Indian Journal of Public Health Research & Development

Print-ISSN: 0976-0245-Electronic-ISSN: 0976-5506, Frequency: Quarterly (Four issues per volume)

Indian Journal of Public Health Research & Development is a double blind peer reviewed international journal. It deals with all aspects of Public Health including Community Medicine, Public Health, Epidemiology, Occupational Health, Environmental Hazards, Clinical Research, and Public Health Laws and covers all medical specialties concerned with research and development for the masses. The journal strongly encourages reports of research carried out within Indian continent and South East Asia.

The journal has been assigned International Standards Serial Number (ISSN) and is indexed with Index Copernicus (Poland). It is also brought to notice that the journal is being covered by many international databases. The journal is covered by EBSCO (USA), Embase, EMCare & Scopus database. The journal is now part of DST, CSIR, and UGC consortia.

Abstract

Garmenting is one of the many labour intensive sector that provides gateway for developing countries in entering into the global market. Southern production centres employ more than 80% women as part of their workforce. Working for a long period of time without rest, absence of personal protective equipment and inadequate provision of ergonomic facilities at workplace leads to discomfort and fatigue.

Method and Method: 150 female workers with common musculoskeletal problems and working at the selected garment manufacturing factories and fulfilling the selection criteria will be randomly assigned to experimental and control group. The work site health intervention will be provided to experimental group, which involves 3 sessions for a week namely orientation to body mechanics, demonstration on neck and lower back exercise and nutritional education. After the demonstration, the female worker will be instructed to perform the exercise, 5 times in a week for 2 week in the workplace and thereafter for at least 3 times in a week for a month in the home. The outcome will be assessed at end of the 2nd week and 5th week. The control group who will not receive any intervention. The data will be analysed by frequency, percentage distribution, mean and standard deviation. Chi-square test and independent t-test will be used to assess the difference in various parameters.

Discussion: The result of the study may help to guide the garment workers to initiate the simple intervention in the worksite and would also reduce the occurrence of the common musculoskeletal problems.

Introduction

Garmenting is one of the many labour-intensive sectors that provide a gateway for developing countries in entering into the global market. It offers important opportunities to countries to start industrializing their economies and in course of time diversify away from commodity dependence[(1)].

The garment sector is a thriving industry in

Bangalore, Tirupur and Chennai in the south, and in Delhi and surrounding NCR region in the north. While the northern production centres employ primarily a male workforce, in the south more than 80% of the workforce is women.[2]

Women who are sewing mission operators perform their tasks sitting which involves two work tasks. The first one is the "sewing" task. The female worker sits on a chair, leans forward at an angle of 45, and moves her hands backward and forward and to the left and right to move the fabric (45-100 times per minute). The arms are positioned over the machine at an angle between 45 and 90 to the trunk. The head is positioned forward at an angle between 10 and 20. One of the legs moves the pedal of the sewing machine but the other is static. During the second work task, the female worker bends down to the right at an angle of 45 in order to get the pieces such as zippers and the like (30-50 times per minute)[3].

A study conducted in India reported, that out of 3858 workers examined during their annual health appraisal, around 694 (18.0%) had applied leave due to illness, of these only 104 (2.7%) had extended to more than 15 days. As a common symptom, worker who performs processing jobs with a longer duration of standing may experience discomfort in the legs, neck and shoulder. If standing position is practiced continuously, the worker may feel discomfort and fatigue particularly in the lower limb muscles, lower back, and feet. As along-term consequence, prolonged standing contributes to severe health problems such as chronic venous disorders, circulatory problems and degenerative damage to the joints of the spine, hip, knees and feet. [4].

Exposure to MSDs risk factors are increasing in younger working population [5]. Though factory workers areat risk for various health problems, the literature support makes it evident that the prevalence of musculoskeletal problem is the most common problems among garment factoryworkers varied from 15.5% to 78.89%.The most reported problem among those involved in sewing, cutting, and deliveringwas back pain,with the prevalence ranging from 22.2% and 68.5%. The common causes for the musculoskeletal problems were continuous sitting for long hours, bending and twisting at the waist, abnormal posture, movements during work and continuous standing. Nutrition plays a key role among these workers as improper or inadequate diet leads to malnutrition, whichmay further aggravate theseproblems[6].

A recent ILO study estimated that 22% of the global workforce, or 614.2 million workers, work more than 48 hours per week. According to a multi-country study in the clothing industry, reports that, workers had to work overtime in order to earn wages. The study also concluded that on an average factory workers worked more than 60 hours per week, and in 88% of cases more than six days in a row[7].

In Bangladesh, many garment workers work 14-16 hours shifts each day (most often six days per week) in Pakistan, 10 or more hours a day. In Thailand during peak season, excessive overtime is common because factory owners are reluctant to hire additional workers. During off-peak season, the average working hours is 7.7 to 10 hours a day. In India and Laos this overtime, though against the law, is compulsory[8].

According to the European survey on working conditions, 8.1% to 72.9% of workers reported exposure to risk factors of musculoskeletal disease[s][5]. Beyond different recognition practices, there are indications that musculoskeletal diseases affect the female working population more than the males. Further, there is a severe lack of awareness about these issues.

The musculoskeletal problems and the discomfort experienced by the individuals is also depend on the way an individual eat and the type of nutrients and fluids that brought into the body. Certain products and treatments may accelerate the rate in which the body heals itself.Some of the treatment included are Transcutaneous Electric Nerve Stimulator, electrotherapy, acupuncture, massage, icing, and anti-inflammatories. While these treatments are available to reduce the inflammation, however it is necessary to control the levels of inflammation around the joints of the back with alternative approaches. One such approach that naturally adopted to reduce the inflammation is by diet modification,and increase the intake of natural anti-inflammatories foods in the diet. There are also vitamins and dietary supplements to improve musculoskeletal health. But the relationship is not studied.

Work-related musculoskeletal problem are often associated with lower level of quality of life. Very few studies only have evaluated the effect of a specific program on the prevention of WMSD and the quality of life (QL)[9].

In the last few decades, workplace ergonomics studies focusedmore;however,limited emphasis

were made on the worksite interventions to prevent work-related musculoskeletal problems. It has also beenreviewed from the literature that there is a strong evidence for positive effect on management of low back pain by exercise training on different population and settings.

With the above evidences, the investigator felt the need to find the Effectiveness of a Worksite Health Intervention on Common Musculoskeletal Problems and Work-Related Quality of Life (WRQoL) among female workers.

Materials and Method

The Primary Objective Includes:

1. To determine the common musculo- skeletal problems experienced by the female workers in the garment manufacturing sectors
2. To assess the Work-Related Quality of Life among female workers with musculo-skeletal problems experienced before implementation of Worksite Health Intervention.
3. To evaluate the effectiveness of Worksite Health Intervention on Common Musculoskeletal problems experienced and Work -Related Quality of Life among female workers

Study Design: The study adopts two-armed randomised control trial methodology, to assess the effectiveness of the Worksite Health Intervention on common musculoskeletal problems and work-related quality of life among females.

Ethical Consideration: As a part of research programme, Saveetha University Ethics Committee, Tamilnadu, approved the study. The ref.no: - 007/09/2017/ IEC/SU, which qualified for registration in the Clinical Trial Registry-India numberCTRI/2018/08/015168.

Setting: Out of the North, South, East and West zones of BBMP, north zone will be selected for data collection as this zone houses majority of the garment factories of Bangalore. The garment manufacturing factories are concentrated in Pennya industrial estate, Rajajinagar industrial estate, Yeswanthapur, Gorguntepalaya and Srirampura. Two study areas are to be selected by simple random sampling from the industrial database available. The factories are categorised into small medium and large sized on the basis of the number of workers in each factory.

Sample: To detect a medium effect size (0.5) in the quality of life (power 0.8; alpha 0.05) at a 2-sided significance level of 0.05, the sample size is estimated was 150, which was inflated to 200 anticipating 10-20% rate. Female workers (75 in experimental group and 75 in control group) in the age group of 18-60 years and are working in the selected setting with the main task as tailoring, helping; checking, cutting, designing,sewing, ironing and finishing will be screened for common musculoskeletal problems. 200 female workers with the musculoskeletal problems will be randomly chosen and assessed into experimental and control group. To recruit the subjects the following criteria will be used.

Inclusion Criteria: Female Workers:

- Working for a minimum of 6-8 hours in a day with minimum of 1year experience in the garment factory.
- Who areable to read and write in Tamil/Kannada/ English.

Exclusion Criteria: Female Workers:

- undergoing physiotherapy/any treatment for this problem
- who had undergone any surgery within a year
- who are diagnosed with structural anomalies
- who have spinal cord compression
- who are pregnant
- suffering with post-traumatic conditions.

Tool: Validity, reliability and pilot study:

The following standardised tools are used.

a. Nordic musculoskeletal questionnaire to assess the common musculoskeletal problem

b. SF 36V2 to assess the work-related quality of life

Nine expert had validated the tool, 3 from the department of community medicine 2 from physiotherapist, 3 nursing faculty with PhD and 1 nutritionist. In order to suit to the current setting the reliability of the tools has been once again tested by SPSS software and the Alpha Coefficient r=0.78 for Nordic musculoskeletal questionnaire and 0.89 for the work related quality of life, which is within the acceptable limit. Pilot study on 15 subjects performed proved the practicability of the study.

The Intervention Program: Written consent will be obtained after the oral and written information given by the researcher regarding the purpose and nature of the study, a detailed plan about the work site intervention, benefits, the risk involved, and withdrawal from the study. Confidentiality of the subjects would be maintained.

Pre-Intervention: Female workers in the garment factories will be assigned in to the experimental and control group. The common musculoskeletal problems and work related quality of life would be assessed.

Approximately 40-45 minutes will be given to the female garment workers to complete the questionnaire. After receiving the questionnaire, the data will be verified for the completion of data.

Work site Health Intervention: The work site health intervention to experimental group refers to a structured program developed by the researcher for the female workers in garment manufacturing sectors to change their unhealthy and ergonomic postures and to enable them to prevent the occurrence of common musculoskeletal problem. It comprises orientation to body mechanics, back exercise training, nutrition education involving lecture cum demonstration by the researcher. Each session would last for 10-15 minutes on all days.

Day 1: Orientation to body mechanics, anatomy of spine, function of the cervical spine and normal postures to be maintained in daily life by lecture method using charts and posters

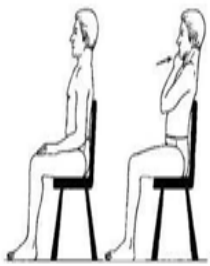
Day 2: Demonstration of exercises, which includes

- Neck exercise
  - Head retraction in sitting
  - Neck extension in sitting
  - Side bending of the neck
  - Neck flexion in sitting
- Low back exercise
  - Lying face down
  - Lying face down in extension
  - Flexion in lying
  - Flexion in sitting
  - Flexion in standing
  - Bottom to heal stretch
  - Bridges
  - Knee rolls
  - Hamstring stretch

The researcher demonstrates the exercise as shown in the Figure 1, at the workplace for 10-15 minutes and the participant are asked to follow. A ready reckoner would be provided to the participant.

Post intervention: After the training, the female factory workers are asked to perform the back exercise every day for at least 5 times a week for 2 weeks in the work place under the supervision of the researcher and at home for at least 3 times a week for a month. On Day 3, the researcher will be providing education on nutrition, which includes food pyramid, function of the food, concept of healthy eating and anti-inflammatory diet for 30-45 minutes by lecture cum discussion method.

The control group will not receive any intervention during the study period. But would receive the same after completion of the data collection.

Head retraction	Neck extension	Side bending of neck	Neck rotations/neck flexion

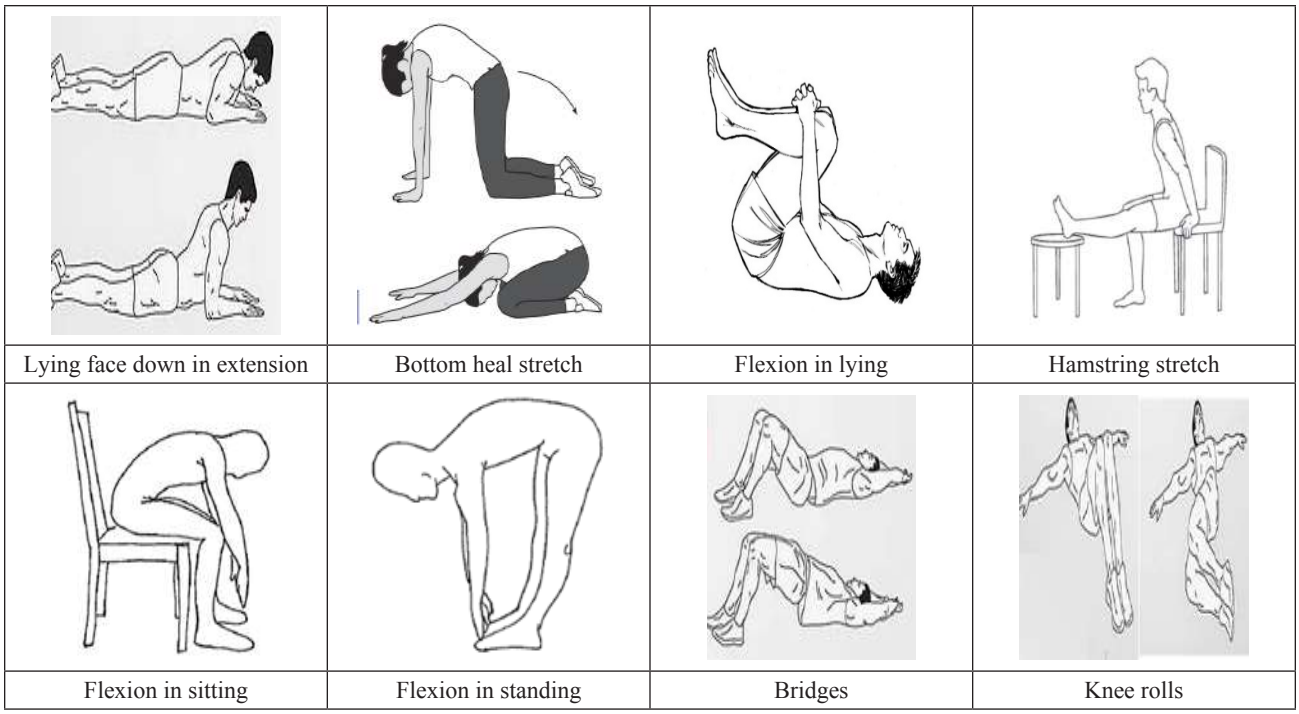


Figure 1: Illustration of the Neck and low back exercise

Outcome Measures: Baseline data includes age, height, weight, total family monthly income, type of family, habits type of job, duration of the work per day, availability of rest period during working hours, and option of over time.

Primary outcome measures

1. Musculoskeletal problems experienced and its intensity
2. Work-related quality of life

Randomization: The list of garment factories from the industrial database will be categorised into small and medium sized on the basis of the number of workers in each factory. A separate list of small size factories and medium sized factories will be prepared. The factories will be clustered into two; Cluster 'A' small sized factories and cluster 'B' medium sized factories. Using simple random sampling technique, from each cluster 2 factories will be allocated to intervention group and control group. Based on selection criteria samples will be drawn 75 in experimental and 75 to control group.

Blinding: Due to the nature of the research, the researcher will not be blinded and may know which factory will be receiving the intervention. However, the female workers participating in the research study neither will be aware of the expected outcomes of the study, nor the other group participating in the research study

Planned statistical analysis: All the data collected will be entered in the excel format. The data will be analysed using SPSS version 20.0. Frequency, percentage distribution, mean, standard deviation, Chi-square test and t-rest will be employed for the difference in the various parameters.

Discussion

Musculoskeletal problem is one of the common health problem experienced by the female factory workers. The workers neither take care of themselves nor have time to meet the health professionals. Studies revealed that incidence and recurrence of pain could be reduced when adequate care is provided. This study aims at designing a worksite health intervention that could be implemented during the working hours. The intervention designed would be simple and can be done in the work place itself. Changes in the intensity of pain in the lower back and neck would be noted before and after the intervention. Educating on the body postures and nutrition helps the workers to monitor their food and beverages conception. Modification in the diet helps to examine the changes in the quality of life. Result of this

study may help to guide the workers to initiate the simple intervention in the worksite reduce the occurrence of the musculoskeletal problems.

Health of the Elderly in India: A Socio-Legal Study

Arti[1], J.K. Mittal[2]

[1]Ph.D. Research Scholar under the Supervision of Professor. J.K. Mittal, Professor Emeritus, Amity Law School, Amity University, Uttar Pradesh, [2]Professor Emeritus, Amity Law School, Amity University, Uttar Pradesh

Abstract

To study the health and social problems of the elderly and their attitude towards life. Materials and Method: Descriptive study carried out in the Field practice area of the Department of Community Medicine in South India. A total of 213 elderly patients (60 years old and above) who attended the outreach clinics were interviewed using a pre-tested schedule. Findings were described in terms of proportions and percentages to study the socio-economic status of the samples and its correlation to social problems. Results: Around 73% of the patients belonged to the age group of 60-69 years old. Nearly half of the respondents were illiterate. Around 48% felt they were not happy in life. A majority of them had health problems such as hypertension followed by Arthritis, Diabetes, Asthma, Cataract, and Anemia. About 68% of the patients said that the attitude of people towards the elderly was that of neglect.

Keywords: *Elderly, Morbidity, Social and Health Problems.*

Introduction

"One who always serves and respects elderly is blessed with four things: Long Life, Wisdom, Fame and Power"- Manusmriti Chapter 2:121.

"Trees grow over the years, rivers wider, Likewise, with age, human beings gain immeasurable depth and breadth of experience "and wisdom. That is why older persons should be not only respected and revered; they should be utilized as the rich source to society that they are."- Kofi Annan.

"A society for all ages is one that does not caricature older persons as patients and pensioners. Instead, it sees them as both agents and beneficiaries of development. It honors traditional elders in their leadership and consultative roles in communities throughout the world." -Kofi Annan United Nations Secretary-General 1 October 1998

"It is not sufficient to add years to life but the more important objectiveis to add life to years"-

WHO Slogan S.:

The popular saying, "old is Gold' which implies the gravity of aged on the earth. All the things get aged. The things around us both animate and inanimate go through this aging process. The things which don't have life earn currency and given a due place and reverence on account of aged.

The thing such as old swords, old Icon, old buildings, Cars and so forth. Are revered due to their aged. On contrary, the objects which have life such as animals, human beings are thrown useless things. The old people are not treated well and they need special care and policies for their autumn days. The increasing number of aged population, due to advancement in medical sciences, health care etc, amount a problem on both developed as well as developing countries. The policy makers and social scientists focus their attention to abate the seriousness of the problem, which pose before countries, particularly third world countries. For understanding the problem of these aged, we have to know the basic concepts like aging.

Aging is natural, inevitable and ubiquitous phenomenon. Everyone should confront this process, if he/she lives. It is irreversible one. Literally it refers to the effects of age. Commonly speaking, it means the various effects or manifestation of old age. In this sense, it refers to various deterioration in the organisms. Aging has been viewed differently by different persons. To politicians and Industrialists, it means power and wealth whereas to a middle class employee, it amounts to a

forced retirement. To biologists and social scientists, it is a field of research on biological cells and problems on individual respectively. Handler defined "Aging is the deterioration of nature organism resulting from the dependent essentially irreversible changes intrinsic to all members of a species such that, with the passage of time. They become increasingly unable to cope with the stresses of the environment thereby increasing the probability of death". Beckar defines aging in the broader sense as "Changes coursing in an individual as the result of the passage of time". He adds "Aging consists of two simultaneous components of anabolic building up and catabolic breaking down". Comfort regards it as "the total effect of all changes which occur in a living being with increasing chronological age and which render it more vulnerable or less viable". Birren and Renner define "aging refers to the regular changes that occur in mature genetically representative organisms living under representative environmental conditions as they advance in chronological age". According to Hurlock, old age is the closing period in the life span. It is a period when people move away from previous, more desirable periods or times of usefulness. Stieglitz has rightly observed that "aging is a part of living.

Aging begins with conception and terminates with death. It cannot be arrested unless we arrest life. We may retire aging or accelerate it but we cannot arrest while life goes on, because it is essentially an element in living"[3]

Demographic Profile of Elderly in India: India, the world's second most crowded nation, has encountered a sensational statistic progress in the previous 50 years, involving very nearly a significantly increasing of the populace beyond 60 years old years. This example is ready to proceed. It is anticipated that the extent of Indians matured 60 and more seasoned will ascend from 7.5% in 2010 to 11.1% in 2025 UNDESA (United Nations Department of Economic And Social Affairs, 2008). This is a little rate point increment, yet a surprising figure in supreme terms. As per UNDESA information on anticipated age structure of the populace (2008), India had more than 91.6 million older in 2010 with a yearly expansion of 2.5 million old somewhere in the range of 2005 and 2010. The quantity of old in India is anticipated to arrive at 173 million out of 2026 and the share of older persons, above 60 years, in 2050, in India's population is projected to increase drastically by 20 percent.

Rundown figures veil the unevenness and complexities of the statistic progress inside India crosswise over Indian states with various degrees of financial improvement, social standards, and political settings. Anticipated appraisals of populace structure in 2025 for North India hold a "pyramidal" shape, while for south India, the portion of the older populace is required to grow significantly. Straight development in the number of inhabitants in the older is normal in the following 100 years, with more extreme slopes of increment in focal and east India and leveling off of supreme quantities of old in the north, south, west, and upper east.

A few important characteristics of the elderly population in India are noteworthy. Of the 8.5% of the population who are elderly, two-thirds live in villages and nearly half are of poor socioeconomic status (2016 report by the ministry for statistics and programme implementation). Half of the Indian elderly are dependents, often due to widowhood, divorce, or separation, and a majority of the elderly are women (70%). Of the minority (2.4%) of the elderly living alone, more are women (3.49%) than men (1.42%). Thus, the majority of elderly resides in rural areas, belongs to low SES, and is dependent upon their families.

While the southern states (Andhra Pradesh, Karnataka, Kerala, and Tamil Nadu) might be viewed as the greatest drivers of maturing in India, other Indian states (quite Haryana, Himachal Pradesh, Maharashtra, Orissa, and Punjab) are likewise encountering an old populace blast, to a great extent in provincial regions. Enormous scale investigations of the wellbeing practices of this developing old Indian populace are rare. In any case, data assembled from various overviews and provincial and neighborhood studies point to the high commonness of a few dangerous practices, for example, tobacco and liquor use, and physical dormancy. With these stressors, typically, total information contrasting the 52nd (1995–1996) and 60th Rounds (2004) of the National Sample Survey (NSS) propose a general increment in the reports of infirmities and usage of human services administrations among the old. Access to administrations, be that as it may, is uneven the nation over.

An analysis of morbidity patterns by age clearly indicates that the elderly experience a greater burden of ailments (which the National Sample Survey Organisation defines as illness, sickness, injury, and

poisoning) compared to other age groups (see National Sample Survey Organisation, 2006, Fig. 1), across genders and residential locations. The elderly most frequently suffer from cardiovascular illness, circulatory diseases, and cancers, while the non-elderly face a higher risk of mortality from infectious and parasitic diseases. In developed countries advancing through demographic transition, there have been emerging epidemics of chronic non-communicable diseases (NCDs), most of which are lifestyle-based diseases and disabilities In contrast, India's accelerated demographic transition has not been accompanied by a corresponding epidemiological transition from communicable diseases to NCDs. As indicated in Figure 15-1, the Indian elderly are more likely to suffer from chronic than acute illness. There is a rise in NCDs, particularly cardiovascular, metabolic, and degenerative disorders, as well as communicable diseases. While cardiovascular disease is the leading cause of death among the elderly, multiple chronic diseases afflict them: chronic bronchitis, anemia, high blood pressure, chest pain, kidney problems, digestive disorders, vision problems, diabetes, rheumatism, and depression. Concurrently, the prevalence of morbidity among the elderly due to re-emerging infectious diseases is quite high, with considerable variations across genders, areas of residence, and socioeconomic status. It is projected that NCD-related disability will increase and contribute to a higher proportion of overall national disability, in step with the graying of the population. However, a very significant shortcoming of most of the above studies is the use of self-reported data, which, in the absence of autopsies and physician examinations of patients, represents enormous lacunae in data on the conditions affecting the elderly. More detailed studies are needed, other than surveys, to extract information on the epidemiology of health conditions experienced by the elderly.

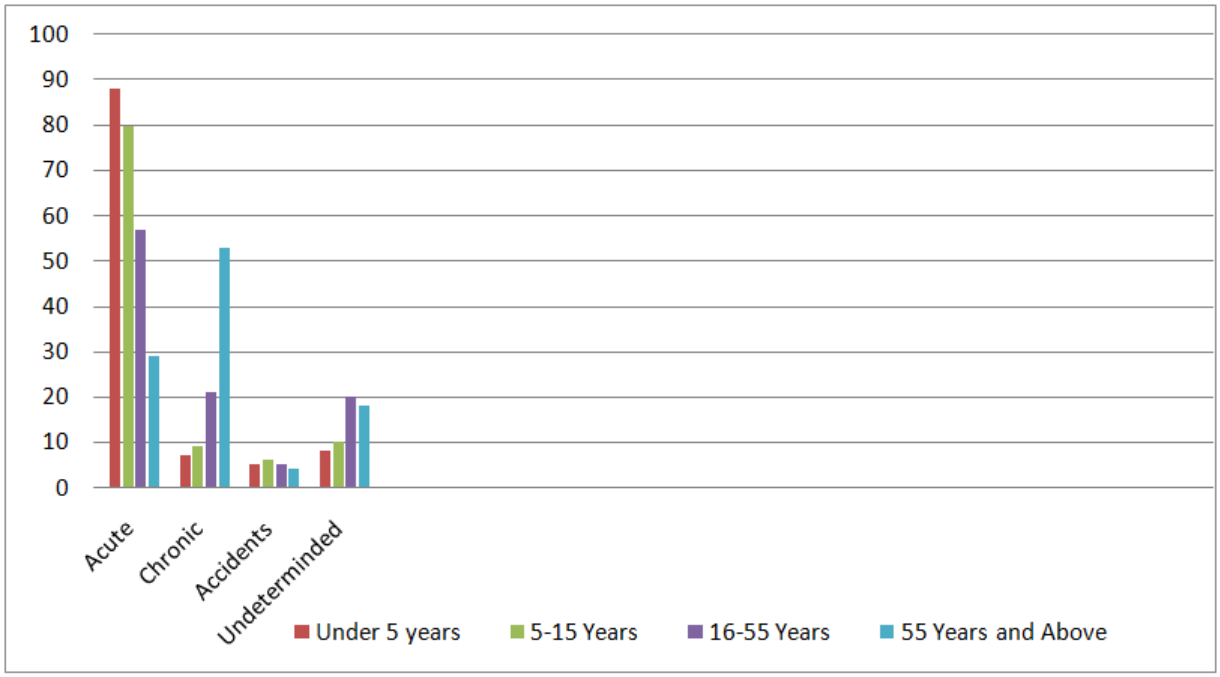

Figure 1: Burden of illness type among Indians. SOURCE: Dror, Putten-Rademaker, and Koren (2008)

Social Factors: A more intensive take a gander at the writing on access to human services uncovers variety over an age angle. More established Indians have revealed higher paces of out-patient and inpatient visi. The age angle in older wellbeing access is overlaid by social determinants of wellbeing. For one, there is a feminization of the old populace; as indicated by the 2001 registration, the sexual orientation proportion among the Indian old matured 60 years and more seasoned is 1,028 females for 1,000 guys. It is normal that by 2016, 51% of India's old will be ladies (in provincial regions, this extent will be a lot higher). More ladies report weakness status when contrasted with guys, but a far more noteworthy extent of men is hospitalized

when contrasted with females (87 versus 67 for each 1,000 matured people).

