it is 59.2% amongst people without any chronic disease .Trust also varied according to the system of medicine followed by the individuals as shown in Table 2.

Bivariate analysis was done using chi-square to test the statistical association between the various factors and trust in medical profession (table 2). Socioeconomic status (p value - 0.04) and system of medicine followed by the participants (p value- 0.010) had a significant association with Trust. Multivariate analysis by logistic regression with "good trust" as the dependant variable did not reveal significant association with any of the independent variables.

The most important quality of a doctor that can influence the trust in medical profession as perceived by the study participants were as follows: 44% of the participants perceived verbal communication as most important followed by behavioural competence(25%), comfort level(16%) and simple elegant appearance(15%). Question number 11 in TMP (table 1) which individually measures the over all trust showed that 74% of the study participants agreed that they "trusted their doctor completely".

Discussion

A cross sectional study was done to assess "trust in medical profession" among adults population in a semi-urban township of Chennai, Tamil Nadu. Proportion of females and unemployed persons were more in our study population when compared to census figures of Tamil Nadu.[6] This may be due to the reason that the data collection was done during day time when males who were engaged at their occupation were not available at household . In this study based on the score calculated trust in medical profession is found to be 56.7% have good trust and about 43.3% have reduced trust and which is similar to study conducted in China by Da-Hai Zhao et al showed that the 67% has strongly trusted and about 33% had reduced trust.[7] Since this is a cross sectional study, deducing a continuous trend in long term was not possible. Mean score in this study is 21.3 out of 44 and in the previous study by Da-Hai Zhao et al the mean score is 35.4 out of 50 (5 point likert 10 item scale)[8]. Here it's important to note that level of trust is good in middle age group (40-60) in this study and is compared to study conducted in north-east Poland by Marcinowicz et al[9] . Based on the Table- 1 ,question number 3 "Doctors are thorough and careful " scored the highest about 68% and shows that the public is confident with Doctors knowledge and which is one of the factor influences trust in medical profession. Question number 8 in Table 1 "Doctors use their best skills and efforts" scored the least about 42% and shows that public has less confidence in transparency and skills in medical profession. During interrogations some people have lower Trust but were reluctant to express to medical students. Here the reduced trust may be due to recent media coverage of unethical practices by the doctors.

Factors affecting trust was studied and there is statistical significance obtained between two independent variables, socio economic status and the system of medications followed and Trust. Economic factors were found to be determinant of trust in doctors by studies done by Birkha et al and Gopichandran[10,11] . Another study done in older population by Guerrero et al also showed similar result [12]. Consistent results with association of trust in medical profession and system of medicine were not available. In this study participants perceived verbal communication and behavioural competence as more important and physical appearance as less important factor in influencing trust. Similar results were seen in another study done in rural and urban setting of Tamil Nadu[13] .

One of the limitations of this study is that it was conducted in a single geographic area . The representativeness of study population was not adequate as the data collection was done during day time and hence the responses of males and working group could not be captured fully.

Conclusion

The final outcome from this study is that 56.7% has good trust and 43.3% have reduced trust in medical profession. Trust have been higher among unemployed,

women , people below poverty line, those following alternate systems of medicine and those not suffering from chronic illness though statistical association could be established only with socio economic status(p 0.04) and system of medicine followed (p 0.01). Doctor's verbal communication skills was perceived by majority(44%) of the study participants as the most important quality that would determine trust in medical profession which should be focused on . The study would recommend the medical professionals to build up a close relationship with their patients and be still more transparent to avoid unethical issues. The trust in doctors have largely been reduced and hence understanding this would lead to better ways of responding to patients requests that preserve or enhance patients trust, leading to better outcomes.

Table-1 : 11-item Trust in Medical Profession(TMP scale)

1.	Doctors care their patients health more than or as similar to their parents
2.	Doctors care more about their convenience than their patients medical need
3.	Doctors are thorough and careful
4.	Completely trust Doctors about which medical treatments are best
5.	Doctors are honest in telling their patients about different treatment option available
6.	Doctors think about what is best for their patients
7.	Doctors do not pay full attention to what patient tells
8.	Doctors use their best skills and efforts
9.	You have no worries on putting your life in Doctors hand
10.	Doctors would never mislead you about anything
11.	You trust your doctor completely

Table-2: Factors associated with trust in medical profession

Effectiveness of Eccentric Exercises on Selfie Elbow

Tharani.G[1], Rajalaxmi.V[2], Yuvarani.G[1], Kamatchi.K[1], Lakshmiprabha.P[3]

[1]Assistant Professor, [2]Professor, [3]B.P.T Student, Faculty of Physiotherapy, Dr.M.G.R Educational and Research institute, Vellapanchavadi, Chennai, Tamilnadu, India

Abstract

Background: Selfitis is an genuine mental condition where people have an obsessive-compulsive desire to take photos of one self and post them on social media as a way to make up for the lack of self- esteem. While clicking a selfie, there is always a possibility that by incorrect stretching of the tendons, an injury can occur to joints like the elbow. Selfie elbow is more of an abnormal and repetitive loading of muscles around elbow, leading to micro ruptures, which cause inflammation and pain. Hence, this study intended to analyze the effects of eccentric exercises on selfie elbow.

Aim: To analyze the effectiveness of eccentric exercises on selfie elbow.

Method: This is an experimental study done in Faculty of physiotherapy, Dr.M.G.R Educational and Research Institute. After approval of the study by Institutional Review Board, both male and female with severe selfitis (using selfie behaviour questionnaire) between 18-21 years having pain on lateral epicondyle & lateral forearm with positive cozens were included in the study. The subjects with any musculoskeletal injuries, neurological disorders and having pain due to other reasons were excluded. Eccentric exercises protocol was given for four weeks along with patient education program. All the exercises was performed 5times/weeks, 3 sets, 1 set = 15 rep, 1 min rest between each Set

Results: A Positive Association was found between the selfie behaviour scale & oxford elbow pain questionnaire in subjects with selfitis and on comparing the oxford elbow pain questionnaire score significant improvement in the post test mean value was seen which suggest that eccentric exercise program is effective in selfie elbow.

Conclusion: The result of this study suggests that proper patient education and eccentric exercise program among selfie takers with sefie elbow will reduce the pain over the lateral epicondyle.

Keywords: *Selfie, Selfitis, elbow pain, Selfie elbow, Selfie behaviour questionnaire, Eccentric exercises, Oxford elbow pain question*

Introduction

Selfitis is an genuine mental condition where people have an obsessive-compulsive desire to take photos of one self and post them on social media as a way to make up for the lack of self-esteem.[1] Selfie takers trust that selfies could boost their self-confidence, the number of positive comments and likes in social media will increase self-confidence level. It may lead to orthopedics complications like carpal tunnel syndrome, tennis elbow, frozen shoulder etc.[2] Like tennis elbow or golfer's elbow, an addition to selfie-taking can cause a pain in the elbow due to primary pic- snapping[3]. The selfie statistics indicated that about half (47%) of adults were taking selfies about 40% of people between 18 and 34 years admitted of taking selfies at least once per week. At the same time, women are believed to take selfies 1.3 times more than men[4].

Taking selfies involves an unusual arm position with excessive forearm pronation and repeating the act eventually put strain over the elbow muscles and pressure on the bone, leading to inflammation and excruciating pain[5]. Due to this abnormal and repetitive loading of muscle there are micro ruptures around the elbow even by minimal stress[3]. The smart phone is not that heavy but during selfie the wrist is in awkward position that will lead to injury, so using selfie stick while taking selfie will reduce injury. The proper positioning of elbow and patient education can reduce the risk of selfie elbow. Clinical signs make diagnosis and symptoms that are discrete and characteristic with the elbow fully extended, the patient feels point of tenderness over the affected point on the elbow, which is the origin of the extensor carpi radialis brevis muscle in the lateral epicondyle. There is also pain with passive wrist flexion and resistive wrist extension.

Eccentric exercise can help to heal tendon injury including chronic tendinitis[6]. It effectively lengthens muscle tendon, increase tensile strength of the tendon, and reduce pain[7]. Eccentric exercises provide neuromuscular benefits through central adaptation of both agonist and antagonist muscles[8]. It also provides structural and functional benefits during tendinopathy rehabilitation[9]. It will increase the muscle strength[10].

Selfie behaviour scale appears to a reliable and valid instrument that was used in this study for assessing selfitis and categorizing the disorder of selfitis into borderline, acute and chronic selfitis. Pre and post selfie elbow pain was assessed using oxford elbow questionnaire. The Oxford elbow questionnaire comprises three unidimensional domains: elbow function, pain and social-psychological, with each domain comprising four items with good measurement properties. As there is dearth of research on selfie elbow, this study intended to find whether eccentric exercise is effective in reducing the symptoms of selfie elbow.

Methodology

This is an experimental study done in Faculty of physiotherapy, Dr.M.G.R Educational and Research Institute. After approval of the study by Institutional Review Board, both male and female with severe selfitis (using selfie behaviour questionnaire) between 18-21 years having pain on lateral epicondyle & lateral forearm with positive cozens were included in the study. After the initial assessment the pretest score of elbow pain questionnaire was taken for all the subjects. Then all the subjects underwent 4 weeks of eccentric exercise training program. All the exercises were performed 5 times a week, 3 sets with 1 min rest between each set (1set = 15 rep). The patient education program regarding proper positioning of mobile phone for taking selfie was given. At the end of 4 week, the posttest score of elbow pain questionnaire was taken.

Eccentric Exercises:

PHASE:1 With forearm supported on a table, the subjects were asked to lift the wrist up with the unaffected hand.	PHASE:2 The subjects were asked to take the unaffected hand away and slowly lower and repeat this process for each repetition.

Addition of Weights:

PHASE:1 The subjects were asked to keep the elbow at 90 degrees and locked in at the side and hold the weight with the forearm in a neutral position.(palm neither facing floor or ceiling and lift the wrist up and down.	PHASE:2 The subject were asked to turn the forearm so that your palm faces the ceiling. Return to the starting position. Repeat this process for every repetition.

Patient Education

Pre selfie stretches*:* Stretch wrist extensor and flexors muscles priors to clicking selfies.

Alternate the arms*:* Keep switching your arm to prevent over stress

Use bilateral arms*:* Prefer using both arms instead of over using dominant arm.

Selfie sticks: Prefer using selfie stick instead of extending your elbow.

Avoid prolonged posture maintenance*:* Keep changing your posture.

Data Analysis

The collected data were tabulated and analyzed using both descriptive and inferential statistics. All the parameters were assessed using statistical package for social science (SPSS) version 24. Paired t-test was adopted to find the statistical difference within the groups & Pearson Correlation of coefficient was adopted to find the Correlation between Selfie Behaviour Scale & Oxford Elbow Pain Questionnaire.

Table - 1: Pearson Correlation of Coefficient between Selfie Behaviour Scale & Oxford Elbow Pain Questionnaire in Subjects with Elbow Pain.

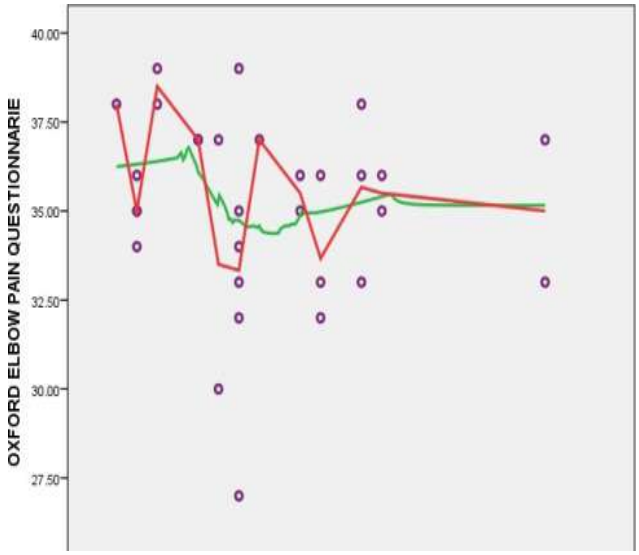
Parameters	Subjects	
	'r' value	P value
SBS	0.417	≤ 0.05
OEPQ	0.555	≤ 0.05

(#SBS - Selfie Behaviour Scale, OEPQ - Oxford Elbow Pain Questionnaire)

The above table reveals the Pearson Correlation of coefficient ' r ' value and p-value within subjects between Selfie Behaviour Scale & Oxford Elbow Pain Questionnaire**.**

There was a positive correlation between Selfie Behaviour Scale & Oxford Elbow Pain Questionnaire in subjects with selfitis. The Selfie Behaviour Scale had the strongest correlation with Oxford Elbow Pain Questionnaire within subjects. **(P ≤ 0.05)**

(Graph-II)



Graph - I: Pearson Correlation of Coefficient between Selfie Behaviour Scale & Oxford Elbow Pain Questionnaire in Subjects with selfitis.

Table - 2

#OEPQ	PRE TEST		POST TEST		t – TEST	SIGNIFICANCE
	MEAN	S.D	MEAN	S.D		
SUBJECTS	35.10	2.68	57.10	2.48	-35.83	.000***

OEPQ - OXFORD ELBOW PAIN QUESTIONNAIRE SCORE

(*- P ≤ 0.001)**

The above table reveals the Mean, Standard Deviation (S.D), t-value and p-value within subjects between pre-test and post-test values.

Oxford Elbow Pain Questionnaire Score shows that there is a statistically highly significant difference between the pretest and posttest values within subjects

(***- P ≤ 0.001).(Graph-I)

Results

A Positive Association was found between the Selfie Behaviour Scale & Oxford Elbow Pain Questionnaire in subjects with selfitis. The Selfie Behaviour Scale had the strongest correlation with Oxford Elbow Pain Questionnaire within subjects at **(P ≤ 0.05).**

On comparing the Oxford Elbow Pain Questionnaire Score within Subjects between Pre & Post Test Values, it shows significant improvement in the Post Test Mean values **(57.10)** when compared with pre test mean values **(35.10)** at **P ≤ 0.001.** Hence Null Hypothesis is rejected.

Discussion

While clicking a selfie, the awkward position of arm and repetitive loading of muscles around the elbow leads to micro ruptures, which cause pain and inflammation around the elbow. Hence, this study intended to analyze the effects of eccentric exercise on selfie elbow.

The common symptom reported by the subjects where pain and tenderness over the extensor origin. The reason behind this seems to be abnormal stretching of tendon and repeated high movements of force beyond the adaptive capacity of the tissue because progressive degeneration as previously stated by Lee DG[11]. In most of the subjects, tenderness was present over the lateral epicondyle. It is because the muscle undergoes micro rupture easily at its attachment to the bone rather than at muscle belly.

P.Malliaras et al in his study stated that eccentric exercises help to reduce and manage tenderness and pain by increasing the strength at the angle of contraction without producing any discomfort or worsening the inflammatory[12]. The findings of this study was similar to that showing reduction in intensity of pain after the eccentric exercise training. The loads of exercises were increased as the patient symptoms declined. Patients performed the exercise at low speed, because slow and static stretching enhances tissue healing and gives comfort to the patient.

In this study patient who followed the patient education after the eccentric exercise training reported less recurrence of pain. Charles kim suggested that the selfie takers, using a selfie stick can work like an arm extensor and take the pressure off the elbow and stretching the wrist extensor and flexors before taking selfie and alternating and using bilateral arms while taking selfie prevent over stress on elbow[13].

This study revealed that through proper patient education and eccentric exercise training the occurrence of selfie elbow can be reduced.

Conclusion

This study reveals that there is a strong correlation between selfitis and selfie elbow and proper positioning of the mobile phones during selfie taking and exercise training can prevent its occurrence.

Abstract

Aim: The aim of this study is to compare and evaluate the cyclic fatigue resistance of 3 different Nickel Titanium rotary file systems: Hyflex CM, Neoendo Flex files and ProTaper Gold by static method in three different curvatures, namely, 45º,60º and 90º.

Materials and Method: Thirty Hyflex CM (25/.06), Thirty Neoendo Flex (25/.06) and Thirty Protaper Gold (25/.08) instruments were included in this study. The static cyclic fatigue test was performed using a custom-made jig. The artificial canal is made of stainless steel jig with an inner diameter of 1.5mm, a 45^0, 60^0, 90^0 angles of curvature and radii of curvature of 5 mm. All the instruments were rotated according to manufacturer's recommendations until failure occurred. The time taken to failure was recorded in seconds for each group using a digital chronometer. The data were analyzed statistically using one way ANOVA, Post hoc test of Bonferroni was performed to identify pair-wise significance via SPSS 21.0 software (SPSS Inc, Chicago, IL). The statistical significance was set at 5%.

Result: In 45º and 60º Hyflex CM and Neoendo Flex are better than Pro Taper Gold. At 90º, Neoendo Flex is better than Hyflex CM ($P< .05$)

Conclusion: Within the limitation of this study, it can be concluded that, Neoendo Flex files exhibited highest cyclic fatigue resistance at 90º angle of curvature. In 45º and 60º angle of curvature Neoendo Flex files and Hyflex CM rotary instrument were more resistant to cyclic fatigue. Protaper Gold showed the least cyclic fatigue resistance than the other files tested.

Key Words: *Cyclic fatigue, Nickel Titanium alloy, Neoendo flex, Protaper Gold, Hyflex CM, Instrument design.*

Introduction

The introduction of nickel-titanium rotary (NTR) instruments have vastly influenced endodontic practice by the virtue of its speed, quality, accuracy, and reduction in risk during the vital phase of chemo mechanical root canal preparation.[1]

NiTi instruments are relatively superior to previously used manual stainless steel instruments and its use increases the success rate of root canal treatment compared to stainless steel hand instruments.[2]

In spite of their advantages, NTR instruments possess a high risk of fracture, especially in curved canals. Instrument fracture in clinical practice used multiple times has an incidence of 0.39% to 21% (Shen et al.2013) The problem is compounded by sudden, unexpected fracture without any previous permanent deformation or another visible warning signs. Radius and angle of curvature, instrument size and cross-sectional area, rotational speed, design, technique and operator experience, torque, metal surface treatments,

and metallurgical characterization of the NiTi alloys are the variables that contribute to file separation.[3]

Though both flexural fracture and torsional fracture occur simultaneously, studies have found cyclic fatigue to be the cardinal cause of file separation accounting for 50% - 90 % of mechanical failures.[4]

The cyclic fatigue resistance is improved by altering the metallurgy, design, kinematics of the files and heat treatment of file.[5]

Hyflex CM (Controlled Memory) NiTi files (Coltene / Whaldent, Switzerland) was introduced in 2010. This CM thermomechanical surface treatment makes the files extremely flexible without rebound providing superior canal tracking and more resistance to cyclic fatigue than non –CM NiTi files.[6]

Neoendo flex files(Orikam Healthcare India Private limited) are recently introduced files designed with a triangular cross section and a proprietary heat treatment rendering them highy flexible. The manufacturers also claim that the flutes do not open when the stress level is reached, which helps in increasing the cyclic fatigue resistance.

Protaper Gold (PTG, Dentsply Tulsa Dental Specialties) has a convex triangular cross-section and a variable progressive taper. PTG is manufactured by proprietary metallurgy that reportedly increases its flexibility and its resistance to cyclic fatigue.[7]

There are no studies in the literature that evaluates the cyclic fatigue resistance of these new rotary file systems. Hence, the aim of the present study is to compare the cyclic fatigue resistance of three different NiTi rotary file systems: Hyflex CM, Protaper Gold and Neoendo Flex files.

Materials and Method

A total of 90 NiTi instruments of 3 different rotary systems of length 21mm were included in the present study. Before testing, all files were autoclaved and examined using a stereomicroscope to detect any deformation. The files were divided into 3 experimental groups (n = 30) as follows: **Group A:** Hyflex CM instruments of size 25, 0.06 taper **Group B:** Neoendo Flex files instruments of size 25, 0.06 taper **Group C:** Protaper Gold instruments of size 25, 0.08 taper

Cyclic fatigue testing device:

The static cyclic fatigue test was performed using a custom-made jig fabricated for this study. The artificial canal was made of stainless steel, with an inner diameter of 1.5 mm, total length of 20 mm and an arc at the end with a curvature radius of 5 mm which simulates the instrument size and taper. This steel jig was constructed in order to retain the rotary instruments within the canal groove by means of a metal frame. It is enveloped by a glass fiber screwed on either side in order to prevent the instrument from distortion. The jig is constructed with 5mm radius of curvature and 45º, 60º and 90º angles of curvature to provide a suitable trajectory with curved segment of canal being 6mm in length (Figure 1).

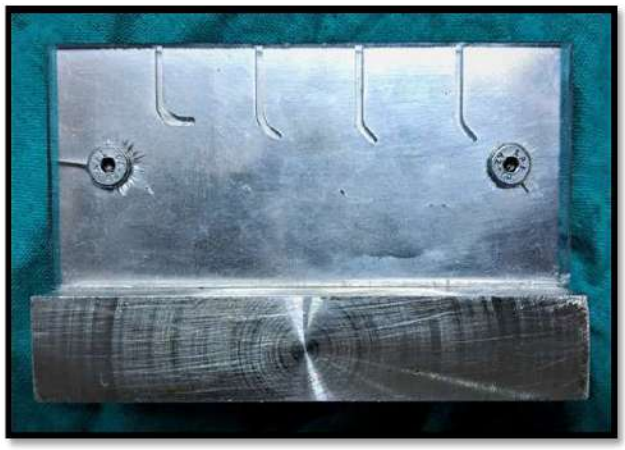

Figure-1: Customized Jig

The dental hand piece (16: 1 reduction hand piece) was attached to the descending cross head of the Instron(8874) testing machine (Boston, US) (Figure 2&3a).

Figure-2: INSTRON (8874) testing machine

Figure-3a: Before failure

Cyclic fatigue test

All the instruments groups (n=90) was tested according to manufacturer 's recommendations as follows: Hyflex CM at 500rpm/2.5Ncm; Neoendo Flex at 350rpm/1.5Ncm; Protaper Gold at 300rpm/1.5Ncm until failure occurred(figure-3b). The time taken to failure was recorded and stopped as soon as the failure was detected visually and/or audibly with the help of computer aided software (figure-3c). The failure was easily detectable because the tip of the instrument was visible at the end of the curve (Figure 4a, 4b, 4c).Mean values were then calculated. The formula to calculate number of cycles to failure (NCF) is **NCF = revolutions per minute × time to failure (seconds)/60**

Figure-3b During procedure **Figure-3c: After failure**

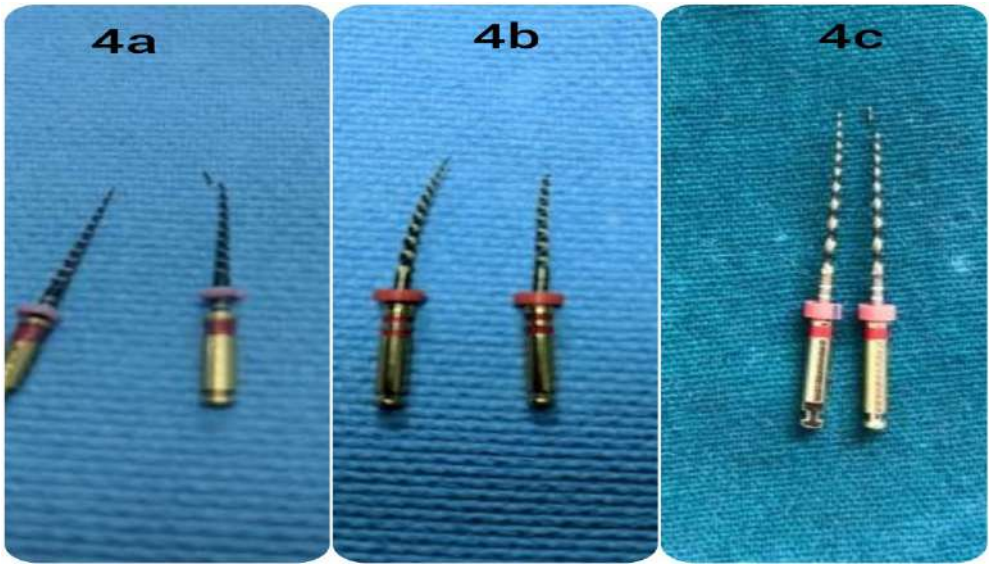

Figure-4 Instruments before and after testing
4a-HyflexCM;4b-Neoendoflex;4c-Protaper Gold

Statistical Analyses

The mean, standard deviation and standard error of the three groups were calculated. The mean time taken to failure (seconds) and the number of cycles to failure were statistically analyzed using SPSS software 21.0 version (SPSS Inc., Chicago, IL). One - way ANOVA was done to determine significant differences among the systems, between groups and within groups. When the overall *F* test indicated significant difference, Post Hoc test of Bonferroni was performed to identify pair wise significance. The criteria for statistical significance *P* value < 0.05.

Result

A statistically significant difference was observed in the mean number of cycles to failure (NCF) between the three groups tested (P< 0.05). The result showed Hyflex CM and Neoendo Flex to be better than Pro Taper Gold at 45º and 60º, (Table-1&2) whereas at 90º Neoendo Flex performed better than Hyflex CM (Table-3).

Discussion

The clinical performance of endodontic files and their resistance to fracture by torsion and/or cyclic fatigue are mainly affected by variables, such as instrument size, taper, cross-sectional design, and manufacturing techniques.[8] for this reason, many studies are performed on the cyclic fatigue resistance of NiTi rotary files. Manufactures aim to improve the cyclic fatigue resistance of NiTi rotary files by altering the design, metallurgy and kinematic of the files and through the various thermal and surface treatments applied to the files. This study is the first to compare cyclic fatigue resistance of Neoendo flex, Protaper Gold, Hyflex CM using a well-established cyclic fatigue model

Several non-tooth devices were used to investigate the *in-vitro* cyclic fatigue resistance in both static and dynamic models. In a static model, the instrument does not move axially. Therefore, this creates alternate compressive and tensile stresses in a particular area of the instrument leading to premature failure.[9] Thus in this study, a static model was preferred because the instruments being tested could be constrained in a precise trajectory and to rule out the confounding factors caused by other mechanisms of instrument separation apart from cyclic fatigue.

Cyclic fatigue resistance refers to the number of cycles to failure that an instrument is able to resist under a specific loading condition. In this study, the fatigue life of the instruments was evaluated by multiplying the rotational speed by the time elapsed until failure.[10]

The rotational speed at which NiTi rotary instruments should be driven is a variable that remains to be clarified. Ideally, rotary instruments should be used at a rate that minimizes the incidence of fracture while maintaining efficiency. De -Deus et al., (2010) stated that higher rotational speeds are more susceptible to fracture than

lower rotational speeds. Hence in this study, continuous rotations according to manufacturer 's recommendations was delivered using endodontic motor (X - Smart™ Endomotor with 16:1 reduction handpiece, Dentsply, UK). Synthetic oil was applied as recommended by Grande et al., (2006) to reduce the friction of the file.

The result of this study showed that Neoendo Flex (#21.06) had higher cyclic fatigue resistance values than the other groups. Thus, the null hypothesis was rejected. The Hyflex CM, Neoendo Flex, and Protaper Gold instruments have the same tip sizes (#25). However, the tapers differ among them; Hyflex CM and Neoendo Flex have a taper of 0.06 mm/mm, and ProtaperGold has a taper of 0.08 mm/ mm. The lower taper value of Hyflex CM and Neoendo Flex when compared with Protaper Gold should ensure a higher cyclic fatigue time; nevertheless, our results showed that only Neoendo Flex presented better results than Hyflex CM and Protaper Gold in 90º angle of curvature. In addition, the Hyflex CM group showed a significantly higher cyclic fatigue resistance value than the Protaper Gold group ($P < .05$) in all three subgroups. Other variables, such as cross -sectional design, and manufacturing process should also be taken into account. The results of this study were probably caused by the different cross –sectional designs and types of NiTi alloy of the instruments, which affect the mechanical properties of NiTi instruments.[11]

A study using a finite elemental analysis demonstrated that a triangular cross-sectional design possessed a higher cyclic fatigue resistance than a square and rectangular cross-sectional design.[12] This difference is related to the reduced metal mass of the instruments with a triangular cross-section compared with that of instruments with other cross-section design. Hence, we have chosen files Hyflex CM and Neoendo Flex files with triangular cross sections and Protaper Gold with convex triangular cross section.

This study showed that its results are in accordance with the study done by Kim et al., (2008) in which they have shown that the Convex Triangular design at the tip of the file showed significantly higher von Mises stress values when compared with the Triangular group and they stated that the outcome of the study may be due to the presence of internal residual stresses indicating that the file has undergone cold work during loading, which eventually led to reduced flexibility at the cutting edge.

Hyflex CM and neoendo Flex files with triangular cross section had higher fatigue resistance than Protaper Gold which has convex triangular cross section. NiTi instruments with larger cross-sectional areas present lower cyclic fatigue resistance.[13] Therefore, this could contribute to the difference in cyclic fatigue resistance of these instruments.

The mechanical properties of NiTi instruments are affected by the type of alloy used in the manufacturing process (Zhou H., Shen Y., 2012) and also proprietary surface treatments. Hyflex CM was manufactured by controlled memory wire technique, whereas Neoendo and Protaper Gold are subjected to gold surface treatment. Since the manufacturers do not reveal the manufacturing process of newer rotary files systems, we could not relate the effect of these manufacturing processes in improving the cyclic fatigue resistance.

The clinical implication of this study is that Neoendo files can be preferred in all types of canal curvatures including severely curved canal as it had the highest cyclic fatigueresistance in all angles of curvature such as 45º, 60º, and 90º. Another advantage of Neoendo Flex files are that they are cost effective and hence can be preferred in all clinical situations. In this study, Hyflex CM is found to have good cyclic fatigue resistance in curved canals in accordance with the previous studies. Though Hyflex CM can be used in mild to moderately curved canals, it should be used with causation in severe acute curvature as the cyclic fatigue resistance of Hyflex CM is less compared to Neoendo flex files in 90º curvature. In this study, Protaper Gold had least resistance when compared to Hyflex CM and Neoendo Flex in all types of canal curvatures. So Protaper Gold has limited use in curved canals.

Conclusion

Within the limitations of this study, it can be concluded that, Neoendo Flex files exhibited highest cyclic fatigue resistance than the Hyflex CM and Protaper Gold file systems at 90º angle of curvature. In 45º and 60º angle of curvature Neoendo Flex files and Hyflex CM rotary instrument were more resistant to cyclic fatigue followed by Protaper Gold file systems . Protaper Gold showed the least cyclic fatigue resistance than the other files tested.

Prediction of Normal & Grades of Cancer on Colon Biopsy Images at Different Magnifications Using Minimal Robust Texture & Morphological Features

Tina Babu[1], Deepa Gupta[2], Tripty Singh[3], Shahin Hameed[4]

[1]Research Scholar, [2]Associate Professor, [3]Assistant Professor, Department of Computer Science and Engineering, Amrita School of Engineering, Bengaluru, Amrita Vishwa Vidyapeetham, India, [4]Specialist, Department of Pathology, Aster Medcity, Kochi, India

Abstract

Classification of colon biopsy images to normal and various cancer grades is a pivotal task for histopathologists as it involves visual analysis under the microscope at different magnifications and hence may give rise to observational inconsistency. This paper emphasis on categorization of colon biopsy images into normal, well, moderate and poor classes thereby analyzing the best magnification and classifier suited for classification. A hybrid feature set consisting of morphological and texture features are obtained from images followed by class balancing to overcome imbalancing problem and then optimized feature selection. Classifiers such as SVM, Random Forest, Multilayer Perceptron and Naive Bayes are experimented for classification. The proposed model is evaluated with colon biopsy images acquired from Aster Medcity, Kochi, India at different magnifications 10X, 20X and 40X where all the magnifications performed well, but 20X gave an improved accuracy of 94.27% with the Random Forest classifier. Advance measures based on entropy triangle are used to rank classifiers apart from the standard performance measures, where Random Forest classifier is best for the proposed model for all magnifications.

Keywords: *Colon biopsy image, cancer, Texture, Morphology, Features, Classification, Normal, Malignant, Magnification*

Introduction

One of the leading cancers that occur today is colon cancer and its second cause for death and third incident cancer worldwide[1]. Identification of colon cancer is performed by microscopic study of biopsies of colon which are obtained either through surgery or colonoscopy. Further pathologist manually examines the structure of colon tissues through microscope and then detects the presence of cancer by analyzing the shape of tissue and degree of distortion to assign different grades to the cancerous ones. This analysis is subjective as pathologist observes the morphology of tissues and grades them accordingly and also lead to inter and intra observer variability[2,3]. Thus an automated diagnostic support system is needed to detect and grade colon cancer, thus overcoming the limitations of manual process and hence assist pathologist[4].

Existing Method

In colon cancer identification techniques, various investigations are done and detailed survey of them are summarized in [5] where simple texture and object-oriented texture-based techniques performed well. Colon Cancer detection techniques[6, 7], based on texture, morphological, geometric features are extracted on single magnified images. However, in [8], different magnified images were used for segmentation and classification. In the initial experiments of[9, 10] combined texture and morphological feature set gave better classification of 91.3\% with Multilayer Perceptron classifier for 10X magnification.

Apart from colon cancer detection techniques, some grading techniques of the malignant colon images are proposed. In [11,12] grading was done with single magnified images based on Haralick, statistical moments of intensity, morphological and topological features. Later classification and grading of colon

images were done with single magnification[13] where 95.4% of detection and 93.47% of grading efficiency was obtained. Multiclass classification based on texture analysis was done[14] where 87.4% was obtained.

In this paper, multiclass classification of colon images into normal and different grades is proposed depending on the texture and morphological features. Class balancing of the image dataset is addressed to avoid imbalance data problem where results are skewed towards majority class. With attribute selection, only the contributing features are considered for classification from rich hybrid feature set of texture and morphological features. Different classifiers are analyzed to know their performance. The work will be evaluated on colon images taken at different magnifications from Aster Medcity, Kochi, India to analyze the best magnification for the proposed model. Apart from standard performance evaluation measures, information theoretic measures will be experimented for the multiclass classification. The results indicate the proposed model performs more accurate where the best magnification of images and classifier are identified.

Proposed Method

The framework of the proposed system consists of four stages namely (1) Pre-processing (2) Feature Extraction (3) Class Balancing and Feature Selection (4). The pre-processing module consists of two phases. In the first phase of preprocessing, color normalization and contrast enhancement are done on the images so as to increase the quality of images. Later, in the second phase of preprocessing, for the extraction of texture features, gray scale conversion is performed whereas for the extraction of morphological features, K-Means clustering with K=3 is done where three clusters pink, purple and white are obtained.

In the next phase, features are extracted and combined to form a feature set. Two major features extracted are the texture and morphological features. Texture features such as Histogram, LBP, GLCM, Gabor, GLRLM, HOG is obtained from the colon images after the gray scale conversion after which they are unified to form a texture feature set. Three clusters obtained from the K-Means clustering are converted to its binary for extraction of Morphological. From each of the clusters, the connected components are chosen where each of the connected components has a minimum area T. The number of connected components in each of the clusters White, Pink and Purple are given C_w, C_p and C_r respectively. In each cluster nine morphological features such as area, perimeter, euler number, extent, orientation, eccentricity, convex area, major and minor axis length are found and their average is taken as the feature vector.

where u_i is the morphological features. The final morphological feature vector m is of length 27 containing feature extracted from white, pink and purple clusters.

Class imbalance is a predominant problem as there is a difference in the number of images in each class and affects the classification ability of the model. Synthetic Minority Over-sampling Technique (SMOTE)[15] is adopted so that the minority class samples are over-sampled to the sample numbers in the majority class leading to same number of images in each of the class. Once the class balancing is done, Attribute Selection is done as feature selection so as to select the most relevant features for the classification.

The combined feature vector after the class balancing and attribute selection, is taken for classification where it's classified into four classes namely normal, well, moderate and poor using 5 popular standard classifiers are used such as Naive Bayes, Random Forest, Support Vector Machine (SVM) with poly kernel and Multilayer Perceptron.

Data Statistics, Performance Evaluation Measures & Experimental Set up

The dataset consists of images at different magnifications 10X, 20X and 40X taken from 5-6μm thick tissue section colon biopsy samples which are stained with H&E taken from Aster Medcity, Kochi, India. For each of the magnifications, 70 Normal, 25 Well, 30 Moderate and 20 Poor images are available. Dr. Sarah Kuruvila and Dr. Shahin Hameed, the respective Senior consultant and Specialist, Department of Pathology, Aster Medcity, Kochi, India analyzed the H&E slides of colon biopsy and the dataset were prepared and ground truth label were given by them.

The classification capability of the proposed work is evaluated using the performance measures such as Accuracy, F-Score, Area under Curve (AUC) and Entropy Triangle. To evaluate the multi-class problems apart from the standard performance measures, Entropy triangle[16,17] is plotted. The classifier at the apex of the entropy triangle indicates good ones.

Results and Discussion

Proposed model was evaluated on Aster Medcity images of different magnifications with various classifiers in terms of the standard performance measures and thus contributing features are analyzed for each magnification. Further, the proposed system is compared with the existing models and other standard colon image datasets available.

Performance Measure Evaluation & Reduced Feature Space Analysis

When analyzing accuracy of the proposed model, Fig.2.1 (a) shows that Random Forest classifier performs well all magnifications with 84.84%, 94.27% and 86.19% respectively for 10X, 20X and 40X magnification respectively. However 20X gives highest accuracy for all the classifiers as 94.27% with Random Forest classifier followed by Perceptron and SVM classifier with 93.22% and finally Naive Bayes classifier with 83.85%. 40X magnification gives next highest accuracy followed by 10X for the Random Forest classifier. Fig.2.1 (b) gives the F-Score for different classifiers for the proposed model, where it's almost same as accuracy for all classifiers. Fig.2.1 (c) shows the AUC, where Random Forest classifier gives better result across all magnifications with 0.968, 0.99, 0.975 for 10X, 20X and 40X respectively. AUC also, 20X gave better result for all the classifiers in order of Random Forest, Perceptron, Naive and SVM. Then comes 40X and 10X magnifications for values of AUC. Thus, for the proposed model, 20X magnification is best suited with the Random Forest classifier.

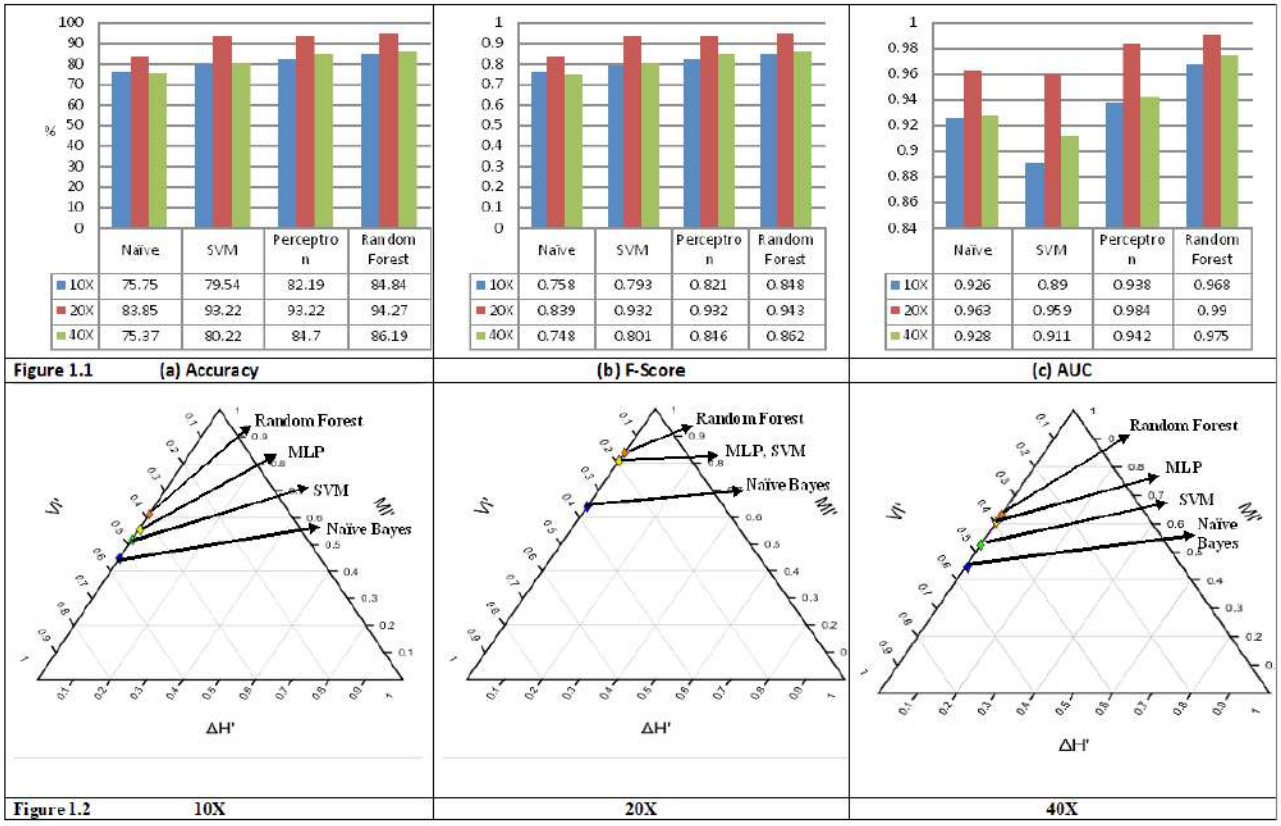

Figure 1.1: Performance Evaluation Measures on Proposed System with Magnifications (a) Accuracy (b) F-Score and (c) AUC. Figure1.2: Entropy Triangle for three magnifications

When analyzing the entropy triangle and the information theoretic measures, Random Forest is the best classifier across all magnifications. Multilayer Perceptron is second best for 10X and 40X as shown in Fig.2.2. Thus considering all evaluation measures, Random Forest is the best classifier for the proposed system followed by Multilayer Perceptron, SVM and Naive Bayes.

For each magnification, the relevant features selected for the classification after the Feature Selection may be different. The features selected from the Texture

and morphological features are given in Table.1. Out of 184 features from 20X magnification 42 is selected, whereas from 10X and 40X, 41 is selected. 37 features are selected out of 157 features for classification with 20X magnification, in which HOG, Histogram, GLRLM and LBP features contribute the more in the order as shown in Table.2. In all the three magnifications, after the attribute selection, Histogram, GLRLM and HOG texture features are more relevant for classification followed by LBP, Gabor and GLCM. Only for 20X magnification, GLCM feature is taken.

Table.3 shows the morphological features selected after attribute selection from each cluster, purple, pink and white. It's observed that most features in all magnifications are selected from the white cluster followed by pink and purple cluster. Out of the morphological features extracted eccentricity, extent, major axis length and minor axis length contribute more for classification.

The variation in the number of features selected for different magnifications may be due to image acquisition illumination condition as well as the staining difference. However white cluster contribute more for the morphological feature.

Table 1: Total Number of Features Selected After Attribute Selection

Magnification	Texture Feature	Morphological Feature	Total No. of Features Selected
10X	34	7	41
20X	37	5	42
40X	33	8	41

Proposed Model Comparison with Existing models & Evaluation with other colon datasets

Multiclass categorization of colon images into four classes on different magnifications has not been experimented and hence comparison to direct similar work is not possible. However, the proposed system could be compared to almost similar works such as Stoean et. al[12], Rathore et. al[11] and Kather et. al[14] as shown in Table.4. These techniques are implemented in Matlab 2017b and performance measures are evaluated with Aster Medcity images of 10X magnification as these works were evaluated with this magnification. The proposed model is evaluated with Random Forest classifier. While comparing, the proposed system shows significant results when comparing all the measures such as accuracy, F-Score and AUC.

Table 4: Comparison of proposed method with existing models on 10X magnification

Technique	**Accuracy**	**F-Score**	**AUC**
Stoean et. al12	65.13	0.645	0.752
Rathore et. al11	51.74	0.498	0.722
Kather et. al14	75.64	0.744	0.850
Proposed Method	84.84	0.848	0.968

Table 5: Comparison of proposed method with other Colon Image Datasets

Dataset	**Magnification**	**Accuracy**	**F-Score**	**AUC**
Warwick QU 18	20X	87.71	0.871	0.974
Stoean et. al12	10X	98.00	0.98	0.999

The proposed model with the Random Forest is evaluated with other colon image datasets which are available in public such as Warwick QU dataset[18] and Stoean et. al.[12]. Table.5 shows the analysis of the proposed model with Random Forest classifier with other colon image datasets. For both datasets, the proposed model performed well in both magnifications. Thus, when analyzing the performance measures of proposed model with both datasets, the proposed model gives promising results for the multiclass classification.

Conclusions

In this work, classification of colon images into four classes such as normal, well, moderate and poor is done based on the minimal features comprising of texture and shape features. In order to address class balancing problem and feature reduction, SMOTE and Attribute Selection were applied respectively before classification. The model is evaluated on the Indian scenario colon images, acquired from Aster Medcity, Kochi, India at various magnifications. The proposed model performed

well for all magnifications of Aster data, however 20X is found to be better across others were an accuracy of 94.27% with the Random Forest classifier. Entropy triangle performance measure is used to address the multiclass classification problem apart from accuracy, F-Score, AUC in order to rank the classifier where Random Forest was best for the model. There are several possible future enhancements for the system. First, the model could be tested on large set of images. Second, some other structural features could be extracted from the region of interest and classified. Color features could also be extracted and tested on the system.

Effect of Scapular Position- Motion Maintenance Exercise Programme During Post Traumatic Shoulder Immobilization

Trusha Shambhubhai Goti[1], Sandeep Babasaheb Shinde[2]

[1]Intern, BPTh. Faculty of Physiotherapy, Krishna Institute Of Medical Sciences Deemed To Be University, Karad, Maharashtra, India, [2]MPTh, Department of Musculoskeletal Sciences. Karad, Maharashtra, India

Abstract

Background: The scapula plays a key role in nearly every aspect of normal shoulder function. Alteration in scapular position and motion is found in association with most shoulder injuries. This alteration is term as scapular dyskinesis. Prevalence of scapular dyskinesis is about 67 to 100 %. But many literature focus on treatment after occurrence but very few aim at prevention during immobilization phase.This made indeed to study the effect of scapular position – motion maintenance programme during shoulder immobilization phase.

Objectives: To determine the effect of scapular position -motion maintenance exercise programme during post traumatic shoulder immobilization phase, To compare the effect of scapular position -motion maintenance exercise programme and conventional physiotherapy during post traumatic shoulder immobilization phase.

Method: A Total of 40 subjects were selected aged between 20 to 50 years. They were divided into two groups. Group A (experimental) and group B (conventional). Both groups received treatment for 6 weeks for a duration of 30 minutes. The outcome measure used wereVAS, Posture assessment, pectoralis minor muscle length ,Linnies test and scapular assistance test.

Result: The study concludes that experimental group (scapular position- motion programme)proved more efficacious in reducing risk of scapular dyskinesisin patients with humerus fracture during immobilization phase as compared with conventional treatment.

Keyword: *scapular dyskinesis, Immobilization phase, proximal humerus fracture, exercise therapy*

Introduction

Effective shoulder position, motion, stability, muscle performance and motor control are largely dependent on the scapular performance. Mechanically, the coordinated coupled motions between the scapula and humerus, is called scapula humeral rhythm.[1] Scapular Dyskinesis is found in association with various shoulder pathologies , although exact relationship between dyskinesis and clinical pathology is doubted.In case of nerve injury , fracture , Ac separation , muscle detachment , the injury results in dyskinesis, affecting shoulder function. In some cases like labral tear, rotator cuff disease , dyskinesis may be causative ,creating pathomechanics that predispose the arm to such injuries.[2]Humeral fractures accounts for approximately 7 to 8% of all adult fractures, further incidence has been reported to increase with age. Proximal humerus fractures being most common(50%) of all humerus fractures.[3]According to a study "Prevalance of scapular dyskinesis in patients with Distal radius fracture with or without shoulder pain" by Hector it was found that almost 80% of all patients with distal radius fracture showed scapular dyskinesis, with an increase in value 90.9% in group of patients with shoulder pain.[4] Scapular Motionsprovide optimal muscle length – tension ratios for accurate movement pattern, and promotes muscular energy conservation during arm motion. The most common causative mechanisms of scapular dyskinesis

Correspondence Author:
Dr. Sandeep Shinde,
MPTh, Department of Musculoskeletal Sciences.
Karad, Maharashtra, India

is soft tissue alterations i.e inflexibility or tightness of pectoarlis minor creating anterior tilt and protraction, glenohumeral internal rotational deficits, which creates a wind up of scapula on thorax leading to horizontal abduction.[5]

One of the most important abnormalities in abnormal scapular biomechanics is the loss of linking function in kinetic chain.[6] The scapula and shoulder are dependent links in kinetic chain. It helps transferring the forces from the large segments, the legs and trunk, to the smaller, rapidly moving small segments of the arm. If scapula becomes deficient in motion or position, transmission of the large generated forces from the lower extremity to upper extremity is impaired. This creates a situation of catch up in which more distal segments work at a higher level of activity for compensation of the loss of proximally generated forces. Calculations depicts that 20% decrease in kinetic energy delivered from hip and trunk to the arm necessitates an 80% increase in mass and 34% increase in rotational velocity at shoulder to deliver the same amount of resultant forces to hand .The kinetic chain is the most efficient system for developing energy and force.[7-8]

Scapular diskinesis causes weakness, tightness and muscle imbalance. most of the scapular motion and position can be treated by means of physical therapy relieving the symptom associated with in flexibility or trigger points, re-establishing muscle strength and activation patterns.[9] But many literature focus on treatment after occurrence but very few aim at prevention during immobilization phase. This made indeed to study the effect of scapular position – motion maintenance programme during shoulder immobilization phase which primarily focuses on linking function of kinetic chain.

Materials and Methodology

This experimental study was carried out with 40 subjects in Krishna Hospital Karad. A total of 40 subjects was divided equally into two groups by Simple random Sampling (Group A and Group B). Subjects were in immobilization phase with proximal humerus fracture. Both males and females between the age group of 20-50 years were included.

The Inclusion criteria in this study was Age group of 20 – 50 age,Both the genders and Patients with Proximal Humerus post reduction or post operative immobilization phase andExclusion criteriawas Neurological condition, Non cooperative patients, Patients with Fracture of scapula, Patients with External fixators, Patients with distal neurovascular deficit and Patients with rib and spinal fractures.

The Outcome measures was Pain assessment – VAS scale,Posture assessment, pectoralis minor muscle length and special test for Linnies test and scapular assistance test.

The materials used in the study was Plinth, Towel, Inch-tape, Swiss ball, Pressure biofeedback, Data collection sheet, Consent form.

Procedure

An approval for the Study was obtained from the Protocol committee and institutional Ethical committee of KIMSDU scapular dyskinesis.Subjects who fulfilled the inclusion and Exclusion Criteria was divided into two groups. Informed consent was taken from each of the subject prior to Participation. Instructions weregiven to the subjects about techniques performed. A total of 40 subjects were divided equally into two groups by Simple random Sampling (Group A and Group B). The subjects were divided into two groups according random allocation.

Pre-test:

Visual Analogue Scale (VAS) and Posture assessment, pectoralis minor muscle length and special test for Linnies test and scapular assistance test was used to assess the Subjects.

Group A

The treatment program was include:

First 3 week scapular stabilization exercise and next 3 week spinal stabilization exercise will be added with scapular stabilization exercise.

Group A(Experimental)[10-12]

Week 1

1. Posture training
- Scapular retraction exercise

2. Isometric exercise for scapular muscle
- .Shoulder Depression
- Shoulder Protraction
- Shoulder retraction

Week 2

Scapular stabilization exercise

1. Scapular clock exercise on a wall
2. T to Y to W exercise on swiss ball

Week 3

Scapular motion exercise (closed chain stabilization)

- Static close chain exercise (weight bearing)

Week 4

Spinal stabilization exercise was added with scapular stabilization

- **Pressure biofeedback in supine**
  - Lumbar flexion
  1. Multifidus facilitation
  2. Alternate single leg heel touch
  - Lumbar extension
  1. Oblique abdominal facilitation
  2. Alternate single leg heel touch
- **Lumbarmultifidus activation**
- **Transv. erseabdominis activation**
  - Abdominal hollowing: activation of transverses abdominis in crook-lying position.
  - Abdominal hollowing: activation of transverses abdominis in sitting.
  - Abdominal hollowing: activation of transverses abdominis in four point kneeling.
  - Activation of multifidus from sitting to lumbar neutral position

Week 5

Swiss ball exercise

- Sitting knee raise on swissball
- Abdominal slide
- Lying trunk curl with leg lift
- Wall slides

Week 6

1. pelvic floor exercise
- Pelvic bridging

2. diaphragmatic strengthening exercise
3. single leg standing on foam

Group B(control group)

- Rest
- Isometric exercise for scapular muscle(Shoulder Depression ,Shoulder Protraction ,Shoulder retraction), active exercise (daily for 6 weeks)

Post-test:

Visual Analogue Scale (VAS) and Posture assessment, pectoralis minor muscle length and special test for Linnies test and scapular assistance test was used to assess the Subjects.

Discussion

The present study "Effect of scapular position - motion maintenance exercise programme during post traumatic shoulder immobilization phase" was conducted to see the effect of scapular stabilization and spinal stabilization exercise during immobilization phase in post traumatic shoulder. The scapula is anatomically and mechanically linked with shoulder function. Alteration in scapular position and motion is found in association with most shoulder injuries, termed as scapular dyskinesis. In a previous study "Prevalence of Scapular dyskinesis in patients withdistal radius fractures with or without shoulder pain" by Hector states that prevalence of Scapular Dyskinesis is shown in 80% of all patients with Distal Radius Fracture , with an increasing value of 90.9 % in patients with shoulder pain.The ratio was found to be 10 times greater in patients with Distal Radius Fracture accompanying with shoulder pain.[13]

A group of adult population with proximal humerus fracture treated conservatively with plaster cast or closed reduction were evaluated.In a similar study by AyhanEt. Al .stated following findings: Distal Radius Fracture had influence on scapular motion, exhibit altered scapular kinematics, increased posterior tilt , internal and upward rotation.[14-16]Further the study added to find the quality of motions at scapula if more proximal structures were affected. Another study by Edward Sheilds, "Scapular dyskinesis following displaced fractures of the middle clavicle"similar results were noted ,Scapular Dyskinesis is common after displaced middle third clavicle fractures.[17] In the present study we found a significant relation of scapular dyskinesis with proximal humerus fracture .Though there is no enough literature to support this evidence, but may studies approve findings of Scapular Dyskinesis occurrence after or with shoulder injuries. In a previous study by Mathew B."Prevalence of scapular dyskinesis in overhead and non overhead athletes" reported that Scapular Dyskinesisin overhead athletes (61%) was more compared to those with non overhead athletes(33%).[6]In a previous study by Poonam SS, "effect of desensitization methods during the early mobilization phase in post fracture conditions of upper extremity" reported that combination of desensitization along with the conventional physiotherapy was effective in decreasing pain, improving ROM and muscle strength than the conventional therapy alone.[18]Another study by Diksha U, "Effect of movement with mobilization in supraspinatus tendinitis" had noted that movement with mobilization, ultrasound, TENS and exercises are effective in management of supraspinatus tendinitis.[19]

The majority of studies included utilized visual observation of abnormal scapular rhythm to identify scapular dyskinesis. Two major abnormalities noted were scapular winging and scapular tilting. Scapular tilting was found in almost all subjects in Group A and Group B.Scapular winging was present in 8 subjects in Group A and 6 subjects in Group B.This interprets the fact not all patient with scapular tilting present with scapular winging. The mean pain values recorded using VAS showed a significant level of pain in both groups with pre values of 7 in Group A and 6.65 in Group B. There was a significant reduction in pain levels post treatment with 4.8 and 3.9 mean values respectively. The two main components scapular motion and scapular position were assessed using Kiblers classification and Linnes test respectively. According to Kiblersclassification it was found that majority of subjects belonged to Type I dyskinesis with 12 subjects(60%) in group A and 14 subjects(70%) in group B. This interprets that inferior angle positioning was severely affected .Group A was found to be more effective in correction of this fault by reduction of number from 12(60%) to 4(20%) as compared to Group B in which only 7 subjects(35%) showed corrections. Also subtype 3 and 4 that is medial border prominence and excessive superior border elevation was found to be noted though there rates were relatively less as compared to Type 1. Post treatment it was found that Group A had 14 Subjects (70%) showing T4 subtype that is symmetric and normal scapulae and group B had 7 subjects(35%) which showed thatcorrection of scapular motion rate was almost double in Group A proving efficacy of scapular positioning program.The second component that is linnies test added to the results of Kiblers classification by providing objective findings. The results of Linnies test showed significant results in group A. However group B showed not significant results. This measure although a subjective approach doesn't much count on the therapist findings rather the results are patient based .From the above gained results we can state that scapular position and motion programme is more effective in prevention of scapular dyskinesis.

Dyskinesis may be caused by multi factors such as bony causes, joint causes, neurological causes and soft tissues causes of alteration. Bony causes include thoracic kyphosis or clavicle fracture non-union or shortened mal-union. Joint causes include high grade acromioclavicularinstability, glenohumeral joint internal

derangement. Neurological causes include cervical radiculopathy, long thoracic or spinal accessory nerve palsy. Soft tissue mechanisms for scapular dyskinesis involve inflexibility or intrinsic muscle problems. The upper and lower trapezius force couple may be altered, with delayed onset of activation in the lower trapezius, which alters scapular upward rotation and posterior tilt. Altered scapular motion or position both decrease linear measures of the subacromial space, increase impingement symptoms, decrease rotator cuff strength, increase strain on the anterior glenohumeral ligaments and increase the risk of internal impingement. [1] The Mechanism contributing to scapular dyskinesis primarily include the following factors like Inadequate serratus anterior activation, excess upper trapezius activation, pectoralis minor tightness, posterior glenohumeral joint soft tissue tightness, thoracic kyphosis or flexed posture. This associated effects leads to lesser scapular upward rotation and posterior tilt, greater clavicular elevation, greater scapular medial rotation and anterior tlit, greater scapular anterior tilt, greater scapular medial rotation and anterior tilt, lesser scapular upward rotation.[13]

This study had some limitations but were majorly due to the small sample size. Further studies can be done on a larger sample size including more age groups. Also similar studies can be done taking into account some other fractures like distal humerus fractures, radius fractures, wrist fractures, elbow dislocation.

Conclusion

The study concludes that experimental group (scapular position- motion programme) proved more Efficacious in reducing risk of scapular dyskinesis patients with humerus fracture during immobilization phase as compared with conventional treatment.

Abstract

Background: Non-adherence to hand hygiene practices is a well-known factor contributing to healthcare-associated infections in any healthcare setting. Mere knowledge of such practices doesn't guaran tee the compliance to the practices by healthcare personnel. In this study we explored the quantum of adherence to hand hygiene practices, the opportunity missed, the steps and the duration to be followed for hand hygiene practices and the training gap among the healthcare providers.

Methodology: A six-month cross-sectional study using a mixed-method approach of observations, interview and feedback mechanism is used to find the effectiveness of hand hygiene practices and any training gap to prevent healthcare-associated infections. Observations for two thousand opportunities for hand washing and written interview of 40 healthcare workers is carried out on hand hygiene practices at a neonatal intensive care unit of coastal Karnataka, India.

Results: The hand hygiene practices are as low as with nearly zero percent observed while with performing non-invasive activity like clearing an alarm at the bedside. There is a gap found in the duration of hand-washing practices, hand hygiene before and after any care activity is performed on the neonate. This gap resulted in the spread of healthcare-associated infections.

Conclusion: During the infections control training emphasis should also be given on the opportunities and hands on practices of hand hygiene.

Introduction

Handwashing is the foundation for infection control practices[1]. Healthcare providers are trained and empowered to practice hand hygiene during their formal training. There can be a high rate of healthcare-associated infections if the perception and practice of hand hygiene are mismatched[2]. Performing hand hygiene

and compliant to complete hand hygiene practices are two different avenues. When all the five steps of hand hygiene are not performed in timely manner is considered ineffective and when all steps are completed with appropriate time duration hand hygiene is considered to be effective[1]. There can be instances when one may presumes completing optimum hand hygiene but it is not. We are exploring the gaps in training adherence to the steps needed to be followed, the opportunity missed for hand hygiene practice and maintaining stipulated time for each step by healthcare provider.

Materials & Method

In a neonatal intensive care unit (NICU) of a tertiary care teaching hospital situated at coastal Karnataka, India, a cross-sectional study was carried out for six months duration July 2017-Jan 2018. Hand washing and hand hygiene practices of all the healthcare workers were recorded for all the five moments and steps of handwashing as suggested by the world health organization. The questionnaire on five moments of hand hygiene was prepared; content and face validation were done. A sample size of 40 healthcare workers considering a 95% confidence level for a definite population N=44 with 5% confidence limit were selected for written interview based on their availability and consent for participation. The healthcare workers working in NICU responded on these questionnaires that include five physicians, 23 nurses, six paramedic trainee and six pediatric postgraduate trainees. Eighty observations at each opportunity for a total two thousand chances of performing hand hygiene were observed for these healthcare providers randomly on different time interval, preferably at non-peak hours using a checklist. The observations and questionnaire were related to WHO five moments of hand hygiene[1]. In each observation, if any step or opportunity was missed or partially completed, it was considered as non-compliance. Completion of activity as per the standard was considered as compliance with the practices. The data obtained was entered in Microsoft excel was analyzed further using R software version 3.1.1. The qualitative variables were summarized as number and percentage. The difference between the reported and observed practices is considered as a gap that needs to be focused on further training on hand-hygiene practices. Institutional ethic committee approval was taken with IEC approval number "MUEC/014/2016-17". Informed written consent for participation was obtained from all the participants before interviewing them.

Findings:

Two thousand observations and forty interviews on twenty-five variables were carried out for healthcare workers at NICU. There was a mismatch in the practices observed and knowledge of hand hygiene reported among healthcare workers. We categorized observations and responses under three subheadings; time duration, hand hygiene before an activity and hand-hygiene after an activity performed.

Time duration*:* Nearly 65% of healthcare workers reported that the ideal duration for handwashing with soap and water is <20 sec. However, only 12.5% healthcare workers practice handwashing with soap and water for >40 sec. 75% opportunities to carry out hand-washing practices were of less than 20-sec duration with soap and water. None of the healthcare workers reported the durations of hand hygiene using hand rub solution as 21 to 40 sec and we also observed the similar findings. Only one opportunity was recorded complying to 21-40 sec duration of hand hygiene using hand rub solution (Table 1).

Table 1: Showing time duration for hand hygiene practices by healthcare workers

Variables	Observations n=80	Reported n =40	The gap in reported vs observed*
	n (%)	n (%)	(%)
Duration of hand washing with soap and water			
05-20 sec	60 (75.0)	26 (65)	-10
21->40 Sec	20 (25)	14 (35)	-10
Duration of hand disinfection with hand rub solution (Min)			
05 - 10 Sec	62 (77.5%)	4 (10%)	-67.5
11- 20 Sec	17 (21.2%)	36(90%)	+68.8
21 - 40 Sec	1 (1.2%)	0 (0)	+1.2

* The gap is the percentage difference between reported and observation practices. A positive or negative gap of more than 20% is considered a significant gap in practice.

Hand hygiene before an activity: Reported compliance for hand hygiene before contacting neonate, handling or moving baby or applying a mask or giving massage was 57.5%, but observations showed more compliance than reported 83.8 % and 57.5% respectively. While performing non- invasive procedures or examination reported hand hygiene was always more than the observed. Considering any opportunity to perform hand hygiene during non-invasive procedure reported and observed was as low as 37.5% and 0% respectively. In case of performing hand hygiene before invasive procedure, reported and observed was always >80% (Table 2)

Table 2: Hand hygiene practice before any activity

Variables	**Observations n=80**	**Reported n =40**	**The gap in reported vs observed***
	n (%)	**n (%)**	**(%)**
Compliance for practice hand hygiene before having contact with neonate	53 (66.2)	23 (57.5)	-8.7
Clean hands before providing personal care activities: handling, moving, bath/sponge, feeding, changing linen, etc.	33 (41.2)	23 (57.5)	+16.3
Clean hands before delivering care and other non-invasive treatment: applying oxygen mask, giving a massage.	67 (83.8)	23 (57.5)	-26.3
Clean hands before Performing a physical non-invasive examination: Taking pulse, blood pressure, chest auscultation, recording ECG.	30 (37.5)	22 (55)	+17.5
Clean hands before Instilling eye drops, examining mouth, nose, ear with or without an instrument, inserting a suppository, suctioning mucous.	34 (42.5)	27 (67.5)	+25
Clean hands before Dressing a wound with or without an instrument, applying ointment On vesicle, making a percutaneous injection/ puncture.	76 (95)	32 (82.5)	-12.5
Clean hands before Inserting an invasive medical device	68 (85)	35 (87.5)	+2.5
Clean hands before Preparing food, medications, pharmaceutical products, sterile material.	80 (100)	25 (62.5)	-37.5

* The gap is the percentage difference between reported and observation practices. A positive or negative gap of more than 20% is considered a significant gap in practice.

Hand hygiene practices after an activity: Reported compliance towards hand hygiene practices post non-invasive procedure was nearly 50% whereas observed was as low as 2.5%. Hand hygiene compliance was reported less than 35% post touching any part of the neonatal environment and observed was nearly 0%. Compliance for hand hygiene was recorded better, >60% in post invasive procedure/ touching any mucosal part of neonate & the noted observations showed >95% compliance (Table 3).

Table 3: Hand hygiene practices after an activity

Variables	Observations n=80	Reported n =40	The gap in reported vs observed*
	n (%)	n (%)	(%)
Clean hands after the contact with a mucous membrane and with non-intact skin end.	78 (97.5)	28 (70)	-27.5
Clean hands after A percutaneous injection or puncture; after inserting an invasive medical device	80 (100)	34 (85)	-15
Clean hands after Removing an invasive medical device.	18 (22.5)	33(82.5)	+60
Clean hands after Removing any form of material offering protection (napkin, dressing, gauze, sanitary towel, etc.).	22 (27.5)	29 (72.5)	+45
Clean hands after handling a sample containing organic matter, after clearing excreta and any other body fluid, after cleaning any contaminated surface and soiled material (soiled bed linen, diaper etc.).	63 (78.8)	34 (85)	+6.2
Clean hands after providing personal care activities: handling, moving, bath/sponge, feeding, changing linen, etc.	44 (55)	20 (50)	-5
Clean hands after Delivering care and other non-invasive treatment: applying oxygen mask, giving a massage.	26 (32.5)	20 (50)	+17.5
Clean hands after Performing a physical non-invasive examination: Taking pulse, blood pressure, chest auscultation, recording ECG.	67 (83.8)	18 (45)	-38.8
Clean hands after an activity involving physical contact with the patients' immediate environment: changing linen, holding a side of the cradle, clearing sides of cradle.	2 (2.5)	20 (50)	+47.5
Clean hands after A care activity: adjusting perfusion speed, clearing a monitoring alarm.	0 (0)	11 (27.8)	+27.8
Clean hands after Other contacts with surfaces or inanimate objects: leaning against the cradle, leaning against a side table /ventilator.	0 (0)	14 (35)	+35
Practice hand hygiene after having contact with neonate?	53 (66)	24 (60)	-6
Practice hand hygiene after removing gloves?	26 (32.5)	29 (72.5)	+40
Wear gloves when hands may be contaminated with bodily fluid (e.g. Suctioning)	65 (81.2)	33 (82.5)	+1.3

* The gap is the percentage difference between reported and observation practices. A positive or negative gap of more than 20% is considered a significant gap in practice.

Discussion

No healthcare worker want any patient especially neonate to suffer from healthcare-associated infection because of any preventable cause. Maintaining good hand hygiene is vital for infection control practices, but mere awareness on how to perform handwashing is an incomplete effort to achieve a goal. The healthcare worker may be aware of the hand hygiene practices required to follow hence they reported at various instances the hand hygiene practices is required. However due to various reasons the practice is not followed and that can be captured through observations[3]. There are reports supporting our findings that there is a gap in the awareness and practices among healthcare workers for handwashing practices[4–6]. The very fact that even

the healthcare providers were not aware of performing hand hygiene post touching the neonatal environment or clearing the alarm provides scope to work further and improve on training programs. Any invasive procedure requires thorough handwashing using soap and water, whereas for non-invasive activities like clearing an alarm or changing linen etc., a hand rub disinfectant solution should be used.[7] Invasive activities do include any contact with bodily fluid during the procedure. Many training programs are carried for healthcare workers to optimize hand hygiene practice. There are limited training opportunities to learn when to perform hand hygiene practices[8]. Routinely in healthcare organizations professionals are also not made aware of the quantity of liquid soap solution or hand-rub solution required for appropriate hand hygiene. The study not only highlights the importance for the healthcare workers to learn and plan for training program on how to perform hand-washing but also when to perform which type of hand hygiene is equally important to prevent healthcare-associated infection. Studies have reported that a single classroom training approach may not work alone, rather a multimodal approach including role-play, video and game activities may show better results[9,10]hand hygiene compliance among health care workers (HCW). Whenever we are planning for handwashing campaign or training program, we need to prepare holistically to get optimum desired outcome. The healthcare workers also need to be clarified on the quantity of hand hygiene substance either soap or disinfectant solution along with clear demarcation on which practice to follow in which circumstances. As it was observed the healthcare workers were not clear whether to use hand rub solution or do handwashing or do both the practices. The significant importance of making the hand dry after any hand hygiene practice was missing that was captured during observations. The difference in reporting and observation practices gives insight to the training team about the focus area. If the gap is considerably high, as we considered a gap >20% as high, such instances need immediate special attention and training.

Conclusion

Training on handwashing must include sessions on when to perform hand hygiene how to perform, and the minimum duration required for optimum hand hygiene. Various identified opportunities should be enlisted in healthcare settings to minimize any mis-opportunity.

Conflict of Interest: All the authors declare of no conflict of interest.

A Study to Assess the Effectiveness of Protocol on Care of Newborn in Phototherapy on Knowledge and Practice among Nurses at Selected Hospitals in South India

V.Santhi [1], S.Nalini[1], Lisy Joseph[2]

[1]Lecturer, [2]Lecturer Faculty of Nursing,
Sri Ramachandra Institute of Higher Education & Research (DU), Porur, Chennai

Abstract

Background: The present study assess the Effectiveness of Protocol on Care of Newborn in Phototherapy on Knowledge and Practice among Nurses at Selected Hospitals in South India

Method and Material: A pre - experimental one group pre and post test study design was used to collect all the necessary and relevant data from nurses. The study was conducted in the maternity ward and phototherapy unit of two hospitals. Based on inclusion criteria 50 nurses were selected and non probability convenient sampling techniques were used.

Results: In pre test level of knowledge of nurses regarding care of newborn in phototherapy, 17 (34%) had inadequate knowledge, 19 (38%) had moderately adequate knowledge and 14 (28%) had adequate knowledge. In post test majority of 44(88%) had adequate knowledge, 6 (12%) had moderately adequate knowledge and no one had inadequate knowledge. The improved mean value for knowledge was 10.43 with "t" value of 13.47 and improved mean value for practice was 6.78 with "t" value of 17.26. This results shows the high statistical significance at $p<0.001$.

Conclusion: The study concludes that there was a significantly improvement of knowledge and practicable in post test after administration of protocol. Thus protocol was observed to an effective tool to improve the knowledge and practice on care of newborn in phototherapy and it may be useful to implement future reference.

Introduction

Newborns are considered to be tiny and powerless beings, completely dependent on others for their adaptation in the external environment. Within one minute of birth the normal newborn adapts from the dependent fetal existence to an independent being capable of carrying on the physiological processes. This transition, in many babies takes place in a smooth, uneventful way.

In controversy to the above, a few newborns face some minor disorders. During the process of physiological adaptation for its survival, the neonate has to face many life threatening problems, such as asphyxia, hypothermia, hyperbilirubinemia, infections etc.

One of the most important minor disorder that occur in the newborn during the transition phase is hyperbilirubinemia. It is the yellow discoloration seen

in the skin and sclera due to an increase in the serum bilirubin level. Excess amount of bilirubin in the blood that causes hyperbilirubinemia. **(Halliday, H. L. 1989)**

Globally, 65% of the newborns develop hyperbilirubinemia making it one of the most common problems in the majority of the newborn.(**William,W. Hay,. 2009).**In India approximately 4 million babies are born every year. Of them, 60 to 70% of the newborns develop hyperbilirubinemia. These statistics indicate that hyperbilirubinemia is a very common condition.

Stokowski, L. A.[3] (2006) said that proper nursing care enhances the effectiveness of phototherapy and minimizes complications. Nursing responsibilities include ensuring effective irradiance delivery, minimizing skin exposure, providing eye protection and eye care, carefully monitoring thermoregulation, maintaining adequate hydration, promoting elimination and supporting parent-new born interaction.

Nurses play a vital role in providing comprehensive care for neonates on phototherapy based on their needs. Meticulous and appropriate nursing care during phototherapy is the best way to prevent the complications.

Newman & Esterling[4] (2000) stated that according to the British Columbia Reproductive Care Program of Neonates, hyperbilirubinemia is a common neonatal problem especially during the 1st week of life when approximately 50 percent of all newborns have visible jaundice, of them 8-20 percent of term neonates exceed the total serum bilirubin values of 13 mg/dl, and need phototherapy.

All the above studies tell about the various complications that occur due to phototherapy, and stress that prevention can be possible with good care of the newborn. Neonates need close monitoring and careful nursing measures to improve their health status and to prevent complication.

During this time nurses play a very vital role in preventing complications and maintaining the well being of the newborn. With growing technology in the health sciences and increasing specialization of the Nursing profession, more rigorous control is required to ensure that nurses should possess sound scientific knowledge and skills to deliver safe and quality care.

Asha P. Shetty [5] (2003) conducted an experimental study, to assess the effect of photo therapy among full term newborn with a view to develop a nursing care protocol. The study concluded that, most often newborns with hyperbilirubinemia are treated with phototherapy which was effective. It was noted that development of a valid protocol for care of newborns in phototherapy would help practicing nurses to act promptly and independently.

Many studies in this area have been conducted in the western countries and protocols have been developed. But in India the investigator has observed that there is no specific protocol used by nurses while caring for babies in phototherapy. Hence the care provided was observed to be inadequate and many complications arose for the newborns. Having this in mind the investigator took up the responsibility of preparing a protocol to be followed while providing care for babies in phototherapy and also decided to test the effectiveness of the protocol through a pre- experimental study. The investigator tries to focus the effectiveness of the protocol which is cheap and resourceful intervention to care for the newborn during phototherapy and to assess the knowledge and practice among nurses for the same.

Method and Material

The study was designed to assess the the effectiveness of protocol on care of newborn in phototherapy on knowledge and practice among nurses at selected hospitals, Madurai. Investigator obtained formal permission from the administrative officer of Kasthuriba hospital and from the medical director of Leonard hospital, Madurai prior to the initiation of the study

Study Design: A quantitative research approach includes the research design in this study was pre experimental one group Pretest – Post test study design was considered to be the most appropriate to achieve the set of objectives in this study. The objectives were to assess the pre & post test level of knowledge and practice of nurses regarding care of newborn in photo therapy. To compare the pre and post test level of knowledge and practice of nurses regarding care of newborn in photo therapy. To correlate the mean improvement level of knowledge and practice among nurses regarding care of newborn in phototherapy. To associate the mean improvement knowledge and practice scores on care of newborn in phototherapy with selected demographic variables. The study was conducted in maternity ward and photo therapy units of two hospitals viz...

Kasthuriba hospital and Leonard hospital, Madurai. Kasthuriba hospital is a 200 bedded hospital which has well established maternity ward and photo therapy unit. Totally 35 - 40 newborns were admitted per month for the treatment of hyperbilirubinemia. Leonard hospital is a 250 bedded hospital.The phototherapy unit has 15 phototherapy machines in which 25-30 newborns were admitted per month for the treatment of hyperbilirubinemia. Totally 25 nurses are employed, all of them are posted in the maternity ward and phototherapy unit in a rotation.

Study Population: Fifty nurses who are qualified and working in maternity ward and phototherapy unit were included in this study

I**nclusion Criteria:** The nurses were working in photo therapy units and maternity wards and nurses were qualified as Diploma, B.Sc (N) Postbasic and B.Sc Basic (N).

Description of the Tool: A non probability convenience sampling technique was used in this study. The tool of the study has three section. **Section A:** The demographic variables which includes age, gender, professional education, year of experience in service, total year of experience in phototherapy unit and source of information.

Section B:A structured knowledge questionnaire, it's consists of 30 multiple choice questions with 4 options and a single correct answer. Correct answer carries 1 mark and wrong answer carries-0 mark.The Questions covered the following aspects -Knowledge about hyperbilirubinemia–13, Knowledge about phototherapy – 7 and Care of newborn in phototherapy - 10.

The knowledge and practices score range as follows

Range	Score
> 75 %	Adequate knowledge
50 – 75 %	Moderately adequate knowledge
< 50 %	Inadequate knowledge

Section C : The observation check list has 25 items. The items were in the 'Yes' or 'No' form. The score for yes is 'one' and No 'Zero'.

Content Validity and Reliability of the Tool

Content validity of the tool and protocol was got from three nursing experts in the field of obstetrics and gynecological nursing and two medical (DGO) experts. The reliability of the tool was established by using test-retest method to assess the reliability for knowledge with the same samples at different timings. The reliability score r = 0.9. To assess the reliability for the observational check-list, inter -rater method was used. The r value was 0.87. It indicated highly positive correlation.

Data Collection Procedure: The formal permission was obtained from the administrative officer and from the medical director of hospital, Madurai. The data for the study was collected with in the period of 4 weeks. During data collection period the investigator worked from 8 am to 4 pm for 5 days a week. The investigator covered 3-4 nurses per day. After getting their oral consent the investigator collected the pre test data using structured questionnaire to assess the knowledge and observational check list for assessing the practice. Each nurse took 30 – 40 minutes to answer all the questions. The investigator spent 25-30 minutes for assessing the nurses' practice on care of newborn in phototherapy. After the completion of the pre test data collection, the protocol on care of newborn in phototherapy was administered to the nurses. After 7 days post test was conducted by using the same structured questionnaire and observational check list for the same samples. The data obtained were analyzed using both descriptive and inferential statistics.

Findings

The findings from the study are tabulated, analyzed and interpreted below. In relation to demographic variables, the majority of 14 (28%) were in the age group of more than 31 years, 40 (80%) were females, 28 (56%) had completed GNM.

Table 1 : Frequency and percentage distribution of the Pre test & Post test level of knowledge of nurses regarding care of newborn in phototherapy.

N=50

VARIABLES	Pre Test						Post Test					
	Inadequate (< 50%)		Moderately Adequate (50 – 75%)		Adequate (> 75 %)		Inadequate (< 50%)		Moderately Adequate (50 – 75%)		Adequate (> 75 %)	
	NO	%	NO	%	No	%	NO	%	NO	%	NO	%
Knowledge about hyperbilirubinemia	16	32	25	50	9	18	-	-	-	-	50	100
Knowledge about phototherapy.	19	38	26	52	5	10	-	-	6	12	44	88
Care of Newborn in phototherapy	13	26	19	38	18	36	-	-	-	-	50	100

Table 2: Frequency and percentage distribution of the Pre & Post test level of practice of nurses regarding care of newborn in phototherapy. **N-50**

PRACTICE VARIABLES	Inadequate (< 50%)		Moderately Adequate (50 – 75%)		Adequate (> 75 %)	
	NO	%	NO	%	NO	%
Pre test	2	4	38	76	10	20
Post test	-	-	6	12	44	88

Table 3 : Comparison of pre test and post test level of Knowledge and practice among nurses regarding care of newborn in phototherapy. **N= 50**

Variables	Knowledge			Practice		
	Mean	SD	't' value	Mean	SD	't' value
Pre test	17.78	6.67	13.47 ***	16.24	2.55	17.26 ***
Post test	28.12	2.88		23.02	2.48	

*** P < 0.001

Table 4 : Correlation between the overall mean improvement level of knowledge and practice of nurses regarding care of newborn in phototherapy.

N = 50

	POST TEST		
VARIABLES	**Mean**	**S.D**	**' r' Value**
Knowledge	28.12	2.88	0.813 ***
Practice	23.02	2.48	

*** P < 0.001

With regard to level of knowledge the post test mean score was 28.12 and S.D was 2.88. With regard to level of practice, the mean was 23.02 and S.D. was 2.48 .The calculated 'r' value was 0.813 which show that there was a positive correlation between the overall mean improvement level of knowledge and practice at a statistically significant level of p < 0.001.

The present study supported by Milly **Mathew (2003)** on the topic can the self instructional module improves the nurse's knowledge on neonatal hyperbilirubinemia. The findings revealed that the self instructional module was effective in increasing the knowledge level of nursing personal with a t value of t=15.68 at p<0.5 level. The correlation r value between the knowledge and practice was r=0.93 which showed a good positive correlation.

Discussion

The present study was done to assess the effectiveness of protocol on care of newborn in phototherapy on knowledge and practice among nurses at selected hospitals, Madurai. The implementation of protocol was effective intervention during phototherapy on the nurses and the overall health profession. Data were analyzed from 50 nurses. The overall pre test mean score was 16.24 with S.D was 2.55 and the post test mean was 23.02 with S.D was 2.48 and the calculated 't' value was 17.26 which had statistically high significance at P < 0.001 level. The protocol was found to be effective in improving the practice of nurses regarding phototherapy

Regarding association of mean improvement level of knowledge of nurses regarding care of newborn in phototherapy with selected demographic variables of source of information at p<0.05. The other demographic variables have no significant association with the knowledge of nurses. Regarding practice the results revealed that there was no statistically significant association of the mean improvement level of practice with the selected demographic variables.

Conclusion

The present study was conducted to assess the effectiveness of protocol on knowledge and practice regarding care of newborn in photo therapy among nurses in maternity ward and photo therapy unit of Kasthuriba and Leonard hospitals at Madurai, 2009. From the results of the study it was concluded that protocol on care of newborn is an effective method to improve the knowledge and practice level of nurses. The findings revealed that the nurses, who had good knowledge about care of newborn in photo therapy, will have good practice too.

Implications:

Nursing Practice:

Nurses working in maternity ward and photo therapy unit should have adequate knowledge and practice about care of newborn in photo therapy . The nurses should update their knowledge by in service education and continue nursing education programs. Nurses who have good knowledge and practice regarding care of newborn in photo therapy will be able to promote the newborns health and thereby reduce the neonatal morbidity and mortality.

Nursing Administration:

The administrator has important role in creating awareness to increase the knowledge about care of newborn in photo therapy. In order to develop professional knowledge she has to make arrangements to conduct regular in-service education and continue nursing education programs on care of newborn in photo therapy.

Nursing Education:

The nursing curriculum should be strengthened to enable nurses to excel in knowledge and practice of care of newborn in photo therapy. Students should be encouraged to have hands on experience in photo therapy units. Monitoring and assessing the newborn condition during photo therapy should be included as a clinical procedure.

Nursing Research:

The findings of study can be disseminated to clinical nurses and student nurses through web site, literature, journals etc. The findings of the study will help the professional nurses and nursing students to improve their knowledge and practice

Recommendations:

− The protocol can be placed in the maternity and phototherapy units for the nurses to read and follow.

− A similar study can be conducted by increasing the samples size in different setting for better generalization.

− A comparative study can be done at various setting.

− A comparative study can be done on knowledge and practice between diploma nurses and B.Sc nurses.

Limitation:

- The investigator faced difficulty in seeking permission in selected hospitals.

- The investigator faced ample difficulty in collecting related literature as there was an only limited study on knowledge and practice among nurses.

Analysis of Dermatoglyphic Pattern in Potentially Malignant Disorder and Oral Carcinoma Patients

Vaishali.S[1], Sreedevi Dharman[2]

[1]Graduate Student, [2]Reader, Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Chennai, India.

Abstract

Aim: To assess the association between dermatoglyphic pattern and potentially malignant disorders and oral squamous cell carcinoma patients which might help in predicting the occurrence of these two disorders.

Background: Dermatoglyphics are the dermal ridge configuration on the digits, palms and soles. They are genetically determined and influenced by environmental forces that are operating before birth. Several studies have shown association between dermatoglyphics and different types of cancer. Hence this study was undertaken to determine whether specific dermatoglyphic patterns exists which help in predicting the occurrence of oral squamous cell carcinoma (OSCC) and oral potentially malignant disorders.

Materials and Method: After explaining about the study to the subjects, an informed consent will be obtained. A detailed history with thorough clinical examination will be done and findings will be recorded . The clinically diagnosed cases of potentially malignant disorders and oral squamous cell carcinoma will be confirmed histopathologically and will be included in the study. Finger and palm prints will be collected using ink method from 10 subjects with oral squamous cell carcinoma, 15 subjects with potentially malignant disorders and 25 healthy controls and will be evaluated qualitatively and quantitatively.

Results: Arches and loops were more frequent in cases than in controls whereas whorls were more frequent in control group. 80% of the patients with potentially malignant disorders have loop pattern, 40% of the patients has arches and 30% have whorls. 50% of the patients with oral squamous cell carcinoma have loop pattern, 30% have arch pattern and 20% have whorl pattern. 68% of the control group have whorl pattern, 20% have arch pattern and 12% have loop pattern.

Conclusion: This study concluded that dermatoglyphic patterns may have a role in identifying individuals either with or at risk for developing potentially malignant disorders like leukoplakia, oral submucous fibrosis , lichen planus etc and oral squamous cell carcinoma . Hence it can be used to identify high risk group, so that early primary and secondary preventive measures can be instituted in order to prevent the occurrence of these lesions.

Introduction

Since the early days of civilization, the features of the hands have fascinated scholars, doctors, and laymen alike. Through decades of scientific research, the hand has come to be recognized as a powerful tool in the diagnosis of psychological, medical, and genetic conditions. Cummins in 1926 first introduced the term “dermatoglyphics” which refers to the study of the

naturally occurring patterns of the surface of the hands and feet[1].Dermatoglyphics is a relatively new science, which involves the study of fine patterned dermal ridges on digits, palms and soles. Cummins and Midlo (1926) coined the term dermatoglyphics (derma = skin; glyphics = carvings), for the scientific study of ridges as well as the ridges themselves [2]. Since then, this approach has been used in various scientific studies to establish relationship of fingerprints as genetic and/or chronic health markers. Dermatoglyphic patterns are genetically determined and remain unchanged from birth to death. Dermatoglyphics is considered as a window of congenital and intrauterine abnormalities. At present, several researches claim this study of dermatoglyphics as an important diagnostic tool for some diseases especially the diseases with obscure etiology and mysterious pathogenesis [3]. Widespread interest in epidermal ridges developed only in the last several decades when it became apparent that many patients with chromosomal aberrations had unusual ridge formations. Unusual ridge configurations have been shown to exist not only in patients with chromosomal defects but also in patients with single gene disorders and in some in whom the genetic basis of the disorder is unclear [4]. In dentistry, dermatoglyphics have been studied to help predict disorders like cleft lip and cleft palate, dental caries, malocclusion, congenital anomalies like ectodermal dysplasia, gingival fibromatosis, periodontitis, bruxism etc [5]. Since epidermal ridge patterns form early in fetal development and remain unchanged throughout life [6,7] unusual dermatoglyphics may indicate gene or chromosomal abnormalities consistent with diseases such as oral leukoplakia, oral submucous fibrosis and oral squamous cell carcinoma. Potentially malignant disorders, conveys that not all lesions and conditions may transform to cancer, some may have an increased potential for malignant transformation. These disorders of the oral mucosa are also indicators of risk of likely future malignancies elsewhere in the oral mucosa and not only site specific predictors [8].This study was undertaken to study dermatoglyphic patterns in individuals with potentially malignant disorders and oral squamous cell carcinoma, so that individuals with habits and similar patterns can be identified at the earliest and preventive measures can be instituted in these susceptible individuals to prevent the occurrence of potentially malignant disorders and oral squamous cell carcinoma.

Materials and method: After explaining about the study to the subjects, an informed consent will be obtained. A detailed history with thorough clinical examination will be done and findings will be recorded . The clinically diagnosed cases of potentially malignant disorders and oral squamous cell carcinoma will be confirmed histopathologically and will be included in the study. Finger and palm prints will be collected using ink method from 10 subjects with oral squamous cell carcinoma, 15 subjects with potentially malignant disorders and 25 healthy controls and will be evaluated qualitatively and quantitatively.

Fig 2: Patient with leukoplakia

Fig 3: Patient with lichen planus

Fig 4: Shows different dermatoglyphic pattern

Results

Arches and loops were more frequent in cases than in controls whereas whorls were more frequent in control group.

Table 1: Fingerprint pattern in patients with potentially malignant disorders

Pattern	Potentially Malignant Disorders
Arches	40%
Loops	80%
Whorls	30%

The above table shows distribution of various finger print patterns in patients with potentially malignant disorders. 80% of the patients with potentially malignant disorders have loop pattern, 40% of the patients has arches and 30% have whorls.

Table 2: Fingerprint pattern in patients with oral squamous cell carcinoma

Pattern	Oral Squamous Cell Carcinoma
Arches	30%
Loops	50%
Whorls	20%

The above table shows distribution of various finger print patterns in patients with oral squamous cell carcinoma.50% of the patients with oral squamous cell carcinoma have loop pattern, 30% have arch pattern and 20% have whorl pattern.

Table 3:Fingerprint pattern in control group

PATTERN	CONTROL GROUP
Arches	20%
Loops	12%
Whorls	68%

The above table shows distribution of various finger print patterns in control group.68% of the control group have whorl pattern, 20% have arch pattern and 12% have loop pattern.

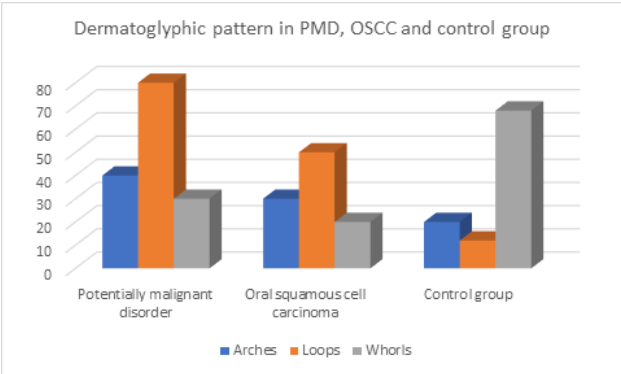

Fig 5: Graph showing different fingerprint pattern in potentially malignant disorder patients, oral squamous cell carcinoma patients and control group

Discussion

Dermatoglyphics refers to epidermal ridges present on the palm, sole, fingers, and toes. These epidermal ridges are formed in the same intrauterine period when neuronal development takes place in the intrauterine life of a fetus. Thus, dermatoglyphics is correlated with genetic abnormalities and is useful in the diagnosis of congenital malformations and many other medical disorders. Since then widespread interest in epidermal ridges developed in medical field since it became apparent that many patients with chromosomal aberrations had unusual ridge formations. Inspection of skin ridges, therefore seemed promising, simple, inexpensive means for determining whether a given patient had a particular chromosomal defect [9]. SCC is a widespread disease associated with considerable amount of morbidity and mortality. It is a major worldwide health problem and the number of sufferers is increasing rapidly due to more and more people embracing deleterious habits such as tobacco chewing, smoking and alcohol abuse. Similarly OSF is a widespread precancerous condition especially prevalent in South East Asia. Areca nut is an important predisposing factor, but not all the patients with chronic habits suffer from the disease. Conversely, not all the patients with OSF have a prolonged history of areca nut or tobacco consumption. It is said that genetic susceptibility is responsible for such variations.

Tobacco and alcohol are established risk factors for oral leukoplakia, oral submucous fibrosis and Oral squamous cell carcinoma, substantial evidence also suggest that the carcinogenic process is driven by the interaction between exposure to exogenous carcinogens and inherent genetic susceptibility. In response to environmental exposures, genetic damage accumulates more quickly in individuals with genetic susceptibility to DNA damage than in those without such instability but with a similar exposure. Consequently, individuals with genetic instability might be at a greater risk for developing these lesions [10].

In this study Arches and loops were more frequent in cases than in controls whereas whorls were more frequent in control group. Atasu et al, in examining dermatoglyphics and cancer patients in general, one of the studies has noted an increase in whorls and a decrease in radial loops in 201 Turkish cancer patients[8] which was contradictory to this study. Kindred et al, found that ,with different cancers found more whorls to be present and in studying high risk found more whorls[11]. Yet another study found an increased proportion of ulnar loops in cancer patients.

The dermal ridges have various notable characteristics which make them important, not only in personal identification, but also in human biology for various reasons. Firstly, unlike many bodily traits the dermal ridges and configuration once formed remain unchanged except in dimensions, i.e. they are age stable. The ridges are environment stable and begin to appear from 5th month of embryonic life. Although the patterns formed by ridges vary in size, shape and detailed structures, still they can be classified into definite main types. The dermatoglyphic features can thus be exploited quantitatively and qualitatively to be used as "genetic marker" of a disorder.

Considering the high mortality and high morbidity rate due to oral cancer in India, we planned to assess palmar dermatoglyphics in potentially malignant disorders and OSCC and find whether a correlation exists between potentially malignant disorders, oral squamous cell carcinoma and palmar dermatoglyphics. Our study revealed differences in the dermatoglyphic patterns among various groups which could be considered genetic markers for detecting those who are predisposed to develop potentially malignant disorders and oral squamous cell carcinoma.Hardly any dermatoglyphic study has been carried out in relation to oral malignancy, hence more studies with larger sample need to be undertaken to conclude the results.

Conclusion

Arches and loops were more frequent in cases than in controls whereas whorls were more frequent in control group.This study concluded that dermatoglyphic patterns may have a role in identifying individuals either with or at risk for developing potentially malignant disorders like leukoplakia, oral submucous fibrosis , lichen planus etc and oral squamous cell carcinoma . Hence it can be used to identify high risk group, so that early primary and secondary preventive measures can be instituted in order to prevent the occurrence of these lesions.

Evaluation of Safety and Efficay of Nifedipine in Pregnancy Induced Hypertension: A Prospective Observational Study

Venkateswarlu K.[1], T. Ram Mohan Reddy [2], B. Naveena[3], E. Sneha Reddy[3], A. Prithi[1]

[1]Assistant Professor, [2] Associate Professor, [3]Pharm. D, Department of Pharmacy Practice, CMR College of Pharmacy, Hyderabad

Abstract

Introduction: Pregnancy induced hypertension (PIH) is a pregnancy specific, multisystem disorder characterized by development of edema, hypertension and proteinuria after 20 weeks of gestation. The group of diseases includes preeclampsia and eclampsia, which are peculiar to pregnancy. Antihypertensive treatment should be commenced in all women with a systolic blood pressure ≥170 mm Hg or a diastolic blood pressure ≥110 mm Hg because of the risk of intracerebral hemorrhage and eclampsia.

Aim: To evaluate the safety and efficacy of nifedipine in gestational hypertension.

Methodology: A Prospective observational study was conducted in outpatient and inpatient department of obstetrics and gynaecology of Government hospital for a period of one year (November 2017 - November 2018).Inclusion criterion of the study was to collect and analyse the case sheets of patients having Gestational hypertension and Gestational age of >20 weeks admitted in the hospital and visited outpatient department during one year duration. Exclusion criterion of this study was patients having chronic hypertension, Gestational age of <20 weeks, Patients who were diagnosed with other causes of convulsions in pregnancy like cerebral malaria and epilepsy and Patients not willing to participate in the study.

Results and Discussion: In the present study, 70(68.62%) patients were treated with nifedipine and rest 32(31.37%) patients were treated with other antihypertensive. Nifedipine showed significantly better clinical outcomes in comparison to other anti hypertensive. Nifedipine safety profile in terms of adverse effects was significantly better than other anti hypertensive. IUGR had greater relative risk compared to other fetal outcomes while relative risk was significantly less for maternal outcomes in patients treated with nifedipine.

Conclusion: Our study results implicated the efficacy of nifedipine in pregnancy induced hypertension in terms of clinical outcomes, type of delivery, maternal outcomes and fetal outcomes and incidence of adverse effects.

Key words: *Pregnancy induced hypertension, Preeclampsia, Anti hypertensive, Nifedipine.*

Introduction

Pregnancy induced hypertension (PIH) is a pregnancy specific, multisystem disorder characterized by development of edema, hypertension and proteinuria after 20 weeks of gestation [1]. The group of diseases includes preeclampsia and eclampsia, which are peculiar to pregnancy [2].Hypertension in pregnancy is defined as systolic blood pressure greater than or equal to 140 mmHg and/or diastolic blood pressure greater than or equal to 90 mmHg. Severe hypertension in pregnancy is defined as a systolic blood pressure greater than or equal to 170 mmHg and/or diastolic blood pressure greater than or equal to 110 mmHg [3].Hypertensive disorders in pregnancy include Gestational hypertension, Preeclampsia – eclampsia, chronic hypertension–

essential, secondary and white coat. Risk Factors for Preeclampsia - Moderate risk: Age 40 years or more, first pregnancy, Multiple pregnancy, Interval since last pregnancy of more than 10 years, Body mass index of 35 or more at presentation, Family history of pre-eclampsia, Nulliparity, Multifetal gestation, Obesity, Preeclampsia in a previous pregnancy and Abnormal uterine doppler studies at 18 and 24 weeks [4]and High risk: Chronic hypertension, Chronic kidney disease, Hypertensive disease during a previous pregnancy, Autoimmune disease, Pregestational diabetes mellitus and Presence of thrombophilia[4].Antihypertensive treatment should be commenced in all women with a systolic blood pressure ≥170 mm Hg or a diastolic blood pressure ≥110 mm Hg because of the risk of intracerebral hemorrhage and eclampsia. Severe hypertension can be treated using drugs like Nifedipine which is administered as a 10mg oral dose initially, with a repeat dose of 10mg if there is inadequate response after 30 minutes. Intravenous labetalol: This is administered as a 20-50 mg bolus dose over 2 minutes. Hydralazine: It is 3rd agent of choice administered as an IV or IM dose of 5-10 mg every 20-30 min to control hypertension of ≥170 systolic and/or 110 diastolic. Ongoing Treatment for Hypertension: In terms of lowering blood pressure in preeclampsia, a number of drugs have demonstrated safety and efficacy [5].Antihypertensive treatment duration depends on clinical symptoms and patients response to therapy [6]. Medication adherence is essential to prevent PIH related complications [7]. First line drugs include methyldopa and labetalol. Second line agents are Hydralazine, Nifedipine and prazosin. Nifedipine prevents calcium from entering cells of the heart and blood vessel walls, resulting in lower blood pressure [8]. Angiotensin converting enzyme (ACE) inhibitors and angiotensin receptor blockers are contraindicated in pregnancy. Their use in the third trimester has been associated with fetal death and neonatal renal failure. Drug of choice for the prevention of eclampsia is $MgSo_4$. Magnesium sulphate therapy is recommended for use antepartum, intrapartum and within the first 24 hours postpartum for severe pre-eclampsia. Need of the Study: Every year nearly 5, 29,000 women die globally due to pregnancy related causes. For each death nearly 118 women suffer from life threatening events or severe acute morbidity. Hypertensive disorders of pregnancy seem to be one of the major causes of maternal morbidity and mortality leading to 10-15% of maternal deaths specially in developing world [2]. World Health Organization (WHO) estimates that at least one woman dies every seven minutes from complications of hypertensive disorders of pregnancy. With efficient antenatal care and early treatment of pregnancy induced hypertensive disorders, the serious form i.e. eclampsia has become almost a clinical rarity in developed countries. However, in developing country like India and in the rural population, it still continues to be a major obstetric problem. Moreover the disease not only affects pregnancy outcome but also predisposes mother and child to long term health complications like cardiovascular diseases [8].This study attempts to look how these complications can be minimised/managed. Also this study helps to know the prevalence of pregnancy induced hypertension and its complications.

Methodology

A Prospective observational study was conducted in outpatient and inpatient department of obstetrics and gynaecology of Government hospital for a period of one year (November 2017- November 2018), which provides specialized healthcare services to people. Before initiation of the study, approval was obtained from Institutional Human Ethical Committee of the hospital. Main aim is to study the management of gestational hypertension. Objectives of the study include comparing different antihypertensive drugs given in the gestational hypertension patients, identify and assess the impact of various factors that influence maternal morbidity and mortality, determining type of delivery and to determine different maternal and fetal outcomes associated with the gestational hypertension. Inclusion criterion of the study was to collect and analyse the case sheets of patients having Gestational hypertension and Gestational age of >20 weeks admitted in the hospital and visited outpatient department during one year duration. Exclusion criterion of this study was patients having chronic hypertension, Gestational age of <20 weeks, Patients who were diagnosed with other causes of convulsions in pregnancy like cerebral malaria and epilepsy and Patients not willing to participate in the study. Data Analysis: The categorical variables were represented in number and percentage. Data was analysed using SAS version 9.1.

Results

A total of 102 patients with pregnancy induced hypertension were identified and managed using anti-hypertensive medications. In the present study, patients with age 22-25 yrs42 (41.7%) showed higher incidence of PIH followed by 18-21yrs 38 (37.25%).In this study

patients of primigravida 57 (55.88%) showed increased risk for PIH when compared to multigravida. In the present study, clinical symptoms like pedal oedema 90 (88.2%) followed by proteinuria 49 (47.65%) showed higher predominance in PIH. In the present study, patients with PIH were treated using Nifedipine70 (68.62%) and further details are given in table 1. In the present study, low birth weight 59 (57.84%) showed predominance in patients diagnosed with PIH. In this study, LSCS showed lower relative risk (0.91) in patients treated with nifedipine and remaining details are mentioned in the table 2. In terms of maternal outcomes in patients treated with Nifedipine, oligohydromnios and placental abrasion showed lower relative risk 0.85 and 1.14 respectively and other information was detailed in table 3. In this study, IUGR showed relative risk of 1.06 compared to other fetal outcomes in patients treated with Nifedipine were mentioned in table 4. In the present study, clinical outcomes in patients treated with Nifedipine and other drugs group was compared using p value and their details were mentioned in the table 5. In the present study, incidence of adverse effect like pedal edema was low in patients treated with Nifedipine 30(42.86%) when compared with other drugs 18(56.25%) and remaining details were mentioned in table 6.

Table -1: Distribution according to choice of drug

S. No	Drugs	No of pts	Percentage
1	Nifedipine+ labetalol and others	70	68.62
2	Labetalol and other drugs without nifedipine	32	31.37

Table - 5: Comparison of clinical outcomes in Nifedipine and other drugs group

	Nifedipine	**Without Nifedipine**	**P value**
Systolic BP	124.81± 18.46	132.16±19.52	0.0063
Diastolic BP	79.86±10.05	85.52±11.23	0.0002

Table-6: Distribution of adverse effects in patients on nifedipine and other anti- hypertensive.

Adverse Effects	**Without Nifedipine**	**Nifedipine**
Pedal edema	18 (56.25%)	30 (42.86%)
Headache	16 (50%)	26 (37.14%)
Sweating	19 (59.37%)	21 (30%)
Dizziness	22 (68.75%)	27 (38.57%)
Nausea and Vomiting	20 (62.5%)	25 (35.17%)
Facial Edema	17 (53.13%)	28 (40%)

Discussion

The aim of antihypertensive therapy in the management of pregnancy induced hypertension is to prevent complications due hypertension while prolonging the course of pregnancy. The aim of antihypertensive therapy is to achieve a blood pressure lower than 170/110 mm of Hg but not lower than 130/90 mm of Hg without compromising uteroplacental blood flow and placental perfusion. In the present study, the incidence of PIH and eclampsia was higher in the age group of 22-25 years followed closely by the age group of 18-21 years. Similar studies were conducted by Vidyadhar et al [1]and stated that maternal age less than 20 years was the strongest risk factor for both preeclampsia and eclampsia. Xu Xiong et al [10]concluded that mean maternal age for PIH was 25.8 years. The present study revealed that, PIH was more common among primigravida when compared to secondpara

and multipara. Studies conducted by Vidyadhar et al [1]revealed that 65% were primigravida among the study conducted in PIH patients. Thus primigravida are under higher risk for PIH than multigravida. It is now believed that the high risk is related to the maternal first exposure to chorionic villi, specifically the trophoblast, which is of fetal origin. Maximum numbers of patients were clinically presented with pedal edema followed by proteinuria. In eclamptic patient headache, vomiting and seizures are also associated with pedal edema and proteinuria. In the present study of the total women who developed PIH, 68.62% were prescribed with Nifedipine and other drugs (methyldopa, magnesium sulphate and furosemide). 31.37% were prescribed with labetalol and other drugs without Nifedipine. Similar results were supported in the study conducted by Punam D. Sachdeva et al[9]. Pregnancy induced hypertension increases the risk of low birth weight. In our study the incidence of low birth weight 59(57.84%) is higher than the ideal birth weight 43 (42.15%) which supported by a study "Impact of pregnancy induced hypertension on birthweight by gestational age" conducted by Xu Xiong et al [10]. As PIH is one of the major maternal complications, in order to prevent maternal and fetal mortality maximum cases are delivered by caesarean section unless vaginal delivery is impossible, LSVD showed relative risk lower than normal delivery concluding appropriateness of the management. In our study the adverse maternal outcomes are at lower incidence implicating efficacy of Nifedipine in PIH patients. The maternal outcomes observed in our study were oligohydromnios and placental having higher relative risk. Similar results were stated in the study conducted by Vidyadhar et al[1]. In this study the observed fetal outcomes were normal 66(94.28%) followed by IUGR 25(35.71%) and still birth 12(17.14%), and the relative risk is higher for IUGR. Similar results were concluded in the study conducted by Xu Xiong et al[10].Clinical outcomes of Nifedipine and other antihypertensives where compared and the p-value calculated showed significant efficacy of Nifedipine among other antihypertensives in PIH treatment and outcomes. Nifedipine was concluded to be the effective drug in treatment of severe hypertension in pregnancy and preterm labour by Patricia Smith et al [11]in their study. Results of our study showed lower incidence of adverse effects with Nifedipine, compared to other anti hypertensive drugs. A study conducted by Chava.Jhansi et al [12] concluded similar results.

Conclusion

PIH needs early diagnosis and treatment through regular antenatal checkups to prevent it and its complications. The incidence of PIH is high among the patients with age 22 to 25 yrs. Our study results implicated the efficacy of nifedipine in pregnancy induced hypertension in terms of clinical outcomes, type of delivery, maternal outcomes and fetal outcomes and incidence of adverse effects. Inclusion of Nifedipine in anti hypertensive treatment is founded to be fairly efficacious over treatment without it.

Comparison of Immunization Coverage Status Reported through NFHS Coverage Evaluation Survey and HMIS in Maharashtra

Vijay Baviskar[1], Rutuja Patil[2], Sudipto Roy[2], Satish Doiphode[3], Arun Dhongade[4], Sanjay Juvekar[5]

[1]Joint Director, Maharashtra State AIDS control society, Gov of Maharashtra, [2]PRERNA Young Investigator, Vadu Rural Health Program KEMHRC Pune, [3]State Immunization Consultant, State Family Welfare Bureau Gov of Maharashtra, [4]Surveillance Manager, Vadu Rural Health Program KEMHRC Pune, [5]Officer in charge, Vadu Rural Health Program KEMHRC Pune

Abstract

Accurate health data is the most crucial factor for effective public health program evaluation, monitoring, planning, and implementation. There are many surveys conducted in India for collating information on the health status of the country, one of which is NFHS (National Family Health Survey). NFHS is a representative sample survey which collects evidence of trends in population, health and nutrition indicators including immunization status of children under five years of age. However, the public health system in India including Maharashtra is dependent on the reports generated by HMIS for assessment of immunization coverage status. There is a relatively large difference in immunization coverage estimates of NFHS-4 and HMIS reports. NFHS and HMIS both have differences in the purpose, design, and interpretation between the two. A deeper and more detailed analysis of the two systems and datasets is required to explore these differences and make evidence-based conclusions on data triangulation.

Key words: *Immunization data, NFHS, HMIS, data, comparison*

Introduction

National health programs are highly reliant on accurate and usable data for successful design and implementation, which is also crucial for identifying programmatic gaps and planning program amendments. In India, health data is commonly sourced from public health reporting system and representative surveys; less commonly from the private health sector. Multiple rounds of various health surveys like National Family Health Surveys (NFHS), District Level Household Surveys (DLHS) and Annual Health Surveys (AHS) have been conducted over past few years [(1)]. These surveys provide information on health indicators in a sample of representative individuals across the country. In spite of the availability of data collected from different surveys with overlapping goals, several gaps remain in the availability of health information in India [(2)] assess the availability of health data in the public domain, and review publications resulting from the National Family Health Survey (NFHS).

NFHS is a representative sample survey conducted throughout India. NFHS 4 which was conducted during 2015-16 included collection of information on health indicators from 29 states and six union territories. It collected evidence of trends in population, health and nutrition indicators. The health indicators focused on maternal child health and selected communicable and non-communicable diseases[(3)].

The recent evolution of National Health Mission (NHM) has provided an opportunity for the health system to gather real-time information and has gradually moved towards digitalization leading to the strengthened base of health information in Indian health system. Health Management Information System (HMIS) is an initiative launched in 2008 by NHM which is a digital

Young Investigator, Vadu Rural Health Program KEMHRC Pune, 3rd Floor, TDH Building, Sardaar Moodliar Road, Pune 11 ru2.patil@gmail.com

platform for monitoring of service delivery with a focus on reproductive, maternal and child health. It captures 70 data items at sub-centers and 117 items at Primary Health Centres. HMIS has provided a platform for collection and aggregation of information which can be further analyzed and the information could be used for monitoring and thus better performance of health systems [4].

The HMIS portal primarily collects information related to Ante Natal Care (ANC) of pregnant women, deliveries and it's outcome, reproductive health and child care, especially the immunization status [5]. Reporting of immunization is an utmost important indicator to assess the health status of the population. Both NFHS and HMIS collects information on immunization from the population.

Background:

The public health systems in India including Maharashtra are dependent on the reports generated by HMIS for assessment of immunization coverage. Moreover, the information is also compared with the information obtained from the recent NFHS rounds. The information present in the public domain for access was used for this comparison. The total immunization reported by NFHS-4 (2015-16) in Maharashtra state is 56.3 % whereas the immunization reported by HMIS is 94.13%. Below is the district wise comparison of total immunization reported by NFHS-4 and HMIS report of the year 2015-16 (Table 1). The full immunization means vaccination with BCG, Measles, and three doses each of Polio and DPT/Penta in children of age-group 12-23 months.

Table 1: District wise comparison of immunization data reported by NFHS and HMIS

District	% of fully immunized as per NFHS data	% of fully immunized as per HMIS data
Ahmednagar	43.4	94.20
Akola	50.8	105.75
Amravati	(64.7)	93.95
Aurangabad	59.3	100.38
Beed	53.9	101.81

Cont... **Table 1: District wise comparison of immunization data reported by NFHS and HMIS**

This relatively large difference in -reports of NFHS-4 and HMIS data raises several questions about the actual proportion of children in Maharashtra who are fully immunized. While this commentary is not a critique of either of the two systems, here we will try to explain factors that may be responsible for this difference and argue that the two reports are probably not comparable; instead, they have different purposes and can be complementary to each other.

Purpose

The National Family Health Surveys are nationwide surveys conducted with a representative sample of households throughout the country. They are designed to provide national, state and for the first time in NFHS-

4, district-level estimates of important indicators of family welfare, maternal and child health, and nutrition including estimates of children that are fully immunized. The NFHS rounds use standardized questionnaires, sample designs, and field procedures to collect data.

The HMIS is a regular health reporting portal in the public health system, i.e. it reports indicators related to maternal health, child health, communicable diseases and other health conditions from public health facilities as well as private facilities. Immunization status of children vaccinated at public health facilities is one of the important indicators that are regularly reported in the HMIS. The HMIS has a reporting structure that builds up from the government sub-centers to primary health centers and further to the district and state level. The HMIS includes data from all public health facilities in districts and state; thus it is not sample-based. The HMIS is an important tool that provides real-time data on health indicators and is used by government program managers as well as policymakers to understand the current health status of communities as well as design interventions to improve health programs including micro-level planning. The HMIS is valuable in identifying lacunae in program implementation and taking immediate corrective actions for the same.

Definitions

Both NFHS and HMIS follow guidelines developed by the World Health Organization wherein children are considered fully vaccinated when they have received a vaccination against tuberculosis (BCG), three doses of diphtheria, whooping cough (pertussis), and tetanus (DPT) vaccine; three doses of the poliomyelitis (polio) vaccine; and one dose of the measles vaccine by the age of 12 months. While the NHHS-3 reported both proportions of children fully immunized before 12 months of age as well as the proportion of children fully immunized at any time before the survey, the NFHS-4 state fact sheet for Maharashtra reports the only proportion of fully immunized children aged 12-23 months.

Method

The NFHS rounds are conducted at intervals that are not regular. While NFHS-1 was conducted in 1992-1993 and NFHS-2 in 1998-1999, the NFHS-3 was conducted in 2005-2006 and the NFHS-4 was conducted after an interval of 10 years in 2015-2016. The NFHS-4 round for Maharashtra gathered information from 26,890 households, 29,460 women, and 4,497 men. Indicators for child immunization was obtained from these 29,460 women as these were included in the women's questionnaire of the survey. All women were asked about vaccines received by all living children in the last five years prior to the survey. To obtain this information woman were first asked to produce vaccination cards for the children and data on individual vaccines along with the date of vaccination was recorded from these cards. If the card were not available, women were asked if their children had received vaccines and thus reported vaccination history was recorded. Data is collected over a period of approximately one year and primary reports are published within two years of data collection.

The HMIS is a regularly updated portal that records information on individual vaccines from vaccination registers maintained at government sub-centers, primary health centers, and other public health facilities. Every primary health center and sub-center are given a '*target population'*, i.e. children eligible for immunization that is estimated from census data and the actual number of eligible children immunized is calculated against the target population. Data on children immunized at other public health facilities are recorded at the primary health center where children reside. Data in HMIS is updated every month and made available to program managers. A critical component of the HMIS is monitoring and evaluation. Data in the HMIS is monitored at all levels from the sub-district level to the national level. At each level, the data is cross-verified by respective program managers and only then reported, thus ensuring the quality of the data.

Critical differences between NFHS-4 and HMIS

The NFHS rounds are sample surveys, with data collected from these sample households expected to provide estimates for the complete population. Though sample size calculations and sampling strategies have been statistically calculated to ensure adequate power and representativeness of the sample estimates, as with any sample survey, there remains an uncertainty in projecting sample data to the larger population, in this case, the complete population of the state and districts. Further, there is a time-lag between a collection of data and publishing results of the survey which can range from one to two years; while immunization trends at the national level usually are not expected to vary significantly, such a lag may not be useful to identify any acute weaknesses. The HMIS records program data on a real-time and regular basis. Data for all children

immunized at public health facilities are recorded in the HMIS and monthly reports are generated from the HMIS to facilitate calculation of number and proportion of children immunized. Thus the HMIS can inform the immunization program about monthly trends at all levels of the public health system

The NFHS surveys generate estimates at a given point of time and while trends in the status of child immunization can be statistically estimated from consecutive survey rounds. The HMIS, by virtue of its regularity of data recording, can provide relatively more accurate estimates of trends in immunization. However, calculation of the *'target population'*, i.e. all eligible children within a given area, which forms the denominator to calculate the proportion of children immunized, may have inaccuracies as it is estimated from the last census and data on new births available from government records. In addition, it is difficult to estimate in and out-migration while calculating *'target population'*. This inherent difficulty in fixing a denominator when using HMIS data is a known weakness in the system; which can be corrected to a large extent using statistical adjustments and more accurate population estimates. However, a discussion on this is beyond the scope of this commentary.

Data on individual vaccination in NFHS-4 was either recorded from vaccination cards or from mother`s recall. Further, data were recorded for all living children in the five years prior to the survey. The accuracy of data in case of unavailability of vaccination cards must be viewed with caution as mother`s recall is influenced by many factors, especially elapsed time in case of vaccinations given 3-5 years ago. While the NFHS-4 has yet to publish detailed estimates, the NFHS-3 reports that vaccination coverage for each type of vaccine and for full vaccination was much higher for children for whom a vaccination card was shown (76% for all vaccines) than for the children whose vaccination information is all based on mother's recall (24% for all vaccines). This seems to be a significant difference in the proportion of children vaccinated. However, the NFHS-3 report does not mention proportion of all respondents that had and did not have a vaccination card. If the proportion of respondents without a vaccination card was high, then there is a higher likelihood of under-reporting of vaccination, based only on maternal recall. Even among those with vaccination cards, the NFHS-3 did not report the completeness of vaccination cards as cards with incomplete information do not necessarily indicate incomplete immunization.

While all these factors do not comprehensively explain differences in immunization status between NFHS-4 and HMIS, there is enough evidence to show significant differences in the purpose, design, and interpretation between the two. Obviously, a deeper and more detailed analysis of the two systems and datasets is required to explore these differences and make evidence-based conclusions. Thus, interpreting either the NFHS-4 data or the HMIS data needs utmost caution when estimating immunization status of the complete population. At this juncture, it is advisable to not draw conclusions about the same before exploring further. A direct comparison between the two datasets would neither be appropriate nor would it generate actionable evidence. Rather, it would be more judicious and efficient to consider the two datasets as complementary to each other and apply appropriate statistical methods to use both to arrive at population immunization proportion estimates.

Conclusion

All these raise a question if actual information could be compared with the estimated one. Although this could be one possible way to compare the actual information, many comparisons could be done if raw data of both the data sets could be made available. We can also independently analyze the available health systems data and publish it responsibly in peer-reviewed journal which would give credibility to the use of health system data for various reasons and purposes. Probably data triangulation exercises including a combination of the two datasets along with an independent verification would provide the most realistic estimates of immunization coverage. Thus, we could initiate by using available data from health systems to produce credible publications to utilize the potential of such datasets for better tomorrow.

Conflict of Interest: The Authors declare no conflict of interest

Source of Funding: This activity was not funded by any funding agency and was self funded.

Ethics: The data used are reports available in public domain which do not include any individual level datasets hence no separate ethical approval was required.

Skin Diseases Prediction: Binary Classification Machine Learning & Multi Model Ensemble Techniques

Vikas Chaurasia[1], Saurabh Pal[2]

[1]Research Scholor, MCA Dept., VBS Purvanchal University, Jaunpur,
[2]Dept. of MCA,VBS Purvanchal University, Jaunpur, UP, India

Abstract

Unlike many other diseases, the skin disease has more irritability. Dermatology sicknesses incorporates normal skin rashes to serious skin contaminations, which happens because of scope of things, like diseases, warm, allergens, framework issue and drugs. First regular skin issue are dermatitis. Atopic dermatitis is relating current (perpetual) condition that causes eager, aroused skin. Most much of the time it appears as patches on the face, neck, trunk or appendages. It will in general erupt sporadically so die down for a period. A large portion of the dermatological sicknesses are not reparable but rather most the treatments depend on the administration of the side effects related with it.

The focus of this research will be the Dermatology database. The problem is to determine the type of Eryhemato-Squamous disease like psoriasis, seboreic dermatitis, lichen planus, pityriasis rosea, cronic dermatitis and pityriasis rubra pilaris. The differential analysis of erythemato-squamous maladies is a genuine issue in dermatology. They all offer the clinical highlights of erythema and scaling, with next to no distinctions. Each pattern is a set of 33 numbers in the range linear values and one of them is nominal. The 80% of the dataset utilize for demonstrating and keep down 20% for approval. Objective is to accomplish best performer algorithm which will convey in dermatology informational collection so for this reason the gut feel recommends distance based calculations like k-Nearest Neighbors and Support Vector Machines may progress admirably. By using 10-fold cross validation and assess calculations utilizing the accuracy metric.

Keywords: *Dermatology, Atopic dermatitis, Eryhemato-Squamous, k-Nearest Neighbors, Support Vector Machines.*

Introduction

Around 1500 BC a medical document on skin ailments Ebers Papyrus was found in ancient Egypt. It portrays different skin maladies, including ulcers, rashes, and tumors, and recommends medical procedure and balms to treat the afflictions [1, 2]. From that point to now the skin sickness portion has indicated colossal development. The predominance of skin malady in India is 10 to 12 percent of the all out populace with Eczema and Psoriasis being the significant benefactors. Because of contamination, bright light, and an unnatural weather change, photosensitive skin issue like tanning, color obscuring, sunburn, skin malignant growths, and irresistible infections are expanding at a quicker pace. A one percent decrease in ozone prompts a two to four percent expansion in the occurrence of tumors. The seriousness of developing skin illnesses in India is additionally underlined by the way that the World Health Organization (WHO) has included skin infection under the most widely recognized non-transferable maladies in India. What's more, there is an absence of offices that give thorough skin related medicines under one rooftop." The circumstance is additionally compounded by the low accessibility of dermatologists in India. At present, there are around 6,000 dermatologists obliging a populace of more than 135 crore. This implies for each 100,000 individuals, just 0.49 dermatologists are

Corresponding author:
Saurabh Pal

accessible in India when contrasted with 3.2 in numerous conditions of the US." Different tertiary consideration private setups come up short on the capacity to treat incessant, hereditary and pediatric skin diseases.

Literature Survey

Investigating the ups and downs of the computerized skin disease conclusion system, several available arrangements are still under research and development. The difference between certain obstacles and shortcomings is that this arrangement subsequently attempts to overcome current problems in a variety of ways.

The different conclusions of erythema - squamous disease are a thorny problem in dermatology. They all provide clinical highlights of erythema and scales, with little difference. The disease at this gathering was psoriasis, sebaceous glands, lichen planus, pityriasis rosea, permanent dermatitis and pityriasis of the hair [3]. Some tests have been carried out in consideration of the discovery of erythematous squamous disease. These surveys link various technologies to specific issues and complete the unique correctness of the representation. In these investigations, the main work of the differential analysis of erythematous squamous disease is Table 1.

Table 1: A few investigations which have dealt with skin disease mining

Method

Initially, differential expression analysis was used to select erythema-scaly, the most informative feature of significant differential expression, and then fed into the following classification process. Then, we use S-fold cross-validation technology to divide the initial data into k groups, training and test data sets. After that, multiple algorithms used for evaluation are learned from the training sets, each of which consist of k-1 of the k groups, and then applied to the corresponding test set, which is the remaining group of the S groups, to output the predicted class of the samples. Then, we will evaluate algorithms using the accuracy metric. This is a general indicator that quickly understands the correctness of a given model. We created a performance baseline on this issue and scrutinized many different issues of algorithms. Now we evaluate the same algorithms with a standardized copy of the dataset because we have the reason to suspect that the differing distributions of the raw data may be negatively impacting the skill of some of the algorithms. In this section we investigate tuning the parameters for most prominent algorithms that show promise from the spot-checking in the previous section. In next section, an ensemble model is another way to improve the accuracy by using four different machine algorithms; two boosting and two bagging methods. We will finalize the model by training it on the entire training dataset and make predictions for the hold-out validation dataset to confirm our findings. We can calculate from the entire training data set and apply the same transformation to the input properties of the validation data set. Finally, the algorithm-adjusted prediction is compared with the aggregate model to reduce the generalization error and obtain more accurate results [15-20].

Evaluation of Algorithms

After the pre-processing of information collection, we evaluated the expected execution of six well-known classification techniques for finding skin diseases. Specifically, we apply Logistic Regression (LR), Linear Discriminant Analysis (LDA), k-Nearest Neighbor (KNN), Classification and Regression Tree (CART), Gaussian Bayesian (NB), Support Vector Machine (SVM). As the first time to arrange the classification model. These six classification strategies are highly accurate in practical applications.

Ensemble Methods

In this research paper ensemble method is used as a method to find the accuracy of the skin disease dataset to improve the performance of algorithms. We will evaluate four different ensemble machine learning algorithms, two boosting Ada Boost (AB) and Gradient Boosting (GBM) and two bagging methods Random Forests (RF) and Extra Trees (ET).

General Procedure of Boosting

The word "boost" refers to a set of algorithms that can transform weak learners into strong learners. Of course, weak learners are only slightly better than irregular guesses, while powerful learners are very close to perfect execution. If the appropriate response is positive, then any weak learner can be promoted to a strong learner, especially if it is difficult to obtain a strong learner rather than a weak learner. The promotion is done by continuously preparing a large number of learners and merging them into expectations, and later learners pay more attention to the mistakes of previous learners.

Input: Distribution of sample S;
Learning base algorithm A;
Total number of learning rounds N.
Process:
1. $S_1 = S$. # Initialization of distribution
2. for n = 1, . . . , N :
3. $h_n = A(S_n)$; # A weak learner trained from distribution S_n
4. $\mu_n = P_{x\sim Sn}(h_n(x) \neq f(x))$; # Evaluation of the error of h_n
5. S_{n+1} = Adjustment of Distribution (S_n, μ_n)
6. end
Output: H(x) = Combine Outputs ($\{h_1(x), \ldots, h_n(x)\}$)

Input: Distribution of sample S = {(x_1, y_1), (x_2, y_2), . . . , (x_m, y_m)};
Learning base algorithm A;
Total number of learning rounds N.
Process:
1. for n = 1, . . . , N :
2. h_n = A(S, S_{br}) # S_{br} is the bootstrap distribution
3. end
Output: $H(x) = \arg\max_{y \in Y} \sum_{n-1}^{N} (\mathrm{hn}(x) = y)$

Bagging Methods

The name Bagging originated from the contraction of Bootstrap AGGregatING. As the name implies, the two key elements of Bagging are bootstrap and aggregation. For training information collection, one probability is to examine various uncovered data subsets by all accounts, and after this preparation is the underlying learner from each subset. In any case, because we do not have endless training data information, such a program will provide few and non-representative examples, resulting in poor implementation of the underlying learners. The bag receives a guided loop to create a diverse base learner. It applies a bootstrap check to get a subset of the data used to prepare the underlying learner,

Results

Here we utilized distance based algorithms like k-Nearest Neighbors and Support Vector Machines We have utilized 10-fold cross validation. The data set isn't excessively little and this is a decent standard test saddle setup. We will assess algorithms utilizing the exactness metric. This is a gross metric that will give a fast thought of how right a given model is. Progressively valuable on binary arrangement issues like this one. Making a standard of act on this issue and spot-check various distinctive algorithms. We will choose a suite of various algorithms fit for dealing with this classification issue. The algorithms all utilization defaults tuning parameters. On comparing the algorithms mean accuracy values are given in following table 2.

Table 2: Output of Evaluating Algorithms

Algorithms	Mean Accuracy Values
LR	0.979425 (0.022806)
LDA	0.962299(0.024175)
KNN	0.855747 (0.051314)
CART	0.935057 (0.028180)
NB	0.890230 (0.072177)
SVM	0.921034 (0.027220)

Evaluation of Algorithms with Standardize Data

We speculate that the differing distributions of the raw data might be adversely affecting the ability of a portion of the algorithms. How about we assess similar algorithms with an standardized copy of the data set. This is the place the data is changed with the end goal that each attribute has a mean estimation of zero and a standard deviation of one. We likewise need to maintain a strategic distance from data leakage when we change the data. A decent method to keep away from data leakage is to utilize pipelines that standardize the data and construct the model for each fold in the cross validation test bridle.

Table 3: Output of Evaluating Algorithms on the Scaled Dataset

Algorithms	Mean Accuracy Values
ScaledLR	0.972529(0.025776)
ScaledLDA	0.962299(0.024175)
ScaledKNN	0.969195(0.018533)
ScaledCART	0.938391(0.029970)
ScaledNB	0.869655(0.087102)
ScaledSVM	0.969310(0.023769)

We can see that LR is as yet progressing admirably. We can likewise observe that the standardization of the data has lifted the aptitude of SVM to be the most precise algorithm tried up until this point. See Table 3.

The outcomes propose delving further into the LR and SVM algorithms. Almost certainly, setup past the default may yield significantly increasingly precise models.

Ensemble Methods

Another way that we can improve the execution of algorithms on this issue is by utilizing ensemble strategies. We will utilize a similar test tackle as previously, 10-fold cross validation. No data standardization is utilized for this situation since each of the ensemble algorithms depend on decision trees that are less sensitive to information distributions. See table 4.

Table 4: Output of Evaluating Algorithms

Algorithms	Mean Accuracy Values
AB	0.588391 (0.062920)
GBM	0.959080 (0.036807)
RF	0.959195 (0.036403)
ET	0.969310 (0.041881)

Finalization of Model

In view of the results, The LR demonstrated the most guarantee as a low intricacy and stable model for dermatology dataset. In this section we will conclude the model via preparing it on the whole training dataset and make predictions for the hold-out validation dataset to affirm our findings. A part of the findings was that LR performs better when the dataset is standardized so all characteristics have a mean estimation of zero and a standard deviation of one. We can ascertain this from the whole training dataset and apply the equivalent change to the input properties from the validation dataset.

We can see that we accomplish an exactness of about 99% on the held-out validation dataset. A score that more and improved to our desires evaluated above amid the tuning of LR. See table 5.

Table 5: Output of Evaluating SVM on the Validation Dataset.

Conclusion

Skin disease is a disturbing and real medical issue around the world. In spite of the fact that the machine learning strategies have been increasingly more generally utilized in disease expectation, nobody technique beats all the others. In this paper, we exhibited six diverse order models and multi-model ensemble way to deal with the prediction of skin disease. The outcomes demonstrate that differential expression analysis is important to diminish the dimensionality of data and to choose effective data, along these lines expanding the accuracy of the prediction and decreasing the computational time to a substantial degree. The multi-model ensemble method at that point uses the expectations of numerous diverse classification models as input. The classification technique decreases the generation error and acquires more data by utilizing the principal organize predictions as highlights than it is trained in isolation. Also, by utilizing classification techniques, the mind boggling connections among the classifiers are found out consequently, in this way empowering the order strategy to accomplish better prediction.

Compressive Strength Evaluation between Metal Ceramic and Zirconia Crowns. An in-Vitro Study

Vikram.V[1], Sanjna Nayar[2], Narayana Reddy[3]

[1]Senior Lecturer, [2]Head of Department, [3]Professor Department of Prosthodontics, Sree Balaji Dental College & Hospitals , Chennai

Abstract

The aim of this study is to evaluate the compressive strength of metal and zirconia cores and also the point of chipping of the veneered porcelain to both the core materials. For the present study, full coverage crowns were fabricated for mandibular molar. The crowns were divided into two groups. First group is five samples of metal ceramic crowns and second group is five samples of zirconia ceramic crowns. These crowns were subjected to static compression loading in a universal testing machine until the fracture of the veneering porcelain. The compressive load was recorded in newton. Data were subjected to student t test analysis. Mean compressive strength for group 1 metal ceramic crowns was 2587.80N and the mean compressive strength for group 2 zirconia ceramic crowns was 1361.00N. The compressive strength of metal when being used as a core material is significantly higher than zirconia. Under static compressive loading, the point of fracture of the veneered porcelains occurred at significantly lower values for the zirconia based restorations when compared to that of metal ceramic restorations.

Keywords*: zirconia, metal ceramic, compressive strength, chipping.*

Introduction

Fixed prosthodontic treatment involves the replacement and restoration of teeth by artificial substitutes that are not readily removed from the mouth. Its focus is to restore function, esthetics and comfort[1]. For the past 40 years the porcelain-fused-to-metal systems have been extensively used in fixed partial dentures (FPDs) and still represents the gold standard. The advantages of the PFM systems are to combine the fracture resistance of the metal substructure with the esthetic property of the porcelain[2]. The drawbacks of these restorations are that the bulk of the natural tooth may need to be sacrificed to provide adequate space to ensure adequate fracture resistance and aesthetics[3]. However, recently the increasing demand for esthetic restorations as well as the questionable biocompatibility of some dental metal alloys has accelerated the development and improvement of metal-free restorations.[4]

All ceramic restorations have become more widely distributed due to their high esthetic potential and their excellent biocompatible properties[5]. Zirconia (ZrO2) is a ceramic material with adequate mechanical properties for manufacturing of medical devices[7]. Since it was introduced in Dentistry, the polycrystalline zirconium dioxide (zirconia) resulted particularly attractive in prosthodontics, due to its excellent mechanical properties and improved natural-looking appearance compared to metal–ceramics. Zirconia stabilized with Y_2O_3 has the best properties for these applications. Zirconia is a crystalline dioxide of zirconium[10].

The first proposal of the use of zirconium oxide for medical purposes was made in 1969[12]. Zirconia exhibits a phenomenon called "transformation toughening," which disables the progress of crack growth and increases toughness against fractures[14]. The tetragonal crystals of zirconium oxide are metastable and the stress applied to cracks or flaws can transform them into larger monoclinic crystals[15]. Yttrium partially stabilized tetragonal zirconia poly crystal (3Y-TZP) is made of transformable t-shaped grains stabilized by the addition of 3mol% yttrium-oxide (Y2O3). Such a polycrystalline material exhibits low porosity and high density; at the moment it is the most popular and frequently used form of zirconia commercially available for dental applications[20].

COMPRESSIVE STRENGTH

In the study of strength of materials, the compressive strength is the capacity of a material or structure to withstand loads tending to reduce size. It can be measured by plotting applied force against deformation in a testing machine[21]. Some material fracture at their compressive strength limit; others deform irreversibly, so a given amount of deformation may be considered as the limit for compressive load.[2] Compressive strength is often measured on a universal testing machine[23].

Dental ceramic materials exhibit many desirable material properties, including biocompatibility, esthetics, diminished plaque accumulation, low thermal conductivity, abrasion resistance, and color stability[24]. However, brittleness and low tensile strength are weak points of ceramic materials. Therefore, the clinical success of all-ceramic fixed partial dentures (FPD) has been disappointing, especially for posterior FPDs when compared with metal-ceramic restorations. Although metal frameworks have inherent disadvantages, studies reveal that the resistance to fatigue failure is comparatively more for metal ceramic restorations when compared to all ceramic restorations.[25]

Porcelain materials present two problems associated with occlusal forces: fracture of the porcelain, which is dependent upon the size and direction of the force (e.g., normal chewing versus bruxing), the type of porcelain (e.g., feldpathic, versus lithium disilicate, versus zirconia), and the time of force application; and wear of the material and its antagonist, whether natural enamel or other restorative materials. This is dependent upon the type of porcelain, quantity and timing of force, glazed versus polished porcelain, and the nature of the antagonist.[27]

Method

For the present study, full coverage crowns fabricated for mandibular first molar were tested for compressive strength. Materials used subjected to testing include:

1) Metal ceramic

2) Zirconia ceramic *(Table 1)*.

In order to standardize the crowns, a conventional tooth preparation was done on a mandibular first molar typhodont tooth model (Nissin)[29]. A full arch mandibular impression tray was used to make impression of the prepared tooth model using Aquasil soft putty/ regular set (DENTSPLY) and Aquasil ultra LV, type 3: light bodied consistency (DENTSPLY) using the double mix technique (fig 1) . The impression was poured using type IV dental stone. The dies were casted in cobalt chromium alloy[32] (fig 2).

Fig. 1 - Impression of prepared Typhodont tooth model

Fig. 2 - Cobalt chromium dies

Fig. 3 - Fabricated crowns on the dies

Bonding Casts To The Crowns

Once fabricated, the crowns were bonded onto the metal dies (fig 4) using dual polymerization composite resin cement (Rely X U 200,3M.) and light cured for a period of 20 seconds for initial setting of the material (fig 5).

A force of 10 N was applied for 5 minutes to ensure even distribution of the bond material and seat the crowns properly[34]. After the cement had set the excess cement were removed from the margins of the restoration .

Fig. 4 - Crowns cemented on the stabilized dies

Fig. 5 - Light curing done for initial setting of the cement

Compression Testing

The compression testing was carried out using a universal testing machine (Instron model: WDW-100). The load applicator (4mm metal ball) descended onto the samples (fig 6) exercising a continuous force with a vertical cross head speed of 1mm/min, moving vertically downward perpendicular to the occlusal zone.

The load force applicator's ball established three point contact with the slopes of the vestibular cusps. Static compression loading was carried out until chipping or fracture took place of the veneered porcelain to the corresponding core material. This value was recorded in Newton (N). The data obtained was tabulated and analyzed using student t-test analysis.

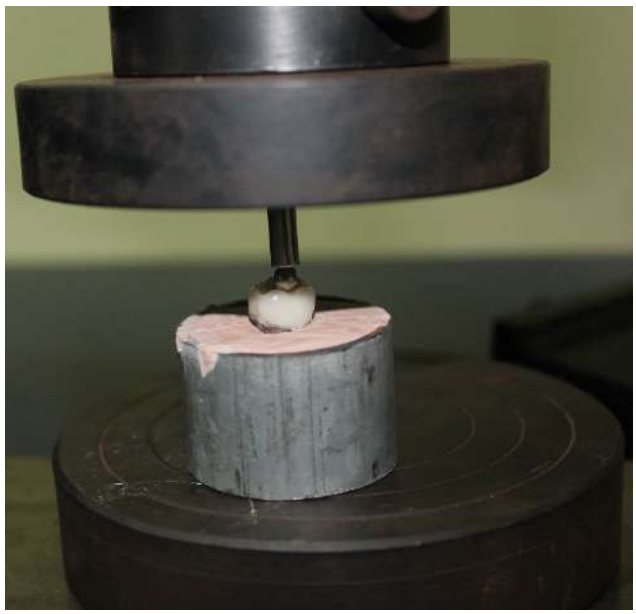

Fig. 6 - Static compression loading done on the samples

Results

Five samples were tested for compressive strength of metal ceramic in which chipping of veneering porcelain was at maximum of 2908N and minimum of 2300N.

Five samples were tested for compressive strength of zirconia ceramic in which chipping of veneering porcelain was at a maximum of 1500N and minimum of 1000N.

Mean values of compressive strength for metal ceramic and zirconia crowns were 2587.80 and 1361.0 N respectively (Table 1). These values were subjected to independent student t-test analysis (Table 2). The t-value obtained was 7.880 with degree of freedom (df) being 7.589 (Table 2). There was a statistically significant difference between the compressive strength of metal ceramic and zirconia crowns (p=0.000) (Table 3).

Discussion

With regard to biting forces in the oral cavity, compressive strength of materials used in fixed restorations plays a significant role in the durability and longevity of the prosthesis. Normal chewing cycle starts

with opening movement from centric occlusion, lateral movement and closure on to working side. Then finally shear movement against slopes of the upper teeth to grind the food particles and bring the jaw back to centric occlusion. The para functional habits like clenching includes sustained amount of compressive forces in centric occlusion, whereas bruxing include sustained compressive and shearing forces.

The choice of compressive test type and its specific design used in this study is best suited to study the resistance of ceramic materials. These have been substantiated by numerous authors (Snyder et al, Panadero et al). The compressive testing would therefore appears to be a validated method for evaluating fracture resistance of crowns or fixed partial dentures. Furthermore the cross head speed (1mm/min) and static compressive load were established in light of a literature review dealing these variables.

Despite the many disadvantages of in vitro study it is important to evaluate isolated mechanical properties under standardized conditions and limited influencing parameters. Although compressive strength does not reproduce conditions in the oral environment as faithfully as in vitro cyclic studies, the results of this type of test provide valid information, which can then be extrapolated in clinical practice.

All-ceramic crowns are subject to fracture during function. To minimize this common clinical complication, zirconium oxide is the material of choice used for the framework of all-ceramic crowns**. Kelly** suggested several recommendations for a clinically relevant *in vitro* load-to-failure test for all-ceramic restorations: use of a die material with elastic modulus similar to dentin, failure test under wet cyclic loading, preparation of the teeth or dies according to clinical guidelines and use of all-ceramic crowns with clinically relevant dimensions.

In the current study, some experimental conditions were different from Kelly's recommendations. The elastic modulus of the die material in this study is higher than that of dentin. However, natural teeth are hard to be standardized in size, mineralization, internal cracks, pulpal chamber dimension, and mechanical properties and would have fractured under the high compressive loads exerted during the test. Clinically, restorations are subjected to dynamic complex loading in saliva, which contains both organic and inorganic components. These conditions are quite different from the conditions used in this study; thus, further investigation should be carried out using stress corrosion or corrosion fatigue methodology so that the long term performance of restorations can be predicted.

The typical failure pattern of a veneering material in the daily clinical practice is known as ceramic chipping. For metal ceramics restorations, the linear coefficient of thermal expansion for metal and ceramic must closely match to achieve a strong interfacial bond. A small mismatch between these two factors results in an unknown amount of residual stress at the interface. This stress is usually confined to the veneered porcelain only.

The bond between veneering ceramic and zirconia framework is currently the subject of comprehensive investigation, when compared to that of metal ceramic restorations and this forms the basis of this study. The results of the present study show that the point of chipping or fracture of the veneering porcelain for the metal ceramic restorations ranges from 2000 to 3000N. Subsequently the chipping for the zirconia based restorations ranges from 1000 to 1500N. There is a statistically significant difference between the two groups.

From the present in vitro study, it may be confirmed that porcelain veneers with the same characteristics behave in response to static loading differently depending on the type of core they cover. Zirconia restorations fracture at lower static load values. Porcelain veneer over a metal ceramic core resisted higher static loading.

A Study on Patients of Scrotal Dermatitis

Akhil Kumar Singh[1], Ranjana Singh[2], Parth H Thakkar[3]

[1]Associate Professor, Dept of Dermatology, Venereology & Leprosy, [2]Professor Dept of Preventive & Social Medicine, [3]Resident, Dept of Dermatology, Venereology & Leprosy, Saraswathi Institute of Medical Sciences NH24 Anwarpur Dist Hapur, UP

Abstract

Scrotal dermatitis is among one of the very common dermatological condition that has been easily overlooked by dermatologists ,treating physicians as well as by patients. The condition is easily mistaken for the common skin disorders affecting the area, like Tinea and scabies. This study will try to find out the various etiological factors and the management of the condition. 85 Male patients between the age group of 15 to 78 years were enrolled in a study period of 8 month. Majority of patients (48.2%) were wearing jeans regularly.54% of patients were wearing Jocky type of underwear. Medicated soaps were used by 30% of patients. 23% of patients were using antiseptic liquids for cleaning the area. Deodorant spray was used by More than 21% of patients. 75.6% of patients used combination creams (self medicated). On examinations 63.5% of patients were having erythema of some grade. Thickening of scrotal skin were observed in 60% of cases.Superficial to deep ulceration /erosion were present in 41.2% of patients. Scabies nodules were present in 22.4% of patients. Associated Tinea cruris was observed in 32.9% of patients. However, fungus infection of scrotum was found in 17.6% of cases.17.6 % of cases were having associated bacterial infections. Irritant reactions/ contact dermatitis was most common cause of scrotal dermatitis observed in 44.7% of cases, followed by neurodermatitis (LSC) in 30.5% of cases.

Key words: *Scrotal dermatitis, Irritant dermatitis scrotum, Scrotal pruritis*

Introduction

Scrotal dermatitis may present in different morphological features and is characterized by severe itching, erythema, scaling, erosion, fissuring and lichenification of the scrotal skin. Apart from these, there may be loss of hairs, Multiple factors are responsible for the condition, the most important being psychological stress and contact dermatitis either allergic or irritant. The condition has been easily diagnosed as fungal infection of the scrotal area. Due to wide spread use of antiseptics ,irritant ,soaps, sprays, hygiene wash and many topical agents, nowthis condition has become very common.

Though very common condition, very limited literature has been published on scrotal dermatitis either because of under reporting by the practitioners. Probably "scratching the balls" is considered as a common male habit.

Though the condition can be treated easily, it causes significant physical and psychological morbidity to the patient in the form of persistent or recurrent symptoms and social embarrassment. Also there is tendency for recurrence, as mostly we stress on medicines part but we ignore the factors behind the condition. Mostly busy practitioners do not explain in detail the factors behind it and the preventive measures to be taken.

Aims and Objectives

1. To classify the different dermatosis affecting the scrotum.

2. To find out the various physical, psychological and chemical factors responsible for this.

3.To treat and to educate the patient to prevent future recurrences.

Material and Method

A total of 85 male patients above age of 15 years attending dermatology OPD in Saraswathi institute

of medical Sciences, Hapur and School of Medical Sciences & research, Gr Noida were included in study. The duration of study was from January 2019 to August 2019. A questionnaire was prepared and all the details including socioeconomic status, personal habits, dressing pattern, type of underwear, toiletries including perfume spray, hygiene wash, antiseptic lotions was also noted. Informed consent was also taken. Proper examinations of the area in good day light condition was done. Any sign of inflammation, thickening, lichenification, ulcerations /erosions, loss of hairs were also recorded. In suspected patients KOH examination was done to rule out dermatophytosis. The final diagnosis was made. The patients were treated and observed for 2 months after successful treatment. Any recurrence was recorded. The patients were advised to change their habits and change their toiletries and dressing pattern.

The data was recorded, tabulated and analyzed by using SPSS software version 20. Percentage, mean and chi square test was used for statistical significance and P value <0.05 &<0.001 were considered significant.

Results

The total numbers of 85 cases were recorded in the department of dermatology were as follows:

Table 1: Characteristics of patients

Age group (Years)	No.	Percentage
15-29	27	31.8
30-44	30	35.3
45-59	15	17.6
60-74	10	11.8
75+	3	3.5
Socio-economic status		
High	12	14.1
Lower	13	15.3
Lower Middle	30	35.3
Middle	30	35.3
Associated Diabetes Mellitus		
Yes	12	14.1

The age of patients was in the range of 15 years and 78 years with mean age of 39.6 years. Majority of patients belonged to between age group of 30 to 45 years (35%) followed by age group of 15 to 29 years (31.8%). Only 3.5% patients were above age of 75 years.

Out of 85 patients, highest number of patients belonged middle and lower mid socioeconomic status 35.3 % each.

Out of the 85 patients, majority (41) were wearing jeans daily for the most of the time (48.2%). 30 patients (35.3%) were wearing pant daily. Pajamas were worn daily by 12 patients (14.1%).Only 2 patients (2.45) were wearing dhoti regularly.

Jocky type (V shaped) underwear were regularly worn by majority of patients 46(54.1%) . Loose Desi or boxer type were worn by 26 patients (30.6%). Long and

tight underwear were worn by 13 patients (15.3%).

Except 5 patients (5.9%) all were using soaps for cleaning the area involved and for regular bathing. Majority of patients were using mild soaps (31, 35.3%). Soap with chemicals were used by 26 patients (30.6%). Herbal soaps were used by 12 patients (14.1%). While 2 patients were using detergent bars for bathing. Surprisingly 3 patients (3.5%) were using V wash (Female hygiene wash) over the area.

20 patients (23.6%) used liquid antiseptics like Dettol, Savlon etc. for cleaning the area or for bathing purposes.

Deodorants over the area was used by 18 patients (21.2 %).

4 Patients (4.6%) used Dithranol (a highly irritant ointment used in treatment of psoriasis) leading to severe irritant contact dermatitis.

35 (41.2%) patients were using various antifungal creams over the scrotum. Most commonly been Luliconazole and Miconazole. One patient used Zalim lotion (containing salicylic acid and herbal ingredients) leading to acute irritant contact dermatitis.

Antihistamines were used by majority of patients 75(88.2%) most commonly being Cetirizine and Pheniramine Maleate.

Clinical Features

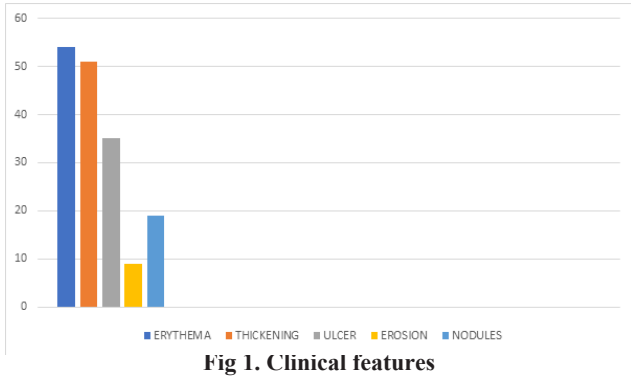

Fig 1. Clinical features

Various grade of Mild to deep erythema were observed in 54 (63.5%) cases. Some grade of thickening of scrotal skin was observed in 51 (60%) cases. Superficial to deep painful ulceration were observed in 35 cases (41.2%), Nine patients(10.6%) showed erosion with serous discharge.

Nodules over the scrotal skin (old or active scabies) were observed in 19 (22.4%) of patients.

Associated Tenia Cruris were observed in 28 patients (32.9 %). Associated Intertrigo was observed in 9 patients (10.6 %). Skin scrapping and KOH mount tests were performed in suspected cases. 15 patients were found positive for superficial dermatophytosis.

15 patients (17.6 %) were also having associated bacterial infections like folliculitis,furunculosis and infected eczema over the scrotal skin.

11 patients were having diabetes with HbA1c level more than 7.

Table.2 Age wise distribution of non venereal dermatosis of scrotum

Age Group Non- Venereal Genital Dermatosis	15-29 Years	30-44 Years	45-59 Years	60-74 Years	75 +	Total	Chi-Squre Value	P Value	Result
*Irritant / Contact Dermatitis	20	11	5	1	1	38	57.317	<0.004	Highly significant
Scabies	3	7	6	4	1	20			
Fungal Infection	3	7	2	1	0	13			
Bacterial Infection Alone	1	1	0	3	0	5			
Lichen Simplex Chronicus	2	9	9	6	1	26			

Irritant and /or contact dermatitis was most common cause of scrotal dermatitis in 38 cases (44.7%) of cases , followed by Lichen simplex chronicus (Neurodermatitis) was present in 26 cases (30.5%). Scabies infestation over scrotum was present in 20(23.5%) cases.Fungus infection could be confirmed mycologically only in 13 cases (15.3%). Bacterial infections like folliculitis were present in 5 cases (5.9%).a highly significant association was observed between type of dermatitis & age ($p<0.004$).

Treatment and response

All the patients improved with the treatment, but in 18 patients (21.2%) there was recurrence of symptoms after the successful treatment. Out of these 18 patients, 7 did not follow the instructions.

Lichen Simplex Chronicus

Acute irritant dermatitis

Discussion

Scrotal dermatitis is among one of the very common dermatological condition having multifactorial origin. In a study in year 2017 by Dipali Rathod et al [4] in non-venereal dermatosis in both females and males showed scrotal dermatitis in 16 % of cases, if we take only male patients in consideration the percentage will come 21.3%. In another study by M Kanta Prasad Rao[7] over male patients ,13 % of patients were having Scrotal dermatitis. The etiological factors are multifactorial & can be classified as:

1. Irritant or allergic reactions to soap or detergents

2. Topical antiseptics like Chlorxylenol, Triclosan, Cetrimide ,Chlorhexidine etc

3. Topical antibiotics like Neomycin, Gentamycin etc

4. Topical Antifungal creams and salicylic acid / benzoic acid based preparations.

5. Diabetes Mellitus

6. Dermatological conditions like Atopic dermatitis, seborrheic dermatitis, lichen simplex chronicus

7. Hygiene or perfume spray

8. Occlusive dresses / tight jeans

9. Tight and hugging under wears

10. Infestations by scabies / pediculosis

Etiopathology – The scrotum is an area with remarkable permeability. It provides a unique percutaneous doorway for the entrance of drugs into the circulation and is thus uniquely susceptible to toxic and irritant agents [4].Allergic reactions of the male genital are most often acute. They are influenced by the dependent position, rich vascularity and looseness of the connective tissue in this area [1]. Further the occlusion in form of tight hugging under wears and followed by release of detergent remnants present in undergarments. The detergent works as an irritant to scrotal skin. Other contributory factors includes friction, maceration, overwashing leads to scrotal dermatitis [12, 13].Riboflavin and other Vit B complex deficiency occasionally produce scrotal dermatitis [9].