Neglected well being needs are progressively articulated among the 33.1% of the old in India who in 2001 were accounted for to have lost their mates, of whom a bigger relative extent is female (half of female old are widows versus just 15% of male older who are single men). Studies have demonstrated that widows are lopsidedly helpless against incapacity, ailment, and poor medicinal services use because of various portability, business, property, and monetary limitations.

Notwithstanding sexual orientation and conjugal status, religion, standing, instruction, financial autonomy, and sanitation have bearing on older wellbeing. Tally displaying of information from the 52nd Round of the NSS shows that the quantity of infections endured by an old individual, determined freely for rustic (Poisson Model) and urban populaces (Negative Binomial Model), incorporate age, sexual orientation, education, accessibility of drinking water and a latrine office, and family unit month to month utilization use. Another investigation of Uttar Pradesh (UP) and Maharashtra found that the older elderly (70 years and more seasoned) were altogether more averse to look for treatment contrasted with the 60–69 age classification, while Muslims were somewhere in the range of 62% and 49% bound to look for treatment in UP and Maharashtra, separately, contrasted with Hindus. This investigation found that old in booked clan/planned standing (SC/ST) classifications were 54% more uncertain and other in reverse classes (OBC) 35% more averse to look for treatment for existing diseases in Maharashtra contrasted with different ranks. At long last, secondary school graduates were twice as likely in UP and multiple times as likely in Maharashtra to look for treatment contrasted with the uneducated gathering. Be that as it may, in the previously mentioned examination, a greater part of the older experienced various bleakness conditions, which makes translating the exhibited outcomes troublesome. The nonattendance of thoroughly structured examinations that evaluate the sorts and seriousness of different sickness conditions in the old further features this reality utilizing information from a similar review, inferred that 9.5% of provincial occupants and 4.2% of urban occupants report absence of access to everyday necessities of drug, near twofold that of apparel and sustenance.

Broad Health Coverage: Planning and Needs: A pathway to national wellbeing change has been imagined by the Planning Commission in the number one spot up to the twelfth Five-Year Plan for India. In October 2010, a High-Level Expert Group (HLEG) was gathered by the Planning Commission to prescribe changes in wellbeing financing, medicate obtainment, network cooperation in wellbeing, wellbeing the executives, and physical and money related standards for wellbeing and HR. Arranging older wellbeing in a more extensive system of all inclusive access and moderateness of Universal Health Coverage (UHC) can possibly change the auxiliary conditions that hamper the prosperity of the matured. We abridge a portion of the manners by which UHC may serve these capacities, all through showing the proof holes that will be required for these capacities to be met.

Key UHC changes relevant to access incorporate the arrangement of extra HR at the Sub-Health Center level (per 5,000 populace), just as the presentation of an extra Community Health Worker (like an Accredited Social Health Activist) in rustic and low-salary urban regions. These changes would guarantee that notwithstanding existing needs of maternal and youngster wellbeing, rising needs in NCD control, just as activity on social and physical hindrances to get to, can be tended to locally (i.e., pair with Village Health and Sanitation Committees and their urban identical). Future research may help decide the extent of consideration at the Sub-Health Center level and the scope of promotive administrations gave at the town/network so as to take into account the necessities of India's older.

It has been proposed by the HLEG, additionally, that a fundamental bundle of consideration (including essential, optional, and tertiary-level administrations) be cashless at purpose of administration using a National Health Entitlement Card (which would likewise fill in as an identifier for Electronic Medical Records, conveying quiet chronicles and care-chasing profiles). This arrangement will be especially valuable for the older poor, and will require advancement and a far reaching exercise in information accumulation and assemblage on both the client and supplier sides. To this end, methodological commitments from progressing associate examinations, for example, the Longitudinal Study on Aging in India (LASI) and parallel endeavors universally will be very significant.

Various administrative instruments under the aegis of a recently proposed National Health Regulatory

and Development Authority will guarantee wellbeing framework backing, accreditation, and nonstop wellbeing frameworks assessment. This procedure may profit, once more, from the developing base of research on old clients of the wellbeing framework, who may have a more drawn out length of collaborations with the framework just as incredible variety regarding need and weight, affected by changing social determinants. Wellbeing frameworks assessment will also need to reflect age-explicit horribleness and mortality designs, just as that of intersectional older gatherings (the bereaved old, matured of religious minority status, and others).

Conclusion

The development of the older populace in the coming decades will carry with it exceptional weights of horribleness and mortality the nation over. As we have laid out, key difficulties to access to wellbeing for the Indian old incorporate social hindrances molded by sexual orientation and different tomahawks of social disparity (religion, position, financial status, shame). Physical obstructions incorporate diminished versatility, declining social commitment, and the constrained reach of the wellbeing framework. Wellbeing moderateness requirements incorporate restrictions in pay, business, and resources, just as the confinements of money related insurance offered for wellbeing consumptions in the Indian wellbeing framework.

Among the most critical discoveries that rose in building up this audit was the inadequacy of information on the weights of access and moderateness among older populaces in India. A noteworthy purpose behind this is standard wellbeing information gathering in India isn't intended to reflect or describe neurotic movement: a procedure wherein, by goodness of being alive longer than others, the older are bound to encounter a pathology, prompting impedance, practical impediments, and at last incapacity. Numerous standard information accumulation strategies (National Sample Surveys, Census information, or passing endorsements) in India don't catch neurotic movement nor do they disaggregate dreariness and inability results among the older.

General Awareness of Diabetes Mellitus among a Hospital Population in Chennai: A Survey

Sridhar M.[1], Abilasha Ramasubramanian[2]

[1]Undergraduate Student, [2]Reader, Department of Oral Pathology, Saveetha Dental College and Hospitals, Saveetha Institute of Medical and Technical Sciences, Chennai

Abstract

Aim and Objective: The aim of this study is to assess the awareness of diabetes mellitus and knowledge about the various aspects of diabetes including types, treatment modalities, preventive measures and lifestyle modification in the patient population visiting a Dental Hospital in Chennai.

Materials and Method: In this study, a questionnaire was prepared and circulated among the subjects to determine the awareness and to inspect the knowledge about the symptoms, diagnosis and preventive measures about Diabetes mellitus among the people. The study sample comprised of totally 100 subjects, both males and females of age group between 20 and 50 years.

Results: According to the survey 52% of the individuals are aware about that diabetes can lead to further complications. 82% of the individuals felt that the diabetes can be controlled by exercise. 19% of individuals have not undergone any confirmatory tests for diabetes. 50% of the individuals were under medication for treatment of diabetes and they experienced side effects while taking those medications. 50% of the individuals who participated in the survey have attended a formal diabetes educational programme and they are aware of diabetes through media,relatives and doctors.

Keywords: *Diabetes, Medications, Dietary Habits, Exercise, Blood Glucose level.*

Introduction

Diabetes is a group of disease characterised by hyperglycaemia resulting from the defects in insulin secretion, insulin action or both[1]. According to recent World Health Organisation (WHO),India today leads the world with over 32 million diabetic patients and the number is projected to increase to 79.4 million by the year 2030[2]. There are two types of diabetes namely Type 1 Diabetes which is due to pancreas which stops producing the hormone insulin and Type 2 Diabetes which is due to combination of both the pancreas having reduced ability to produce insulin and body being resistant to action of insulin[3].

Further researchers have predicted a 65% rise in prevalence of diabetes due to population growth rate, age structure, urbanisation, unfavourably modifications of dietary habits and lifestyles, economic and health transition of the country and thus actual number of diabetes could be as high as 52 million by 2025[4]. And also the type 2 diabetes is seen in early adult lifeand seen in all age group of Indian populations. So for these reasons WHO declared India as the "Diabetic Capital"[5]. Several studies have been carried out to so as to reveal about the diabetes its complication,medications,diet plans and lifestyle modification for the treatment of it[6].

Failure to diagnose diabetes mellitus art an early stage due to various factors like insufficient knowledge, lack of public awareness about symptoms of diabetes,

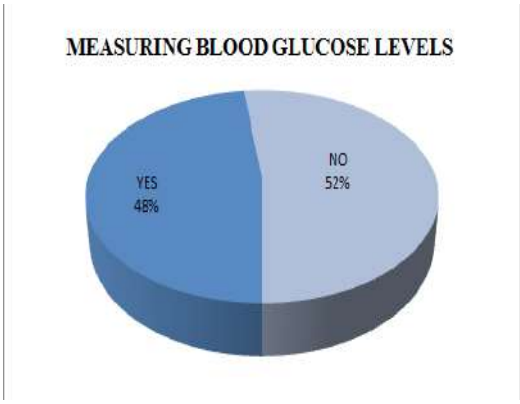
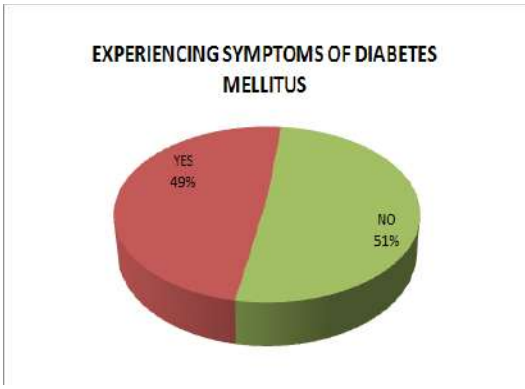
further complication of diabetes and its prevention, short of infrastructure for proper screening camps to identify diabetic screening and identification of high risk individuals are those factors which make diabetes mellitus a common disease [7]. Many young diabetics who as year's progresses live into their old age where they develop and suffer from chronic morbidity due to complications of diabetes mellitus thus forcing them to lead a life of poor quality. Many studies have identified that main step in tackling diabetes mellitus disease is only through providing knowledge to community regarding the disease, symptoms, complications, positive attitude towards control, prevention and various treatment modalities [8]. The aim of the present study is to assess the awareness about diabetes mellitus and its causes, treatment modalities, lifestyle modification and preventive measures to improve the knowledge among the population about one of the most prevalent diseases in the country.

Materials and Method

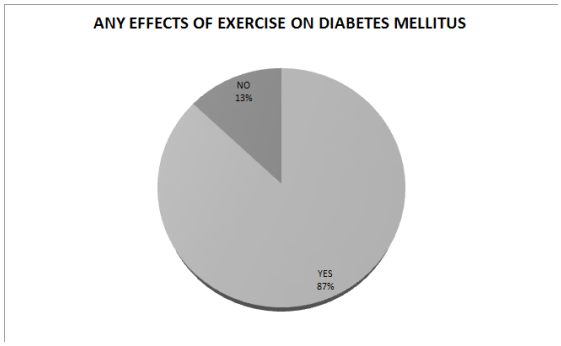
In this study, a questionnaire was formulated which mainly focussed on the general knowledge about awareness and prevention of diabetes mellitus. The sample for the study includes 100 subjects including male and females within the age group of 20 to 50 years. The questionnaire contained information like medications for diabetes, any side effects or type of medications received by them,about their consultancy with physician and at last the general details about the support and general method of control diabetes and awareness. Questionnaire was based on questions which determine the awareness and inspects the knowledge about the symptoms, diagnosis and preventive measures about Diabetes mellitus among the people. The results were tabulated and statistical analysis was done.



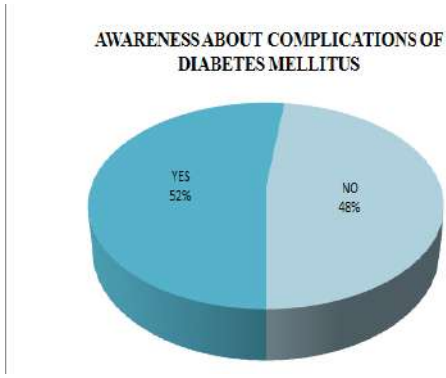
Graph 1: Population experiencing symptoms of diabetes mellitus



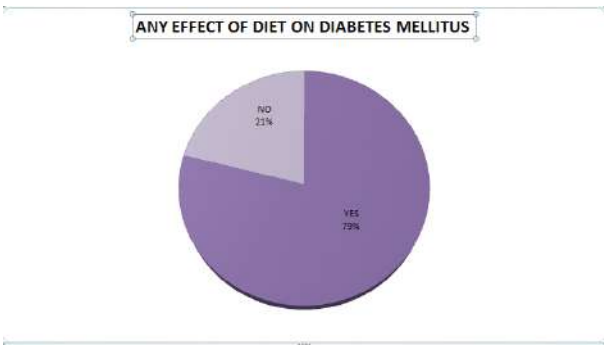
Graph 2: Population measuring blood glucose levels regularly



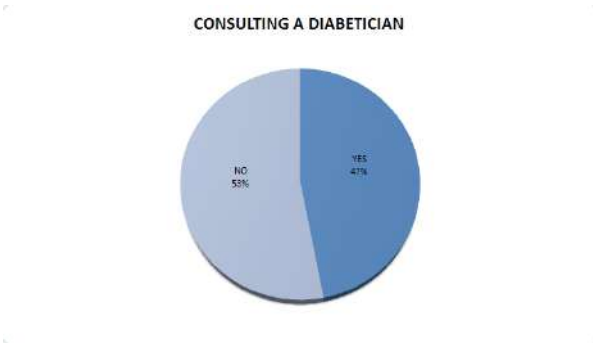
Graph 3: Population aware of effects of exercise on diabetes



Graph 4: Population having awareness about disease complications



Graph 5: Population consulting a diabetician



Graph 6: Population aware of dietary effects on diabetes

Results

From the survey, 53% of the individuals who has participated on the survey has visited the diabetes care provider in the last 12 months. 48% of the individuals do not often check their blood glucose levels and they do not have any machine to measure it.

Questions related to risk factors for diabetes revealed that misconceptions were present and worrisome fact is that only 50% of the individuals who were diabetics were aware of the risk factors and further complications.

Awareness about the complications that diabetescan lead to is there among 52% of the populations in which the individuals say that diabetes can lead to respiratory,cardiac problems and some say that it may lead to death.

Individuals were not sure that they had any confirmatory test for diabetes which is around 81% and so they were not able to answer any one of the confirmatory tests for diabetes mellitus.

Many individuals were unaware that diabetes is a disease which has two subtypes. Only 47% of the individuals were able to differentiate two types of diabetes Type 1 and Type 2[9]. Individuals have an argument that they experience changes in result when consulting one or more physician which makes them uncomfortable to discuss about the management of diabetes. This was reported by 48% of the individuals. Patients undergoing treatment for diabetes had an increased familial support for them to do so according to our results.

Discussion

The main aim of this study is to find out about the awareness and prevalence of knowledge in controlling diabetes among the individuals who were participating in this survey. A study by Deepa Mohan et al found that 75.5% of the individuals in Chennai were aware of diabetes[10]. However, the same study had revealed poorer knowledge about the complications of diabetes only 74.2% among diabetics which was similar to the results obtained from our study.

Our survey has only basic questions which tests the knowledge of individuals about the diabetes in questions like types,preventive measures,treatment options etc. Similarly another study was conducted in Singapore by Wee about public awareness on diabetes which showed low scores on general knowledge but good understanding of complications[11]. This implicatesthat majority of the patients have not been taught about diabetes by their physicians and the same results were obtained from the survey which was obtained from the study.

In this survey,there is mixed responses for the question regarding the frequent monitoring of blood glucose level. A similar study is done by Kaur and others in chandigarh where the people are poor in tooth care and infrequent monitoring of blood sugar[12].

Generally, Prevention of diabetes can be done with help of medications and other physical activities. Majority of the people who participated in the survey identified that dietary habits and physical activities can help in a greater extent to control diabetes. The prevention has an impact by reducing both the need for diabetes care and to treat diabetic complications[13].

In our survey, there is finding that comprehensive programmes, mass media, relatives, doctors can have an large impact as an important step in preventative health service which was similar to study conducted by parks in which he discussed about the social mobilisation and communication in TB control programmes[14].

The results of the study represent only the tip of the iceberg, in depth community based studies has to be undertaken to assess the awareness, about diabetes. Community level awareness programs are to be launched so as to increase the awareness about diabetes.

Conclusion

Awareness about diabetes is insufficient among the population our study and hence a dearth for proper knowledge in prevention and management of diabetes mellitus. This study is done in order to emphasise the need of increasing diabetes awareness activities in form

of campaigns or educational programmes in both urban and rural area of India in order to improve the disease outcome and prevention of the disease.

Vitamin D Deficiency in Rural Area of Gautam Buddh Nagar: An Observational Study

Vijay Deepak Verma[1], Ajai Kumar Garg[2], Suresh Babu[3], Ashish Satyarthi[4]

[1]Assistant Professor, [2]Associate Professor, [3]Senior Consultant, [4]Resident, Department of Medicine, Government Institute of Medical Sciences, Greater Noida

Abstract

Background: In addition to bone formation, mineralization,calcium and phosphorus metabolism, vitamin D is also involved in maintaining normal neuromuscular function. Vitamin D deficiency is a public health problem in our country. Its deficiency is widely prevalent in urban population. However, rural Indian population is perceived to be at low risk of vitamin D deficiency due to their lifestyle exposing them to more sunlight.

Aim: To study the prevalence of vitamin D deficiency in rural population of Gautam Buddh Nagar district of national capital region.

Methodology: Consequent 80 apparently healthy subjects of either sex from both rural and urban background, with nonspecific symptoms were studied for their demographic profile and 25(OH) vitamin D levels.

Results:25(OH) vitamin D level was 14.96 ng/ml in rural group and 16.25 ng/ml in urban group. A high prevalence of vitamin D deficiency was observed in both rural and urban population of Gautam Buddh Nagar.

Conclusion: Vitamin D deficiency is widely prevalent in our society including rural India. Apparently healthy subjects of rural population particularly women with nonspecific symptoms should be evaluated for vitamin D deficiency.

Introduction

Vitamin D deficiency is a global problem and its deficiency is widely prevalent in urban Indian population across all age groups and sections of society[1,2,3]. In large chunk of population vitamin D deficiency is subclinical which is characterized by non specific musculoskeletal clinical manifestations[4]. However, there is limited data available about deficiency of vitamin D in rural population of our country. Factors such as low sunlight exposure, age related decrease in vitamin D synthesis in the skin, and diet low in vitamin D are the main causes of vitamin D deficiency. Physical factors like clothing, sunscreens, and glass-shielding attenuate UV-B exposure of skin and thereby, markedly reduce synthesis of vitamin D.

Population in rural areas generally has different occupation and lifestyle. In rural areas, large proportion of men and women work as farmers and are exposed to more sunlight whereas people living in urban areas generally work indoor and do not get adequate exposure to sunlight[5]. People in urban areas are also involved in activities that avoid sun light, e.g., protection from sunlight by use of umbrella and sunscreen[6,7]. On the other hand, melanin pigment, produced by melanocytes

Corresponding Author:
Ajai Kumar Garg
Associate Professor, Department of Medicine, Government Institute of Medical Sciences, Greater Noida
e-mail: drajaigarg@yahoo.co.in

on exposure to sunlight absorbs UV-B rays and thus attenuates the final dose of UV-B energy reaching 7-dehydrocholesterol in basal layers of epidermis. Therefore,melanin functions as natural sunscreen and reduces the skin's ability to synthesize vitamin D as much as 99%. Therefore persons with dark skin are more likely to have vitamin D deficiency and need more direct sunlight to have optimum amount vitamin D synthesis by skin[7,8].

UV-B rays of sun trigger the photolysis of pro-vitamin D3 (7-dehydrocholesterol) to previtamin D3 in plasma membrane of keratinocytes of human skin. This plasma membrane previtamin D3 is isomerized to vitamin D at skin temperature. Serum 25(OH)vitaminD is major circulating metabolite and standard clinical measure of vitamin D status. 1, $25(OH)_2$ vitamin D should not be measured to determine vitamin D status, as it can be normal or even elevated in patients with vitamin D deficiency. Studies have shown that serum 25(OH) vitamin D level around 30 ngm/ml (75 nmol/L) induce a minimum steady state level of PTH.

Material and Method

The present study was conducted in the department of medicine, Government Institute of Medical Sciences, Greater Noida for a period of one year. Consecutive 80 patients attending medical OPD with complaints of backache, generalized bodyache, joint pain, fatigue, and muscle weakness were included in the study. Patients with history of diabetes mellitus, chronic liver disease, chronic kidney disease, thyroid disorders, malignancy, chronic diarrhea, or any other chronic illness, were excluded from the study. Patients taking vitamin D or with past history of Vitamin D supplementation were excluded from the study. Patients who were bed ridden and forced to stay indoor due to any chronic condition or otherwise were also excluded from this study. Patients were evaluated for demographic profile and serum 25(OH) vitamin D level.

Results

In the present study out of 80 subjects 38 had rural background whereas 42 subjects belonged to urban class. Out of 80 subjects 27 were male and 53 were female. In this study 34 subjects belonged to 21-40 and 41-60 year age group each, 11 subjects belonged to >60 year age group, whereas only 1 belonged to < 20 year age. Severe vitamin D deficiency was found in 25% (20/80), vitamin D deficiency was found in 48.75% (39/80) with insufficiency in 18.75% (15/80) in the study population. Sufficient vitamin D level was found in only 7.5% (6/80) cases. 25(OH) vitamin D level was 14.96 ng/ml in rural group and 16.25 ng/ml in urban group. Vitamin D deficiency in rural area was comparable to urban population and it was as common in males as in females.

Table 1: Number of subjects in both the groups

Patient Profile	Rural	Urban	Total
Male	9	18	27
Female	29	24	53
Total	38	42	80

Table 2: Average vitamin D level in ng/ml in both groups

Patient Profile	Rural	Urban
Male	12.44 ng/ml	14.38 ng/ml
Female	15.87 ng/ml	17.52 ng/ml
Total average	14.96 ng/ml	16.25 ng/ml

Table 3: Age of patients in both the groups

Age Group in Years	Rural Male	Rural Female	Urban Male	Urban Female	Total
<20	1	0	0	0	1
21-40	5	14	4	11	34
41-60	4	13	7	10	34
>60	0	1	6	4	11

Table 4: Severity of vitamin D deficiency in study groups

Vitamin D Status	25(OH) D (ng/ml)	Rural male	Rural female	Urban male	Urban female	Total
Severe deficiency	<10	2	5	7	6	20
Deficiency	10-20	5	18	7	9	39
Insufficiency	20-30	3	4	2	6	15
Adequate	30 -40	0	1	1	4	6

Discussion

India, despite being a tropical country with abundant sunshine is found to have high burden of vitamin D deficiency among the public irrespective of their socioeconomic status. *GRet. al.,* in one study reported vitamin D deficiency in epidemic proportion with a prevalence of 70-100% in general population both in urban and rural settings across all socioeconomic strata[9]. *Agarwal N et.al.*, observed in their study that vitamin D deficiency was present in 83.7% of subjects (<20 ng/ml) at baseline among Indian postmenopausal women[10]. High prevalence of vitamin D deficiency in patients with type 2 diabetes mellitus has been observed by some studies. *Selvarajan S et.al*., observed that vitamin D deficiency was prevalent among apparently healthy Indians living in different regions irrespective of their exposure to sun light[2]. *Choy EY* in one study among Korean adults observed that vitamin D deficiency peaked in summers and higher vitamin D levels were correlated with summer, the 60s age group, rural residence, moderate to vigorous physical activity, and multivitamin supplementation. He also observed that higher education and unmarried status were inversely related to vitamin D levels in both male and female[11]. Interestingly in the present study maximum number of subjects with vitamin D deficiency belonged to 20-60 years and fewer subjects belonged to above 60 years of age. The possible reason for this observation may be increasing awareness about vitamin D deficiency in the society and increasing medical attention in the form of calcium and vitamin D supplementation received by elderly people. *Roland VK et. al.*, in one study conducted on 174 patients in Switzerland observed that vitamin D deficiency was present in 71% of chronic pain patients and another 21% had insufficient vitamin D levels[12].

Conclusion

In this small study it is concluded that vitamin D deficiency is as common in rural population as in urban population of Gautam Buddh Nagar district of national capital region, although deficiency of this vitamin is more prevalent in females than in males. One of the reasons of vitamin D deficiency in rural India could be the decreased synthesis of vitamin D because of high melanin skin pigment and reduced intake of dietary products rich in vitamin D. Therefore apparently healthy subjects of rural population particularly women with nonspecific symptoms of bodyache and weakness should be evaluated for vitamin D deficiency and if found so they should be supplemented with vitamin D and calcium.

Identifying the Status of Menstrual Hygiene Management

Amrita Shilpi[1], Rajasree Roy[2], Gobina[3], Spriha Roy[4]

[1]Assistant Professor, Department of Political Science, [2]Assistant Professor, Department of Philosophy, [3]Assistant Professor, Department of History, [4]Student, Philosophy Hons, Lakshmibai College, University of Delhi

Abstract

For women, the onset of puberty is marked by menstruation. To bleed is natural and indispensable essence of being a woman. However, innumerable myths and taboos perceive menstruation as a negative phenomenon and lead to pessimistic attitudes toward this biological experience and women going through it. The culture of silence around menstruation increases the perception of menstruation as something shameful that needs to be hidden, and may reinforce misunderstandings and negative attitudes toward it. Proper menstrual hygiene management is the most significant and crucial aspect of female health but has been grossly neglected not just in developing countries but across the globe.

The paper presents ground assessment of the knowledge, beliefs, and source of information regarding menstruation among the adolescent school girls and also identifies the status of menstrual hygiene among them. This study was undertaken, under the Innovation Project of Delhi University in the year 2015-16. This interdisciplinary undergraduate program had two components: Awareness generation and action oriented. Awareness generation was related to providing information through workshops about menstruation among the college going young women adolescent school girls of the secondary school. Action component was related to production of low cost sanitary napkins by using simple technology that has been locally developed.