Clinical features – The Scrotal dermatitis may present itself as severe itching with burning sensation In Lichen simplex chronicus the scrotal skin shows thickening, hypo or hyper pigmentation[2].

Krishnan Ajay & Kar Sumit suggested the following classification[1] depending upon clinical features.

Type 1- Mild & acute type: In it there is severe burning and itching. Heals with mild desquamation after some days or weeks.

Type 2- Severe chronic dry: Scrotum looks bright red and hypopigmented with severe itching.

Type 3 –Chronic wet: Whole of scrotum and inner thighs become macerated with oozing Fetid odor and telangiectasia may present.

Type 4 -Ulcerated and edematous: The scrotal skin is edematous with fluid or pus discharge, associated with severe pain.

The majority of patients(57)in our study were young in age group of 15 to 44 years (67.1%) this is the age when most of the persons were wearing jeans, tight pants etc. also this is the age when the teenager ,students and young adult try various toiletries and perfumes.

In this study 42 % of patients belong to middle and high income group. These group usually have enough surplus money to spend on expensive jeans, toiletries, deodorant and perfume etc. In our study only 12 patients were having Diabetes as shown by blood sugar levels and HbA1C levels.

Jeans were regularly worn by 41 patients (48.2%). The pants were worn regularly by 30 patients (35.3%). The students and young men wear jeans most of the time, wearing the same jeans for days together without washing or drying. The jeans and tight synthetic pants act as occlusive dress preventing evaporation of moisture, increasing local temperature thereby making the environment conducive for growth of bacteria and fungus. It also facilitate transcutaneous absorption of irritants.

The jockey type of tight and hugging underwears were worn regularly by majority of patients 46 (54.1%) . these underwears covers scrotum all around and are constantly in contact with scrotal skin. Any remnant of detergent, feces & urine acts as an irritant to scrotal skin. In this study 26 patients (30.6%) were using antiseptic soaps (Dettol , Savlon , lifebuoy). These soap contains Chlorxylenol (Dettol) and Triclosan. Chlorxylenol or 4 chloro 3,5-dimethylphenol present in various commonly used antiseptics preparations and soaps is also an important cause of dermatitis of the scrotum[11]. It also causes the removal of normal microbial flora of the skin and facilitates the colonization by pathogenic groups[1]. Twenty patients (23.6%) were using antiseptics liquids either directly over area or mixing with water for bathing. Cetrimide is one of the most common cause of contact sensitivity [11]. Deodorants were used over the area by 17 patients (20%) . Irritant reactions can occur from fluorinated hydrocarbon propellants sprayed too close to the genitals.[15]

Surprisingly 3 patients were using V wash (vaginal Wash containing Lactic acid & having pH of 2.5) over the area . 2 patients were using highly irritant detergent bar for bathing. To treat itching combination creams containing steroids, antibiotics and antifungals were used by majority of patients 66 (75.6%). 35 patients (41.2%) were using antifungal creams over the scrotum. Since the inflamed skin has a higher permeability, the various over the counter products applied over the lesions further aggravate the condition[1].

Four patients had used Dithranol ointment which led to development of acute irritant erosive contact dermatitis over the scrotum and surrounding skin.

In this study mild to deep erythema was observed in majority of patients 54 (63.5%). Various grade of thickening in 51 patients (60%).

Superficial to deep painful ulceration were observed in 35 cases (41.2%), leading to difficulty in walking. 9 patients(10.6%) showed painful erosion with serous discharge.

Nodules are very common over genital areas in case of scabies . Scabies nodules in treated or untreated cases were found in 20 cases (23.5%). In a study by M. Kanka Prasad Rao Genital scabies was present in 18.33% of cases of nonvenereal dermatosis [7].

An intact skin barrier prevents the penetration of harmful substances into the skin. Irritants and allergens that stay on the skin surface and come into contact with the stratum corneum only do not harm the skin [8].

Associated Tenia cruris was present in 28 cases (32.9%).However presence of dermatophytes was demonstrated microscopically in 15 cases (17.6%) by skin scraping and KOH examination. Tenia cruris cases are very common but spread over the scrotum is rare. Decreased scrotal skin barrier function facilitating permeation of antifungal factors into the stratum corneum and decreased eccrine sweat secretion in the penile skin resulting in lowered skin hydration have been proposed as the mechanism of the relative resistance, but neither has any rigorous proof [14].

Acute and chronic contact / irritant dermatitis were observed in 38 patients (44.7%).Lichen simplex chronicus were diagnosed in 26 (30.6%) patients. In a study by Bhatia et al over cases of Neuro dermatitis scrotal involvement was present in 12% of cases [3].

15 patients were also having associated or only bacterial infections. In a study by Woskoff A et al it was found that Candida and Staphylococcus were most commonly involved [5].

All the patients were counselled and treated. Most of them were advised to change detergents, soaps, underwear etc. They were also advised not to use combinations creams and antiseptics soap/liquids. Mild steroid creams were given for short periods, in cases of Dermatitis and Lichen simplex chronicus (LSC) along with advice to shun itching. Sedating antihistamines were given at night in cases of LSC. All the patients improved with medicines and changing the toiletries and clothes. However, in 18(21.2) patients there were recurrence of symptoms within two months of completing the treatment.

Conclusion

Though scrotal dermatitis is a very common condition, still it is underreported and underrated condition. For successful treatment, apart from medicines, lifestyle changes are also required.

Health Status of Children in Assam

Chayanika Goswami

PhD Research Scholar, Dept of Economics, Gauhati University, Assam

Abstract

Children are the most valuable asset of a nation; their good health is the cornerstone for survival and development for current and succeeding generations which guarantee the sound and sustained economic development. Child health is a state of social, emotional, intellectual, mental and physical well- being which does not merely represent the absence of disease or infirmity. The term nutrition refers to a process of attaining necessary food for proper health and growth of human being. The nutritional status of children impacts their health, cognition and educational achievements. But underweight and malnutrition are most prominent health indicators in India and also in Assam (According to NFHS-3 & NFHS-4). Assam is situated in the North-East of India, bearing a considerable percentage of its population under the poverty line. Assam does not have shown much improvement in its health and nutrition indicators. Almost 36.4 percent children under age 5 are stunted and Infant Mortality Rate as high as 48(NFHS-4). The health status of children in rural areas of Assam is very pathetic. 55 percent children are stunting in rural areas. Various reports states that though Assam has made progress in its health indicators, still there is a great need to strengthen its existing health care services especially in the rural areas. The present study has made an attempt to study the health status of children in Assam. This study may be able to provide a base line information and need for effective implementation of various schemes and programmes for the improvement of health status of children in future.

Keywords: *Assam, Child, Economic Development, Health Care, Health Indicators, Nutrition.*

Introduction

Childhood is a significant phase of life and deprivation during this period can have long term adverse impact on the well being of children[1]. Child health is a state of social, emotional, intellectual, mental and physical well- being which does not merely represent the absence of disease or infirmity. The term nutrition refers to a process of attaining necessary food for proper health and growth of human being. According to World Health Organization (WHO), "Malnutrition means the cellular imbalance between, supply of nutrients and energy and the body's demand for them to ensure growth, maintenance and specific functions.[2]"

Healthy children have the fullest potentialities to attain proper weight in relation to height and resistance to diseases. Thus, it may increase life expectancy and help human beings to enjoy life fully, may also increase work capacity that results in increased productivity of nation and it enhances economic growth and development. Assam is situated in the North-East of India, bearing a considerable percentage of its population under the poverty line. Assam does not have shown much improvement in its health and nutrition indicators. Almost 36.4 percent children under age 5 are stunted and Infant Mortality Rate as high as 48 (NFHS). Various research article and study has reported that children in the developing country are most vulnerable as 50 percent of all deaths were occurring during the first 5 years of life. Despite inclusive efforts for improving malnutrition like ICDS programme, malnutrition among children remains a significant problem in India as well as in Assam.

The most common method used to assess the health status of children is given by World Health Organization (WHO). WHO growth standard can be used to assess whether children are growing and developing. It can also be used to observe whether efforts to reduce child mortality and disease are effective. According to WHO, growth standard are:-

- If < -1 to > -2 Z-score implies Mild Malnutrition
- If < -2 to > -3 Z-score implies Moderate Malnutrition and

- If < -3 Z-score implies Severe Malnutrition

On the basis of the above growth standard, three common anthropometric indicators are used to measure the nutritional status are -

1. Height-for-age (HAZ). HAZ is used to denote "stunting"- or low height for age,

which is an indicator of chronic form of under-nutrition. It is caused by long-term

insufficient nutrition intake and frequent infections.

2. Weight-for-height (WHZ). WAZ or low weight corresponding to height stands

for "wasting" or more acute or current form of under nutrition. It is a strong

predictor of mortality among children under five. It is usually the result of acute

significant food shortage or disease.

3. Weight-for-age (WAZ). The WHZ, low weight for age, is an indicator of chronic form of under-nutrition, denoting "under-weight."

Objective:

1. To study the health status of children in Assam.

Methodology

The present study is based on the secondary data that are collected from different government reports and organizations. The sources of secondary data are:-

i. The Department of Social Welfare, Government of Assam;

ii. National Family Health Survey -3 (NFHS-3)

iii. National Family Health Survey - 4 (NFHS-4)

iv. Census reports, Govt. of India.

v. Health and family welfare reports.

vi. Statistical Handbook of Govt. of Assam.

vii. Nutrition Policy reports of Govt. of India, etc.

Results and Discussions

Assam happens to be one of the worst performers in reducing child's nutritional status. A scrutiny of the nutritional status of the children, the adults of tomorrow, is important to assess the wellbeing and health[3]. Detailed studies were prepared by NFHS-3 and NFHS-4 and the main findings shows that stunted rate is 46.5 percent, wasted rate is 13.7 percent, severely wasted rate is 4.0 percent and underweight rate is 36.4 percent. However, according to NFHS-4, stunted rate has reduced to 36.4 percent and underweight rate also reduced to 29.8 percent. On the other hand, wasted rate and severely wasted rate has increased to 17.0percent and 6.2 percent respectively. Again in Assam, the infant mortality rate and under 5 mortality rates is 48 and 56 respectively which is 66 and 84[4].

The following table shows the percentage of malnourished children in Assam –

Table-1: Child Malnutrition Status in Assam

ASSAM		
INDICATORS	**NFHS-3 (2005-6)**	**NFHS-4(2015-16)**
Stunted	46.5	36.4
Wasted	13.7	17.0
Severely Wasted	4.0	6.2
Under-weight	36.4	29.8
Infant Mortality Rate	66	48
Under Five Mortality Rate	84	56

Source: NFHS - 3 & NFHS - 4

In Assam, the percentage of stunted children has decreased from 46.5 percent to 36.4 percent whereas wasted and severely wasted children are increased from 13.5 percent to 17 percent and 4 percent to 6.2 percent respectively. But the percentage of underweight children has reduced from 36.4 percent to 29.8 percent.

The district wise nutritional status of children in Assam is shown in table 1.2. It can be seen from table 1.2 that that Dhubri district has the highest number of

"stunting" children with 47.4 per cent. Goalpara district has the highest number of "under-weight" children with 39.5 per cent. Cachar district on the other hand, has the highest number of "wasting" children with 30.6 per cent.

Table 2: Child Nutritional Status in Various Districts of Assam (In percentage)

District	Stunted	Wasted	Severely Wasted	Under Weight
KOKRAJHAR	30.6	15.7	6.1	27.1
DHUBRI	47.4	22.2	9.5	39.0
GOALPARA	42.7	22.1	8.9	39.5
BARPETA	41.7	16.6	5.8	33.1
MARIGAON	38.4	10.3	0.9	25.8
NAGAON	38.4	13.3	4.4	31.3
SONITPUR	28.7	21.5	10.9	26.9
LAKHIMPUR	29.3	11.2	4.4	24.2
DHEMAJI	35.5	6.2	0.8	15.8
TINSUKIA	36.0	14.8	2.2	32.7
DIBRUGARH	33.3	22.4	8.2	33.0
SIVSAGAR	35.5	8.3	1.5	22.2
JORHAT	25.5	14.8	5.4	18.1
GOLAGHAT	32.6	13.9	6.5	20.2
KARBI ANGLONG	28.1	18.7	11.0	23.7
DIMA HASAO	34.7	6.3	1.3	18.2
CACHAR	36.3	30.6	11.3	36.3
KARIMGANJ	42.3	17.6	6.1	35.6
HAILAKANDI	38.1	19.1	6.3	32.5
BONGAIGAON	39.1	23.6	12.7	32.9
CHIRANG	40.1	13.0	4.4	24.7
KAMRUP (R)	33.3	18.8	5.3	29.6
KAMRUP (M)	24.6	11.0	2.4	23.2
NALBARI	26.8	15.3	6.2	20.0
BAKSA	32.4	10.5	2.7	22.4
DARRANG	43.5	19.2	5.3	37.9
UDALGURI	39.1	18.3	8.1	31.8

Source: NFHS-4

If we look at the table of health status of children of Assam in the geographical diversity category, it was found that the number of "stunting" children is highest in general area (66.1 per cent) followed by Char areas (61.8 per cent). According to the Human Development Reports (HDR) Assam- 2014, the multiple diversity areas and border areas are more vulnerable to "under-weight" and "wasting" children. Number of wasting and under-weight children is highest in multiple diversity

areas (24.6 percent and 45.8 per cent) followed by border areas (22.3 percent and 39.8 per cent). The following table shows the health status of children according to geographical diversity-

Table-3: Health Status of Children in Geographically Diverse Area of Assam

GEOGRAPHICAL DIVERSITY	STUNTING	WASTING	UNDERWEIGHT
Char areas	61.8	14.7	37.9
Flood affected areas	49.7	17.3	33.7
Hills	36.6	4.9	28.3
Tea-garden area	46.8	18.2	33.6
Border areas	47.8	22.3	39.8
Multiple diversity	55.1	24.6	45.8
General	66.1	12.6	37.7

Source: Assam HDR, 2014

The HDR Assam-2014 studied the male-female break up regarding the nutritional status of children under age five and it was found that 55 per cent male children against 52.9 per cent female children are "stunting", 17.7 per cent male against 16.1 per cent is "wasting", 39 per cent male children against 35.7 per cent female children are "under-weight." Again, the rural-urban break up has shown that 55 per cent rural children against 44.3 percent urban children are "stunting"; 17.1 per cent rural children against 15.6 urban children are "wasting" and 38.2 rural children against 30.4 urban children are "under-weight." The following table shows male-female and rural-urban break up in the three category of nutritional status of children in Assam:-

Table - 4: Malnutrition in Assam

ATTRIBUTORS	**STUNTING**	**WASTING**	**UNDERWEIGHT**
Male	55	17.7	39
Female	52.9	16.1	35.7
Rural	55	17.1	38.2
Urban	44.3	15.6	3.4

Sour Source: Assam HDR, 2014

Conclusion

From the above, we can conclude that Assam has made progress in its health indicators, but it is most urgent to strengthen its existing health care services especially in the rural areas. The percentage of proper nourished children in rural Assam is not very satisfactory. 55 percent children are stunting in rural areas. According to National Family Health Survey- 4, the health profile of Assam shows that about 29.8% children below the age of 5 years are underweight. Besides, 35.7% children between the age group of 6-59 months are anemic and about 25.7% women have body mass index (BMI) below normal. It indicates the state of acute malnutrition which may be attributed to lack of proper nutritious foods, illiteracy among parents, lack of proper sanitization facilities, irregular heath checkup, food scarcity and various socio economics factors that affect the nutritional status of children. Under National Rural Health Mission (NRHM) various quality development programme has been launched and under the Ministry of Social Welfare, ICDS programme has been introduced to facilitate regular health check-up, immunization, health education and other child health education programme.

Relationship of Character Strengths to Influence Psychological Well-Being During Adolescence

Mallika Vohra[1], Neelam Pandey[2]

[1]Research Scholar, [2]Assistant Professor, Amity Institute of Psychology & Allied Sciences, AUUP, Noida

Abstract

The primary research study examined the association and influence of VIA Character strengths on satisfaction, efficiency, sociability, mental health, interpersonal relations and above all the overall well- being. Research showed that (for n=300 adolescents who participated in the study), several character strengths (e.g., self-regulation, prudence, honesty, social intelligence, hope, courage and curiosity) are highly significantly positively correlated with measures of subjective well-being and its overall formation. Acknowledgment of the requirement for programs for positive youth advancement makes the evaluation and improvement of character qualities an exceptionally significant exercise in the present situation. An investigation of character qualities and their applications during adolescence period along these lines expect high significance because of its suggestions for prosperity of the young generation just as for psychological overall well-being advancement. In the above setting, the present examination of the profile of character qualities in Indian adolescent's as planned revealed featuring qualities that are most supported by them to advance well-being and bring prosperity.

Keywords: *character strengths, well-being, adolescence, satisfaction, mental health, positive psychology*

Introduction

At the point when parents, guardians and teachers talk about the characteristics they most would like to develop in children, they frequently notice character qualities such as, honesty, prudence, teamwork, love of learning.[1]These ethical characteristics are esteemed in their own right, despite the fact that they are additionally accountable to profit society and the people who have them. We expect that youngsters who build up these characteristics will add to society and have satisfying lives. Ongoing examination in positive brain research demonstrates that many character qualities are related with momentum levels of prosperity.[2] Only a few researches look at whether character qualities anticipate or advance future prosperity, nonetheless. The significant discussion was to look at whether character qualities foresee consequent prosperity during pre-adulthood. Character qualities are impacted by family, network, environmental, cultural, and other relevant elements. From a certain perspective, character qualities are pliant; they can be educated and obtained through training. There are numerous courses through which character qualities could advance positive results and avoid psychopathology. For instance, coordinated qualities may create situations of friendships and increment the social help individuals get from others, which thusly could expand positive encounters that lead to enjoyment, harmony, satisfaction and mental health. Numerous examinations have analyzed co-relationship and indicators of subjective wellbeing in grown-ups, yet there is less research on emotional prosperity, especially positive records of prosperity and its indices, in young children's. [3&4] The study investigates whether young people's character qualities toward the middle school would foresee their downturn, bliss, and life fulfillment. Research suggests that building character strengths can increase well-being. For example, interventions that promote social intelligence and self-regulation can reduce substance abuse, aggression and other behavioral problems among children, and increase the likelihood that youth will graduate from school.[5&6]

The primary reason for this investigation was to look at whether character qualities relate and foresee mental prosperity during youthfulness. We inspected whether adolescents' character qualities toward the middle school would foresee their satisfaction, efficiency, sociability, mental health and interpersonal relations;

joined together their abstract prosperity. Character qualities are the subset of personality attributes that are ethically esteemed. Like other personality attributes, character qualities are airs that show in individuals' musings, feelings and practices. [4,7&8]Demeanor, nature and personality styles may encourage qualities and facilitate strengths. For instance, personality styles, such as, amiability and approach (rather than withdrawal) may encourage character qualities, such as, kindness and courage. Though demeanor, nature and personality styles are not ethically esteemed, be that as it may, character qualities have an ethical importance and the vast majority of these characteristics are esteemed crosswise over societies and from the beginning of time.[9]Psychological well-being alludes to individuals' cognitive and enthusiastic assessments of their lives. It incorporates decisions eg. life fulfillment, pleasance feelings and less unsavory passionate encounters like discouragement.[10]As we learn we create inward qualities and qualities which furnish us with a solid inner locus of control and assembles our confidence. Studies have demonstrated that youngsters who experience a more significant level of emotional prosperity have improved inward locus of control. It has been said that adolescence is the time of "growing up" and early adulthood is the ideal opportunity for "settling down".

Materials and Method

Participants and Procedure

This study examined the profile of character strengths and well-being of adolescents enrolled in a school in National Capital Region of India and who participated in a psychological study for middle school students. The data was obtained from 300 adolescents, 100 each from class 6, class 7 and class 8, further comprising 50 boys and 50 girls from each grade class. This study was approved by the school board of the participating school. Students are represented by various regional, religious, cultural, environmental differences. In general, it was ensured that student participation depends on the availability of permission from parents and the sole interest of the student to participate. All the participants and their parents/ guardians were informed about the purpose of the study and were enrolled after obtaining their written informed consent. The questionnaires were mostly administered in groups of sizes varying between 10 and 30, under the supervision of the research staff.

Measures

The Values in Action Inventory (VIA) Classification describes 24 Character strengths that are thought to be the fundamental building blocks of character. These building blocks are universally considered to be qualities that define and lead people being their best. Character strengths are defined as capacities for thinking, feeling and behaving. Every person possesses each of these 24 Character strengths in different degrees, resulting in unique profiles that constitute the rich array of human personalities we observe. Adolescents completed the Revised Values in Action Inventory of Strengths for Youth (VIA Youth; Park & Peterson, 2006), designed for young people (ages 10–17). The questionnaire consists of 198 items that adolescent's rate on a Likert scale ranging from 1 ('Not like me at all') to 5 ('Very much like me'). Sample items on the VIA-Youth include 'I often tell my friends and family members that I love them' (love), 'I am very careful at whatever I do' (prudence),and 'I like to tell jokes or funny stories' (humor). The VIA Youth strength scales have been standardized and justified for the Indian adolescents under study demonstrated good internal consistency (with Cronbach alpha 's ranging from 0.72 to 0.93)

The psychological Well-being (PWB) scale comprises of 50 statements developed by Dr. Devendra Singh Sisodia with a view to measure several aspects of well-being vis. Satisfaction, Efficiency, Sociability, Mental Health and Interpersonal Relations. All statements are of positive manner developed using Likert criteria wherein the ratings are described as 1 '(Strongly Disagree)' to 5 '(Strongly Agree)'.This scale is useful in a variety of research and applied settings such as quality of life index, a mental health status appraisal and a measure of psychotherapy outcome evaluation and a social indicator of measuring population changes in sense of well-being over time.

Statistics

Descriptive Analysis was used to summarize which direction whether Disagree or Agree targeted students representing the population under study, are concluding their opinions. Internal consistency was examined for scale and subscale's using Cronbach alpha. Due to the nature of the study and moreover since Likert scale is used for self-assessment of both character strength and well-being dimensions non-parametric correlation analysis was performed using Spearman's rho to explore

the strength of relationship between them.

Results

The current research was conducted to study subjective well-being and character strength among Indian youth. Internal consistency reliabilities and descriptive statistics for the study variables are presented in Table 1 and Table 2. The results of correlational examination are presented in Table 3. The self-assessment of VIA character strengths amongst adolescents revealed that topmost virtues are Humor, Fairness, Kindness, Perseverance and Love. Likewise, the bottom most virtues are found to be Prudence, Honesty, Self-Regulation, Forgiveness and Curiosity.

Findings state that the character strength measures vis. Prudence, Honesty, Self-Regulation, Forgiveness, Curiosity, Courage, Leadership, Social Intelligence, Humility, Teamwork, Hope, Judgment and Gratitude have a positive and significant correlation with satisfaction, efficiency, sociability, mental health, interpersonal relations and overall with the formation subjective well-being at 0.01 level. However, Perspective, Creativity and Appreciation of Beauty have a positive and significant correlation with fewer of the well-being measures. Opposing the dimensions Spirituality, Zest, Love of Learning, Humor, Fairness, Kindness, Perseverance and Love showed no relationship with subjective well-being and it's formative measures.

Discussion

As far as we could possibly know, youthful to adulthood transition has been a sacked process in the formation stages of their character qualities. Recognizing the importance of its association with well-being, determining virtues that promote such developmental process is deemed significant and integral. Youthful adulthood might be described as the period that is set apart by solidification of one's personality on one hand and the accentuation on dominance of various ecological requests on the other. The developing acknowledgment of the requirement for programs for positive youth advancement makes the evaluation and improvement of character qualities an exceptionally significant exercise in the present situation. The positive youth improvement approach underlines on enabling youth to be the specialist of their own development with grown-ups propelling the revelation of their possibilities.[11] An investigation of character qualities and their applications during this period along these lines expect high significance, because of its suggestions for prosperity of the young, just as for psychological well-being advancement. In the above setting, the present examination as planned and determined for looking at the profile of character qualities in Indian youth, featuring the qualities that are most supported by them. Encounters containing positive feelings in this manner prompts higher life fulfillment. Diener (2000) clarified well-being as "peoples' evaluations that are both affective and cognitive".[12] In positive brain science (psychology), pleasure is communicated utilizing the term 'well-being' which is a multi-dimensional construct. Character strengths form the foundation where a person's personality that grows step by step with time. Previous researches expresses that high psychological well-being correlates with the absence of mental and social issues like state of mind issue and useless family connections, and such people are in every case better at critical thinking, execution at work, opposing pressure and more beneficial in contrast with others.[13&14]Utilizing correlational investigation, the present examination supported and found that psychological well-being is noticeable among youth. The finding can be credited to the formative parts of a person with respect to constructive mental development. Maturing is identical to development that prompts development. Development creates, with various encounters which people experience during their life span. Maturing is identical to development and is framed on a person's characteristic qualities.

Future Implications

Future research will recognize the systems by which the VIA character qualities increment well-being. Such research is probably going to have significant ramifications for intercession and counteractive action work. Implementing character strength development in turn well-being interventions and programs in the school curriculum not only increase subjective feelings of happiness among students, but also protect them against the negative effects of stress and the development of psychopathological problems.[1] &[15]Research has demonstrated that certain strengths of character are linked with increased life satisfaction, decreased psychopathology, fewer internalizing and externalizing behavior problems and academic achievement.[16] A promising approach to increase well-being among adolescents is through positive psychology interventions – that is, intentional activities that aim to cultivate positive feelings, behaviors, or cognitions.[17] Moreover, strengths can be clearly cultivated and strengthened through regular activity and application in life.[18]Along these lines, advancement of positive mental character qualities based interventions that can be used as a major aspect of the school educational plan is an auspicious interest.

Conflicts of Interest: Authors declare no conflict of interest.

Dental Health Handbook as Parents Monitoring in the Formation of Independence for Brushing Teeth in Early Childhood

Ngatemi[1], Tedi Purnama[1]

[1]*Lecturer Departement of Dental Health, Ministry of Health Polytechnic Jakarta I, South Jakarta, Indonesia*

Abstract

Oral health problems that many have encountered are dental caries and periodontal disease where the prevalence of dental caries of children aged 5-6 years by 93% with def-t index of 8.43. Such conditions do not meet the WHO target and FDI is 50% of children aged 5-6 years free of dental caries, it is because children are not capable of independent activity in brushing teeth. Proper behavior change strategies can be done by providing dental health education by parents. Dental health handbook could be a learning brushing teeth in efforts to establish the independence of brushing their teeth in early childhood. This study aims to effectiveness of dental health handbook as monitoring the parents in the formation of independence of brushing teeth in early childhood. Method: This study uses quasy experiment with pretest and posttest design with one group, by providing dental health guide books and training to parents. This research was conducted in PAUD Fatahillah Pangkalan Jati Depok. The independent variables: dental health guide books, variable between: knowledge and attitudes of parents and the dependent variable: the skills brushing teeth free of plaque and score early childhood. Data were tested using a paired sample test and wilcoxon. Result: the provision of dental health handbook effectively improve the knowledge and attitudes of parents ($p < 0.001$) and effectively to the improvement of skills brushing teeth and a decrease in plaque score ($p < 0.001$). Conclusion: effective dental health handbook as monitoring the parents in the formation of independence of brushing teeth in early childhood.

Keywords*: dental health handbook, independence brushing teeth, early childhood*

Introduction

Oral health is for general health, meaning that if someone toothache then general health will be disturbed. Oral health problems that many have encountered are dental caries and periodontal disease.[1-3]

Dental caries is a disease in hard tissue of teeth that is characterized by the breakdown of enamel and dentin caused by the metabolic activity of bacteria in plaque that causes demineralization. Dental caries if left untreated will cause periodontal infection. Bacteria periodontal pathogens are inflammatory mediators which then enter the bloodstream, causing systemic disease, such as: increasing the risk of heart attack, stroke risk, increase the severity of diabetes, respiratory diseases, preterm labor, rheumatoid arthritis, osteoporosis, pancreatic cancer, kidney disease and interfere with the system digestion, especially in children. Dental caries in preschool children is commonly known as early childhood caries, because the enamel of primary teeth is thinner than permanent teeth, so it is more susceptible to dental caries.[4-7]

Dental caries in Western Australian Aboriginal children aged 1-4 years especially preschool disease is number 5 of the disease to be treated from the hospital. According to Kwan in Santoso (2017), more than 50 million hours of school per year is lost as a result caused

by toothache in children who have an impact until the life of an adult, meaning that dental caries in preschool years greatly affect the quality of life of children and growth.[8, 9]

Riskesdas in 2018 proved that the prevalence of dental health of children aged 5-6 years by 93% with def-t index of 8.43. Such conditions do not meet the WHO target and FDI is 50% of children aged 5-6 years free of dental caries.[9, 10]

One cause of the high prevalence of dental caries for dental health maintenance behaviors are less than the maximum, this is evidenced Indonesia's population had brushed his teeth with the categories of behavior really only reached 2.8% and by 2.8 West Java Province.[10, 11]Efforts to prevent the occurrence of dental caries can be done through the behavior of most major dental maintenance and recommended by way of brushing your teeth. That is the simple act of brushing teeth to remove plaque and food debris with a toothbrush and toothpaste, because plaque and leftover food is a major cause of dental caries, therefore it is necessary to build a habit of brushing their teeth at an early age.[12,13]

Early childhood is a "golden age period", meaning the golden period for all aspects of human development, whether physical, emotional and social cognition, where the development of intelligence in this period increased by 50%. Early childhood is the ideal time for a child's motor skills, including brushing teeth, so that will cause a sense of responsibility for the cleanliness of himself.[14]

Changes in a child's behavior depends on the ability of adaptation to the stimulus response beyond himself. It fits in the Roy adaptation theory (Sari et al, 2012) suggests that changes in a person's behavior depends on the incoming stimulus and adaptability of the person, that is to say through the right stimulus and the appropriate development of children, will help in entering the next phase of development is well. It is also affecting the child's behavior change is a stimulus from the environment, namely the involvement of family members. Through the active participation of parents it will be better the child's behavior in brushing teeth and guidance of parents in brushing teeth to prevent dental caries.[13, 15, 16]

Dental health guide books selected as the media for dental health education because it can accommodate writing and drawing in large numbers so as to help parents who have young children in maintaining their oral health. The use of guide books can also be motivated to instill a sense of responsibility for the maintenance of oral health of their children. This is evidenced research Darwis et al (2011) that the use of guide books can improve the status of early childhood dental hygiene.[17,18]

Based on this background, researchers interested in proving that the administration of dental health handbook as monitoring the parents in the formation of independence of brushing teeth in early childhood.

Method

The method used in this study is quasy experiment with the design of pre- and post-test with one group design. The experiment was conducted in PAUD Fatahillah Pangkalan Jati Depok during September and October 2019. Samples were taken with total sampling, as many as 46 students and 46 parents. The independent variable in this study are dental health handbook, the between variable is parents' dental health behavior (knowledge and attitude) and the dependent variable is the independence of brushing and plaque score early childhood.

Data collection knowledge and attitudes of parents measured the questionnaire with the following activities: pre-test, training and provision of health handbooks in the elderly and post-test. In early childhood intervention for 10 days with details of activities as follows: pre-test, intervention by parents and post-test measurement tool is a checklist sheet brushing and plaque index measurement sheets. The research data using a ratio scale statistical test, if normal data using a paired sample test, while not normal using wilcoxon test.

Results

Research result shows that the respondents to the age of 4 years as many as 4 children (8.7%), aged 5 years as many as 18 children (39.1%) and the age of 6 years sebnyak 24 children (52.2%). While respondents male sex as many as 18 children (39.1%) and female gender of respondents were 28 people (60.9%), he explained in the following table 1.

Table 1. Characteristics of respondents

No	Variables	Total	Percentage
1	Age		
	4 years	4	8.7
	5 years	18	39.1
	6 years	24	52.2
2	Gender		
	Male	18	39.1
	Femele	28	60.9

Table 2. The mean value of plaque index of children, knowledge and attitudes of parents

No	Variables	Mean	SD	Min-Max
1	Tooth brushing skills			
	Pre-test	4.37	1.142	3-7
	Post-test	8.48	1.110	6-10
2	Children's plaque index			
	Pre-test	36.22	10:50	12-60
	Post-test	26.83	9291	10-48
3	Knowledge parents			
	Pre-test	7:28	1.760	5-11
	Post-test	10:07	1.806	7-13
4	Attitude parents			
	Pre-test	36.41	8.798	25-35
	Post-test	50.33	9.031	55-65

Table 2 shows the average value of the value of the skills children brushing their teeth increased from 4.37 became 8.48. The value of the index on the child plaque scores decreased from 36.22 into 26.83. The average value of the knowledge of parents has increased from 7.28 into 10.07, and the average value of parents' attitudes also increased from 36.41 into 50.33.

Table 3. Test of normality

No	Variables	Pre-test	Post-test
1	Tooth brushing skills of child	0.000	0.001
2	Plaque index of child	0.184	0.067
3	Knowledge of parents	0.001	0.008
4	Attitude of parents	0.001	0.008

** Shapiro-Wilk*

Table 3 shows the results of the normality test for the plaque index score of children with normal distribution because the p-value >0.05 then proceed parametric test, while for the results of the child's teeth rub skills, knowledge and attitudes of parents are not normal distribution because the p-value of <0.05 so non-parametric test.

Table 4. Test the effectiveness of the knowledge and attitudes of parents and after intervention

Variables		Mean ± SD	P-value
Knowledge	Pre-test	7.28 + 1.760	0.001
	Post-test	10.07 + 1.806	
Attitude	Pre-test	36.41 + 8.798	0.001
	Post-test	50.33 + 9.031	

** Wilcoxon*

The results of the effectiveness test given knowledge before and after treatment showed that the p-value was 0.001 (p <0.05) means that the provision of dental health handbook effectively improve the knowledge of parents and the p-value the attitude of parents is 0.001 (p <0, 05) means that the provision of dental health handbook effectively improve the attitudes of parents.

Table 5. Test effectiveness skills brushing teeth plaque index scores before and after intervention

Variables		Mean ± SD	P-value
Tooth brushing skills *	Pre-test	4.37 + 1142	0001
	Post-test	8.48 + 1.110	
Plaque index **	Pre-test	36.22 + 10.50	0001
	Post-test	26.83 + 9.291	

** Wilcoxon ** Paired Sample Test*

The results of the effectiveness test of skills brushing teeth before and after treatment showed that given the p-value was 0.001 (p <0.05) means that the provision of dental health handbook in older people effectively improve the skills of early childhood brushing teeth and plaque index score of p- value is 0.001 (p <0.05) means that the provision of dental health handbook in older people effectively lower the score the plaque index in early childhood.

Discussions

Provision of dental health guide books and training to parents do to improve the knowledge and attitudes of parents in the maintenance of oral hygiene. According to Santoso (2017), is a dental health maintenance training activities planned through the learning process that aims to provide knowledge, inculcate and practice the skills until someone can independently perform maintenance actions oral hygiene.[9]

The result of the effectiveness of variable data and knowledge of dental health maintenance attitude of parents shows that the p-value 0.001 (P <0.05) means that dental health guide books effectively improve the knowledge and attitudes of parents in raising their children's oral health. Improved knowledge and attitudes caused by the guidebooks can be learned in time at any time, parents can actively learn independently so that the retention of material oral hygiene maintenance can easily catch. Health education is essentially a business activity or health messages to the community, group or individual. With the training given, respondents get the learning that results in a change from the previously unknown becomes known, the former did not understand being understood. This study is also consistent with the results of research Amin (2014) found a positive effect of dental health education to changes in values, attitudes and actions of parents to maintain their children's oral health.[19, 20]

Besides given a guide book, parents who have given their dental health maintenance training because then parents will be monitoring the activities of brushing teeth as efforts to establish the independence of children brushing their teeth. According Subekti (2017) assisting parents in toothbrushing influence behavioral change brushing and dental hygiene level of the child.[21]

The results of the effectiveness test the skills of data brushing teeth showed p-value was 0.001 (p <0.05), meaning that the provision of dental health guide books in older people brushing their teeth effectively improve the skills of early childhood. Intervention during 10 days of brushing teeth effectively improve the skills of young children because parents provide mentoring children in the learning process of brushing his teeth, parents and children directly involved in how to brush their teeth properly. This is in line with research Purnama (2019) mentoring brushing teeth for 10 days by a parent can shape the behavior of preschool children brushing their teeth. This success has also seen an increase in plaque

free scores of children. The results of the effectiveness test data indicate that the p-value was 0.001 ($p < 0.05$), meaning that the provision of dental health guide books to parents free of plaque effectively improve the scores of children. Score plaque free early childhood has increased since the sample has been taught to understand the practice to brush their teeth. Practice brush their teeth will be able to remove plaque. Research Raj (2013), proving that brushing your teeth with the correct technique will improve oral hygiene preschoolers.[22, 23]

Conclusions

Based on the results research, it can be concluded that:

1. Dental health handbook is effective in increasing knowledge of parents' oral health maintenance. This was proven significantly

2. Dental health handbook is effective in increasing the attitude of maintaining oral health of parents. This was proven significantly

3. Dental health handbook is effective as a monitoring for parents in the formation of independence in brushing teeth at early childhood. This was proven significantly

4. Dental health handbook is effective as monitoring of parents in reducing index plaque scores in early childhood. This was proven significantly

Women's Mental Health in India: An Analysis through the Gender Lens

Parismita Bhagawati

Designation: PhD Research Scholar, Political Science, Cotton University, Panbazar, Guwahati, Assam

Abstract

As opposed to the traditional biomedical view of health, the social model of health defines it essentially, as a positive concept which significantly hinges on and is impacted by the social settings, personality of the individual , as well as physical capacities.' It is in this context, mental health issues among women in general and Indian women in particular, as a subset of the larger corpus of health concerns needs to be inevitably understood and contextualised in the societal and cultural milieu within which women operate. One of such important societal constructs that seems to have a significant impact on mental and emotional health and experience of women is the the construct of gender and its corollaries like gender roles, expectations, demeanour, stereotypes etc. The social construct of gender engineers a woman's position in the social hierarchy and also has a prominent bearing on her social and personal life experiences. Consequently, socio-cultural context and gender need to be understood as powerful decisive factors of one's mental and emotional make-up that colludes with other variables like age, family, educational attainment, occupational structure, income and social support etc. The paper attempts to study the mental health concerns among women in India by especially, trying to locate its causes in the socio-cultural factors amid which the women live. Conclusively, the paper tries to highlight various suggestions for developing holistic solutions towards the improvement of mental health of women.

Keywords: *Mental health, gender, domestic violence, social model of health*

Introduction

The World Health Organization's Ottawa Charter for Health Promotion (1986) sees health as multidimensional and espouses a social model of health. It defines health as 'a positive concept emphasising social and personal resources, as well as physical capacities.' In the social model of health, while human biology, physiology and health care are considered as important elements, besides these, it incorporates within its purview a variety of other variables and factors that have the potential to impact the health of an individual. These factors range from social and cultural attributes, political environment, economic and financial factors, psycho-social factors to various other inter-personal and environmental factors as well as their reciprocal communications that might lead to health or illness. Therefore, the concept of health is definitely not unidimensional, it is multifaceted and involves multiple causal factors and similarly, the concept of women's mental health is no exception.

The inevitable foremost step towards sculpting a socially-rooted and contextualised model for improvement of women's mental health is figuring out a definition of mental health that can be usefully applied to women. The 1981 WHO report on the social dimensions of mental health, states that: ***'Mental health is the capacity of the individual, the group and the environment to interact with one another in ways that promote subjective well-being, the optimal development and use of mental abilities (cognitive, affective and relational), the achievement of individual and collective goals consistent with justice and the attainment and preservation of conditions of fundamental equality.'***

This definition is apt for a holistic understanding of women's mental health because it:

- emphasises the intricacies of mutuality and interrelations among a host of variables that that determine mental health and that the determinants of health function at multiple stages.

- looks and reaches beyond the 'biological' and 'individual' concedes the significance of the society and the 'social'

- Acknowledges the primal importance of values and principles of justice and equality in configuring mental and emotional well-being.

The social construct of gender engineers a woman's position in the social hierarchy and also has a prominent bearing on her social and personal life experiences. Consequently, socio-cultural context and gender need to be understood as powerful decisive factors of one's mental and emotional make-up that colludes with other variables like age, family, educational attainment, occupational structure, income and social support etc.

Objective and Method

The primary motive of the paper is to study the present scenario of women's health in India. This research paper whilst trying to enquire into the status of women's health, particularly, tries to understand and highlight the role of the contextual socio-cultural factors and gender constructs that operate in society; in serving as determinants of women's mental health. To this effect, a predominantly qualitative research approach has been adopted to critically inquire into the topic at hand. Data at all stages are secondary in nature and garnered from a variety of published sources. A thorough study of journal articles, newspaper and government health reports, books relevant to the topic has been undertaken. The methodology of data analysis is descriptive, explorative and analytical whereby observations, facts and ideas relating to women's mental health indices and conditions corresponding to the socio-cultural patterns and process of gender socialisation operating in the society are recorded and systematically presented in the prescribed format.

Findings and Discussions

The findings of the study have been presented and discussed in various sections dealing with various related observations and ideas. The first concrete finding of the study is the inevitable relationship shared by the social realities and indicators of women's mental health . The next section discusses exclusively the gender specific risk factors that have a significant bearing on women's mental health. The subsequent sections deal with mental health issues like prevalence of suicide among women with special emphasis on locating the socio-economic and gender identities and positionalities of women as a determinant. In the final analysis, on the basis of various suggestions as presented by credible health organisations and reports that might prove beneficial in improving mental health of women, a future roadmap to a holistic solution to the mental health crisis among women has been forwarded.

The Indian social reality and women's mental health

It has been evident that women in modern India face a paradoxical situation[1]. While women are increasingly making inroads into erstwhile male-dominated professions and admirably hiking up the corporate hierarchy, there is still a sizeable section of Indian women languishing without any sense of their identity or any form of human rights. Although, the government is striving hard to bring in women-centric legislations and devise policies for women empowerment and uplift, what is happening in ground reality remains unaffected; women still in a very large number and in variegated ways receive systemic discrimination in society. Patriarchy as the basis of India's social functioning operates within a web of norms that possess an inherent tendency to disempower and control women's every aspect of life. The women in India having to survive and grow up in such an environment and simultaneously having to do their best and live up to their own best potential as well society's expectations from her, proves to be a burdensome toil for all women throughout their life-cycle. This can often lead to emotionally explosive situations wherein women start experiencing mental health problems. Indian society is in an indecisive phase of passage from traditional to modernity, while new modern liberal values are being circulated and are afloat in the socio-cultural milieu, they have not been able to completely eradicate and displace certain old parochial traditional values that are endemically gender discriminatory; This kind of gender discrimination reinforces women's feeling of social disadvantage and further aggravates their psychological conditions[1].

Gender–specific risk factors featuring in women's mental health scenario

Gender plays an important role when it comes to deciding women's mental health. Gender also determines one's ability and capacity to avail various resources and facilitates. Self evaluation, self concept, self image, styles of interpersonal interactions, spirituality, mechanisms of

coping with stress, needs, expectations and all the other individual differences are, up to some extent determined by gender.

The mental health issues of women are a result various gender based risk factors like; violence, low income, income inequality, care giving responsibility, role stereotyping and etc. Mental disorders commonly seen in women are depression, anxiety, somatic complaints and eating disorders. The various atrocities faced by women like sexual violence, domestic violence and issues of multiple roles, overwork fairly contribute to mental disorders they suffer from, resulting in poor mental health. A positive correlation has been established between the scales of these social variables and the occurrence of mental disorders in women.. However, the taboos related to mental health issues and the differential treatment of genders stand as an obstacle in stimulating adequate mental health development and care amongst women.

Gender and Depression

"In 1977 Weissman and Klerman reviewed the evidence for differing rates of depression between the sexes, in the United States and elsewhere, during the previous forty years. They found that studies showed women experienced depression at rates much higher than men,"[12] The higher occurrence of depression in women cannot be solely attributed to biological factors. The social and culturally dictated mores and gender roles too have a part to play in propelling depression in women. The unequal power status cemented by the prevailing patriarchal social system has resulted in women reeling under a vicious circle of feminisation of poverty where women more often find themselves stuck in a state of economic deprivation inciting feelings of helplessness and hopelessness. Due to the advantages bestowed upon by globalisation and acceptance of liberal values, women now are able to make inroads into the public sphere breaking the patriarchal shackles ordaining them to relegate and confine themselves to the domestic sector only. While women are moving up the corporate ladder and marking their place in the public sphere, this does not necessarily entail that they have been liberated from the confines of domesticity. The perplexity reality is that the educated and working women today end up shouldering an excessive double burden of both work and domestic chores whisking away all of their personal time and energy, finally taking a toll on their emotional well-being. Additionally, gender crimes like sexual violence, domestic violence, eve-teasing , stalking which is a common occurrence in India cumulate to act as catalysts for mental diseases.

Women and suicide

There appears to be deeper connexion between gender and suicidal behaviour. Factors like childhood abuse, marital rape, domestic atrocities play a significant role in goading suicidal behaviour among women. A socio-cultural variable responsible for female suicide typical to Indian society is the practice of dowry in marriages. There are legislations in place that prohibit dowry dealings in marriages in India. In spite of this, the practice of dowry-related disputes still remains a leading cause of women's atrocities and death. Failure to meet dowry demands in many cases, leads the bride to be forced to commit suicide or even killed by the in-laws. "The precipitants for suicide, according to Indian government statistics, among women compared to men are as follows: Dowry disputes (2.9% versus 0.2%); love affairs (15.4% versus 10.9%); illegitimate pregnancies (10.3 versus 8.2); and quarrels with spouse or parents-in-law (10.3% versus 8.2%). The common causes for suicide in India are disturbed interpersonal relationships followed by psychiatric disorders and physical illnesses"[7].

Gender-violence

"According to an eye-opening United Nations report, around two-third of married women in India were victims of domestic violence and one incident of violence translated into women losing 7 working days in the country. Furthermore, as many as 70% of married women between the ages of 15 and 49 years are victims of beating, rape or coerced sex."[9] Female Indian psychiatric patients share a serious concern of sexual coercion. "Sexual coercion was reported by 30% of the 146 women in an Indian study. The most commonly reported experience was sexual intercourse involving threatened or actual physical force (reported by 14% of women), and the most commonly identified perpetrator was the woman's husband or intimate partner (15%), or a person in a position of authority in their community (10%)."[11]

Gender-based violence can cause untold sufferings and permanent damage to one's emotional and psychological well-being. Resultantly, women as victims of violence, suffer from emotions despondence and

stress, post-traumatic stress disorders, fertility problems and other variants of psychosomatic diseases etc

Suggestions for promotion of mental health among women

Women make up half of the human resource repository in India. Therefore, ensuring good mental health and emotional well-being of the women is quintessential to the country's progress and development. As we have been discussing, societal impositions, expectations, bindings, control, gender roles and stereotypes in Indian society impacts significantly on the emotional and mental well-being of a woman throughout her life-cycle- as a young girl, teenager, adult, married woman, mother and also as an older woman. Therefore, it is very important to undertake efficient intervention and assistive strategies to promote and sustain women's mental health under the prevailing social conditions.

Various suggestions for a preventive, protective, remedial and promotional framework for women's health in India can be advocated as follows:

- constructing evidence-based knowledge on the causative factors and extant of women's mental health issues as well as on the interceding and defensive factors. ;
- Policy stage interventions to efficiently sculpt policies that are sensitive and responds to women's mental health needs from childhood to old age and take steps for speedy and effective implementation.
- Calibrate and strengthen the capacities of primary healthcare providers enabling them to address and cure mental health consequences in victims of domestic violence, abuse, sexual assault.
- Promoting action research initiatives in the field of women's mental health.
- Promoting awareness of mental health issues and its curability among women to de-emphasise and eradicate its taboo nature in Indian society.
- Disseminating useful information of health care services and legal consequences and the various rights available to women against evils of rapes, sexual assault, domestic violence, stalking and other such crimes.
- "collaborating with international agencies and organizations to reduce/eliminate intimate partner and sexual violence globally."[10]

The health care services available to women need to gender sensitive taking cognisance of the special needs of women in terms of the differential social roles they play along. Gender-mainstreaming in health care services is a pre-requisite for offering timely and effective remedies against women's mental health concerns.

Conclusion

Therefore, it has been made inarguably clear that women's mental health is not a lone impervious variable, it has to be considered in association with their socio-cultural context and gender roles . Any policy or mere discussion on women's health concern should involve her emotional and mental well-being along with her physical health at all stages of her life. It is a common occurrence where policies in India view women's health very narrowly in terms of reproductive and maternal health solely. Such a constricted policy worldview in India has greatly contributed towards reinforcing the idea that women only exist as mothers and procreators. Moreover, when an individual woman suffering from a certain mental health concern is focused in isolation as a singular independent biological entity divorcing her condition from her sociological realities, it runs a risk of placing the burden of reformation on the women alone. But as we would agree that change for women is well beyond their control and is possible only with a bigger positive social transformation. Given these realities, it becomes imperative to undertake stratagems and schemes that would target the social factors responsible for having a degrading impact on women's health. Such strategies may involves social policies to reduce gender gaps in all fields of social existence, enhance women's status in society by giving them their due or at least empower and educate them enough that they are able to voice out their demands and grasp their rights for themselves. Although a large portion of the responsibility of change lies on the policy makers but women in India too must speak up to bring about the change they want in their lives. There are ample instances where women have taken on a social-acvitist vesture to fight off their own devils, for instance, the anti-arrack movement in Andhra Pradesh where they fruitfully succeeded in fighting off liquor addiction in their husbands and wife battering. Movements on the same line for fighting evils of sexual abuse, rape etc can go a long way in remedying the unjust social circumstances under which women live in India. "In summary, concerted efforts at social, political, economic, and legal levels can bring change in the lives

of Indian women and contribute to the improvement of the mental health of these women."[4]

Transmission of Actinobacillus Actinomycetemcomitans & Porphyromonas Gingivalis in Periodontal Diseases

Prabhu Manickam Natarajan[1], Sura Ali Ahmed Fuoad Al Bayati[2], Dusan Surdilovic[3]

[1]Associate Professor in Periodontics & Specialist Periodontist, [2]Associate Professor in Oral Medicine and Associate Dean, [3]Associate Professor and Head of Pediatric and Preventive Dentistry, College of Dentistry, Gulf Medical, University, UAE

Abstract

Periodontitis is one of the most common bacterial infections in humans. The disease is a consequence of destructive host immune responses to pathogenic bacterial species resulting from the dysbiosis of oral microbiota. Criteria for defining periodontal pathogens have been developed and include association, elimination, host response, virulence factors, animal studies and risk assessment. The bacteria associated with periodontal diseases are predominantly gram-negative anaerobic bacteria and may include A. actinomycetemcomitans, P. gingivalis, P. intermedia, B. forsythus, C. rectus, E. nodatum, P. micros, S. intermedius and Treponema sp. The bacterial numbers associated with disease are up to 10(5) times larger than those associated with health. The transmission of A. actinomycetemcomitans and P. gingivalis is discussed in this article.

Keywords: *Transmission, bacteria, A. actinomycetemcomitans, P. gingivalis, periodontal disease.*

Introduction

Bacteria inhabit the oral cavity in various concentrations. They colonize the soft tissues including the gingiva, cheeks, tongue and in the presence of teeth, bacteria colonize them both supra and sub gingivally. It is estimated that between 300-400 different species can colonize the oral cavity and an individual may typically harbor 150-200 different species. In the subgingival areas, bacterial concentrations range from about 10^3 in healthy shallow sulci to $>10^8$ in deep periodontal pockets. Among these microorganisms, about ten to 80 different species are capable of inducing or initiating periodontal disease.

The healthy and diseased clinical areas have been examined for the presence of microorganisms. Many researches have been done in this regard. It was found that in clinically healthy sites, streptococci, facultative species of Actinomycetes [esp. A.*viscosus* & A. *naeslundi*], Rothia *dentocariosa* account for about 85% of the total cultivable flora. Small proportions of gram-negative species including Prevotella *intermedia*, Fusobacterium *nucleatum*, Capnocytophaga, Niesseria and Veillonella species are also found most frequently in the subgingival areas. Microscopic studies prove the presence of a few spirochetes and motile rods in these diseased areas. The ratio of non-motile forms to motile forms in health is 40:1.

Periodontal disease has been proved to have a complex etiology. When the microbial etiology is concerned, the obligatory anaerobic species Porphyromonas *gingivalis* (**P*g***), Prevotella *intermedia* and Peptostreptococcus *micros* and the facultatively anaerobic species Actinobacillus *actinomycetemcomitans* (**A*a***) and Campylobacter *rectus* are regarded as principal periodontal pathogens today. Most individuals have acquired strains of suspected periodontal pathogens at some time in their lives which may or may not lead to periodontal disease. The progress of the disease depends on the resistance offered by the host. It has been quoted that the subgingival species found in humans are unique to that environment.

Transmission of periodontal pathogens occurs through various means which are to be discussed in this article. The typical pattern requires the transmission of periodontal pathogens from the oral cavity of one individual to the oral cavity of another. A major focus of this article is to provide a critical review of selected studies on the transmission of A. actinomycetemcomitans and P. gingivalis which are the prime periodontal pathogens of a chronic periodontitis. The information may be used in the future to decrease the susceptibility to oral infection by A. actinomycetemcomitans and P. gingivalis and to arrest transmission of these pathogens to uninfected individuals.

Transmission of Periodontal Microbes

During recent decades, it has become evident that gingivitis and chronic periodontitis are the most common form of periodontal diseases seen in the population. This might be due to various reason including hereditary, habits, oral hygiene maintenance, susceptibility to infections and the presence of systemic diseases. Apart from this, environmental factors have been documented to influence the development of periodontitis. Besides plaque, it is proposed that the development of periodontal disease and its severity depends on the presence of a critical number of more putative periodontal pathogens. It is well established that periodontal pathogens cluster in families. This suggests that bacteria are transmitted between family members or that family members share susceptibility to colonization by these bacteria. Keeping the above statement in mind, two types of transmission are recognized including vertical transmission between parents and children[2,4] and horizontal transmission between siblings and between spouses. The latter may have consequences for the periodontal condition of a subject who marries a periodontitis patient harboring A. actinomycetemcomitans and P. gingivalis. If the spouse has poor oral hygiene and gingivitis, transmission of these bacteria may lead to conversion of gingivitis to periodontitis. This hypothesis is supported by the results of a recent study, which showed that spouses of severe periodontitis patients had a worse periodontal condition in comparison to spouses of periodontally healthy subjects.[9]

Techniques to Study the Transmission of Pathogens:

The mechanism of transmission of microorganisms has been studied thoroughly for generations. Different concepts of periodontal disease progression had been hypothesized and data had been published about the same. Evidence for both forms of transmission has been provided using molecular epidemiology techniques like REA (Restriction Endonuclease Analysis), AP-PCR (Arbitrary Primer-Polymerase chain reaction), serotyping, ribotyping, etc. The DNA is cut with restriction endonucleases, run on agarose gel electrophoresis and the resulting fingerprint patterns are compared either directly or with the help of various DNA probes. Through DNA probing technique.

A. actinomycetemcomitans and P. gingivalis frequently occur as monoclonal infections in the oral cavity. Other periodontal bacteria may show extensive genetic diversity. It was found that nearly 67%-80% of Aa species and 75%-85% of Pg species from most infected people are monoclonal in nature.

Transmission of Actinobacillus Actinomycetemcomitans

Actinobacillus actinomycetumcomitans (Aa) is a gram- negative, facultative, capnophilic coccobacillus suggested as playing a key role in the pathogenesis of several forms of periodontal diseases. Its possible exogenous origin has also been discussed recently**.** The evidence pointing to Aa as an exogenous pathogen in humans indicates the importance of understanding its mechanism of transmission.

This bacterium and elevated serum antibody titers against it have been associated with periodontal diseases including prepubertal, juvenile and adult periodontitis and refractory cases. However, this bacterium can also be detected rather frequently in periodontally healthy teenagers and even in children with primary dentition. Aa. may belong to the normal oral microflora. The occasional recovery of the organism in low proportions of the flora from healthy gingival sites and in periodontally healthy individuals supports the view of the opportunistic nature of infections associated with Aa.

Aa is acquired early in life from one or the other parent and is less likely to colonize the subject after reaching a certain age. Transmission of Aa to an established flora may be difficult in a healthy person where protective immune mechanisms and microbial antagonistic process are intact. However, it is possible that once anti-infective therapy is instituted, a new microbial ecology may be established in the oral cavity, which will more easily allow transmission of Aa.

When the resistance offered by the host decreases, bacterial transmission happens at a faster pace. It results from a combination of a sufficiently large and concentrated inoculum of the bacterial species enabling its survival during colonization, combined along with the environment where the recipient's macro and microenvironment accepts the intrusion of an microorganism; or in other words, the intruding microorganism evades the host defense and proceeds to infect the organism. These factors are again dependent on the behavioral patterns of the family members (i.e.) hygiene, proximity and differences in these practices among different family members. Therefore, theoretically any combination of acquisition or transmission between spouses and between parents and children exists. There are phases like periods of stress, when adults are more susceptible to bacterial infections, and when local changes promote the acquisition of the disease-causing bacterium because of decreased resistance, which enables bacterial transmission to occur.

Disease progression is most commonly seen in populations with low socio economic and educational levels as they in general maintain lower standards of oral hygiene as sprove din study by Preus *et al* (1994) and Tinoco *et al* 1988[7]. Although intra familial transmission of Aa has been demonstrated by Zamben *et al* it appears likely that transmission of pathogens also occurs between unrelated individuals Socransky & Haffajee described the transmission of ANUG both within troops in trenches in world war I and in communities outside the war zone, after world war I. If such reports are accurate, then it appears that periodontal pathogens can be transmitted rather readily, perhaps even on casual contact. Thus, while there has been an intuitive feeling that the oral microbiota is relatively stable within an individual, it seems likely that new species or different clonal types of the same species can be introduced into an individual at various stages of his on her life. If the newly acquired strain is more virulent than the preexisting strain of that species, then a change in disease pattern could occur.

Transmission of Porphyromonas Gingivalis

Porphyromonas gingivalis (Pg) is a bacterial species, which is specifically associated with severe periodontitis lesion in adults. In subgingival areas harboring Pg, it often comprises a relatively large part of the microbial flora. In healthy sites and in gingivitis sites, the isolation frequency of this species is low. The microorganism is quite uncommon in children although it can be seen in children with aggressive type of periodontitis. It was demonstrated recently that chronic periodontitis patients can be infected with more than one clonal type of Pg. Most often only one clonal type has been recovered, suggesting that chronic periodontitis patients are in general colonized with one predominant clone of Pg. It is not clearly known whether periodontal break down in spouses favored the transmission of Pg or the transmission of Pg from the spouses had initiated the disease process or had an aggravating effect on the present status.[8]

In untreated periodontitis, an increasing prevalence of Pg with increasing age of the patients was found. Though transmission of Pg is not a common phenomenon, it is suggested that the suspected periodontal pathogen Pg can be transmitted between spouses. Further research will be necessary to determine whether spouses of periodontitis patients are at risk for getting periodontal destruction and delayed wound healing following surgical management, because of transmission of Pg[12].

Clinical Significance of Transmission

It is well known that Aa and Pg play a major role in the etiology of periodontal diseases. The transmission rate of Aa appeared to be 14 – 60 % and Pg is 30 – 75% of the bacterium positive spouses pair studied. A seven-year longitudinal study of the periodontal condition of young Indonesian couples who had been married for an average of ten years was conducted.[13] Results suggested that transmission of Aa and Pg were uncommon between spouses regarding the intimate cohabitee of several years. Based on the results, it was found that the transmission occurred more frequently but did not lead to persistent colonization or detectable levels of the organism. Also, it was found that bacterial colonization is host dependent and depends on the characteristics of the strain. The numbers of bacteria in the transfer inoculum were too low or exposure to infection occurred too rarely. Based on the study, it was inferred that the older or established microbiota did not easily accept new bacterial invaders. This result contrasts with those of Von Troil linden *et al* 1995[9] & Asikainen *et al* 1997[6] who found that spouses of patients with periodontitis had significantly more gingival suppuration, supra gingival and sub gingival calculus and deeper periodontal pockets than the spouses of patients without periodontitis. Therefore, it seems that not only were periodontal pathogens transmitted between the same spouses, but also the transmission resulted in periodontitis in the recipient spouse. This possibility

needs to be further analyzed and the prophylactic consequences still need to be determined.

Source of Pathogens & Route of Infection

In humans, the highest frequencies and levels of Aa and Pg are usually seen in periodontal pockets subgingivally, although the organisms can be recovered from supra gingival plaque, oral mucosal surfaces, dorsum of the tongue and pharynx. These two microorganisms play a major role in the initiation and progression of periodontal diseases. While Aa can colonize a healthy and clean oral cavity, Pg does not seem to colonize clean tooth surfaces but prefers sites showing inflammation due to poor oral hygiene and sites harboring gram positive dental plaque bacteria.

Saliva play a role in the prevention and transmission of periodontal diseases. It was found that high salivary levels of periodontal pathogens are seen in patients with advanced periodontitis and in relation to patients with initial periodontal destruction.[9] These findings underscore the potential of saliva as transmission vehicle of periodontal pathogens. The role of saliva as a transport vehicle has been supported by the findings that Aa and Pg could be cultured from salivary samples, which indicates that these bacteria are able to survive in saliva during transportation to a new host. It can be said that the higher their load in saliva, the greater their risk of colonization of the recipient. Therefore, the suppression of the pathogens in saliva may prevent this spread among individuals.

Summary & Conclusion

The periodontal disease is confirmed by a group of illnesses affecting the gingiva and dental support structures. They are caused by certain bacteria found in the bacterial plaque. These bacteria are essential to the onset of illness; however, there are predisposing factors in both the host and the microorganisms that will influence the pathogenesis of the illness. Periodontopathogenic bacterial microbiota is needed, but by itself, it is not enough to cause the illness, requiring the presence of a susceptible host.

Bacteria have been seen to play a leading role in the onset and subsequent development of these illnesses. Therefore, when it comes to treatment of these diseases, coadjuvant antimicrobial treatment will be needed, since we already know that scaling and root planing alone will be insufficient to eliminate the periodontal pathogens[14]. The bacteria associated with periodontal diseases are predominantly gram-negative anaerobic bacteria and may include A. actinomycetemcomitans, P. gingivalis, P. intermedia, B. forsythus, C. rectus, E. nodatum, P. micros, S. intermedius and Treponema sp. The bacterial numbers associated with disease are up to 10(5) times larger than those associated with health. Data on the rare presence of multiple Aa clones within a single person indicate that an additional Aa clone or replacement of a previous clone is difficult. This hypothesis is supported by the finding that fewer than half of the married couples in whom both spouses harbored Aa, shared identical Aa genotype[6]. While human subgingival plaque harbors more than 500 bacterial species, considerable research has shown that *Porphyromonas gingivalis*, a Gram-negative anaerobic bacterium, is the major etiologic agent which contributes to chronic periodontitis. This black-pigmented bacterium produces a myriad of virulence factors that cause destruction to periodontal tissues either directly or indirectly by modulating the host inflammatory response[15]. Chronic periodontal diseases involve major pathogens like Porphyromonas gingivalis, Treponema denticola, and Tannerella forsythia, which have an immune armoury that can circumvent host's immune surveillance to create and maintain an inflammatory mediator rich and toxic environment to grow and survive. A full understanding of the microbial factors, their pathogenicity as well as host factors are of the essential importance for pathogenesis of periodontal disease. In this way it could be possible to treat the periodontal patients adequately.

Application of a Health Belief Model to Hypertension within Rural India

Rajkumar E[1], Romate J[2]

[1]Assistant Professor, Central University of Karnataka; [2]Professor, Central University of Karnataka

Abstract

Cardiovascular diseases are the principal cause of mortality among adults across the globe as well as in India. Hypertension is one of the leading factors contributing to cardiovascular disease; and its prevalence rate in India is 23% among urban population and 22.6% among rural populations. Beliefs play a significant role in managing and controlling health problems and depend in part on knowledge about the illness or disease. The present study uses the Health Belief Model framework to enhance understanding of the relationships of health beliefs with knowledge, risk factors for hypertension and hypertension. The present study focused on a south western state of India from which a taluk with one of the lowest socio-economic ratings was identified. A total of 263 participants were selected by multi-stage random sampling technique. The measures for data collection were comprised of a demographic data sheet, the WHO Steps tool, a hypertension knowledge questionnaire, hypertension belief scale, and physical assessments. Results were analysed using descriptive statistics, Pearson correlation, Independent sample t test, and binary logistic regression. Findings revealed that health belief model constructs, perceived susceptibility, severity, benefits, barriers, cues to action, and self-efficacy were significantly correlated with hypertension knowledge. Further it was observed that the health belief construct perceived severity was correlated with a risk factor and there was no significant association found between health belief constructs perceived susceptibility, severity, benefits, barriers, cues to action, and self-efficacy and hypertension.

Key words: *Health beliefs, Hypertension, Knowledge, Rural, India*

Introduction

Changes in life style and economic progression lead to epidemiological health transition with high rates of adaptation to urbanization. The shift from communicable to non- communicable diseases in the disease spectrum is seen as one of the major consequences of economic progression. Globally there has been a gradual increase in the burden of non-communicable diseases. According to WHO [2], 67% of the 56 million deaths in 2012 were due to non-communicable diseases; among these, 46.2% were due to cardiovascular diseases. Hypertension ranks among the most salient risk factors for cardiovascular diseases. It is estimated that it affects more than one-third of adults aged 25 and above, and thus one billion people worldwide suffer from this disease and contribute to nearly 9.4 million deaths from cardiovascular diseases each year Further, it is estimated that 23 million cardiovascular deaths will occur due to hypertension by 2030 [3].

Hypertension is a public health problem that results in 1.1 million deaths every year in India. It is deemed to be conducive to 10.8% of all deaths and 4.6% of all disability-adjusted life years in India [4]. Gupta, Brahmbhatt, Sharma, & Halappanavar [5] reported that the prevalence of hypertension in India is 23% for urban and 22.6% among rural populations and is directly responsible for 42% of coronary heart disease deaths and 57% of all stroke deaths [6].

The Health Belief Model, Rosenstock [7] predicts health-related behaviours with four constructs of perception, namely susceptibility of the health problem, the severity of the health problem, benefits of taking action, and barriers to taking action. These four constructs account for the readiness to act by people. In addition to these four original constructs, another element which prompted action seemed necessary hence cue for action was subsequently added to the model [7]. Finally, self-efficacy, which is the belief in one's own ability to

complete a task successfully, was a recent addition to the model [8]. This was done to better connect the interpersonal challenges of changing unhealthy behaviours with the model. The model postulates that for an individual to avoid a disease, the person should believe that he/she is personally susceptible to it, the occurrence of the disease will have at least a moderate level of severity on some aspects of the individual's life, undertaking a particular action would be beneficial by reducing its severity, and the action would overcome the barriers such as cost, convenience, pain, or embarrassment [9]. Cues to action then act as a trigger for protective health behaviour. The cues can be internal like the bodily states of a person or external such as the impact of mass media. Lastly, the individual ought to have credence in his/her ability to complete an action with success. Newell, Modeste, Marshak, & Wilson [10] examined the role of beliefs in the prevention of hypertension; their findings have shown that there was a significant negative association between perceived severity and systolic or diastolic blood pressure. Self-efficacy was negatively associated with risk scores. Most respondents thought that adopting strategies to reduce the risk of hypertension was useful and believed that their self-efficacy could help in changing these behaviors. Rosenstock [7] reported that self-efficacy; perceived susceptibility and severity of an illness or disease are partly dependent on knowledge about the illness or disease.

Appropriate knowledge about hypertension and its related consequences can motivate individuals to modify their lifestyle, such as weight loss [11] , restricting alcohol consumption, engaging in regular exercise [12] and increased intake of fruits and vegetables [13] Individuals with little or no knowledge about hypertension will most likely believe that they are neither at risk of becoming hypertensive, nor will they believe hypertension to have emotional, social or medical consequences to themselves or others. Gammage & Klentrou [14] employed Health Belief Model to analyse the perceptions and behaviors surrounding osteoporosis, and he reported that persons of all ages lacked knowledge about osteoporosis; their knowledge and expertise to understand the risk factors, protective factors, and the insidious nature of osteoporosis which was related to reduced perceived vulnerability for osteoporosis and practices aiming at preventing osteoporosis, were inadequate [15].

While the health belief model has shown to help and explain behaviour related to hypertension among western populations, less is known about its applicability within a South Asian context. The model purports that an individual would need to believe that one was personally at risk of developing the disease to take appropriate preventive actions. Beliefs serve an integral part in determining the management and control of health problems and depend in part on knowledge about the illness or disease. Knowledge and perceived susceptibility to disease are considered as an important factors that change the behavior of individuals. [16]. The present study aims to enhance understanding of the relationships between health beliefs model constructs, knowledge, risk factors for hypertension and hypertension.

Method

This study utilized a cross-sectional survey to describe the relations between health belief model constructs (perceived susceptibility, perceived severity, cues to action, perceived benefits, perceived barriers, and self-efficacy), knowledge about hypertension, risk factors for hypertension, and hypertension.

Study Area and Sample:

The present study focused on a south western state of India. This community-based study was located in Jewargi taluk, which ranks 174th out of 175 taluks in the state of Karnataka on various socio-economic indicators [17]. Based on the 2011 Census data, there were 159 total number of villages in Jewargi taluk.

A multi-stage random sampling method was used to recruit 263 study participants. Initially, the researcher selected 3 villages randomly from Jewargi taluka by lottery method; after selecting the villages, a unique number was given to each household in the three villages and another random draw was made to select sample households. A final lottery process was conducted to select the study participant among those in the household who were 18 years or older. Of 318 selected individuals, 263 consented to participate in the study. The main reason given for non-participation was a busy work schedule. Ethical clearance to conduct the study was obtained from the department and permission to conduct the study was obtained from the district health officer and taluka health officer.

Measures:

Health Beliefs Model:

A six subscale measure developed by Robinson

[18] assessed the constructs within the Health Beliefs Model. Thirty-one items on a five-point Likert scale assess six subscales namely perceived susceptibility (4 items), perceived severity (5 items), cues to action (4 items), perceived benefits (7 items), perceived barriers (5 items), and self-efficacy (6 items). Subscale mean scores were calculated and inter-item reliability analyses were conducted. Alpha reliability scores for each subscale were as follows: perceived susceptibility 0.357, perceived severity 0.687, and cues to action 0.639, perceived benefits 0.81, perceived barriers 0.795, and self-efficacy 0.602. Sub-scales were created by calculating an average score.

Hypertension Knowledge: the level of knowledge regarding hypertension was explored by asking questions about the reasons (high salt intake, family history, obesity, smoking, alcohol intake, high fat diet, stress, physical inactivity and unknown reasons), consequences (stroke, heart disease, kidney problem, eye problems and diabetes) and preventive measures (reduce salt intake, reduce weight, reduce intake of fatty food, exercise regularly, start medicine, quit smoking, stop drinking alcohol and regular check-up) of high blood pressure and recorded all the responses from the participants. Response options are dichotomous (Yes/No) [19]. A single summed index score was calculated for knowledge of consequences, and knowledge of preventive measures.

Behavioural Risk Factor Index: The WHO Steps Tool [20] was used to assess behavioural risk factors, namely smoking, alcohol consumption, dietary behaviour, physical activity, and obesity. Obesity via a body mass index calculation was derived from height and weight measurements taken at the time of the interview by the researchers. Each risk factor was coded 0/1 to represent the presence of behaviour categorized by the Steps Tool, for example, being a current smoker, if physical activity less than WHO guidelines, if fruit and or vegetable consumption was lower than five servings/ day, and being obese. Subsequently, a risk factor index was created by summing up across factors.

Hypertension: Blood pressure was measured three times with a minimum of 5 minute rest period in between each reading; participants were in a sitting position with the measurement on their right arm and taken over loose clothing using a portable digital blood pressure device. Hypertension is defined as a systolic blood pressure 140 mm Hg or higher; or diastolic blood pressure 90 mm Hg for average of the three readings; the history of diagnosis of hypertension, or receiving antihypertensive medication and captured in a dichotomous coded variable.

Demographics: Six items were taken from the WHO Steps Tool [20] to assess age, gender, education, income, occupation, and marital status.

Data Collection:

The written questionnaire was first translated from English to Kannada which is the most popular language in Karnataka. Three research assistants trained by the principal investigator conducted the in-person structured interviews.

Data Analysis

All data were entered into SPSS 20th version. Initially scales were created and alpha reliability analyses completed. Descriptive statistics were performed along with correlations and independent sample t test to examine the relationships and assess the differences between scales. Lastly a binary logistic regression was conducted to examine the contribution of health belief model constructs and hypertension knowledge on hypertension status

Results

Table 1 shows comparison of demographic information between the hypertensive and non-hypertensive group. It was found from results that, 51.56% of males had belonged to hypertensive group forming majority in comparison to female (48.43%). Observing the demographic details of education qualification, participants who had no formal schooling (67.18%) had formed majority of hypertensive group, followed by participants, less than primary school (12.5%). Majority of the participants were daily wage labourers 28.12% followed by unemployed and unable to work 26.6% and self-employed 20.31% respectively in terms of their occupation levels. The married participants (78.12%) were majority in the category of hypertensive groups. Majority of the hypertensive were found to be of the age group of 46 and above (64.06%; $p< 0.001$) comparing based on the age group.

Table 2 shows Differences in Health Belief constructs between hypertensive and non- hypertensive. Using independent sample t test it was revealed that in the sub scales perceived susceptibility, severity cues to action and self-efficacy hypertensive group had higher

average score as compare to the non-hypertensive groups which indicates hypertensives have more perceived threat and readiness to action as compare to the non-hypertensives but in the subscale perceived barriers and benefits non hypertensive groups score higher average score which indicates non hypertensive groups were able to overcome barriers and perceive more benefits from healthy behaviour. Further there was no significant difference was found between hypertensive and non-hypertensives in all the subscales of health belief model

Table 3 shows the relationship between health belief constructs and the risk factors index. Perceived severity was positively correlated with the risk factor index (r= .156, $p<0.05$) suggesting that those participants categorized with more behavioural risk factors are related to higher perceived severity of the disease. Other health beliefs constructs were not significantly related to the risk factor index.

From table 4, it was observed that all of the belief sub-scales and knowledge index are significantly correlated with one another. All significant correlations are positive, in other words, the greater the beliefs the greater the knowledge with the exception of perceived barriers which was negatively significantly related with the other constructs of health belief scale.

Table 5 shows the association of health belief constructs, hypertension knowledge, and socio-demographics with hypertension. Findings revealed that preventive knowledge of hypertension and age significantly associated with the odds of hypertension (OR=1.96.; CI: 1.22-3.14) $p<0.05$ and (OR=1.02; CI 1.02-1.07) $p<0.01$ respectively. From the table it is observed that none of the health belief constructs perceived susceptibility, severity, benefits, barriers, cues to action, self-efficacy were significantly associated with odds of hypertension. The knowledge about reasons and consequences of hypertension efficacy were also not significantly associated with odds of hypertension.

Discussion

Hypertension is considered as a major public health problem in India leading 1.1 million deaths per year [4]. Literature suggests that health beliefs and knowledge have a vital role in the prevention and control of health conditions. There is a paucity of evidence examining these health constructs among rural Indian populations. The present study aimed at investigating relationships between health beliefs, knowledge related to hypertension, risk factors, and hypertensive status.

Health belief and Hypertension knowledge:

It was observed that all the health belief constructs and hypertension knowledge are significantly correlated with one another. All significant correlations are positive, in other words, the greater the beliefs the greater the knowledge with the exception of perceived barriers which was negatively significantly related to the other constructs. From the findings, it could be inferred that higher the knowledge the greater the perception of threat and taking preventive actions and minimizing barriers to follow healthy behaviours. Our findings are consistent with those reported by Rashrash, Maneno, Ettiene, & Daftary [21] to assess the relationship between Hepatitis C knowledge and health belief model constructs wherein they found that Hepatitis C Knowledge was positively correlated with perceived benefits and perceived severity. Similarly, Midi & Tsai [22] found that among South Asian women participants, who were unaware of osteoporosis did not consider themselves to be susceptible to it and did not consider osteoporosis to be a severe disease. Elsabagh, Aldeib, Atlam & Saied [23] reported osteoporosis knowledge was negatively correlated with barriers to calcium intake and barriers to exercise. On the other hand, there was a significant positive correlation between knowledge and the benefits of exercise with a higher knowledge level associated with positive beliefs of exercise benefits.

Health beliefs and Risk factors

From the findings it was observed that the health belief constructs, perceived susceptibility, benefits, barriers, cues to action, self-efficacy were not significantly correlated with risk factor index which is the sum of all the risk factors. Present study findings are in contradiction to the study conducted by Larki, Tahmasebi & Resisi [24] found that self- efficacy and perceived susceptibility were associated with holding on to low salt diet, making use of common weight management strategies, involving in physical activity, and not smoking in hypertensive patients. Similarly in another study conducted by Kamaran, Ahari, Biria, Malpour & Hyedri [25] reported that adhering to medicines decreases with lower perception of disease severity. These contradictory results might be due to the reason that, in the present study most of the participants 62.3% were with low health literacy, patients with low literacy tend to feel less confident in their capability to execute self-care behaviours and also may have less motivation for performing self-care tasks. Subsequently, it is required to increase confidence among uneducated people to select appropriate behaviours which help them to engage in healthy behaviours. The concept of perceived susceptibility was introduced by Dehghani-Taftiet.,al [26] as an pertinent component in behavioural change among diabetic patients.

To adopt self-care behaviour, health care providers need to involve themselves to increase the level of awareness about the hypertension and improve the proficiency to modify beliefs of the patients so that they accept that they were susceptibile to get these diseases.

Hence, providing awareness related to hypertension to persons with low level of information will help in developing beliefs to know the danger of high blood pressure which helps them to engage in healthy behaviours.

Health Beliefs, hypertension knowledge and hypertension:

Form the findings it was observed that the health belief constructs perceived susceptibility, severity, benefits, barriers, cues to action, self-efficacy were not significantly associated with odds of hypertension. As the findings show, health belief subscales were not associated with hypertension this may be due to the reason that constructs of health model alone is not sufficient to predict the hypertension, there might be some other factors such as socio-demographic characteristics, psychosocial factors, personal factors, and cultural beliefs all of which will have to be present to activate the beliefs and follow healthy behaviours [27 & 28].

Knowledge about reasons and consequences of hypertension were not associated with the odds of hypertension but the knowledge about preventive measures has been associated with the odds of hypertension. It could be attributed to the reason that,

the person who is diagnosed with the disease frequently visit to hospitals and try to get the knowledge about the preventive measures from doctors, nurses and family and friends this might have been raised the knowledge about the preventive measures of hypertension.

Conclusion

Findings of the present study indicate that strong correlations between health beliefs and knowledge of the hypertension. In the present study except perceived severity none of the health belief constructs correlated with the risk behaviours this might be due to the reason that in the present study most of the participants 62.67% were without formal schooling. Perhaps, the poor health literacy might have been the reason for the people to have less knowledge about hypertension and its complications. Finally, health belief constructs perceived susceptibility, severity, benefits, barriers, cues to action, self-efficacy have not been significantly associated with odds of hypertension this may be due to the reason that constructs of health belief model alone is not sufficient to manage the hypertension.

Limitation:

In the present study the values of perceived benefits and knowledge preventive measures are closer to the association but significant association was not found this might be due to small sample size. While the present study utilized a random sampling methodology on rural participants, its findings cannot be generalized outside its rural sample. The study may also have been under powered with its sample size particularly when the sub-categories of hypertensive and non-hypertensive participants were examined. The health belief subscale for susceptibility had a low alpha reliability though still was significantly related to the three knowledge subscales. Regardless this may have impacted its performance in the logistic regression model examining hypertension status. Overall these limitations to not over shadow the conclusions that were drawn from the study

Future direction

In the future study could be extended to the different parts of India including urban areas with more sample size. Future studies, should emphasize on other behaviour models with emphasis on socio-demographic characteristics, literacy, psychosocial factors, personal factors, and cultural beliefs.

Conflict of Interest: The authors declare no conflict of interest.

Funding: This study was not supported by any funding agency; it was a self funded study

Abstract

Introduction: - Dermatophytosiscomprise approximately 15- 75% of all the mycological infections. It is common in tropical and subtropical countries including India where high temperature and humidity play an important role in the pathogenesis. Dermatophytes are closely related keratinolytic fungi with the ability to degrade keratin and invade the skin, hair and nails causing dermatophytosis.

Objective: - To find out the distribution of various dermatophytefungi responsible for the different clinical types of dermatophyte infections.

Methods: - KOH mount were prepared from the skin scrapings, nail clippings, and hair bits to look for fungal elements. The specimens were also inoculated on Mycosal media and Sabourauds dextrose agar with chloramphenicol. The dermatophytes were identified on the basis of colony characteristics, lactophenol cotton blue mount, nutritional requirement, temperature tolerance, urease production, and in vitro hair perforation test.

Result: - A total of 245 patients were included in the study. Tinea corporis was most common clinical type with 102(41.6%) cases followed by T. facei[15 (6.1%)]. T. corporis +T. cruris [88(35.9%)] was most common mixed clinical type. Out of 245 patients, fungal hyphae were seen in 162(66.1%) samples and the rest 83(33.9%) were negative by KOH mount. In the 162 KOH positive samples, 151(91.5%) samples were culture positive and 11(13.7%) were culture negative. In 83(58.9%) KOH negative samples, 14(8.5%) were culture positive and rest 69(86.3%) were culture negative. A total of 165 samples were culture positive, of which T. mentagraphyteswas isolated in 153(92.7%) followed by T. rubrum in 5(3.03%), T. violaceum in 3(1.8%), T.tonsurans in 2(1.2%) and M.canis in 2(1.2%) samples.

Keyworgds:- *Dermatophytosis, Fungal Culture, Mycosal media, Taenia corporis, Trichophyton, Microsporum*

Introduction

Dermatophytosis is the term given to infections caused by dermatophytes; also called tinea according to the site of infection as for example tineacorporis involving the arms, trunk and legs, tineacapitis involving the scalp, and tineapedis involving the foot, etc. Dermatophytes are distributed into three closely related genera: Epidermophyton, Trichophyton and Microsporum. These fungi can be classified on the basis of their normal habitat: geophilic dermatophytes are naturally present in the soil, zoophilic in animals, and anthropophilic in humans.[1]

Zoophilic andanthropophilic dermatophytes evolved from a geophilic origin, with the anthropophilic dermatophytes being the most highly specialized

groups. They seldom infect other animals and they are additionally limited to some body parts. Anthropophilic fungi are responsible for most superficial fungal infections. Transmission can happen by direct contact or from introduction to desquamated cells. Direct inoculation through breaks in the skin happens moreregularly in persons with depressed cell-mediated immunity. Once organism enter the skin, they germinate and invade the superficial skin layers.[2]

This infection is typicallynot life threatening, happens even in immunocompetent hosts, and in several cases is long lasting, recurrent and troublesome to cure. Superficial mycoses are among the most frequent types of human infections, being estimated to effect over 20-25% of the world's population, and their incidence is constantly increasing.[3,4]The distribution of dermatophyteinfectionsand their causative agents varies with geographical region and is influenced by a wide range of factors likeclimatic factors, lifestyle, migration of population, cultural practices,socioeconomic conditions, incidence of strange comorbidities and drug therapy.[4, 5]This study was therefore undertaken to find out the distribution of causative dermatophyte species from clinically suspected cases of dermatophytosis.

Material and Method

This Study was conducted in the Department Of Microbiology, SGT University, Gurgaon, Haryana and Muzaffarnagar Medical College and Hospital, Muzaffarnagar. The study was done from January 2017 to December 2018 over a time of a year.All consecutive cases of dermatophytosis were included in the study.

Specimen Collection

The patients who presented to the dermatology outpatient department with lesions on skin/ hair/ nails (vesicles, scaleson skin and nails and breakdown of hairs) suggestive of dermatophytosis were refered to the mycology laboratory where samples were collected from the patients.A total of 245 samples were collected, depending upon the site of infection, samples were:

- Skin scrapings
- Nail scrapings and clipping
- Hair plucking and scales scrapings

Cases of dermatophytosis with secondary bacterial infections and patients already on antifungal drug treatment were excluded from the study. Wet mount of different samples e.g., skin scrapings, hair and nail clipping were prepared using 10-20% KOH. This preparation was examined under the microscope to look for the presence of dermatophytic fungi which appear as thin branching fungal hyphae. The presence of fungal hyphae in clinical material was not enough to identify the organisms with certainty. Samples were culturedon Sabouraud's dextrose agar with chloramphenicol and Mycosel agar. Plates were incubated at 25^0C for up to 4 weeks. The characteristic features of the colony that were considered were rate of growth, texture, topography and color of the colony, and the production of pigment on the reverse of the colony. Microscopic morphology was examined by lacto phenol cotton blue mount of the colonies and Slide culture. Further identification of dermatophytes included:

- nutritional requirement (such as vitamin and amino acid utilization) on Bactotrichophyton agar
- temperature tolerance
- urease production
- In vitro hair perforation test.

Result: - A total of 245 samples were taken, of which 189 (77.1%) were from male patients and 56(22.9%) were from female patients. The commonest age group was 16-30 (59.2%) followed by 31-45 (19.6%), 46-60 (8.6%), <15(7.8%) and 61-75 (4.9%) years. (Table 1)

Table 1: Distribution of study population according to age and gender

Variables	Number	Percentage
Age (years)		
< 15	19	7.8
16-30	145	59.2
31-45	48	19.6
46-60	21	8.6
61-75	12	4.9
Sex		
Male	189	77.1
Female	56	22.9
Total	**245**	**100**

Out of 245 cases, T. corporis was commonest clinical type and was seen in 102(41.6%) patients. Maximum number of cases of T.corporis were seen in the age group of 16-30 years[61(59.8%)].T.corporis + T.cruris were the commonest mixed clinical type with 88(35.9%) cases; out of which 51(57.9%) caseswere in the age group 16-30 years. Second most common single clinical type seen was T. facei with 15 (6.1%) cases; followed by T.mannumin 7(2.9%) cases,T.cruris and T.ungiumin 5(2.04%) cases each, T. pedis and T. capitisin 3(1.2%) cases each.

Second commonest mixed clinical type seen was T.corporis+T.cruris+T.facei in 7(2.8%) patients; T.corporis+ T.facei was found in 5(2.04%) patients; T.corporis+T.cruris+T.mannum were found in 2(0.81%) patients. Rest of mixed clinical types, T.facei +T.mannum, T.corporis +T.pedis and T.facei+T.cruris was seen in 1(0.4%) patient each. Most of these infections were more common in 16-30 years age group except for T. pedis and T. capitis which were more common in <15 years age group.

In general Males were 3 times more commonly effected than females by almost all the Tinea infections except for T. ungium which was more common in females. Variance of clinical condition with sex was not found statistically significance. (Table 2)

Table 2: Association of clinical condition with gender

Clinical condition	Sex n (%)		Total (%)	p-value
	Male	Female		
T.corporis	77 (75.5)	25(24.5)	102(41.6)	0.593
T.facei	9(60)	6(40)	15(6.1)	
T.mannum	6(85.7)	1(14.2)	7(2.9)	
T.cruris	5(100)	0	5(2.04)	
T.ungium	2(40)	3(60)	5(2.04)	
T.pedis	2(66.7)	1(33.3)	3(1.2)	
T.capitis	3(100)	0	3(1.2)	
T.corporis+T.cruris	71(80.7)	17(19.3)	88(35.9)	
T.corporis+T.cruris+T.facei	6(85.7)	1(14.3)	7(2.9)	
T.corporis+T.facei	3(60)	2(40)	5(2.04)	
T.corporis+T.cruris+T.mannum	2(100)	0	2(.81%)	
T.facei+T.mannum	1(100)	0	1(0.40)	
T.corporis+Tpedis	1(100)	0	1(0.40)	
T.facei+T.cruris	1(100)	0	1(0.40)	
Total	189(75.9)	56(22.8)	245	

Out of 245 samples, 162 were KOH positive samples, out of which 151 (91.5%) were culture positive and 11 (13.8%) samples were culture negative. In 83 (33.9%) KOH negative samples, 14 (8.5%) were culture positive and rest 69 (86.2%) were negative by culture. (Table 3)

Table 3: Comparison of KOH mount and culture in identification of fungus

	Culture negative N (%)	Culture positive N (%)	Total N (%)
KOH negative	69 (86.2)	14 (8.5)	83 (33.9)
KOH positive	11 (13.8)	151 (92.6)	162 (66.1)
Total	80 (37.7)	165 (67.3)	245 (100)

From the 165 culture positive samples; T mentagraphytes was the most commonly isolated dermatophyte with 153 (%) isolates, followed by T. rubrum from 5(3.03%), T. violaceum from 3(1.81%), T. tonsurans and Microsporum canis from 2(1.21%) samples each.

Majority (68/153) of cases of T mentagrophytes were isolated from cases of T corporis, whereas 3/5 cases of T. rubrum were isolated from mixed infection of T. corporis +T. cruris. All T. violaceum were isolated from cases of T. capitis, all (2/2) isolates of T. tonsurans were from cases of T. corporis+ T. cruris, and both isolates of M. canis were from mixed infections with T. corporis.

Discussion

Dermatophytes fungi are the etiologic agents of skin infection commonly referred to as ringworm. These infections are not dangerous but as chronic cutaneous infections they may be difficult to treat and can also cause physical discomfort for patients.

In the present study, out of the 245 cases, 189 (77%) were male and 56 (22.9%) were female. The commonest age group was 16-30 years (59.2%) followed by 31-45 years (19.6%). Other studies done by Singh et al, Kaur et al, Siddappa et al andJanardhan et al have similar findings[6,7,8,9].They also saw a male preponderance and the age group most commonly affected was 16-30 years in these studies as well.The reason for this could be due to increased outdoor physical work and increased chances for contact infection than female. Noronha et al reported T.corporis was more common clinical presentation with 37 cases (24.7%) which was affecting more common in female with 20 cases (54%) compared with male with 17 cases (45.9%) [10].Higher incidence may be due to common practice of sharing cloths, bathing towel and overcrowding. Janardan et al showed the incidence of T.facei was 10 cases (5%) effecting 4 male and 6 female.This could be because of sharing of common or contaminated face products, rough scrubbing and contaminated objects such as Towel and by increased exposure to harsh detergents while doing household work.T. ungium was also more commonly seen in females.[9]contrary to our study, Karmakar et al showed a preponderance of cases in 0-11 years age group[11].

In the present study out of 245 patients, T.corporis was commonest clinical type and was seen in 102 (41.6%) patients followed by T.corporis+T.cruriswith 88(35.9%) cases. In studies by Singh et al, Noronha et al and Bindu et al, also T. corporis was the main clinical presentation observed[6,10,12,].

Only 3(1.2%) cases in our study had T. capitis. T.capitis has been reported to be rare entity from some other studies also in northern India[13, 14, 15].Whereas in studies by Siddappa et al, Janardhan et al and Karmakar et al,and the prevalence of T. capitis was reported to be 18%, 9% and 6.93% respectively which was higher than our study[8,9,11].Similar to our study,in studies by Sidappa et al, Janardhan et al T capitis was more commonly seen in males[8, 9]. Higher incidencein males may be due to visit to saloons where they use contaminated razors and combs.

In the present study, most of clinical presentations were seen in the age group of 16-30 years followed by 31-45 years while T.capitis was found most common in the age group <15 years.

The incidence of T.mannumin our study was 2.8% which is in concordance with studies of Vena et al (1.7%)and Janardhan et al (3%).[3,9] Occupational trauma may act as a precipitating factor.

In the present study the prevalence of T.pedis was1.2% which is very less as compared to studies

by Janardhan et al, Bindu et al and Huda et al who reported incidence of T.pedis as4%, 7% and 3.3% respectively[9,12,16].

The most common mixed clinical infection seen in the study was T.corporis+T.crurisin35.9% patientswhich was similar to a study by Noranha et al (35.3% prevalence of T corporis + T. cruris)[10]. However, Janardhan et al showed the incidence of mixed types of infection to be only 2% which is far less than these studies[9]. The higherprevalence of multiple site involvement showed in our study may be due poor hygiene and delay in seeking treatment.The role of fomitesin the spread of dermatophytosiscannot be undermined in dermatophytic infection because sharing of beds, linen, and clothing is all too common in family.

In the present study out of 245 samples, 162 were KOH positive samples, out of which 151 (91.5%) sample culture positive and 11(13.8%) samples were culture negative. The positivity of KOH in different studies ranges from 53% to as high as 90%. (Table 6).In 83(33.9%) KOH negative samples, 14 (8.5%) were culture positive and rest of 69 (85.2%) were negative by culture.The handiness involved in these techniques of sampling and in examining the KOH mount might be different at different places, which might account for the difference in microscopic and culture finding makingit essential that all the KOH negative samples should be cultured.

In the present study, among the total of 165 isolates; majority were [153(92.7%)]T.metagraphytes, 68(66.7%) of which were isolated from T.corporis. There was no T. mentagraphyte isolate from cases of T.capitis. Noronha et al showed that among 29(48.3%) isolates ofT.mentagraphytes, majority [9(45%)] were isolated fromT.corporis.In a study by Madhavi S et al majority of [5(55.5%)] T.mentagraphyteswere isolated from T.corporis, however,T.rubrum was the predominant isolate in their study comprising 51.7%of the total isolates[17].

Among the 5(3.1%)isolates of T.rubrum, majority [3(60%)] were isolated from mixed clinical types T.corporis+T.cruris. Among the 15(51.7%) T.rubrum isolates, majority [5(33.3%)] wereisolated from T.corporis followed by T.cruris.Similar to our study Noronha et al showed T.rubrum was second most common isolate in the study comprising 23(38.3%) of the total isolates[10].

In the present study T.violaceum was isolated from 3 cases, all the cases being T.capitis. Similarly Madhavi et al showed 2(6.9%) isolates of T.violacium, all cases being T.capitis. Noronha et al showed T.violaceum 3(5%) were isolated from mixed clinical types with 2(6.9%) and T.capitis with 1(20%) [10].

In the present study, only 2(1.2%) isolates of T.tonsurans were found and both were isolated from mixed clinical infection ofT.corporis+T.cruris.Similarly in a study by Pulariet al 2 (1.2%) isolates of T.tonsurans 2(1.2%) were cultured; 1 each from T.corporis+T.cruris and T.capitis[18].

In our study 2(1.2%) isolates of M. canis were seen; 1 each from T.corporis+T.cruris and T.corporis+T. cruris+T.facei.In a study by Sundaram etal only one isolate ofM.canis 1(0.5%) was isolated from a case of T.corporis[19]. Generally dermatophytes exhibits a cosmopolitan profile, that is they found in different region of the world with variations in the frequency of particular species as geoclimatic and social conditions interfere with the distribution of dermatophytes species.

Conclusion

T corporis was the most common clinical presentation and T.mentagraphytes was the most common species isolated from the samples. The infections were more common in 16-30 years age group and in males. There are variations in the distribution of the clinical infection and the isolates in different studies.

Professional and Psychological Help Seeking Behavior among College Students

Shreevidya P

Ph. D Scholar, School of Social Work, Roshni Nilaya, Affiliated to Mangaluru University

Abstract

Mental and behavioral problems are the leading causes of health problems in young people both in high and low resource countries, accounting for one third of all years lost productivity due to this disability. It implies that, healthy students can productively contribute to the development of a country.[19] As India is the world's most youthful nation college students seeking professional and psychological help for their mental health issues and becoming mentally healthy is essential for their successful college life. This study is conducted to understand the Professional Psychological Help Seeking Behavior of college students for their Mental health issues and to know the gender differences. Convenient sampling was used with 60 respondents from a reputed college of Mangaluru, Karnataka. Attitude towards professional psychological help seeking scale (Fischer, 1995) and Socio demographic profile were used for data collection. The study revealed poor attitude among college students for professional help seeking for mental health and recommends for an increased education and awareness to reduce the perceived stigma for help seeking. More defined policies and programmes have the potential to improve students' access to a full range of mental health services which in turn contribute to overall development.

Keywords; *Professional Help-seeking, Mental Health, College Students*

Introduction

Students in India

According to World Health Organization (WHO), Mental and behavioral problems are the leading causes of health problems in young people in both high and low resource countries, accounting for one third of all years lost productivity due to this disability. It implies that, healthy students can productively contribute to the development of a country. As stated by Division for Social Policy and Development Disability of United Nations, Mental health issues are among the ten leading causes of disability in both developed and developing countries. Poor mental health is both a cause and a consequence of poverty, compromised education, gender inequality, ill-health, violence and other global challenges. It impedes the individual's capacity to work productively, realize their potential and make a contribution to their community. There is growing recognition within the international community that invisible disabilities, such as mental health is one of the most neglected yet essential development issues in achieving internationally agreed development goals. India is the world's most youthful nation, with two-thirds of population under the age of thirty-five. It is the strength and skills of these youngsters that will usher in New India. [20] Therefore, college students seeking professional and psychological help for their mental health issues and becoming mentally healthy is essential for their overall development which in turn contributes for healthy nation.

Mental Health Issues among College students

WHO defines Mental Health as "a state of well-being in which the individual realizes his or her own abilities, can cope with the normal stresses of life, can work productively and fruitfully, and is able to make a contribution to his or her community". It also emphases that "mental health is not just the absence of mental disorder".

Mental health issues are a set of clinically recognizable symptoms present in an individual for a period of time and the individual experiences distress due to these symptoms as they interfere with his or her personal functioning like academic work, relationships

and social interactions. Mental health professionals associated with college mental health services also opine that late adolescent and college going persons are highly vulnerable to the limitations in personal growth, imposed by emotional disturbances of varying severity. [21]

Transition from college students to adulthood, especially among college students can be an extremely stressful period owing to many challenges those can ultimately affect their mental health. Stress can be negative or positive to an individual, depending on the factors such as strength and persistence of the stress, social support. [22]

The Mental-health symptoms during the transition period have a significant impact on the development of students and their social and economic integration, including employability. Mental-health issues have a significant impact across a wide range of developmental outcomes, limiting opportunities for social integration. One area that can be impacted by mental-health conditions during adolescence and young adulthood is the development of safe and healthy relationships with peers, parents, teachers and romantic partners. In fact, adolescence is the developmental period that is critical for identity formation and taking on roles, especially with peers. [23]

According to the Report on Mental Health and Development 2008 Mental and behavioural issues are the leading causes of health problems in young people in both high- and low-resource countries accounting for one third of all years lost productivity due to this disability.

Attention to global mental health moves beyond treatment-oriented programmes in health-care settings to include broader approaches inspired by public-health and social-inclusion considerations. Recently, mental-health issues have attracted global attention. The 2007 Lancet Series on Global Mental Health led to the launch of a coordinated Movement for Global Mental Health, comprising over 95 institutions and 1,800 individuals worldwide.

In 2010, the World Health Organization (WHO) produced a Report on Mental Health and Development (2010a), highlighting people with mental illnesses as a vulnerable group subject to stigma and social isolation, human-rights violations and exclusion from policies and decision-making that affected them. Later that year, in its resolution on global health and foreign policy, the United Nations General Assembly recognized the need to target mental health in development, reinforcing previous international commitments toward mainstreaming disability issues in development. The WHO has developed the Mental Health Gap Action Programme, along with technical tools to support non-specialist mental-health service capacity in low- and middle-income countries. This international momentum to acknowledge and address the global burden of mental-health problems is critical to dealing with this issue at a global level.

Review of Literature

Kumar Rajesh, Prinja Shankar and Lakshmi P.V.M.[24] conducted a study to assess the perceived health problems and help seeking behavior and utilization pattern of adolescent health clinics. A pre-tested, semi-structured questionnaire was administered to 360 school going college students who were selected by stratified random sampling from two sectors of Chandigarh where services were being provided by a school-based and dispensary-based adolescent health clinic. The study revealed that majority (81%) of the college students having some health problem during last three months prior to the survey; predominant (60%) problems were psychological and behavioral in nature. To resolve these problems boys consulted mainly friends/peers (48%) while girls consulted their mothers (63%). Compared to the dispensary-based adolescent health clinic, utilisation was significantly higher in a school- based clinic where proportion of psychological or behavioral problems reported was also significantly higher.

Daniel Eisenberg [25] conducted a study using random sample of 5,555 college students from a diverse set of 13 universities, with an objective to see the association of help-seeking behavior with both perceived public stigma and people's own stigmatizing attitudes or personal stigma. There were three main findings: (a) Perceived public stigma was considerably higher than personal stigma; (b) personal stigma was higher among college students with any of the following characteristics: male, younger, Asian, international, more religious, or from a poor family; and (c) personal stigma was significantly and negatively associated with measures of help seeking whereas perceived stigma was not significantly associated with help seeking.

Eisenberg, Golberstein and Gollust [26] conducted a study with the objective of quantify mental health service

use and estimate how various factors are associated with help-seeking and access in a university student population. A Web-based survey was administered to a random sample of 2785 college students attending a large, public university with a demo- graphic profile similar to the national student population. The study revealed that, 30% of respondents perceived a need for professional help for their mental or emotional health in the previous year. As expected, college students with current mental health issues, as indicated by positive screens in the PHQ (Patient Health Questionnaire) depression or anxiety instruments, were significantly more likely to perceive a need for services and to receive services.

Reviewed studies show that the help-seeking behaviour of students has focused mainly on the friends, parents or try to cope alone, and subsequently turn to adult. Stigma is a considerable barrier to mental health service delivery among students. In addition to that, embarrassment and the lack of basic knowledge about mental health impact on the Help seeking behaviour of students. The issue of stigma is further challenged by the lack of quality mental-health services.

Methodology

Title: Help-seeking Behavior of College students for Mental Health Issues

Aim of the Study: To assess the Help-seeking Behavior of College students for Mental Health Issues.

Objectives: 1. To understand the Professional Psychological Help seeking behavior of college students for their Mental health issues

2. To know the gender differences in Professional Psychological Help Seeking Behavior among college students.

Importance of the study: Mental health issues among college students are detrimental to the development of an individual and also to the country**.** Mental and behavioral problems are the leading causes of health problems in young people in both high and low resource countries, accounting for one third of all years lost productivity due to this disability [i] Thus, healthy students productively contribute to the development of a country. Transition from college students to adulthood, especially among college students can be an extremely stressful period owing to the many challenges those can ultimately affect their mental health.[4] Hence, seeking professional and psychological help for mental health is essential for the college students. This study is conducted in Mangalore, Karnataka which is known for its educational excellence and attracts student from across the nation.

Research Design: Cross-sectional Research design was applied.

Population: The target population was first-year degree college students of two reputed colleges in Mangaluru, Karnataka, India.

Sample Size and Technique: The sample size was 60, Convenient Sampling method was applied for the study.

Sources of data: The study used Primary data and reviewed secondary literature.

Description of the Tools

1. Socio Demographic Sheet developed by the researcher includes age, gender, religion, hobbies, type of college, mode of stay, financial background, parents' occupation and qualification of parents, and such other information that taps their college life.

2. Attitude towards Seeking Professional Psychological Help Scale (Fischer et.al., 1995): The scale contains 10 items, reverse score items 2,4,8,9 and 10, and then add up the ratings to get a sum. Higher scores indicate more positive attitudes towards seeking professional help. Calculate a mean for males, for females, and for each of the groups to examine group differences. The scale is on public domain.

Data Analysis: The data is analyzed through descriptive statistics. Frequency, Mean and Standard Deviation are used and SPSS 17.0 Version is applied.

Results and Discussion

Table 1- Demographic Variables

Variables	Frequency %
Male	30 (50%)
Female	30 (50%)
Total	60 (100%)

Cont ... **Table 1- Demographic Variables**

18 Years	39 (65%)
19 Years	21 (35%)
Total	60 (100%)
High Income	8 (13.3%)
Middle Income	48 (80%)
Low Income	4 (6.7%)
Total	60 (100%)

Table No.1 shows that there were equal number of male (50%) and female (50%) college students. There were 65% college students in the age of 18 years, 35% were of 19 years age group. Regarding the financial background of the participants, 8% of college students were from high income background, 48% were middle income background and 4% were from low income background.

Table 2- Help Seeking behaviour among College students

ATPPHS (Attitude towards professional psychological help seeking)	**Mean Score Mean Percentage**	**Standard Deviation**
Help Seeking Behaviour among college students	14.06 (46.86%)	±6.20
Male	11.46 (38.2%)	±5.38
Female	14.86 (49.53%)	±5.17

Table No. 2 shows the mean score of Attitude towards professional psychological help seeking behaviour among college students. The maximum score of the scale was 30 whereas the overall mean score obtained in this study is 14.06 (±6.20) with mean percentage 46.86%. It shows a low level of help seeking behaviour among college students. With regard to gender, the mean score of male college students was 11.46(±5.38) with mean percentage 38.2%. This shows low level of help seeking attitude among male college students. Whereas, the mean score of help seeking (ATPPHS) among female college students was 14.86 (±5.17) with mean percentage 49.53% which also shows low level of help seeking attitude among female college students. Thus the study shows poor level of help seeking behaviour among both male and female college students. This will hamper the overall development of the student population by affecting their mental health and lead to mental health issues.

The study shows that the Professional and Psychological Help Seeking Behaviour among both the male and female college students are in low level. The mean score of ATPPHS among male college students is much lower than the mean score of female college students who in turn also seek poor level of help for their mental health issues. This will lead to unprofessional help seeking resulting in intensifying mental health issues among college students which is highlighted in study by Chandrashekar [iii] that 15 to 20% of the college students having recognizable mental disorders. Only a few colleges provide counseling services through trained manpower in our state. College students with mental morbidity do not seek Psychiatric treatment because psychiatric services are not available in an affordable and approachable manner, stigma attached to mental disorders and lack of awareness. Thus majority of the college students, who need help, remain unattended and uncared. Similarly, NAMI conducted a national survey of college students to learn about their mental health in colleges in U.S.A. and highlighted that, stigma remains the number one barrier to college students seeking help and survey respondents shared valuable ways in which schools can work more effectively to combat stigma.

Thus, there is a need to create awareness on mental health among college students. The professional help seeking also need to be encouraged through the active involvement of teachers and college management who can help the college students for professional intervention by introducing Campus Mental Health Services which will help to combat stigma and promote mental health among college students. The same has been highlighted by Eisenberg, Hunt and Speer [10] who emphasized about help-seeking behavior for mental health issues in college population and offers a perspective on next steps for improving knowledge and practice in this area. He also stressed that, traditional barriers such as stigma can only partially explain the high prevalence of untreated disorders and suggested for campus-based intervention strategies such as anti-stigma campaigns, screening programs and gatekeeper trainings. Such programs will create awareness among students; helps to adopt

healthy coping styles and also to seek professional and psychological help for their mental health issues.

Conclusion

In total, healthy students can productively contribute to the development of a country. Mental health is not popular area in India where the concept of campus mental health and policies to promote mental health in schools and colleges is minimal. The help seeking behaviour of college students for their mental health issues need to be encouraged by the government and policy makers in such a way that promotes their mental health and intergenerational equity which will contribute to their overall development.

Evaluation of Prehypertension among School Going Adolescents in Chennai

Srihari R[1], Dilara K[2], Latha R[3], Manikandan S[4]

[1]Demonstrator, [2]Professor, Department of Physiology, [3]Professor, Department of Paediatrics, Sri Ramachandra Medical College & RI, Chennai, [4]Associate Professor, Department of Physiology, Tagore Medical College & Hospital, Chennai

Abstract

Aim:- Adolescence is an important phase of life and increased stress has made them prone for early development of Metabolic disorders. Worldwide prevalence of Prehypertension is increasing and early identification of which will help to manage the development of early hypertension and its associated complications. Hence, current study aims to evaluate the prevalence of prehypertension among school going adolescents in Chennai.

Methods:- The study was conducted among school going adolescents *(n-264)* in Chennai between the age group 15-19yrs. Anthropometric measurements were taken and stress and sleep hygiene were assessed using validated questionnaires. Blood pressure was recorded using Hawkley random zero sphygmomanometer.

Results:- The overall prevalence of Prehypertension was found to be 22.3%. Prehypertension was found to be more in females (23.1%) than males (21.6%).

Conclusion:- There is an increased prevalence of prehypertension among school going adolescents in Chennai. Adolescents should be taught about the importance and benefits of healthy lifestyle for a healthy future.

Keywords:- *Adolescents, Prehypertension, Sleep, Stress, Cardiac issues*

Introduction

Adolescence is a critical and crucial phase of human life and plays an important role in determining an individual's future. As per WHO, Adolescence is the 'period between 10-19years of life'[1]. Adolescence is recognized as both enjoyable and stressful period, and the stress phase of adolescence is reported as the most stressful period in the entire lifespan of an individual. In current era, along with the pre-existing psycho-physiological stress, academics, family and peer pressure has increased the stress level and have made adolescents more prone for psycho-somatic disorders [1].

Prehypertension is a recently coined term and in 2003, the Seventh Report of the Joint National Committee on prevention, detection, evaluation and treatment of high blood pressure (JNC7) has defined prehypertension as 'the Systolic blood pressure (SBP) between 120-139mmHg or the diastolic blood pressure (DBP) between 80-89mmHg'[2]. Prolonged persistence of Prehypertension makes an individual more prone for early development of sustained hypertension[3,4]. Hypertension is a global health issue and has been identified as major risk for most of the cardiovascular diseases. In 2010, Hypertension has been reported as major cause for morbidity and mortality worldwide [5].

In recent years, prevalence of prehypertension is increasing among adolescents and remains undiagnosed[6,7]. Prehypertension being a risk factor for hypertension if left undiagnosed makes adolescents to

Mob.: 9840067879

develop early hypertension thus making them prone for early cardiovascular diseases and premature death [8,9]. Hence, early identification of prehypertension among adolescents becomes need of the hour.

Material and Method

Study participants:-

A cross sectional study and was commenced after obtaining permission from the institutional ethics committee. Study participants were recruited from a private school in Urban Chennai, and the school was selected using computerized randomization software from the school list of urban corporation. Participants were healthy school going adolescents and between the age group (15-19yrs) *(n-264)*. Students with pre-existing primary and secondary hypertension were excluded and participants those who got parent's consent and also gave assent were included in the study.

Study tools:-

General and demographic details about the participants were collected using a questionnaire. Anthropometric measurements like Height, weight, Neck circumference (NC), Waist and Hip Ratio were measured. Blood pressure was assessed using Hawksley random zero sphygmomanometer.

Stress was assessed using Perceived Stress Scale (PSS). PSS is a 10 item self reported questionnaire where the participants answer to ten different questions/ situations. Based on a structured scoring pattern the participants will be categorized in to mild, moderate and severe stress[10]. Sleep hygiene was assessed using Epworth Sleepiness Scale for Children and Adolescents (ESS-CHAD). ESS-CHAD has eight different situations for which the participants should answer his chances of dozing in a scale of 0-3. Total score < 10 signifies good sleep hygiene and total score >10 signifies presence of Excessive Daytime Sleepiness, a sign of compromised Sleep hygiene[11].

Study Procedure:-

The school authorities were explained about the purpose and benefits of the study and written permission was obtained. Informed consent form was distributed two days before the data collection day to get consent from parents and assent was also obtained from the participants. General questionnaire, Perceived Stress Scale, Epworth Sleepiness Scale were explained to the participants and were assisted to complete them. Anthropometric measurements like Height, weight, Neck circumference (NC), Waist-hip ratio (WHR) were taken and BMI was also calculated.

Arterial Blood pressure was measured using a Hawksley random zero sphygmomanometer with appropriate size cuffs. The participants were asked to relax in supine lying for 10minutes and Blood Pressure (BP) was recorded in sitting position. Three readings were taken with regular intervals and BP was noted[5]. BP of all the participants were recorded by trained healthcare professionals

Statistical analysis

The Data were tabulated in MS Excel sheet and SPSS Version 21.0 was used to analyze the data. Descriptive statistics was calculated for background variables. Association between categorical variables was tested by chi-square test and $p<0.0.5$ was taken as statistically significant.

Findings

Total number of participants considered for the study were 271 and those who willingly participated and completed the study were 264, consisting of 134 males and 130 females (n-264). Mean age of the study participants was 15.75+0.65. Among the total participants 50.8% were males and 49.2% were females. Majority of the study participants were from board exam appearing class (39%).

22.3% of the study participants were found to have prehypertension out of which 35.5% of them belong to the board appearing class. (Figure 1)

Genderwise, 21.6% of males and 23.1% of the females were found to have prehypertension though the p value was statistically insignificant.

Majority of the participants were found to be moderately stressed. 19% of participants with mild stress, 26.8% of participants with moderate stress and 17.2% of participants with severe stress were found to have prehypertension and p value was found to be statistically insignificant.

32.2% of the participants with compromised sleep hygiene were found to have prehypertension and p value was found to be statistically significant showing that reduced sleep hygiene increases chances of developing

blood pressure.

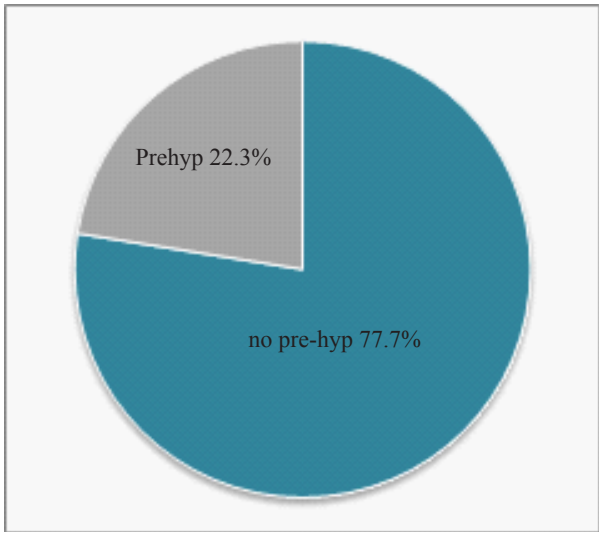

Fig 1. Prevalence of Prehypertension among adolescents

Table 1. Genderwise prevalence of Prehypertesnion among adolescents

Gender	Prehypertension	p value
Males	29 (21.6%)	0.780*
Females	30 (23.1%)	

*p<o.o5 is statistically significant

Table 2. Stress and Prehypertension

PSS Score	Prehypertension	p value
Mild stress	15 (19%)	0.244*
Moderate stress	34 (26.8%)	
Severe stress	10 (17.2%)	

*p<o.o5 is statistically significant

Table 3. Sleep and Prehypertension

ESS Score	Prehypertension	p value
ESS <10	40 (19.5%)	0.03*
ESS ≥ 10	19 (32.2%)	

*p<o.o5 is statistically significant

Discussion

The current study shows the prevalence of Prehypertension among school going adolescents to be to be 22.3%**.** A study conducted among adolescents in East Nigeria showed prevalence of Prehypertension among adolescents to be 17.3% with females having more prevalence than males[12]. Another study conducted in Houston showed that atleast 30% of adolescents had one elevated BP during recording[13]. A study conducted in Kerala reported prehypertension among adolescents to be 24.5%[14] and another study conducted in southern part of Tamilnadu showed prevalence of prehypertension among school going adolescents to be 14.1% [5]. These reports reveal the fact that prevalence of prehypertension is more among adolescents which could be due to their psycho-physiological, psycho-social factors and other lifestyle modifications**.** Genderwise, prehypertension was found to be more in females (21.6%) than males (23.1%). Ingeneral females are more prone for stress and related psychological issues due to hormonal and other psycho-social factors, which along with academic pressure would have made females to develop prehypertension than male adolescents [13].

Stress is common among school going adolescents and has negative impact on health. Distress is a phenomenon which triggers negative pathways in the host and increases the level of stress hormones. Stress hormones such as cortisol, catecholamines increases heart rate, damages blood vessels and causes prehypertension, which if undiagnosed slowly progresses to chronic Hypertension[15]. In our study we found that adolescents with stress develop prehypertension though the p value was statistically insignificant

The results have shown that adolescents with compromised sleep hygiene (ESS>10) have prehypertension. Sleep is required for good physical and mental health. In adolescents sleep becomes an indispensable component required for learning, memory consolidation and healthy growth. Sleep deprivation triggers stress hormones and sympathetic nervous system. Frequent stimulation of sympathetic nervous system increases free radicals and damages blood vessels predisposing to prehypertension and early cardiac diseases [15,16,17,18,19]**.**

Persistent prevalence of prehypertension makes adolescents more prone for development of early hypertension. According to WHO, Hypertension is major risk factor for increased mortality. Young individuals with hypertension were more prone to develop hypertensive cardiovascular complications than older individuals [20], which leads to decreased quality of life and premature death. Prehypertension

among adolescents has been found to be associated with cardiac, renal alterations and target organ damage [21,22]. Adolescents with prehypertension were found to have Left Ventricular Hypertrophy (LVH). Even adolescents with mild elevated blood pressure were found to have target organ damage and early occurrence of metabolic syndrome [23]. Than normotensive adolescents prehypertensive adolescents were reported to have increased arterial stiffness and decreased diastolic function [24].

Conclusion

The current study shows that prevalence of prehypertension is high among school going adolescents in Chennai. Persistent prevalence of prehypertension makes them more prone for development of early hypertension and cardiac diseases which inturn reduces their quality of life. Hence, adolescents should be taught about stress management, importance of physical exercises and healthy diet to lead a healthy life [16,17].

Study of Death among Children Below Five Years of Age and its Relation to Parentseducation and Place of Residence Using Verbal Autopsy as a Tool in Deharadun

Sushil Dalal[1], Kiran Pande[2], Vishal Modgil[3]

[1]Associate Professor dept of Community Medicine MMU Mullana Amballa, [2]Assistant Professor Dept of OBG MMU Mullana Ambala, [3]Final Year PG Student

Abstract

Around the world more than 10 million children under the age of five die every year and the world poorest countries continue to bear the burden of these deaths [1]. Prevalence of under-five mortality vary from 4 to more than 28 deaths per 1000 live births The study was conducted to find out relation in-between child mortality of under-five years of age and parents education along with place of residence using verbal autopsy in Dehradun.

Methodology: The survey was done on all the house of the deceased children residing in our field practice areas by visiting their houses.

Results: Most of the parents were found illiterate among 83 deaths reported during study period.

Conclusion: Many of the under five children deaths can be prevented if parents are literate, which can help in reducing mortality rate among under five children.

Keywords:*poorest countries****,*** *parent's education****,*** *deceased children.*

Back ground

Information on factors leading to death is extremely important for policy-making, planning, monitoring and evaluation of health programs, as well as necessary for field research, comparisons, and awareness. This is particularly more so important for childhood deaths, which is constituting a major portion of all deaths, and of which many intervention programs are currently attempting to reduce mortality among under five deaths1.. Education has been one of the key concepts used as a variable in explaining health. The influence of parental education on infant and child health and mortality has proved to be universally significant. In the literature on child health, parental education has received particular attention, as indeed have all other social, demographic and health characteristics of the parents 2.

Material and MethodsThe study was undertaken for one year in the field practice areas of department of community medicine HIHT Dehradun after taking approval of institutional ethical committee. The total population registered under Rural Heath Training Centr e(Rajeev Nagar) & Urban Health Training Centre was 12,588 and 12,930 respectively out of which under five children were 1297 at RHTC and 1325 at UHTC.

All deaths except still births registered with Rural and Urban Health Training Centre were included in the study. When a child died, the mother or the respondent was questioned in detail about the parents education and place of residence of children prior to death. A drafted questionnaire (Englishversion) developed by WHO, was modified suitably, as well as certain variables were added to it to find out any correlation in-between under five children death and parents education along with place of residence[3]. The information so collected, was first coded and then entered in the computer. The analysis was done by using SPSS software. Appropriate statistical methods (proportion and chi – square test) were applied as per

requirement.

Result

Total number of deceased children in both the areas were 83, out of which 39(46.9 %) were in rural area and 44 (53.1 %) in urban area. Out of 39 deaths in rural area, 29 (74.4 %) died before the age of one year while 10 (25.6 %) died in age group of 365 days - < 5 year. Similarly in urban areas 44 deaths took place. Out of these 25 (56.8 %) died below age of 1 year and 19 (43.2 %) died in age group of 365 days- < 5 year. Table 2 and table 3 shows that proportionately more children's had died of illiterate parents then of literate parents irrespective of urban and rural areas.

Table 1 distribution of deceased children by age, sex and place of residence (n=83)

	Rural (%)	Urban (%)	Total deaths (%)	Chi squar value	Degree of freedom	P value

Discussion

In the present study higher percentage of mortality was observed amongst children, belonging to fathers who were illiterate (53.8 % - rural and 50.0 % - urban). Children belonging to illiterate mothers also showed higher percentage of mortality in both rural and urban areas i.e. 74.4 % and 72.7 % respectively. It is generally observed that the literacy status of mothers in urban and rural areas has a greater impact on the health status of children particularly in relation to mortality, than that of fathers.According to NFHS – 3 Uttarakhand [4] under 5 mortality was 97.2 % whose parents had no education, while it was 54.1 % among those whose education was less than 10 years and 28.1 % where parents had education , of 10 years or more. Findings by other authors also showed that mortality rates in illiterate parents were higher as compared to the literates.The literacy rate in the study area particularly in the urban slums is very low which could be again due to migratory population from other states. If we compare the literacy level with that of Uttarakhand NFHS – 3 (Uttarakhand)[4] we find that 86 % of males and 65 % females are literate in Uttarakhand while reverse is the case of our study population.

In a study done by Katz et al (2003)[5] observed that maternal and paternal education was important as predictors of mortality only for infant who died in the post-natal period, with maternal education providing more protection than paternal education. Maternal and paternal education were independent predictors of mortality beyond the neo natal periodwhich suggests the importance of educated men in this paternalistic society in addition to the role played by the mothers in protecting the infant from mortality risks. In another study done by Syamala(2004)[6]observed that the association between mother's education and survival rate of children during infancy is strong and direct. This pattern of association is observed in each group of the mother.

In another study done by Khalique et al (1993) [7]concluded in his study conducted in 9 villages of Rural Health Training Centre, Jawan, Aligarh, India observed that higher percentage of mortality was presents amongst children belonging to fathers who were illiterate or just literate (59.38 % Rural and 56.25 % Urban) . Children belonging to illiterate or just literate mothers also showed high percentage of mortality in both rural and urban areas i.e. 73.44 % and 62.50 % respectively. It was observed that the literacy status of mothers in urban and rural had a greater impact on the health status of children particularly in relation to mortality, than that of fathers in terms of percentage. It was also observed that mortality was low in children whose fathers had intermediate or degree qualification (6.25 % rural and 12.50 %). Children of mothers with similar educational

qualification also showed low mortality (3.12 rural and 12.50 urban).It was also observed in NHFS-3 Uttarakhand (2006)[4] that children, whose mothers have no education are thrice as likely to die before their first birthday as children whose mothers have completed at least 10 years of school. Our study also indicates more or less similar results in accordance of previous studies.

In a study done in Turkey byToros and Kuluamong 1982 birth cohorts found that father's education to stand out as one of the most important factors associated with infant survival. They report that babies whose fathers do not have primary school education are 1.6 times more likely to die within the first year of life than babies whose fathers have at least finished primary school. Babies whose mothers have no primary school education, however,are 1.15 times more likely to die in their first year[8].Where as in a cross-national study by Mensch, Lentzner and Preston (1985), it was shown that mother's education was a more powerful explanatory variable than father's education in rural areas[9].In another study done by Hobcraft, McDonald and Rutstein (1984) showed in their cross-national study that in Latin American countries, mother's education had more explanatory power, while in some Asian and Islamic countries, father's education and occupation and mother's work status emerged as rival predictor variables .[10]GŸrsoy-Tezcan also found in their study in 1992 that the husbands' formal education surpassed the women's formal education as well as all other criteria in explaining child mortality[11]. Where as In 1989 Preston's Is literacy a missing link between female schooling and reduced child mortality in developing countries? An affirmative answer might be based on Preston's (1989) model of mortality reduction, which gives a central place to literacy in the spread of improved health knowledge to mothers of young children[12].

Another study done by Jain in 1985found the effect of female education is complementary to that of health services. In fact, under certain circumstances the effects of the two factors may even be synergistic, because both facilitate changes in health seeking behaviour. These points were illustrated in an earlier study by comparing education-specific infant mortality rates among rural women of two states in India, Kerala and Uttar Pradesh (Jain 1985b)[13]. In an interesting study done by Caldwell in Nigeria 1975 found that maternal behaviour is probably important, he observed an area in Nigeria far from medical services much better survival rates were found among the children of mothers with schooling (usually incomplete primary schooling) than those without schooling.(Orubuloye and Caldwell 1975)[14] whereas Caldwell in 1980 reached to the conclusion that the main proselytizer for modern science is the school, even in its earliest grades when no science is taught formally (Caldwell 1980) [15].

Education of mother that were significant in their magnitude and each likely to result in the greater survival of the children of more educated mothers. The first of these is that educated mothers were more likely to take children to the health centre for both preventive and curative medicine. Their mothers-in-law allowed it and expected it, for most parents now try to arrange their sons' marriages to educated young women and one of their strongest motives is that such women are more likely to ensure the survival of their grandchildren (Caldwell,1983b) [16]. It was observed that

Belief in the necessity of access to modern health services intensifies with each year at school. It is this import of both modern medicine and modern education with its commitment to modern medicine, and indeed all modern science, which determines how thoroughly both curative and preventive services are used; it explains the large differentials in child survival by maternal duration of education found in the contemporary Third World to a greater degree than has ever been the case in the West (Caldwell1986).[17]

Conclusion

literacy of parents plays a crucial role in decreasing under five mortality in one way or the other ways especially in poorer countries. Our emphasis must be on parent's literacy rate while we make policiesand programs for under five children.

Abstract

Background: Iodine Deficiency Disorders is a significant public health problem all over the world.Iodine is essential element for thyroid function, necessary for normal growth, development and functioning of brain and body. **Objectives:** To estimate the prevalence of goiter among school children and to assess the prevalence of useof iodized salt. **Material and Methods:** A Cross sectional study conducted among Children between 6-12 years of agein Mappedu area.A pre-tested questionnaire, Rapid test kit to find iodine content of salt and clinical examination to assess goitre was done for the study subjects.The sample size calculated was120.Dataanalysis:Proportions and chi-square was used for analysis. **Results:** 65% were using iodized salt and remaining 35% were using non-iodised salt.The prevalence of goiter was found to be 17(14.2%). **Conclusion**: One-third of children and their family were not consuming adequately iodized salt. The consumption of iodized salt is still less in the community and Iodine Deficiency Disorders continue to be a public health problem.

Key words: *IDD, Goiter, Iodized Salt, Rapid test kit.*

Introduction

Iodine Deficiency Disorders is known to be a significant public health problem all over the world. Iodine is essential element for thyroid function, necessary for normal growth, development and functioning of brain and body.Iodine deficiency is known to cause endemic goitre.[1]

Salt iodization programs is being implemented in many countries of the world for more than five decades ,currently only two-thirds of the global population (71%) is estimated to be covered by iodized salt, while the rest (31%) of the world population have insufficient iodine intakes, with the most affected WHO regions being South-East Asia and Europe.[2]

Iodine deficiency disorders are estimated to result in loss of 2.5 million disability adjusted life years (DALYs) (0.2% of total globally).[3] In India it is estimated that more than 71 million individuals suffer from Iodine Deficiency Disorder, while another 200 million people stay in iodine deficient areas.[4]The Iodine Deficiency Disorder control goal in India was to reduce the prevalence of IDD below 10% in the entire country by 2012.[5]

In Tamil Nadu, the IDD control cell was established with Central Government assistance and is functioning since 1st July 1994.Goiter surveys and resurveys of all the districts are being carried out periodically since 1991. According to National Family Health Survey (NFHS)-4 in Tamil Nadu proportions of households using iodized salt is 82.8%.TotalGoitre rate is reported as 13.5% in Tamil Nadu.[6]

Although the importance of iodized salt and its usage has increased in the community,Iodine deficiency poses a threat to health, wellbeing and economic productivity of the community.Progress toward the elimination of Iodine Deficiency Disorder can only be demonstrated if it is measured.

Monitoring iodine levels of salt and iodine status of population are the two important components of Iodine Deficiency Disorder program monitoring, hence the study has been conducted.

Objectives

1.To estimate the prevalence of goiter among school children in rural area.

2.To assess the prevalence of use of iodized salt among them .

Methodology

A cross sectional study was conducted in Primary School,Mappedu between May 2018 – July 2018. Children between 6-12 years of age were selected by using Simple Random Sampling method. The sample size of 120 was calculated by using 76.2% of households residing in rural area were using iodized salt.[7]Using a pre-tested questionnaire,details regarding edible salt used within the family was obtained. Children were asked to bring 1-2 teaspoon of salt which is used for cooking purpose at their home in a sealed plastic bag and Iodine content in salt wasestimated using Rapid Test Kit.

Children were clinically examined for the presence of enlargement of thyroid gland.Children who were not present in the school at the time of data collection and those who are not willing to participate were excluded from the study. Data was entered in MS Excel. Proportions and chi-square were used for data analysis.

Salt Sample Collection & Testing:

One teaspoon of salt was obtained from each household for testing purposes.Rapid test kit was used to estimate the iodine content of salt. [8,9,10]

- One to two drops of the test solution was put on the salt sample,if the colourchanged from white to blue/ purple, indicated the presence of iodine to threshold of 15ppm.

- For alkaline salt samples or salt with high moisture content, one drop of recheck solution followed by starch solution was used to test the presence of iodine in salt.

Clinical Examination:

Enlargement of thyroid gland was assessed and presence of goiter was graded as per WHO guidelines. [6,11]

- Grade 0: Thyroid gland was neither palpable nor visible/ no goiter.

- Grade 1: A mass in the neck that is consistent with an enlarged thyroid that is palpable but not visible when the neck is in normal position. The mass moves upwards with deglutition/goitre palpable not visible.

- Grade2: A swelling in the neck that is visible when the neck is in normal position and consistent with enlarged thyroid when the neck is palpated/goiter visible and palpable.

Operational Definition For Iodised Salt:

Iodised salt is defined as one which contains iodine content of ≥ 15ppm at the household level as determined by Rapid Test Kit.[12,13,14]

Results

120 children participated in the study, they belonged to 6-12 years age group mean age was found to be 9.14 years. Majority of them (50.8%) were using powdered form of salt. 80% of the study population were storing salt away from the fire.More than 90% of respondents have kept the salt in closed container.Majority of the households have bought packed type of salt 88.3% while 11.7% were found to purchase unpacked type of salt. (Table-1)

Table 1: Background Characteristics of Study Subjects(N=120)

BACKGROUND CHARACTERISTICS OF THE STUDY SUBJECTS (n = 120)			
S.NO	**CHARACTERISTICS**	**(N)**	**(%)**
1	AGE		
	6 years	18	15.0
	7 years	15	12.5
	8 years	14	11.7
	9 years	16	13.3
	10 years	18	15.0
	11 years	20	16.7

Cont... **Table 1: Background Characteristics of Study Subjects(N=120)**

	12 years	19	15.8
2	FORM OF SALT		
	Powdered	61	50.8
	Crystalline	59	49.2
3	PLACE OF KEEPING THE SALT		
	Kept near fire	24	20.0
	Kept away from fire	96	80.0
4	TYPE OF SALT BOUGHT		
	Packed	106	88.3
	Unpacked	14	11.7
5	STORAGE OF SALT		
	Open container	8	6.7
	Closed container	112	93.3

All the 120 children brought the salt samples from their houses. On testing the salt samples with Rapid Iodine testing kit 65% of the samples colour was changed to blue which indicate the presence of iodine≥15ppm. (Table-2).

Table 2- Distribution of Iodized Salt among Study Participants.

Iodine Content of Salt	N	(%)
Non-Iodized	42	35.0
Iodized	78	65.0
Total	120	100.0

Among the salt samples which the participants told they buy packed salt 70.8% were found to be iodised. While only 21.5% of unpacked salt was iodised. This difference was found to be statistically significant. (Table-3)

Table 3-Association between Iodine Contentof Salt and Types of Salt.

Type of salt	Iodized (%)	Non-Iodized (%)	Total
Packed	75(70.8)	31(29.2)	106
Unpacked	3(21.5)	11(78.5)	14
Total	78(100)	42(100)	120

*Chi square:13.225,P value: 0.000 ***P<0.05 is considered as significant.**

In the present study 61 salt samples were in powdered form and remaining 59 were crystalline. 70.5% of powdered salt was found to be iodised while 59.3% of the crystalline salt was iodised.This difference was not found to be statistically significant.(Table-4)

Table 4- Association Between Iodine Contentof Salt and Form of Salt.

Form of salt	Iodized(%)	Non-Iodized (%)	TOTAL
Powdered	43(70.5)	18(29.5)	61
Crystalline	35(59.3)	24(40.7)	59
Total	78(100)	42(100)	120

Chi square: 1.644,P value :0.199. ***P<0.05 is considered as significant**

Clinical examination was done among school children, the presence of enlargement of thyroid was checked and grading was done as per WHO guidelines. Goitre was diagnosed in 17 children. The prevalence of goiter was found to be 17(14.2%). Among those 17 children, 15(12.5%) of the children were found to have grade 1 and 2 children (1.7%) were found to have Grade 2 Goiter.(Table-5).

Table 5- Distribution of goitreamong the participants

Grading of Goiter	N	(%)
G0	103	85.8
G1	15	12.5
G2	2	1.7

Among 17 children who were clinically diagnosed to have goiter, 16 (94.2%) were not consuming iodised salt while only 25.2% children without any signs of clinical goiter were not consuming iodised salt. The difference was found to statistically highly significant.(Table-6)

Table 6- Association between iodized salt and goiter among study participants.

Iodine Content	Goitre Present (%)	Goitre Absent (%)	Total
Non-Iodized	16(94.2%)	26(25.2%)	42
Iodized	1(5.8%)	77(74.8%)	78
Total	17(100%)	103(100%)	120

*Chi square:30.42,P value : 0.000 ***P<0.05 is considered as significant OR= 47.**

Discussion

This study was carried out to assess the utilization of iodized salt in the rural community and prevalence of Clinical goiter.In the present study only 65% of the participants were consuming iodized salt which was less than reported by NFHS 4 in rural Tamil Nadu 76.2%.[7]

In our study 49.2% of the participants were using crystalline form of salt and 11.7% were getting unpacked salt.

The prevalence of goiter was found to be 14.2% in our study which was found to be similar to the results of national level survey data conducted by ICMR where the goiter prevalence was 14.1% (5-14 years age group).[15]Chandrakant et al reported 13.5% of school children showed enlargement of thyroid gland.[6] Zargar et al reported a higher prevalence of goiter30.2 % in children less than 6 years old and 50.6 % in children greater than 12 years old in Kashmir.[15]

In the present study all except 1 child who were diagnosed to have clinical Goiter were not consuming iodised salt. Odd's Ratio was found to be 47, this shows all those who were not consuming iodised salt were at 47 times greater risk of getting Goiter. Goiter is just one of the clinical manifestation of Iodine Deficiency Disorders,IDDs can also manifest as mental retardation, still birth, abortion, deafness, mutism, squint and neuromotor defects.[16]

More number of packed and powdered salt samples were found to be iodized in comparison to unpacked and crystalline salt. Indian government has issued the notification on banning the sale of non-iodised salt for direct human consumption in the country in May 2006 under the Prevention of Food Adulteration Act 1954.[17] In the present study one third of the families are found to consuming non-iodised salt. Therefore Government should take necessary actions to check the sale of unpacked salt and non-iodised crystalline salt in the market.

Conclusion

One-third of children and their family were not consuming adequately iodized salt. National Iodine Deficiency DisordersControl Programmewas startedfifty years back, but the consumption of iodized salt is still less and Iodine Deficiency Disorders continue to be a public health problem. Hence health education regarding Iodine deficiency disorders and adequate utilization of iodized salt is the need of the hour. Strict actionsshould be taken on the sale of non-iodised salt to have significant impact on the health and well-being of the country.

Limitation: The Urinary iodine excretion level was not estimated in this study.

Conflict of Interest: Nil

Source of Funding: Nil

Ethical Clearance: Ethical approval was obtained from the Institutional Review Board (IRB) and Institutional Ethics committee. Written informed consent was obtained from the parents of the study participants and information sheet regarding the study was given to all the participants.

Health Care Facilities in Child Care Institutions in Delhi

Hrishika[1], Rakesh Rai[2]

[1]PhD Scholar, [2]Assistant Professor, Amity Institute of Social Sciences, Amity University, Noida, Uttar-Pradesh, India

Abstract

UNCRC which is known as United Nation's Convention on the Rights of the Child has clearly distinct that an individual who has not accomplished 18 years of age is known as a child. The recent figures in the area of child rights shows that total child population in India is 472 million which makes thirty nine percent (39%) of India's entirety population [1]. Orphaned and destitute children in India are found to be 20 million [2]. Children who found in difficult circumstances are categorized in two categories that is Children who needs care and protection and who are conflict with law [3] and these children placed in custody of institutions where they stay for long period or short period which depends on the recognized need of the child. Children living in institutions or children homes necessitate basic care, health and educational services. These integration and rehabilitation functions must address needs of children and helps in removing challenges from their path of development. As endorsed in Juvenile Justice (Care and Protection) Act 2015 these institutions must follow standardized norms and provide services to cater the obligatory requisite to all children. The services include food, protected shelter, apt attire, remedial aid and other required service. The aim of this research study is to understand significance of the facilities provided to children with special reference to health care facilities in Child Care Institutions in Delhi.

Keywords: *Child Care Institutions (CCIs), Children in Need of Care and Protection (CNCP), Condition of Health, Health- facilities, Medical-care, Medical-services*

Introduction

In India population of the children (including 0-18 years) is estimated 472 million. According to National Institute of Urban Affairs (2016) in India 39% of the total population contains children. Even after end numbers of laws and policies have been implemented after the independence era the visible extreme poor condition of children can be seen through recent surveys and research studies. Children have equal rights but issues related to protection of children have always indeterminate and unaddressed matters of nation. The studies have shown that a huge number of children suffer abuse, neglect, unequal access to resources, poverty, discrimination, and homelessness despite of existence of laws and policies [6]. A number of researches have been taken up over a period of time to describe the deprived condition of children living in difficult circumstances in India. It is factual and so evident that children are dependent on adults primarily on their parents for their needs, growth and development. It is believed that family holds the primary responsibility of the child. Family caters all kinds of needs which comprise emotional support, physical care, psychological desires and economic needs of the child. A family is usually the most important and protective environment of the children (Richard Carter, 2005). Both bodies UNCRC and the Juvenile Justice (Care and Protection of Children) Act 2000 [3] mentioned that it is the prime duty of biological families of the children to help children grow in protected environment. Further it states that in deficiency of familial support it is the accountability of State to obligatory protects children who are underprivileged and destitute of family love and support [9]. All Children who by the law are identified in need of protection are located in institutions. The duration of the stay of children in these institutions can be up to days, months or years depending on the nature of each child case [4]. India's population of orphaned and destitute children is anticipated to be 20 million which reflects the needs of these institutions [3]. State plays a vital role in providing safe shelter to these children so that they must grow with their full potential. Special provisions are made in Juvenile Justice (Care and Protection) Act 2015 (abbreviated as J.J Act) which

promotes accurate rehabilitation and adaptation of children in society [5].

Understanding Children in Need of Care and Protection CNCP cases:

A child is known as a person below 18 years of his/ her age as mentioned in Convention on the Rights of the Child (abbreviated as CRC) but it is also noted that age of a child defined in diverse legislations pertinent to them in different circumstances [7]. A child who is in any circumstances like abused, working, orphaned, at families at risk, abandoned, differently abled, victims of sexual exploitation, on streets, beggars, affected by disasters, physically and mentally abused, drug falls under the purview of CNCP cases as mentioned in JJ Act. Cases of CNCP are hear by the proficient government organization namely Child Welfare Committee (abbreviated as CWC). CWC is a work surface of members wherein a chairperson and four members designate to exercise their rights in cases of CNCP. These members are proficient in their fields and every case of CNCP produces before the bench. The best interest of the child is main objective of the committee and keeping the needs of every case of the child it takes decision to return them to their original parents or custodian or to available suitable members of family. CWC issues certificate to child who is with permission is available for adoption in the cases where child cannot be placed in original family. There are also cases where child cannot be placed in family or family like environment thus child stays in children homes depending upon his/ her age and needs identified in the respective cases.

Significance of Child Care Institutions (CCIs):

The foundation of Child Care Institutions was laid down to address the challenges of children who live in extreme complicated circumstances and are in need of long term place of safety. It is widely measured as one of the best sources to rehabilitate children. Under the provisions of the JJ Act the term "child care institution" is defined as any home for children whether run by the government or non government authority or place of safety or specialized adoption agency and a fit facility intended to provide care and protection to children. The basic and fundamental function of all types of children homes is to address the developmental needs of the children. It means that CCIs are designated to grant physical, emotional, mental and educational facilities to all children. These children homes are endorsed to register under the act. It is mandatory to pursue the uniform rules and regulations defined in the act [8]. To regulate CCIs a provision of cancelation of the registration and punishment is given if the home violates rules, regulations and standard norms prescribed under the act. Children residing in homes are in need of rehabilitation and require integration in the society [11]. These institutions are being established to provide secure place of stay children, to address whole rehabilitation, to uphold physical and mental health and on the whole growth and development of all children.

Facilities provided in Child Care Institutions:

i. Basic and essential care facility:

Basic and essential care facilities provided in Child Care Institutions are meant to endow with basic necessities to children including safe accommodation, age and gender suitable garments, sufficient as well as healthy food, supervision and attention from the adults [10].

ii. Health care facility:

Providing proper medical assistance and taking care of children health is the most vital function of Child Care Institutions. The heath care services given to children includes: facilitate immunization as per their age, monitoring of physical growth and maintenance of the records, routine check ups and arranging visits of the doctors, taking children to doctors as and when needed, giving children medicinces on time, taking care of their diet and ensuring proper medical care.

iii. Educational facility:

Children living in CCIs are attending formal education. Every child has right to be admitted to school. Children who require extra attention bridge and tuition classes are arranged for them to ensure that no child would lack behind in education because of their past events.

iv. Counseling facility for psychological needs:

Child Care Institutions provide regular counseling sessions to all children which is done by a qualified psychologist to address and cater psychological and mental well being of every child in institutional care.

v. Recreational facility:

Child Care Institutions arrange and organize age suitable recreational activities such as dance, yoga, music, picnics, outings, sightseeing, monuments visits, educational visits, participation in cultural events, festival celebrations, national and international days celebration, birthdays celebration this further enlightening child's concentration and aptitude as well as provide children opportunity to explore and experience new world.

Objectives

- To understand the significance and facilities provided to children in Child Care Institutions in Delhi.
- To study the health care facilities provided to children residing in Child Care Institutions in Delhi.

Methodology

The study was undertaken to understand health care services provided to children who are staying in Child Care Institutions in Delhi. Integrated research approach using both quantitative and qualitative method is been adopted to gain better understanding of contemporary status of children in institutional care. A interview schedule (semi structured) was used as tools and techniques of data collection. Data analysis was done using thematic analysis also using Statistical Package for Social Science (SPSS) software.

The study was conducted in children homes in Delhi and included both types of children homes- NGO as well as government. The children who are in long term care were interviewed.

The sample was collected from 4 children homes out of which 2 were NGO homes and 2 homes were of government in nature. The sample sizes of 20 children- 10 male and 10 female from both children homes were approached. The children were from the age group of 10 - 18 years. A total number of 5 stakeholders working under heath care unit of the children homes were also interviewed to know the process of health care services.

Findings

Thematic Analysis:

Health of the children: It was found that at the time of the admission of children in institutions children are diagnosed with infirmity similar to skin diseases, fits, lower immunity, low weight, malnourishment and other diseases due to the inappropriate and harmful events occurred in their previous life prior coming to homes [12]. Children are found to be frequently ill and have complains of frequent fever, stomach pain, headache, etc, due to lower immunity system and malnourishment.

Heath care facilities in Child Care Institutions: Each child care institutions have medical staff including a full time nurse and a visiting physician. When children are admitted in child care institutions the medical staffs takes care of all the health related needs of the children and essential amenities are being provided. Children homes have both visiting as well as regular doctors and other staff to examine standard health check of children. The health care team or staff members are responsible to provide following services to all the children:

- Facilitating immunization as per the age of the child,
- Monitoring of physical growth including weight, height, head and chest circumference,
- Maintenance of the health records and individual files,
- Routine check ups,
- Arranging visits of the doctors in case of refer to special doctors,
- Taking children to hospitals as and when needed,
- Giving children medicines on time,
- Taking care of the eatery habit and diet of each child,
- Ensuring delivery of medical services to all the children.

Quantittive Analysis:

Relationship between health of the children and nature of children homes:

As this study covered both type of children homes government and NGO hence to find out the relationship between health of the children and nature of the children homes test namely Two sampled t test was applied.

Row Labels	Don't Know	Good	Not Good	Grand Total				
	Count	%age	Count	%age	Count	%age	Count	%age
Govt. Home	3	30.00%	4	40.00%	3	30.00%	10	50.00%
NGO Home	1	8.33%	8	83.33%	1	8.33%	10	50.00%
Grand Total	4	18.18%	12	63.64%	4	18.18%	20	100.00%

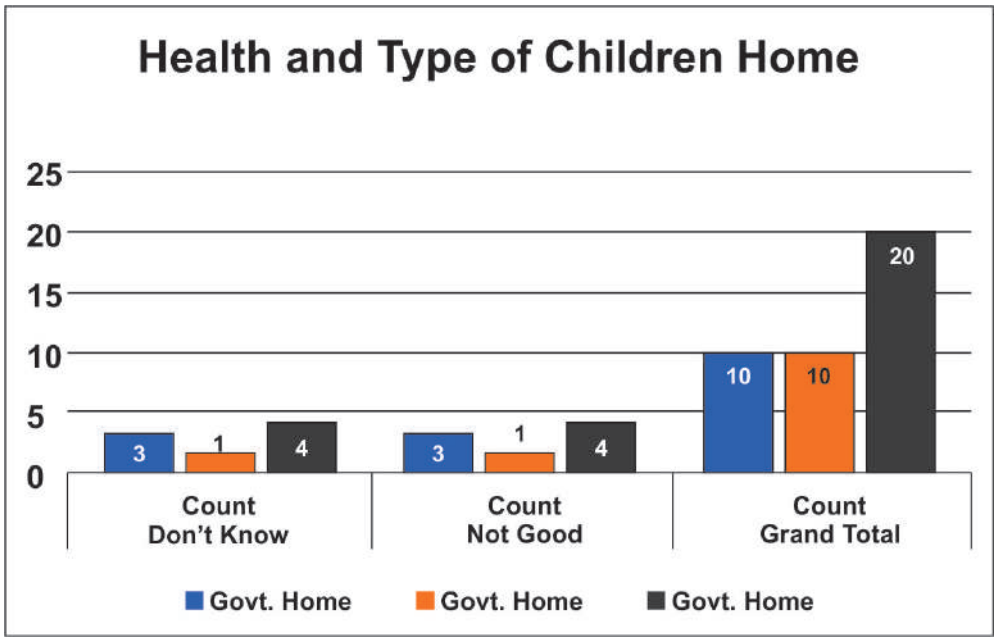
Name of the test - Two Sample t-test

t = 0.22086

df = 4

p-value = 0.418

95 percent confidence interval: (-5.768231,Inf)



The above mentioned data indicates no connection between health condition of children and the nature of children home. It further indicates that children in NGO home are evenly healthy as in children living in government homes. And the same health facilities are offered to children in both the homes.

Conclusion

The establishment of Child Care Institutions was initiated to save children from any type of complex and destructive situation and is considered as one of the finest mean to cater to the needs of children who are not in parental care due to some reasons and have need of safe- place, support and care which can be for long or short period of time depending on the needs identified by the competent authorities. It is known as fit facility for children. Child Care Institutions are approved and obliged to fulfill all requirements from giving basic facilities to health, a place of safety, and educational as well as emotional support to all children residing in these children homes. This study was conducted to understand health care facilities provided to children living in institutions covering both types of children home that is NGO and Government. Outcomes of the study indicate both the children homes that are government and NGO provides facilities to children and adhere rules and

guidelines as endorsed in JJ Act. It was found in the study that children who are admitted in Child Care Institutions gone through horrendous encounters occurred in their early period of life because of which they are more prone with sickness like fits, skin illnesses, worse resistance, low weight, malnourishment and others. Children when admitted to child care institutions their wellbeing needs are taken consideration by staff members and all essential and fundamental things is been given to them. There are ordinary and low maintenance specialists and staff medical caretakers who screen customary registration of the children. At the point when they fall ill they are taken to the medical clinics and hospitals by their caregivers. The information proposes that children in government home are similarly healthy as children living in NGO run homes. And the same health facilities are offered to children in both the homes.

Ethical Clearance: As part of the primary data, the data was collected under the PhD programme of Amity University by the PhD scholar from children living in child care institutions and stakeholders. The consent of the primary respondents was taken at the time of interviews and their identities remain confidential. Hence, data does not contain any identifiers and no ethical issues were involved in this research study. Therefore, no ethical clearance was taken.

Source of Funding: The data was collected under the PhD programme hence this research study is self financed by the PhD scholar.

Quality Assessment Using EFQM Model for Overall Excellence of Indian Health Care Sector

Bindusagar Pattanaik[1], Aurolipy[2]

[1]Research Scholar, [2]Associate Professor, Faculty of Management Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar

Abstract

Quality point of reference is the main priorities of hospitals and quality assessments in hospitals is the biggest challenges which is determined by many tangible and intangible factors. The purpose of the paper is to investigate the quality assessment of hospitals in Odisha using the European Foundation for Quality Management (EFQM) model. Prior literature had focused on different sectors but less applicability of this model in the hospitals. In order to address the gap, the present research used a quantitative methodology to collect the data through a questionnaire from the healthcare professionals including doctors, hospital managers and Senior Executives in hospitals of Odisha. Random sampling was used where 87 respondents participated in this study. The results confirmed the significant contribution of the EFQM determinants in relation to each other .The results emphasis on the results of the EFQM model and it had both practical as well as academic contribution in the quality assessment in the hospitals and finally it has conclude EFQM model has played a vital role in influencing the quality assessment of hospitals.

Keywords: *Quality assessment, Healthcare, EFQM Model, Quality Management.*

Introduction

Quality has become a vital part of our day to day life. Quality as a tool is used by hospitals to gain a competitive advantage over competitors. By quality improvement it reduces waste, lower cost, market share is increased. Which in turn provides a hospital patient satisfaction and other stake holders in productivity and profitability. Health Care providers provide a variety of services various factors are taken into consideration in delivery of these services. Services have a multidimensional concept which specifies healthcare quality as the application of science and technology to maximize benefit to health without increasing risk. Quality service delivery is the most important priority of the hospital. Service quality and EFQM are most popular model implemented in the hospitals. EFQM most popular quality excellence model focus on continuous improvement organizational process. EFQM tries to improve service quality and is a tool helping hospitals to measure the path of excellence and helps in finding the gap and suggest for further improve or enhancement. EFQM model provides a total view approach, satisfies patients and its stakeholders, financial concern and self assessment instrument used in finding out the gaps in process improvement. This it is essential for the study of quality aspect in the hospital and implement model for excellence in health care delivery services.

Literature Review: Vallejo et al (2007) used the EFQM model in a psychiatric ward and found EFQM model as a excellent framework for quality assessment and a good tools for identifying the areas for quality improvement. Only one criteria didn't apply to the ward out of the 232 sub criteria. The study was in Spain used quasi experimental research design using EFQM

model which aimed at quality by which the number in admission increased, length of stay and readmission process time decreased.[2]. TQM model was implemented to improve the quality standards of the Palestinian public and private hospitals [12].Implemented the EFQM model and the factors were extracted to measure the quality perceptions of health care organizations and measured the relationship between quality dimensions. Strong relationship was based on leadership, resource management, people management and customer satisfaction[9]. Moeller J (2001) used EFQM model in German health care services, the model was proven to a quality management tool to gain a competitive advantage [1]. Sanchez et al(2005) Studied in Spain using Observational Methodology used EFQM model. The study aimed at quality, efficiency. They found satisfaction level increased and average length of stay and waiting time for surgical is increased. The majority of EFQM criteria improved, especially noticeable in 'processes' and 'people results'[3].Leadership and employees greatly affect quality initiatives on success or failure in the healthcare organizations [10].Leigh et al(2005) study in UK using Survey methodology EFQM model Qualified nurses Confidence, competence and retention of newly nurses increased.[4]. Rodriguez Cerrillo et al. (2002)in Spain used quasi experimental with ISO 9001. The result outcome was patient satisfaction improved[5]. Excellence Organizational Model of European Foundation for Quality Management has been on nine criteria [7]. They proposed a model which include four stakeholders i.e. patients, activities, resource and their effects. They used six levels and the model proposed by them was compatible with other models [8]. The 9 principles of EFQM model are Leadership, Policy and strategy, People, Partnership and resources, processes, customer results, people results, society results and key performance results. EFQM model implemented in thermal sector in order to improve the excellence in quality [11]. Human resources and customer results should be given more emphasis for improving the organization excellence model [6].

Research Objectives:

1. To find out the factors which determines the EFQM model in hospitals in India.

Materials and Method

Descriptive research design is used in the study. The population in the study was the hospitals in Odisha and the samples was confined to the health care professional including doctors, senior executives, top management A total of 87 questionnaire was found to be correct Respondents 45% were male and 55% were women and belonging to age group consisting of 18% of respondents having age between 24 to 29 years whereas maximum respondents belonged to age category 40-49 years. 80% of respondents had master degree and having job experience of more than 10 years.

Assessment of Hospitals using the SCORE of EFQM:

a. Leadership: Hospitals showed the score in between the range of 55 to 67 points.

b. Policy and Strategy: Hospitals showed the score 65,66,54

c. People: The scored varied between 45 to 56

d. Partnership & resources: Hospitals showed score between 52 to 67

e. Processes: Scored varied between 75 to 96

f. Customer result: Score varied between 130 to 160 out of 200.

g. People result: Score varied between 55 to 78 out of 90.

h. Society Results: Highest among all the hospital was 56.

i. Key Performance Results: The highest score was 126 among all the hospitals

Correlation matrix specified the e correlation between the various parameters of the EFQM model and their relationship positive relationship exists between the variable towards the EFQM.

Discussions

The above table specified the correlatinship-which is represented as the correlation matrix. 9 factors of the EFQM model was suggested i.e. leadership, policy & strategy, people & partnership and resources, process, customer results, people results, society results and key performance results. Positive relationship was established between leadership and policy strategy, positive relation is shown between leadership and people, positive relationship between partnership and resources. Policy and strategy have a positive impact on process. Leadership influences the policy strategy, people and partnership resources. So, it very much essential for the managers to understand these factors and to know to what degree leadership can influence the strategy formulation and people and partnership resources. Knowledge of different stakeholders should be known as per that policy and strategy has to be formulated. In order to achieve excellence in hospitals people have to be involved. Partnership and are aligned with strategic alliances and that gives more value to the chain. Key performance results in the hospitals are linked with customer, process and people results. The results obtained are being compared with EQA (European quality association) benchmark scores and the hospitals selected in the study have the score above the average score of EQA. The process, customer and key performance results showed a difference among them. Society results had been below the average score of EQA. The EFQM model criteria are being divided into enablers and results and there a strong causality between the enablers and the results criteria as being found in the study. The identify excellence factors are leadership, partnership and resources, policy strategy, people and processes. These criteria perform the operational excellence in the hospitals. Patients are important than stakeholders,employee,partners. Not only processes, performance, are important but also patients are very important for the excellence in the hospitals.

Conclusion

The study focused on implementing the EFQM model in hospitals and it had a strong contribution in the way of EFQM in the health care sector. The study done in hospitals tried to fill the gap between various parameters on the basis of results. Society, key performance results, people results are the different variables focusing on the quality in hospitals. EFQM focused on improving the organization performance results. The study would help the hospital managers, administrators and the top management in understanding the parameters and implementing it for the success of the hospitals growth. Different strategy can be implemented in improving

the overall growth of the organization by which in turn improving the patient care quality.

Ethical Clearance: Not Required (It does not involve any experimental data collected from human as well as Animals. The data is collected from healthcare professionals working in different hospitals which purely their personal view or opinion which does not violate the ethical standards.)

A Modified Technique for Establishing the Occlusal Plane in Complete Denture Prosthesis

Pradeep S.

Additional Professor, Dept. of Prosthodontics, Manipal College of Dental Sciences

Abstract

Occlusal plane position is considered to be the primary link between function and esthetics. Canted occlusal planes result from the canted interpupillary line if the latter issued as reference plane. Establishing this occlusal plane correctly by orienting is of prime importance. Bubble gauge mounted to the fox plane provides more accurate orientation of occlusal plane irrespective of reference planes. This modification can be used to achieve optimum result in facial asymmetries and canted interpupillary lines, since interpupillary line cannot be used as a guide in such cases.

Clinical Implications: If a clinician uses bubble gauge-fox plane approach for establishingocclusal plane, then the aesthetic outcome will be enhanced. This method is also of value since it reduces subjective variations.

Keywords: *Occlusal cants, reference planes, complete denture esthetics, interpupillary line.*

Introduction

Occlusal plane is the average plane established by the incisal and occlusal surfaces of the teeth. Generally, it is not a plane but represents the planar mean of the curvature of these surfaces[1]. The orientation of the occlusal plane is lost in patients rendered edentulous and should berelocated if complete dentures are to be esthetic and to function satisfactorily. It is the most important plane to be determined in complete denture work, as it is a vital and importantbasis for tooth arrangement[2]. Complete dentures are constructed to function in the mouth asan integral part of the masticatory system; therefore, they should be designed to conform to the patient's physiologic jaw relations. The plane of occlusion forms one essential physiologic concept of jaw relation and occlusion. A well contoured occlusal rim with occlusal plane parallel to ridge posteriorly and parallel to interpupillary line anteriorlystabilises the denture3.

During the maxillomandibular relations after forming the rim with the correct vertical heights, the plane of occlusion is modified until it is parallel with a line projected from ala of nose to the superior edge of the tragus of ear (Camper's line). The incisal-canine esthetic line should be made parallel to the interpupillary line when the patient is looking straight ahead[2,4,5,6].

An occlusal plane indicator such as a Fox plane guide is used to achieve this goal[7]. In practice, a metallic scale is used along with Fox plane[8,9,10]. The Fox plane is placed inside the mouth touching the occlusal rim and is held by the operator, while the metal scale is held at the level of Camper's line or interpupillary line. Conventional method have the following disadvantages:

It is difficult to hold the scale steady. The scale position changes every time the operator checks the parallelism. Moreover, when checking with naked eye, the operator has to be at eye-level to check the parallelism as any change in angulation of eye leads to incorrect results. This not only increases the chances of error but also makes the procedure tedious and time-consuming. Trying to imagine the interpupillary line and

Corresponding Author:

e-mail: paddusb@gmail.com

comparing it with the Fox plane guide is quite difficult. It is difficult for the practitioner to compare between the fox plane guide and an instrument that represents the interpupillary line with a distance of several centimetres apart. It is difficult to fix or stabilize the pupils because the patient doesn't understand the importance of stabilizing the pupils, nor does he/she know in which correct position to stabilize the pupils. In elderly subjects who receive the majority of the complete dentures the muscle coordination is poor[3].

A range of facial asymmetries can influence the choice of occlusal plane duringprosthodontic treatment. Thus, an occlusal plane parallel to the ala tragus and interpupillary lines, as often supported by prosthodontists, may result in less than ideal esthetics in the final restoration[11,12].

In the event that one eye is higher than the other (which often occurs), the incisal-canine line would be made slanted in relation to true horizontal when the patient's head is erect. The interpupillary is not the best esthetic reference line and has advocated making the incisal-canine line parallel to horizontal when the patient's head is perfectly erect regardless of the eyes or any other facial feature[13].

To overcome the above disadvantages a modification to the Fox plane in which, bubble gauge is mounted to the Fox plane (Fig 1). The bubble gauge consists of coloured liquid in a tube consisting of bubble and markings in the centre. The presence of the bubble in between the markings indicates that the surface is parallel to ground level or the truehorizontal[14]. Bubble gauge is used in automobile industry, water level monitoring etc.

Applying the same principle to complete denture prosthodontics, it can be used inmaxillomandibular relations procedure where the planes are of utmost significance.

Procedure for use of bubble gauge: The patient is made to sit erect looking straight ahead at horizon. The labial form of occlusal rim should provide adequate lip support and labial fullness. The vertical length of the maxillary occlusion rim is established. The occlusal plane is adjusted using the centralisation of bubble in between the markings as a guide (Fig 2). The procedure is carried out independent of the interpupillary line.

Fig 1: Mounted bubble gauge on fox plane

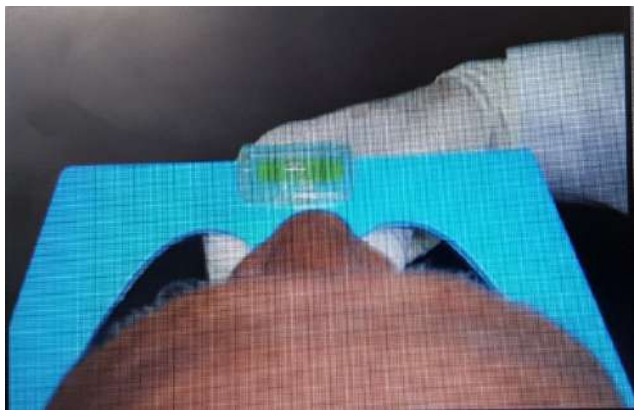

Fig 2: Centred bubble gauge

Discussion

Several method for the determination of occlusal plane have been proposed[15,16,17,18]. Conventional method have their inherent demerits. This modification is simple and inexpensive. It is very easy to use for the beginners. Need to be at eye level is eliminated and hence the chances of change in the angle of operator eye level leading to incorrect plane of occlusion are nil. This method is of advantage in cases with facial asymmetries and canted interpupillary lines. The practitioner would not need to imagine or try to present the interpupillary line with any instrument. Posture of the patient can bring about changes in the position of bubble. So the patient is made to sit erect looking straight ahead at horizon. When mounting the bubble gauge to the Fox plane, it should be done on a flat base as any inclination in surface can lead to incorrect mountings.

Conclusion

Arranging the teeth in the correct plane of occlusion is important for the success of complete denture prosthesis. This modification is thus reliable alternative

method for the orientation of the occlusal plane and can be used with less subjective bias than that of the conventional method utilizing the interpupillary line

Neurosciences Nursing, Amity College of Nursing, Amity University Haryana, India

Abstract

Background and Aims: Aim of this study was to compare the doses of Propofol and Etomidate using Entropy Monitor and per kilogram body weight doses and hemodynamic effects of both the drugs after induction and intubation.

Material and Method: Hundred patients of ASA grade I and II in the age group of 18-60, scheduled for elective surgery under general anesthesia were randomly allocated in two groups. In group A: Induction dose of Etomidate was given till Entropy reached value of 40. In group B: Induction dose of Propofol was given till Entropy reached a value of 40. The doses given in ml were noted and calculated. Hemodynamic parameters like SBP, DBP, MAP, heart rate, oxygen saturation (SpO2), end tidal carbon dioxide were noted at baseline, induction, 1 min, 2 min, 3 min, 4 min, 5 min and 10 min thereafter. Data was subjected to statistical analysis.

Results: There was reduction in induction doses using Entropy guided hypnosis level. The mean dose of Etomidate according to entropy was 16.9±2.8mg (0.27mg/kg) and per kilogram body weight dose was 18.61±3.4mg (0.3mg/kg). The mean dose of Propofol according to Entropy was 108.8±17.6 mg (1.72mg/kg) and per kilogram body weight dose was 124±23.1mg (2mg/kg). Incidence of hypotension and tachycardia was more with Propofol than Etomidate

Conclusion: Use of Entropy resulted in decrease in the dose of Etomidate and Propofol. Etomidate provides more hemodynamic stability than Propofol after induction and intubation.

Keywords: *Entropy monitor, hypnotic doses, hemodynamic response, Propofol, Etomidate.*

Introduction

Propofol and Etomidate can be used as an induction agent alone or for both induction and maintenance during general anesthesia.[1,2,3] Earlier loss of verbal commands and eyelash reflex were used for assessing awareness. But these end points are not accurate. For assessing depth of anesthesia newer monitors are now available which helps in preventing awareness from inadequate doses and side effects from higher doses. These monitors include spectral entropy, bispectral index and narcotrend.[4,5]

Datex-Ohmeda module calculates two separate entropy values over variable time duration. State entropy has frequency of 0.8 to 32 Hz and its index ranges from 0 to 91. It reflects the cortical state of

patient. Response Entropy has a frequency range of 0.8 to 47 Hz and its index ranges from 0 to 100 and is an indicator of analgesia.[6] Readings between 40 and 60 are considered as satisfactory level of anesthesia. This is the point where awareness can be avoided and unnecessary prolongation of recovery is also prevented. Adequate level of anesthesia is considered when values of RE and SE are identical.[7]

In this study we aim to assess the hypnotic doses of Etomidate and Propofol using entropy for laryngoscopy and intubation and also determine their hemodynamic effects during induction and on endotracheal intubation.

Material and Method

After obtaining approval from the Institutional Ethics Committee with IEC approval number- 613 and a written informed consent from all the patients, this prospective randomized comparative study was conducted for 2 years on 100 healthy adult patients, aged 18-60 years, of ASA grade I & II, who were scheduled to undergo elective surgical procedure under general anesthesia. Patients with hypertension, cardiac, hepatic and renal disease, respiratory distress, diabetic patient, epilepsy, pregnant patients, MP grade III and IV were excluded from study. 100 healthy patients were randomly allocated in two groups each. **Group A:** (n=50) Induction dose of injection Etomidate was given intravenously till entropy of 40 was achieved. **Group B:** (n=50) Induction dose of injection Propofol was given intravenously till entropy of 40 was achieved. Preanesthetic evaluation was done a day prior to surgery and all investigations were carried out. All patients were kept fasting for 8 hours. After ascertaining that the patient was fit for surgery, a written informed consent was taken. In OT, IV line was secured with 18 G cannula and normal saline was started. Monitors were attached. Baseline vitals SBP, DBP, MAP, HR, SpO_2 and EtCO2 were noted. Study drug was prepared according to the groups allocated randomly by a computer generated randomization. Patient was given injection Glycopyrrolate 0.2mg/kg and injection Fentanyl 2mcg/kg intravenously and pre oxygenated with 100% oxygen via face mask for 3-4 minutes. Anesthesia was induced with IV induction agents (Propofol/Etomidate), as per study group, while observing entropy. Hypnotic dose was noted when entropy reached a value of 40. After ensuring adequate mask ventilation, neuromuscular blockade was achieved with injection vecuronium 0.1mg/kg followed by laryngoscopy and endotracheal intubation. After confirming correct position of ETT, anesthesia was maintained with oxygen and nitrous oxide (40:60), sevoflurane (0.5-1%) and intermittent top ups of injection vecuronium (0.02mg/kg) with controlled ventilation. SBP, DBP, MAP, HR, SpO_2, and $EtCO_2$ were noted at induction and 1, 2, 3, 4, 5, 10 min thereafter. On conclusion of surgery, patient was reversed and provided 100% oxygen via venturi mask. The dose was calculated in mg from the noted volume of drug (ml). Any perioperative side effects such as hypotension, bradycardia, hypertension, tachycardia, myoclonic jerks, and seizures, pain on injection, bronchospasm or laryngospasm, nausea/vomiting were noted. Data from above study was systematically collected, compiled and statistically analyzed to draw relevant conclusion. This study did not impose any financial burden to participants.

Results

Demographic profiles of patients in both the groups were comparable with respect to the age, gender, weight, ASA physical status, Modified Mallampatti Classification**.** In comparison of Mean arterial pressure in both groups at different time intervals statistically significant fall in MAP was observed in Group B as compared to Group A at T_1, T_2 and T_3 (p-value = <0.005). After laryngoscopy statistically significant rise in MAP at T_5 in group B compared to Group A (p-value = 0.000) [Table 1].

Baseline heart rate was comparable among groups. Mean HR in group A was 79.16±10.241 and in group B was 78.12±9.115 (p-value = 0.593). Statistically significant rise in HR was seen 1 minute after laryngoscopy and intubation in group B (mean 99.7±13.0) but no significant rise in group A (mean 94.1±10.2), p-value calculated was 0.018 [Table 2].

The mean dose according to entropy (DE) in group A was 16.9±2.8 and according to per kg body weight (DW) was 18.6±3.4 (p-value = 0.000). There was a statistically significant difference in the induction dose in Group A when calculated according to entropy and per kg body weight. As evident from the table mean dose according to entropy (DE) in group B was 108.8±17.6 and according to per kg body weight (DW) was 124.3±23.1 (p-value = 0.000), which showed statistically significant difference in induction dose in Group B when calculated according to entropy and per kg body weight [Table 3].

Incidence of high blood pressure (HBP) was 29% in group B and 12% in group A. There was a statistically

significant difference (p value=0.000) between two groups. Incidence of low blood pressure (LBP) was 60% in group B and 10% in group A and this was found to be statistically significant (p-value = 0.000). Incidence of tachycardia (Tc) was 18% in group A and 38% in group B (p-value = 0.026). Incidence of bradycardia (Bc) was 0% in both groups [Table 4].

Adverse effects of Etomidate and Propofol were also noted in our study. Myoclonus was observed in 16% patients with group A and none with group B. There was a statistically significant difference (p- value=0.000) between two groups. Pain on injection was observed in 42% patient receiving group B and 0% with groups A. There was a statistically significant difference (p value=0.000) between two groups. Nausea and vomiting was seen in 6% patients with group A and only 2% with group B and this was neither clinically nor statistically significant (p-value = 0.610) [Table 5].

Discussion

In our study we have used Entropy monitor to calculate the hypnotic dose of Etomidate and Propofol. Entropy monitor gives us combined state of adequate muscle relaxation, adequate pain suppression and adequate hypnosis.

Demographic profile of patients in both groups was comparable with respect to age (p-value = 0.868), gender (p-value = 0.548) and mean weight (kg) distribution (p-value = 0.843). Demographic profile done by **K Meena et al** also had comparable age group (p-value = 0.178) and comparable gender distribution (p-value = 0.241).[8]

In our study baseline MAP was comparable in both groups. Mean MAP in group A was 89.7±9.2 and in group B was 90.7±10.2. After induction there was fall in MAP in group B but no significant fall in group A. Mean MAP 1 min after induction in group A and B was 85.9±10 and 75.5±8 respectively. After laryngoscopy MAP in group A and B was 98.4±8.1 and 105.3±9.1 respectively.

Shah SB et al compared hemodynamic effects of Propofol and Etomidate after induction, laryngoscopy and intubation and concluded that there was significant fall in MAP after induction with Propofol compared to Etomidate. Baseline MAP in Etomidate and Propofol group was 98.03±9.58 and 97.43±5.67 respectively. 1 min after induction the MAP in Etomidate and Propofol group was 82.47±8.23 and 73.10±9.98.[9] **Bendel SI et al** compared fall in MAP after induction with Propofol and Etomidate and found out that the decrease in mean blood pressure was more with Propofol (p-value = 0.006).[10] In our study no significant change was seen in SpO_2 between two groups (p-value = >0.05). In our study $EtCO_2$ varied from minimum 35mmHg to 45mmHg maximum. This was statistically significant at various time intervals but changes in EtCO2 are not clinically significant and therefore no clinical intervention was required. **Singh R et a1** studied that the increase from baseline in heart rate was significant (p= 0.001) at 1 minute after intubation.[11] In our study the baseline heart rate was comparable among groups. Mean HR in group A was 79.16±10.241 and in group B was 78.12±9.115, p- value calculated was 0.593. Statistically significant rise in HR was seen 1 minute after laryngoscopy and intubation in group B (mean 99.7±13.0) but no significant rise in group A (mean 94.1±10.2), p- value calculated was 0.018.

In our study induction doses of Etomidate and Propofol were compared separately in different groups using entropy monitor and per kilogram body weight

doses (0.3mg/kg for Etomidate and 2 mg/kg for Propofol). We found out that the doses were significantly reduced in both the groups when entropy monitor was used. Mean dose per kg body weight in group A was 18.61 but mean dose with entropy was l6.98 (p-value = 0.00). Mean dose per kg body weight in group B was 124.32 and mean dose according to entropy was 108.80 (p-value = 0.00).

Arya S et al in 2013 studied clinical versus EEG guided Propofol induction. According to this study mean dose of Propofol when given clinically was 1.85±0.48 mg/kg and 1.79±0.41 mg/kg when it was guided by BIS which was comparatively lesser.[12] **Raid et** al did a study on entropy guided Propofol induction in 72 elderly patients and total dose of Propofol and per kilogram body weight dose were significantly reduced by 37.1% and 31.8% respectively in entropy group. They found out that with the use of entropy, dose was reduced and recovery was faster when compared with control group.[13] High blood pressure was observed in 29% patients in Propofol group and 12% patients in Etomidate group. Low blood pressure was observed in 60% patients in Propofol group and 10% patients in Etomidate group. Tachycardia was present in 38% patients in Propofol group and 18% patients in Etomidate group. No incidence of bradycardia was seen in both groups.

Myoclonus was observed in 16% patients with Etomidate and none with Propofol. Pain on injection was observed in 42% patients receiving Propofol and 0% with Etomidate. Nausea and vomiting was seen in 6% patients with Etomidate and only 2% with Propofol. Adverse reactions were found in 2% patients with Propofol and 0% with Etomidate.

Miner et al concluded higher incidence of myoclonus (20% vs 1.8%) in Etomidate and Propofol groups respectively. Pain on injection was observed only in Propofol group.[14]

Ethical Approval: This clinical study has been approved from the institute ethics committee with IEC approval number-613.

A Study on Work Life Balance and Stress of Female Employees in IT Sector: A Study with Special Reference to Employees in Chennai

Mary Sudharshini Fernando[1], M. Kavitha[2]

[1]Ph.D. Research Scholar, [2]P.G. Professor & Research Supervisor, M.Com, M.Phil, MBA, Ph.D, SET, Department of Commerce, VISTAS, Pallavaram, Chennai

Abstract

The main aim of this study is to find the work life balance and it causing stress among the female employees working in IT sector. The primary data is collected by using primary method such as questionnaires. For this study questionnaires are used to collect primary data from the respondents. Factor analysis is used to find the result by the researcher. The results shown that Work-life-balance is an important issue in IT profession. In today's competitive era, with changing demands, regulations and so much pressure the work needs have increased a lot. This leads to increase in stress level of the female IT employees .Majority of the respondents expressed that there is no separate policy for work life balance in their organisation and many people were doing work overtime.

Keywords: *Work life balance, Stress, Job Performance.*

Introduction

Every individual is an integral part of the family in particular and the society in general. In today's business world, employee performance is key determinant in the achievement of organizational goals. As a result, organizations look for different ways of motivating their employees, in order for them to give their best to the organization. Employee performance is a focal point in any establishment. Every policy should be geared towards increasing the employee performance. For organizations to remain on top they should be able to improve their employee performance and monitor it. In a situation where this does not occur, they are liable to face several challenges which stands as a set back to the organization in the sector where they belong.

Work life balance is a very important phenomenon that is of great concern to various employees in both private and public sector. It goes beyond prioritizing the work role and one's personal life. It also affects the social, psychological, economical and mental well being of the individual. All these is been reflected in the output of the individual, which affects his or her performance in the work place on the long run. Work life balance has implication on employee attitudes, behaviours, wellbeing as well as organizational effectiveness (Eby, Casper, Lockwood, Bordeanx and Brindley, 2005). The competition for market leadership in the banking sector, may lead to bank managers giving their employees excessive work load in order to meet up with their target. Employees try their best to be retained in the organization by putting in more time at work which may be at detriment of their personal life. All these may affect the upbringing of children, lead to broken and unhappy homes and poor social life.

The conventional wisdom indicates that a happy worker is a better worker. But it seems that the employers find it difficult to understand this fact. We all experience pressure on a daily basis. We need it to motivate us and enable us to perform at our best. However, when the pressure becomes excessive, it leads to stress. Many of the stressful life events are related to the workplace, e.g. lack of job security, changes in working hours, changes in working conditions, layoffs, downsizing, organizational readjustments, etc. IT industry in India has long been exempted from labour regulations in order to facilitate its rapid growth and competency in the global market. Although this is a sound argument in the wake of our

developing economy struggling to sustain and expand economic growth, yet it needs to be checked whether the burden is not being borne by the industry's labour force.

The recent past is a witness to changes in work schedules. A larger part of the IT sector is hence moving from a standard eight-hour a day regime to operating twenty four hours a day for seven days of the week. Many employees need to work on Saturdays and Sundays too. Moreover, there is a changing pattern in the working hours which is quite different from the standard one, which normally operates from 9 am to 5 pm. While some employees work in the standard time some others need to be available for work that normally starts early in the evening and continues well through the night. Sometimes they need to even work beyond the normal eight hours. Increasing workloads have pressurised employees to demonstrate their commitment to work in more obvious ways. Consequently, a larger part of them have tended to be present at their work place for longer periods of time, thereby reducing the time for which they are available at home.

Employees who start to feel the pressure to perform are likely to get caught in a downward spiral of increasing effort in order to meet rising expectations but no increase in job satisfaction. The internet and mobile phones have made it possible for the organizations to keep in constant touch with the employees both during the day and at night. To a large extent in the IT sector, the employee is expected to be engaged on the job almost at all times. Consequently, there are growing reports of stress and work imbalance. The constant requirement to work at optimum performance takes its toll in job dissatisfaction, employee turnover, reduced efficiency, illness and even death in some cases. Absenteeism, alcoholism, bad or snap decisions, indifference and apathy, lack of motivation or creativity are all by-products of an over stressed workplace. So the distinctions between work-life and family-life have vanished.

Review of Literature: Chassin et al. (1985) found three types of conflicts in their research on a sample of 83 working parents who have pre-school kids. These differences were related to (a) the demands of multiple roles, (2) between role expectations of self and spouse, and (3) lack of congruence between expectation and reality of roles[4].

Frone et al. (1992a) in their randomly drawn sample of 631 comprising 278 male and 353 female respondents also found that work to family conflict is more prevalent than family to work conflict. Their study suggested that family boundaries be more permeable to work demands than are work boundaries to family needs[8].

Bachmann (2000) found that work arrangements such as flexi-time, telework ethic are depicted as an important component of an individual's work preference towards work time. There is a suggestion that such work arrangements will help the employee achieve a better blend between their work and non-work activities. This will assist the organizations recruit, retain and motivate their workforce[1].

Hochschild (1997) has observed that to enhance commitment to an organization, the promotion of work life balance policies is of a compulsory interest to the governing body[10].

Burke (2002) noted that an organization that supports work life balance is preferred by both women and men. The benefit for Men appeared to be more than women. Satisfaction was more for Men when their achievement in job was more even at the cost of ignoring the family. On the other hand, women emphasized the need to strike a balance between work and family sources for their gratification. Women feel unhappy, disappointed and frustrated when work prevents them from taking care of their family. Women do not like the crisscrossing of the boundaries between work and home[3].

De Bruin and Dupuis, (2004) and Greenblatt (2002), emphasized the integration of the work and non-work roles of employees. Then the levels of multiple-role conflict, and the associated stress and job-dissatisfaction, can be minimized or avoided[5].

Doherty (2004) in the study on working life balance initiatives for women in the hospitality industry explored the main barriers to advancement into managerial roles. It was found that managerial roles called for long working hours[7].

Grady and McCarthy (2008) in their study defined that work-life integration is an outcome of the complex relationship between the dynamics of employment and personal factors. They found the balance between work and life is achievable through the funding and coordination of multiple activities which included the organization's interest. Children were given first priority by the respondents exhibiting a deep sense of motherhood. Factors like work stimulation, challenges, achievement

and enrichment were given high importance and sought more self-care time to balance work and family[9].

Baral (2010) studied 485 employees working in varied organizations in India found that working men and women in India experience more work family enrichment than the work family conflict. It was also found that there were no gender differences in the employee perception of work family enrichment[2].

Desai et al (2011) found that home-based working women had less stress, able to adjust better and were more satisfied with their careers[6].

Objectives of the Study:

- To find out problems faced by women employees in IT sector
- To determine the factors affecting work-life balance and causing stress
- To examine the effect of work life balance on Job performance

Hypothesis of the Study:

1. There is no significant difference among the factors influencing work-life balance.
2. There is no significant impact of Work life balance on the Job performance of the female employees.

Research Methodology: Research methodology is a method to solve the research problem research systematically. It involves gathering data, use of statistical techniques, interpretations and drawing conclusions about research data. Keeping in view the objectives of the study, data is collected from the following sources. Source of data are:

- Primary data
- Secondary data

Primary data - The primary data is collected by using primary method such as questionnaires. For this study questionnaires are used to collect primary data from the respondents.

Secondary data - Secondary data collected from various journals, websites and other research reports.

Sample size

Under this research 50 respondents in Chennai opinion are being to obtained on the basis of convenient sampling method.

Analysis and Interpretation:

Factors affecting work-life balance: The factor analysis results in five important work-life-balance factors of the respondents and the names were considered based on the list of items under each component and the respective loadings of the item. The Eigen value and the percent of variance explained by factors are presented in the below table

Table 1: Factors Constituting Work-Life-Balance

Sl.No	Factors	Number of Variables	Eigen Value	Percent of Variation Explained	Cumulative Percent of Valuation
1.	Job Nature	9	13.001	12.841	12.841
2.	Work Load	7	2.081	11.336	24.177
3.	Work environment	10	1.838	13.303	37.480
4.	Organizational support	6	1.428	10.864	48.343
5.	Family Domain	3	1.316	7.838	56.182

Source: Computed data

It is clear from Table 4 that five dominant work-life-balance factors, which consist of thirty five work life-balance components, accounted for 56.182 percent of total variance.

Inference: 'Job Nature' is the dominant factor that influences the work-life-balance since its Eigen value and percent of variation explained are 13.001 and 12.841 respectively. Work load is the next significant factor with Eigen value of 2.081 and percent of variation explained is 11.336. 'Work environment' is the third important factor followed by 'Organisation Support' and 'Family Domain' in terms of their Eigen value of 1.838, 1.428 and 1.316 and percent of variation explained with value of 13.303, 10.864 and 7.838 respectively. It is concluded

that 'Job Nature', 'Workload', 'Work Environment', 'Organizational Support' and 'Family Domain' are the predominant factors of work life balance.

Relationship and Impact of Work Life Balance on Employee's professional life: Correlation analysis was carried out to study the relationship between work life balance and professional life of working female employees. The results were shown in the below table.

Table 2: Professional Life

Work Life Balance	Pearson Correlation	.594
	Sig. (1 – tailed)	.000

Source: Computed data

Table 3: Showing Coefficients

Model	Unstandardized Coefficients		Standardized Coefficients	T	Sig.
	B	Std. Error	Beta		
(Constant)	6.053	1.30	.594	5.231	.000
Worklife balance	.612	.085		6.943	.000

Dependent Variable: Professional Life

Source: Computed data

Value of t for human resource system comes out to be 6.943, p value is .000 and beta value is .594 which is significant at 5 percent level of significance. Thus null Hypothesis 2 was not accepted in this regard.

Inference: The result depicted significant positive relationship between work life balance and employees' professional life. Coefficient of correlation 0.594 is significant at 5 percent level of significance. The result depicted that there exists a significant positive relationship between work life balance and female employees' professional life.

Thus there is significant impact of work life balance on employees' professional lives. Hence there must be focus on improving the work life balance which will further improve their professional life leading to more productive and efficient staff.

Findings and Conclusion

Work-life-balance is an important issue in IT profession. In today's competitive era, with changing demands, regulations and so much pressure the work needs have increased a lot. This leads to increase in stress level of the female IT employees .Majority of the respondents expressed that there is no separate policy for work life balance in their organisation and many people were doing work overtime. Also management has not done much in terms of designing and implementing effective work life balance policies and practices. If the personal and professional lives of female employees are balanced, they can devote more time to their children and can focus on their upbringing. It was found that the number of hours worked per week, the amount and frequency of overtime, and inflexible work schedule increase the likelihood of employees to experience conflict between their work and family roles as it kills their time to perform family related activities.

Also there is significant positive relationship and impact of work life balance on employee's professional life. Study also revealed some of employees feel so stressed that they are not able to handle family responsibilities even after coming from workplace as they feel so tired and exhausted because of long working hours. Breaks are also very short so they were not able to take proper rest. However, their company provides no policy as such to help their employees meet their family commitment. Thus focus must be there in making policies that can help the female employees to have balance between the two.

The study was also able to measure women IT employees' work-life-balance and found that 'frequently extended work schedule', 'frequent changing requirement of clients', 'role overload', 'lack of flexible options' and 'unrealistic deadlines' are some important determinants which influenced women employees' work-life-balance. The analysis also reveals that five factors namely, Job Nature, Work Load, Job Environment, Organizational Support, and Family Domain constitute work-life-balance of women

professionals. The result of correlation analysis also confirms the positive correlation among the above five factors. The companies in IT industry may consider the above five factors and modify their HR policies suitably and create conducive work environment to maintain work–life-balance among women professionals so as to improve their performance.

Effectiveness of Sublingual Versus Oral Misoprostol for Induction of Labour at Term

Rekha Parimkayala[1], Shraddha Shetty K.[2]

[1]Registrar, Department of Obstetrics & Gynecology, Rainbow Hospitals, Currency Nagar, Vijayawada, Andhra Pradesh, [2]Associate Professor, Department of Obstetrics & Gynecology, Kasturba Medical College, Mangalore, Manipal Academy of Higher Education, Karnataka, India

Abstract

Objective: To compare the efficacy and safety of 50 microgram (μg) sublingual Misoprostol with 50 microgram (μg) oral misoprostol for labour induction at term.

Method: One hundred twenty women with medical or obstetric indication for induction of labour at term with unfavorable cervix were randomized to receive 50mcg of misoprostol either orally or sublingually. Primary outcome was number of women delivering vaginally within 24hrs of induction. The need for oxytocin, mode of delivery, doses of Misoprostol required and neonatal outcomes were analyzed and compared between the groups.

Results: Induction to vaginal delivery time was <24hours in 43(71.7%) in sublingual group and 36(60%) women delivered vaginally in <24hours in oral group. No significant difference was found in the number of women delivering vaginally within 24hrs of induction among both the groups. Time from administration of first dose to delivery in sublingual group was lesser compared to oral group. 46.7% of women required oxytocin in sublingual groups, whereas 75% in oral group which was statistically significant. Sublingual group had lesser number of women requiring more than 1 dose of misoprostol compared to the oral group.

Conclusion: Sublingual misoprostol seems to be having better efficacy than the oral misoprostol and has lesser induction to delivery interval. Hence can be considered to induce labour at term for ripening of cervix.

Keywords: *Sublingual administration; oral administration; misoprostol; induction; labour.*

Introduction

"Induction of labor is defined as intervention designed artificially to initiate uterine contractions leading to progressive dilatation and effacement of the cervix and birth of the baby".(1) Induction is indicated when the mother and fetus are benefited with higher chance of healthy outcome than the birth being delayed.(1) Misoprostol is commonly used for induction of labor as it is stable at room temperature and has rapid onset of action. It can be administered in oral, sublingual or rectal routes. The efficacy of misoprostol varies with different routes of administration due to change in their pharmacokinetics. Sublingual route has better efficacy compared to other routes as it bypasses enterohepatic circulation and has lesser hyperstimulation rates.(2) The objectives of the study were to compare the efficacy of 50microgram of sublingual Misoprostol with 50microgram of oral misoprostol for labor induction at term, number of women delivering vaginally within 24 hours of the induction, induction to delivery interval and adverse effects and neonatal outcomes in two groups.

Method

This hospital based non blinded randomized comparative study was conducted in the Department of Obstetrics and Gynecology department in a medical college in Karnataka over a period of one year six months between September 2014 and March 2016 after approval from the Institutional Ethical Committee of Kasturba Medical College, Manipal University, Mangalore. Informed and written consent was obtained from the women on a predesigned consent form.

Statistical Analysis: Sample size was taken as 120 women with term gestation with indications for labor induction 60 in each group.[3] Fisher's exact test and chi square test were applied for the statistical analysis. A statistical package SPSS version 17.0 is used to do statistical analysis. P value < 0.05 is considered to be significant.

Women were admitted in the hospital after satisfying the inclusion criteria. Demographic details such as age, height, weight, parity, gestational age and amniotic fluid index (AFI) and indication for induction were noted. They were randomized to receive either 50 mcg of sublingual (Group A) or 50 mcg of oral misoprostol (Group B) every 4th hourly till a maximum of three doses. A pelvic examination was done to assess the Bishop's score which was followed by a 20 minute Non stress test (NST) to rule out non-reactive fetal heart rate. Fetal and maternal monitoring was done by clinical auscultation of fetal heart rate and monitoring uterine contractions. Vaginal examination was done every 4 hours to assess Bishop's score. The dose was repeated every 4hours, a maximum of 3 doses were given. The dose was with-held in presence of active labor or contractions > 3 in 10 minutes or a Bishop's score of ≥ 8 or non-reassuring fetal heart status (NRFHS). Labor was managed according to labor room protocol for decisions regarding oxytocin augmentation and amniotomy. Failure to establish active labor even after three doses of misoprostol was considered as failure of induction.

Inclusion criteria were women in the age group between 18-35 years, live singleton pregnancy at term gestation (gestational age of > 37 weeks) with medical or obstetric indication for induction, cephalic presentation, unfavorable cervix (Bishop's score ≤ 6) and reassuring fetal heart tracing. Exclusion criteria were Cephalopelvic disproportion, history of caesarean section or any uterine surgery, multiple gestations, malpresentation, hypersensitivity reactions for prostaglandins, contra indications for prostaglandins usage (e.g. Asthma) and parity > 4.

The Primary outcome studied were number of women delivering vaginally within 24 hours. The Secondary outcomeanalyzed includetime interval between induction to vaginal delivery, number of misoprostol doses required, patients requiring oxytocin augmentation, failed inductions, number of caesarean section, neonatal outcomes-meconium stained amniotic fluid, non reassuring fetal heart status, Apgar score at 1 and 5 min and NICU admissions and side effects like uterine hyperstimulation, gastrointestinal disturbances and pyrexia.

Results

A total number of 120 women with term pregnancy were included and 60 women were assigned to receive a 50 mcg sublingual misoprostol and 60 women are assigned to receive a 50 mcg oral misoprostol.

Table 1 shows the indication of labor in both the study groups. Main indications for labor induction were postdatism and premature rupture of membranes. No significant difference were found between the two groups. Most of the participants were in the age group of 18-26 years i.e.45 (75%) and 37(61.2%) in Group A and Group B respectively. Most of the patients were nulliparous accounting to 80% in sublingual group and 70% in oral group. Induction to vaginal delivery time was <24hours in 43(71.7%) in sublingual group and 36(60%) women delivered vaginally in <24hours in oral group. No significant difference was found in the number of women delivering vaginally within 24hrs of induction among both the groups (Table 2). Time from administration of first dose to delivery in sublingual group was 11hrs 16min with standard deviation of 4hrs 15min, while in oral group the mean time from induction to delivery was 15hrs 15min with standard deviation of 6hrs 30min and was found to be statistically significant. These observations suggest that there was increased induction to delivery interval when misoprostol was used by oral route compared to sublingual route (Table 3).

In sublingual group, 45 (75%) required a single dose of Misoprostol for labor induction compared to 31 (51.7%) in oral group. In oral group, 29(48.3%) of the women required more than 1 dose of misoprostol compared to the sublingual group with p value of 0.029 which was statistically significant. In sublingual group, 53.3% of women did not need oxytocin for augmentation

of labor where as in Oral group, 75% of women required oxytocin (Table 4).

In sublingual groups, failed induction was observed in 8(13.3%), where as in oral group it was 9 (15%) and the result was not statistically significant. Number of women delivered vaginally was 44 (73.3%) in sublingual group and 40 (66.7%) in oral group. Cesarean delivery was 26.7% in sublingual group and 33.3% in oral group with a p value of 0.426 which was not statistically significant.

Most common indication for Cesarean delivery was failed induction in 8 (50%) in sublingual and 9 (45%) in oral group which was not statistically significant. Other indications were meconium stained amniotic fluid, non reassuring fetal heart status and secondary arrest of descent. Table 5 compared the neonatal outcome in both the groups. Meconium stained amniotic fluid, non reassuring feta heart status, low APGAR scores and NICU admissions were the neonatal outcomes and there were no statistical significance found among the two groups.

The most common side effects among both the groups were GI disturbances in 2(3.3%) sublingual and 6(10%) in oral group and pyrexia in 1(1.6%) sublingual and 3(5%) in oral group which was not statistically significant. There was no hyperstimulation noted in any of the cases in both the groups.

Table 1: Indications for induction and their distribution in both study groups

Indication for Induction	Sublingual Misoprostol N (%)	Oral Misoprostol N (%)	P value
Post datism	30(50)	36(60)	>0.05
Oligohydramnios	5(8.3)	2(3.3)	
Hypertension in Pregnancy	4(6.7)	3(5)	
PROM	21 (35)	19 (31.7)	
Total	60	60	

*p value<0.05 is considered significant

Table 2: No. of women delivered vaginally within 24hrs of induction

Induction to Vaginal Delivery Time	Sublingual N (%)	Oral N (%)
< 24 hours	43 (71.67)	36 (60)
> 24 hours	1 (1.6)	4 (6.6)
Total	44(73.3)	40(66.6)

Table 3: Time from induction to delivery

Induction to Delivery Time	Sublingual Group	Oral Group	P value
Mean	11 hour 16min	15hour 15min	0.001*(s)
Standard deviation	4hours 15 min	hours 30min	

*p value<0.05 is considered significant: s: significant

Table 4: No. of women required oxytocin augmentation

Oxytocin Augmentation	Sublingual N (%)	Oral N (%)	
Not required	32 (53.3)	15 (25)	0.001(s)
Required	28 (46.7)	45 (75)	
Total	60	60	

*p value<0.05 is considered significant: s: significant

Table 5: Neonatal outcomes among both the study groups

Neonatal Outcome	Sublingual N (%)	Oral N (%)	p value
MSAF	5 (8.3)	9 (15)	0.225 (NS)
NRFHS	3 (5)	4 (6.7)	0.697 (NS)
APGAR 1min <9	1 (1.7)	5 (8.3)	0.209 (NS)
APGAR 5min <9	1 (1.7)	1 (1.7)	1.000 (NS)
NICU admission	1 (1.7)	0 (1.7)	(NS)

*MSAF: Meconium stained amniotic fluid, NRFHS: Non reassuring fetal heart rate, *NS: Not significant

Discussion

The present study was a prospective study designed to study the effectiveness of the sublingual and oral misoprostol for term induction of labor. Post-datism and PROM were the most common indications for induction. Similar indications for induction of labor were noted in other studies.[3-5]

Forty three (71.6%) women delivered vaginally within 24 hours of induction with sublingual misoprostol compared to 36 (60%) women in oral group. According to the study conducted by Bartusevicius and colleagues, there was no statistical difference noted among women delivering vaginally within 24hours of induction with 50 mcg of sublingual misoprostol or 25 mg of vaginal misoprostol. 58 women (83%) in the sublingual group and 53(76%) in the vaginal group delivered vaginally within 24 hours.[4]

In the present study, time from administration of first dose to delivery in sublingual group was 11hrs 16min, in oral group the mean time from induction to delivery was 15hrs 15min and was found to be statistically significant. These results suggested that induction to delivery interval was increased when misoprostol was used by oral route compared to sublingual route. Similar results were observed in other studies.[4,5] Humaira Zaman Malik and colleagues compared 100 µg oral misoprostol with 50µg sublingual misoprostol for induction of labor, they observed that 92% women delivered within 12 hours of induction in sublingual group and 84% of women in oral group.[6] In sublingual group, 45 (75%) required a single dose of Misoprostol for labor induction compared to 31 (51.7%) in oral group. In oral group, 29(48.3%) of the women required more than 1 dose of misoprostol compared to the sublingual group. In sublingual group, 53.3% of women did not need oxytocin for augmentation of labor where as in Oral group, 75% of women required oxytocin. These results were comparable to other studies.[4–7]

In sublingual groups, failed induction was observed in 8(13.3%), where as in oral group it was 9 (15%) and the result was not statistically significant however in H.Z. Malik study, there were no cases of failed induction in both the groups.[6] Number of women delivered vaginally was 44 (73.3%) in sublingual group and 40 (66.7%) in oral group. Cesarean delivery was 26.7% in sublingual group and 33.3% in oral group with a p value of 0.426 which was not statistically significant whereas Bartusevicius and colleagues observed in their study, that there were no difference in the mode of delivery among both the groups. Seven(10%) in the sublingual group and 8(11%) in the vaginal group underwent emergency cesarean section for non reassuring fetal heart status.[4]In a study conducted at Mashhad University of Medical Sciences, where 25 µg vaginal misoprostol was compared with 25 µg sublingual misoprostol for induction of labor, women underwent cesarean section due to non establishment of active labour.[8]

The most common side effects among both the groups were GI disturbances in 2(3.3%) sublingual and 6(10%) in oral group and Pyrexia in 1(1.6%) sublingual and 3(5%) in oral group which was not statistically significant. There was no hyperstimulation noted in any of the cases in both the groups. In a study done by Sedigheh A and coworkers, Tachysystole, vomiting and abdominal pain were the common side effects in both the groups. Abdominal pain and vomiting were more in sublingual group than vaginal group.[9]

Meconium stained amniotic fluid, non reassuring feta heart status, low APGAR scores and NICU admissions were the neonatal outcomes and there were no statistical significance found among the two groups. Similar results were noted in other studies.[5,6,10,11] According to

Bartusevicius and colleagues, neonates were admitted in NICU for neonatal respiratory distress syndrome in the sublingual group and congenital infection and neonatal respiratory distress syndrome in the vaginal group.[4]

Conclusion

Sublingual misoprostol has better efficacy than the oral misoprostol and has shorter induction to delivery interval. It can be considered for ripening of cervix before induction of labor in high risk conditions and prolonged pregnancies.

Study of Death among Children Below Five Years of Age and its Relation with Socio Economic Status and Place of Residence Using Verbal Autopsy as a Tool in Deharadun

Sushil Dalal[1], Kiran Pande[2], Md Abu Bashar[3]

[1]Associate Professor Dept. of Community Medicine MMU Mullana Amballa, [2]Assistant Professor Dept. of OBG MMU Mullana Ambala, [3]Assistant Professor Dept. of Community Medicine Mullana Ambala

Abstract

In India about 2.1 million child deaths occur every year, which is the highest with in a single country worldwide. Mortality in under – fives is an indicator of diverse socioeconomic and cultural factors. This present study was conducted to find out relation in-between child mortality of under-five years of age and their socio economic status along with place of residence using verbal autopsy in Dehradun.

Methodology: The survey was done on all the house of the deceased children residing in our field practice areas by visiting their houses.

Results: Most of the deaths were found from lower socio-economic class among the 83 deaths reported during study period.

Conclusion: The study shows that as we moves up the socio economic class, the mortality rate tends to decline.

Keywords: *Verbal autopsy, socio-economic, deceased children, mortality, policy making, Millennium development goals.*

Introduction

The Millennium development goals (MDG) represent the widest commitment in history to addressing global poverty and ill health. The fourth goal (MDG-4) commits the international community to reducing mortality in children aged younger than five years by two – thirds between 1990 and 2015. Between 1960 and 1990 the risk of dying in the first five years of life was halved a major achievement in child health. However achieving (MDG - 4) will be depend on mortality reductions even greater in percentage terms than those achieved in the past[(1)]. Information on factors leading to death is extremely important for policy-making, planning, monitoring and evaluation of health programs, this is particularly more so important for childhood deaths, which is constituting a major portion of all deaths, and of which many intervention programs are currently attempting to reduce mortality among under five deaths[(2)].

Material and Method

The study was undertaken for one year in the field practice areas of department of community medicine HIHT Dehradun after taking approval of institutional ethical committee. The total population registered under Rural Heath Training Centre (Rajeev Nagar) & Urban Health Training Centre was 12,588 and 12,930 respectively out of which under five children were 1297 at RHTC and 1325 at UHTC.

All deaths except still births registered with Rural and Urban Health Training Centre were included in the study. When a child died, the mother or the respondent was questioned in detail about the parents socio-economic status and place of residence of children prior to death. A drafted questionnaire (English version) developed by WHO, was modified suitably, as well as certain variables were added to find out any correlation in-between under five children death and parents socio-economic status along with place of residence[3]. The information so collected, was first coded and then entered in the computer. The analysis was done by using SPSS software. Appropriate statistical method (proportion and chi – square test) were applied as per requirement.

Result

Table 1: Distribution of deceased children by age, sex and place of residence (n=83)

	Rural (%)	Urban (%)	Total deaths (%)	Chi squar value	Degree of freedom	P value
Age of Deceased Children						
0-28 days	17 (43.6)	15(34.1)	32(38.6)	3.219	2	>0.05
29-<365 days	12(30.8)	10(22.7)	22(26.5)			
365 days-< 5Yrs	10(25.6)	19(43.2)	29(34.9)			
Sex of Deceased Children						
Male	18(46.2)	26(59.1)	44(53.0)	1.389	1	>0.05
Female	21(53.8)	18(40.9)	39(47.0)			

Table 2: Distribution of children by socio – economic status and place of residence

Discussion

Present study shows that in rural area 55.1% belonged to lower socio – economic class which was followed by 35.8% in upper lower, and 8.6% were in lower middle class. In the urban area 46.3% children were from the upper lower class, 37.9% were in lower class and 15.4% in the lower middle class. There were no children in upper socio-economic class in both the area while only 0.5% children in both the area belonged to upper middle class. This could be due to the fact that urban slums were selected for the study purpose, and they consisted mainly of the migratory population. The socio-economic status of both the study area is same and comparable however association between socioeconomic status and place of residence was found to be statistically insignificant.

In the present study maximum mortality in both urban (71.8%) and rural area (78.3%) were in children belonging to lower and upper lower class. No mortality

was seen in children belonging to upper class. This could be that being coming from lower and upper lower socio-economic class they were not well off financially and could not afford medical expenses. The findings suggest that as we move up the socio-economic class, the mortality rate tends to decline. Similar observations were observed by Hosseinpoor et al (2005) [4] that the infant mortality was concentrated among people of low socio-economic status. Similarly,Sharma and Gupta (2005)[5]also observed in their cross-sectional study on the prevalence of at risk under – five children in rural area, that at-risk children were significantly from the low socio-economic group. Calazzo et al (2004)[6]also states that socio economic inequality and its impact on health is a growing concern in the European public health debate.

Amouzou and Hill (2002)[7] found that at risk children were significantly from the low socio-economic group. They found a clear association of high mortality with low income. In another study done by Reddiah and Kapoor (1992) [8]showed in their study on socio biological factors in under – five deaths analyzed 281 under – five deaths and found that deaths in socially and economically disadvantage cases constituted 77.6%.

According to NFHS–3 Uttarakhand (2006)[9] Children living in the highest wealth quintile households are much less likely to die before their first birthday as children living in other wealth quintile households. Another study done by Cornelius Nattey (2013)[10] that household socio-economic inequality and maternal education were observed to be strongly associated with under-five mortality in rural Tanzania.

The UN Inter-agency Group for Child Mortality Estimation (UN IGME) reported that, out of 99 surveyed LMICs, children born to the poorest families were on average, twice as likely to die before the age of five compared with children born to the wealthiest families (UN IGME 2017)[11].A systematic review and meta-analysis done by Bernadette O'Hare(2013)[12]on income and child mortality in developing countries also came to this conclusion that there is an inverse and significant relationship between income and child mortality.

McKinnon B(2014)[13] published his work in Lancet Global Health,that a substantial survival advantage remains for babies born into wealthier households with a high educational level, which should be considered in global efforts to further reduce NMR. Khadka KB(2008)[14] also stated that socioeconomic distal and proximate determinants are associated with infant mortality in Nepal. Infant mortality was higher in the poor and middle classes than the wealthier classes. Park (2005)[15] In industrial world a dominant factor in the decline in infant mortality has been social and economic progress. Study done by Victora CG (2003)[16] also shows that poor infants are more likely to be exposed to health risks than their better-off peers, and they have less resistance to disease because of under-nutrition and other hazards typical in poor communities.

Conclusion

Our study as well as studies from different parts of globe establishes an inverse and significant relationship between income and child mortality, so while making policies to bring down under five mortality specially in developing and under developed countries, socioeconomic conditions of people must be kept in consideration.

Impact of Body Mass Index and Age on Mental Health of Adolescents Girls

Reeta Venugopal[1], Priyamvada Srivastava[2], Aniksha Varoda[3], Mahendra Kumar[3]

[1]Professor Dept. of Physical Education, [2]Professor, Dept. of Psychology, [3]Research Scholar, Pt. R.S.U. Raipur, C.G.

Abstract

Adolescent girls in India may face poor nutritional status due to low access to healthy food and high mental health symptoms attributed to high stress. Total 72% of infants and 52% of married women have anaemia. Researches indicated that malnutrition during pregnancy causes the child to have increased risk of physical retardation and reduce cognitive abilities. The objective of the present study was to investigate the impact of body mass index and age on mental health of adolescent girls. 1000 adolescent girls were selected through stratified random sampling technique from different government school of Raipur, India. Mental health was measured by Mental Health Battery. Anthropometric measurement and age was collected by the standard procedure. Multivariate analysis of variance and post Hoch test were employed to analyze the data. Results revealed that adolescent girls significantly differ in emotional stability, overall adjustment, autonomy, security-insecurity, intelligence and over all mental health with increasing age. Post Hoch test showed that adolescent girls with low body mass index differ significantly on overall adjustment and self concept dimension of mental health in comparison to adolescent girls with normal BMI. It is concluded from the study that adolescent girls of early years (12-14) must be given environment to develop Emotional Stability, Autonomy, Security-Insecurity and Intelligence. Proper nutrition is needed to improve self concept and over all adjustment. Findings of the study draws attention to create awareness related to mental health and nutrition.

Keyword: *Mental health, BMI, Adolescent Girls.*

Introduction

Adolescence is transitional stage of human life cycle with different kind of physiological change. This period is very crucial since these are the formative years in the life of an individual when major physical, psychological and behavioural changes take place [1,2]. Every stage of human growth and development is affected by mental health. The mind and the body are connected[3]; hence affect each other patterns of activity, poor diet, poor sleep habits etc are factors which determine health[4]. Diet can have both significant positive and negative impacts on physical and mental health. Positive associations were observed between mental health problems and menstrual cycle irregularity among adolescent girls[5].

The nutritional status of an individual is influenced by a variety of factors, including: Life stage, environment, food access, and socioeconomic status[6]. In turn, each of these factors can influence mental health[7]. Mental health problems are the highest prevalence of any age group[8].

Malnutrition occurs when there is an imbalance of energy and protein in an individual's diet or body may become unable to absorb the nutrients[9]. Nutritional deficiencies lead various health problems which are found everywhere, and most often go without cures/ treatment. Deficiency of both macro- and micronutrients

e-mail-mksahu4135@gmail.com

has been associated with increased behavioural problems[10]. There is a strong relationship between nutrition and mental health in adults[11,12,13]. Malnutrition is also associated with mental health, particularly depression among elderly individuals[14]. Studies have found depressive symptoms to predict malnutrition in community living elderly[15], Further more, studies of the relationship body mass index (BMI) and age with mental health in adolescent's girls' individuals have yielded conflicting results. However, no studies have yet identified the impact of body mass index and age on mental health in Indian adolescent's girl's population of government school setting.

Therefore, the aim of this study was to determine the status of mental health in a government school-attending adolescents girls population and examine the impact of BMI and age on mental health & its dimensions (Emotional Stability, Over-all adjustment, Autonomy, Security-Insecurity and Intelligence).

Method

Sample: Seven independent samples of students from 12, 13, 14, 15, 16, 17, and 18 year age groups were selected (see figure-1). In this study stratified random sampling technique was used; 8 State government schools were selected based on the principle of randomness.

Exclusion Criteria: Who are not interested to participate, not able to understand Chhattisgarhi and Hindi, participants with an associated somatic and psychiatric problem (CVA, cancer, dementia other several medical problems) were excluded.

Research Design: A cross-sectional design was used.

Tools: Mental Health status was measured by Mental Health Battery [16]. It consisted 48 items with six dimensions, of Mental Health viz. emotional stability, over-all adjustment, autonomy, security-insecurity, self-concept and intelligence. The test-retest reliability was found to be 0.74. The concurrent validity was found to be 0.77.[16]. Anthropometric measurement (height and weight) was collected following the standard procedure as described bygivson[17]. And Body Mass Index (BMI) was calculated by WHO and categorized[18],[19]. Age was obtained by the demographic checklist.

Procedure: First of all the authorities of different schools and parents of students were requested to give permission for collecting data from the students. After getting permission the female students they were contacted in group in their respective schools. Participants were assured that their involvement was voluntary and anonymous and that they maintained the right to withdraw their participation at any time. Written consent in printed proforma was obtained from the individual participants and their parents of the sample included in the study. The investigator explained about purpose of the research to the authorities of schools, participants and there parents. Than after the instructions given on the questionnaire were explained to them. At the completion of the inventory, participants were thanked for their contribution.

Statistical Analysis: Descriptive statistics, MANOVA and Post Hoch test were analyzed with the help of SPSS 16.0 version.

Results

The results are obtained in terms of frequency with respect to age variables are presented figure 1.

Figure 1: Indicates total number of participants in different age group.

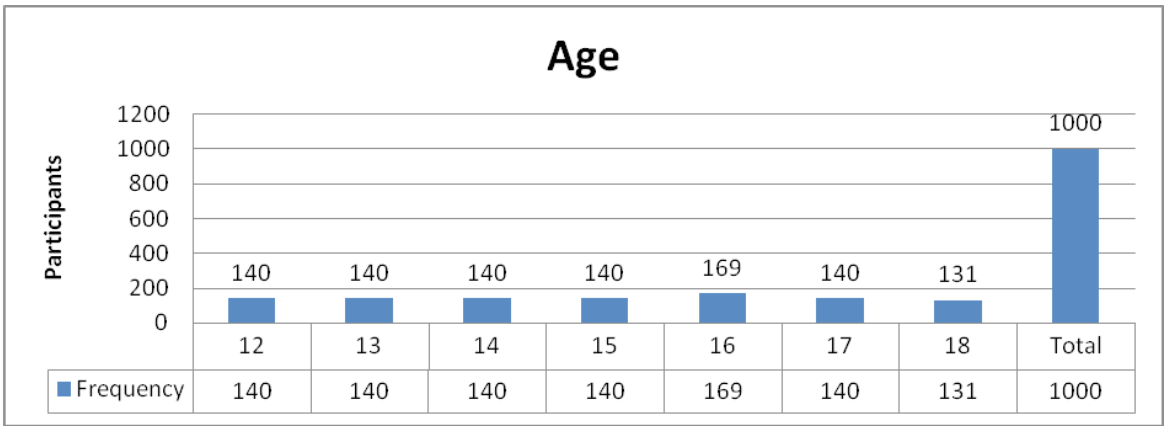

Table 1. Results of the appropriateness of MANOVA of mental health with respect to different age and BMI groups of adolescents' girls.

	Name of test	Value	F	Hypothesis df	Error df	Sig
Age Group	Roy's Largest Root	.048	7.691	6.000	971.0	.000
BMI Category		.013	2.148	6.000	968.0	.046
Group * BMI Category		.040	2.168	18.000	971.00	.003

Among the test of appropriateness of MANOVA (Pillai's trace, Wilks' Lambda, Hotelling's Trace and Roy's Largest Root) Roy's Largest Root was considerd appropriate to find out the difference in mental health and its various dimensions with respect to age and BMI. As shown in table 2 the F ratio is significant for age group, BMI as main effect and interaction effect between age group and BMI. It gives appropriateness for computing MANOVA.

Table 2. Univariate effects of age, BMI and their interaction in mental health and its various dimensions

Tukey's post hoc test showed pair wise comparisons, significant difference (P<0.05) existed in total Mental Health between 12 and 14, 12 and 16, 12 and 17, and 12 and 18 years age groups. In cases of ES, OA, AY and SI dimensions of mental health, significant difference (P<0.05) between 14 and 15, 16 and 18, 18 and 15 for ES the difference were observed between 12 and 14 for OA, differences were observed 12 and 18, 13 and 17, 18, 14 and 18, 15 and 17, 18, 16 and 18 in case of AY, difference between 12 and 18 was observed for SI difference was noted between 12 and significant differences between 15, 15 and 18 were also recorded for IG.

Table 4. Results of Post ANOVA comparison BMI group difference on mental health dimension.

	Severe Malnutrition	Normal	-.5816*	.19120	.013

Table 4 revealed that the adolescent girls with normal nutrition and severe malnutrition differ significantly on OA and SC dimensions of mental health.

Discussion

Results indicates increasing trend with age in over all mental health and it's dimensions (ES, AY, SI and IG)

of adolescent girls. It indicates that girls develop stable feeling, self determination in thinking, sense of safety and general ability in behaving purpose fully in ones environment as they age. Over all mental health refers to manifesting self evaluation and adjustability which increases with increase in age. Various laboratory and survey measures show that spontaneous use of cognitive regulatory strategies increases during childhood and adolescence[20-21]. The findings convey early of girls, are of low on over all mental health with low level of ES, OA, AY, SI & IG in comparison to other age groups. It is because of the physical physiological & social change in development taking place. Eating patterns and mental health problems in young adolescents is significantly associated. A diverse diet rich in unrefined plant foods, fish and regular meals was associated with better mental health, while energy-dense, nutrient-poor diets and irregular meals were associated with poorer mental health[22]. Previous work has found that females who have suffered from mental health problems consume greater quantities of unhealthy foods [11,12,13]. Results indicate significant difference in emotional stability of girls of age group 14 & 15 yrs, 16 & 18 yrs & 18 & 15 yrs. 14 year age group girls seem to be more stable in comparison to 15 & 16 year old girls. It may be because the physiological turmoil puberty age ceases at 14yrs. ES during 15 & 16 is low which may be due to the heterosexual attraction and social approval becomes prominent concern for girls in these age groups, mean values indicate that the late adolescent groups are significantly stable in ones feeling, in comparison to early and middle adolescent age groups.

Early and middle age group adolescents girls differ significantly from girls of late adolescent age groups on autonomy dimensions and also significant deference between 12 and 14 on over all adjustment. Girls of middle adolescent level exhibit more in harmony with environment and their cognition in comparison to early adolescent girls. Increase in age the girls are able to govern and control their own affairs and gain higher level of self determination. The ability to make choices and exert control on life plays an important role in psychological health and well being, On SI dimension adolescent girls of, 12 year differ significantly from 18 years. In late adolescent stage the girls are physically and psychologically matured feel more sense of safety than early adolescent group of girls. On over all mental health, early adolescent girls showed significantly lower values as compared to middle and late adolescent groups, which indicated that as age increases self evaluation and adjustability also increases, leading to maturity.

The adolescent girls with severe malnutrition showed poor over all adjustment and self-concept. Malnutrition leads to disharmony in cognition and environment they are unable to understand and perceive the conditions in right way, leading to poor adjustment. The adolescent who suffer from malnutrition also have low self concept, that is attitude toward self and evaluation of their achievement is negative. The impact of BMI reveals the importance of nutrition in growth and psychological health.

Early adolescents group show low ES, OA, AY, SI, IG and overall mental health which can be attributed to physiological changes and social development during adolescent period. In later adolescent period parent and social control loosens and the adolescents conflict level decreases resulting into improved mental health and adjustment.

The results are in contradiction with the findings of earlier researches which state mental health of early adolescent group is better than later adolescent group [23]. As the present finding indicate that the middle & late adolescent group is mentally health and emotionally stable well adjusted & more secure. The finding of the study is also coherence with the findings who reported extremely low BMI was related with mental problems[24,25,26].

Conclusion

It is concluded from the study that adolescent girls of early years (12-14) must be given environment to develop Emotional Stability, Autonomy, Security-Insecurity and Intelligence. Proper nutrition is needed to improve self concept and over all adjustment. Mental health was strongly affected by the malnutrition in school going adolescent girls and this impact was also significant for subthreshold mental health symptoms. Findings of the study draws attention to create awareness related to mental health and nutrition.

Abstract

Introduction: Early Childhood Caries (ECC) is a preventable chronic disease which is mainly affecting infants and children worldwide. The early identification and detection of ECC can reduce pain, life threatening conditions and helps in the growth and the overall development of the child.

Aim: To find out the prevalence of Early childhood caries (ECC) among the children attending the Anganwadi's of Ukkali Vijayapur district, and its relationship with parent's education, occupation, socio economic status of the family with feeding habits and early oral hygiene mentions.

Materials and Method: Community based cross sectional study among the selected Anganwadi's children of 1-5 years of age at Ukkali district Vijayapura.

Result: A total 142 subjects, 34 children were found to be having ECC, 57(40.1%) males and 85 (59.9%) females. A significant association was found in these study with the age of the children, breast feeding duration and the oral hygiene proposes, out of 142 cases 34 cases were having ECC therefore the prevalence of ECC was 23.9%.

Conclusion: Future health promotion and education programs in Anganwadi's should include oral health issues and the risk factors for ECC, and its consequences should be addressed.

Keyword: *Children, Early childhood caries, Prevalence, Primary teeth.*

Introduction

Dental caries is one of the most common chronic diseases of early childhood Dental caries in primary dentition is often neglected since they exfoliate, and its treatment is considered as economic burden among lower socioeconomic families. [1]. Early childhood caries (ECC) is a chronic, disease with its complex and multifactorial etiology [2]. ECC is commonly seen in any tooth surface of primary teeth between the age group of children 1 to 5 years [3]. Dental problems in early childhood age have shown to be predictive of future dental problems, with the growth and development of child also interfering with nutrition, concentration, and school participation[4].

India, Is a developing country and the incidence of dental caries is increasing due to the changing

lifestyle and dietary patterns.[5] The Government of India initiated a National Scheme known as the Integrated Child Development Services (ICDS) which aims at the delivery of a package of basic health services through various functionaries. Anganwadi worker (AWW) is the most periphery functionary of the ICDS scheme. She delivers services to mainly children below the age of 6 years, including mainly nonformal, preschool education, health, and nutrition maintenance. Most of the preschool children belonging to low socioeconomic status attend Anganwadi schools [6]. The prevalence of ECC in the developing countries is reported to be as high as 70%[7]. Some of the published studies showed an ECC prevalence of 19-54% in the Indian population[8]. An early identification of dental caries provides an opportunity to identify the children who are at a greater risk for the disease so that appropriate preventive interventions can be initiated to protect the unaffected teeth and protect the permanent dentition[10]. To the best of our knowledge, no other studies have been conducted to assess the prevalence of dental caries among Anganwadi children in Ukkali village of Bijapur district. The present study is an effort to determine the prevalence rate and evaluate its associated risk factors of ECC among the Anganwadi's children within 5 years of rural health centre Ukkali.

Method

The study group consisted of 142 preschool children of 1 to 5 years of age group from various Anganwadi centers, rural health Ukkali. Institutional Ethical Committee Clearance (IEC) was obtained, and the consent for examining the children was procured to the Anganwadi's worker and the parents of the children. Clinical examination was done using a sterile mouth mirror, and probe. The decayed teeth were recorded and patients who required treatment for the decayed tooth cards were issued for the treatment and instructions are given to the children to accompany with their parent for the dental treatment.

Total children in eleven anganwadi centre of rural health Ukkali were about 1264. Male 668 and female were 596. All the children of preschool who were accompanied with their parents and present on the day of examination are included in the study. Children suffering from systemic disease and absent on the day of examination were excluded from the study.

Results

Out of the 142 subjects examined, 40.1% (57) were males and 59.9% (85) were females. On the whole 23.9% (34) had ECC while 76.1% (108) children had no caries.

Birth orders of total 142 children were distributed in five groups. The total 36 children in 1st order having ECC were, 10 (27.8%), 53 children in the 2nd order having ECC were, 13(24.55%), 37 children in the 3rd order having ECC were 5(13.5%), 13 children in the 4th order having ECC were 6(46.2%) and children with 5th order were total are 3 none of them were effected with ECC. No difference was found between the birth order of the child and ECC. Mothers of total 97 children were illiterate, children effected with ECC were 25(25.8%), mother with primary education total are 31, children effected with ECC were 6(19.4%), mother with secondary education total are 11, 2(18.2%) were effected with ECC, and 3 of them are higher education with ECC are 1(33.3%). No difference was found between mother's educations. No difference was found between the social class of the family and ECC.

Table 2 shows that all study subjects were having the history of breast feeding. Around 9 children were breastfed for less than 6 months. No children were having ECC. Out of 105 children were breastfed for one year, 31(29.5%) showed ECC present. 28 children are breastfed more than a one year around 3(10.7%), were having ECC positive. A significant association was found between the history of breast feeding and ECC. P- 0.026.

*significant with p<0.05

Bottle Feeding: Total 18 children gives a history of bottle feeding with 6(33.3%) shows ECC present. No significant difference with history of bottle feeding and frequency of bottle feeding with ECC. No significant difference seen with the content of bottle feeding, bottle feeding at night and frequency of meals per day with ECC.

Table 3 showed that 42 children not started cleaning only 4 of these children showed ECC present. About 35 children started cleaning from 4 months and 8 of these children showed ECC positive. Around 44 children started cleaning.

Method of Cleaning: 54 children used to clean their teeth with brush and paste, out of these 16 (29%) were having ECC. 31 children used to clean their teeth with finger and paste, out of these 9(29.0%) were having ECC. 15 children used to clean their teeth with finger and powder (Lal Manjan, salt with coal powder) out of these 5(33.3%) were having ECC. 42 children not is to clean their teeth, around 4(9.5%) of these showed ECC present. No significant p value seen between method of cleaning and ECC.

Table 3: Association of ECC and Teeth cleaning variables of the Subjects

Discussion

The present study was undertaken to assess the existing knowledge of early childhood oral health related factors among eleven Anganwadi centre of rural health Ukkali, so that effective pediatric oral health measures can be provided, there by safe guarding the growth and development of young children.

A total of 142 children of less than 5 years of age groups are selected and screened to determine the prevalence of ECC from the 11 Anganwadi's at Ukkali. The prevalence of ECC in the present study was, out of 142 cases 34 cases were having ECC therefore the prevalence of ECC is 23.9%.

The mean dmft found in Karnataka (Bangalore), Andhra Pradesh and Kerala were 0.6, 1.63, and 2.1 respectively[11]. Another study was conducted to compare the prevalence and pattern of caries in 4-5½-year-old children of urban Bangalore and non-urban Chikkaballapur within Karnataka state, India. The results showed caries prevalence of 66.3% with a mean deft of 2.9 in Bangalore city whereas in Chikkaballapur, the prevalence was 58.4%[12.] The prevalence of ECC in urban Bangalore within Karnataka state was 27.5%[10]. In the present study ECC prevalence is low compared to all above studies.

In this present study no significant association was found between the age of the children and ECC, this finding does not coincide with finding of Wendt L K in Sweden showed that the prevalence increases with high age group[13].

The present study the prevalence of ECC was found to be more among girls (22.4%) compared to

boys (26.3%). ECC among male and female shows no significant association. The present study doesn't coincide with study done Olmez S[14].

Children with birth order 1 and 2 showed higher prevalence of ECC than children with subsequent birth orders. However no significant association was found in the birth order and ECC.

No significant association was found between the social class and mother's education with ECC. Some study showed that higher ECC prevalence found with the lower family income[15].

Significant prevalence of ECC with breast feeding is seen in the present study. Correlates with study done Roberts GJ[16], showed that prolonged and excessive breast feeding also has been suspected as a causative factor in ECC.

In present study bottle feeding duration, frequency, with or without sugar and frequency of meals shows no significant correlation with ECC. Some study showed that increased frequency of bottle feeding increases the prevalence of ECC[17, 18].

Maximum of children in the present study started cleaning their teeth after the age group of 3 years. The children in the age group of 3, 4, 5 years showed a significant prevalence of ECC with cleaning of the teeth. As in accordance with other studies, caries prevalence was seen to increase significantly with age. As children grow older, change in their dietary habits and oral hygiene practices pose a greater cariogenic challenge[19, 20]. The method of cleaning teeth did not show any significant relation with ECC. Tooth brushing, early onset of tooth brushing, parental supervision of tooth brushing and daily use of fluoride dentifrices were shown to significantly reduce prevalence of ECC [21, 22].

Conclusion

Dental health services should be made available in the peripheral areas to meet the needs of young children. Future health promotion and education programs in Anganwadi's should include oral health issues and the risk factors for ECC, and its consequences should be addressed. Public funded oral health program should be started and targeted at children from lower socioeconomic status

Ethical Clearance Oral consent from parents and children has been taken

Knowledge, Attitude and Practices of Biomedical Waste Management among Dental Practioners in Karad City, Maharashtra, India

Surabhi Mahajan[1], Shivakumar K.M.[2], Vidya Kadashetti[3]

[1]Intern, [2]Professor & Head, Public Health Dentistry, [3]Assistant Professor, Oral Pathology & Microbiology, Forensic Odontology, School of Dental Sciences, Krishna Institute of Medical Sciences Deemed to be University, Malkapur, Karad, Satara (Dist.), Maharashtra, India

Abstract

Introduction: Biomedical waste is generated routinely in high amounts in the dental office, the correct disposal of which bears importance to the dentist, staff and healthcare workers. This is the first of its kind study in the city of Karad which will provide an important insight into the proper method and knowledge of disposal of health care waste by the dental practitioners. The application of this study will be in accessing the legal necessity and social responsibility of the healthcare personnel's in the effective management of biomedical waste.

Materials and Method: The study population included 100 private practitioners in Karad City, Maharashtra. A self-administered questionnaire was distributed to assess the knowledge, attitude and practices regarding dental waste management. Descriptive statistics was used to summarize the results.

Results: Out of 100 study participants, 73 (73%) were males and 27 (27%) were females. The maximum number of participants belonged to the age group of 34-38 years (29%). Undergraduate qualification was more (80%) and 43% participants had an experience of 0-5 years. Chi-square analysis showed a highly significant association between participant who attended continuing dental education (CDE) program and their practice of dental waste management.

Conclusion: Lack of knowledge and professional training in disposal of biomedical waste becomes a direct threat to the humans as well as the environment. CDE programs would help bring about a change in the management of healthcare waste.

Keywords: *Biomedical waste, dentist, hospital waste.*

Introduction

The health care sector produces a huge amount of biomedical waste in the course of curing health problems. The management of hospital waste or biomedical waste is considered as an important aspect to avoid various hazards to the humans and environment. Since this waste keeps generating continuously, it is the legal necessity and social responsibility of every healthcare professional to meticulously segregate and dispose the waste.[1] Biomedical waste means any waste, which is generated during the diagnosis, treatment and immunization of human beings or in research activities pertaining thereto or in the production or testing of biological, and including categories mentioned in Schedule 1 of the Government of India's Biomedical Waste (Management and Handling) Rules 1998.[2]

On an average per day per bed, 0.5-2 kg waste is generated in India. Annually 0.33 million tons of hospital waste is generated in India. Biomedical waste not only poses great threat to the environment and the general population, but also to the ones who handle it and carry out the disposal.[3] 15% of the total waste generated is infectious and hazardous. This waste pertains to be a threat to the living as well as the non living thing.[4]

This waste plays a significant role in the spread of pathogens like HIV, Hepatitis B & C. Dental offices generate a large amount of biomedical waste daily. This waste is of equal harm to the environment and atmosphere as to the humans.[5] Lack of knowledge persists regardless of the professional training and thus, necessary measures to deliver awareness is the need of the hour.[6,7] Hence this study has been undertaken to assess the knowledge of dental practitioners in Karad city, understand the practices of waste disposal, train the healthcare workers and to take measures in establishing a protocol.

Materials and Method

A cross-sectional study was conducted among the dental practitioners in Karad city, Maharashtra, India from December 2018 to February 2019.

A pre-tested, self-administered, closed-ended questionnaire was designed for recording all the relevant data pertaining to general information of the study participants and knowledge and practices regarding dental waste management in a private clinic. Ethical approval was obtained from the Institutional Ethics Committee of KIMS Deemed to be University, Karad. Questionnaires were adopted from previous studies and modified.[1,8] A few new questions were formulated, some questions were modified while some were considered unnecessary and removed since this did not hamper with the fluidity of the questions.

The questionnaire consisted of 18 questions to assess the knowledge and the practice of biomedical waste management. The questions were grouped under Knowledge/Cognizance, Attitude and Practices/ Execution of biomedical waste and its management.

Questions to access knowledge were of a multiple choice type, only one response being the correct one. Questions to access attitude were presented in positive or negative response format (Yes/No/Don't Know). Questions regarding practice were of multiple choice type, including the various method which may be implemented in routine practice. Each correct and incorrect response in the knowledge section and each yes and no or don't know for the attitude and practice question are to be given 1 and 0 mark, respectively.

The study sample was collected. The study population comprised of 112 private dental practitioners, of which 100 dental Practioners gave consent to participate in the study. The study participans were given sufficient time to answer the questionnaire and the questionnaire was collected back on the same day or the next day. Questions about KAP were assessed for scores individually. Descriptive summary using frequencies, proportions and cross tabs were used to present study results. The collected data was entered in Microsoft excel sheet and subjected to statistical analysis. Statistical significance was analyzed using Chi-square test. The level of significance was set at 5%. The Statistical Package for Social Sciences (SPSS) version 21.0 was used for the statistical analysis.

Results

A total of 100 participants were recruited for this study, with a 100% response rate. As shown in Table 1, 73(73%) participants were males and 27 (27%) were females. The maximum number of respondents belonged to the age group of 34-38 years (35%). Respondents with undergraduate qualification were more (80%) compared to postgraduate qualification (20%). 43 (43%) participants had an experience of 0-5 years.

Graph 1 shows that 47 participants have attended CDE programs on dental waste management, Graphs 2 and 3 show that the distribution of respondents by correct knowledge and practice answers.

Table 2 shows the association between CDE program an knowledge scores of dental waste management. Knowledge score was good among 31.91% subjects who attended CDE programs.

Table 3, it is evident that good waste management practice was observed in those who attended CDE programs 36.17% compared to those who did not attend CDE programs. Association between CDE program and practice scores of dental waste management was statistically significant (<0.05).

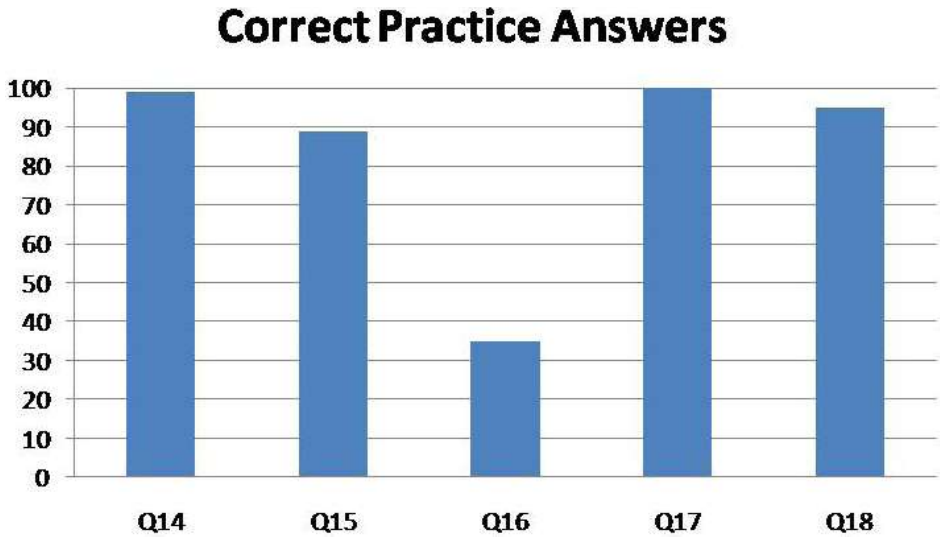

Graph 3: Distribution of Respondents by correct practice answers

Discussion

Hospital waste generation is a continuous process. This waste needs to be disposed in place or, it may serve to be a potential carrier for various diseases and pollution. A major contribution to this waste is from dental clinics. Dental waste consists of a wide range of materials from amalgam, cements and files to bloody cotton swabs, needles and human anatomical waste.

Although the dental profession is a team effort, management of biomedical waste is done at an individual level. The dental waste travels through the hands of numerous individuals and thus, monitoring of proper disposal is one of the many tasks the dental professional needs to observe. In order to assess the present situation and to gain insight on the efforts that need to be undertaken to help with the cultural needs, a learning instrument (questionnaire) based on the knowledge, attitude and practices of the dentist has been arranged.[1,5] 100 subjects involved in this study, including 80 graduate and 20 post-graduate qualification. 99% subjects reported to be aware of the different categories of biomedical waste and that efficient segregation of this waste was carried out in their practice. While, only 71% of these subjects had knowledge of the color coding given by the biomedical waste management in India. 65% individuals showed knowledge of the use of yellow bag/containers to dispose human anatomical waste.

96% subjects reported to be registered with a certified waste carrier service to recycle or dispose the biomedical waste generated in the clinic. 34% dental clinics were registered with a private biomedical wastage service. Most of the private dental clinics did not show much use of dental amalgam. 69% private dental professionals were aware of mercury spill kit being the most effective way to remove accidental spill of mercury. This result is similar to a study conducted at dental clinics in Karnataka, India.[1] 89% subjects informed that they used needle burn to dispose infected needles.

In the present study, 47% of the participants have attended CDE program based on biomedical waste management, the results of which showed increased awareness and better practice of waste disposal. 78% subjects are willing to attend training on biomedical waste management or think they need more knowledge regarding the issue. Although specialized waste carrier services are available in India, dental professionals and students need to be made accustomed to the availability of these services.

Conclusion

Insufficient professional training regarding this topic becomes a major contributor to the neglect of biomedical waste management. Lack of awareness and interest fails one to register their clinic under certified waste management services. Dentists should be focused not only in delivering healthcare needs up to the mark but also, taking responsibility of the effects of waste generated routinely.

Limitation of Study: As this study was confined to the only single city but this topic is relevant to large regional area so more extensive studies with larger and broader population cohort are required for better assessment and implementation of biomedical waste guidelines.

Exploring the Role of Hatha Yoga in Altering Dispositional Mindfulness

Teesta Saksena[1], Ritu Sharma[2], Ishwar V. Basavaraddi[3]

[1]Research Scholar, Amity Institute of Psychology & Allied Sciences, AUUP, Noida, [2]Assistant Professor, Amity Institute of Psychology & Allied Sciences, AUUP, Noida, [3]Director, MDNIY, Ministry of AYUSH, Govt of India, New Delhi

Abstract

The present research study was an intervention study conducted to elucidate the effects of different Hatha yoga practices on dispositional mindfulness among young adults not characterized by any clinical condition. 280 participants were assigned to three different Hatha yoga intervention groups and a control group for duration of three months. Baseline and post intervention scores for mindfulness were recorded for all the four groups using the Five Facet Mindfulness Questionnaire. Data was analyzed using analysis of covariance for measuring the mean difference between-groups. A highly significant difference was observed between groups on the ability to observe and describe emotions/inner experiences and act with awareness, all of which are positive indicators of dispositional mindfulness. Analysis of *t*-test revealed maximum significant and positive change in dispositional mindfulness in the combined intervention group of yoga asana and pranayama and meditation, followed by the pranayama and meditation group and the yoga asana group, respectively. Findings reinforce Hatha yoga as a significant predictor of dispositional mindfulness and further contribute to the insufficient literature examining the psychological benefits associated with Yoga among adult masses with no specific clinical condition. It further suggests employing stronger interventional research designs and a mixed-method approach for in-depth assessment of participant experience to accurately evaluate the benefits associated with specific yoga practices and their effects on dispositional mindfulness.

Keywords: *Hatha yoga, mindfulness, FFMQ,clinically healthy adults.*

Introduction

This research is intrigued and inspired by the growing emphasis on Yoga in the effective management of mental health problems and as an aid to improve mental health status.[6,16] Much awareness and popularity is witnessed among the clinically healthy population to adopt Yoga as a medium for advancing health standards, preventing health-related issues, and as a spiritual pursuit. Research identifies Yoga as an integral component of mindfulness-based interventions.[24] Empirical efforts in relation with investigating the effects of yoga-based interventions on mindfulness among young Indian adults have largely targeted an audience characterized with specific conditions associated with aggression[2,4], stress[11], emotional regulation[17], memory and concentration[5], clinical conditions[15], thereby, creating a need to understand the effects of Yoga on dispositional mindfulness among young adults recruited in an intervention without the basis of a clinical condition. Sizeable research efforts in the previous years have been vested into examining Yoga in relation to mindfulness as a single measure.[20] However, a noticeable gap has been identified in literature addressing how Yoga affects different facets of mindfulness independent of each other. This research investigation was conducted with an aim to examine the association between Hatha yoga and the five facet construct of mindfulness.[1] Along with endorsing mindfulness as a multidimensional construct, this study also intended to examine a greater need of its individual subcomponents– observing of emotions/inner experiences, describing of emotions/inner experiences, acting with awareness, non-judging towards emotions/ inner experiences and non-reactivity towards emotions/ inner experiences as critical aids in mental health

promotion among young adult masses characterized with no specific clinical condition.

Materials and Method

Aim: To examine the difference in effects of Hatha yoga practices on five facets of mindfulness among young adults characterized with no specific medical condition.

Objectives: To investigate the mean difference between groups– (I) yoga asana (II) pranayama and meditation (III) combined intervention of yoga asana and pranayama meditation, and (IV) control group after 3-months of intervention.

Hypotheses: It is hypothesized that Hatha yoga will play a significant role in enhancing the subcomponents of mindfulness. Further speculations are made that the intervention group III will exhibit most significant and positive effects on five facets of mindfulness as compared to intervention groups I and II, as a result of a composite, more advanced, and systematically designed approach.

Participants: Study recruited 280 participants aged between 25-35 years and selected as a result of convenience sampling. Participants were divided into Intervention Groups (N=210) and Control Group (N=70). The intervention groups were further subdivided into three groups with equal number of participants (70 each), in order to study the difference in effects of three different Hatha yoga interventions– (I) Yoga Asana, (II) Pranayama and Meditation, and (III) Yoga Asana + Pranayama and Meditation. The Control Group (IV) comprised of participants who were not actively engaged in any form of mind-body-spiritual practices or physical exercise. The premises of the intervention was Morarji Desai National Institute of Yoga, New Delhi.

Interventions:

Yoga Asana: The intervention schedule was designed for a period of 3-months with 3 days in a week. Everyday module included theory as well as practical ranging between 2.5-3 hours on an average. The content of theory and practical was evenly distributed and covered over the intervention period.

Pranayama and Meditation: The intervention schedule was designed for a period of 3-months with 3 days in a week. The everyday module included theory as well as practical ranging between 2.5-3 hours on an average. The content of theory and practical was evenly distributed and covered over the intervention period.

Combined Intervention: This intervention incorporated a combination of both, yoga as an as well as pranayama and meditation. The intervention schedule was designed for a period of 3-months with 6 days in a week. This group was given the yoga asana a intervention for 3 days and the pranayama and meditation for 3 days. The module for each day included theory as well as practical ranging between 2.5-3 hours on an average.

Instrument: Data was collected using the preliminary information form standardized by the institution and the Five Facet Mindfulness Questionnaire (FFMQ).[1]

In order to test the hypotheses, the measurement of following dependent variables was required:

1. Observing of Emotions/Inner Experiences
2. Describing of Emotions/Inner Experiences
3. Acting with Awareness
4. Non-Judging towards Emotions/Inner Experiences
5. Non-Reactivity towards Emotions/Inner Experiences

Data Analysis: Data analysis was performed using SPSS 24.0. The analysis involved computation of means and SD. The mean difference between-groups was calculated through ANCOVA along with the effectiveness of the interventions which was ascertained using Paired t-Test.

Results

The results obtained upon analysis of covariance indicated an overall significant difference between groups on the facets of '*Observing'* ($F=4.93$, $p<.01$), '*Describing*' ($F=2.68$, $p\leq.05$), and 'A*cting with Awareness*' ($F=3.30$, $p<.05$), with their corresponding pretest scores used as covariate.

Table 1: Pairwise Comparisons of Post Adjusted Means

Dependent Variable	(I) Groups	(J) Groups	Mean Difference (I-J)	Sig.b
Observing	4	1	-1.13**	0.00
		2	-1.02**	0.01

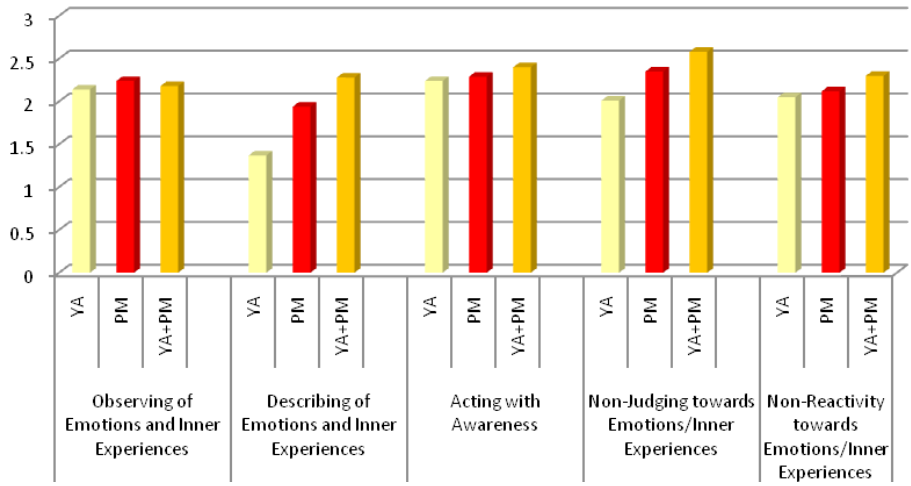

Figure 1: Graph Representing Effects of Intervention in Intervention Groups

Table 2 and Figure 1 validate the speculations made for the group III, wherein findings for within-group difference indicate that this group exhibited greatest significant difference and scored highest on four out of five facets of mindfulness followed by group II and group I, respectively.

Discussion

Analysis of covariance indicated a significant effect on the mean difference between intervention groups on observing emotions/inner experiences, describing of emotions/inner experiences, and acting with awareness post intervention. A common trend is observed across the findings of observing emotions/inner experiences, describing emotions/inner experiences, and acting with awareness, with the intervention group II experiencing most considerable positive change, followed by the intervention group I and III, respectively, in comparison to the control group.

Practices of pranayama and meditation operate primarily on the mind principle to conquer mental processes under voluntary control through the practice of concentrated attention and awareness[23], reinforcing a more significant role of mental faculties in practicing mindfulness. This claim was later reinforced by examining that pranayama and meditation involve greater voluntary control of mental capacities[3] necessitating concentrated breath control, centering of attention on bodily sensations, maintenance of posture, and guided instructions at short intervals; aiming at elevating deeper states of consciousness by reassessing the state of mind[12] and heightening mindfulness.[19] Yogasanas, on the other hand, are a balanced blend of effort and ease, which teaches one to put in efforts to get into a posture, experience relaxation in that posture, and try to detach from the result.[13] They operate on gross body level and are more than just mere physical exercises and a fundamental medium for a deeper understanding of mind and body.[14] Every movement of the body has a direct correlation with the way mind responds to it.[14]

A gain in mean scores of observing emotions/inner experiences after the interventions of pranayama and meditation and yogasana respectively, is attributed to the principles on which these practices operate. Pranayama and meditation are advanced practices with potential to lead to positive effects on observing inner experiences.[21] Yogasanas involve equal engagement of mind and body on the premise of shaping the physiological state of the body to regulate emotions, thoughts, and attitudes[10], thereby maximizing the ability to observe internal and external experiences.

Describing of emotions/inner experiences refer to being able to explain inner experiences in words or label them.[1] Participants reported guided meditation practice in playing an instrumental role in enabling them to reflect upon the experience of different thoughts and emotions and in allowing them to flow freely without fixating the mind on them. Obtained findings are supported with earlier research suggesting a positive impact of yoga and meditation on cognitive functionality.[22] Meditation has reportedly led to a significant decrease in cortisol[7], a hormone which is responsible for having a quietening effect on mind. Lower pace of processing equipped the participants with an increased ability to differentiate between positive and negative affective states, which in turn helped them to attain clarity in thought and be able to identify and label their feelings and experiences with great ease. Active inhalation and exhalation during yogasanas and meditation have the potential to lead to significant structural changes in orbitofrontal and hippocampus regions in brain[8], larger volumes of which may account for positive emotions, retention of emotional stability, and engagement in mindful behavior.[39] Regularity in these practices accounts for habitual changes among practitioners. Research findings indicate an increase in levels of oxygen and serotonin after practicing yogasanas, agents which are chief contributors in channelizing the mind towards experiencing higher positivity, emotional stability, calmness[18], and organization in thoughts.

Obtained findings indicate significant positive effects on acting with awareness, suggesting greater control over thoughts and maximized attention towards the moment in hand after engaging in yoga. Participants reported feelings of a mental slow down post intervention allowing them more time for conscious engagement in everyday actions and self-reflection. This finding may be supported with a research investigation regarding yoga as a complex blend of physical, moral and spiritual practices aiming at attaining self-awareness and working on activating the inner energies to reduce the pace of mental activity, thereby leading to a clear state of mind.[9]

Results of the study add to strength of association between yogasana, pranayama, and meditation, and components of dispositional mindfulness among young adults with no specified clinical condition. Obtained

findings may substantively support yoga-based controlled trials investigating the difference of effects between clinical and nonclinical population groups. A significant chunk of research in mindfulness has examined it as a single overarching construct, with less emphasis on investigating its subcomponents independent of each other. This investigation intended to bridge this gap by studying the five facets of mindfulness in relation with Hatha yoga to find them as independent yet interacting.

Implications: This study implicates adopting a more qualitative approach, such as a well-designed interview method, in gathering knowledge about participant experience after engaging in mind-body-spiritual practices. Considerable research initiatives have been undertaken in support of the health benefits associated with aggregated practice of yogasanas, pranayama, and meditation. Yet the results seem less conclusive of which one would be more favorable. Therefore, this study implicates stronger interventional research designs to provide in-depth insight into benefits associated with specific yoga practices. The study suggests further research incorporating and exploring the effects of extrinsic variables such as length of practice, time of practice and consistency in teaching instruction on psychological components, as these factors are integral to the success of a yoga-based intervention.

Morphometry of Acromion Process of Scapula with Respect to Gender

Pushpa N.B.[1], Roshni Bajpe[2], Pushpalatha K.[3], Deepabhat[4]

[1]Assistant Professor, Department of Anatomy, JSS Medical College, JSSAHER, Mysore, [2]Professor, Department of Anatomy, KIMS, Bangalore, [3]Professor & Head, [4]Associate Professor, Department of Anatomy, JSS Medical College, JSSAHER, Mysore, Karnataka, India

Abstract

Background: Of the wide spectrum of musculoskeletal disorders affecting the shoulder, subacromial impingement syndrome is considered to be quite common. The main objective of the present study is to evaluate the morphometry of acromion and to measure other parameters like acromiocoracoid distance (ACD) and acromioglenoid distance (AGD).

Materials And Method: Study was conducted on 100 male and 100 female adult scapulae. Length and breadth of the acromion, ACD, and AGD were measured using vernier callipers. Measured parameters were tabulated and analysed for statistical significance.

Results: Acromial length, acromial breadth, ACD and AGD varied significantly with sex. Positive correlation was observed between above parameters in male scapulae, whereas positive correlation was seen only between ACD & AGD among female scapulae.

Conclusion: The studied parameters could be help during diagnoses and treatment of shoulder pathologies. They can also be used for forensic and anthropological purposes for determining gender, ethnicity

Keywords: *Acromion, Impingement syndrome, Rotator cuff tears, Acromiocoracoid distance, acromio glenoid distance.*

Introduction

The most common causes of pain and disability in the upper limb are inflammation of rotator cuff tendons and rotator cuff tears that relates to the structure of the acromion[1].

Scapula, large flat triangular bone has thee processes–spine, coracoid, and acromion. Medial aspect of acromion gives attachment to coracoacromial ligament, while the other end of the ligament is attached to coracoid process. These three structures form coracoacromial arch. Tendon of biceps, subacromial bursa, rotator cuff tendons and proximal humerus travel beneath this arch. Subacromial space is defined by the undersurface of anterior third of acromion, coracoacromial ligament and the acromioclavicular joint above and head of the humerus below. Various factors contribute in narrowing of subacromial space which can lead subacromial impingement syndrome (SAIS)[2].

Subacromial impingement syndrome is the most common disorder of shoulder accounting for 44-65% of all the complaints of shoulder pain. Chronic impingement of rotator cuff can result in inflammation of tendons, subacromial bursitis and eventually rupture of tendons[3]. Anterior acromioplasty is the surgical treatment of choice for impingement syndrome which

includes removal anterior third of acromion and release of coracoacromial ligament[2]. Anatomy of acromion and related structures is important in successful interpretation of shoulder images and carrying out of surgical procedures in pathologies associated with joint[4].

Present study was undertaken to study the morphometry of acromion parameters which influences the subacromial space like length & breadth of acromion, ACD and AGD in male and female scapulae.

Materials and Method

Study was done on 100 male and 100 female dry human scapulae of different people collected from department of Anatomy, KIMS, Bangalore. Only adult scapulae with all ossification centres fused were included, damaged scapulae were excluded from the study. Sexing of the scapulae was done using maximum transverse diameter measured by Vernier callipers. Scapulae with transverse diameter more than 105cm were grouped into male scapulae and those with less than 91 cm into female scapulae[5,6,7]. After grouping, in each scapulae following measurements were taken using Vernier's callipers.

1. Anteroposterior length of the acromion along longitudinal axis (Length) - L ph-1
2. Distance between the medial and lateral border of the acromion at the midpoint of insertion of acromio clavicular ligament (breadth) - B ph-2
3. Acromio coracoid distance ACD - distance between acromion and coracoid process along an imaginary line representing the midpoint of coracoacromial ligament.ph-3
4. Acromio glenoid distance AGD - distance between inferior surface of acromion and supraglenoid tubercle. Ph-4

Inferior surface of acromion was examined to see whether it is rough or smooth. Each measurement was taken twice and then average was considered to reduce the bias errors. The data obtained is tabulated and statistical analyses were done using Statistical Package for Social Sciences (SPSS) software. Descriptive statistics like percentage, mean and standard deviation were used to analyse the data. The inferential statistics is done using Chi square test, Student't' test and Pearson's correlation test. Microsoft word and excel were used to generate graphs and tables. Values of male and female subjects were compared. The results are considered statistically significant when $p < 0.05$ and highly significant when $p \leq 0.001$.

Photograph 1: Measuring length of Acromion

Photograph 2: Measuring breadth of Acromion

Photograph 3: Measuring ACD

Photograph 4: Measuring AGD

Results

Among 100 male scapulae 64 had rough undersurface and the rest had smooth undersurface. Among 100 female scapulae 41 had rough undersurface while rest of them (59) had smooth undersurface. Statistically significant association was observed between gender and nature undersurface of acromion (table 1).

Table 1: Percentage of male and scapulae with rough & smooth acromion undersurface (*denotes significant association)

Under Surface	Male		Female		χ^2	P-Value
	N	%	n	%		
Rough	64	64%	41	41%	10.607	0.001*
Smooth	36	36%	59	59%		
Total	100	100%	100	100%		

Mean length of acromion was 4.6cm (45.94mm) in male scapulae and 3.9 cm (38.99mm) in female scapulae. Mean breadth of acromion was 2.5cm (25.58mm), 2.3cm (23.09) in male and female scapulae respectively. Both parameters showed statistically significant difference with p<0.001. In male scapulae mean ACD was 2.8cm (28.61 mm) and AGD was 2.7cm (27.5mm), while in female scapulae they were 2.6cm (26.55mm) and 2.6cm (26.01mm) respectively. ACD and AGD showed statistically significant difference in male and female scapulae (p=0.001). All the measured parameters were higher in male scapulae compared to female.

Table 2: Comparison of different parameters of acromion between male and female scapulae

Parameter	Gender	Range (mm)	Mean	SD	SE of Mean	Mean Difference	T	P-Value
L	Male	35.0-56.48	45.94	4.09	0.41	6.950	10.305	<0.001*
	Female	23.0-5.0	38.99	5.36	0.54			
B	Male	19.8-34.0	25.58	2.80	0.28	2.496	5.451	<0.001*
	Female	17.0-46.8	23.09	3.62	0.36			
ACD	Male	17.16-38.6	28.61	4.27	0.43	2.062	3.254	0.001*
	Female	9.0-37.0	26.55	4.69	0.47			
AGD	Male	17.0-38.8	27.50	3.33	0.33	1.496	3.251	0.001*
	Female	16.5-38.8	26.01	3.18	0.32			

Pearson's correlation equation was applied for all measured acromial parameters among male and female scapulae. There was significant correlation among length & breadth, ACD & AGD among male scapulae (p<0.001) (table 3).

Table 3: Correlation between different parameters in male scapulae

Correlations		L	B	ACD	AGD
L	r	1	0.441	-0.066	-0.026
	P-Value	---	<0.001*	0.517	0.795
B	r	0.441	1	0.059	0.127
	P-Value	<0.001*	---	0.559	0.208
ACD	r	-0.066	0.059	1	0.412
	P-Value	0.517	0.559	---	<0.001*
AGD	r	-0.026	0.127	0.412	1
	P-Value	0.795	0.208	<0.001*	---

Among female scapulae significant correlation was seen only between ACD & AGD (table 4).

Table 4: Correlation between different parameters in female scapulae

Correlations		a APL	b TD	ACD	AGD
L	r	1	0.192	-0.165	0.175
	P-Value	---	0.056	0.101	0.081

	P-Value	0.101	0.959	---	0.001*
AGD	r	0.175	-0.171	0.340	1
	P-Value	0.081	0.090	0.001*	---

Discussion

With the evolution of bipedal gait and more distal migration of deltoid insertion, scapula has shown enormous evolutionary changes. From being broad and short in pronograde man to long and slender in orthograde man, it has undergone various changes like broad and down sloping acromion, narrow coracoacromial arch and more laterally oriented glenoid cavity. All the above parameters contribute in compromising subacromial space.[8]

In 1972 Neer described impingement syndrome, according to him the anterior inferior part of acromion is the principal site of the disease. Even anterior acromial spur, one of the etilogies of impingement syndrome are due to acquired ossification of coracoacromial ligament, which is inserted to the inferior surface of anterior third of acromion[9]. In our study among 200 scapulae 105 (52.5%) had rough undersurface while 95 (47.5%) had smooth undersurface. In the literature Paraskevas reported rough undersurfaced acromion in 51 (57%) and smooth undersurfaced acromion in 37(42%) studied scapulae[10]. In other two studies done on Indian population Singh et al and Gupta et al found the undersurface of acromion to be rough in 57(44%) and 45 (90%) scapulae respectively, whereas the undersurface of acromion was smooth in 72 (55.8%) & 5 (10%) respectively[11,12].

Morphometry of acromion is an important factor implicated in the impingement syndrome of shoulder joint[13]. In our study mean acromion length recorded was 42.46mm which is agreement with all other studies like Paraskevas et al(46mm), Mansur et al (46mm), Sushmitha et al (41mm), Musa et al (45.85mm) except a study done on Chile population by Collipal et al where they reported length of acromion to be 65.8mm[10,13,14,15,16]. Mean breadth of acromion reported in our study was 24.33mm and it is in agreement with that of other studies like Paraskevas et al (22.3 mm), Mansur et al (26.9 mm), Sushmitha et al (21.8mm), Musa et al (23mm) and Collipal (24.5mm)[10,13,14,15,16]. In the literature acromio coracoid distance showed wide spectrum of measurement 15.48mm (Musa et al) – 39.6mm(Collipal et al[15,16]. In our study ACD was 27.58mm which is in consistent with one more Indian study where they found it 28.4mm[14]. Lowest AGD was recorded by Parakevas (17.7mm) and highest by Mansur et al (31.9mm). In our study mean AGD was found to be 26.75mm, which is again in consistent with that recoreded by Sushmitha et al (26.2mm)[14].

In the literature there are various studies regarding comparison of acromion morphometry in right and left scapulae but there are very few studies which throws light on sexual dimorphism of acromion morphometry (table 5).

Table 5: Comparison of acromion parameters with other studies with respect to gender

Study	Length		Breadth		ACD		AGD	
	Male	Female	Male	Female	Male	Female	Male	Female
Nicholson[9]	48.5	40.6	19.5	18.5	-	-	-	-
Paras[10]	48.3	43.9	22.6	22	28.9	27.3	17.9	17.5
Von Schroeder[17]	50.7	43.6	22.9	20.4	28.7	24.6	16.1	14.9
Present Study	45.9	38.9	25.5	23	28.6	26.5	27.5	26

The mean value of length of acromion in both male and female scapulae is less compared to other studies[9,10,17]. But higher values are recorded for the breadth of the male scapulae compared to other studies[9,10,17]. Acromio coracoid distance is almost in agreement with values recorded in previous studies[10,17]. Higher values are recorded for acromioglenoid distances for both male and female scapulae compared to other studies[10,17]. Higher values of ACD & AGD enables the subacromial structures to glide smoothly within the subacromial space. These differences in the measured parameter among various studies could be because of study sample, different specimens and method followed.

There are many studies in the literature about the types of acromion and its morphometry. Few authors have correlated the acromion morphology of right and left scapulae. But there are very limited studies which throws light on sexual dimorphism of acromion morphometry. In this aspect our study stands unique in which we have compared the length, breadth, ACD & AGD among male and female scapulae and there is statistically significant difference of the above parameters with respect gender. Knowledge of morphometry of acromion and significant difference with respect to gender helps clinicians in diagnosing and planning for the treatment of subacromial pathologies. Morphometry of acromion process is also of interest to the anthropologist while studying about bipedal gait & evolution of erect posture in man.[14]

Conclusion

Morphometric parameters of acromion and its sexual dimorphism is quite important in diagnosing and treatment of subacromial pathologies. Morphometric analysis of acromion provides an additional knowledge for better understanding of shoulder disorders and treatment especially while planning acromioplasty.

Conflict of Interest: None

Financial Assistance: Nil

Ethical Clearance: As the study involved only dry scapulae, it was exempted.

Evaluation of Knowledge and Attitude of Undergraduate Medical and Dental Students towards Integrative Medicine and Integrative Dentistry: A Questionnaire Study

Jaber Emad Mohamed[1], Ishita Mittal[1], Sukanya Goswami[1], Swathi Pai[2], Vishal Bhat[3]

[1]Former Student, [2]Reader, Department of Conservative Dentistry and Endodontics, [3]Associate Professor, Department of Pharmacology, Melaka Manipal Medical College, Manipal and Coordinator, Centre for Integrative Medicine and Research, Manipal Academy of Higher Education, Manipal, India

Abstract

Background: Integrative medicine (IM) and Integrative Dentistry (ID) is healing-oriented medicine that takes account of the whole person (body, mind, and spirit), including all aspects of lifestyle. It emphasizes the therapeutic relationship and makes use of all appropriate therapies, both conventional and alternative. It includes Ayurveda, Acupuncture, Chiropractic, Dietary supplements, Reiki, Homeopathy, Massage therapy, Hypnotherapy,etc

Methodology: A self-validated questionnaire study was conducted amongst 600 undergraduate (Indian and Malaysian) dental and medical students to evaluate their knowledge and attitude towards IM and dentistry.

Results and Statistical Analysis: The preclinical Indian and Malaysian students showed similar responses to the IM related questions but for ID questions there were varied responses, although not statistically significant different. When the preclinical and clinical dental students were compared, there were differences in the answers for ID related questions. However there was no statistical significance.

Conclusion: Although the students are aware and would recommend IM to their patients, the knowledge and attitude towards ID still needs to be explored.

Keywords: *Holistic approach, Indian and Malaysian students, Integrative Dentistry, Integrative Medicine, Knowledge and Attitude.*

Introduction

Integrative Medicine (IM) and Integrative Dentistry (ID) is healing-oriented medicine that takes account of the whole person (body, mind, and spirit), including all aspects of lifestyle. It comprises of all appropriate therapies, both conventional and alternative medicine. It includes Ayurveda, Acupuncture, Chiropractic, Dietary supplements, Reiki, Homeopathy, Massage therapy, Hypnotherapy etc.[1] It is well understood that no single system of therapeutic medicine addresses a disease completely. Allopathic medicine has its own disadvantage in being ineffective in disease prevention and adverse drug reactions. This has led to increase in IM treatment approaches[2]. It adopts a humanistic approach to treatment of a disease emphasizing on therapeutic approaches that match the individual's global perspective.[3,4] In a study conducted in Israel, It was noted that family physicians play a central role in referring patients to complementary and alternate medicine(CAM). The Practitioners should learn how to communicate and

Phone: 0820-2933018

collaborate effectively with CAM practitioners for the benefit of their patients[5]. Conventional dental treatment provides only symptomatic management such as restorations, orthodontic corrections, oral prophylaxis, periodontal therapies, extractions followed by prosthetic rehabilitation, without targeting much on the actual etiology causing the problem. This questionnaire study was conducted to evaluate knowledge and attitude of undergraduate medical and dental students towards IM and dentistry.

Methodology

A self validated questionnaire study following the Institution ethics committee approval (IEC 393/2016) was conducted amongst 600 undergraduate (Indian and Malaysian) dental and medical students to evaluate their knowledge and attitude towards IM and dentistry. It was conducted during the regular class hours after obtaining an informed consent from the volunteering students.

Results

The response rate of the study was 98%. There were 17 questions with different scale of answer options. The data obtained was cross tabulated and chi square test was done using SPSS software version 20. There were similar responses to questions related to the knowledge about IM and ID amongst the students (Figure 1,2). However, the responses regarding the attitude and willingness to adapt the same into the regular practice were varied. The results showed that the preclinical Indian and Malaysian students showed similar responses to the IM related questions (Figure 3-6). but for ID questions there were varied responses, although not statistically significant different. When the preclinical and clinical dental students were compared, there were differences in the answers for ID related questions. However, there was no statistical significance.

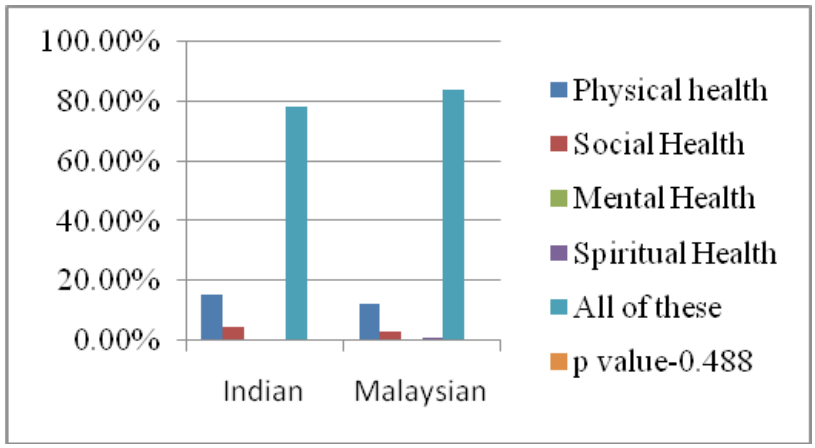

Figure 1: Physician's role is primarily to promote

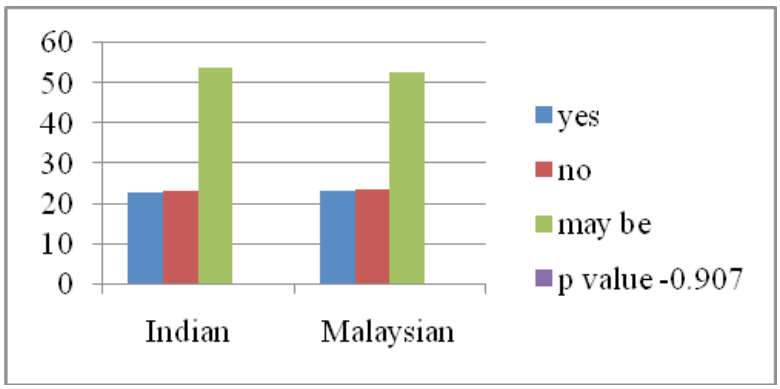

Figure 2 Can Incurable diseases be treated with alternative medicine/therapies

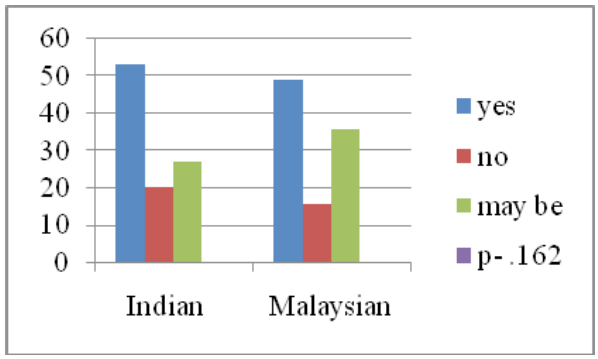

Figure 3 Do you recommend Subtle energy fields for medical therapy

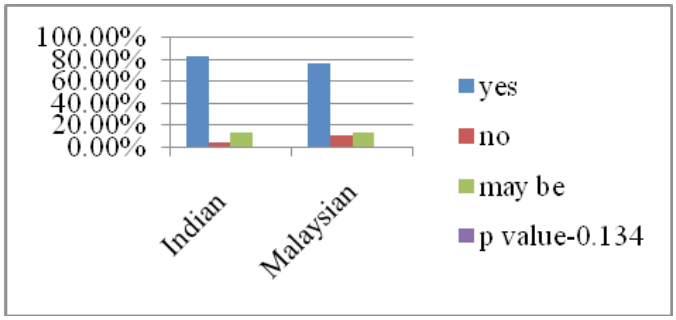

Figure 4 Do you think physicians should have knowledge about both conventional medicine and alternative therapy

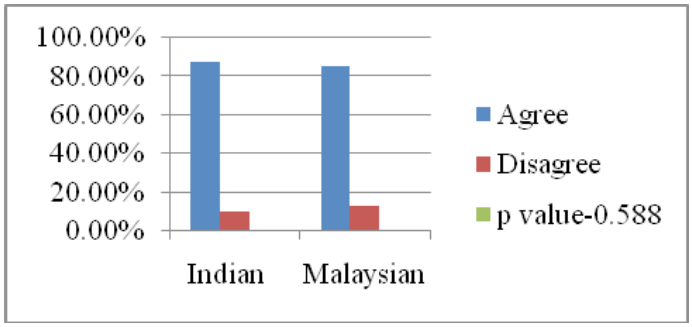

Figure 5 Do you think formation of a Heath center that combines all the conventional & Alternative therapies as an integrated approach will promote overall wellbeing of patients

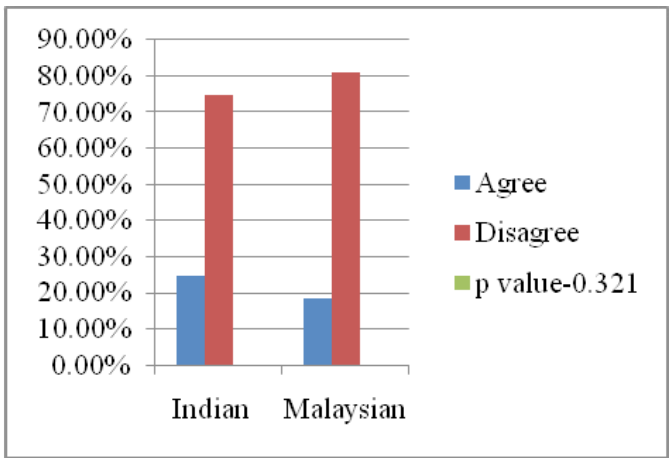

Figure 6 Proper diagnosis and treatment plan plays no role as long as oral lesions such as epulis, gingival inflammation,oral ulcers are healed using homeopathic/ayurvedic medicines

Discussion

In the present study, it is noted that the Indian as well as the Malaysian students are well oriented towards IM and ID. However the attitude towards ID is neutral. Another similar study shows that there is much need to improve the orientation of dental professionals towards IM, although they do not specify ID[6]. The Malaysian dental students have also supported the integration of CAM education in the dental curriculum[7]. In our study, it is seen that the attitude of students towards IM and ID was neutral. Many of them were not sure of using IM and ID into practice. In an Irish study, a satisfactory response rate was seen regarding the attitudes of undergraduate medical students towards the use of CAM, the relevance of IM, and their incorporation into the medical curriculum[5]. It can be attributed to the lesser clinical evidences available on success or failure of ID. Further, in this study there was no difference in the responses of preclinical and clinical students. Although in our curriculum we have not incorporated IM and ID, technological advances and globalization has probably led to a similar responses. However in a previous study it was seen that the junior medical students were more positive toward CAM and its instruction than senior medical students[8]. As the student gets exposed more to allopathic techniques and procedures during the last year of medical school, their attitudes toward CAM decreases. [9]

Majority of the students felt that IM knowledge is necessary to be a well-rounded professional and there should be a health center that combines all the conventional & Alternative therapies as an integrated approach will promote overall wellbeing of patients. This is also supported by many other studies conducted other parts of the world.[10,11,12]

Conclusion

Although the students are aware and would recommend IM to their patients, the knowledge and attitude towards ID still needs to be explored.

Antibacterial Activity of Combination between Probiotic Milk and Mango Honey Against Streptococcus Mutans

Inaaroh Waachidah Azzulfiyyah[1], Isnaeni[1], Noor Erma[1]

[1]Chemistry Pharmacy, Faculty of Pharmacy, Universitas Airlangga, Dharmawangsa Dalam Street No.4 - 6, Airlangga, Surabaya (60286), Indonesia

Abstract

Background: *Streptococcus mutans* commonly found in oral cavity and can be a pathogenic bacteria that leads to dental caries. Rinsing the oral cavity with antibiotic oral therapy is not suggested as the treatment of dental caries, because it has side effects. It can cause resistance of *Streptococcus mutans* towards antibiotic.

Objective: To analyze the antibacterial activity of honey of mango, prebiotic milk, and the combination of both against *Streptococcus* mutans bacteria

Method: The antibacterial activity test was performed by agar diffusion method with Müeller Hinton agar medium to determine the minimal inhibitory concentration inhibition (MIC). A study had been conducted on the antibacterial activity of the combination of honey of mango and probiotic milk of *Lactobacillus paracasei* ATCC BAA52 on the growth of *Streptococcus mutans*. Fermented milk was made by inoculating *Lactobacillus paracasei* ATCC BAA52 fermented milk, mango honey and their combination at optimum ratio (propotition) into fresh milk at 45°C, then incubated for 24 hours at room temperature

Result: The result of probiotic milk characterization showed that the pH of probiotic milk decreased compared to fresh milk from from pH 6.33 to 3.89. Furthermore, the MIC of each samples against *Streptococcus mutans* were determined

Conclusion: Combination between mango honey (*Mangifera indica*) and probiotic mlik (*Lactobacillus paracasei* ATCC BAA52 can give optimum anti bacteria activities against *Streptococcus mutans*

Keywords: *Antibacterial activity, probiotik milk of Lactobacillus paracasei ATCC BAA52, Mango Honey, Streptococcus mutans.*

Introduction

Streptococcus mutans is a facultative anaerobic bacterium, gram positive cocci bacterium. It is commonly found in human oral cavity and being the most pathogenic bacteria which causes dental caries [(1)]. The characteristics of *S. mutans* are acidogenic, which produces acid, acidoduric, which is capable surviving in an acid environment, and capable to produce a sticky polysaccharide, called dextran. *S. mutans* can adhere to the dental enamel and promote other acidoduric bacteria towards dental enamel, which leads to dental caries [(1).]

Rinsing the oral cavity with liquid containing antibiotic is one of solution to prevent dental caries. Unfortunately, it can not prevent dental caries compeletely because it has side effect that leads to that antibiotic resistance[(2)]. To avoid the antibiotic resistance, scientists nowadays develop extracts and biological active compounds isolated from nature that used for herbal medicine [(3)].

Exploring the probiotics usage is one of the ways to resolve that problem. Probiotic contains hydrogen

peroxide (H_2O_2), organic acids, and peptide compounds namely bacteriocin which are active as antibacterial[4]. Probiotic milk *Lactobacillus paracasei* has ability to inhibit the growth of pathogenic bacteria *S. mutans* in its host[5]. Consuming probiotics regularly can inhibit the growth *S. mutans* without causing side effects.

In addition to probiotics, currently it has been developed the treatment using natural ingredients that have activity as antimictobial, on of which using honey. Honey is a sweet liquid that derived from plant nectar, which processed by bees and stored in honeycomb cells[4]. The high consentration of sugar in honey, which is 38.5% fuctose, can cause hipertonic condition that promotes bacterial cell plasmolysis. It results inhibiting bacterial growth and promoting bacterial cell death[6]. The carbohydrates in honey are in the form of reducing sugars, which are glucose and fructose, with minimum content is 65% [7].

Both probiotic milk and honey have antibacterial activity with different mechanism[8]. Probiotic milk *Lactobacillus paracasei* contains hydrogen peroxide (H_2O_2), organic acids, and peptide compounds namely bacteriocin which are active as antibacterial[9]. Honey also has ability to inhibit the growth of phatogenic bacteria, such as *E. coli, Listeria monocytogenes,* and *S. aureus,* which is influenced by the concentration of reducing sugars and high concentration of sucroses in honey [6].

Probiotic milk *Lactobacillus paracasei* and honey of mango *Mangifera indica* have a different ingredient, which is active as antibacterial. This study will observe the antibacterial activity of combination of probiotic milk *Lactobacillus paracasei* and honey of mango *Mangifera indica* in various ratio, then it will be found the combination of both ingredients in certain ratio which has maximum antibacterial activity[10]. The purpose of this study is to observe the best ratio of mango honey and probiotic milk to impede the growth of *mutans*.

Materials and Method

Materials: The samples includes, *Lactobacillus paracasei* ATTCC BAA52 honey mangoes and *Streptococcus mutans*. The media was *de Man Ragosa Sharpe Agar* (MRS) (Himedia Lab), Müeller Hinton Agar (OXOID), NaCl (Pa Merch), clindamycin antibiotic (p.g.) as positive control group, and sterile destilled water from the Microbiology Laboratory.

Equipment: The equipment that used in this study were analytic scales (Sartorius BL10S), incubator (Menmert), Öse (Sengkelit), ring (Silinder), vernier caliper (Jason), vortex (Maxi Mix II Type 37600), micro pipette (Socorex), autoclaf (Huxley HL-340), spectrophotometer (Parkin Elmer Lambda EZ201), ependorf, *shaker, colony counter, centrifuge* (EBA 20), Oswald viscocity-meter, *Cup and Bob* viscocity meter, pH meter (Schott glass mainz tipe CG 842), *laminar air flow cabinet,* petri dish and the other laboratory glassware.

Results

Table 1: The minimum inhibitory concentration of probiotic Lactobacillus paracasei against Streptococcus mutans in various concetrations (% v/v)

Probiotic Milk Concentration (% v/v)	The diameter of inhibitory zone against Streptococcus mutans (mm)			Mean ± SD
	Replication 1	Replication 2	Replication 3	
100	15,35	16,40	15,75	15,38 ± 0,53
90	14,10	14,95	15,05	14,70 ± 0,52
80	11,75	12,05	11,55	11,78 ± 0,25
70	11,60	11,85	11,05	11,50 ± 0,41
60	11,05	11,75	10,80	11,20 ± 0,49
55	11,00	10,50	10,45	10,65 ± 0,30
Control (+)	26,75	26,70	27,20	26,88 ± 0,28

The results showed the minimum inhibitory concentration of probiotic milk *Lactobacillus paracasei* against *Streptococcus mutans* is 10.65 + 0.30 mm at concentration 55%. It can be interpreted if the concentration of probiotic milk *Lactobacillus paracasei* was less than 55%, so it could not inhibit the growth of *Streptococcus mutans*.

Table 2: The minimum inhibitory concentration of honey of mango in various concentration (% v/v)

Concentration of honey of mango (% v/v)	The diameter of inhibitory zone against Streptococcus mutans (mm)			Mean + SD
	Replication 1	Replication 2	Replication 3	
50	14,80	16,55	17,35	16,23 + 1,30
25	13,50	13,20	12,00	12,90 + 0,79
12,5	-	-	-	-
6,2	-	-	-	-
3,1	-	-	-	-
1,6	-	-	-	-
Control (+)	26,75	26,70	27,20	26,88 + 0,28

The result shows that the minimum inhibitory concentration of honey of mango was 10,40 + 0,96 mm at concentration 17.5% against the growth of *Streptococcus mutans***.** It can be interpreted if the concentration of honey of mango solution that was less than 17.5%, could not inhibit the growth of *Streptococcus mutans*.

Table 3: The minimum inhibitory concentration of honey of mango in various concentration (% v/v)

Concentration of honey of mango (% v/v)	The diameter of inhibitory zone against Streptococcus mutans (mm)			Mean + SD
	Replication 1	Replication 2	Replication 3	
22,5	11,95	11,80	12,40	12,13 + 0,24
20	11,50	11,20	10,05	10,91 + 0,77
17,5**	9,50	11,40	10,30	10,40 + 0,96
15	-	-	-	-
Control positive	26,75	26,70	27,20	26,88 $\pm$ 0,28

The measurement diameter of inhibitory zone of combination honey of mango and probiotic milk *Lactobacillus paracasei* against tested bacterial in various concentration is displayed in Table 5 and Figure 4. The test of antibacterial activity of the combination honey of mango and probiotic milk *Lactobacillus paracasei* was conducted at ratio 1:9, 2:8, 3:7, 4:6, 5:5, 6:4, 7:3, 8:2, 9:1. The antibacterial activity was determined by the clear zone around hole, that could be measured. To obtain the combination which had maximal antibacterial activity could be done by measuring the diameter of inhibitory zone using Varnier Caliper[9].

Table 4. The antibacterial activity of the combination honey of mango and probiotic milk Lactobacillus paracasei against Streptococcus mutans at vairous ratio (% v/v)

The ratio of (% v/v) honey of mango solution 50% : probiotic milk	Diameter of Inhibitory Zone (mm)			Mean	SD
	Replication 1	Replication 2	Replication 3		
1:9	15,75	14,50	15,40	15,22	0,64
2:8	14,10	16,35	14,20	14,88	1,27
3:7	15,15	15,65	15,30	15,37	0,25

Honey of mango solution 50%	14,80	16,55	17,35	16,23	1,30
Probiotic milk L. paracasei 100%	12,95	14,50	14,15	13,87	0,81
Control positive	18,15	18,10	18,10	18,12	0,03

Discussion

The result of this research shows the positivity. The combination of honey of mango and probiotic milk *L. paracasei* at the ratio 8:2 showed the optimum antibacterial activity against *S. mutans,* with diameter of inhibitory zone as 17,12 + 0,22 mm. Based on statistical analysis using one way ANOVA, the combination honey of mango and probiotic milk *L. paracasei* at the ratio of 8: 2 did not show a significant difference in antibacterial activity compared to the inhibition zone of 50% honey of mango solution. Despite the diameter of inhibition zone of probiotic milk *L. paracasei* is greater than the diameter of inhibition zone of a honey of mango solution. However, when compared to the inhibitory zone of probiotic milk *L. paracasei*, there were significant differences in antibacterial activity [11].

The result shows that there was a decrease in the diameter of the inhibition zone along with the decreasing concentration of honey of mango. It can be seen from the diameter of the inhibition zone produced by 50% and 25% honey of mango of 13.03 + 0.15 mm and 13.03 + 0.57 respectively. While the concentration honey of mango below 25% did not produce antibacterial activity. The test results showed that the MIC of mango honey solution to *S. mutans* was at a concentration of 17.5% with a inhibition zone diameter of 10.40 + 0.96 mm.

After that, the determination of MIC in probiotic milk *L. paracasei* was carried out at various concentrations, namely at concentrations of 100%, 90%, 80%, 70%, 60%, 55%, 50%, 45%, 25%, 12.5%, 6.2%, 3.1% and 1.6%. In the result was found that the MIC of probiotic milk *L. paracasei* against *S. mutans* was at a concentration of 55%, with a inhibition zone diameter of 10.65 + 0.30 mm. By knowing the MIC of probiotic milk *L. paracasei* at a concentration of 55%, it proved that probiotic milk *L. paracasei* has a smaller antibacterial activity compared to honey of mango which has MIC at a concentration of 17.5% [12].

The result showed the combination honey of mango and probiotic milk *L. paracasei* at the selected ratio was 25% with inhibition zone diameter 13.03 + 0.57 mm against *S. mutans*. When compared to MIC each sample of honey of mango and probiotic milk *L. paracasei*, it can be said that the combination of honey of mango and probiotic milk *L. paracasei* at the selected ratio has a minimum inhibitory concentration greater than honey of mango [13]. But it is lower than the concentration minimum inhibition of probiotic milk *L. paracasei*. Then the optimum combination characterization was carried out, which included organoleptic (color, taste odor), pH, viscosity and specific gravity [14]. Based on the results of the selected combination characterization it has a pH of 3.89 + 0.00, the viscosity is 5.33 ± 0.390 cps and the specific gravity is 1.096 ± 0.000 g/mL.

In the combination of honey of mango and probiotic milk *L. paracasei* at the optimum ratio 8:2, there was a synergistic effect even though the concentration of probiotic milk was less than honey of mango [14]. It caused by honey of mango containing more sources which can be used as an energy for probiotic bacteria *L. paracasei*. In a combination honey of mango and probiotic milk *L.paracasei*, honeyof mango can play a role in two things, namely as an energy source for probiotic milk bacteria *L. paracasei* or can inhibit the growth of probiotic milk bacteria *L. paracasei* [15]. This study examnies the effect honey of mango on the growth of probiotic bacteria *L. paracasei*, proved that mango honey did not inhibit the growth of probiotic bacteria *L. paracasei*.

The analysis of antibacterial activity in this study using difusion method, because of its advantages. This method is quite simple, does not require long time and preparation, and can also be used to see the senstivity of antibacterial samples at certain concentratiom of various types of tested bacteria [16]. The standard solution used in this study was clindamycin with a concentration of 0.01 ppm which was previously optimized for the antibacterial activity of clindamycin with various concentrations of *S. mutans* [3]. A concentration of 0.01 ppm was chosen because at concentrations above 0.01 ppm clindamycin produced a diameter of the inhibition zone that was too large which could lead to difficulty of measuring the diameter of the sample inhibition zone. Clindamycin is chosen as a standard solution or positive control because it is an effective antibacterial used to cure tooth damage due to the growth of Streptococci bacteria [17].

Conclusion

Based on the results of this study, it can be concluded that the Minimum Inhibitory Concentration (MIC) of probiotic milk *Lactobacillus paracasei* ATCC BAA52 on *Streptococcus mutans* was 55%, with inhibition zone diameter of 10.65 + 0.30 mm. Minimum Inhibitory Concentration (MIC) of honey of mango solution against *Streptococcus mutans* was 17.5%, with inhibition zone diameter 10.40 + 0.96 mm.

Minimal Inhibition Concentration (MIC) combination of honey of mango (*Mangifera indica*) and probiotic milk *Lactobacillus paracasei* ATCC BAA52 at a ratio of 8: 2 to *Streptococcus mutans* by 25% with inhibition zone diameter 13.03 + 0.57 mm.

Ethical Clearance: This research process did not involve any participant in the survey, but instead using agar diffusion method in laboratory in accordance with the ethical research principle based on the regulation of research ethic committee. The present study was carried out in accordance with the research principles. This study implemented the basic principle ethics of respect, beneficence, non-maleficenct, and justice.

Conflict of Interest: There is no report about any conflict related with this author's research.

Prevalence of Premarital Sex among Adolescents in Kulende, Sango in Ilorin South Local Governmrnt Area, Kwara State, Nigeria

Oniyangi, Shuaib Olanrewaju[1], Jamiu Abdul Qudus Tosin[1], Umar Ibrahim Babangida[2], Ahmad Makama Getso[2], Sindama Helen[3]

[1]Department of Health Promotion and Environmental Health Education,University of Ilorin. Ilorin, [2]Department of Physical and Health Education, Bayero University, Kano, [3]University of Jos, Plateau, Nigeria

Abstract

Premarital sex is explained as a penetrative vaginal or anal sexual intercourse performed between couples before formal marriage. It is characterized as being unanticipated, unpredictable, inconsistence with values and personality, uncontrollable and becoming the common feature of adolescents. This study investigated (i) peer pressure and (ii) poor parents-adolescent communications as factors influencing premarital sex among adolescents in Kulende, Sango, Ilorin South Local Government Area, Kwara State, Nigeria. A descriptive research design of survey type was employed for this study. The population for the study comprised of all Adolescents in Kulende, Sango, Ilorin South Local Government Area, Kwara State, Nigera. A multistage sampling technique was used for the study. Simple random sampling technique was used to select four two hundred (200) respondents for the study. Researcher's designed structured questionnaire which was validated by four experts from the Departments of Health Promotion and Environmental Health Education; University of Ilorin. A correlation co-efficient of .75r was obtained through test re-test method using Pearson Product Moment Correlationon respondents outside the study sample. Data collection was conducted by the researchers and four trained research assistants. The two postulated null hypotheses were tested using the inferential statistics of chi-square @0.05 alpha level. The finding of this study revealed that i. Peer Pressure influenced premarital sex among adolescents in Kulende, Sango, Ilorin South Local Government Area, Kwara State, Nigeria with the calculated chi-square (χ^2) value of 159.842 is greater than the table chi-square (χ^2) value of 16.92 at the freedom (df) 9 @ 0.05 alpha level and ii. Poor Parents-adolescents communications influenced premarital sex among adolescents in Kulende, Sango, Ilorin South Local Government Area, Kwara State with the calculated chi-square (χ^2) value of 165.853 is greater than the table chi-square (χ^2) value of 16.92 at the freedom (df) 9 @ 0.05 alpha level. Based on the findings of the study it was concluded that peer pressure and poor parents-adolescent communication influenced premarital sex among adolescents in Kulende, Sango, Ilorin South Local Government Area, Kwara State, Nigeria. Therefore,it was recommended that i. teachers and school guardians should sensitize their students on the influence of peers in the engagement of adolescents in premarital sex and ii. parents and guardians should take it as their responsibility to create an intimacy, a good relationship and communication skills with their children as this will limit adolescent's early exposure to premarital sex.

Keywords: *Prevalence, Premarital, Sex and Adolescents.*

Introduction

Sex is one of the most profound emotionally charged, mysterious experiences that mortals have. Its necessity and importance in proper adult's physical and emotional functioning is incontrovertible. However, in order for it not to have negative consequences, there is need to apply caution and restraint. Sexual activities among adolescents have been reported to be increasing worldwide. Several studies in sub-Saharan Africa have also documented high and increasing premarital sexual activities among adolescents[9]. Premarital sex is an act of deviation, it is a departure from social norms that attract

social disapproval which is likely to elicit negative sanctions[1].

Furthermore, Pre-marital sex is explained as a penetrative vaginal or anal sexual intercourse performed between couples before formal marriage. It is characterized as being unanticipated,unpredictable, inconsistence with values and personality, uncontrollable and becoming the common feature of adolescents. More than half of the world population constitutes young people that are less than 25 years old, and majority of the populations live in developing country. Starting from a recent time, premarital sexual action during adolescence and emerging adulthood leads to a wide range of adverse outcomes in sub Saharan Africa which include unintended pregnancies, illegal abortions, and sexually transmitted Infections[10].

Premarital sex and early initiation of sexual activity may prolong the period of exposure to risks of unwanted pregnancy and contracting Sexually Transmitted Diseases (STDs) such as HIV/Aids during their reproductive life span[2]. Ethiopia is one of the country where an increasing number of adolescents are involved in unsafe sexual practices and hence face undesired outcomes such as unplanned pregnancy, early childbirth, unsafe abortion and sexually transmitted disease. High level synthesis may be enhanced as a result of an increasingly large number of adolescent's enrolment in preparatory schools[11]. Recently, early initiation to sexual intercourse without having proper protection has been one of the concerns. Adolescents often encounter high risk situations, such as contracting STDs, HIV/AIDS and often experience unintended pregnancy, illicit abortion and its negative sequel[7].

In Southwestern Nigeria, sex before now was regarded as sacred and limited only to adult males and females within marriage but today, many adolescents engage in various delinquent behaviour such as drinking of alcohol, smoking and premarital sexual activities. Furthermore, it was discovered that the prevalence of premarital sex among adolescents was caused as a result of certain social and demographic factors among which include age, gender, parental style, culture, religion, peer influence, among others. Concluded. Among the background variables considered mother education, age, ethnicity and employment status were among the most important predicators of attitudes towards women premarital activity[3].

Peer group influence is another factor that encourages premarital sex.They were of the opinion that young people often face enormous pressure especially from peers to engage in sex. Most information for their knowledge comes from peers of the same sex who may themselves lack adequate information or are incorrectly informed. Growing peer pressure of premarital sex plays major role in sexual decision making among youths[12]. Furthermore, Gender is an important factor in understanding attitudes towards sexual intercourse. It is a factor which is consistent with findings from Asian countries, whereas, premarital sexual activity for boys is considered a socially acceptable rite of passage[8], while girls tend to be labeled and stigmatized, and are often blamed for sexual encounters that result in pregnancy and sexually transmitted infections. It is likely that both girls and boys internalize subtle and overt messages about gender roles from friends, family and society which, in turn, shape different attitudes and beliefs about sexual initiation. However, the process by which gender roles influence the attitudes and beliefs about gender-distinct sexual initiation has rarely been studied, especially in Asian societies that are influenced by Confucianism having doctrines on gender role[5].

Premarital behaviours of adolescents, tend to pose major threats to life and the future of the country as they involved in reckless sexual activities[10]. Public opinion polls have consistently shown that premarital sex is wrong and dangerous to health, resulting in abortions, teenage mothers and sexually transmitted disease. In sub-Saharan Africa, HIV infection is primarily spreading through heterosexual relations. Young people are the most vulnerable to HIV infection. They are also the most affected as they are often called upon to carry the burden of caring for risk family members[4].

Statement of the problem: The researcher observed that the prevalence of premarital sex among adolescents in Kulende, Sango Society in Ilorin South Local Government Area of Kwara State is high, and this leads to high incidence of unintended pregnancies, contraction of sexually transmitted diseases, induced abortion and death. The prevalence of premarital sex among the adolescents is due to the influence of social and demographic factors such as gender, age, family background, peer pressure, parent education, age, ethnicity, socio-economic status, religion, and parents-adolescents communication. The researcher observed that gender is one of the factors influencing the prevalence of premarital sex among adolescent. It was

observed that male adolescents are more engaging in premarital sex than their female counterparts because it was believed that boys are the initiator of premarital sex.

Adolescent is typified by great energy, pursuit of adventure, dating, experimentation with sex and the attendant outcomes most often compromise the young person's sexual and reproductive health. The desire to be regarded as the "macho man" makes boys to start having sex early and to indulge in risky sexual behavior. Most girls are coerced into having sex by adolescent boy friends who want to prove masculinity. Furthermore, the age is also a predicator for the prevalence of premarital sex among adolescents. The researcher observed that most adolescents engage in premarital sex at early ages, and this has caused a lot of serious problem to them because there is no background knowledge of what premarital sex is all about. For this cause, adolescents (11-19years) are under the risk associated with premarital sex such as psychological imbalance, anxiety, feeling guilt and loss of self-respect.

The researcher also observed that adolescents in Sango area of Ilorin South do not have good parent-adolescents communication style such as talk on sex education, sexual health matters among others, and this contributes to the prevalence of premarital sex among them. The supply and amount of parental emotional resources for control can have a significant influence on the youth to have or not to engage in premarital sex. Due to ineffective communication and good upbringing between parents and adolescents, most adolescents are exposed to premarital sex. Also, due to lack of control, the adolescent can contract sexually transmitted diseases or even thought of having abortion that may lead to death or obstetric complications. The researcher also observed that peer influence is also considerable predicting factor for prevalence of premarital sex among the adolescents. Peers like roommates, classmates, club associates and other members of one's social group members equally influence one to be a deviant or conformist. In the cause of peer pressure, most adolescents are lured into the practice of sexual deviant behaviors such as adulteries, alcohol dinking, premarital sex, drug abuse, smoking among others.

These predicting factors has led to various health and emotional issues among the adolescents among which include, dropping out from school, unintended or unwanted pregnancy, contraction of sexually transmitted diseases (Human papilloma virus, herpes, HIV/Aids etc), induced abortion, depression, feeling guilt and shame among others. In this study, the issue of premarital sexual practice among students is fast emerging as a serial social and public health problem. Based on this study the researcher intends to explore the prevalence of premarital sex among adolescents in Kulende, Sango, Ilorin South LGA, Kwara state.

Research Questions:

The following questions were raised to guide this study

1. Will peer pressure influence premarital sex among adolescents in Kulende,Sango, Ilorin South Local Government Area, Kwara State, Nigeria?
2. Will parent-adolescents communication influence premarital sex among adolescents in Kulende, Sango, Ilorin South Local Government Area, Kwara State, Nigeria?

Research Hypotheses:

The following hypotheses were formulated for this study.

Ho1. Peer pressure will not significantly influence premarital sex among adolescents in Kulende,Sango, Ilorin South Local Government Area, Kwara State, Nigeria.

Ho2. Parent-adolescents communication will not significantly influence premarital sex among adolescents in Kulende,Sango, Ilorin South Local Government Area, Kwara State, Nigeria.

Research Methodology:

Descriptive research design of survey type was used for this study. The Population for this study comprised all individuals between ages of 18 to 20 years in Ilorin South Local Government Area, Kwara State, Nigeria. The target population of this study consisted of adolescents in Kulende, Sango Area in Ilorin South Local Government Area, Kwara State, Nigeria.A Multi-stage sampling technique was adopted for this research. Simple random sampling technique was used to select respondents (adolescents) in four (4) Secondary Schools and Market places in Ilorin South Local Government. Purposive sampling technique was used to select adolescents from ages (18-20) due to their maturity. In the second stage proportionate sampling technique of 10% was used for the study. Simple random sampling

technique was used to select the actual respondents for the study. The instrument that was used in collecting data for this research is a researcher designed questionnaire. David (2007) stated that a questionnaire allows the researcher to collect required information quickly and accurately from a large number of people at the same time. The questionnaire titled "Prevalence of Premarital Sex among Adolescents in Kulende, Sango, Ilorin South Local Government Area, Kwara State, Nigeria" consist of two (2) sections. Section A contain demographic information of the respondents, while section B elicit information on prevalence of Premarital Sex among Adolescents in Sango, Kulende in Ilorin South Local Government Area, Kwara State, Nigeria. The items were based on the 4-points Likert scale of Strongly Agreed = 4 (SA), Agreed =3 (A),Disagreed=2 (D),and Strongly Disagreed=1 (SD).In order to ascertain the validity of the instrument, three drafted copies of the questionnaire was given to three (3) experts in Departments of Health Promotion and Environmental Health Education, University of Ilorin, Nigeria. Their suggestions and comments were used to make the final draft of the instrument. The reliability of the instrument was carried out using test re-test technique. Twenty (20) copies of questionnaire were given to twenty (20) respondents outside the case study area after two (2) weeks another twenty copies were administered to the same respondents. The result of the first administration was compared with the second administration using Pearson Product Moment Correlation (PPMC).A coefficient of 0.75r was arrived at which shows that the instrument is reliable for the study. Description statistics of frequency count and percentage was used to analyze the demographic data of the respondents, while non-parametric statistic of chi-square was used to test the four (4) postulated hypotheses at 0.05 alpha level.

Results/Discussion of Findings

Hypothesis 1: Peer pressure will not significantly influence premarital sex among adolescents in Kulende, Sango, Ilorin South Local Government Area, Kwara State, Nigeria. The calculated chi square value of 159.842 was greater than critical table value of 16.92 at the degree of freedom of 9 @ 0.05 alpha level of 0.05, the result of hypothesis one revealed that peer pressure influenced premarital sex among adolescents in Kulende Sango of Ilorin South Local Government Area of Kwara State, Nigeria. This was supported by a research which was of the opinion that young people often face enormous pressure from peers to engage in sex[4].

Hypothesis 2: Parents-adolescents communication will not significantly influence premarital sex among adolescents in Kulende, Sango, Ilorin South Local Government Area, Kwara State, Nigeria. The calculated chi-square value of 149.491 was greater than the critical value of 16.92 at degree of freedom of 9 @ 0.05 alpha level, the result of hypothesis two revealed that parents-adolescents communication influenced premarital sex among adolescents in Kulende, Sango, Ilorin south Local Government Area, Kwara State, Nigeria. The result of this findings agrees with a research which affirmed that frequency of parent-child communication about sex is the most common variable used to study parental impact on adolescent's sexual attitudes and behaviours[6].

Recommendations:

The following are the recommendations based on the outcome of this research;

1. Teachers and school guardians should sensitize their students on the influence of peers in the engagement of adolescents in premarital sex.

2. Parents and guardians should take it as a thing of responsibility to create an intimacy and have a good relationship and communication skills with their children as this will limit adolescent's early exposure to premarital sex.

Perceived Effect of Sleep Deprivation on the Health of Undergraduates in Kwara State University, Malete, Nigeria

Oniyangi, Shuaib Olanrewaju[1], Jamiu Abdul Qudus Tosin[1], Umar Ibrahim Babangida[2], Ahmad Makama Getso[2], Sindama Helen[3]

[1]Department of Health Promotion and Environmental Health Education,University of Ilorin. Ilorin, [2]Department of Physical and Health Education, Bayero University, Kano, [3]University of Jos, Plateau, Nigeria

Abstract

Sleep is a physiological state occurring in alternation with wakefulness, and its duration and quality are equally important for the quality of life, sleep deprivation on the other hand is described as not obtaining adequate total sleep or a condition of not having enough sleep. This study therefore examined the Perceived Effect of Sleep Deprivation on the Health of Undergraduates in Kwara State University Malete Kwara State. The study investigated; (i) Physical Health; & (ii) Mental Health; as Perceived Effect of Sleep Deprivation. A descriptive research design of survey method was used for the study. The population of the study consists of all undergraduates in Kwara State University. A multi stage sampling techniques was used to select 284 respondents for the study, Researcher's designed questionnaire was validated, by the supervisor and three experts from the Department of Health Promotion and Environmental Health Education, University of Ilorin. A correlation co-efficient 'r' of 0.7 was obtained through split half method using Pearson Product Moment Correlation. Data collection was conducted by the researchers and other trained research assistants. The two postulated null hypotheses were tested using the inferential statistics of chi-square @0.05 alpha level. The findings from the study revealed that; i. Sleep deprivation have effect on undergraduates Physical Health with the calc. X^2 value of 247.01 > table X^2 value of 16.92 at the freedom df 9 @ 0.05 alpha level and ii. Sleep deprivation have effect on undergraduates Mental Health with the calc. X^2 value of 132.14 > table X^2 value of 16.92 at the freedom df 9 @ 0.05 alpha level. Based on the findings,it was concluded that sleep deprivation had effects on physical health and mental health, of Undergraduates in Kwara state University, therefore it was also recommended that Undergraduates should be enlightened deeply on the adverse physical and mental health effect that sleep deprivation can have on their health. These can be done through public health sensitisation and advocacy by Federal Government, State Government, NGO's, and the University Lecturers and Health Worker. The mass media and social media also have their part to play in public health education and also religion leaders can also invite health workers to enlighten the entire congregation on the best sleeping practices.

Keywords: *Perception, Effect, Deprivation, Health and Undergraduates.*

Introduction

Sleep deprivation consists either in a complete lack of sleep during a certain period of time or a shorter-than optimal sleep time. The most common causes of sleep deprivation are those related to contemporary lifestyle, school-related factors, and work-related factors; thus the condition affects a considerable number of people. A chronic reduction in the sleep time or the fragmentation of sleep, leading to the disruption of the sleep cycle[11]. Sleep is a major aspect in our everyday lives; however, fewer people are getting enough sleep each night and more are slowly becoming sleep deprived. Sleep deprivation is defined as a condition that occurs when an individual does not get enough sleep each night. We spend almost a third of our life sleeping, Good quality sleep is essential for good health and well-being. However, lifestyle and environmental factors are increasingly causing difficulties in sleeping. Sleep disturbance is frequently considered the most serious consequence of environmental noise[14].

Behaviors such as managing diet, exercising, and getting regular health checks are all important to promoting good health. Likewise, avoiding harmful behaviors like smoking and substance abuse are also very important behaviors. However, unlike these behaviors, there is one behavior that is shared, regardless of background, and socioeconomic status. That behavior is sleep. Like the passage of time, sleep is an absolute part of life. Sleep is also a part of life that is often overlooked as it relates to health. While sleep is as important to life as nutrition, it is often taken for granted, and even considered unimportant or unnecessary. Not only is sleep an absolute requirement for good health, like nutrition and exercise, the amount and type of sleep have a significant impact on both physical, social, and mental health. Poor sleep health is a common problem, with 25% of U.S. adults reporting insufficient sleep or rest at least 15 out of every 30 days[3]. Therefore, as a health behavior, proper sleep has the potential to provide significant health benefits. This is especially true for certain age groups; primarily those in the 18-24-year-old age group who suffer the highest rate of sleep deprivation[8].