Keywords: *Menstruation, Menstrual hygiene, Innovation Project.*

Introduction

For women, the onset of puberty is marked by menstruation. To bleed is natural and indispensable essence of being a woman. However, scores of myths and taboos continue to perceive menstruation as a negative phenomenon[1] and lead to pessimistic attitudes toward this biological experience and women going through it. The culture of 'silence' around menstruation increases the perception of menstruation as something shameful that needs to be hidden, and may reinforce misunderstandings and negative attitudes toward it[2].

Proper menstrual hygiene management is the most significant and crucial aspect of female health but has been grossly neglected not just in developing countries but across the globe. Increased knowledge and safe practices related to menstruation right from adolescence may help in diminishing the suffering of millions of women[3] (Yasmin et al: 2013).

With this background the present study was undertaken, under the Innovation Project 2015-16, to assess the knowledge, beliefs, and source of information regarding menstruation among the adolescent school girls and also to identify the status of menstrual hygiene among them.

This interdisciplinary undergraduate program had two components: Awareness generation and action oriented. Action component was related to production of low cost sanitary napkins by using simple technology that has been locally developed.

Awareness Generation Component: Awareness generation was related to providing information through workshops about menstruation among the adolescent school girls of the secondary school. It was based on the hypothesis that awareness generation and promotion of low cost technologies can play a vital role in combating the harmful consequences of menstrual hygiene mismanagement. The objectives were as followed

i. Developing an acquaintance in girls with the subject of menstrual hygiene mismanagement,

ii. Understanding on traditional practices during menstruation.

iii. Myths related to menstruation.

iv. Unhygienic practices and their health impacts.

v. Management of menstrual waste.

vi. Products to be used during menstruation.

vii. To encourage low cost sanitation technologies

viii. To generate acceptability in community for handmade sanitary materials,

ix. To develop a mechanism within the institutions with the help of trained population groups for production and sale of sanitary pads.

The study focussed on assessing the knowledge, beliefs, and source of information regarding menstruation among adolescent school girls and also to identify the status of menstrual hygiene among them. The purpose of the project was awareness generation, facilitation of information and training on handmade sanitary napkins.

From the review of literature it was clear that many times social taboo[4,5,6,7,8]and unhelpful outlook of parents and teachers in discussing the issues related to menstruation have obstructed the access of adolescent girls to the proper information about the entire phenomenon[9]. After a survey of Government primary and secondary schools near Chandrawal area in North Delhi and series of interaction with several NGOs, individuals and school authorities the team prepared a list of eight schools which could be approached for the study. An informal visit to each school was made and the purpose of study was explained. Most of the Principals and teachers welcomed the idea. However, one of the Principals was totally apprehensive about the interaction with the students. She insisted that open discussions about 'such things' leave the growing up girls more confused.

After the informal interaction, the investigators approached Deputy Director of Education (North District) with a request for holding Awareness Workshop on Menstrual Health and Hygiene among students of class 6^{th}, 7^{th}, 8^{th},and 9^{th} standard in four Government Girls Secondary Schools of North Delhi. With her consent, the team held awareness workshops and conducted focus group discussions with the girl students of the selected schools.

Method of data collection: The basic method for collecting data on the awareness levels among the target groups were direct personal observation supplemented by interviews and focus group discussions. It was supplemented by series of workshops and interactive sessions on menstrual hygiene management.

For the Innovation Project team, there were series of sessions on sanitary pad preparation. It began with familiarizing the participants with the materials and then involving them in the production. The team also interacted with a number of civil society organizations working in this field.

Sampling and development of structured Interview Schedule: A random selection of 400 girl students from four Government Girls Secondary Schools of North Delhi (100 from each school) was done for the data collection.

Data was collected on the structured interview schedule so that it could be comparable in all respects. For this purpose items were framed following scientific procedures of item writing and discussion with a number of experts from social work and education background. On the basis of the suggestions the schedule was finalized which contained the following areas:

Demographic Characteristics, Information about Menstruation, Knowledge and Perception regarding Menstruation, Practice of Menstrual Hygiene, and Restrictions practiced during Menstruation.

This schedule was earlier administered on a small sample of students of Lakshmibai College to see if language was suitable for the population.

Interview and Focus Group Discussion: A pre-designed pre-tested structured interview schedule was eventually administered on a sample of 400 schools going girls specified in the study as per the sampling design. They were explained about the purpose of the study and were assured of confidentiality. A verbal consent was obtained from the girls before administering the questionnaire which included questions regarding the knowledge about menstruation, the source of information and practices followed to maintain menstrual hygiene. Investigators instructed on how to fill the schedule and adequate time was given to fill up the same. Any difficulties in answering the schedule were sorted out by the investigators.

At the end of the data collection a FGD was conducted with girls of different age groups. The discussion was

focussed on the normal physiology of menstruation, the importance of maintaining hygiene and safe hygienic practices during menstruation. Questions and concerns of the participants were also addressed at the end of the session.

Result and Discussion

As explained above, the interview schedule was divided into five sections. The aim was to understand the perception, experience and information about menstruation.

Menarche becomes a significant experience in girls at the threshold of adolescence[10]. The age of the respondents ranged between 10 to 13 years. 87.25% of the respondents were aged between 11 to 12 years. One of the items of the schedule sought information on the source of information about menarche. Mostly, mothers are the main informants as well as confidant of the girls at this age. However, there is always an element of concern as to how the girls are informed about this phenomenal change in their bodies. Out of 400 respondents 336 replied that mothers were the first informants for them. It was followed by friends/sister (35), teacher/health worker (20). Amongst other options, television was an important source of information about menstrual hygiene (9).

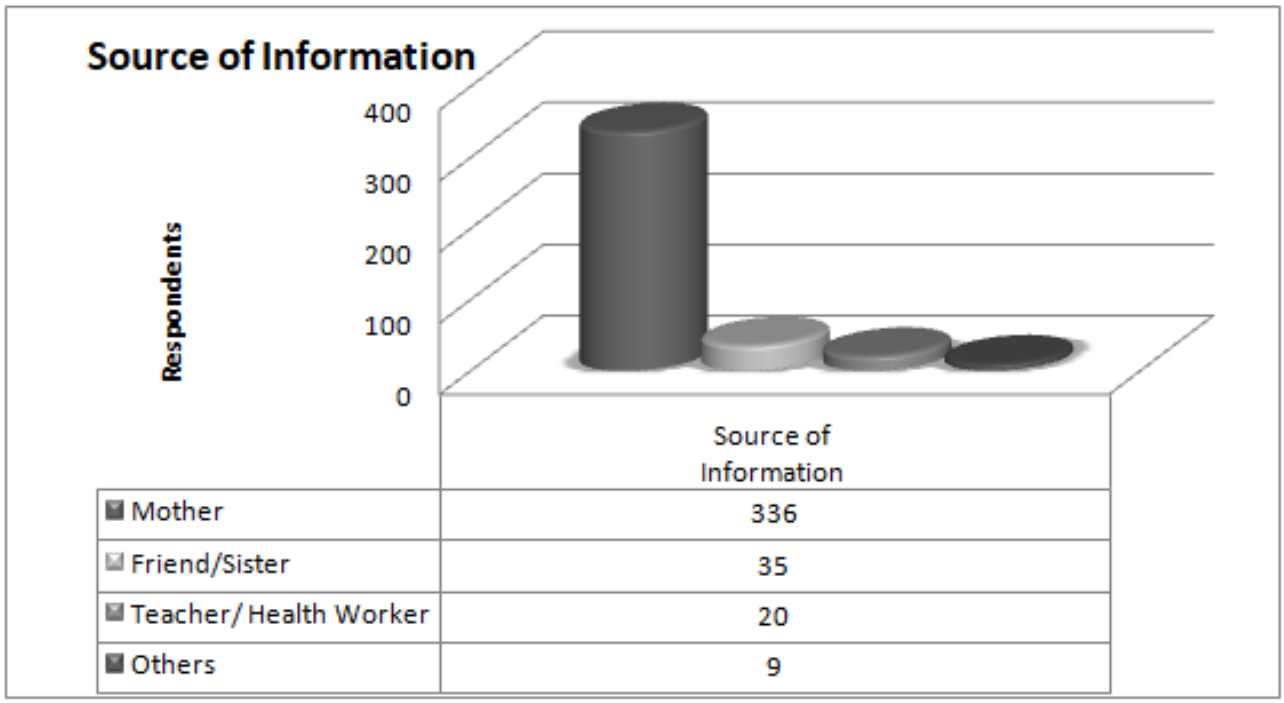

Figure 1

Awareness regarding menarche and menstruation among respondents before attaining menarche was found to be low. Out of 400 respondents, 252 knew about it after menarche. After reaching puberty, girls are faced with challenges related to menstruation. Lack of information, misconceptions and adverse attitudes to this natural process have lead to a negative self-image among girls. This often results in a lack of self-esteem as they mature as women. Most often this emotion, the negative self-image, grips them with the onset offirst 'period'. It was interesting to talk to girls about their first period and how they felt about it. When asked about the cause of menstruation, 61% of the respondents believed it to be a physiological process. It was interesting however to note that 9.5% of the total respondents believed it to be some kind of curse. 27% of the respondents had no idea about the cause of menstruation.

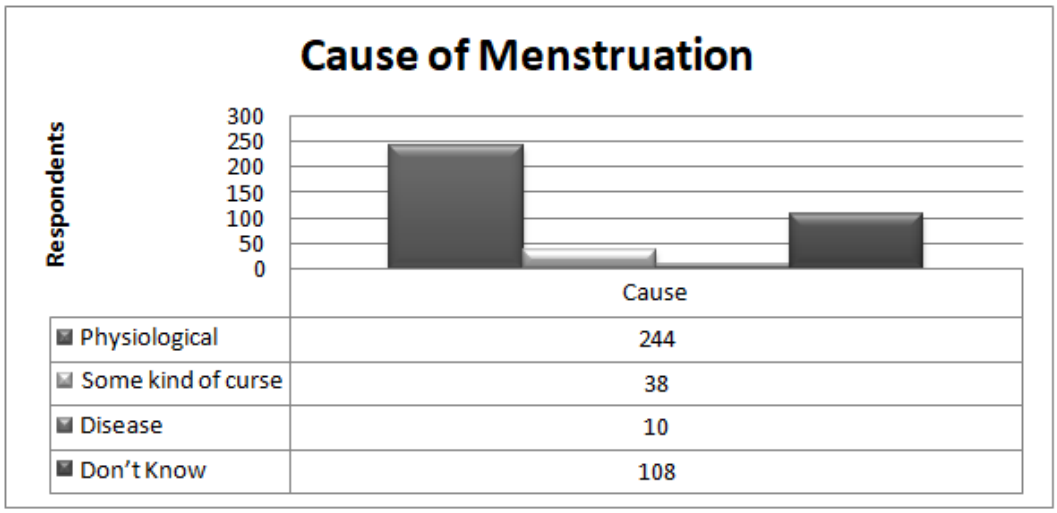

Figure 2

Awareness level was quite low about where the menstrual bleeding originated from. 68% of the respondents had no idea about it. There were three other items in this section that showed lack of awareness about menstruation and menstrual health.

The next section of the schedule tried to understand the common practices of menstrual hygiene. The type of absorbent material used was of primary concern. The reuse of any absorbent material, most commonly, cloth, could be a cause for infection if it was not properly cleaned dried and stored. This study revealed that girls both cloth and sanitary pads as absorbent during menstruation depending on the availability.

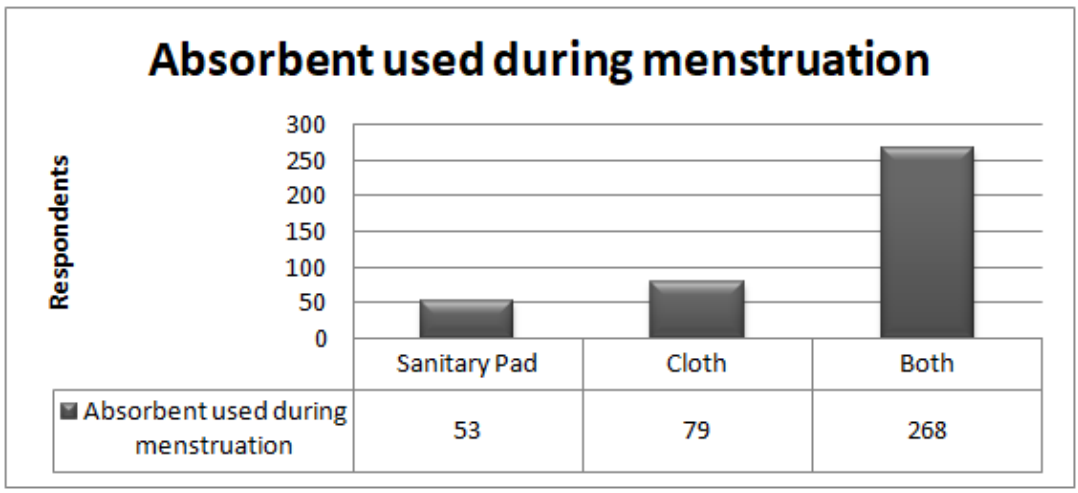

Figure 3

However, some of the girls informed that they preferred cloth pieces rather than sanitary pads as menstrual absorbent because they did not have proper undergarments to support it. Some of the teachers shared their concern that due to lack of proper undergarments the girls did not attend school during those days. It was also suggested that provision of undergarments and sanitary pads at low cost might increase the use of sanitary pads.

The place of storage of the cloth or napkins was equally important for cleanliness and hygiene. The practice of storing them was not witnessed. They procured cloth or pads as and when required.

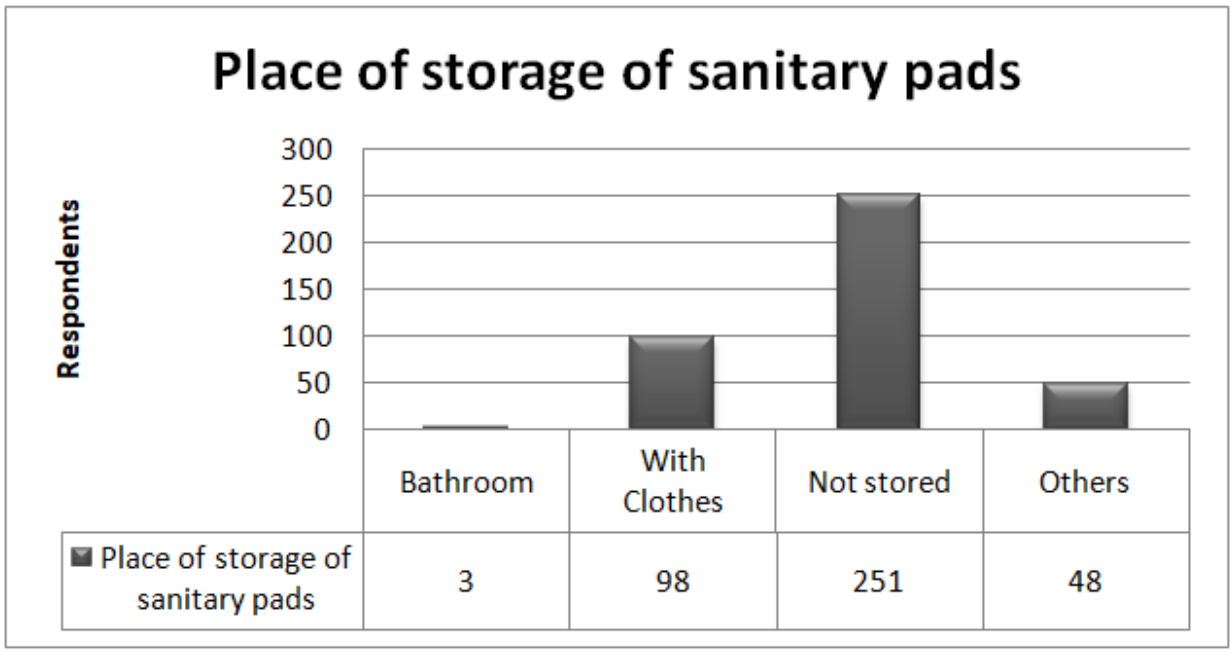

Figure 4

The proportion of the participants who used the bathroom as a storage place was very low.

In the present study, the most common method of disposal of the used absorbent was wrapping it in paper and disposing it in routine dustbin which was used for solid waste disposal. However, 32% of the respondents admitted to throwing the sanitary waste on the roadside as it got dark.

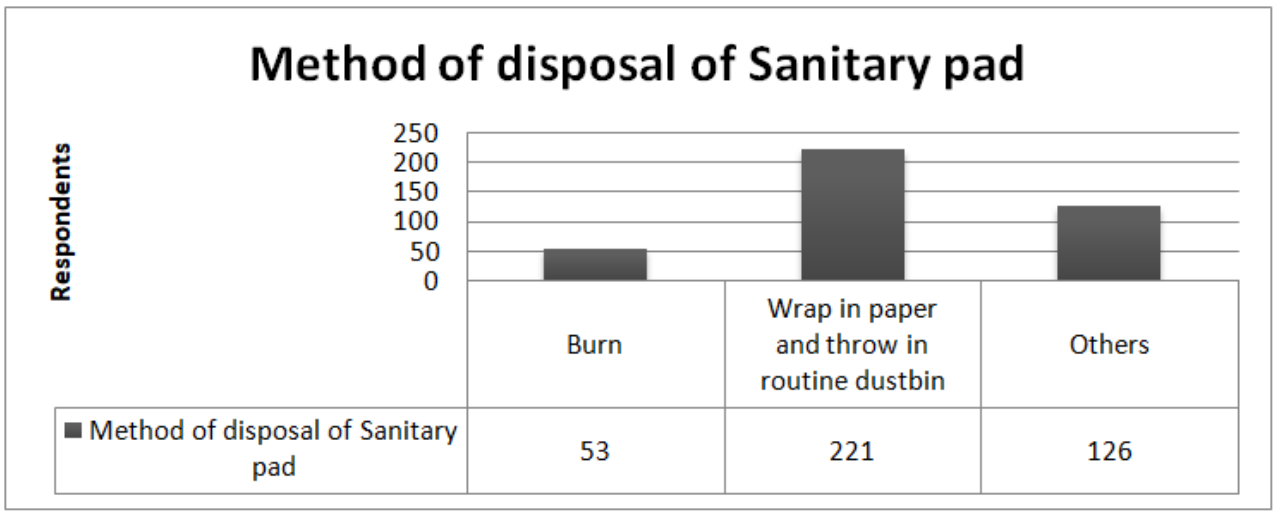

Figure 5

In the present study restrictions were practiced by most of the girls, visit to holy places and touching stored food being the most common restrictions.

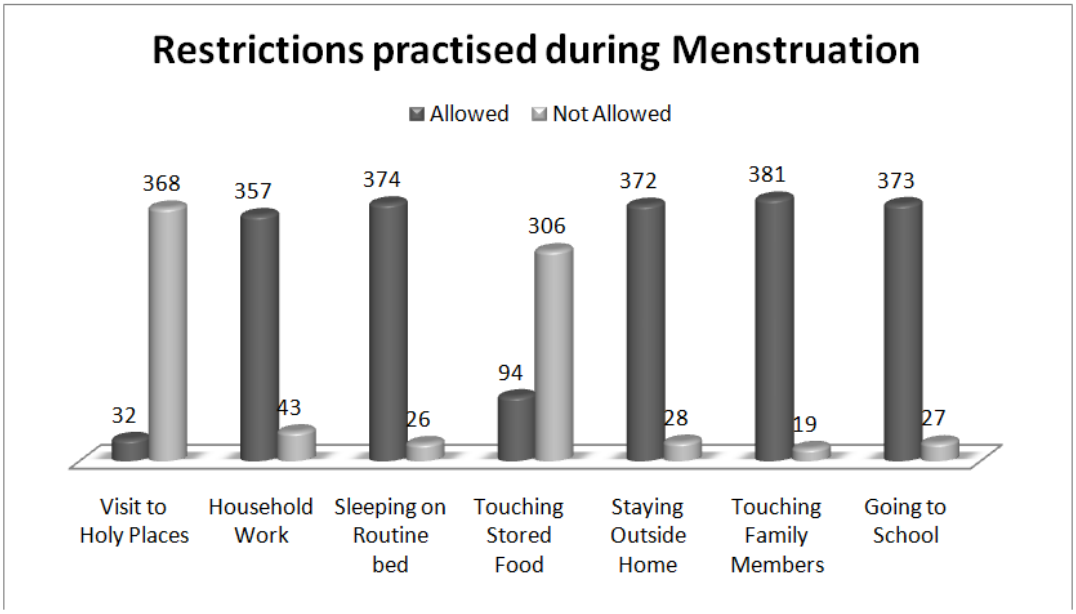

Figure 6

Considering the limitations of this study in terms of sampling method, additional studies may be needed using a wider geographic scope, in order to produce sufficient and comprehensive results.

Action Component: The College provided for an Innovation Room where the project team has produced Sanitary napkins at low cost. The production of the napkins has been done entirely by the college students (a team of ten students selected for the project).

Innovation shown and its future impact: Contemporary political thinker, Nancy Fraser[11] opines that, "institutionalized patterns of cultural value constitute some actors as inferior, excluded, wholly other, or simply invisible, hence as less than full partners in social interaction, then we should speak of misrecognition and status subordination"(p.29). Both these cultural constructs are visible when one places women and the world face to face.

Sciences rightly have the first claim to inventions and discoveries. The Social Sciences keep exploring the continuity and change within the society which makes every stratum significant.

As members of academics, it becomes one's responsibility to take such issues to the ground using awareness and information as the working tools. The innovative techniques have evolved within the country that enhances easy and low cost access to something as essential as sanitary napkins.

This project has wide social contribution as well as commercial implication.

Conclusion and Future direction

Menstrual hygiene is an issue that is quite unsatisfactorily acknowledged. It has not received ample attention in the reproductive health and Water, Sanitation and Hygiene (WASH) sectors in developing countries including India[12]. Its connection with and effect on achieving many Millennium Development Goals (MDGs) is hardly ever recognized[13].

This study has tried to tackle several issues at the ground level. The low and lower middle class strata more often than not lack knowledge as well as money for availing basic necessities as sanitary napkins. Females mostly use old and dirty clothes due to their impoverished background. They do not know how to manage menstruation properly. It can lead to extreme forms of infections and diseases. The introduction of the concept of handmade sanitary material to the school students, teachers, college youth and other sections of the society eventually would at least help in addressing the basic health issues.

Ethical Clearance: Taken

Source of Funding: Research Council, University of Delhi provided the grant for undertaking this Innovation Project in the year 2015-16.

Effect of Strengthening of Scapular Stabilizers in Treatment of Rounded Shoulder Posture in Dental Students

Ankita M. Patil[1], Sayali Gijare[2]

[1]Intern, [2]Assistant Professor, Department of Pediatrics, Faculty of Physiotherapy, KIMS "Deemed to be University" Karad, Maharashtra, India

Abstract

Objective: The objective of this study was to investigate the effects of scapular stabilizer strengthening in rounded shoulder posture in male dental students.

Method: Ethical clearance was obtained from the institutional ethical committee. Total 30 Subjects were selected as per the inclusion criteria and rests were excluded. Participants were informed about the study & written consent was taken prior to participation. In pre test assessment, subjects were assessed by scapular index. They were given strengthening exercises of scapular stabilizers as a treatment of rounded shoulder posture before they start working for 30 minutes per day, 5 days a week and were continued for 4 weeks. Post test assessment was done by using same outcome measure. Interpretation of the study was done on the basis of comparing pre test and post test assessment. Thus, the study was concluded with the help of statistical analysis by using paired 't' test.

Results: The study showed effect of strengthening of scapular stabilizers on rounded shoulder posture in dental students is ($p>0.0001$), which is extremely significant.

Conclusion: On the basis of the results of our study, it is concluded that strengthening of scapular stabilizersis extremely significant effective in correcting rounded shoulder posture among male dental students.

Keywords: *Rounded shoulder, external rotation, scapular stabilizers.*

Introduction

Rounded shoulder posture is characterized by acromion protraction in front of the line of gravity, shoulder protraction and downward rotation as well as anterior tilt[1]. According to previous study rounded shoulder is described as abduction and elevation of the scapula and a forward position of the shoulders which gives appearance of a hollow chest[2]. Posture and comparative alignment of the body is affected due to shortening and weakness of the muscles. rounded shoulder posture deform the normal relationship of the muscles and the bony structures which are correlated to each other[3]. It is described as a result of shoulders being pulled forward by over-developed, shortened or tight anterior shoulder girdle muscles such as serratus anterior, upper trapezius etc.[4, 5] Additionally, it may also caused by weakness and lengthening of the upper and middle trapezius muscle that function to pull the scapulae toward spine[1].

It has been also documented in factors which are contributing to head, shoulder as well as neck pain[6]. Trapezius and lower serratus anterior act as the prime movers for scapular upward rotation. Rhomboids and levator scapulae are downward rotators and serratus anterior, rhomboids, trapezius, levator scapulae are stabilizers of scapula[7]. Position and control of the scapula on thorax, play a critical role in the normal function of the shoulder. While doing overhead activities periscapular muscles provide stability and help in pain free mobility at shoulder complex in healthy individuals[8].

Although many technical advances have arrived in recent years, many occupational health problems

still persists in modern dentistry [9].Musculoskeletal disorders are common problem in dentists as its incidence is 63 to 93%.Some of these musculoskeletal disorders may recognized to postural abnormalities or poor posture specifically in demanding jobs such as dentistry. Prevalence of rounded shoulder posture in dentists contributes to 68.8% [10]. There are some factors which may play important role in pathogenesis and constant complaints are prolonged static and dynamic awkward postures and repetitive movements, physical conditioning [11]. Previous studies have acknowledged that these postural problems may considerably influence the social life and result in diminished working efficacy and early retirement in dentistry [12, 13].

It is found in early studies that, Stretching, McKenzie and Kendall exercises for shoulder girdle muscles are commonly used in the treatment of shoulder dysfunctions and correction of posture [1]. However there is limited research available to show any significant impact of strengthening of scapular stabilizers in treatment of rounded shoulder posture in dental students.

Strengthening exercises are defined as a systematic procedure of a muscle or muscle group lifting, lowering or controlling resistance for a relatively low number of repetitions or over a short period of time [14].These types of exercises can be performed in both closed chain as well as open chain positions. Exercise interventions aimed at strengthening of the weak that is scapular stabilizing muscles [15].The purpose of this study was to evaluate the effect of 4 weeks of strength training on rounded shoulder posture by scapular index as outcome measure. For assessing rounded shoulders, scapular index was used [16].