Sleep is essential for a person's health and wellbeing. Surveys conducted by the NSF reveal that at least 40 million Americans suffer from over 70 different sleep disorders and 60% of adults' are reported having sleep problems a few nights in a week or more[9]. A Study indicate that sleep problems result from abnormalities in both physiological systems such as: brain and nervous system, cardiovascular system, metabolic functions, and immune system as well as unhealthy conditions such as: hypertension, emotional disorders, obesity, and substance abuse[1].Recent findings show that acute sleep deprivation and looking tired are related to decreased attractiveness and health, as perceived by others. This suggests that one might also avoid contact with sleep deprived, or sleepy looking, individuals, as a strategy to reduce health risk and poor interactions[2].

Furthermore, it is well established that enough and undisturbed sleep are essential for an individual's personal wellbeing and the ability to perform correctly. With the increasing economic and social demands of the modern society, more and more people work and stay active outside the regular day and curtail their sleep. The negative effects of chronic sleep restriction on productivity and Health have begun to appreciate as a Public Health concern, yet are still often underestimated[4]. Nothing seems to bring much clarity to the function of sleep as spending a night without it. When deprived of sufficient sleep, most of us feel sleepy and physically drained, our mood is noticeably flattened if not somewhat dour, and our thinking feels sluggish and unfocused. Even to the non-expert, sleep has obvious importance for sustaining normal functioning at several levels, including basic alertness, emotional experience and a host of complex cognitive processes[13].

In a research study carried out, it was suggested that overall sleep deprivation strongly impairs human functioning. Moreover, they found that mood is more affected by sleep deprivation than either cognitive or motor performance and that partial sleep deprivation has a more profound effect on functioning than either long-term or short-term sleep deprivation. In general, these results indicate that the effects of sleep deprivation may be underestimated in some narrative reviews, particularly those concerning the effects of partial sleep deprivation[5].

However, over the last decades, there has been growing evidence suggesting a strong association between sleep duration and mortality risk, with some evidence suggesting that individuals sleeping between seven and nine hours' nightly, experience the lowest risks for all-cause mortality, whereas those who sleep for shorter or longer periods have significantly higher mortality risks[11]. Insufficient sleep duration has been linked with seven of the fifteen leading causes of death in the U.S. including cardiovascular disease, malignant neoplasm, cerebrovascular disease, accidents, diabetes, septicaemia and hypertension[6].

Finally, insufficient sleep is often the norm among many professions, such as medical residents, military personnel and shift-workers. Thus, scientific study of the effects of sleep deprivation can provide unique insights, not only regarding the nature and function of sleep but also of practical importance for enhancing the Health and wellbeing of workers who must perform optimally despite periods with little to no sleep[13]. Sleep at the same time is well identified as a complex biological process that is a very essential component of human health and wellbeing. The way that sleep is regulated in the body is similar to the manner in which other necessary function are controlled, such as eating and breathing. Sleep pays a vital role in promoting Physical, Mental, and Emotional Health[12]. This study therefore sought to determine the Perceived Effect of Sleep Deprivation on the Health of Undergraduates in Kwara State University, Malete, Kwara State.

Statement of the Problem: Receiving adequate sleep each night ensures proper maintenance of bodily processes. Unfortunately, sleep deprivation is becoming an increasingly common problem in the society today. Many university undergraduates in the society suffer from illnesses resulting in severe sleep deprivation. Many other individuals, however, disregard the need for sleep in order to accommodate the daily activities of life. Sleep deprivation is becoming especially prevalent as longer study hours, medical problems and voluntary behaviour are becoming an acceptable part of undergraduate's culture[1].

The Centers for Disease Control and Prevention (CDC) in the United States has declared insufficient sleep a public health problem. Indeed, according to a recent CDC study, more than a third of American adults are not getting enough sleep on a regular basis[10]. However, insufficient sleep is not exclusively a U.S. problem, and also concerns other industrialised countries such as the United Kingdom, Japan, Germany, or Canada[9]. Everywhere you go, you hear people complain that they are tired and do not have any energy. Students stay up late because they had to work the night before, in order to pay for school, they are trying to finish an assignment that is due the next day, there is some sort of issue at home, or they decided they would rather do some other leisure activity they enjoy rather than go to bed at a more appropriate time. However, studies have shown that sleeping is one of the most important things a person must do. Sleep plays a vital role in learning and when a person fails to obtain enough sleep the night prior, neurons in the brain might not fire properly, the body becomes out of synch, and it can even lead to accidental physical injuries[1].

According to recent evidence, the proportion of people getting less than the recommended hours of sleep is rising and is associated with lifestyle factors related to a modern 24/7 society, such as psychosocial stress, unbalanced diet, lack of physical activity and excessive electronic media use, among[10]. This is alarming as insufficient sleep has been found to be associated with a range of negative health and social outcomes, including adverse performance effects at school and in the labour market[7]. Insufficient sleep duration has been linked with seven of the fifteen leading causes of death in the U.S. including cardiovascular disease, malignant neoplasm, cerebrovascular disease, accidents, diabetes, septicaemia and hypertension[6].

Research Question:

This study aims at answering the following questions:

1. Will sleep deprivation have effect on the Mental Health as perceived by Undergraduates' in Kwara State University?
2. Will sleep deprivation have effect on the Physical Health as perceived by Undergraduates' in Kwara State University?

Research Hypotheses:

The following hypotheses will be tested in this study:

1. Sleep deprivation will not have effect on the Mental Health as perceived by Undergraduates' in Kwara State University.
2. Sleep deprivation will not have effect on the Physical Health as perceived by Undergraduates' in Kwara State University.

Research Methodology: The research design adopted in this study is descriptive research design of the survey type. The population for this study consists of all Undergraduates in Kwara State University, Malete, Nigeria. The population is a total of 14,399 undergraduates, while the target population is a total of 4,734 undergraduates. Multi stage sampling techniques was used for this study. Simple random sampling technique of Fish Bowl method was used to select five (5) colleges out of six (6) colleges in Kwara State University Malete, Nigeria. Purposive sampling technique was used to select the 300 level and 400 level students in all five selected colleges based on their experience and years spent in the university. Proportionate sampling of 6% was used to select the respondent. Simple random sampling technique was used to select the actual respondent for the study. The instrument used for this study is a researcher-designed questionnaire tagged Perceived Effect of Sleep Deprivation on the Health of Undergraduates in Kwara State University. The questionnaire consists of two sections. Section A elicits information on the demographic data of the respondents such as gender, age, marital status etc. while Section B consistof questions formulated from each of the hypotheses in the study. The instrument was presented in a modified four points Likert rating scale of Strongly Agree (SA) = 4, Agree (A) = 3, Disagree (D) - 2, Strongly Disagree (SD) = 1. The instrument was validated

and tested for reliability and a coefficient of 0.7r was obtained which shows that the instrument is reliable for the study. Descriptive statistics of frequency count and percentage was used to analyze the demographic data while inferential statistics of chi-square was used to test the hypotheses set at 0.05 alpha level.

Results/Discussion of Findings

Hypothesis 1: The calculated chi square value of 247.01 is greater than critical table value of 16.92 at the degree of freedom of 9 and significant level of 0.05, the result of hypothesis one revealed that Sleep Deprivation have Effect on Physical Health as perceived by Undergraduates' in Kwara State University, this finding was supported by a findings which affirmed that sleep deprivation of less than 7 seven hours per night may have wide ranging effect on the endocrine, immune and nervous system including obesity in adult and children, diabetes and impaired glucose tolerance, cardiovascular diseases and hypertension, all these mirrors on the physical health of an individual[11].

Hypothesis 2: The calculated chi square value of 132.14 is greater than critical table value of 16.92 at the degree of freedom of 9 and significant level of 0.05, the result of hypothesis two revealed that Sleep deprivation have effect on Mental Health as perceived by Undergraduates' in Kwara State University**.** This was supported by a research which ascertained that sleep deprivation increases your chance for health conditions such as Alzheimer and frequent mental distress, also affirmed that sleep affect our mental health as profoundly as it does to our physical health. Sleep deprivation have been found to have strong connection with practically every mental disorder we know of, especially depression and anxiety[6].

Recommendations: Based on the findings and conclusion of the study, the following recommendations were made.

1. Undergraduates should be enlightened deeply on the adverse physical health effect that sleep deprivation can have on their health. These can be done through public health sensitization and advocacy by Federal Government, State Government, NGO's, and the University Lecturers and Health Worker.
2. Undergraduates should be enlightened deeply on the adverse mental health effect that sleep deprivation can have on their health. These can be done through public health sensitization and advocacy by Federal Government, State Government, NGO's, and the University Lecturers and Health Worker.

Noise Relationship with Complaints of Disorders of Hearing in Crafts Industry with Iron in Parigi Moutong District

Abdul Hamid[1], Abdul Rohim Tualeka[1]

[1]*Department of Occupational Health and Safety, Faculty of Public Health, Airlangga University, Indonesia*

Abstract

Hearings Invasive complaint constitute complaint that experienced by workers on Industrial Forger diligence at Regency Parigi Moutong effect most obstreperous flat at forger work area. Result of measurement on three dots at base area forges, panjak's area and finishing's area Forger diligence, utilize Sound is Meter Level known by noise intensity zoom varies among 80,3, 82,2, 97,5, 97, 9 and 101,5 dB. Multi Center Study naming Indonesia turns in at 4 invasive supreme South-east Asia states hearings effect noise. If noise exposure happening continually will beget energy loss hears that makes a abode and pulih can't return. This research intent to know noise relationship with hearings invasive complaint on industrial forger diligence at Regency Parigi Moutong. This research gets quantitative character by design Cross sectional with trusty level 95%. Observational result on 60 respondents, 39 among those experience hearing trouble complaints. Protecting tool factor ear (APT) (ρ=0,003), working life (ρ=0,002), so long job (ρ=0,004) and condition of work condition (p=0,003) in reference to hearing trouble complaint. Result observationaling to declare for available relationship among APT'S purpose, working life, so long job and condition of work condition with hearings invasive complaint on worker. Suggested that workers gets to reduce noise presentation by use of ear shielding tool accords default and manage rotation working worker job so long at base area forges by noise intensity the very top.

Keywords: *Protecting tool factor ear, working life, long job, and condition of work condition.*

Introduction

Noise in the work environment is a major problem in occupational health in various countries. At least 7 million people (35% of the total industrial population in America and Europe) are exposed to noisy 85 dB or more[1].

National of Occupational Safety and Health (NOSH) obtained data that NIHL (Noise Induced Hearing Loss) is a major problem in the United States today. In the United States around 10 million adults, and 5.2 million children already suffer from hearing loss due to noise and 30 million more can be affected by dangerous noise every day and as many as 30 million workers are proven to have been exposed to noise that exceeds the threshold value[2].

2012 World Health Organization (WHO) found 360 million (5.3%) deaf people in the world with a proportion of 91% adults and 9% children. This number is dominated in Asia. Southeast Asia has 278 million people suffering from hearing loss, 75-140 million in adults. Whereas in infants, there are 0.1-0.2 million suffering from deafness from birth or every 1,000 live births there are 1-2 babies suffering from deafness. 16% of deafness suffered by adults is caused by noise in the workplace, so NIHL (Noise Induced Hearing Loss)[3] The Multi Center Study (MCS) states that Indonesia is one of four countries in Southeast Asia with a high prevalence of hearing loss, which is 4.6% while the other three countries are Sri Lanka (9%), Myanmar (8.4%), and India (6.3%)[4].

Based on the results of a preliminary study conducted on blacksmiths using US-628 Sound Level Meter measuring instruments, the value of noise intensity measured in 5 locations of blacksmith craftsmen is 87, 92, 93, 88 and 89 dB. Of the many cases of noise and illness caused by work that occur among workers throughout the world, every 15 seconds there are 153 workers in the world experiencing work-related accidents and diseases. From the results of this problem it is necessary to get good attention and handling considering the high prevalence and consequences.

Material and Method

The type of research used in this study is analytic observational research using a cross sectional approach where this study aims to find the relationship between a situation with other conditions contained in the same population[5]

This sampling is done by using a total sampling method, which is a sampling technique where the number of samples is equal to the population. The sample size in this study was 60 people where the population in this study were craftsmen in 15 places in Parigi Moutong Regency.

Findings:

Table 1: Relationship of Noise with Complaints of Hearing Disorders in the Blacksmith Craft Industry in Parigi Moutong Regency

Causative factor	Hearing Loss Complaints				Total	ρ value
	Having disorders		Not experiencing interference			
	n	%	N	%		
Penggunaan APT						
Not Using	31	79,5	8	20,5	39	0,003
Use	8	38,1	13	61,9	21	
Years of service						
≥ 10 years	32	78,0	9	22,0	41	0,002
< 10 years	7	36,8	12	63,2	19	
Length of working						
≥ 8 hours/day	31	77,5	9	22,5	40	0,004
< 8 hours/day	8	40,0	12	60,0	20	
Conditions of the Work Environment						
≥ 85 dB	23	53,5	20	46,5	43	0,003
< 85 dB	16	94,1	1	5,9	17	

Sumber: Data Primer, 2017

Table 1. The results of Chi Square test ρ value 0.003 (ρ≤0.05) indicate a relationship between the use of APT and complaints of hearing loss, years of work with complaints of hearing loss with a value of ρ value 0.002 (ρ≤0.05), length of work with complaints of hearing loss the value ρ value is 0.004 (ρ≤0.05), the working environment condition with hearing loss complaints is ρ value 0.003 (ρ 5 0.05).

Discussion

Ear Protective Equipment: APD in this case ear protection device is a set of safety tools used by workers to protect the entire body or part of his body from the possibility of potential hazards from the work environment against accidents and work-related diseases acquired during work [6]

The results of research conducted on the blacksmith craft industry in Parigi Moutong Regency showed that the value of ρ = 0.003 (ρ <0.05), H0 was rejected and Ha was accepted, meaning that there was a relationship between the use of ear protectors and complaints of hearing loss.

The results of this study are also in line with research conducted by Hatim M, et al (2015). The results of the analysis show that the values obtained from the Pearson Chi-Square test (p = 0.002), which means that p <0.05 there is a statistically significant relationship between PPE and NIHL in Batu Saw workers on the West-Palestinian Bank. However, this research is not in line with the research conducted by Leancy Ferdiana (2013). The results of the statistical test between the use of headsets in flight and an increase in the hearing threshold indicate a significance value greater than 0.05. This means that there is no significant relationship between the use of headsets with an increase in the hearing threshold of respondents.[7]

Years of Service: The longer the working period of a worker is likely to be more easily exposed to noise in his workplace. If the longer it is in a noisy environment, the more dangerous it is for hearing workers [6]

The results of research carried out on the blacksmith craft industry in Parigi Moutong Regency showed that the value of ρ = 0.002 (ρ <0.05) then H0 was rejected and Ha was accepted, meaning that there was a relationship between years of work and complaints of hearing loss.

The results of this study are in line with the research conducted by Sam et al. (2017). From the results of the study, there was a statistically significant relationship between the length of work and the condition of hearing loss among Small and Medium Business Workers in Selangor, Malaysia, with a score of χ (4) = 10.51, p = 0.033. The level of association as indicated by the Kendall tau-c correlation is positive and weak (p = 0.18). But it is different from the results of research conducted by Defrin, E & Suyanto (2014). The results obtained that the value of p = 0.91 which means the value of p> 0.05 so that there is no significant relationship between years of work with complaints of hearing loss [8 9].

Length of working: Permenakertrans number PER.13/MEN/X/2011 is also mentioned that, time is allowed for exposure to noise of 85 dB is 8 hours. The duration of a day's work based on the Law of the Republic of Indonesia Number 13 of 2003 article 77 (1) is 8 hours a day and 40 hours a week with a minimum half-hour day's rest time[10].

The results of this study are in line with the research conducted by Hatim M, et al (2015). The results of the analysis show that the long duration of the work was obtained with a value (OR 1.08; CI 1.02 -1.14; p = 0.004) which means there is a statistically significant relationship between the duration of work and NIHL on the Edge Stone Workers West-Palestine. But it is different from the results of a study conducted by Suryani et al. (2015). The value of the results of the statistical test with chi-square between the variable working hours per day with hearing sensorineural type disorders obtained X2 = 2,283 and p = 0,273 (0,273> 0,05) which means that there is no significant relationship between working hours per day and sensorineural type hearing loss in noise workers in the Wood Furniture Industry in Pekanbaru City [11 12].

Conditions of the Work Environment: The work environment must be thoroughly evaluated, each workplace must be such that optimal workplace health and work productivity can be realized. Where if the work environment is not always evaluated, the effects that will be caused are workplace accidents and work-related illnesses from the work environment [6]

The results of research carried out on the blacksmith craft industry in Parigi Moutong Regency showed that the value of ρ = 0.003 (ρ <0.05) then H0 was rejected and Ha was accepted, meaning that there was a relationship between working environment conditions and hearing loss.

The results of this study are in line with the research conducted by Tjan et al. (2013). The results of the analysis showed a value of p = 0.032 (p <0.05) which means that there was a significant relationship between the intensity of high noise and hearing loss in workers in Sario District, Manado City, North Sulawesi. But it is different from the results of research conducted by Rusiyanti et al (2012). The results of the analysis show p value = 0.076 (p> 0.05), which can be interpreted as not having a significant relationship between noise intensity and disturbance in the right ear hearing threshold in blacksmith craft industry workers in Hadipolo village, Jekulo District, Kudus Regency [4 13].

Conclusion

The conclusions from the results of this study are as follows: There is a relationship between ear protectors and complaints of hearing loss in the Blacksmith Craft Industry in Parigi Moutong District with a value (ρ = 0.003 <0.05).

There is a relationship between years of work with complaints of hearing loss in the Blacksmith Craft

Industry in Parigi Moutong District with a value (ρ = 0.002 <0.05).

There is a relationship between the length of work and complaints of hearing loss in the Blacksmith Craft Industry in Parigi Moutong Regency with a value (ρ = 0.004 <0.05).

There is a relationship between working environment conditions and complaints of hearing loss in the Blacksmith Craft Industry in Parigi Moutong District with a value (ρ = 0.003 <0.05).

Conflicts of Interest: All authors have no conflicts of interest to declare.

Source of Funding: The source of this research costs from self.

Ethical Clearance: This study was approved by the institutional Ethics Council of the Tadulako University Institute of Public Health.

All subjects were fully informed about the procedures and objectives of this study each subject prior to the study signed an informed consent form.

The Role of Cultural Social Factor in Decision Making of Choosing Female Family Planning Contraception

Abdul Jalil Amri Arma[1], Surya Utama[1]

[1]Universitas Sumatera Utara, Medan, Indonesia

Abstract

The purpose of this research is to determine the factors that influence the decision to choose the female family planning contraception. This type of research is qualitative research by obtaining key informants (family acceptors), supporting informants (husbands) with in-depth interview method. Data analysis is carried out by the method of focused group discussion. The results used are rational motives with only one social variable, namely 'husbands' supports, the informants agree that these social variables do have a strong influence on the contraception selection of the female family planning acceptors.

Keywords: *Female Family Planning Acceptors, Cultural Social, Rational Motive, Emotional Motive.*

Introduction

Family Planning Program is not solely the responsibility of women. The issue of women's empowerment in family planning programs needs to be properly understood so that there is no gender-biased view. However, full involvement and partnership between women and men is important in efforts to control population and improve quality of life. The Family Planning Program (KB) not only aims to improve the health of mothers and children or suppress population growth. However, this family planning program is expected to improve the quality of the population through the preparation of healthy and prosperous families[16]. There is no single method of contraception that is safe and effective for all clients, because each has the suitability and individual compatibility of the client[2],[9],[17]. Along with the development of science and technology that bring many changes to human life both in terms of lifestyle changes and social order including in the health sector which is often faced with a matter that is directly related to the norms and culture adopted by the people living in a certain place[10]. Whereas the embodiment of culture is objects created by humans as cultured beings, in the form of behaviors and objects of a real nature, for example patterns of behavior, language, living tools, social organizations, religion and art, etc., which all of which are intended to help humans carry out community life[7],[23][24].

The large population and population growth rate which is still high or equal to 1.49% and equivalent to 4.5 million people each year is a complicated problem faced by the Indonesian people today[22]. The results of the Population Census show that the population of Indonesia is 237.6 million in 2010. This figure places Indonesia in the fourth rank of the most populous country in the world after the People's Republic of China, India, and the United States. In 2010, around 118.3 million people (50 percent of the population) lived in urban areas. At the same time the initial fertility rate in Indonesia has fallen sharply since the 1980s. The Crude Birth Rate (CBR) is estimated at 28 per 1,000 populations in the period of 1986-1989, down to 23 per 1,000 populations in the period of 1996-1999, resulting in an average decline of 2.1 percent per year [5] [16].

Those numbers indicate that there has been an acceleration in the decline in birth rates. But in 2010, the CBR again rose to 23 births per 1,000 inhabitants. Likewise, life expectancy at birth for both men and women increases. Male life expectancy increased from 58 years in 1990 to 69 years in 2010, and in women, life expectancy increased from 62 years in 1990 to 73 years in 2010. [18]. Regardless of the extent of the Family Planning (KB) program, and the Population of Family Planning and Family Development (KKBPK), the success of the family planning program still refers to the Total Fertility Rate (TFR). The smaller the TFR number, the more successful the KB program is. TFR

can go down when the Contraceptive Prevalence Rate (CPR) rises consistently. Conversely, if CPR does not increase, it is difficult to reduce TFR. CPR itself will not rise if the PB (New Participant) does not rise. CPR in Indonesia has fluctuated from year to year, such as 61.9% in 2012, 60.1% in 2014, and 66% in 2015, so it is appropriate if contraception is placed as a necessity for couples of childbearing age at the same time can improve the health of mothers, infants and children and contribute to the reduction of Maternal Mortality Rate (MMR) and Infant Mortality Rate (IMR) so as to help realize a small, happy and prosperous family [5].

Based on the Indonesian Demographic and Population Survey, recorded that TFR this year reaches 2.6 per woman of childbearing age. This means that on average women of childbearing age in Indonesia have an average of 3-4 children. This achievement is far from the target to be achieved this year, which is 2.4. From this year's achievement, the BKKBN admitted that it was almost certain that the opportunity to achieve the ideal TFR in 2015, which is 2.1 was closed. It is believed that TFR is still high due to the high drop out of contraception. The level of participants dropping out of family planning programs is on the road due to the majority of family planning participants currently using non-MKJP contraception, such as short-term pills that are quite high [11].At present, according to the calculations of experts, the ability of the earth to support the existence of the population has been 1.5 times its ideal capacity. In 2050 the condition has doubled andvery worrying[5].

In overcoming the problem of high population growth, the government has implemented a rational, effective and efficient contraceptive use policy including the use of Long Term Contraception Method (MKJP). According to the WHO and American College of Obstetricians and Gynecologists (ACOG), MKJP is the most effective contraceptive method. When viewed from the data, there is a tendency for contraceptive usage patterns to be considered irrational, of which 57.9 percent of the Contraceptive Prevalence Rate (CPR) is 47.3 percent using Non-Long Term Contraceptive Method (Non MKJP) and only 10.6 percent using the Long Term Contraception Method (MKJP).The pattern of use of the Long-Term Contraceptive Method even tends to decrease ie 18.7 percent in 1991 to 10.6 percent in 2012. The high use of Non MKJP also occurs in new family planning acceptors, which is 82.48 percent, while those using MKJP are only 17.52 percent even though the national MKJP target is 27 percent. [5].

In North Sumatra in 2015 showed that the number of PUS (Fertile-Age Couple) reached 2,201,509 people,with the number of active family planning participants amounting to 1,525,388 people (69.29%),while the number of new family planning participants was 419,691 people (19.06%), while the number of dropped-out KB acceptors which is 418,713 people or 18.57%. (Deli Serdang Regency/BPS, 2016). In Deli Serdang District in 2015 showed that the number of PUS reached 337,331 people, with the number of active family planning participants amounting to 232,372 people (68.88%), while the number of new family planning participants was 2,653 (0.78%), while the number of dropped-out family planning was 175,917 (52.14%).Female Surgery Method (MOW) as many as 38 people and Male Surgery Method (MOP) of 29 people [8].The tendency of the Non-MKJP KB use pattern also occurs in North Sumatra Province. Throughout the year 2013, turned out to be not less than 80 percent of new family planning acceptors in West Java chose to use Non-LTM. Non-LTM user is dominated by injectable contraceptives is equal to 33 percent and 29 percent of contraceptive pills [6]. Similarly, the usage pattern in Deli Serdang reported the achievement of KB participants noted of 22 districts in Deli Serdang, active birth control pills the number of participants as much as 23.18 percent, while the number of new family planning participants pills as much as 3.5 percent. Operation Method Women (MOW) as much as 3.4 percent and Operation Method Man (MOP) of 2.6 percent [6].

Theoretical Review:

Social Aspects Affecting Health Status and Health Behavior: Some social aspects that can affect participation in family planning, among them are Age, Education of husband or wife, The work of a husband or wife, Socio-Economic, Number of children, Availability of contraception and Husband's support[2].

Socio Cultural Behavior: According to [1],[4] culture is all the behavior and results of human behavior that are organized by the behavior that must be acquired by learning, and which are all arranged in the life of the community. There are three forms of culture, namely:

1. The form of thoughts, notions, ideas, norms, regulations, and so on.
2. Human's patterned behavior activity in society.
3. Physical form, is the total physical result of human's behavioral activities.

Humans are considered cultured creatures if the human has the mind and thought that are always actual in filling his life without being tired of looking for any knowledge to develop his personality.

Family Planning Program as Social Innovation: Family Planning (KB) is one of the most basic and primary preventive health services for women. Many women must determine the difficult contraceptive choices, not only because of the limited number of method availability, individual health and female sexuality or the costs of obtaining contraception [12]. This is not only due to the limited method availability, but also by ignorance of the requirements and safety of the contraceptive method. There is no single method of contraception that is safe and effective for all clients, because each has an individual fit and suitability for the client [17].

Research Method: This research was conducted with a qualitative method, where data was collected from informants using in-depth interviews and focus group discussions (FGD)[22]. In-depth interviews were conducted for female KB acceptors (24 informants) and husbands (12 informants). The FGD was conducted twice, FGD 1 extracted information on other female family planning acceptors including those who were discontinuing contraception (12 informants). FGD 2, for sub-district KB (PLKB) service officers, family planning service providers, family planning service providers for private clinics, religious leaders and district level community (15 informants).

Results and Discussion

Result:

The Analysis of the Influence of Socio-Cultural Factor with Moderate Rational Motives on the Decision in Choosing Females' KB Contraception: According to [14], age was one of the factors that could influence a person to behave, including in choosing the type of contraception to be used. This research was not in line with the research conducted by [15]which stated that age affected couples of childbearing age in the use of contraceptives, especially MKJP.According to [14] education is needed to obtain information, therefore the higher the level of education of a person, the easier it is to receive information, therefore more knowledge is owned, and the easier the person receives information, thus someone is more receptive to the newly developed values. This research is not in line with the research conducted by [19] who said that the level of education had a considerable influence on the utilization of the KB–MKJP method.This research is in line with the research conducted by [13]find that the occupation of a woman did not have a big influence in determining the choice of a mother to become an injection KB acceptor. Thirteen informants said there was no influence on socio-economic status with the use of family planning, for various reasons, such as family planning costs were still affordable, and family planning services were provided free of charge at the Center of Health Care and Information (POSYANDU).

The Analysis of the Influence of Socio-Cultural Factors with the Strong Rational Motives on Decisions in Choosing a Female KB Contraception: The results of the research concluded that out of 24 key informants there were 23 informants who had the support of their husbands to participate in the family planning program, only 1 informant did not get husband's support, but was allowed to join the family planning program. The results of this study are also reinforced by the [15] research which states that there is an influence of husband's support with the use of contraception.

Discussion

In general, it can be concluded that husband's support greatly influences his wife in choosing to use contraception, because with the support of husband and wife, they will be more motivated and easier to run family planning programs so that family harmony can be maintained. Therefore the child's welfare is very necessary to be considered including in terms of providing a decent life for children [15]. The results of the FGD among female family planning acceptors, stakeholders and the family planning community also agreed that the number of children affected the decision of female family planning acceptors for family planning, in addition to the number of children who were sufficiently considering economic difficulties. This research is in line with the research conducted by [13] which states that the choice of contraceptive method is strongly influenced by the number of children it has. If Fertile-Age Couple has many children, it is increasingly great to choose solid contraception as an option to stop fertility.

The second variable is the availability of contraceptives. Completeness of service describes the level of service quality. The statement is in line with the

theory put forward by Green*et al*., (1980) which states that service quality is included in the factors that support the emergence of health behavior. The results of this research are also in line with the research conducted by [20] about the factors associated with the use of long-term contraceptive method in the work area of the Pancoran Mas Public Health Center in Depok, which states that there is a significant relationship between the completeness of family planning services and the use of the term contraception method Length (MKJP). According to [1] states that, as social beings, human life cannot be separated from culture, and can even be influenced by the culture where he lives. This research is in line with the research conducted by [21] which states that there is a local socio-cultural relationship with the selection of contraceptive method.

Conclusion and Suggestion

Conclusion: There are 7 (seven) social factors that characterize rational motives and there are also 8 (eight) cultural factors that characterize emotional motives. The results of the analysis formed 4 (four) main factors, namely: socio-cultural factors-1 named **"moderate rational motives"**, socio-cultural factors-2 named **"moderate emotional motives"**, socio-cultural factors-3 named **"strong rational motives"**, socio-cultural factors-4 named **"strong emotional motives"**. Socio-Cultural Factor-1 consists of 5 (five) indicators, namely: 'Age of female and husband family planning acceptors', 'Women's and husband's family planning acceptor education', 'Women's and husband's family planning acceptor's work', 'family social economic status', and 'The fatalistic attitude of female, family and community family planning acceptors in the neighborhood'. Furthermore this dimension can be called **"moderate rational motive"**.

Epidemiology of Hypercholesterolemia among Adults in Samara City

Abid Ahmad Salman Al-Mahmood[1], Ehan Abdulhadi Hussein Al-Sharifi[2], Asia Abed Al-Mahmood[3]

[1]College of Medicine, Tikrit University, Tikrit, [2]College of Dentistry, Ibn Sina University of Medical and Pharmaceutical Sciences, Baghdad, [3]College of Dentistry, Al-Iraqia University, Baghdad, Iraq

Abstract

Hyperchloremia is elevation of serum cholesterol level above normal (> 200 mg/dl). There are an association between cardiovascular diseases and high level of blood cholesterol. There are many risk factors of hypercholesterolemia as genetic, environmental, systematic disease as diabetes mellites and some drugs factors. A cross sectional study was conducted on adults who were attending Samara general hospital outpatients clinicduring the period from 5th February-30th April 2017. The information regarding the problem and demographic characterestics of persons was obtained according to a questionnaire and the weight, height, blood pressure, total blood cholesterol level was recorded. The results shows that the frequency of hypercholesterolemia among sample study was (54%).There is no significant association between frequency of hypercholesterolemia according to gender, age group, body mass index, family history and smoking habit but it has been reported that a significant association between high serum cholesterol and presence of hypertension, cardiac diseases and diabetes mellites.

Keywords: *Hyperchloremia, Epidemiology, Samara.*

Introduction

Hypercholesterolemia is defined as the presence of high levels of cholesterol in the blood (a form of hyperlipidemia)[1,2]. Normal serum level of cholesterol is < 200 mg/dl (< 5 mmol/l) and considered high (200 mg/dl and above)[3,4].

Cholesterol is manufactured by all animal cells. Steroid hormones and bile acid precursors are cholesterol. It is transported in blood plasma as lipoproteins which classified according to their density (very low, intermediate, low- and high-densitylipoprotein [5].

It has been documented the relation between longstanding high serum cholesterol and atherosclerosis.[6], these processes may lead to narrowing of affected arteries and may cause a clot which obstruct blood flow[7]. There is a correlation between hypercholesterolemia and coronary heart disease [8] and it has been documented increase of risk five times than those with normal level of blood cholesterol[9].

The most important risk factors of hypercholesterolemia are a combination of environmental and genetic factors. Environmental factors include obesity, diet, and stress, diabetes mellites[8]and certain medications and other systematic diseases)[6]. It has been found an association between high level of blood cholesterol and cigarette smoking,diabetes mellites and obesity[10]. There is an effect of diet on blood cholesterol but the effect varies between individuals[11].

Patients and Method

A descriptive study was conducted on adults attending outpatient clinic in Samrageneral hospital. The study started from 5th February-30th April 2017. The patients were sent for investigation of blood total cholesterol. The sample study individuals demographic information was obtained according to structured-designed questionnaire and by direct interview. The cholesterol level was considered high if it exceeds 200 mg/dl. Blood pressure,

Telephone Number: +9647732553263

body weight, height, were measured in addition to obtain from patients investigation the total blood cholesterol level.

Statistical Analysis: By using SPSS 25.0 statistical software package the results were presented as the frequencies, per cent and Chi-square test was used to assess association. Statistical analysis at p-value < 0.05 was considered significant.

Results

It has been revealed that the frequency of hypercholesterolemia among study sample was 54%. Regarding the gender the frequency of hypercholesterolemia was 54% among each of male and female (Table 1).

Table (2) shows that hypercholesterolemia was more frequent among age group > 40 years (55.9%) than those among age group <40 years (48.7%) but without significant association. Table (3) shows that hypercholesterolemia was more frequent among those with body mass index (BMI > 25) (55.1%) than those with BMI <25 (51.9%) but without significant association. Table (4) shows that hypercholesterolemia was more frequent among those with hypertension (65.5%) than those without hypertension (46.7%). There is a significant association. Table (5) shows that hypercholesterolemia was more frequent among those with cardiac disease (87%) than those without cardiac disease (48%). There is a significant association.

Table (6) shows that hypercholesterolemia was more frequent among those with diabetes mellites (71.4%) than diabetes mellites those without hypertension (50%). There is a significant association.

Discussion

It has been documented in the current study that the frequency of serum hypercholesterolemia was (54%). This result is similar to result obtained by Al-Nozha *et al* in Saudi Arabia[12], and higher to that reported in Egypt (38%)[13], and by other study done by WHO (36%)[14], in Kuwait (10.6%)[15], in Oman (15.6%)[16], in Sudan (7.8%)[17], in other studies in Saudia (32%)[18], in India (33.2%)[19], other studies (37%)[20], in Korea (1.2%)[21]. The current result is lower than that reported in north Kerala in India the prevalence of hypercholesterolemia was 63.8% [22], in other studies (57%)[23], in Nigeria (62.5%)[24] and in Poland (66.4%)[25].

Regarding the gender in the sample study there are no differences in frequency of hypercholesterolemia between male and female (54%). This result is nearly to similar to that reported in Saudi Arabia[12]. It is higher to that reported in Egypt (male 39.7%, female 38.3%) but there is no significant association [13] like other studies[26,27]. Other studies in India revealed that hypercholesteremia is more frequent among female (67.6%) than male (57.6%) with a significant association[22].

In the current study the frequency of hypercholesterolemia was more frequent among age group more than 40 years (55.9%) and below age group below 40 years (48.7%) but there is no significant association (P value = 0.442). This result was nearly similar to that reported in Saudi Arabia[12], while in Egypt about (38.9%) above age 20 years and (38.7%) below 20 years without significant association[13].

In the current study the frequency of serum hypercholesterolemia is more frequent among persons with body mass index more than 25 Kg/M^2 (55.1%) than those with body mass index less than $25Kg/M^2$ (51%) but there is no significant association (P value= 0.71). This result is nearly similar to result reported by Al-Nozha et al in Saudi Arabia [12]. In India it has reported that about (69%)of those with body mass index more than $25Kg/M^2$ having hypercholesterolemia and (59%) among those with normal weight[22] while in Egypt the result of hypercholesterolemia among those with high BMI and normal BMI was (48.8%,33.9%)respectively [13]. Many studies reported that there are a significant association between obesity and hypercholesterolemia [28, 29, 30, 31].

In current study the frequency of hypercholesterolemia among patients with and without hypertension was (65.5%, 46.7% respectively) and among patients with and without cardiac disease was (87%, 48% respectively). Statistically, there is a high association (Pvalue = 0.025 for hypertension and P value = 0.001 for cardiac diseases). This result is more than that reported in Fayoum in Egypt (frequency of hypercholesterolemia among hypertensive and non-hypertensives 54.5%, 36.8% respectively) and also there is a significant association[13]. A significant relation was reported by hypercholesterolemia and high blood pressure by other studies[27,32].

There was a significant association between diabetes mellitus disease presence and hypercholesterolemia among study sample group (P = 0.04). The frequency

of hypercholesteremia in this study among diabetic and nondiabetic patients was (71.4%, 50%) respectively. This result is going with results of other studies which reveal that diabetes mellitus is one of causes of hypercholesterolemia and there are a strong association between them[8,10].

Conclusions

The current study revealed that there are a significant association between hyperchloremia and hypertension, cardiac diseases and diabetes mellites.

Corn Silk Based Ethosomal Gel: A New Treatment for Periodontitis in Diabetic Albino Rats a Prelimenary Study

Riuwpassa I.E.[1], Kim YR[2], Tenrilili A.N.A.[2], Untung J.S.[3], Djamaludin N.S.[4], Achmad M.H.[5]

[1]Oral Biology Department, Faculty of Dentistry, [2]Undergraduate Student Faculty of Dentistry, [3]Undergraduate Student Faculty of Pharmacy, [4]Departement of Public Health Dentistry, [5]Departement of Pediatric Dentistry, Hasanuddin University, Makassar, South Sulawesi, Indonesia

Abstract

Objective: Periodontitis and diabetes are related and high blood glucose level plays an important part in this correlation. Corn silk has the property of anti-hyperglycemic and anti-inflammation. The aim of this study was to determine the capability of corn silk based Ethosomal gel to reduce blood glucose level and degree of inflammation in alloxan induced rats.

Material and Method: 15wistar male rats with initial weight of 150gram were included in this study. Alloxan was used to induce diabetes and 5-0 silk ligatures to induce periodontitis. Blood glucose level was analyzed before and after induction, 3 days after administration, and 7 days after. Degree of inflammation was examined with histopathology test.

Results: Blood glucose level in F1 is unstable ($p=0.0583>p=0.05$), whilst F2 and F3 both showed stable blood glucose decrease (F2: $p=0.0086<p=0.05$; F3: $p=0.035<p=0.05$). Anti-inflammation effects best shown in F3, which has mild inflammation ($p=0.001<p=0.05$).Whereas both F1 and F2 have moderate inflammation (F1: $p=0.225>p=0.05$; F2: $p=0.423>p=0.05$).

Conclusion: Corn silk based Ethosomal gel treatment manage to reduce blood glucose level and periodontitis in alloxan induced diabetic rats.

Keywords: *Corn silk extract, Diabetes Mellitus, Ethosomal gel, Periodontitis.*

Introduction

Periodontitis is a disease caused by specific micoorganism that derived from dental plaque. These bacterian can cause progressive periodontal tissue and alveolar bone damage by inducing the formation of periodontal pocket, gingival ressesion, or both. Clinical signs of periodontitis are gingivitis, periodontal pocket, and loss of attachment.[1,2] Diabetes itself is a risk factor for gingivitis and periodontitis, and the degree of glycemic control appears to play an important part in this correlation.[3] Diabetes is a clinically and genetically heterogeneous group of metabolic disorders manifested by abnormally high levels of glucose in the blood. This hyperglycemia results from either a deficiency of insulin secretion caused pancreatic β-cell dysfunction or resistance to the action of insulin in liver and muscles, or both.[1]Diabetes itself is a risk factor for gingivitis and periodontitis, and the degree of glycemic control appears to play an important part in this correlation.[4] High glucose level in gingival crevicular fluid directly hinders fibroblast's ability to heal itself by inhibiting the attachment and spreading of cells needed for wound-healing and normal tissue turnover).[5] Abnormality in neutrophil's adherence, chemotactic, and phagocytosis has been observed in some DM patients. Neutrophil's impairment may inhibit bacterial killing in the periodontal pocket and significantly increase

periodontal destruction. Apparently, this impairment can be subdued with better glycemic control. In conditions of sustained hyperglycemia, protein binds with glucose molecules and undergo glycationthus forms Advanced Glycation End Products (AGEs). AGEs formed on collagen increases collagen crosslinking. Due to this cross linking activities collagens formed become highly susceptible to enzymatic degradation by collagenase, which is mostly present in active form in people with diabetes. Human gingival fibroblasts also produce decreased amounts of collagen and glycosaminoglycans in the hyperglycemic state.[6] As a result of collagen crosslinking and collagen deficiency, collagen metabolism is disturbed, thus affecting wound-healing process.[7] AGEs bind with RAGE (Receptor for AGEs) on the surface of monocyte; therefore monocytes are forced to stay in one place because it limits their migration. AGE-RAGE interaction induces phenotype changes in monocyte, which increase the production of cytokine TNF, Prostaglandin E (PGE), Interleukin (IL-1β).[8] Host immune response stimulates pro-inflammatory mediators such as IL-1, TNF- α, IL-6, 1L-7 and a whole lot more PGE_2, which promotes periodontal tissue damage.[9] PGE_2 is an important mediator in periodontitis process and bone destruction also plays important part in inflammatory response regulation. PGE_2 surpresses limphocyte production, collagen synthesis by fibroblas, and bone osteoclast resorbtion.[10]

Corn silk (*Stigma maydis*) is made from stigmas, the yellowish thread like strands from the female flower of maize. It is a waste material from corn cultivation and available in abundance.[10] Throughout the world corn silk has been used as a treatment of edema as well as for cystitis, gout, kidney stones nephritis and prostatitis.[10] Corn silk contains numerous bioactive compounds such as volatile oils, steroids, alkaloids, sitosterol and stigmasterol and natural antioxidants such as flavonoids, saponins, tannins, and other phenolic compounds.[12,13] Variation in secondary metabolite compound would affect its pharmacological activities. Phytochemical contents of plant are affected by various factors such as environmental conditions, season, plant age, growth factors, and leaf maturity.[14,15,16,17]Flavonoids has the ability to inhibit α-amylase and α-glucosidase activities *in vitro*, inhibit glucose transport, prevent cytokine induced β-cell damage, and ameliorate insulin resistance peripherally.[18] Saponins can reduce blood glucose level by increasing insulin secretion, glucose uptake, and hamper glucose absorption in the small intestine. Alcaloid can decrease glucose absorption by inhibiting α-glucosidase enzyme. Tannins and phenol can interact with protein and are capable of slowing down carbohydrate catabolism. Phenolic compound also has antioxidant properties therefore it can help repair damaged β-cell hence increasing insulin secretion.[19] Aside from having anti-hyperglycemic activities, corn silk extract also has anti-inflammation, antioxidant, anti-depressant activity, diuresis, and many more.[20]

Ethosom gel is one of the Transdermal Drug Delivery System (TDDS) that can increase drug penetration despite being applied topically. The Ethosom itself is a lipid vesicle modified from liposomes. Ethosom is comprised from phospholipid, relatively high concentration alcohol (ethanol or isopropyl alcohol), and water. Ethosom vesicle sizes are varied from micrometer (μm) - 10 nanometer (nm). Ethosom needs lesser time to penetrate the skin and significantly increase transdermal drugs flux value. Ethosom also decrease the risk of GI Tract irritation due to orally administered medication.[21]

Materials and Method

Animals: Wistar strain rats weighing 150gram were purchased from local breeder in South Sulawesi. The rats were maintained at room temperature under alternating natural light/dark photoperiod and were fed twice a day with standard feed water was available *ad libitum*.

Chemicals: Alloxan was used to induce diabetes and were purchased from Tokyo Chemical Industry. Metformin used for positive control was of generic brand.

Corn silk extract preparation: Corn silk from 40 days old corns were obtained from local farmers in Jeneponto a region in South Sulawesi. The corn silk were washed and dried at room temperature (24.2 ± 1.0°C) till dried and an ethanol extraction was performed by adding 5L of ethanol 80% and 200gram dried corn silk. After 3 days of maceration process, the ethanol solvent was evaporated using rotatory evaporator.

Corn silk extract based Ethosomal gel formulation: Three corn silk based Ethosom formulas were made (refer to Table 1). Lecithin and phospatidilcolin were dispersed in heated distilled water (40°C). Corn silk extract entered lipid phase and stirred with magnetic stirrer for 5 minutes and 700rpm till it entered coloidal system. Propylene glycol and ethanol 96% were heated till 30°C and entered coloidal

system. Lechitin or phospatidilcolin, corn silk extract, propylene glycol with ethanol 96% were mixed together and homogenized with magnetic stirrer for 5 minutes and 700rpm till Ethosom suspension was formed. The suspension were cooled in room temperature then stored in the refrigerator.

After the Ethosom formulas were made, they were put in gel system (refer to table 2) and corn silk ethosomalgel were made. Carbomer 940 was dispersed in distilled water that contain methylparaben for 24 hours. After that triethanolamine was added drop by drop whilst being stirred till a clear gel mass was formed. Ethosom (Formula A, B, C) mixed with a small amount of distilled water were added to the gel base and stirred till homogenized, after that glycerin and distilled water were added to the mixture.[21]

Experimental design: 15 rats were fasted for 8h and blood glucose level was measured with blood drawn from the vein in tail. Each rat's weight was measured and then alloxan (150 mg/kg) dissolved in sterile saline were injected intraperitoneally. Three days after inducing diabetes, periodontitis was induced as well. 5-0 silk ligatureswas tied around the mandibular first incisor and tied gently to prevent damage to the periodontal tissue. The ligature was thought to facilitate local accumulation of bacteria and thereby enhance bacteria mediated inflammation. One week after alloxan was administered blood sample were drawn again from the tail vein. One week after periodontitis was induced, 14 hyperglycemic rats (the blood glucose level greater than 126 mg/dL) were selected randomly and divided into 5 groups. Metformin dissolved in water were administered orally (positive control), each formula was administered topically once a day to each specified group, and the clear gel base without corn silk extract was administered once a day (negative control group). 3 days metformin, Ethosom gel, and clear gel base was administered blood sample were drawn again for analysis. 7 days after administration, blood sample were collected for final analysis and periodontal tissue were collected for histopathology test.

The periodontal tissues were embedded in paraffin blocks after formalin fixation: After tissue fixation in formalin, tissue samples were processed in tissue processor machine. After being processed, the tissue samples then moved to embedding machine to make paraffin blocks. Paraffin blocks were then cooled down and trimmed with microtom after that moved to waterbath in 37°C. The tissue sample were then taken out using slides that were numbered. Slide then heated on hot plate at 60°C till the paraffin that surrounds the tissue melts. The section was examined after hematoxylin and eosin stainning.

Statistical Analysis: All data were analyzed using students t-test. The data represents means and standard deviations. The significant level of 5% ($P<0.05$) was used as the minimum acceptable probability for the difference between the means.

Results and Discussions

The blood glucose level of hyperglycemic rats are presented in Fig. 1. The blood glucose level for negative control kept increasing because it hasn't been given any treatment just a clear gel base as a placebo. The positive control, F2, and F3 level of blood glucose kept decreasing. In contrast with other experiments group, in F1 the blood glucose level decreased at first and starting to increase again. Eventhough, the final blood glucose level for F1 is still lower than it's blood glucose level after being induced the p value shows no significance by landing a p value at 0.0583 which is slightly bigger than p value 0.05. This indicates that F1 can not stabilize blood glucose level and has no significance in lowering blood glucose level. Metformin administered orally to positive control group shows decreasing blood glucose level but apparently has no significance statistically with p value of 0.264. Experimental groups F2 ($p=0.0086<p=0.05$) and F3 ($p=0.035<p=0.05$) both shown decrease in blood glucose level and both have significance statistically

Due to extremely large number of inflammatory cells such as leukocyte and PMN that are too many to count, the inflammation rate are shown with 3 different grades. 1 for mild, 2 for moderate and 3 for severe. As seen in fig. 2, negative control group has the highest inflammatory grade which is 3 and accompanied with cell necrosis (Fig. 3). Second highest inflammation grade is F2, in contrast to it's blood glucose level and other experiment groups. Supposedly, the degree of inflammation decreases as the blood glucose level decrease. One other important factor to note when it comes to periodontitis is that stress also affects periodontitis by altering immune system response, delayed wound healing, hormonal changes, and changes in behaviour that supports periodontitis formation.[22,23,24,25,26]

F2 control group has been observed to have high stress levels. In spite of having higher inflammation

grade than negative control, F2 has new connective tissue formation. F1 falls into moderate catagory but has no statistic significance with p value of 0.225. Only F3 has low inflamation grade and statistic significance with p value of 0.001. This imply that corn silk extract based Ethosomal gel has the ability to reduce blood glucose level and inflammation response.

Table 1. Corn Silk Based Ethosom Formula

Formula	Phospatidilcolin (F)/ Lecithin (L) (g)	Ethanol (g)	Propylene Glycol (g)	Corn Silk Extract (g)	Distilled Water
A	1 (F)	10	1	0,1	Till 50gram
B	1 (F)	10	1	0,05	
C	1 (L)	10	1	0,025	

Table 2. Corn Silk Based Ethosomal Gel Formula

Formula	Bahan					
	Corn silk extract Ethosom base	Carbomer 940	Triethanolamin	Glycerin	Methyl paraben	Water
F1	Formula A	1	2	5	0,15	Till 100gram
F2	Formula B	1	2	5	0,15	
F3	Formula C	1	2	5	0,15	

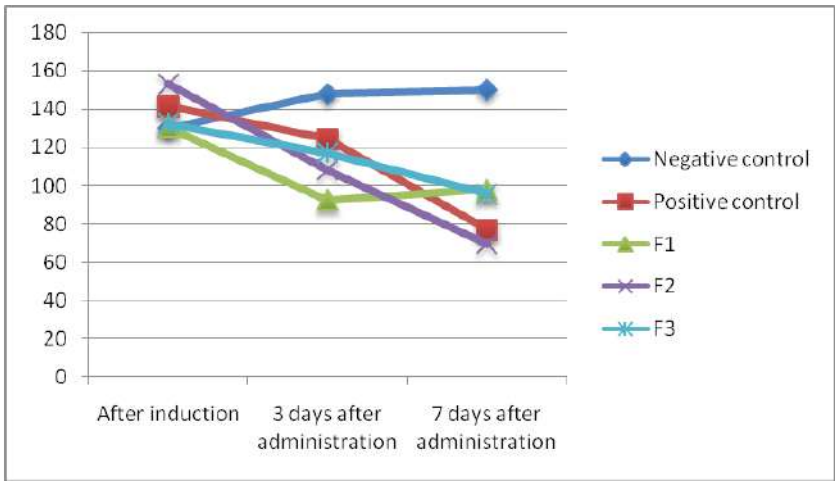

Figure 1. Blood glucose level. Values are mean

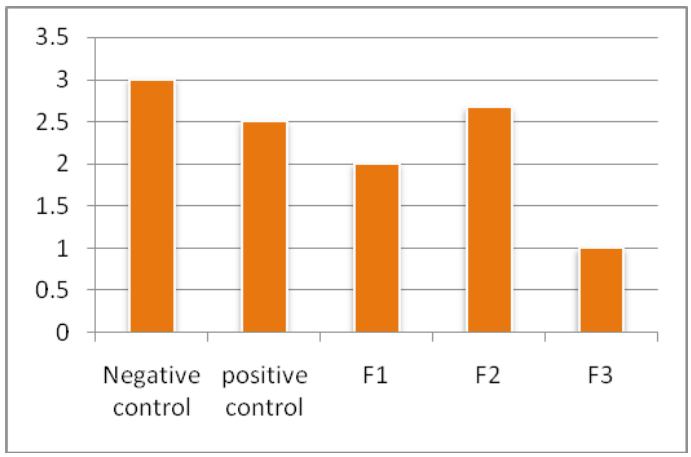

Figure 2. Degree of inflammation. Values are mean

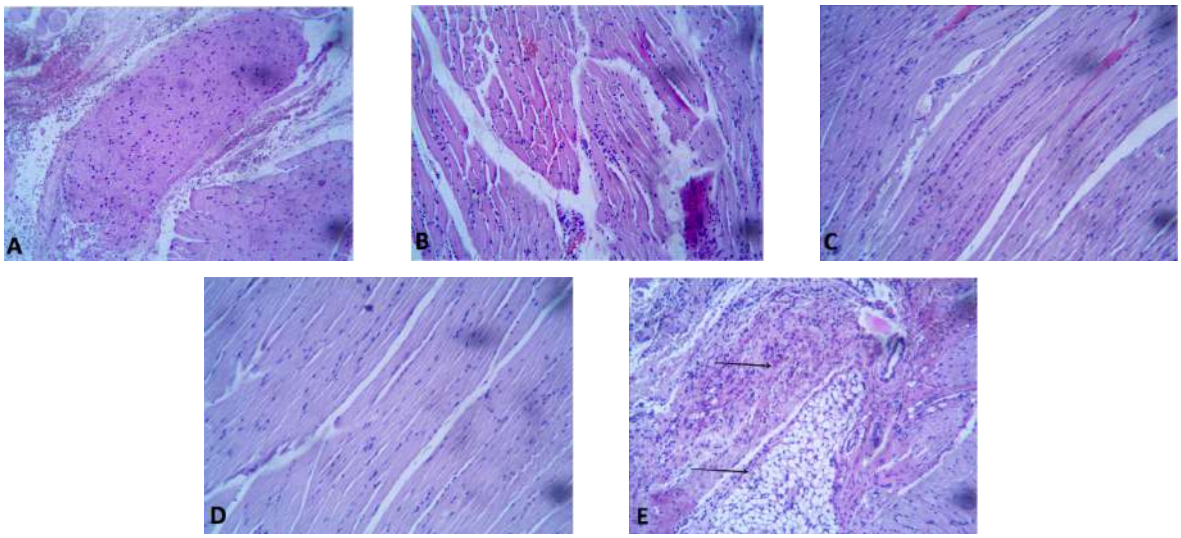

Figure 3. Inflammatory response in periodontal tissue represented by HE. (A) Negative control group showed severe inflammation response accompanied with cell necrosis (B) Moderate inflammation shown in rats administered with F1 (C) F2 administered rats shown moderate inflammation accompanied with newly formed connective tissue (D) F3 administrated rats shown mild inflammation (E) Positive control group showed severe inflammation response

Conclusion

The results showed that corn silk extract based Ethosomal gel treatment markedly reduces blood glucose level and periodontitis in alloxan induced diabetic rats. With F3, lecithin and 0.025gram corn silk extract as the formula that manages to have both anti-hyperglycemic and anti-inflammation effects.

Abstract

In playing basketball, body fitness is important. It is closely related to biomotor abilities which consist of several components, one of which is endurance. An attack movement in a basketball game would require good cardiorespiratory endurance. Aerobic endurance is related to oxygen intake. This study aims to determine the improvement of cardiorespiratory endurance in male students who took basketball as a preferred extracurricular activity gained through circuit training. This is experimental research with one-group pretest-posttest design. The sample of this research consisted of 15 male students. Circuit training was carried out three times a week for four weeks at an exercise intensity of 65% –90% of maximum heart rate. From hypothesis testingwitha paired t-test,it was found out that P = 0.000 (0.000 < 0.05), suggesting that there was a meaningful difference. This result shows that circuit training improved cardiorespiratory endurance.

Keywords: *Circuit training, cardiorespiratory endurance, male basketball players.*

Introduction

Basketball games are considered to be one of the most dynamic and flexible sports which require high levels of physical fitness[1]. Physical relations are associated with biomotor abilities because biomotor abilities are the abilities to measure human performance[2]. One of these biomotor components greatly affects a person's endurance, namely resilience. Resilience is the ability of the heart, lung, and blood vessels to work optimally when carrying out activities for a long time without experiencing interference[3]. Resilience can be grouped into anaerobic resistance and aerobic resistance[4],[5].

The training session applied by the coach was directed more to technical training and games. This affected the physical strength of poorly trained players[1],[6].

Cardiorespiratory endurance can be increased by a variety of training techniques, one of which is circuit training[1],[7]. Circuit training is a combination of several types of exercises carried out in several training posts [2]. At each training post, an athlete will perform a predetermined type of exercise[8]. One circuit training set is said to be complete if an athlete has completed training in all training posts according to the prescribed dose. The movements included in this circuit training are as follows: push-ups, sit-ups, vertical jumps, abdominal curls, back extensions, astride jumping over benches, pull-ups, bench stepping, burpe, shuttle run, thrust squats, side bend, skipping, and running on the spot[9].

Material and Method

Participants: The population in this study was all male students who took extracurricular activities at a middle school in Denpasar, Bali. The sample in

this study was male students who took basketball as a preferred extracurricular activity. The sample used had to meet the following criteria: the participants were male middle school students who took basketball as an extracurricular activity, were aged 13–14 years, had low cardiorespiratory endurance of < 35 (poor), and did not take part in any cardiorespiratory resistance training program other than circuit training during the study. After each of these posts the students were given a break period of 15 to 20 seconds before proceeding to the next post. After completing one circuit, the students were also given a break period of 15 to 20 seconds.

Circuit Training Measures: In this study, some interviews and observations were carried out, and information related to age and some complaints experienced was generated. This would affect the daily physical activity and the training process and would let the researchers know whether the respondents observed were not too large. Several circuit training posts consisting of running on the spot, shuttle run, skipping, squats, push-ups, sit-ups for each set were established. This exercise was performed in 2 repetitions (sets) with a break time of 15–20 seconds between stages and between circuits.

a. Stage 1: Running on the spot. This training post lasted for 20 seconds.

b. Stage 2: Shuttle run. This training post lasted for 30 seconds (the students run back and forth and touched the predetermined boundary line).

c. Stage 3: Skipping or jumping rope. This training post lasted for 30 seconds (the students made a leap using the rope provided).

d. Stage 4: Squat. This training post lasted for 30 seconds (the students stood then bent both knees to a half squatting position and repeated continuously for a specified time period).

e. Stage 5: Push-up. This training post lasted for 30 seconds.

f. Stage 6: Sit-up. This training post lasted for 30 seconds.

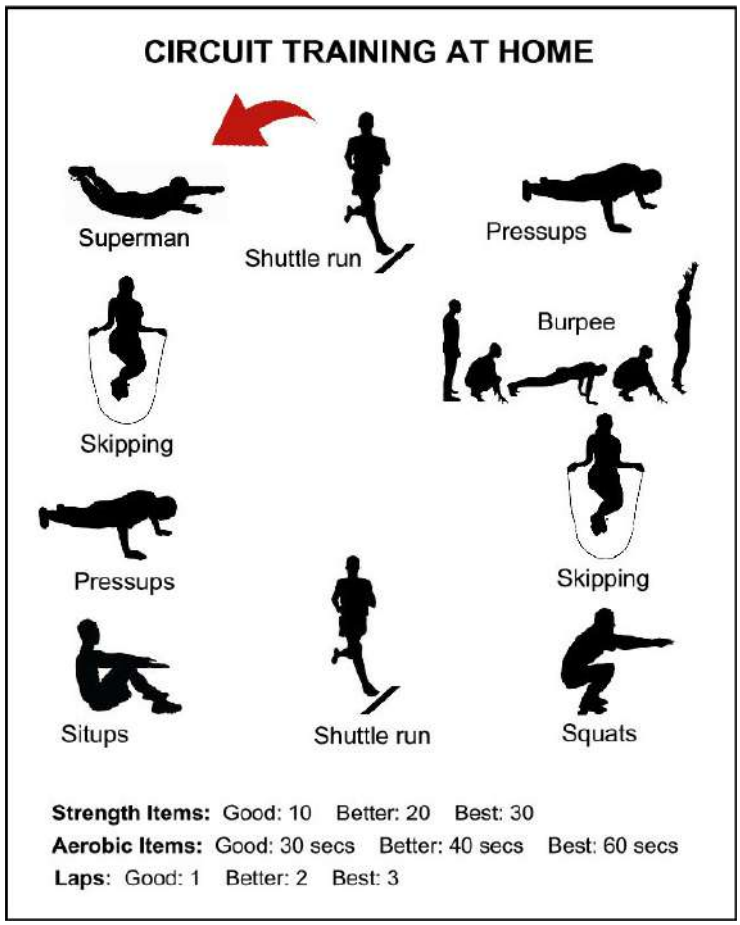

Fig. 1: Circuit trainning[9]

Statistical Analyses: This study used an experimental method with one-group pretest-post design. The data in the study were analyzed using SPSS. The analysis was conducted to describe the results of the research in the field without having to manipulate the facts. The data from the group were subjected to a Shapiro-Wilk test at a significance level of 0.05. It was used to examine the average chest expansion before and after treatment in each group.

Finding and Results: Table 1 shows the number of respondents based on age:10 respondents (66.7%) were 13 years old, and the remaining 5 respondents (33.3%) were 14 years old.

Table 1: Age distribution of respondents

No	Age	Frequency	Percentage (%)
1	13	10	66,7
2	14	5	33,3
	Total	**15**	**100%**

Table 2 shows the number of respondents based on the VO_{2max} values obtained from the Balke test before the circuit training was performed: 5 respondents (33.3%) obtained values of < 35 and fell into the very poor category, 8 respondents (53.3%) obtained values of 35–37 and fell into the poor category, and 2 other respondents (13.3%) obtained values of 38–44 and fell into the fair category.

Table 2: Distribution of VO2 max values through Balke Test before being given Circuit Training

The VO2 max value in the balke test	Total		
	Category	F	Percentage (%)
< 35	Very poor	5	33,3
35 – 37	Poor	8	53,3
38 – 44	Fair	2	13,3
Total		**15**	**100%**

Table 3 shows the number of respondents based on the VO_{2max} values from the Balke test after the circuit training was performed: 1 respondent (6.7%) obtained a value of < 35 and fell into the very poor category, 6 respondents (40.0%) obtained values of 35–37 and fell into the poor category, and 8 respondents (53.3%) obtained values of 38–44 and fell into the fair category.

Table 3: Distribution of VO2 max values through Balke Test after being given Circuit Training

VO2 max value	Total		
	Category	F	Percentage (%)
< 35	Very poor	1	6,7
35 – 37	Poor	6	40,0
38 – 44	Fair	8	53,3
Total		**15**	**100%**

Table 4 shows that the average VO_{2max} value obtained by a sample of 15 from the Balke test before the circuit training was performed was 35.68, the median was 36.2, the lowest value was 31.60, and the highest value was 39.60. Meanwhile, from the Balke test after the circuit training was performed to the same sample, the average VO_{2max} value was 38, the median was 38.5, the lowest value was 33.30, and the highest value was 44.

Table 4: Results of Measurement The average VO2 max value through the balke pre-test and post-test.

Variable		Mean	Median	Min	Max	%
Balke test	Pre-test	35,68	36,20	31,60	39,60	6,5%
	Post-test	38,00	38,50	33,30	44,00	

Table 5 shows the results of the normality test using the Shapiro-Wilk test. The pre-test VO_{2max} was 0.980. Because 0.980 > 0.05, the pre-test data were normally distributed. Meanwhile, the post-test VO_{2max} was 0.848. Because 0.848 > 0.05, the post-test data were normally distributed.

Table 5: Data Normality Test Results Measurement of VO2 max values through the balke test

Variable		Statistics	Sig,	Interpretation
Balke test	Pre-test	0,982	0,980	Normal
	Post-test	0,969	0,848	Normal

Table 6 shows that the paired t-test comparing the pre-test and post-test VO_{2max} values obtained from the Balke tests conducted on the sample yielded a significant result of 0.000 (0.000 < 0.05), indicating that there was a change in cardiorespiratory endurance after circuit training was performed.

Table 6: Results of paired t-test analysis

Results		Df	Sig	Information
Balke test	Pre-test	14	0,000	There are significant differences
	Post-test			

Discussion

Cardiorespiratory endurance in males aged 13–14 (adolescents) can increase if training is applied in accordance with a stipulated dosage or training load[10], [11].Age affects all components of physical fitness, and VO_{2max} plays an important role in respiratory fitness. VO_{2max} of children aged 8–16 years shows a progressive and linear increase in peak aerobic ability. Thus, it can be increased by applying active sports such as circuit training[12], [13], [14]. However, circuit training produces different levels of VO_{2max}, causingnon-optimal VO_{2max}achievement[6], [15]. Circuit training is designed to develop cardiorespiratory fitness, cardiovascular endurance, flexibility, strength, and muscle endurance [16]. This exercise has a number of advantages: it can be performed in a short time period;it can be applied to one person or a group of persons; and it does not require any complicated equipment [2]. Circuit training is designed to stimulate the cardiorespiratory organs, and, as a result, the resistance aspect is emphasized [17].

Some research studies reveal that male basketball players aged 10–12 years saw an increase of VO_{2max} after carrying out circuit training exercises for 6 weeks as well as average initial score and average final score by 7.68 ml/kg BW/minute (20.68%) [18],[3]. According to the American College of Sports Medicine in 2006, the target heart rate rangeone should achieve when conducting a circuit training exercise to experience cardiorespiratory benefits is 65% –90% of the maximum heart rate [15],[21]. This is in accordance with the results of the research conducted—that is,the dose used should be based on the size of the maximum heart rate to achieve changes in the cardiorespiratory aspect [19]. Recent studies related to exercises that have an effect on cardiorespiratory function have shown that breathing exercises are able to increase the amount of O_2 intake, for instance, chest expansion, with a p value of <0.05[20], [22]. Thus, the exercise also has an impact on the aerobic capacity of both sick patients and healthy people.

The results of this study show an increase in the cardiorespiratory endurance of male students taking basketball as an extracurricular activity based on the VO_{2max}values obtained from a Balke test (p= 0.000). The students were given circuit training 3 times a week for 4 weeks of meetings with a training load of 65% –90% of the maximum heart rate. Each circuit training treatment consisted of 2 sets of exercises, each of which consisted of 6 types of exercises that had to be carried out in each training post provided. Based on the VO_{2max} values before the circuit training was given to the sample, 20% of the respondents fell into the very poor category, 66.7% to the poor category, and 13.3% to the fair category. The 6 types of exercises were running on the spot, shuttle run, skipping, squats, push-ups, and sit-ups. This study's results are supported by previous research that was conducted on middle school students, which reveals that 6-week circuit training exercises on leg muscle strength could increase VO_{2max}[18], [23], [8].

The main limitation of our study is that we have yet to find anyother types of training comparative to circuit training for increasing the cardiorespiratory fitness of middle-school basketball players, thus we are in need of literature related to other types of aeorbic training. Therefore, more precisely, we recommend exercise to overcome the decline in cardiorespiratory fitness, for example, a decrease in the functional aerobic capacity.

Conclusions

From the observations conducted three times a week for four weeks, it was found that the provision of circuit training could increase the cardiorespiratory endurance of male students who took basketball as an extracurricular activity. However, in order to gain further insights regarding the improvement of cardiorespiratory fitness of long-term male basketball players, the sample size should be greater because the fitness level of each man may vary.

Conflict of Interest: The authors declare that there is no conflict of interest related to this study.

Source of Funding: The authors declare that there is no source of funding from anyone.

Ethical clearance: The experiment was approved taken from by the Research Ethics Committee of Medical Faculty of Udayana University/Sanglah Hospital.

Abstract

Chronic kidney failure is progressive and irreversible which caused metabolism disorder as well as electrolyte imbalance. This condition makes the patients to conduct hemodialysis. Patients with hemodialysis must have the ability to do self-care for fluid limitation management. Self-care deficit in managing fluids can cause interdialytic weight gain. The aim of this study was to measure the correlation between self-care for fluid limitation and interdialytic weight gain among chronic kidney disease patients with hemodialysis in Ratu Zalecha hospital Martapura. This study used cross-sectional study, total sampling and the final sample was 50 respondents. Data were collected in 2018. We used Spearman Rank Correlation to analyze the data. The result showed that there was a correlation of self-care for fluid limitation and interdialytic weight gain among patients with hemodialysis in Ratu Zalecha Hospital Martapura (p-value< 0,000; r= 0,589). The capability of self-care for fluid limitation and increase self-confidence among patient with hemodialysis to prevent interdialytic weight gain is needed.

Keywords: *Self-care, Fluid limitation, Interdialytic weight gain, hemodialysis.*

Introduction

Kidney has an important role in the human body to maintain fluid volume and distribution [(1).] Kidney failure requirements long treatment [(1)]. More than 500 million people had Chronic kidney failure [(2)]and only 0.1% of kidney failure was detected [(3)]. 2,622,000 people with kidney failure conducted end-stage renal disease (ESRD), and 77% undergo hemodialysis treatment [(3)]. *National Center For Chronic Disease Prevention and Health Promotion* (2014) noted that the prevalence of chronic kidney failure was increased [(4)].

Chronic kidney failure is progressive and irreversible. The urea creatinine will increase as the body inability to maintenance metabolism and keep fluid and electrolyte balance[(5)]. Additionally, kidney failure caused endocrine disorder and metabolic disorder, so it needs hemodialysis or kidney transplantation [(5)]. Hemodialysis is needed to remove metabolic residual from the blood such as water, sodium, potassium, hydrogen, urea, creatinine, uric acid, and others substance through semi-permeable membranes [(6)]. Hemodialysis also assists to maintain fluid balance, but the patients have to control their fluid regularly.

Patients with hemodialysis need to be trained to calculate fluid balance within 24 hours so they can control the fluid based on their needs. The fluid restriction will prevent fluid excess, because fluid excess can cause disruption of function in other organs, such as lung and cardio [(7)]. Another consequence is interdialytic weight gain, edema, wet rheumatism in the pulmonary, swollen eyelids and shortness of breath [(5)].

Patient with hemodialysis is required to do self-care independently, it refers to self-care. Self-care is an individual effort to fulfill their needs by optimizing

intellectual abilities, behavior and utilizing the environment[8]. Self-care can be achieved by applying Dorothea E. Orem's nursing self-care theory. According to Orem's theory, every individual with a certain age and condition has the ability to treat, protect, control, minimize and maintain the body to get healthy and well-being as well as optimal life both healthy and sick, or recovering from illness [5].

Self-care deficit in managing fluids can cause an increase in body weight between two dialysis times due to increased body fluid volume, it refers to interdialytic weight gain [9]. Interdialytic weight gain is one of the complications in patients with chronic renal failure who undergo hemodialysis caused by the inability of the renal excretion function. Increasing the value of the interdialytic weight gain will cause a negative effect such as hypotension, muscle cramps, hypertension, shortness of breath, nausea vomiting [10], also cause hypertension, peripheral edema, pulmonary edema, and increase the risk of dilatation and cardiac hypertrophy [7]. The problem in this study was to measure the relationship between self-care of fluid limitation and interdialityc weight gain among patients with chronic renal failure and hemodialysis in RatuZalecha Hospital Martapura.

Method

Participants and Settings: All of the procedures of this study got permission from Institutional review board in one of University in Indonesia. This study used cross-sectional design to analyze the correlation between self-care for fluid limitation and Interdialytic Weight Gain. The Dependent variable was self-care for fluid limitation and the independent variable was Interdialytic Weight Gain.

Data were collected from patient with hemodialysis in RatuZalecha Hospital Martapura, South Kalimantan, Indonesia, and used total sampling. We collected the data from Januari until February 2018. Total patients with hemodialysis in this hospital were 81. It produced 60% respond rate, so the final sample was 50 respondents.

Instruments: We used self-report questionnaires to collect the data.

Self-care for fluid limitation: We developed this questionnaire based on self –care concept from Orem theory (11, 12). It had 3 dimensions self-care maintenance, self-care management, and self-care confidence with total of 20 items. Self-care maintenance refers to knowledge regarding decision–making with true-false question (7 items), self-care management refers to behavior regarding health maintenance (7 items), with Likert scale (always-never), and self-care confidence regarding self-efficacy (6 items) with Likert scale (strongly disagree-strongly agree). The score between 51-80 means high score in self-care, and score between 20-50 means low score in self-care. This questionnaire had good convergent validity (r> 0.2) and adequate internal consistency with cronbach alpha= 0.839.

Interdialytic weight gain (IDWG): This is an observational instrument and measure body weight before hemodialysis, body weight after hemodialysis. We used Nerbass theory to determine the different bodyweight as well as the percentage of body weight (13). If the percentage of bodyweight < 5% refer to normal.

Statistical analysis: We used SPSS for windows to analyze the data (p value of < 0.05 are considered to describe statistically significant differences). Descriptive statistics (frequency and percentage) were used to calculate all variables. A spearman correlation was used to explore the relationship between self-care for fluid limitation and Interdialytic Weight Gain. Regarding response rate we used the recommendation from the previous study, that was 60% response rate [14].

Findings:

Characteristic of Respondents: Table 1 shows the characteristic of participants, included in this study: age, gender, and length of hemodialysis. Regarding age, 34% of participants were 45-55 and 56 -65 years old, the proportion of male was 54% and female was 46%. Length of hemodialysis showed that 54% of participants undergo hemodialysis around 12-24 months and 40% of participants undergo hemodialysis > 24 months.

Table 1. Demographic characteristic of participants

Characteristic	N	%
Total = 50		
Age (Years)		
18-40	3	6
41-45	8	16
46-55	17	34
56-65	17	34
>65	5	10

Characteristic	N	%
Gender		
Male	27	54
Female	23	46
Length of Hemodialysis		
<12 months	3	6
12 – 24 months	27	54
>24months	20	40

Descriptive statistics among variables: Table 2 shows 58% participants had good self-care for fluid limitation and 42% had low self-care for fluid limitation. In term of Interdialytic Weight Gain, 58% participants had normal Interdialytic Weight Gain and 42% participants had abnormal Interdialytic Weight Gain.

Table 2. Statistical Description of variables

Variables	N	%
Total = 50		
Self-care for fluid limitation		
High	29	58
Low	21	42
Interdialytic Weight Gain		
Normal	29	58
Abnormal	21	42

Correlation among Study Variables: Table 3 shows significant correlation between self-care for fluid limit and Interdialytic Weight Gain with moderate relationship (r = 0.589, *p* value < 0.01)

Table 3. Relationship between self-care for fluid limit and Interdialytic Weight Gain

	Interdialytic Weight Gain
Self-care for fluid limit	0.589**

**p value < 0.01

Discussion

Self-care for fluid limitation among patients with hemodialysis in Ratu Zalecha Hospital Martapura: Patients with hemodialysis generally have complex problems and require to fulfill their needs. One of their needs was related with ability to care themselves. Patients with hemodialysis must have ability to maintain their fluid intake to achieve optimum quality of life. Self-care in this study used Orem theory[11,12,15]. Based on this study, 58% of respondents had good self-care for fluid limitation (table 2). Most respondents showed higher self-care maintenance (knowledge) followed by self-care confidence (self-esteem) and self-care management (behavior). Previous study noted that quality of life could be achieved by increasing self-care[3].

This study also showed most of the respondents had low self-care management to manage the fluid intake. The patients did not calculate the fluid intake and urine output a day. They consume 2-3 glasses of water in a day, with urine output 500 ml/24 hours and also manage thirst by brush their teeth and gargling. However, they did not know that they must restrict salty food that induces thirstily. Previous study mentioned about the obstacle of self-care management among patients with hemodialysis was internal and external factors. Internal factors were low of motivation to diet and fluid restriction during activity. External factor was cost of hemodialysis [16]. Fluid restriction is needed to give comfort to patients before and after conducting hemodialysis [5].

Interdialytic weight gain among patients with hemodialysis in Ratu Zalecha Hospital Martapura: Interdialytic weight gain is related to the patient's fluid restriction. Fluid restriction is one of the treatments for end-stage renal disease (ESRD) to prevent worse conditions. The amount of fluid was determined for a day, and it depends on kidney function, the patient's edema and urine output [17]. This study showed that 58% participants increased of body weight and it was normal range. 42% of participants were an abnormal range (table 2). Fluid intake among patients with chronic renal failure related to Interdialytic weight gain. This study was similar to previous study [17]. We assumed that Interdialytic weight gain due to thirsty condition among participants, it was similar to Black and Hawks theory[18].

Increased interdialytic weight gain exceeding 5% of dry weight can cause several of complications such as hypertension, interdialytic hypotension, left heart failure, ascites, pleural effusion, congestive heart failure, and also can lead to mortality. Many factors contribute to interdialytic weight gain, such as internal factors (thirst, stress, and self-efficacy) also external factors such as family support and fluid intake [19].

Relationship between self-care for fluid limitation and Interdialytic weight gain among patients with hemodialysis in RSU Ratu Zalecha Martapura: In this study showed 82.8% respondents had high self-care for fluid restriction experienced an increase in normal

interdialytic weight gain and the remain was respondents with low self-care for fluid restriction experienced an increase in abnormal interdialytic weight gain. This study also showed that self-care for fluid restriction was statistically significant with interdialytic weight gain (table 3) with moderate correlation (r = 0.589). This study was similar previous study about significant relationship between fluid intake and interdialytic weight gain[17].

Limitation: This study had some limitation. This study used cross-sectional study and relatively small sample size. Therefore, the results may be generalized carefully. Further study is needed to increase self-care for fluid limitation among patients with hemodialysis to prevent Interdialytic weight gain.

Conclusion

Besides the limitations, this study produced enough response rate. We are confident that self-care for fluid limitation related to interdialytic weight gain. This study suggests evidence to increase self-care for fluid limitation to prevent Interdialytic weight gain.

[1]Professor of General Surgery, [2]Assistant Professor of General Surgery,
[3]Assistant Lecturer of General Surgery, General Surgery Department, Cairo University, Egypt

Abstract

Objective: The aim of the present prospective study was to evaluate the role of preoperative prophylactic biofeedback therapy on the anorectal continence of patients with high anal fistula who will be subjected to fistulectomy operation.

Method: This was a randomized control study which included 40 patients who presented to the Out Patient Department (OPD) of Kasr-al ainy Hospitals, from March 2015 to September 2016. Allpatients (40) have been presented with high complex anal fistulae. They were divided into two equal groups; group (A) has twenty patients who had undergone prophylactic preoperative anorectal biofeedback and group (B) has the other twenty patients who didn`t receive the prophylactic preoperative anorectal biofeedback therapy. For group (A) patients, six sessions of biofeedback were done two weeks. All patients were assessed postoperatively (0, 3 and 6 months) for continence by Cleveland Clinic Score for incontinence.

Results: Among these forty patients only four (10%) had developed anal incontinence with variable degrees (two of them gas incontinence and another two developed frank stool incontinence), these four patients belong to the group (B), on the other hand, none of group (A) patients had developed incontinence.

Conclusion: In conclusion, we can rely on preoperative prophylactic biofeedback has an important role to minimize incontinence post high anal fistula surgery.

Keywords: *Fistula in ano, Fecal Incontinence, Biofeedback.*

Introduction

Surgery of perianal fistulas remains a challenge because of potential sequences including fecal incontinence (FI) that may impair quality of life. [1]

Reported incidences of incontinence following fistulas surgery range from 5% to 60%. Sphincter preserving approaches such as core fistulectomy or mucosal advancement flap are recommended for high complex fistulas as better approaches to preserve continence.[2-4]

About 70% of the resting tone is achieved by internal anal sphincter (IAS). This is supported by the finding lateral internal sphincterotomy could be complicated by fecal incontinence.[5]

The external anal sphincter (EAS), similar to the IAS, is in a state of tonic contraction even at rest and the activity is reflexly raised when intra-abdominal pressure is increased e.g. when coughing, laughing or lifting. Activity is maximally raised when the EAS is contracted voluntarily but contraction.[6]

Both American College of Gastroenterology and the American Gastroenterological Association

recommend anorectal biofeedback for the treatment of FI. Biofeedback treatment protocols for FI aim to strengthen pelvic floor muscles, to increasethe ability to sense rectal filling and to teach patients to perceive and react even if the rectum is dilated slightly.[7-9]

Aim of work: The aim of this article was to describe a standardized biofeedback anal exercises protocol as aprophylactic measure prior to complex anal fistulas surgery to minimize the incidence of postoperative fecal incontinence**.**

Material and Method

Patients: Our study included **40** patients who came to the Out-Patient Department (OPD) of Kasr-el Ainy Hospital, from **March 2015** to **September 2016**.

After agreement from the Scientific and Ethical Committee of General Surgery Department and Faculty of Medicine Cairo University, the procedure and the study were explained to all individuals participating in the study and informed written consents were taken.

Forty patients who were candidates for high anal fistulas surgical treatment were randomized into two equal groups (A and B) using closed envelope. Neither patients nor physicians were blinded to the group assignment because of the nature of the study. Group (A) included 20 patients who had preoperative biofeedback program while group (B) included 20 patients that were not undergone biofeedback program. Patients' selection was done using the closed envelope method.

Patients, not fit for surgery didn't accept treatment modality, at extreme ages, and/or those with low anal fistulas were excluded from the study

Method

Pre-operative: All patients were underwent proper history taking (age, presentation, occupation, presence of previous abscess, contributing factors, continence assessment by Cleveland Clinic Score for incontinence and previous anal surgeries) and full general and local examination (P/R examination) to determine: External fistulous opening, Internal fistulous opening,primary, secondary tract, sphincter tone, scars and presence of abscess cavity.

Anatomical assessment of the fistula tract, its relation to the anal canal and muscular complex were studied by magnetic resonant imaging (MRI) and/or Endoanal Ultrasonography (EUS).

After the agreement of the scientific and ethical committee of the general surgery department, the procedure and the study were explained for all individuals participating in the study and all of them consented for agreement.

Biofeedback protocol: The biofeedback protocol was explained in details to patients in group (A). It was done in the colorectal unit with the subject in the left lateral position a multi-lumen catheter was placed in the rectum with 8 side holes with varying distances from the anal verge. These were perfused with water and connected to water filled transducers. A 5 cm latex balloon was attached to the catheter and linked to an air filled transducer. Catheter used: with 8 side holes 3,4,5,6,7,8,9 and 10 cm from the balloon and at angles 0, 45, 90,135,180,225,270 and 315 respectively. Recordings were made on a computer using the machine software to be printed when needed.

Six sessions were performed preoperatively each of which lasting 20 -30 minutes, the sessions are performed every other day with average three sessions per week. First sensation: the balloon of the catheter is inflated until the first sensation is reached at which the patient is asked to contract his sphincters; this is done to improve sensation and coordination. Challenge pressure, the patient is asked to pass the obstacle over a bar (representing the challenge pressure) by maximum squeeze. The muscle response measured by pressure transducers is translated into a visual display so that the patient receives immediate feedback regarding the strength and duration of pelvic floor muscle contraction. Challenge time, during which the patient squeezed. Resting time, during which the patient rested. Challenge pressure, challenge time and resting time could be adjusted through the program before starting the session

Operation: For all patients general anesthesia without muscle relaxant was used. Patients were operated in lithotomy position. They were received prophylactic antibiotic.

Core fistulectomy was done to all the patients. Its principle was to remove the chronic, epithelialized tract to allow healing by secondary intention of healthier tissue. Dissection was typically carried out from the external opening up to the internal fistulous opening.

Postoperative care: The patients started oral fluids

same day of procedure intake advanced gradually as patient tolerating feeding. Analgesia (usually IV or IM nonsteroidal anti-inflamatory) started immediately postoperative.

Patients were discharged 24 hours postoperative with instruction for frequent dressing. Early assessment for anorectal continence was carried using Cleveland Clinic incontinence score (table 1)[10].

Table (1): Cleveland Clinic continence score

The Wexner score					
Type of Incontinence	**Frequency**				
	Never	**Rarely**	**Sometimes**	**Usually**	**Always**
Solid	0	1	2	3	4
Liquid	0	1	2	3	4
Gas	0	1	2	3	4
Wears pads	0	1	2	3	4
Lifestyle alteration	0	1	2	3	4

Never, 0; rarely, <1/month; sometimes, <1/week, 1/month; usually, <1/day, 1/week; always, 1/day. 0, perfect; 20, complete incontinence.

The patients were advised for follow up in outpatient clinic 7-14 days to assess the wound and early postoperative complications. 6 months later, anorectal continence was reassessed after complete wound healing.

Findings: Both groups were matched regarding the age and gender. The mean age for group (A) was 41.35 while that for group (B) was 39.5.

In group A, there were 8 (40%) with extrasphincteric fistulas, 4 (20%) with suprasphincteric fistulas and 8 (40%) with high transphincteric fistulas while in group B, there were 5 (25%) with extrasphincteric fistulas, 6 (30%) with suprasphincteric fistulas and 9 (45%) with high transphincteric fistulas.

There were 4(20%) patients with recurrent fistulas in group A and 3 (15%) in group B.

Four patients in each group had associated abscess collections that had been drained during fistula surgery.

According to Cleveland Clinic incontinence score for postoperative follow up, 4 patients developed incontinence in group B while all patients in group A were fully continents postoperatively (p = 0.038).

Table (2): Analytical results of the patients with high anal fistulas without preoperative biofeedback who had developed incontinence.

Fistula type	Preoperative Wexner score	Postoperative Wexner score
Extrasphincteric with abscess formation	0	8
Suprasphinctericfistulas with abscess	0	20
Suprasphincteric fistulas with abscess	0	20
Suprashincteric	0	4

Discussion

The fecal incontinence is a very frequent pathology, the frequency considered in the general population being 2-3%, although the studies of prevalence in the general population show a great variability[11]. Biofeedback training has been regarded as the conservative therapy of choice for fecal incontinence secondary to a variety of medical and surgical disorders in all age groups[12].

The preoperative biofeedback and pelvic exercises improve urinary control and decrease severity of urine incontinence following radical prostatectomy[13].

This was a randomized control study, which included forty patients who presented to the outpatient clinic of the colorectal unit in Kasr Alainy hospital in the period between from March 2015 to September 2016for colorectal surgery.

The purpose of this study was to assess anorectal biofeedback as a prophylactic measure for fecal incontinence after fistulectomy surgery for patients with complex fistulas.

In 2003, Fernandez et al. studied the effect of anorectal biofeedback on a total of 145 patients with anal incontinence (118 female and 27 male) Four weeks following completion of the sessions, 59 patients (76%) had improved significantly, 13 (17%) had improved slightly and 6 (8%) had not changed[14].

In 2007, Byrne et al. studied 513 patients, 385 (75 percent) completed the treatment program. In those completed the treatment program maximum anal sphincter pressure increased by a mean 12 mmHg (14 percent; from 90 to 102 mmHg)[15].

In 2004, Kairaluoma et al. studied biofeedback therapy in treating 22 patients with anal incontinence; 21 female and one male, with a median age of 57 (range 27–84) years. In this study manometry results suggested that the external sphincter function is improved by biofeedback therapy. However, there is no effect on resting pressure and internal sphincter function[16].

In 2003, Kienle et al. studied a consecutive patient series (N = 70) with anal sphincter deficiency and compare the efficacy of biofeedback and electrostimulation as conservative treatment options. Forty patients were treated by biofeedback therapy; Patients were not specifically selected for one or the other treatment. Resting and squeeze pressure increased significantly after biofeedback training ($P < 0.05$ and < 0.001)[17].

In 1994, Keck et al. studied fifteen patients (13 women and 2 men) with incontinence underwent a mean of three (range, 1–7) biofeedback sessions. The cause was obstetric (four patients), postsurgical (five patients), and idiopathic (six patients). Total resolution of symptoms was reported in four patients, favourable improvement in four patients and some improvement in three patients. Manometric measurements showed a mean increase of 15.3 mmHg in resting pressure and 35.7 mmHg in squeezing pressure after biofeedback[18].

In 2006, Dobben et al. studied 266 patients (91% female) and observed that the improvement in incontinence with the use of biofeedback was not associated with results in tests including anorectal manometry[19].

Conclusion

In our study twenty patients with high anal fistulas had received prophylactic biofeedback therapy with mean age of 41.35 years, all of them were completely continent postoperatively; another twenty patients with high anal fistulae had not received prophylactic preoperative biofeedback with mean age of 39.45 years, among them four patients had developed fecal incontinence with varying degrees (two patients had developed gas incontinence and another two had developed complete incontinence), so it had been found that preoperative prophylactic biofeedback has an important role to prevent or minimize incontinence post high anal fistula surgery (with P value of 0.038 when comparing both groups using the Wexner score) as it enhances the contraction capacity of the external sphincter muscles and has a role to teach the patients to perceive and react even the rectum is slightly dilated.

Preoperative prophylactic anorectal biofeedback reduces the incidence on anorectal incontinence after anal operations for high anal fistulae.

The use of biofeedback has shown that autonomic functions can be conditioned by training the mind to control them.

Biofeedback enhances the contraction capacity of the external sphincter muscles.

Biofeedback teaches the patient to perceive and react even if the rectum is slightly distended.

Abstract

Objective: To evaluate the value of human epididymis protein 4 (HE4) in predicting endometrial pathology in women with postmenopausal bleeding (PMB).

Method: A cohort study included 100 women with PMB. Women with endometrial thickness (ET) >5mm were subjected to hysteroscopic guided fractional curettage (FC) followed by total abdominal hysterectomy and bilateral salpingo-oophorectomy with or without pelvic lymphadenectomy.

After exclusion of 10 patients, the value of serum HE4 was tested in 90 patients for the ability to predict endometrial pathology based on hysterectomy specimen.

Results: Level of HE4 showed a significant difference among women with different endometrial pathologies. HE4 showed a significant positive correlation with the severity of the endometrial lesion, with mean values of 38.33±27 pmol/L for atrophic endometrium (11 cases), 51.26±28.59 pmol/L for simple endometrial hyperplasia (SEH, 51 cases), 148.4±67.34 pmol/L for atypical endometrial hyperplasia (AEH, 16 cases) and 390.9±351.72 pmol/L for endometrial carcinoma (EC,12 cases) Using the cut-off value of 69.5 pmol/L for preoperative HE4 yielded a sensitivity of 75% and a specificity of 88.5% in prediction of EC.

Conclusion: HE4 can predict endometrial pathology in women with PMB with a high specificity and a fair sensitivity.

Keywords: *Human epididymis protien4 (HE4); postmenopausal bleeding; endometrial carcinoma; endometrial pathology.*

Introduction

Endometrial carcinoma accounts for 20% to 30% of malignant tumors in the female reproductive system. As a consequence to increased obesity, hypertension, diabetes, and prolonged life expectancy, the incidence and mortality of endometrial carcinoma have risen lately, with a tendency for onset at a younger age [1]. The prognosis is closely related to the disease stage. If the diagnosis is during stage I, then the survival rate is about 90% [2].

There are no specific tumor markers for endometrial carcinoma. CA-125 was detected in 1983 by Bast et al.[3] as the epithelial ovarian carcinoma antigen. However, CA-125 is less effective in the diagnosis of EC compared with the diagnosis of other gynecological carcinomas. CA-125 can only produce obvious effect in diagnosing some common tumors in advanced stage [4] .

HE4 biomarker has been recently studied. It was identified in the epithelium of the distal epididymis and was predicted to be a protease inhibitor involved in sperm maturation [5]. In 2003, HE4 was approved by the FDA as a serum tumor marker for ovarian carcinoma and attracted great attention[6]. Recent studies indicate that HE4 is highly expressed in ovarian and endometrial carcinoma tissues with increased serum level in these patients as well[7].

Materials and Method

This prospective cohort study included 100 women with PMB who were recruited from Kasr Al Aini Hospital, Cairo University, Egypt between June 2014 and August 2016. An informed written consent was obtained from all participants prior to inclusion.

All patients included in the study had single or multiple episodes of PMB with an ET of more than 5mm. Exclusion criteria were having history of other malignancies, history of intake of chemotherapy or radiotherapy, the use of hormone replacement therapy, and being unfit for surgical intervention.

Full history was taken (including the duration of menopause, the number of episodes of PMB, and previous investigations and current medications), general examination was performed (including blood pressure measurement, calculation of body mass index (BMI= weight (kg)/[height (m)]^2, and the presence of any signs of systemic diseases), and local examination was performed for all patients.

Transvaginal ultrasound (TVS) done by the same observer to nullify the effect of inter observer variability.

For the level of HE4: 5 ml of venous blood were withdrawn from all patients. The samples were left to clot. The separated sera were stored at -20˚ until all samples were obtained. Frozen samples were allowed to reach room temperature prior to use. Samples were then mixed thoroughly by gently inverting multiple times before analysis. HE4 was quantitatively assayed using the enzyme immunoassay (EIA) method (Fujirebio Diagnostics, Inc. Göteborg, Sweden). The functional sensitivity of the HE4 EIA is ≤ 25pM. The analytical specificity is 100 ± 15%.

All patients were then submitted to hysteroscopy under general anesthesia and guided endometrial biopsy.

Definitive management was later performed in the form of total abdominal hysterectomy, bilateral salpingooophrectomy, with or without pelvic lymph nodal dissection and histopathological examination.

Results

Women with malignancy had significantly older age, lower parity, higher BMI and longer duration of menopause when compared to those with non-malignant lesion (table 1).

ET of the malignant group was significantly higher than that of the non-malignant group (20.33 ± 7.4 versus 12.68 ± 4.22mm, p: <0.001), level of preoperative serum HE4 was significantly higher in the malignant group as compared to the non-malignant group (390.92 ± 351.72 versus 61.25 ± 31.65pmol/L, p: <0.001) (table 1).

The level of HE4 in different endometrial pathologies of the cases group is presented in (table 2).

A scale was proposed in which the endometrial pathologies were arranged in a descending manner according to the severity of the lesion, where malignancy was the severest, followed by AEH, then SEH, and atrophic endometrium being the least severe form. Hence, correlation between the preoperative HE4 level and the severity of the endometrial lesion could be evaluated. This study showed that there was a significant strong positive correlation between the preoperative level of HE4 and the severity of the endometrial pathology (r= 0.735, p: <0.001).

ROC curve was generated to evaluate the performance of the preoperative level of HE4 in distinguishing malignant from non-malignant endometrium (figure 1).

Using the cut-off value of 69.5 pmol/L for preoperative HE4 yielded a sensitivity of 75%, a specificity of 88.5% and an AUC-ROC of 0.933 (table 3).

All malignant cases (12 cases) were of the endometrioid type, 5 were stage Ia, 5 were stage Ib, and 2 were stage II. All were operable and a total abdominal hysterectomy and bilateral salpingo-oophorectomy with pelvic lymphadenectomy was performed for all.

For the degree of differentiation, 2 cases were grade 1 (G1), 8 cases were grade 2 (G2), and 2 cases were grade 3 (G3).

Multivariate stepwise linear regression for factors with significant differences between malignant and non malignant cases as age, parity, and duration of menopause are shown in table 4.

The level of HE4 in the malignant cases according to the tumor stage, grade and lymph node involvement is described in table 5.

Discussion

In this study, we focused on examining the role of HE4 in distinguishing malignant from non-malignant lesions of the thickened endometrium in women with PMB through histopathological examination of hysteroscopic directed endometrial curettage followed by hysterectomy, and to correlate HE4 level with the endometrial lesion.

The prevalence of EC in the present study was 13.3%. This is similar to that reported in previous studies[8].

HE4 is a new detection index. Being highly expressed in ovarian and endometrial carcinoma cells [7].

In this study, the preoperative level of HE4 was significantly higher in the endometrial carcinoma cases than its level in the non-malignant cases.

HE4 actually exists in normal tissues e.g. male vas deferens, mammary gland epithelium, female genital tract including the endometrium [9]. So its level is suspected to increase with increased endometrial thickness. As suspected its level is increased in cancers arising from these tissues [10].

The National comprehensive cancer network in 2012 signified the value of HE4 as a tumour marker for epithelial ovarian tumors and as both the uterus and the ovary share a common embryological origin so HE4 can be used as a marker for endometrial tumors [11].

In the present study, upon examining the diagnostic performance of HE4 in predicting the presence of EC among patients with PMB, using the cut-off value of 69.5 pmol/L for preoperative HE4 yielded a sensitivity of 75% and a specificity of 88.5%, and an AUC-ROC of 0.933, Having more serious consequences separating AEH and EC patients from SEH and atrophic endometrium cases,HE4 was significantly higher in the former group 218.14 ± 273.46 versus 54.2 ± 22.45, $p < 0.001$ with a new cut off value calculated to help differentiation of AEH and EC cases, HE4 value of 62.5 pmol/L yielded a sensitivity of 85.9% and specificity of 62.9% with AUC of 0.832 .

Similar to our findings, previous study on 2015 reported the sensitivity and specificity of HE4 in distinguishing EC patients from healthy females were 62.2% and 95% respectively, with an AUC of 0.996 . Another one on the same year reported a sensitivity of 72.4% and a specificity of 75.4% for the cut-off 76.5 pmol/L [15]. Also, Capriglione et al in 2015 [16] reported sensitivity and specificity that are near to ours in detecting EC patients 83.3% and 96% respectively.

An earlier study on 2013 has reported that the sensitivity of HE4 in detecting malignant cases was 75% and the specificity was 65.5%, and that the sensitivity was improved after combining HE4 with other markers (CA-125, CEA, and serum amyloid –A) to be 84% [13].

Another publication in the same year revealed that the sensitivity of HE4 in detecting malignant endometrium was 59.4% with 100% specificity for the cut-off value of 70pmol/L. After adding CA-125, the sensitivity was elevated to be 60.4%. The authors concluded that HE4 at cutoff of 70 pmol/L yields the bestsensitivity and specificity [12]. The lower sensitivity of the marker in their study compared to ours might be due to that they took into consideration other types of EC while all our cases were of the endometrioid type.

Previous study on 2016 have reported that HE4 was significantly higher in grade 3 (G3) carcinomas compared with grade 1 (G1) and 2 (G2), and that patients who needed lymphadenectomy had significantly higher HE4 level than those who had no indications for this procedure[14].

A recent study on 2017 stated that preoperative serum HE4 is significantly correlated with primary tumor diameter and depth of myometrial invasion, but not with tumor grade or cervical involvement and lymphovascular infiltration and that serum HE4 levels could be useful in identifying EC patients at high risk of lymphatic spread who would benefit from lymphadenectomy[17].

A meta-analysis done in 2014 reported that HE4 is the most accurate and sensitive EC marker identified to date. In particular, this new marker seems to have a good performance in diagnosis. The best cut-off of HE4 in diagnosis ranges between 50 and 70 pmol/L, resulting at least in 78.8% of sensitivity and 100% of specificity in

all stages. Another important aspect to consider is HE4 capacity in predicting the stage of disease and myometrial involvement, which can help scheduling the appropriate timing of imaging and surgery in a more individualized fashion and as indicator of patient prognosis[18].

Our study confirmed the known fact that malignancy is suspected to be found in women with postmenopausal bleeding when they are older, lower parity, higher BMI and have longer interval between menopause and presentation.

ACOG confirmed these findings by stating that the clinically identified risks for carcinoma endometrium include age and high body fat [19].

The present study is strengthened by its prospective nature, and that it depended on hysterectomy specimen for diagnosis of different endometrial pathologies as well as malignancy, beside the analysis of positive results of lymphadenectomy.

The main limitation of the study is the small sample size included which resulted in a limited number of malignancy cases with the resultant limited variations in malignancy stages and pathological subtypes. Larger number of participants would have better detected the value of the studied marker (HE4) in diagnosis and prognosis of endometrial malignancies. Nevertheless, the study highlighted the presence of this new marker and pointed to its possible value in diagnosis of the disease and the prediction of its occurrence at certain cut-off value with the reported sensitivity and specificity.

Table (1): Characteristics of the studied population

	Malignant Group (n=12)	Non-malignant Group (n= 78)	P value
Age (Years)	63.5 ± 6.86	55.97 ± 5.68	<0.001
Parity	2.67 ± 1.49	4.71 ± 2.15	0.002
BMI (Kg/m2)	37.19 ± 5.58	32.95 ± 6.49	0.034
Duration of menopause (Years)	11.67 ± 5.41	4.83 ± 4.26	<0.001
Endometrial thickness (mm)	20.33 ± 7.4	12.68 ± 4.22	<0.001
Preoperative HE4 (pmol/L)	390.92 ± 351.72	61.25 ± 31.65	<0.001

Data are presented as mean±SD

Table (2): Level of HE4 in different endometrial pathologies

	EC (n= 12)	AEH (n= 16)	SEH (n= 51)	Atrophic endometrium (n= 11)	P value
HE4 (pmol/L)	390.92 ± 351.72	148.44 ± 67.34	51.26 ± 28.59	38.33 ± 27	<0.001

Data are presented as mean±SD

Table (3): Tests of diagnostic accuracy of preoperative HE4 level in distinguishing malignant from non-malignant endometrium

		Cut-off value	Sensitivity (%)	Specificity (%)	AUC-ROC	PPV	NPV	Accuracy
HE4 level (pmol/L)	Malignant versus non-malignant cases	69.5	75	88.5	0.933	50	95.8	86.7

Table (4): Multivariate stepwise linear regression for age, parity, and duration of menopause

	Beta Coefficient (Adjusted)	S.E.	Wald	p value	OR	95% CI for OR	
						Lower	Upper
Age	0.259	0.294	0.779	0.377	1.296	0.729	2.304

Evaluation of Eye Relaxation to Decrease Eye Strain in PT Japfa Comfeed Indonesia Unit Sragen

Aisy Rahmania[1], Noeroel Widajati[1], Abdul Rohim Tualeka[1]

[1]Departement of Occupational Health and Safety, Faculty of Public Health, Airlangga University, 60115, Surabaya, East Java, Indonesia

Abstract

Office worker currently relies heavily on the role of the computer to make work easier to input, processing, storage and transmission of data. The work at the office of PT Japfa Comfeed Indonesia Sragen is a job that demands labor staring at a computer screen for 8 hours per day, 5 days a week. However, looking at a computer screen for a long time can give negative effects called eyestrain which complaints such as: dry eye, red eye, eye sore, feels the eyes of blur, the eyes become doubles, headaches and neck strain. This research is a study of experiments provide relaxation eye on workers. Before working, eyestrain of worker group A and B were measured, then group A was given a relaxation of the eyes while the B was not. At the end of the work, the eyestrain of group A and B were measured again. The results of this research show that there are significant differences between the group A and B of workers with eyestrain. It can be drawn the conclusion that granting eye relaxation on workers using computer were able to decrease the complaints of eyestrain. The eye relaxation will have an optimal positive effect in reducing eye fatigue if the workers do correctly and routinely on every working day.

Keywords: *Eye Relaxation, Eye Strain.*

Introduction

Currently, computer users in Indonesia recorded about 55 percent of 88.1 million internet users[1]. Staring at the computer screen can cause an impact such as the strain-muscles of the eyes, neck pain, headaches, and dry eye. In 2016, as much as 90 percent of computer users in the United States are exposed to radiation from a computer screen more than 9 hours of work, while the common complaints can arise at least after the first two hours of work, and there were 57.8 percent of computer users had experienced the eyestrain[2]. Globally, prevalence of eyestrain in the world has reached 64-90 percent[3]. If the complaint of the eyestrain experienced by the workers are not prevented, that could arise more serious things such as strain on eyes and a decrease the ability of the eye's accommodation or loss of vision function[4]. One of the solution for the eyestrain is Eye Relaxation which is called 20's Rule.

Field survey was done by the researcher at PT. Japfa Comfeed Indonesia Tbk Unit Sragen found that about 70% of workers using computer complained of dry eye, and eye strain. These condition needs to be worried and should be given a prevention so as not to be worse.

Materials and Method

This study is experimental study with a certain eye relaxation. This research conducted at PT. Japfa Comfeed Indonesia Tbk Unit Sragen on Juni 2017. The population of the research are workers using computer at PT. Japfa Comfeed Indonesia Tbk Unit Sragen, with number 50 workers.

Relaxation is a series of eye relaxation activities which include: close the eyes for 10 seconds and open the eyes for 10 seconds with viewing direction ahead as far as 6 meters. That must be done three times, conducted every 20 minutes of exposure to radiation electromagnetic waves.

Measurement of the eye strain is using Questionaire CVSS17 that adopted from Gonzalez-Perez *et al* on 2014[5].

e. Term of work Group B	0.769	0.062
f. Sex Group B	0.974	-0.007

Source: Primary Data, June 2017.

From the statistical analysis above show that Respondents' Characteristics including age, work period, and sex of each group are not significantly related with eye strain of the workers. Then, the statistical analysis by *Independent T-test* shows that there is a significant differences between eye strain of workers in the group A and B, with the *p value* = 0.000.

Eye relaxation activities can reduce the fatigue or strain of workers' eyes because of staring at computer screen. This decrease occurs because of changes in the condition of the eye muscles. When looking at a computer screen, the eye muscles work to focus on the computer screen and experience tension due to maximum accommodation. Eye relaxation is done by changing the visibility of workers, seeing objects with a distance of six meters. Visibility change causes the eye muscles to relax and relax. Eyes that focus on a computer screen can trigger dry eyes. Eye relaxation is done by blinking at the object with a distance of six meters can help even the tears to the entire surface of the eye, so that the eyes stay awake in humid conditions. Statistically it also shows that there is a significant effect of eye relaxation on eye strain. The results of the study of Barthakur (2013) also showed that eye relaxation significantly affected eye strain[6].

The group A who did eye relaxation had a lower eye strain score compared to the group B who did not relax the eye with an average difference of 0.52. The difference shows a decrease in eye strain by 2.4%. The results of the study by Lertwisuttipaiboon *et al* (2016) also showed that giving eye relaxation can significantly reduce eye strain[7]. Another study was conducted by Gupta *et al* (2014) and it was proven that eye relaxation can reduce eye strain by 46.5% [8].

Eye strain can arise as the duration of a person stares at a computer screen[9]. Thorud *et al* (2012) showed that eye muscle strain arises after sixty minutes of accommodation. Eye relaxation activities are carried out every twenty minutes after staring at the computer screen. This activity is one of the steps to prevent eye strain, which is done before the eye muscles begin to experience significant tension[10].

Workers in this study have characteristics ranging in age from 20 to 45 where at that age a person naturally has normal functioning vision. Guyton and Hall (2014) also stated that someone over the age of 45 years will experience a decrease in accommodation power which will then affect the working of the eye muscles[11]. Test of correlation between age and eye strain in the two groups in this study showed a non-significant relationship, namely *p value* = 0.177 and *p value* = 0.227. The results of this study are supported by previous studies indicating that age does not have a significant relationship to eye strain (*p value* = 0.716)[12]. Das *et al* (2016) research also shows that age under 45 years does not have a significant relationship to eye strain (*p value* = 0.939)[13].

A total of 40 workers (80%) in this study were men where the remaining 10 workers (20%) were women. Correlation test in the control group and intervention in this study showed that gender did not have a significant relationship to eye strain, *p value* = 0.154 and *p value* = 0.974. This research is in line with the research of Zainuddin and Isa (2014) with *p value* = 0.205[12]. Another characteristic inherent in the workers of this study is the period of work. The results of the correlation test between work period and eye strain in the two groups showed a non-significant relationship, amounting to *p value* = 0.700 and *p value* = 0.769. This result is in line with the Arumugam study (2014) which shows that there is no relationship between years of service with complaints of eye strain(*p-value* = 0.328) and Zainuddin and Isa (2014) with *p value* = 0.664[14]. This study shows that all inherent characteristics of workers are not significantly related to the perceived strain of workers.

This study shows that all the characteristics inherent in the respondents were not significantly related to the perceived eye strain of the respondents. Giving eye relaxation in the intervention group produced an average eye strain score of 21.00 while in the control group had an average eye strain score of 21.52. Statistically, the strain scores of the two groups had significant differences. As for other factors that can trigger eye strain so that only the difference in eye strain was obtained in both groups of workers by 0.52 or 2.4%, may caused by the technique of implementing inappropriate to eye relaxation, history of eye disease (myopia, hypermetropy and astigmatism).

Conclusion

Based on this research, it can be conclude that: There is a difference of the eye strain significantly between Group A and B due to granting eye relaxation, amounted to 2.4% decrease eyestrain of workers who perform a eye relaxation.

1. Characteristics of the workers in this research include age, period of employment and gender have no risk to experience eyestrain.
2. Doing the eye relaxation as well as the workers' try to do, relax the eye correctly and routinely on every working day so that workers can get optimal results of doing the eye relaxation.

Conflicts of Interest: All of Authors have no conflicts of interest to declare.

Source of Funding: This article "Evaluation of Eye Relaxation to Decrease Eye Strain in PT Japfa Comfeed Indonesia Sragen" was funded by the Author.

Ethical Clearance: The study was approved by the institutional Ethical Board of Dr. Moewardi Hospital, Surakarta with the registration number: R0213002-4547.

All of subjects were fully informed about the procedures and objectives of the study then each subject signed an informed consent form.

Effectiveness of Dorsata Honey Suplement on Interleukin-3 Levels in Breast Cancer Patients Who Underwent Chemotherapy

Aji Kurniawan[1], Daniel Sampepajung[1], Salman Ardy Syamsu[1], Prihantono Prihantono[1]

[1]*Department of Surgery, Faculty of Medicine, Hasanuddin University, Makassar, Indonesia*

Abstract

Chemotherapy causes debilitating side effects include a decrease in blood cell counts. Interleukin-3 (IL-3) is a hematopoietic growth factor with extensive and multipotent activity. Honey is a natural product that has been widely used and researched for its therapeutic effects including increase the formation of blood cells. The purpose of this study was to determine the effect of honey supplement to IL-3 levels in breast cancer patients who underwent chemotherapy. The study sample included all populations diagnosed with breast cancer by the clinician in the Surgical Oncology Department of Dr. Wahidin Sudirohusodo Hospital Makassar who met the criteria for the period September to November 2018, divided into two groups, intervention and control. The intervention group was given honey orally three times a day at a dose of 15 ml (2 tablespoons) for 15 days. Examination of blood samples to measure IL-3 levels through ELISA. The statistical analysis performed is descriptive statistic calculation, frequency distribution and Chi Square statistical test, Independent-t and Paired-t test, with P <0.05. The results of this study showed a significant increase in mean IL-3 levels in the group that received honey which was 70.07 pg/dL compared to 143.46 pg/dL with an average increase of 73.4 pg/dL (104.7%; p < 0.05), while the group that did not get honey did not experience a statistically significant change of 88.88 pg/dL compared to 84.36 pg/dL, the mean decrease was 4.52 pg/dL (5.1%; p> 0.05). Conclusion: Honey supplementation increases IL-3 levels in breast cancer patients underwent chemotherapy.

Keywords: *Breast Cancer, Chemotherapy, Interleukin-3, dorsata, honey.*

Introduction

Breast cancer is the most malignancy in women and affects the lives of one in 10 women. Breast cancer is the leading cause of death in women worldwide, representing 38 million (23%) of total new cancer cases and 458,400 (14%) of total cancer deaths in 2008.[1] In 2015 an estimated 231,840 new breast cancer cases were found in women and 40,730 deaths due to breast cancer occurring in the United States. [2]

Breast cancer therapy requires multiple therapeutic modalities, each of which has its own advantages and disadvantages. Some of them are surgery, chemotherapy, radiotherapy, hormonal therapy and molecular therapeutic targeting. As one of the modalities in the treatment of breast cancer, chemotherapy still has a major role in the treatment of patients with breast cancer. Widely used as adjuvant therapy after patients undergo surgical removal of tumors for healing or preventing recurrence and as palliative therapy in patients with metastatic disease. Chemotherapy causes a wide range of effects that cause symptoms that weaken and greatly affect the quality of life of patients. Nausea, vomiting, hair loss and a decrease in the number of blood cells are the most frequent acute side effects. Decreasing the number of blood cells can be a decrease in the number of erythrocyte cells (anemia), platelets (thrombocytopenia) and white blood cells (leukopenia). In chemotherapy, neutropenia associated with chemotherapy doses is at risk for infection. Thrombocytopenia is another problem with the toxicity of chemotherapy which can lead to delayed chemotherapy, reduction in dosage and requiring platelet transfusion

Interleukin-3 (IL-3) is a hematopoietic growth factor with clear thrombopoietic activity and extensive

and multipotent activity. IL-3 is a glycoprotein which is produced mainly by activated T cells. IL-3 regulates the proliferation and differentiation of pluripotent stem cells and progenitor cells from various hematopoietic lineages, including megakaryocytes, granulocytes, and erythrocytes. IL-3 also stimulates the function of several adult cells, including neutophils, eosinophils and monocytes. Available for clinical trials since 1993, IL-3 has been used by more than two thousand patients. From the research data so far it has been shown that IL-3 alone or in combination with other cytokines has become the first thrombopoietic factor available for clinical use which allows patients to undergo chemotherapy at intervals and doses according to standards that are expected to increase recovery rates. Recombinant human (rh) IL-3 has been evaluated in patients undergoing cancer chemotherapy, after bone marrow transplantation, bone marrow failure, for blood mobilization and hematopoietic progenitor cell transplantation and in combination with other Colony-stimulating factors (CSF) including Granulocyte -macrophage (GM) -CSF and granulocyte (G) -CSF. Results from stage I-II studies indicate that IL-3 alone or in combination with G- or GM-CSF can reduce or eliminate the duration and severity of thrombopenia and reduce neutropenia. [3]

Honey is a natural product that has been widely used for its therapeutic effects. It has been reported that honey contains more than 200 substrates. Its main composition is glucose and fructose but also contains fructo-oligosaccharides and many amino acids, mineral vitamins and enzymes. The composition of honey varies depending on the plant's nectar source. But almost all honey contains flavanoids (such as apigenin, pinocembrin, kaemferol, quercetin, galangin, chrysin and hesperin), phenolic acids (such as ellagic, caffeic, p-coumaric and ferulic acid), ascorbic acid, tocopherols, catalase (CAT), superocside dismutase (SOD), reduced glutathione (GSH), Milard reaction products and peptides. Most of these components work together to provide a synergistic antioxidant effect. Honey has long been used in health, both as a supplement and in medicine. Because of its potential, research on honey has begun to be carried out.[4] Flavanoids and polyphenols are the two main bioactive molecules present in honey. According to modern scientific literature, honey has a protective effect for therapy in various conditions such as diabetes, respiratory, gastrointestinal, cardiovascular and nervous systems, even useful in cancer therapy. Honey should be considered a natural therapeutic agent for disease conditions and therefore the use of honey in clinical care is highly recommended.[5] Some studies have mentioned the effects of honey as an antioxidant, natural antimicrobial, immune booster, anti-inflammatory, potentially in cancer therapy and can increase the formation of blood cells. From studies it has been found that there is an increase in CD4, CD8, erythrocytes, leukocytes, platelets, neutrophil counts and lymphocytes after 30 days of honey intake.[6] This is important because CD4, CD8 and lymphocytes are the main sources of IL-3. From other studies honey is also effective in reducing the incidence of anemia in 64% of patients and decreases the incidence of severe neutropenia, although 40% of patients still need CSFs.[7]

From the above, it is necessary to study the effects of honey on the levels of Interleukin-3 breast cancer patients who are undergoing chemotherapy because Interleukin-3 greatly affects the process of hematopoiesis, especially in breast cancer patients who underwent chemotherapy with the potential for interference. The purpose of this study was to determine the effect of giving honey to IL-3 levels in breast cancer patients who underwent chemotherapy

Materials and Method

Collection of Samples: This study was a experimental study using the pretest-posttest group control model, the experimental effects were measured before and after treatment. The study sample was the population of breast cancer patients, diagnosed by the clinician in the Surgical Oncology Department of RSUP Dr. Wahidin Sudirohusodo Makassar, from September to November 2018.

Inclusion criteria: Adult women diagnosed with locally advanced breast cancer by the clinician in the Surgical Oncology Departement and confirmed by histopathological examination, had never received breast cancer therapy, were willing to take part in the study by signing an informed consent.

Exclusion criteria: Lipemic, jaundice or hemolysis specimens, patients detected with other primary malignancies.

The study began with random sample selection for the control group and intervention group. Each informed consent was given, for the treatment group, dorsata honey was given orally three times a day (morning/ afternoon/night) at a dose of 15 ml (2 tablespoons) for

15 days. And for the control group recommends patients to take vitamin supplements and nutritious foods. Blood sampling as inspection is done twice, before the start of the intervention (day 0 chemotherapy), and then continued the examination of 2nd samples on day 16th (post chemotherapy). Interleukin-3 levels were measured from blood plasma samples and measured by ELISA.

Data Analysis: All collected data are grouped according to the purpose and type of data, then analyzed using SPSS version 22. The statistical analysis performed is descriptive statistic calculation, frequency distribution and Chi Square statistical test, Independent-t and Paired-t test, with P <0.05.

Ethical Clearance: Ethical approval for this study was obtained from the Research Ethics Committee, Faculty of Medicine, Hasanuddin University, Makassar, Indonesia. Number; 732/H4.8.4.5.31/ PP36-KOMETIK/2018.

Results

Sample Characteristics: The samples analyzed were 30 breast cancer patients, consisting of groups who received honey supplements (intervention) and groups that did not get honey supplements (controls), each of them 15 people. The age of subjects was 23-61 years with a mean of 47.3 ± 7.5 years (median 47 years). The results of IL-3 measurements before chemotherapy varied between 11.78-350.00 pg/dL with a mean of 79.47 ± 70.70 pg/dL (median 63.6), whereas after chemotherapy had a value between 35.64-350.00 with an average of 113.91 ± 87.54 pg/dL showed in Table 1.

Table 1. Age and IL-3 Descriptive Statistics (n = 30)

Variable	Min (pg/dL)	Max (pg/dL)	Median	Mean	SD
Age	23	61	47,00	47,30	7,51
IL-3 Before Chemotherapy	11,78	350,00	63,60	79,47	70,70
IL-3 After Chemotherapy	35,64	350,00	82,83	113,91	87,54

The distribution of samples based on chemotherapy regimens, histopathology grading and stadium showed that most subjects received TAC (docetaxel, adriamicin, cyclophosphamide) chemotherapy (76.7%), grade moderate (83.3%) and stage III B (73, 3%) showed in Table 2.

Table 2. Distribution of Chemotherapy Regiment, Histopathological Results, Grading and Stage of Carcinoma Mammae

Variable		n	%
Chemotherapy Regiment	TAC (Docetaxel, Adriamycin, Cyclophosphamide)	23	76,7
	CAF (Cyclophosphamide, Adriamycin, Fluorouracil)	7	23,3
Grade	Low	1	3,3
	Moderate	25	83,3
	High	4	13,3
Stadium	III A	2	6,7
	III B	22	73,3
	III C	6	20,0

Comparative Analysis of IL-3 Levels by Group: The mean IL-3 level before chemotherapy was found to be higher in the control group than in the intervention group, which was 88.88 pg/dL compared with 70.07 pg/dL, although it was not statistically significant (p> 0.05). showed in table 3.

Table 3. Distribution of Chemotherapy Regiment, Histopathological Results, Grading and Stage of Carcinoma Mammae

Variable	Group	N	Mean	SD	P
IL-3 Before Chemotherapy	Intervention Control	15 15	70.07 88.88	69.45 73.08	0.476
IL-3 After Chemotherapy	Intervention Control	15 15	143.46 84.36	112.20 37.61	0.070

The mean IL-3 levels after chemotherapy were found to be higher in the intervention group than in the control group, namely 143.46 pg/dL compared to 84.36 pg/dL, although it was not statistically significant ($p > 0.05$). showed in table 3.

In the intervention group, there was a significant increase in IL-3 levels after chemotherapy compared to before chemotherapy, which was 143.46 pg/dL compared to 70.07 pg/dL ($p < 0.05$). The mean increase in IL-3 after chemotherapy was 73.4 pg/dL or increased by 104.7%. showed in table 4.

Table 4. Comparison of IL-3 levels before and after chemotherapy

Group	Variable	N	Mean	SD	P
Intervention	IL-3 Before Chemotherapy IL-3 After Chemotherapy	15 15	70.07 143.46	69.45 112.20	0.01
Control	IL-3 Before Chemotherapy IL-3 After Chemotherapy	15 15	88.88 84.36	73.08 37.61	0.84

In the control group, there was a decrease in IL-3 levels after chemotherapy compared to before chemotherapy, namely 84.36 pg/dL compared to 88.88 pg/dL, but not statistically significant ($p > 0.05$). The mean reduction in IL-3 after chemotherapy was 4.52 or decreased 5.1%. showed in table 4.

Discussion

In this study, there were 30 samples of breast cancer patients where 15 were given treatment and 15 were controls. The age of subjects was 23-61 years with a mean of 47.3 ± 7.5 years (median 47 years). From this study, the average age of respondents was 47 years. This is in line with the journal presented by Irwan in 2014 which stated that the incidence of breast cancer was more in patients over the age of 40 years. The Partini study in 2016 showed the same pattern.[8]

Based on grade, the highest was moderate grade (83.3%). This is in line with the intensive study in 2010 where it was stated that moderate grade was the most common tumor grading. Research data by Irwan also showed the same thing.[7,8]

Stage III B (73.3%) is the most common stadium found in this study. Partini in 2016 stated that the most stadiums were stage III B. So this study had stadium distribution conformity with the research.[10]

The mean IL-3 level before chemotherapy was found to be higher in the control group than in the intervention group, which was 88.88 pg/dL compared with 70.07 pg/dL, although it was not statistically significant ($p > 0.05$). This shows that although the average IL-3 level before chemotherapy in the control state is higher than the intervention group does not have a statistical effect.

The mean IL-3 levels after chemotherapy were found to be higher in the intervention group than in the control group, namely 143.46 pg/dL compared with 84.36 pg/dL, although it was not statistically significant ($p > 0.05$). This shows that although the rate of IL-3 levels after chemotherapy in the intervention group was higher than the control group did not have statistical effect. When viewed from changes in IL-3 levels between before and after chemotherapy, in the control group there was a decrease in the mean IL-3 levels in the control group 84.36 pg/dL compared to 88.88 pg/

dL, but not statistically significant (p> 0.05). The mean reduction in IL-3 after chemotherapy was 4.52 pg/dL or decreased 5.1%.

According to Verma et al .'s study, it was said that T lymphocyte levels, B lymphocytes and NK cells decreased significantly within 2 weeks after chemotherapy even especially B cells and CD4 T cells remained significantly decreased in 9 months post chemotherapy. [11] In another study, Mackall said that although the number of neutrophils, monocytes and platelets consistently improved due to therapy at the end of each cycle, the number of lymphocytes did not improve in the same period of time. Because CD4, CD8 and lymphocytes are the main sources of IL-3, of course this affects the IL-3 levels.[12]

Whereas in the intervention group there was an increase in the mean IL-3 level of 143.46 pg/dL compared to 70.07 pg/dL (p <0.05). The mean increase in IL-3 after chemotherapy was 73.4 pg/dL or increased by 104.7%. Honey supplementation according to Heidari in his research led to an increase in CD4, CD8, erythrocytes, leukocytes, platelets, neutrophil counts and lymphocytes after 30 days of honey intake. [6] In addition, Porcza in a review of his study said that consumption of honey 1.2 g/kg body weight dissolved in 250 cc of water could produce a 50% increase in the number of peripheral monocytes and slightly increase the presentation of lymphocytes and eosinophils. [13] This increase in cells can increase IL-3 levels according to this study. Even honey supplements are also given to reduce the incidence of anemia in 64% of patients and reduce the incidence of severe neutropenia in chemotherapy patients whose treatment is by giving CSFs including human IL-3, although 40% of patients still need CSFs.[7]

Conclusion

The result of this study shows that honey supplementation increases IL-3 levels in breast cancer patients underwent chemotherapy. Suggested to for honey supplements in breast cancer patients undergoing chemotherapy so that the patient's IL-3 levels are maintained.

Acknowledgments: We give our gratitude to Hasanuddin University Hospital staff and also for breast cancer patients who supported and participated in this research.

Effect of Blood Sampling Method During a Mating Time in Male Camels (Dromedary Camels)

Alaakamil Abdulla[1], Ali Habeeb Jaber AL-bdeery[2], Basim Hameed Abed Ali[2]

[1]Department of Medical Biotechnology, Faculty of Biotechnology, [2]Department of Surgery and Obstetrics, Faculty of Veterinary Medicine, University of Al-Qadisiyah, Iraq

Abstract

This study was to shed light on levels of testosterone and cortisol hormones in male dromedary camels during the mating time, by collection the blood samples using the manual method and compared with the remote-controlled blood sampling (RBS) method, to assess whether either these method had affected changes in the concentration of the hormones or not. The blood samples were collected from fifteen adult male camels, via two experiment with one-day intervals: first experiment by manual method during three periods (pre-mating, mating, and post-mating) one hour between each period, and the second experiment by the RBS in the same protocol. The serum testosterone and cortisol concentrations of all animals were determined via ELISA technique. The result which appearance a significant difference in the mating time used RBS compared with manual method. These findings might be due to the withdrawal of blood remotely which could cause a reduction of excitement in animals using the manual blood sampling at the presence of veterinarians, so it was considered as an ideal method to measure hormonal concentrations, especially in experiments which need accurate results.

Keywords: *Camels, Cortisol, Mating, Remote-Controlled Blood Sampling, Testosterone.*

Introduction

The breeding season of dromedary camels is at the coldest winter months of the year[(1)]. In this season, these camels become very aggressive towards other males and humans and their handling is thus considered very difficult and the copulation begins with foreplays and such behaviors are disappeared after rutting[(2)]. Most researchers have adopted different procedures to determine the blood testosterone level in order to clarify the characteristics of reproductive phenomena, reach an understanding of physiological status, and also determine libido and sexual behaviors in these animals[(3)]. The cortisol hormone has been similarly used as an indicator of stress in dromedary camels[(4)] and in other animals[(5)], the serum cortisol which increases during acute stress is largely made up of free cortisol; therefore, its concentration can be influenced by stress and physical stimulation of dromedary camels when they are exposed to stressors which also cause deregulation of sexual hormones[(6,7)]. Collection of blood samples to measure hormones can be invasive, and values can potentially be confounded by handling stress which may lead to alternative measurements of hormone levels[(8)]. In this respect, remote-controlled blood sampling (RBS) is a powerful device to take blood samples and consequently give important information on animal health status, like hormonal access[(9)], yet the traditional or manual blood sampling method has its own restrictions and it cannot be possibly used due to male camel aggression during this time. The same restrictions can also lead to stress reactions even in animals accustomed to the given procedure[(10)] which results in increased levels of cortisol due to the activation of hypothalamic stimulation-pituitary-adrenal axis during this sampling[(11)]. It is clear that the RBS device placed on animals will be more convenient than the manual blood sampling method, especially when a series of blood samples are needed [(12)]. Accordingly, the present study aimed to verify the levels of testosterone and cortisol hormones in the breeding season of male dromedary camels during the mating time. To this end, blood samples were taken using the traditional method and compared with the levels of these hormones using the RBS device, to assess whether either the given method had affected changes in the concentration of

the hormones or not, and to improve understanding of reproductive mechanisms and development.

Materials and Method

The present study was conducted in the bio-molecular laboratory of the College of Biotechnology at the University of Al-Qadisiyah, Iraq. The blood samples were then collected from camel herds in southern of Iraq, during the rutting season (December-February/2017-2018), with intervals. There were a fifteen of adult males (8-10 years of age) with good bodily conditions. Animals' age was also determined based on dental formula described in Ibrahim et al [13].

Experimental Protocol: All samples were collected by two experiments with a one-day interval from a total numbers of the male camels marketed from dromedary camels which were clinically healthy.

First Experiment: The blood samples (5 ml) were collected from the jugular vein by the manual (traditional) method via syringe (gauge 18) in three periods. The first period was before the male camel's exposure to estrus she-camel (pre-mating), the second period occurred one hour following the first period during the copulation time (mating period), and the third period took place after one hour from copulation (post-mating). In this experiment, the researchers had great difficulty in blood sample collection due to the camels became very dangerous and often unfriendly, so the camels were frequently motion and kicking. They also lost the jugular vein was puncture and occasionally the needle and the syringe were broken.

Second Experiment: Following one day after the first experiment, the blood samples were taken remotely in the same periods by the made locally modified RBS device of the AUTOMATIC BLOOD SAMPLING which used by Fonss A and Munksgaard[9] which was to reducing the weight, size and facilitate its fixation on the camel's neck using installation belts to prevent animal sensitivity and reduce nervousness (Figure 1). All blood samples were further allowed to clot for two hours at room temperature and then centrifuged for 20 minutes at 3000 rpm., the supernatants were also collected carefully, and then placed in the eppindroph tub before storage at -20°C until hormonal analysis.

Hormonal Assay: The serum testosterone and cortisol levels of all animals were determined in the bio-molecular laboratory of the College of Biotechnology at the University of Al-Qadisiyah using the enzyme-linked immunosorbent assay (ELISA) in adult male camels, validated and accredited by male dromedary camel's serum (all samples were analyzed in duplicate). The results were then expressed in ng/ml

in which both kits (MyBioSource Company, TESTO Elisa kit, Camel Testosterone ELISA Kit - MBS107991 and CORT Elisa kit, Camel Cortisol ELISA Kit-MBS082766/USA) were also processed, according to the manufactory protocol.

Statistical Analysis: All the values were expressed as mean ± standard error (SE) and subjected to analysis using two-way analysis of variance (ANOVA). The significance level among different parameters was calculated at $p<0.05$. The software used was the IBM SPSS program package (Version 23)[14].

Results

First Experiment: The findings revealed that the mean±SE of the serum testosterone concentration in pre-mating, mating, and post-mating periods were 14.1438±0.5833, 26.2675±0.8523, and 24.037±1.0071 ng/ml of; respectively, yet the serum cortisol in these periods were 44.8725±5.0133, 32.4775±1.9738, and 40.7688±3.0897 ng/ml; respectively (Table 1 & Figure 2).

Second Experiment: Using the RBS device, the concentration values of the serum testosterone concentration were reported by 16.8925±0.7008, 32.8563±1.3292, and 29.8519±1.0736 in pre-mating, mating, and post-mating periods respectively. However, the means of serum cortisol concentration in three periods, such values were 30.1918±3.0299, 21.4425±1.8629, and 22.4013±1.8645 ng/ml; respectively (Table 1 & Figure 2).

Table 1: Concentrations of testosterone and cortisol hormones (ng/ml) using the manual method and the RBS device in three periods for fifteen samples.

Periods	Testosterone (Mean±SE)*		Cortisol (Mean±SE)	
	Manual	RBS device	Manual	RBS device
Pre-mating	14.1438±0.5833 ^{Aa}	16.8925±0.7008 ^{Ba}	44.8725±5.0133 ^{Aa}	30.1918±3.0299 ^{Aa}

Discussion

The present data obtained from the manual method of blood sampling (first experiment) indicated that the serum testosterone level increased in the mating time compared with those in the pre-mating and post-mating ones (Table 1 & Figure 2). The given rise may be due to

interactions with libido in male camels, these findings were in agreement with Aubè et al[15]. The testosterone hormone acting as a positive regulator of sexual desire has been also reported in many animals like horses, camels[15], monkeys[16] and in humans[17]. that were confirmed by studies of Goldey and Van Anders[18] in which recorded decrease the testosterone level in men had led to reduced libido; moreover, increase in the activity of enzymes synthesizing the testosterone hormone was greater in the breeding than the non-breeding season [19]. The activation of the hypothalamus-pituitary-adrenal axis and this can lead to a suppression of luteinizing hormone release because of the dysregulation of homeostasis (stress) and triggers an adaptive stress response [20]. Our study results were discrepancy with concluded of Exton et al [21] that orgasm in humans did not acutely affect testosterone levels in the blood. It was also argued that sex in men did not have any effects on testosterone levels but rather it could positively influence the production of testosterone [22]. Yet, a statistically significant increase in serum testosterone concentration in our study during mating time by using both sampling method were in consonance with those experiments in men in which plasma levels of testosterone were compared and examined before and after mating periods, yet in the second experiment, the RBS device as another method employed for blood collection which was applied on the same camels after one day following the first experiment to record the results in the same periods of libido. These findings confirmed the relationship between testosterone hormone levels and mating efficiency. On the other hand, the concentration of this hormone was highly significant ($p<0.05$) in a way that it had elevated greater compared with the manual method (Table 1 & Figure 2), The manual method might have caused stress or fear in animals, so the mean testosterone level in the pre-mating, mating and post-mating periods were significantly lower than those in the second experiment. The reason for given elevation was significantly reduced tension, stress, and fear in animals induced by veterinarians. So, the withdrawal of blood in routine method by syringe or cannula may lead to the secretion of some hormones like cortisol, that may cause a reduction of secretion in the testosterone hormone during intercourse. That testosterone hormone could influence libido in male camels. According to Peeters et al [23], one needs to assess the stress state when measuring free cortisol in serum. In this regard, the cortisol hormone level was elevated in all three periods using the manual method compared with the second experiment in which this level had declined because cortisol had been increased in response to physiological stress and fear which was in line with studies such as Chen et al, [24], Erickson et al [25]. According our result, we suggested the cortisol can be blocked by the testosterone actions and cause less testosterone which influences behaviors like mating since, but finding of Tajik et al [5] it was argued that the serum cortisol did not change significantly due to stress in the sheep and cattle; however, yet Chen et al [24] showed a significant increase which did not consistently change. The findings of this study were in line with other research investigations like Gordon et al [26] in which it was indicated that there were numerous interactions between stress and reproductive functions, and stress lead to stimulation of the hypothalamic-pituitary-adrenal axis might have reduced fertility in horses, caused by stress. In addition to the cortisol hormone in most mammals as well as fish and amphibians, corticosterone in reptiles and birds also plays an important role in all stasis as they are involved in the regulation of the hypothalamic-pituitary-adrenal axis [27].

Conclusion

There was a statistically significant difference between the concentrations of the testosterone hormones during the mating period and intercourse. Using the RBS device which led to reduced cortisol concentrations, the testosterone levels increased. These findings might be due to the withdrawal of blood remotely which could cause a reduction of excitement in animals using the manual blood sampling at the presence of veterinarians, so it was considered as an ideal method to measure hormonal concentrations, especially in experiments which need accurate results.

Hyaluronidase Versus Magnesium Sulphate as Adjuvants to Bupivacaine in Ultrasound Guided Supraclavicular Brachial Plexus Block in Upper Limb Surgeries

Amany K abo Elhusein[1], Mamdouh Hassan[1], Nagat A. Ali[1]

[1]Department of Anesthesiology, Faculty of Medicine, Minia University, Minia, Egypt

Abstract

Background: Aim of this trial was to assess the effect of hyaluronidase and MgSo4 when added separately or in combination to bupivacaine on the onset of sensory and motor block, quality of block and effect on duration of action.

Method: Eighty ASA I, II patients of either sex undergoing upper limb Surgery under ultrasound-guided supraclavicular brachial block were recruited in this prospective randomized double blinded controlled study and divided in to four groups each group contain 20 patients. First group received (28 ml 0.5% bupivacaine and 2 ml 0.9% normal saline). Second group received (28 ml 0.5% bupivacaine and 1000 unit hyaluronidase dissolved in 2 ml 0.9% normal saline). Third group received (28 ml 0.5% bupivacaine and 2 ml of MgSo4 containing 200 mg). Fourth group received (28 ml 0.5% bupivacaine and 2 ml of MgSo4 containing 200 mg mixed with 500 unit hyaluronidase).

Results: Hyaluronidase fastened the onset but didn't affect the duration however MgSo4 prolonged the duration of postoperative analgesia without effect on the onset of block

Keywords: *Regional, brachial plexus; local anesthetics, bupivacaine, equipment, ultrasound machines; hyaluronidase; MgSo4.*

Introduction

Supraclavicular nerve block is ideal for procedures of the upper arm, from the mid humeral level down to the hand. It has a rapid onset, with a dense and predictable level of pain control [1].

Hyaluronidase, the mucolytic enzyme which acts on the muco-polysaccharide hyaloronic acid, is generally considered to be "spreading factor". When used with local anesthetics, hyaluronidase hastens the onset of analgesia and shortens its duration of effect[2].

Magnesium sulphate acts as an adjuvant in analgesia due to its properties of calcium channel blocking and N-methyl-D-aspartate antagonism. Magnesium has been shown to decrease peripheral nerve excitability and to enhance the ability of lidocaine to raise the excitation threshold of A-beta fibers[3].

Ultrasound guidance has dramatically improved nerve localization and offers several advantages as direct visualization of nerves and anatomical structures, facilitated visualization of local anesthetic spread in real time, produced good compensation for anatomical variation, reduced incidence of complications[4].

Method

This prospective, randomized, double blind controlled clinical study was carried out after obtaining the local ethics committee of El-Minia university hospital approval and written informed consent was taken from the patients. It was done between September

2017 to December 2018, 90 patients of both sexes, ASA I and II, aged between 18-65 years old scheduled to undergo elective and urgent distal arm, forearm and hand surgeries under ultrasound guided supraclavicular brachial plexus block, 80 patients were enrolled in this study and ten were excluded due to block failure.

Preoperative assessment and preparation: A careful assessment of medical history was done. Routine preoperative general examination and local examination of the site of injection for signs of infection or any other pathology were carried out. Routine investigations were done. Explanation of visual analogue pain scale was done VAPS is consisted of a straight, vertical 10-cm line; the bottom point represented "no pain"= (0 cm) and the top "the worst pain you could ever have. Two mg midazolam IV was given as a premedication 5 minutes before the block.

Equipment: The ultrasound device Sonosite, micromaxx, Lubricating gel, 21-gauge 50 mm length short bevel insulated stimulating needl, 10-ml syringes for injection, Sterile gloves, 25-gauge needle for skin infiltration, Sterile towels and sterile antiseptic solution (Povidone-iodine 10%).

All medications were prepared in similar sterile coated bottles and coded then passed to the anesthesiologist who is blind to its manner. In this prospective randomized double blinded controlled study 80 bottles numbered from 1 to 80 were prepared and divided in to four groups each group containe 20 bottles. Then the patients were randomly assigned to study groups.

Group (I): Received 28 ml bupivacaine (0.5%) + 2 ml saline (0.9%).

Group (II): Received 28 ml bupivacaine (0.5%) + 1000 unit hyaluronidase dissolved in 2 ml saline (0.9%).

Group (III): Received 28 ml bupivacaine (0.5%) + 2 ml MgSo4 containing 200 mg.

Group (IV): Received 28 ml bupivacaine (0.5%) + 2 ml MgSo4 containing 200 mg mixed with 1000 unit hyaluronidase.

Block Technique: A 20 G intravenous cannula was inserted in a peripheral vein of unaffected upper limb and standard monitoring was provided. Patient lie down supine with head turned to the contralateral side and ipsilateral arm adducted gently by the assistant. Skin was sterilized and infiltrated with 1-2 ml of lidocaine 2% at the needle entry site.

The brachial plexus was visualized by placing ultrasound probe in the sagittal plane in the supraclavicular fossa behind the middle-third of the clavicleas 3 hypoechoic circles with hyperechoic outer rings or as a grape like cluster of 5 to 6 hypoechoic circles, lateral and superior to the subclavian artery between the anterior and middle scalene muscles at the lower cervical region.

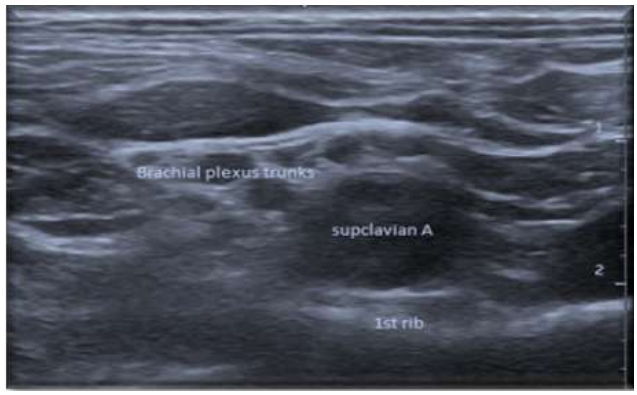

Fig (1): Ultrasonographic imaging of brachial plexus

Parameters Assessed: The anesthesiologist who gave the block recorded the onset of sensory and motor block and recorded intraoperative data then the postoperative care physician recorded the duration of block and postoperative data.

The hemodynamic variables were assessed and recorded 5 minutes before the block as a baseline value, immediately after the block 0,10,20,30,60, 90 minutes during the operative time then 1,2,4,6, and 12 hours after the end of operation. Quality of sensory block was assessed by pin prick test using a 3-point scale [5] Grade 0 = normal sensation, Grade 1 = loss of sensation of pin prick (analgesia), and Grade 2 = loss of sensation of touch (anesthesia).

Also motor block quality was determined by thumb abduction (radial nerve), thumb adduction (ulnar nerve), thumb opposition (median nerve), and flexion of elbow (musculocutaneous nerve) according to the modified Bromage scale 1997 [6] on a 3-point scale. **Grade 0:** Normal motor function with full flexion and extension of elbow, wrist, and fingers. **Grade 1**: Decreased motor strength with ability to move the fingers only. **Grade2:** Complete motor block with inability to move the fingers.

Pain intensity was assessed using **VAPS**. It was

measured before starting the nerve block then 15, 30, 60, 90, 120 minutes after nerve block. When it is more or equals 4 cm we gave analgesia or sedation using fentanyl and propofol during operation. Then Patients were asked to rate their pain intensity at 2, 4, 8, 12, and 24 hours postoperative and if it was more than four paracetamol 1000 mg bottle was given. Time of first analgesic request: The time from supraclavicular brachial plexus block administration to the patient's first request for analgesic medication by hours. Total analgesic requirements in 24 hours: The total amount of intravenous paracetamol which was given to the patient as a rescue analgesia or maintenance during 24 hours. Adverse effects: any adverse effects such as hypotension (i.e. 20% decrease relative to baseline), bradycardia (HR <50 beats/min), nausea, vomiting, hypoxemia (SpO2 <90%),local hematoma, hemothorax, pneumothorax,recurrent laryngeal nerve block, intravascular injection, Horner's syndrome and signs of local anesthetic toxicity were recorded during the operation and for 24 hours postoperative.

Results

During studying hemodynamic data changes among groups, The Mean Arterial blood pressure (mmHg) and arterial oxygen saturation changes during intraoperative or postoperative period were statistically insignificant between the four groups. As regard the Heart rate (beat\ min) we found it was lower in group (II, IV) than the other two groups (I, III) at time intervals of 10,20,30 and 60 minutes intraoperative but these changes were statistically insignificant.

Sensory, motor block onset and density of block were faster in groups (II & IV) than in groups (I & III) but the duration of sensory and motor block was found to be longer in groups (III & IV) than in groups (I & II) as presented in fig (2, 3, 4).

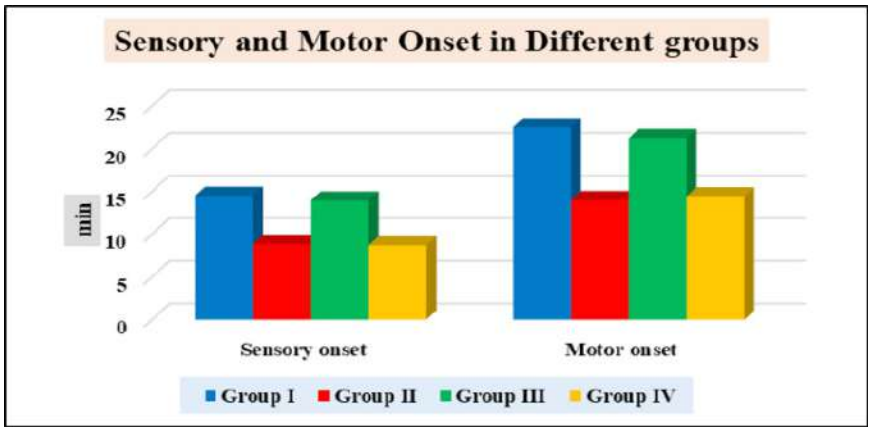

Fig (2)

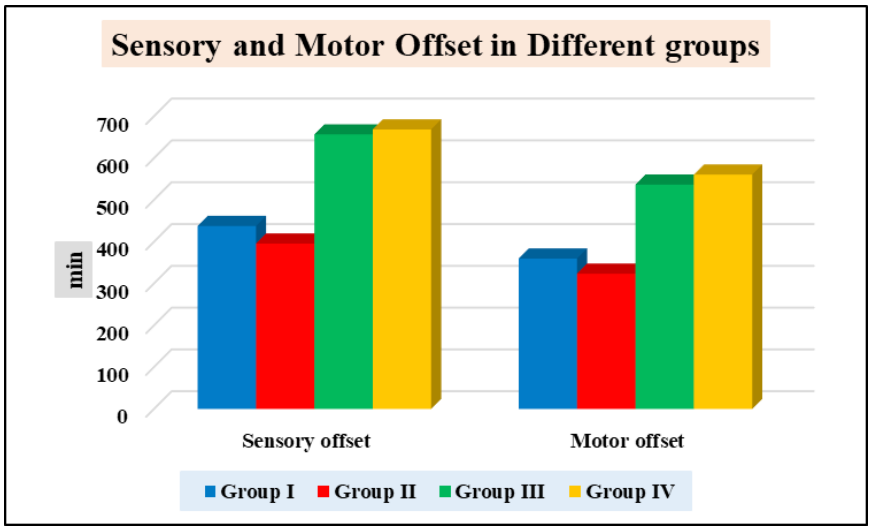

Fig (3)

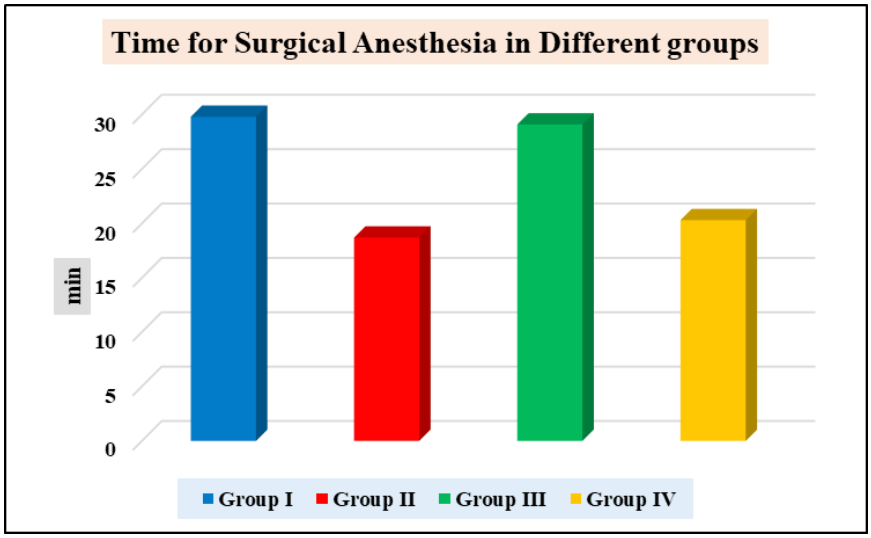

Fig (4)

Pain measurement presented by VASP during intraoperative period at 15 min post injection the pain score was significantly lower in patients received hyaluronidase in groups (II & IV) than in groups (I & III) but no significant difference was found after that during operation. In the postoperative period the VASP was significantly lower at 4, 8, 12, 24 hours in patients received MgSo4 in groups (III & IV) than in groups (I & II).

Intraoperative need for sedation and fentanyl was insignificantly different between the four groups. But the mean time of for postoperative 1st analgesic (minutes) request was significantly longer in groups (III & IV) (360-900) and (540-950) minutes in comparison to groups (I & II) (300-620) and (300-700) minute. And total analgesic requirement (mg) in groups (III & IV) was less than groups (I & II).

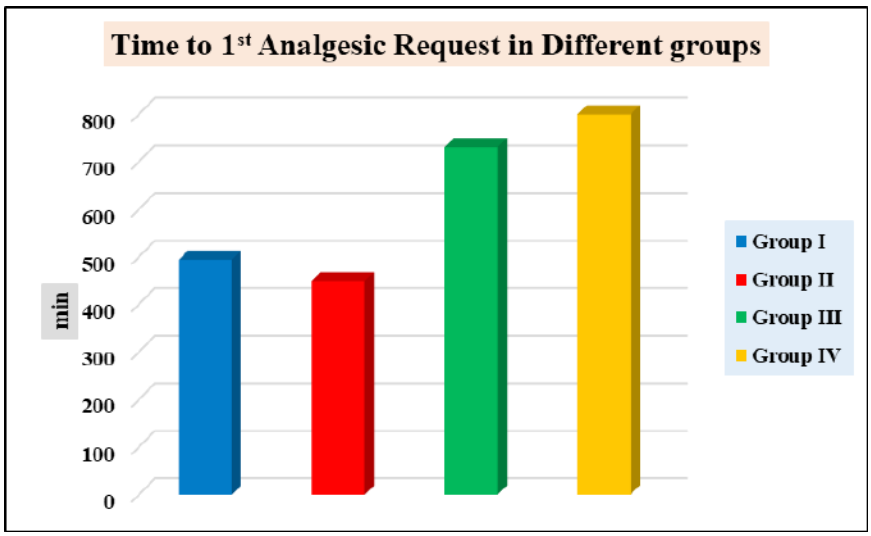

Fig (5)

As regard complications happened during the study no significant differences were found between the four groups.

Discussion

Brachial plexus block is a safe reliable anesthetic technique for upper limb surgery with fewer

complications, especially with the introduction of ultrasound which decreased the complications dramatically.

Hyaluronidase, the mucolytic enzyme which acts on the muco-polysaccharide hyaloronic acid, is generally considered to be "spreading factor". When used with local anesthetics, hyaluronidase hastens the onset of analgesia and shortens its duration of effect [7].

A number of studies have shown that addition of hyaluronidase during ocular blocks has beneficial effects including higher quality of anaesthesia and improved success rates.

In a study done by **Koh et al** investigated the hypothesis that addition of hyaluronidase to ropivacaine may reduce the time to achieve complete sensory block after axillary brachial plexus block. The patients were randomly assigned into a hyaluronidase group (n = 24) and a control group (n = 24). The hyaluronidase group received ropivacaine 0.5% with 100 IU.ml_1 of hyaluronidase, and the control group received ropivacaine alone. The primary endpoint was the time to achieve complete sensory block. The hyaluronidase group demonstrated significantly shorter mean (SD) sensory block onset time **(13.8 (6.0) min)** compared with the control group **(22.5 (6.3) min),** $p < 0.0001$). Addition of hyaluronidase to ropivacaine resulted in a reduction in the time needed to achieve complete sensory block [8].

Another previous study by **Keeler et al** reported the effect of the addition of hyaluronidase to bupivacaine 0.5% for axillary brachial plexus blocks. In that study, 3000 IU hyaluronidase mixed with bupivacaine significantly reduced the duration of the sensory and motor block, and had no effect on the number of patients experiencing a complete sensory block after 30 min while the duration of sensory anesthesia was significantly shorter in the hyaluronidase group and the duration of motor block showed a shorter trend [9].

In our study hyaluronidase had obvious effect on decreasing the sensory onset that recorded by pinprick test at 5 min interval after performing the block till complete sensory block occurred and motor onset detected by detection of complete thumb block also detected at 5 min interval after the block in comparison with control group and Mgso4 group. The mean sensory onset was (8.9 ± 3.3) minutes in hyaluronidase group in comparison to the mean sensory onset (14.5±4.5), (14± 3.8) minutes in control and Mgso4 groups respectively. The mean motor onset was (14±5.1) minutes in hyaluronidase group in comparison to the mean motor onset (22.5±4.9), (21.3±5) minutes in control and Mgso4 groups respectively, and both results were significant with p value < 0.001. However it didn't affect the duration of sensory or motor block or the postoperative analgesic requirement in comparison with other groups.

Mgso4 can act as an adjuvant in analgesia due to its properties of calcium channel blocking and N-methyl-D-aspartate antagonism. Magnesium has been shown to decrease peripheral nerve excitability and to enhance the ability of lidocaine to raise the excitation threshold of A-beta fibers [10].

Haghighi et al. in Guilan, Iran, in 2014, investigated the effect of Mgso4 in axillary brachial plexus block when added to lidocaine in upper limb surgeries, and reported that the addition of Mgso4to lidocaine significantly increased the duration of sensory and motor blocks in comparison with the use of lidocaine alone [11].

Rao et al, found thatThe addition of MgSo4 to 0.5% bupivacaine increased the duration of motor and sensory supraclavicular brachial block in the upper extremities during surgeries when compared to the use of 0.5% bupivacaine alone,The mean sensory block duration in the group MgsSo4 was 249±9.36 and in control Group was (160±5.62) (p<0.39). The mean motor block duration in the group MgsSo4 was (232±9.64) and in control group was (147±26.52) (both p<0.32). The mean onset of sensory block in group MgsSo4 was (15.5±2.16) and the onset of block in control group was (12.73±1.18) (p<0.4) statistically not significant). Alsothe mean onset of motor block in group Mgso4 was (23.5±1.1) and the onset block in control Group P was 41±3 (p<0.53; statistically not significant) [12]

In our study the addition of Mgso4 to 0.5% bupivacaine in supraclavicular brachial plexus block for upper limb surgeries increased the duration of sensory and motor blocks with mean sensory block duration (643.1±144.8) in Mgso4 group vs (423.5±89.4) in control group or (387.2±78.3) in hyaloronidase group and mean motor block duration (546.6±99.8) vs (337.5±77.6) in control group or (310±84.9) in hyaloronidase group with (p value <0.001) for both. Also Mgso4 decreased the postoperative pain with mean VAPS at 4, 8, 12, 24 (0-2.8), (0-3), (2-6), (5-6) vs (2-3), (4-6), (6-7), (7-7.8) in control group vs (2-3), (3.3-6), (6-7), (6-7.8) with (p value <0.001) for all. Also Mgso4 reduced total

analgesic requirements in comparison with the use of 0.5% bupivacaine or bupivacaine plus hyaluronidase with mean total analgesic requirement (1-2) in Mgso4 vs (2-3) in both control and hyaluronidase groups and the change was statistically significant with (p value <0.001). However MgSo4 didn't affect the onset of sensory or motor block when compared to the control and hyaluronidase group.

The most recent in our study is the addition of both MgSo4 and hyaluronidase to bupivacaine 0.5% which resulted in significant decrease in the onset of motor and sensory block and also significant increase in the duration of the block which produced rapid surgical anesthesia, reduced postoperative pain and decrease postoperative analgesic requirement, the mean sensory block onset was (8.7±2.7), the mean motor block onset was (14.5±4).mean VAPS at 4, 8, 12, 24 hours was (0-0), (0-2), (2.3-5), (5-6) which was significant in comparison with control and MgSo4 groups with p value < 0.001. Mean sensory duration was (660.3±94.9), Mean motor duration was (546.6±99.8) both was significantly increased than control and hyaluronidase groups with p value < 0.001. Mean total postoperative analgesic request was (1-1.8) also it was significantly less than control and hyaluronidase groups.

Conclusion

The present study shows that the use of hyaluronidase reduces the time to reach complete sensory and motor block and therefore shortens the total anesthetic time before operation, hyaluronidase has no influence on the total analgesic duration or the consumption of postoperative analgesics.

Also the study shows that the use of Mgso4 increases the duration of motor and sensory block, increases the analgesic duration and reduces the postoperative analgesic consumption. However MgSo4 has no effect on the sensory or motor onset of block.

Last conclusion was that the combination of both MgSo4 with hyaluronidase as adjuvants to bupivacaine produces significant effect on reducing the time to reach complete sensory and motor block and therefore shortens the total anesthetic time before operation, increases the duration of motor and sensory block, increases the analgesic duration and reduces the postoperative analgesic consumption.

The Institutional Ethics Committee approved this study of the School of Medicine, Minia University, Egypt, and all patients gave informed consent before participation in this study. The study conducted in accordance with the ethical guidelines of the 1975 Declaration of Helsinki and International Conference on Harmonization Guidelines for Good Clinical Practice.

Influence of Social Cultural Capital and Marketing on Skin Whitening Products Use among Higher Education Female Students in the Northeast of Thailand

Anawat Phutongnak[1], Wongsa Laohasiriwong[2], Kittipong Sornlorm[3]

[1]Doctor of Public Health Program, Faculty of Public Health, Khon Kaen University, Thailand, [2]Faculty of Public Health, Khon Kaen University, Thailand, [3]Thakhantho District Public Health Office, Kalasin Province, Thailand

Abstract

Introduction: There have been increasing trends of skin whitening products use globally. Social cultural capital has been identified as one of a significant determinants of skin whitening products use. However, there was no study on these issues in Thailand. Therefore, this study aimed to identify skin whitening products use situation and the association between social cultural capital, marketing, and skin whitening products use among female higher education students in the Northeast of Thailand.

Method and Materials: This cross-sectional study was conducted in the Northeast of Thailand among 1,143 female higher education students. Data was collected using a self-administered structured questionnaire. The Generalized Linear Mixed Model (GLMM) was used to identify the associations between social cultural capital, marketing and skin whitening products use when controlling other covariates.

Results: Most of the respondents ever used skin whitening products (84.95% : 95% CI: 82.88–87.03), of which 52.66% (95% CI: 49.77–55.57) were current users, and 17.41% (95% CI: 15.21–19.61) were inappropriate use. The social cultural capital factor that were associated with skin whitening products use were those who were not satisfied with skin colors (Adj. OR=3.48; 95% CI=2.18–5.55; p<0.001), had friends using skin whitening products (Adj. OR=2.63; 95% CI=1.71–4.04; p<0.001, had thin to normal figures (Adj. OR=2.53; 95% CI=1.54–4.15; p<0.001), and had family members using skin whitening products (Adj. OR=1.86; 95% CI=1.10–3.15; p=0.020), studied in humanities and social sciences (Adj. OR=2.07; 95% CI=1.25–3.45; p=0.005) and product marketing (Adj. OR=1.92; 95% CI=1.15–3.20; p=0.012). Moreover, other factors that were also associated with skin whitening products use were family monthly income.

Conclusion: Majority of the higher education female students were current skin whitening products users of which about one-sixth was inappropriate users. Both social cultural capital, marketing had influence on skin whitening products use.

Keywords: *Skin whitening, Social cultural capital, Marketing, Female students.*

Introduction

Skin whitening products use is an ancient and widespread practice in many cultures[(1)], and is one of the most popular products of the global beauty industry, particularly in Asia. Marketing forecasters predict the business will be worth about USD 31.2 billion by 2024[(2)]. In several Asian countries, particularly India, Japan, Korea, China, and Thailand, women face pressure to lighten their skin due to the social perception that light skin is considered to be a cultural marker of beauty, class, and wealth, and has been reflective of high social status for many decades[(3-4)]. The social cultural capital refers to social, political, economic, cultural assets, and imperceptible health resources[(5-6)],

Corresponding Author:
Wongsa Laohasiriwong, Ph.D.
Faculty of Public Health, Khon Kaen University, Thailand
e-mail: drwongsa@gmail.com

with a growing recognition of the socioeconomic status and social determinants of health[7]. It has been described as a feature of trust, norms, networks, skill, cultural knowledge, and education that can improve the efficiency of society by facilitating coordinated actions[8]. In addition, previous studies reported that the advertising industry has recently created a market on notions of beauty, and enhance social cultural capital for the improvement in confidence and career prospects through the use of products advertised to promote white skin[9].

However, skin whitening products frequently contain toxic ingredients that are directly associated with adverse health and skin problems [10]. A study on the use of skin whitening products among university students indicated that 70.7% of females reported using skin whitening products [11] of which their use was associated with adverse skin effects, lack of personal control, risky sexual behaviors, and low social support [12]. In Thailand, as well as the Northeast region, the country biggest region both in term of land areas and population, there are still lack of research specifically concerned with social cultural capital, skin whitening products use, and their relationship to female higher education students.

Hence, this study aimed to describe skin whitening products use situation and to identify the association between social cultural capital, marketing, and skin whitening products use among female higher education students in the Northeast of Thailand. The findings of this study will provide evidence for health, education and relevant sectors to formulate appropriate measures to improve inequalities in health and reduce the use of skin whitening products.

Method

This cross-sectional analytical study was conducted between March to July 2019. The population were female higher education students in the Northeast of Thailand. The inclusion criteria were female higher education students aged 18 years old and older, currently studying for a bachelor's degree in universities of the Northeast of Thailand, able to verbally communicate, and agreed to participate in the study with written informed consent. The sample size was calculated by using the formula to estimate the sample size for a logistic regression analysis of Hsieh [13]. The estimated sample size was 1,143. We recruited students from 18 universities of the Northeast by using a multi-stage random sampling method. The sampling frame was all 18 universities in the Northeast of Thailand. The first stage was a random selection of 4 universities, followed by randomly selecting 3 fields from each university. Then, one faculty from each field was randomly selected. Therefore, a total of 12 faculties were included in the study. Simple random sampling was applied to select participants proportional to the size of the estimated total samples. A total number of 1,143 individuals were chosen to participate in this study.

Research Tools: A structured questionnaire was developed based on the research questions and relevant literatures. The structured questionnaire consisted of 4 parts including: 1) Demographic and socioeconomic: age, university level, field of study, residence, allowance, family monthly income, adequacy of expense, and family members. 2) Skin whitening products use included; Have you ever used skin whitening products in your lifetime? Do you currently use skin whitening products? Inappropriate use was assessed by using a list of dangerous cosmetics from the FDA (Food and Drug Administration, Ministry of Public Health, Thailand), defined as those who reported any use of dangerous cosmetics. 3) Social cultural capital included; satisfied with skin color, have a friend using skin whitening products, have any family members using skin whitening products, Figures were assessed by using BMI (Body Mass Index). The scores were categorized into four groups according to the WHO (World Health Organization) [14] for Asian-Pacific cutoff points, as follows: Underweight (<18.5 kg/m^2), Normal (18.5–22.9 kg/m^2), Overweight (23–24.9 kg/m^2), and Obese (≥25 kg/m^2). Finally, the scores were dichotomized as thin/normal (<23) and overweight/obesity (≥23). 4) Marketing: Product, Price, Place, and Promotion. Using the 5 scores (Very Low, Low, Moderate, High, Very high). After summing up the total marks, according to Best's theory, the scores were categorized into 3 groups (Low, Moderate, High). Finally, the scores were dichotomized as low/moderate (<3.68) and high (≥3.68) by using the mean as the cutoff point.

The questionnaire was undergone content validation by 5 experts and was revised to improve its validity. The Cronbach's alpha coefficient of social cultural capital was 0.80, marketing was 0.87. A self-administer questionnaire was used for data collection. The researcher responded to possible questions raised by the respondents, and assisted them when necessary. The completed questionnaires of each student were placed

into an individual envelope, sealed, and put into a box. Confidentiality of all data was fully assured.

Data Analysis: The data was analysed using STATA® (ver. 13; College Station, TX, USA: Stata Corp). Frequency and percentage were presented to describe the categorical variables. Continuous variables were described as mean and standard deviation, median and range. The generalized linear mixed model (GLMM) was performed to model the random effects and correlations within clusters. In the modelling, the universities were set as random effects. Bivariate analysis was used to determine the association of each independent variable with skin whitening products use. The variable that had p-value<0.25 were proceeded to multivariable analysis, of which the backward elimination method was used for model fitting. The final model results were presented as adjusted Odds Ratio (Adj. OR), 95% CI, with the levels of significance of 0.05.

Results

The average age of female higher education students was 20.67 ± 1.25 years old. Almost equal proportion of students were form each 4 universities (about 25%) and were from freshman (24.06%), sophomore (24.41%), junior (27.91) and senior: 23.62%. Majority of the student lived in private accommodation. Their median family monthly income was USD 940 with the ranged of USD 163 to USD 6,528. Nearly half of the respondents had adequate financial support but were unable to save any money. Most of respondents (84.51%) had thin and normal figure, and had friends (71.22%) using skin whitening products. Almost one-third had family members using skin whitening products and were not satisfied with their skin colors. Majority of respondents (53.81%) perceived a moderate level of overall marketing strategies and about 60% perceived a high level of product marketing.

Most of the respondents used skin whitening products (84.95%), 52.66% were current use and 17.41% were inappropriate use.

Table 1: Number and percentage of skin whitening products use among female higher education students in the Northeast of Thailand (n = 1,143)

Characteristics	Number	Percent	95% CI
Use of Skin Whitening Products			
Never	172	15.05	13.09 – 17.24
Ever	971	84.95	82.76 – 86.91
Current Use			
No	541	47.34	44.44 – 50.24
Yes	602	52.66	49.76 – 55.56
Inappropriate Use			
No	944	82.59	80.28 – 84.68
Yes	199	17.41	15.32 – 19.72

The bivariate analysis indicated that social cultural capital factor including satisfied with skin colors, had friends using skin whitening products, figures, had family members using skin whitening products, and field of study, product marketing and marketing on place, age, family members, family monthly income, and allowance might associated with skin whitening products use (p-value <0.25). These variable were proceeded to the multiple variable analysis using GLMM. The results indicated that satisfied with skin colors (adj. OR=3.48: 95% CI; 2.18-5.55), had friends using skin whitening products (adj. OR= 2.63: 95% CI; 1.71- 4.04), were thin-normal (adj. OR= 2.53: 95% CI; 1.54- 4.15), studied in the field of humanities and social sciences (adj. OR= 2.07: 95% CI; 1.25- 3.45), had product marketing level (adj. OR= 1.92: 95% CI; 1.15- 3.20), and had monthly family income ≥ 980 USD (adj. OR= 2.13: 95% CI; 1.41- 3.20)

Discussion

Skin whitening products use among female higher education students was 84.95%. This finding is consistent with previous studies reporting a high prevalence of skin whitening products use [1,15]. However, this was inconsistent with a study among African women, observed only 60% the respondents using skin whitening products [16]. Our study observed that 52.66% of students were current users, which was higher than the 37.60% found in India. It probably due to the greater range of ages (16-60 years) as well as the cultural setting of the study [17]. About one sixth were using the products inappropriately, a little lower than 46.7% of teenage females reported using harmful cosmetics [18].

The multivariable analysis of this study confirmed that social cultural capital was significantly associated with skin whitening products use. Regarding social cultural capital and satisfaction with skin colors, students who were dissatisfied with their skin colors were 3.48 times more likely to use skin whitening products. This finding was consistent with a previous study [15]. Social and cultural notions connected females using skin whitening products[15]. The presence of social cultural capital among university students was associated with their entire health and individual life [19]. Shroff, H et al suggested enhanced social cultural capital for prevention of use among women[17]. Students who had friends using skin whitening products were 2.63 times more likely to use skin whitening products as well as having family members using skin whitening products were 1.86 times more likely to use them. It might be that both peers and families could have direct communication with the students that could have influence on their behaviors. These findings were consistent with another study [20]. Students with thin to normal figures were 2.53 times more likely to use skin whitening products compared to those in the overweight and obese group. This was in similar with the study in India [17], but inconsistent with the study in Sudan [15]. This might be due to the body image and beauty concerns of female students engaged in weight control. Students who studied in humanities and social sciences were 2.07 times more likely to use skin whitening products than students who studied science and technology. The finding was also consistent with another study [21]. Students with a high level of product marketing were 1.92 times more likely to use skin whitening products, which was similar with a study in United Arab Emirates [22]. Students with family monthly income ≥ USD 980 were 2.13 times more likely to use skin whitening products. This was also similar with a study conducted in Southeast Asia [19]. It might be that they had money to spend on nonessential items.

Conclusion

As high as 84.95% of the higher education female students ever used skin whitening products of which more than half were current skin whitening products

users. About one-sixth was inappropriate users. Both social cultural capital, marketing had influence on skin whitening products use.

Limitation of the Study: Since this is a cross-sectional study, it could not identify the causal relationship between independent variables with skin whitening products use.

Conflicts of Interest: The authors declare no conflicts of interest.

Ethics Clearance: After explaining the study objective, written informed consent was taken from all the participated in the study. Confidentiality of the data was fully assured. The Khon Kaen University Ethics Committee in Human Research approved the exemption for ethical approval of this study (reference no. HE 612343).

Knowledge Management Based Performance Improvement on Certified Health Workers in Health Center of South Sulawesi

Andi Mansur Sulolipu[1], Ridwan Amiruddin[2], Sukri Palutturi[3], Ridwan M. Thaha[4], Arsunan A.A.[2]

[1]Doctoral Program Student, [2]Professor, Department of Epidemiology, [3]Professor, Department of Health Policy and Administration, [4]Senior Lecturer, Department of Health Education and Behavioral Sciences, Faculty of Public Health Hasanuddin University, Makassar, Indonesia

Abstract

Introduction: The aim of this research was to determine the effect of Knowledge Management on improving the performance of health workers force at Primary Health Center of South Sulawesi.

Material and Method: The research used qualitative method. The informants were 12 health workers. Data collection used was in-depth interviews. The tools used were tape recorders and camcorders.

Finding and Discussion: This study found that the Knowledge Management method was relevant to be used in increasing the performance of health workers force in a group of health workers (Doctors, Nurses, Midwives, and SKM (Bachelor of Public Health) who come from different functional health positions) at the South Sulawesi Community Health Center.

Conclusion: Performance of health work force could be done using one method which was knowledge management.

Keywords: *Health workers force, Knowledge management, Performance.*

Introduction

Global Health Workforce Alliance (GHWA) Conference reported that the quality of Human Resources Health is still a problem at the global level. In Indonesia, various efforts to improve the quality of health human resources to achieve sustainable competitive advantage and increase profitability were carried out through education and training. However, the education and training system have been criticized for years. The quality of the results of education and training of health workers in general is still inadequate[1]. According to various studies showed that health workers are the main key in the success of achieving health development goals. Health workers contribute up to 80% in the success of health development. In 2006, WHO reported that Indonesia was one of 57 countries that faced a health HR crisis, both in number and distribution.

Competence is an ability possessed by someone in carrying out a task or a job based on skills and knowledge. The development of human resource competencies in the health sector is a strategic component of health development in order to accelerate the distribution of health services and the achievement of health development goals. The performance of an organization will be determined by one of the main elements, which is the quality of human resources[2].

The implementation of non-quality training will have an impact on the low competency of graduates which ultimately affects the performance of institutions/ organizations. According to Hendry, the practice of improving the quality of human resources (training, job design, employee skills, employee attitudes, work motivation, etc.) has an impact on the performance

Doctoral Program Student in Faculty of Public Health, Hasanuddin University, Makassar, Indonesia
e-mail: amsulolipu@gmail.com

of various business units[3]. Likewise, Sule findings showed a significant positive relationship between competency-based training and development and employee performance[4]. Knowledge management is a concern of what is called Knowledge Management (KM). According to Qwaider, Knowledge Management helps manage knowledge individually or in group within organizations or between organizations that can affect the quality and benefits of knowledge[5].

Several studies were conducted on knowledge management related to variables such as performance, competence, training, learning, and others. Research conducted by Tongsamsi discovered the effect of knowledge management and training on manager competencies[6]. Knowledge management positively influences organizational performance. Another study was conducted by Chandavimol, which isthe development of a mixed training model by applying the principles of knowledge management and learning actions, in order to develop the design competency of health human resource development staff training programs in the government sector[7]. Furthermore, the working team will form collaboration between participants in education and training [8] . The aim of this research is to improve the performance of the health work force at the Primary Health Center of South Sulawesi. In the era of knowledge-based society in the 21st century, the way people learn has changed. New knowledge is gained by learning from training, work and exchange of experiences. The US Department of Labor estimated that more than 70% of knowledge occurs from experience and 30% from education and training[9].

Knowledge of each individual in the organization or the company is certainly different so it causes the knowledge does not develop evenly within the environment. Knowledge Management is one solution to assist knowledge processing, so that individuals in training or learning classes can have the same knowledge[9], then with the same knowledge it can help to develop an organization or company. Knowledge management is formed from a knowledge, where knowledge is divided into two types, those are Tacit Knowledge and Explicit Knowledge. This knowledge can be in the form of: books, journals, scientific works, references or others. This knowledge is obtained and developed from the content and information contained in it.

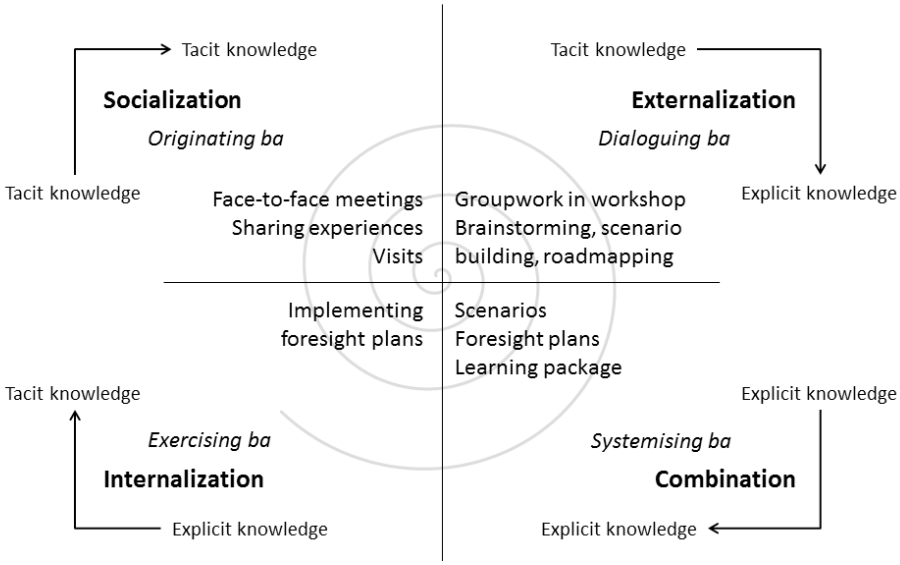

Figure 1. SECI Model

Figure 1 is known as the SECI Model[10], in the figure where there are two types of knowledge, those aretacit knowledge and explicit knowledge. In university education activities, knowledge management can improve administrative services related to the improvement of curriculum, teaching and learning processes usingtechnology, as well asimproving response by monitoring and combining lessons from student experience and evaluation[11]. Nawaz and Gomez, presented two Knowledge Management Model Concepts.

The first model concentrates on how knowledge sources are transformed into strategic knowledge, where the process of converting tacit and explicit knowledge into knowledge diffusion converts it again as the application of knowledge. Participants develop their knowledge by understanding the concept of subject matter and converting it into strategic knowledge. The second model strategic knowledge is a source of knowledge for students, while learning knowledge learners diffuse knowledge and choose strategic knowledge. This enhances procedural knowledge owned by the students, generates core subject skills and algorithms, core subject techniques and method as well as formula knowledge to determine when and how to use appropriate procedures to solve problems. The Strategic Knowledge Model can be implemented in universities, then for Knowledge Models can be implemented in advanced training institutions.

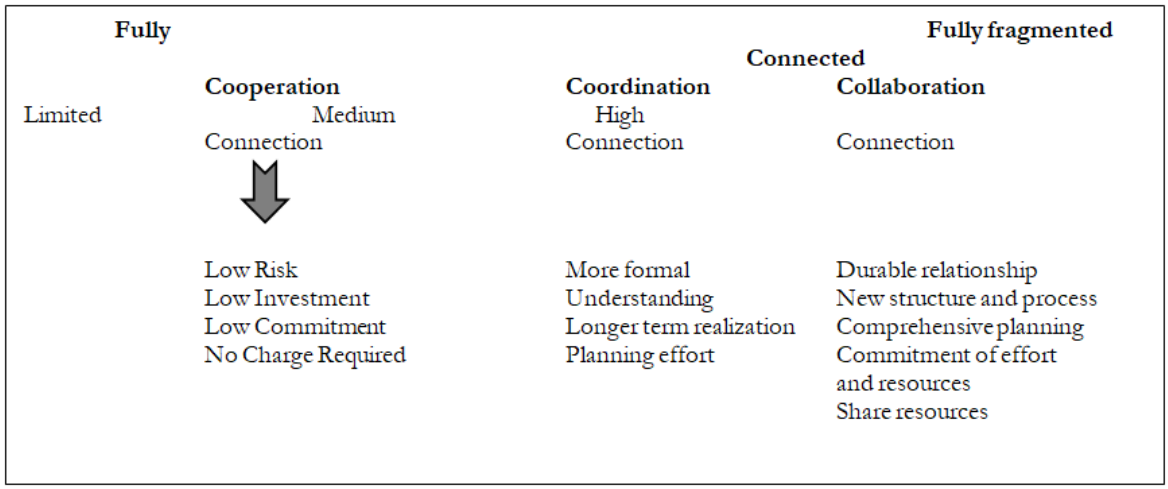

Figure 2. The Victorian council and social services

Knowledge Management strategy is very much needed to cooperate or collaborate, namely Cooperation, Coordination and Collaboration. Simple horizontal integration between cooperation, coordination and collaboration is shown in Figure 2.

Material and Method

Based on the conceptual framework, the variables in this study consisted of: Knowledge Management Strategy as an independent variable, and Enhancing Performance and competency as the dependent variable. This study used qualitative research method to obtain comprehensive, valid and objective data.

Finding and Discussion

The results of in-depth interviews showed that the application of knowledge management in the form of face-to-face socialization had a positive impact and benefits for the health workers in the Primary Health Center. Thus, it was very well implemented for every training attended by the health workers in the Primary Heath Center, since knowledge management is very helpful in understanding the management of the health center. In addition it is also able to be directly held.

Knowledge management can improve organizational performance[12] even though not all knowledge resources affect organizational performance directly. However, it cannot be ignored because they work in combination with other supporting sources, including knowledge acquisition and application knowledge that can contribute directly to the organizational success.

Based on the results of research at the Primary Health Center that have implemented knowledge management, it shows that it indirectly affects the performance of health workers so that it can encourage the management of the health center to improve the function of health services. The following are the results of the interview:

.....Socialization of training results improved performance, seen from the document management of the health center that had been produced.....

Performance is a work achievement that can be measured based on the standards or criteria set by the Primary Health Center. The completion of basic tasks and functions is the performance of a health worker who is physically and mentally attached.

.....At our place (Primary Health Center),every employee who participated inthe training must be trained to conduct socialization of training in meeting each patient in the Primary Health Center.....

Knowledge Management focuses on the identification, acquisition, distribution and maintenance of substantial and relevant knowledge. Rush (2005) described the term of Knowledge Management related to the exploitation and development of knowledge assets of an organization with the intention of improving the organizational goals. Knowledge management has been implemented in many organizations with the expectation that they will have a positive effect on performance [11].

Conclusion

The results showed that knowledge management had an effect on performance, and it could be concluded that health workers in the Primary Health Center who were committed to organizing had an impact on completing their main tasks and functions as health workers. Knowledge management provides development and the ability to think, work and manage work well so as to produce performance that affects the health services. Furthermore, research on learning strategies and knowledge management are suggested to be combined because they can facilitate the learning well.

Determinants that Influence Relationship between Motivation and Job Satisfaction of Health Workers at Primary Health Care in Indonesia

Armedy Ronny Hasugian[1,3], Jaslis Ilyas[1], Besral[2], Adang Bachtiar[1]

[1]Administrative Policy and Health Department, [2]Biostatistics Department, Faculty of Public Health, University of Indonesia, Depok, Indonesia, [3]National Institutes of Research and Development, Ministry of Health Republic of Indonesia

Abstract

Background: The result from first National Study in Indonesia showed motivation and job satisfaction of health worker was low. The objective of this study was to identify determinants factor that influence relationship between motivation and job satisfaction of health worker at PHC in Indonesia.

Method: This was an advance analysis of RISNAKES 2017, a crossed sectional study which conducted at PHC in Indonesia. The respondents were physician, dentist, nurse, and midwife. Structural Equation Modelling (SEM) was used for analysis the relationship.

Result: Total 402 health workers recruited from 302 at PHC in Indonesia and the model association was fit (Critical Ratio=8.057, p<0.000). Motivation was responsible for 51% variance of job satisfaction. "Length working at current PHC" was the only determinant relate significantly, but there were some significance on parts of observed variable which associated with construct variable.

Conclusion: "Length working life at current facility" was determinant that influenced the relationship between motivation and job satisfaction.

Keywords: *Human Resource, Health Worker, Job Satisfaction, Motivation, Indonesia.*

Introduction

Primary Health Care/PHC (PUSKESMAS) is a first line of community health service in Indonesia, located in every sub district in Indonesia, and their duties are to promote, prevent, curative and rehabilitate of health communities based on National Health. The best performance and productivity of health worker is important to manifest it. The most common approach to achieve that is optimizing motivation and job satisfaction of health worker.[1] National study showed motivation and job satisfaction of Indonesia's health workers were only 43% and 23%.[2]

World Health Organization (WHO) already recommended the policy to improve motivation and job satisfaction of health worker at health facility.[3–5] The strategies were incentive, learn new skill[6], supportive supervision[7], strategy for future carrier[8], work atmosphere[9], and etc. All of the strategies are depend to the basic characteristics of health worker and their working environment or determinant factor. Understanding determinants of motivation and job satisfaction and their relationships is a basic to choose the best strategy, including at Primary Health care/PHC (PUSKESMAS) in Indonesia.

The objective of this article was identified the

determinants that influence relationship between motivation and job satisfaction at PHC in Indonesia. Structural Equation Modelling (SEM) is a tool of statistic and one approach that can be used to understand and identified the determinant. Through this approach would help policy maker to develop design policy option on health worker responses.

Material and Method

This is an advance analysis from the first study of National Human Resource of Health Study (RISNAKES) 2017 for health worker at government health facility including PHC [2].This was a cross sectional study, the respondent was a physician, dentist, nurse and midwife at PHC and observed at "time study" by independent enumerator from open until closed time of PHC. They were also answer "motivation and job satisfaction questionnaire" themselves (self-administered questionnaire) too. Entry and cleaning of this data were already doing by laboratory Management Data on National Institutes of Health Research and Development, Ministry of Health Republic Indonesia. The respondents signed inform consent voluntary before start the study and they had opportunity to understand the questioner before start answer. All of the initial names or place during recruitment and publication were confidential.

Measurement of motivation was using indicators from instrument in Kenya by Muntale at all, with 23 questionnaires.[10] Meanwhile, the of job satisfaction was using short questionnaire Minnesota Satisfaction Questionnaire (MSQ) that already using in many field study to measure the satisfaction. The determinants factor were "Job suitability" (suitable of health services activity at PHC[11],<80% vs ≥80%), "Regional"(Jawa vs Non-Jawa-Bali, "Occupational"(Physician vs Not Physician), "Adequate income" (adequacy of one month salary for their live activity; Yes vs No), "Saving money" (capability of health worker to saving his income from 1 month salary; Yes vs No), "Length of working life at health facility(<8 years vs ≥ 8 years), and "Length of working life at current PHC"(<5 years vs ≥ 5 years).

Univariate analysis used to identify characteristic of respondent, and analysis of reliability indicator of motivation and job satisfaction questionnaire used Cronbach Alpha test with cut off > 0.7.[12] Structural Equation Modelling (SEM) assessed association between motivation and job satisfaction with model fit were CMIN/df<2, RMSEA <0.08, GFI >0.90, CFI>0.90, TLI>0.90 and SRMR nearest <0.08.[13]The reliability and validity of construct variableof model was analysed by Average Varian Extracted (AVE) and Construct Reliability (CR). Invariant measurement was done to identify determinants influence association between motivation and job satisfaction, only p value ≥0.05 can be compared. SEM analysis used AMOS 24.

Results

Total 402 respondents analysed at 302 PHC from 1430 respondents at 425 PHC in "time study", the entire characteristic was showed at table 1.

Table 1: Characteristic respondent of the study (n=402)

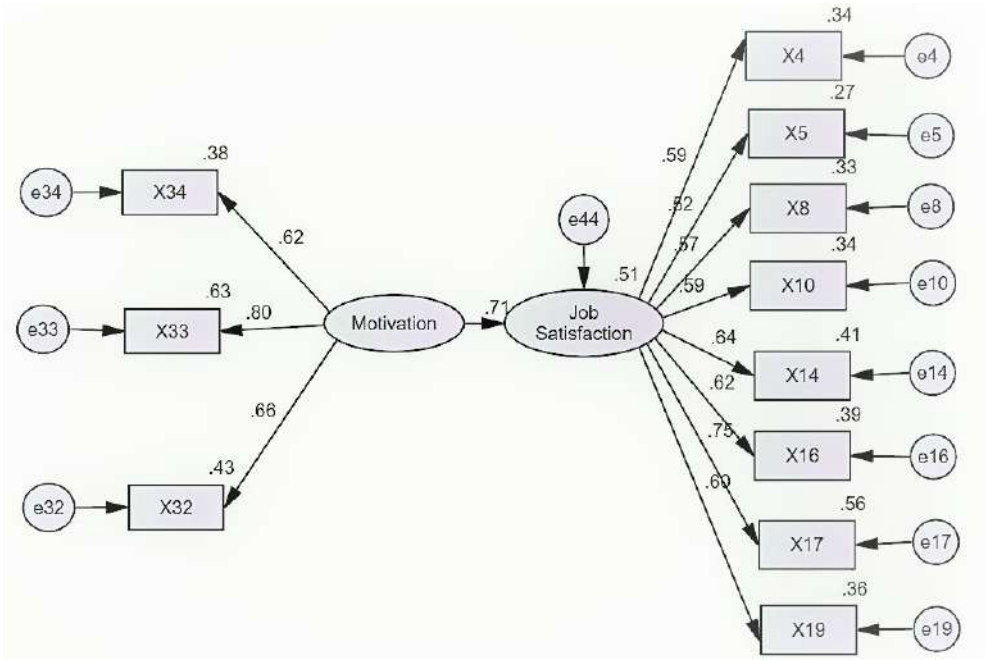
Characteristic	Group	Frequency	Percentage
Sex	Man	79	19.7
	Woman	323	80.3
Occupational	Physician	166	41.3
	Dentist	46	11.4
	Midwife	97	24.1
	Nurse	93	23.1
Job suitability	≥80%	137	34.1
	<80%	265	65.9
Regional	Jawa Bali	140	34.8
	Non Jawa Bali	262	65.2
Adequacy Income	Yes	191	47.5
	No	211	52.5

Characteristic	Group	Frequency	Percentage
Saving Money	Yes	170	42.3
	No	232	57.7
Length of working life at health facility	≤8 years	208	51.7
	>8 years	194	48.3
Length of working life at current PHC	≤5 years	224	55.7
	>6 years	178	44.3
	Median (SD)	**Minimum**	**Maximum**
Age (Years)	34(8.18)	22	60
Length of working life at health facility (Years)	8 (7.99)	0.5	37
Length of working at life current PHC (Years)	5 (6.09)	0.5	31

Source: Own research

Mean of 23 indicator of motivation was range (SD) 1.85(0.89) - 4.19(0.56) and 20 indicator of job satisfaction was 2.86(1.04) – 3.89(0.62). The indicators reliable to analyse as a motivation and job satisfaction construct variable with Cronbach Alpha 0.75 and 0.90.

The model based on 23 indicators motivation and 20 indicators job satisfaction were developed and showed only 3 indicator of constructs motivation and 8 of job satisfaction were selected. The model was fit with CMIN/df=1.696, GFI=0.971, TLI=0.969, CFI=0.976, RAMSEA=0.042, SRMR=0.036, all the path diagram was differently significant (p<0.000) (figure 1). The AVE for construct motivation was 0.48 and job satisfaction was 0.36, meanwhile CR of construct motivation was 0.73 and job satisfaction was 0.83. This result can be accepted and indicating the variable were reliable and valid[14].



Note: X4="The chance to be "somebody" in the community", X5="The way my boss handles his/her workers", X8="The way my job provides for steady employment", X10="The chance to tell people what to do", X14="The chances for advancement on this job", X16="The chance to try my own method of doing the job", X17="The working conditions", X19="The praise I get for doing a good job", X32="I am proud to be working for this hospital",X33= "I find that my values and this hospital's values are very similar", X34="I am glad that I work for this facility rather than other facilities in the country". Source. Own research

Figure 1: Model fit of relationship between motivation and job satisfaction (standardized regression weight).

The result of invariant measurement for determinants showed only factor "Job suitability" (P value of measuring weights=0.122, P value of structural weight 0.167), "Regional" (0.231, 0.283), "Length of working life at health facility "(0.189, 0.091), "Length of working life at current PHC (0.288, 0.070)" can be compared and the model was fit. The comparative analysis showed only "Length of working life at current PHC" influences association between motivation and job satisfaction (regression weight estimate <5 years vs ≥5 years; 0.81 vs 0.47, p<0,05) with significantly different indicator "glad work at current PHC"< 5 years higher than ≥5 years. There were still significances different on some parts of observed variable at "Regional" construct; i.e. job stability (X8) and job advancement (X14); and "Job suitability"construct; i.e. praise/appreciation for good job(X19);although no significant influenced to relationship between motivation and job satisfaction. Meanwhile, there were dominantly different indicator for determinants "Occupational", "Adequate income" and "Saving money", i.e indicator the way of X5, job stability (X8), job advancement (X14), chance used own method (X17), praise/appreciation for good job(X19), and glad work at current PHC (X34), though they were no invariant.

Discussion

There was a significantly association between motivation and job satisfaction of physician, dentist, nurse, and midwife (health worker) at PHC in Indonesia. The 11 indicators depicted the working environment (extrinsic motivation) of organization and showed the harmonization between environment and health worker and this confirmed the "work motivation" theory and "work adjustment theory".[15,16] In this study, the motivation has related with 51% variance of job satisfaction, this condition showed motivation of health worker play an important role for job satisfaction of health worker at PHC in Indonesia. Someone with higher motivation had a power from inside and makes the person do important better for themselves and make them satisfy. [6,17–19]

The association between motivation and job satisfaction was significantly different in "Length of working life at current PHC" group, which working life ≤ 5 years had higher association than > 5 years. It showed that manage "length time of working "was important to improve relationship between motivation and job satisfaction. The important indicators to manage that were the working condition and happiness. This situation consistent with other studies and showed "working condition" such as quality team collaboration, positive work environment, moral distress, interaction with management and health worker, length of working, would influence the motivation and job satisfaction.[20-22] Moreover, the management of human resource, leadership, job description, infrastructure, environment, "being important" might relate with the situation of health facility/PHC that influence the happiness of health worker.[23] However, the relationship was same after 8 years working at PHC.

Praise/appreciation,jobstabilityandjobadvancement were important indicators that differently significance in determinant "Job suitability" and "Regional" even both of them were not influencing the relationship between motivation and job satisfaction. Praise/appreciationis important in order get high job suitability and study on Chinese Nurses showed that psychological reward as a praise/appreciation would increase job satisfaction beside a psychological payment.[24] Meanwhile, many health workers had hesitation about their job stability and advancement if their work at remote area or with the low economic is. This is consistent with study at Pakistan, that building carrier progression was needed for motivation and retention of health worker.[25]

Determinants "Adequate income", "saving money" and "Occupational" were not influence the relationship between motivation and job satisfaction, buttheir dominant indicator showed working condition was crucial for health worker. How organizational factor such as reward from leader, manage the job description, incentive and etc. are important. This is consistent that the health worker need good environment to make sure they get what their need and achieve the target.[6,25,26]

There were limitations of this article, first, the total sample size only a part of total sample of National Human Resource of Health Study (RISNAKES) 2017, but this was enough to show the association with Structural Equation Modelling (S'EM). Second, RISNAKES conducted only one day activity observed of health worker, but based on their job description, one daily activity in one PHC similar with others, so the measurement enough to show the activity. Third, when measure the motivation and job satisfaction, the study used self-determined questionnaire, so the potential bias could happen, to reduce the possibility, the enumerators trained to explain answer the question.

Conclusion

"Length of working life at current facility" influences the relationship motivation and job satisfaction of physician, dentist, nurse, midwife and pharmacist at PHC in Indonesia. Working condition/environment is important to optimize the relationship between motivation and job satisfaction.

Policy Option: The policy option based the result of this study are:

1. Develop and optimize working condition to manage length of working before and after 5 years working at PHC. The health worker should be given opportunity to move or stay to other facility with their intention periodically (after 5 years) based result of evaluation and monitoring.
2. Make motivation and satisfaction survey for health worker periodically to ensure their intention working at PHC

Acknowledgment: The author wants to thank the entire individuals who have helped the process of writing this article and the respondent of National Human Resource of Health Study (RISNAKES) 2017. We like to thank the NIHRD data management laboratory for helping manage the data process for this article

Conflict of Interest: Authors declare that there is no conflict of interest.

Funding: This study was no grant from any institution.

Risk Factors for Obesity in Patients with Hypertension

Aylinda Wahyuni Putri[1], Ratu Ayu Dewi Sartika[2]

[1]Student of Magister Program of Nutrition Department, [2]Professor of Nutrition Department, Faculty of Public Health, Universitas Indonesia, Depok, Indonesia

Abstract

Background: Non-communicable diseases (NCDs) are a leading cause of death worldwide. In 2018, NCDs' prevalence had reportedly increased since 2013. Hypertension was the biggest cause of NCDs diagnosed in health facilities, from 25.8% to 34.1%. Patients with hypertension and obesity are at increased risk of complications from diabetes mellitus and kidney disease.

Objective: The present study aimed to determine risk factors for obesity in patients aged 25–69 years with hypertension.

Materials and Method: This was an observational study with a cross-sectional design, using secondary data from the 'Cohort Study of Risk Factors of Non-communicable Diseases', conducted in Bogor City, Kebon Kelapa Village in 2017. The population in this study included adult patients with hypertension aged 25–69 years.

Results: The prevalence of obesity in patients with hypertension was 47.4%.Risk factors that were significantly related to obesity in patients with hypertension included age groups 25–44 and 45–59, female gender and excessive energy intake (p = 0.009, 0.050, 0.025 and 0.039, respectively and odds ratio = 2.43, 1.73, 1.85 and 1.85, respectively).

Conclusions: Risk factors associated with obesity in patients aged 25–69 years with hypertension included age, gender and energy intake.

Keywords: *Obesity, hypertension, adult, elderly.*

Introduction

Non-communicable diseases (NCDs) are the leading cause of death worldwide. Around 15 million people aged 30–69 years die each year from NCDs, with 85% occurring in low and middle-income countries.[1] NCDs' prevalence increased in Indonesia between 2013 and 2018.[2]

Hypertension is a leading cause of cardiovascular disease that can lead to strokes, coronary heart disease, kidney failure and premature death.[3–6] It is estimated to cause 12.8% of deaths worlwide.[7] In 2018, hypertension was the main cause of NCDs diagnosed in health facilities. Hypertension's prevalence increased from 25.8% in 2013 to 34.1% in 2018.[2]

Studies have reported that the prevalence of obesity among patients with hypertension is increasing. A study by Ford et al. using data from the National Health and Nutrition Examination Survey showed that obesity's prevalence increased from 25.7% from 1976–1980 to 50.8% from 1999–2004 in adults with hypertension.[8] Qin et al. also reported an increase in the prevalence of obesity and central obesity in hypertensive adults in China.[9] A study by Sartika et al. showed that obesity's prevalence in Indonesian patients with hypertension was 40.7% in urban areas and 18.9% in rural areas.[10]

Patients with hypertension and obesity are at increased risk of complications of type 2 diabetes mellitus and kidney disease.[11, 12] Obesity status in patients with hypertension is associated with a significant difference in the average onset age of type 2 diabetes mellitus.[12] In patients with hypertension, obesity and insulin resistance also play major roles in the genesis of kidney failure, which is known as 'nephrosclerotic hypertension'.[11]

Risk factors such as age, gender, education, income, diet, physical activity, hypertension treatment, smoking and stress contribute to the incidence of obesity in patients with hypertension. Risk factors for obesity complications in patients with hypertension vary greatly among regions.

The present study aimed to determine the risk factors for obesity complications in patients with hypertension aged 25–69 years in Bogor City in 2017. This study's results are expected to provide an evidence base for appropriate health programmes to prevent obesity in patients with hypertension.

Materials and Method

The present study was cross-sectional in design and analysed secondary data from the 'Cohort Study of Non-communicable Diseases', conducted by the National Institute of Health Research and Development, Republic of Indonesia, in Bogor City, Kebon Kelapa Village, in 2017. This study's population were all patients with hypertension aged 25–69 years who were respondents in 2017. Hypertension was defined as systolic blood pressure >140 mmHg and/or diastolic blood pressure >90 mmHg, doubling of blood pressure within 5 min under appropriate conditions, diagnosis of hypertension by a health professional or undergoing treatment for hypertension. A population of 489 patients with hypertension aged 25–69 years was selected from the 'Cohort Study of Non-communicable Diseases', conducted in 2017. This research sample was selected using total population sampling. Respondents with heart disease (n = 50), stroke (n = 44), diabetes mellitus (n = 118) and pregnancy (n = 1) were excluded from the study sample. Thus, 318 respondents were included in the study.

The dependent variable in this study was obesity status, with a body mass index (BMI) parameter >27 kg/m². BMI was calculated as body weight in kilograms divided by the height in metres squared and categorised as: underweight (<18.5 kg/m^2), normal weight (18.5–25.0 kg/m^2), overweight (25.1–27.0 kg/m^2) and obese (> 27 kg/m^2).[13] Independent variables were age, gender, education, conversation, nutrition intake, physical activity, hypertension treatment, smoking and stress. Nutrient intake was measured as the amount of energy, carbohydrate, protein, fat and sodium consumed daily compared with dietary recommendations for people with hypertension (DASH).[14] Intake of nutrients was categorised as low (<90%), moderate (90% –119%) and high (≥120%).[15]

Data processing involved cleaning and transforming data and was performed by univariate and bivariate using chi Square test with a 95% confidence interval (CI) (α = 0.05) and odds ratios (ORs).

Results

Characteristics of patients with hypertension: Analysis of nutritional status in patients hypertensive aged 25–69 years showed malnutrition in 1.6%, normal nutrition in 35.3%, with 15.7% overweight and 47.4% obese. The prevalence of hypertension was greatest (53%) among those aged 45–59 years (pre-elderly). The incidence of hypertension was highest (72.6%) among females compared with males. Most (65.1%) patients with hypertension were of low education status. The patients' characteristics are presented in Table 1.

Table 1. Characteristics of patients with hypertension aged 25–69 years

Variables	Category	N	%
Nutritional Status	Underweight	5	1.6
(n = 312)	Normal	110	35.3
	Overweight	49	15.7

Source: Secondary data processed

Prevalence and risk factors for obesity in patients with hypertension: The prevalence of obesity in patients with hypertension was quite high (47.4%) and was higher in females compared with males (51.5% vs. 36.5%). Obesity in patients with hypertension mostly occurs in adulthood, from age 25 to 44 years. The prevalence of obesity was higher in patients with a low education status compared with those who were highly educated (50.2% vs. 42.3%). Nutrient intake in obese hypertensive patients showed high energy (58.2%), high carbohydrate (54.8%), adequate protein (61.4%), moderate fat (52.4%) and low sodium (50.3%) intake.

The bivariate analysis showed that factors were significantly related ($p < 0.05$) and the risk factors for obesity in patients with hypertension were age, gender and energy intake. Adult patients with hypertension aged 25–44 years showed a 2.43-fold higher risk of obesity compared with that of elderly patients (aged 60–69 years), and pre-elderly patients (aged 45–59 years) showed a 1.73-fold higher risk of obesity compared with that of elderly patients (aged 60–69 years). There were 1.85 times more female than male patients with hypertension. High energy intake in patients with hypertension was 1.85 times higher than low energy intake. The results of the bivariate analysis of risk factors for obesity in patients with hypertension are presented in Table 2.

Discussion

Our results indicate that the prevalence of obesity in patients with hypertension aged 25–69 years in Bogor City in 2017 was high (47.4%). This high prevalence is in line with findings from previous studies by Ford et al. (2008), Qin et al. (2013) and Sartika (2015).[8,9.10] The cause of obesity among patients with hypertension is multifactorial. The level of hypertension, socioeconomic status, residential area, consumption of red meat, physical activity, hypertension treatment, family history of diabetes, hypertension and heart disease, which is associated with obesity among people with hypertension.[9]

In the present study, risk factors for obesity complications in patients with hypertension were found to be age, gender and energy intake. Residential area, consumption of red meat, family history of diabetes, family history of hypertension and family history of heart disease could not be analysed due to limited secondary data.

The prevalence of obesity in patients with hypertension was higher in adults aged 25–44 years than in pre-elderly (45–59 years) and elderly (60–69 years) patients. Under normal conditions, age is associated with obesity as metabolism decreases with age, which increases the risk of obesity. However, in the present study with a population of patients with hypertension, adults (25–44 years) showed a higher risk of complications of obesity that was 2.43-fold higher than elderly (60–69 years) patients, whereas this value was 1.73-fold higher in pre-elderly (45–59 years) compared with elderly patients.

The prevalence of obesity in female patients with hypertension was higher than that of males. These findings reveal a significant relationship between gender and incidence of obesity in patients with hypertension. Females with hypertension showed a 1.85-fold higher risk of obesity compared with males with hypertension. This study's results are in line with those reported by Qin et al. (2013).[9] They conducted a study in Lianyuangang, China from October 2008 to September 2009 and showed that the prevalence of obesity in females with hypertension was higher than that of males.[9] Females are at greater risk of obesity since they generally have more fat than males, including a higher amount of subcutaneous fat and more fat deposits in the glutaeal–femoral area or peripherals that determine the typical pear-shaped female (peripheral or gynoid type obesity).[16]

Excessive energy intake is related to obesity in patients with hypertension and is associated with a 1.85-fold increased risk of obesity compared with those with low energy intake. When energy intake exceeds energy expenditure, a positive energy balance occurs, leading to an increase in body mass. A 60% –80% increase in body mass is associated with an increase in body fat.[17] An imbalance between excess energy intake and output results in weight gain, both under normal conditions and in patients with hypertension.

Conclusion

The prevalence of obesity in patients with hypertension aged 25–69 years in Bogor City in 2017 was 47.4%. Risk factors that were significantly related to obesity in patients with hypertension included age (adults aged 25–44 and pre-elderly aged 45–59 years), female gender and excessive energy intake ($p = 0.009$, 0.050, 0.025 and 0.039, respectively and OR = 2.43, 1.73, 1.85 and 1.85, respectively). The high prevalence of obesity in patients with hypertension is a health problem requiring appropriate treatment since controlling weight gain is fundamental to improving quality of life in patients with hypertension. Our results are expected to be used to plan appropriate health programmes and prevent obesity in patients with hypertension.

Abstract

This study aims to identify how the type of coping stress strategy for the type-2 diabetes mellitus patients, who experienced gangrene complication. Coping stress strategy is an efforts strategy to overcome feelings of stress due to illness. Coping stress strategy in this study is divided into two types, namely problem-solving effort, and emotion-focused coping. The method used in this study was a qualitative approach by taking three people with type-2 diabetes mellitus and complications of gangrene as participants. The method used for selecting the participants was a purposive approach. The data were collected using structured interviews and field notes. The data was analyzed by using thematic analysis with a theory-driven approach. The result shows that the three participants had a coping stress strategy to heal their stress while experiencing diabetes and gangrene complication. Patients were able to cope well with stress control routine, change their eating patterns, look for information on diabetes mellitus, and exercise regularly. Patients also got supports from professionals, family, and friends. Coping stress strategy techniques for each different subject depend on their surroundings. This study found that there is three dominant coping stress strategy chosen by the patients which are the planful problem solving and the seeking social support that belongs to the problem-solving effort section, and the positive appraisal section that belongs to the emotion-focused coping section. However, three patients also performed stress diversion, called escape/avoidance, to cope with their stress.

Keywords: *coping stress strategies, type-2 diabetes mellitus patients, gangrene complication.*

Introduction

Diabetes mellitus is one of the chronic diseases that have an increased number of patients and become a major public health problem worldwide[1]. According to the World Health Organization, in 2010 the number of people with diabetes mellitus in the world has reached 271 million[2]. In 2010, Indonesia was at the 4th rank globally with 8 million diabetes patients[3]. Diabetes mellitus is differentiated into type 1 and type 2[4].

Type-2 diabetes mellitus causes helpless feeling to its patient, a feeling that appears because he/she cannot change his/her future anymore. This feeling arises based on many causes, such as uncertain health condition, added with recovery and recurrence and also physical regression[5]. Psychologically, when the patient knew that they had diabetes mellitus, there would be concern inside his/her mind about what they will face later. This will lead them to stress stage. The emotions of denying, obsessed, anger, and frustration become the main reasons that eventually can cause stressfulness. This condition will give a negative impact on his/her body[4].

Rustini describes that diabetes mellitus type 2 patient that experience gangrene complication has go through changes in his/her life behaviour, start from dietary habit, physical exercise, blood sugar control, gangrenous wounds treatment, etc that will happen throughout life with patience and in order to make his/her condition stable. Furthermore, patient will suffer physical regression. Gangrenous wounds condition will get worse and rot[6].

Anggraeni and Cahyanti stated that one way to cope with psychological stress that diabetes mellitus patient had is by using a management strategy done by the patient. With this stress management strategy, people with diabetes mellitus, especially those who experience gangrenous complications, will be able to develop their own experiences about their disease including emotional and cognitive aspects which will ultimately help them to decide which stress management strategy is suitable for him/her to handle the stress[7].

Stress management strategy is a process to resolve many demands both internally and externally, which exceed capacity from the patient. The stress management strategy refers to various efforts, both mental and behavioral, to master, tolerate, reduce, or minimize a stressful situation or event[8]. A study conducted by Vázquez *et al.* about stress management strategy showed that optimistic individuals performed problem-solving effort directly in dealing with stressful events and problems associated with their health which in the end will affect their self-care and healing process in the future[9]. Rohmah *et al.* on her research on coping mechanisms said that a good combination of both stress management strategies, namely problem-solving effort, and emotion-focused coping, would provide good results in improving the life quality of people with diabetes mellitus. Understanding of how to regulate diet, treatment, and self-acceptance, as well as the social support from family and surrounding is a strategy of the diabetics which makes their life better[10].

Until today, research about psychological stress condition of a diabetic patient who suffers gangrene complication is still rarely found. Whereas, the data compiled by Rustini shows that the percentage of diabetic patients with gangrene complication has reached 50% of the total number of people with diabetes[6]. Therefore, it is important to make a research to find what type from the stress management strategy that the type-2 diabetes mellitus patients with gangrene complication use.

Materials and Method

This study is a qualitative research with an intrinsic case study. Through a case study approach, the researcher could get a bold and integrated understanding of a special case. The special case was related to the individual. The type of case study used for stress management strategy research on type 2 diabetes mellitus patient with gangrene complication was intrinsic case stud. This type was used to fully understand the case without making new concepts or theories or any generalizations[11].

The participants were appointed purposively, which means the selection of participants was based on meeting certain criteria. The participants were typed 2 diabetes mellitus patients who have gangrene complication. Participants were gone through a screening test using an instrument by Sarafino. This instrument would help to find which participants have the lowest stress level, that later would be interviewed on how they use their stress management strategies that make them survive until now. The participant criteria in this study were type-2 diabetes mellitus patients who experience gangrenous complications, 40-60 years old, have diabetes mellitus and gangrenous complications for more than 5 years, and passed the screening test. The data was collected using interview and field notes. The interview was guided by general guidelines. These general guidelines were used to remind the interviewer about the questions, and as a checklist for whether the aspects discussed and asked was relevant or not. This research used thematic analysis. Thematic analysis is an information coding process which produces topic lists, topic models and related qualification[12].

Results

In this research, there were various reactions from diabetes mellitus patient with gangrene complication, for example; shocked, disappointed, and depressed because his/her incomplete feet, pulling themselves from society and becoming helpless. We also found that this disease not only caused patients to lose physically but also psychologically. A patient who has stress experience because of this disease can also be found in this research. Initially, after suffering from gangrene complications and having to be amputated, diabetics could not accept the condition and often felt anxious about their current physical limitations. On their attempts to accept the reality they used stress management strategy in the form of confrontative coping. They did a lot of confrontative coping efforts such as not wanting to be taken to the hospital, lying to cover up their actual foot and physical condition to the doctor, and also not wanting to be amputated. Because of that, one of the patients had to go through longer treatment because he/she refused to get amputated.

Diabetics also need support from people around them. Social support is one of the indicators of the

stress management strategy from the problem-solving dimension, called seeking social support. Social support from the surroundings is very much needed to motivate the patients in order to recover. Without it, they might not survive until now. The types of social support that are received and needed by each person with diabetes are actually the same, but they also depend on the individual character and the environment. Patients with diabetes mellitus who have a supportive family would tend to ask help from their children and their partners, while patients who are closer to their friends would tend to ask support from friends. Patients admitted that social support from people around them has enhanced their spirits during their treatment. Diabetics with gangrene complication also have long-term plans to maintain their condition, focusing on how to heal the wound, to prevent stress, and to stay healthy. This step is included in a stress management strategy, specifically belongs to the problem-solving effort dimension, and called planful problem-solving. The action of planful problem solving performed by the patient, in this case, was shown by doing treatment and taking medication regularly. The other actions were shown by running diabetic diets to maintain blood sugar levels, fasting, consulting to a doctor, and treating the wounds regularly. These patients also learned about their disease in order to understand what to do with it.

In this study, diabetics with gangrenous complications also had a stress management strategy in the form of self-control to deal with stress due to their illness. It was found that self-control performed by the patients by not telling their problem if they could solve it themselves. They tried to sort out what things need to be told and what to be handled by their own. The next stress management strategy that these patients used was distancing. It was found that the distancing was performed by not to overly think about their illness and not to mourn about it. Patients tried to prevent stress by assuming that everything has its time.

In this study, it was found that diabetics with gangrene also carried out stress management strategies in the form of positive appraisal. The positive appraisal done by the patients was by being grateful to be able to survive until now and trying to find a positive meaning behind their situation. Patients also had an inspiration that makes them optimistic to be recovered. They had goals and had known what was important in their lives, for example, patients were eager to be healthy because they wanted to see their children succeeded and grew up. Patients also tried to get closer to God by increasing worship and pray. They felt relieved after poured out all his heart during their prayers. It helped him/her to be calmer and less stressful in living his/her life. These positive appraisals helped the patients to relax and get optimal treatment. These patients have also done stress coping strategies in the form of accepting responsibility. In this study, the action of accepting responsibility was shown by acknowledging their diet mistakes which have led them to experience diabetes mellitus and gangrenous complications.

Discussion

Even though they have good planning to maintain their condition, diabetics with gangrene complication have also been in a condition where he/she is truly saturated with all the medical routines he/she has been doing. This is a stress diversion called escape/avoidance. In this study, it was found that the patients tried to divert stress by imagining a condition where he/she was not a person with diabetes mellitus. As explained above the patient was an active person, with the current situation sometimes they really wanted to feel normal like before. The patient also forgot to eat the diet that was suggested, even though he/she knew that the food was not good for his/her health. The stress management strategy in this study used the basic strategy described by Taylor. Stress management strategies are divided into 2 types, namely problem-solving effort, and emotion-focused coping that will be done by everyone when experiencing a stressful experience. In this study, diabetics with gangrene condition used both stress management strategies to manage their stress. Problem-solving effort is an attempt to do something constructive to overcome a situation that creates social stress, including an adverse, dangerous or challenging event faced by an individual. Meanwhile, emotion-focused coping is an attempt to regulate the emotions felt by individuals while facing social stressful event. In this study, we found that there were three biggest stress management strategies performed by the three patients. In the problem-solving effort section, there were the planful problem-solving actions and the seeking social support actions. While in the emotion-focused coping section, there were positive appraisal actions. These means that the three patients focused on their plans to solve the problem, their steps to overcome the wound condition so that they could prevent stress condition. After that, the three patients surrendered entirely to God. All of them agreed to surrender themselves and looked for the positive

meaning behind their current situation. They were aware of their priorities at the moment and not focusing on their sadness. The third is a stress management strategy that will not succeed without the support of people around the patient[8]. This support makes the patient strong and eager to go through the day as well as motivates them to be healthy and healed. This support comes from family, neighbors, friends, and people closest to the patients, including medical personnel.

Conclusion

Diabetes mellitus is not only caused by genetic factors. All the three patients in this study, despite having the genetic factors, they also did not maintain their diet well. It was this diet that eventually led them to have diabetes mellitus and gangrene complications. The three patients showed different performance on handling stress using stress management strategies. There were three biggest stress management strategies performed in this study: the planful problem solving and the seeking social support which belongs to the problem-solving effort section, and the positive appraisal section which belongs to the emotion-focused coping section. The strategies focused on how they plan to solve the problem, what steps they must take to overcome the wound condition, and then surrender entirely to God. All three patients looked for the positive meaning behind their current situation and were aware of their priorities at that moment. Then, those strategies would not succeed without the support of people around the patient. This support made the patient strong and motivate them to heal. The support came from family, neighbors, friends, and people closest to the patients, including medical personnel. There was a difference regarding which was the most dominant stress management strategy used by each patient. The difference is caused by how the environmental conditions where the patient live.

Conflict of Interest: The authors declare that they have no conflict of interest.

[2]Department of Public Health, Faculty of Health Sciences, Muhammadiyah Surakarta University, Indonesia

Abstract

Metal casting industry which is having high risk to work accidents and have applied work instructions (IK) to all unit working parts. Based on preliminary survey in PT X the level of work instructions compliance is 70% and 80% of workers safe behavior. The majority of workers work instructions compliance and safe behavior, but there are still workers did not compliance with work instructions and safe behavior. This study aimed to analyze the relation of work instructions compliance with safe behavior of production part workers in PT X. The kind of research is quantitative observational with cross sectional analytic approach that studies the relationship independent variabel with dependent variabel. The research population is all labor production section in PT X many as 74 people with the sample many as 48 people has been present working on the research day. The results of the fisher's exact test showed (p=0,03) < 0,05 which means Ho rejected so that there was a correlation between work instructions compliance with safe behavior at production line workers in PT X. Conclusions of the study, that there is a significant relation exsist between work instructions compliance with safe behavior. Advice for the company are to be able to establish P2K3, hold an inspection formal and informal.

Keywords: *Work instructions compliance, safe behavior.*

Introduction

The development of industrialization and modernization is increasingly rapid resulting in increased operational work intensity, so that there are various impacts such as fatigue, loss of balance, lack of skills, lack of knowledge about sources of danger are the causes of accidents and work-related diseases that can affect company performance[8]. Manpower, Transmigration, and Population offices of the Central Java Provincial Government noted an increase in work accident data in 2015 which amounted to 3,083 work accidents compared to 2014 which amounted to 2,549 work accidents[3].

Accident events based on data, facts and experience are a series of events because of the potential for interrelated hazards, workplace accidents can be caused by work or unsafe actions such as those related to protective machinery, can be moved or modified sequences, work indoors withbad lighting and so on.In various studies of workplace accidents dangerous behavior is an important indicator[7,10].

There is a significant relationship between compliance with work instructions and safe behavior obtained p value of 0.01 <0.05 which indicates the relationship of compliance with work instructions and safe behavior is being at the mechanical part employees of PT Y[1].

PT X has applied Work Instruction (IK) to all work units. All work process activities and actions are carried out daily based on abbreviated work instructions (IK) which are supervised by each section head. Based on the

results of the preliminary survey in the production section of PT X the level of compliance with work instructions was 70% and as much as 80% of workers behaved safely. Most workers obey work instructions and work safely, but there are still workers who do not comply with work instructions and behave unsafe. Based on this background, researchers are interested in knowing the relationship of work instructions compliance with safe behavior of production part workers in PT X.

Material and Method

This type of research is an observational quantitative study using an analytical cross sectional approach that studies the relationship of independent variables, namely work instructions compliance with dependent variables, namely safe behavior that is assessed and measured simultaneously in one time[5].

The population of this study is that all the production workforce in PT X numbered 74 people with a minimum sample size of 43 people and at the time of the study a total of 48 workers were present and were willing to be studied. The independent variable is work instructions compliance using the obedient category ≥ mean and <mean for the non-compliant category and the dependent variable for safe behavior using the safe category ≥ mean and<mean for the unsafe category. Using univariate and bivariate analysis with the provisions of the chi-square test, namely the null hypothesis (Ho). If p value <0.05, then Ho is rejected and if p value is ≥ 0.05 then Ho is accepted.

Findings:

1. **Age of Respondents:**

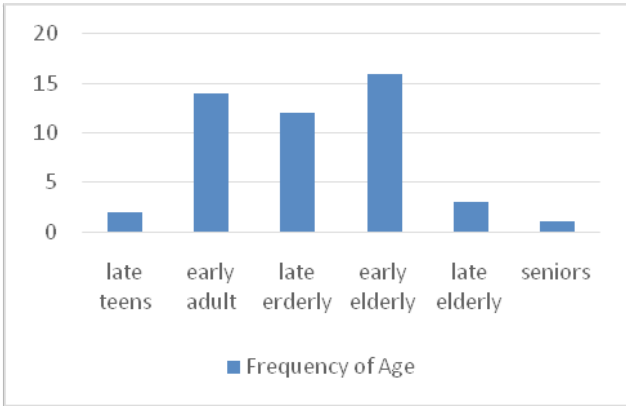

Figure 1. Age of Respondents

Most of the production workers at PT X were in the early age, 33.3% and only 2.1% were elderly workers. age is directly proportional to one's physical capacity and reaches its peak at the age of 25 years, increasing age will be followed by a decrease in physical capacity such as sharpness of vision, hearing, speed of distinguishing things, making decisions and the ability to remember. Production workers at PT X are almost all productive and can work well[8].

2. **Work Period of Respondents:** The number of workers with the highest working period of production at PT X for a very long working period is 37.5% and the number of workers with the least working period during the long service period is 10.4%. a long working period can have an influence on the experience of workers so that the longer the working period, the experience they have will be more and more mature and vice versa[2,4]. Most of the workers in the production of PT X have very long working hours so that they have good experience and skills that can support the smooth running of the work and can complete their tasks quickly and precisely.

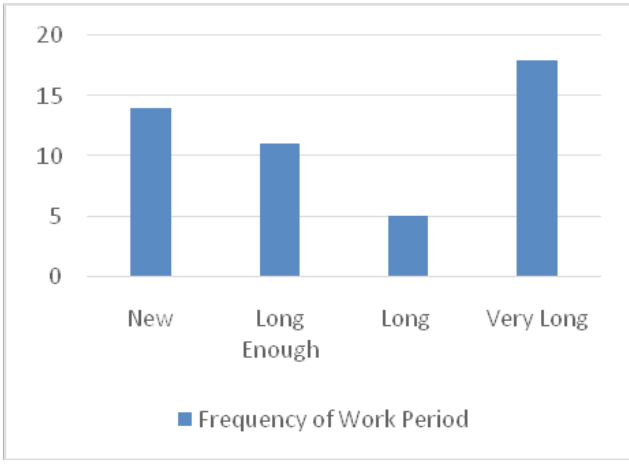

Figure 2. Work Period

3. **Education of Respondents:** From the table known that the majority of workers with high school education or equal to 70.8%, and only 2.1% of workers who did not go to school or did not complete elementary school. education is important in dealing with technological developments, so workers can use and maintain it if damage occurs. Based on research, production department workers at PT X have mastered the work they are doing, skillfully and skillfully using equipment, and processing materials such as printing sand without mold, pouring steel liquid in the production process, where education is needed in this case because of

the accuracy in calculations when pouring hot steel liquid, it must be measured correctly[8].

Table 1. Education of Respondents

Age	Behavior		Total
	Safe	Unsafe	
Late teens	2	0	2
Early adult	10	4	14
Late adult	9	3	12
Early elderly	12	4	16
Late elderly	2	1	3
Seniors	1	0	1
Total	36	12	48

4. **Age with Behavior:** Most of the workers who behave safely are in the early age, which is 25%, with early aged workers who behave unsafe at 8.3%. age is directly proportional to one's physical capacity and reaches a peak at the age of 25 years, increasing age will be followed by a decrease in physical capacity such as sharpness of vision, hearing, speed of distinguishing things, making decisions and the ability to remember[8].

Table 2. Age with Behavior

Education	Frequency	Percent (%)
No school	1	2,1
Graduated from elementary school	9	18,8
Graduated from junior high school	4	8,3
Graduated from high school	34	70,8
Total	48	100

5. **Work Period with Behavior:** Most workers who behave safely enter a very long working period of 27.08%, but there are still those who behave unsafe at 10.42% even though they have entered a very long working period.the longer a person's working period, the more experience he has and the more mature he has, but there are still those who do not behave safely because they already feel experienced and skilled in doing work[4].

Table 3. Work Period with Behavior

Work Period	Behavior		Total
	Safe	Unsafe	
New	10 20,86%	4 8,34%	14 29,2%
Long enough	8 16,65%	3 6,25%	11 22,9%
Long	4 8,32%	1 2,08%	5 10,4%
Very long	13 27,08%	5 10,42%	18 37,5%
Total	35 72,91%	13 27,09%	48 100%

6. **Education with Safe Behavior:** The biggest workers with high school education were 52.06% who behaved safely but still had workers who did not behave safely with a high school education of 18.74%.

Table 4. Education with Safe Behavior

Education	Behavior		Total
	Safe	Unsafe	
No school	1 2,1%	0 0,0%	1 2,1%
Graduated from elementary school	7 14,6%	2 4,2%	9 18,8%
Graduated from junior high school	3 6,2%	1 2,08%	4 8,3%
Graduated from high school	25 52,06%	9 18,7%	34 70,8%
Total	**36 74,98%**	**12 25,02%**	**48 100%**

7. **Working Conditions:** Working conditions in the production section of X can be seen that 100% of respondents observed work in safe working conditions.

Table 5. Working Conditions

Working Condition	Frequency	Percent (%)
Safe	48	100
Unsafe	0	0
Total	48	100

8. **Work Instructions Compliance:** Work instructions compliance for the production workforce of PT X amounting to 71% of respondents obeying work instructions while 29% of respondents did not comply with work instructions given by the company.

   Most workers have complied with the work instructions well even though there are no officers

who supervise, such as checking equipment before use, writing work reports that have been completed, using personal protective equipment arranged in work instructions such as glasses, earplugs, masks, clothes protectors, gloves, shoes. They follow work instructions correctly because they understand that they work with considerable danger, namely the risk of being exposed to melt and hot steel splashes, but there are still workers who are not obedient such as not checking the equipment to be used first, not using personal protective equipment when work because workers reason that when using personal protective equipment they will feel uncomfortable and disrupt their activities, that is, they are not free.

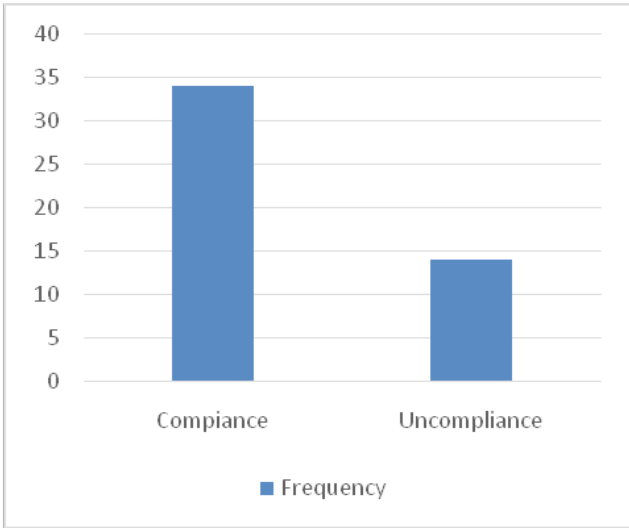

Figure 3. Work Instruction Compliance

9. **Safe Behavior:** The safe behavior of production workers at PT X at 73% of workers behave safely while 27% of workers who do not behave safely when working.

   Workers behave safely such as using personal protective equipment even though they are not supervised, use equipment according to their functions, do not joke while working, but based on research there are still workers who behave unsafe such as smoking in the work area, black sand workers who do not use protective equipment self at all, do not use personal protective equipment that is complete using earplugs, gloves but do not use glasses when welding, unsafe work positions such as working positions for too long squatting and bending when forming sand resulting in back pain, exposed to sparks during the induction process and when pouring steel liquid into the mold.

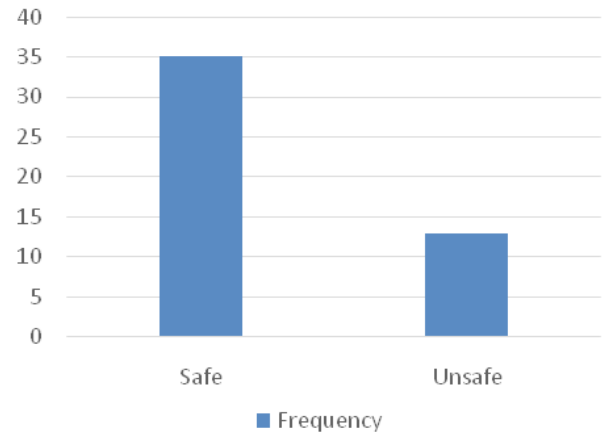

Figure 4. Safe Behavior

10. **Relationship between Work Instructions compliance with Safe Behavior:** The results of the chi-square statistic test showed that the use of the chi-square test was not fulfilled because there was an expeted value <5 so that using the value of fisher's exact test, the results of fisher's exact test showed p value of 0.03 <0.05 which means that Ho was rejected between compliance with safe conduct of work instructions for production workers at PT X. Statistical test results, the correlation between work instructions compliance with safe behavior produces a number of 0.29, the figure shows a low correlation level[6].

    Based on the results of statistical tests, it was found that production workers at PT X were observed, workers who obeyed work instructions and behaved safely were 52.08%, workers who did not comply with work instructions but behaved safely were 20.83%, obedient workers work instructions but not as safe as 18.75%, workers who do not comply with work instructions and do not behave safely are 8.34%.

    This research is in line with previous research that there is a relationship of work instructions compliance with safe behavior on employees of the mechanical part of PT Y with a p value of 0.01 <0.05[1]. and there is a relationship between the practice of applying the SOP with the incidence of workplace accidents and the practice of nurses with a p value of 0.002[9].

    It is known from statistical tests that the more obedient to work instructions, the workers tend to behave safely in the workplace. Workers at PT X who are obedient to work instructions realize that the importance of work instructions to be

understood and adhered to because they know they work in a place that is at high risk for accidents and by behaving safely such as using personal protective equipment that is using glasses, earplugs, masks, protective clothing, shoe gloves so that they can protect them while working.

But there are still workers who do not comply with work instructions because they feel familiar with the work done such as not checking equipment to be used, not using personal protective equipment, then behaving unsafe such as smoking in work areas because there are no sanctions directly given, no using personal protective equipment based on research workers reasoned uncomfortable and felt complicated when they had to use personal protective equipment and they used personal protective equipment completely only when there was a visit.

Table 6. Relationship between Work Instructions compliance with Safe Behavior

Compliance	Behavior		Total	P/r
	Safe	Unsafe		
Compliance	25 52,08%	9 18,75%	34 70,83%	0,03/0,29
Uncompliance	10 20,83%	4 8,34%	14 29,17%	
Total	35 72,91%	13 27,09%	48 100%	

Conclusion

Base on the result of the study it can be concluded that the Most of the production workers at PT X are in the early age, which is 33.3% and those who behave safely for the early elderly are 25%. The working period of most production workers has entered a very long working period of 37.5% and workers who enter very long work periods behave safely at 27.08%. Most of the workers have high school education or equal to 70.8% with workers with high school education who behave safely at 52.06%. 100% safe working conditions, namely the work area free from garbage, there are no water spills on the floor, there are label items, equipment used in good condition, personal protective equipment is available in good condition, there are hygiene facilities, and there is a first aid kit in each part of the work. Workers who adhere to work instructions based on the results of the study are 71%.Workers who behave safely are based on the results of research, which is 73%.

There is a significant relationship between work instructions compliance and safe behavior of production part workers in PT X.

The Relationship of Age and Work Period with Hearing Disorders on Workers Which are Exposed to Noise Above Threshold Limit Value of Loom Part Weaving Ajl Department in Pt Bintang Asahi Tekstil Industry

Bella Oktavia[1], Rezania Asyfiradayati[2], Abdul Rohim Tualeka[1]

[1]Department of Occupational Health and Safety, Faculty of Public Health, Airlangga University,
[2]Department of Public Health, Faculty of Health Sciences, Muhammadiyah Surakarta University, Indonesia

Abstract

The production process at Loom part Weaving AJL Department PT Bintang Asahi Textile Industry using machines with loud noise can cause noise and the risk of causing hearing loss for workers. PT Bintang Asahi Textile Industry been providing a blob ear protective devices threads to protect workers from exposure to noise. But the level of awareness of workers are still lacking in the use of PPE compliance. This study aimed to analyze the relationship between length of service and age with hearing loss of workers exposed to noise> Threshold Limit Value on the Loom Weaving Department AJL PT Bintang Asahi Textile Industry. This research uses a quantitative research design with cross sectional analytic. The population in this study were working Loom part Weaving AJL Department with a sample of 71 respondents taken by simple random sampling. Data analysis used Product Person. The results showed no relationship between age and hearing loss of workers part Loom Weaving Department AJL (p = 0.0001), there is a correlation between working period with a hearing loss of workers Loom part Weaving AJL Department (p = 0.0001).

Keywords: *Age, years of service, hearing loss, noise.*

Introduction

Occupational hazards are classified into several types, one of which physical hazards such as noise. Noise that exceeds the threshold value >85 dBA can cause hearing loss. Hearing loss is directly proportional to age, and reaches its peak at the age of 25 years, with increasing age it is followed by a decrease in physical capacity such as decreased hearing[1].

A person's hearing power in capturing sound is influenced by internal and external factors. Of the various factors that can affect the hearing threshold, the most prominent in internal factors are age and external factors, namely the length of exposure to noise[2]. Based on research, results showed no correlation with age and years of hearing threshold value of workers exposed to noise in the Steel Melting Shop production unit of PT. X Sidoarjo[3].

PT Bintang Asahi Textile Industry or in short with PT BATI is a company that is in the area of Sragen and engaged in the textile field. The production process at PT BATI using machines that could potentially cause noise, one of its engines on the Loom Weaving AJL Department. Workers in the Loom Weaving AJL Department work for 8 hours in a day.

Based on the preliminary survey to measure the noise level at the Loom at two points, the result of measurement exceeds the threshold limit value (85 dBA).

At a noise level of >85 dBA after a 10-year work period workers will experience hearing loss[4]. While the results of interviews with 15 workers Loom part Weaving AJL department in PT Bintang Asahi Textile Industry with tenure below 10 years, there were seven workers have a hearing loss. The purpose of this study was to analyze the relationship between age and years of service to the hearing impaired workers exposed to noise exceeding the threshold limit value at the Loom part Weaving AJL Department in PT Bintang Asahi Textile Industry.

Research Method

This type of research is quantitative analytic using cross sectional design. The population in this study were all employees of section Loom part Weaving AJL department in PT Bintang Asahi Textile Industry with the number of 156 workers and obtained a sample with the number of 71 respondents. The sampling technique in this study is simple random sampling where each population has the same chance to be selected as a sample.

The variables in this study consisted of two variables, namely the independent and dependent variables. The independent variables in this study were age and years of service workers Loom part Weaving AJL department, and the dependent variable in this study is hearing impaired workers Loom part Weaving AJL department. While confounding variables were measured in this study is the intensity of the noise at the Loom part Weaving AJL department.

Collecting data on age and years of using a questionnaire, hearing loss using audiometric tool and noise using a sound level meter. The research was conducted during the hours after work in accordance with the work shift respondents. For the morning shift it takes place at 14.00, for the afternoon shift at 22.00, and the night shift at 06.00. while the noise measurement was carried out at 10:00. Data analysis using computerized statistical programs included univariate analysis and bivariate analysis.

Findings:

Table 1. Measurement Method

Measuring Point	Noise Measurement Result (dBA)
Point I	86.93
Point II	87.25
Point III	87.46
Point IV	87.77
Point V	87.88
Average	87,45

Based on Table 1, results in the lowest measurement point 1 to the value of 86.93 dBA. While the results of the highest measurement at the point to 5 with a value of 87.88 dBA. With an average overall measurement result is 87.4 + 0.325. The results of measurements of noise at the Loom part Weaving AJL department Textile Industry PT Bintang Asahi show all >85 dBA, these results do not match or exceed the Threshold Limit Value has been determined.

Table 2. Age of Respondents

Respondents Age	Frequency	Percent
28	4	5.6
29	1	1.4
30	3	4.2
31	1	1.4
32	6	8.5
35	1	1.4

Based on Table 4. The results of the hearing level measurement section worker Loom Weaving AJL Department highest value of 68.12 dB measurement only 1 respondent with a percentage of 1.4%, while the lowest is the measurement results are 7.50 dB 2 respondents with a percentage of 2.8%. The average yield of the overall measurement of hearing that is 31.09 + 14.16 dB.

Table 5. Test Results Minimum Relations with Hearing Loss

Variables	Average	Significance
Age	41.80	0.0001
Hearing disorders	31.09	

Based on Table 5, the results of the Person Product statistical test show a significance of 0,0001 <0,05, which means that Ho is rejected so there is a social relationship with hearing loss in the Loom part Weaving AJL Department at PT Bintang Asahi Industrial Textiles. The strength value of the relationship between age and hearing loss was 0.574 (strong relationship strength).

There are studies that suggest that there is a significant relationship between age and hearing threshold value of respondents surveyed. These results indicate a p-value of 0.000, which means there is a relationship or correlation between age and the Threshold Limit Value[3]. In another study states that there is a relationship between age and degree of hearing loss right ear (p = 0.046), left ear (p = 0.042), and the degree of deafness double ear (p = 0.006) in residents around highways exposed to noise[5].

Table 6. Test Results Work Period Relations with Hearing Loss

Variables	Average	Significance
Years of service	11.58	0.0001
Hearing disorders	31.09	

Based on Table 6, the results of statistical test showed Person Product Significance value of 0.0001 <0.05, which means that Ho is rejected so that no future relationship with a hearing loss of workers working Loom part Weaving AJL Department in PT Bintang Asahi Textile Industry. Rated strength of the relationship between working life with a hearing loss is 0.493 (the strength of the relationship is strong enough). The correlation is in line with the results of the correlation between working period with a hearing loss of 0,455, the correlation results are also included in the category strong enough[4].

The results are consistent with the theories and studies that have been done, including the theory that suggests that the tenure effect on hearing threshold value of labor. increase in hearing threshold on the working life group> 10 years higher than the working age group <10 years[1]. While the research results are consistent with research that has been done the results show that there is a relationship between length of service with NIHL events at home exhaust industry workers in Sub Purbalingga Lor[6].

Based on the results of interviews with workers in the Loom section of the AJL Weaving Department, many workers complained about the effects of engine noise such as the disruption of communication with other workers, the feeling of always wanting to get angry, and decreased hearing. The main effect of working continuously on a noisy environment will be uplifted to health, namely damage to the auditory senses caused by loud sounds such as the sounds of production machines.

Other factors that can affect hearing loss is the use of ear protection device. PT Bintang Asahi provide ear protective devices such as earplugs in the form of lumps of fabric, wherein the fabric blob should be used during the job. The control efforts that can be made with the conditions at PT Bintang Asahi Textile Industry on noise levels include engineering through good maintenance of equipment such as checking machines every day, giving lubricants on the moving parts so that lubricant can function to muffle the noise of the machine being move, and put a damper with rubber pads so that noise caused by vibration and machined metal parts, rubber pads mounted on moving machine parts fall so that the noise can be controlled with the rubber pads. PT Bintang Asahi Industrial Textiles has not provided ear protectors that comply with the standards of health and safety of its workers, making efforts to provide protective equipment such as ear earplug and earmuff is required by PT Bintang Asahi Textile Industry to maintain the health of their workers. Efforts to control the rotation of workers who enter the category of elderly age early and exposed to noisy exceeds the threshold limit value, can be moved on a part that has a low noise level.

Conclusion

The average age of the respondents, 41.80 ±7.593 years, with the difference in age is 28-62 years. The average tenure of respondents ie 11.85 + 5,518 years, with the difference in working period is 3-27 years. The hearing threshold measurement results with the average respondent is 31.09 ± 14.16 dB, the difference in hearing threshold respondents are from 7.50 to 6.18 dB. The average results of measurements of noise intensity is 87.45, the value is> 85 dBA exceed the Threshold Limit Value (TLV), by a margin of 86.93 to 87.88 dBA. Statistical test results in getting the relationship between

age with hearing loss of workers with significant value of 0.0001 and a correlation value of 0.574 (strong) statistical test results in getting the relationship between working life with a hearing loss of workers with significant value of 0.0001, and the results a correlation of 0.493 (strong enough).

Health Literacy on Weighing Control and Use of Weight Loss Products among Working-age Women in the Northeast of Thailand

Chalee Yaworn[1], Wongsa Laohasiriwong[2], Kittipong Sornlorm[1]

[1]Doctor of Public Health Program. Faculty of Public Health, [2]Faculty of Public Health, KhonKaen University, KhonKaen, Thailand

Abstract

This cross-sectional study aimed to describe weight loss products' use patterns and identify the association of health literacy on weight control and weight loss products use among working-age women in the Northeast of Thailand. The study was conducted among 1,190 respondents who were multistage randomly selected from 4 provinces of the Northeast region. Data were collected using a self-administered structured questionnaire. The generalized linear mixed model (GLMM) was used to identify the association between health literacy and weight loss products use when controlling the effects of other covariate presenting adjusted OR and 95% confidence interval. The results indicated that 23.19% (95% CI = 20.79-25.59) of the respondents ever used weight loss products, of which 11.60% (95% CI = 9.77-13.41) were current users. Levels of health literacy on weight control was statistically significant with weight loss products use including having; sufficient level of health literacy (adj. OR = 2.62: 95% CI=1.59-4.31, p-value <0.001), problematic level of health literacy (adj. OR = 4.71: 95% CI=2.87-7.72, p-value <0.001) and inadequate level of health literacy (adj. OR = 10.97: 95% CI=6.17-19.51, p-value <0.001) when compared with having excellence level. The significant covariate was had waist circumference ≥ 80 cm. (Adj. OR = 4.12: 95% CI = 2.79-6.11, p-value =0.025), finished lower than bachelor degree (adj. OR = 2.11, 95% CI = 1.78-3.70, p-value <0.001), had average monthly income ≥ 15,000 THB =(adj. OR = 3.08: 95% CI = 2.20-4.31, p-value <0.001), About twenty three percent of working-age womenever used weight loss products. Health literacy was highly associated with used weight loss products.

Keywords: *Weight loss products, Health literacy, working-age women.*

Introduction

Overweight and obesity cause various health problems all over the world[1], obesity particular is one of the main causes of morbidity and mortality[2] especially cardiovascular disease (CVD). Awareness of the serious health consequences, people turn their attention to weight control to be within the standard[3]. It is wildly accepted that lifestyle modification, such as healthy dietary habits and regular physical activity is necessary for weight control, however, with a long term effort [4]. Therefore, many people use various weight loss products because they are quicker and easier than exercising or dieting[5]. Although this method is dangerous or has many side effects[6], as well as being unable to confirm the weight loss results as to whether or not effective[7]. The main target groups of these products are working women[8]. Because they are a person with financial readiness, able to make independent purchase decisions and pay attention to the shape[9].

Health literacy is linked to the ability of individuals to understand and apply health information to practice for disease prevention and health promotion[10]. People with an excellent level of health literacy should be less likely to use weight loss products since they are well aware of their complications than those with inadequate

health literacy. Social-cognitive factors also play an important role in behavioral determination[11].

Although different health behavior theories have been used to explain weight management, roles of social-cognitive factors on weight loss remain poorly understood[12]. Also, there is limited evidence concerning the influence of socio-demographic gradients on dieting and attempts at weight loss[13] such as women are more likely to concern about their shape.

The Northeastern region of Thailand is the biggest region both in terms of areas and population. Most of the labor forces of the country are from this region. With the long term continuously economic expansion, there has been an increasing trend of overweight and obesity among northeasterner women. Therefore it is essential to the determinants of weight loss products use among them.

Objective: To describe the weight loss products use and identify the association between health literacy on weight control and weight loss products use among working-age women in the Northeast of Thailand.

Materials and Method

This cross-sectional study was conducted in 2019. The population was working-age women aged 20 to 59 years old in the Northeast of Thailand. The sample size was calculated by using the sample size estimation formula for the logistic regression analysis of Hsieh[14]. The estimated sample size was 1,190. The respondent was recruited from 4 provinces of the Northeast of Thailand by using multi-stage random sampling method to respond to a structured questionnaire.

Data Analysis: All analyses were performed using Stata version 10.0 (Stata Corp, College Station, TX). Descriptive statistics including frequency and percentage to describe categorical data whereas mean, standard deviation, median, and maximum-minimum for continuous data. A simple logistic regression was used to identify individual the association between each independent variable and weight loss products use. The independent factors that had p-value <0.25 [15] were processed to the multivariable analysis using the generalized linear mixed model (GLMM) to identify the association between health literacy and weight loss products use when controlling the effect of other covariates, of which 4 provinces were selected to include as random effects. The magnitude of association was presented as adjusted odds ratio (Adj. OR), 95% confidence interval (CI) and p-value <0.05 as statistical significant level.

Result

Socio-demographic: The average age of the respondents was 39.46 ±10.71 years old, 58.74 were married, 67.15 percent had education lower than a bachelor's degree. the occupation was employee 25.04 percent, an average monthly income 10,000-19,999 baht, average monthly expenditures less than 10,000 baht, normal body mass index 40 percent, waist circumference exceeds the standard threshold 50.25 percent without chronic disease 86.47 and healthy status of 81.26 percent.

Almost a quarter of the respondents ever used weight loss products (23.19% : 95% CI = 20.79-25.59) of which 11.60% (95% CI = 9.77-13.41) were current users. The most common type of weight loss product use were diet pills which were consumed by 7.84% of the respondents, followed by diet coffee (6.68%) and fiber products (4.50%), see table 1.

Table 1: Number and percentage of weight loss products use pattern (n = 1,190 people)

Weight loss products use pattern	Number	Percent
1. Weight loss products use		
Currently, use	138	11.60
Used for less than 6 months and stop using	39	3.28
Used for more than 6 months and stop using	99	8.32
Never used but would like to use in the future	90	7.56
Never used and want to use	824	69.24
2. Type of weight loss product use (Can answer more than 1 question)		
Diet pills	101	7.84
Diet coffee for weight loss	86	6.68
Fiber products	58	4.50
Konjac Extract	55	4.27
Wearable products for weight loss	12	0.93
Tea products	11	0.85
A traditional procedure such as massage	10	0.78
Chitosan	9	0.70
Weight loss program	8	0.62
Equipment	7	0.54
Garcinia extract	5	0.39

Weight loss products use pattern	Number	Percent
Increased metabolism products	4	0.31
Other weight loss products	8	0.62
Do not use weight loss products	914	70.96

Association between health literacy and weight loss products use among northeastern working women when controlling other covariates: A multivariable analysis: Association between health literacy and weight loss products use among northeastern working women were identified by using the Generalized Linear Mixed Model (GLMM) to control the clustering effect in each health zone. The results indicated that levels health literacy were associated with weight loss products use including had sufficient level of health literacy (adj. OR = 2.62 :95% CI=1.59-4.31, p-value <0.001), had problematic level of health literacy (adj. OR = 4.71:95% CI=2.87-7.72, p-value <0.001) and had inadequate level health literacy 10.97 times the use of weight loss products for those with excellent health literacy (adj. OR = 10.97: 95% CI=6.17-19.51, p-value <0.001) when compared with those with excellent level of health literacy. The other significant covariates were, those with waist circumference ≥ 80 cm. (adj. OR = 4.12: 95% CI = 2.79-6.11, p-value =0.025), graduated bachelor degree or higher (adj. OR = 2.11,95% CI = 1.78-3.70, p-value <0.001), had average monthly income ≥15,000 THB (adj. OR = 3.08:95% CI = 2.20-4.31, p-value <0.001), see Table 2.

Table 2: Association between health literacy and weight loss products use among northeastern working women when controlling other covariates: a multivariable analysis using GLMM

Factors	Number	Percent	Crude OR	Adj. OR	95% CI	P-value
Health literacy						
Excellent	320	9.69	1	1	1.60-4.24	<0.001
Sufficient	407	18.92	2.17	2.61	2.88-7.61	<0.001
Problematic	331	30.32	4.15	4.68	6.04-18.62	<0.001
Inadequate	132	50	9.32	10.6		
Education Level						
≥ Bachelor Degree	391	18.41	1	1	1.78-3.70	<0.001
<Bachelor Degree	799	25.53	1.52	2.57		
Income per month (THB)						
<15,000	667	15.59	1	1	2.20-4.31	<0.001
≥15,000	523	32.89	2.65	3.08		
Waist circumference(cm.)						
<80	588	10.54	1	1	4.48-8.98	<0.001
≥80	602	35.55	4.68	6.31		

Discussion

This present study observed that about 23% of working-age women ever used weight loss products. This proportion was a little lower than those found in a study in 2015 in Bangkok, Thailand indicated that 27.7% of the respondents used weight loss products[16]. However, it was higher than those found in a study in 2017 in Ratchaburi Province, Thailand that observed that 19.6% of the participants used weight loss products[17]. A possible explanation was that there was a higher level of economic development in Bangkok, people have higher income and might concern about shape more than the northeasterners. Ratchaburi, on the other hand, had a lower income. The multivariable analysis of this study also indicated that higher income had a high influence on weight loss products use (adj. OR = 3.08) which was similar to a study in Sweden [13].

Health literacy (HL) played an important role in weight loss products use. Our finding indicated that those who had excellence level of health literacy on weight control were less likely to use weight loss products when compared to those who had sufficient, problematic, and inadequate levels of HL (adj. OR= 2.61, 4.68, and 10.60 respectively). A study of Cheong et all. Indicated that

HL had a positive impact on weight loss behaviors. There was also evidence that interventions focusing on improving knowledge and HL skills could effectively control the weight[18]. HL influences reach and moderates weight effects. These findings underscore the need to integrate recruitment strategies and further evaluate programmatic approaches that attend to the needs of low-HL audiences. HL is necessary and an important indicator when making decisions about weight loss products. Having HL can influence the choice and decision not to use weight loss products. Therefore, encouraging the public to have good HL will help people to avoid using weight loss products and choose to use the right weight control[19].Our finding also observed that there were socioeconomic gradients to overall health and showed that those with lower levels of education had poorer health and higher mortality. A previous study of Barbering et.all[13] also indicated that proper dietary regimen and overweight were associated with higher education levels. Similarly a studied of Ball observed that males who were married, living in households with shared income and who had less education were more likely to use weight loss products[20]. Waist circumference(WC) is one of the conditions of metabolic syndrome, which is an important risk factor of cardiovascular disease[21]. Women with higher WC have a bigger belly which made them looked fat. This might lead to more concern about weight loss. They might try to reduce the WC as quick as possible by using weight loss products[22]. Therefore, it requires effective measures to improve health literacy on appropriate weight control especially among those with lower education having a big belly and had a higher income that has more purchasing power.

Conclusion

The study indicated that about 23 percent of working-age women ever used weight loss products. Health literacy was highly associated with used weight loss products when considering the influenced of waist circumference, educational level, and income.

Awareness Regarding Heart Diseases among Middle Aged Adults in a Rural Area of Rupandehi District

Chanda Sah[1], Priyanka Gyawali[2]

[1]Lecturer, Department of Medical-Surgical Nursing, Universal College of Nursing Sciences,
[2]Clinical Instructor, Department of Medical-Surgical Nursing, Devdaha Medical College, Rupandehi, Nepal

Abstract

Cardiovascular diseases (CVDs) are the number one cause of death globally. Lack of awareness about CVDs risk can lead to delays in seeking treatment and increased risk for sudden death. This study was conducted to assess the awareness on heart diseases among middle-aged adults in a rural area of Rupandehi district, Nepal. Descriptive cross-sectional study was conducted among 107 middle-aged adults of Shudhodhan rural municipality, Rupandehi district. The samples were selected by non-probability purposive sampling technique. Pretested and pre validated semi-structured questionnaire was used for data collection. The data was analyzed using SPSS 16.0 version. More than half of the respondents (55.14%) had high level awareness on heart disease. About 71.03% had family history of heart diseases. Regarding risk factors of heart diseases cent percent respondents were aware of alcoholism,98.13% were aware of smoking, 47.66% were aware of family history and 14.02% were aware of menopause. 99.07% respondents were aware of elevated blood pressure and chest pain as cardinal symptoms of heart diseases. The study reveals that respondents had low awareness on family history as risk factor of heart diseases whereas there is statistically significant association between family history of respondents and level of awareness regarding heart disease (p=0.002). Respondents (14.02%) also had low awareness on lifestyle changes with medicines as management of heart disease. Hence it is necessary to educate people about heart diseases risk factors and lifestyle changes for management and prevention of heart diseases.

Keywords: *Awareness, heart disease, middle-aged adults.*

Introduction

Cardiovascular diseases (CVDs) are disorders of the heart and blood vessels and they include coronary heart disease, rheumatic heart disease, congenital heart disease and other conditions. Triggering these diseases-which manifest primarily as heart attacks and strokes-are tobacco use, unhealthy diet, physical inactivity and harmful use of alcohol. An estimated 17.9 people died from CVDs globally in 2016, representing 31% of all global deaths and 85% of all CVD deaths are due to heart attacks and strokes. Over three quarters of deaths take place in low- and middle-income countries.[1]

In Nepal from 2005 to 2015, the ischemic heart disease increased around 25.3% and Coronary heart disease reached 10.79% of total deaths.[2] About 40% of non-communicable admissions are due to CVDs.[3] These facts create as enormous social burden reducing labour productivity and creating an overcharge of public fees, in a country with a poor healthcare system and a feeble economy. The earthquakes of 2015 also imposed critical social and epidemiological effects to the population resulting in lifestyle changes.[4]

A government data has shown that 99.6% of the Nepali population is at the risk of contracting cardiovascular diseases. The national survey carried out by the Health Research Council has recently found that a majority of people has one or more risk-factors

Lecturer, Universal College of Nursing Sciences,
Bhairahwa, Rupandehi, Nepal
e-mail: chanda.sah08@gmail.com

including tobacco use, alcohol consumption, low fruit and vegetable consumption and physical inactivity that pose a threat for disease. Biological factors such as obesity, high blood pressure, high blood glucose level and abnormal lipids also contribute to the risk of the disease.[5]

The aim of the study was to assess the awareness on heart diseases among middle-aged adults in a rural area of Rupandehi district, Nepal.

Material and Method

Descriptive cross-sectional design was used for the study to find out awareness regarding heart disease in middle-aged adults.The study was conducted in Shudhodhan rural municipality, ward number 2, Rupandehi district, Nepal.The total population residing in thisrural municipality is 8,865. Total 107 samples were selected using purposive sampling technique. Interview schedule was used for data collection with use of pretested and prevalidated semi-structured questionnaire, developed by researchers. There were 22 questions regarding heart diseases. Data was collected in between April to September, 2017. Administrative and ethical approval was obtained from concerned authorities prior to data collection. The researchers contacted each respondents, written informed consent for the study was obtained and interviewed. Descriptive statistical method was used with SPSS 16 version to analyze data using frequency, percentage and mean.

Resuits

As shown in table 1,out of 107 respondents, 40.19% of respondents belong to 40-46 years and 21.50% belong to 54-60 years of age. Similarly 56.07% respondents belong to female gender. Regarding educational status, 50.47% respondents are literate. As regard to occupation, 40.19% of respondents are homemakers. Majority of respondents (71.03%) had family history of heart diseases.

Table 1: Respondents' Socio-demographic Variables n=107

Variables	Frequency	Percentage
Age		
40-46years	43	40.19
47-53 years	41	38.32
54-60 years	23	21.5
Gender		
Male	47	43.93
Female	60	56.07
Educational Status		
Literate	54	50.47
Illiterate	53	49.53
Occupation		
Business	18	16.82
Farmer	34	31.78
Service holder	10	9.35
Homemaker	45	42.06
Family History		
Yes	76	71.03
No	31	28.97

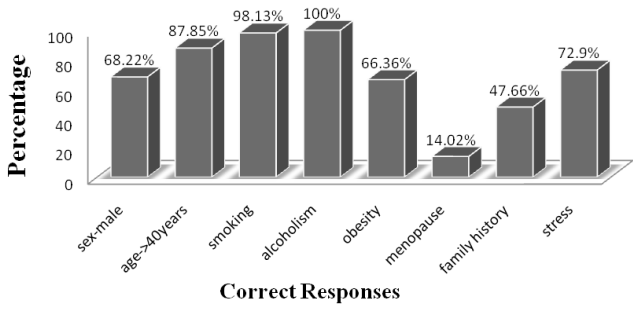
From the table 2 below, more than half of the respondents 59 (55.14%) had high awareness and others 48 (44.86%) had low awareness regarding heart diseases.

Table 2: Respondents' Overall Awareness Regarding Heart Disease n = 107

Level of Awareness	Frequency	Percentage
High	59	55.14
Average	-	-
Low	48	44.86

Mean awareness score=14.35, Total score=20

Out of 107 respondents, cent percent answered alcoholism, 98.13% answered smoking and minority answered family history (47.66%) and menopause (14.02%) as risk factors of heart diseases as shown in graph 1 below.



Graph 1: Respondents' Awareness Regarding Risk Factors of Heart Disease

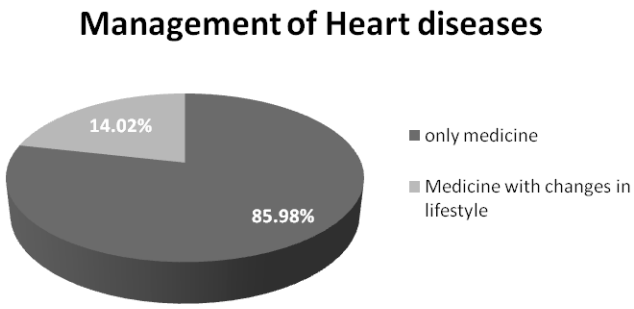
Regarding to cardinal symptoms awareness, majority of respondents (99.07%) answered elevated blood pressure and chest pain and minority (44.86) answered extreme fatigue as shown in table 3.

Table 3: Respondents' Awareness Regarding Cardinal Symptoms of Heart Diseases n = 107

Cardinal Symptoms**	Frequency	Percentage
Elevated blood pressure*	106	99.07
Chest pain*	106	99.07
Palpitation*	56	52.34
Back pain	10	9.35
Muscle rigidity	9	8.41
Extreme fatigue*	48	44.86

*Correct response, **Multiple responses

As regard of management of heart diseases shown in graph 2 below, out of 107 respondents, 85.98% answered only medicine and minority (14.02%) of respondents answered medicine with change in life style. 17.6% of respondents answered there is free treatment of heart disease from Government.



Graph 2: Respondents' Awareness Regarding Treatment of Heart Disease

Table 4 below shows the association between family history and awareness level on heart diseases. It shows that there is statistically significant association between family history of respondents level of awareness regarding heart disease.

Table 4: Association between Family History of Respondents and Level of Awareness Regarding Heart Disease

Variables	Level of Awareness		X^2	p-value
	High (%)	Low (%)		
Family History				
Yes	36 (47.37)	40(52.63)	6.47	0.002
No	23(74.19)	8(25.81)		

Significance level at 0.05

Discussion

The findings of the present study reveal that more than half of the respondents that is 55.14% had high level of awareness on heart disease which is consistent with the findings of study conducted by Tecla et al. (2015) in Western Kenya which showed that 58% of the respondents had knowledge regarding heart disease.[6]

The findings of the study showed that 68.22% of respondents had awareness about sex, 87.85% were aware about age as non-modifiable risk factors of heart disease which is not consistent with the findings of study conducted by Acharya et al. (2012) in Kathmandu which showed 13.8% knew about sex and 46.9% knew age as risk factors of heart disease.[7]

The findings of the study showed that 47.66% of respondents had awareness about family history as risk factors of heart disease which is consistent with the findings of study conducted by Aharyaet al. (2012) in Kathmandu which showed 46.9% respondents knew about family history as risk factor of heart disease.[7]

The findings of the study showed that 98.13% respondents are aware about smoking, 66.36% are aware about obesity and 72.9% knew stress as risk factors of heart disease which is not consistent with the findings of study conducted by Acharya et al. (2012) in Kathmandu which showed that 70.4% respondents are aware of smoking, 58.8% knew obesity and 63.7% knew stress as risk factors of heart disease.[7]

The findings of the study showed that 99.07% of respondents had awareness regarding chest pain as cardinal symptoms of heart disease which is not consistent with the findings of study conducted by Aharya et al. (2012) in Kathmandu which showed 24% knew about chest pain as cardinal symptoms of heart disease.[7]

The findings of the study showed that 24.30% of respondents had awareness regarding medicine with change in lifestyle as treatment of heart disease which is not consistent with the findings of study conducted by Ingvar et al. (2007) in Sweden which showed 48% knew medicine with change in lifestyle as treatment of heart disease.[8]

Conclusion

More than half of the respondents had high level awareness on heart disease. The study reveals that respondents had low awareness on family history, menopause as risk factor of heart diseases whereas there is statistically significant association between family history of respondents and level of awareness

regarding heart disease (p=0.002). Respondents also had low awareness on lifestyle changes with medicines as management of heart disease. Hence it is necessary to educate people about heart diseases risk factors and lifestyle changes for management and prevention of heart diseases.

Abstract

Aim: This research is expected to revealed the correlation between urinary osteocalcin and bone density in menopausal women.

Method: Descriptive study with case series design, conducted at Department of Obstetrics and Gynecology H. Adam Malik General Hospital Medan and Integrated Laboratory of Medical Faculty, University of North Sumatra and Setia Budi Hospital for DEXA Scan measurements in January 2019. The research sample was taken by 21 menopausal women using non-probability sampling with consecutive sampling techniques. Analysis of the correlation of urinary osteocalcin with bone mass density using Pearson correlation.

Results: The mean value of urinary osteocalcin in women with normal bone mass density was 6.67 ± 0,53 and the mean value for the osteopenia group was 9.05± 1.30. The results of the Pearson correlation showed a r score -0.803 and p <0.001. In this research shows that the higher level of urinary osteocalcin, the lower the T score.

Conclusion: This research shows a significant negative correlation of urinary osteocalcin levels with bone mass density (T score) in menopausal women.

Keywords: *Osteocalcin, Bone Mass Density, Menopause, DEXA, Osteoporosis.*

Introduction

Menopause is cessation of menstruation in 12 months. Post menopause is time after menopause. Menopausal transition is time when irregularity of menstruation occur after 12 months forward. Average age of menopause is 51,5 years old.[1]

Estrogen deficiency will cause a disruption of bone remodeling that will cause osteoporosis in postmenopausal women. This will cause loss of bone mass and bone quality. Increased secretion of osteoclastogenic cytokines such as interleukin-1 (IL-1), interleukin-6 (IL-6), and tumor necrosis factor (TNF-α), imbalance in RANKL/OPG gene expression, and inhibition of osteoclast apoptosis are several mechanisms in osteoporosis.[2,3,4]

Bone Mass Density (BMD) is a standard for

Corresponding Author:

e-mail: cherrykumalasari@gmail.com

measuring bone mass and is assessed using Dual Energy X-ray Absorptiometry (DEXA) in the lumbar, radius, and femur. According to WHO, to diagnose osteoporosis, a T score can be used which osteoporosis is defined by BMD> -2.5.[1]

Osteocalcin also has several properties, namely in the normal state of kidney function, osteocalcin and fragments will be cleared quickly by the kidneys and contribute to free Gla in the urine. However, in the case of kidney failure, these fragments accumulate and can be detected. Problems related to circulating osteocalcin instability (S-OC) after sampling tend to be less severe than urinary osteocalcin (U-OC), which is thought to be the final product of fragmentation.[5]

Serum OC levels can be detected by various tests, such as tests using monoclonal antibodies to OC N-mid and OC N-terminals fragments. Lack of calcium and phosphorus in women with osteoporosis decreases the formation of hydroxyapatite crystals, which make osteocalcin free circulating in the blood. This explains the increasement of concentration of serum OC levels in postmenopausal women who have osteoporosis.[6]

From the research of Rusda M in 2016, there was a positive correlation between serum estradiol and T score with r = 0.53. This shows that BMD is reduced in postmenopausal women who have osteoporosis compared with nonosteoporosis due to decreasement of estrogen levels as the main etiology in postmenopausal women. Calcium and phosphate deficiency in osteoporosis women decreases the formation of hydroxyapatite crystals, which causes osteocalcin to circulate freely in the blood. This explains the high concentration of osteocalcin in menopausal women. This can be taken into consideration that osteacalcin can be used to detect low Bone Mass Density (BMD) conditions.[7,8,9,10]

Material and Method

This is a descriptive study with a case series design to examined the correlation of urinary osteocalcin levels with bone mass density in 21 menopausal women which is conducted at Department of Obstetrics and Gynecology H. Adam Malik General Hospital in Medan which takein using non-consecutive sampling, while for urine osteocalcin examination performed at the Integrated Laboratory of Medical Faculty, University of North Sumatra and Setia Budi Hospital for DEXA Scan measurements. This research was conducted in January 2019.

Work Arrangement: After obtaining approval from the ethics commission to conduct research, research begins with collecting samples. Body Mass Index (BMI) was measured, then measurement of L2-L4 lumbar bone mass density using Dual Energy X-Ray Absorptiometry (DEXA). For measurement of urinary osteocalcin levels, the N-MID Osteocalcin (N-MID-OT) ELISA kit is used. Urine Osteocalcin (U-OC) levels were measured by quantitative ELISA using the manufacturer's instructions and using a central portion of urine taken in a 24-hour period. 100 µl of reagent and urine osteocalcin are mixed, covered with adhesive, incubated for 2 hours at 37 ^{o}C. Pipette layouts are prepared to measure standard solutions and samples. The liquid in each pipette is removed, but not washed.

Statistical Analyzed: Data were analyzed descriptively to see the frequency distribution of research subjects based on characteristics. To analyze the relationship of urine osteocalcin with bone mass density, the data were analyzed by Pearson correlation. The results of the analysis are said to be significant if p <0.05 with a 95% confidence level. Data analysis using SPSS version 20.

Results

The description of the research subjects characteristics based on age, bone mass density, and body mass index can be seen in the table below.

Table 1: Frequency Distribution Based on Sample Characteristics

Variable	n (21 person)	Persentage (%)
Age		
50-55 years old	3	14,3
56-60 years old	10	47,6
61-65 years old	8	38,1
Body Mass Index		
Underweight	1	4,8
Normoweight	7	33,3
Overweight	5	23,8
Obesity	8	38,1
Menopause Duration		
1-2 years old	4	19,0
2-4 years old	7	33,3
≥ 5 years old	10	47,6
Total	**21**	**100**

Characteristics of research subjects based on majority which is age56-60 years as many as 10 subjects

(47.6%),normoweight as many as 7 subjects (33.3%) and menopausal duration ≥ 5 years as many as 10 people (47.6%).

Table 2. Frequency Distribution of Characteristics and Average Bone Mass Density in Menopausal Women

Bone Mass Density	n	Per. (%)	Mean	SD
Normal	10	47,6	-0,47	± 0,56
Osteopenia	11	52,4	-1,51	± 0,29
Total	**21**	**100**		

The characteristics of the subjects are based on Bone Mass Density, osteopenia group as many as 11 people (52.4%). While the mean bone mass density in the normal group was -0.47 ± 0.56 and the osteopenia group was -1.51 ± 0.29.

Table 3. Mean Value of Urine Ostocalocalcin based on Bone Mass Density in Menopausal Women

Osteocalcin	Mean	SD
Normal	6,67	± 0,53
Osteopenia	9,05	± 1,30

Mean value of urinary osteocalcin in women with normal bone mass density was 6.67 ± 0.53, the mean value for the osteopenia group of women was 9.05 ± 1.30.

Table 4. Correlation of Urine Osteocalcin with Bone Density in Menopausal Women

Parameter	R	P
Urine Osteocalcin Levels	-0,803	<0,001
T Score		

* Pearson Correlations

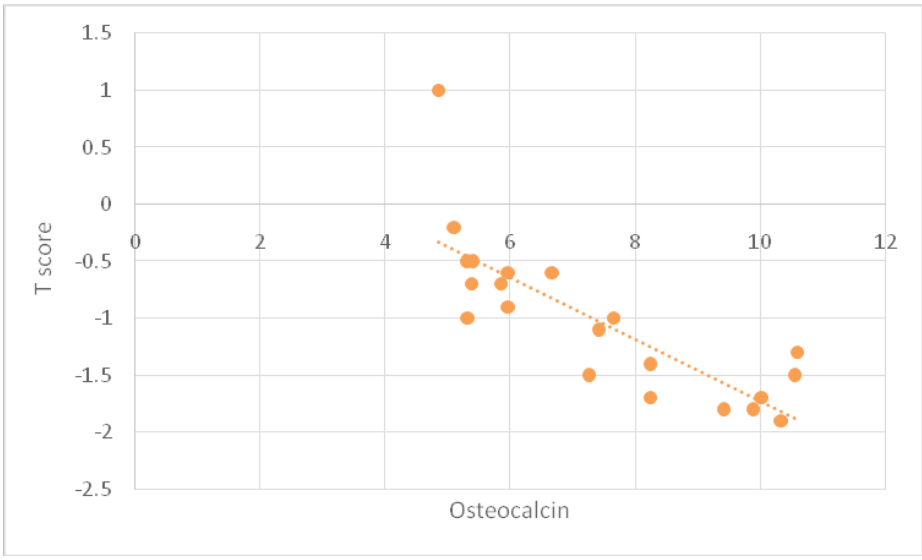

Figure 1. Osteocalcin Correlation Chart and T Score

From table 4., it was found that there was a significant negative correlation between urinary osteocalcin levels and T scores with r -0.803 and p <0.001. This shows that the higher the level of urinary osteocalcin, the lower the T score in this research.

Age: From the research of Hachul et al 2016, the mean age of menopause was 58.9 ± 0.8. From the study of Bjelland et al 2018, it was found that the average age was 56.7 years, and the study of Shadyab et al 2017 found an average of 74.7 years old research subjects, while the Banack et al study, 2018, found that the average age was 61 years old. In general, the age of menopause throughout the world is 50 years. Then, from studies in Thailand on postmenopausal women aged 50-54 years and 55-59 years, the prevalence of osteoporosis was 9.4% and 22.6%. The type of osteoporosis that occurs in postmenopausal women is the primary type. Where this is due to estrogen deficiency. Estrogen plays a role in osteoblast and bone mineral homeostasis. The older a woman is, the more she will lose bone mass density of about 50% of trabecular bone mass and 30% of cortical bone mass due to estrogen deficiency. [11,12,13,14,15]

Body Mass Index: This is in line with Bjelland et al 2018 study found that the average BMI was overweight with 25.8 kg/m^2, research Banack et al., 2018 found that the highest BMI data was in the overweight category with 26.7 kg/m2. Weight gain during old age is associated with a decrease in energy expenditure (EE), due to a decrease in physical activity, loss of body mass. Adipose tissue and weight will affect bone mass density as individuals with overweight and obesity BMI will have a greater body weight, weight will also affect bone peak mass, and adipocyte tissue in menopausal women will be converted to estron, so that postmenopausal women obesity will have more endogenous estrogen.[16,17,18,19, 20,21]

Menopause Duration: From Sarabi's research, 2018, it was found that the average menopause was 2.8 ± 1.5. Siregar Research, MFG, 2014, found that the average duration of menopausal women was 1-2 years from 50 samples (100%). From the study of Najmutdinova, 2016, the menopause duration of 0-3 years had a percentage of osteopenia of 36.2%, 4-7 years menopause duration has a percentage of osteopenia of 43.3%, and a duration of> 7 years has a percentage of osteopenia of 41.6%. Menopausal women with a menopausal duration of> 7 years have an increased risk of osteoporosis. Peak bone mass was achieved at the age of decade 30. In addition, the duration of menopause also has an impact on decreasing bone mass density, especially in the lumbar and distal radius. Menopausal women will experience a loss of bone mass 1-2% each year in a period of 5-10 years. Loss of bone mass is more common in the trabecular bone with a fracture of the vertebrae or distal radius. At the onset of menopause, there will be a loss of trabecular bone mass density of 1.8% and 2.3% in the vertebrae. After 5 years postmenopause, there will be a 7-10% decrease in bone mass density in the vertebrae.[4,18,24,26]

Bone Mass Density: From the Sarabi study, 2017, data was obtained that 35% of respondents were osteopenia. From the Montazerifar study, in 2014, there were 36.2% of subjects experiencing osteopenia, and Sahu's study, 2018, found that 72 research subjects (36%) were osteopenia groups The effect of estrogen will directly and indirectly suppress bone resorption. Where the dominant effect of estrogen is suppression of new osteoclast formations. modulates the Activator of Nuclear Factor kB (RANK) Receptor in osteoclasts and stimulates osteoclast apoptosis where RANKL plays a role in increasing osteoclast activity. But in menopausal women who experience a decrease in estrogen, bone mass loss, increased RANKL, inhibition of OPG, and increased production of cytokines such as IL-1, IL-6, and TNF-α. Estrogen deficiency will increase the production of TNF-α. by T. TNF-α cells will increase the production of RANKL and Macrophage Colony Stimulating Factor (M-CSF). Other cytokines that play a role are Inerleukin-7 (IL-7) which increases osteoclastogenesis. This will cause imbalance of resorption and bone formation, which will increase bone loss. Thus, an increase in RANKL after menopause will cause an increase in bone resorption and osteoporosis in menopause.[1,4,22,23,24,25,26]

Mean Value of Urinary Ostocalocalcin to Bone Mass Density: In the study of Singh et al, 2015, the mean serum osteocalcin level was 19.25 ± 5.1 ng/m. From the research of Zahrany et al 2014, there was a significant increase in osteocalcin levels in the osteopenia group of women compared to the control group, but there was no significant difference in osteocalcin levels between the osteopenia and osteoporosis groups. From these data it was also found that serum osteocalcin was 10% higher in the postmenopausal osteoporosis group. However, there are no data on the mean value of osteocalcin in urine with T scores.[19, 27]

Correlation of Urinary Osteocalcin with T Score: This shows that there is a significant relationship between urinary osteocalcin levels with T scores, namely the higher the level of osteocalcin, the T score will decrease further with a correlation value of 0.822. This is in line with the research of Singh et al, 2015 which obtained a negative correlation between osteocalcin and bone mass density with r = -0.527. From these research it was also found that osteocalcin can distinguish the normal bone density of postmenopausal women with low bone density in postmenopausal women. From the research of Zahrany et al 2014, it was found that there was a significant negative correlation between osteocalcin and bone mass density in postmenopausal women with r = -, 909. This shows that the higher bone turnover, the more loss of bone mass in osteoporotic women. Calcium and phosphorus deficiency in osteoporosis women will cause a decrease in the formation of hydroxyapatite crystals, which will cause osteocalcin to circulate freely in the blood. This can explain why osteocalcin levels increase in postmenopausal osteoporosis women.[19,6,27]

Conclusion

The mean value for urinary osteocalcin for bone mass density status in this research was the osteopenia

group with a mean of 9.05 ± 1.30. There is a significant negative correlation between urinary osteocalcin and bone mass density status in this research with r = -0.803 and p <0.001. This shows the higher the level of osteocalcin in the urine, the lower the bone mass density.

Benefit of Thai Hermit Exercise on MCI Patients': A Randomized Controlled Trial

Chomlak Kongart[1], Yuttachai Likitjaroen[2], Surasak Taneepanichskul[1], PhD

[1]PhD., College of Public Health Sciences, Chulalongkorn University, Phayathai Road, [2]Md, PhD., Department of Neurology, Faculty of Medicine, Chulalongkorn Hospital, Rama IV Road, Pathumwan, Bangkok, Thailand

Abstract

Background: Mild Cognitive Impairment (MCI) is a recurrent brain disorder with the memory. It is caused by the degeneration of the brain cells that is different from an individual's age and that develops to dementia. One way to help reduce stress is by exercising. Thai hermit exerciseis a wisdom in Thai exercise, which improves psychological status for this condition.

Method: This study was evaluated for a period of 10 weeks in regards to the Thai hermit exercise on psychological status among patients with MCI. 84 participants were recruited and randomized into intervention (n=42) control (n=42). The intervention group practiced Thai hermit exercise for 10 weeks. Psychological effect was evaluated by measuring the psychological status which was futher determined by the psychological status indicator questionaire. The control group received standard treatment. Both study groups were assessed by the test at the baseline then at 6th week, 8th week and 10th week of the study. Results: At baseline there were no significantly difference statistically between the two groups ($p<0.05$). After the intervention there were statistically significantly improvement of psychological status ($p<0.05$).

Conclusion: The results strongly suggested the capability of Thai hermit exercise to be a psychological effect for patients with MCI.

Keywords: *Mild Cognitive Impairment (MCI), Psychological status,Thai hermit exercise (ruesidatton).*

Introduction

Mild cognitive impairment (MCI) is defined as cognitive decline greater than what is expected for an individual's age and education level, which does not interfere with daily life activities[(1)]. For the people with aged 60 years and above, the reported prevalence of MCI rangedfrom 14 to 18% and the progression rate of dementia is about 5-15% per year[(2)]. Mental component - MCI behavior at getting unwitting, where it is a major predictor of tendency to become dementia and futheridentified two clusters neuropsychiatric symptoms, namely:

(1) Cluster frontal (aberrant motor behavior, disinhibition, agitation and problems of appetite), was found to be associated with functional disability even after controlling the cognitive status and the mood cluster scores.

(2) Cluster mood (including stress, depression, anxiety, apathy, irritability and sleep problems), is more common than frontal cluster of symptoms (95% of subjects had at least 1 symptom mood: 53% of subjects had at least 1 symptom frontal)

Stress requires one to use physiological and psychological energy to respond and adapt to the stressor with increased tolerance to stress reflecting early symptoms of dementia[(3)]. According to[(4),(5)] and [(6)]stress

that takes place within a short time frame will disrupt the short term memory which is basically the verbal memory. Whereas when stress occurs long term and repeatedly, will result in the exposure to the hormone cortisol which becomes more frequent maycause shrinkage in hipoccampus and also trigger a further decline in the cognitive function that leads to dementia. Epidemiological research looking at the role of stress in neurodegenerative disease is still relatively small.

MCI risk factor have many causes which includes increased age, diabetes mellitus, smoking, depression, hypertention, and lack of physical activity[7]. The positive effect of physical activity on brain vascularity includes pressure reduction, improvement of the lipoprotein profile, increased perfusion which is direct on the brain through the preservation of the neuronal structure and major changes in plasticity in the hippocampus[8]. Finally, it has been reported that an active lifestyle with regular physical exercise may prevent distress and reduce in the cortisol levels[9]. It is also a known fact that even the slightest amount of physical activity done outside can improve posture, reduce stress and loneliness, sleeping better at night, and even preventing depression[10].

Thai hermit exercise (RuesiDatTon)is a traditional Thai healing technique that mainly consists of breathing exercises, self-massage, acupressure, dynamic exercises, poses, mantras, visualization and meditation which is similar to the Hathayogic practices. In recent years, the Thai Ministry of Public Health has published several books on ReusiDat Ton. According to these modern texts, some of the benefits of ReusiDat Ton practices include; improved agility and muscle coordination, increased joint mobility, greater range of motion, better circulation, improved in respiration, improved in digestion, assimilation and elimination, detoxification, stronger immunity, reduced stress and anxiety, greater relaxation, improved concentration and meditation, oxygen therapy to the cells, pain relief, slowing of degenerative disease and greater longevity. However, there are very few studies in people that have compared the effects of RuesiDat Ton practice on psychological status. Since no previous evidences regarding these aspects of the exercise that have been investigated, thus, this study aims to measure the effect of stress in the aspect from practicing Thai hermit exercise among MCI patients.

Materials and Method

Design and Instruments: This study is a randomized controlled trial, 84 subjects will be elaborated at the multicenter. The target population of this study was participants who had been formally diagnosed with Mild Cognitive Impairment (MCI) and treated in King Chulalongkorn Hospital, Bangpli elderly club, Thai traditional medicine clinic at Ramkhamheang University. The participants were recruited following the eligibility criteria as follows.

Inclusion Criteria:

1. Patients who were diagnosed withMCI of age60 years and older.
2. Able to read speak and understand Thai with no severe hearing and blinding impairment.
3. Able to walk
4. Willingness to participate in the study and are able to provide the informed consent

Exclusion Criteria:

1. Regular practice of Thai hermit exercise (Ruesi dad ton)
2. Those that had been diagnosed with severe osteoporosis
3. Emergence of a new symptom
4. Does not have any previous cognitive impair by Medical illness
5. Does not have any sort of injury on the brain, skull, or scalp

Subject Allocation: The sample size for this study was calculated that a total sample size, based on a previous study[11], using power to detect 20% of effect size, with the power 80% and the alpha probability at 0.05. The G power computer application was applied to calculate the sample size. Participants were randomly assigned into one of the two parallel groups, either to an intervention group to receive the intervention or to a control group to receive usual care.The randomization list will be generated by using random number from the Excel program[12].Participants were provided with an information sheet as well as a consent form.

Ethical Consideration: In regards to the ethical principle, it has been approved by ethics committee of King Chulalongkorn Hospital.

Intervention: Thai hermit exercise (Ruesidat ton): This study was selected by some Thai traditional medicine experts for 3 postures from the original 80 postures that were involve with psychological status. For the intervention group about one hour a day and 3 times a week of Thai hermit exercise was arranged for 10 weeks. These exercises are indicated via Figures 1, 2 and 3.

Outcome Measurements: The Outcome will be assessed at the beginning of the exercise, week 6, and week 8 and again at week 10 in term of cognitive functions. Cognitive function used the standard test which are Verbal Fluency Test (Letters/categories), Trail making A-B Test and Digit Span. Each test has details as follows shown below

Psychological Indicators Questionnaire: This questionnaire will show how stress affects different parts of your life. Circle the response which best indicates how often you experience each stress indicator during a typical week, which apply to the international counseling team[13].

Figure 1: The posture to relieve face muscle, includes 7 postures numbered (a) - (g) and should be performed in sequential order

Figure 2: The posture to relieve laziness includes 7 postures numbered (a) - (g) and should be performed in sequential order

Figure 3: The posture to relieve headache, blur vision and general weakness includes 9 postures, numbered (a) – (i) and should be performed in sequential order.

Data Analyis: The demographic variables and the psychological status were analyzed using descriptive statistics such as: Chi-square test, frequencies, percentages, means, and standard deviations. The chi-squared tests were used to summarize the relationship of variables. Frequencies and percentages were used to summarize the categorical variables. Means and standard deviations were used to summarize the continuous variables.

Results

Demographics: From Table 1, the Chi-Square Tests results were not significantly correlated with the control and trial at 0.05 and it can be seen that the control group mainly consisted of female subjects which was about 36 people or up to 85.7% whereas there were only about 6 male subjects or about 14.3%. The age range of most participated subject were between 60-65 years old which consisted of 20 people or about 47.6%.The number of subjects between the age of 66- 70 years were about 18 people or about 42.9% and there were 4 people or about 9.5% in the age group of 70 years and older. The Marital status of most of the subjects were married which consisted of 36 people or about 85.8% while the subjects who were single consisted of 3 people or about 7.1%. Divorce, Widows/Separation subjects were also included in this research and there were also about 3 people or about 7.1% belonging to this category. The majority of the subjects which was about 29 people or 69.1% completed primary schools while about 8 subjects or only 19.0% completed their High school and there were few subjects about 5 people or 11.9% who completed their Bachelor degree. All of the 42 subjects (100%) worshipped Buddhist religion and are of Thai race.

The Intervention group mainly consists of 35 female subjects or about 83.3% and only about 7 male subjects or about 16.7%. More than half of the subjects were in the age group between 66-70 years old, which consisted of 23 people or about 54.8%.About 17 subjects or 40.5% of the subjects were in the age range between 60-65 years and there were only 2 subjects or 4.7% in the age range of 70 years and above. The Martial status of most of the subjects were married which consisted of 36 person or 85.7% and there were about 2 subjects or 4.8% whose status is single. Divorce, Widows/Separation subjects were also included in this research and there were also about 4 person or 9.5% of the subjects. More than half the subjects about 25 people or 59.5% completed their high school while about 10 subjects or 23.8% completed their Primary school. 7 subjects or 16.7% completed their bachelor degree. All of the 42 subjects (100%) worshipped Buddhist religion and are of Thai race.

Table 1: Comparisons of socio-demographic between the intervention group and the control group at pre-test

Characteristics	Control group		Experimental group		x^2	P value
	N	%	N	%		
Sex						
male	6	14.3	7	16.7	0.091	0.763
Female	36	85.7	35	83.3		
Age						
60 - 65 years	20	47.6	17	40.5	8.142	.087
66 – 70 years	18	42.9	23	54.8		
More than 70 years	4	9.5	2	4.7		
Status						
Single	3	7.1	2	4.8	2.657	.617
Marry	36	85.8	36	85.7		
Divorce/Widow/Separation	3	7.1	4	9.5		
Education						
Primary school	29	69.1	10	23.8	4.663	.324
High school	8	19.0	25	59.5		
Bachelors degree	5	11.9	7	16.7		

($p < 0.05$)

According to the result from the Table 2 (in the pre-test phase) it can be seen that there is no difference between control group and experimental group on psychological status (stress) at statistical difference of 0.05 ($p > 0.05$).

Table 2: Comparison between control group and experimental group on psycological statusin the pre-test

Variable	Control group		Experimental group		t	P value
	$\bar{x}$	S.D.	$\bar{x}$	S.D.		
Psychological Status						
Stress	3.76	0.32	3.63	0.34	1.81	0.074

($P< 0.05$)

According to the results from the Table 3 on Psychological Status, it can be seen that there were no differences in the control group at pre-test, after 6 weeks, after 8 weeks and after 10 weeks at statistical significance of 0.05 ($p > 0.05$). However, from Table 4, it can also be observed that a difference was found in the experimental group (for pre-test,6th week,8th week and 10th week) for the Psychological Status at a statistical significance of 0.05 ($p < 0.05$).

Table 3: Comparisons between the control group and experimental group on psychological status (stress) at pre-test, after 6 weeks, after 8 weeks and 10 weeks

Discussion

The present study determined to examine the condition of MCI patients by using a verbal influence test, a trail Maker B test and a Digit Span Test before and after the Thai Hermit exercise. Particularly, the aim was to examine the influence of psychological condition(stress) toward the advance of the Thai hermit exercise. In addition, this research aimed to compare the effect of Thai hermit exercise between the intervention and the control groups along the time period of observation. Two studies are in line with these findings, stating the fact that good physical performance seems to play a protective factor against cognitive decline whereby regular exercise promotes reduced risk of MCI and dementia[14, 15].Furthermore, the present study discovered that the observed psychological status at pre-test differed from that at the 6th, 8th and 10th weeks with a statistical significance ($p < 0.05$). Additionally, the results from the 6th week differed from the 8th and 10th week as well as the results from the 8th week differed from that of the 10th week at a statistical significance for the psychological status category ($p<0.05$). This is similar to results found in a study conducted by Lam *et al.*[16]whereby the authors reported a significant decrease in depressive symptoms after a 12-month group-based multi-modal exercise program compared with the pre-test level.

Conclusion

The psychological status showed that pre-test results differed from the 6th, 8th and 10th weeks at a statistical significance of 0.05 ($p < 0.05$) while the 6th week differed from the 8th and 10th weeks at statistical significance of 0.05 ($p< 0.05$). The 8th week was also seen to differ from the 10th week at a statistical significance of 0.05 ($p< 0.05$).

This study was successful in showing statistically significant results for the use of Thai hermit exercise as a tool for the improvement of psychological status in individuals with MCI. Future research should seek to identify population traits (such as age at which physical activity began, intervention duration, and baseline activity level) and intervention characteristics (such as type, frequency, duration, and intensity) that trend toward positive outcomes among these trials. Studies then could be designed appropriately to test the identified characteristics for research and knowledge purposes. In addition, long-term trials that enroll younger adults with interventions sustained for a longer periods would benefit the field and provide important insight on prevention. Although a physically active lifestyle often is proposed as a way to reduce stress and that cause of MCI and may be progress or leads to dementia. But some studies also indicate that there is not enough evidence to determine whether a single component like physical activity interventions actually offer or lead to the benefit of psychological effect. However, clinical practice largely encourages physical activity to prevent or dilute other chronic conditions, and this practice should continue, because it may offer benefits for improving psychological status as well.

Conflict of Interest: The authors declare that there are no conflicts of interest

Relationship of Individual Characteristics and Noise Intensity with Subjective Hearing Loss to Workers at Pt. X

Cut Suci Almadiana T.[1], Sumihardi[2], Abdul Rohim Tualeka[1]

[1]Department of Occupational Health and Safety, Faculty of Public Health, Airlangga University, [2]Department of Public Health, Faculty of Health Sciences, Baiturrahmah University, Indonesia

Abstract

One company that has a risk of hearing loss is PT. X engaged in the supply, processing and distribution of steel and ready-mixed materials for construction, electricity, mining, telecommunication and transportation industries. Location of noise intensity there are 4 parts that is part of iron pole, elbow, pipe and work shop. The purpose of this study was to determine the relationship of individual characteristics and noise intensity with subjective hearing loss to workers in PT. X..The type of this research is analytic research with cross sectional design. Population in this study are all workers in unit production of PT. X as many as 157 people with a sample of 61 people. The sampling technique is simple random sampling. The study was conducted in January - October. The data were analyzed univariate using frequency and bivariate distribution using Chi-Square statistical test with significance level 95% $\alpha = 0,05$. The results showed less than half (49.2% of respondents subjected to subjective hearing loss. Less than half (39.3%) of respondents were at risk. More than half (68.9%) of respondents have long worked.

More than half (68.9%) had less intensity than NAB (<85 dB). More than half (60.7%) of respondents did not use ear protective equipment. There is a significant relationship of age, length of service, noise intensity, ear protection with subjective hearing loss in PT. X .It is expected that the company minimizes noise intensity by using silencers. The sound-proofing device can use the barrier wall between the machine and the worker or the silencer can be mounted on the sound source on the machine and it is expected that the company provides clear rules with sanctions for workers who do not use ear protection.

Keywords: *Age, Working Period, Noise Intensity, Use of PPE and Subjective Hearing Loss.*

Introduction

The ear is a very vulnerable organ that although it can accept the imposition of a certain range, finally ear will react and stop functioning, how the ear and some action should be taken in the workplace to protect workers' hearing ability [1].

Data from the World Health Organization (WHO) in 2012 there were 250 million people worldwide with moderate or severe hearing loss, this figure rises to more than 275 million people. Based on the amount of 80% of them are in developing countries. In America, more than 5.1 million workers exposed to noise with an intensity of more than 85 dB[2].

A total of 246 workers in the United States for the purposes of hearing checked indemnity insurance, found 85% had nerve deafness and of that number 37% the frequency of 4000 Hz and 6000 Hz. Also according to NIOSH (National Institute for Occupational Safety and Health) note that 22 million workers have the potential for hearing impaired annually and 10 million workers in the United States have a hearing loss problem associated with the job[3].

The prevalence of hearing loss increased due to advances in the field of industrial technology and environmental noise. Indonesia including emerging industrial countries, so in an effort to increase the construction of used industrial equipment which can cause noise in the workplace. It is a damaging impact on workers if it is not prevented by the noise control programs include the use of hearing protection for workers exposed to noise[4].

In Indonesia, the problem of noise included in the major problems in the industrialized world. It is evident from the prevalence of hearing loss due to noise exposure in the workplace. Noise exposure received by workers with a prevalence ranging from 86.1 to 108.2 dB Noice Induced Hearing Loss (NIHL) amounted to 31.81% [5].

Occupational hearing disability (occupational deafness/noise-induced hearing loss) is the partial or complete loss of hearing someone permanent, on one or both ears caused by the continuous noise in the workplace environment. Hearing loss due to noise can be prevented by doing some preventive measures such as by the use of noise protection devices, limitation of exposure time and periodic audiometric examinations for early detection of disturbance. In connection with the effort to implement health and safety, the use of personal protective equipment is one attempt to control workplace noise. Act 1 of 1970 on Occupational Safety, in particular Articles 9, 12 and 14, which govern the provision and use of personal protective equipment at the workplace[6].

factors associated with hearing loss is noise, age, years of service, the use of personal protective equipment, history of smoking, use of ototoxic drugs, neighborhood, gender and medical history. The factors that most affect the value of hearing threshold is the age and length of exposure to noise. Someone workers have a longer service life may be at risk of occupational diseases than workers who have shorter working lives[7].

Age is a determining factor the increase someone listening threshold value. The level of compensation is used a correction factor of 0.5 dB per year for workers with more than 40 years of age. Age is a determining factor the increase someone listening threshold value. Some of the changes associated with the aging can occur in the ear. Membrane in the middle ear, including the ear drum becomes less flexible as we age[8].

Clinical symptoms of patients with hearing loss due to noise complaints worker after working for 5 years and it was only realized after the other party as a wife, children, and friends associate said that people need a voice loud enough to be able to hear. The increase in hearing threshold on the group work period> 5 years. Exposure to noise below 85 dB for a while does not cause a decrease in auditory function permanently[7].

Factors associated with hearing loss in the Production Department of Labor PT. Japfa Comfeed Indonesia in Makassar Unit found the results of the risk of age 23.9%, 45.7% work period risk, risk working long 45.7%, 58.7% do not wear APT, high noise intensity of 41.3% and complaints of hearing 60, 9% [10], Rahmawati research on factors associated with hearing loss in workers in the department of metal forming and heat treatment of PT. Dirgantara Indonesia (Persero) in 2015 found no association with the use of ear protectors non audiotory with subjective complaints (p value = 0.001)[5].

One company that has the risk of hearing loss is PT. X engaged in business in the supply, processing and distribution of steel and concrete material ready for konsruksi industry, electricity, mining, telecommunications and transportation. The company has a staff of about 485 people with as many as 157 production employees. Locations intensity of noise, there are 4 parts, iron pole, elbow, pipe and work shop.

A preliminary survey of researchers in July through interviews with 10 workers on each production PT. X said there were complaints of hearing in 6 (60%) say often experience dizziness, impaired communication and concentration at work less hard because the engine sound with the sound of pipe cutting machine, grinding machine iron, zinc plate waves and 4 (66.7%) with an average age of workers> 35 years. 5 people (83.3%) had hearing loss such as ringing in the ears due to work more than five years, 10 people have been interviewed four people no hearing loss because when working with ear protection equipment.

Method

This type of research is analytic with cross sectional approach, in which both the data collection for the independent variables (the noise intensity, age, years of service, the use of PPE) and the dependent variable (hearing loss subjectively) done together at the same time.[11]

This research was conducted at PT. X. When the

study in January-October. The population in this study were all workers at the production unit of PT. X as many as 157 people with a sample of 61 people. The sampling technique using proportional random sampling technique.

The statistical test used chi-square in data processing with SPSS is as beikut [12]:

a. When the table 2 x 2 found value E (expectation) <5 then the test value used is the fisher exact.

b. When the table 2 x 2 and not found the value of E (expectation) <5 then the test value used is the continuity correction.

Findings:

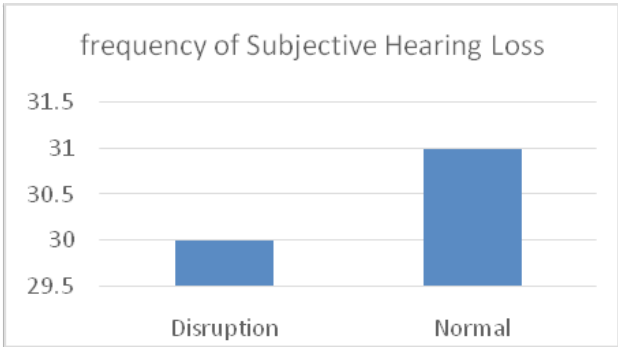

Figure. 1 Subjective Hearing Loss

The results of the study can be seen that less than half (49.2%) of respondents have a hearing loss subjectively. It can be seen from the results of the research answers as much as 57.4% despite having to leave the workplace steadily reduced hearing ability, 52.5% work while anxious, 47.5% often feel ear buzzing 44.3% others say workers face hearing loss, 42.6% worked in the company since the health of 41% easily distracted and easily tired while working.

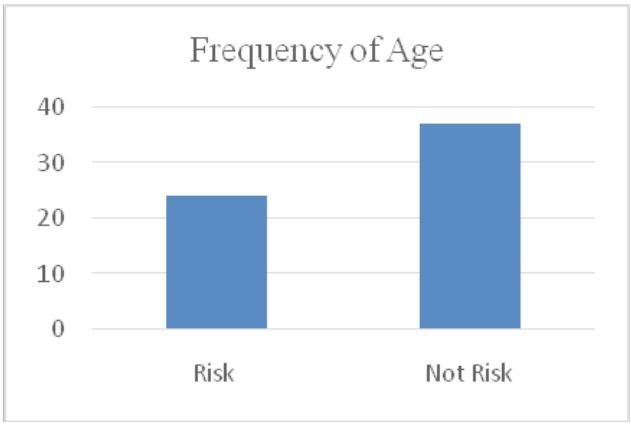

Figure 2. Age of Respondents

Based on Figure 2 above it can be seen that 39.3% have a lifespan of at risk at PT. X. The results are consistent with research done Ibrahim factors associated with complaints of hearing loss in manpower production PT. Japfa Comfeed Indonesia, Tbk. Makassar unit found the results of which 40.5% have a lifespan of at risk [9]

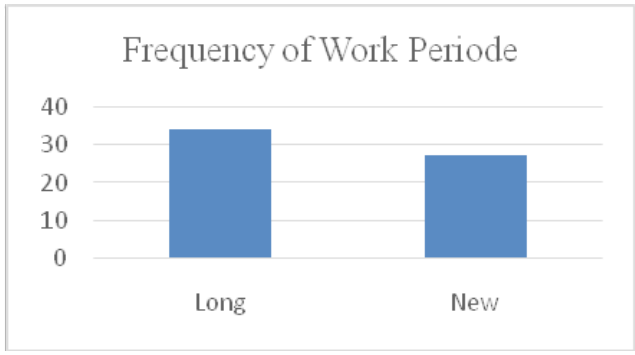

Figure 3. Work Period of Respondents

Based on the above Figure it can be seen that more than half (55.7%) of respondents have long worked. The results are consistent with research conducted Asriani Risk Factors Associated with Genesis Hearing on Mine Employees at PT Aneka Tambang (ANTAM) Southeast Sulawesi Pomalaa results found that 55.7% of workers have long worked[12].

Table 1: Age relationship with Subjective Hearing Loss

Age	Subjective Hearing Loss				Total		p value
	Disruption		Normal				
	f	%	f	%	f	%	
Risky	19	79.2	5	20.8	24	100	0,000
Not Bersiko	11	29.7	26	70.3	37	100	
Total	30	49.2	31	50.8	61	100	

Based on table 1 can be seen the proportion of workers who are experiencing hearing loss at the age of subjective higher risk (79.2%) compared to age without risk (29.7%). Based on test results obtained statistical p value = 0.000 (p <0.05) there is a significant correlation between age with hearing loss subjectively PT. X Padang.

Results of this research is similar to research done Ibrahim (2016) factors associated with complaints of hearing loss in manpower production PT. Japfa Comfeed Indonesia, Tbk. Makassar unit results found no correlation between age with symptoms of hearing loss

Table. 2: Relations with Hearing Loss Work Period Subjective

Years of Service	Subjective Hearing Loss				Total		p value
	Disruption		Normal				
	f	%	f	%	f	%	
Long	20	74.1	7	25.9	27	100	0,001
New	10	29.4	24	70.6	34	100	
Total	30	49.2	31	50.8	61	100	

According to the table 2can be seen that the proportion of workers with hearing loss subjectively higher on longer working lives (74.1%) compared with the new working period (29.4%). Based on test results obtained statistical p value = 0.001 (p <0.05) correlation meaningful working lives with hearing complaints of subjective PT. X Padang.

The results are consistent with research conducted Asriani Risk Factors Associated with Genesis Hearing on Mine Employees at PT Aneka Tambang (ANTAM) Pomalaa Southeast Sulawesi future results found no relationship working with the incidence of hearing loss[12].

Table. 3: The intensity of the relationship Subjective Noise with Hearing Loss

Intensity Noise	Subjective Hearing Loss				Total		p value
	Disruption		Normal				
	f	%	f	%	f	%	
More than NAB	25	59.5	17	40.5	17	100	0,034
Less than NAB	5	26.3	14	73.7	14	100	
Total	30	49.2	31	50.8	61	100	

According to the table 3 can be seen the proportion of workers who have a hearing loss subjectively higher the noise intensity over NAB (59.5%) compared with the intensity of the noise is less than the NAV (26.3%). Based on test results obtained statistical p value = 0.034 (p <0.05) there was a significant relationship with the noise intensity of subjective hearing loss in PT. X Padang.

Results of this research is similar to research Susanti, the fertilizer production plant, the results showed that there was correlation between intensity of noise with subjective complaints of hearing loss[14], The results are consistent with research at the hospital Ulandari Makasar results found no correlation of noise intensity with subjective complaints of hearing loss[15]

Conclusion

Based on research conducted by PT. X can be summarized as follows:

a. Less than half (49.2%) of respondents have a hearing loss subjectively PT. X .

b. Less than half (39.3%) of respondents have a lifespan of at risk at PT. X .

c. More than half (55.7%) of respondents have long worked in PT. X .

d. There was a significant association of age with hearing loss subjectively PT. X .

e. There is significant correlation tenure with hearing loss subjectively PT. X.

f. There is significant correlation with the noise intensity of subjective hearing loss in PT. X .

Conflicts of Interest: All authors have no conflict interest to declare.

Source of Funding: the source of the research cost from self.

Ethical Clearance: This study was approved by Bord Etis institutional Baiturrahmah University, Faculty of Public Health.

All subjects were fully informed about the procedures and objectives of this study each subject prior to the study signed an informed consent form.

The Role of Matrix Metalloproteinase-9 (MMP-9) and Tissue Inhibitor Metalloproteinase-1 (TIMP-1) Level in Dengue Hemorrhagic Fever

Dasril Daud[1], Nina Cicci Hasnani[1], Husein Albar[1]

[1]Departement of Pediatrics, Faculty of Medicine, Hasanuddin University, Makassar, South Sulawesi, Indonesia

Abstract

Introduction: Vascular leakage is a hallmark of Dengue Hemorrhagic Fever (DHF), due to changes in interactions between cells and extracellular matrix in endothelial basement. It major components is type IV collagen that can be destaged by MMP-9. However, MMP-9 has an endogenous regulator, TIMP-1.This study aimed to evaluate between MMP-9 and TIMP-1 serum levels in children with DHF.

Method: A cross-sectional study, conducted in Wahidin Sudirohusodo Hospital Makassar, Indonesia. Population of children aged 1 to 18 years from September 2014 to March 2015.

Results: Out of 38 subjects, DHF stage I (34,2%), stage II (39,5%), stage III (26,3%) and no stage IV. No significant different levels of MMP-9 and DHF (P>0.05). There was difference levels of TIMP-1 in stage I and II (P<0,05). Level of MMP-9/TIMP-1 ratio is higher in stage I than II (P<0.05). Positive correlation between MMP-9 and TIMP-1 levels in stage II (P<0.05).

Conclusion: The levels of MMP-9 serum could not represent vascular condition in DHF. However, TIMP-1 serum, MMP-9/TIMP-1 ratio, and correlation between the levels of MMP-9 and TIMP-1 in DHF describe the vascular state instage I and II.

Keywords: *MMP-9, TIMP-1, Dengue Hemorrhagic Fever, Children.*

Introduction

As the endothelium forms the primary barrier of the circulatory system, dysfunction of the endothelial cells during acute diseases can broadly affect vascular permeability and cause plasma leakage.[1] Plasma leakage is a major marker of dengue hemorrhagic fever (DHF) and dengue shock syndrome (DSS) associated with the secretion of inflammatory mediators in the circulation system, changes in adhesion cell interactions – extracellular matrix (ECM) and adhesion cell.[1,2,3] ECM - adhesion cells in endothelial basement membrane with the main components is type IV collagen, which is destaged by MMP-9, causing detachment from the basement membrane.[3,4]

Matrix Metalloproteinase-9 (gelatinase B) is a local proteolysis by degrading elastin (fibrous structural protein), collagen type IV and some other ECM molecules. MMP-9 which has been fully activated can be inhibited by natural inhibitors that TIMP-1. TIMP-1 binds non-covalently with the active MMP with a molar ratio of 1:1. The ability to inhibit MMP is shown by its ability to bind to the zinc-binding site in the catalytic domain of active MMP.[5] Vitro studies on immature dendritic cells are infected and uninfected dengue virus DV, an increase of about 5-fold for MMP-9 and 20-fold for TIMP-1,1.[6] however this has not been poven in humans yet.

The aim of this study was to evaluate the levels of MMP-9 and TIMP-1 in children with DHF. Hypothesis inthis study are MMP-9 levels were higher in DHF with higher stages, TIMP-1 levels were lower in DHF with higher stages and the ratio of MMP 9 and TIMP-1 were higher in DHF with higher stages.

Method

This is a cross sectional study to evaluate the MMP-9

and TIMP-1 levels in patients with DHF. The study conducted in pediatric ward of Child Health Department of Dr. Wahidin Sudirohusodo hospital, Makassar, Indonesia from September 2014 until March 2015.

The study population was patients with DHF without shock (stageI and II) and with shock (stage III and IV), aged 1 to 18 years.On the day of admission all patients diagnosed with DHF based onWHO criteria. The diagnosis was confirmed by IgM and IgG anti dengue serological examination. Patients who met the inclusion criteria were grouped into DHF stage I, II, III and IV according to the WHO 1997. The age, sex, weight, height, and nutritional status were measured. From each group, blood sample were taken to evaluate the MMP-9 and TIMP-1 levels. The inclusion criteria are the dengue patient, age from 1-18 years and want to be the sample of study and signed the informed consent. While the exclusion criteria are the dengue patient with another disease, blood transfusion, and corticosteroids. The study protocol was approved by Commission on Human Biomedical Research Ethics, Faculty of Medical, Hasanuddin University.

The obtained data were grouped based on the objective and types of data into DHF wihout shock (stage I and II) and DHF with shock (stage III and IV) to be analyze using appropriate statistic method; univariat, bivariat, and multivariate analyses.

Results

Table 1 shows sample characteristics in term of sex, age, nutritional status, DHF stage I, II, III, and IV, MMP-9 and TIMP-1 levels. In sex category it is shown that there are 23 (60.5%) male and 15 (39.5%) female. In age group it is found that the median is 6.75 year old, range 1-14 years old, with mean age of 6.87 years and standard deviation of 3.83 years. In nutritional status column, it is found that there is 1 patient who were overweight (2.6%),23 (60.5%) with a good nourished,13 (3.42%) with undernourished,and 1 (2.6%) with malnourished. In DHF stage I group there are 13 (34.2%) patients, 15 (39.5%)in stage II, 10 (26.3%) in stage III, and none in stage IV DHF group.