Method

Ethical clearance was obtained from the institutional ethical committee. Total 30 Subjects were selected as per the inclusion criteria and rest were excluded. Participants were informed about the study & written consent was taken prior to participation. In pre test assessment, subjects were assessed by scapular index. They were given strengthening of scapular stabilizers as a treatment of rounded shoulder posture before they start working. The exercises were given for 30 minutes per day, 5 days a week and was continued for 4 weeks.

Post test assessment was done by using same outcome measure. Interpretation of the study was done on the basis of comparing pre test and post test assessment. Thus, the study was concluded with the help of statistical analysis.

Sampling method: convenient sampling

Treatment

Exercise protocol for activation of scapular stabilizers:

1. Side lying external rotation with elbow 90° flexion using dumbbell.
2. Side lying external rotation with forward flexion using dumbbell.
3. Prone horizontal abduction at 90° with full external rotation using dumbbell.
4. Prone external rotation at 90° abduction and elbow at 90° using dumbbell.
5. Shoulder shrug at 0° abduction.
6. Shoulder shrug at 30° abduction.
7. Standing wall shrugs.

All the exercises were performed 30 minutes/day for 5 days/week for continuous 4 weeks.

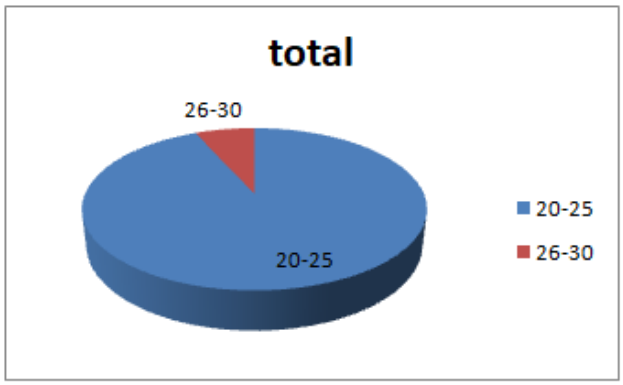
Strengthening exercises of scapular Stabilizers:

1. Scapular retraction against handheld resistance in prone
2. T to Y to W exercises
3. Scapular-clock exercise on the table
4. Scapular-clock exercises on a wall
5. Corner press-out

Subject Criteria: Total of 30 subjects, male interns and male PG dental students working more than 5 hours were selected in the study. They were aged between 20 to years. The explanations about the study procedure were given. The outcome measure was scapular index. The subjects who were not included in the study were dental students having history of diagnosed rheumatoid disorders,history of any neurological disorders,Female dental students,Trauma as well as surgery in shoulders and spine.

Results

1. Age Distribution in this Study:



Graph No. 01: Age distribution

Interpretation: This graph shows that, the age distribution in this study included is 28 in age group between 20-25 and 2 in 26-30 age group.

2. Pre and Post Comparison:

Table No. 01

Scapular Index	Pre	Post
	70.733	72.917

Chart: Pre and Post Comparison

Table No. 02

Group	PRE	POST	P value	t value	Remark
Scapular Index	70.733±2.337	72.917±2.567	<0.0001	8.297	Extremely Significant

Statistical Analysis: The outcome measure was assessed at the baseline. The collected data in this study was statistically analyzed using descriptive statistics as mean, standard deviation and percentage. The scapular index was analyzed by paired t' test. T values were calculated in the scapular index. Statistical significance was accepted for the values of ($p < 0.0001$).

Discussion

There are many technical advances arrived nowadays still many occupational health problems persists in dentists[9]. Musculoskeletal disorders are common problem in dentists as its incidence is 63 to 93%. Prevalence of rounded shoulder posture in dentists contributes to 68.8%[10]. A variety of factors which may contribute important role in pathogenesis and constant complaints are prolonged static and dynamic awkward postures and repetitive movements, physical conditioning [11].

In the current study, dental students between age group 20-30 fulfilling the inclusion criteria were included. Dental students working for more than 5 hours were included in this study.

The aim of our study was to find out the dental students having rounded shoulders and to strengthen their scapular stabilizers. Statistically the present study showed that there were significant changes in the outcome measure with significant difference seen in rounded shoulder posture mean difference (-2.183)(p value <0.0001).In our study we analyzed that the changes in scapular index,after incorporating strengthening exercises for rounded shoulder posture for 4 weeks were significant.

A study conducted to investigate the specific effects of a McKenzie exercises, Kendall exercises, self stretch exercises on rounded shoulder posture and forward head posture. In this study, rounded shoulder posture was measured by scapular index in which they found no significant differences between the groups ($p>0.05$)[1].

A study performed on intramuscular activation of scapular stabilizing muscles during push up plus and proprioceptive neuromuscular exercises. The proprioceptive neuromuscular exercises showed statistically significant higher level of lower trapezius and lower serratus anterior activities than push up plus exercises[7].

A study was done on the review of the exercises that produce optimal muscle ratios of the scapular stabilizers

on normal shoulder which included optimal positions and exercises for periscapular stability exercises. A conclusion that standing exercises tend to activate the upper trapezius at higher ratio,especially during 60-120^0 range[8].

At the end of 4 weeks in our study,it was seen that there were statistically significant difference between pre interventional and post interventional values of scapular index in rounded shoulder posture of male dental students after applying paired 't' test, concluding that there is a positive effect of strengthening of scapular stabilizers on rounded shoulder posture in dental students.

Conclusion

On the basis of the results of our study, it is concluded that strengthening of scapular stabilizersis extremely significant effective in correcting rounded shoulder posture among male dental students.

Conflicts of Interest: The authors declare that there are no conflicts of interest concerning the content of the present study.

Elder Abuse in Indian Setting–A Misconception or a Reality– A Deductive Analysis

Anusha Rashmi[1], Linda Sequeira[2], Prianka Shashi Kumar[2], Rashmi[3]

[1]Assistant Professor, [2]Post Graduate, Community Medicine, AJIMS & RC, [3]Professor, Community Medicine, K.S. Hegde Medical Academy, Mangalore

Abstract

Background: Elderabuse has come to the limelight only since the past decade. WHO estimates that 15.7% of individuals above 60 years undergo abuse in various forms and is proposed to increase in the coming years owing to ageing population in many countries. Hence this study attempts to find out the perception of individuals towards elder abuse.

Method: A qualitative study was done by conducting Focussed group discussions (FGDs) amongst elders and those between 18–60 years of age. The discussion was audio taped and scribed which was then analysed by deductive thematic analysis. The findings have been presented based on the themes that emerged along with verbatim.

Results: The study groups were of the consensus that elder abuse is prevalent in our country. Themes that emerged were: 1) Elders are considered a burden in the society, 2) Sons and daughter in laws abuse elders more, 3) Elderly females are abused more than elderly males. The discussions also revealed a low level of knowledge amongst the groups regarding helplines for elderly/schemes for the elderly in our country.

Conclusion: Elderly abuse though prevalent in our societies lay hidden mostly because complaint registrations of such instances are very few owing to the fact that elders are dependent and are not aware of where and how to seek help.

Keywords: *Elderly, abuse, deductive analysis, FGD, Misconception, Qualitative study.*

Introduction

Though Domestic violence and Child abuse and gender-based violence have been receiving considerable attention, Elder abuse has come to the foray only since the past decade. Based on available evidence, WHO estimates that 15.7% of people 60 years and older are subjected to abuse.[1] These are likely to be underestimates as many cases of elder abuse are not reported.

Corresponding Author:
Dr. Anusha Rashmi
Assistant Professor, Community Medicine, AJIMS & RC, Mangalore
e-mail: anurash7@gmail.com

Elder abuse can be defined as "a single, or repeated act, or lack of appropriate action, occurring within any relationship where there is an expectation of trust which causes harm or distress to an older person".[1] Elder abuse can take various forms such as financial, physical, psychological and sexual. It can also be the result of intentional or unintentional neglect.

Globally the number of people affected are predicted to increase as many countries are experiencing rapidly ageing populations. While in India, 8 percent of its population was recorded 60 years and above in 2011 Census, it is expected to increase its share to 12.5 percent and 20 percent by 2026 and 2050 respectively.[2] With this kind of an ageing scenario, there is pressure on all aspects of care for the older persons–be it financial, health or shelter.

Studies have also shown that the phenomenon of elder abuse has been considered a social taboo by many and people struggle to discuss such a sensitive issue and report elder mistreatment.[3] Family members have been the most common perpetrators of elder abuse.[4,5]

Survey conducted by Help Age India in 23 cities in 2018 revealed that 60% of adults confirmed that elder abuse is prevalent in the society. 25% confirmed to being victims of the abuse as well. Elder Abuse was reported maximum in Mangalore, Ahmedabad, Bhopal, Amritsar, Delhi and Kanpur. It was least in Jammu, Mumbai, Vizag, Kochi, Guwahati.[2]

Hence this study tries to find out situation of elders through perceptions and views about the same from representative populations in Mangalore.

Objective:

1. To assess perception regarding elder abuse amongst the elders in selected urban field practice area in Mangalore
2. To assess perception regarding elder abuse amongst the General population in selected urban field practice area in Mangalore

Methodology

Study site: Urban field practice area of A J Institute of Medical Science and Research Centre

Study duration: Study was conducted over a period of 2 months (October–November 2018)

Study participants: Elderly individuals (>/= 60 years)

Individuals from the general population (> 18 years and < 60 years)

Individuals consenting to participate were included in the study. Those individuals with debilitating diseases were excluded considering that the FGDs were conducted at the health centre.

For assessing the perceptions regarding elder abuse focussed group discussions were carried out at health centre of urban field practice area of AJIMS & RC. Study subjects were recruited from the said area. Discussion was based on the FGD guide prepared after a literature review,whichwas also validated. The FGDs were continued till repetitive answers were obtained from consecutive groups. With this method we collected information from 2 groups of Elderly (> 60 years) having 5 and 6 members each and 2 groups from general population group (> or = 18 yrs - <60 years) having 4 and 5 members each. Hence a total of 4 FGD sessions were conducted. Each session lasted for 45 minutes. It comprised of a moderator who was the principle investigator of the study, a scribe to note down the verbal discussions during the FGD as well as audio taping of the entire session. The recruited participants were explained about the purpose of the study and informed consent was obtained from each of them. Themes that emerged from the discussions have been analysed using deductive analysis and the same has been reproduced in the results along with the verbatims of the participants.

Areas discussed were

1. Elder abuse in our country
2. Elders are considered a burden in our society
3. Elder abuse and financial status are related
4. Elder abuse is related to gender of the individual
5. Elder abuse is done by people whom you know
6. Helplines and Schemes for the elderly
7. Elder abuse is a punishable offence
8. Personal experience regarding elder abuse

Results

Elder abuse: Most of the elders concluded that elder abuse is a phenomenon where elders are not cared for. “Elder abuse is something where the elders are not looked after well.” All of them agreed to the fact that elder abuse is prevalent in our country. Though they were not aware of geographical areas where elder abuse is present at a high rate, they did say that Mangalore is a city where elder abuse is present. When asked regarding the situation outside Mangalore they said that did hear it through media. “These days one gets to hear of such things on television and also in newspapers.” There were a few elders who also said that their children cared for them well. The youngsters also opined that elder abuse is happening in many ways “we read in newspapers that elders get beaten up at their homes. Some of these incidents come out in the open while some others don’t as the elders do not complain of the same”.“Abuse is happening in many ways. Especially when it concerns family property matters, relatives too abuse them, and since they have grown old, they feel helpless.” “Some elders even get kicked out of their homes.” All

participants felt that elder abuse is a heinous act, but such instances should not happen as reciprocating the love and affection towards elders is but the duty of their children. 3 of the total 11 elders from the elderly group had experienced verbal abuse and neglect. "These days they don't even ask if we need a drop even to the hospital when we are sick."

Elders are a burden: Many elders confirmed that children these days consider elders to be a burden. "At this age we cannot earn. So, we become a burden to them." One elderly male stated "When I used to earn, I was looked after at home. Now that I have stopped earning since the last 1 year, I must end up begging for money even for bus charges. That is my state currently. Plus, ill health adds to the situation." They were also of the opinion that in some families children prefer that their parents stay in old age homes. "These days expenses have increased. So, when there are members in the family who do not contribute to the finances, they become a burden." "If the elders are financially better off, they are looked after well. If not, then they get treated badly." Both the elders and the youngsters felt that sometimes even if the elders have money or property then it adds to elder abuse since children start bargaining over their property share and pressurize the elders. Some of the younsters commented saying "Elders are not a burden. Their presence gives us happiness. They give us blessings. They have seen much more of life and their experience and advice can solve a lot of our problems."

Sons and daughters in law abuse elders: "It is the sons who abuse their parents more." "Previously the daughter in laws would be abused. These days it is the other way around. The daughter in law abuses the elders at home." A participant from the younger group mentioned that "when I am not at home my wife treats my mother differently." One of the elders also stated that "for me the abuse is not only at home by my son but also by the neighbours. Neighbours create lot of trouble". Some of them also opined that son in laws tend to abuse more since they have a good hold in the household matters. One of the youngsters said, "in the neighbourhood there was family where the elder daughter used to hit her mother who was later 'sent to the sons house where, the daughter in law started hitting her and then would close her in a bathroom and deprive the elderly lady of food."Some also said"We cannot tell who does the abuse, most times it depends on the bread earner and decision maker in the family."

Elder females are abused more: Most of the elders felt it is the elder females who are abused more. They said "the females stay at home mostly. And the daughters in law abuse their mother in law". The younger group similarly opined saying "the mother in law would not like the daughter in law and later the daughter in law would care less for the elderly female." Some believed "since the males no longer earn after a certain age, they undergo abuse more. The mothers are looked after while the fathers are cared less." Some participants from both groups felt that "abuse is same for both, be it males or females, when there is a financial burden no one sees if it a male or a female."

The discussions also showed that neither the elders not the youngsters knew about any helplines for the elderly. The youngsters however believed that the perpetrators need to be punished. However, one elderly stated that "whatever neglect we face we will have to continue living with them."

Discussion

Our FGD revealed that elderly females are at a higher risk of being abused as compared to males which has been similarly reported in other studies[6,7] as well. In a male dominated society, females generally are more at risk since they are more vulnerable than the rest. The common forms of abuse discussed were verbal abuse and neglect which is also seen in other studies.[6,7,8]The elderly are often a marginalized sect who are dependent financially and emotionally on others especially their family for support. These factorspose them at a risk for abuse from their close family, relatives and many a times even the neighbours.

This study has its findings in line with other studies[2,7] where sons have been commonly implicated as main perpetrators of abuse over elder individuals. This may be because sons continue to stay with their parents and later take over the responsibility of the household. But the finding is ironic that in a country like India where a male child is preferred over the female child at birth, the same male offspring is later implicated in elder abuse by most elder individuals.

It has also been seen in our study that though there are certain personal experiences of abuse there has been no complaint whatsoever registered against the crime which also goes to show that the elders are irrevocably dependent on their children and others that they either do not want such incidents to come to the limelight fearing

retaliation or they just simply ignore the incidents as a part and parcel of growing old.

Conclusion

The study shows that though not much about the elder abuse gets reported it continues to happen behind the closed doors of households. Financial reasons being the most common factor behind the abuse, it is a matter of great concern as well a matter for action in the light of facing an ageing population in the coming years.

A Study on Women Entrepreneurs Dealing Through Stress

Archana R.V.[1], K. Vasanthi Kumari[2]

[1]*Research Scholar, VELS Institute of Science, Technology & Advanced Studies (VISTAS), Pallavaram,*
[2]*HOD, Department of Business Administration,RV Government Arts College, Chengalpattu*

Abstract

Modern living is occupied of stress. Stress is an unavoidable consequence of socio-economic intricacy and to some extent, its stimulant as well. Even as stress is foreseeable in today's complex life, it is essential for individual life. When a women entrepreneur's gains practice and self-assurance in her work, the stress is leap to turn down. The proficient women entrepreneurs are found to suffer greatest extent of stress. Numerous aspects contribute for the escalating stress level of these women entrepreneurs and an effort is made in this study to analyze such contributory factors.

Keywords: *Women entrepreneurs, stress, entrepreneurial constraints.*

Introduction

Women entrepreneurs play a very important role in generating employment to others in the well-organized segments and place the drift for other women entrepreneurs to grow[1]. The participation and progress of women entrepreneurs is now very much evident in India. Entrepreneur being women have to carry out and keep up a sense of balance among several responsibilities and its concern obligations. It is eminent that women entrepreneurs were suffering from role divergence i.e. one had to concurrently be a mother, a wife and a boss and this put forth's a lot of mental stress and strain[2].

Stress: Stress grounds a commotion in the emotional firmness of an individual that brings about a state of ineffectiveness in the personality and conduct[3]. It is well thought-out to be an internal state or response to anything actual or imagined that an individual deliberately or instinctively perceives as a threat [4].

Women Entrepreneurs: The women entrepreneurs create new jobs for themselves and also for others and render a great service to the society[5]. Women Entrepreneurs may be defined as the woman or group of women who initiate, organize and co-operate a business enterprise

Entrepreneurs' stress: Entrepreneurial position stress can be described as the detrimental physical and emotional responses that take place when the necessities of the enterprise or job do now not in shape the capabilities, resources, or needs of the entrepreneurs[6]. The stress of the women entrepreneurs will be decreased based on their work knowledge, experience and confidence in the work [7]. Every entrepreneur deal with some problems and the most unpleasant part is that women entrepreneurs were greatly encountered by plentiful difficulties and obstacles than men.

Problems faced by women entrepreneurs: Women entrepreneurs stumble upon a problem such as an inadequate training, financial strain and family errands, worked time is not measured with respective wages, the rate of struggling to go on in the market is high, and certain entrepreneurs have not even used the internet in their business [8]. Women entrepreneurs endure various personal problems like the absence of business contact, the lack of adequate experience and suspicious attitude towards risk. They also face certain familiar social problems like family responsibilities, unwritten rules of society, and male supremacy, no possession of properties, the lack of economic power, depending on male members on banking and few economic related issues[9].

Stress faced by women entrepreneurs: Compared to the other occupation categories women entrepreneurs sense more stress in their profession [3]. The role related stress experienced by the women Entrepreneurs can be characterized into three major magnitude, role

overload, role conflict and role ambiguity [10]. Women entrepreneurs experience role stress in performing twin responsibilities [2]

Constraints faced by women entrepreneurs: It is observed that women entrepreneurs were facing many constraints in running an enterprise[11] as follows.

Knowledge associated: Women entrepreneurs are in general not conscious of whom to contact when there is a need. The sources which they have contact with are on the whole did not endow with full knowledge and sometimes even exploit them. Most of the women entrepreneurs lack knowledge in many financial activities. They also lack knowledge in practice and advancement in technology. They are not alert concerning the loans and the financial schemes offered for the entrepreneurs. They does not seize any economic credibility too.

Man Power: The success of an endeavour is for the most part rely on the hands of skilled labour. Many women entrepreneurs find difficulty in reaching cooperation from the male employees. At times, they were being dominated by the male employees and they were not ready to accept a woman as boss and attempt to show non co-operative approach.

Raw Material: According to the demands and choice of customer's diligent selection of raw material is important. It is one of the important spot to be determined and if it is not properly scrutinized there may be immense interruption in production process. Selecting a trustful supply agency is yet another intricate task. Determining the prices of raw material is an additional constraint.

Marketing: For any venture, competition is a great challenge. As many of the women entrepreneurs have not attended any training programme, lack of business education and knowledge make them ignorant of the marketing strategies like market segmentation, market positioning and marketing mix strategy, hence the survival of the business against the competition is found to be a huge constraint.

Effect of stress among women entrepreneurs: Stress among the women entrepreneurs generates a interruption in the emotional stability which includes a circumstances of inefficiency in the performance, personality and encompass expensive misplace for themselves, organizations and society[12], such situation have been defined as 'role novelty', which refers to an untutored characters for a precise role, which can be extended from education or experience [13].

Stress coping strategies: Stress arises when perceived strain exceeds your perceived ability to cope [14].Stress can be coped by emotional focus; it is finding a way to ease their reaction to emotional issues by giving them an emotional support. Secondly, stress coped by problem focus, it is categorising the issue and adopting a direct and constructive strategies to solve the issue[15].

Conclusion

It is necessary to involve women entrepreneurs on an equal foothold with men and this can be done only if women are given the proper means to improve themselves, and their entrepreneurial situation. The government is enchanting numerous initiatives for improving the growth of women entrepreneurs so the women who aspire to become an entrepreneur must make use of the facilities provided. Women's definitely play a major part in the economic progression. It is the responsibility of the society to facilitate every women entrepreneur to cross the obstruction such as education type, availability of fund, management skills and so forth. Women are becoming great victims to increasing stress as they are taking multi-role duties from career and home so it is the responsible of family affiliates and society to help her out to attain a balance between work and life.

Effect of Bilateral Scapular Muscles Strengthening on Dynamic Balance in Post Stroke Individuals

Arpan Dhoka[1], G. Varadharajulu[2]

[1]MPTh (Neurology), [2]Dean/Professor/HOD, Krishna College of Physiotherapy, Krishna Institute of Medical Science Deemed to be University, Karad, Maharshtra, India

Abstract

Aim: To determine the effect of bilateral strengthening of scapular muscles to improve dynamic balance in post stroke individuals.

Objectives: To find the effect of bilateral scapular muscles strengthening in stroke and to find the upper trunk balance in stroke after intervention.

Materials and Method: 42 patients were included according to Brunstrom's recovery stage 2 and voluntary control grade 2 of upper limb were randomized by chit method into two groups, group A (conventional Physiotherapy{PT}) and group B (bilateral scapular muscle strengthening and conventional PT) - with 21 patients in each group. All the patients were assessed with Berg balance scale (BBS), voluntary control grading of upper limb (VCG), and bilateral scapular muscle recruitment by Electromyography (EMG). The treatment was given for 5 days a week for 4 weeks. After 4 weeks effect of interventions were assessed by BBS, VCG and EMG.

Conclusion: Bilateral scapular muscles strengthening combined with conventional PT showed improvement in dynamic balance and had an additional effect on muscle recruitment, control of upper limb and mobility in stroke patients.

Keywords: *Stroke, scapular muscles, berg balance scale, EMG, Dynamic balance.*

Introduction

The defination of stroke was issued by the WHO as: a rapidly developing clinical signs of focal or global disturbances of cerebral function, with symptoms lasting for more than 24 hours or leading to death, with no apparent cause other than of vascular origin. [1] It is the most common life threatening neurological disorder. [2]

Cerebrovascular stroke (CVS) is a neurologic event related to diseases of the cerebral circulation.[1] CVS has been shown to be a major cause of death and disability in all communities. According to the American Stroke Association, about 87% of strokes are ischemic, and the remaining 13% are hemorrhagic. Stroke is the fourth leading cause of death and long term disability in developed countries among adults. Each year approximately 7, 95,000 individuals experience stroke; approximately 6, 10,000 are the first attack and 1, 85,000 are recurrent strokes. Women have a lower age–adjusted stroke incidence then men, but this is reversed in older ages, women with 85 years and above have high rate of risk compared to men.[3]

After an immediate discharge from the hospital, stroke patients are at a high risk of fall (1.3–6.5 falls/person/year) while performing transfer activities on bed and out of bed. After an insult to the brain falls it can cause various problems in everyday life disturbing the daily activities. Stroke survivors' has more frequency of fall and injury compared to general older population.[9]

Approximately, one third of the stroke survivors will have residual disability on the affected side, with the severity of hemiparetic upper extremity, a significant determinant of post-stroke disability and quality of life of the patient. Therefore, impact of upper limb impairments on disability and health is very obvious.[5]

However, limited attention has been given to upper-extremity rehabilitation after stroke, and generally functional recovery of the upper limb and hand is limited compared with that of lower extremities. Upper limb hemiparesis leads to various impairments of daily living like eating, dressing, bathing, self care activities and writing, which result in reduced functions of daily living. Therefore, stroke individuals must participate into various rehabilitation programs to improve their activities of daily living.[5]

In stroke survivors', ability of controlling balance is reduced. Especially, the postural sway in static position is more than twice that of the healthy individual of the same age group, which consequences for safety.[10] Balance is described as the co-ordination in which all forces acting on body are balance such that the center of gravity (COG) is within stability limits, the boundaries of base of support (BOS).[11] Balance has been implicated in the poor recovery of activities of daily living (ADL) and mobility and increased risk of falls. Therefore, it is important to maintain balance in activities of daily living (ADL), posture control is essential, while motor, sensory and higher cognitive functions play an important role in postural control. There are various factors that influence selection of balance strategies and they are as follows 1) Speed and intensity of the displacing factors. 2) Characteristic of support surface 3) Magnitude of the displacement of the COM 4) Subject's awareness of the disturbance 5) Subjects posture at the time of perturbation 6) Subjects prior experiences.[22]

The scapula provides dynamic stability with controlled mobility at the glenohumeral and scapulo-thoracic joint. It plays a significant role in facilitating shoulder joint function, as anatomy and biomechanics of the scapula allow for controlled movement of shoulder joints. Scapular stabilization exercise may be effective in increasing muscle strength, balance and decreasing scapular dyskinesis.[13]

In stroke condition, it is observed that lattisimusdorsi, teres major and serratus anterior do not take part in any of the synergic patterns (flexion synergy and extension synergy).[3]

Muscles are providing stability. The serratus anterior and rhomboid muscles, attached to the scapula, have the crucial function of scapular stabilization. The serratus anterior is to stabilize the scapula during elevation and pulls the scapular forward. Weakness in the serratus anterior can impair scapular orientation and stability, thereby contributing to pathologic kinematics. Latissimusdorsi is a trunk muscle but it assists in scapular depression with various agonist muscles like serratus anterior, lower fibers of trapezius and pectoralis minor. Adducts, extends and internally rotates the arm at the shoulder.[14]

As per Brunstorm's recovery stage, stage 2 of Brunstorm is a stage where there is change in muscle tone i.e from flaccidity to spasticity emerges, which leads to impairment of upper limb, lower limb and trunk control. From these impairments one of the problems chosen is dynamic balance. There are various forms of exercise for stroke patients to improve balance in the individuals like manual perturbation, rhythmic rotation, rhythmic stabilization and many more. Therefore by using scapular muscles strengthening to improve dynamic balance is being introduced.

Stroke is a chronic condition and have to spend the more time of rehabilitation, and from the early stage that is inpatient in the acute care hospitals physiotherapy intervention are the primary mechanisms by which functional recovery, mobility and functional independence of patient are achieved in stroke.[9] There are various therapeutic interventions which can be given to improve balance by using electrotherapy, exercise therapy and many more.