Kruskal Wallis test results showed no significant difference with p = 0.766 (p >0.05) between MMP-9 levels in group DHF stage I, stage II, and stage III (table 2). Allegedly it is associated with the function of MMP-9 as a local proteolysis and binding of MMP-9 to TIMP-1 in vascular that serum MMP-9 levels were not significantly different in DHF.

However, Kruskal Wallis test between TIMP-1 levels of DHF stage I, stage II and stage III shows a significant difference with p = 0.043 (p<0.05).*Post Hoc* analyses to determine which DHF group has difference by using a Mann Whitney test, it is found a significant difference of TIMP-1 levels in group DHF stage I and II,p value = 0.020 (p<0.05) (table 3). Presumably it has something to do with the binding between MMP-9 and TIMP-1; therefore, the levels of TIMP-1 were significantly only in DHF stage I and II.

Kruskal Wallis test between MMP-9/TIMP-1 ratioin DHF stage I, stage II, and stage III does not show a significant difference with p = 0.074 (p >0.05). Nevertheless, there is a significant difference with p = 0.018 (p<0.05) between MMP-9/TIMP-1 ratio in DHF stage I and II (table 4).This is influenced by the levels of MMP-9 and TIMP-1 serum so the meaningful significant is only between DHF stage I and II.

Linear regression analyses between MMP-9 and TIMP-1 in table 5 shows a positive correlation of 0.220 in DHF stage 1 and 0.531 in DHF stage 2, negative correlation of-0.139 in DHF stages 3. There is no significant correlation inDHF stage 1 and 3 with p 0.470 and 0.701 (p >0.05). There is a significant correlation between MMP-9 and TIMP-1 in DHF stage 2 with p 0.042 (p <0.05) (table 5). Allegedly this is due to the stage of complex 3 is formed MMP-9: TIMP-1 were significantly.

Table 1: Characteristics sample

No.	Characteristics Sample	Total (n=38)
1	Sex	
	Male : Female (%)	23 : 15 (60.5 : 39.5)
2	Age (Year)	
	Median (Range)	6.75 (1 – 14)

Discussion

The results of this study, there were no significant difference between the levels of MMP-9 and DHF, but there is a difference between the levels of TIMP-1 DHF stage I, stage II and stage III with significant differences in stage I and II. There is a significant difference between the ratio of the levels of MMP-9/TIMP-1 DHF stage I and stage II, and there is a significant positive correlation between levels of MMP-9 and TIMP-1 in DHF stage II. Retrieved 38 samples were grouped into 4 groups, DHF stage I have 13 samples (34.2%), stages II have 15 samples (39.5%), stage III have 10 samples (26.3%) and none in stage IV. Analyses was performed on the levels of MMP-9 and TIMP-1. Study on MMP-9 and virus dengue (VD) is still rare. Some of these studies are studied in vitro and vivo, while the relationship between TIMP-1 and VD so far are obtained only a study in vitro.[7,8,9]

In vitro study by Luplerdlop et al.he obtained a significant difference between the levels of MMP-9 imature dendritic cells are infected and uninfected VD and research by Luplerdlop and Misse obtained a non-significant difference between the levels of MMP-9 MVEC (macrovascular endothelial cells) of infected and uninfected VD.[7,8] It means that VD activate the dendritic cells or monocytes to produce MMP-9 and did not activate endothelial cells to produce MMP-9. This study was supported by the research of Seanpong et al.which he found that the levels of MMP-9 increased in monocytes (U937) and not in hepatocytes (HepG2) infected with VD.[9]

In this study found a mean value of the MMP-9 DHF levels corresponding increase in rank, but there was no significant difference with p = 0.766. This is according to the research by Voraphani et al. which obtained a non-significant difference between dengue and DD. This is related to the function of MMP-9 as a local proteolys is and binding of MMP-9 by TIMP-1 in vascular; therefore,the levels of MMP-9 serum did not differ significantly on dengue and the study did not measure the levels of MMP-9 complex: TIMP-1 that measures MMP-9 after it tied with TIMP-1.[4] In vitro study obtained significant difference between the levels of TIMP-1 imature dendritic cells infected and uninfected VD, while the other ones obtained a significant difference between the levels of TIMP-1 MVEC (macrovascular endothelial cells) of infected and uninfected VD. This means VD activates the monocytes and derivatives to produce MMP-9, the monocyte and endothelial derivatives to produce TIMP-1. This study was supported by the research of Seanpong et al.[9]which found that there were expressions of TIMP-1 in monocytes (U937) and not in hepatocytes (HepG2) were infected with VD. TIMP-1 is activated by endothelial due to stress on the blood vessels due to changes in the interaction between endothelial-MES and endothelial caused by MMP-9.

Studies in vivo TIMP-1 and dengue have not been obtained by the author. Kruskal Wallis test results between the levels of TIMP-1 DHF stage I, stage II, stage III and obtain the result of significant differences with p values of 0.043 ($p < 0.05$). After a post hoc analyses to determine the DHF group that have different, with Mann Whitney test obtained significant differences in the levels of TIMP-1 DHF stage I and II, the value of p = 0.020 ($P < 0.05$).TIMP-1 Activated by monocytes and derivatives as well as endothelial response to vascular leakage caused by MMP-9. Allegedly levels of TIMP-1 gives an overview of the initial damage vascular function due to vascular leakage caused by MMP-9 destages collagen type IV result, whereas type IV collagen is a major component of basement membranes endotel.[3]

Study for MMP-9/TIMP- 1 ratio and DHF has not been found in the journals, but the research ratio of MMP-9/TIMP-1 in community acquired pneumonia showed higher than control.[10] In this study, there were no significant differences between the ratio of MMP-9/TIMP-1 DHFstage I, stage II and stage III, but there is significant difference between the ratio of MMP-9/TIMP-1 DHF stage I and stage II with ratio of the levels of MMP-9/TIMP-1 were higher in stage I compared the stage II. This is not in accordance with the initial hypothesis. MMP-9 as a function of local proteolysis, thereby MMP-9 are found abundantly in the vascular tissue and not so that play a role in DHF stage I and II are TIMP-1, which is visible from the ratio of the levels of MMP-9/TIMP-1. But for DHF stage III, the levels of MMP-9 ratio/TIMP-1 and TIMP-1 is no longer meaningful, presumably this is due to the binding of TIMP-1 to MMP-9 which can be measured with a complex MMP-9: TIMP-1 examination. This is supported by the results of the linear regression correlation is performed as TIMP-1 is a specific endogenous inhibitor of MMP-9. [5] There is a positive correlation between levels of MMP-9 and TIMP-1 in DHF stage I and stage II, this means that the levels of MMP-9 in line with the levels of TIMP-1. However, the only significant correlation when there is spontanously bleeding (DHF stage II).

However, this study has absence of data and dengue fever on how day longof patient in stage IV, the number of small sample, and not an examination of the serotypes VD because of differences would affect the levels of MMP-9 and TIMP-1, and the absence of MMP-9 complex measurements: TIMP-1. The strengths of this study is dengue is a disease that causes changes in the interaction or adhesion between endothelial vascular and between endothelial-MES that cause vascular leakage. Vascular leakage rate is directly proportional to the severity of DHF. This study describes the various pathomechanism MMP-9 and TIMP-1 in DHF, the in vivo studies that provide new insights into the levels of TIMP-1, the ratio of MMP-9/TIMP-1, and the correlation between MMP-9 and TIMP-1 in various DHFstages. Thus providing new insights into the MMP-9, TIMP-1, and vascular function.

We concluded that there is no relationship between serum MMP-9 levels and severity of dengue. But there is a relationship between serum levels of TIMP-1 and the ratio of MMP-9/TIMP-1 against DHF stage I and II, as well as a significant and positive correlation between levels of MMP-9 and TIMP-1 in DHF stage II. This means that the levels of MMP-9 serum could not represent vascular condition in DHF. However, serum levels of TIMP-1 and MMP-9/TIMP-1 ratio describe the vascular state in DHF stage I and II.

Conflict of Interest: None.

Abstract

Introduction: Preeclampsia is one of the complications that occur in pregnancies. This study was aimed to study the factors that affect the of giving ethanol extract with black cumin (*Nigella sativa)* against sFlt-1 level and VEGF serum on laboratory mice induced preeclampsia.

Method: Laboratory experimental research with post test only control group design. This study used 30 BALB/C laboratory mice, divided into 6 groups, namely negative controls: pregnant mice injected serum from normal pregnant women, positive controls; mice modeled preeclampsia, and treatment groups 1, 2, 3 and 4 are preeclampsia mice received a dose of 500 mg, 1000 mg, 1500 mg and 2000 mg/kg weight of Nigella sativa ethanol extract for 5 days. Statistical analysis using ANOVA

Result: The mean serum sFlt-1 level in mice modeled preeclampsia and treatment group dose 500mg, 1000mg, 1500mg and 2000mg (2510.3+182.2 pg/mL, 2142.5+171.9 pg/mL, 1309+161.3 p/mL, and 1500+169.9, respectively) pg/mL) showed a significant difference ($p<0.05$) and found a decrease in serum sFlt-1 levels with increasing doses. The mean serum VEGF levels in preeclampsia mice and treatment groups were 500 mg, 1000 mg, 1500 mg and 2000 mg (50.25±2.85b pg/mL, 60.18±4.81c pg/mL respectively, 71.89±2.38d pg/mL, 66.51±1.87 e pg/mL) showed a significant difference ($p<0.05$) and found an increase in serum VEGF levels as the dose increased.

Conclusion: Giving of Black Cumin extract (Nigella sativa) decreases serum sFlt-1 levels and increases serum VEGF levels in preeclampsia mice model and the effect is dependent dose.

Keywords: *sFlt-1, VEGF, Nigella sativa, preeclampsia.*

Introduction

Preeclampsia is one of the complications that occur in pregnancies of more than 20 weeks which is characterized by an increase in systolic blood pressure greater or equal to 140 mmHg or diastolic pressure greater than or equal to 90 mmHg and the amount of proteinuria 300 mg or more than 30 mg/dL per 24 hours[1]. Preeclampsia occurs in about 3-5% of pregnant women worldwide and the number two cause of death for pregnant women. In the United States, 15% of maternal deaths are caused by preeclampsia [2,3].

The pathogenesis of preeclampsia occurs with a variety of mechanisms, but placental ischemia/hypoxia is likely to be a major factor due to disruption of trophoblast invasion[4]. Placental ischemia will stimulate excessive production of sFlt-1 or VEGFR-1. The presence of sFlt-1 as a competitor for surface VEGF receptors (Flt-1), causes VEGF cannot attach to receptors on the cell surface. This situation causes serum VEGF levels

to decrease and induce endothelial cell damage in the glomerulus, producing a urine protein[5,6].

Black cumin has been used as a traditional medicine for thousands of years for various diseases such as asthma, coughing, bronchitis, headaches, fever, and rheumatism[7]. Seed extracts of both water and oil have the potential to be anti-tumor, antioxidant, anti-inflammatory, anti-hypertensive, anti-diabetic and anti-seizure. Thymoquinone (TQ) is the main constituent of Black Cumin essential oil[8,9]. As an antioxidant, thymoquinone synergizes with other compounds such as dithymoquinone and thymol as a free radical scavenger[10]. As TQ Anti-inflammatory inhibits activation of NFκβ. In cases of preeclampsia where placental hypoxia occurs, activation of NFκβ will affect the expression of hypoxia-inducible factor 1-α (HIF1-α)[11] which is a VEGF[12] transactivator.

By referring to the above facts because Black Cumin (Nigella Sativa) has the potential as an antioxidant and anti-inflammatory, it is necessary to conduct research on the molecular mechanism of Black Cumin extract (BC-e) on serum sFlt-1 and VEGF levels in preeclampsia mice.

Design and Method

This research is a laboratory experimental study with a post test only control group design. This study measured serum sFlt-1 and VEGF levels in the mice model of preeclampsia after being given several doses of Nigella sativa extract. A total of 30 pregnant BALB/C mice were used in this study, divided into 6 groups: pregnant mice injected with serum of normal pregnant women were used as negative controls, preeclampsia mice were as positive controls, and 4 groups of preeclampsia mice were treated with BC-e with a dose of 500 mg, 1000 mg, 1500 mg and 2000 mg/kg of body-weight/day for 5 days. Mice model preeclampsia made by injecting serum of preeclamptic pregnant women on the 10th and 11th days of gestation each 0.1cc intraperitoneally[13.14]. The manifestation of preeclampsia in mice is obtained by finding hypertension and proteinuria on the 15th day of gestation. Maintenance of mice and modeling of preeclampsia were carried out at the Pharmacology Laboratory of the Faculty of Medicine, University of Brawijaya and got standard food and drink.

Mice are terminated at 20 weeks' gestation and blood and kidney organs are collected. Examination of sFlt-1 and VEGF levels in mice serum was measured using an ELISA kit, pg/Ml unit.

Result

The comparison test results showed a difference (p = 0.000 <) the mean serum sFlt-1 level between the negative control group (healthy mice) (579.8 ± 114.8 pg/mL) and the positive control group (preeclampsia mice) (2752.8 ± 188.7 pg/mL)) Likewise there was a significant difference (p = 0.000 <) mean serum VEGF levels between healthy groups (88.56 ± 5.58 pg/mL) with preeclampsia mice model (44.85 ± 2.15 pg/mL). As shown in table 1.

Table 1: Results of Comparison of Control Groups

Variable	Negative Control (Healthy) Mean ± SD	Positive Control (Eclampsia) Mean ± SD	p-value
sFlt-1 serum level (pg/mL)	579.8±114.8	2752.8±188.7	0.000
VEGF serum level (pg/mL)	88.56±5.58	44.85±2.15	0.000

Based on the results of the one way ANOVA test on serum sFlt-1 level data, there were significant differences in the mean serum sFlt-1 level in the five observation sample groups (p-value<0,000). Furthermore, the Multiple Comparisons with the Least Significant Difference (LSD) showed that there was a difference between the mean serum sFlt-1 levels between the positive control group (model preeclampsia mice) (2752.8±188.7apg/mL) and the treatment group gave ethanol extract Nigella sativa doses 500mg (2510.3±182.2b pg/mL), with a dose of 1000mg (2142.5±171.9cpg/mL), with a dose of 1500mg (1309±161.3dpg/mL), and also with a dose of 2000mg (1500±169.9dpg/mL). This means that there is a treatment effect of giving 500mg, 1000mg, 1500mg and ethanol Nigella sativa extracts to serum sFlt-1 levels in preeclampsia mice.

Table 2: The influence of Nigella sativa ethanol extract on mean serum sFlt-1 levels and VEGF levels

Intervention Group	Mean Serum sFlt-1 levels (pg/mL)	Mean Serum VEGF (pg/mL)
Negative control	579,8	88,56
Positive control	2752,8	44,85
Preeclampsia Mice + Ethanol Extract 500 mg	2510,3	50,25
Preeclampsia Mice + Ethanol Extract 1000 mg	2142,5	60,18
Preeclampsia Mice + Ethanol Extract 1500 mg	1309,0	71,89
Preeclampsia Mice + Ethanol Extract 2000 mg	1500,0	66,51

Based on the results of the One Way ANOVA test on VEGF level data, there were significant differences in the mean VEGF levels of the five observation sample groups (p-value=0,000). Furthermore, the Multiple Comparisons with the Least Significant Difference (LSD) showed that there were significant differences in the mean VEGF levels between the positive control group (preeclampsia mice) (44.85±2.15 pg/mL) and the treatment group administered ethanol extract Nigella sativa at a dose of 500mg, 1000mg, 1500mg and 2000mg (50.25±2.85b pg/mL, 60.18±4.81c pg/mL, 71.89±2.38d pg/mL and 66.51±1.87e pg/mL). There appears to be an increase in serum VEGF levels along with an increase in the dose of ethanol extract except at doses of 2000 mg. If based on the average value of VEGF levels, the treatment group doses 1500mg show the highest value of the average VEGF level (71.89±2.38d pg/mL) compared to the group in other doses and can be considered the fastest dose in increasing VEGF levels in mice models preeclampsia.

The occurrence of a decrease in serum sFlt-1 levels and an increase in VEGF in line levels in increasing doses. The 1500mg dose seems to be the optimal dose of reducing serum sFlt-1 levels and increasing serum VEGF levels.

Discussion

This study showed that sFlt-1 serum levels in pregnant mice injected with pre-eclampsia maternal serum (2752.8±188.7 pg/mL) significantly increased compared with negative control mice. The administration of pre-eclampsia serum intraperitoneal injection with high TNF levels in pregnant mice increase blood pressure and serum sFlt-1 levels[14] which caused by an increase in angiotensin II[15].

The previous study reported that the administration of IgG injection of preeclampsia mothers increase TNF serum levels in pregnant mice. Increased levels of sFlt-1 in preeclampsia patients can reduce levels of free VEGF and PlGF in the circulation resulting in the onset of symptoms of preeclampsia[16,17]. Soluble Fms-like tyrosine kinase-1 (sFlt-1), also known as Soluble vascular endothelial growth factor receptor 1 (sVEGFR-1) which is a soluble receptor for VEGF and PlGF[18] which acts as VEGF and PlGF against by binding and inhibiting interactions both of them against endogenous receptors[19].

This study showed the serum VEGF levels of preeclampsia mice have a significant decrease compared to control mice. The injection of serum for pregnant women PEB in pregnant mice causes pre-eclampsia-like symptoms because TNF-α found in maternal serum binds to TNF type 1 receptors (TNFR-1) mice which in turn activate the NF-κB[20] transcription factor. NF-κβ activation by TNF α may play a role in inducing HIF-1α[21] which is a transcription factor for sFLT formation in the placenta[22]. sFlt does not have a transmembrane domain and membrane[6] cytoplasmic domain, so the bond between VEGF and PlGF to sFlt-1 cannot provide a second messenger for angiogenic and has an antiangiogenic effect[5]. The presence of sFlt-1 as a competitor for surface VEGF receptors (Flt-1) causes VEGF cannot attach to receptors on the cell surface. This condition causes serum proangiogenic VEGF levels to drop by 5/6. Decreasing levels of free VEGF can also indirectly increase in blood. The low levels of free VEGF in serum could decrease in nitric oxide (NO) which cause in blood vessel vasoconstriction followed by an increase in blood pressure.

There was a significant difference in serum sFlt-1 levels in preeclampsia mice with a treatment group given a dose of BC-e dose of 500 mg, 1000 mg, 1500 mg, and 2000 mg. Antioxidant supplements to preeclampsia patients able to reduce serum sFlt-1 levels

and increase serum PlGF levels. Black cumin with the main content of Thymoquinone (TQ) has the potential as an antioxidant so that it can reduce serum sFlt-1 levels in preeclampsia mice significantly[23]. TQ is able to inhibit organ damage caused by free radicals[10]. The antioxidant effects of TQ, dithymoquinone, and thymol be able to inhibit some reactive oxygen species (ROS). TQ and dihydrothymoquinone (DHTQ) have the ability as free radical scavengers with a half inhibitory concentration (IC50) in nanomolar concentrations and micromolar[10]. All ingredients of black cumin have a strong antioxidant effect, where thymol works by quelling single oxygen production, while TQ and dithymoquinone show activities such as superoxide dismutase (SOD)[24].

There was a significant difference in the mean serum VEGF levels of preeclampsia mice with a treatment group that was given a dose of 500 mg, 1,000 mg, 1500 mg, and 2000 mg of BC-e. The effect of BC-e on increasing serum VEGF levels in preeclampsia mice is not fully understood. TQ has the ability to inhibit transcription factors, nuclear factor kappa β (NFκβ) is thought to be the cause. TQ as an inflammatory inhibitor works through anti-inflammatory and proapoptotic action[25].

TQ can inhibit the bonding of NFκβ to DNA through direct interaction with sub-unit p65. TQ will inhibit activation by IkBα kinase which in turn will inhibit degradation and phosphorylation of IκBα thereby inhibiting the activation and translocation of NFκβ from the cytoplasm to the cell nucleus[26]. Barriers to activation of NF-kβ cause decreased HIF1-α expression. In preeclampsia placenta, the inhibition of activation of HIF1-α can reduce the synthesis of sFlt anti-angiogenic factors, and ultimately increase the VEGF angiogenic factor that enters the maternal circulation.

The role of BC-e as an antioxidant is also thought to play a role in increasing VEGF levels. Antioxidant supplementation caused a significant decrease in the concentration of sFlt-1 and increased PlGF in plasma. Whereas in vitro studies showed beneficial effects of antioxidants on VEGF. BC-e has considerable antioxidant properties both in vivo and in vitro[8,24]. In its activity as an antioxidant, thymoquinone synergizes with other compounds such as dithymoquinone and thymol to capture free radicals[10].

The average increase in serum VEGF levels along with the increase in the dose of black cumin extract given and the optimal dose of NS in increasing VEGF levels in serum is 1500 mg. At a dose of 2000 mg, there is a decrease in serum VEGF levels. This is presumably because the effect of hormesis is found in the effects of the response dose[27], where at low doses black cumin ethanol extract has a beneficial effect while at high doses it has a detrimental effect.

Conclusion

Giving of Black Cumin extract (Nigella sativa) decreases serum sFlt-1 levels and increases serum VEGF levels in preeclampsia mice model and the effect is dependent dose.

Abstract

Teenager are the future generation, with the cognitive abilities of a good expected level of education will be good. The impact of nutritional status abnormal, low hemoglobin levels, and disorders psychosocial emotional behavior associated with cognitive abilities in teenager, especially in female teenager. The objective of this study is to analyze the effect between nutritional status, hemoglobin levels, and psychosocial emotional behavior with cognitive function in female teenager. This research used observational analytic method with cross sectional approach. Data were collected during February-March 2019. Respondents in this study were students or female teenager in accordance with the inclusion and exclusion criteria. Sampling technique in this research is probability sampling type simple random sampling with a total sample of 72 female teenager respondents. The independent variables studied are nutritional status, hemoglobin levels, and psychosocial emotional behavior and dependent variable was cognitive function in female teenager. Data nutrition status collected by BMI measurements according to age, hemoglobin levels by hemocue tool, psychosocial emotional behavior was measured by PSC-35 and cognitive function was measured by MMSE-test. Analysis was using logistic regression. The results of research obtained that there is effect between the nutritional status of skinny, low hemoglobin levels (anemia) and suspect there are disorders psychosocial emotional behavior with a value of $p < 0.05$. Risk factors nutritional status of skinny, low hemoglobin levels (anemia) and suspect disorders psychosocial emotional behavior on cognitive function below normal, amounted to 81,4% and 18.6% was caused by other factors. Nutritional status, hemoglobin levels, and behavior psychosocial emotions affect the cognitive function of female teenager.

Keywords: *Nutritional status, hemoglobin levels, psychosocial emotional behavior, cognitive function, female teenager.*

Introduction

Teenager is a time of transition from children to adult. A period when a lot of things in life changed with a very high speed and this period is a preparation for adulthood that will pass through several stages of development is important.(1)Some research mention, teenagers at risk of impaired development of cognitive function caused by several factors such as factors of physical and mental health, family, environment and peers.(2)

Data from the Ministry of education and culture occurs to a significant decrease in the average yield of the ability of cognitive function of learners of Indonesian in the school. The upper level, the obtained average results of cognitive function in students of Vocational High School as a whole in 2015 is 62,11 and 2016 have average 57,66.(3)Nutritional problems in teenager will have an impact on the decline of brain function, decrease in body to do physical activity, and loss of physical fitness will affect the health of a teenager.(4)

The prevalence of the risk of lack of energy chronic in women of childbearing of age group 15-19 years in Indonesia in 2007 amounted to 30,9% increased to 36,3% in 2018. Overall, the prevalence of the risk of less energy chronicle women of childbearing of age group 15-19 years is high when compared with other age groups. Based on Basic Health Research 2018 the prevalence of obesity in teenager (≥15 years) in

Indonesia increased from 26,6% in 2013 to 31.0% in the year 2018. In addition to the prevalence of the risk of lack of energy chronic and obesity in teenager, the prevalence of anemia in female teenager has increased from 37,1% in 2013 to 48.9% in the year 2018.(5)

In addition to the nutritional problems in teenager, there is a relationship between the psychosocial conditions of a person with a cognitive ability. The stability of the psychosocial is very important in the development of cognitive abilities, the inability of a person to control the depression and emotions will lead to instability of the psychosocial so that individuals will experience difficulties in learning. Learning difficulties are due to instability of the psychosocial is one of the causes of low academic potential.(6) According to the data of Basic Health Research, the prevalence of mental emotional disorder in the population aged ≥15 years increased from 6% in 2013 to 9.8% in the year 2018.(5)

Based on preliminary studies conducted in 22 female teenager in SMK Negeri 1 Grogol, showed female teenager with the status of malnutrition, anemia, and disorders psychosocial emotional behavior, 22% to obtain the value of the cognitive function that is not normal. Teenager are the future generation, with the cognitive abilities of a good expected level of education will be good.

The impact of nutritional status, hemoglobin levels, and psychosocial emotional behavior associated with cognitive abilities in adolescents, especially in female teenager. These things clearly corroborate that the health of the teen determine the effort in quality of the next generation in the future. This research was conducted because the author wanted to examine the influence of nutritional status, hemoglobin levels, and psychosocial emotional behavior with cognitive function of female teenager in SMK Negeri 1 Grogol Kediri.

Materials and Method

The study was conducted with cross sectional method. Sample of this study is female teenager in SMK Negeri 1 Grogol Kediri during February-March 2019 that meet the inclusion and exclusion criteria. The criteria for inclusion of respondents in this research is female teenager, are already experiencing a menstrual and sign a letter of informed consent to be a respondent. Exclusion criteria from this study are the respondents who are menstruating and respondents who have health problems such as diarrhea and menorrhagia.

The method of sampling is with simple random sampling technique. This study the independent variables are nutritional status, hemoglobin levels, and psychosocial emotional behavior, the dependent variable is cognitive function. Datanutrition status collected by BMI measurements according to age, hemoglobin levels by hemocue tool, psychosocial emotional behavior was measured by PSC-35 and cognitive function was measured by MMSE-test.

Statistical analysis using a computer program namely SPSS version 21. The analysis of the analytic wear test statistics non parametriclogistic regression to determine whether there is influence between nutritional status, hemoglobin levels, and psychosocial emotional behavior with the cognitive function of female teenager. This analysis is used for dependent variables with a measurement scale of categorical variable. In logistic regression the quality of the formula is obtained from the ability of discrimination and calibration. Calibration by the method of Hosmer and Lameshow. In addition, the value of Nagelkerke R Square is also seen to see how much the proportions of independent variables can predict the occurrence of the dependent variable.

This research has received approved from the Health Research Ethics Committee from the Public Health Faculty of Airlangga University Surabaya by letter No.76/EA/KEPK/2019.

Finding: The number of samples obtained by simple random sampling technique as many as 72 female teenager respondents.

Table 1: Distribution of nutritional status, hemoglobin levels, psychosocial emotional behavior and cognitive functions of female teenager.

Variable	Total (n = 72)	
	Frequency	Percentage (%)
Nutritional Status		
Underweight	22	30,6
Normal	27	37,5
Overweight	23	31,9
Hemoglobin Levels		
Anemia	19	26,4
Normal	53	73,6
Psychosocial Emotional Behavior		
Suspect Disorder	19	26,4
Normal	53	73,6
Cognitive Function		
Under normal	20	27,8
Normal	52	72,2

Table 2: Effect of nutritional status, hemoglobin levels, psychosocial emotional behavior with cognitive function of female teenager

Variable	β	Exp (β)	p	Description
Nutritional Status			0,137	Not Significant
Underweight	-3,547	0,029	0,048	Significant
Normal	-1,253	0,286	0,366	Not Significant
Overweight	Reference Group			
Hemoglobin Levels				
Anemia	-6,133	0,002	0,001	Significant
Normal	Reference Group			
Psychosocial Emotional Behavior				
Suspect Disorder	-3,808	0,022	0,007	Significant
Normal	Reference Group			
Constant	6,276	531,524	0,001	Significant
Nagelkerke R square = 0,814				

Test results analysis using logistic regression showed there is the influence of the nutritional status of skinny, low hemoglobin levels (anemia) and suspect disorders psychosocial emotional behavior with a value of $p < 0.05$. The influence of risk factors nutritional status of underweight, low hemoglobin levels (anemia) and suspect disorders psychosocial emotional behavior on cognitive function below normal, amounted to 81,4% and 18.6% was caused by other factors.

Discussion

Teenagers actively construct their cognitive world, where the information obtained is not directly accepted so just into their cognitive schema. Teenagers have been able to distinguish between ideas that are more important than other ideas, and adolescents also develop this idea. A teenager does not just organize experienced and observed, but also able to process their way of thinking thus giving rise to a new idea.[7]

The effect of nutritional status on cognitive function: The results of the statistical test of the effect of nutritional status on cognitive function showed that nutritional status has no effect on cognitive function. The results obtained p-value = 0,137 ($p > 0.05$) showed that the nutritional status is not a factor that affects the cognitive function of respondents is below normal, but on the nutritional status of underweight $p = 0.048$ ($p < 0.05$) showed that the nutritional status of the underweight is a factor that affects cognitive function below normal. The value of Exp(β) = 0,029 mean that the respondents nutritional status underweight then it is likely to have the ability of cognitive function below normal 0,029 times compared to respondents with normal nutrition status.

Teenagers have nutritional needs that are unique when viewed from the point of view of biology, psychology, and from a social point of view. As if viewed from the point of view of the social and the psychological, the adolescents themselves believe that they do not pay too much attention to health factors in the dropping of food choices, but rather paid more attention to other factors such as the adults around them, the hedonistic culture, the social environment, and other factors that strongly affect it.[8]

The results of the other studies mentioned teenagers with malnutrition give poor results on test of attention, working memory, learning and memory as well as the ability visuospatial except on the test of motor speed and coordination.[9] The nutritional Status of low or excess will lead to a difficult teenager to live in a healthy, active and productive. State of malnutrition can hinder the intelligence of the teenage brain because of the cognitive abilities of a person affected by the nutrients consumed. [10]

When it reaches peak growth velocity, teenagers usually eat more often in large quantities. After the growth spurt, they usually will be paid more attention to her appearance, especially female teenager. They are often times too strict in your diet in maintaining her appearance, so it could cause nutritional deficiencies. Increased activity, social life, and the busy teen will affect their eating habits. Food consumption patterns

are often irregular, frequently snack, often do not eat breakfast and not lunch.[11]

The effect of hemoglobin levels on cognitive function: The results of the statistical test the effect of hemoglobin levels on cognitive function showed that hemoglobin levels have an effect on cognitive function. The results of the research the value of p = 0.001 (p < 0.05) showed that the levels of hemoglobin is a factor that affects cognitive function below normal. The value of Exp(β)= 0.002 to mean that respondents with anemia then it is likely to have the ability of cognitive function below normal to 0.002 times compared to respondents with hemoglobin levels normal.

Iron deficiency is prolonged it will limit the amount of oxygen carried by red blood cells to the body and the brain. The impact of anemia which is most clearly visible is the reduced ability of concentration, in addition anemia can also interfere with cognitive development and physical.[12] Levels hemoglobin is one of the indicators of the determinant of anemia. Iron deficiency causes motor coordination is disturbed and the concentration of attention or concentration to be decreased. Anemia that occurs in teenager had an impact on the inhibition of mental and intelligence as well as decreased concentration and enthusiasm for learning. [13] The low power of concentration effect on the focus students in accepting and understanding the subjects that can have an impact on learning outcomes. In addition to anemia, a factor that can affect learning achievement is intelligence, learning motivation and learning style.[14] According to the study, iron deficiency with or without accompanied with anemia in infancy is connected with the increasing problem of cognitive function in the aspect of internalization, externalization, and social in teenager.[15]

The effect of psychosocial emotional behavior on cognitive function: The results of the statistical test of the effect psychosocial emotional behavior on cognitive function showed that the psychosocial emotional behavior have an effect on cognitive function. The results of the research value of p = 0.007 (p < 0.05) shows that the psychosocial emotional behavior are factors that affect cognitive function under normal. The value of Exp(β) = 0,022 mean that the respondents with suspicious disorder psychosocial emotional behavior then it is likely to have the ability of cognitive function below normal 0,022 times compared to the respondents with the psychosocial emotional behavior are normal.

Teenager is a period marked by the rapid development of aspects of biological, psychological, and also social. These conditions resulted in a variety of disharmony which requires offsets so that teens can reach the level of development of psychosocial emotional behavior are mature and adequate in accordance with the age level. These conditions vary greatly between the young and show the difference that is individualized.[6]

In general, symptoms of conduct disorder psychosocial emotional behavior can be divided into three kinds, namely disorder externalization, disorders of the internalization and attention disorders. Disorders of internalization in the form of various kinds of disorders such as anxiety, depression, withdraw from social interactions, eating disorders, and a tendency to suicide. Disorders externalization can impact directly or indirectly to others, for example aggressive behavior, defiant, disobedient, lie, steal, and lack of self-control. While attention disorders either do not want to learn, the child cannot be silent, fast switching of attention, both at home and at school. The third interruption of that type have the same effect of the poor against the failure of teenagers learning in school.[14]

A variety of psychosocial stressors often associated with the occurrence of emotional disturbance and behavior in adolescents, such as the presence of physical illness, parenting the inadequate, domestic violence, relationships with peers inadequate, as well as poverty. Psychosocial stressors that affect the process of cognitive development.[16]

Perception, recollection (memory), thinking, and process-cognitive processes that others can be influenced by the emotional state is ongoing in one's self. A person's emotional state can affect the cognitive processes, for example stress, depression, anxiety, and mood. the influence of emotions can occur on any part of the overall cognitive activity of man; ranging from recording information, transformation information, storage of information in the arsenal of memory, then extracting information that has been stored in the memory to appear back in order to give a response to a task, until the process of thinking, problem solving, and creativity.[14]

Conclusion

From this study, we can concluded that the risk factors for female teenager with cognitive function abnormal is nutritional status, hemoglobin levels and

psychosocial emotional behavior. Therefore, it takes the role of all parties such as family, peers, teachers, and government for the prevention and handling of the problem of low cognitive function of female teenager through programs of cooperation with related parties.

Conflict of Interest: The Authors declare no conflicts of interest

Life Experience of Adolescents with Thalassemia: A Qualitative Research with Phenomenological Approach

Dini Mariani[1,2], Sri Mulatsih[3], Fitri Haryanti[4], Sutaryo[3]

[1]Doctoral Program, Faculty of Medicine, Public Health and Nursing Universitas Gadjah Mada, Yogyakarta, Indonesia, [2]Health Polytechnic Ministry of Health of Republic of Indonesia, Tasikmalaya, West Java, Indonesia, [3]Department of Pediatrics, Dr.Sardjito Hospital Faculty of Medicine, Public Health and Nursing Universitas Gadjah Mada, Yogyakarta, Indonesia, [4]Department of Pediatrics and Maternity Nursing Faculty of Medicine,Public Health and Nursing Universitas Gadjah Mada, Yogyakarta, Indonesia

Abstract

Introduction: Adolescents with thalassemia, an inherited blood disorder resulting in anemia, have multiple problems. Not only do the sufferers have to face developmental issues, but also the challenges that arise from their disease both physically and psychologically. This research aimed to understand the variety of difficulties or problems faced by adolescents with thalassemia in Tasikmalaya, West Java, Indonesia.

Method: This research was a qualitative study. Samples used in this research were 7 adolescents with thalassemia who were chosen by purposive sampling with inclusion criteria as follows: 1) Adolescents with thalassemia aged 11-19 years old, 2) Regularly visit Hospital dr. Soekardjo and. Prasetya Bunda for transfusion purposes, and 3) Willing to be involved in the research. For data triangulation, interviews were also conducted with 3 mothers of children with thalassemia. Data were analyzed using Creswell's 6 steps for data analysis which consist of data transcription, data reading, data coding, reducing information to themes and categories, making data and theme description into qualitative narration, and transforming findings and results into qualitative interpretations and report writing.

Results: From the interviews conducted with adolescents with thalassemia and their parents, several findings were addressed: physical problems that arise from thalassemia are slowed growth and development rate, fatigue and weakness, and pain. Meanwhile, other problems arise in psychological aspects, such as emotional burden, anxiety and sadness about the future and frustration because of feeling different from others. In addition, the research also found that adolescents with thalassemia are experiencing difficulties in social interactions because of bullying and isolation.

Conclusions: This research provides basic information to define proactive strategies for interventions in order to increase the quality of life of adolescents with thalassemia.

Keywords: *Thalassemia, adolescence, quality of life experience, bullying, social stigma.*

Introduction

Thalassemia is a group of genetic blood disorders from synthesis of alpha or beta globin chain either totally or partially. Symptoms of thalassemia are varied based on the amount and effected globin chain type. Thalassemia is commonly found in the Mediterranean, Middle East, India Subcontinent, North Africa, Central Africa and Southeast Asia including Indonesia. The number now has the attention of the Government of

Indonesia considering that it has seen the numbers of populations with thalassemia and also the fact that Indonesia is one of the countries that has high many thalassemia carriers, with a frequency of 3-8% and up to 10% in several regions. In Indonesia, there are 9082 people with thalassemia and these patients are spread in every region of Indonesia with the highest number in West Java region with 40.3%[4,8,14].

Thalassemia is well-known as a lifetime genetic disorder. The sufferer would experience many problems not only as part of the impact of the disease itself but also from the impact of the medication. Considering the impact of the disease, it is necessary for us to put our attention to the sufferer, especially those in the age range of child to adolescent who have physical maturation and development phases which determine their quality of life[15]. Moreover, adolescents with thalassemia are the most susceptible regarding the social issues because they tend to have dual problems, both physically and psychologically. Besides the impacts from medication, they sometimes are losing control and have the tendency to involuntarily embrace the differences with their normal friends[5]. Other research about adolescents with thalassemia using the Pediatric Quality of Life (Peds QoL) instrument has shown that their QoL only 68.91, and a low rate is also shown on emotional function and school performance, while average QoL from control groups is 79.79[11].To have a better understanding about the experience of adolescents with thalassemia and how they embrace their chronic condition, it is necessary to explore these dimensions with qualitative research.

Method

This research is a qualitative study. Samples used in this research include seven adolescents with thalassemia who were chosen by purposive sampling with inclusion criteria as follows: Adolescents with thalassemia aged 11-19 years old, regularly visit for transfusion purposes, and willing to be involved in the research by completing an informed consent form. For data triangulation, interviews were also done with three mothers of children with thalassemia. Semi-structured interviews were used for the data collection. The research was conducted in 2017 in the Thalassemia Unit of Tasikmalaya Indonedsia. All participants had already been explained about the purposes of the research and completed the consent form before participating. The semi-structured interviews were done in the Thalassemia Unit when all participants were undergoing blood transfusion. The interview took approximately 60 minutes for each participant using interview guide, field notes, and tape recorder to record participants' responses. Data were then analyzed using Creswell's 6 steps for data analysis, which consist of making data transcription, data reading, data coding, reducing information to themes and categories, making data and theme description into qualitative narration, and transforming findings and results into a qualitative interpretations and report writing.

Results

From the semi-structured interviews conducted with six adolescents aged 11-19 years old with education level from elementary school to university with thalassemia and three parents, three common themes from the discussions were obtained, which were physical problems, psychological problems, and social problems.

Physical Problems: It is common that several physical problems are found in people with thalassemia. From several issues, the physical problems were categorized as follows: delayed growth and development rate, fatigue and weakness, and pain. Those categorizations are in-line with the statements of the participants as follows:

"From the physical appearance, it is can be seen that normal adolescents look normal as the way they should, but those who suffer thalassemia there is physical differences from body weight, and body height aspects." (P.5)

"In people with thalassemia, puberty is delayed, unlike normal people. We also suffer delayed growth, especially menstruation, we experienced it delayed compared to normal people, but it is relatively the same between other people with thalassemia." (P.6)

Delayed growth and development in people with thalassemia are also confirmed by parent as follows:

"For body growth, we could see from elementary school to junior high school compared to their relatives, their body looks smaller." (P.1)

Three participants explained how their thalassemia makes them fatigue easily. It is explained as follows:

"Something I feel the most is fatigue, sometimes dizzy... either I do activities at home or at school, I am easily tired." (P.1)

"If my Hb is low, I feel so dizzy, tired, exhausted and sometimes also have fever." (P.5)

"Nowadays I often feel dizzy. I was, maybe once in a month, felt exhausted, but now that I have monthly menstruation, I feel it more often" (P.6)

Physical disorders are also confirmed by parents of adolescents with thalassemia as follows:

"Since being diagnosed with thalassemia for the first time, He has always been weak, easily tired. After having transfusion, it only supports his body for 7-10 days, a week later, he becomes weak again" (P. 2)

Some of participants also experienced pain related to their disease, such as follows:

"During transfusion, I experienced back pain until I have to be treated in hospital." (P.2)

"I have never done any exercise because I could not do much of it. My body become easily exhausted, also there are no friends of mine who have the same things and have big and painful stomach." (P.4)

Psychological Problems: Psychological problems that arose for adolescents with thalassemia can be categorized as follows: emotional burden, anxiety and sadness about the future and frustration because of feeling different from others. Those categories are constructed from the explanations below from patients:

"I once was so angry when I was tired. I was so irritable." (P.2)

"It is so sad and maddening when I was mocked by other people but I cannot defend myself." (P.5)

Emotional burden of thalassemia sufferers was also confirmed by parents as follows;

"When transfusion time comes, they (sufferer) tend to be easily angered, such as when I yelled at them, they were so emotional. I think they just tired." (P.3)

"Other psychological problems experienced by adolescents with thalassemia are anxiety and sadness about the future, explained as follows:

"I am obviously slowly becoming old. I am afraid that my future children will experience the same thing with me and have a lot of friends who are not able to fully embrace my weakness." (P.3)

"I once did not disclose it to my boyfriend because I am afraid that he will not accept me and I'm also afraid of being underestimated." (P.6)

Those arguments are also supported by the statements from parents as follows:

"As my son is growing up, it is undeniable that I have my own anxiety about their future especially about their acceptance and love life in the future. I am afraid that they won't get married because no one will accept them." (P.1)

"I cannot imagine their future." (P.2)

Another psychological problem faced by sufferer of thalassemia is that they feel that they are different from normal people. It is obviously stated from the statements of the participants as follows:

"I have tried getting a job, but it was so difficult for me to get one. For a normal people, getting a proper job has been already a difficult task, then how about people like me? Of course, I feel disappointed with this. I do hope that I will get the same opportunity for job, I want to be like others." (P.4)

"I do feel different from others. If normal people can do anything they want, I have to have transfusion regularly in hospital. I also never had any exercise because I have no friends like me." (P.7)

"I have ever in a condition where I feel abandoned by other people. Maybe it was because I am just being myself, we are different physically." (P.6)

The different feelings towards others are also strengthened by statements from parent about people with thalassemia, as follow:

"In school, their friends are much bigger and taller. I told my child that maybe a miracle will come to us in the future someday." (P.3)

Social Problems: On social interaction issues, people with thalassemia also experience problems that can be categorized as follows: bullying and social interactions difficulties. Those categories are constructed from the explanations below from participants:

"It is a common for me to be mocked at school. I do hope that my friend will never bully me again." (P.5)

Bullying towards people with thalassemia are also reported by parents, as follows;

"Way back from school, they had nosebleed. At first, I think that they have fatigue or something, but when I force them to tell me, they told me that they have been bullied." (P.2)

Bullying is also corroborated by other parents, written as follows:

"Based on their explanation, they often being hit in the head and stomach. Sometimes their belongings, like book, bottle, hat are just thrown by their friends so if my child were trying to get that, they will throw it further. Maybe it is just fun for them." (P.3)

Other social problems faced by adolescents with thalassemia is social interactions difficulties. It is in-line with the explanations of participants as follows:

"I have no friends, maybe just playing around with kindergarten children." (P.5)

The argument is also supported by parents: "I am afraid that they will just be fatigued when they play with my friends, so I asked them to just directly go home to sleep and not play." (P.2)

"In the neighborhood they are only able to play around with younger children, around 5-6 years old or on the 1st or 2nd grade of elementary school. The point is that they are not able to play with their friends." (P.3)

Discussion

This research provides basic information to define proactive strategies for effective interventions in order to increase the QoL of adolescents with thalassemia, especially in physical, psychological and social aspects. The qualitative research with phenomenological approach has produced some themes, such as physical problems, psychological problems, and social interaction problems. Physical problems in adolescents with thalassemia can be categorized by several points that include: slowed growth and development rate, fatigue and weakness, and pain. Delays of sexual developments were reported by 50% of males and females. Glucose tolerance disorder, short body, hypocalcemia, and hypothyroidism also often happen to adolescents with thalassemia. It shows that the effect of excessive iron depends on disease duration and frequency of blood transfusion and slow disease development progress[1]. Other research showed frequent number of growth failures happen in children and adolescents with thalassemia causing body image disorder. The research also highlights the number of events between 30-50% [12].

Psychological problems in adolescents with thalassemia among others are emotional burden, anxiety about future, and feeling different from others. For adolescents and parents who have chronic disease, they face specific problems related to their health issues. Specific problems for sufferers and their parents are feeling of failure and despair about the future, low self-esteem and emotional burden. Adolescents with thalassemia have higher number of psychosocial problems than normal adolescents [10,13.]. Another systematic review also found that several psychosocial problems such as distress, less social function, problems in school performance, feeling guilty, rejection due to disease and/or medication impact are also experienced by adolescents with thalassemia[3].

Social interaction problems experienced by adolescents with thalassemia in this research are bullying and social interaction issue. Bullying happens as an outcome from physical problems experienced by sufferers who position themselves as a victim and an object to be bullied. Self-identity in chronic sufferers can become compromised and their dependency to others become higher than normal adolescents. Those psychosocial problems then impact on adolescents with thalassemia in many aspects such as education, playing time with friends, physical activities, and ability to adapt. Those conditions further impact on the emergence of anxiety, social isolation, and depression. The results of systematic review about bullying prediction on adolescents with thalassemia showed that most bullying is related to their physical condition. One systematic review explained that adolescents with chronic thalassemia who have physical disorders have higher risk to be the object of bullying[6].

Conclusion

The interviews with adolescents with thalassemia and parents provide several themes of physical problems which consist of slowed growth and development rate, fatigue and weakness and pain. Psychological issues consisted of emotional burden, anxiety about the future and feeling different. Social interaction problems consist of bullying, and stigma from looking different. The research provides basic information to define proactive

strategies for effective interventions in order to increase the quality of life of adolescents with thalassemia.

The Effect of Metabolic Syndrome on Systolic Function of Left Ventricle Using Echocardiographic Examination

Doaa H. EL-Farook[1], Hatem A. Sarhan[2], Manal M. Mohamed[3], Ahmed EL-Barbary[4], Khaled A. Khaled[2]

[1]Clinical Pharmacy Department-Faculty of Pharmacy –Misr University for Science and Technology, Egypt, [2]Pharmaceutical Department-Faculty of Pharmacy-Menia University, Egypt, [3]Internal Medicine Department-Faculty of Medicine-Misr University for Science and Technology, Egypt, [4]Cardiology Department Faculty of Medicine-Misr University for Science and Technology, Egypt

Abstract

Objective: Metabolic syndrome may cause bad prognosis on diastolic or systolic function of the left ventricle. Thus, this research aimed to recognize the possible effect of metabolic syndrome on systolic and diastolic function of left ventricle using ECHO.

Study Design: Prospective case-control study.

Place and duration of study: Soad Kafafi Hospital, Egypt, from May 2016 to March 2018.

Methodology: This research included forty patients with metabolic syndrome (18 male, 22 female, mean age=54.13±6.33 years) and forty control matching age and sex volunteers without history of metabolic syndrome disorder (15 male, 25 female, mean age=52.20±5.27).MS was defined according to ATP-NCEP III criteria. Waist circumference will be measured to all participants at the start of study inclusion. Height and weight was measured to calculate Body mass index using standardized formula. Participants underwent laboratory investigations and complete echo cardiography. Left ventricular function of the heart was assessed using Echo cardiographic examination.

Results: There was a statistical significant difference regarding Left atrial (LA) diameter, Interventricular septum and posterior wall thickness in metabolic syndrome patients than normal control persons. The incidence of diastolic dysfunction was significantly higher in metabolic syndrome group compared to control.

Conclusion: MS may cause LV diastolicdysfunction although systolic function was preserved.

Keywords: *Metabolic syndrome, diastolic dysfunction, diabetes, hypertension, left ventricular function.*

Introduction

Metabolic syndrome is defined as a group of interacted risk factors which includetruncal obesity,type II diabetes mellitus (DM), hypertension,high triglyceride level and low high density lipoprotein level[1]. The component ofmetabolic syndrome may be the cause development of cardiovascular disease (CVD) [2]. Its prevalence is further growing in both males and females due to a life style characterized by high calorie consumption and low physical activity [3, 4]. Plandevall et al. recommend routine waist circumference measurement to determine metabolic syndrome and its related diabetes and coronary heart disorders[5]. Interestingly it was found that metabolic syndrome components(diabetes, obesity,and hypertension develop before the development of cardiovascular disease[6]. Previous studies demonstrated that heart failure may occur as a result of diastolic dysfunction although ejection fraction was normal[7]. The mechanisms by which Left Ventricular diastolic dysfunction developed to heart failure were not completely identified. Some proposed mechanisms are that metabolic syndrome may alter function and geometry of the left ventricle which may results in coronary heart disease. Some studies have shown that LV dysfunction independently to metabolic syndrome components. However,some studies have

shown relation between hypertension as a component of metabolic syndrome and increased left ventricular mass inMS patients. Further studies might conduct to define different mechanisms for the development of cardiovascular disease as a result of metabolic syndrome[8].

Methodology

This research included forty patients with metabolic syndrome (18 male, 22 female, mean age=54.13±6.33 years) and forty control matching age and sex volunteers without history of metabolic syndrome disorder (15 male, 25 female, mean age=52.20±5.27). Patients were recruited from the outpatient department at soad-kafafi hospital. Diagnosis of metabolic syndrome was performed according to IDF criteria. According to this criterion MS diagnosed with waist circumference ≥80 cm for women or ≥90 cm for men plus abnormal two parameters of the following: High density lipoprotein cholesterol ≥50 mg/dL for women or ≥40 mg/dL for men; triglyceride levels ≥150 mg/dL and random blood glucose levels ≥100 mg/dL, blood pressure ≥130/85 mmHg.

At inclusion medical history of all subjects was taken then echo cardiographic examination was done for all subjects included in the study. Blood pressure was measured by available sphygmomanometer. Height and weight was measured to calculate Body mass index using standardized formula. Complete lipid profile test, random blood sugar, liver and renal function test and urinalysis using standard operating procedures.

The study approved by ethical committee of Soaad-Kafafi hospital. The exclusion criteria include; Patients suffer from MI, cor pulmonale, atrial fibrillation, cardiomyopathy, valvular heart disease,atrioventricular block hypothyroidism and renal failure.

Echo cardiographic examination wasdone with available machine (GE Vingmed, Horten, Norway) with a 1.5 or 3.2 MHZ phased array transducer. Patients were lying in the left lateral position and breathing gently.A comprehensive echo cardiographic study following standardized protocols was carried for all subjects[9]. Participants are asked to perform passive expiration the whole cardiac movement.

Statistical analysis: Statistical package SPSS version 21 was used for entered of statistical data. Data was summarized using number and percentage for qualitated variables,mean and SD for quantitative variables which are normally distributed while median and interquirtile range formula were used for quantitative variables which are not normally distributed. Independent sample t-test was used for quantitative variables which are normally distributed while non-parametrical Mann-Whitney Test was used for quantitative variables which are not normally distributed. P value<0.05 was considered statistically significant. Normality was checked by Shapiro test.

Results

Table 1: Clinical characteristics of the study groups

Variables	Metabolic Syndrome	Control	P-Value
Age	54.13±6.33[a]	52.20±5.27[a]	.143*
BMI	36.22 ± 7.53[a]	25.55±4.96[a]	<.001*
WC (cm)	119.65±14.36[a]	83.03 ± 7.24[a]	<.001*
SBP	142.50 (130:160)[b]	114.50 (110.00:120.00)[b]	<.001**
DBP	90.00 (80.00:95.00)[b]	76.00 (75.00:80.00)[b]	<.001**
RBS	97.00 (83.00: 143.00)[b]	87.00 (81.00:90.00)[b]	.003**
TG	146.50 (120.00:210.75)[b]	131.00 (113.00:144.75)[b]	.003**
HDL	43.68±8.47[a]	53.10 ±6.56[a]	<.001*

BMI: Body mass index; WC; waist circumference; SBP: systolic blood pressure; DBP: diastolic blood pressure; RBS: random blood sugar; HDL: high density lipoprotein cholesterol.

Indicates a significant *p*-value ($p < 0.05$). mean ± standard deviation ([a]), median (IQR) ([b]), P value by independent sample t-test (*); P value by Mann-Whitney Test (**).

Table 2: Sex distribution among control and metabolic syndrome groups

Sex	Metabolic Syndrome		Control		P-Value
	N	%	N	%	
Female	22	55.0	25	62.5	0.496
Male	18	45.0	15	37.5	

Both gender and age were not significantly different among the two studied groups (Table 1a & b). Regarding clinical parameters, the result shown that both body mass index and waist circumference were found to be significantly higher in patients with metabolicsyndrome group compared to normal control group. The prevalence of hypertension was found to be significantly higher in group I (metabolic syndrome group) compared to group II (normal controlgroup) (Table 1a). Among laboratory investigations, triglyceride level and random blood sugar were statistically significant higher in metabolic syndrome group compared to control group. However, HDL-cholesterol level was found to be significantly higher in control group compared to metabolic syndrome group compared to (Table 1a).

Table 3: Comparison of standard echo cardiographic parameters between metabolic syndrome group and normal control group

Variables	Metabolic Syndrome Group	Control	P-value
LVED(mm)	47.58±5.08[a]	46.48±4.96[a]	.330*
LVES(mm)	29.90±4.83[a]	28.33±4.03[a]	.118*
EF%	68.58±8.48[a]	67.68±5.50[a]	.575*
FS%	37.30±6.26[a]	38.58±8.67[a]	.453*
LA(mm)	38.53±3.83[a]	27.98±3.77[a]	<0.001*
AO(mm)	29.83±4.90[a]	28.23±4.69[a]	.140*
IVS	10.00 (10.00:11.00)[b]	9.00 (9.00:10.00)[b]	.002**
PW	11.00 (10.00:12.00)[b]	9.00 (9.00:10.00)[b]	<0.001**

LVED: left ventricular end-diastole; LVES: left ventricular end-systole; EF% : ejection fraction; FS: fractional shortening; LA: left atrium; AO: Aortic root dimension, IVS: Interventricular septum; pw: Posterior Wall thickness.

Mean ± standard deviation ([a]), median (IQR) ([b]), P value by independent sample t-test (*); P value by Mann-Whitney Test (**).

LVED, LVES,and LV ejection fraction LV fractional shortening were shown to be within normal ranges and no statistically significant difference was detected between both studied groups regarding the previously mentioned ECHO features (Table 2). Additionally, AO was found to be normal within the two groups with no significant difference (Table 2). However, Left atrial anteroposterior diameter, posterior wall thickness and Interventricular septum and were found to be statistically significant higher in metabolic syndrome group compared to normal control group (Table 2).

Table 4: Effect of controlled and uncontrolled hypertension on diastolic dysfunction of the left ventricle

Diastolic Dysfunction	Hypertension						P-Value
	Absent		Controlled		Not Controlled		
	N	%	N	%	N	%	
Present	1	16.7	0	0.0	14	87.5	<0.001
Absent	5	83.3	18	100	2	12.5	

Uncontrolled hypertensive patients show echocardiographic features of diastolic dysfunction which was found to be significantly higher compared to controlled hypertensive patients and normotensive patients.

Table 5: Effect of controlled and uncontrolled diabetes on diastolic dysfunction of the left ventricle

Diastolic Dysfunction	Diabetes						P-Value
	Absent		Controlled		Not Controlled		
	N	%	N	%	N	%	
Present	6	30	1	10	8	80	0.003
Absent	14	70	9	90	2	20	

Uncontrolled diabetic patients show echocardiographic features of diastolic dysfunction which was found to be significantly higher compared to controlled diabetic patients and patients with no diabetes.

Table 6: Effect of controlled and uncontrolled dyslipidemia on diastolic dysfunction of the left ventricle

Diastolic Dysfunction	Dyslipidemia						P-Value
	Absent		Controlled		Not Controlled		
	N	%	N	%	N	%	
Present	5	37.5	3	23.1	7	53.8	.281
Absent	9	64.3	10	76.9	6	46.2	

This table shows that there is no difference in the frequency of diastolic dysfunction among the three studied groups.

Discussion

The term metabolic syndrome (MS) represents a clustering of components including truncal obesity,hypertension,diabetes mellitus anddyslipidemia. Eachcomponent of metabolic syndromemay be considered as important risk factors for the development of cardiovascular disease[10]. Previous literatures study the impact of both insulin resistance and obesity on left ventricular function; however, there is lack of studies that show the impact of MS on left ventricular function. Furthermore, some studies demonstrated that individuals with idiopathic dilated cardiomyopathy were diagnosed with insulin resistance;these studies concluded that MS may cause coronary heart disease[11]. Thus, the present study was conducted to evaluate the impact of metabolic syndrome on left ventricular performance using ECHO.

In the current study, all components of metabolic syndrome were found to be significantly higher in patients with metabolic syndrome compared to normal control group. The analysis of traditional echocardiographic parameters showed that both ejection fraction and fractional shortening which represents left ventricular systolic function were not different among MS patients and normal control group. The major finding of the current study was that metabolic syndrome causes diastolic dysfunction as assessed by standard echocardiographic measurements. Previous studies have demonstrated the effect of metabolic syndrome on the function of left ventricle, but consensus is still lacking. A study by[12] has examined the impact of metabolic syndrome on diastolic function of left ventricle in American Indians using ECHO. They noticed altered of both left ventricular relaxation and of left ventricular diastolic function which is consistent with the current study. Also they concluded that American Indians with the metabolic syndrome had greater posterior wall thickness, left atrial diameter and diastolic dysfunction which are consistent with the current study [12]. In the present study, left atrial diameter of metabolic syndrome group was increased compared to control group, which corresponds to results from other literature[13]. [14] Have shown that left ventricular diastolic function was impaired in MS patients; however ejection fraction and fractional shortening (left ventricular systolic function) is preserved which corresponds to the findings of the present study.[15] Also have shown that only left ventricular diastolic function altered in patients with MS

although systolic function is preserved. In contrast, [16] some studies demonstrated that metabolic syndrome is associated with global left ventricular dysfunction (diastolic and systolic) in subjects with MS but no CVD. Previous studies have demonstrated that diastolic function observed in the current study may be as a result of hypertension. Arterial Stiffness, caused by hypertension may be results in cardiovascular abnormalities [17].In contrast, another study demonstrated that hypertension and obesity were not associated with left ventricular diastolic dysfunction.

4. Watcher et al.,demonstrated that left ventricular diastolic dysfunction occurs at a higher percentage in diabetic patients (80.6%) when compared with patients with no diabetes (69.2%). furthermore, diabetes cause serious effect on the left ventricular diastolic function[18]. In the current study the incidence of diastolic dysfunction rise significantly. The rate of Prevalence of diastolic dysfunction was found to be significantly higher among uncontrolled diabetic patients (80%) compared topatients under glycemic control(10%) and patients with no diabetes (30%). Both studies are comparable. Control of glycemiaby drug or life style modification in diabetic patients can help in maintaining normal diastolic function. According to the Strong Heart Study there was a relation between degrees of glycemic control and diastolic function [19]. However, in the present study glycemic control markers were excluded from the research.

The potential limitations of the present study are a small sample size and lack of randomization.

The Role of Mean Arterial Pressure (MAP) Roll Over Test (ROT) and Body Mass Index (BMI) in Preeclampsia Screening in Indonesia

Dwi Putri Rahayu Tampubolon[1], Lilik Herawati[2], Nursalam[3], Ernawati[4]

[1]Student in Midwifwery Program, [2]Physiology Department Faculty of Medicine, [3]Faculty of Nursing, [4]Obstetrics and Gynecology Department Faculty of Medicine Universitas Airlangga

Abstract

Objective: To evaluate the role of MAP, ROT, and BMI in preeclampsia screening in low resources setting.

Method and Material: This is a retrospective study conducted on 1011 pregnant women who had an antenatal care at Public Health Center in Indonesia. Data taken from public health medical report. The sample groups were 45 preeclampsia patients who have had complete screening of MAP, ROT and BMI. The control groups were normal pregnant women who attained same inclusion criteria.

Results: The pre eclampsia group had positif MAP and obesity result respectively 95.6% and 40% of patients, but in control group only had 40% and 11.1% of patient have positive MAP and obesity respectively. Statistical test illustrates a significant association between MAP and BMI screening with the incidence of preeclampsia (p 0.0001, OR = 32.250 and p 0.002, OR = 5.333).Whereas positive ROT showed in 40% PE groups and 57.8% control group. There is no association between ROT screening and the incidence of preeclampsia (p 0.092).

Conclusion: MAP and BMI can be used as baseline screening tools of preeclampsia in low resources setting. But ROT is not associated with the incidence of preeclampsia.

Keywords: *Preeclampsia Screening, MAP, ROT, BMI.*

Introduction

Preeclampsia (PE) is a complex medical disorder, who is is responsible for neonatal and maternal deaths worldwide. It is also becomes the biggest cause of high Maternal Mortality Rate (MMR) in Surabaya Indonesia from 2013-2017[1]. Accurate prediction and aggressive prevention allowed to elude this pregnancy complication. Effective screening to predict PE in the first trimester of pregnancy is important to identify women who are at risk of developing PE so that early enough prevention treatment could start to prevent or reduce the frequency of its occurrence.

Preeclampsia screening vary from clinical to biomolecular level depend on the resources availability. In low and middle income countries where resources are limited, variations of the first-trimester combined test can be considered but difficult to reached. The baseline test which is possible to do are combine of maternal risk factors with Mean Arterial Pressure (MAP) and Roll over Test (ROT). In the absence of other biomarker(s), risk calculation can still be done but the detection rates will be reduced .

MAP and ROT are a method to describe hemodynamic conditions in patients with preeclampsia. ROT is not a perfect predictor, but it still have advantages

email: ernawati.spog@gmail.com

to use in populations with high PIH associated maternal and perinatal mortality, mostly in low resources setting[2]. It has been used in many contries but some literature shows that ROT is not related to the incidence of preeclampsia[3]. The purpose of this study is to determine the effectiveness of preeclampsia screening (MAP, ROT, and BMI) to the incidence of preeclampsia in Indonesia.

Material and Method

This is a retrospective study conducted on 1011 pregnant women who performed an antenatal care at Sidotopo Wetan Public Health Center (*Puskesmas Sidotopo Wetan*), Surabaya, Indonesia from October 2017 to October 2018. Et Data taken from public health medical report. The sample groups were 45 preeclampsia patient during that period time who fulfilled inclusion criteria: patients in the first and second trimesters who have had complete screening of MAP, ROT and BMI. The control groups were normal pregnant women who attained same inclusion criteria. It was takenby consecutive sampling. Positive result noted if MAP is > 90 mmHg. ROT classified as positive result if there were different of diastolic pressure between supine and lateral position more than 15 mmHg[3]. The values on BMI screening classified as obesity if the result >30.The samples were traced retrospectively to see the MAP, ROT and BMI screening history and demographic data.

Finding:

Table 1: Demographic Characteristics

Age (Year)	PE group	Control group	Total
	n (%)	n (%)	n (%)
< 20	0 (0)	3 (6.7)	3 (3.3)
20-35	37 (82)	38 (84.4)	75 (83.3)
> 35	8 (18)	4 (8.9)	12 (13.3)
Parity			
Primi	9 (20)	13 (28.9)	22 (24.4)
Multips	36 (80)	32 (71.1)	68 (75.6)
Risk Factor			
Anemia	3 (6.7)	0 (0)	3 (3.3)
Gestational diabetes	5 (11.1)	2 (4.4)	7 (7.8)
History of Preeclampsia	1 (2.2)	0 (0)	1 (1.1)
Obesity	16 (35.6)	5 (11.1)	21 (23.3)
Tuberculosis	2 (4.4)	0 (0)	2 (2.22)
HbsAg (+)	1 (2.2)	0 (0)	1 (1.1)
History of IUFD	1 (2.2)	0 (0)	1 (1.1)
Under nutrition	1 (2.2)	6 (13.3)	7 (7.8)

Baseline demographics of study participants are presented in Table 1. Most pregnant women in both groups are in reproductive ages. It also worked on parity data, which is multips showed have larger number than nulips. Obesity has the highest rank in PE risk factor in this study. It counts a percentage of 35.6% obesity cases. Followed by Gestational diabetes and anemia.

Table 2: MAP, ROT, BMI and the incidence of preeclampsia

Screening	PE Group	Control Group	Total	P	OR
	n (%)	n (%)	n (%)		
MAP (-)	2 (4.4)	27 (60)	29 (32.2)	0.0001	32.250
MAP (+)	43 (95.6)	18 (40)	61 (67.8)		
ROT (-)	27 (60)	19 (42.2)	46 (51.1)	0,092	-
ROT (+)	18 (40)	26 (57.8)	44 (48.9)		
Obesity (-)	27 (60)	40 (88.9)	67 (74.4)	0,002	5.333
Obesity (+)	18 (40)	5 (11.1)	23 (25.6)		

The MAP test in this study pointed out that 95.6% preeclampsia samples have a value of positive MAP, while only 40% samples of control groups have a positive MAP. This study in accordance with another study by Gasse et al in 2017, which is showed that first-trimester MAP is a strong predictor of gestational hypertension and preeclampsia in nulliparous women[4].

Table 2 also showed that 60% preeclampsia patients have negative ROT screening and are inversely proportional to control group that most of them have positive ROTscreening with p value 0.092 which means that there is no association between ROT measurement and the incidence of preeclampsia.

The results of BMI measurement and the incidence of preeclampsia in this study showed that 40% preeclampsia patient are obese but only 11.1% control group patient recorded obese. Statistical analysis noted p value 0.002 which could be explained that there is a relationship between BMI and the incidence of preeclampsia.

Discussion

Baseline data in this study discordant with the theory of preeclampsia and other study which is reproductive ages and multips are low risk group to have hypertension in pregnancy. It could be explained that reproductive age in this study has preeclampsia risk factor ie gestational diabetes, obesity, history of preeclampsia and infection. Another study from Indonesia also pictured that more than 50% patients who experienced preeclampsia are between 20 to 35 years old[5]**.**Parous women without prior history of PE have lower risk of PE; however, this protective effect will change when they have different conception partner[6].

MAP test showed strong relationship with incidence of preeclampsia in this study, it revealed odd ratio 32.25. This data inline with Poon study in 2008 which reported first study on MAP measurement using validated automated blood pressure devices according to a standardized protocol and maternal variables in 11+0 to 13+6 weeks pregnancy can predict PE.Maternal blood pressure was measured in 5590 singleton pregnant women. the detection ratesfor PE, at 10% false positive rate, were 38% and 63%, respectively for MAP alone and in combination with maternal history[7].

MAP is a reflection of hemodynamic perfusion pressure from vital organs. Another follow-up study on MAP measurement of more than 9000 pregnancies at 11–13 weeks of gestation compared the screening using systolic blood pressure, diastolic blood pressure, and MAP.MAP performed best as a marker, with an increasing of detection rate for early onset PE from 47% (based on maternal factors alone) to 76% (based on MAP and combination of maternal factors) at 10% false positive rate[8].MAP screening in first-trimester is a strong predictor of gestational hypertension and preeclampsia[9,10].

The value of roll-over test has advantages in its simplicity. It requires simple equipment and no special skill. ROT is performed by positioning the patient in a lateral state and then a blood pressure measurement is made until there is no change in blood pressure. Then, the tension is measured in the supine position and the tension results are recorded again.

Some study showed roll-over test are highly variable among different investigators and also inconsistent reproducibility in the same patient. Literature review reveals sensitivities varying between 0 to 93% and specificities between 54 – 91% and false positive results up to 90%. Walia et all study in 2015 also reported roll-over test performed at 24 weeks had negative in all study cases. So, it is clear that ROT has no role as early predictive in preeclampsia[3].

The relationship between preeclampsia and obesity has been greatly studied. Obesity prevalence has increased over 25 years it is similar to preeclampsia prevalence. This study showed obesity has correlation with incidence of PE. It revealed OR 5.3 in obesity cases compare non obesity cases.

This data support substantial evidence which is show that obesity (BMI $\geq$30 kg/m^2) confers a higher risk for PE[10,11,12]. Obesity also state as meta inflammation, associated with chronic stress and inflammatory response. The inflammatory response was found to increase in obese women and contribute to vascular targets and vascular changes induce endothelial dysfunction and placental ischemia in turn exaggerated maternal inflammatory response and induce preeclampsia[13,14,15].

This study in line with FIGO guideline on preeclampsia screening where state that if it is not possible to measure biomarker (PLGF) and/or uterine artery doppler, combination of maternal risk factor and MAP has advantages than maternal risk factor alone. Simple method to measure in Public health will increase

awareness, access, affordability, and acceptance prenatal screening of preeclampsia[16].

Conclusion

MAP and BMI can be used as baseline screening tools of preeclampsia in low resources setting with OR = 32.250 and 5.333. But ROT is not associated with the incidence of preeclampsia.

Strategic Contribution of Health Services in the Indonesia-Malaysia Border to the National Resilience: Analysis of Implementation in the West Kalimantan Province

Dwi Rachmatullah[1], Dumilah Ayuningtyas[2], Raden Roro Mega Utami[2]

[1]National Resilience Strategic Study, Strategic and Global Study School, Universitas Indonesia,
[2]Department of Health Policy and Administration, Faculty of Public Health, Universitas Indonesia

Abstract

Background: The length of "open access" areas from Indonesia which leads to the vulnerability state is the factor that influence terrorism, disease, and other transnational crimes. This study aims to analyze the contribution strategies made by the Government of Indonesia in efforts to equalize health services in the Indonesia-Malaysia border region in order to strengthen health resilience as an important part that is inseparable from national security.

Method: The method used in this study is narrative review of published articles and news related to the policy environment and health service facilities in the border regions of Indonesia and in the other countries that have been published in Scopus-accredited and indexed journals.

Results: It was found that there were obstacles faced by the health providers during the implementation process, including the lack of availability of human resources as health workers as well as health facilities in the border area. As such, many Indonesians living on the border choose to seek treatment in Malaysia. The entry and exit routes from neighbor countries are inevitably becoming vulnerable areas which need attention to prevent various threats from entering the border line which will have an impact on National Resilience.

Conclusions: The fulfillment of human resources availability for health workers and health facilities in the border area has not been maximized due to the difficulty of distribution and limited access. Managing the Indonesian border by relying solely on security and military approaches is not enough, that it requires a multi-sector approach that involves all relevant stakeholders. Good management of border areas is needed as an effort to strengthen Indonesia's national security.

Keywords: *Cross-Border; Health Sector; Health Personnel; Health Facility; National Resilience.*

Introduction

Indonesia has a very long border line, which is around 2914.1 km. The length of the "open access" of the Indonesian border region has resulted in the vulnerability of the state gates to be the entry point for threats that have the potential to disrupt national stability and resilience, particularly in the form of terrorism, diseases, narcotics, and other transnational crimes. Health is an integral part in supporting national resilience.

As the front line, the border community in Indonesia will be the first guard to face the threats coming from the outside. This threat is not only classified as a military threat, but it can also another non-military threat, such as health, which can disrupt national stability and resilience especially in the border region.

Health policies in Disadvantaged Areas, Border and Islands are an integral part of the Government's efforts to accelerate health development, especially in the aspect of equity. The limitations of existing facilities, amount and quality of Human Resources, geographical and weather conditions are among the most important factors in this regard.[1] One of the efforts in accelerating the health development that has been done is providing Social Assistance funds according to the Decree of

the Minister of Health No. 329/*MoH/Reg*/III/2010 concerning social assistance for health services in disadvantaged areas, border and islands year 2010. In addition, the issued Decree of the Minister of Health No. 758/*MoH*/DL/IV/2011 appointed Districts and Primary Health Care in land borders and outer population islands that became the target of national priority programs for health services for disadvantaged areas, border, and islands. Based on the Decree of Health Ministry, 45 regions are designated as the main targets of healthcare programs in DABI. The uneven distribution of health workers in the lower DABI, as in Minister of Health Regulation No. 027 of 2012 concerning health troubled regional disaster management shows that 90 districts/ cities including DABI struggled in health problems. This fact indicates that the public health development index is quite low ranging between the average of -1 (minus one) raw intersection, but has an above average value based on economic status data.[2]

Further to the above issue, realizing the importance of health issues as a threat to national security of a country, the Ministry of Defense of the Republic of Indonesia (MOD) and the Ministry of Health of the Republic of Indonesia (MOH) signed a Memorandum of Understanding on Cooperation in Health until June 26, 2015. This agreement aims to increase the capacity of health institutions in MOD and MOH in implementing health services and health support functions to improve public health as a potential and strength of the national defense. One of the scopes discussed in this agreement is the implementation of health services on DABI. Although the leading sector for non-military threat control in the health sector is held by MOH, MOD is also responsible if the threat has disrupted the country's defense system. To date, MOH and MOD have taken various steps to anticipate the existence of any outbreaks happening both at home and abroad. One of which is to build the infrastructure including the equipment, facilities, and health workers which can deal with non-military threats in the health sector.[3]

Health is an inseparable part of Indonesia's national security. Health is one of the variables of the welfare aspects in the social and cultural context. There are twelve indicators of measuring instruments that are used as parameters for National Resilience in health variables. 8 out of 12 of these indicators have a focus on measuring the quality and quantity of facilities and human resources.

Hence, this study aims to analyze the contribution strategies made by the Government of Indonesia in efforts to equalize health services in the Indonesia-Malaysia border region in order to strengthen health resilience as an important part that is inseparable from national security.

Method

The study was using a narrative review of published articles associated with health services in the Indonesia-Malaysia cross-border area to the national resilience as well as other countries experiences. The study focused on obtaining secondary information sources from the articles published in several accredited indexes in Scopus which were searched by using the keywords of health service, cross-border, Indonesia-Malaysia, national resilience, and Kalimantan. The search was limited to the last 10 years (2008-2018). A critical appraisal of selected articles was performed by using the PRISMA method.

Result and Discussion

Between West Kalimantan and Sarawak, land routes have been opened between countries, namely through Pontianak-Entikong-Kuching (Sarawak, Malaysia) for about 400 kilometers and can be reached in six to eight hours. In the northern part of West Kalimantan, there are four districts that are directly adjacent to Malaysia, namely Sambas Regency, Sanggau District, Sintang District, and Kapuas Hulu Regency, which stretch along the Kalingkang-Kapuas Hulu Mountains.[4]

Based on data from the Central Bureau of Statistics in 2016, there were 244 Primary Health Care units, 899 Supporting Primary Health Care units, and 277 mobile Primary Health Care units in West Kalimantan. The hospital is one of the most vital health infrastructures in West Kalimantan. The number of hospitals in the same year was 45 units with the number of beds available were 4,143 units. In 2015, the total population of West Kalimantan Province reached 4.89 million with a population growth of 1.67 in 2010-2015.[5]West Kalimantan is one of those border areas. State border management is a very important and strategic thing that aims to:

a. Ensuring territorial integrity and upholding the sovereignty of the Unitary Republic of Indonesia;

b. Enforcing the national defense and security;

c. Utilizing the resources and equitable distribution of development and its results for the benefit of public welfare;

d. Building the competitiveness of the border community members to be able to balance the more superior social economic activities of the neighboring countries;[6]

Various threats that disturb Indonesia's national security often occur in the state border area. Based on the mapping carried out by the National Border Management Agency, the most frequent illegal activity in the province of West Kalimantan is illegal border entry and narcotics smuggling. These two activities are serious threats to the Indonesian state which can disrupt the stability of Indonesia's national security.[6]

State border crossing is the entry and/or exit point of people and goods. There are three patterns of crossing people/goods in the state border area. The unofficial crossing pattern has caused disruption to national security stability. Appropriate cross-border management is needed to answer complex and specific problems. State boundary management requires the integration of various elements, including the elements of security, customs, immigration, quarantine, and other elements or supporters.

In the West Kalimantan Region, there are four districts that are directly adjacent to the Malaysian State, namely Sambas Regency, Sanggau District, Sintang District, Kapuas Hulu Regency. The following is the distribution of the number of health workers and health facilities in the four districts:

Table 1: Number of Health Personnel by Regency in 2016[5]

	Medical Specialist	General Practitioners	Dentist	Midwife	Nurse	Total
Sambas	14	47	6	304	386	757
Sanggau	15	38	4	83	182	322
Sintang	24	42	11	50	216	343
Kapuas Hulu	11	50	2	252	456	771

Table 2. Number of Hospitals and Beds in 2016 [5]

Districts/City	Primary Health Care	Supporting Primary Health Care	Mobile Primary Health Care	Hospital	Number of Beds
Sambas	28	92	25	3	330
Sanggau	19	90	21	3	300
Sintang	20	60	51	3	161
Kapuas Hulu	23	85	39	2	145

Health problems in border areas are very complex and considered as a threat that can interfere Indonesia's national resilience, partly because it allows the entry or exit of disease-causing agents. The small number of hospitals and health workers in the border region of West Kalimantan has caused many Indonesians to seek treatment in Malaysia, instead of in Indonesia. Consulate General of the Republic of Indonesia (KJRI) in Kuching, Malaysia, records an average of 300 West Kalimantan residents per day visit a hospital in Kuching, Sarawak, Malaysia for treatment. Even in 2011, there were more than 415,000 Indonesians visiting Sarawak for treatment. Of that amount, the most visited hospitals were Normah Hospital, Timber Lyne, and Kuching Specialist Hospital (KPJ). It is estimated that the number of visits will increase by 8 percent every year.[7]

The elevated level of visit of Indonesian citizens who seek for treatment in Malaysia is caused by the transportation access problems. A resident from Sekayam District, Sanggau Regency, West Kalimantan Province said that the road to the primary health care in Sanggau District was terrible and difficult to pass. This condition causes the cost needed to go there is very high. For example, if he uses an ambulance to go there, it takes around 700 thousand rupiahs and two-hour travel time. Whereas for seeking treatment to Malaysia, he spent at most 7 ringgit, which is equivalent to 25 thousand rupiahs.[8]

The progress of information and technology does not rule out the possibility of causing an increase in the volume of people in choosing treatment. The location of the primary health careis far from the capital and adjacent to neighboring countries causes the population to have the option to go to a neighboring country, even though the primary health care as a health facility has been equipped with adequate health workers and medical devices. Based on the results of interviews in a study conducted by Laksmiarti (2014), there was an Indonesian citizen who lived very close to the primary health care in Entikong (only about 10 minutes), while going to the polyclinic in Malaysia took him 20 minutes from the border. But for a long time, these residents prefer to seek for treatment in Malaysia. According to him, he received excellent service from nurses and midwives at the Malaysian clinic. He spent 200 thousand rupiah for one treatment – 70 thousand for transportation and 100 thousand for medical expenses. He claimed that it was not a problem to spend that much money, provided that the services provided made him comfortable. He did not check himself at the Entikong health center because the health workers at the primary health care were still young because the senior officers and the head of the Primary health care were often not in place. Therefore, he trusted his health and his family's in the Malaysian polyclinic. Moreover, for the people of Entikong, they do not need to use a passport, they only need to provide their KTP to the immigration officers, then they can pass and enter Malaysia.[9]

Based on the above description, it is clear that the border which is not effectively supervised can be used as a gateway to activities that are likely to disturb national security. In the West Kalimantan region, there are three state boundary posts namely Entikong National Budget in Sanggau District, Badau National Budget in Kapuas Hulu District, and Aruk National Budget in Sambas District. There should be a good integration between immigration, customs, and health quarantine in the PLBN, which is one of the functions carried out by the port health office.

Every PLBN is reminded to tighten the supervision efforts on health quarantine to prevent the spread of unwanted diseases. This was emphasized by the Minister of Health of the Republic of Indonesia when he visited the Entikong National Budget in Sanggau District, West Kalimantan in April 2018. Special attention should be given to disease vectors such as animals that come in and out the neighboring countries to be 'cleaned up' before crossing over.

Port Health Office said that in safeguarding the border, the officer has the duty and function to prevent deterrence from the entry and exit of diseases, and to supervise drugs, food, cosmetics, medical devices, and addictive substances. The Head of the Pontianak Port Health Office added that for the land route, the Port Health Office placed several officers in Entikong, Badau, Aruk, and JagoiBabang. This officer is in charge of supervising the people's means of transportation and their luggage. The supervision also includes the corpse that enters. The body must be ensured to not carry an infectious disease agent that can cause emergency. In carrying out its duties, the Port Health Office working area also cooperates with the agricultural quarantine division in the local cross-border posts which is responsible in carrying out operational activities in quarantining animals and plants, as well as animal-based biological safety security.[10]Unfortunately, the existence of this port health work area is not supported by adequate health laboratory facilities in the border area although it was mandated by the International Health Regulation (IHR) 2005 which was updated to be the Global Health Security Agenda (GHSA). The regulation said that in order to maintain global health, each country should have a national laboratory system in the Detect-1 package action. As such, health-related security becomes the concern in the Indonesia-Malaysia border region in West Kalimantan.

Conclusion

One of the problems in the border region is border management that has not been carried out in an integrated manner. The problem of several border areas is still handled ad-hoc, temporarily (temporarily) and partially so as not to provide optimal results. Managing the Indonesian border by relying solely on security and military approaches is not enough, it requires a multi-sector approach that involves all relevant stakeholders. Good border area management is needed as an effort to strengthen Indonesia's national security. Doing so will help to realize not only the third verse of nawacita, which is to develop Indonesia from the periphery by strengthening regions and villages within the framework of a unitary state, but also the third principle of *Pancasila,* namely Indonesian Unity.

Survival Analysis of Chronic Kidney Failure with a History of Degenerative Disease

Efri Tri Ardianto[1], Alinea Dwi Elisanti[2]

[1]Medical Record Program Study, [2]Clinical Nutrition Program Study, Health Department, Politeknik Negeri Jember

Abstract

Survival analysis is a statistical procedure for analyzing data with variables that are in focus is time until an event occurs. Kaplan-Meier is one simple method to describes a survival curve. Chronic Kidney Disease (CKD) is the 18th cause of death in the World. CKD has been classified as number two catastrophic disease after heart disease. Many studies have been conducted on the survival of CKD patients, but there have not been many studies on CKD based on degenerative disease. The study want to assess the survival of hemodialysis patients with degenerative comorbidities. This retrospective non-reactive design cohort study uses the right sensor. 34 samples were selected according to the inclusion criteria from 155 populations through simple random sampling. Secondary data were taken from the medical record at 2010 to 2015. The estimated survival of CKD patients with degenerative diseases in men reaching 144 weeks and women 132 weeks, patients with a basic education of 112 weeks and an advanced education of 180 weeks, patients working 132 weeks and not working 212 weeks, patient normal nutrition 200 weeks and abnormal 112 weeks. Need screening efforts on CKD, increased endurance, regular exercise and maintenance of nutritional status in hemodialysis patients.

Keywords: *Survival Analysis, Chronic Kidney Failure, History of Degenerative Disease, Kaplan-Meier, Hemodialysis Patient.*

Introduction

Survival analysis is a statistical procedure for analyzing data with variables that are in focus is time until an event occurs[1]. One of the simplest and easiest method of survival analysis is Kaplan Meier. It does not require too much data, only describes the survival curve and descriptive analysis. Descriptive analysis in survival data must be done statistically, because the differences that appear descriptively are not necessarily descriptive. The statistical test used is the Log Rank test. It can show the differences between categories in each factors[2].

Chronic Kidney Disease (CKD) is a public health problem throughout the world[3]. The prevalence and incidence of CKD continues to increase, has a poor prognosis and requires high medical costs. The Global Burden of Disease in 2010 report CKD was the 27th leading cause of death in the world in 1990 and rose to 18th in 2010. In 2016 the global prevalence of CKD reached 13.4% [4]. About 1 in 10 global populations experience CKD at a certain stage. In Indonesia, the treatment of kidney disease is the second largest ranking of financing from BPJS after heart disease. East Java, including number 2, has the highest prevalence of kidney failure, which is 0.3% higher than the national average[5], which is 0.2%[4]. This increase is same with the increasing number of elderly people, the incidence of diabetes mellitus and hypertension.

The number of patients with CKD at Ibnu Sina Gresik General Hospital in 2012 reached 481 patients and experienced an increase every year [6]. Risk factors for CKD include age, gender, history of diabetes mellitus, and a history of consumption of supplemental drinks[7]. Other opinions describe sex, hypertension, diabetes, gout, traditional drug use and a history of kidney stone

disease as risk factor of CKD[8,9] there is relationship between kidney failure and a history of hypertension, diabetes mellitus, urinary tract infections and urinary tract stones.[10] obesity can increase risk factors for CKD. [11] The high body mass index have the potential for kidney failure. Indonesian Ministry of Health, 2017 reports that triggering chronic kidney failure is Diabetes mellitus, Hypertension, Chronic Glomerulonephritis, Chronic Intersial Nephritis, Polycystic Kidney Disease, Obstruction, Urinary Tract Infection, Obesity, and unknown causes.Indonesian Renal Registry (IRR), (2017) has report from January to October 2016, there were 44.2% of dialysis service facilities in Indonesia that sent data.

Hypertensive kidney disease increased to 37% followed by diabetic nephropathy by 27% [12].Diabetes mellitus (DM) was included in the second cause after hypertension in CKD cases. [13], reported the prevalence of diabetics in Indonesia was 5.7%, but only 26.3% had been diagnosed. This condition is an obstacle in establishing a diagnosis of CKD based on co-morbid diseases, especially DM which certainly requires prior investigation. Risk factors for hypertension and DM are the focus of the study in this study because it has the potential to cause damage to various organ systems if not handled properly. [14]reported the explanatory research that blood sugar levels of 2 hours post fasting independently influence the incidence of terminal renal failure in DM patients.

The highest number is still patients with Hypertensive Kidney Disease (E4), as in previous years. This still needs to be evaluated with regard to the possibility of shifting trends in world epidemiological data, although it is still possible that in Indonesia the etiological distribution of dialysis patients is indeed not similar to other countries.

Method

This study is a non-reactive study, with a type of observational analytic study. Using a retrospective cohort design. Observations use the right sensor calculation (*Right Censoring*). Independent variables of diabetes mellitus and hypertension influence the response variable, namely survival of hemodialysis patients.

The population in this study were 155 new patients at Hemodialysis Poly Ibnu Sina Gresik Hospital. This study uses secondary data of patients' medical records from 2010 to 2015. Inclusion criteria are patients with renal failure who have two degenerative concomitant diseases (hypertension and diabetes mellitus). The sampling technique used was simple random sampling, with a sample size of 34 people. The instruments in this study use the form of data collection sheet and checklist.

Result

The relationship identification between the response and the predictor variables using the Kaplan-Meier method. Failure survival function expressed as reaching failure event (death) and the rate of failure to achieve the death is expressed as a function of hazard. Estimated survival function and hazard function performed by Kaplan-Meier. Characteristics of patient and statistic valuecan be showed on the table 1.

Table 1: Characteristics of Hemodialysis Patients Based on Degenerative Diseases

Characteristics		Status		Median of Survival			P-value
		Censor	No Censor	Estimation	95%		
					Lower Bound	Upper Bound	
Gender	1. Man	7	14	144.00	89.985	198.015	0.892
	2. Woman	5	8	132.00	18.318	245.682	
Education	1. Basic Education (Primary School to Senior High School)	10	20	112.00	55.192	168.808	0.392
	2. Further Education (Diploma to Doctoral)	2	2	180.00	-	-	
Job Status	1. Work	8	18	132.00	83.688	180.312	0.632
	2. Unwork	4	4	212.00	-	-	
Nutritional Status	1. Normal	7	5	200.00	169.826	230.174	0.074
	2. Abnormal	5	17	112.00	56.022	167.978	

Table 1.61.7% of hemodialysis patients are male, have a history of primary education (elementary to high school) (88.2%), work (76.5%), have abnormal nutritional (64.7%).

The female patient have a higher chance of survival than male. Log-Rank test results p-value> 0.05, expain there was no difference in survival time between female and male. Statistically the survival time of male patients is estimated at 144 weeks, while the female reaches 132 weeks. There are differences in the survival life of male and female, the survival life of male hemodialysis patients is 12 weeks higher than women.

Hemodialysis patients with advanced education have a higher survival than primary education (elementary to high school). The results of the Log-Rank test, obtained p-value> 0.05, meaning that there was no differences in survival time of the basic education and the advanced education. Statistically the survival time of hemodialysis patients with advanced education levels has an estimated 180-week and primary education have an estimated 112-week. Hemodialysis patients with working status have a higher likelihood of survival than non-working status. Log-Rank test results p-value> 0.05, there was no difference in the survival time of the working and not working patient. Statistically the survival time of working patient has an estimated 132 weeks and non-working patient have an survival time of 212 weeks.

Hemodialysis patients with normal nutritional had a higher survival than abnormal nutritional. Log-Rank test results p-value> 0.05, show there was no difference in survival time of normal nutritional and abnormal nutritional. Statistically the survival time of normal nutritional has an estimated of 200,000 weeks, while the abnormal nutritional reach 112,000 weeks. So the survival time of hemodialysis patients with normal nutritional is higher. The following figure is the Kaplan-Meier analysis curve based on the predictor variables of hemodialysis patients:

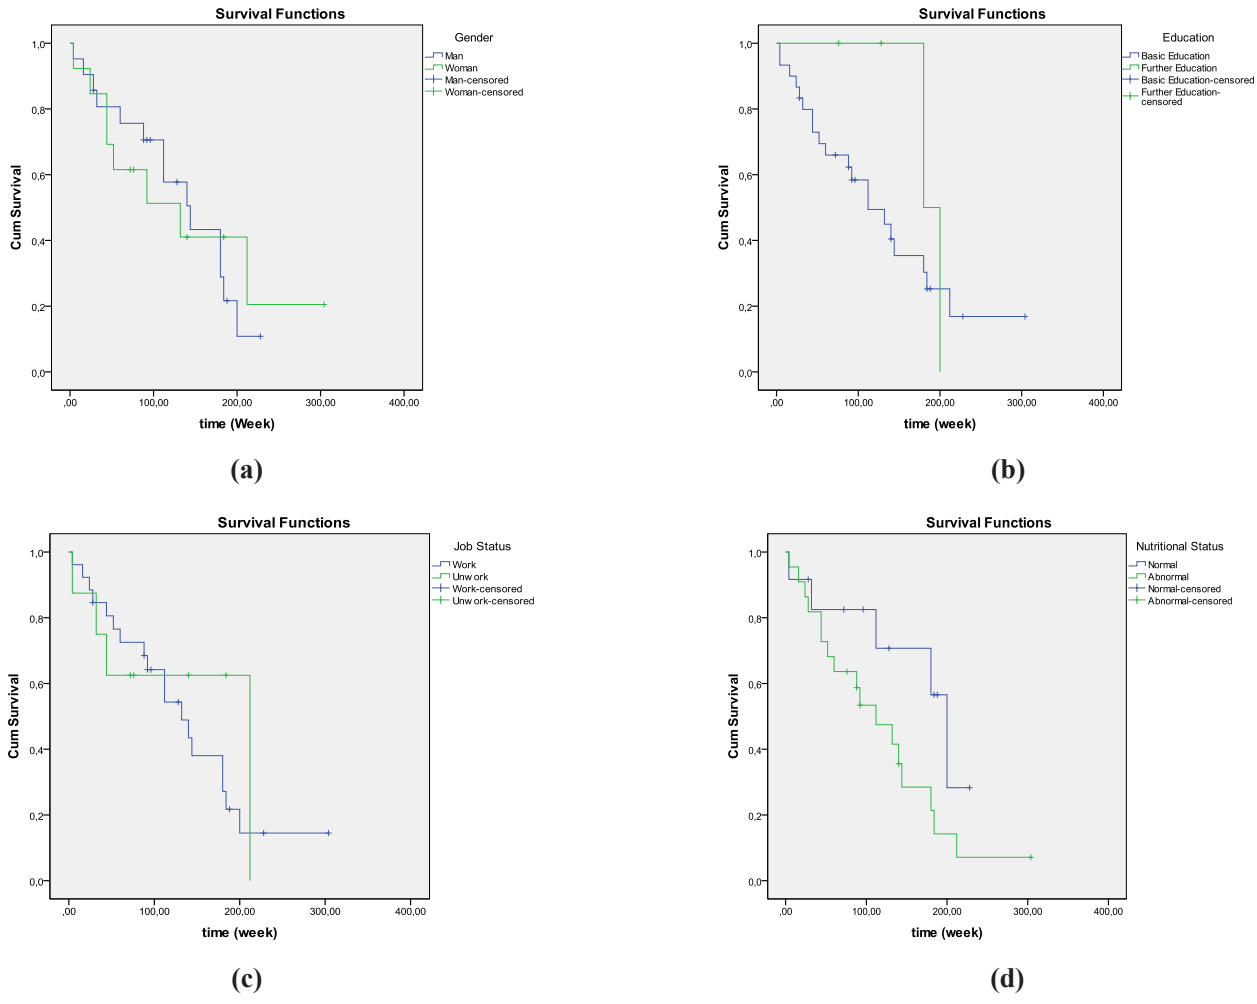

Figure 1. The Results of Kaplan-Meier Analysis (a) Gender, (b) Education, (c) Job Status, (d) Nutritional Status.

Figure 1. Kaplan-Meier curves showed there is a difference in time between two categories, but the curve is merely subjective. Based on statistical values, the Log-rank statistics show the significant variables was Gender, Education, Job Status and Nutritional Status. It concluded that there are no differences in survival time.

Discussion

Hypertension and diabetes mellitus (DM) are the factors that cause death of hemodialysis patients in Ibnu Sina General Hospital. The results of this study was simmilar with the[9] research that there is relationship between kidney failure and a history of hypertension, DM, urinary tract infections and urinary tract stones. [15] has reported that 78.9% of CKD patients have hypertensive comorbidities. Likewise, [8]stated that hypertension, diabetes, gout, can affect the occurrence of chronic kidney failure.

The research of[16], explained patients with CRF caused by DM nephropathy reached 21.9%. [17]reports that 30% of CKD patients have DM and 70% are caused by non-DM. The results of this study also reported that the characteristics of hemodialysis patients, allegedly contributed to the incidence of CKD. According to[8], age, gender, hypertension, diabetes, gout, traditional drug use and a history of kidney stones can affect the occurrence of CKD. [18] explain CKD causes were glomerulonephritis, chronic infections, vascular disease (nephrosclerosis), obstruction (calculi), collagen disease (systemic lupus), nephrotic agents (amino glycosides), endocrine disease (diabetes). [19], show CKD were causes by infection such as chronic pyelonephritis, inflammatory diseases such as glomerulonephritis, hypertensive vascular disease such as benign nephrosclerosis, malignant nephrosclerosis, renal artery stenosis, connective tissue disorders such as systemic lupus erythematosus, polyarteritis nodosa, progressive systemic sclerosis, congenital and hereditary disorders such as polycystic kidney disease, renal tubular acidosis, metabolic diseases such as DM, gout, hyperparathyroidism, amyloidosis, toxic nephropathy eg analgesic abuse, lead nephropathy, obstructive nephropathy such as upper urinary tract: calculi neoplasm, netroperitoneal fibrosis. [7] explain that age, gender, history of DM, and a history of consumption of supplement drinks are risk factors for CKD.

The majority of hemodialysis patients with degenerative diseases were male, had basic education, worked and had abnormal nutritional status. The male patients have a higher survival than female patients. This fact is in line with the Ministry of Health's statement (2017), the prevalence of CKD in men (0.3%), higher than women (0.2%). The trigger factors as background of this fact are the late recognition of early disorders of the kidneys, because CKD initially does not show typical symptoms. Signs and symptoms that arise from kidney disease are very common and can be found in other diseases such as high blood pressure, changes in the frequency of urination in a day, the presence of blood in urine, nausea, vomiting and swelling especially in the feet and ankles [4] In addition [20]states that the characteristics of chronic renal failure in women are slower, and also the occurrence of psycho-socioeconomic barriers such as low awareness of women related to kidney disease and low family income as a cause of female dialysis delay. This condition eventually led to lower prevalence of hemodialysis in women compared to men.

Patients with advanced education levels have higher survival than primary education. This fact is related to the level of understanding of patients which has an impact on patient compliance both in treatment and in patient health care. This result is same with [21] researchthat reported the relationship between the level of education and patient compliance in limiting fluid intake in patients with chronic renal failure with p value 0.019. [22]showed patients with a higher level of education will have broader knowledge and also enable patients to control themselves in dealing with problems they face, have high self-esteem and understand what is suggested by health workers.

The hemodialysis patients who do not work have a longer life than work. It was related to the mind burden of working hemodialysis patients. [23]reported that depression can affect immunological function, nutrition, and compliance factors that can affect prescription and administration of dialysis. Depression can be an independent factor in influencing the survival of hemodialysis patients. Physical activity actually affects the survival of hemodialysis patients, as stated by[24]who reported that there was a relationship between exercise 4 to 5 times a week with an increase in survival life of dialysis patients. [25]explain that low income jobs are prone to cause infections because there is a tendency to consume poor quality of foods.

Patients with normal nutritional have higher survival than abnormal nutritional. [25]stated that good energy intake would not cause nausea and vomiting. The in

adequacy of energy continuously will cause the protein to be broken down into an energy source and cause an increase in the remaining protein metabolism in the form of blood urea. Protein requirements for CKD that get hemodialysis treatment are higher than CKD without hemodialysis. Protein requirements are used to maintain nitrogen balance and replace amino acids lost during the dialysis process. Protein plays an important role as a result of the accumulation of prenatal catabolism in the body when symptoms of uremic syndrome occur [26]

Conclusions

The estimated survival time for male hemodialysis patients is 144 weeks, and women reach 132 weeks, hemodialysis patients with advanced education levels have an estimated 180-week survival time and 112-week for primary education level, working hemodialysis patients have an estimated 132 weeks and not working reach 212 weeks, hemodialysis patients with normal nutritional have an estimated 200 weeks survival time, and abnormal nutritional reaches 112 weeks.

Suggestions: This research is expected to be used as a reference and initial screening for health workers in dealing with chronic renal failure through counseling especially for patients with chronic renal failure with a history of degenerative diseases. providing health education to the community, routine follow-up to working patients, increasing endurance, routine exercise and maintaining nutritional status in hemodialysis patients and can be used as a reference for future studies with variables that have not been studied.

Capital Knowledge Concept: Accounting Behavior and Health Management in Indonesia

Entar Sutisman[1], Bambang Tjahjadi[2], Hamidah[2]

[1]Ph.D. Student in Universitas Airlangga Surabaya, Indonesia, [2]Universitas Airlangga Surabaya, Indonesia

Abstract

The purpose oft his study is to discuss the accounting behavior oft he capital knowledge concept in which gender and skills playa role in the performance of financial statements. Types and sources Data, this study uses secondary data manufacturing company financial statements in Indonesia from 2009 to 2016. The research met ho de used is a quantitative correlation and variable control for independent variables have a greater influence on financial performance. The results showed that the skill influenced the asset turn over (0.007), current ratio (0.004), cash ratio (0.001), and fixed asset turnover (0.002) and Gender had an effect on financial performance. DER (0.048), Asset turnover (0.000), debt ratio (0.005) and ROA (0.045). Originality research, capital knowledge concept plays an important role to improve the performance of corporate financial statements.

Keywords: *Capital Knowledge, Accounting Behavior, Financial Performance.*

Introduction

Aboard of directors provides strategic direction using their networks to provide resources for the organization[4,7,15,25,36,44]. To improver elations hips with shareholders and other externals take holders, a board of directors must be more strict in delegating operational management,operational management balance accountability at the management level. Business is a multi-dimensional partnership and openness is essential to building trust;the relationship between owner and manager,shareholder relationship and asymmetric bondholders information between both parties leads to agency conflict and agency costs[14,19]. The feature of the company's condition means that the owner oft he company cannot observe and therefore he monitors all managerial actions,the bondholder cannot observe managerial and shareholder actions, because he limits them from potential actions that endanger the wealth of the bondholder.

The important role of free cash flow in investment decisions Investor's decision to invest is subjective[10,21,22,23,24]. The decision depends on the expected cost,decision depends on the expected cost techniques and his perceived risk, which is entirely a subjective factor[1,6,34,43,50]. For good investment decisions, investors need to fully understand and correct the opportunities that may occur and this decision should not bed one in a hurry. A wrong investment decision can cause the company to even bankruptcy. It is important to understand the basic idea of investment decisions to get the most value from the assessment process. In the investment evaluation, indicators should be selected on the specific nature of the project and profitability[3,11,17,37,38,42,33,36,41,45]

Material and Method

The method used is the quantitative correlation between independent and dependent variables and control variables. This study is to assess financial performance[13,16,22,24,30,31,37,5,18,32,39,46]

Data Collection and Samples: This study is quantitative correlation research using secondary data such as financial statements Manufacturing companies listed on the 2009 to 2016.

Variable Measurement:

Variable Independent:

a. Skill[2,9,27,45], to develop the agency theory,it is important to consider human capital, external social capital and internal social capital to develop board capabilities called Aboard capital, ie the ability of knowledge,skills and ties to impact company performance[8,12,25,]

$$\textbf{Skill}_S = \beta_0 + \beta_1 \text{ firmsize}_t + \beta_{2a} \text{ board of direct}_{ors} + \varepsilon_t$$

b. Gender,directors purpose $\beta_0 + \beta_1 \text{firmsize}_t + \beta_{2a}$ **board of director** $_t + \varepsilon_t$

Where:

Firmsize=Log (sales)

A board of directors= average of aboard to year

Dependent variable

Variable dependent corporate financial performance[8,18,35,36,39,44,47,51]. In this research use 9 indicators that is DER, Profit Margin,Turnover Asset, Current Ratio, Cash Ratio, Debt Ratio, NPM, Fixed asset turnover and ROA.

$$Y = \beta_0 + \beta_1 \text{ Skill}_t + \beta_2 \text{Gender}_t + \beta_3 \text{firmsize}_t + \beta_{4a} \text{ boardof director}_t + \varepsilon_t$$

Findings:

Correlationof Skill to Financial Performance: In this study, thes kills proxiedin Ph.D. statements. From the table below shows the skill effect on (0.007), current ratio (0.004), cash ratio (0.001), and fixed asset turnover(0.002).

Gender Correlation to Financial Performance improve the impact of corporate governance reform on its (0.048), Asset turnover (0.000), debt ratio (0.005) and ROA (0.045).

Discussion

The Board of Director's Performance Assessment differs from company performance as evidenced by annual financial and disclosure reports. The role of the Board of Directors is broader than that characterized by the agency's control paradigm. Board of direct directors involved in the corporate strategy includes, that is Overseeing managers as fiduciary shareholders, Advising CEOs and top management on strategic issues, Feedback and guidance to the CEO; and Think of it as a source of external knowledge. Collaborative work experience, expertise,reputation,politics, and organizational knowledge reflect the board of director's more effective performance dimensions [8,39,52] Characteristics of a board of directors are also important indicators of a board of director's performance appraisal.

Skill Sets Represented: To develop the agency theory, it is important to consider human capital, external social capital and internal social capital to develop board capabilities called Aboard capital, the ability of knowledge, skills and ties to impact company performance[8,12,25]. This allows the board to function as a cohesive team that implements and mobilizes resources derived from human capital,board members and external social capital[33,35]. The composition oft he board of directors also affects the performance oft he company[18.] During the process of recruitment oft he board of directors, new members are assessed fort heir ability to contribute the required technical skills; arole-fit[12]

H1 = skills with education Ph.D. effect on financial performance

Gender: The gender component of a board of directors has become an obligation of its purpose is to improve the impact of corporate governance reform on its performance. Corporate Governance has been identified as a very intense and controversial area of business administration literature. For managers, shareholders and policy makers the role of corporate governance affects the company's performance. Previous research has shown that a large number of boards impacts on better performance and has implications for multinational corporations[5,18,32,39,46]

H2 = Gender in the board affect the financial performance

Conclusion

Ph.D. and Gender Education has an influence on the performance of financial statements. From the table below shows that Ph.D. Education has an effect on Asset Turnover (0.007), Current Ratio (0.004), Cash Ratio (0.001), and fixed asset turnover (0.002) and Gender influences financial performance. DER (0.048), Asset turnover (0.000), debt ratio (0.005) and ROA (0.045). then the approach to accounting behavior of Ph.D. and gender education can affect significant financial performance.

Early-Onset Neonatal Sepsis in Low-Birth-Weight and Birth-Asphyxia Infants at Haji Hospital Surabaya, Indonesia

Euvanggelia Dwilda Ferdinandus[1], Berliana Devianti Putri[2]

[1]Department of Maternal and Child Health, Faculty of Public Health, [2]Department of Health, Faculty of Vocational Studies, Universitas Airlangga, Kampus C Universitas Airlangga, Kec. Mulyorejo, Kota Surabaya, Jawa Timur 60115

Abstract

Introduction: The incidence of early-onset neonatal sepsis is still high, therefore special attention is needed early detection of risk factors for early management. Many risk factors could affect early-onset neonatal sepsis such as birth-weight and birth-asphyxia.

Aim: This study explored the risk factors for early-onset neonatal sepsis among neonates at Haji Hospital, Surabaya City, Indonesia.

Method: This study was observational analytic with a cross-sectional design. The data used retrospective document review was conducted in NICUs of Haji Hospital, Surabaya City, Indonesia. 1.461 infants were born from January 2018 to December 2018. The data analysis of this study was the Chi-Square Test and Multiple Logistic Regression Test using SPSS for windows v.17.

Result: This study involved 1.461 infants with one hundred seventy-eight suffered of sepsis. The study found out that low-birth-weight and birth-asphyxia were significantly associated with neonatal sepsis ($p<0.001$). Last, the result of multiple regression analysis showed that early-onset sepsis was influenced by low-birth-weight ($p<0,001$; RR: 10.405; CI: 6.346 to 17.061) and birth-asphyxia ($p<0.001$; RR: 17.038; CI: 10.644 to 27.271).

Conclusion: The neonatal sepsis was influenced by low-birth-weight and birth-asphyxia. Based on these results we recommend to focus on the intensive treatment for infants who suffered asphyxia and had low-birth-weight.

Keywords: *Neonatal sepsis; low-birth-weight; birth-asphyxia.*

Introduction

Infant Mortality Rate (IMR) is an indicator that reflects the state of health in society including Indonesia and is a sensitive benchmark of all management efforts undertaken by the government, especially in the health sector[1]. IMR in Indonesia in 2015 was still high at 22.23 per 1,000 live births while in East Java the IMR in 2014 reached 26.66 per 1000 live births[2]. IMR in East Java decreased compared to the previous year but it was not significant, namely in 2013 several 27.5 per 1000 live births. IMR in the city of Surabaya in 2015 amounted to 6.48 per 1000 live births. This figure has increased compared to 2014 which was 5.62 per 100 live births. The United Nations set this indicator on the 2030 Suistanable Development Goals (SDG's) at point 3, namely in 2015-2030, which is to reduce the infant mortality rate to at least 12 per 1,000 live births.[3].

According to WHO in 2016 neonatal deaths account for 45% of child deaths under 5 years. The majority of all

Correspondence Author:
Euvanggelia Dwilda Ferdinandus
Department of Maternal and Child Health, Faculty of Public Health, Universitas Airlangga
e-mail: euva.dwildaferdinandus@gmail.com

neonatal deaths (75%) occur in the first week of life, and between 25% to 45% of neonatal deaths occur within the first 24 hours. Almost all (98%) of five million neonatal deaths occur in developing countries. Neonatal sepsis accounts for nearly 80% of neonatal deaths[4].

Sepsis was initially defined as a suspicion or proven infection accompanied by clinical conditions of SIRS (Systemic Inflammatory Response Syndrome) but the definition is now abandoned. As per the consensus regarding the latest sepsis, sepsis is defined as a state of life-threatening organ dysfunction/failure, caused by an unregulated host response to infection. The cause of early onset neonatal sepsis is different from the cause of slow onset neonatorum sepsis. The cause of SNAD is microorganisms that are transmitted vertically from mother to baby, both before and during labor[5].

As per the consensus regarding the latest sepsis, sepsis is defined as a state of life-threatening organ dysfunction, caused by an unregulated host response to infection. Neonatal sepsis is divided into two namely early-onset neonatal sepsis (age <72 hours) and advanced (age> 72 hours)[6]. Early-onset neonatal sepsis causes high morbidity and mortality in newborns. The incidence of early-onset neonatal sepsis is higher in developing countries (1.8 to 18 per 1000 live births) than in developed countries (1 to 5 per 1000 live births). The case fatality in EONS ranges from 16.7% to 19.4% [7]. The incidence rates of neonatal infection in several referral hospitals in Indonesia is approximately 8.76% –30.29% with the mortality rate is 11.56% –49.9%. The incidence rates of neonatal sepsis in several referrals hospital in Indonesia is 1.5% –3.72% with the mortality rate is 37.09% –80% [5].

In Haji Hospital Surabaya there was an increase in cases of newborn infections in 2015-2017 to 21.50%. Several factors of mother, babies, and environment are contributed to the infection exposed and non-optimal of NM immunologic response so as the newborn become susceptible to be infection[8]. The objective of this study is to explore the risk factors for early -onset sepsis among neonates at Haji Hospital, Surabaya City, Indonesia.

Material and Method

This study was observational analytic with a cross-sectional design. The data used retrospective document review was conducted in NICUs of Haji Hospital, Surabaya City, Indonesia. 1.461 infants were born from January 2018 to December 2018. The independent variables of this study were birth-weight and birth-asphyxia. The dependent variable of this study was early-onset sepsis.

This study used SPSS Statistics 17.0 for data analysis. Bivariate analysis was correlated using cross-tabulations and Chi-Square Test with α=0.05. A multivariable logistic regression model was created to examine the causal association between independent variables and breast milk production using Multiple Logistic Regression with α=0.05. This study was received ethical approval from the Health Research Ethics Committee, Faculty of Medical, Universitas Airlangga.

Findings: Most of the 928 infants (63.51%) were female while almost half were 533 infants (36.48%) were male. Almost entirely, 1353 babies (92.61%) were born with clear membranes while only a small portion, namely 108 babies (7.39%) were born with turbid green membranes.

Furthermore, almost 1350 babies (92.40%) were born full term and a small part, namely 107 babies (7.30%) were born with a premature period as well as babies born over time (postdate) only a small portion, 4 babies (0.30%). Other data show that almost all 1340 infants (91.72%) had no low birth weight (LBW) while only a small portion, 121 babies (8.28%) were born with LBW.

The data of asphyxia in infants shows that almost all of 1333 infants (92.61%) were born not asphyxia while only a small proportion of 128 infants (8.76%) experienced asphyxia. And it shows that almost all 1420 babies (97.19%) were single born and only a small portion, 41 babies (2.81%) were born twin (multiple)

Based on data which fulfill our inclusion criteria. These are the result.

Table 1: Bivariate analysis between independent variables and early-onset sepsis

Variables	Early-Onset Neonatal Sepsis				Total		p
	EONS		Non-Sepsis

Table 2: Summary of multiple logistic regression

Variables	B	SE	P	RR
Birth-weight				
Low	2.342	0.252	< 0.001*	10.405
Normal (Reference group)				
Asphyxia				
Yes	2.835	0.240	< 0.001*	17.038
No (Reference group)				

*Significantly associate using Multiple Logistic Regression Test ($p < 0.05$)

This study involved 1.461 infants with one hundred seventy-eight suffered of sepsis. As shown in **Table 1**, there was a correlation between LWB and neonatal sepsis ($p<0.001$). Most of infants who had normal weight (96.5%) did not suffer sepsis than infants who had LBW. In contrast, almost half of participants (42.7%) who had LBW were suffer early onset sepsis highly than infants who had normal weight. It could be concluded that the early onset sepsis was more suffered by infants who had low-birth-weight (less than 2500 gram).

Table 1 also shows that there was a correlation between asphyxia and neonatal sepsis ($p<0.001$). Only 3.2% (n=41) infants who are getting sepsis were infants who had asphyxia. In contrast, almost half of participants (48.9%) who had asphyxia were suffered early onset sepsis highly than normal infants. It could be concluded that the sepsis was more suffered by infants who had asphyxia.

Table 2 shows that the results of multivariate analysis with Multiple Logistic Regression Test ($\alpha = 0.05$). The result showed that neonatal sepsis was influenced by low-birth-weight ($p<0,001$; RR: 10.405; CI: 6.346 to 17.061) and birth-asphyxia ($p<0.001$; RR: 17.038; CI: 10.644 to 27.271).

The infants who had LBW were at risk for getting early onset sepsis 10.405 times greater than infants who had normal weight. Then, infants who suffered asphyxia were at risk for getting early onset sepsis 17.308 times greater than infants who not suffered asphyxia. So that, asphyxia most likely has an influence.

Discussion

Following approval from the institutional ethical committee, almost half of participants (42.7%) who had LBW were suffering early onset sepsis highly than infants who had normal weight. It could be concluded that the early onset sepsis was more suffered by infants who had low-birth-weight (less than 2500 grams).

The results of this study are in line with the results of a research namely LBW has three times the risk of developing sepsis than non LBW[9,10]. This is in line that infants with sepsis had more low birth weight (85.7%)[11]. The central regulation of breathing is not perfect, the respiratory muscles and ribs are still weak in LBW infants resulting in less oxygen entering the brain, if oxygen is lacking, anaerobic germs easily develop which causes easy infection. In contrast to research conducted by Rahmawati in Dr. M. Djamil Padang Hospital, the

results showed that there was no statistically significant relationship between birth weight in the form of low and normal categories with the incidence of neonatal sepsis. A significant relationship appears in LBW infants with prematurity where the maturation of their organs (liver, lungs, enzymes, digestion, brain, immune system against infection) is not perfect, so LBW babies often experience complications that end in death[12,13].

Then, infants who lived asphyxia were at risk for getting early onset sepsis 17,308 times greater than infants who didn't live asphyxia. So that, asphyxia most likely has an influence to. Neonatal asphyxia facilitates systemic infections. This is due to inhibited leukocyte activity because it requires energy (ATP) for cytoskeletal microfilament contractions. The state of hypoxia will also inhibit the microbicidal activity of *polymorphonuclear* cells[14]. Neonatal asphyxia increased the risk of EONS with a positive blood culture result 4-fold (RO = 4.102; 95% CI 1.04-16.14)[15,16].

Neonatal asphyxia was assessed by examining APGAR scores. A low APGAR score increases the risk of EONS. Research conducted by Muhammad et al in 2015 found that Apgar scores <7 in the first minute had a risk of 14.05 times (95% CI 5.487-35.987) for EONS events[17]. APGAR scores <7 in the first minute were also reported by Shah et al., which were significant with each OR being 5.7 for EONS eventsc. In general, the first minute APGAR score is associated with *Potential Hydrogen* (pH) umbilical cord blood and intrapartum depression and is not related to the results, whereas the APGAR score then reflects changes in the baby's condition during resuscitation[10,18].

Asphyxia neonatorum is very closely related to health problems of pregnant women, including infections. Babies with asphyxia neonatorum appear unfit and have a history of fetal distress before birth. Neonatal asphyxia facilitates systemic infections. Neonatal asphyxia increases the risk of early onset neonatal sepsis with positive blood cultures. In addition, low birth weight babies, including this risk group. Most problems occur in infants who weigh less than 1500 grams with high mortality and require special medical care and treatment for infants at 2.75 times higher risk of neonatal sepsis[10,13,16].

The diagnosis of early onset neonatal sepsis is very important in the management and prognosis of the patient. Delay in diagnosis can potentially threaten the survival of the baby and worsen the patient's prognosis. The prognosis of neonatal sepsis depends on diagnosis and therapy. The prognosis of neonatal sepsis is good if the diagnosis is made early and the therapy is given appropriately. Mortality rates can increase if clinical manifestations and risk factors for neonatal sepsis are not well identified. Midwives and doctors play an important role in efforts to improve the health of mothers and children, especially in clinical cases[19,20].

Conclusion

The neonatal sepsis was influenced by low-birth-weight and birth-asphyxia. Based on its conclusion, it is suggested to Health Service Centre to focus on the intensive treatment for infants who had low-birth-weight and suffered asphyxia. It is also suggested to society, especially for husband, to keep supporting the pregnant-mothers for check their pregnancies regularly.

Conflict of Interest: There was no conflict of interest in this study.

Humanoid Robot Integration in Rehabilitation of Musculoskeletal Conditions

Fayz S. Al-Shahry[1], Rayan F. Al-Shehri[2]

[1]Assistant Professor COAMS, KSAU-HS, Consultant Rehab, KAMC, [2]Engineering Student, KSU, Riyadh

Abstract

Robots find numerous applications in medical/health domains and are extensively used in commercial as well as domestic applications to support daily life activities. Human robot (HR) has widened their wings to be used in rehabilitation applications. Interest in robots that provide health care is growing as one of the upcoming fields of next generation. In this study we investigated the Robot -patient performance in physical rehabilitation. A group of musculoskeletal patients diagnosed with pain in muscles or joints or both, aged 20 to 65 years was chosen for the study. The robot was programmed to instruct and guide the patients for physical rehabilitation activities for three trials of 30 minute sessions on different days. The sessions involved interaction with a humanoid robot. Robot was programmed for a set of active exercises with a classified sequences that are time and motion managed. Verbal communication between the robot and patients allowed for re-start, stop, resume and replay functions. The whole performance was filmed and reviewed from the perspectives of the impact on the patient as well as the performance of the robot. The whole process was validated by performing the same procedure on a trial basis with healthy individuals to ensure the setup is operated smoothly. The performance of each variable was evaluated in three successive sessions. Evaluated functions include clarity, therapy sequence, interaction, voice, timing, independency, operation, technical performance and degree of freedom. Results were computed as percentages by an external assessor. Results demonstrated dynamic learning in the 1st and 2nd sessions which showed a remarkable improvement in the 3rd, 4th and 5th sessions. The overall average of the performance for the last 3 sessions was 91+%. Referring to this outcome, it could be concluded that the robot may have the potential to influence the physical therapy imitation. However,to establish the extent of this influence affirmatively, a bigger sample will be needed with a wider variety of patients.

Keywords: *Humanoidrobot, interaction, integration, rehabilitation, musculoskeletal.*

Introduction

Robots are being designed to complement human skill sets, reduce workload and enable professionals to focus on more important activities that have a greater impact on patient care delivery. As this technology advances and becomes more affordable, we can expect more health care institutions to adopt robotics.

Robots are still not a replacement for human interaction. Hospital operations are complex and involve uncertainty. Robots are good for performing repetitive tasks and tracking data, but this technology should only be used to make the clinicians' workflow easier so that they may focus on the most critical part of their jobs, which is caring for patients.

Advanced humanoid robots are employed in a variety of applications in medical/health domains and are also used extensively in commercial establishments as well as in the home support for daily life activities. Beyond the traditional scope, robot can be engaged in the rehabilitation process and it is poised to become one of the most important technological innovations of the 21st century. Literature showed specific uses with elderly patients and some pediatric applications.[1,2]

In this article, we offer a trial study on the possible uses of robots in rehabilitation, particularly in the management of musculoskeletal conditions.

Human Robot (HR) has widened their wings to be used in rehabilitation. Interest in health care robots is

growing as one of the upcoming fields of next generation in this smart industry, especially as assistive tools in rehabilitation[1]. It is believed that humanoid Robot promises excellent experience for CP children to learn motor tasks[3]. Many studies involving CP children investigated robotic exoskeletons[4] to replace or support function. There is still a lack of intervention therapy which involves complicated functional tasks.

Some of the robotic technologies were designed to assist the user primarily through social rather than physical interaction[5]. For example, a previous study[6] has established Kindergarten Assistive Robotics (KAR) as a tool for learning and development for normal children in preschool education. KAR has increased children's motivation and communication during the interaction. Robots have been successfully introduced into physical therapy and rehabilitation of children with disabilities[7,8,]. Thus, KAR is suggested to be applied for CP children. One of the studies involved KAR as a Robotics Agent Coach for CP motor Function (RAC CP FUN)[9]which is designed to improve their motor functions and activities associated to daily living. Further, anotherstudy[10]employed a mobile robot named "Neptune" and used a toy robot named "Cosmobot" and the derived results showed that robot can become a social mediator for learning. The results of a study [11,12]that used Lego Mind storms robots[13] for CP children's play activities demonstrated that the children reacted positively toward the robots, while some children increased their attention span and could be better engaged when they used the robots. However, most explored robotic systems earlier were mainly in the form of toys, and not in humanoid form. Thus, this study is designed to use a humanoid robot to instruct patients in physical therapy sessions with musculoskeletal problems. An expert software programmer and a physiotherapist jointly developed the therapy program. Details of the therapy were tailored specifically to meet the needed conditions, interact with the patients, with the mode and specification capable of offering several options.

Methodology

The intended group is a set of musculoskeletal patients diagnosed and referred for P.T clinic. A strengthening exercise was prescribed and endorsed by a licensed physiotherapist specialized in the musculoskeletal disorders, This particular group was for improving the back strength, with age range between 20 to 65 years. Other inclusion criteria were no physical or mental disability, no hearing and vision deficiency, and a cognitive ability to follow simple commands in English. Signed informed consent was obtained from the participants. Five trials, each of 30 minutes session were performed on different days. The sessions involved interaction with humanoid robot. The experiment protocol was approved by the Occupational Therapy Association Research Board. The robot was programmed for a set of active exercises with a classified sequence managed in time and motion. Verbal communication between the robot and patients allowed re-start, stop, resume and replay functions. The robot was equipped with 4 cameras and programmed to take photos of the patient's face and voice print to enable individual recognition in order to recall the personal therapy program and update the patient information at the end of the session. The whole performance was filmed and reviewed from the perspectives of both the patient and robot. The whole process was validated by performing the same procedure on a trial basis with healthy individuals to ensure the setup is operated smoothly.

Patients were educated about the robot and the study aim. An introduction session was made to familiarize the group(robot, patient, operator and the assessor) with the study methodology. The study was conducted in a simple gym, with the exercise mat laid on the floor for the patients and the NAO was placed on the non-slippery floor. The performance assessment will use met partially me or not met.

NAO has 23 degrees of freedom: 2 degrees of freedom for head, 4 degrees of freedom for each arm, 1 degree of freedom for pelvis, and 5 degrees of freedom for each leg.

Result

The aim of this robotic-patients application is to instruct patients with musculoskeletal problems for several pre-structured and programmed exercises. The overall aim is to measure several factors that govern the robot-patient performance, e.g. clarity, sequence, interaction, voice, timing, independency, operation, technical performance, and degree of freedom. The assessment is expressed by% of excellence for the three times and then the% average is gathered for all patients. The total for each parameter in each session and the total for the five patients for each session is presented. The data in the table below is the grand total for the three sessions for five patients and expressed in %.

Table 1: The data here is representing the% of performance of each item. The performance of the last three visits are averaged in the last column and the grand average for the overall performance (91+) is also presented. The 1st and 2nd sessions were considered as learning sessions.

Item	Trial sessions		3rd session	4th session	5th session	Average %
	1 st session	2nd session				
Clarity	50%	70%	90%	95%	95%	93+
Therapy sequences	30%	60%	90%	90%	100%	93+
Interaction	20%	60%	95%	95%	95%	95
Voice	70%	70%	80%	90%	95%	88+
Timing	40%	60%	100	95%	100%	98+
Independency.	60%	80%	80%	90%	90%	86+
Operation	70%	90%	90%	90%	95%	91+
Technical performance	90%	90%	90%	90%	95%	91+
						Grand 91+

Consequently, there are few points to be highlighted and discussed. The data presented represent the external assessor evaluation of the performance. It is clear that the 1st session is a learning step which shows low levels of performance. Second session showed remarkable improvement and a continuous improvement is recognized in the 3rd session. The overall impression is supporting the fast and reliable interaction integration. The total performance related to the robot therapy assignment is seen as highly satisfactory and manageable with the patient acceptance of the whole process.

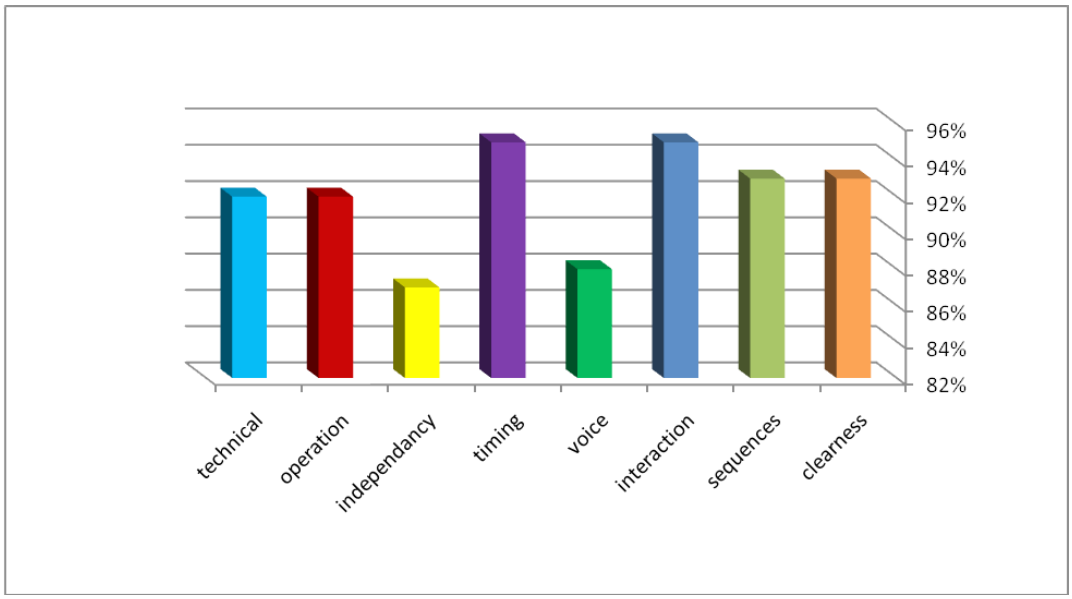

Fig. 1: Shows the representation of various performance parameters. This indicates the average percentage of the last three sessions.

Fig 2: A, and B, The robot is oppositely facing the patient to assure face to face communication, both in lying position. The robot NAO asks the patient to imitate each movement. NAO starts to perform the exercise and patient is expected to follow, patients should match the time in a steady sequence and follow and repeat for several times matching the robot command. The robot is watching the patient through the cameras and has the capability to stop, rectify, adjust and resume.

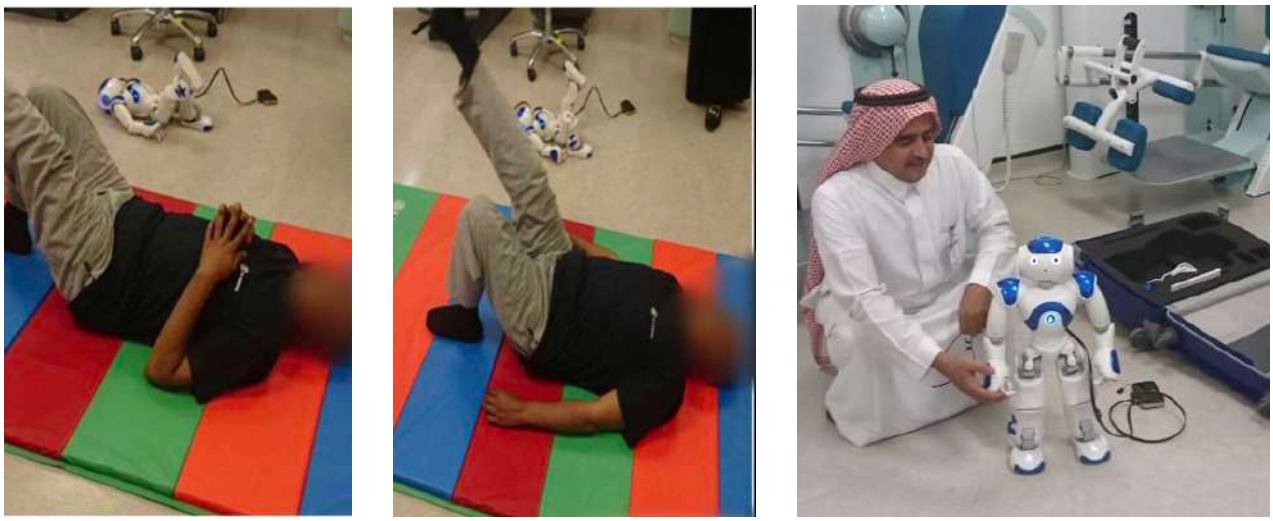

Fig 3: The instructor checks and makes sure that NAO is ready

Discussion

The set up of this robot rehab program was made to serve patients at the clinic or at home. The overall performance was great,smooth and relatively reliable in this small trial group. This work encourages interest groups to proceed with robot rehab therapy. The available data from this trial study showed the robot-patient performance and the technical performance as well as the operational performance. The imitation of movement simultaneously with the robot confirmed the possibility of independent execution of serial therapy program in the rehab clinic or at home particularly for chronic conditions. The total percentages core of the last three sessions was around 92. However, further optimization of the robot programming and proper prescription of exercise program and careful selection of patients could make the work performance highly efficient. Each of the eight parameters of this study were assessed in five different sessions. These parameters are believed to be the most important factors to govern the implementation. Optimizing them will enable the robot to work independently with the patients at the clinic or at the home and this will enable to personalize this technology and the outcomes[7,8] are in line with this result.

It is worth saying that the interaction was very successful and the options of stop, resume, restart were used many times to cater to patients' requests, and this was considered healthy. The clarity of steps and voice level was perfect and the patient's follow-up on sequence was also maintained to a high level. Progressing with time is a notable and clear indicator which means that the patient-robot relation is supporting the level of confidence of the patient as well as the therapist, and this matches earlier reported outcomes[13]. This is an improvement of the technology with a friendly perspective. The overall satisfaction of the patient and the acceptance were high and very promising. The grand total performance of all eight parameters was very high(almost 92%) which substantiates its applicability in the clinical robotic industry in line with the[16,17,18].

This article is meant to cover solutions at different stages of applications. Thereafter it is up to the developer to commercially make it ready and available in the market or to look to some alternative or to go for more phases of research and experimentation. The existing data provides examples and pointers to proceed to clinical applications and other major ingredients for the success of these applications as well as the main issues surrounding their adoption for a wide range of everyday physiotherapy use are to be developed further. We have examined how robotics could partially fill in some of the identified gaps in current telehealth-care through internet connectivity since the robot is equipped with 4 Cameras and can recognize individuals by face and by voice tone. Introducing a tele control can pave the way for program modification and alteration based on instantaneous robot-patient interaction and would bring in a possibility of remote sharing with a third party or more in audio-visual mode.

We conclude with a brief glimpse at a couple of emerging developments and promising applications in

this field that are expected to play important roles in the future. Readers should note that this paper is intended to be read mainly by non-roboticists, with little or no background in the field. Specifically, the paper is meant to ignite the interests of conventional health informatics and telemedicine/telehealthcare specialists and clinicians, physiotherapists and rehabilitation professionals into such emerging possibilities. It would also be of interest to experts in robotics who are interested in its potential applications, especially about how robotics may help users in the healthcare and social care sectors. This also my facilitate investments and businesses in the long-term to commercialize use of robotics in health sectors, both in health care centers and in homes.

Conclusion/Recommendations

This trial outcome is highly supportive to the use of robot in rehabilitation of patients. More focus may be needed to improve the friendly interaction and flexible sequence between exercises. Logistic support may be included e.g. refreshment time, rest, short breaks may be considered upon patient request.

There is also a need to address some challenges encountered in the set up. The degree of freedom for all joints was of acceptable level except the pelvic rotation. There is a need to improve on the robustness of the pelvic movement.

The issue of the NAO system getting heated up during the performance causing an interruption in the session needs to be investigated and resolved.

Based on this trial, it is recommended that this work be continued with a larger sample and varying conditions to ensure consistent approach and reliable outcomes.

Does Give Malnourished Pregnant Mothers with Supplementary Feeding Biscuit Can affect Pregnancy Outcomes?

Henrick[1], Andi Imam Arundhana Thahir[2], Khartini Kaluku[3], Elsye Theresia[4], Saifuddin Sirajuddin[2], Veni Hadju[2], Abdul Razak Thaha[2]

[1]Fatima Nursing Academy, Pare-pare, [2]Nutrition Department, Faculty of Public Health, Hasanuddin University, Makassar, [3]Health Polytechnic of Maluku, Ministry of Health, Ambon, [4]Doctoral students, Faculty of Public Health, Hasanuddin University, Makassar

Abstract

Objective: Malnutrition in pregnancy is still problematic in the majority of developing countries. Malnourished pregnant women may result in fetal growth restriction and adverse pregnancy outcomes. This study examined the impact of nutrition intervention in the forms of biscuit on pregnancy outcomes.

Method: This study was an evaluative study on the supplementation program implemented in Pare-pare city, Indonesia. Each package of supplementary feeding biscuit consists of two biscuits (50g) containing 260 kcal of energy, 13g of fat, 8g of protein, 28g of carbs, nine vitamins, and ten minerals. The variables measured were placental weight and diameter, umbilical cord length and Hb, birth weight and length, head circumference, and chest circumference. All measurements were done by trained health workers in the Community Health Service. The analysis of this study was t-test, ANOVA, and regression linear using SPSS v. 24.

Result: The result of the study shows no effect of the biscuit dose on pregnancy Hb, MUAC, and gestational weight among malnourished mother. In comparison between malnourished and healthy mothers, there are no differences in the pregnancy outcomes. The effect of biscuit dose on the outcomes of pregnancy in malnourished mother demonstrated no significant difference among doses given on placental weight and diameter, umbilical cord length and Hb, birth weight and length, head circumference, and chest circumference.

Conclusion: In conclusion, this study demonstrated that given malnourished with a supplementary biscuit will not provide any improvements on the pregnancy outcomes. A clinical trial design study is necessary to examine the beneficial effect of complementary foods.

Keywords: *Pregnancy, complementary feeding, pregnancy outcome.*

Introduction

Malnutrition in pregnancy strongly associated with adverse pregnancy outcomes and can affect the health of the child early in life. Malnutrition is mainly caused by low dietary intake before and during pregnancy influencing the mother's capacity of storing, utilizing, and circulating the nutrients to the fetus[1]. Therefore, maternal nutritional status is the key to supporting fetal growth and development, along with other factors, such as placental, fetal, and genetic factors (Sharma et al., 2016). Women with acute malnutrition are likely to have stunted children compared to healthy pregnant women[2] and this associated with the increase of noncommunicable diseases risk[3]. However, recent reports illustrate that majority of children affected by stunting were in developing countries where the population is predominantly with low socio-economic status and exacerbated by intergenerational effects (short or malnourished mother)[1,4]. Several dietary interventions have been implemented to prevent the negative effect

of nutrient deficiency experienced by many pregnant women, especially in developing countries. However, there was no effect of nutrition interventions on pregnancy outcomes and only a small effect on the reduction in the incidence of preterm birth[5,6]. The result of intervention might be varied accordingly the specific problem in the population. For instance, the population with chronic energy malnutrition may be inappropriately given with micronutrient interventions.

A recent survey in 2018 shows that the number of chronic malnourished pregnant women in Indonesia, defined as mid-upper arm circumference less than 23.5cm, reached 17.3% [7]. In Pare-pare city, located in South Sulawesi, the prevalence of malnourished mother was 23.2% [8].Nutritional status before and during early pregnancy is critical, although the result is inconsistent in terms of its effect on pregnancy and pregnancy outcomes. A prospective cohort shows that maternal BMI was not associated with a gestational weight gain of the mother[9]. However, the limitation of this study was the malnourished participants were small. A systematic review indicated that maternal nutrition is associated with neurocognitive function during childhood, implicating that health pregnancy states may be beneficial in supporting fetal growth and development and child outcomes[10]. Another study shows that the nutritional status of the pregnancy was positively associated with birth weight. Thus, the nutritional status of pregnancy should be improved[11].

In improving maternal nutritional status during pregnancy, many supplementation programs have been implemented. To date, a supplementation of nutrient-rich biscuit, called complementary feeding program or PMT, has been implemented by the government in Pare-pare with an intended to support nutrients for the pregnant mothers and their fetus. However, it is not known yet to what extent the effect of this supplementation program on the pregnancy outcomes, specifically for those with chronic malnutrition. This study aimed to examine the impact of supplementation program given to malnourished pregnant women on the pregnancy outcomes.

Material and Method

This study was an evaluation program observing the pregnancy outcomes of the mother received complementary feeding program in the form of a biscuit. The design of the study has been described in the previous publication[8]. This study has been done in Pare-Pare City, Indonesia.Malnourished mother was defined as the mother with MUAC measurement at enrolment <23.5cm and healthy mother was otherwise. Each package of supplementary food consists of two biscuits (50g) containing 260 kcal of energy, 13g of fat, 8g of protein, 28g of carbs, nine vitamins, and ten minerals (Table 1).

Table 1: Nutrient contents of each biscuit package (50g; 260 kcal)

Nutrients (g or% RDA)	Nutrients (g or% RDA)
Fat (13g)	Vitamin C (50%)
Protein (8g)	Natrium (16%)
Carbohydrate (28g)	Folic acid (50%)
Vitamin A (50%)	Pantothenate acid (55%)
Vitamin D (60%)	Selenium (55%)
Vitamin E (55%)	Fluor (60%)
Vitamin B1 (60%)	Iodine (25%)
Vitamin B2 (55%)	Zinc (25%)
Vitamin B6 (60%)	Iron (25%)
Vitamin B12(60%)	Phosphor (15%)
Vitamin B3 (55%)	Calcium (15%)

The variables measured were placental weight and diameter, umbilical cord length and Hb, birth weight and length, head circumference, and chest circumference. The measurement of the umbilical cord Hb was performed at birth using HemoCue (Hb 201+ systems).Placenta and baby were weighed using baby scale meter provided in Community Health Services. Placental diameter, umbilical cord, head circumference and chest circumference were measured using tape. All measurements were done by trained health workers in the Community Health Service. The analysis of this study was t-test, ANOVA, and regression linear. All data analysis was performed using SPSS v. 24 (IBM Corp.).

Results

The results of the changes of hemoglobin, MUAC, and gestational weight gain of pregnant women after given supplementation have been previously published, but the effect of biscuit dose is still presented. **Table 2** shows no effect of the biscuit dose on pregnancy Hb, MUAC, and gestational weight among malnourished mother.

Table 2: Dose effect of complementary biscuit on Hb, gestational weight, and MUAC changes during pregnancy

Changes (n=49)	Dose			p
	≤ 1 biscuit (n=33)	> 1–2 biscuits (n=13)	≥ 3 biscuits (n=3)	
DHb1 – Hb2	-0,25±1,82	-0,54±1,31	-0,63±0,40	0.776
DHb1 – Hb3	-0,25±1,80	-0,16±1,68	-0,73±1,90	0.865
DHb2 – Hb3	-0,01±1,24	0,38±1,92	-0,10±1,80	0.431
DGestational weight	5,03±1,46	5,00±1,83	5,83±1,89	0.875
DMaternal MUAC	1,84±0,89	1,82±1,00	2,67±1,04	0.297

Table 3 shows the difference in the pregnancy outcomes between malnourished and healthy pregnant women. Between the two groups, there are no differences in the outcomes.

Table 3: Differences of pregnancy outcomes between malnourished and healthy pregnant women

Variables	Malnourished (n=49)	Healthy (n=162)	Total (N=211)	p
Placental weight	541.53±175.01	542.685±187.22	542.42±184.05	0.969
Placental diameter	19.13±2.23	19.41±2.12	19.35±2.14	0.429
Umbilical cord length	43.71±9.70	45.25±8.81	44.89±9.02	0.298
Umbilical cord Hb	13.42±2.87	13.37±2.35	13.38±2.47	0.890
Birth weight	3,033.04±367.47	3,036.17±367.26	3,035.45±366.44	0.958
Birth length	47.74±2.00	47.85±1.69	47.82±1.76	0.700
Birth head circumference	32.74±1.34	32.56±1.72	32.60±1.64	0.518
Birth chest circumference	31.96±1.44	31.80±1.68	31.84±1.62	0.544

The effect of biscuit dose on the outcomes of pregnancy in malnourished mother is demonstrated in **Table 4**. There was no significant difference among doses given on placental weight and diameter, umbilical cord length and Hb, birth weight and length, head circumference, and chest circumference.

Table 4: Dose effect of biscuit supplementation on various outcomes of pregnancy among malnourished women

Variable (n=49)	Biscuit Dose			p
	<1 Biscuit (n=33)	>1–2 Biscuits (n=13)	>2 Biscuit (n=3)	
Placental weight	559.39±200.67	495.77±105.10	543.33±75.06	0.547
Placental diameter	19.52±2.41	18.12±1.58	19.33±1.53	0.119

Birth chest circumference	31.89±1.41	32.15±1.48	32.00±2.00	0.877

Discussion

The main finding of this study reveals that there was no difference in terms of pregnancy outcomes of malnourished women by the dose of energy-dense biscuits. The complexity of the metabolic process during pregnancy mainly affects fetal growth and developments, determining pregnancy outcomes. Intrauterine growth retardation (IUGR),one of the common forms of complications during pregnancy,is associated with the oxidative stress caused by exceeding of pregnancy complexity end products, called reactive oxygen species (ROS)[12]. However, to what extent the impact of oxidative stress on the specific outcome of pregnancy is poorly understood. A prospective cohort study shows that oxidative stress biomarker is associated with adverse pregnancy outcomes, although the age of participants of the study was in the risk (>30 years) that probably affect the metabolic process during pregnancy[13].

Most studies correlate oxidative stress during pregnancy to antioxidant-functioned micronutrients, such as iron, copper, zinc, and manganese[14,15].Casanueva and Viteri suggested that iron intake is critical determining balance oxidative stress in thehuman body. A proper dose and timing of iron supplementation potentially cause the reduction of oxidative stress. Conversely, iron overload may induce oxidative stress[15]. In the present study, malnourished participants received iron-folic acid supplementation. This supplementation may correct the nutrient status of the participants, resulting in a positive result in fetal growth which is manifested in pregnancy outcomes. Energy-dense biscuits supplement given to the participants may successfully support the nutrient supply for the mother and fetus and complement the role of iron-folic acid supplement in various metabolic mechanisms during pregnancy. Hence, the dose of the biscuits could not be seen explicitly in this study. This finding is supported by the result in which the outcomes of pregnancy between malnourished and healthy pregnant women were not statistically different. Supported by a previous study[8], it can be assumedthat the nutrients status in the malnourished body, both macro and micronutrients, potentially resemble those healthy pregnant women.

The interesting finding of this study was that the placenta and birth weight outcomes in malnourished women are similar to health pregnancy women. Given that this finding implicates for the potential treatment of minimizing the risk factor of stunting. Low birth weight is one of the determinant factors causing stunting in children under five[16]. Whereas the placenta is the supportive feature for maternal-fetal oxygen transport and nutrient exchange which affects birth weight. Placental weight is the manifestation of fetal growth in utero characterized by many dimensions of growth[17]. One of the dimensions is umbilical cord length. In this study, malnourished women have similar cord length to healthy pregnant women (43.71±9.70 vs 45.25±8.81, p=0.298), indicating that the growth of fetus established. Therefore, it can be fairly stated that the supplementation of biscuit along with iron-folic acid may be effective in reducing the risk of adverse pregnancy outcomes in malnourished women. However, this study did not measure the impact of biscuit supplementation in healthy pregnant women which may reveal other mechanisms involved in metabolic pathways during pregnancy.

The limitation of this study was that the dietary intakes were not observed. Dietary intake can potentially justify the explanation to what extent the contribution of those supplementations to meet the nutrient requirements of malnourished pregnancy. Second, the number of pregnant women who consumedbiscuits as recommended (two biscuits per day) was underestimated (only three mothers). However, since this is a study which was observed nutritional program of the government, it then describedthe real setting that a real challenge in the population. Hence, the government understands which has to be improved in order to support maternal and child health.This study also did not measure the impact of the biscuit supplementation on the healthy pregnancy as the program only be given to those malnourished women. The strength of this study was in the outcomes of the pregnancy measured. Measuring placenta, umbilical cord, and birth weight may give a comprehensive explanation of the supplementation effect during pregnancy.

Conclusion

In conclusion, this study demonstrated that given malnourished with a supplementary biscuit will not provide any improvements on the pregnancy outcomes. The government should review the program of biscuit supplementation in order to improve pregnancy outcomes. Further research is necessary using clinical trial design to examine the beneficial effect of complementary foods.

Heavy Metals Concentration and Biochemical Parameters in the Blood and Nails of Industrial Workers

Kameran Sh. Husien[1], Mohsin O. Mohammed[2], Tamara N. Ahmed[2]

[1]Professor, College of Nursing, [2]Assistant Professor, College of Science, Kirkuk University-Kirkuk, Iraq

Abstract

This study amied to measure the concentration of heavy metals (Pb, Cd) and certain biochemical variables in blood and nails of(50) samples(male and female) of workers (who were in risk of exposition to these heavy metals) from Northern Gas Company in Kirkuk city/Iraq. Flame atomic absorption spectrometer was used for measuring these elements. The results showed significant differences ($P < 0.01$) in the concentration of lead and cadmium in the studied samples (whole blood and nails) of workers compared to the control group. The concentration of lead and cadmium were higher in blood and Nails. As of the biochemical variables, significant differences ($P < 0.05$) showed in the concentration of antioxidant enzyme (SOD) in serum. As of oxidative stress (MDA), results showed significant differences ($P < 0.05$) in serum, the highest value of (MDA) was recorded in serum samples.

Keywords: *Heavy metals, Antioxidant, Oxidative stress.*

Introduction

Heavy metals have found as natural constituents of the Earth's crust and are non-degradable in nature and tend to form pollutants of living organisms in the environment,[1] and living organisms inhabiting contaminated sites may be exposed to very high amounts of heavy metals as they are toxic and may cause adverse effects, even if in small concentrations.[2-3]

Different sources of heavy metals were found in the environment (natural and industrial). Natural sources such as weathering and volcanic eruption contribute significantly to the pollution of heavy metals,[4-6] and industrial sources such as; mineral processing in refineries, power plants, coal combustion, oil combustion, nuclear power plants, chemical and metal industries, in addition to the plants of wood preservation, and paper processing.[7,8]

Malondialdehyde (MDA), one type of oxidant, is the final product for the oxidation of polyunsaturated fatty acids, which is an indicator for estimating oxidative stress.[9] Antioxidants are of great importance as they are the first line of defence against free radicals, and the need for antioxidants becomes more critical with increasing exposure to free radicals.[10] The human antioxidant defence system consists of enzymatic and non – enzymatic systems. Many enzymatic systems are stimulatingreactions to neutralise free radicals. These enzymes include Superoxide Dismutases (SOD), Catalases (CAT), Glutathione Peroxidases (GPX), Glutathione Reductases (GRX), and these mechanisms form the internal defence mechanisms of the body to help protect against cell damage caused by free radicals.[11] These enzymes also require co-factors such as copper, zinc, and selenium as a stimulant to activate enzymes to maintain functions and prevent oxidation in human cells, and the need for antioxidants has become very important with increased exposure to free radicals.

Materials and Method

The samples of blood and nails were collected from 50 employees (males and females) aged between 20-65 years of the Northern Gas Company in Kirkuk governorate, while the duration of exposure or years of work ranged between (1-30) years. The control group was selected from 20 people outside the North Gas Company, which did not work in the industrial sector.

The samples were collected in January 2019. The elements were estimated in all studied samples by an atomic absorption device (ASS), where the lead element was measured by the flame atomic absorption device (FAAS), while the Cd element by non-flammable atomic absorption device (GFAAS).[12]

Preparation and Sating Samples:

1. **Blood:** 10 ml of blood was collected from each person; blood samples were divided into two parts; in the first part, (5 ml) was placed in an anticoagulant tube and kept at room temperature to measure lead and cadmium. In the second part, (5 ml) was placed in plastic tubes with tight lids and free from any anticoagulant (Plain tube), and was left at room temperature (25 C) until coagulated, and then placed in the centrifuge for 10 minutes at a speed of 3000 rpm, afterword serum was collected by micropipette to measure biochemical tests. It was then transferred to dry plastic tubes and kept at 10° C using Deep Freezer [13] until tests were carried out. The concentration of lead and cadmium in the blood of the workers was estimated by Haswell method.[13]
2. **Nails:** Each person's nails were trimmed with clean, sterile scissors, and then placed in sealed plastic bags. Nails were then washed with non-ionic cleaners. After a standard wash, the nail samples were soaked in acetone. Finally, the samples are rinsed five times with deionised water and then dried in the oven at 110 c̊ and stored in the desiccant pending analysis. The samples were divided into two parts, the first part for measuring the heavy elements and the second part for measuring the biochemical variables. The heavy elements in the nail samples were estimated, according to Abdul-Rahman et al.[14] method.

Statistical analysis: Results were statistically analysed using ANOVA test and the results obtained were described in the tables as (mean and standard deviation) and with a probability level (P <0.05) and P <0.01).

Results and Discussion

1. **Heavy Metals:**

Estimation of heavy metals in whole blood:

Lead-(Pb): The results of table (1) showed different concentrations of the lead element; the concentration of the lead in whole blood of workers during the study period was (25.40 ± 4.20) and control (13.91 ± 2.02), respectively (Figure 1). Statistically significant differences were found (P<0.01) between the concentration of the lead in the whole blood of workers and the control group, that it was found to be higher than the control group. The reason for the high concentration of lead in the workers could be attributed to the tetraethyl lead, chemicals that emitted from North Gas Company. Furthermore, a study has shown that high concentrations of lead in industrial atmospheres are humanmade, as it is almost 100 times higher in industrial atmospheres compared to natural atmospheres [15]. Increasing the concentration of lead in the whole blood leads to many adverse consequences such as hypertension, renal failure, and brain damage.[16] These findings are consistent with those reported by others [17, 18].

Table (1): Concentration of heavy metals ($Pb_{\mu g/dl}$, $Cd_{\mu g/dl}$) inworkers' whole blood and control group

Elements	Groups	Mean±SD	P-Value
Pb	Workers	25.40±4.20	P<0.01
	Control	13.91±2.02	
Cd	Workers	1.0904±0.0416	P<0.01
	Control	0.2782±0.0291	

Cadmium-(Cd): The results of table (1) showed different concentrations of the Cadmium; the concentration of the Cadmium in whole blood of workers during the study period was (1.0904±0.0416) and control group (0.2782±0.0291), respectively (Figure 1). Statistically significant differences were found (P<0.01) between the concentration of the lead in the whole blood of workers and the control group, that it was found to be higher than the control group. The high concentration of cadmium in workers was attributed to industrial emissions, especially the mining and mineral refining industry. Also, cadmium occurs naturally with zinc and lead in sulfide ores. Cadmium has a direct relationship with some chronic diseases, such as hypertension, which is an excellent indicator of exposure to cadmium in occupationally exposed individuals.Cadmium leads to an increase in systolic and diastolic blood pressure, and thus an increase in high blood pressure.[19]

The results obtained were mostly consistent with studies conducted on gas station workers in Babil[17] and Basrah[18] governorates, where there was a decrease in the concentration of (Cu, Zn, Mg) and an increase in the concentration of (Cd, Pb) in the blood of gas station workers compared to the control group.