This study examined the effect of scapular muscles strengthening on dynamic balance in post stroke individuals. We also investigated the balance of the patient using BBS, scapular muscles recruitment of the patient at its maximum effort by EMG, and pattern of movement by VCG to see the postural and trunk control during change in position. Therefore, to improve balance and postural control during the dynamic movement's bilateral scapular strengthening exercise has been given to the patients.

Method

Study Type: Experimental study

Study Design: Pre test or post test

Sample Size: 42 (21 + 21)

Place of Study: Krishna Hospital and Physiotherapy OPD, Karad

Criterion for Study:

Inclusion criteria:

- Stroke with MCA infarct
- Both males and females
- Age ≥ 30 years
- Brunstorm stage 2 and above
- Voluntary control grade ≥ 2
- Poor or fair balance in sitting and standing

Exclusion criteria:

- Patient not willing to give consent
- Sensory impairment
- Any associated orthopedic and cardio respiratory condition
- Patients with unilateral neglect
- Visual impairment

Procedure: By using random sampling method the participants had been divided into 2 groups by chit method; Group A, Group B. subjects with stroke with impaired balance and scapular muscle weakness had been assessed by BBS, EMG, VCG of upper limb.

The intervention had been given for 4 weeks and treatment will be given 5 times a week.

Intervention protocol for group A and group B

Group A (Control Group)	Group B (Experimental Group)
• Sustained stretching • Slow icing • Tapping • Slow brushing • Continuous joint compression • Trunk rotation in supine specific to shoulder joint • Passive movement • Active assisted exercise • Resisted exercise • Sit on a chair and place the pelvis and the spine in the neutral position • Put the less affected arm on a support table • Balance exercises • Manual pertubation • Electrical stimulation	• Conventional exercise and • Stabilization Exercises (Open chain, • Closed chain and Dynamic closed chain scapular stabilization exercise) • Dynamic strengthening exercises of scapula • Reaching out with the arm in different direction moving the scapula out as far as possible

Outcome Measure:

1. **BBS:** BBS is a 14 item rating 5 point ordinal scale, used to evaluate the balance in elderly population and other neurological conditions. It is easy to administer and doesn't require specialized training and takes 15-20 mins. It has moderate to excellent sensitivity while measuring balance in stroke patients, maximum scoring in BBS is 56.
2. **VCG of upper limb:** VCG has 7 components in it rating from 0- 6 point Ordinal Scale, which is used in various upper motor neuron (UMN) lesions. It is used to assess the control of the limbs in UMN lesions. It is an active movement performed by the patient and depending upon the quality of movement performed the grading is done.
3. **EMG:** It was done by a physiologist. The EMG machine was of the company "octopus clarity"

Results

Table No. 1: Comparison of post- post BBS between the group

Statistics: The outcomes were assessed at the 1st day prior to treatment and at the end of 4th week post treatment. Inter group analysis was done by paired t test and intra group analysis was done by using unpaired t test. The inter and intra group analysis was done by using Instat 3.

Discussion

Dynamic balance is a very complex process which requires interaction between various components like vestibular, visual, proprioceptive, musculoskeletal and cognitive systems. Dynamic control to stabilize the body when the support surface is moving or when the body is moving on a stable surface, such as sit to stand transfer or walking.[18]

One of the keystone structures of the body is scapula which plays an important role in postural control.

Muscle sling in the trunk are necessary for facilitating reciprocal gait pattern between upper and lower extremity as well as for rotational trunk stabilization. Muscle sling plays an important role in maintaining and providing dynamic movements of the body. As all the slings are inter-related to each other, if one part of the muscle sling is activated automatically other muscles involved in the sling are activated to provide the dynamic movement while performing any activity of daily living. There are three types of sling and they are anterior, posterior and spiral. Therefore, wrapping from the posterior to the anterior the muscles are rhomboids and serratus anterior.

In the present study, the participants were selected on the basis of inclusion and exclusion criteria. In the study there were 11 males and females in group A whereas, 16 males and 5 females in group B. in group A there were 13 right and 8 left hemiperatic side, in group B there were 12 right 9 left hemiperatic patients.

In this, the efficacy of the scapular stabilization and strengthening exercises in improving dynamic balance in post stroke individuals were investigated. They were investigated using BBS, VCG upper limb and bilateral scapular recruitment by EMG. The intervention was given for 5 days a week for 4 weeks. In group A the conventional PT was given whereas, in group B scapular strengthening (stabilization) exercise along with conventional PT was given. Scapular strengthening exercises were given in various positions like prone and sitting.

Post- intervention it was found that there was significant improvement in all the muscles strength when examined on EMG. But only Lt Serratus anterior muscle was found that there is no significant improvement may be because Lt Serratus anterior muscle works more at acromio- clavicular joint and is responsible for more work at shoulder complex and another reason may be because of dominance of hand as dominant side muscle are strong as compared to non- dominant side.

During the initial stages, patient had difficulty in moving trunk or in performing trunk activities due to which it happened that various upper limb and lower

limb activities of daily living. As the intervention was going on for the patient, they felt more free mobility and enhanced the activity of daily living. Some patient had impaired scapular position initially, as the scapular muscle got strengthen, it helped in correction and better mobility of the scapula and upper limb

Relatively, small changes in the scapular muscles affect the alignment and forces out the shoulder complex. Because scapula plays an important role in controlling shoulder joint position and joining it with the humeral head. [5]

Chiang-Song reported concluded that scapular stabilization exercise program did not have any improvement in berg balance and basic daily activities.[5]

Karatas M concluded that trunk muscle strength had a significant improvement in BBS and FIMS.[18]

Dae-Jung Yang concluded that scapular stabilization exercises are more effective then task oriented training in facilitating muscle activity and functional capacity of upper limb.[7]

After comparing with the previous study, scapular stabilization exercise is important for performing the mobility. One of the studies had no significant improvement in the balance due to limitation of the subjects and exercises given to the patients.

In the present study, after comparing the results with the previous study it suggests that to perform dynamic balance, scapular strengthening (stabilization) is important and also helps in maintaining postural stability.

Therefore, scapular stabilization and strengthening plays an important role in maintaining dynamicity of the body. There was an additional effect on scapular muscle strength an improvement in upper extremity control.

Conclusion

The present study provided the evidence to support that the bilateral scapular muscles strengthening along with conventional physiotherapy and conventional physiotherapy alone has shown improvement in balance, voluntary control and strength in stroke patients.

However, the subjects treated with bilateral scapular muscles strengthening along with conventional physiotherapy showed an additional benefit on Dynamic Balance and Mobility of the patients.

Conflict of Interest: It is difficult to get samples who are having Brunstorms recovery stage 2 and VCG at 2 simultaneously.

Funding: This study was funded by Krishna Institute of Medical science Deemed to be University, Karad.

Ethical Clearance: The study was approved by the institutional etjics committee of KIMSDU.

In Vitro Antibacterial and Anticancer Study of Bioactive Compounds Isolated from Punica Grantum Peel

Arunava Das[1], J. Bindhu, M. Bharath[2], Nithin Johnson[3], M. Jeevanantham[3]

[1]Associate Professor, [2]Research Associate cum Assistant Professor, Molecular Diagnostics and Bacterial Pathogenomics Research Laboratory, Department of Biotechnology, Bannari Amman Institute Technology, Sathyamangalam, Erode District, Tamil Nadu, India, [3]III-Year Biotech Students

Abstract

Plants have been used as natural medicines since the dawn of human kind. This research was focused on phytochemical analysis of Punica grantum peel extract consist of ethanol: chloroform (99:1) as solvent and its constituents were molecularly characterized by GCMS analysis and its ability as an antioxidant, anticancer against K562 cell and antibacterial against some food borne pathogens which comprises of 5 gram-positive and 3-gram-negative bacteria. The phytochemical analysis was performed biochemically and results reveals the presence of secondary metabolites such as Flavonoids, Alkaloids, Tannins, Saponins, etc. and absence of glycosides. The extract was tested against both gram-positive and gram-negative bacteria by agar well diffusion method and its results have shown that the streptococcus faecalis have shown highest susceptibility against the extract. Its antioxidant potential was quantitatively determined by DPPH assay and results showed high range of antioxidant present in the extract with IC50 as 504.9µg/ml. The cytotoxicity assay was performed with peel extract of different concentration against K562 cancer lines which is a myelogenous leukemia cell line. However, the cytotoxicity is less when compared with cell viability and its effects were mild against the cancer cells.

Keywords: *Punicagranatum, DPPH, GCMS, K562 cancer cells (myelogenous leukemia).*

Introduction

Punicagranatum, whose common names are pomegranate, grenade, granats and punica apple, belongs to the Punicaceae family which is a deciduous shrub that grows between 5 and 10m tall with multiple spiny branches and lives extremely long. The fruit is red purple in colour and it is cultivated in Mediterranean region since 3000 BC.[1,8] Some researchers studied the phytochemistry of P. granatum peels and found that the peel extract had abundant polyphenolic compounds mainly tannins and flavonoids, which are responsible for astringent and antioxidant properties.[13] The secondary metabolites of P. granatumpeel extract such as tannis, flavonoids, other polyphenols and some anthocyanins have various pharmacological activities like anticancer activity by flavonoids and antimicrobial activity by tannins and also some alkaloids are useful for treating HIV infection.[2,4]Agrobacterium tumefaciens, which is the causative agent of plant tumour was suppressed by the crude extract of P. granatum peels.[4] Various parts of P. granatum have been used in traditional medicine for treating many diseases like diarhoea, diabetes, ulcer and also digestive system disorders.[1,4] P.granatum also reported antivirus, antiproliferative, antimutagenic, antidiabetic, antidiarrheal, anti-obesity, antifungal properties and also photo-protection activity. [12,13] Antibacterial activity against different strains of bacteria like E. coli, L. monocytogenes, E. aerogenes,

K. oxytoca, B. subtilis, S. agalactiae and S. aureus was shown by P. granatum peel extracts.[3] The components in P. granatum juice that inhibits the cancer cells was identified by scientist in December,2010.[6] The peel extract of P. granatum was tested on Human Chronic Myeloid Leukemia (CML) (K562) cell lines in order to test the anticancerous property.[5] The compounds present in P.granatum peel extracts like gallocate chins, delphinidin, cyaniding, gallic acid and ellagic acid, pelargonidin and sitosterol show therapeutic properties.[7] The infections present in sexual organs of humans and also infections like mastitis, acne, etc., were treated by the pericarp of P.granatum.[8] The antioxidants which are present in the fruits and vegetables such as ascorbic acid, flavonoids and tannins are used to play an vital role in the prevention of diseases. The biomolecules such as proteins, lipids, DNA, RNA are when reacted with the unstable Reactive Oxygen Species (ROS), it will react rapidly and destructively. Most microorganisms that colonize gingival margin or gingival sulcus are compatible with periodontal health.[9,10] The Phytoestrogenic compounds are present in the pomegranate seed oil and also the fruit has strong antioxidant activity which is because of the high levels of phenolic compounds. The pomegranate seed oil has an inhibitory activity on skin and breast cancers.[11] The incidence of collagen-induced arthritis was reduced due to the consumption of pomegranate extract.[12] The characterization of the phytochemical constituents present in P. granatum peel extract was done by GCMS analysis.[14]

Identification and Handling of Sample: Fruits were collected from local market in Sathyamangalam, which is situated in the southern part of India and brought to laboratory. The fruit was thoroughly cleaned with H_2O. The leathery peel was separated from edible portions by cutting it carefully. Later the peel was dried in a hot air oven at 45°C for 48 hours. Later the dried peels were pulverized into fine powder by using a blender and then it is stored in air tight compartment.

Extraction: The shattered peel powder of 10g was packed was packed within the filter paper. The Soxhlet's extraction method was carried out at 65°C for 6 cycles and the solvent was ethanol: chloroform (99:1) of 250ml. After extraction process the extract was concentrated to 25ml through steam distillationprocess.

Phytochemicalanalysis: Test for Tannins: The peel extract of 1ml and 5%ferric chloride were mixed together and the dark blue or green colour formation indicates the presence of tannins.[17]

Test for Saponins: The peel extract of 1ml was mixed with 1ml of distilled water and shook it vigorously. Formation of foam layer of about 1cm indicates the presence of saponins.[17]

Test for Quinones: 1ml of peel extract and 1ml of H_2SO_4 were mixed together and the red colour formation indicates the presence of quinones. [17]

Test for Flavonoids: 1 ml of peel extract was mixed with 1ml of 2N NaOH and the yellow colour formation indicates the presence of flavonoids. [17]

Test for Alkaloids: The peel extract of 1ml and 2ml of conc.HCl were mixed together and then few drops of Mayer's reagent was added. Presence of alkaloids was confirmed by formation of green or white colour precipitate. [17]

Test for Glycosides: One ml of the peel extract was added to 3 ml chloroform and 10% ammonium solution. Formation of pink col our indicates the presence of glycosides. [17]

Test for Cardiac Glycosides: 1ml of peel extract, 2ml of glacial acetic acid and few drops of 5% ferric chloride was mixed together. Then it was under layered with 1ml of conc. H_2SO_4. Presence of cardiac glycosides was confirmed by brown ring formation at the interface.[17]

Test for Terpenoids: 1ml of peel extract and 2ml of chloroform were mixed together and then few drops of conc. H_2SO_4 was added. The presence of terpenoids was confirmed by the formation of red brown col our at the interface.[17]

Test for Phenols: 1 ml of peel extract and 2ml of distilled water were mixed together and then few drops of 10% ferric chloride was added. The presence of phenols was confirmed by formation of blue or green colour.[17]

Test for Steroids: 1ml of the peel extract and 2ml of chloroform followed by 1ml of H_2SO_4 were added and the presence of steroids was confirmed by formation of reddish-brown ring at interface.[17]

GC-MS:

The sample was subjected to GC-MS analysis to

quantify the number of molecules and its structures. The analysis was carried out using GC–MS (Perkin Elmer model: Clarus 680) and also it is equipped with mass spectrometer (Clarus 600 (EI) analysed using (Turbo Massver 5.4.2) software. Fused silica which is packed with Elite-5MS. At a constant flow rate about 1ml/ min, carrier gas such as helium was used to separate the components. The temperature of the injector was adjusted to 260ºC while performing the experiment. The extract sample of 1µl was injected into the equipment the temperatures of the oven were 60ºC (2 mins); followed by 300ºC at the rate of 10ºC min^{-1}; and 300ºC for 6mins. The conditions of the mass detector were: the temperature of transfer line was 240ºC; and ionization mode electron impact at 70eV, the duration time of scan interval is 0.2sec and scan interval is 0.1sec. The fragments from 40 to 600Da. The spectrum of components was corresponding to the database of the spectrum of established components gathered in the GC-MS NIST library.

Antibacterialassay: The antibacterial assay was performed against 5-gram positive bacteria such as Listeria. monocytogenes, Bacillussubtilis, Streptococcus agalactiae, Staphylococcus aureus, Streptococcus faecalis and 3-gram negative bacteriasuch as Escherichia coli, Klebsiella oxytoca, Klebsiellaaerogenes by following Agar well diffusion method. The following bacteria were inoculated in the sterile nutrient plates individually in triplicates by swabbing technique. The wells in diameter of 3.5mm were made using the sterile agar well puncher. The peel extract sample was diluted at different concentration (20%, 40%, 60%, 80%, 100%) using distilled water.Then the agar plates were placed in an incubator at ±37ºC. After 24 hours of incubation, the zone of incubation was measured in mm.

Antioxidantactivity: The antioxidant activity oft he extract was determined by 2,2-Diphenyl-1-picrylhydrazyl (DPPH) assay. Both Samples and Standards (Ascorbic acid) were taken in different concentrations and the volume was adjusted to 100µl using methanol. The DPPH solution of 0.1mM was prepared by using methanol as solvent. About 3ml of 0.1mM DPPH solution was mixed with samples of different concentrations and the negative control was prepared by adding 100µl of methanol to the 3ml of DPPH solution. The tubes with mixtures were allowed to stand in dark at room temperature for 30mins. The color change from violet to yellow indicates the presence of antioxidants and the quantification was done by measuring its absorbance at 517nm against the blank. The IC50 value (inhibitory concentration) was calculated for both sample and standard. The percentage of inhibition was calculated using the following formula:

$$\% \text{ of inhibition} = [A_0\text{-}A_1/A_0] * 100$$

Where A_0 is absorbance of control (i.e. DPPH solution without sample) and $A_1$is absorbance of sample or standard (i.e. DPPH solution with sample/standard).

Cytotoxic assay (MTT method): The results of each test were reported as the growth percentage of treated cells compared to untreated control cells. A 0.1 mL aliquot of the cell suspension (5×10^6 cells/100µl) and 0.1 mL of the test solution (10-50µl) were added to the wells, with the plates kept in an incubator (5% CO_2) at 37 °C for 18 h. After 18 h, 1mg/ml of MTT was added, and the plates were kept in the CO_2 incubator for 4h, followed by the addition of propanol (100µl). The plates were covered with aluminum foil to protect them from light and subsequently agitated in a rotary shaker for 10–20 min, afterwards the well plates were processed on an ELISA reader to obtain absorption data at 517 nm.

Cytotoxicity = [(Control- Treated)/Control] * 100

Cell viability = (Treated/Control) * 100

Results and Discussion

The researchers are continuously exploiting the plant extracts to produce potential drugs with reduced toxicity and increased medicinal properties. The ethanol: chloroform extract of Punica granatum peel was subjected to different phytochemical tests such as secondary metabolites flavonoids, tannins, saponins, alkaloids, cardiac glycosides, glycosides, quinones, terpenoids, phenols and steroids were qualitatively analysed by biochemical method and the results reveals the absence of glycosides in the peel extract. In plants glycosides are the energy source in inactive form. However, another study report shows glycosides are present in sample contains acetone as solvent.[17]

The GCMS analysis revealed the compounds present in the extract in molecular level. The molecule 4-hexen-3-one, 4,5- dimethyl which is an oxygenated hydrocarbon showed highest peak followed by 4-ETHYL-2-hydroxycyclopent-2-en-1-one and 3-heptanol, 3, 6-dimethyl showed high peaks, Figure 1.

The antibacterial assay was performed using the peel extract against different bacterial strains such

as Bacillus subtilis, Escherichia coli, Streptococcus agalactiae, Staphylococcus aureus, Listeria monocytogenes, Enterobacter aerogenes, klebsiella oxytoca and streptococcus faecalis. The results indicate that streptococcus faecalis and Listeria monocytogenes have shown the highest susceptibility to the peel extract. Bacteria such as Streptococcus agalactiae, Staphylococcus aureus were less susceptibility to the peel extract. The gram-positive bacteria have exhibited both high sensitivity and resistivity. The gram-negative bacteria such as Escherichia coli, Klebsiella oxytoca, Klebsiellaaerogenes has exhibited moderate sensitivity. The zone of inhibitions is represented in the Figure 2.

The DPPH results indicate the high number of antioxidants were present in the sample. The IC50 value for both standard (Ascorbic acid) and sample (peel extract) were measured from the graph reveals that standard has 482.5µg/mland the sample have 504.9µg/ml. The obtained values are represented in Figure 3.

The MTT results reveals the peel extract have shown mild effects over the K562 cancer cells. The cell death was increased with increase in concentration on the sample. Another experimental result tested against the Hepato-cellular carcinoma and Colon cancer cell lines have shown a severe effect where they tested with Punica granatum seeds and husks.[15] Another experimental study tested using polysaccharide (PSP001) separated from P.granatum fruits against the K562, MCF-7, KB cancer cell lines have proved its potential ability as an antitumor agent.[16] The activity of sample at different concentrations against the cells are displayed in Figure 4 and the cytotoxicity is represented in Figure 5.

Abstract

Background: Primary healthcare is a vital strategy which remains the backbone of health service delivery. As on March 31st 2017, there were a total of 25, 650 primary health centres(PHC) functioning in the country. Though the number of PHC's had increased, the utilization is declining over the years as people seek private health sectors due to various reasons. Objective: To assess the awareness and utilization of primary health care services provided by Thirumazhisai PHC. Methodology: A Community based cross-sectional study was conducted among people residing in Thirumazhisai. The Sample size of 233 was calculated. The study population was selected by simple random sampling technique. A pre-designed, pre-tested semi- structured questionnaire was used to collect data. Data entered in MS excel and analyzed using proportion. Results: Among 233 people, 183 (78.8%) people knew about PHC services. Regarding utilization of services, 165(70.8%) were availing services provided by PHC. The reasons given for non utilization of services were long waiting time (51.4%), dissatisfaction of Doctor-Patient relationship(17.7%), non-availability of essential medicines (14.7%), PHC not clean (8.8%), and PHC does not have all required services (7.4%). Conclusion: In resource-constrained developing countries like India, all efforts should be undertaken to bring about the maximum efficiency of health care delivery. Role of primary healthcare is essential in the progress towards achieving universal health coverage (UHC).

Keywords: *Primary health care, primary health centres, awareness, utilization.*

Introduction

The Alma-Ata Conference held in 1978 set the goal of attaining the 'Health for all' by 2000 through primary health care approach.[1] Primary health care is defined as "Essential health care made universally accessible to individuals and acceptable to them, through their full participation and at a cost the community and country can afford". In India Primary health care is delivered through a network of Primary Health Centers (PHC).[1]

Corresponding Author:
Dr. B. Charumathi

PHC is the first level of contact and also direct link between the health care provider and the community. According to the National Health Plan 1983, the primary health centers were reorganized on the basis of one PHC for every 30,000 rural populations in the plains, and one PHC for every 20,000 population in hilly, tribal and backward areas for more effective coverage.[1]

PHC provides OPD services, free medicines, health education, antenatal services, immunization, family welfare services and information on basic sanitation.[2] As on March 31st 2017, there were a total of 25, 650 PHCs functioning in the country. Percentage of PHCs functioning in government buildings has increased significantly from 78% in 2005 to 90.9% in 2017. In Tamilnadu, out of total 1835 PHCs, 473 PHCs are in urban areas.[3]

Though the number of primary health centres had increased, the utilization is declining over the years as

people seek private health sectors due to various reasons.[4] In 2015, an estimated 8% of the Indian population had been pushed below the poverty line by high out-of-pocket expenditure for health care.[5]

This study is conducted to assess the awareness and utilization of primary health care services provided by a Government PHC in urban field practice area of a Private Medical College near Chennai.

Methodology

A community based cross sectional study was conducted in Thirumazhisai, a semi–urban area located near Chennai. The study was conducted between May 2017- July 2017. Households in Thirumazhisai were selected by Simple Random Sampling. One person from each household was selected. The sample size of 233 was calculated by using prevalence of 62% utilization of PHC services.[6] A pre-designed, pre-tested semi-structured questionnaire was used to collect data. Data on socio-demographic details, awareness and utilization of PHC services and reasons for non utilization was collected. People who were willing to participate in the study were included and those who were not available in households were excluded. Data was entered in MS excel and analysed using proportions.

Results

Details regarding demography of study population: In the present study, majority of participants belong to the age group 25-34 years (36.5%). Male population was 128 (55%) and female population was 105 (45%).Modified Kuppuswamy scale was used to assess the socio economic status of study population. Majority of the population belonged to upper middle class (40.8%). (Table 1)

Table No. 1: Demographic details of study population

Demographic Details	Number (n = 233)	Percentage
Age		
15-24	9	3.8%
25-34	85	36.5%
35-44	60	25.7%
45-54	79	34%
Sex		
Male	128	55%
Female	105	45%
Socio Economic Status		
Upper Class	10	4.3%
Upper-Middle Class	95	40.8%
Lower-Middle Class	60	25.8%
Upper-Lower Class	50	21.4%
Lower Class	18	7.7%

Details regarding awareness of PHC services in study population: Among the 233 people,183 (78.5%) people were aware of PHC services and among all services the awareness for OPD services was high (28.9%). (Table 2).

Table No 2: Awareness of PHC services in study population:

PHC Services	Number of People Aware (n = 183)	Percentage
Immunization services	15	8.2%
Family welfare services	42	23%
Lab facilities	23	12.5%
Antenatal services	20	11%
Essential medicines	30	16.4%
OPD services	53	28.9%

Details regarding utilization of PHC services in study population: Among 233 people, 165(70.8%) were availing services provided by PHC. Majority of the population utilized OPD services (29%) followed by family welfare services (23.6%).

Table No 3: Utilization of PHC services in study population:

PHC Services	Number of People Utilize (n = 165)	Percentage
Immunization services	13	7.9%
Family welfare services	39	23.6%
Lab facilities	20	12.2%
Antenatal services	19	11.5%
Essential medicines	26	15.8%
OPD services	48	29%

Details regarding non utilization of PHC services in study population: In the present study one third (29.1%) of the participants were not availing PHC services. The major reason for non utilization of services was the long waiting time (51.4%). (Table 3)

Table No 4: Reasons for non utilization of services in study population

Reasons for non utilization	Number of People (n = 68)	Percentage
Long waiting time	35	51.4%
PHC not clean	6	8.8%
PHC does not have all required services	5	7.4%
Dissatisfaction of Doctor-Patient relationship	12	17.7%
Non-availability of essential medicines	10	14.7%

Discussion

The present study was focused on the awareness and utilization of PHC services. In the present study, 78.5% people were aware of PHC services in their area and this was found to be similar (76.2%) as reported by Rajpurohit et al in Barabanki, a rural area of Northern India.[7]

Majority of people in the present study were aware of OPD services followed by family welfare services. In the present study, 70.8% study population reported that they utilize PHC services. This was found much greater than the study in Barabanki, Northern India[7] and Nepal[8] which reported only 36.3% and 48% utilization respectively. Majority people in the present study utilized PHC for OPD services, family welfare and free drug services.

In the present study the major reason given by people who were not utilizing PHC services was long waiting time(51.4%) followed by dissatisfaction in doctor patient relationship (17.7%), non-availability of essential medicine (14.7%), cleanliness issues (8.8%) and not all required services available in PHC (7.4%). Rajpurohit et al [7]and Kumari R[9]also reported long waiting time 43.9% and 62.5% respectively as the main reason for non- utilization of PHC services in Barabanki and Lucknow.

In present study, low utilization of health care services was reported in spite of good accessibility to the PHC. Though, the facilities were existing, poor quality care and lack of drugs resulted in the non utilization of PHC services. Similar findings were also reported by YadavD K in rural Nepal.[8]

Recently Quality of Care has emerged as a crucial area for both Policy Makers and Public Health Practitioners. It is a key tool for optimal utilization of resources and improving health outcomes and client satisfaction.[10] Improving the quality of health care is also essential to meet the health related targets of the Sustainable Development Goals (SDGs). [11]

As a major initiative of Ministry of health and family welfare (MoHFW) under National Health Mission, Kayakalp initiative was launched in 2015 to promote cleanliness, hygiene and infection control practices in public health facilities. Under this initiative, public health care facilities are appraised and those facilities that meet the standard protocol receive awards and commendations. National Quality Assurance framework was rolled out in November 2014 to improve the quality of health care in over 31000 public facilities including PHCs.[12]

More qualitative research had to be carried out to determine the factors influencing utilization of services; this will lead us to develop a public health marketing strategy for care access.

For last two years (2018 & 2019) World Health Days Day theme is “Universal Health Coverage: Everyone, Everywhere.” Universal health coverage (UHC) means that all people and communities can use the promotive, preventive, curative, rehabilitative and palliative health services they need, of sufficient quality to be effective, while also ensuring that the use of these services does not expose the user to financial hardship. UHC can only be achieved by proper delivery and utilization of Primary health care services through PHCs.[13]

Conclusion

Only two third of the study population was found to be aware and were utilizing PHC services. In resource-constrained developing countries like India, all efforts should be undertaken to bring about the maximum efficiency of health care delivery. Role of primary healthcare is essential in the progress towards achieving Universal health coverage.

Limitations of the study: This study was conducted in our field practice area covered by one Urban PHC, therefore the findings cannot be generalised to all PHCs.

Conflict of Interest: Nil

Source of Funding: Nil

Ethical Clearance: Ethical approval was obtained

from the Institutional Review Board (IRB) and Institutional Ethics committee informed consent was obtained from study participants and information sheet regarding the study was given to all participants.

An Empirical Relationship between Stress and Job Performance: A Study with Private School Teachers

D.S. Premalatha[1], S. Subramanian[2]

[1]Research Scholar, [2]HOD & Research Supervisor, Department of Commerce (Ca), Vistas, Pallavaram, Chennai

Abstract

Stress reacts in the human body with physical, mental and emotional responses. It may be positive or negative. Negative stress affects the concern person and the environment also. It is part of our body. Stress can experience stress from our environment, body, and thoughts. The main purpose of this study is to find the factors causing stress among the teachers working in private schools. The researcher used linear regression analysis to find the result. The results show that the main factor causing stress are role conflicts and Pay. The stress and job performance are negatively correlated. Stressful teachers not performed well compared with other teachers.

Keywords: *Stress, Job Performance, Role conflicts.*

Introduction

Stress is the important factor that affect employee's mood, health, behaviour and relationship with other employees. Some Individuals suffered with their young age and they are very healthy also. This is called acute stress. Nowadays, stress mostly affected on employees with high job pressure. There is a limit of stress i.e. it cross more than this limit it given negative, impact on their job otherwise the impact is positive.

The stress is affected not only because of job sometimes unhealthy behaviour causes stress. The main thing is to the person should know how to handle the stress without affecting their health and society. There is lot of awareness programs are conducting in the organisation to get rid from stress.

Stress is affected to the teachers those who are working in private schools. There are lot of reasons for causing the same such as pay, work load, long working hours, culture, task etc., To overcome the stress to the teachers management has to arrange some remedial classes like yoga, Meditation etc.

Stress Meaning: Stress is a feeling of people when the expectation is not fulfilled or demand is not satisfied it affects the concern person. The expectation or demands are related to work, promotions, finance, maintaining the relationship with other people. If this is failed stress can cause. It affects the people physically and mentally.

Some people feel the stress as a motivator. This is essential to survive and to fight with the problems day to day faced by the people. It teaches people how to respond in a risky situation.

Impact of Stress:

- Blood Pressure
- Breathing problems
- Digestive problems
- Reduce Immunity power
- Mental problems
- Affects Job
- Affects Family

Factors Causing Stress of Employees:

- Promotion
- Status of the Job
- Discrepancies in the pay
- Conflicts between the employees
- Target

- Competition
- Management problems
- Cultural differences
- No cooperation
- Work load
- Environment of the work place
- Job insecurity

The main factor of causing stress is the work place of the person. The demand and pressures of the Management causing stress to the employees. Conflicting role in the work place also affects employees to cause stress. The management has to arrange or follow the cope up strategies of stress to reduce and recover from the same.

In this research the researcher finds the factors causing stress to the private school teachers and impact on stress on their performance.

Review of Literature: Ahmad Usman et al (2011). Work Stress Experienced by the Teaching Staff of University of the Punjab, Pakistan: Antecedents and Consequences. This study tends to examine the relationship between role conflict, role ambiguity and attitudinal outcomes of the job i.e. job satisfaction and organizational commitment of teaching staff in the largest and most populated university of Pakistan i.e. University of the Punjab. The findings of the study suggests that there is a positive and significant relationship between role stress i.e. role conflict and role ambiguity and work stress however work stress is negatively and significantly associated with job satisfaction and organizational commitment of the teaching staff of the university under examination[1].

Sai Mei Ling and Muhammad Awais Bhatti (2014). Work Stress and Job Performance in Malaysia Academic Sector: Role of Social Support as Moderator. The present study aims to investigate the relationship role conflict, job control, social support and job performance among administration staff in University Utara Malaysia (UUM), Kedah. Results indicate that a positive and significant relationship found between job control, social support and job performance. Besides, results indicated social support moderate between role conflict and job performance showed significant relationship[6].

Janine, Oosthuizen et al (2013) Coping with stress in the workplace. The researchers investigated a simplified process model, a so-called salutogenic approach, of coping with stress in the workplace. As expected, individuals with a stronger sense of coherence and a stronger internal locus of control experienced lower levels of stress and vice versa. Nevertheless, in a regression analysis only the sense of coherence and external locus of control variables contributed significantly to variance in the criterion variable stress[3].

Moaz Garib et al(2016) The impact of job stress on job performance: A case study on academic staff at dhofar university. The purpose of this study is to determine the levels of job stress among the academic staff at Dhofar University, to measure the job performance level, and determine the impact of the job stress factors (workload, role conflict and role ambiguity) on job performance. Results show that the level of academic staff of job stress was medium and sometimes low. In addition, the level of Job performance was somewhat high. Moreover, it was found that workload has a positive statistical effect on job performance[5].

Ashfaq Ahmed, Dr. Muhammad Ramzan (2013). Effects of Job Stress on Employees Job Performance A Study on Banking Sector of Pakistan. This study examines the relationship between job stress and job performance on bank employees of banking sector in Pakistan. The results are significant with negative correlation between job stress and job performances and shows that job stress significantly reduces the performance of an individual. The results suggest to the organization that they have sustained a very health, cooperative and friendly environment within the team for better performance[2].

Mai Ngoc Khuong and Vu Hai Yen(2016). Investigate the Effects of Job Stress on Employee Job Performance—A Case Study at Dong Xuyen Industrial Zone, Vietnam. The purpose of this research was to analyse the effects of five working factors including work overload, role ambiguity & role conflict, working relationship, career development, and working environment on job stress and employee job performance in six different industries at Dong Xuyen Industrial Zone, Ba Ria–Vung Tau province, Vietnam. As a result, these working factors had significant and positive influence on job stress and in contrast, job stress had negative influence on employee job performance. In addition, this research also found that career development did not directly affect employee job performance, but indirectly through job stress. It is recommended that organizations

at Dong Xuyen Industrial Zone should reduce job stress by reducing conflicts in working relationship, career development, and working environment in order to improve employee job performance[4].

Sharmilee Bala Murali (2017) Impact of Job Stress on Employee Performance. The main Purpose of this study is to analyses the impact of job stress on employee performance. It found that time pressure and role ambiguity have significant and negative influence on employee performance. The other two factors of workload and lack of motivation do not have any significant influence on employee performance. Therefore we concluded that increasing time pressure and role ambiguity would reduce employee performance in all aspects[7].

Objectives of the Study:

1. To find the factors causing stress among the employees working in Private schools.
2. To know the impact of stress on Job Performance

Hypotheses of the Study

1. There is no significant difference among the factors causing stress among the employees working in Private schools.
2. There is no significant impact of stress on Job Performance

Result and Discussion

Influence on Stress on Job Performance: The stress consist of eight variables and it subsequent influence over Job performance is measured through linear multiple regression analysis. The variables are Role conflicts, Culture variance, Competition, Completion of target, Work load and Pay. The influence of these variables on Job performance are presented in the following regression analysis.

Table 1: Model Summary

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.950[a]	.902	.901	.435
a. Predictors: (Constant), S5, S1, S5, S3, S4, S2				

Source: Computed data

From the above table it is found that R=.950 R square = .902 and adjusted R square .901. This implies the stress causes 90% variance over the Job performance. The cumulative influence of six variables of stress over Job performance is ascertained through the following one way analysis of variance.

Table 2: ANOVA[a]

Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	860.347	6	143.391	757.758	.000[b]
	Residual	93.291	493	.189		
	Total	953.638	499			
a. Dependent Variable: Job Performance, b. Predictors: (Constant), S5, S1, S5, S3, S4, S2						

Source: Computed data

Table 2 presents that F = 757.758 p=.000 are statistically significant at 5% level. This indicates all the six variables cumulatively responsible for Job performance. The individual influence of all this six variables is clearly presented in the following co-efficient table.

Table 3: Coefficients[a]

Model B		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		Std. Error	Beta			
1	(Constant)	.257	.073		3.506	.000
	Role conflict	.681	.059	.626	11.617	.000
	Culture variance	.282	.086	.244	3.291	.001
	Competition	.217	.082	.198	2.651	.008
	Completion of Target	.101	.070	.082	1.432	.153
	Work load	.434	.075	.385	5.797	.000
	Pay	.356	.059	.356	6.078	.000
a. Dependent Variable: Job Performance						

Source: Computed data

From the above table it shows that Role conflict (Beta=.626, t=11.617, p=.000), Culture variance (Beta=.244, t=3.291, p=.001), Competition (Beta=.198, t=2.651, p=.008), Work load (Beta=.385, t=5.797, p=.000) and Pay(Beta=.356, t=6.078, p=.000) are statistically significant at 5% level. Completion of Target (Beta=.082, t=1.432, p=.153) are not statistically significant at 5% level.This indicates that role conflict among the teachers working in private schools causes more stress followed by pay given by the management. It reflects in their job performance as low performance level compared with other teachers.

Findings and Conclusions

1. There are many factors causing stress among the employees working in private schools.
2. The factors are role conflicts, culture variance, Competition, completion of target, work load and Pay.
3. The most important factor causing stress are role conflicts among the teachers followed by Pay and the least factors are completion of target and competition.
4. The impact of stress reflected in the Job performance of teachers working in Private schools.
5. They perform very low and they could not complete their target with in that period.
6. Finally, it concludes that the management should takes steps to reduce stress by the way of arranging motivational programs, given the pay based on their performance.

Testing of Hypotheses:

1. There is no significant difference among the factors causing stress among the employees working in Private schools - Rejected
2. There is no significant impact of stress on Job Performance - Rejected

Conflict of Interest: Nil

Ethical Clearance: Taken from UGC Committee

Discovery of Hidden Pattern in Thyroid Disease by Machine Learning Algorithms

Dhyan Chandra Yadav[1], Saurabh Pal[2]

[1]Research Fellow, Dept. of MCA, [2]Associate Professor, Head Dept. of MCA, VBSPU Jaunpur, U.P.

Abstract

Background: Decision tree provides help in making decision for very complex and large dataset. Decision tree techniques are used for gathering knowledge. Classification tree algorithms predict the experimental values of women thyroid dataset. The objective of this research paper observation is to determine hyperthyroidism, hypothyroidism and euthyroidism participation in hormones can be good predictor of the final result of laboratories and to examination whether the propose ensemble approach can be similar accuracy to other single classification algorithm.

Results: In the proposed experiment real data from 499 thyroid patients were used classifications algorithms in predicting whether thyroid detected or not detected on the basis of T3, T4 and TSH experimental values. The results show that the expectation of maximization classification tree algorithms in those of the best classification algorithm especially when using only a group of selected attributes. Finally we predict batch size, tree confidential factor, min number of observation, num folds, seed, accuracy and time build model with different classes of thyroid sickness.

Conclusion: Different classification algorithms are analyzed using thyroid dataset. The results obtained by individual classification algorithms like J48, Random Tree and Hoeffding gives accuracy 99.12%, 97.59% and 92.37 respectively. Then we developed a new ensemble method and apply again on the same dataset, which gives a better accuracy of 99.2% and sensitivity of 99.36%. This new proposed ensemble method can be used for better classification of thyroid patients.

Keywords: *J48, Random Tree, Hoeffding, Prediction, T3, T4, TSH, hypothyroidism, hyperthyroidism, euthyroidism and ensemble model.*

Introduction

Hormones play major role in blood stream to maintain metabolism in human. The production of high hormones and low hormones both are dangerous. The general objective of thyroid gland is to produce thyroid hormones. The main objective of thyroid gland is to maintain bloodstream through the regulation of metabolism. If thyroid gland produces more hormones then it will be hyperthyroidism and if thyroid gland produces less hormones then it will be hypothyroidism[1].

The three hormones tri-iodothyronine (T3), L-thyroxin and TSH regulate the metabolic functions of human body. These hormones utilize proteins and manage fats in human body. In pituitary gland thyrotrophic stimulating is released if require more hormones. The pituitary gland control and manage production of hormones in the blood stream [2].

Thyroid disease is a different thing about all other diagnosis system. It's visibility and treatments are different. Thyroid hormone has many symptoms in initial to final stage. It is generally arises from disorder life style and foods after it increasing and decreasing hormones production finally make health system [3].

The paper analysis is organized on batch size, confidential factor, num decimal places, num folds, seed and accuracy of a model in decision making through J48, Hoeffding and Random Tree. The discuss about all dataset of thyroid in multiple way of classification tree algorithm and finally measure the evaluation accuracy increases with time built model training set.

Classification decision tree provide many types help in identification of thyroid disease. It provides better help in dataset classification as a tree model in which attributes represents root, nodes and leaf nodes. Analyst easily analysis all the functions of related dataset [4].

By the help of proposed three algorithms easily classify hyperthyroidism, hypothyroidism and euthyroidism. We easily indentify as a tree path and finally reach on decision node to leaf nodes. collect Present paper discuss to all the symptoms of thyroid patients and declare types of problem. It is very difficult to identify hyperthyroidism and hypothyroidism problems in another way [5].

Related Work: Ahmad et.al discussed about thyroid endocrine gland in blood issue and function of the body. They discussed by feature selection, Fuzzy rule, maximal absolute difference Linguistic Hedge and total serum thyroxin. They provided classification accuracy 98.604% and achieved different testing phase of clustering one, two, three and four clusters for each class and 12 fuzzy rules. The generated 88.372%, 90.6977%, 91.6744%, and 97.6744% cluster size during training phase [6].

Tahaniet.al discussed about clustering ensemble model and how combines multiple clustering models. They analyzed adaptive clustering ensemble model. Adaptive algorithm measured and transformed initial clusters into binary representation aggregation to produce final clusters. They used co- association, k-means, similarity measurement, machine learning and data mining[7].

Xiyu et.al discussed about new class of tissue system. They analyzed traditional tissue P systems to new class of tissue system. They used thyroid disease analysis, tissue P system,membranes structure and clustering algorithm. They analyzed thyroid disease for classification [8].

Amrollahiet.al discussed about effect on thyroid gland of human bodies. They analyzed how thyroid function managed and balanced the metabolism. They used expert systems Bio-chemistry. They used fuzzy rules to system provided help in non expert who are suspicions of their thyroid function and provided help in expert for their diagnosis [9].

Ahmad et.al discussed about thyroid hormones production from thyroid gland. They analyzed compression hard and fuzzy clustering for thyroid disease and find optimal number of clusters. They used thyroid disease K-means, K-model clustering fuzzy C-means. They improved actual number of clusters present in thyroid data set and find clustering performance is much better to compare to other[10].

Saiti et.al discussed about thyroid cancer by different classifier algorithms. They increase accuracy of thyroid cancer dataset. They generated an ensemble model to predict thyroid cancer and provided much accuracy compare to other previous prediction [11].

Vikas et.al discussed about medical dataset by different machine learning algorithms. They used data mining different algorithms for taking decision as a decision tree and regression tree. After all the prediction find 93% classification accuracy. They suggested to boost algorithm for prediction [12].

Vikas et.al discussed about breast cancer in women by some different machine learning algorithms. They used supporting key as like: Breast, Data Mining, Naïve Bayes and RBF Network. After all the prediction they find Naïve Bayes give the highest accuracy 97.36% [13].

Bridget et al. discussed about circulation serum FT4 level in pregnant women. In circulation FT4 perchlorate exposure is negatively associated with circulating levels in third trimester pregnant women. They used Perchlorate, Iodine, Pregnancy, birth and Weight[14].

Awasthiand Anil Antony discussed about classification and diagnosis of thyroid disease. They used KNN, Support Vector Machine, T3, T4 and TSH for diagnosis. They find some values missing while the user entering the values. They used K-Nearest Neighbor algorithm in thyroid diagnosis for approximating the missing values in the user input[15].

This analysis paper analyze classification tree algorithms: J48, Random tree and Hoeffding for predicting where thyroid hormones as like T3, T4 and TSH experimental values. The results show that the expectation maximization classification tree algorithmsin those of the best classification algorithm especially when using only a group of selected attributes. Summaries all the analysis paper predict batch size, tree confidential factor, min number of observation, num folds, seed, accuracy and time build model withdifferent classes of thyroid sickness.

Methodology

Collected thyroid dataset is from githubuci and pathology. The use of these data sets for only experimental purposes. We have used all methodology are used in four stages:

- Data Description
- Algorithm description
- Result and discussion
- Conclusion

Data Description:

Table 1: Thyroid Dataset variables representation

Source	**Rahul thyroid diagnosis center, https://github.com/mikeizbicki/datasets/blob/master/csv/uci/new-thyroid.names**		**References**
Sample Size	499= Total: 228 =Hyperthyroidism, 237= Euthyroid State and 34= Hypothyroidism		
Dependent Variables			
Hyperthyroidism	Too much hormone production		[3],[16]
Hypothyroidism	To little hormone production		
Euthyroidism	The state of normal thyroid function		
Independent Variables			
T3	(60-200)ng/dl	Triiodothyronine Stimulates the metabolism	[3],[16],[17]
T4	(4.5-12.0)µg/dl	Thyroxin produced by thyroid gland	
TSH	(6.3-5.5)µl/ml	Thyroid Stimulating Hormone pituitary hormone	

In our experiment we select data from Rahul thyroid diagnosis center and githubuci. All the dependable variables have definition with his explanation as like: Hyperthyroidism: Too much hormone production, Hypothyroidism: To little hormone production, Euthyroidism: The state of normal thyroid function. All the hormones (T3, T4 and TSH) define in with his evolution ranges in ng/dl, µg/dl and µl/ml. The values of T3, T4 and TSH mentioned in above table.1.

Algorithms Description: In this analysis developed model provides support to doctor in treatment. Proposed model is for consulting only doctors but final decision follow by doctors in treatment. Three classification algorithms J48,Random Tree and Hoeffding. Generate and combine model with carrying the majority by voting algorithms. Different varieties of seeds and portioned into different classes which is based on many features.

Random Tree: Random tree provide a platform for merging the individual learners. It constructs a random field of data for constructing decision tree. Every nodes of generated tree behaves as like best split for all variables and randomly choose best node. If we use random tree as a group of tree then it will be tree predictors or forest but all the mechanism follows the random trees and the outputs the class level has received the majority of votes. Random tree improve the performance of single decision tree and conscience more way of randomization[17-20].

J48: The generate the building model of thyroid data set classes by J48 algorithm from a set of records that contain class level. The decision tree find out the way of attribute direction behaves for all thyroid instances. By the help of this algorithm we will generate the rules for prediction for all target variables. The main objective of this algorithm in decision generation more progressive, decision tree and gain more accurate result by decision tree[21].

Hoeffding: Hoeffding decision tree algorithm support in generating stream. Now generate an incremental generating stream that will not be change over time [22].

Propose Method: This analysis uses algorithm for classification and prediction, by the help of these decision trees easily organize form of tree structure of thyroid dataset. Nodes of the tree shows the attributes of the dataset and edges will be use for represent the value of these attributes and finally find the leaf nodes as decision nodes. In propose model select women thyroid dataset from laboratories and after the preprocessing of missing values evaluate the correlation of attribute and take the values of T3, T4 and TSH then apply the algorithm in many faces of tree. Classify all thyroid dataset with different iteration of attributes and compare with tree ensemble model and finally evaluate the majority of voting for different classes of thyroid as like hyperthyroidism, hypothyroidism and euthyroidism.

Results and Discussion

Thyroid dataset in which 499 cases included as a record in csv file. The classification model has four attributes T3, T4, TSH. The target variables as a class level observation have three type of classes that are: hypothyroidism, hyperthyroidism and euthyroidism.

Some issues overcome in random split thyroid dataset in training and testing set. The randomsplits find contradiction between getting results and realistic results. In this paper, discuss and compare three tree algorithms with an ensemble model:

Experiment-I:

Table 2: Computational table for thyroid dataset using J48

Iterations	Batch Size	Confidential Factor	Min Num Obj	Num Folds	Seed	Accuracy	Time (in Second)
1	100	0.25	2	3	1	97.32	0.04
2	200	0.50	3	5	2	97.34	0.04
3	300	0.75	4	10	3	99.12	0.03

The role of J48 tree algorithm in thyroid dataset for different number of samples as like 100, 200 and 300, by the help of these batch prediction easily perform instances process. In this analysis observe confidential factor (0.25, 0.50 and 0.75) pruning and find minimum number of branches of instances in thyroid dataset experiment are 2, 3 and 4,. Analyze and discuss about controlling the sequences by number and reduce error pruning for randomize dataset. By the experiment it is clear that the default value of seed is 1, but select different sequence of random attributes by changing the seed 2 and 3. In this experiment find, if increase batch size (300), MinNumObj (4), Number of fold (10) and seed (3) then find highest accuracy (99.12%) with less time build model 0.03 seconds.

Experiment-II:

Table 3: Computational table for thyroid dataset using Random tree

Iterations	Batch Size	Confidential Factor	Min NumObj	Num Folds	Seed	Accuracy	Time (in Second)
1	100	0.25	2	3	1	93.67	0.02
2	200	0.50	3	5	2	93.67	0.02
3	300	0.75	4	10	3	97.59	0.02

The role of random tree algorithm in thyroid dataset for different number of samples. In this experiment find, if increase batch size (300), MinNumObj (4), Number of fold (10) and seed (3) then find highest accuracy (97.59%) with less time build model 0.02 seconds.

Experiment-III:

Table 4: Computational table for thyroid dataset using Hoeffding

Iterations	Batch Size	Confidential Factor	Min NumObj	Num Folds	Seed	Accuracy	Time (in Second)
1	100	0.25	2	3	1	89.31	0.07
2	200	0.50	3	5	2	89.22	0.07
3	300	0.75	4	10	3	92.37	0.05

The role of hoeffding tree algorithm in thyroid dataset for different number of samples. In this experiment find, if increase batch size (300), MinNumObj (4), Number of fold (10) and seed (3) then find highest accuracy (92.37%) hoeffding tree with less time build model 0.05 seconds.

Experiment-IV:

Table 5: Computational for thyroid dataset using Ensemble Model

Iterations	Batch Size	Confidential Factor	Min NumObj	Num Folds	Seed	Accuracy	Time (in Second)
1	100	0.25	2	3	1	98.43	0.05
2	200	0.50	3	5	2	98.43	0.05
3	300	0.75	4	10	3	99.20	0.05

The role of ensemble model in thyroid dataset for different number of samples. In this experiment find, if increase batch size (300), MinNumObj (4), Number of fold (10) and seed (3) then find highest accuracy (99.20%) with less time build model 0.05 seconds.

Table 6. Computational figure with table of thyroid dataset for comparing

Observations	Ensemble	J48	Random Tree	Hoeffding
Time Build Model	0.05	0.03	0.02	0.05
Accuracy	99.2	99.12	97.59	92.37
Seed	4	4	4	4
Num folds	10	10	10	10
Min Num Obj	4	4	4	4
Confidential Factor (%)	75	75	75	75
Batch Size	100	100	100	100

In the above all analysis of experiment I, II, III and IV, find the heighest batch size(300), confidental factor (75%), mnimum number of objects (4), number of folds (10) and seed (4) claculated heighest classification accuracy (99.2%). It is generated by Ensemble model of all given tree algorithms so majority of voting find that ensemble model of these tree algorithm is best. There is not major difference between generated time build models.

Conclusion

Hormones disorders in thyroid are a major problem in human. Various researchers work continues on this thyroid field and they used classification based data mining techniques. In this analysis used J48, Hoeffding and Random tree on thyroid dataset and identify more accurately model of decision tree on all possible experiments. In experimental study collect data from the values of T3, T4, TSH, Thyroid gland, Hyperthyroid, Hypothyroid and Euthyroidism at various levels and find (99.2%) classification accuracy in thyroid dataset. It is more accurate result of ensemble model compares the all other used tree algorithms with (0.05 seconds) time built model. Summaries all the experimental results and implement decision tree using more helpful data mining technique. In this analysis the ensemble classification technique improved evaluates accuracy and test thyroid dataset. In future work observe the identification of different affected factors of thyroid dataset and test more different and large dataset for diabetes, heart disease etc.

A Descriptive Study to Assess the Knowledge on Child Birth Preparation among Primigravid Mothers in a Selected Tertiary Care Hospital at Kelambakkam, Kanchipuram District, Tamilnadu, India

J. Chrislin Jebisha[1], R.J. Joey Persul[1], D. Joaniepriya[2]

[1]III[rd] Year B.Sc. (N) Student, [2]Asst. Professor, Guide, Chettinad College of Nursing, Rajiv Gandhi Salai, Kelambakkam, Kancheepuram, District Tamil Nadu, India

Abstract

A descriptive study to assess the knowledge on child birth preparation among primigravid mothers in a selected tertiary care hospital at Kelambakkam, Kanchipuram district, Tamil Nadu, India. The objectives are to assess the knowledge on child birth preparation among primigravid mothers in a selected tertiary care hospital at Kelambakkam, Kanchipuram district, Tamil Nadu, India. To find out the association between level of knowledge with demographic variables. The convenience sampling technique was used to select 41 samples. Validity and reliability data collection tools were established. The data were collected by self-administered questionnaires. The collected data were tabulated and analyzed. Descriptive and inferential statistics were used. The study shows that 2.5% of the women had adequate knowledge, 61% of the women had moderate knowledge, and 36.5% of the women had inadequate knowledge regarding child birth preparation.