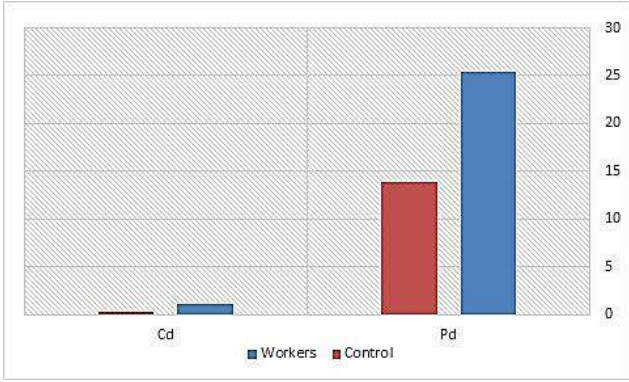

Figure 1: Concentration of Heavy Metals ($Pb_{\mu g/dl}$, $Cd_{\mu g/dl}$) in workers' Whole Blood and control group

Estimation of heavy metals in workers' hair compared to the control group

Table (2): Concentration of heavy metals ($Pb_{\mu g/dl}$, $Cd_{\mu g/dl}$) in workers' hair and control group.

Elements	Groups	Mean±SD	P-Value
Pb	Workers Control	15.70±2.18 7.75±1.29	P<0.01
Cd	Workers Control	0.1330±0.0264 0.0820±0.0194	P<0.01

Lead-(Pb): The lead element poses a real concern among heavy metals because of its toxicity, and there is no primary function in the human body, the damage can occur only after its absorption from air or water [20].

The results of table (2) showed different concentrations of the lead element; the concentration of the lead in whole blood of workers during the study period was (15.70±2.18) and control (7.75±1.29), respectively (Figure 2).

Estimation of heavy metals in workers' nailcompared to the control group:

Table (3): Concentration of heavy metals ($Pb_{\mu g/dl}$, $Cd_{\mu g/dl}$) in workers' nail and control group

Elements	Groups	Mean±SD	P-Value
Pb	Workers Control	14.57±2.50 9.11±1.60	P<0.01
Cd	Workers Control	0.1362±0.0217 0.0925±0.0189	P<0.01

Lead-(Pb): The results obtained, shown in Table (3), indicate the concentration of the lead element in workers' nails compared to the control group, where the concentration of lead in workers' nails was 14.57 ± 2.50), and in the control group (9.11 ± 1.60), (Figure 3). Statistically, there were significant differences (P <0.01) for the average concentration of lead in workers' nails compared to the control group.This is due to occupational exposure, which contributes to the absorption of minerals, and these results are like those reported by others.[21, 22]

Cadmium-(Cd): The results obtained, shown in Table (3), showed the concentration of cadmium in workers 'nails compared with the control group, where the concentration of cadmium in workers' nails was 0.1362 ± 0.0217), and in the control group (0.0925 ± 0.0189), (Figure 2).Statistically, there were significant differences (P <0.01) on the average concentration of cadmium in workers' nails compared to the control group. The reason for the high concentration of cadmium is due to the complex occupational exposure of the elements, and the results obtained are consistent with the findings.[21, 22]

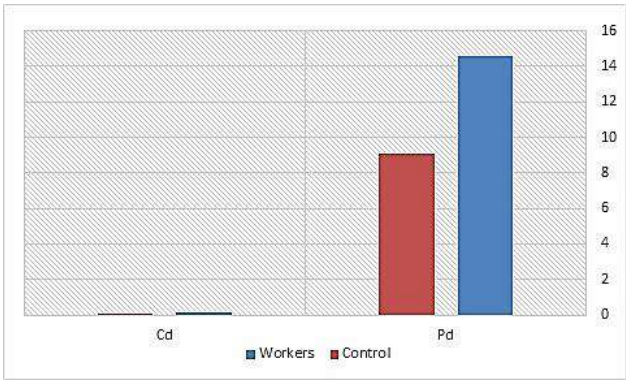

Figure 2. The concentration of heavy metals ($Pb_{\mu g/dl}$, $Cd_{\mu g/dl}$) in workers' nail and control group.

Biochemical Variables:

Estimation of oxidative and antioxidant concentrations in blood serum:

Table (4): Concentration of Enzymes (SOD $_{U/ML}$, MDA $_{\mu mol/L}$) in the blood serum of workers and control group

Variables	Groups	Mean±SD	P-Value
SOD	Workers Control	30.7±3.1 49.3±10.5	P<0.05
MDA	Workers Control	123.6±16.9 70.0±13.7	P<0.05

The concentration of Superoxide dismutase (SOD) enzyme: The results of table (4) show the concentration of enzyme (SOD) in the serum of workers and the control

group, where the concentration of enzyme in the serum of workers was (30.7 ± 3.1) which was lower than the control group was (49.3 ± 10.5),(Figure 4).Statistically, there were significant differences between the workers and the control group ($p < 0.05$). The reason for the decrease in the concentration of the enzyme SOD is that it is common in contaminated environments because this enzyme is necessary to protect the body's cells from free radicals and excessive oxygen that promote ageing or cell death.[23] Moreover, trace elements (Zn, Cu, Mg) are SOD components and are associated with antioxidant functions, so their deficiency may lead to poor control of free radicals, and all these elements are replaced by lead, which reduces the activity of (SOD).[24] The results obtained were in contrast with that reported in another study [25] and coincide with the others.[17, 18, 26, 27]

Concentration Serum lipid peroxidation (MDA): The results are shown in Table (4) indicate that the concentration of MDA in the serum of the workers (123.6 ± 16.9) was high in comparison to the control group (70.0 ± 13.7),(Figure 4). Statistically, there were significant differences between the workers and the control group ($p<0.05$). The reason for this is that the rise in the level of heavy metals leads to the destruction of oxidative stress by increasing the production of free radicals (ROS), which reduces the system of antioxidant defence in cells and increase the concentration MDA.[28,29] These results are consistent with other findings.[17,18,26,30]

Figure 4: The concentration of Enzymes (SOD $_{U/ML}$, MDA $_{\mu mol/L}$) in the blood serum of workers and control group

Conclusion

The results of this study concluded that the concentration of heavy metals (Pb, Cd) was high in the whole blood and nails of the workers in the North Gas Company. Moreover, the concentration of SOD enzyme in the blood and samples was low;the MDA was high in all samples of studied workers.

Conflict of Interest: None of the authors have any conflicts of interest to declare.

Source of Funding: The research was performed independently, there is no funding

Ethical Clearance: The project was approved by the local ethical committee in University of Kirkuk.

Impact of Workplace Violence Educational Program on Self-Confidence for Nursing Staff Working in Psychiatric Hospital

Mohga Fathy Abd Elmoteleb Ali Hamza[1], Afaf Abd Elhamed Abd Elrahman[2]

[1]Assistant Lecturer, [2]Professor, Psychiatric Mental Health Nursing, Faculty of Nursing-Cairo University-Egypt

Abstract

Inpatient mental health clinicians need to feel safe in the workplace. They require confidence in their ability to work with aggressive patients, allowing the provision of therapeutic care while protecting themselves and other patients from psychological and physical harm. **The aim** of this study is to evaluate the impact of educational training program on self- confidence for nursing staff working in psychiatric hospital. **Design**: A quasi-experimental design" pre-posttest assessment" was utilized for the current study. A sample of convenience of 45 psychiatric nurses who agree to participate and were in Al-Abbassia mental health hospital were included. **Two tools** were utilized in the current study including Socio- Demographic including Department Data Sheet, Confidence in Managing Service user Aggression. **The results** showed that: there was a highly statistically significant difference was found for all items in nurses' pre versus post self- confidence assessment. Also there was a positive significant correlation between nurses' level of self-confidence and the frequency of isolation for the patients & nurses' years of experience in pre & post assessment, while there is no significance correlation between nurses' level of self-confidence and their age, gender, or duration of patient's isolation. **To conclude that**, nurses who received the educational training program about workplace violence showed higher score in their post assessment of self- confidence than before receiving the program. So the research hypotheses was accepted. Further studies was **recommended** in addressing the effect of training on staff behavior to be measured through direct observation.

Keywords: *Workplace Violence, self-confidence, Psychiatric Nursing Staff.*

Introduction

Workplace violence (WPV) toward nurses working in the hospital environment is a well-known issue worldwide. It compromises not only health care professionals' physical well-being but also their psychological well-being. The victims may suffer physical and mental stress and a high degree of anxiety, nurses are one of the professional groups most exposed to physical aggression, verbal abuse, and threats because nurses have more frequent and longer contacts with patients or families and are responsible for providing direct care.[1]

According to[2], professional quality of life reflects how individuals feel about their work as helpers. A crucial factor in improving the delivery of service to patients in acute care psychiatric units appears to be the confidence level of staff to deal with aggression both in the antecedent stages and when physical aggression occurs.

[2]added that,a crucial factor in improving the delivery of service to patients in acute care psychiatric units appears to be the confidence level of staff to deal with aggression both in the antecedent stages and when physical aggression occurs. There are many factors that impacted on clinicians' confidence to manage aggression as colleagues' knowledge, experience and skill, management of aggression, use of prevention and intervention strategies, teamwork and the staff profile.

Subject and Method

Aim of the study: The current study is to evaluate

the impact of educational training program on self-confidence for nursing staff working in psychiatric hospital.

Research Hypothesis: Nurses who will receive the educational training program about workplace violence will show higher score in their post assessment of self-confidence than before receiving the program.

Sample: A sample of convenience of 45 psychiatric nurses who agree to participate and were in Al-Abbassia mental health hospital were included.

Tools of Data Collection:

1. **Socio-Demographic & Department Data Sheet:** It was developed by the researcher. It was divided into two parts, first part was about nursing staff Scio-demographics included gender, education level, and years of experience etc.... The second part was about the department's data such as department type (in-patient or out- patient), the approximate number & duration of using seclusion & or restraints in the section per year etc....
2. **Confidence in Managing Service user Aggression:** The questionnaire was developed by[3] & was selected as suitable for measuring confidence in coping with patient aggression. But it was modified & adopted from[4] to assess nurse's self- confidence in managing service user aggression and their ability to deal with violent situations. It consists of a 7 items rating scale ranged from (1-7) and one qualitative (open ended question). In the rating scale, respondents were asked to indicate their degree of confidence to the questions using a 7 point rating scale with verbal descriptors at each end, e.g. 7 = very sure/very able/ very save, and 1 = very unsure/very unable/safe. Respondents were asked to circle the number 7 at the upper end of the scale if their response to a question was very positive, or the number 1 if their response was very negative. If the response was somewhat positive respondents were asked to circle 5 or 6 and if they was somewhat negative to circle 2 or 3. Where they were unsure or undecided they were asked to circle the number 4.

Procedure:

1. **Obtaining required tools and designing the program:** A review of related literatures was done using available books, articles, and journals, to cover various aspects of nurse's self-confidence in managing aggressive patients and their relatives, and also to obtain the relevant standardized tools and to develop workplace violence prevention program.
2. **Recruitment and interviewing:** An official permission from the research ethics committee in the faculty of nursing was obtained upon the feasibility of the research tools and study. There searcher met with the responsible about training department at El Abbassia Mental Health Hospital after receiving the permeation from the hospital manager in order to recruit staff nurses for participation in the study according to inclusion criteria. Written informed consents were obtained from each participant after complete description of the purpose and nature of the study, all participants were assured and informed that participation in the study is voluntary.
3. **Intervention:** Figure (1), represents the researcher's own interpretation about the information map and skills that each member of the nursing staff must have and mastering in order to enabling them limiting, intervening & managing the in -patient's aggression continuum.

Preventive Strategies

- Awareness & understanding
- Self- awareness
- Assertiveness training

Anticipatory Strategies

- Warning Signs
- Violence assessment
- De-escalation Strategies
- Communication Strategies
- Behavioral actions

Containment Strategies

- Escaping from Holds & Grabs
- Seclusion
- Restraints
- Reporting & Recording

4. **Evaluation:** All participants recruited in the study who receive the program were evaluated for the benefits of the workplace violence prevention program by using the study tools.

Ethical consideration: Written informed consent was taken from each participant who was willing to participate in the research. All participants were informed that, participation in the research is voluntary and any one can withdraw from this study at any time without giving any reason. Confidentiality of the participants were assured through coding the data; a unique identifying number was assigned to the data collected for each participant. Only the researcher had access to these information in the database.

Pilot Study: A pilot study was conducted at the beginning of the study. It included 5 psychiatric nurses. The designed tools were tested on those subjects who were three male and 2 female staff nurses.

Statistical Analysis: Data were analyzed using Statistical Package for Social Sciences (SPSS) version 20. Numerical data were expressed as a mean and standard deviation. Qualitative data were expressed as frequency and percentage. Probability (p-value)> 0.05 indicates non-significant result, p-value< 0.05 is considered a significant result and p-value <0.001 is considered highly significant result.

Results

Table (1) shows that, more than half of nurses (53.3%) were male. More than two thirds (62.2%) were aged from 19<30 years old with mean age (X 30.18±9.1 years). As for years of experience, 46.7% of them have experience 10<25 years with a mean =9.6±8.8 while 22.2% have less than 10 years of experience.

Table (2) shows that, regarding to frequency of using isolation within a year 53.3% of nurses reported that it was ranged from once to less than 20 time/year with mean 16.1±13.4, Regarding to isolation duration, 71.1% of nurses mentioned that it was from one to less than 6 hours with mean 3.5±3.7.

Table (3) revealed that it was a highly statistically significant difference was found for all items in nurses' pre versus post self- confidence assessment (p<0.0001) except for question 7 (p>0.05)

Table (4) showed that there was a positive significant correlation between nurses' level of self-confidence and years of experience & the frequency of isolation for the patients in pre & post assessment .While there is no significance correlation between nurses' level of self-confidence and their age, gender, or duration of patient's isolation.

Table 1: Socio-demographic characteristics of the study sample (n = 45)

Items	No.	Percent	Range/Mean±SD
Gender			
• Male	24	53.3%	
• Female	21	46.7%	
Age			
• 19<30	28	62.2%	
• 30<45	10	22.2%	30.18±9.1
• 45-60	7	15.6%	
Years of Experience			
• 0<10	10	22.2%	
• 10<25	21	46.7%	9.6±8.8
• ≥25	14	31.1%	

Table 2:Work place information of the study sample (n = 45)

Items	No.	Percent	Range/Mean±SD
Duration of Patient's Stay (Month)			
• Zero for out patient	4	8.9%	1.3±0.79
• 1<6	28	62.2%	
• 6<12	8	17.8%	
• ≥12	5	11.1%	
Frequency of Using Isolation within a Year			
• No time	4	8.9%	16.1±13.4
• 1<20	24	53.3%	
• 21<40	12	26.7%	
• ≥40	5	11.1	
Duration of Isolation			
• Zero time	4	8.9%	3.5±3.7
• 1<6	32	71.1%	
• 6<12	8	17.8%	
• 12-24	1	2.2	
• >24	0	0.0%	

Table 3: Nurses' pre versus post self- confidance assessment regarding managing aggressive patients (n = 45)

Items	Mean±SD	t	p
1. How confident are you in your work with hostile and aggressive service users?	1.4±1.5	6.24	0.000**
2. How safe do you feel around aggressive and aggressive service users?	0.3±1.4	1.26	0.215
3. How able are you to de-escalate an aggressive service user?	1.5±1.4	7.26	0.000**
4. How able are you to contribute to the restraint of an aggressive service user?	1.1±1.5	4.93	0.000**
5. How able are you to maintain your own safety in the presence of an aggressive service user?	1.2±1.5	5.42	0.000**
6. How confident are you in the ability of your colleagues' ability to maintain your safety and manage an aggressive service users?	0.8±1.0	5.36	0.000**
7. How safe do you feel the environment in El Abbasiamental health hospital?	0.3±1.6	1.37	0.179

** Highly statistically significant difference at p<0.0001

Table 4: correlation analysis of nurses' self confedance assessment and the sociodemografic data (n= 45)

	Pre		Post	
	r	p	r	p
Age	0.13	0.36	0.06	0.72
Gender	0.10	0.51	0.06	0.72
Years of experience	0.18	0.24	0.33	0.03*
Frequency of isolation	0.33	0.03*	0.31	0.04*
Duration of isolation	0..22	0.15	0.07	0.64

Discussion

The findings of the current study showed a highly significant improvement for all items in nurses' pre versus post self-confidence assessment. And it's also clear that there was an increase in the total weighted mean of the scale in post assessment than the pre. On the same line[5] concluded that there was an overall increase in the nurses' confidence in post assessment.

The greatest area of improvement was in question three "how able are you to de-escalate an aggressive user?" followed by question one "how confident are you in your work with hostile and aggressive service users?" this results are in congruent with[6] who stated that verbal de-escalation training improves confidence of all participants after they provided the training program.

From the researcher's own point of view the overall improvement in the staff confidence is open to at least two interpretations. First, the course specifically focused on teaching staff strategies to deal with aggressive behavior in a more confident manner and directly focused on staff fears when managing challenging behaviors. Second, this particular form of staff training may have a relatively specific effect on staff confidence because prior to this experience, the majority of these participants had not received a theoretical content about how to interact with aggressive patients confidently many years ago.

The current result revealed that, there is no significance correlation between nurses' level of self-confidence and their age, gender, or duration of patient's isolation. This not in the same line with [7]who stated that nurses those are older, had more self-confidence as compared to others.

Furthermore, there was a positive significant correlation between nurses' level of self-confidence and there years of experience & the frequency of isolation. This is not in the same line with [7]who concluded that there was no significant correlation between the lengths of mental health practice with any of the confidence ratings. This was in congruent with [8] who added that, age maturity and increase numbers of years of experience are important in development of assertiveness and as regard development of self-confidence, because the old nurses had ability to solve problem and negotiate work situations.

Conclusion

Nurses who received the educational training program about workplace violence showed higher score in their post assessment of self- confidence than before receiving the program.So the research hypotheses was accepted.

Recommendations:

1. Variables that mediate staff confidence, such as staff fear and anger may be useful to consider infuture studies.
2. The effect of training on staff behavior measured through direct observation should also be addressed.

Source of Funding: Self-funding.

Conflict of Interest: The authors declare that there is no conflict of interest.

The Association of Glutathion Peroxydase-1 Serum and Sensorineural Hearing Lossin MDR TB Patients with Kanamycin Therapy

Ratna Anggraeni[1], Arif Darmawan[1], Febri Wisudawan F.[1]

[1]Department of Otorhinolaryngology-Head and Neck, Faculty of Medicine, Universitas Padjajaran

Abstract

Introduction: Kanamycin therapy in Multi-Drug Resistance Tuberculosis (MDR-TB) patients increases the possibility of sensorineural hearing loss through increasing the level of Reactive Oxygen Species (ROS) production in cochlea, particularly in hair cells. In normal state, ROS is detoxicated by numerous antioxidant enzymes, including glutathione peroksidase-1 (GPx-1). Imbalance of antioxidant enzymes and ROS production leads to death of hair cells and eventually sensorineural hearing loss.

Objective: This study aimed to observe the association of GPx-1 level and sensorineural hearing loss in MDR-TB patients with Kanamycin therapy.

Method: This study was a prospective observational study conducted at Dr. Hasan Sadikin General Hospital, Bandung, Indonesia, between February to April 2017. 17 patients were included into the study with pre- and post-kanamycin therapy examination within 3 weeks duration using pure tone audiometry and serum level of GPx-1. Statistic analysis was done using Man Whitney test with significant level of $p < 0.05$.

Result: A significant reduction of GPx-1 level in 3 weeks period after the initial Kanamycin administration was found in the study; $p < 0.001$. Furthermore, there was a significant alteration in the hearing threshold on frequency of 500-800 Hz after Kanamycin administration; $p < 0.05$. There was a significant association between GPx-1 level and sensorineural hearing loss in Kanamycin therapy; $p < 0.05$.

Conclusion: Sensorineural hearing loss in patient with history of Kanamycin therapy was associated with level of GPx-1 degradation.

Keywords: *GPx-1, Kanamycin, MDR TB, Sensorineural hearing loss.*

Introduction

Tuberculosis (TB) remains a concern among global health problem with a high mortality and morbidity rate.[1] WHO also stated that Indonesia had approximately 6,800 new Multi Drug Resistance TB (MDR TB) annually with approximately 2% of new cases and 12% of re-treatment TB were MDR TB.[2,3,4] Among all injection drugs for MDR TB, Kanamycin is widely used as stated in WHO's recent MDR TB guideline due to its wide distribution area and affordable price.[5,6,7,8]

In general, three types of antioxidant present in human body.[14] Among all GPx, Glutathione peroxide-1 (GPx-1) is the main glutathione peroxide enzyme family; mainly found in erythrocyte, liver, lungs, kidney, and almost in all cells' organ (cytosol, mitochondria, and peroxisome).[15,16] Furthermore, in cochlea, GPx-1 has a higher enzymatic activity in organ of corti, spiral ganglion, stria vascularis, spiral ligament, and another supporting cell.[17,18,19] Higher activity of SOD and CAT are also found in stria vascularis and organ of corti. GSH and GPx are the main antioxidants in those areas.[14]

Study conducted by Alli, et al. in 2014 on 83 MDR TB patients showed that there was a significant degradation of antioxidant enzyme activity, including glutathione transferase and glutathione peroxide.[20] It was strengthened by Madebo et al who also showed a significant decrease in glutathione peroxide level in TB MDR patients.[20,22]

Rakhmawati in her study found sensorineural hearing loss, particularly in high frequencies, 4000-8000 Hz, in MDR TB patient treated using Kanamycin within the 19th to 22nd day of therapy, affecting high frequency hearing ability to lower frequency.[8] Study conducted by Jiang et al in 2006 found that there was a shift in auditory brain stem response (ABR) by 45-50 dB in the 14th day that was remained for 5 weeks also showed that the death of hair cells happened in the 11th day and 30% of the superficial hair cells died after 14 days.[24] It is proposed that hearing loss due to Kanamycin's toxicity mostly started on higher frequency tone as it is located on the basal of cochlea; this progressivity happens due to difference of survival ability among the hair cells on basal and apex cochlea; as explained by the lower level of GPx-1 in basal hair cell in comparison with apex of cochlea.[25]

This study aims to observe the association between GPx-1 level and SNHL in MDR TB patients treated using Kanamycin.

Material and Method

This study was an analytic prospective observational study with pre- and post- intervention examination for association between variables, which had been ethically legalized before. **Participants.** Patients with MDR TB at MDR TB Policlinic of Internal Medicine Department of Dr. Hasan Sadikin General Hospital, Bandung between February to April 2017. The inclusion criteria for the study were patients with MDR TB with plan for Kanamycin therapy, aged 20-50 years old, had intact tympanic membrane in both ears, had type A result on tympanometry examination, normal hearing threshold on DPOAE examination and audiometry. Exclusion criteria for the study were patient with history of treatment using ototoxic drugs except TB-MDR treatment, had a history of another diseases, including renal failure, diabetes mellitus, liver diseases, systemic lupus erythematosus (SLE), and cardiovascular diseases. **Intervention**. Data was collected from physical examination and laboratories data of already diagnosed MDR TB patients and planned for kanamycin therapy. Data before and 3 weeks after treatment consist of personal data collection, physical exam of ENT, tympanometry, pure tone audiometry, DPOAE, and blood sample collection for glutation peroksidase-1 (GPx-1) serum. **Outcome.**The data then analyzed for comparison of subject group characteristic using paired t-test if the data is normally distribute, and using Wilcoxon if the data is abnormally distribute. The data is also analyzed for GPx-1 level correlation with SNHL using Mann-Whitney test. The result is statistically significant if p≤0,05.

Findings: This study was held from February 2017 to April 2017, using 17 subject that fulfill the inclusion criteria. All subject received same test for pre and post Kanamycin therapy, which includes tympanometry, pure tone audiometry, DPOAE, and GPx-1 level.

Table 1: Subject Characteristic

Characteristics	**n=17**
Gender, n (%)	
Male	7 (41,2)
Female	10 (58,8)
Age (Years)	
Mean ± SD	36 ± 8
Range	23 – 46

Table 2. GPx-1 Level Before and After Kanamycin Therapy

	Measurement		**Decendants (%)**	**p-value**
	Before therapy (u/l)	**After 3 weeks therapy (u/l)**		
GPx-1				
Mean ± SD	4,49 ± 3,12	1,2 ± 1,0	70.42 ± 20,94	<0,001*
Range	1,01 – 14,01	0,07 – 5,15	18.81 – 98,54	

Analysis using paired-t test. *significant if p ≤ 0.05

Based on these table GPx-1 level before therapy with range 1,01-14,01 (4,49 ± 3,12) and GPx-1 level after therapy (1,2 ± 1,0) with range 0,07 – 5,15.

Table 3. Correlation between GPx-1 level and DPOAE value

	DPOAE test (Dp-NF)		p-value
	Pass n=4 (23,5%)	Refer n=13 (76,5%)	
GPx-1			
Mean ± SD	66,60 ± 21,02	84,59 ± 14,86	0,062*
Range	18,81 – 92,36	64,40 – 98,54	

Analysis using paired-t test. *significant if $p \leq 0.05$

From the analysis above, GPx-1 median value at ear that having DPOAE test a "refer" value is higher (84,59 ± 14,86) compared to those who have DPOAE test a "pass" value (66,60 ±21,02), but it's not significant statistically (p=0,062).

Table 4. Audiometry examination before and after Kanamycin therapy

Frequency	Ear	Threshold (dB)		p-value
		Before Therapy Mean ± SD	After Therapy Mean ± SD	
500 Hz	AD	20,6 ± 5,6	23,7 ± 5,3	0,002
	AS	21,2 ± 4,5	24,7 ± 4,1	0,020
1.000 Hz	AD	18,8 ± 3,3	19,4 ± 5,0	0,041
	AS	18,2 ± 5,0	21,8 ± 3,5	0,048
2.000 Hz	AD	14,4 ± 3,6	17,7 ± 3,3	0,045
	AS	14,4 ± 3,9	18,5 ± 5,8	0,016
4.000 Hz	AD	16,8 ± 5,6	20,9 ± 4,4	0,050
	AS	15,3 ± 6,0	21,8 ± 6,4	0,020
8.000 Hz	AD	19,1 ± 7,3	24,4 ± 6,6	0,003
	AS	18,0 ± 7,7	25,9 ± 10,3	0,004

Analysis using paired-t test. *significant if $p \leq 0.05$

There's a significant increase in hearing threshold on both ear from pre to post Kanamycin therapy using audiometry each frequency.

Table 5. Correlation between GPx-1 Level and Sensorineural Hearing Loss

	SNHL		P value
	Yes n=13 (76,5%)	No n=4 (23,5%)	
GPx-1 Pre Therapy			
Mean ± SD	3,68 ± 1,99	7,13 ± 4,88	
Median	3,73	5,88	0,049
Range	1,01 – 6,32	2,75 – 14,01	
GPx-1 Post Therapy			
Mean ± SD	0,95 ± 0,71	1,99 ± 2,17	
Median	0,82	1,30	0,013
Range	0,07 – 2,59	0,21 – 5,15	

Analysis using Mann-Whitney test. *significant if $p \leq 0.05$

There's a significant correlation between GPx-1 level and SNHL condition.

Discussions

This study conclude MDR TB is mostly suffered by female (58.2%) compared with male (41,8%). Liu et.al hypothesized that female mostly spend their day taking care of their family who has MDR TB, compared to male, so the risk of bacterial infection transmission is higher in female.[28] This result also found in Pelaquin et.al study and WHO data survey on 2015.[2,29] Pelaquin study stated that gender does not affect the ototoxic effect of Kanamycin in MDR TB therapy and there is no direct correlation between MDR TB incidence and gender.[29]

Based on age group, this study conclude that MDR TB cases occur mostly on productive age (23 – 46 years old). This result was supported by Rakhmawati and Reviono et.al study that also found that MDR TB cases most likely occur on age 20 – 50 years.[7,8] Medical record data at Dr. Hasan Sadikin General Hospital, Bandung, Indonesia on 2016 stated that MDR TB mostly happen in age group 25-54 years.[4] Productive age have higher working time than other age group, which may affect the obedience for taking medicine, which then lead to drug resistance. Productive age also has more contact to different people in work, school, or other activity, so the risk of bacterial transmission is higher and could influence the incidence of MDR TB.[28]

Kanamycin is known for its side effect damaging outer hair cell of cochlea. This study used DPOAE on frequency ranged 1,500 Hz to 8,000 Hz which was tested prior and 3 weeks after the therapy begin. The result was most of the study subject exhibit "refer" value, which indicates damage at cochlear cell hair. Other study by Mustikaningtyas also exhibit the same result.[25,30] DPOAE test could provide initial data of hearing condition and early detection of ototoxicity. Reavis et.al stated that DPOAE could detect around 78% of hearing problem cases, which then confirmed using HFA. Other study also stated that DPOAE test is sensitive in monitoring of ototoxicity caused by drugs.[28]

MDR TB infection is a chronic infection, marked by a decrease in one of antioxidant enzyme. Study of Alli et.al and Madebo stated that the antioxidant enzyme known to be decreased by chronic infection is GPx-1.[16,17] This study found that GPx-1 level is significantly decrease after 3 weeks therapy of Kanamycin. ROS production happens continuously inside the cell, together with a decrease in antioxidant production, which results an imbalance level of antioxidant and ROS. This imbalance leads to DNA, cell membrane, cell protein and kinase protein damage. DNA damage can be repaired by Base Excision Repair (BER) mechanism, but if the damage exceeded BER capability, the cell will activate protein P53 and result in apoptosis.[27] GPx-1 level is determined by many factor, such as inflammation process, inadequate nutritional intake, and low social economy condition.[20]

Pure tone audiometry testing is used to monitor the change of hearing threshold due to Kanamycin therapy. A study conducted by Rakhmawati also shows a decrease on sensorineural hearing function from frequency 4.000 Hz to 8.000 Hz.[7] Other study conducted by Mustikaningtyas shows that SNHL after Kanamycin therapy happens in several level (48% mild, 24% moderate, 4% moderate-severe, 1% severe and 15% very severe).[30]

Baseline data, consist of HFA, tympanometry, speech audiometry, and OAE, should be recorded before administration of ototoxic therapy to determine the hearing threshold. Pure tone audiometry is the only exam that still used before administering ototoxic therapy.[26]

Early stage of Kanamycin therapy does not exhibit hearing problem on speech frequency (500 – 4.000 Hz), so not many patient realized that hearing problem is already happened. HFA exam can be useful for early detection of hearing problem, so further and more severe condition can be prevented.[14]

Table 3 showed a tendency of diminishing level of GPx-1 level after Kanamycin therapy, although it is not statistically significant. This may result from a minimal number of samples. On this study, decreasing level of GPx-1 level is more likely to be lower on "refer" value ear compared to "pass" value ear after therapy, whereas GPx-1 level is higher on "refer" value ear compared to "pass" value ear before therapy. This may result from higher exposure of ROS on "refer" value ear cochlea as an effect of intracellular defense, which then lead to an increase in GPx-1 level at the beginning to balance ROS level. This mechanism will end at some point due to maximal compensatory effect of GPx-1 enzyme, so the imbalance of ROS and antioxidant enzyme is no more tolerable, which lead to the damage of cochlear hair cell.[14,23]

Table 5 shows that GPx-1 level is significantly related to SNHL. Low GPx-1 level decreasing the capability of this enzyme to eliminate ROS, especially in basal area of cochlea.[31] This phenomenon is because GPx-1 level in basal area of cochlea is lower than in

apex area, causing basal area to be more vulnerable.[15] Study conducted by Sharma et.al showed that 18 MDR TB patient that is given Kanamycin therapy for 6 weeks, develop sensorineural hearing problem, 2% on the first week and 12% after 6th week. Mostly having bilateral hearing problem.[25]

The limitations of this study were the fact that GPx-1 examination performed with ELISA which only saw serum levels or amount of the enzyme, but not the activity of the enzyme.

Conclusion

There is a significant correlation between GPx-1 level and SNHL condition proceeding Kanamycin therapy on MDR TB patient, characterized by a decrease in GPx-1 level and an increase in hearing threshold on subjects after administration of Kanamycin therapy.

Conflict of Interest: There was no conflict of interest in this study.

Post-Traumatic Growth with Police Officer: System Review (Focused on Korean and Foreign Studies)

Seung Woo Han[1]

[1]*College of Emergency Medical Technology, Kyungil University*

Abstract

Purpose: The purpose of this study was to analyze literature related to post-traumatic growth with police officer. Method: Systematic review of studies published were conducted through a vatiety of databases such as Ovid-Embase, Ovid-Medline, The cochrane library, Pubmed, RISS. The research terms included Police officers, Police, Trauma, Posttraumatic growth, Growth. Results: All studies were correlation analysis. In the Korean researches, PTG was positively correlated with self-esteem, problem focused coping, emotion focused coping, social support, self-disclosure and deliberate rumination. In the foreign researches, PTG was correlated with thriving, resilience, events involving threat, personal relationship stress, trauma severity, life stress, and gratitude. Demographic variables such as Female, White were also associated with PTG. Conclusion: To improve post-traumatic growth of police officers, strategies to increase stress coping, social support, are needed. Strategies to decrease stress, trauma and PTSD symptoms should be developed.

Keywords: *Police officers, Police, Post-traumatic, Growth, Review literature as topic.*

Introduction

The increases in crime and violence in Korea may have a great impact on the life and safety of police officers, and according to the statistics of the National Police Agency, of 9,552 on-duty-injured people for the last five years, the assaulted injuries, traffic accidents, and negligent accidents accounted for 97% of the total number of on-duty-injured people.[1] Particularly, these traumatic events will be directly linked not only to the police officers' lives but also to the protection for the lives of the people. In DSM-IV (1994) of the American Psychiatric Association, the trauma cases were extended to direct or indirect experiences that may threaten physical well-being, including life threats, serious injuries, striking events and so on.[2]The experiences of various traumatic events, such as witnessing of the murder scene, usage of guns, and violence during the suppression process, which should be undergone on duty, cause the anxiety, pain, and trauma to the relevant event. These various traumatic experiences lead to Posttraumatic Stress Disorder (PTSD).

Accordingly, in the meantime, the studies on post-traumatic stress have been actively conducted, which have focused on negative physical and psychological experiences and symptoms, accompanied by traumatic events, such as depression, anxiety.[3] However, not all people will be led to the post-traumatic stress after experiencing traumatic events, and even if they experience the same trauma, most people will overcome it well, sometimes experiencing physical and mental growth.[4] In other words, they may experience positive psychological changes that would be perceived after the traumatic event or crisis, and such changes are called as the posttraumatic growth (PTG).[5] The positive psychological change, mentioned here, may mean a genuine positive change that transcends the psychological functioning level and the self-awareness level of life – simply beyond physical and psychological functioning levels prior to trauma.[6] Further, rather than the focus on the physical and pathological symptoms which have been induced by the event itself, mentioned in PTSD, the posttraumatic growth implies a more comprehensive concept focusing on the psychological and subjective response, the individual internal-strengths and adaptive aspects, which would be experienced in the event experiences.[7]

These positive changes had been diversely interpreted by each scholar, which had been used in various terms, such as discovery of benefits, stress-related growth, etc., by the 1990s, but Calhoun and Tedechi suggested the

terminology of 'Posttraumatic Growth', different from their concept.[8,9] Examining the research trend on the posttraumatic growth in the meantime, the initial studies on posttraumatic growth have been performed in the field of psychology, but in recent years, the research has been actively conducted in nursing, medicine, etc., as the interest in prevention of diseases and health promotion increases.[3] In most precedent studies, the studies concentrating on the posttraumatic growth for specific disease subjects including cancer patients, women experiencing physical violence, the subjects who have experienced war have been conducted. However, the posttraumatic growth studies for high-risk occupational groups experiencing various traumatic events, like police officers, fire-fighting officers, and prison officers, are in very short.

Thus, this study is going to search for and then, systemically investigate various variables related to the posttraumatic growth of police officers.

Study Method

Selection of Searching Database: In terms of searching, the literature search started from 1996, when the posttraumatic growth was developed and the term of the original author began to be used, and all the literature associated with the related keywords and the like were searched by January 2018 based on the search date. In order to conduct the systematic literature review of this study, researcher collected studies focusing on the posttraumatic growth aimed at police officers. In this study, Pubmed, Ovid-medline, Ovid-Embase and The cochrane library were used as the overseas database and RISS (Korean/English) as the Korean one. The research objects included Police officers, Police, Trauma, Posttraumatic growth, and Growth. In addition, the literature search was limited to articles providing abstract and full text.

Literature Screening and Quality Assessment: Based on the literature search strategy, all literature retrieved by each database was merged and then, the duplicate literature was removed. After the elimination of duplicate literature, the studies that did not satisfy the core questions of this study were excluded through the titles and abstracts of the primary study. The primary study, which was unclear to judge whether it might be selected or excluded or which fully met the selection criteria, based on the title and abstract, was judged by securing the full text.

As all the primary studies included in the literature review of this study are the study analyzing correlations, the quality evaluation on the literature was conducted by utilizing the 'Quality Assessment and Validity Tool for Correlational Studies' which was used in the existing study of Wong and Cummings.[10]

Results

Based on the literature search criteria of this study, the total number of retrieved literature was 2683 units, and of these, 420 duplicate literature units were excluded. Among 2263 theses by excluding 420 theses, 351 theses related to PTSD and 407 literature units were left by excluding 505 literature units which were not related to the subject, after reviewing abstract, titles and contents. Of them, in the posttraumatic growth, by excluding 322 theses which were studied on the samples not related to police officers of the subject of this study, 8 review theses, 18 qualitative research theses, 23 experimental theses, 4 non-English theses, and lastly, 11 literature units which were retrieved as the poster-presented literature, the final 24 theses were selected. 24 literature units were systematically analyzed by 2 researchers, and if the exclusion was not identical, they discussed it until they reached the agreement.

Discussion

In this study, with respect to the correlations between variables related to posttraumatic growth of police officers, it was found in Koreanstudies that self-esteem, problem-centered coping, emotion-centered coping, self-exposure, social support, and intentional rumination had a significant correlation with posttraumatic growth. These results are in agreement with the study[21] that the higher self-esteem becomes, the higher posttraumatic growth is, and since self-esteem correlates with positive cognition control strategies, it is considered that it has the significant correlation with posttraumatic growth, as a factor of protection and internal growth to control negative emotions in the process of accepting events after experiencing traumatic events. In other correlation studies, problem-centered coping and emotional-centered coping also showed a significant correlation with posttraumatic growth of police officers. This suggests that the adaptive mechanisms and responses will vary depending on the stress coping strategies used by individuals, even if they may experience the same trauma. In the precedent study[22], they stated that if the negative emotions, such as trauma and stress, was controlled

well, and the emotion-centered coping was well exerted after the traumatic experience, so that problem-centered coping, one of the active coping strategies, was utilized more, it would be in charge of the responses for well-understanding of their own psychological emotions and expression of their emotions. Therefore, the stress coping strategies, such as problem-centered coping and emotional-centered coping, after traumatic events, will be served as important variables to induce the posttraumatic growth. Self-exposures were also established to have a significant correlation with posttraumatic growth, and in the precedent study[15], it was said that those who actively engaged in self-disclosure were more likely to participate in cognitive processes related to growth than those who did not. It was confirmed that self-exposure was statistically related to posttraumatic growth as an important factor of psychological recovery in the growth of trauma experience. In the precedent studies[15,16,17], social support and intentional relativity also showed a significant correlation with posttraumatic emotions. In precedent research[23], when social support was well supported after experiencing the traumatic event, it was considered to be an important factor in well coping with stress situations and functioning for the psychological adjustment in adverse situations, which was regarded as an important parameter to induce posttraumatic growth after experiencing the traumatic event. Finally, intentional rumination was found to have a significant correlation with posttraumatic growth, which was considered as an important parameter to promote posttraumatic growth to bythinking carefully about the cast through that event and discovering the positive meanings or benefits from that case, rather than that the trauma experience was not just regarded as a negative event[23]. As a result of precedent studies of such Koreanstudies, the valuables significantly correlated with posttraumatic growth was found to be self-esteem, problem-centered coping, emotion-centered coping, self-exposure, social support, and intentional rumination. By getting out of these phases to explore the relations with valuables, the future research will provide the baseline data for developing programs to promote a positive and healthy direction and posttraumatic growth of police officers, and be helpful as an important factor in conducting a more realistic and multifaceted research. In overseas theses, as the posttraumatic growth-related variables, prosperity and resilience, appreciation, traumatic event threatening the personal life, stress induced from human relations, severity of trauma, PTSD symptoms, relationship stress, working stress, and depression were identified. It suggested that in overseas studies, Positive variables, such as prosperity and resilience, and negative variables, like stress and trauma, were found to be more variously related to posttraumatic growth than in domestic ones, as a variable related to posttraumatic growth of police officers. Prosperity and resilience were found to be significantly correlated with posttraumatic growth in the precedent theses. In the positive psychology, the constructively adaptive ability, well-being, and individual strengths focused on the prosperity of humans, and in the self-formation and prosperity theory, Frederikson[24] argued that the positive emotions, such as prosperity, would undergo a process to promote posttraumatic growth. In addition, referring to resilience as one of coping abilities when confronting a crisis after generally experiencing a traumatic event, he stated that this had a static correlation with posttraumatic growth causing less psychological trauma in crisis. Finally, the appreciation, as a positive variable, corresponded to the study results[25]suggesting that the higher the appreciation tendency, the higher the posttraumatic growth.

Conclusion

The purpose of this study was to investigate and explore the precedent literature on posttraumatic growth aimed at police officers, to establish the variables related to the posttraumatic growth of Korean and abroad police officers, and at the same time, to provide baseline data for the development of programs that can promote posttraumatic growth. In the present study, as a result of investigating the literature that have been created since 1996 when the term of posttraumatic growth was firstly used, in the Korean theses, self-esteem, problem-centered coping, emotion-centered coping, self-exposure, social support, and intentional rumination were identified and in overseas theses, prosperity and resilience, appreciation, stress caused by traumatic events threatening the individual live and human relationships, severity of trauma and PTSD symptoms, relation stress, work stress, and depression were confirmed.

HIV Stigma among Clinical Medical Students in East Java, Indonesia

Firas Farisi Alkaff[1], Adila Taufik Syamlan[2], Presstisa Gifta Axelia[2], Jovian Philip Swatan[2], Sulistiawati[3]

[1]Department of Pharmacology, Faculty of Medicine Universitas Airlangga, [2]Faculty of Medicine Universitas Airlangga, [3]Department of Public Health and Preventive Medicine, Faculty of Medicine Universitas Airlangga

Abstract

Background: HIV-related stigma is considered as major barrier for controlling the spread of HIV/AIDS. People living with HIV/AIDS (PLWHA) that experienced stigma were less likely to disclose their HIV status to their sexual partners and health care professionals. Medical students as the future physicians are expected to be at the forefront to prevent and treat HIV/AIDS. This study aims to explore the stigmatized attitude and practices towards HIV/AIDS patients among medical students in East Java, Indonesia.

Material and Method: Observational study was conducted at one of the faculty of medicine in public university in East Java, Indonesia. Respondents of this study was last year clinical medical students. Instrument used in this study was self-administered questionnaire that assess medical students attitudes and practices towards PLWHA.

Results: Most respondents empathize PLWHA patients equally with non-PLWHA. Forty percent of the respondents agreed that PLWHA needs to be separated from non-PLWHA in health care services. Around 39% of the respondents think that PHLWA should not become a healthcare worker and Eighty two percent of the respondents did inform their friends if there was a PLWHA patient to be cautious. More than half of the respondents used unnecessary protection when examining PLWHA patients.

Conclusion: HIV-related stigma among clinical medical students in East Java was still exist, in both attitudes and practices. Medical schools should consider developing a teaching method that improves their students attitudes and behaviors towards PLWHA patients.

Keywords: *HIV, Stigma, Medical Students, Indonesia.*

Introduction

HIV/AIDS is still one of the most important global public health problem. Globally, 2.1 million people were estimated to have become newly infected with HIV, representing a rate of 0.3 new infections per 1000 uninfected people in 2015. An estimated 36.7 million people were living with HIV at the end of 2015[1]. Data from USAID showed that around 620000 people living with HIV in Indonesia with 48000 new infection in 2016, and among them only 13% accessing antiretroviral therapy (ART)[2].

HIV/AIDS related stigma is considered as major barrier for controlling the spread of HIV/AIDS. Stigma is not only devastating for social and economical aspect of the individual, but also a major barrier for accessing HIV/AIDS prevention and treatment services. Feeling afraid of being stigmatized is the main reason why people feel reluctant to see doctors for having HIV counseling and testing (HCT)[3,4]. HIV/AIDS related

stigma also impact patient's adherence to highly active anti-retroviral therapy (HAART). People living with HIV/AIDS (PLWHA) who disclosed their status were likely to skip doses to avoid their families, friends, or doctors finding out their status[5]. Study conducted in 4 countries in Asia (Indonesia, India, Philippines, and Thailand) shows that 80% of HIV respondents reporting discriminatory experiences, including discrimination in the health sector (54%), community (31%), family (18%), and workplace (18%)[6].

Good health care access is important for maintaining quality of life PLWHA. HIV/AIDS-related stigma from health care providers result in lack of access or delayed access which speeds up progression of the disease [7]. There are only 3 studies in Indonesia about the HIV/AIDS-related stigma in health worker until now, and all of the studies found that HIV/AIDS-related stigma among health care worker did exist, and it is unacceptably high [8-10]. Although only few studies conducted in Indonesia, stigmatizing attitudes toward PLWHA likely to occur in clinical settings throughout the country.

Medical students as the future physicians are expected to be at the forefront to prevent and treat HIV/AIDS. Thus, their professional behavior and attitudes against HIV/AIDS patients have profound impact on the course of the disease, treatment compliance, and prognosis. Until now, there are no study regarding the HIV/AIDS-related stigma among medical students. This study aims to explore the stigmatized attitude and practices towards HIV/AIDS patients among medical students in East Java, Indonesia.

Material and Method

This study was a observational study conducted in March 2017 at one of the faculty of medicine in public university in East Java, Indonesia. This study follows the principles of the Declaration of Helsinki. All respondents gave their informed consent prior to their inclusion in the study. Information for informed consent was given before respondents signed the informed consent. Details that might disclose the identity of the respondents under study were omitted.

In general, medicine in Indonesia is taught in minimum of 11-semester and divided into two phases. The first phase is preclinical study, consisted of 7-semester study program. The second phase is clinical study, consisted of 4-semester study program. After the students finish the second phase, they are eligible to take national examination, consist of theory and Objective Structure Clinical Examination (OSCE) test. After students pass the national examination, they are entitled for Medical Doctor degree. In this study, the respondents were medical students whose already finish their clinical study in the academic year of 2016/2017 but not yet took the national examination. We choose these students as respondents in our study because they had already interacted with patients and involved in the tending process during their clinical study.

Study instrument in this study was self-administered questionnaire, consisted of three sections as follows: 1) The characteristic of the medical students; 2) The medical students attitude towards PLWHA; and 3) The medical students practice towards PLWHA during their clinical years. The medical students attitude section contained 9 questions, and the medical students practice section contained 8 questions. There were only 2 possible responses to each statement in attitude and practice section, which were 'yes' or 'no'. The questionnaire was given to the respondents in Indonesian. We did not measure the score in each section of the questionnaire in this study. All the acquired data from the questionnaire was entered to SPSS (SPSS Inc., Chicago, IL, USA) for descriptive analysis.

Results

A total of 150 medical students were recruited as respondents, with the response rate of 100%. Mean age of the participants was 23.23 ± 0.734 years old. There were more female respondents than male respondents in this study. Most of the participants had an average GPA of 3.0-3.5 out of 4.0 throughout their study as medical students. More than half of the respondents was raised in the healthcare worker (HCW) family (table 1).

In the medical students attitude towards PLWHA section, almost all of the respondents would have a friendship with PLWHA. Forty percent of the respondents agreed that PLWHA needs to be separated from non-PLWHA in the health service. There were 28% of respondents that would prefer to treat PLWHA. Few respondents agreed with the statement that PLWHA doesn't deserve to be cured, and 28.7% agreed that all PLWHA got the disease because of their own fault. Around 39% of the respondents agreed that PLWHA should not become a healthcare worker, and 15.3% agreed that PLWHA has no right to be a public figure or leader (Figure 1).

In the medical students practice towards PLWHA patients section, most of the respondents empathize PLWHA patients as much as they empathize other patients. Eighty two percent of the respondents did inform their friends if there was a PLWHA patient so that their friends will be more careful in tending that patient. There were 20% of the respondents who did not do complete physical examination on PLWHA patients as complete as on other patients, and 33.3% try to avoid physical contact with the PLWHA patients. More than half of the respondents used unnecessary protection when examining PLWHA patients. Around 20% of the respondents did HIV screening test in the patients that they suspect of having an HIV infection without making any proper counselling (Figure 2).

Table 1. Characteristic of the respondents

	N (%)
Age (Mean ± SD)	23.23 ± 0.734
Gender	
Male	64 (42.7)
Female	86 (57.3)

Family Background	
Health worker	50 (33.3)
Non-health worker	100 (66.7)

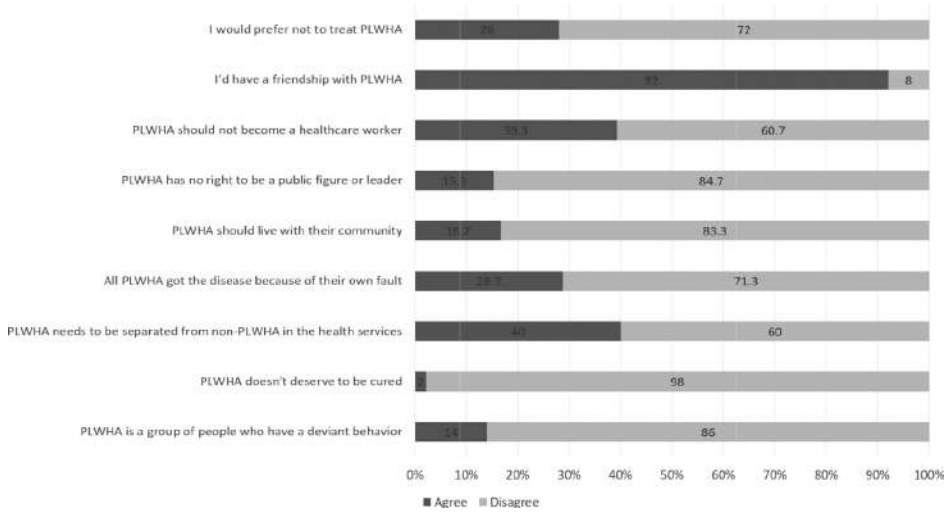

Figure 1. Medical Students Attitude Towards PLWHA

The percentage represents the number of respondents who agreed (dark grey) or disagreed (light grey) with the following statement out of 150 respondents in this study.

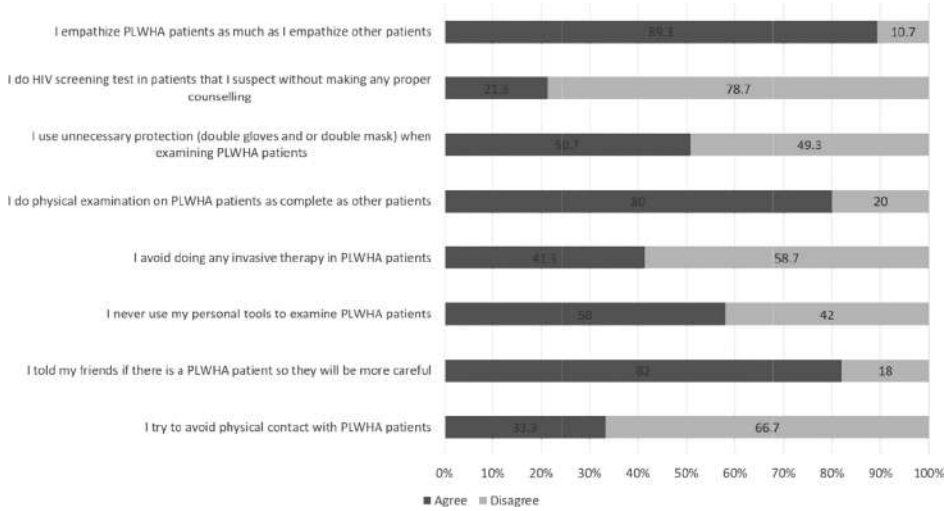

Figure 2. Medical Students Practice Towards PLWHA Patients

The percentage represents the number of respondents who agreed (dark grey) or disagreed (light grey) with the following statement out of 150 respondents in this study.

Discussion

We found that there was still stigma towards PLWHA among medical students in Indonesia, which was observed in their attitudes and practices toward PLWHA. There were several previous studies that evaluate the attitude of medical students regarding HIV/AIDS that shows same result to stigmatizing attitude[11-14].

Almost all respondents in our study had an average GPA of 3.0 to 3.5 out of 4.0 throughout their study in medical faculty. Several studies have been conducted to seek the correlation between knowledge and stigmatizing attitude towards HIV/AIDS among medical students. Previous study in China found that there was no association between knowledge of medical students in HIV/AIDS and stigmatizing attitude [11]. Other studies found that there are no positive changes in students' attitudes as students progressed through their studies although their knowledge showed a significant improvement[12-14].

There are several studies that compare the knowledge and attitude between medical students and students from other faculties. Study by Turhan et al which compare the knowledge and attitude of students from faculty of medicine, faculty of dentistry, and medical technology vocational training school towards HIV/AIDS found that there was no significant difference between these students in terms of both knowledge and attitude [14]. In contrary, study done by Chauhan et al showed that HIV/AIDS knowledge in medical students was higher than allied health sciences students, and the attitude was also more positive[15]. Comparative study between final year of medical and pharmacy students conclude that overall medical students' knowledge appeared to be better than pharmacy students regarding HIV/AIDS, and there was significant difference between students group in attitudes and risk perceptions about HIV/AIDS [16]. Until now, there are no study that compare between medical students and society in general.

There were only 3 studies regarding HIV-related stigma in Indonesia among HCW to date, and only 1 study involved medical student intern. Study of HCW in Banda Aceh city found that the average of stigmatized attitudes among doctors and medical student interns was significantly lower from those of nurses [8]. Another study in Aceh region conclude that although the HIV caseload is very low, the discriminatory attitude was high. Discriminatory attitudes were higher amongst HCW with low-level of formal education and low-level knowledge on transmission and prevention of HIV, non-doctor profession, Islam, have not experience direct contact with HIV-positive patients, rarely attend HIV/AIDS-related trainings, high value-driven stigma and overestimated risk to HIV transmission, and working in bad health facilities [10]. Study done by Walyuo et al. among 396 nurses at 4 different hospital in Jakarta, the capital city of Indonesia, found that stigmatizing attitudes towards HIV were significantly predicted by formal education, HIV training, perceived workplace stigma, religiosity, Islamic religious identification, and affiliation with the Islamic hospital, but not by HIV knowledge[9].

In order to reduce HIV/AIDS stigma, knowledge alone is not adequate if not followed by proper clinical experience and clinical situational analogue training [17]. Moreover, in order for knowledge itself to change the medical students' attitude, more time is needed. Personal experience and convincing role model also plays role in building the knowledge to prevent HIV-related stigma. [13]. To our knowledge, medical schools in Indonesia did not gave specific lecture and training to eliminate the stigma. This issue is similar to Israel, where HIV content taught in medical schools curricula focus mainly on matters such as the pathogenesis of HIV infection and the affects on its host, but there are no specific programs that pruposely address the importance of preventing stigma and if it already occured, dealing toward specific patient populations [12]. Previous studies found that the medical students' main source of HIV/AIDS information is not from the class lecture, but from the mass media instead[12,15]. Because most of the medical students receive information about HIV/AIDS from the same source as general population, one might argue that these might be the reason why the stigma against HIV is still exist in medical students.

It has been suggested that other than providing adequate knowledge to medicals students, it is important to also focusing on dealing with stigma, anxiety and misperceptions about HIV/AIDS and PLWHA, Medical schools should modify their curricula to include teaching method aimed at improving HIV-related attitudes and behavior, and adherence to medical professionalism. It could be done by providing the lecturer's comprehensive experience that address all the possible prejudice and

discriminatory health beliefs in the students, engaging PLWHAs to speak of their life experience and interact with the students, bed-side teaching with PLWHA supervised by an experienced physician who was a proven good role model in clinical practice and teaching, having a structured elective program for knowledge enhancement and cognitive exercise to improve their skills in handling PLWHA[11-16].

Conclusion

HIV-related stigma among clinical medical students in East Java was still exist,in both attitudes and practices. Having a knowledge of HIV/AIDS does not guarantee that there will be no stigmatizing attitudes towards PLWHA. Other than providing adequate knowledge by giving classical lecture, medical schools should also develop a teaching method that improves their students attitudes and behaviors towards PLWHA patients before they enter their clinical years study. Future study needs to be done to compare the attitude between medical students and society in order to evaluate the effectivity of the teaching method regarding the HIV-related stigma.

Effectiveness of Falls Prevention Education on its Prevention Behavior among Older Adults: A Systematic Review

Goh Jing Wen[1], Devinder Kaur Ajit Singh[1], Suzana Shahar[2]

[1]Physiotherapy Programme, Center for Rehabilitation and Special Needs, [2]Center for Healthy Aging and Wellness, Faculty of Health Sciences, Universiti, Kebangsaan Malaysia

Abstract

Introduction: Falls prevention education is important to provide early awareness of falls prevention among older adults. However, information on the effectiveness of falls prevention education on its prevention behavior among older adults is limited.

Objective: The objective of this systematic review was to identify effects of falls prevention education on the practice of falls prevention behavior among older adults.

Method: A search of three electronic databases: PEDRO, EBSCHOHOST and OVID & MEDLINE, was performed in May and June 2018. Studies with falls prevention education as a single prevention intervention either in the hospital, long term care or community settings, participants aged 60 years and above and falls prevention behavior as an outcome measure were included.

Results: A total of 129 studies were found with 16 being duplicates. A total of 14 and 62 studies were excluded for review after screening by title and abstract respectively. Another 31 studies were excluded for not fulfilling the inclusion criteria. Only six studies were finally eligible for inclusion in our present review. The results of our review suggested that falls prevention education significantly improved falls prevention behavior practice among older adults. However, there is limited information on periodic falls risk screening or assessment practice among older adults.

Conclusion: Falls prevention education seems to be effective in heightening falls prevention behavior among older adults. More information about the effects of periodic falls risk screening or assessment on falls prevention behavior among older adults is required.

Keywords: *Falls prevention education; Falls prevention behavior; Elderly; Older adults.*

Introduction

Falls among older adults have been reported as one of the major causes of mortality and morbidity among older adults,[1] which can lead to serious and devastating consequences to older adults themselves, their families and their communities due to burden of care. Even though falls prevention programs have been implemented, the number of falls has not decreased. Moreover, the number of older adults who can be categorized as "old" is increasing and, as a result, the number of falls will also be increasing.[2]

Falls prevention behavior is referred as the prevention strategies adopted and practiced by older adults in their daily life, to protect themselves from falls.[3] It had been reported that older adults tend to behave carefully to prevent falls with advancing age which indicate their awareness about falls prevention.[4] Nevertheless, there are older adults who fall due to risky behaviors. Jeon et al.[5] reported that the reasons behind such risky behaviors were increased self-confidence, pride and contentment.

Hence, falls prevention education, in particular, the identification of individual risky behaviors, is significant to provide early and self-awareness of falls prevention among older adults. While, falls prevention education is an important components in the efforts to prevent falls, its focus has been on the fall rate and

number of injurious falls and percentage of older adults who fall.[6,7] Information assessing the effectiveness of falls prevention education as an intervention on its own right and in the adoption of falls prevention behaviors is limited. Our current review was conducted to identify the effects of falls prevention education program on the practice of falls prevention behavior among older adults.

Methodology

Search Strategy: We searched for computer-based electronic databases: EBSCHOHOST, OVID & Medline, and PEDRO, in May and June 2018.

The search was done based on the Population Intervention Comparisons Outcomes Study Design framework. The search applied the following keywords: "falls prevention education", "falls prevention behavior" or "falls prevention practice" and "elderly" or "aged" or "older" or "elder" or "geriatric". Similar keywords were used in each database. The keywords were truncated to search for any studies which were related to the root words. Boolean operator 'OR' and 'AND' were applied to combine the keywords.

Study Selection: Literature selection criteria were as follows: studies in which (1) participants were aged 60 years and above; (2) falls prevention education was used as a single intervention; (3) falls prevention behaviors were addressed as an outcome measure; (4) peer-reviewed publications; (5) full text; and (6) available in English language. The researcher excluded retrospective studies, such as case-control studies, studies that were not diagnostic, not original or did not provide sufficient information to identify falls prevention behaviors.

All duplicates were removed from the initially retrieved articles. Inclusion and exclusion criteria were then used to examine the titles and abstracts. If it was difficult to decide whether to include a retrieved article, its main text was reviewed. Two independent reviewers reviewed all processes and a third party was consulted if there was any disagreement.

Quality Assessment: Modified McMaster Quantitative Critical Appraisal Tool (MMQCAT) was used to critically appraise the quality of each included studies. MMQCAT was developed by Law et al. (1998) to critically appraise the papers which report the quantitative studies by considering 15 criteria (Table 1). A higher total score with a maximum total score of 14, was then indicates a higher quality of the reporting studies.

Results

Selection process and bias risk assessment: A total of 129 articles were retrieved from the electronic databases. Sixteen duplicate articles were removed and the titles and abstracts of the remaining (113) articles were examined based on the inclusion and exclusion criteria. The main text was reviewed if it was difficult to make a decision. Finally, 6 articles were included for review.

Participant Characteristics: The effectiveness of falls prevention education on the practice of its prevention behavior was examined among a total of 459 older adults aged ≥60 in the six reviewed studies. Three studies were conducted in the senior community centers, facilities or housings.[8–10] One study was carried out in long term care setting, a nursing home. Whereas, another two studies were conducted among patients in hospitals[11] and those discharged to the community.[12] The reviewed studies were from mainly Asia[3,8,10] and Asia Pacific regions.[9,11,12]

Comparison Groups: In two studies falls prevention education was compared to usual care.[10,12] In one study there was no comparison group.[3] General education for the comparison group was provided in one study.[8] While, in another study the effectiveness of education provided was compared between that delivered via workbook and DVD.[11] Specifically tailored falls prevention education between two groups (authenticity and motivation) was compared in one study.[9]

Quality Assessment: The assessment of the methodological quality for each study is presented in Table 1.

The total scores of MMQCAT of the review studies ranged from 9 to 12 out of a maximum score of 15.

Table 1: Quality assessment

Authors	Criteria (Modified McMaster Critical Appraisal Tool for Quantitative Study)															
	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	Total Score

Hill et al. (2009) [11]	/	/	RCT	x	x	/	/	/	x	x	/	/	x	/	/	9

MMQCAT Criteria: 1) clearly stated study purpose; 2) background of literature review; 3) appropriateness of study design; 4) sample described in details; 5) sample size justification; 6) reliability of outcomes measures; 7) validity of outcomes measures; 8) intervention description; 9) contamination avoided; 10) co-intervention avoided; 11) result were reported based on statistical significance; 12) appropriateness of statistical analysis method; 13) clinical implication reported; 14) dropouts reported; 15) relevant conclusion RCT = Randomized Control Trial; PRCT= Pilot Randomized Control Trial; Q-E = Quasi-Experimental = Yes (1 point); x = No, Not Address, Not Applicable (0 point).

Contents of falls prevention education: In most of the studies, falls prevention education included topics such as definition, causes, risk and consequences of falls. As for falls preventive measures, regular exercise, periodic eye examination, safe drug use, environmental change and protective behavior development were the main highlights.

Method used to deliver falls prevention education in each setting

Mode of delivery: Majority of the studies used face-to-face session as the mode of delivery for falls prevention education.[3,8–12]

Intervention settings: One-to-one education session was applied mostly,[3,9–12]while only in one study a group-based settings for falls prevention education was used.[8]

Material provided: Multimedia such as videos (DVD), was the most common method used to deliver the falls prevention education in most settings (5 studies).[3,9–12] The combination of video materials, medication counseling and poster presentations were used in one study[3] with both video and written falls prevention education materials used in another one.[12] In the study by Jang & Lee [8], both booklets and presentation files were used. Individually tailored multimedia based falls prevention education was applied in one study.[9]

Duration of intervention: Multiple sessions of falls prevention education were used in two studies.[8,12] In the rest of the studies only one session was conducted.[3,9–11] The overall duration for each session ranged from 15 minutes up to 1 hour.

Findings of the Studies: Falls prevention behavior was assessed using a variety of self-reported outcome measures. Some of these outcomes were used in combination. In all studies, falls prevention education was found to have a positive effect on at least one practice of falls prevention behavior among older adults. In two thirds of the studies, a positive effect on various aspects of falls prevention behavior was demonstrated in older adults.[3,9,10,12] One out of six studies addressed positive impact on the behavioral intention towards or on home renovation.[8] While, in one study significant effect of falls prevention education on identifying its strategy to reduce falls was reported.[11]

Discussion

In our review, we aimed to identify the effectiveness of falls prevention education as a stand-alone intervention on the practice of its prevention behavior among older adults. We found that falls prevention education has been used as a single intervention, delivered using several method and was effective in promoting at least one falls prevention behavior among older adults.

The results of our review demonstrated that face-to-face session was the most preferable mode of delivery for falls prevention education. The possible reason for this preference may be due to the report that such method leads to a larger positive effects.[13] Mostly,

falls prevention education was conducted via one to one education session with group education method used only in one study by Jang & Lee (2015).[8] Falls among older adults could be due to multiple risk factors and may be different in individuals. Hence using individually tailored method may be more effective in addressing the specific risk in individuals.[9,15]

Our review results suggested that there is no difference in the contents for falls prevention education based on settings of the study. Generally, falls prevention education components that were delivered focused on falls consequences, risks, and its prevention strategies such as regular exercise, periodic eye examination, safe drug use, environmental changes and protective behavior development. This is in line with the updated falls prevention guidelines by National Institute for Health and Clinical Excellence (2015, updated 2017). Recent emphasis has been on early falls risk identification using multifactorial assessment identification among older adults with risk of falls. Suggested multifactorial assessment includes: (1) falls history; (2) balance, gait, mobility and muscle weakness; (3) risk of osteoporosis; (4) perceived functional ability and fear of falling; (5) visual impairment; (6) cognitive and neurological impairment; (7) urinary incontinence; (8) home environment and; (9) medication review.

In regard to the method used for falls prevention education, video (DVD), written information and posters were mostly used. However, video educational delivery method was most preferred by older adults due to its attention grabbing aspects, ability to relate and engage multiple senses.[16] Our results showed that the outcomes were not influenced by the method used to provide falls prevention education. In most studies, these method were used in combination. Similar method were utilized to engage participants below age 60 in falls prevention practice.[17] Up to date, there were no falls prevention education delivered via web based method. It is noteworthy that web-based education has been demonstrated to improve awareness of physical activity among older adults.[18]

Facilitating positive effects on practice of falls prevention behavior through related educational intervention has been explained using health belief model (HBM).[19] Summarized findings from a previous review[20] suggested that falls prevention education may have a positive effect across a range of outcomes, but the findings focused primarily on falls rate, number of injurious falls, perception of falls risk, knowledge and self-efficacy. Despite consistent positive outcomes, the measures were neither uniform nor clear.

One of our study limitation is that by including falls prevention education as a single intervention, there were limited studies which fulfilled this inclusion criteria. Although the general is ability of our review findings may be limited, it provided information if falls prevention education could be used as a single intervention. This method may be more cost effective in addressing falls prevention as an early health promotion and prevention strategy among community dwelling older adults.

Our review has highlighted the need for developing and implementing generic falls prevention education programs and standardized outcomes measures in future research. The results of our review indicate that falls prevention education as a single intervention is effective in facilitating the practice and engagement of falls prevention behaviors among older adults. To determine futuristic best practice in engaging the community in the prevention of falls among older adults, it is important to determine the effectiveness of using mobile health falls prevention education and periodic falls risk screening or assessment.

Chipping Resistance of Nanosilica Treated Zirconia Cores Veneerd with Porcelain after Thermocycling and Cycling Loading

Hanaa F Mahmoud[1], Yaser F Gomaa[2], A Nour A Habib[3]

[1]Assistant lecturer of Dental Material, Biomaterials Department, Faculty of Dentistry, Minia University, [2]Professor of Dental Materials, Head of Biomaterials Department and Dean of Faculty of Dentistry, Minia University, [3]Professor of Dental Materials, Cairo University

Abstract

Aim: This study was conducted to evaluate the effect of nanosilia surface coating of pre-sintered zirconia on chipping of veneered zirconia crowns after thermocycling and cyclic loading.

Method: Twenty zirconia cores were subjected to nanosilica slurry treatment before sintering then veneered and fired to produce crowns. The crowns ere cemented by resin cement on their epoxy dies and 10 crowns were subjected to 10000 thermocycles and 10000 cyclic loading. All crowns were loaded till chipping of veneer layer then the chipped surfaces were examined by SEM/EDX.

Results: Crowns which were subjected to thermocycling and cyclic loading gave lower chipping resistance than the non-aged crowns.

Conclusions: Treatment of zirconia cores with nanosilica before sintering and after thermal and mechanical aging didn't increase the chipping resistance of the veneer layer.

Keywords: *Nanosilica, Zirconia,Chipping,Veneer.*

Introduction

Yttria-stabilized tetragonal zirconia polycrystal (Y-TZP) became the most ceramic material used for production of fixed partial dentures. The successful outcome of Y-TZP has been associated with the intrinsic material toughening mechanism that occurs through phase transformation from tetragonal to monoclinic crystalline form[1,2].

Due to the relative opacity, zirconia substructure needs to be veneered for better esthetic performance. Veneering porcelains are used to coat the surface of zirconia to enhance the natural appearance of prosthesis. Porcelain-veneered zirconia restorations are subjected to failure by the fracture of the veneering layers which dominant clinically observed failure mode and it iscalled chipping[3].

Studies proved that nano silica had performed greatly in many branches of dentistry[4,5]. Modifying zirconia surface in its pre-sintered stage is an effective technique to change the properties of zirconia based dental restorations[6].

Many previous studies documented that thermal and mechanical aging for the prediction of restorations durability is recommended as they simulate oral conditions in thermal and mechanical fluctuations with less period of time and they have great effect on the chipping resistance[2,7,8].

Hypothesis: The treatment of zirconia core surface with nanosilica before sintering may increase the chipping resistance of the veneer layer.

Aim of the study: To evaluate the effect of nanosilia surface coating of pre-sintered zirconia on chipping of veneered zirconia crowns after thermocycling and cyclic loading.

Method

A model acrylic tooth (Typodont, Columbia) simulating mandibular first molar was prepared after imbedding vertically in a cylindrical Teflon mold with self-cured acrylic resin (Trayresin™, Dentsply sirona, USA) to obtain a full anatomy ceramic crown preparation having the dimensions of 1.5mm Axial walls reduction, 2mm occlusal surface reduction and 1mm gingival margins reduction using a high speed hand piece (NSK, Tokyo, Japan), size 010,012 tapered diamond stones with flat end and size 012 flame shaped stone (Dentsply, sirona, UK). The angle of convergence was 6°-8° and all line angles were rounded to prevent stress concentration.

Twenty silicon impressions (Speedex®, Coltène/ Whaledent AG Altstätten, Switzerland)were recorded for the prepared acrylic tooth by using double mix 2 steps technique (heavy and light). Impressions were poured by epoxy resin die material (Kemapoxy 150, CMB international, Egypt) and the resulted dies dimensions were measured by a digital caliper (APT, china). Dies with dimensions exceed the range of error ±0.1mm were discarded.

Each die was coated with a thin layer of optical reflection spray (Occlutec Spray, Renfert Dental Corp, USA) and optical impressions were recorded using a scanning machine (Ceramill map400, Amnn Girrbach, Austria). Twenty zirconia cores (Ceramill zirconia, Amnn Girrbach, Austria)were designed and milled by the aid of computerized milling machine (Ceramill map400, Amnn Girrbach, Austria) with a uniform thickness of 1mm and with cuspal inclination of 30°. Milled cores were air dried with oil free air for 1 minute.

Nanosilica slurry was prepared by mixing the nanosilica powder of average size 40 wt% (Jiangsu, Mainland, China) with ethyl alcohol (Elahram, Cairo, Egypt) by ratio 4:1 wt%. The slurry was applied to the outer surface of zirconia cores with porcelain brushes size 4 and 6 (Koli, Bredent, Germany).Surface treated zirconia cores were sintered in a sintering furnace (Ceramill therm, Amnn Girrbach, Austria) following the manufacturer instructions.

A full-contour wax pattern with cuspal inclination 30° was built up onto one of the copings to mimic the final veneer layer dimensions; silicon impression was recorded for the pattern. This silicon key provided a uniform thickness and shape of the veneer layer for all specimens. Veneering porcelain (GC® Initial, Illinois, America) was sequentially built up by the same technician following the manufacturer's instructions with the help of the silicon key, followed by firing according to manufacturer instructions. The thickness of the crowns was measured with a digital caliper to ensure uniformity among all specimens.

Fired crowns were cemented to their corresponding dies using resin cement (Rely™ x ultimate 3M Deutschland, Germany). The cement was mixed and applied to the fitting surface of the crowns according to manufacturer instructions. The crowns were seated firmly and 1kg weight was applied to the occlusal surface for 3minutes to ensure equal pressure for cementation of all specimens. That was followed by light curing (LED blue phase, Ivoclar Vivadent, Germany) from each side for 10 seconds. The specimens were left undisturbed for 15 minutes and were stored in distilled water for 24 hours.

The specimens were divided into 2 groups (n=10). Group I was the control and group II was subjected to thermocycling and cyclic loading before chipping resistance test. Thermocycling was done in thermocycling machine (Robota automated thermal cycle; Bilge, Turkey). Thermocycling was performed for 10000 cycles intermittently with a 300 cycles per day in a water bath; dwell times were 25 seconds in low temperature point of 5C° and the high temperature point was 55 C° with the lag time of 10 seconds.

The thermocycled crowns were stored in distilled water for 24 hours and then they were transferred to chewing simulator (Robota, ad-tech technology, Germany) to receive 10000 successive compression loads with 200N. All specimens were stored in distilled water for 24 hours.

For chipping resistance test each cemented crown was fixed in the lower jaw of the universal testing machine (Instron, 3345L8741, Assembled Canton, USA). Compressive loadwas applied directly to the central fossa of crowns by a steel ball (5mm in diameter) with rate of loading 0.5mm/min. A piece of polyethylene sheet was placed between the ball and the crown in order to properly distribute the load.

The area of loading was calculated by the help of articulating paper (Zogear, China) to determine the points of loading between cusps and the steel ball. As the cuspal inclinations were tangential to the steel ball in certain points so the line between two opposing points

is the diameter of the formed circle. 3D CAD design software (Solid works 2015)[9] was used to help in drawing the circle and calculating the area (Figure 1,2,3); so by knowing the diameter of the drown circle; the area could be calculated through the following equation:

$$A = \pi r^2$$

Load was applied until chipping of the veneer layer took place. The load at chipping for each specimen was recorded and the compressive chipping stresses were calculated using the following equation:

$$\text{Chipping stress (MPa)} = \frac{\text{Load at chipping (N)}}{\text{Stress area (mm}^2\text{)}}$$

Fractured surfaces were coated with gold by gold sputtering machine (JEOL, JFC-1100E, Fine coat, USA.) then examined by scanning electron microscope (SEM) (JSM-IT200, JEOL ltd, Tokyo, Japan) and elemental analysis was performed by using energy dispersive x ray spectroscopy (EDX) in order to reveal the presence or absence of silica and its percentage.

Results

I. Chipping Resistance: There was a significant difference between both groups in chipping resistance (p value was<0.05). Group I showed higher mean of chipping load which was 1300.404±340.361N with chipping stress of 413.877MPa. Group II mean of chipping load was 820.913±396.200N with chipping stress of 261.270MPa.

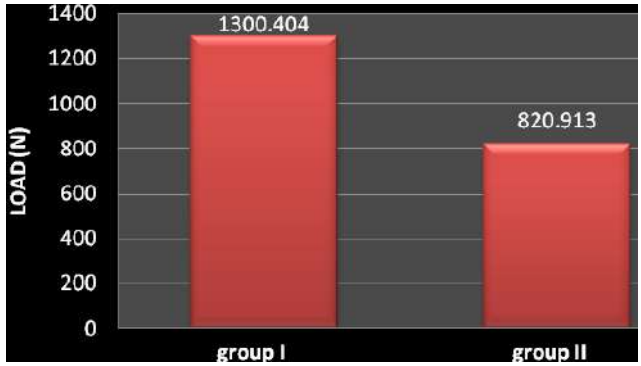

Fig. 2: Means of load at chipping of both groups.

II. SEM and EDX Results: Scanning electron microscope examination and EDX analysis showed that the mode of failurewas mainly mixed (70% of specimens)in group I in which there was areas of zirconia not covered with nanosilica in EDX analysis. The failure was mainly adhesive (70% of specimens) in group II in which the zirconia surface was completely covered withnanosilica revealing that the fracture was between nanosilica layer and veneer layer (Figure 3, 4).

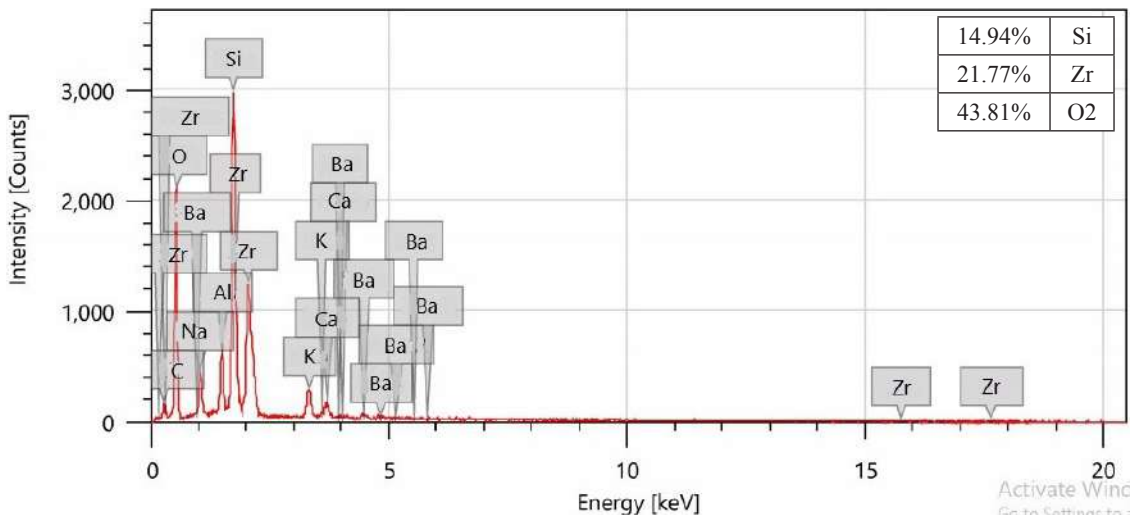

Fig. 3: EDX analysis of zirconia surface of group I(Mixed mode of failure).

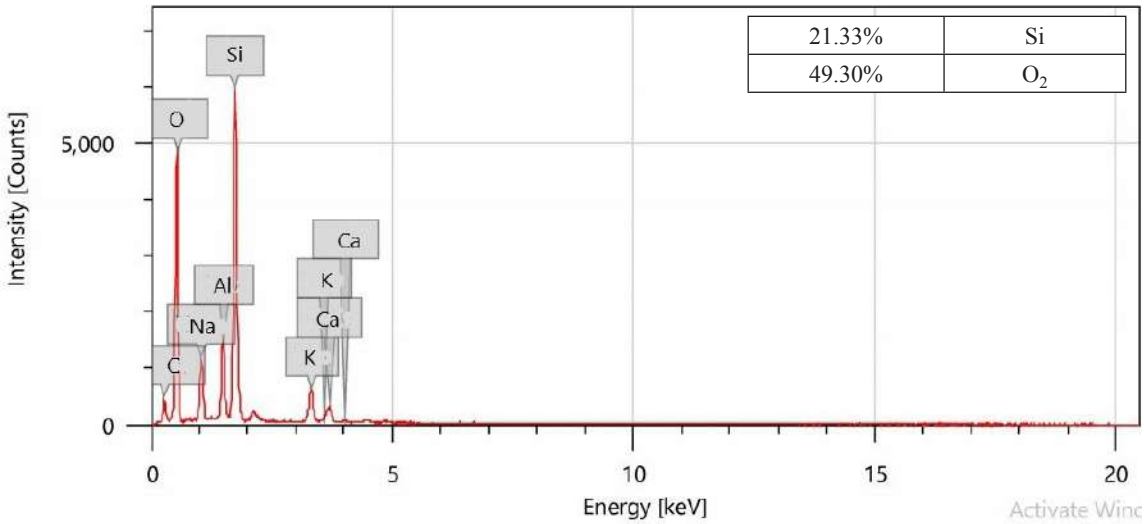

Fig. 4: EDX analysis of zirconia surface of group II (adhesive mode of failure).

Scanning electron micrographs of chipped zirconia showed areas of detachment in the mixed mode of failure and empty holes on the chipped veneers surface. In the adhesive mode of failure there were no empty holes (Figure 5).

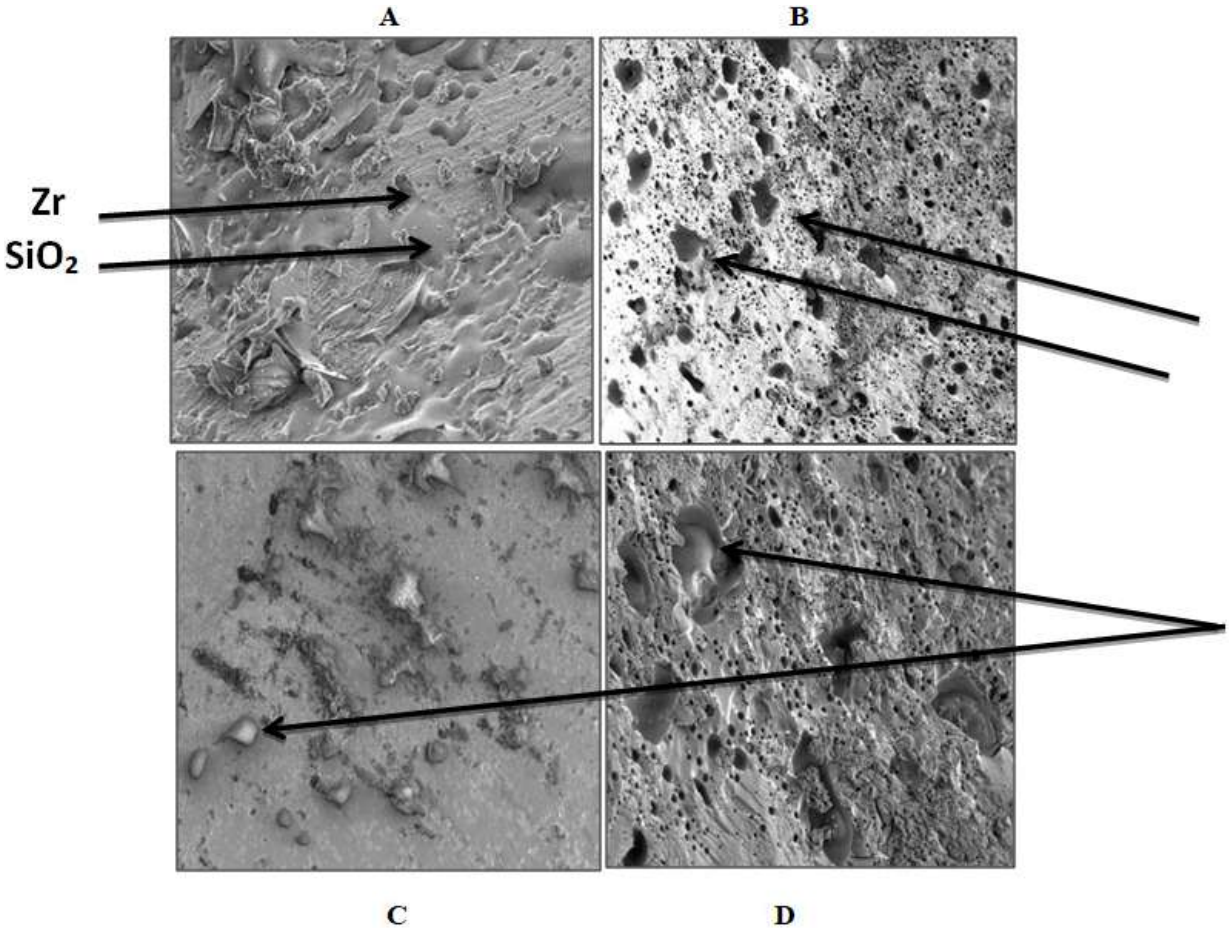

Fig. 5: SEM (800X) micrographs show the surface topography of zirconia core of group I (A); arrows refer to elevations. The opposing porcelain veneer surface of the same sample (B) after chipping; arrows refer to empty holes (Mixed mode of failure). The surface topography of zirconia core of group II (C) and the opposing porcelain veneer surface of the same sample (D) after chipping; arrows refer to silica rich areas (adhesive mode of failure)

Discussion

The incidence of veneering porcelain fracture when a zirconia core is used became a major complication that has been reported in the dental literatures. The cause of veneer chipping is complex material factors, including differences in coefficient of thermal expansion between veneer and core, likely create residual stresses which enhance veneer chipping[10-12].Evaluation and comparing chipping resistance of veneered zirconia crowns had been conducted in several previous studies[2,10].

This study was conducted to evaluate the chipping resistance of nanosilica treated zirconia-porcelain interface after thermocycling and cycling loading.

According to ISO 11405, the use of 500 thermal cycles between 5°C and 55°C is considered to be suitable to simulate short-term aging of dental materials[13]. In addition, *Gale and Darvell*[14] supposed that 10,000 cycles might represent approximately 1 year of *in vivo* functioning, with 20 to 50 cycles considered equivalent to a single day.

There is a large variation between number of cycles and the vertical loading applied in aging studies in the literature. Combining both thermocycling and cyclic loading is more clinically relevant protocol and might give prediction of longer time service[2,15,16].

The resulted load which cause chipping of veneers of group I was comparable to the results of previous studies with slight non-significant difference. This may be attributed to different techniques of veneering, different core design or thickness and different testing methodology[17-19].

Group II showed lower chipping resistance than previous studies; however it is important to consider that both groups showed higher loads than the maximum chewing forces reported in literature of previous studies. Studied showed that the average maximum biting force of healthy and young adults is approximately from 400 -700N[20,21]. Therefore, the results indicated that the load at chipping of both tested groups in this study may withstand the clinical services without failure.

Mode of failure in group II was mainly adhesive failure between silica and veneer. As stated by many researchers[22-24]that chipping mainly occurred due to difference in coefficient of thermal expansion which lead to unfavorable thermal stresses at the interface between silica and porcelain veneer layer. However, the SEM and the EDX results indicate the strong bond between the silica coat and zirconia.

The difference in coefficient of thermal expansion between silica and porcelain may be the cause of veneer chipping and lower chipping resistance than the control. This may draw a tension to the possibility of using a veneering ceramic compatible with the nanosilica coat.

Conclusions

Within the limitations of this study it was concluded that:

1. The treatment of pre-sintered of zirconia cores with nanosilica before sintering without aging lead to high chipping resistance.
2. Aging decreased this resistance to chipping but it is still within acceptable limits of human maximum biting force.

Recommendation:

1. Nanosilica layer thickness, particle size and shape play great role and should be subjected for further research.
2. The results of this study did not support the hypothesis but revealed that surface treatment of pre-sintered zirconia with nanosilica is a potential cause increasing chipping resistance if the composition of the veneering ceramics is modified to be compatible with the coefficient of thermal expansion of the nanosilica.

Assessment of Fracture Force of CAD-CAM-fabricated Occlusal Veneer Restorations with Different Thicknesses

Hanaa Saber Rabeae[1], Cherif Adel Mohsen[2], Shams Waaz Amgad[3]

[1]Assistant Lecturer, [2]Professor and Chairman, [3]Lecturer, Fixed Prosthodontics Department, Faculty of Dentistry, Minia University, Minia, Egypt

Abstract

Purpose: To evaluate the fracture force of occlusal veneer restorations using ceramic material (Lithium di-silicate) and hybrid ceramic (VITA Enamic) Computer Aided Desingn/Computer Aided Manufacturer (CAD/CAM) material at different thicknesses after thermocycling.

Material and method. Thirty CAD/CAM occlusal veneer restorations were fabricated from group E (IPS e.max CAD), V (VITA Enamic) and divided into subgroups according to thickness 0.3, 0.6, 1 mm. The occlusal veneers were luted to epoxy dies (n=5). The specimens were subjected to thermocycling test then they were subjected to load until fracture using a computer controlled materials testing machine. Data were tabulated and statistically analyzed using Two-ways analysis of variance (ANOVA).

Results: There was no significant difference in the fracture force between the two materials regardless the thickness. The fracture force increases with the increase of the thickness.

Conclusion: VITA Enamic hybrid ceramic material is closer to IPS e.max CAD ceramic material in the fracture force. With the increase of thickness, it leads to increase of fracture force.

Clinical Implication: Within the limitation of this in-vitro study, hybrid ceramic (VITA ENAMIC) and IPS e.max CAD are clinically applicable as occlusal veneer restoration with thickness 0.6 mm and more.

Keywords: *Hybrid ceramics, Fracture force, CAD/CAM.*

Introduction

Ceramics are the materials of choice as long term functional indirect restorations, due to their properties esthetic, biocompatibility and high strength. Nowadays dental technologies such as CAD/CAM are in continuous evolution offering both, the dentist and the patient. All ceramic restorations are cemented by using resin cement as they provide low solubility and they have high bond strength and better esthetic. Due to high bond strength of resin to tooth structure and complicated bonding between ceramic and tooth structure, resin was added to ceramic material to make a new compound structure called hybrid ceramics. Resin bonding is required for clinical success of indirect restorations at long time. With the use of CAD/CAM indirect restorations, there is a need for successful bonding for new hybrid ceramic materials.[16] All ceramic materials are superior to composite in its physical and mechanical properties. The hypothesis of this study, that there is a significant difference between all ceramic and hybrid ceramic occlusal veneer restorations; the fracture force of all ceramic is better than hybrid ceramic.

Materials and Method

The materials were used are: IPS e.max CAD ceramic blocks; low translucency, shade A2 and size C14 (Ivoclar Vivadent/Italy), VITA ENAMIC Innovative ceramic blocks; low translucency, shade 2M2 and size C14 (VITA Zahnfabrik spitalgasse3 D-79713 Bad Säckingen Germany),and RelyX™ Ultimate adhesive dual cured resin cement (3MESPE, Seefled, Germany).

Sample Size Calculation for fracture force test: A sample size of 15 samples in each group was determined to provide 80% power for independent samples T test at the level of 0.05 significance using G Power 3.19.2

software. So we made our study on 15 samples for each material (5 samples for each thickness). (Figure 1)

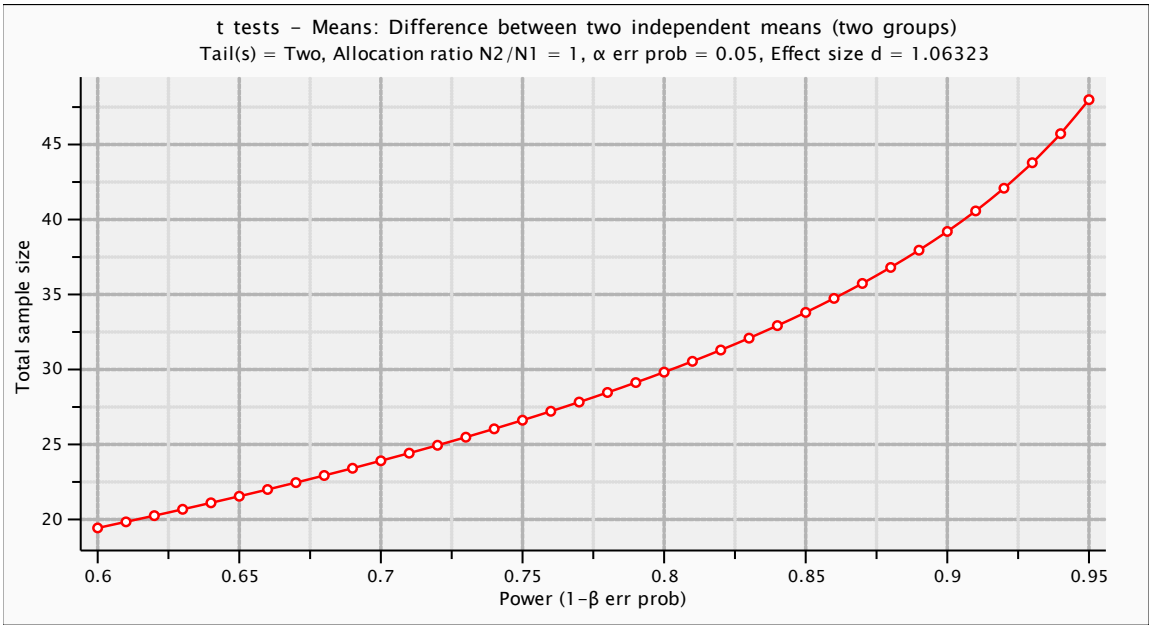

Figure (1)

Maxillary molar teeth with occlusal dimension average size (6mm x 5mm) were collected from the outpatient clinics of faculty of Dentistry Minia University. Teeth were freshly extracted, free from caries, restorations and fracture. The teeth were ultrasonically cleaned (Coltene Whaledent, Biosonic UC50 Ultrasonic, USA)of any surface debris then they were ready for use for samples construction.

Proper powder/liquid ratio of self-curing acrylic resin (cold cure acrylic resin, Acrostone, Egypt) was mixed according to the manufacturer's instructions. As it reached the dough stage, it was poured into customade split Teflon mold with (2.5cm diameter x 2.5cm height). The roots of the tooth were inserted into the center of the mold till 2 mm apical to the cement enamel junction. With the use of customade paralleling device (Egypt), to centralize the tooth in the mold. The excess of the acrylic resin was rapidly removed with metallic wax carver (Miltex. Stainless steel. pakistan**).** After complete polymerization of acrylic resin, the split Teflon mold was removed. The samples were subjected to uniform occlusal reduction with diamond cutting tools (Komet Dental. Gabr. B raseler GmbH & Co.KG Trophagener Weg 25.32657 Lemgo. Germany.) to produce a uniform preparation. Before preparation, condensation silicone rubber base (Speedix putty Ivoclar Vivadent, Liechtenstein) indices were made for tooth to aid in standardization of preparation thickness Silicone indices made by hand mixing of putty paste with catalyst according to manufacturer's instructions and loaded into a custom made metallic perforated tray. After impression setting, the index was removed[12].

The molar teeth were prepared manually using diamond cutting stones size 14 with high speed handpiece (W & H Dental Work, Burmoos, Austria) under water cooling. The occlusal surface reduction was 0.3 & 0.6 & 1.0 mm at the central fossa[19].

The preparations resulted were flat occlusal reduction without finish line (butt joint preparation). The three different preparation thicknesses were checked using a digital caliper (Miltex, stainless steel, Pakistan) with the silicon guide on the preparation**.**Epoxy resin dies construction; by the use of custom made perforated tray that has an internal diameter of 20 mm and 25 mm height[24].

Thirty impressions of prepared teeth were made using condensation silicone rubber base impression material (Speedix, Ivoclar VivaDent, Liechtenstein) by hand mixing according to manufacturer's instrucitons. The impression was loaded into the tray, prepared tooth was embedded in the impression and after setting the tooth was removed. The impression was poured by epoxy resin (kemapoxy 150, CMB, Egypt). The method

was repeated to create sixty epoxy dies. One size of epoxy paste and 1.5 size of activator were mixed under vibration (Vibromaster Bego Bremer, GmBA, Germany) for two minutes then it was leaved ten minutes before pouring to become homogenous mixture. The mixture was poured into the impression and leaved to set for 48 hours in order to reach complete setting and dimensional stability. The dies were removed from impressions, then was finished by low speed straight hand piece (Sirona Dental systems GmbH Fabrikstra Be 31 64625 Benesheim Germany)and polished by pumice (Dental Lab Pumice, Dentsply, USA) with smooth electronic brush (Miltex. Stainless steel. Pakistan).

Occlusal surfaces were surface roughened by low speed wheel stone (Komet Dental. Gabr. B raseler GmbH & Co.KG Trophagener Weg 25.32657 Lemgo. Germany) and it was ready for occlusal veneers construction (figure2).

Figure (2): Epoxy die

Designing, milling and crystallization of occlusal veneers;all occlusal veneers (IPS e.max CAD & VITA ENAMIC) were fabricated according to the direction of manufacturing companies for each fabrication system. Epoxy dies were scanned sequentially with camera system without powder (Cerec Omnicam 4.4.4 by Dentsply Sirona).Designing of all occlusal veneers were carried out using a standard protocol, on the computer software.

The thickness of occlusal veneers was 0.3 mm, 0.6 mm and 1.0 mm.

The integrity of the structure was visually checked before crystallization. The IPS e.max ceramic occlusal veneers were placed into the oven (programat P310 by ivoclar vivadent) for crystallization. At the end, the veneers were removed from the oven when it reached at room temperature. (Figure 3)

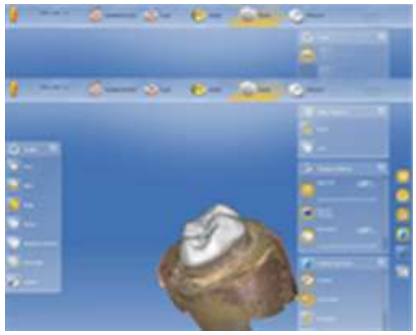

Figure (3) Visual veneer in position

Cementation of the occlusal veneers to the corresponding epoxy resin dies; occlusal veneers were etched using hydrofluoric acid gel 9.5% (*BISCO-Schaumburg U.S.A*) for 60 seconds, for VITA ENAMIC and 90 seconds, for IPS e.max CAD according to manufacturer instructions. After etching, the veneers were washed with water and dried using air spray (dental chair Roson. China). Then, veneers were brushed by silane coupling agent (BISCO-Schaumburg U.S.A) and wait for 30 seconds then it was dried with air syringe according to manufacturer instructions. Epoxy dies were left clean dry; bonding agent (Adper Single Bond 3M ESPE U.S.A) was brushed to the epoxy dies and light cured (Denjoy, China) for 20 seconds.

RelyX-Ultimate dual cured resin cement clicker was used. One click applied on the veneer and applied on the die and loaded by the loading device 6 N load □[9]□

Under load, the excess was removed then curing of the samples for 40 seconds.

After complete cementation of all occlusal veneers, the samples were ready for the tests. (Figure 4)

Figure (4) sample after cementation

Thermocycling procedures :- In this study the number of cycles used was 1000 cycles representing nearly 2years clinically. Dwell times were 25s in each water bath (Robota automated thermal cycle; BILGE, Turkey) with a lag time 10s. The low-temperature point was 5°C. The high temperature point was 55°C.

Fracture Force Test: According to manufacturer instructions,samples were secured to the lower fixed compartment of testing machine by tightening screws. Fracture test was done by compressive mode of load applied occlusally using a metallic rod with spherical tip (5.6 mm diameter) attached to the upper movable compartment of testing machine (Model 3345; Instron Industrial Product, Norwood, MA, USA) travelling at cross-head speed of 1mm/min. The load at failure manifested by an audible crack and confirmed by a sharp drop at load-deflection curve recorded using computer software (Bluehill Lite Software Instron Instruments). The load required to fracture was recorded in Newton.

Results

There was no significant difference in the fracture force between the two materials regardless the thickness. There was significant diffirence between different thicknesses regardless the material type. There was no significant difference between the two materials at thickness of 0.3mm. In the group with 0.6 and 1mm mm thicknesses, there was a significant difference and IPSe.max CAD had higher strength than VITA Enamic. The fracture strength increases with the increase of the thickness in both materials.

1. Fracture force measurement:

Table 1: Effect of material, thickness and interaction between both on Fracture force

Fracture Force	F	P Value
Material	12.89	0.001*
Thickness	92.98	<0.001*
Material * Thickness	1.49	0.245

Two-ways-ANOVA test, *: Significant level at P value < 0.05

Table 2: Comparison of fracture force between the two materials regardless the thickness

		Material		P value
		E-max	Vita Enamic	
		N=15	N=15	
Fracture force	Range	(632.5-2310)	(547.3-1723)	0.272
	Mean ± SD	1329.5±552.9	1096.5±418.3	
	Median	1292.5	1049	

Mann Whitney test for non-parametric quantitative data (expressed as median) between the two groups, Significant level at P value < 0.05

Table 3: Comparison of fracture force between the different thicknesses regardless the Material type

		Thickness			P value
		0.3 mm	0.6 mm	1 mm	
		N=10	N=10	N=10	
Fracture force	Range	(547.3-846)c	(820-1393.8)b	(1410-2310)a	<0.001*
	Mean ± SD	706.5±93.3	1147.8±188.1	1784.8±309.7	

One-way ANOVA test for parametric quantitative data between the three groups followed by post hoc analysis between each two groups, Superscripts with different small letters refer to a significant difference between each two groups, *: Significant level at P value < 0.05

Discussion

Egbert J S, et al (2015) stated that in case of patient with severly worn dentition, CAD/CAM occlusal veneer restoration made of hybrid ceramic is an alternative to full coverage restorations. The failure load of teeth restored with full coverage with 1.5- 2.00 mm was to be 771-1183 N[3], that is lower than this study (1727-2415). This fracture strength was reported to be higher than human masticatory forces (585-880) **Kikuchi M et al, 1997.**

In accordance to **Chen C, et al (2014)**reported that with increase the thickness of IPS e.max CAD, the fracture resistance increased. There is no change between 0.5 mm and 1.5 mm thickness but sharp increase occurred at

2.0 mm. Tha normal occlusal load is 100 N-200 N in the molar area and 965 in accidental bite. 1000 N is required for clinical longivety. This requirement was achieved in the test specimens of Chen et al, 2014 and also at 0.5 mmor 1.0 mm thickness.[4 & 5 & 6].

Stawarczyk B et al (2016)reported that the fatigue resistance of occlusal veneers was increased by CAD/CAM composite in comparison with lithium disilicate ceramics (schlichting et al., 2011). Results of their study (stawarczyk) CAD/CAM revealed higher flexural strength than VITA Enamic, but lower than lithium disilicte ceramic.

Hamburger J T, et al (2014): Using a total-etch adhesive system improved the resistance to fracture[7]. Normal occlusal forces are 50-300 N and reaches to 1200 N in case of clenching[8]. E.max CAD showed minimal occlusal thickness 1.5 mm. In the study of **Hamburger J T, et al;** Direct composite restorations give good properties at high occlusal load.

The hypothesis of this study was partially rejected that there was no significant difference between IPS e.max and VITA Enamic materials in fracture force test but there was a significant difference between the two materials at 0.6 mm thickness.

Conclusion

Within the limitation of this study:

1. IPS e.max CAD and VITA Enamic are clinically applicable for occlusal veneer restorations and they are closer to each other in the fracture force.
2. Thickness has great effect on the restoration force, as with increase of the thickness the force increases.
3. Thin thickness as 0.3 has questionable survival in the oral environment. In case of patients with bruxism, it is advised to use restoration thickness not less than 0.5 mm.
4. Occlusal veneer restorations are advised to be used as a conservative approach and accepted force.

Abstract

Objective: To conduct a comparative analysis of the dynamics of changes in the willingness-to-pay (WTP) indicators concerning introduction of the innovative technology in the healthcare systems of the post-Soviet countries.

Materials and Method: The studies used the "Willingness-to-pay" calculation method proposed by the WHO Commission on Health Macroeconomics and Economics. Calculation of willingness-to-pay indicators in the reference countries was carried out on the basis of the purchasing power parity (PPP) of the population.

Results: In the group of reference countries a wide range of average values of the willingness-to-pay indicators was characteristic. Thus, it ranged from 7,7 USD Thousand in Tajikistan to до 72,54 USD Thousand in Russia. The systematic growth rate of the willingness-to-pay indicators was observed in 5 out of 12 reference countries (Armenia, Georgia, Kyrgyzstan, Turkmenistan, and Uzbekistan). Most countries, namely 8 out of 12, can be attributed to the group of countries with the average (from 25,0 to 50,0 USD Thousand) and low (up to 25,0 USD Thousand) WTP values. It significantly reduces the potential of national healthcare systems in introducing innovative technologies in practical medicine. The fact that in all countries the average growth rate is positive (from 101.0% in Belarus to 109.0% in Turkmenistan) is promising.

Conclusion: As a result of the research significant differences in the willingness-to-pay indicators in the reference countries have been found. This problem requires a systematic solution in the post-Soviet countries, primarily in order to increase the availability of innovative drugs for socially disadvantaged groups of patients.

Keywords: *Innovative drug, innovative health technology, health technology assessment, pharmaceutical provision of the population, willingness-to-pay indicator.*

Introduction

The active development of innovative approaches in elaboration and promotion of new advanced drugs to the pharmaceutical market significantly expand the current opportunities for the treatment of many diseases that have long been considered incurable.[1-3] Currently it is difficult to imagine at least one area of medicine, which would not use high-tech innovative drugs.[4-5] It is difficult

to overestimate the modern role of innovative drugs in the pharmacotherapy of cancer pathologies, orphan diseases, etc.[6-8] On the way of active implementation of innovative health technologies, which include the use of pharmacotherapy regimens with high-cost innovative drugs, in practical medicine many national healthcare systems are faced with the problem of resource shortage for their use.[5,8-10] The application of direct method of price regulation for innovative drugs do not always allow to achieve the desired result, i.e. to increase the availability of using these drugs.[11-12] Implementation of Health Technology Assessment (HTA) methodology allows us to effectively assess the resource potential of national healthcare systems for the introduction of innovative technologies.[13-15] HTA uses a range of tools, among them determination of the willingness-to-pay indicator (willingness-to-pay analysis – WTP) of the state and society as a whole for the use of innovative drugs in various fields of practical medicine is becoming increasingly important.[16-18] This indicator was first determined in the 80s of the last century in the United States and Canada (Kaplan RM, Bush JW).[19] The indicator determines all costs of the society in monetary form in preservation of one year of additional quality life (quality adjusted life years – QALY) of a patient with renal insufficiency who is on hemodialysis.[19-20] The determination and use of the WTP indicator analysis data is of particular relevance for countries that are at the stages of reforming national healthcare systems in the direction of constructing rational models of public service.[21-24] Countries of the former Soviet Union with full responsibility can be attributed to such countries.[21] The aforesaid facts determined the aim of our research, namely to perform a comparative analysis of the dynamics of changes in the WTP indicators in the post-Soviet countries.

Materials and Method

The object of our research was the data of the World Bank for Reconstruction and Development reflecting the main macroeconomic and demographic indicators of the post-Soviet countries for 2010-2017. In addition, the data presented on the official websites of the relevant ministries and departments of the reference countries were used. When determining WTP the method proposed by the WHO Commission on Health Macroeconomics and Economics was used.[15,21,25] This method is recommended for macroeconomic calculations and the appropriate analysis of the WTP indicators.[15,16,21] Thus, to determine the WTP indicator the country's GDP data calculated per capita and multiplied by three are used. This method has a number of limitations within the application of a particular health technology.[15,16.21,25] However, the relative simplicity of this method allows it to be used for the preliminary analysis of the resource potential of the society for the introduction of innovative medical technologies, including in developing countries.[15,16.21,26] The GDP data calculated by the Purchasing Power Parity (PPP) indicator expressed in international dollars were used in the studies.[27,28] Intermediate indicators for the WTP calculation are presented in Table 1.

Table 1: The GDP per capita calculated by the Purchasing Power Parity indicator of the population for 2010-2017

Country	2010	2011	2012	2013	2014	2015	2016	2017	Average Value
GDP Calculated by PPP, USD Thousand									
Azerbaijan	15,63	15,75	16,18	17,17	17,61	17,82	17,28	17,53	16,87
Armenia	6,57	7,02	7,65	8,00	8,40	8,74	8,85	9,48	8,09
Belarus	15,91	17,17	17,80	18,27	18,90	18,38	18,09	17,84	17,80
Georgia	6,60	7,32	8,03	8,54	9,22	9,63	10,02	10,74	8,76
Kazakhstan	19,69	21,28	22,39	23,77	24,85	25,10	25,33	24,40	23,35
Kyrgyzstan	2,73	2,92	2,92	3,23	3,35	3,45	3,56	3,70	3,22
Moldova	3,83	4,18	4,23	4,70	5,02	5,06	5,34	5,19	4,70
Russian Federation	20,50	24,07	25,32	25,48	25,47	23,70	23,16	25,74	24,18
Tajikistan	2,06	2,21	2,37	2,53	2,68	2,82	2,99	2,88	2,57
Turkmenistan	9,74	11,21	12,47	13,72	15,14	16,00	16,94	18,16	14,17
Uzbekistan	4,15	4,47	4,85	5,24	5,66	6,08	6,53	6,72	5,46
Ukraine	7,67	8,28	8,48	8,63	8,68	7,95	8,27	8,75	8,34

Such research method as historical, system, logical, comparative, graphic, mathematical and statistical, content analysis, as well as method of logical modeling were used. Both a comparative analysis of the average values of WTP calculated by PPP in the reference countries, and the analysis of changes in the WTP indicators in the dynamics of years (2010-2017) were conducted. In the analysis of the dynamics of indicators the chain growth and the growth rate (%) of indicators, as well as the chain coefficients (k) of the growth/decline rate, were applied. In the analysis all reference countries were divided by the average WTP indicators into three groups with equal value intervals. The first group of countries "A" included countries with an average value of the WTP indicator from 50,0 to 75,0 USD Thousand. The second group "B" were countries with the WTP indicator, which ranged from 25,0 to 50,0 USD Thousand, and the third group "C" – below 25,0 USD Thousand. The statistical data processing was carried out using the statistical package StatSoft. Inc. (2014), STATISTICA version 12.0 and Excel spreadsheet. After the preliminary assessment of the data all indicators were imported into a Statistica 6.0 standard program for the applied statistical analysis. The p-value <0.05 was considered statistically significant.

Results And Discussion

Our studies demonstrated the following results. In the post-Soviet space, the WTP indicator calculated by PPP for 2010-2017 fluctuated in a wide range of values. Thus, the minimum value was typical in Tajikistan in 2010 (6,19 USD Thousand), and the maximum in Russia in 2017 (77,22 USD Thousand) (Tab. 2). The most important positive characteristic of the dynamics of the WTP indicators for countries was its systematic increase in most countries. Thus, the annual increase with different growth rates was typical for Armenia, Georgia, Kyrgyzstan, Turkmenistan and Uzbekistan. These countries showed a stable growth of the WTP indicator. In countries, such as Azerbaijan (2016), Kazakhstan (2017), Moldova (2017), Tajikistan (2017) and Ukraine (2015), the WTP reduction in relation to the data of the previous year was observed only once in a dynamics of indicators. In Russia, the WTP indicator was negative the growth dynamics in 2015 and 2016 compared to the data of the previous year, and in Belarus there was the negative dynamics for three consecutive years (from 2015 to 2017). Further, the average WTP indicators in the countries, as well as their average values of the chain growth rates during 2010-2017 were calculated. The results of the research are presented in Fig. 1 and 2. As can be seen, Russia is the undisputed leader by the WTP indicator, while the lowest value is observed in Tajikistan.

Table 2: Analysis of the dynamics of change in the WTP indicators calculated by PPP in the group of reference countries

Country	Unit of measurement	WPT and the growth rate within the research years							
		2010	2011	2012	2013	2014	2015	2016	2017
Azerbaijan	USD Thousand	46,86	47,25	48,54	51,51	52,83	53,46	51,84	52,59

	%	–	1.07	1.09	1.05	1.05	1.04	1.01	1.07
Belarus	USD Thousand	47,72	51,50	53,41	54,82	56,71	55,15	54,27	53,52
	%	–	1.08	1.04	1.03	1.03	0.97	0.98	0.97
Georgia	USD Thousand	19,80	21,95	24,08	25,63	27,65	28,89	30,07	32,22
	%	–	1.11	1.10	1.06	1.08	1.05	1.04	1.07
Kazakhstan	USD Thousand	59,07	63,83	67,18	71,32	74,53	75,29	76,00	73,20
	%	–	1.08	1.05	1.06	1.05	1.01	1.01	0.96
Kyrgyzstan	USD Thousand	8,20	8,76	8,77	9,69	10,05	10,36	10,67	11,1
	%	–	1.07	1.00	1.10	1.04	1.03	1.03	1.04
Moldova	USD Thousand	11,50	12,54	12,68	14,10	15,05	15,19	16,03	15,57
	%	–	1.09	1.01	1.11	1.07	1.01	1.06	0.97

Country	Unit of measurement	WPT and the growth rate within the research years							
		2010	2011	2012	2013	2014	2015	2016	2017
Russian Federation	USD Thousand	61,49	72,22	75,95	76,44	76,43	71,11	69,49	77,22
	%	–	1.18	1.05	1.01	1.00	0.93	0.98	1.11
Tajikistan	USD Thousand	6,19	6,64	7,10	7,58	8,05	8,45	8,96	8,64
	%	–	1.07	1.07	1.07	1.06	1.05	1.06	0.96
Turkmenistan	USD Thousand	29,22	33,63	37,41	41,16	45,42	48,00	50,82	54,48
	%	–	1.15	1.11	1.10	1.10	1.06	1.06	1.07
Uzbekistan	USD Thousand	12,46	13,41	14,56	15,73	16,97	18,25	19,58	20,16
	%	–	1.08	1.09	1.08	1.08	1.08	1.07	1.03
Ukraine	USD Thousand	23,00	24,85	25,43	25,89	26,05	23,84	24,82	26,25
	%	–	1.08	1.02	1.02	1.01	0.92	1.04	1.06

The WTP indicator variation range in the countries was 64.84 USD Thousand. Thus, in Tajikistan this figure was 8.5 times less than in Russia. The fact that in all CIS countries the average chain growth rate had only positive values is promising (Fig. 2). In ascending order of this indicator the countries were distribute as follows: Belarus; Ukraine and Azerbaijan; Kazakhstan; Russia and Kyrgyzstan; Moldova and Tajikistan; Armenia; Uzbekistan and Georgia; Turkmenistan. Therefore, the best indicators of the dynamics of growth rates were demonstrated by Turkmenistan, while Belarus had the worst indicators.

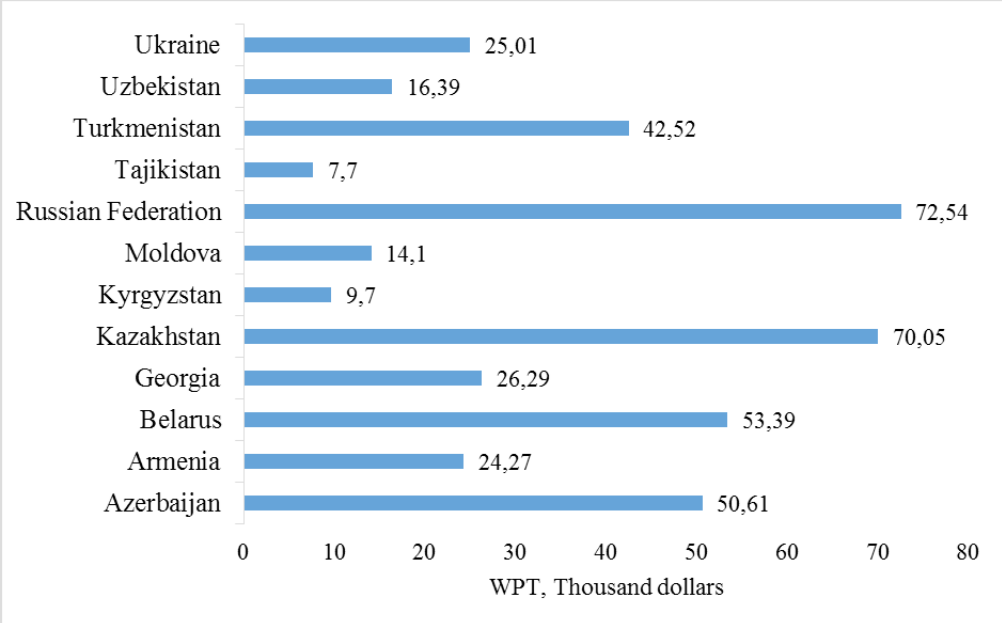

Fig. 1: Analysis of the average WTP indicators in post-Soviet states (within 2010-2017)

When dividing countries into groups by the average value of the WTP indicator the following results were obtained:

- 4 countries of group "A" – Russia, Kazakhstan, Azerbaijan, Belarus;
- 3 countries of group "B" – Turkmenistan, Georgia, Ukraine;
- 5 countries of group "C" – Armenia, Uzbekistan, Moldova, Kyrgyzstan and Tajikistan.

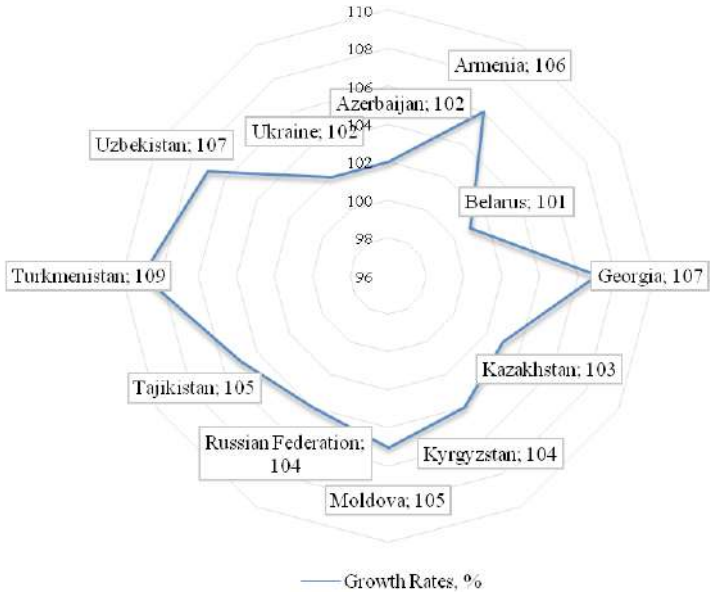

Fig. 2: Analysis of the average WTP indicators in post-Soviet states (within 2010-2017)

As can be seen, most reference countries, namely 8 out of 12, can be attributed to the group of countries with the average (from 25,0 to 50,0 USD Thousand) and low (up to 25,0 USD Thousand) WTP values. It significantly reduces the potential of national healthcare systems in introducing innovative technologies in practical medicine. Therefore, many expensive innovative drugs may remain inaccessible to different groups of patients in these countries in the near future.[21,29,30]

Conclusion

Systematizing data of the studies conducted the following conclusions can be made. Despite the historical commonality of the development of the reference countries that were part of the former USSR, as well as the active actions of the governments of these countries in the direction of reforming national healthcare systems, the availability of innovative technologies in practical medicine for many patients remains problematic. The solution of this problem is in the expansion of state guarantees for socially disadvantaged groups of patients against the background of the gradual introduction of new forms and method of financing of practical healthcare, for example, due to the implementation of complementary health insurance programs or microinsurance.

Molecular detection of *C5a* Peptidase (*scp*B) Gene in Group B Streptococcus Isolated from Pregnant Women and the Correspondence with Adverse Pregnancy Outcome

Hassan Saad Sakap[1], Jabbar S. Hassan[2], Sahar Hisham Abdul Razak[3]

[1]Medical Laboratory Techniques, [2]Medical Microbiology, College of Medicine, Al-Nahrain University, [3]Gynecology and Obstetrics, College of Medicine, Al-Nahrain University, Iraq

Abstract

Group B *Streptococcus* is Gram-positive cocci non motile encapsulated bacteria which produce an arrow zone of beta-hemolysis on blood agar. It belongs to Lancefield group B antigen. Group B *Streptococcus* is the mainly cause of neonate's invasive bacterial disease such as neonatal sepsis meningitis, septicemia and pneumonia. The study planned to evaluate the vaginal colonization rate of *Streptococcus agalactiae* and virulence genes in pregnant women with adverse pregnancy outcome. A cross-sectional study was designed included 200 pregnant women at 34–37 weeks of gestation. A total of two hundred vaginal swabs was taken from all pregnant women enrolled in this project by the gynecologist. GBS isolated bacteria was evaluated by means of using classical microbiological approach, after DNA extraction the isolated GBS strains were screened for the presence of *scpB* gene by polymerase chain reaction. Thirty-six (18%) out of 200 pregnant women enrolled in this project were positive for group B *Streptococcus* by culture method, the majority of them were from age ranged (18-36 years), 20 (20.6%) of them with a history of abortion, females with positive vaginal colonization indicated that they had a history of rupture membrane only in 10 (9.9%) with prolonged rupture membrane >18hr in 3 (30%).The specific PCR primer was used for the detection of *scpB* gene. It was found that *scpB* gene was observed in 17 (47%) isolate.It can be conclude that there is no statistical significance between repeated abortions with the presence of *scpB*gene as a virulence factor in GBS while there are statistically significant between the presences of these virulence gene with rupture membrane.

Keywords: *Group B streptococcus, Streptococcus agalactiae, Premature rupture of membrane (PROM), Maternal colonization.*

Introduction

Streptococcus agalactiae or group B streptococcus (GBS) are members of normal flora in human genitourinary and gastrointestinal systems. GBS is the main agent for serious infections such as meningitis in newborns, asymptomatic bacteriuria, urinary system infections, cystitis, pyelonephritis, chorioamnionitis, postpartum endometritis, pre and postpartum bacteremia, and post-cesarean wound infections in pregnant women[(1)]. The colonization of GBS in the urogenital or gastrointestinal system of the mother is the most important risk factor for the development of invasive newborn disease [(2)]. When no precaution is taken, early-onset GBS infections develop in 1–2% of the infants of women with GBS colonization, usually in the first days of life, which often progresses to fulminant disease. The majority of GBS infections are early-onset infections and can be prevented with intra-partum antibiotic prophylaxis [(3,4)].Revised CDC guidelines for the prevention of early-onset GBS disease (2010) recommend universal culture-based screening of all pregnant women at 35th and 37th weeks of pregnancy to identify those who should receive prophylactic intrapartum antibiotic treatment[(5)]. Although the CDC guidelines indicate culture as the gold standard method for GBS detection, these same guidelines include

expanded laboratory method for detecting this organism. In particular, polymerase chain reaction (PCR)-based assays comprise an additional option for the rapid detection of GBS colonization[5,6]. The goals of this investigation were to study the vaginal colonization rate of Streptococcus agalactiae in pregnant women with adverse pregnancy outcome.

Subjects and Method

A cross-sectional study was designed included 200 pregnant women at 34–37 weeks of gestation, all females were examined clinically by the gynecologist. Data information was collected from each participate in this study included; age, previous abortions, a history of premature rupture of membrane (PROM), premature labor and neonatal anomalies.

Vaginal swabs have been accumulated from pregnant ladies attending the antenatal clinic of AL-Imammian AL-Kadhmain teaching hospital. Baghdad, Iraq. During the period from February to October 2018. The age of patients ranged from 15 to 45 years. Exclusion criteria include; pregnant women who were on antibiotic treatment two weeks prior to recruitment, women with vaginal bleeding and pregnant women with UTI. The current research authorized by the ethical Committee College of Medicine Al-Nahrain University and it's conducted in the department of the medical Microbiology College of Medicine Al-Nahrain University.

Specimens Collection and Processing: A total of two hundred samples, including 200 vaginal was taken from all pregnant women enrolled in this project by the gynecologist. Swabs from each patient were directly inoculated in Todd-Hewitt broth media containing 10 µg/ml colistin and 15 µg/ml nalidixic acid, and aerobically incubated at 37°C overnight.

GBS isolated bacteria was evaluated by means of using classical microbiological approach, which included used by Todd-Hewitt broth as an enrichment and selective media for group B streptococcus then subcultured on blood agar to select the appropriate colony, Then, the plates were inspected and identified for GBS organisms by the following criteria: colonies with narrow zone of beta hemolysis, Gram-positive cocci, catalase negative, resistance to bacitracin, sodium hippurate hydrolysis-positive.

DNA extraction and polymerase chain reaction assay

DNA extracted by using presto TM mini g DNA, bacterial kit Geneaid Company.

The primers and PCR conditions used to amplify gene encoding virulence factors with PCR are listed in Table (1).

Table (1): The primers sequence for *scpB* and PCR program conditions[7]

Gene	Primer sequence (5′-3′)	Size (bp)	PCR condition
*scpB*gene	5'-ACAATGGAAGGCTCTACTGTTC-3' 5'-ACCTGGTGTTTGACCTGAACTA-3'	255	94°C 3 min 1 Cycle 94°C 45 sec 57°C 45 sec 72°C 1min 33 Cycle 72°C 7 min 1 Cycle

Statistical Analysis: Quantitative variables were expressed as a mean± standard deviation (SD) while binomial variables were expressed as frequency and percentage and analyzed by Chi-squared test whenever possible. The statistically significant was set at *P value* ≤0.05.

Result

Distribution of streptococcal colonization according to the age of Patients and maternal medical history: Two hundred pregnant female were recruited in this study after meeting the inclusion criteria with age ranged from (15-39 years). Results of vaginal colonization showed the majority were from age ranged (18-36 years), 20 (20.6%) of them with a history of abortion, females with positive vaginal colonization indicated that they had a history of rupture membrane only in 10 (9.9%) with prolonged rupture membrane >18hr in 3(30%). Table (2).

Table (2): Frequency distribution of vaginal colonization according age and Maternal Medical history.

		Vaginal colonization		P. value
		Positive	Negative	
Age (Mean) Yrs. Range (15 – 39 Yrs) Std. Deviation		26.11 (18-36 yrs) 4.646	27.49 (15 - 39 yrs) 4.940	
History of abortion	With	20 (20.6%)	77 (79.4%)	0.350
	Without	16 (15.5%)	87 (84.5%)	
History of rupture membrane	With	10 (9.9%)	91(90.1%)	0.003
	Without	26 (26.3%)	73 (73.3%)	
Prolonged rupture membrane	>18hr	3	23	
	<18hr	7	68	

Molecular identification of *C5a* Peptidase (*scp* B) gene: PCR based to the C5a Peptidase (scpB) gene, revealed that out of 36 bacterial isolates by culture dependent method, *scpB* gene was detected in 17(47%) with (255 bp) amplification fragment. Figure (1).

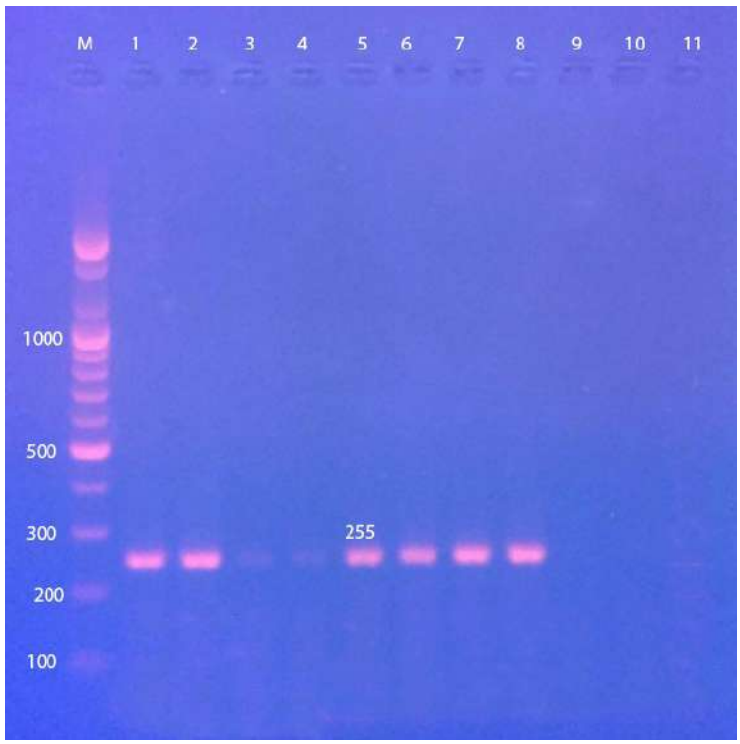

Figure (1): 2% Agarose gel electrophoresis at 70 volt for 30 min for *scpB* PCR products visualized under U.V light at 280 nm after staining with ethidium bromide. L: 1500 bp ladder; lane (1 - 8) were positive for this gene, the size of product is 255 bp.

The relation between *scpB* Gene with maternal outcomes: There are 17(47%) patients with positive result for *scpB* gene, in those patients there are 11 (11.3%) from all patients presented with abortion, with no statistical significant p value <0.05 (0.162), the most common maternal outcomes reported in current study in association with *scpB* gene positivity were rapture of membrane *p* value (0.001) (Table 3).

Table (3): The relationships between *scpB* gene with maternal outcomes

	scpB gene		P. value	Odds ratio
	Positive	Negative		
With abortion	11 (11.3%)	86 (88.7%)	0.162	2.068
Without abortion	6 (5.8%)	97 (94.2%)		
Rapture mem	2 (2%)	99 (98%)	0.001	0.113
Non-rapture	15 (15.2%)	84 (84.8%)		

Discussion

Based on data obtained from current study, the prevalence of group B streptococcus among pregnant women was 36 (18%) out of 200 samples, This remark disagreement with a observe executed in Iraq by Taiseer*et al*.[8] who found that (10%) of pregnant women were positive for vaginal colonization, another study conducted by Hamid *et al*.[9] stated that carriers of group B streptococci in pregnant women was (24.3%). However, a study conducted in Turkey by Alp *et al*.[10] Reported that colonization rate for GBS was (9.8%) out of 215 pregnant women.

This discrepancy in such outcomes, can be attributed to the difference in the number of specimens in each study, methodology used such as the way of taking samples from vaginal mucosa, timing of swab, presence of an intrauterine device and the types of transport media in each study, ultimately affect the cultivation of GBS, in addition to the exclusions and inclusions criteria which differ from study to another.Current investigation reported that, there was no statistically significant relationship between GBS carriage with age and history of abortion. Such results similar to Karadag *et al*.[11]. This study identified GBS colonization in 10 (9.9%) women who had Premature rupture of membrane (PROM) demonstrating a statistically significant relationship between GBS positivity and history of PROM. This result comes compatible with study by Alp F and Findik[10].

Premature rupture of membrane (PROM) one of the most culprit in maternal morbidity and mortality and also lead to fetal death as a result to sepsis, asphyxia, and pulmonary hyperplasia [12]. Many studies have indicated a close relationship between Women with intrauterine bacterial infection such as GBS with rupture of membrane and infants born for those women have a mortality rate four times higher than those without[13,14].

Detection of C5a Peptidase Virulence Gene by PCR: Data in this study reported that scpB gene was detected in 17 (47%) out of 36 bacterial isolates. this result contradicted with recent study conducted in Iraqi by Tiasire*et al*.[8] and in Argentina by Laczeski who stated that scpB gene were present in percentage of (100%) [15]. While Shabayek *et al*., reported scpBgene found in 30% [16].It is important to note that discrimination in such results may be due to regional or strain variations which affect gene expressions or as a result of mutations in such gene. Reichenberger *et al*., reported that bacterial mutations may occur spontaneous, or induced by a mutagen in the environment .However, it has also been hypothesized that bacteria might probably able to selectively increase mutation rates when they are presented to certain "stressful" or growth-limiting condition, it conceivable to demonstrate that ecological elements drive changes in nucleotide content, not only between highly diverged environment types, but also between specimens obtained from the distinctive human[17].

Relationship between C5a Peptidase gene of GBS and pregnancy outcomes: Our data demonstrated that there are no correlations between repeated abortions with the presence of C5a peptidase gene as a virulence factor in GBS, while there are statistically significant correlations between the presences of this virulence gene with membrane rupture. In relations with infection, an examination of PROM principally centered on the catabolic degradation of collagen mediated by matrix metalloproteinases (MMP) with certain investigations of different pathways including apoptosis and oxidative stress [18].

Inflammation of the chorioamnion and within the amniotic fluid is thought to assume a critical role in the pathogenesis of premature rupture untimely in preterm delivery. Infection-related preterm labor is commonly characterized by raised amniotic fluid cytokine levels in

pregnant [19]. Vanderhoeven *et al*., 2014 hypothesized that premature membrane rupture may be due to ascending infection during pregnancy that may increase risks of chorioamnionitis, in addition to mediating inflammation, cytokines have additionally been related with increased collagen remodeling and, ultimately, biophysical weakening of the fetal membranes or chorioamnion in vitro[20]. Data in current study, in harmony with a study by Surve*et al*., (2016) who demonstrated in a rat model that, GBS produces membrane vesicles, which lead to chorioamnionitis and damage to the rupture of membranes as a results to significant elevations of amniotic fluid cytokines (TNF-α, IL-8, IL-1β, IL-6) that stimulated by virulence factors of GBS [21].

Conclusion

Our data suggest that GBS highly prevalent among pregnant women, there was high degree of correspondence between vaginal carriage for GBS and Premature rupture of membrane (PROM)which is the must adverse pregnancy outcome associated with GBS carriage in this study.

Abstract

Introduction: Spleen is the largest lymphatic organ in the body that is responsible for initiating an immune response to antigens, consistof macrophages and lymphocytes. Macrophages are cells that engulf foreign bodies by migration, phagocytosis, O_2 burst, lysosomes fusion, synthesis and secretion of various cytokines which would require enormous amounts of energy. Therefore, macrophages needs of $O_2$to increase resulting in hypoxia relative. To overcome this situation, the cell is equipped with a special mechanism which is under the control of HIF. They are highly dependent to O_2existence to produce energy. This process is important for biochemical adaptation in homeostasis. Macrophages expressing Cygb for supplying O_2 and PGC-1 for mitochondrial biogenesis in producing energy. This study aims to determine whether the spleen macrophages in mice being immunized intraperitoneally with SRBC increase the expression of HIF, Cygb and PGC-1α.

Method: 24 male BALB/c mice, aged 2 months were immunized by injecting 0.2 ml SRBC 2%. Macrophages were taken from spleen of mice. Expression of mRNA and protein levels of HIF-1α, HIF-2α, Cygb, PGC-1α in macrophages were measured by real time RT-PCR and ELISA, respectively. Level of O_2burst were measured with WST Salts. Observations were made at 24, 48, and 72 hours post-immunization.

Results: The ability to oxidize antigen levels (O_2burst) found higher at 24 hours after immunization. The levels of protein and mRNA expression of HIF-1α and HIF-2α showed the highest increase at 24 and 48 hours after immunization. The levels of Cygb protein increased at 48 hours group after immunization while mRNA expression increased at 24 hours after immunization. PGC-1α protein levels decreased in 24 hours after immunization and then increased gradually.

Conclusion: This study shows the expression pattern of several proteins in spleen macrophages of mice that was immunized

Keywords: *Spleenmacrophages, HIF-1α, HIF-2α, Cytoglobin, PGC-1α, Immunization.*

Introduction

Spleen is the largest lymphatic organ in the body that is responsible for initiating an immune response to antigens that blood-borne antigen. Spleen is divided into two compartments; red pulp and white pulp. Both compartments contain a set of macrophages.(1,2) Macrophages are very important cells in immunity, innate as well as acquired immunity.(1) They join both immunities and undertake several activities which are high in energy cost. Moreover, macrophages have to oxidize the engulfed foreign bodies.(3) Each activity increases the oxygen (O_2) consumption and as the O_2 supply remains static, the macrophages should undergo

hypoxia condition. To prove it, 24 male BALB/c mice, aged 2 months were immunized intraperitoneally with Sheep Red Blood Cells (SRBC) as antigen and analyzed several factors involved in overcoming relative hypoxia, supply O_2 and energy. For this purpose, we measured Hypoxia Inducible Factors(HIF)-1α, HIF-2α, cytoglobin (Cygb) and Peroxisome proliferator-activated receptor (PPAR) gamma coactivator (PGC)-1α protein and mRNA levels. It is widely known that, HIFs are very important for cell survival in relative hypoxia,[4]and Cygb is assumed as intracellular O_2 binding protein[5] whereas PGC-1α is needed in biogenesis of mitochondria an indispensable organelle for ATP synthesis in energy supply.[6]We used the spleen macrophages due toit's role as the major secondary lymphoid organ in the body and practically all cells involved in immune response will pass and stay in the organ.[7] We studied spleen macrophages 24, 48, and 72 hours after SRBC immunization.

Materials and Method

Experimental animals used were 24 male BALB/c mice, weigh 20-25 grams, aged 2 months from Animal Laboratory Unit, Faculty of Veterinary Medicine, Bogor Agricultural University-IPB. Mice divided into 4 groups and each group consists of 6 mice: not immunization as a control group, 24 hours post immunization group, 48 hours post immunization group, 72 hours post immunization group. Immunization using SRBC 2% as antigen then undergo cervical dislocation. Whole spleen was taken and put in Phosphate Buffer Saline(PBS) pH 7.4. The Spleen chopped into small pieces and washed with PBS pH 7.4. Splenocytes were centrifuged at 3000 rpm for 30 minutes at 4°C. Red blood cells were removed using red blood cell lysis buffer and then washed with PBS. The pellet is suspended in PBS pH 7.4, centrifuged at 400xgfor 30 minutes at room temperature and macro phages are found at the bottom of the tube. The cells were washed again with PBS pH 7.4.

Oxygen burst activities measured with Water Soluble Tetrazolium Salt (WST) method. Macrophages were resuspended with 100 µL Roswell Park Memorial Institute (RPMI) medium and after several minutes followed by addition of Hank's Balanced Salt Solution (HBSS) 1 mL and finally 2 µL WST. Acquired macrophage cells then added HBSS and WST, incubated for 4 hours at 37°C, and wait until precipitated. The supernatant were measured using a spectrophotometer at450 nm.[8]

Total cellular RNA was extracted with Tripure isolation reagent (Roche) and used only 100 ng of total RNA for RT-PCR. Primer sequences for HIF-1α, HIF-2α, Cygb and β-actin for each mRNA (forward and reverse) are presented in table 1.

Table 1: Primer sequences of HIF-1α, HIF-2α, Cygb and β-actin

Primer	Forward	Reverse
HIF-1α[9]	[5'-GCA CTA GAC AAA GTT CAC CTG AGA-3 ']	[5'-CGC TAT CAT CAA CCA AGC AA-3']
HIF-2α[10]	[5'-CTC CTC GAG CAG AGG AAA TG-3']	[5'-CAG GTA AGG CGA CTC GAA TG-3']
Cygb[11]	[5'-CGC AGC CTA CAA GGA AGT G-3']	[5'-CCT GAA GGC GAG AGA GTG G-3']
β-actin[12]	[5'-CT GTG AAA ACC AGG CCA AG-3']	[5'-ACC AGA CAG GGA GGC ATA CA-3']

Reaction components are used based on a modification of the protocol in the kit iScript™ One Step RT-PCR with SYBR®Green. The threshold cycle (CT) was determined, and the relative gene expression was calculated with Livak Formula.[13]

Measurement of expression HIF-1α, HIF-2α, Cygb and PGC-1αprotein using Enzyme-linked immunosorbent assay(ELISA) kits from Elabscience. These ELISA assays were performed in accordance with the instruction of the respective manufacturers. Data analysis is performed using SPSS program version 20.0.

Results

High level of O_2 burst activity of macrophages on oxidizing the antigen was observed after 24 hours in the groups then decreased progressively ($p<0.05$) (figure. 1A). The relative expression of HIF-1α in 24, 48, and 72 hours groups were higher significantly than control groups, however the level was significantly lower than 24 and 48 hours (figure. 1B). These relative same phenomena was observed at the level of HIF-1α protein level. Group of 24 hours had a significant higher level of protein than the control, but in 72 hours group was lesser than 24 hours ($p<0.05$) (figure. 1C).

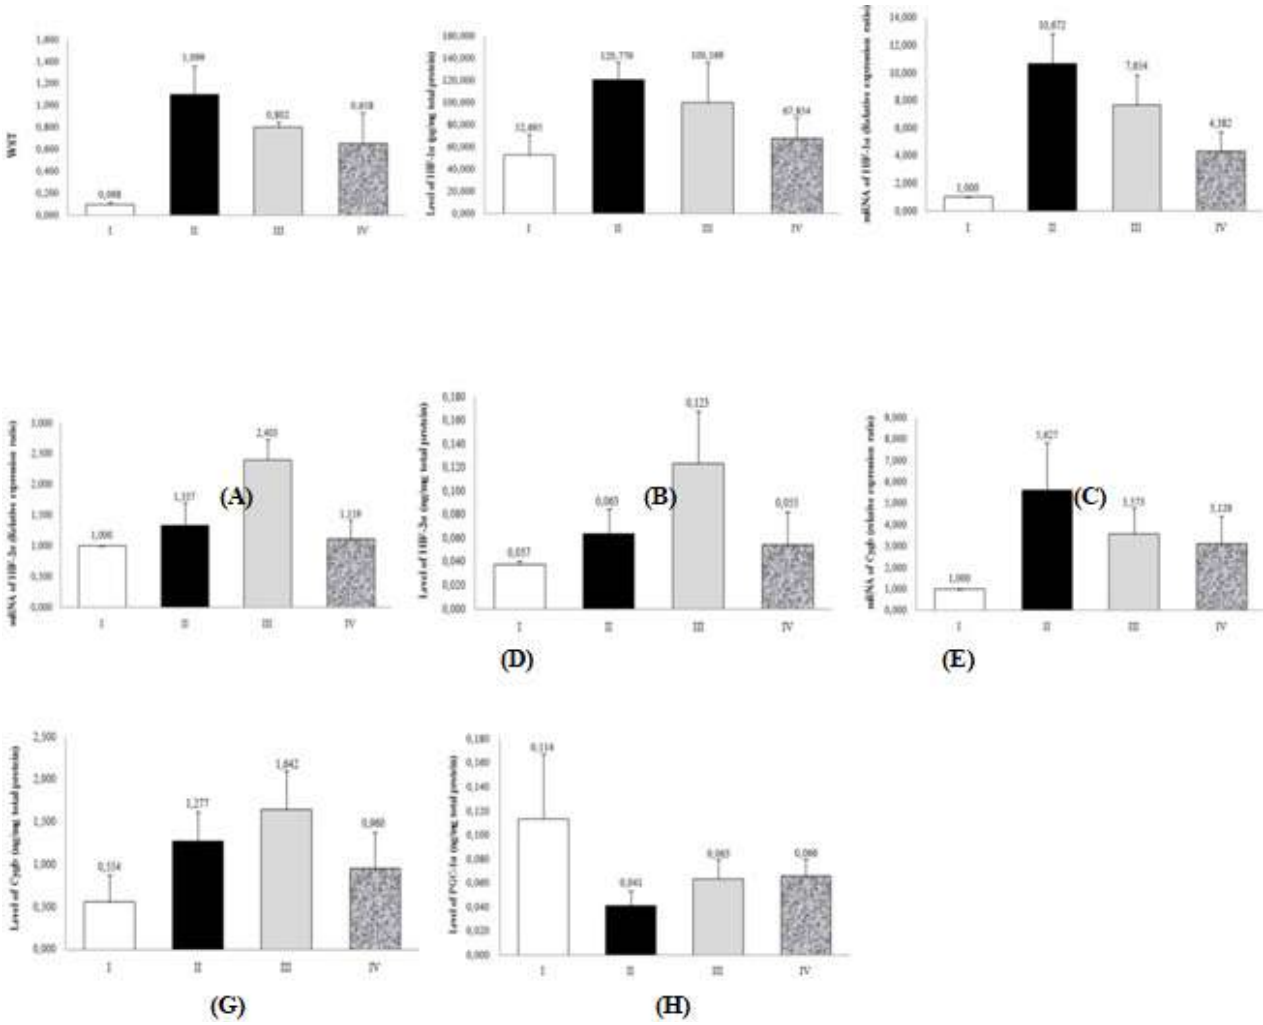

Figure 1. The results of the measurement of macrophages activity

Relative expression of HIF-2α mRNA start to increase significantly after 48 hours than control group, whereas in the 72 hours group, the level is lower significantly than 48 hours group (figure.1D). The same phenomena was found in the HIF-2α protein level (figure.1E).

Relative expression of Cygb mRNA was significantly increased on 24 hours group (figure.1F), however different phenomena was found in the Cygb protein level. Level of Cygb protein was significantly increased on 48 hours group ($p<0.05$) (figure.1G).

PGC-1α protein level decrease significantly in 24 hours group than control group, however 48 and 72 hours group were not differ significantly from control group (figure.1H).

Discussion

Infiltration of foreign bodies will trigger a series of defense reaction which can be divided in two stage, i.e. innate and adaptive immunity responses. Both kinds of immune response are connected each other by macrophages in the innate immunity response. Macrophages migrate to the conflict area and engulf the foreign bodies and destroy it by two main mechanism; oxidative and lysis destruction.[1]

Those foreign bodies which injected intraperitonealy, and then observation were made on the spleen macrophages. It means that some of macrophages migrated and stay in the spleen, a process which needs; a great number of energy. The destructing of foreign bodies by oxidation is well known as oxidative burst, a process which consume great number of O_2 exceeding

the metabolic needs. These stage of innate immune response requires big amount of O_2 used for energy supply and the O_2 burst.[1,14] This caused macrophages were in relatively hypoxic conditions. This conditionsis demonstrated by high level of HIF-1α and HIF-2α mRNA (figure.1B and1D) as well as protein (figure.1Cand1E). The relative hypoxic conditions continue to the next period because in this stage the macrophages begin to involve in more specific immunity.

In this stage, the macrophages have to cleave foreign bodies, presented on the cells surface in a complex with MHC II. To complete the immune response, the lymphocytes should arrive around the activated macrophages, in response of chemokine and interleukin.[1,15]

It's clear in this stage of immune response the macrophages must synthesis and secrete various type of proteins, which is high energy consuming process. To meet this energy needs, macrophages have to activate the aerobic metabolism, which occur in mitochondria.[15] All of this processes made the macrophages undergo a relative hypoxic condition. This proven by the persistent of HIF-1α and HIF-2α mRNA, as well as protein. Peyssonnaux C,et al[16]proved that macrophages, were exposing to bacteria, there will be an elevation of HIF-1α content. If the expression HIF-1α was inhibited, the bacteria killing activity will also decrease. Takeda N,et al[17] mentioned that inhibited HIF-1α expression on macrophages may also decrease iNOS expression which then used to eliminate antigen. Cygb, an extra erythrocytes hemoglobin, is needed as an O_2 binder in the cell and will transfer the O_2 to mitochondria, which are active as shown by high level of Cygb mRNA and protein beyond 24 and 48 hours (figure.1F and1G), high optical density from WST beyond 24 hours (figure.1A). In addition, elevated activity of Cygb were markedby high level of PGC-1α in the relatively chronic stage, i.e. 48 and 72 hours after exposure to SRBC (figure.1H). Burmester T, et al[18] indicates that Cygb is significantly raised on low O_2 condition. This elevation is an adaptation effort of macrophages in hypoxic condition. Correlation between HIF-1α and Cygb are significant and positive, which proved that HIF-1α and Cygb are associated into each other. Thus, if the relative hypoxia occurs then the expression pattern Cygb also increased. Other studies have shown that HIF-1α also regulate the increased expression of Cygb mRNA and protein on condition of hypoxia in rat liver.[19]

HIF-1α generally response only to hypoxia for the first 24 hours (figure.1B). In this observation we found that HIF-1α were in high level during the observation. HIF-2α is often associated with chronic stage hypoxia and also in differentiated cells process. In our observation we could assume that the macrophages might differentiate from resting tissue response macrophages to antigen presenting macrophages. It is also possible that the macrophages differentiate into M1 and M2 types.[18, 20]

Over all, activated macrophages are in relatively hypoxic condition as a result the increase of O_2 needs,[21] which is used in innate and more specific immunity process. All of this is indicated by the high level of HIF-1α, HIF-2α, Cygb and PGC-1α.

Conclusion

This study shows the expression pattern of several proteins in spleen macrophages of mice that was immunized. The different expression pattern is the adaptation responses that occurs in macrophage cells.

The Emerging Risk of Interaction Between Complementary Alternative Medicines and Cardiovascular Medicines

Huda S. Husni

College of Baghdad for Medical Sciences, Iraq

Abstract

Herbal medicinal use has increased dramatically in recent years. Use of herbal products forms the bulk of treatments, particularly by elderly people who also consume multiple prescription medications for comorbid conditions, which increases the risk of adverse herb-drug-disease interactions. Despite the paucity of scientific evidence supporting the safety or efficacy of herbal products, their widespread promotion in the popular media and the unsubstantiated health care claims about their efficacy drive consumer demand. In this review, we highlight commonly used herbs and their interactions with cardiovascular drugs.

Keywords: *Interaction, Alternative Medicines, Cardiovascular Medicines*

Introduction

Herbal medicine is still the mainstay of about 75-80% of the world population, mainly in the developing countries,for primary health care[1]. This is primarily because of the general belief that herbal drugs are without any side effects besides being cheap and locally available[2]. According to the World Health Organization (WHO), the use of herbal remedies throughout the world exceeds that of the conventional drugs by two to three times[3]. The use of plants for healing purposes predates human history and forms the origin of much modern medicine. Many conventional drugs originated from plant sources: a century ago, most of the few effective drugs were plant based. Examples include aspirin (willow bark), digoxin (from foxglove), quinine (from cinchona bark), and morphine (from the opium poppy)[4].

Medical history from the beginning of time is filled with descriptions of persons who used herbs to heal the sick of the society. However, parallel to the onset of the industrial revolution we witnessed the rise of allopathic medicine. Herbal medicine was also an effective healing method, but was viewed less enthusiastically[5]. Herbal products were discarded from conventional medical use in the mid-20th century, not necessarily because they were ineffective but because they were not as economically profitable as the newer synthetic drugs [6]. In the early 19th century, scientific method become more advanced and preferred, and the practice of botanical healing was dismissed as quackery. In the 1960s, with concerns over the iatrogenic effects of conventional medicine and desire for more self-reliance, interest in "natural health" and the use of herbal products increased. Recognition of the rising use of herbal medicines and other non-traditional remedies led to the establishment of the office of Alternative Medicine by the National Institute of Health USA, in 1992. Worldwide,herbal medicine received a boost when the WHO encouraged developing countries to use traditional plant medicine to fulfill needs unmet by modern systems [7].

Patients are increasingly using herbal products for purportedly preventive and therapeutic purposes[8]. Some products have direct effects on the cardiovascular or hemostatic system, whereas others have indirect effects through interactions with medications that could lead to serious consequences[9]. Common herbal remedies that produce adverse effects on the cardiovascular system include St. John's wort, mother wort, ginseng, gingko biloba, garlic, grapefruit juice, hawthorn, saw palmetto, danshen, echinacea, tetrandrine, aconite, yohimbine, gynura, licorice, and black cohosh (Table 1).