Keywords: *Knowledge, Child birth preparation, Primigravid mothers.*

Introduction

Back Ground of the Study:

"Giving birth should be your greatest achievement not your greatest fear"

Birth preparedness is a strategy to promote utilization of maternal healthcare services and to ensure safe motherhood. Birth preparedness concept is based on the theory that preparing for childbirth and being ready to deal with complications reduces the delays in obtaining timely care and addressing the three delays of deciding to seek care, reaching health facility and receiving care[1].

Corresponding Author.
Ms. J. Chrislin Jebisha
III[rd] Year B.Sc. (N) Student, Chettinad College of Nursing, Rajiv Gandhisalai, Kelambakkam, Kancheepuram, District, Tamil Nadu, India

Pregnancy and giving birth to a child are normal physiological process, but the circumstances both internal and external, in which the child is conceived and born, affect the life of mother and child. Every pregnancy is associated with certain amount of unpredictability of risk of complication. Socio-cultural beliefs and lack of awareness in mothers and family members on how to recognize danger signs and symptoms, where to go when complication occurs, results in delay in seeking care and unprepared families waste time in recognizing problem, getting organized, getting money, finding transport and reaching the appropriate referral facility[2].

Ms. Supriyachinchpure (2015)

In spite of important progress towards attaining the Millennium Development Goals (MDGs), maternal and neonatal mortality continue to figure as major public health problems in developing countries[3,4]. Improvements in maternal health and reductions in maternal mortality have been slower than anticipated and–despite isolated successes–remain far from the

MDG5 target of a 75% reduction in the maternal mortality ratio (MMR) from 1990 to 2015[5]. Maternal mortality is a global burden, about 287,000 women died in 2010 due to pregnancy and childbirth related complications[6]. In India, Maternal Mortality Ratio is 212 per 100,000 live births[7].

Morbidities related to pregnancy are related to medical causes which goes uncounted. Most maternal death occurs during delivery due to unpreparedness for childbirth and managing complications, which results in delivery by the mother itself or untrained attendant. These maternal deaths are unjust and avoidable if preventive measures are taken on time like ensuring antenatal care to all mothers, delivery by skilled birth attendant and timely referral to hospital. As in most rural and tribal areas, delivery takes place at home, far from emergency obstetric services or without access to skilled attendant, there is more risk associated with mother and child life[8].

Many birth preparedness programs widely promoted by governments and international agencies to reduce maternal and neonatal health risks in developing countries; however, their overall impact is uncertain. Thus investigator felt need to assess whether pregnant women have adequate knowledge on antenatal, Intranatal and postnatal preparedness. **Dr. Alka Despande (2015)**

Research Methodology: A Quantitative approach with descriptive design was used in the study. The study was conducted among primigravid mothers attending OPD at selected tertiary care hospital. A purposive sampling technique was used to select 45 samples with the following inclusion criteria. Primigravid mothers who are willing to participate in the study and the mothers who all are attending Antenatal OPD.

Tool for the Study: Self-structured questionnaire used to elicit the demographic variables and to assess the knowledge on child birth preparation among primigravid mothers.

Scoring and Interpretation:

Score	Level of Knowledge
Above 75%	Adequate Knowledge
51-75%	Moderate Knowledge
Below 50%	Inadequate Knowledge

Study Findings: The majoriy (85.3%) of the mother is under the age group of 21-25 years, (78%) of the mother had married at the age of 21-25 years, (83%) of the mother were living in nuclear family, (85.3%) of the mother taking mixed diet, (83%) of the mother were living in the town, (48.8%) of the mother working as a professional, (58.6%) of the mother had monthly income of above Rs.15,000, (51.2%) of the mother were in second trimester.

The Chi-square association revealed there was no significant association between demographic variables in related with the knowledge aspects of primigravid mothers with aspects of knowledge on child birth preparation. It shows that there is no significant association between knowledge aspects with Age of the mothers (X^2=4.25), Age at marriage (X^2=1.48),Types of family (X^2=1.61), Dietary pattern (X^2=0.6), Area (X^2=4.63), Occupation (X^2=10.32), Monthly income (X^2=7.32). There is Significant Association Between Trimester (X^2=14.27).

Ethical Clearance:

Summary, Findings, Discussion, Implication, Limitataion, Recommendation And Conclusion.

The essence of any research project lies in reporting in the findings. This chapter gives a brief account of the present study including conclusion drawn from the findings, recommendations, limitation, suggestion for future studies and nursing implication.

Summary: The study is to assess the knowledge regarding child birth preparation among primi gravid Mothers attending antenatal OPD and ward at selected tertiary care hospital. This will enhance the primi gravid mothers to improve the knowledge regarding child birth preparation.

The objectives of the study were,

Assess knowledge on child birth preparation among primi gravid Mothers.

Associate the knowledge on birth preparation among primi gravid Mothers with selected demographic variables.

The study attempted to examine the following null hypothesis that

H_0: There is no significant association between demographic variables with the knowledge on child birth preparation among primigravid mothers in a selected

tertiary care hospital at Kelambakkam, Kanchipuram District, Tamil Nadu, India.

The review of literature enabled the investigator to develop methodology of the study literature review was done and organized as studies related to knowledge on child birth preparation among primigravid mothers.

The research approach used was quantitative approach with descriptive design. The main study was done in a selected tertiary care hospital at Kelambakkam, Kanchipuram District, Tamil Nadu, India. 41 samples were selected by convenience sampling.

The self-administered questionnaire was used to collect the data regarding demographic variables and the knowledge on child birth preparation among primigravid mothers. The data gathered were analyzed by using descriptive and inferential statistical method. The findings were presented on the basis of objectives of the study.

Findings: Findings of the study were presented under the following headings based on the study objectives

Objective 1: Assess the level of knowledge on child birth preparation.

The finding of the present study reveals that

1 (2.5%) had adequate knowledge

25 (61%) had moderate knowledge

15 (36.5%) had inadequate knowledge

OBJECTIVE 2: Associate demographic variables with the level of knowledge on child birth preparation.

Finding-1: Age and level of knowledge of child birth preparation.

There is no significant association between the age and level of knowledge of child birth preparation. X^2=4.25, (P<0.05).

Finding-2: Age at marriage and level of knowledge of child birth preparation.

There is no significant association between the age at marriage and level of knowledge of child birth preparation. X^2=1.48, (P<0.05).

Finding-3: Type of family and level of knowledge of child birth preparation.

There is no significant association between the type of family and level of knowledge of child birth preparation. X^2=1.61,(P<0.05).

Finding-4: Dietary pattern and level of knowledge of child birth preparation.

There is no significant association between the dietary pattern and level of knowledge of child birth preparation. X^2=0.6,(P<0.05).

Finding-5: Area and level of knowledge of child birth preparation.

There is no significant association between the area and level of knowledge of child birth preparation. X^2=4.63, (P<0.05).

Finding-6: Occupation and level of knowledge of child birth preparation.

There is no significant association between the occupation and level of knowledge of child birth preparation. X^2=10.32, (P<0.05).

Finding-7: Monthly income and level of knowledge of child birth preparation.

There is no significant association between the monthly income and level of knowledge of child birth preparation. X^2=7.32, (P<0.05).

Finding-8

Trimester and level of knowledge of child birth preparation.

There is significant association between the trimester and level of knowledge of child birth preparation. X^2=14.27, (P>0.05).

Implication: The findings of the study have implication in Nursing services and research.

Nursing Service: Community health nurse conduct educational programs to improve knowledge on child birth preparation.

In hospital Nurse can provide health education to create knowledge.

Limitation: Primigravid mothers only included in the study.

Recommendation: This study can be replicated an large sample studies can be conducted in different settings to validate findings

A similar study can be conducted on general public regarding child birth preparation.

Conclusion

Create awareness about child birth preparation. This study helps us to understand the need for child birth preparation to the primigravid mothers, it becomes necessary to involve the primigravid mothers as and when during pregnancy and it can also able to prevent the complications, miscarriage and fetal death during pregnancy.

Lateral Periodontal Cyst Masquerading Dentigerous Cyst: A Rare Case Report

Jagannath Patro[1], Swagatika Panda[2], Sreepreeti Champatyray[2], Alkananda Sahoo[2], Neeta Mohanty[3]

[1]Post Graduate Student, [2]Associate Professor, [3]Dean & Head, Department of Oral Pathology and Microbiology, Institute of Dental Sciences, Siksha 'O' Anusandhan, Deemed to be University, Bhubaneswar, Odisha, India

Abstract

Dentigerous cyst is the most commonly occurring developmental odontogenic cyst. Because of the typical clinical and radiologic attributes, the present case was clinically misdiagnosed as Dentigerous cyst which was later confirmed histopathologically as Lateral periodontal cyst. Lateral periodontal Cyst is defined as non-keratinized developmental cyst located lateral to the root of a vital tooth. This case report presents a unique case of lateral periodontal cyst present in 58-year-old female patient. Atypical presentation of lateral periodontal cyst as is presented in this case report should be considered by the histopathologist while interpreting microscopic preparations of odontogenic cysts.

Keywords: *Lateral periodontal Cyst; Dentigerous cyst; Histopathology; Orthopantomograph.*

Introduction

Lateral periodontal Cyst (LPC) is defined as non-keratinized developmental cyst located lateral to the root of a vital tooth. This cyst is most frequently associated with mandibular premolars but has been reported to occur at the other areas.[1] Since pain or other clinical symptoms have seldom been reported, the lesion is often discovered on routine radiographic examination. Radiographs of the lateral periodontal cyst show a well-circumscribed round or ovoid radiolucent area, usually with a sclerotic margin. Most of them are less than 1 cm in diameter.[1-4] Owing to the common prevalence of dentigerous cyst among developmental odontogenic cyst, radiological presentation of unilocular radiolucency circumscribing crown of impacted supernumeraries are usually diagnosed as dentigerous cysts. This article reports a classic case of Lateral periodontal cyst which was clinically diagnosed as dentigerous cyst along with a brief literature on the clinical, radiological and histopathological features of LPC.

Case Report: 58-year-old female patient reported with the chief complaint of mild pain and swelling in the lower left back tooth region with oozing of pus for 5 days (Figure 1). Patient gives a history of extraction of lower left second premolar one year back. Intra oral examination reveals an intraoral sinus with respect to 36. Orthopantomograph revealed four supernumerary impacted teeth in the lower left pre molar region with unilocular radiolucency encircling the crown of impacted teeth and involving the root of 34 (Figure 2).A provisional diagnosis of infected dentigerous cyst was given.Microscopic sections(Figure3) of the submitted biopsy specimens showed non keratinized squamous epithelial lining of uneven thickness supported by delicately collagenous connective tissue wall, which is infiltrated with minimal focal collection of chronic inflammatory cells. At areas focal nodular thickening of epithelial cells with many glycogen rich clear cells is observed. Connective tissue wall shows evidence of daughter cysts. Histopathological diagnosis was conclusive of lateral periodontal cyst.

Discussion

LPC is considered as developmental odontogenic cyst which represents approximately 0.8% to 2% of all odontogenic cysts which is most of the time identified in routine radiographic examination.[5,6] The LPC was described for the first time by Standish and Shafer in 1958.[7] In the year 1973, Wysocki et al. considered it as a representation of intrabony counterpart of the gingival cyst of adults. In the same year, Weather and Waldron reported for the first time an unusual form of the LPC called Botryoid Odontogenic Cyst owing to its appearance as a bunch of grapes.[8] Wysocki et al. suggested that the polycystic variant of LPC formed through cystic transformation of multiple islands of dental lamina and some authors consider it to originate from fusion of adjacent multiple LPCs.[9]Literature review shows that the LPC is more prevalent in adults in the 5th - 7th decades of life with mean age of 52 years, without preference for race or sex. The most frequently reported location of LPC is the mandibular premolar area. In most cases the LPC does not present distinctive clinical symptoms, the associated teeth are vital, unless secondarily infected.

Figure 1: Mild swelling in relation to 36 and missing 35

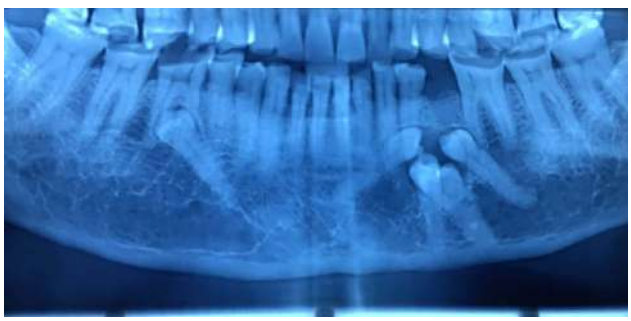

Figure 2: Orthopantomograph reveals unilocular radiolucency encircling the crown of impacted supernumerary teeth in the lower left pre molar region

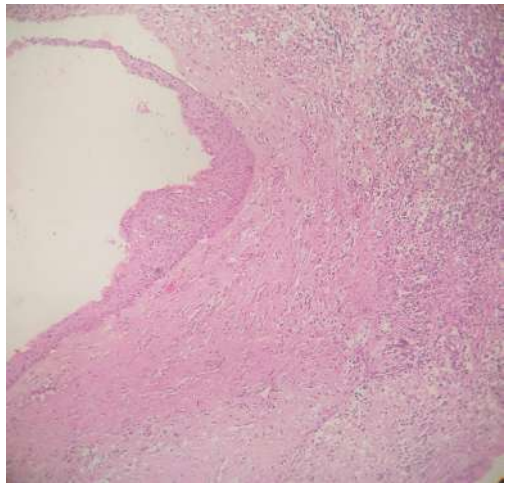

Figure 3: Microscopic features (10X) show focal nodular thickening of epithelium with many glycogen rich clear cells

The pathogenesis of LPC may be related to the three aetiopathological hypotheses: reduced enamel epitheliumremnants of dental lamina and cellular remnants of Malassez.[5,6,10] The first hypothesis is that the cyst is lined by non-keratinized epithelium reminiscent of the reduced enamel epithelium which is supported by PCNA immunohistochemical expression. The second theory is related to dental lamina remnants, because LPC histopathologically presents glycogen-rich clear cells, which is also seen in the dental lamina. The third hypothesis offered that the epithelial remnants of Malassez presented in the roots surface, principal location of the LPC, play a role.

The diagnosis of LPC should be restricted to cysts that are in the periodontal side. Radiographically, the orthopantomograph represents four supernumerary impacted teeth in the left lower premolar region with unilocular radiolucency encircling the crown of impacted tooth and involving the root of vital tooth of first premolar region. The periodontal ligament space as a rule is not enlarged and there must not be a communication between the cyst's cavity and the oral environment.[1,10,11] Occasionally, LPC may be multicystic, and called as odontogenic botryoid cyst due to macro- and microscopic features resemble to "bunch of grapes" (from the Greek word "botrios"). [10,11]

The radiographic features may be inconclusive relative to the diagnosis. Other interradicular radiolucencies must be distinguished from the LPC: anatomic radiolucencies, such as the mental foramen, maxillary sinus and the nutrient canals; cyst of pulpal

origin, other cysts of the jaws, odontomas and other tumours. It may resemble a cyst that develops laterally through a side channel accessory in a non-vital tooth.[11] The histopathology revealed that LPC is a developmental cyst characterized by a thin layer nonkeratinized stratified squamous epithelium of with uneven thickness supported by delicately collagenous connective tissue wall, which is infiltrated with mild focal collection chronic inflammatory cell infiltration.

At focal areas thenodular epithelial thickening, referred to as plaques or theca, are commonly found and composed of the clear fusiform cells rich in glycogen. However, it is possible to observe the histopathological variant of LPC - botryoid cyst, that should receive a greater attention considering the rate of recurrence and unusual presentation.[12-16.] The botryoid cyst represents a histopathological variant which presents with multilocular cystic "grape-like" appearance inside the bone. Histopathological findings show multiple cystic spaces lined by nonkeratinized stratified squamous epithelium.[12,15,16] The mobility of mandibular lateral incisor and canine reported by the patient can be justified by the cyst growth. However, LPC does not reach proportions that are larger than 1 cm while cysts of inflammatory origin tend to grow continuously.[13,15,17] In cases of a vital tooth, LPC can still be clinically confused with cysts that develop in inflammatory processes in cases of advanced periodontal disease, where the presence of periodontal inflammation stimulates epithelial proliferation. In most cases the differential diagnosis must be established with radicular cysts, in a view of their high frequency. These lesions are characterized by necrosis of the affected tooth, as a result of which vitality testing proves negative. Follicular or dentigerous cysts are always associated to an impacted tooth (particularly a lower third molar), while primordial cysts are mostly located in the ascending mandibular ramus. Authors suggest the investigation of the possibility of LPC causing isolated bone defects.[15,16]

The common treatment modality for LPC includes enucleation of the cyst in toto.[16,18] In general, LPC has a low rate of recurrence from 3 to 4% hence, long-term follow-up is necessary.

Investigation of a Food Poisoning Outbreak in a Private Hostel in Kanchipuram District, Tamilnadu

Jayashri Damodharan[1], Prashanth Rajendiran[1], Charumathi Boominathan[1], Muthulakshmi Muthiah[2], Gomathy Parasuraman[3], Ruma Dutta[3], Timsi Jain[4]

[1]Postgraduate, [2]Assistant Professor, [3]Associate Professor, [4]Professor & Head, Department of Community Medicine, Saveetha Medical College, Chennai, India

Abstract

Food borne disease can be defined as any disease of an infectious or toxic nature caused by the consumption of food or water(1). The investigation was carried out after receiving information on food poisoning cases from the RMO of SMCH among the inmates of a private women's hostel.

Methodology: Epidemiological case sheet was prepared and details from the affected individuals were obtained. On the same day, the kitchen and the mess were inspected and food handlers were examined.

Findings of the Outbreak: During the investigation, it was found that among the 120 inmates who consumed the dinner, 79(65.8%) inmates developed symptoms of food poisoning and 41(34.2%) inmates did not develop any symptoms. Diarrhea, abdominal pain, fever, headache, nausea and vomiting were the symptoms and the incubation period ranged between 3–38 hours.

Among those who developed symptoms, 30(37.9%) inmates were hospitalised for conservative management while 49(62.1%) inmates rested in the hostel, resorted to self medications. All of them completely recovered within 3 days.

Conclusion: Curd rice is the food item suspected to be contaminated and probable source for food poisoning outbreak. Based on the signs and symptoms of the inmates, incubation period ranging between 3–38 hours, enquiry findings and clinical examination of the employees presumably the suspected causative agent of the outbreak could be due to Salmonella.

Keywords: *Food poisoning, Outbreak investigation, Attack rate, Attributable risk.*

Introduction

Food poisoning is an acute gastroenteritis caused by ingestion of food or drink contaminated with either living bacteria or their toxins or inorganic chemical substances and poisons derived from plants and animals(2). Outbreaks of food poisoning commonly occur in closed communities where food is prepared and served centrally for a sizable population(3). Outbreaks of food poisoning are recognized by a large number of persons affected at the same time, similarity of signs and symptoms and history of ingestion of common meal(4). As people increasingly consume food prepared outside the home, growing numbers are potentially exposed to the risks of poor hygiene in commercial food service settings(5).

Methodology: The investigation was carried out after receiving information on food poisoning cases from the RMO of SMCH among the inmates of a private women's hostel.

Corresponding Author:

e-mail: gomathy.p.gopinathan@gmail.com

Verification of the Diagnosis: The illness was confirmed by the doctor at the hospital and based on their symptoms; preliminary case history the investigation was done.

Confirmation of the Outbreak: The information on symptoms and type of food consumed was gathered from the patients at the hospital. On the same afternoon, the two women's hostels were visited and details from all individuals who had taken food in the mess were obtained. On the same day, the kitchen and the mess were inspected and clinical examination of food handlers was conducted.

Description of Cases in terms of Time, Place, and Person: A case is defined as gastrointestinal illness in any resident of the hostel who as a previously well individual developed diarrhea or vomiting with or without abdominal pain, fever, headache within two days of consuming food in the hostel mess.

Epidemiological case sheet was developed; through interview method the details on demographic information, food items eaten, quantity of food consumed, time of exposure, presenting symptoms, time of onset of initial symptom and time of reporting, treatment and history of consumption of water or food outside the mess and were obtained from the inmates.

Survey was undertaken to assess the hygiene and sanitation of the kitchen. Details of food processing, food preparation and storage of prepared food were ascertained by interviewing food handlers. Medical examination of food handlers was conducted.

Sample Handling and Processing: Stool samples were collected from those consented for the microbiological examination. Food samples were not available for analysis. Water (drinking, cooking purposes) from the premises of both the hostels; mess and kitchen were collected and analyzed for residual chlorine and bacteriological examination.

Data Analysis: Data analysis was done using SPSS 16.0 version. Attack rate, Relative risk and Attributable risk were calculated for each food item to establish an association with the illness.

Results and Discussion

During the investigation, it was found there were 530 inmates in the Hostel–I. As it was festival holidays, 136 of them remained in the hostel. The mean age of the subjects was 22 years; ranged between 18–30 years and all belonged to upper middle class. Among those who remained in the hostel, 126 inmates consumed food served in the mess while 10 inmates did not consume food in the mess.

Among those who consumed food in the mess, 120 inmates consumed dinner on 15 January 2018; 79(65.8%) inmates developed symptoms of food poisoning while 41(34.2%) inmates did not develop any symptoms. Only breakfast was consumed by 6 inmates served on 16 January 2018 and did not develop any symptoms. The detail of population at risk is given in Figure 1.

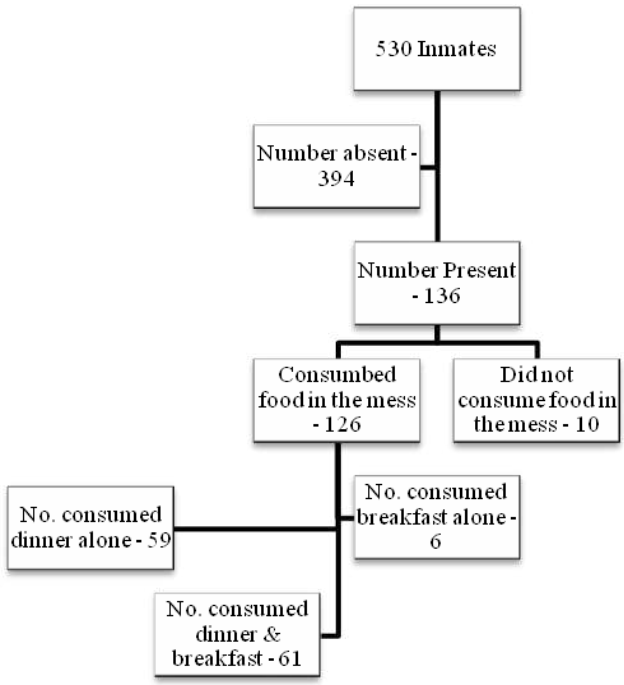

Figure 1: Detail of population at risk

Dinner, breakfast prepared in the common kitchen are sent to the mess of two hostels. However symptoms of food poisoning were reported only by the inmates of Hostel–1 while the inmates from Hostel–2 did not report any symptoms.

Diarrhea, abdominal pain, fever, headache, nausea and vomiting were the symptoms suffered by the subjects after the consumption of food and details are given in Table 1. Incubation period ranged between 3–38 hours[6] and median incubation period was 16 hours.

Table 1: Details of symptoms suffered by the inmates of Hostel-1

S.No	Symptoms	Frequency (N=126)*	Percentage (%)
1	Diarrhoea	79	62.7
2	Fever	59	46.8
3	Vomiting	51	40.4
4	Abdominal Pain	39	31
5	Nausea	19	15.1
6	Headache	17	13.5

*Mutliple responses for each variable–hence percentage will not sum up to 100%

The suspected primary case consumed the food at 7PM and developed symptoms at 10PM; incubation period of 3 hours. The subject complained of passing loose stools–10 episodes, watery, not mixed with mucus, not blood stained, vomited food particles (1 episode), high grade fever associated with chills and abdominal pain, got admitted on 16th January at 9.30PM

The index case consumed the food at 7PM and developed symptoms at 9AM; incubation period of 14 hours. The subject complained of passing loose stools–4 episodes, watery, not mixed with mucus, not blood stained, vomited food particles (3 episodes), high grade fever associated with chills, got admitted on 16th January at 4PM.

Epidemic curve of the outbreak investigation showed a "common vehicle point exposure"[7] curve typical of food poisoning is given in Figure–2.

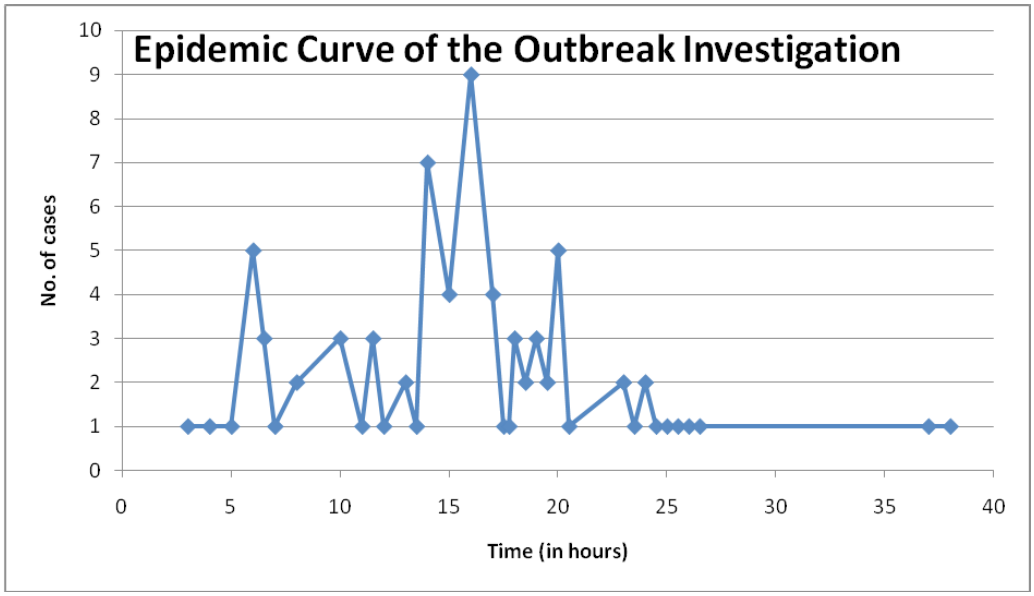

Figure 2: Epidemic curve of the outbreak investigation

Among those who developed the symptoms, 30(37.9%) inmates were hospitalised for conservative management while 49(62.1%) inmates rested in the hostel, resorted to self medications. All of them completely recovered within 3 days. Stool examination (only four patients consented)–there was no ova/cyst.