Table 1: Herbal Products to Avoid in Patients With Cardiovascular Diseases*[9]

Herb	Purported Use	Cardiac Adverse Effect of Interaction
Alfalfa	Arthritis, asthma, dyspepsia, hyperlipidemia, diabetes	Increasesbleedingriskwithwarfarin
Aloevera	Wounds (topical), diabetes (oral)	Hypokalemiacausingdigitalistoxicityandarrhythmia
Angelica (dongquai)	Appetiteloss, dyspepsia, infection	Increasesbleedingriskwithwarfarin
Bilberry	Circulatorydisorders, localinflammation, skinconditions,	Increasesbleedingriskwithwarfarin diarrhea, arthritis
Butcher's broom	Circulatorydisorders, inflammation, legcramps	Decreaseseffectsofalpha-blockers
Capsicum	Shingles, trigeminalanddiabeticneuralgia	Increasesbloodpressure (withMAOI)
Fenugreek	Highcholesterol	Increasesbleedingriskwithwarfarin, hypoglycemia
Fumitory	Infection, edema, hypertension, constipation	Increaseseffectsofbeta-blockers, calcium-channelblockers, cardiacglycosides
Garlic	Highcholesterol, hypertension, heartdisease	Increasesbleedingriskwithwarfarin
Ginger	Highcholesterol, motionsickness, indigestion, antioxidant	Increasesbleedingriskwithwarfarin
Ginkgo	Poorcirculation, cognitivedisorder	Increases bleeding risk with warfarin, aspirin, or COX-2 inhibitors
Potentialriskofseizures		
Ginseng	Aging, diminishedimmunity, improvesmentaland Increasesbloodpressure physicalcapacityandstress tolerance Decreaseseffectsofwarfarin	
Hypoglycemia		
Gossypol	Malecontraceptive	Increaseseffectsofdiuretics
Hypokalemia		
Grapefruitjuice	Weightloss, topromotecardiovascularhealth	Increaseseffectsofstatins, calcium-channelblockers, orcyclosporines
Greentea	Improvecognitiveperformance, mentalalertness,	Decreaseseffectsofwarfarin (containsvitaminK)
weightloss, diuretic		
Hawthorn	CHF, hypertension	Potentiatesactionofcardiacglycosidesandnitrates
Irishmoss	Ulcers, gastritis	Increaseseffectsofantihypertensives
Kelp	Cancer, obesity	Increaseseffectsofantihypertensiveandanticoagulantagents
Khella	Musclespasms	Increaseseffectsofanticoagulantagentsandcalcium-channelblockers
Licorice	Ulcer, cirrhosis, cough, sorethroat, infections	Increasesbloodpressure
Hypokalemia		
Maypotentiatedigoxintoxicity		
Lilyofthevalley	CHF	Increaseseffectsofbeta-blockers, calcium-channelblockers, digitalis, quinidine, steroids
Ma-huang (ephedra)	Obesity, cough	Increasesheartrateandbloodpressure
Night-bloomingcereus	CHF	Increaseseffectsofangiotensin-convertingenzymeinhibitors, antiarrhythmics, beta-blockers, calcium-channelblockers, cardiacglycosides
Oleander	Musclecramps, asthma, cancer, CHF, hepatitis,	Heartblock psoriasis, arthritis
Arrhythmia		

Herb	Purported Use	Cardiac Adverse Effect of Interaction
Death		
St.John'swort	Depression	Increasesheartrateandbloodpressure (withMAOI) Decreasesdigoxinconcentration
Storphanthus	CHF	Increaseseffectsofcardiacglycosides
Yohimbine	Impotence	Increasesheartrate

Results

Forty-three case reports (appeared in 21 publications) and eight clinical studies were located [10–38]. Warfarin was the most common drug involved (37 cases and 1 clinical trial) [14–30]. Key data from these publications are summarized below.

Clinical interactions between herbal medicines and conventional cardiovascular drugs

1. Digoxin:

a. It interacts with **Gum guar** which will decrease plasma digoxin concentration by decreasing its absorption (Guar gum reduces gastric emptying, which result in a transient delayed digoxin absorption) [10].

b. It interacts with **St. John's wort** which will decrease plasma digoxin concentration by Induction of P-glycoprotein (Digoxin is a substrate of P-glycoprotein which is induced by St. John's wort)[11].

c. It interacts **Siberian ginseng** which willincrease plasma digoxin concentration, Some component of Siberian ginseng might impair digoxin elimination or interfere with the digoxin assay (Siberian ginseng inhibits the metabolism of hexobarbital in mice)[12].

d. It interacts with **Wheat bran** which will decrease plasma digoxin concentration by decreasing its absorption (Bran contains fibers which can trap digoxin) [13].

2. Warfarin:

a. It interacts with **Boldo/Fenugreek** that will lead to increase the anticoagulant effect of warfarin due to the additive effect on coagulation mechanisms (Both boldo and fenugreek contain anticoagulant coumarins) [14].

b. It interacts with **Curbicin** that will lead to increase the anticoagulant effect of warfarin due to the additive effect on coagulation mechanisms (Vitamin E contained in curbicin can antagonize the effect of vitamin K on coagulation) [15].

c. It interacts with **Danshen** that will lead to increase the anticoagulant effect of warfarin due to the additive effect on coagulation mechanisms (In addition to its antiplatelet activity, danshen decreases)[16-18]

d. It interacts with **Devil's claw** that will lead to increase anticoagulant effect, purpura through unknown mechanism (In contrast to NSAIDs, devil's claw does not affect platelet function) [19].

e. It interacts with **Dong quai** that will lead to increase the anticoagulant effect of warfarin due to the additive effect on coagulation mechanisms (Dong quai contains anticoagulant coumarins) [20-21].

f. It interacts with **Garlic** that will lead to increase anticoagulant effect and increase in clotting time of warfarin due to the additive effect on coagulation mechanisms (Garlic has antiplatelet activity) [22].

g. It interacts with Ginkgo which will lead to intracerebral hemorrhage due to the additive effect on coagulation mechanisms (Ginkgolides from ginkgo have antiplatelet activity and are PAF receptor antagonists) [23].

h. It interacts with **Ginseng** that will lead to decrease anticoagulant effect through unknown mechanism (Antiplatelet activity of ginseng has been reported but would not seem to explain this case of decreased anticoagulation; a pharmacokinetic study in rats did not reveal a significant interaction between warfarin and ginseng) [24].

i. It interacts with **Green tea** that will lead to decrease anticoagulant effect through pharmacological antagonism mechanism (Warfarin produces anticoagulation by inhibiting production of the vitamin-K dependent clotting factors. Green tea contains vitamin K and thus antagonize the effect of warfarin) [25].

j. It interacts with **Lycium** that will lead to increase the anticoagulant effect of warfarin through unknown mechanism (The weak inhibition of Lycium on hepatic enzyme could not explain such interaction)[26].

k. It interacts with **Mango** that will lead to increase the anticoagulant effect of warfarin through Hepatic enzyme inhibition (Mango contains high amounts of vitamin A and human studies have shown that vitamin A (retinol) inhibits CYP2C19 enzymes) [27].

l. It interacts with **Papaya** that will lead to increase anticoagulant effect through unknown mechanism[28].

m. It interacts with **PC-SPES** that will lead to increase anticoagulant effect through Additive effect on coagulation mechanisms (PC-SPES contains anticoagulant coumarins) [29].

n. It interacts with **Soy** that will lead to decrease anticoagulant effect through unknown mechanism[30].

o. It interacts with **St. John's wort** that will lead to decrease anticoagulant effect through hepatic enzyme induction (Warfarin is metabolized by CYP 1A2 in the liver, which is induced by St. John's wort)[31].

3. **Diuretic Thiazide:** Ginkgo Increase in blood pressure with an unknown mechanism, This action may be due to effect of Ginkgo as a vasodilator for peripheral blood vessles. Which may have a dangerous effects on patients[31].

4. **Liquorice:** Liquorice may interact with antihypertensive agents, this interaction may result in Hypokalemia, this effect is explained by liquorice ability to increase potassium excretion due to its mineralcorticoid effects, Serum potassium levels should be monitored closely in patients who are predisposed to cardiac arrhythmias and who are concurrently treated with digitalis glycosides[32].

5. **Aspirin:**

   a. Ginkgo biloba extract may interact with Aspirin and increase bleeding tendency, this effect is thought to be caused by Ginkgolides ability to inhibit platelets aggregations and also by ginkgolides antagonsitic activity on PAF receptors, rarely, some pateints develop spontaneous bleeding from the iris into the anterior chamber of the eye[33].

   b. Tamarind interacts with Aspirin with an unknown mechanism but it is known that Tamarind increases the oral bioavailability of Aspirin[34]

6. **Phenprocoumon:** St. John's Wort interact with Phenprocoumon and decreases its anticoagulant activity through its inductive effects on hepatic enzymes that are responsible for the metabolism of the drug, this effect is seen as an increase in Quick-Wert test which means a reduction in anticoagulant effect[35].

7. **Simvastatin:** St. John's Wort interact with Simvastatin and Decreased plasma simvastatin concentration, this effect is due to Hepatic enzyme induction, Simvastatin is extensively metabolized by CY3A4 in the intestinal wall and liver, which are induced by St. John's wort[33].

8. **Lovastatin:** It interacts with Oat bran and Pectin, both cause decreasing in Lovastatin absorption and the decreased absorption of Lovastatin resulted to an increase in LDL levels which led to the abortion of the trial. Lovastatin pharmacokinetics and LDL returned normal after pectin discontinuation[35].

Method

Systematic literature searches were made using Medline (via PubMed, from January 1966 to February 2003). The search terms were herbal medicine, botanical medicine, phytotherapy, drug interaction, adverse effects, side effects, adverse drug reaction, safety and toxicity. Recent books on herb–drug interactions or herbalism[21–26] were also searched for further relevant information. Additional publications were identified by checking all reference lists and by searching our files. No language restrictions were imposed. All clinical reports on interactions were read and relevant data were extracted by the first three authors into predefined table and validated by the senior author. In vitro experiments have been excluded.

Discussion

Herbal medicines follow modern pharmacological principles. Hence, herb–drug interactions are based on the same pharmacokinetic and pharmacodynamic mechanisms as drug–drug interactions [5]. Herbal medicines may affect absorption (e.g. guar gum reduces digoxin absorption) [27], metabolism (e.g. St.

John's wort increases warfarin metabolism, causing decreased anticoagulant effect) [9] or excretion (St. John's wort increases digoxin renal excretion) [28] of concurrently administered cardiovascular drugs. Herb–drug interactions that involve distribution mechanisms have not been reported. Moreover, interactions may be additive or synergetic, whereby the herbal products potentiate the action of the conventional cardiovascular drug (e.g. ginkgo potentiates the antiplatelet effect of aspirin) [33]. Conversely, the herb may be directly antagonistic to the action of the drug (e.g. green tea antagonizes the anticoagulant effect of warfarin) [35].

Based on the above evidence, there can be little doubt that interactions between herbal medicines and cardiovascular drugs exist. The real incidence of such interactions is probably unknown, as is the likelihood that a patient will have an adverse event when taking two drugs (i.e. herbal and conventional medicines) with the potential to interact. Much of the available information about the interaction between herbal medicines and cardiovascular pharmacotherapy is gleaned from case reports, although clinical studies are now also beginning to appear in the literature. Obviously, case reports have to be interpreted with great caution, ascausality is not usually established beyond reasonable doubt. To establish causality is, of course, a difficult task. Rechallenge would be the most straightforward clinical test, but for obvious reasons, this option is not always available. Hence, even well-documented case reports (and many are not well documented) can only serve as a critical early warning system.

Conclusion

Interaction between herbal medicine and cardiovascular drugs is a potentially important safety issue. Patients under anticoagulant pharmacotherapy are at the highest risk. Healthcare professionals need to be aware of potential herb–drug interactions and researcher should strive to fill the numerous gaps in our present understanding of this problem.

Effect of Exercises Using a Pressing Tool on Some Biochemical and Skilled Variables of Tennis Players

Hussein Ali Hussein Al Kufi

Instructor, College of Basic Education, Al-Mustansiriyah University, Baghdad, Iraq

Abstract

This study aims to identify the effect of exercises using a pressing tool for the arms on some biochemical and skilled variables for tennis players. An experimental design was used to guide this study. The study included a purposive sample of six players from Al-Jaish Sport Club who practice tennis. These players were received the administered intervention. To ensure the subjects' homogeneity and normal distribution, the researcher used the mean, standards deviation, and skewness for the filed survey. The researcher concluded that there were statistically significant, within normal limit increase in the white and red blood cells counts as they include all what lead to increase body toxins and waste-products of harmful cells. The researcher recommends paying attention to the biochemical variables for the players throughout training in order to develop their physiological abilities.

Introduction

Athletes' abilities have witnessed a dramatic improvement [(1)] seen in Olympic events since the launch of the modern Olympic chapter has been accounted for by different mechanisms[(2)]. The increase in the rate of participation, professional behavior (of participants and coaches), natural selection, enhanced training, nutrition, and psychological preparation, step forward in technique, and the innovation in technology in terms of the design of equipment and ergonomic aids collectively have served as contributing factors[(3-4)].

The fact of what happens to the athletic body; due to using training efforts, became one of the most important requirements of training currently. This could be attributed to the scientific revolution that the scientists have made in the sport discipline in terms of advancement in devices and practical and scientific method that fit achieving the sport performance. Thereafter, the performance depends on the level of adaptation of the functional systems on the training work. Such a work is currently measured depending on the response of the different body organs; particularly if we know that the sport training; from physiologic perspective, is "a set of exercises or physical efforts that lead to adaptive goals or functional change in body systems and internal organs in order to achieve high level of achievement". As such, the training efficiency related to assessment of the response of functional systems and their adaptation drawn the trainers' attention and preparing their method to achieve good and new results the player frequently seeks.

Selecting the exercise in accordance with the specific game, the player's level, the training duration that they are on, and intensity and amount of training are considered as of the most important indicators of direct effect on the systems and tissues of the players' body. Thus, in order to know what happens in the body of tennis players who experience required training for hours. In order to overcome the negative points owing to overload and improving the players' levels, it is crucial to adopt special training in the light of hypoperfusion using a pressing tool over the arms to cause hypoperfusion for the given extremity. As such, the occurrence of hypooxygenation and nutrients consequences, which in turn increase the ability to resist fatigue owing to hypoperfusion during training.

After finishing the training, the pressing tool is removed to shift to the perfusion stage. Thus, the delivery of large amount of oxygenated blood and nutrients. This is a modern method that leads to increase player's ability to perform for as long as possible without the occurrence of muscular fatigue during games and training. The

importance of this study represented in adapting the tennis players on the hypooxygenation statuses and the muscle's tolerance for acids that result from anaerobic system and benefit from adaptations occurred as a result of hypoperfusion for the arms in increasing the tolerance strength of the muscle for physical stress in lack of oxygen and increase blood Ph.

Problem Statement: The main research problem lays in the question "Is the tool pressing over the arms of positive effect in improving the muscles' ability in tolerating the burden of hypoperfusion and in turn the lack of oxygen and nutrients delivered to the muscles and urging the muscles to work much strongly and maximum muscular tolerance? As well, as this training method increases the muscles' dependence on the anaerobic systems to release the energy required for muscular work, so such a method can serve to develop the speed ability irrespective of the compound abilities. This in turn serves to improve the performance of the working muscles; particularly in the forehand and backhand shots in tennis.

Study Objectives: This study aims to identify the effect of exercises using a tool pressing over the arms on some biochemical and skilled variables for tennis players.

Research Hypothesis: The researcher hypothesizes that there are statistically significant differences in the pretest and posttest in terms of some biochemical and skilled variables among tennis players.

Research Dimensions:

The Human Dimension: Al-Jaish Sport Club tennis players

The Time Dimension: The duration from January 12th, 2018 to May 22nd, 2018.

The Spatial Dimension: Baghdad – Al-Jaish Sport Club field for tennis and Al-Shaab Stadium for tennis.

Definition of Terms:

The Pressing Tool: It is a pressing belt (arterial pressing tool) that is tied to the arm over the brachia to impede blood delivery to the arm, lower brachia, and the hand.

Method

The researcher used the experimental design as it fits the research problem, "Controlling over the influencing factors surrounding the experiment; except for the independent variable in order to measure its effect on the dependent variable[5].

Sample and Sampling: The study included a purposive sample of six advanced tennis players who were selected from Al-Jaish Sport Club. All these players are exposed to the experimentation (pre-posttests).

Tools:

Observation and experimentation

Information sheet

Personal interview

Resources and references

Exercises

Internet

A tool pressing over the arm

Whistle

Legitimate Tennis racket size (53-58 cm), (n = 10)

Tennis balls (n = 50)

A basket for the balls

Legitimate tennis field

Medical syringes

Devices used in the study:

Timer watch (Chinese-made – Swan, n = 2)

Blood centrifuge

Restameter (to measure height and weight)

Camera (Nikon, n = 2)

Stopwatch (n = 3)

Clinical procedures:

Tests used in the study:

Forehand and Backhand Shots Precision Test[6]

Forehand and Backhand Shots Depth Test[6]

Pilot Study: The pilot study was conducted in Al-Karkh Sport Club field in Baghdad City on January 27th, 2018 on three tennis players who are not included in the final sample size.

Pretests: The pretests were conducted under the researcher's supervision. The study procedures, number

of trials, points counting method and recording, and the conditions of other tests were explained to the study participants on February 3rd, 2018 to conduct the skilled tests.

The Main Experiment: The researcher has prepared exercises that are set in 24 training sessions distributed over three training sessions per week. They include exercises in the main part of the training sessions designated for the tennis players after the thorough reviewing of the literature and experts in tennis in accordance with the training tool that the researcher used for training in hypoperfusion for the arms. This can be implemented via closing the artery in the working brachial muscle for a specific duration and the augmentation of using the pressing tool in line with the exercise duration. The level of oxygen is decreased inside the muscular tissues where the blood stream (unoxygenated blood) is impeded to the cells which leads to hypooxygenation. This process is accompanied by an increase in the accumulation of the lactic acid in the muscles and dilation of the blood vessels. On accomplishing "opening the artery and releasing blood stream", the blood circulation supplies the muscles with oxygen and eliminate the cellular waste products that cause arterial dilation, in addition to the elimination of lactic acid through transforming some of its compounds into other compounds. The time of using the pressing tool goes in line with the time of performing the exercises that includes four sessions in a time of one minute for each frequency and 30-second for rest among frequencies. That is, four minutes for using the pressing tool in the exercise and so on. The exercises were initiated on February 10th, 2018.

Posttests: The researcher conducted the posttests at 11:00 a.m. on April 28th, 2018. The same method used in the pretest was used in the posttest, considering the same spatial and time conditions, and the same testing method and devices, and the auxiliary team who helped in conducting the pretest.

Statistical Measures: The statistical package for social sciences (SPSS) for windows, version 24, IL, Chicago was used to analyze data.

Study Results: Results of Ph, hemoglobin, precision of forehand and backhand shots, and the depth of forehand and backhand shots.

Table 1: Mean, standard deviation, t-value, and significance level

List	Variables		Pretest		Posttest		T-value	Sig.	Ass.
			Mean	SD	Mean	SD			
1.	Biochemical	White blood cells g/L	6.980	20.08	9.210	0.760	5.340	0.000	S
2.		Hb	14.640	0.650	14.740	0.890	3.760	0.000	S
3.	Precision of forehand and backhand shots		27.290	1.760	32,460	1,650	9.640	0.000	S
4.	Depth of forehand and backhand shots		25.120	2.180	30.650	1.870	10.760	0.000	S

Ass. = Assessment; Hb = Hemoglobin; SD = Standard deviation; Sig. = Significance; S = Significant
Significance level is at (0.05) and a degree of freedom (df) = 5

Discussion of Pretest and Posttest

Table (1) demonstrates the statistically significant differences and the t-value in favor of the posttest for the variables under investigation. This indicates the development of skills for the learners. The researcher attributes this to the used exercises in the helping tool which effectively contributed to skills development. The researcher explains this to that the tool used works to impede the delivery of oxygen to inside the muscular tissues, where the blood stream (unoxygenated) is impeded from the cells which in turn leads to a decrease of oxygen and the dependence of the muscle in generating the energy anaerobically. When finishing (opening the artery and allowing the arterial blood to normally pass through, in which the blood supply to the cells is increased, where the blood circulation supplies the muscles with oxygen and eliminates the waste products of the cellular interaction. Furthermore, the lactic acid is eliminated through its oxidation and the transformation of some of its compounds into other compounds. Moreover, the exercises that are applied with the help of the tool contributed to increase the number of white blood cells which is attributed to the increase in the uniting ability of these cells to eliminate what the exercise produce of debris of cell membranes after accomplishing the performance of exercises. This was emphasized by Alexander in that "The modification of exercises that

are performed daily by their practitioners increase the white blood cells numbers owing to the increase of immunologic response [7]. This means that following the player up in the training from the physiologic perspective contributes a lot to know the effect of training on the training sessions. The decrease of oxygen delivery to the working extremities leads to increase the release of red blood cells from their storages. Wang indicates that the exercise greatly increases the red and white blood cells counts owing to their exit of their storages [8]. Using the pressing tool helped in increase the secretion of Erythropoietin from the kidney which is triggered by the decrease of arterial blood saturation with oxygen, which in turn works and triggers the increase of production of red blood cells within few hours. This is cannot be done in an altitude of 2100 feet. Despite of increasing the secretion of hormone, it is observed that no increase in the mass of red blood cells for several weeks [9].As a result of the biochemical changes and their importance in the physical, anaerobic effort which contributed to the improvement in the precision and depth of the forehand and backhand shots which require incessant physical effort; particularly during competition.

Conclusions

1. The training using the pressing tool have affected the biochemical, anaerobic variables.
2. The increase of white and red blood cells to a statistically significant degree within normal limits owing to their inclusion of all what to lead to increase the bodily toxins or harmful waste products.
3. An improvement in the precision and depth of the forehand and backhand shots in tennis.

Implications:

1. It is necessary to pay attention to the players' biochemical variables throughout the training duration and considering these variables with the goal of improving the players' physiologic abilities.
2. It is crucial to conduct the periodic measurements for the players' biochemical variables in order to identifying the level that these players arrived.
3. There is a need to conduct further studies for the biochemical variables.
4. There is a need to replicate similar studies on different samples of players in different age groups.

Conflict of Interest: The researchers report no conflict of interest.

Funding: This study did not receive any funding from any agency.

Ethical Clearance: A permission to conduct this study was obtained from the ethical committee in the College of Basic Education, University of Mustansiriyah.

Evaluation of Angiopoietin One and Angiopoietin Two with Missed Abortion

Hussien Saeed Masood[1], Sami Akreem Zbaar[2], Bushra Mustafa Mohamed[3]

[1]Lecturer, Department of Biochemistry, College of medicine, Tikrit University, Iraq, [2]Lecturer, College of Medicine, Tikrit University, Iraq, [3]Lecturer, Ministry of oil, North Oil Company, K1 Hospital, Iraq

Abstract

Missed abortion (MA) is a type of miscarriage, refer to pregnancy in which there is fetal demise without intervention, and also uterine that may expel the product of conception prior to 20 weeks of gestation. To assess the role of ANG1 and ANG2 level in early pregnancy and compare these level with healthy pregnancy women, ANG1 play role in new blood vessels maturation and stabilization, the inhibition of endothelial apoptosis and reduction of vascular permeability in stable environment. ANG2 is an antagonist of ANG1 and it known to enhance the plasticity, destabilization and permeability of blood vessels and vascular remodeling site.A prospective cross - study, all women were attended to obstetrics and gynecology outpatient**,**and this study was carried out from Jan 2019 to July 2019. Sixty Women with missed miscarriage fetus heart negative 6-8 weeks were screened to participate in the present study group, Ages were between 18 – 35 years old, and they were from center and the periphery of Kirkuk city to comparative forty apparently health women with early pregnancy fetus heart positive a control groups. A serum level of ANG1 and ANG2 was measured by ELIZA. The result shows that the mean serum level of Angiopoietin one was significantly decrease in missed mischarge compared to control women (2.92±2.4 *vs*. 5.6±3.2 ng/ml) respectively at a $P < 0.05$. And this study showed that there was the significant decrease serum level of angiopoietin two in missed miscarriage patients compared with the control group women (8.12±3.5 *vs*. 16.81 ±12.3). This study showed that there were the positive correlations of Angiopoietin one and two with missed miscarriage. It can be conclude that the level of serum Angiopoietin-1 and level of serum angiopoietin-2 in missed abortion decrease and it is can be used as an early and effective biomarker for diagnosis of missed abortion.

Keywords: *Angiopoietin-1, Angiopoietin-2, missed abortion, Biomarker.*

Introduction

Spontaneous abortion in the ending of pregnancy by removal or expulsion of an embryo or fetus before it can survive the uterus; an abortion without intervention is known miscarriage or spontaneous abortion. Spontaneous abortion can be divided into various subtypes: threatened, inevitable, incomplete, complete, and missed abortion.(1) When deliberate step are taken to end the pregnancy it called an induced abortion or less frequently induced miscarriage. Miscarriage also known spontaneous abortion is the intentional expulsion of an embryo or fetus before the 24 week gestation. Missed abortion is defined is a condition with retained products of conception, with no cardiac activity but the uterus is still silent making no attempt to expel the fetus or unrecognized intrauterine death of the embryo or fetus without expulsion of the product of conception it is constitutes approximately 15% of the clinically diagnosed pregnancies(2). Accurate differentiation between normal pregnancy and pregnancy loss in early gestation remains a clinical challenge; it is estimate that approximately 30-40% of implanted pregnancy result in spontaneous abortion during first trimester(3). Clinical feature in the typical instance .early pregnancy appearance to be normal .with amenorrhea, nausea, vomiting, growth of uteruses and breast change after fetal death there may or may not be vaginal bleeding, abdominal pain, cramping, vaginal spotting .other symptoms denoting missed miscarriage many woman have no symptoms during this period except persistent amenorrhea. No symptoms for missed abortion appear for several weeks and if appear, these vary from spotting

to heavy vaginal bleed and loss of pregnancy symptoms. Signs of missed abortions include loss of fetal heart sounds and closure of cervical[4]. The etiological factors for missed abortion include chromosomal abnormalities, maternal, fetal and embryonic malformations, placental and uterine anomalies, history of recurrent abortions, sexually transmitted diseases, thyroid disease and maternaldiabetes.[5] Complications of missed abortions may include pain, Fever, hemorrhage, retained products of conception, septic shock, bladder, bowel and uterine injuries andperforation [6]. Angiopoietin 1 encodes a 484 amino acid with M.W 57 KD, has ability to form higher order multimers though it super clustering. However not all structure can interact with tyrosine kinase receptor, the receptor can be only be activity at the tetramer level or high[7]. ANG1 act as chemo attractant for endothelial cell while also promoting endothelial cell sprouting and facilitating tissue invasion by nascent blood vessels through activation MMPS[8]. It plays critical role in mediating reciprocal interaction between the surrounding matrix and mesenchyme and inhibits endothelial permeability protein also contribute to blood vessel, maturation and stability and may be involved in early development of the heart[9]. Angiopoietin 2 encodes 466 amino acid polypeptides with mocular weight 75 KDa. AGPT2 are secreted glycoproteins that play a complex role in angiogenesis and inflammation, ANGPT2 is widely expressed during development, but it is to restricted postnatal to high angiogenic tissue such as placenta, ovaries and uterus.[10]. The aim of this study is to estimate the level of angiopoietin 1 and angiopoietin 2 in patient missed abortion. Furthermore, the current study objectives are:

1. To determine the serum angiopoietin one with patient missed abortion.
2. To determine the serum of angiopoietin two with patient missed abortion.
3. To determine the serum angiopoietin one and two with pregnancy women.
4. Find correlation and level angiopoietin one and two with patient with missed abortion and compared with pregnancy women as control group.

Materials and Method

Study design: A prospective cross–sectional study, hospital based study the protocol of this study was approved by the scientific committee of Tikrit University College of Medicine, the agreement of attendance to Azadi Teaching Hospital, Kirkuk General Hospital and Kirkuk Department of Obstetrics and Gynecology Center, that approved by Kirkuk Health Directorate, to collect the samples from the patients.

This study was carried out from March 2019 to august 2019. The patients admitted Department of Obstetrics and Gynecology, unit in hospitals Kirkuk City-Iraq. An interview was carried out with these patients using questionnaire form designed by the investigator including their name, age, etc.

Study Population

Patient and Control: Sixty women with missed abortion were screened to participate in the present study. Men ages were between 18–35 years old, and they were from center and the periphery of Kirkuk city. Sixty–case with missed abortion were considered as study group, while thirty woman normal pregnancies as control group.

Patient sample were inclusion criteria:

1. Woman in the age between 18 -35 years
2. Natural conception
3. History of positive pregnancy test
4. Intrauterine pregnancy
5. First attendance in the pregnancy

Patient sample were Exclusion criteria:

1. Pregnant women who refuse to participate in this study
2. Gestation age less than 6 weeks or more than 8 weeks
3. Multiple gestations
4. Ectopic pregnancy
5. Previous history of infertility
6. History of autoimmune or endocrine diseases (D.M, ALP, POS)
7. Smoker patient
8. Patient with recognizable cause of recurrent missed abortion

Sampling: Five ml of blood sample were taken by vein puncture from each subject enrolled in this study. Blood samples were placed into disposable gel test tubes, after 20 minute blood clotting, centrifuged at

5000 rpm for 15 minute and the obtained serum were aspirated using mechanical micropipette and transferred into clean test tubes which labeled and stored in deep freeze at –80 C^O for biochemical measurement of the levels of angiopoietin one and angiopoietin two were measured.

Result

This study includes ninety pregnant women and in there is first trimester they were divided into two groups:

1. First group represent 60 pregnant women with missed miscarriage were considering studies group F.H (-ve).
2. Second group represent 30 pregnant with normal intrauterine pregnancy .were considered as control group F.H (+ve).

There ages were ranged between 18 -35 years, were investigation for determination Angiopoietin one and Angiopoietin two in both group.

Serum level of angiopoietin one in missed miscarriage and the

Control Group: As show in the table (1), the mean serum level of angiopoietin one was significantly decreased in women compared to control women

(2.94 ± 2.4 *vs* 5.6 ± 3.2 ng/ml*)* respectively at a p< 0.05**.**

Table (1): The mean and standard deviation of serum Angiopoietin one in missed miscarriage and control group.

Angiopoietin One (ng/mL)	Missed Miscarriage Women	Control Group
NO	60	30
Mean	2.94	5.6
SD.	2.4	3.2

t.test 4.02 p. value < 0.05 Highly Significant

Serum level of angiopoietin two in missed miscarriage and the

Control Group: As show in the table (2), the mean serum level of angiopoietin two was significantly decreased in women compared to control women

(8.12 ± 3.5 *vs* 16.81 ± 12.3 ng/mL)respectively at a p < 0.05**.**

Table (2): The mean and standard deviation of serum Angiopoietin two in missed miscarriages and control group.

Angiopoietin Two (ng/mL)	Missed Miscarriage Women	Control Group
No	60	30
Mean	8.12	16.81
SD.	3.5	12.3

t.test 3.79 p. value < 0.05 Highly Significant

Correlation between angiopoietin one and angiopoietin two in missed miscarriage women: This study showed strong positive correlation between angiopoietin one and two with missed miscarriage women figure (1).

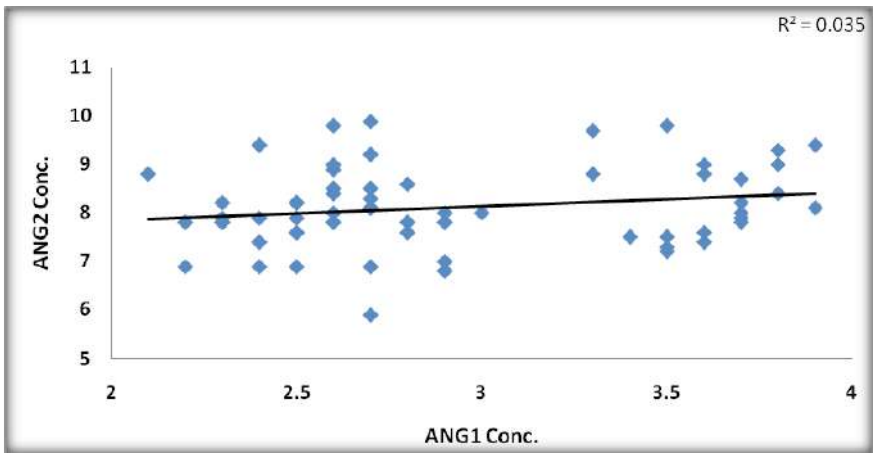

Figure (1): Correlation between angiopoietin one and two with missed miscarriage women

Discussion

Serum level of angiopoietin one in missed miscarriage and the Control group: This study showed that there was a significantly decrease serum level of Angiopoietin one in missed miscarriage compared with that of control group(intrauterine pregnancy)women same gestational age 6 – 8 weeks.

The result of study was agreement with Daponate*et al*[11] their study showed that optimal levels of serum Angiopoietin -1 were around 963.5 pg./ml (793.9 – 1277.6) in normal pregnancy women with gestation age 6-8weeks, and 810 pg/ml (595-767.9) in women with missed miscarriage. The current study showed that these value relatively higher level of angiopoietin one in normal pregnancy compared with women failed pregnancy, angiopoietin one is responsible for vascular growth and maturation of placenta, so deceased levels lead of angiopoietin one leads to increase chance of failure of pregnancy because of the defective vascular formation,when the every step of vessels formation is impaired starting from sprouting of vessels to maturation, then the chance of survival of the fetus decease due to lack of exchange of nutrient and waste product, impaired placental vascular development is related to imbalance in angiogenic factor, as implicated in pathological pregnancy .

Schneuer FJ, Roberts CL, Ashton AW, [12] studies conducted high level Angiopoietin one is mainly expressed in perivascular sertoli cell including pericyte, vascular smooth muscle cells,it binds specifically to the TIE2 receptor on peripheral endothelial membrane through paracrine function, causing phosphorylation of its receptor and subsequent signal transmission.

Serum level of angiopoietin two in missed miscarriage and the Control group: This study showed that there was a significantly decrease serum level of Angiopoietin two in missed miscarriage compared with that of control group(intrauterine pregnancy)women same gestational age 6 – 8 weeks.

The hypothesis of this study were compromised fetal growth is the result of compromised placental development and potential markers in maternal blood can detected those pregnancies risk, in view of it control role of angiogenesis we hypothesized that ANG2 maternal blood vessels would be increased at the first trimester when both maternal uterine vascular remodeling and placental branching angiogenesis take place, and level would be lower than normal in pregnancy destined for abnormal pregnancy.

This study shows it agreement with GevaE,*el at*[13] for angiopoietin -2 significantly decrease in missed miscarriage patient and recorded high level in normal pregnancy, and this result ANG-2 observed in women at 6-8weeks gestation may indicated that ANG-2 plays an important role in early placental angiogenesis, particularly in maternal vascular remodeling the lower maternal serum level of ANG -2 observed in women whose fetus subsequently developed IUGR may indicate compromised placental angiogenesis early pregnancy well before any clinical evidence of IUGR.

High level angiopoietin -2 in the normal pregnancy that ANG-2 mat also target fetal endothelial cell which also express the TIE-2 receptor thus potentially facial ting branching angiogenesis, and affect placental villous vascular change, interestingly TIE-2 is also express in endovascular trophoblast invading the uterine spiral arteries suggesting that an interaction between ANG-2 and TIE-2 may play significantly role in trophoblast behavior placental development.

Correlation between angiopoietin one and angiopoietin two in missed miscarriage women: This study showed strong positive correlation between angiopoietin one and angiopoietin two with missed miscarriage women. Angiopoietin -1 and angiopoietin-2 are both expressed in the placenta from the very early stage of pregnancy and they mediate number of endothelial and non-endothelial effect that are thought to be pivotal for proper placental development, ANG-2 stimulation an increase in trophoblast synthesis, ANG-1 act as a potent chemotactic factor for trophoblast .ANG-1 expression was restricted to the perivascular stroma of stem villi surrounding large blood vessels, supporting the hypothesis that angiopoietin -1 play role in maturation and maintenance of the placental vessels in contrast ANG-2 was expressed by the perivascular stroma of all placental villi. Furthermore this study show that level of ANG-1 and ANG-2 were significantly reduced in missed miscarriage and suggests that this decreased expression may therefore contribute to be reported poor angiogenesis.

Seval*el at*[14] with agreement with study a few previous in site hybridization studies have described the localization pattern of angiopoietin in the placenta in different stage of pregnancy in very early human

placenta (as early as the 4 theweek) ANG-1 protein was localized only in the cyncytiotrophoblast while ANG-2 was localized primarily in the cyncytiotrophoblast and less lesser extent in the cytiotrophoblastic layer of placental villi.

Previous study Dunk *el at*[15] demonstrated that ANG-1 and TIE-2 were detected in the trophoblast bilyar of first trimester placenta, where ANG-2 was restricted to cytotrophoblast in same study ANG-1 and ANG-2 were show to be implicated the regulation of trophoblast behavior through different mechanisms and to promote the growth and migration of trophoblast in vivo, which ANG-1 and ANG-2 and TIE-2 localized to the trophoblast, suggestion that the angiopoietin may play an autocrine role in the trophoblast function.

Conclusion

Serum angiopoietin -1and angiopoietin -2 levels decrease during pregnancy failure. The measurement angiopoietin -1 and angiopoietin -2 can be used first tool, to support the conformation of diagnosis of missed miscarriage.

Predictive Value of Toprs Score in Outcome of Pediatric Patient in Emergency Installation

Idham Jaya Ganda[1], Fitriya Idrus[1], Dasril Daud[1]

[1]Departement of Pediatrics, Faculty of Medicine, Hasanuddin University, Makassar, South Sulawesi, Indonesia

Abstract

Background: Scoring of severity of illness in pediatric emergency is rarely found. The aim of this study was to evaluate TOPRS Scores of children admitted to pediatric emergency.

Method: It was a prospective cohort study on severity illness score on pediatric patient in emergency instalation of Wahidin Sudirohusodo Hospital during October until November 2016. The study population was all children admitted to pediatric emergency unit Wahidin Sudirohusodo Hospital. TOPRS scores were assessed since admission. Subjects were followed up two classified the outcome into two groups, improved group and died group Predictive ability of this scorring system was analyzed using ROC curve.

Results: Among 218 subjects, 46 were died, and 172 were recovered. TOPRS scores were higher in non survivor group, with the optimal cut off value ≥2 to distinguish survivor and died group. P=0.000, sensitivity=100%, specificity=89.5%, PPV=100%, and NPV=74%. Multivariate analysis showed that TOPRS scoring system was independent variable and can be used as a parameter to evaluate the aoutcome of the patients, with p value 0.000 (95% CI 0.00-).

Conclusion: TOPRS scoring system has a predictive value on children admitted to pediatric emergency instalation. Optimal cut off value to distinguish mortality is ≥2.

Keywords: *TOPRS score, pediatric emergency, outcome.*

Introduction

Systemic inflammatory response syndrome (SIRS) is a complex and unspecified inflammatory response to a body which is harmful to the body.[1,2] A study conducted in 2007 - 2010 at the National Hospital Ambulatory Medical Care Survey (NHAMCS) United States got the incidence of SIRS in children by 21.7%. Based on that research, 53% SIRS cases was caused by infection.[3]

TOPRS Score (Temperature, Oxygen Saturation, Pulse Rate, Respiratory Rate, Sensorium and Seizurer) is a relatively new scoring in illness severity degree. This score uses the physical symptoms (symptomatic) parameters in Systemic Inflammatory Response Syndrome (SIRS) and the criteria mentioned in Advanced Pediatric Life Support (APLS).[4] The TOPRS score was developed in a study as a tool that can be applied in emergency rooms especially in places with limited facilities.[5]

SIRS is non-specific and may be caused by ischemia, inflammation, trauma, infection, or some combination of damage. SIRS is not always associated with infection. Infection is defined as a microbiological phenomenon with characteristics as an inflammatory response to microorganisms or the normal invasion of

sterile tissue by the organism.[6] A prior study by Daniela[7] during 2006-2009 in Craiova was obtained prevalence of pediatric patients with SIRS and having sepsis was 78%. Another study in Latvia found the prevalence of SIRS in treated children with febrile clinical symptoms was 72%.[8]

The presence of predisposing factors such as infectious diseases (respiratory tract, urogenitalia, skin and soft tissue), immune disorders (malignancy, radiation therapy, hormonal therapy), and invasive procedures may trigger the release of cytokines and vasodilator substances which will subsequently trigger the response systemic inflammation characterized by symptoms of tachycardia, tachypnea, hypotension, hypoperfusion, pyrexia or hypothermia, leukocytosis or leukopenia. Continuous inflammation will cause tissue damage, cellular metabolic changes, hemodynamic changes that will eventually lead to organ dysfunction and failure. Therefore, scoring system using clinical symptom variables is important to test the ability of predicting output.

Some research on scoring systems as predictors of outcomes has been done. One of the earliest physiological scoring systems in children is the PSI (Physiology Stability Index), in which the system assesses 34 variables. Furthermore, a simpler scoring system that is PRISM, which assesses 14 variables, in which the variable consists of physical and laboratory assessment. On the other hand, there is also a PIM (Pediatric Index Mortality) scoring system assessed at the time of admission to pediatric intensive care. Those kind of scoring systems cannot be used in emergency department, but it need a longer time to wait for laboratory results. It is also less suitable for use in developing countries such as Indonesia. Therefore, it is necessary to examine the scoring system as a simpler external predictor that combines vital signs,so this study is aimed to determine the TOPRS score of pediatric patients in pediatric emergency care.

Materials and Method

Design and Variable Study: This study was an observational with a prospective cohort approach at the emergency instalation of Wahidin Sudirohusodo Hospital, Makassar which conducted during October until November 2016. It has been approved by the ethical committee of Faculty of Medicine, Hasanuddin University.

The study variables consist of: independent variables (infectious and non-infectious diseases), dependent variables (TOPRS score and outcome), confounding varia bles (biological processes occurring in patients during treatment), random variables (sex, nutrition, and genetic), and control variables (age, basic disease treatment).

Population and Sample: Population of the study were patients who entered in the IRD of children aged 1 month to 18 years who underwent treatment at DR Wahidin Sudirohusodo Hospital, Makassar. The study sample was the entire affordable population that met the inclusion and exclusion criteria which obtained by using consecutive sampling method based on the order of admission in the hospital.

Method of Collecting Data: Anamnesis and physicals examination in patients aged 1 month -18 years was conducted at the first admission to the hospital. The result was confirmed by TOPRS score check. Age, sex, nutritional status, vital signs (awareness, blood pressure, respiration, pulse, temperature), oxygen saturation, presence or absence of seizures were checked. During the treatment, study subjects were observed until the effect (outcome) of the patient improved or died. The end result observed is the outcome (improved or died).

Data Analysis: All the data obtained are recorded in the study data form and then grouped by the destination and type of data. Appropriate statistical method was used analyse the data, namely: 1) the univariate analysis; and 2) the bivariate analysis which includes: test Student's t, Mann Whitney Test, X2 (Chi square) or Fisher's Exact test, to assess the accuracy limit levels as a predictor, calculating the sensitivity, specificity, positive predictive value and predictive value negative (with CI 95%).

Results

Out of 218 patients, there were 172 patients improved and 46 patients died. Based on the sex category, male group consists of 31 patients (24.21%) who were died and, 97 (75.78%) were improved, while female group consists of 15 patients (16.66%) who were died and 75 patients (83.33%) were improved. Statistical analysis showed no significant difference between the two groups with $p = 0.17$ (Table 1).

Table 2 showed the correlation between nutritional status and the patients' outcome. In well nourish group, 13 patients (11.92%) were died and 96 patients (88.07%)

were improved. In the under nourished group, 17 patients (34%) were died and 33 patients (66%) were improved, while malnutrition group consists of 16 patients (27.11%) who were died and 43 patients were improved (72.88%). Statistical analysis showed that there were significant differences in terms of improved outcome or death based on nutritional status with p = 0.003.

Based on the data analysis, it was found that the mean age of patients did not different significantly between the two groups that compared with p = 0.26. (Table 3). It means that age was not a prognostic factor in the outcome of patients in emergency installation, while nutritional status was a prognostic factor.

The average score of TOPRS score of study subjects showed that the average score of TOPRS score of patients who improved was lower than the score of the patient who died. Mann-Whitney test results show that there was a very significant difference between these two groups with p = 0.000 (Table 4).

The logistic regressi on analysis of the independent variables in predicting the outcome showed that the nutritional group B had p = 0.283 with confidence interval 95% (0.60-5.62). While the TOPRS variable ≥2 has p = 0.000 with confidence interval 0.00-, which shows the score of TOPRS is independent variable which is not influenced by nutritional status. Thus TOPRS can be used as parameters to generate output (Table 5).

Discussion

This study shows that the TOPRS score is higher in the deceased group. The TOPRS score is an independent variable, which can be used as a parameter to determine the output with p = 0.000 with (95% CI 0.00-). The TOPRS score has a predicted outcome score in the admitted patient to emergency care. The best cutting point for distinguishing two outcomes (improved or dead) is ≥ 2.

The sex correlation with the outcome of the treated patient did not differ significantly, which means that sex is not a prognostic factor. Overall, there was no significant difference by sex, but death was found more in girls. Similar with the results obtained by Faisal[9], there is no significant difference in sex with outcome of patients in Wahidin Sudirohusodo Hospital based on SICK score.

In relation to nutritional status, the incidence of SIRS and sepsis leading to death more frequently affects malnourished children. This is associated with a decrease in the antibody immune response to the presence of a worse antigen (infection) to allow for severe SIRS/ sepsis.[10]

Generally, the value of TOPRS score in patients who died is much higher than the value of the improved patients. The mean value of TOPRS score of patients in improved group was lower compared to the patients who died. It means that the role of SIRS/sepsis parameters is particularly prominent in patients who die and correlates with the weight and outcome of the disease. It occurs because of the increase of SIRS signs, the appearance of proinflammatory status characterized by tachycardia, tachypnea or hyperpnea, hypotension, hypoperfusion, oliguria, leukocytosis or leukopenia, pyrexia or hypothermia. Several molecules that signal from cell to cell are thought to be involved in proinflammatory status events include interleukin (IL) -1, IL-5, IL-6, IL-8, IL-11, IL-15, and multiple colony stimulating factors, and chemokacin (monocyte chemotactic protein-1, growth-related oncogene alpha protein). Similar findings have been made for tumor necrosis factor (TNF) -alpha and other related molecules derived from pathogenic microbes, eg lipopolysaccharides, staphylococcal enterotoxins A-E. it showed that there is no single trigger for SIRS. In other words, SIRS is a common organism response to various types of immune system challenges. SIRS can affect all organ systems and lead to MODS.[5]

TOPRS score can be used as a differentiator between groups of patients who have a good and bad prognosis. From this study it was found that the lowest cutoff point of the TOPRS score lies in the 97.5 percentile of the improved group, with the TOPRS score of 2 and the highest cutoff point lying in the 2.5 percentile of the deceased group, with the TOPRS score 3. In between the two cut off point, there are 2 cut off points, for each cut point then assessed sensitivity, specificity, positive predictive value and negative predictive value. It aims to find the best TOPRS score value in determining outpatient outcomes admitted to emergency room.

These values are then analyzed and described into the ROC curve, and it is found that the furthest point from the diagonal line and the upper left corner is the green line ie the cutoff point of the TOPRS score ≥3, which has the same under-curve (AUC) value with the cutoff point of TOPRS score score ≥2 is 0.945 or in other words from two points of this cut has the same AUC. Since both are the same, in order to establish the prognosis we choose the earlier value, TOPRS ≥2.

This cutting point has a sensitivity value of 100%, specificity 89.5%. In which, this TOPRS score has the ability to identify patients treated with a good prognosis of 100% and states have a poor prognosis of 89.5% if the score of TOPRS patients ≥2.

This point has a positive predictive value of 100%, and a negative predictive value of 74%. Positive and negative predictive values are also quite good. When applied clinically, the patients have a good prognosis if the TOPRS score is less than <2 of 100%. Patients' outcome depends on many factors, such as the type of illness, the speed of the diagnosis, and the treatment. Accumulation of these factors will lead the patient to a good or bad prognosis.

The TOPRS <2 score score limit shows very significant differences in terms of output. The odds ratio can not be calculated because there is one table cell that is zero value. The TOPRS score value (<2) has a better predictive prognosis for an earlier assessment in emergency room with the best treatment (as per clinical pathway). In contrast, patients with a TOPRS score (≥2), which means there are 2 or more abnormal (SIRS) parameters, should be wisely translated in their clinical application. The specificity of 89.5% is quite high (optimal), so that the patient with the TOPRS score ≥ 2 needs more rigorous monitoring, but does not necessarily

direct the bad outcome (death). The results of this study expose the same value, with previous studies conducted by Harmesh bain in India who found the cutoff point of TOPRS ≥2 score. In a study conducted by Gupta et al.[5], the severity of the disease assessed by the SICK score found a score of 2.5. It is also similar to Faisal's[9] result, by using a SICK score to find a cutoff point ≥2. 3.

Based on bivariate analysis, there were two variables, TOPRS score and the identified nutritional status, which had significant relationship with the outcome of the infected patient in pediatric emergency instalation. Therefore, multivariate analysis is done. From multivariate analysis showed that TOPRS score is independent variable which is not influenced by nutritional status. Thus, the TOPRS score can be used as a parameter to determine the output.

The TOPRS score can be said to reflect the severity of a disease, because every disease, has some or all of the vital signs/symptoms present in the TOPRS score. In this study, there are 4 patients who died with the score of TOPRS 2, it can be explained that the possibility due to the basic disease of each patient, which at the beginning of hospital admission is relatively mild but the history of disease/treatment experience worsening.

In conclusion, TOPRS score had a prognostic value on patient outcome in pediatric emergency instalation. The best cutting point to determine the outcome of the patient is the TOPRS score ≥2, where the result below this score is a good prognosis, after an optimum management according to the protocol.

Conflict of Interest: There is no conflict of interest that can be reported in this study.

Abstract

The increasing use of cell phones and laptops in today's modern society has a negative impact on health; one such impact is on informatics students, who struggle with the use of cell phones and computers in their daily activities. This study aimed to determine the relationship between radiation exposure to cell phones and laptops with subjective complaints in the form of sleep quality, headache, dry eye syndrome (DES) and concentration disorders.

The research is analytic observational and cross-sectional approaches. The study used simple random sampling to select 112 respondents, all of which were informatics students of Universitas Sebelas Maret (UNS). The Pearson correlation test results were obtained from cell phone and laptop radiation exposure with sleep quality ($p < 0.05$; $r = 0.192$), headache ($p < 0.05$; $r = 0.510$), dry eye syndrome ($p < 0.05$; $r = 0.1950$) and disturbances concentration ($p < 0.05$; $r = 0.406$).

Keywords: *Radiation exposure, sleep quality, headache, dry eye syndrome, disturbances concentration.*

Introduction

Cell phones and laptops are very essential in today's world, and their use is inevitabel. However, for all the benefits associated with their use, they also have downsides. For example, cell phones and laptops are major sources of electromagnetic pollution, which has unpleasant effects on public health. The results in 2015 showed that 54% of the world's total population or 3.996 trillion of the 7.476 trillion people on earth have cell phones, and most users are 18-34 years old[(1)], while in America, cell phone use is mostly among adolescents aged 8 to 18 years[(2)]. In 2015, cell phone use in Indonesia is currently at 56.92% of the total population[(3)]. The use of laptops has also become a lifestyle in the community, especially among students and employees. In 2013, the majority of laptop users in the UK were 14-24-year olds, and they accounted for as much as 70% of the total users[(4)]. Meanwhile, in Indonesia, the number of laptop users reached stood at 42% of the total population, and consisted mostly of students, entrepreneurs and housewives[(5)].

The increasing use of cell phones and laptops has an adverse effect on health. Based on the research in Sweden, young adult cell phone users complained of subjective complaints in the form of stress, depressive symptoms, and decreased sleep quality[(6)]. The study showed that sleep disturbances were experienced by 19.2% of students and concentration disruption was experienced by 14.5% of the students due to exposure to cell phone radiation[(7)] and an effect on the pattern of Electroencephalograph (EEG) and human sleep patterns[(8)]. Cell phone usage disrupts the pattern of sleep at night and also affects the quality of sleep if one's phone is still turned on[(9)]. Decreased sleep quality is associated with cellular phone radiation exposure due to metabolic and cardiovascular disorders which have an

e-mail: isnaqadrijati@staff.uns.ac.id
Tel: (+62)8122613360

effect on the occurrence of insomnia and decreased sleep duration[10].

Exposure to cell phone radiation in the form of electromagnetic waves acutely causes headache, eye disorders, fatigue, and sleep disorders. According to the NIOSH, it is reported that 88% of those who use laptops for at least 3 hours will experience fatigue and dry eye syndrome[11]. Dry eye syndrome could be in the form of sensitive eye, feeling discomfort when exposed to bright light, the eyes feeling itchy and sandy, eye aches, blurred vision and reduced vision.

The body can recognize cell phone radiation exposure as a carrier of information that disrupts the body's metabolism and biochemical reactions by interfering with the body's physiological processes and which cause an increase in intracellular free radicals, genetic damage, inter-cell communication disorders, leakage in the blood-brain barrier, and the risk of tumor. However, exposure to radiation from cell phones does not directly causeharm to one's health, but rather triggers biochemical responses in cells so that the manifestations of the disorder usually occur for a long time, as carcinogenic and has the potential to cause interference with various organs of the body[12].

Exposure to electromagnetic radiation from cell phones can cause physical stress where the body responds by secreting hormones from the hypothalamus. Increased hormone secretion in the hypothalamus results in increased levels of glucocorticoid hormones, which increases cortisol levels and causes a decrease in the levels of HMG-CoA reductase. The decrease in the level of HMG-CoA reductase will cause a decrease in the rate of endogenous synthesis of cholesterol. A decrease in endogenous synthesis will cause a decrease in plasma cholesterol levels.

Any physical and psychological stress on the body for just a few minutes can lead to an increase in ACTH secretion. Consequently, there will be an increase in the secretion of glucocorticoids and cortisol. Glucocorticoids play an important role for catecholamines to fully implement the effect of free fatty acid mobilization. Increased secretion of glucocorticoid hormones will also increase the secretion of the hormone epinephrine which can increase the rate of lipolysis in adipose tissues, and norepinephrine, which can increase the use of circulating lipoproteins, so that cholesterol levels in the plasma will decrease. The secretion of cortisol is higher when the body is exposed to stress, both physical and psychological. Cortisol can modulate the immune system because all leukocytes have receptors for cortisol. Increased cortisol levels will cause a decrease in the levels of HMG-CoA reductase. Decreasing levels of HMG-CoA reductase will cause a decrease in the rate of endogenous synthesis of cholesterol. The decrease in endogenous synthesis will cause a decrease in cholesterol levels in the plasma which results in subjective complaints in humans[13].

Material and Method

The research is observational analytic with cross-sectional approaches to analyze the relationship between radiation exposure from cell phones and laptops with subjective complaints by students. The study utilized simple random sampling to select 112 UNS informatics students from a population of 155 students. The respondents were adjusted to the inclusion criteria in the form of UNS informatic students who used cell phones and laptops every day, while the exclusion criteria were: 1) Students who consume sleeping pills, antiarrhythmic agents, corticosteroids, diuretics, and theophylline; and 2). Students who consume coffee or soft drinks 6 hours before going to bed.

The independent variable was the duration of exposure to electromagnetic radiation from cell phones and laptops as revealed by a questionnaire, with the results indicating the average duration cell phone and laptop usage each day, expressed in minutes. The questionnaire used scale measurement in ratios.

The dependent variable was subjective complaints in the form of:1) Sleep quality, measured using the Pittsburgh Sleep Quality Index (PSQI) questionnaire which had 7 main components with a score range 0-21. A score of 0 indicates that sleep quality is getting better, while a score of 21 indicates that sleep quality is very poor. For the sake of statistical analysis, sleep quality was grouped into two, namely good sleep quality (score <5) and poor sleep quality (score> 5)[14]; 2) Headache, which was revealed using a questionnaire containing the description/degree of headache with a score range of 0-10, so that the scale of measurement was a ratio; 3) Dry eye syndrome, which was revealed using the Ocular Surface Disease Index (OSDI) questionnaire. OSDI scores were obtained using the formula: total number of scores x 25. OSDI scores were categorized into four, namely: normal (score 0-12), mild (score 13-20), moderate (score 21-32) and severe (score 33-100)[15] and 4) Headache symptoms

which was revealed by a questionnaire about headache symptoms that had undergone validation and reliability. Disturbance concentration, which was revealed using the Grid Concentration Test. Grid Concentration Test scores were categorized into two, namely: normal (score > 10), severe (score 0-10).[16] Pearson correlation test was used to determine the relationship between cell phone and laptop radiation exposure and subjective complaints, at a significance level of 0.05.

Findings:

Table 1: Distribution of repondents' characteristics

Characteristic	Amount (n)	Percentage (%)
Gender		
Male	50	44.3
Female	62	55.7
Duration of Radiation Exposure		
High (> 2 hour)	105	93.75
Low (< 2 hour)	7	6.25
Subjective complaint:		
Sleep quality		
Good	42	37.50
Bad	70	62.50
Headache		
Tense muscle headache	78	69.64
Migraine	26	23.22
Cluster	8	7.14
Dry Eye Syndrome		
Normal	27	24.10
Mild	19	16.96
Moderate	31	27.68
Severe	35	31.26
Concentration Disorder		
With	68	60.72
Without	44	39.28

Table 2: Variable correlation test for exposure to cell phone and laptop radiation and subjective complaints

Subjective Complaints Variables	Correlation Coefficient (r)	p Value
Radiation cell phones and laptops exposure with sleep quality	0.192	0.042
Radiation cell phones and laptops exposure with headache	0.510	0.000
Radiation cell phones and laptops exposure with dry eyes syndrome	0.195	0.034
Radiation cell phones and laptops exposure with concentration disturbance	0.406	0.020

Discussion

Based on research data, 93.75% of the research subjects used cell phones and laptops for more than 2 hours per day. This shows that, in terms of cell phone and laptop usage, UNS informatics students are in the high intensity category, in accordance with the research of Saxena; 57% of their respondents use cellphones and laptops for more than two hours each day.[17]

The results of the Pearson statistical test showed a significant relationship between exposure to cell phone and laptop radiation and sleep quality in UNS informatics students (p = 0.042; r = 0.192). The results of other Pearson statistical tests also show a significant relationship between exposure to radiation from cell phones and laptops and interference with concentration among UNS informatics students (p = 0.020; r = 0.406). This situation is consistent with the research in which there was a positive correlation between cellphone use and deteriorating sleep quality among medical students[16]. Exposure to radiation from cell phones and laptops can disrupt the diurnal rhythm; reduce the production of melatonin hormone in the pineal gland which can reduce sleep onset, thereby reducing sleep; and encourage the secretion of cortisol hormone which can affect the metabolic cycle, the sleep-wake cycle, and of sleep quality in the REM phase.[18]

Concentration is defined as a person's ability to maintain attention in a long period. Attention involves parts of the brain called alerting, orienting, and attention executives.[19] Orienting as a process of directing attention to sources of stimulation involving visual orienting functions. The anatomical structure associated with orienting is the parietal and frontal lobes which produce neurotransmitters acetylcholin and play a role in the process of orienting. The function of acetylcholin is to help communicate between the nerves and muscles of the eye and the process of storing and recalling memories and attention. Physical environment such as radiation exposure can affect the production of acetylcholin so that it can cause interference with concentration in a person.

The results of the Pearson statistical test showed a significant relationship between radiation exposure to cell phones and laptops and headache among UNS informatics students (p = 0.000; r = 0.510). The resulting headache is related to the occurrence of electrical hypersensitivity resulting from oxidative damage in brain cells. Brain cells will change the electrical activity of the brain, followed by changes in the blood-brain

barrier permeability, resulting in the disruption of the active transport of Na+ and K+ ions, and the release of Ca ++ ions by cellular membranes.[20] When the cell experiences stress, there is a regulatory disorder so that the Ca ++ ion undergoes regulation opposite to that of Ca ++ ions going into the cell and triggering focal ischemics in the brain region, thus causing complaints of headache.[21] The exposure to radiation for one hour caused a stress response to the cell endothelium in the form of a change in phosphorylation status of certain types of proteins namely Heat shock protein 27 (Hsp 27). This will facilitate the elements of albumin, ions, metal, chemicals and viruses to pass through so that microedema and inflammation occur, thus causing complaints of headache.[22]

The results of the Pearson statistical test showed a significant relationship between exposure to radiation from cell phones and laptops and the incidence of dry eye among UNS informatics students ($p = 0.034$; $r = 0.195$). This is consistent which states that dry eye syndrome results from continuous radiation exposure to the eye, resulting in hyperosmolarity in the tear layer, which causes irrigation in the eyeball to be disrupted, thus causing inflammation on the eye surface.[21],[23] The severity of dry eye syndrome can be influenced by different eye distances to the monitor, as well as the brightness level of the monitor and the different light conditions around the location.[24] Exposure to cell phone radiation increases the concentration of free radicals such as reactivity oxygen species (ROS) in cells. The high level of ROS results in oxidative stress and injury to the cell, namely Lipid peroxidation in membranes is characterized by increased levels of malondialdhyde (MDA).(21) Long radiation exposure can cause damage to cell structures, resulting in decreased function and death of cells.[25]

Conclusion

Exposure to electromagnetic radiation from cell phones and laptops causes subjective complaints such as decreased sleep quality, headache, dry eye syndrome and impaired concentration among UNS informatics students.

Conflict-of-Interests Statement: The authors declare that there are no competing or potential conflicts of interest.

Comparing the Effectiveness of Video-Assisted Teaching and Simulation on Nurses' Knowledge in Performing Cardiopulmonary Resuscitation

Jatim Sugiyanto[1], Karyono Mintaroem[2], Titin Andri Wihastuti[2]

[1]Master Program of Nursing, Faculty of Medicine, [2]Lecturer in Medical Faculty, University of Brawijaya

Abstract

Cardiac arrest is one of the main health problems in the world with high mortality rate. The problem requires quality and comprehensive treatment at the hospital especially in the process of performing cardiopulmonary resuscitation. Quality and comprehensive cardiopulmonary resuscitation must be performed by nurses with adequate knowledge about cardiac arrest. This knowledge may be obtained through simulation-based and technology-based training such a *video-assisted teaching.* The objective of the study was to compare the effect of training using *video-assisted teaching* and simulation on nurses' knowledge of performing cardiopulmonary resuscitation. The study used quasi-experimental design and *pretest-posttest with control group* approach. There were 42 respondents who were divided into 2 groups. Knowledge was measured before and after trainings. Data were analyzed using *Wilcoxon* and *Mann Whitney* tests. Result of the study indicated that there was difference in nurses' knowledge between before and after training using video-assisted teaching and simulation with p-value of 0.000. However, there was no difference in nurses' knowledge after training using video-assisted teaching and simulation with p-value of 0.372. Thus, training using video-assisted teaching and simulation may increase knowledge about performing cardiopulmonary resuscitation although there was no difference in knowledge score between the video-assisted teaching group and the simulation group.

Keywords: *Cardiopulmonary Resuscitation knowledge, Video Assisted Teaching, Simulation.*

Introduction

Emergency cases such as *In-Hospital Cardiac Arrest* (IHCA) happen suddenly and require rapid, correct, and accurate response. IHCA is a case of cardiac arrest that occurs at the hospital[1].

Data from the *World Health Organization* (WHO) indicated that cardiac arrest is the leading cause of death both in developed and developing countries, accounting for 60% of the total number of death[2]. Mortality rate of IHCA in the United States is predicted at 200.000 cases every year[3]. According to Girotra *et al* mortality rate of in-hospital cardiac arrest (IHCA) reached 23.1% [4]. In-hospital patients who survived in-hospital *cardiac arrest* was around 20% [5]. In Indonesia, the prevalence of coronary heart disease reached 883.447 or about 0.5% of the total number of population, while the number of patients diagnosed with coronary heart disease was higher at 1.5% or about 883.447. There were 375.127 patients with coronary heart disease in East Java Province or around 1.3% of the population[6].

AHA recommended quality cardiopulmonary resuscitation as a solution to decrease the rate of sudden cardiac death. Cardiopulmonary resuscitation (CPR) is a procedure to maintain and restore heart and lung functions by administering chest compression and

artificial breathing[7]. This procedure becomes the focus in the effort to prevent sudden cardiac death by health professionals[4].

Since health professionals plays key role in increasing patients' health status and quality of life, they need to have better knowledge to support their skills in providing health services[8]. Therefore, as health professionals, nurses should increase their knowledge and skills[9].

Nurses play a key role in preventing worse prognosis of cardiac arrest. Factors contributing to nurses' ability to prevent the worsening of prognosis are levels of knowledge, skills, and motivation. Knowledge can be increased using nursing education. Nursing education is an effort to apply knowledge about health into skills through learning process[10, 11]. The ability to rapidly and effectively respond to cardiac arrest lies in nurses' competency in managing cardiac arrest. Limited skill in cardiac arrest management i.e., inability to perform resuscitation may worsen cardiac arrest[12].

Studies show that there is a relationship between nurses' knowledge and skills. Knowledge will have an effect on nurses' skill in delivering nursing care[13]. Improving nurses' knowledge about cardiopulmonary resuscitation may be done by providing them with education and training. Farshi *et al* (2012) stated that training for nurses may be delivered using traditional method such as simulation or non-traditional one such as technology-based learning[14]. Hadid and Suleiman (2012) claimed that simulation may improve nurses' knowledge and skills in performing cardiopulmonary resuscitation[15]. Similar previous study also showed that there was a significant difference between pretest and posttest result on group trained using simulation when compared with pretest and posttest result of group trained using traditional lecture method[16].

Sadeghi *et al* (2014) stated that besides simulation, teachers may also use technology-based method such as video-assisted teaching to facilitate learning. Both method, however, have their weakness and strength[17]. In general, simulation is a favored method in teaching cardiopulmonary resuscitation to health care professionals and the general public because this method is more interactive. Moreover, during simulation, learners find it easier to ask questions directly to the facilitators. Unfortunately, simulation is time consuming and needs a lot of space in its implementation. Meanwhile, when learning through video-assisted teaching, learners are more independent and have greater freedom with learning time as they are free to decide when they want to learn. In addition, video-assisted teaching provides a consistent learning material for the learners which facilitates better learning. This method may become an innovative solution to simulation method to increase nurses' knowledge[18].

The preliminary study found that in 2017 there were 117 cases of cardiac arrest requiring immediate response in resuscitation room and ICU of dr. Slamet Martodirdjo Regional General Hospital (RSUD) Pamekasan. The total number of patients with heart disease from January until September 2018 was 1187 with a mortality rate of 40% of the total in patients. From January to August 2018, the number of cardiac arrest incidence was 104 with a high mortality rate of 71 deaths.

The preliminary study also found that not all nurses performed cardiac arrest management as some of the ICU or Emergency Departement nurse did not know how to manage cardiac arrest. The Regional General Hospital on dr. H. Slamet Martodirdjo had already had a *Code Blue* team although its implementation had not been maximum. The result of interview and observation of 10 ICU and Emergency nurses indicated that 90% of cardiac arrest management had not conformed to the recommended AHA 2015 algorithm. Some of the nurses had not known *Ventricular Tachycardia* (VT) or *Ventricular Fibrilation* (VF) rhythm and *Asistole* or *Pulseless Electric Activity* (PEA). Consequently, when treating VT/VF *cardiac arrest,* they only performed cardiopulmonary resuscitation, without defibrillation. This may contribute to the high mortality rate of patients with cardiac arrest. The preliminary study also discovered that dr. H. Slamet Martodirdjo Regional General Hospital Pamekasan had not had SOP for the management of patients with cardiac arrest.

Based on these conditions, the researcher was interested in comparing the effectiveness *video-assisted teaching* and simulation in increasing nurses' knowledge in performing cardiopulmonary resuscitation.

Method And Material

The study used quasi-experimental design with pretest-posttest with control group approach. There were 42 respondents, nurses of dr. Slamet Martodirdjo Regional General Hospital Pamekasan, who were divided into video-assisted teaching group and simulation group.

The video used by the researcher in video-assisted teaching group was in compliance with 2015 AHA guidelines and the simulation was delivered by an instructor with AHA license. The video had a duration of about 10 minutes, while the simulation was around 10-20 minutes in length.

The inclusive criteria for the respondents were nurses who had at least 2 years working experience, had performed cardiac arrest management, and were willing to become a respondent for the study. Nurses' knowledge was measured using questionnaire. The validity and reliability of the questionnaire were tested using cronbach' alpha with a value of 0.988. Knowledge was measured before and after intervention. Bivariate analysis was done using Wilcoxon and Mann Whitney test. The study was conducted after obtaining ethical clearance from the ethical commission ofdr. Slamet Martodirdjo Regional General Hospital Pamekasan.

Results

Univariate:

Table 1: Respondents' Characteristics by Age, Working Experience, and Knowledge Score

	Mean	Median	Min-Max	SD
Age	34.74	33	25-55	7.245
Working experience	12.26	10	4-28	6.56
Knowledge Score				
• Pre	7.98	8	6-10	1.334
• Post	12.6	12.5	11-14	0.912

Table 1 shows that the youngest age was 25 years old and the oldest one was 55 years old with a median value of 33. The longest working experience was 28 years and the shortest one was 4 years with a median value of 10. The highest knowledge score before intervention was 10 and the lowest one was 6 with a median value of 8. The highest knowledge score after intervention was 14 and the lowest one was 11 with a median value of 12.5.

Table 2: Respondent's General Characteristics by Sex, Education, and Competency

No	Variable	Category	f	%
1	Sex	Male	25	59.5
		Female	17	40.5
2	Education	Diploma 3 (Associate Degree)	28	66.7
		Bachelor+Ners	14	33.3
3	Competency	BLS	42	100
Total			42	100

Table 2 shows that the number of male respondents was higher than female ones, with 25 and 17 respectively. There were more respondents who held a diploma 3 degree (28 respondents. All respondents had BLS competency.

Table 3: Score Change in of Nurses' Knowledge in Managing Cardiac Arrest before and after Video Assisted Teaching

Measurement	Median (Min-Max)	p
Score before Intervention	8 (6-10)	0.000
Score after Intervention	12 (11-14)	

Table 3 shows a p value of 0.000 ($p<0.005$). Therefore, it can be concluded that there was a change in knowledge score between before and after intervention using *video assisted teaching*.

Table 4: Score Change in of Nurses' Knowledge in Managing Cardiac Arrest before and after Simulation

Measurement	Median (Min-Max)	p
Score before Intervention	8 (6-10)	0.000
Score after Intervention	13 (12-14)	

Table 4 shows a p value of 0.000 ($p<0.005$). Therefore, we can conclude that there was a change in nurses' knowledge score between before and after intervention using simulation.

Table 5. Comparison between Knowledge Scores Before and After Intervention using Video-assisted Teaching and Simulation

Group	Median	Min-Max	p
Video	5	3-5	0.372
Simulation	5	4-6	

Table 5 indicates a p value of 0.327. Therefore, there was no score difference between before and after intervention with video-assisted teaching and simulation. In other words, nurses' score knowledge about managing cardiac arrest in dr. H. Slamet Martodirdjo Regional General Hospital Pamekasan before and after intervention with video-assisted teaching and simulation was quite similar.

Discussion

The result shows that there was a difference in knowledge score before and after intervention using *video-assisted teaching*.

This result is also supported by Jance, Cheetham and Baumgartner (2009) who maintained that learning process using method which is based on advanced technology increases prefrontal cortex activation in the human brain. Increased activation of prefrontal cortex triggers cognitive stimulation and strengthen memory recall[19].

Technology-based learning process provides a learnered-centered learning in managing information process to improve cognitive skill in accordance with the desired objective. The learning process can be done autonomously with available supporting technology [11].

The study also showed that there was a difference in nurses' knowledge score between before and after intervention using simulation.

This result is also in line with study by Everett-Thomas *et al* (2016) which showed that there was an increase in knowledge score of cardiopulmonary resuscitation performance after simulation. The increase in knowledge was in the form of better quality cardiopulmonary resuscitation which was reflected in its compression rate as well as precise compression depth and position [20].

However, the study did not find a difference in nurses' knowledge score after being trained using video-assisted teaching and simulation.

This finding is in line with a study by Hsieh *et al* (2016) which showed that the result of training of cardiac arrest management using *video assisted teaching* was not significantly different from that using simulation. Both method increase knowledge score through its own mechanism[21]. However, previously study also suggested that there was a difference in the knowledge of performing cardiopulmonary resuscitation between with-instructor group and without-instructor group in which the latter group gained higher score than the former one. Respondents in without-instructor group were given freedom in learning about quality cardiopulmonary resuscitation in various ways, so their knowledge score was higher than the knowledge score of respondents in with-instructor group[22].

Every method increase respondents' knowledge in different way. Video-assisted teaching works by creating *audio imaginary* effect. The effect increases long-term memory retention and facilitates memory recall[23].

This result is also supported by Jance, Cheetham and Baumgartner (2009) who maintained that learning process using method based on advanced technology increases prefrontal cortex activation in the human brain. Increased activation of prefrontal cortex triggers cognitive stimulation and strengthen memory recall[19].

Simulation increase respondents' knowledge by promoting critical thinking in the process of solving a problem[16,24]. Cheng *et al* (2018) also maintains that cases given in a simulation will encourage the respondents to analyze the problem which will increase the respondents' knowledge through critical thinking[25]. Further, respondents also find it easy to learn about cardiac arrest management with the help of facilitators who are knowledgeable about cardiopulmonary resuscitation[20].

Based on the above explanation, we can conclude that there was no difference in nurses' knowledge score of cardiac arrest management between video-assisted teaching and simulation. Each method may increase knowledge though different mechanism.

Conclusion

In summary, there was a change in nurses' knowledge of performing cardiopulmonary resuscitation after training using video-assisted teaching and simulation. However, there was no difference in knowledge between the video-assisted teaching group and the simulation group.

Association of Exon Deletion of MXI1 Gene with Cervical Abnormalities and Cancers Incidence in Some Iraqi Married Women

Jinan J. Al-Mussawy[1], Abdul-Hussein M. Al-Faisal[1], Saife D. Al-Ahmer[1], Asan A. Qasim[2]

[1]Researcher, Institute of Genetic Engineering and Biotechnology for Postgraduate Studies, University of Baghdad,
[2]Researcher, Oncology Department, Al-Elwiy Materninty Teaching Hospital

Abstract

Cervical cancer is one of the most frequently diagnosed malignancies representing the fourth leading cause of cancer-related death in females' worldwide, with approximately 500,000 new cases diagnosed and 280,000 deaths occurring each year. Mxi1, an antagonist of c-Myc, maps to human chromosome 10q24-q25, a region altered in a substantial fraction of prostate tumors, in prostate cancer, where a high frequency of loss and mutation of the *MXI1* gene has been reported. The aim of present study was to find out the possible association of exon deletion of MXI1 gene with incidence of cervical abnormalities and cancers in some Iraqi married women. The present study include collection of 120 scraping cervical cells samples from women clinically diagnosed with cervical abnormalities and cancer, and 30 scraping cervical cells samples from apparently healthy women and all these samples were submitted for cytological and histopathological examination. DNA was extracted from all these samples, and then the singleplex PCR was performed with primers targeted the exon1, 2, 3, 4, 5 and 6 of MXI1 gene.The results of cytological examination showed that 30(25%), 21(17.5%), 15(12.5%), 11(9.16%), 2(1.66%), 1(0.83%), 22(18.33%) and 18(15%) out of 120 scraping cervical cells samples were detected for ASCUS, LSIL, HSIL, SCC, AGUS, cervicitis, and cervicitis with squamous metaplatia, respectively. Also the results of histopathological examination showed that 32(26.66%), 19(15.83%), 17(14.16%), 11(9.16%), 1(0.83%), 22(18.33%) and 18(15%) out of scraping cervical cells samples were detected for CINI, CINII, CINIII, SCC, adenocarcinoma, cervicitis, and cervicitis with squamous metaplatia, respectively. The results of singleplex PCR revealed that the positive singleplex PCR samples were identified by presence of 240, 140, 210, 200, 260, 300 bp amplicons of the exon1, 2, 3, 4, 5 and 6 of MXI1 gene respectively. The PCR results exhibited that 57(47.5%) out of 120 scraping cervical cells samples were showed deletion in the exon5 represented by 22(38.59%), 11(19.29%), 8(14.03%), 7(12.28%) and 9(15.78%) out of 57 positive deletion samples that were detected for ASCUS, CINI, CINII, CINIII and SCC, respectively. In addition, the results showed that 22(73.33%) out of 30 ASCUS, 11(34.37%) out of 32 CINI, 8(42.1%) out of 19 CINII, 7(41.17%) out of 17 CINIII, and 9(81.81%) out of 11 SCC were had exon5 deletion. Whereas 63(52.5%) out of 120 scraping cervical cells samples were didn't show any deletion in the exon5 of MXI1 gene.

Conclusion: The exon deletion of MXI1 gene was clearly associated with the exon5, whereas other exons of MXI1 gene didn't show any deletion, and the results revealed there was remarkable association between the exon5 deletion and the incidence of precancerous stages include ASCUS, CINI, CINII, CINIII and cancerous stage represented by SCC.

Introduction

Cervical cancer is the third most common cancer worldwide and a major fatal malignancy among women, causing about 275,000 deaths annually worldwide, mostly in developing countries. It can be a preventable

disease if identified at its early (precancerous) stages and treated by ablation[1,2]. Max interactor 1 gene (MXI1) is a transcription factor that belongs to the mad family of Myc antagonists, which encode proteins that are highly homologous to c-Myc. Mxi1 opposes the growth-promoting activity of c-Myc by repressing transcription of c-Myc activated target genes. Mxi1 inhibits the ability of c-Myc to transform cells in vitro, and its expression is associated with cellular differentiation[3]. The MXI1 gene has been localized to chromosome 10q24-25 [4], a region demonstrating deletions or rearrangements in 60-97% of human glioblastomas and up to 30% of human prostate cancers. Although loss of heterozygosity for MXI1 is seen in a substantial fraction of glioblastoma tumors (64%), no MXI1 coding sequence mutations have been seen in these tumors [5]. Furthermore, a majority of studies have failed to demonstrate MXI1 mutations in prostate tumors[6]. By counteracting c-Myc, MXI1 functions as a growth suppressor, resulting in reduced cell proliferation in vitro [4,5,7], previously localized the human MXI1 gene to chromosome 10q24-q25. Deletions resulting in loss of alleles in this region of chromosome 10 are observed in 30±50% of human prostate tumors[8].

Materials and Method

Samples Collection: During the period of study, from beginning of March 2017 to the end of September 2017. 120 scraping cervical cells samples were collected from Iraqi women clinically diagnosed with cervical abnormalities and cancer, and 30 scraping cervical cells samples from apparently healthy women who attended to Baghdad Medical City and Al-Elwiya Maternity Teaching Hospitals in Baghdad City, Patients' ages ranged from 20 to 70 years of age. This study was carried out after obtaining the approval from the Institute of Genetic Engineering and Biotechnology for Post Graduate Studies/Baghdad University and Ministry of Health/Iraq.

Extraction of DNA: The DNA was extracted from scraping cervical cell samples using DNA-Sorb-A nucleic acid extraction kit (Sacace Biotechnologies/ Italy), according to the manufacturer's instructions.

Agarose gel electrophoresis: After extraction of DNA carrying out, agarose gel electrophoresis was adopted to confirm the presence and integrity extracted genomic DNA [9].

Detection of MXI1 gene by using PCR: The PCR was adopted to detect the exons 1, 2, 3, 4, 5 and 6 of MXI1 gene in the extracted DNA of scraping cervical cells from clinically diagnosed women with cervical cancer. To select PCR primers that can give specific amplification for exons 1, 2, 3, 4, 5 and 6 of MXI1 gene. The (MXE1-F/MXE1-R) for exon 1, (MXE2-F/ MXE2-R) for exon 2, (MXE4-F/MXE4-R) for exon 4, (MXE5-F/MXE5-R) for exon 5, (MXE6-F/MXE6-R) for exon 6, were used according to [10], the (MXE3-F/ MXE3-R) for exon 3 was used according to [11]. The general properties of these primers were checked by using Oligocalc Oligonucleotide Porperties Calculator program, the name and sequence of these primers are listed below in table (1).

Table (1): The name, sequence and product size of PCR primers for exons of MXI1 gene.

Name of Primer	Sequece of Primer 5'-3'	Size of Product (bp)
MXE1-F	ATGGAGCGGGTGAAGATGAT	240
MXE1-R	GCACTGCCGAAAAAGATTAG	
MXE2-F	GGGTCAATGGATTTGGGTAC	140
MXE2-R	TAAGCGTTCCCAGCTTGCTA	
MXE3-F	GCAACAAAGCATGGCTAATG	210
MXE3-R	TTCACAATGGGCTATACATCTGA	
MXE4-F	TAACCAGACTGTGCTGATTTG	200
MXE4-R	ACCAGAACTGAGGGAATTGTG	
MXE5-F	TGTTTGTACTGGACTATACAC	260
MXE5-R	ATGTTTAGTATTTCATTAGAGAAG	
MXE6-F	GTTAGTTTTTGAAGGTGCGC	300
MXE6-R	TGTTATGTCATGCTGGGTTC	

The PCR reactions for detection of exons of MXI1 gene were performed in 25 µl volumes containing, amplification of exons of MXI1 gene was carried out with initial denaturation at 94°C for 1 minutes, followed by 35 cycles of denaturation at 94°C for 30 seconds, annealing at 66, 65, 55, 66, 65 and 56°C for F and R primers of exons1, 2, 3, 4, 5 and 6 respectively for 1 minute, and extension at 72°C for 1 minutes. The thermal cycles were terminated by a final extension for 5 minutes at 72°C [(11)]. The PCR products were resolved by electrophoresis. Chi-square test was used to significant compare between percentage (0.05 and 0.01 probability) in this study[(12)].

Results

Agarose gel electrophoresis was adopted to confirm the presence and integrity of the extracted DNA**.** The results of PCR showed that samples of present study gave positive result for PCR of exon 1, 2, 3, 4, and 6 of MXI1gene products with 240, 140, 210, 200 and 300 bp molecular weight, whereas no amplification was observed with exon 5 (260bp) in 57 out of 120 samples and negative control (Figures 1).

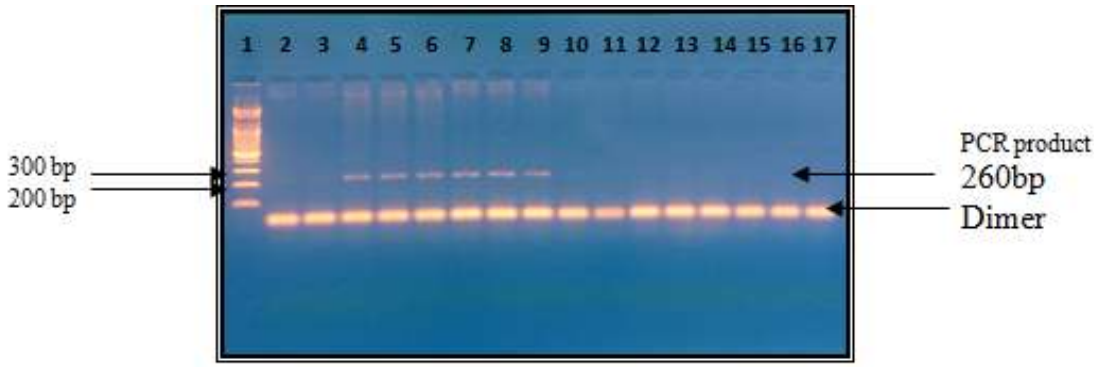

Figure (1): Gel electrophoresis of singlplex PCR products of exon 5 of MXI1 gene on 1.5% agarose gel at 10volt/cm for 1 hour. Lane 1: 100 bp DNA ladder, lane 2-17: PCR products of exon 5.

The patient group was divided to eight groups according to cytology examination; i) Atypical squamous cells of undetermined significance (ASCUS) 30 samples, ii) low grade squamous intraepthelial lesion LSIL 21 samples, iii) high grade squamous intraepthelial lesion HSIL 15 samples, iv) squamous cervical cancer 11 samples, v) atypical glandular cells of undetermined significance 2 samples, vi) adenocarcinoma 1 sample, vii) cervicitis 22 samples, and viii) cervicitis with squamous metaplatia 18 samples. The samples were also including 30 specimens (scraping cervical cells) of healthy women used as a control (Table 2).

Table (2): Distribution of samples study according to cytological examination.

Cytological Examination	No. of Cases	Percentage of Cases (%)
ASCUS	30	25.00
LSIL	21	17.50
HSIL	15	12.50
Squamous cervical cancer	11	9.16
AGUS	2	1.66
Adenocarcinoma	1	0.83
Cervicitis	22	18.33
Cervicitis with squamous metaplasia	18	15.00
Total	120	100%
Chi-square value	---	9.074 **
P-value	---	0.0005

** (P<0.01).

ASCUS: Atypical squamous cells of undetermined significance, **LSIL:** Low-grade squamous intraepithelial lesion, **HSIL:** High-grade squamous intraepithelial lesion. **AGUS:** atypical glandular cells of undetermined significance.

Also the results of histopathological examination showed that 32(26.66%), 19(15.83%), 17(14.16%), 11(9.16%), 1(0.83%), 22(18.33%) and 18(15%) out of scraping cervical cells samples were detected for CINI, CINII, CINIII, SCC, adenocarcinoma, cervicitis, and cervicitis with squamous metaplatia, respectively (Table 3).

Table (3): The distribution of sample study according to the histopathological examination.

Histological Examination	No. of Case	Percentage of Case (%)
CIN I	32	26.66
CIN II	19	15.83
CIN III	17	14.16
Squamous cervical cancer	11	9.16
Adenocarcinoma	1	0.83
Cervicitis	22	18.33
Cervicitis with squamous metaplasia	18	15.00
Total	120	100%
Chi-square value	---	9.261 **
P-value	---	0.0003

** (P<0.01).

CIN: Cervical intraepithelial neoplasia.

A total of 120 cases of cervical abnormalities were studied, the MXI1 deletion were identified in 57/120 (47.5%) and 63/120 (52.5%) not deleted table (4).

Table (4): Distribution of the study sample according to deletion of exon5 of MXI1.

PCR	Number	Percentage (%)
Positive	57	47.5
Negative	63	52.5
Total	120	100%
Chi-square value	---	2.071 NS
P-value	---	0.0966

NS: Non-Significant.

The PCR results exhibited that 57(47.5%) out of 120 scraping cervical cells samples were showed deletion in the exon5 represented by 22(38.59%), 11(19.29%), 8(14.03%), 7(12.28%) and 9(15.78%) out of 57 positive deletion samples that were detected for ASCUS, CINI, CINII, CINIII and SCC, respectively (Table 5).

Table (5): Correlation samples of study and deletion of exon5 of MXI1 according histopathological examinatin

Cytology	Number	Percentage (%)
ASC-US	22	38.59
CINI	11	19.29
CINII	8	14.03
CINIII	7	12.28
Squamous cervical cancer	9	15.78
Total	57	100%
Chi-square value	---	6.944 **
P-value	---	0.0078

** (P<0.01).

In addition, the results showed that 22(73.33%) out of 30 ASCUS, 11(34.37%) out of 32 CINI, 8(42.1%) out of 19 CINII, 7(41.17%) out of 17 CINIII, and 9(81.81%) out of 11 SCC were had exon5 deletion.

Discussion

Extension of our study to include *MXI1,* located at 10q24-45, identified mutations in 2 cell lines but no detectable change in exon sequences of this gene in bladder tumors. This finding is consistent with *MXI1* mapping outside of the critical region of loss on 10q in bladder tumors (13), where mutations in *MXI1* do not play a role in urothelial neoplastic progression. These results contrast with observations in prostate cancer, where a high frequency of loss and mutation of the *MXI1* gene has been reported (6).

Wang and colleges have found no evidence for loss or mutation of *MXI1* in bladder tumors, in contrast to findings in prostate carcinomas (11). We have found deletion in MXI1 gene in precancerous stages of cervical cancer in Iraqi married women.

Conclusion

Presence of exon deletion in exon5 of MXI1 gene whereas other 5 exons didn't show any deletion in scraping cervical cell samples that collected from some Iraqi women clinically diagnosed with cervical abnormalities and cancers.

The exon5 deletion was found with high variable percentage in precancerous stages included ASCUS, CINI, CINII, CINIII and cancer stage represented by SCC. whereas the exon5 deletion didn't present in cervicitis and Cervicitis with squamous metaplasia as well as the result revealed high (81.81%) incidence of exon 5 deletion in SCC comparing with other precancerous stage include ASCUS, CINI, CINII, CINIII.

According several points that mention above can be conclude that there is a strong association between the exon5 deletion and the incidence in cervical abnormalities and squamous cervical cancer in marred women which can refer to possible use the exon5 deletion of MXI1 gene as early molecular marker for

cervical abnormalities and squamous cervical cancer detection in marred women.

Curcumin and 6-Shogaol Increase Hemoglobin F Levels by Inhibiting Expression of STAT3 mRNA Gene in K562 Line Cell

Joko Setyono[1], Ahmad Hamim Sadewa[2], Edy Meiyanto[3], Mustofa.Mustofa[4]

[1]Department of Biochemistry, Faculty of Medicine, University of Jenderal Soedirman, Purwokerto, Indonesia, [2]Department of Biochemistry, Faculty of Medicine, Public Health and Nursing, University of Gadjah Mada, Jogjakarta, Indonesia, [3]Cancer Chemoprevention Research Center, Faculty of Pharmacy, University of Gadjah Mada, Jogjakarta, Indonesia, [4]Department of Pharmacology, Faculty of Medicine, Public Health and Nursing, University of Gadjah Mada, Jogjakarta, Indonesia

Abstract

One of the approaches for beta-thalassemia therapy is the induction of the Haemoglobin F (Hb F). Curcumin and 6-Shogaol are empirically known to induce HbF, but the signalling cascade has not been widely explained. This study aims to uncover the potential of Curcumin and 6-shogaol in inhibiting the expression of STAT3 mRNA gene. This study uses the K562 erythroleukemic line cell model with an experimental design post-test only with a control group. There are 5 groups, each group has 3 replications, named the control group without treatment, the positive control group with Hydroxyurea treatment (75 μM), the combination treatment group of Curcumin (2 μM) and 6-Shogaol (10 μM), the single curcumin (2 μM) treatment group and a single 6-Shogaol (10 μM) treatment group. Test samples were taken in 72-h and 96-h time series, then RNA extraction from the cell line was continued by cDNA synthesis. The expression of STAT3 mRNA gene was measured using the qRT-PCR technique; then, the Hb F level was measured by the ELISA method. Statistical analysis using ANOVA test with significance level $p < 0.05$. In the 72-h time series, there was a significant decrease in STAT3 Gena mRNA expression ($p < 0.05$). The lowest single curcumin group ($p < 0.01$) followed by a single 6-Shogaol group ($p < 0.05$) compared to the untreated control group, while the positive control group with hydroxyurea treatment and the Curcumin and 6-shogaol combination treatment groups are not significant. Hb F levels, there was an increase in 96-h time series ($p < 0.05$) respectively from highest to lowest in the curcumin group ($p < 0.05$), 6-shogaol ($p > 0.05$) compared to the control group, but in the positive control group ($p > 0.05$) and the combination group ($p > 0.05$) it is lower than the control group without any treatment.Curcumin and 6-shogaol increase Hb F levels through inhibition expression of STAT3 mRNA Gene on K562 cells. The results of this study could be the basis for further research in vivo to reveal the signalling pathway in Hb Finduction therapy.

Keywords: *Curcumin, 6-shogaol, STAT3 Gena mRNA, Hemoglobin F, K562 cells.*

Introduction

β-Thalassemia is a group of heterogeneous recessive autosomal hereditary genetic diseases associated with point mutation or small deletion resulting in the absence or reduction of β-globin chain protein synthesis, resulting in haemoglobin deficiency. There are alternative therapies that can be developed to overcome the severity of this disease by inducing Fetal Haemoglobin (Hb F). The globin-ϒ chain, which is similar to the globin-β chain, is produced during pregnancy when it joins with globin-α chain, is to form Fetal Hemoglobin ($\alpha_2\Upsilon_2$). Hence, one of the potential current therapeutic approaches to haematological disorders, including β-thalassemia, is the stimulation of induction of fetal haemoglobin production [1-4].

One of the transcription factors that play a role in the production of Hemoglobin F is the phosphorylated STAT3 protein. This protein, which is the dominant-negative regulator, which acts in the 5'-untranslated globin-ϒ promoter region bound to AϒSTAT3, thus inhibiting the expression of globin-ϒ-dependent concentrations [5]. Therefore, it is necessary to have a potential inhibitor to STAT3 in the framework of globin-ϒ induction. Curcumin is a STAT3 inhibitor in the SH2 domain. Inhibition of the SH2 domain, not only disrupts activation but also dimerization of transcription factors [6]. Other active compounds of herbal ingredients that have molecular targets related to the regulation of Hemoglobin F are Shogaol. 6-shogaol is the most potent inhibitor of STAT3 activation when compared to analogues such as 6-gingerol, 8-gingerol and 10-gingerol [7]. The purpose of this study was to uncover the potential of Curcumin and 6-shogaol on the expression of STAT3 mRNA as one of the induction signals for Hemoglobin F.

Material and Method

1. **Provision of Curcumin and 6-shogaol and Hydroxyurea:** Curcumin (BioBasic, Canada) with > 95% of purity, 6-shogaol (Fortopchem, China) with >98% purity and Hydroxyurea (HU) (Sigma-Aldrich, USA) with approx >98% of purity. Curcumin, HU and 6-shogaol are dissolved in 100% dimethyl sulfoxide (DMSO) to reaches the final concentration of curcumin 271,000 µM, 6-Shogaol 361,000 µM, and HU 1,315,000 µM as a stock solution, then stored at -20ºC.

2. **K562 Cell Culture:** Erythroleukemia K562 cells obtained from CANCER CHEMOPREVENTION RESEARCH CENTER (CCRC) Faculty of Pharmacy in the University of Gadjah Mada was cultured with RPMI 1640 supplementary media (without phenol red) with 10% Fetal Bovine Serum (FBS) and 50 U/ml - 50 µg/ml penicillin-streptomycin (pen-strep). Culture was maintained under atmospheric humidity with 95% air/5% CO_2 at 37ºC with cell densities between 2 x 104 to 1 x 105 cells/ml.

3. **Cytotoxic test with MTT method assay 24 hours, 48 hours and 72 hours:** Cytotoxic tests were performed to obtain IC_{50} values following the protocol of CCRC Faculty of Pharmacy in the University of Gadjah Mada. The results of the IC_{50} values of each sample were taken from 24 hours, 48 hours and 72 hours incubation. The IC^{50} values obtained were 60 µM curcumin, 40 µM 6-shogaol and 300 µM HU, respectively.

4. **Combination Test:** K562 cells were distributed into 96 wells as much as 100 µL and incubated for 24 hours. Enter the Curcumin and 6-shogaol concentration series into the wells of 50 µL with five series of concentrations each consisting of ½ IC_{50}, ¼ IC_{50}, 1/8 IC_{50}, 1/16 IC_{50} and 1/32 IC_{50}. Incubation for 24 hours. Cells were counted by using a haemocytometer so that the number of living and dead cells in each well was obtained. The highest number of living cells is an indicator of the best combination dose, named Curcumin 2 µM, 6-shogaol 10 µM, and for HU it is determined by treatment of 75 µM (¼ IC_{50}).

5. **ELISA test to measure Hb F levels:** K562 cells that have been given the appropriate treatment in their groups are then carried out protein extraction by the procedure of the M-PER Kit (Thermo Scientific, USA). The lysate obtained was used for examination of Hb F levels measured by the Human HBF Cat ELISA kit. No: EH3213 (Fine Test, China) according to the manufacturer's instructions.

6. **Analysis of STAT3 Gena mRNA expression:** Total K562 RNA cells were extracted at different times depending on the treatment, using # RB100 (Geneaid, Taiwan), 1 µg of total RNA from each sample was carried out reverse transcripts to cDNA using the cDNA Synthesis Kit (Toyobo, Japan). Real-time PCR is done by machine (ABs) using the SensiFAST SYBR Lo-ROX Kit (Bioline, Germany). The relative mRNA levels of the target gene are normalized to the mean of the internal control gene, β-Actin.

   Primary mRNA with STAT3, forward: 5'-ATC ACG CCT TCT ACA GAC TGC-3 ', reverse: 5'-CAT CCT GGA TCT CTA CCA CT-3 '. β-ACTIN forward: 5 '-ACG GCC AGG TCA TCA CCA TTG-3', reverse: 5 '-GGC GTA CAG GTC TTT GCG GAT-3 TT'. The STAT3 gene expression between treated and untreated samples was calculated as $2^{-\Delta\Delta Ct}$ relatively to the reference gene, β-actin.

7. **Statistic analysis:** Data is displayed in mean ± SD and statistical analysis using one way ANOVA test followed by post hoc LSD. The test results are considered significant if $p < 0.05$ and 95% confidence intervals.

Findings: In this study, the impact of Curcumin, 6-shogaol and their combination on the interpretation of STAT3 mRNA expression were measured by the qRT-PCR method, and the results can be seen in Figure 1.

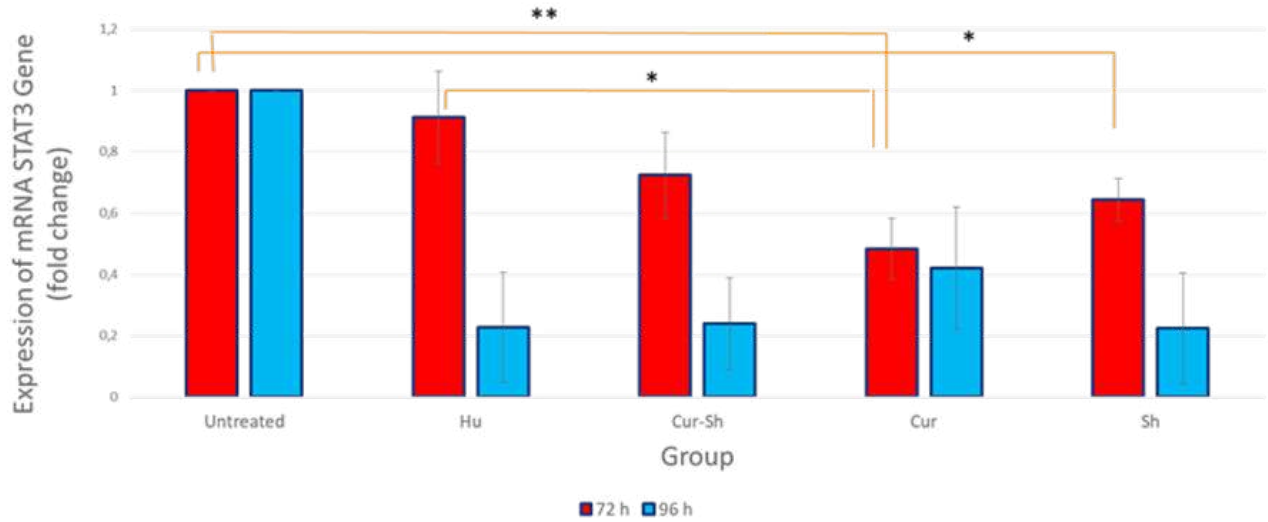

Figure 1: Differences in fold changes of STAT3 mRNA between groups after incubation of Curcumin (Cur), 6-Shogaol (Sh) and Hydroxyurea (Hu) on serial K562 cells for 72 and 96 h. Curcumin showed the strongest expression followed by 6-Shogaol compared with the control group without treatment (* p <0.05, ** p <0.01).

The results showed a decrease in STAT3 mRNA expression in all treatment groups in both the 72-h and 96-h time series compared to the untreated group. In the 72-h time series, the results are significantly different p <0.05. Then followed by post hoc LSD test, in the Curcumin treatment group, the lowest expression of STAT3 mRNA gene was 0.48 ± 0.1 (p = 0.008) which was significant compared to the control group without treatment. Next, in the 6-Shogaol treatment group, the expression of STAT3 mRNA gene (0.64 ± 0.07, p = 0.045) was significant compared to the control group without treatment. In the combination group of Curcumin with 6-shogaol, the expression of STAT3 mRNA gene (0.72 ± 0.14) was lower than the positive control group but higher than the curcumin and 6-shogaol group. In the 96-h time series, the results did not have significantly different (p = 0.098) between the treatment group and the control group without treatment. So, in the 96-h time series, there was a decrease in STAT3 mRNA expression, which was not significantly different.

The effect of Curcumin and 6- shogaol on haemoglobin F levels measured by the ELISA method can be seen from Figure 2. The results show that in a 96-h time series, Hb F levels were the highest in the curcumin group (1.6 ± 0.15; p = 0.015), then followed by the 6-shogaol group (1.11 ± 0.29). In the positive control group hydroxyurea and the combination of Curcumin + 6-shogaol, Hb F levels were consecutively (0.85 ± 0.16), (0.41 ± 0.01) lower than those in the untreated control group. The combination group of Curcumin with 6-shogaol was the group with the lowest Hb F level compared with the treatment group and the control group without treatment (p <0.05). In the 72-h time series, the Hb F level of all treatment groups was lower than the control group without treatment. Based on the one way ANOVA test, the 72-h treatment did not differ significantly (p> 0.05), but in the 96-h treatment, there was a significant difference (p <0.05). So, in the 96-h time series, the highest Hb F level occurred in the curcumin group, and the lowest Hb F level occurred in the combination group of Curcumin with 6-shogaol.

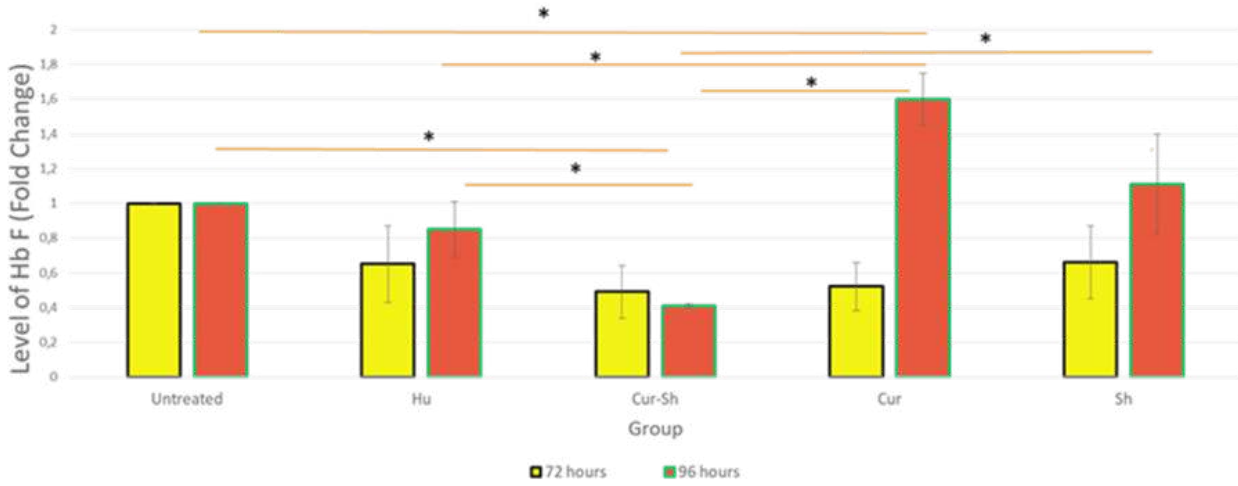

Figure 2: Differences in fold changes of HbF levels between groups after incubation of Curcumin (Cur), 6-Shogaol (Sh) and Hydroxyurea (Hu) on 72 and 96 h serial K562 cells. In the 96-h time series, Curcumin showed the highest effect on changes in HbF levels followed by 6-Shogaol compared to the control group without treatment (* p <0.0).

Reduced hexahydro-bisdemethoxy curcumin (HHBDMC) reduced curcuminoids were most effective in inducing gamma-globin mRNA (3.6 ± 0.4 fold) and Hb F (2.0 ± 0.4 fold) in erythroid primary precursor cells for seven days[8]. Curcumin works to reduce the expression of STAT3 genes so, the decrease in STAT3 gene expression will increase the production of Hb F. The role of 6-shogaol in Hb F induction through the activation of the p-p38 MAPK signal[9] whereas p38 MAPK is reduced by two weeks of curcumin activation[10].

Discussion and Conclusion

In beta-thalassemia patients there is an imbalance in the number of globin-α/globin-β chains, due to the lack or absence of globin-β synthesis, resulting in precipitation of free globin-α chains in erythroid precursors which results in the maturation and damage of erythrocyte cells, causing prolonged anaemia [11]. Therefore the best choice for the treatment of thalassemia patients is reactivation/ induction of globin-ϒ, so that replaces globin-β to join globin-α to form fetal haemoglobin and ultimately there is no excess free globin-α chains [12]. Individuals with elevated Hb F levels (> 8.6%) show a reduction in symptoms and increase patient life expectancy; hence, the induction of Hb F has the potential as a therapy in beta-thalassemia patients. Of the current therapeutic options, Hb F induction through pharmacological agents is the most feasible therapeutic choice [8].

Other transcription factors that play a role in the production of haemoglobin F are the phosphorylated STAT3 protein. Therefore, it is necessary to have a potential inhibitor to STAT3 in the framework of gamma-globin induction. Pharmacological inhibitors targeting STAT3 can be done in 5 ways, namely inhibition of STAT3 DNA-binding domain, abrogation of the STAT3 N-terminal domain, suppression of the STAT3 SH2 domain, inhibition of the STAT3-importin interaction, and/or blockage of upstream kinase activity [13].

The active compounds of the following herb, Curcumin, have broad molecular targets related to various molecular and biochemical cascades interacting directly on the target protein and epigenetic modulation of the target genes. Curcumin, as an epigenetic agent, functionally in modulating multiple biological processes, occurs at low concentrations. Curcumin plays a role in the expression of genes through direct interaction with transcription factors such as nuclear factor kappa-light-chain-enhancer of activated B cells (NF-kB), epigenetic modulation through inhibition of DNA methyltransferase I (DNMT1), histone acetyltransferase (HAT), histone deacetylase complex (HDAC) [14]. Various molecular targets of Curcumin include inflammation, kinase activity (MAPK, PKA,

JAK), transcription factors (CREB, STAT3, PPARϒ), enzyme activity (COX- 2, INOS, MMP), and others (VEGF, adiponectin, ROS) [15-16]. The 6-Shogaol are other active compounds of herbal ingredients that have molecular targets related to the regulation of Hemoglobin F. The 6-shogaol suppresses the expression of the products governed by STAT3. It was also reported that 6-shogaol caused the activation of JNK, p38 and ERK, as well as downregulating the expression of p38 MAPK, NF-κB and COX-2 [17]. Therefore, 6-shogaol can play a role in the induction of Hemoglobin F.

Hydroxyurea (100 μM) has a link between the regulator of globin-ϒ expression (MYB, BCL11A and KLF-1) with specific miRNA, and reveals the mechanism of Hb F production through inhibition of HU-induced miRNA [18]. Treatment with HU combined with HDAC2 knockdown increases gamma-globin expression. It was also reported that CD34 + cells treated with HU and MS-275 (HDAC inhibitors 1,2 and 3) had a relative induction of gamma-globin expression [19].

Curcumin is a decreasing expression of STAT3 mRNA gene and increases Hb F levels compared to 6-shogaol on K562 cells. While the combination of the two substances was not significant either in inhibiting STAT3 expression or HbF levels. The results of this study could be the basis for further research in vivo to reveal the signalling pathway in Hb F induction therapy ($\alpha_2\Upsilon_2$).

Vernadsky Crimean Federal University, Simferopol, Russia

Abstract

The efficacy of using probiotic preparations of the yogurt type was studied in 136 patients with lymphogranulomatosis, suffering from intestinal dysbiosis while taking antibiotic therapy and polychemotherapy (BEACOPP-II protocol). It was found that probiotics of this type are highly effective for the treatment of dysbiotic disorders of the intestines in cancer and hematological patients. Their use significantly reduces the risk of complications such as an unpleasant aftertaste in the mouth, belching, heartburn, diarrhea, constipation, flatulence, discomfort or periodic abdominal pain. It is recommended that prolonged therapy with a probiotic of the yogurt type be used in these groups of patients.

Keywords: *Probiotic, dysbiosis, eubiosis, dyspepsia, lymphogranulomatosis, polychemotherapy.*

Introduction

Every year, the problem of dysbiotic conditions of the gastrointestinal tract is increasing among the world's population in general and among Russian citizens in particular [1]. Along with other reasons, the use of antibacterial drugs is one of the main causes of intestinal dysbiosis. Currently, observed dysbiosis is mainly of natural microbial origin. This is due to a violation of homeostasis of the natural microflora of the gastrointestinal system, leading to the occurrence of intestinal dysbiosis (dysbiosis). The prevalence of this clinical condition among all age groups in the human population exceeds more than 90% and is constantly increasing[2]. This negatively affects the clinical course, diagnosis and treatment of various nosologies, leading to the aggravation of various diseases and their pathomorphism [3,4].

Nowadays, lymphogranulomatosis has become one of the few highly liable diseases in the hematological practice. According to the German Hodgkin Study Group, achieving complete remission in patients with advanced stages is possible in 70-90% of cases, using effective polychemotherapy regimens in combination with or without radiation therapy [5]. Thus, polychemotherapy regimes in lymphogranulomatosis is very important and such regime usually given with antibacterial therapy leads to dysbiosis. Traditionally, the correction of dysbiotic conditions is achieved by introducing microbial associations of a healthy person in the form of probiotics into the patient's digestive system [6]. But most modern drugs all over the world are created on the basis of a limited number of bacterial strains, which are often poorly effective [7,8]. Probiotics such as yogurt are especially recommended when conducting antibacterial therapy, taking cytostatics, as well as for correcting the

microflora of the digestive system in people with lactase deficiency. Due to the simplicity of their administration and relatively high bioavailability. Probiotics of the yogurt type are widely used in the complex therapy of various pathological conditions, including diseases of the gastrointestinal tract, oncological diseases with long courses of chemotherapy, which are characterized by inhibition of normal microflora with the development of dysbiosis syndrome.[9,10,11]

Purpose of the Study: To analyse the effectiveness of probiotic therapy in patients with dysbiosis initiated by polychemotherapy and antibiotic therapy in conditions of cancer alertness. Also to determine the effectiveness of yogurt-type probiotic preparations in patients with the above conditions.

Materials and Method

The study was conducted according to the results of treatment of 136 patients with lymphogranulomatosis, suffering from intestinal dysbiosis with the background of chemotherapy (BEACOPP-II protocol) and concomitant antibacterial therapy. The study involved patients with excluded organic pathology of the digestive system such as scars, erosion, hernia of the esophagus, gastritis, peptic ulcer of the stomach and duodenum, ulcerative colitis, Crohn's disease, primary tumors of the gastrointestinal tract; diseases leading to excretory insufficiency of the liver and pancreas. Patients underwent a course of polychemotherapy in the Department of Hematology and Chemotherapy of the State Budgetary Healthcare Institution of the Republic of Crimea "Crimean Republican Oncological Clinical Dispensary named after V.M. Efetov" in Simferopol, from April 2015 to March 2017.

The preparation used in the study contained: a lyophilized microbial composition of live strains of lactobacilli (Lactobacillus rhamnosus and Lactobacillus murinus), which differ from other lactobacilli by more pronounced (40–45%) viability in the presence of antibiotics and have higher activity (35–40%) suppression of pathogenic and conditionally pathogenic microflora.

Statistical processing of the results was carried out using the Microsoft Office Excel 2013 program, with the calculation of the t-criterion by the Student method for relative values, the data were considered reliable at t = 2, the reliability was Pt = 95.5%, and the risk of error was $p < 0.05$.

In our study involving all human participants were in accordance with ethical standards of the responsible committee on human experimentation and with the Helsinki Declaration of 1964 and later amendments.

Research Results: 136 patients with lymphogranulomatosis (Hodgkin's lymphoma) were examined, who received a course of polychemotherapy and suffered from intestinal dysbiosis that developed while taking antibacterial therapy.

An initial examination of patients revealed that in 47 (34.56%) patients, dysbiosis of the II degree was observed, and in 89 (65.44%) patients there was dysbiosis of the first degree. In 31 (22.79%) patients, dyspepsia/unstable stool type was observed and dyspepsia/constipation was observed in 18 (13.24%) of the examined patients. Flatulence was observed in 32 (23.53%) patients before probiotic therapy. 55 (40.44%) patients complained of discomfort and abdominal pain. Only the most pronounced subjectively and clinically significant syndrome complexes were taken into account.

The results of a retrospective analysis and dynamic examination of 136 patients before and after treatment of intestinal dysbiosis with and without antibiotic, radiation and polychemotherapy was observed (Table 1).

After 2 months of treatment with a probiotic type of yogurt in the study group, it was recorded that; II degree dysbiosis was not detected in the observed patients, but I degree dysbiosis was detected in 42 (30.88%) patients. Unstable stool, diarrhea after 2 months of treatment was determined in 3 (2.21%) patients. Constipation after treatment was observed in 2 (1.47%) patients. Flatulence was detected in 6 (4.41%) patients. Discomfort, abdominal pain were observed in 8 (5.9%) examined patients after the course of the treatment. In 23 (16.91%) patients it was observed that, after 2 months of treatment with a probiotic-type of yogurt, grade I dysbiosis was determined bacteriologically, despite the absence of any clinical symptoms and complaints of the digestive system from patients. In 94 (69.1%) patients, intestinal eubiosis was clinically and bacteriologically determined. The significance of differences for all of the above groups is t = 2, *Pt = 95.5%* and $p < 0.05$.

Table 1: The clinical condition of patients with intestinal dysbiosis before and after probiotic therapy.

Study Period	Prevailing of Clinical Syndromes (Number of Patients)			
	Unstable Stool, Diarrhea	Constipation	Flatulence	Discomfort, Abdominal Pain
Before treatment	31	18	32	55
After treatment	3	2	6	8

In the control group, after two months, no statistically significant changes were recorded. The observed patients still noted various disorders of the digestive system, such as belching, heartburn, diarrhea, constipation, flatulence, discomfort or periodic pain in the abdomen.

Conclusion

Probiotics such as yogurt demonstrate high efficiency in the correction of intestinal dysbiosis in oncological and hematological patients on the background of polychemotherapy and concomitant antibacterial therapy.

It has been proven that taking probiotics such as yogurt significantly reduces the incidence of dyspeptic disorders such as an unpleasant aftertaste in the mouth, belching, heartburn, diarrhea, constipation, flatulence, or periodical abdominal pain in patients suffering from dysbacteriosis, which has developed with the use of antibiotics.

Long-term therapy with a drug probiotic such as yogurt, which lasts more than 2 months, makes it possible to correct conditions such as grade I and grade II dysbiosis, contributing to intestinal eubiosis in a significant part of the observed patients.

Conflict of Interests: None declared.

Influence of Mental Health and Social Relationships on Quality of Life among Myanmar Migrant Workers in the South of Thailand

Kanit Hnuploy[1], Wongsa Laohasiriwong[2], Kittipong Sornlorm[3], ThitimaNutrawong[4]

[1]Doctor of Public Health Program, Faculty of Public Health, Khon Kaen University, [2]Faculty of Public Health, Khon Kaen University, Khon Kaen, [3]Tha Khantho District Public health Office, Kalasin, [4]Faculty of Medicine, Khon Kaen University, Khon Kaen, Thailand

Abstract

Background: Previous studies indicated that mental health and social relationships have influence on quality of life. However, there are limited studies on the association between mental health and social relationships on quality of life among Myanmar migrant workers in Thailand.

Method: This study aimed to determine the prevalence of quality of life and the influence of mental health and social relationships on quality of life among Myanmar migrant workers in the South of Thailand. This cross-sectional analytical study was conducted among 794 Myanmar migrants who were selected by using a multi-stage random sampling from 2 provinces in the South of Thailand to respond to a structured questionnaire interview. The generalized linear mixed model analysis was performed to determine the association between mental health and social relationships on quality of life when controlling other covariates.

Results: The prevalence of good quality of life among Myanmar migrant workers was 11.46% (95% CI:9.24-13.68). Mental health and social relationships were significantly associated with good quality of life were; no had depressive symptoms (adj. OR=3.83; 95% CI: 2.28-6.43, p-value < 0.001), had good relationship with employers (adj. OR=3.02; 95% CI: 1.71-5.31, p-value < 0.001) and had high level of involvement with peers (adj. OR=1.90; 95% CI: 1.09-3.32, p-value < 0.023). Significant covariates were average personal monthly incomes and received health information. About one-tenth of Myanmar migrant workers had a good quality of life. Mental health, social relationships and access to health information had influenced their quality of life.

Keywords: *Myanmar migrant workers, Quality of life, Social relationships, Thailand.*

Introduction

Quality of life (QOL) is a multidimensional level of an individual life's happiness where they live in societies to achieve their goal in life. QOL consists of 4 domains including physical, psychological, social relationships, and environmental domains[(1)]. The concept of QOL is commonly used to describe the well-being among various susceptible populations, such as migrants, refugees, etc.[(2-4)], since QOL describes the degree to which a person enjoys the important possibilities of his or her life[(5)].There were a number of factors influencing QOL. Social relationships were one of the factors associated with QOL of which it increased the likelihood of survival[(6)]. A study carried out in the Basque Country, Spain suggested that low social support was related to poor HRQOL, of which identifying the social support is a key in understanding health inequalities among immigrants[(7)].

Migrating to a new country is an extremely complex and stressful process because it involves changes in all areas of life-socially, culturally and psychologically[(8)]. Psychosocial factors such as lack of social and emotional support from relatives and friends[(9)] were common among migrant workers. Some studies indicated that migrant workers were refused by local citizens[(10)] and lack of legal migration status in migration processes[(11)].

Depression, one of the most common mental health disorders, was identified as having a positive relationship with occupation injury[12]. Depression imposes an immense social burden which leads to functional impairment, decreased quality of life, low productivity and impaired interpersonal relationship[13].

Thailand economic growth has attracted an increasing number of migrant workers from neighboring countries[14]. Migrant workers in Thailand are mostly involved in the ''3 Ds'' jobs (dangerous, dirty and degrading jobs). These 3Ds conditions push them at risk for health problems. One notable health hazard of migrant workers is the deterioration of mental health, which has been implicated to suicide that is more common among migrant workers than that of local citizens [15].The Office of Foreign Worker Administration of Thailand reported that in July 2019 there were 2.83 million migrants residing in Thailand, and about 1.87 million were from Myanmar. About 358,530 Myanmar migrant workers were in the South region. Most of these migrants worked in the manufacturing sectors, agriculture and animal husbandry,fishery, and construction. Therefore, this study aimed to determine the prevalence of quality of life and the influences of mental health and social relationships factors on quality of life among Myanmar migrant workers in the South of Thailand.

Materials and Method

Study design and sampling: This cross-sectional analytical study was conducted in 2018. The populations were Myanmar migrant workers in the South of Thailand. The sample size was calculated by using the formula to estimate the sample size for logistic regression analysis of Hsieh [16]. The estimated sample size was 794. We recruited Myanmar migrant workers from 2 southern provinces by using multi-stage random sampling method.

Questionnaire: A structure questionnaire was developed based on the research questions and relevant literatures. The structured questionnaire consisted of 6 parts: A) Demographic and socioeconomic characteristics, B) Social relationships, C) Health behaviors and physical health status, D) the Perceived Stress Scale (PSS) of Cohen et al.[17], E) The Center for Epidemiology Studies Depression Scale (CES-D)[18], and F) WHOQOL-BREF was used to assess the quality of life. QOL scores were categorized into three groups: a)poor level (26-60scores), b) moderate level (61-95scores), c) good level (≥96scores)[1]. The questionnaire was undergone content validation by 5 experts and revised to improve its validity. The Cronbach's alpha coefficient of PSS, CES-D, and WHOQOL-BREF were 0.78, 0.70, and 0.85 respectively.

Statistic Analysis: All analyses were performed using Stata version 10.0 (StataCorp, College Station, TX). Demographic and socioeconomic characteristics of the participants were described by using frequency and percentage for categorical data as well as the mean and standard deviation for continuous data. A simple logistic regression was used for bivariate analysis to identify individual factor associated with QOL. In the bivariate and multivariable analysis, quality of life was classified into 2 groups using the cutoff score of ≥ 95 points which mean 'hada good quality of life'. The independent factors that had p-value <0.25[19]were processed to the generalized linear mixed model (GLMM) analysis to identify the association between mental health and social relationships with QOL when controlling the effect of other covariates and reported the adjusted odds ratio (Adj. OR),95% confidence interval (CI) and p-value<0.05 as the magnitude of effect and statistical significant level.

Results

Majority of the Myanmar migrant workers were male (58.31%) with the average age of 32.79 (±9.00) years old, 69.52% were married and 37.78% finished only primary education. Most of them lived in urban settings (81.74%), 75.19% lived with a family and 46.98% lived in a labor camp. The highest proportion worked in manufacturing (29.97%) followed by agriculture and animal husbandry, fishery and construction. Their average personal monthly incomes was 9,201.17 (±2,681.29) Baht, of which 3,203.21 (±1,660.17) Baht were average personal monthly expenditures. Almost all had health insurance (99.62%).

Most of the workers worked both indoor and outdoor (64.23%) and the rest (35.77%) worked only indoor. Most of them satisfied with their living and working conditions as well as the relationship with others, except that 58.56% had a limitation on traveling. About one-third were smokers(38.16%), 16.12% were drinkers. More than half of the migrant workers (54.91%) had a physical check-up and 11.08% had chronic diseases. Most of them (88.66%) had a moderate level of stress and more than half (52.77%) had depressive symptoms.

Concerning the quality of life, 85.77% (95% CI: 83.15-88.03) of the migrant workers had a moderate level, 11.46% (95% CI: 9.42-13.87) had a good level and 2.77% (95% CI:1.82-4.17) had a poor level.

Factor associated with good quality of life:

Bivariate Analysis: The bivariate analysis results indicated that the independent variables that possibly associated with good QOL (p-value<0.25) were;average personal monthly income, physical health check-up, involvement with peers, relationship with employers, relationship with co-workers, relationship with family, received health information and depressive symptoms. These factors have proceeded to the multivariable analysis (Table 1).

Discussion

The findings observed that most of the Myanmar migrant workers perceived of having a moderate level of QOL (85.77%), only 11.46% having good QOL. It might be that the situations where they lived and worked were as they expected. They were not much better. This study also observed that those who had no depressive symptoms had a significantly better quality of life in comparison with those who had depressive symptoms, of which similar with previous studies conducted in China[20, 21].Besides, those who had a good relationship with employers had a significantly better quality of life in comparison with those who had a poor and average level which was similar with a study conducted in Thailand[22]. It might be that the relationship with peer could result in job security and incomes. The migrant workers who had a high level of peer involvement had significantly better QOL than those who had low to moderate levels of peer involvement which was similar to a study in Sweden[23]. It might be that they could share various issues and able to release their tensions. Concerning personal monthly incomes, this study indicated that those who had average personal monthly incomes ≥9,300 Baht were more likely to have good QOL in comparison with those who had lower incomes. A study conducted in China was also observed a similar finding[20]. Concerning health, migrant workers who received health information were more likely to have a better quality of life in comparison with those who had not received health information. Migrants have usually accessed health information

through social networks more than formal health service providers due to language and access barriers[24].

Conclusion

About one-tenth of Myanmar migrant workers in the South of Thailand had a good QOL. After adjusting for other covariates which were personal monthly income and access to health information;mental health especially depressive symptoms and social relationships including had a good relationship with employers, and high level of peer involvement were found significantly associated with QOL.

Lumbosacral MRI Findings in Chronic Lower Back Pain

Kermanj Ismail Bakr[1], Israa Mohammed Sadiq[2], Saman Anwer Nooruldeen[3]

[1]MBChB (Al-Mustansariy University), [2]MBChB (Tikrit University), DMRD (Baghdad University), FIBMS Radiology (Iraqi Board for Medical Specialization), Department of Surgery/Radiology, College of Medicine, University of Kirkuk, , [3]Azadi Teaching Hospital, Kirkuk/Iraq

Abstract

Background: Low back pain (LBP) is one of the most common musculoskeletal disorders demanding hospital visits. Inter vertebral discdegeneration is a known cause of chronic low LBP back pain. The relation between changes in the lumbar spine and lower back pain is controversial.

Objectives: To assess LSS MRI findings in patients with CLBP, and to show the relation of disc degeneration with age and gender.

Material and Method: 218 adult patients with chronic lower back pain (pain more than 12 weeks) did Lumbosacral spine MRI, at Azadi Teaching Hospital/Kirkuk city, from March/2017 to April/2018, those with a positive history of spinal pathology other than osteoarthritis were excluded. The disc degenerative MRI changes at each lumbar disc were assessed and correlated according to age and gender.

Results: 146 of patients were male, and 72 of them were female, their age ranged from (16-73 years). Males and elderly patients were affected by disc degeneration more. 92.2% of patients had disc degeneration, followed by disccontour abnormality, facet joint arthrosis, high-intensity zone (HIZ), spinal canal stenosis, Modicchanges (MC), Schmorl's nodes (SN), and spondylolesthesis. L4-L5 disc was the most commonly involved level by disc degeneration, followed by L5-S1disc, the least level was L1-L2.

Conclusions: Most patients with CLBP have DDD. Older males are the most susceptible people to develop DDD which affect most commonly L4-L5 disc level, other findings may associate with DDD are MC, SN, HIZ, facet joint arthrosis, spinal stenosis, and spondylolesthesis.

Keywords: *Chronic, lumbosacral, lower back pain, MRI.*

Introduction

Low back pain (LBP) is one of the most common musculoskeletal problems demanding hospital visits, and the main contributing cause of disability in adults. LBP occurs in most of the people during any period of life.[1,2,3,4,5] Although several causes have been implicated in low back pain, disc degeneration disease (DDD) is a known cause of this pain.[6,7]. Chronic pain is defined as pain for more than 12 weeks.[8]

DDD of the lumbosacral spine (LSS) in adults can start in the third decade of life.[6] There are several risk factors related to disc degeneration in the LSS, including age, increased physical loading, obesity, and genetic influences.[4,9,10]

Magnetic resonance imaging (MRI) is often requested and of choice in the management of patients with LBP as different abnormalities can be seen on spinal MRI.[11,12,13] LSS MRI findings of DDD include decreased disc space, decreased signal intensity on T2W images which indicates disc dehydration. Disc degeneration on T2-weighted sagittal magnetic

resonance images of the lumbar spine is appeared and graded as:

Grade (0): Normal No signal changes; Grade (1): the signal intensity of the nucleus pulposus is slightly decreased; Grade (2): seen as hypointense nucleus pulposus with preserved disc height; Grade (3): seen as hypointense nucleus pulposus with narrowing of disc space. [14]

Disc degeneration may be associated with disc bulging/herniation, and high-intensity zone(HIZ). [9, 15] Herniated disk is defined as a "focal displacement of nucleus, cartilage, a piece of annulartissue or fragmented apophyseal bone beyond the space of the intervertebral disc.Disc displacement most commonly is classified into fivegrades (normal, disc bulge, protrusion, extrusion, and sequestration). [16, 17](HIZ) represents tear in the annulus fibrosus of the disc, seen as very bright signal intensity on T2 weighted images at the posterior part of the disc. [18]Other findings which associated with DDD include Modic changes (MC), Schmorl's Nodes (SN), facetjoint degeneration, spondylolesthesis, and spinal stenosis. [19]

This study was done to assess LSS MRI findings in patients with CLBP, and to showthe relation of DDD with age and gender.

Patients and Method

Subjects: Inclusion criteria: Two hundred eighteen (218) adult patients with chronic lower back pain (more than 12 weeks) were sent to MRI department at Azadi teaching hospital/Kirkuk city/Iraq, as a part of the management of lower back pain, over the period from March/2017 to April/2018. Their ages range from 16 to73 years.

Exclusion criteria: Those who had a history of spinal surgery or back trauma, known spinal pathology, malignant diseases,and athletes were excluded from the study. Clinical information was obtained from the documentation of physicians.

Imaging: All lumbosacral spine MRI examinations were done using the 1.5-T unit (Philips Acheiva,

Netherland 2010) with a dedicated lumber coil, imaging protocol was as follows:

1. T1-weighted sagittal Turbo spin echo (TSE) with 8 msec echo time (TE) and 500 msec repetition time(TR).
2. T2- weighted sagittal TSE with 100 msec TE and 4000 TR.
3. T2-weighted axial TSE with 120 msec TE and 4000 TR, and
4. Myelography with 1000 msec TE and 8000 TR.

The images were interpreted by two board-certified radiologists with 7 years experience, any difference in opinion were settled by consensus. Each lumber level of 218 patients was assessed for disc degeneration scoring, disc bulging and herniation, HIZ,presence of MC, SN, facet joint degeneration, spondylolesthesis, and spinal stenosis.

Statistical analysis: It was a cross-sectional analytic study. The study population demographic criteria including age in years, weight in kilograms (kg), and height in centimeters (cm)were expressed as means(SD). Percentage of Disc degeneration at different lumber disc levels was assessed and related to gender and age, total degeneration score was estimated for each patient as average degeneration score of all lumbar disc levels and related to age, using Chi-square test. *P*-value level of less than 0.05 was required for significance. Percentage of disc bulge/herniation, HIZ, MC, SN, sponylolisthese, facet joint arthropathy, and spinal stenosis were also estimated. SPSS software, version 17, was used for the statistical analyses.

Results

The demographic criteria of the study sample were as seen in table 1.

Table 1: The demographic criteria of the study sample

Category	Male ([a]N = 146) Mean (SD)	Female (N=72) Mean (SD)	t-value	P value
Age (Years)	43.5 (12.1)	42.5 (12.7)	0.5645	0.5730
Height (cm)	174.3 ± 6	161.3 ± 5.8	15.3747	0.0001
Weight (kg)	83.31 ± 14	74 ± 8	5.2332	0.0001

[a]Number.

There were 146 males and 72 females in the study sample; male to female ratio was 2:1, 141 males (96.6%) and 60 (83.4%) of females had disc degenerative changes in their LSS MRI.

Males were significantly more affected than females by disc degeneration (*P*=0.0006).

Most of the patients had abnormal MRI findings 201 (92.2%), and only 17 (7.8%) had a normal MRI study. 32 patients were less than 35 years old, 140 patients were 36-55 years old, and 46 patients were more than 55 years old. 68.8% of < 35 years old group,95% of 35-55 years old group, and All patients >55 years old group had disc degeneration change. The incidence of disc degeneration was significantly increased with advancing age (P<0.001) as seen in table 2.

Table 2: Relation of disc degeneration with age.

Age	Disc Degeneration		Total
	Male	Female	
< 35	17	5	22
35-55	98	35	133
>55	26	20	46

The total number of the affected disc was 588 levels of a total of 218 patients. The most commonly affect level was L4-L5 in 32%, followed by L5-S1, L2-L3, L3-L4, and L1-L2 in

21.2%, 19.1%, 18%, and 9.2% respectively as seen in figure 1.

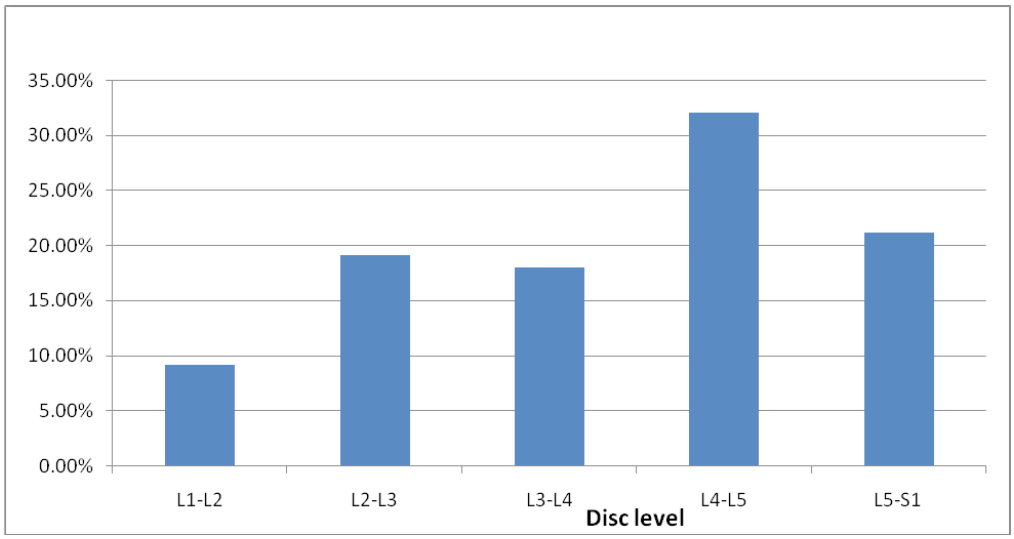

Figure 1: Distribution of disc degeneration according to disc level.

Disc degeneration was present at one level in 25%, and multilevel in 75%. The average disc degeneration score of each patient was score 0 in 7.8% (17 patients), score I in 30.1% (66 patients), score II in 37.2 (81 patients), and score III in 24.8% (54 patients) (Table 3).

Table 3: The relation between disc degeneration score and age.

Age (Years)	Total Degeneration Score				Total
	0	I	II	III	
>35	10	18	4	0	32
36-55	7	40	61	32	140
55<	0	8	16	22	46
Total	**17**	**66**	**81**	**54**	**218**

Score 3 disc degeneration was not seen in <35 year's age group, and all patients who were <55 years old group had degeneration with different scores, the score of degeneration was significantly increased with increasing age (*P*> 0.001).

Other LSS MRI findings were as the following: disc contour abnormality (70.7%), HIZ (27.8%), SN in (12.9%), MC (19.3%),spinal stenosis (20.4%), facet joint degeneration (45.2%), and spondylolisthesis (6.4%).

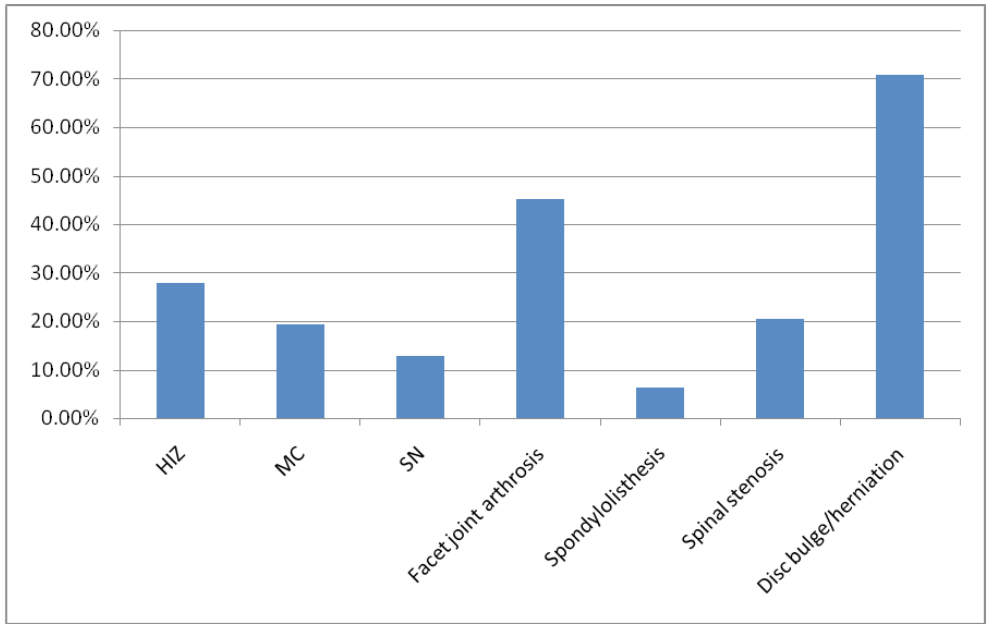

Figure 2: Percentage of MRI changes associated with disc degeneration.

Discussion

Degenerative changes were seen in the majority (92.2%) of patients with chronic lower back pain;most of these changes were observed at L4/L5 and L5/S1 levels and lowest rate of involvement was noted at L1-L2 level. Similar outcomes had been perceived in most of the previous studies,due to the highest mechanical strain at these levels[20, 21,22, and 23].

Multiple disc level involvement was common as compared to the single-disc involvement; which was also in line with past studies.[16, 24]In this study the incidence of disc degeneration significantly increased with age, due to aging process which involves decreased vascularization, and decreased delivery of nutrients and growth factors to the disc.[25] This result was similar to several studies.[20,26] The fewer percentage of DDD that's seen in younger age group also noticed in other studies like us, its exact etiology is not clearly known, but issues like genetic, autoimmune, and biochemical factors may play a role inthe pathogenesis of disc degeneration.[27]

Males were affected significantly more than females in our study which was comparable with other studies,[28,29] as men engage in jobs associated with heavy workload compared with women.[30]Mechanical load that contributes to DDD might also have a role in the pathogenesis of disc contour abnormalities, HIZ, MC, and SN.[31,23,33].

Conclusions

Most of patients with CLBP have DDD. Older males are the most susceptible people to develop DDD which affect most commonly L4-L5 disc level, other findings may associate with DDD including MC, SN, HIZ, facet joint arthrosis, spinal stenosis, and spondylolesthesis.

Joint Effect Obesity and Oral Contraceptive Use towards Hypertension among Women in Thirteen Provinces in Indonesia

Kuuni Ulfah Naila El Muna[1], Helda[2]

[1]Master of Epidemiology, [2]Department of Epidemiology, Faculty of Public Health, University of Indonesia

Abstract

Introduction: Hypertension complications cause 9,4 million people died in the whole world every year. Hypertension in a woman is more dangerous than man, as they affect mortality and morbidity not only at herself but also the fetus in a pregnant woman. Hypertension is stimulated by many risk factors, some of them were obesity and using oral contraception. The purpose of this study is to evaluate obesity, oral contraceptives use and their joint effect on the risk of hypertension among women in Indonesia.

Method: A cross-sectional study from Indonesian Life Family Survey 5 data, including 10.270 women with age ≥18 years old lives in Indonesia. Weight, Height and Blood Pressure were measured. Hypertensive respondents if the blood pressure ≥140/90 mmHg, while obese defined by body mass index ≥27,5 kg/m^2. History of contraceptive used, smoking behavior and age were investigated. The effect between the independent and dependent variables in this study can be determined by Prevalence Ratio (PR) and estimated under Cox Regression Model.

Results: Our study showed that obesity, oral contraceptive used, and age significantly become risk factor of hypertension with PR (95% CI) respectively 2,12 (1,94 – 2,31); 1,21 (1,10 – 1,33); and 2,65 (2,42 – 2,91). Combination OC users and obesity significantly elevated the risk of hypertension by PR 2,149 (1,90 – 2,42) among women in Indonesia. Compared with OC, Obesity was more strongly associated with hypertension with PR 1,93 (1,74-2,13).

Conclusions: Obesity, OC users and their joint effects significantly increased the risk of hypertension among women in thirteen Provinces in Indonesia. The way better to prevent being obese than preventing using OC in the case of hypertension.

Keywords: *Hypertension; Obesity; Oral Contraceptive.*

Introduction

Hypertension complications cause 9,4 million people died in the whole world every year.[26] Hypertension in a woman is more dangerous than man, as they affect mortality and morbidity not only at herself but also the fetus in a pregnant woman.[7] Hypertension prevalence in people aged ≥ 18 years in Indonesia continues to increase from 2013 to 2018. Based on the basic health research 2013 and 2018, the prevalence of hypertension in Indonesia is 25.8% and 34.1% respectively.[9,10] The proportion of hypertension in 2018 was 31.34% in men and 36.85% in women.[10]

Hypertension induced by obesity cause of adipocytes in obese people induced increase in renin-angiotensin system which increasing sodium absorption, fluid volume, and also activate sympathetic nervous system. Those adipocytes also induced inflammation and reduced insulin sensitivity which attends to become endothelial dysfunction and arterial stiffness or vasoconstriction which leads to hypertension.[12] Obesity has been defined by the World Health Organization (2000) and The National Heart, Lung and Blood Institute (1988) as a body mass index (BMI) ≥ 30 kg/m^2.[2] This classification not appropriate to describe the association of various diseases due to obesity in Asia, because the percentage of

subcutaneous fat in Asians is more than the Caucasian at the same age, sex and BMI.[2,21,23] In 2004, WHO Expert Consultants suggested the classification of the latest BMI in terms of the risk of cardiovascular disease where the risk cut or point of obesity in the Asian population is ≥27.5 kg/m^2.[23] The prevalence of hypertension in the overweight and obese group is 40.8% while the prevalence of hypertension in the group with normal and thin BMI is 25.3%.[14]

Using oral contraceptives or pills containing estrogen and progesterone causes cardiac hypertrophy and increases the presenting response of angiotensin by involving the renin angiotensin system which causes high blood pressure.[3,15,16] The prevalence of hypertensive patients increased in line with the long duration of oral contraceptive use. It is known that the prevalence of hypertension in women who do not use oral contraceptives, use less than 1 year, less than 2 years and more than 2 years in a row were 14.3%; 13.9%; 21.3%; 22.8%.[16] Oral contraceptives is the second contraceptives most chosen by women 15-49 years old in Indonesia after giving birth to the last child is 8,5%, and the first one is injection every 3 months is 42,4%.[10]

A study using the 2013 basic health research data explained that women of childbearing age (WUS) who had a body mass index of more than 25 kg/m^2 had 2.7 fold risk of developing hypertension.[11] A crossectional study states that those who are obese (> 25kg/m^2) have a risk of hypertension of 1,681 times compared to non-obese after being controlled by age variables, a history of family hypertension and physical activity.[18] Hypertensive women and those without hypertension (adjusted) were 1.96 for oral contraceptive use>2 years and 1.22 for use at>1 year.[16] Wang's research in 2011 showed the combined effect of obesity and the use of oral contraceptives at a risk of 8.02 times (OR 8.02, CI 5.05-12.74) greater than hypertension with an addictive interaction of P = 0.039.[21]

Method

This study using cross-sectional design from Indonesian Life Family Survey 5 (IFLS-5) data. IFLS-5 is the fifth survey was held in 13 of 27 provincein Indonesia in 2014. This survey used household survey from IFLSdata. The subjects of this study including 10.270 women 18-49 years old, live in Indonesia and have complete data for each variable would be analyzed in this study. Weight, Height and Blood Pressure were measured. Hypertensive respondents if the blood pressure ≥140/90 mmHg, diagnosed by health workers, or consuming hypertension pills. While obese defined by body mass index ≥27,5 kg/m^2 this cut off based on WHO Expert Consultant.[23] Oral contraceptive used, smoking behavior and age were investigated. Collecting, editing and analyzing data IFLS-5 using software STATA (v.12, StataCorp). The effect between the independent and dependent variables in this study can be determined by Prevalence Ratio (PR) with confidence intervals (CI) 95% and estimated using Cox Regression Model in constant time.

Results

Sociodemographic characteristic between hypertensive and non-hypertensive cases: Majority women with any kind of characteristic classified as not hypertension case. Our study showed that obesity, oral contraceptive used, and age significantly become risk factor of hypertension with PR (95% CI) respectively 2,12 (1,94 – 2,31); 1,21 (1,10 – 1,33); and 2,65 (2,42 – 2,91). This individual risk factors are shown in (**Table 1**).

Association obesity and the risk of hypertension: After adjustment for age, the obese women have 1,93 fold (PR 1,93, 95% CI 1,74-2,13) increased risk of hypertension compared with non-obese women. This effect less than PR before adjustment (PR 2,16, 95% CI 1,95–2,38) (**Table 2**).

Association oral contraceptive use and the risk of hypertension: After adjustment for age, the obese women have 1,22 fold (PR 1,22, 95% CI 1,07 – 1,38) increased risk of hypertension compared with non-obese women. This effect is the same with PR without adjustment (**Table 2**). There is association was observed between Obesity and OC users (p< 0,001) (data not shown).

*Adjusted for Age

Joint Effect obesity and OC users on the risk of hypertension: As shown in **Table 2**, before adjustment combination obesity and OC users significantly elevated the risk of hypertension by compared to among women in Indonesia with PR 2,4 (2,08 – 2,76).OC users slightly elevated the risk of hypertension among both obese and non-obese women. The joint effects of Obesity and OC users significantly increase the risk of hypertension by 1,11 fold (PR 2,11, 95% CI 1,83 – 2,43).An antagonism biologic interaction between obesity and OC users was detected (p = 0,0174).

Discussion

From this cross-sectional study we evaluate that obesity, OC users and their joint effects on the risk of hypertension in women of 13 provinces in Indonesia. Our results indicated that Obesity and OC users were all risk factors for hypertension. We suggested a strong effect of obesity (BMI ≥ 27,5 kg/m^2) on hypertension risk, which attribute 35,97% in population. Same study in Chinese population showed effect of increased BMI on hypertension attributed 32,51% of PAR (Population at Risk) with BMI ≥ 24 kg/m^2 vs BMI <24 kg/m^2.[21] There are many studies emphasized whether biologic mechanism obesity induced hypertension,[5,12] also their association around the world. This also proved in the present study, we verified that obesity was the risk factor for hypertension significantly. Therefore, in the future the body mass index (BMI) such as obesity should never be underestimated.

OC use as hypertension risk have attributable risk not as much as obesity was 9,75%. OC used is well known could change blood pressure by few millimeters and 2-3 fold increase incidence of hypertension.[3,24] Both World Health Organization (WHO) and American College of Obstericians and Gynecologists (AJOG) have formally offered that Hypertension was one of contradiction to use COC but AJOG would allow COC use in women with well-controlled hypertension in some circumtances.[4] Low dose COC consist ethinyl estradiol dose less than 50 µg would increase risk of myocardial infraction and ischemic stroke approximately 2 fold

in the general population of COC users.[4,21,24] This cross-sectional study also confirmed OC as risk factor of hypertension significantly.

Interestingly we found there is joint effect between Obesity and OC use towards hypertension. Biologic Interaction identified by this study was antagonism although the risk of joint effect was bigger that independent risk of obesity or OC use. In the contrary,a case-control study in China also found joint effects general and central obesity, combined oral contraceptives (COC) use and hypertension, also shown a synergism interaction($p = 0,039$).[21] They found that the higher body mass index and the more longer respondent using COC therefore the risk of hypertension became a lot higher. The risk increased dramatically in combination of COC use with a BMI $\geq$ 28 kg/m^2 or Waist Circumference (WC) $\geq$ 90 cm with OR 8,02 (5,05 – 12,74) and OR 5,76 (3,65 – 9,12) respectively.[21]

This research found increasing risk to hypertension in joint effect obesity and OC use but have antagonism interaction. This might be caused by first, the operational definition of OC users had been used in this research was consist of women that using OC; women have used OC in her lifetime with proportion consecutively 11,20% and 10,92%.Women have used OC would have been stop for a long time ago or short time, a cohort study included 2112 hypertension people found that stopping OC in 6,6±7,5 months was an effective antihypertensive intervention in a clinical setting.[13] The study showed there is association between stopping OC and improved prognosis as reduction of at least 10 mmHg in Diastolic Blood Pressure (DBP) or 20 mmHg in Systolic Blood Pressure (SBP) with OR 0,27 (CI 95% 0,06 – 0,90) adjusted by age, weight and drug prescription.[13] Another study state that COC users would increase 5-6 mmHg of SBP and 1-2 mmHg in DBP.[3] Besides, the period of time women who have a history used OC did not provide by RAND cooperation therefore we did not have information about that. Also as the limitation of our study, we did not identify the period of time using OC.

Second, there are two types of oral contraceptives used in Indonesia which were mini pil (progestin only pill/POP) and pil KB (Combination Oral Contraceptive/ COC), but this study was blinding that because there are no information about that. Although whether POP or COC could increase blood pressure in experimental study in rats, which increasing blood pressures (systolic and diastolic) were higher in COC user that POP.[3]But,contraryin some study literature review and meta-analysis about POP and hypertension drawn conclusion no association POP and increasing blood pressure.[6,8]This two condition affect the risk of OC and their joint effect with obesity towards hypertension become antagonism. However, we found the risk of joint effect still bigger than the risk of obesity or OC users alone.

Conclusions

Our study indicated that obesity, OC users and their joint effects significantly increased the risk of hypertension among women in thirteen Provinces in Indonesia. The way better to prevent being obese than preventing using OC in the case of hypertension. For further research it would have been better if the variable not nominally categorized but depend on the usefulness and richness of the research. Also it would have been wonderful to include the long time using OC and using cohort design study. Besides, we recommend for future research for including waist circumference (WC), if the research conducted in Asian Population.

Tithonia Diversifolia vs Catechin: Role in Regulating Blood Glucose, Malondialdehyd, and Super Oxide Dismutase Level on Rat Induced Diabetes Mellitus and High-Fat Diet

Lailatul Muniroh[1], Rondius Solfaine[2], Indra Rahmawati[2]

[1]Department of Nutrition, Faculty of Public Health, Universitas Airlangga, [2]Department of Anatomy and Pathology, Faculty of Veterinary Medicine, Wijaya Kusuma Surabaya University

Abstract

Tithonia diversifolia (TD) is known as medicine plant which contains antioxidants and has been known as anti-diabetic medicine. Diabetic patient has increased blood glucose, reactive oxygen species (ROS), and malondialdehyd (MDA) level. In other side, the super oxide dismutase (SOD) level commonly attenuates. The aims of this study was to analyze the effect of Tithonia diversifolia and catechin in blood glucose, malondialdehyd (MDA), and Super Oxide Dismutase (SOD) level on diabetic and high fat induced rats.

The design of this study was Randomized Posttest Control Group Design using Wistar strain rats which were divided into 4 groups. After treatment, all groups of rats were sacrificed to take blood samples then measured blood glucose, MDA and SOD level. Statistical analysis of data to examine differences in treatment and control was conducted by one way Anova test with a 95% confidence level (α=0.05). There was difference of glucose level (p=0.020) between control and treatment groups, but there were no differences in MDA level (p=0.103) and SOD level (p=0.207).

Keywords: *Tithonia diversifolia, catechin, malondialdehyd, super oxide dismutase, blood glucose level, diabetes.*

Introduction

Tithonia diversifolia is known as medicine plant. It has several functions relate with disease prevention and treatment. The habitats of Tithonia diversifolia is in tropical and subtropical area. In Indonesia, this plant is known as Kembang Bulan. Traditionally, all part of this plant, especially leaves, use to treat wounds, abdominal pain, abscesses, malaria, fever, hepatitis, and diabetes mellitus [1]. It contains active substances such as: alkaloids, saponins, saponin glycosides, tannins, balsam, and volatile oil [2].