Dinner comprising of tomato rice, curd rice, egg, kuruma was served between 7PM–9PM and breakfast comprising of uppuma, coconut chutney was served between 7AM–9AM. Tomato rice, kuruma, egg was prepared at 3PM; stored for 4 hours while curd rice was prepared at 5PM; stored for 2 hours. Uppuma, coconut chutney was prepared at 5AM; stored for 2 hours. Food prepared in common kitchen was distributed in trolleys in closed containers to the serving area. Food was not re–heated before serving.

The main course of the dinner was served by a staff employed in the mess while the other items of the platter were self served by the inmates using a common laddle. However, according to the food handlers they wear aprons and caps while cooking or dispensing food. The details of risk estimation are given in Table 2.

Table 2: Details of Estimation of Risk of the Population at Risk (N = 126)

Food Item	Consumed			Not Consumed			Relative Risk (95% CI for RR)	Attributable Risk
	Total consumed	Symptoms Present	Attack Rate	Total not consumed	Symptoms Present	Attack Rate		
	N*	N*	%	N*	N*	%		%
Tomato rice	112	71	63.4	14	8	57.1	1.109 0.690–1.784	9.9
Curd rice	75	63	84	51	16	31.4	2.678 1.763–4.066	62.6
Egg	64	44	68.8	62	35	56.5	1.218 0.926–1.602	17.8
Kuruma	63	42	66.7	63	37	58.7	1.135 0.866–1.488	11.9
Uppuma	67	46	68.7	59	33	55.9	1.227 0.929–1.621	18.6
Coconut chutney	35	24	68.6	91	55	60.4	1.135 0.858–1.500	11.9

*Mutliple responses for each variable

Inspection of the kitchen: Kitchen is located 100 metres away from both the hostels. Water–RO supply (cooking) is present, maintenance is done once in a fortnight.

Separate store area is present near the kitchen where the vegetables, groceries are stored. Refrigerator is available to store dairy products but temperature log is not maintained.

Liquid waste disposal and solid waste disposal are indiscriminate. Flies nuisance are present. Separate wash area for cleaning vessels is present, which was found to be untidy.

Inspection of the mess of both the hostels: Separate serving areas are present with adequate lighting and ventilation. The floor and walls are clean. Tables, chairs are adequate and clean. Plates are cleaned and stacked up in the stand. Drinking water (RO supply) is present and the maintenance is done once in a fortnight.

Separate store area is present in the mess where dry items like pickles, papads are stored Separate wash area for washing hands, plates, vessels is present and it is clean.

Water (drinking and cooking purposes) collected from the premises of both the hostels; mess and kitchen were sent for microbiological analysis. There was no growth after 3 days in the water samples. Food samples were not available for analysis.

Clinical examination of the food handlers: Cook and the person who served the food in the mess were employed for the past 1 year and the details of clinical examination are given in Table 3.

Table 3: Details of clinical examination of the food handlers

Characteristic	Details of the Cook	Details of the food handler
Personal Habits	Satisfactory	Satisfactory
Personal history	Smoking, alcohol consumption, Use of pan present	Smoking, alcohol consumption, Use of pan present
General examination	Satisfactory	Satisfactory
Clinical findings suggestive for infections	None	None
Last medical check up	Not aware	Not aware

Possible Diagnosis: Curd rice is suspected to be the probable source for food poisoning outbreak. (Attack rate = 84%, relative risk = 2.678, 95% CI for RR (1.763–4.066) and attributable risk = 62.6%). As the inmates in hostel–2 were symptom free, probable source of contamination could be at the distribution system or where the food was served.

Given the signs and symptoms, incubation period ranging between 3–38 hours, enquiry findings, clinical examination of the employees presumably the suspected causative agent of the outbreak could be Salmonella[8,9]

Conclusion

Food poisoning outbreaks are common when adequate measures of food safety guidelines are not followed. Due to the lack of appropriate samples, causative organism could not be isolated. However, clinico epidemiological evidence is suggestive of Salmonella. This investigation revealed it is essential to lay emphasis on food hygiene, adequate and proper storage, education of food handlers on food handling techniques, safe distribution system, and improved sanitary conditions with scrupulous surveillance systems.

A Review on Process of Data Mining Approaches in Healthcare Sectors

K. Baalaji[1], V. Khanaa[2]

[1]Research Scholar Dept of Computer Science, [2]Dean-Information Technology, Dept. of IT, Bharath University, Chennai

Abstract

Data Mining is one of the foremost motivating areas of research that is become additional and more wide unfolds in health organization. Processing plays an awfully vital role for uncovering new trends in health care organization that in turn helpful for all the parties associated with this field. This survey explores the utility of various processing techniques like classification, clustering, association, regression in health domain. Throughout this paper, we have a tendency to tend to gift a brief introduction of these techniques and their blessings and drawbacks. This survey together highlights applications, challenges and future issues with processing in health care. Recommendation with reference to the suitable choice of accessible processing technique is in addition mentioned throughout this paper. A Clinical information Repository will be used within the hospital setting to trace prescribing trends in addition as for the looking of infectious diseases. One area CDR's would possibly likely be used is looking the prescribing of antibiotics in hospitals significantly as a result ofthe range of antibiotic- resistant microorganism is ever increasing. In 1995, a study at the letter Israel deacon centre conducted by the Harvard graduate school used a CDR to observe antibiotic use and prescribing trends since vancomycin-resistant enterococci is also a growing draw back. They used the CDR to trace the prescribing by linking the individual patient, medication, and thus the biology science laboratory results that were all contained at intervals the CDR.

Keywords: *Data Mining, Classification, Clustering, Association, Healthcare.*

Introduction

Data Mining is one in all the foremost very important and motivating space of analysis with the target of finding purposeful data from Brobdingnagian knowledge sets. In gift era, data processing is changing into fashionable in attention field as a result of there's a requirement of economical analytical methodology for detective work unknown and valuable data in health knowledge.

According to ***DiviyaTomar and Sonaliagarwalet, al., 2013***, in health business, data processing provides many advantages like detection of the fraud in insurance,accessibility of medical answer to the patients at lower value, detection of causes of diseases and identification of medical treatment strategies. It additionally helps the attention researchers for creating economical attention policies, constructing drug recommendation systems, developing health profiles of people etc. the information generated by the health organizations is incredibly large and sophisticated owing to that it's troublesome to investigate the information so as to createvital call relating to patient health[1].

Data processing techniques {are also accustomed analyze the varied factors that are liable for diseases as an example kind of food, completely different operating atmosphere, education level, living conditions, accessibility of pure water, health care services, cultural, environmental and agricultural factors.

Data Mining: Data Mining came into existence

Corresponding Author:
K. Baalaji
Research Scholar Dept. of Computer Science, Bharath University, Chennai, Tamilnadu, India
e-mail: baalaji.kadarkarai@hotmail.com

within the middle of 1990's and appeared as a strong tool that's appropriate for attractive antecedently unknown pat larid and helpful data from Brobdingnagian data set[2]. Numerous studies highlighted that data processing techniques facilitate information holder to investigate and find out unexpected relationship among their data that successively useful for creating call[3].

In general, data and information Discovery in Databases (KDD) area unit connected terms and area unit used interchangeably however several researchers assume that each terms area unit completely different as data processing is one in every of the foremost necessary stages of the KDD process In line with Fayyad et al., the information discovery method area unit structured in numerous stages wherever as the primary stage is information choice where information is collected from numerous sources, the second stage is pre - process of the chosen information, the third stage is that the transformation of the info into applicable format for additional process, the fourth stage is data processing wherever appropriate data processing technique is applied data for extracting valuable information and analysis is that the last stage as shown in Figure 1[4].

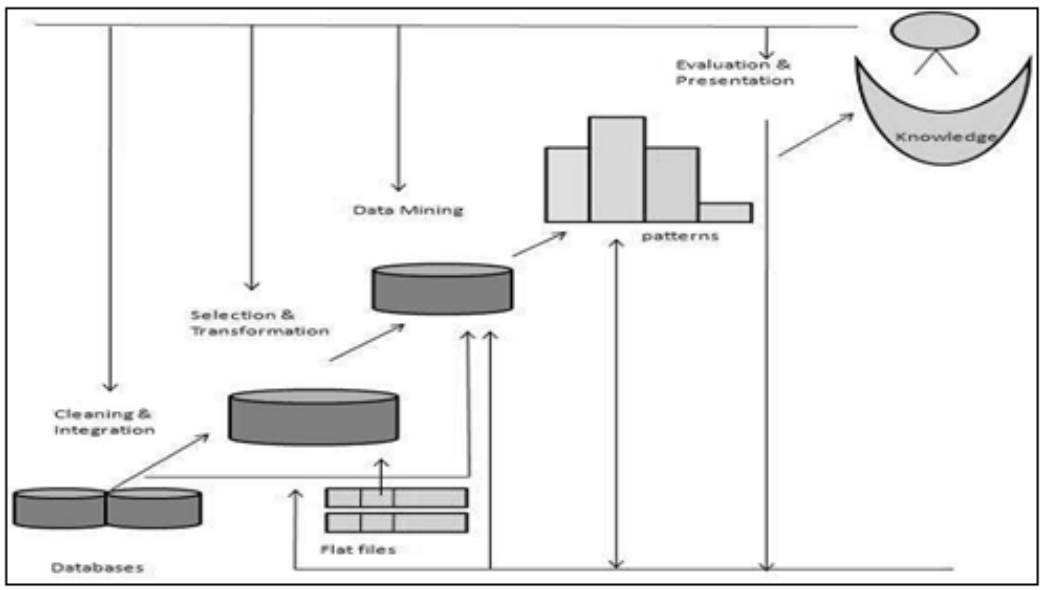

Figure 1: Stages of Knowledge Discovery Process

Skills and data are essential demand for performing arts the info Mining task as a result of the success and failure of knowledge Mining comes is greatly addicted to the one who ar managing the method as a result of inconvenience of normal framework[5]. CRISP-DM (CRoss trade normal method for data processing) provides a framework for concluding information Mining activities. CRISP-DM divides the info mining task into six phases[6]. The primary part is that the understanding of the business activities whereas the info for concluding business activities are collected and analyzed within the second part[7]. Information pre-processing and modelling is completed within the third and fourth part severally. Fifth part evaluates the model and last part is to blame for preparation of the construed model. McGregor et al., projected associate extended CRISP-DM framework for up clinical care through group action the temporal and flat aspects [8].

In gift era varied public and personal tending institutes square measure manufacturing hugeamounts of information that square measure troublesome to handle. So, there's a desire of powerful machine-driven data processing tools for analysis and deciphering the helpful info from this knowledge[9].

Classification: Classification divides information samples into target categories. The category technique predicts the target class for every information points. for instance, patient are often classified as "high risk" or "low risk" patient on the idea of their sickness pattern exploitation information classification approach[10].

It's a supervised learning approach having best-known category classes. Binary and construction area unit the 2 ways of classification. In binary classification, solely 2 potential categories like, "high" or "low" risk patient is also thought-about whereas the multiclass approach has over 2 targets for instance, "high", "medium" and "low" risk patient. information set is divided as coaching and testing dataset.

K-Nearest Neighbour (K-NN): K-Nearest Neighbour (K-NN) classifier is one in all the only classifier that discovers the unidentifiedin formation exploitation the antecedently best-known information points (nearest neighbour) and classified information points in keeping with the legal system . K-NN classifies the information points exploitation over one nearest neighbour[11]. K-NN contains a range of applications in numerous areas like health datasets, image field, cluster analysis, pattern recognition, on-line selling etc. Jen et al., used K-NN and Linear Discriminate Analysis (LDA) for classification of chronic sickness so as to come up with early warning system.

Decision Tree (DT): DT associate degree alogous to the flow chart within which each non-leaf nodes denotes a check on a specific attribute and each branch denotes an outcome of that check and each leaf node have a category label. The node at the highest most labels within the tree is named root node. For instance we've a financial organization call tree that is employed to choose that someone should grant the loan or not. Building a call for any drawback does not would like any variety of domain data. call Trees could be a classifier that use tree-like graph. The foremost common use of call Tree is in research analysis for shrewd conditional chances[12].

The additional improvement of the prevailing call tree model to classify totally different activities of patients in additional correct manner. Within the similar domain, Moon et al. exemplify the patterns of smoking in adults victimization call tree for higher understanding the health condition, distress, demographic and alcohol . Chang et al., additionally used associate integrated call tree model for characterize the skin diseases in adults and kids.

Support Vector Machine (SVM): The thought of SVM that is predicated on applied math learning theory . SVMs were at the start developed for binary classification however it may well be with efficiency extended for multiclass issues . The support vector machine classifier creates a hyper plane or multiple hyper planes in high dimensional house that's helpful for classification, regression and different economical tasks[13].

SVM have several engaging options owing to this it's gaining quality and have promising empirical performance used SVM classification approach for classification of assorted diseases and SVM along side k-meansbunch was applied on microarray information for distinctive the diseases. SVM is one amongst the foremost widespread approaches that area unit utilized by scientist in attention field for classification. Fei planned Particle Swarm improvement SVM (PSO-SVM) approach for analyzing heart disease and build a prophetical model for carcinoma designation exploitation hybrid SVM primarily based strategy.

E.Avci planned a system exploitation genetic SVM classifier for analyzing the center valve malady. this technique extracts the vital feature and classifies the signal obatined from the ultrasound of heart valve.

An ensemble neural network methodology is planned by Das et al., for diagnosing of cardiovascular disease so as to develop effective call network used ANN for locating the respiratory organ diseases. This analysis work analyze the chest computed axial tomography (CT) and extract important respiratory organ tissue feature to cut back the information size from the Chest CT and so extracted matter attributes got to neural network as input to get the assorted diseases relating to respiratory organ .

Clustering: Clustering is associate unattended learning methodology that's completely different from classification. Clump is not like to classification since it's no predefined categories. In clump massive info square measure separated into the shape of tiny completely different subgroups or clusters[14]. Clump divided the information points supported the similarity live. Clump approach is employed to spot similarities between information points. Every information points at intervals an equivalent cluster square measure having bigger similarity as compare to the information points belongs to alternative cluster.

Partitioned clump: In this clump methodology the information sets having 'n' data points divided into 'k' teams or clusters. Every cluster has a minimum of one datum and every datum should belong to only 1 cluster. During this clump approach there's a necessity to outline the quantity of cluster before partitioning the

datasets into teams. supported the selection of cluster centre of mass and similarity live, partition clump methodology is split into 2 categories-K-means and K-Mediods. K-Means clump approach is one among the foremost wide used approach that partition the given 'n' information points into 'k' cluster supported similarity live in such the simplest way that information points belong to an equivalent cluster have high similarity as compare to the information points of alternative cluster . It initial selects the k-centroid willy-nilly so assign the information points to those 'k' centre of mass supported some similarity live. for each iteration, a knowledge purpose is handed over to the cluster supported similarity of cluster mean (the distance between the information points) . The most recent mean is calculated and this step is recurred to accommodate each freshly arrived information points.

Density primarily-based agglomeration: The problem with partition and hierarchical agglomeration technique is that they'll handle solely spherical formed cluster and don't seem to be appropriate for locating cluster of whimsical shapes.

Density agglomeration ways take away this downside and expeditiously handle outliers and whimsical formed cluster[15]. DBSCAN and OPTICS area unit 2 approach of Density primarily based agglomeration that discover cluster on the idea of density property analysis. DENCLUE is another approach of density primarily based agglomeration ways that kind the grouping of knowledge points on the idea of distribution price analysis of density operate .

Association Association is one in every of the foremost very important approach of information mining that's accustomed establish the frequent patterns, fascinating relationships among a of information things within the data repository. it's additionally referred to as market basket analysis as a result of its capability of discovering the association among purchased item or unknown patterns of sales of consumers in an exceedingly group action info. for instance if a client is shopping for a pc then the prospect of shopping for antivirus software system is high. This info helps the merchandiser to more enhance their sales[16]. Association additionally hasnice impact within the aid field to observe the relationships among diseases, health state and symptomsused Apriori, prophetical apriori for generating the principles for heart condition patients. during this analysis work rules square measure created for healthy and sick folks. supported these rules, this analysis discovered the factors that cause heart downside in men and girls. when analyzing the principles authors conclude that girls have less chance of getting coronary heart condition as compare to men .

Data Mining Challenges in Healthcare: One of the foremost important challenges of the information mining in health care is to get the standard and relevant medical data. It's troublesome to accumulate the precise and complete health care information. Health information is advanced and heterogeneous in nature as a result of it's collected from varied sources like from the medical reports of laboratory, from the discussion with patient or from the review of doctor. For health care supplier, it's essential to keep up the standard of information as a result of this data is beneficial to supply value effective health care treatments to the patients. Health Care finance Administration maintains the minimum information set (MDS) that is recorded by all hospitals. In MDS there square measure three hundred queries that square measure answered by the patients at arrival time. However this method is advanced and patients face downside to retort the complete queries. So, it's essential to keep upthe standard and accuracy information for data processing to creating effective call.

Conclusion and Future Issues

The purpose of this section is to produce AN insight towards needs of health domain and regarding appropriate selection of obtainable technique. Following ar the rule for exploitation totally different data processing techniques:

- Before applying classification technique there's a necessity to acknowledge the redundant and inappropriate attributes as a result of these attributes act as a noise and outlier that successively hamper the process task.
- These attributes conjointly had AN adverse have an effect on the performance of classifier. Applied mathematics ways are used for recognizing these attributes. On the opposite hand the foremost relevant and helpful attributes is recognized by feature choice ways that successively enhance the performance and accuracy of classification model.
- We have a tendency to conjointly analyzed that there's no single classifier that turn out best result for each dataset. So as to examine the performance of classifier, a dataset is split into 2 parts-coaching and testing. So, a classifier is chosen only if it turn

out higher performance among all classifiers. The performance of a classifier is evaluated exploitation testing knowledge set.

- However there is drawback with testing knowledge set. It slow it's complicated and a few time it becomes simple to classify the testing knowledge set. The performance of classifier depends on testing knowledge set.
- To avoid these issues we are able to use cross validation technique so each record o f information set is employed for each coaching and testing.

Ethical Clearance: Since the article is based on review studies there is no need of clearance.

Prevalence of Musculoskeletal Pain among Manual Drummers and Electric Pad Drummers

K. Jothi Prasanna[1], S. Rahul Prabhu[2]

[1]Assistant Professor, SRM College of Phsiotherapy, [2]Student, SRM College of Physiotherapy

Abstract

Background: Work-related musculoskeletal problems exists almost in every areas that cause pain, disability and loss of employment . Although performing arts medicine is a growing field, the health problems of musicians remain under-recognized and under-researched. In order to play their instrument, musicians need to frequently repeat physically strenuous movements which has a dramatic impact on physical mobility and function. Musculoskeletal problems among instrumental musicians are common which occurs in both men and women. This study examines professionals who play musical instruments especially drums who are potentially at risk of developing problems, including pain and injuries related to their playing activities.

Objective: To find out the prevalence of musculoskeletal discomfort among manual drummers and electric pad drummers.

Study Design: Observational study design, comparative type.

Procedure: 60 subjects were selected based on inclusion and exclusion criteria and among them 30 manual drummers and 30 electric pad drummers were seggregated into two groups, aged between 15-35 years of both men and women were given a format of Musculoskeletal Pain Intensity And Pain Interference Questionnaire for Musicians (MPIPIQM) which depicts the prevalence of both pain intensity and interference of drummers.

Results: Results were analysed the IBM SPSS version 20 software. The statistical tool used in the study was the WILLCOXON SIGNED RANKS TEST to compare both the group data which gives the mean value of 5.45 for manual drummers and the mean value of 1.97 for the electric pad drummers pain intensity and interference score.

Conclusion: The study concludes that the manual drummers have more pronounced musculoskeletal pain intensity and interference when compared to that of the electric pad drummers.

Keywords: *Musicians, Musculoskeletal problems, Pain intensity and Pain Interference Questionnaire, Drummers.*

Introduction

Music is the most essential ingredient of any entertainment. In order to create successful entertaining event musicians plays an imperative role. Musicians are enchanters who spread the fragrance of joy by absorbing woes, in the form of Playing Related Musculoskeletal Disorders (PRMDs), for themselves. Most professional classical musicians will suffer at some time during their career from a musculoskeletal disorder (MSD). As many as 12% of them have been reported to give up their profession permanently.

Like other occupations, musicians also suffer from work related musculoskeletal disorders which are often disabling [1,2] Since the occupation of instrumental musicians involves playing musical instruments, therefore, work related musculoskeletal disorders are called as Playing Related Musculoskeletal Disorders (PRMDs)[3.]

Playing musical instrument requires technical precision, repetitive and striking movements and is often performed in constrained posture for longer period of time[1,5.] All types of instrumental musicians (string,

drums, woodwind, brass and percussionists) are prone to Playing Related Musculoskeletal Disorders .[6]A high prevalence of work-related musculoskeletal disorders has been found in musicians, ranging from 73.4% to 87.7%.[7]

The term "Musculoskeletal disorders"includes wide range of inflammatory and degenerative condition affecting the muscles,tendons,ligaments,joints,periphe ral nerves and supporting blood vessel. These include clinical syndromes such as tendon inflammation and related conditions and standardized conditions such as myalgia, low back pain, and neck pain.

Musculoskeletal disorders are put into different categories according to pain location. One category is upper limb disorders which includes any injury or disorder located from fingers to shoulder or the neck. Another category is lower limb disorders which include injury and disorders from hip to toe.

Drummers represent one of the largest and fastest growing among professional musicians. The drum is the member of the percussion group of musical instruments. Playing drums requires effort, speed and highly repetitive movements. Drumming is a very demanding and dynamic activity requires a tremendous amount of muscle conditioning, endurance, strength and coordination.

Learning to play a musical instrument is one of the most complex tasks that the human body can perform with muscles, joints and nerves often operating above its normal capacity.

To become a professionalist in drumming it needs long hours of practice and should perform the same repetitive activity over and over again to develop the necessary muscle memory to perform night after night.

Risk factors for drumming-related musculoskeletal disorders include high repetition, high force, and other factors, such as vibration.Drums is usually played by striking with the hand or with one or two sticks. Drums are of two types' manual drums and electric pad drums.

The manual drums consist of snare, high-hat, side tom, double tom and two symbols. The electric pad drum consists of six small pads.

These two drums have the same posture for the musicians,but the way of playing these instruments vary sometimes,that isthe electric pad drummers can play the instruments by sitting as well as standing also,but in manual drummers the musicians should have a sitting posture so that the rhythm comes fine. The manual drums also consists of double bass were both the limbs are used to play the instrument.

The frequently used body parts in playing these instruments are the upper and lower limb, wrist, elbow and fingers. Comparing these two drummers, manual drummers turn their whole body to play the instruments so the beats are clear and perfect, while the electric pad drummers don't rotate their body and they can adjust their instrument according to their comfort.

There are very few studies in India done on musicians' especially on drummers and also there are no specific studies focussing on the different types of drummers. In today's world, as music has evolved, the pressure on drummers has increased. A drummer must have increasingly more speed, control, power and endurance in order to be exceptional, but very few studies have been done to address the injuries faced by them. Thus the study aimed to find the prevalence of playing related musculoskeletal discomfort among manual and electric pad drummers.

Procedure: Thisstudy commenced after getting clearance from the Institutional Ethical Committee and was conducted in various music academies and schools. Thestudy design is Non Experimental Design, study type is observational type, sample size is 60, sampling method was convenient sampling and the study setting isMusic academy. The participants who fulfilled the inclusion criteria (Age: 15-35 years, Experience of 1 year and above, both men and women) and exclusion criteria (History of pain in both upper limb and lower limbs, History of recent fracture. Musculoskeletal pathologies, recent injury Peripheral nerve lesions) were included in the study, written consent form was obtained from the Professional drummers after explaining the procedure, the benefits of the study was said to the drummers.

A sample size of 60 subjects with age group of 15-35 years, both male and female was taken, in which 30 subjectswere manual drummers and 30 subjects were electric pad drummers and they were asked to complete the questionnaire .A format of MUSCULOSKELETAL PAIN INTENSITY AND PAIN INTERFERENCE QUESTIONNAIRE FOR MUSICIANS (MPIPIQM) depicting the prevalence of pain intensity and interference which consists of four parts that is musicians profile and hours of playing, there are four questions about pain and

rest five question about the interference. The data was recorded and tabulated.

Figure 1: Electric Pad Drum Standing Posture

Figure 2: Electric Pad Drum Sitting Posture

Figure 3: Manual drum posture

Outcome Measures:

Musculoskeletal Pain Intensity and Interfrence Questionnaire for Musicians: There was a substantial test-retest reliability for pain intensity items (range 0.78-0.82) and moderate to substantial test-related reliability for the pain interference items (range 0.56-0.76)

Data Analysis: The collected data were tabulated and analysed using IBM SPSS version 20 software. The statistical tool used in the study was the WILLCOXON SIGNED RANKS TEST. The WILLCOXON SIGNED RANKS TEST was used to analyse and compare both the groups.

Table 1: Pain intensity and pain interface among manual drummers using musculoskeletal pain intensity and interference questionnaire for musicians.

Variable	N	Mean	STD.Deviation	Wilcoxon Signed Ranks Test	SIG (2-Tailed)
Manual drummers pain intensity	31	5.4	6.460	-1.588	0.112
Manual drummers pain interference	31	5.45	6.612		

This table infers 30 samples which were taken in which the mean value of manual drummers pain intensity score is 5.24 and the mean value of manual drummers pain interference score is 6

Table 2: Pain intensity and pain interface among electric drummers using musculoskeletal pain intensity and interference questionnaire for musicians.

Variable	N	Mean	STD. Deviation	Wilcoxon Signed Ranks Test	SIG (2-Tailed)
Electric pad drummers pain intensity	31	1.87	5.365	-0.378	0.705
Electric pad drummers pain interference	31	1.97	5.282		

This table infers 30 samples which were taken in which the mean value of electric pad drummers pain intensity score is 1.87 and the mean value of electric pad drummers pain interference score is 1.97 .

Table 3: Comparison of pain intensity and pain interface between manual drummers and electric drummers using musculoskeletal pain intensity and interference questionnaire for musicians.

Variable	N	Mean	STD. Deviation	Wilcoxon Signed Ranks Test	SIG (2-Tailed)
Manual drummers & Electric pad drummers pain intensity interference	31	5.45	6.612	-2.716	0.007
Electric pad drummers pain intensity interference	31	1.97	5.282		

This table shows that the mean value of manual drummers pain intensity & interference score is 5.45 and the mean value of electric pad drummers pain intensity & interference score is 1.97 .

Discussion

Work related musculoskeletal disorders have been widely studied over the past several decades. Several factors such as sustained repetition, excessive force, static load and awkward position which paves the way for the development of the above said disorder.

Musculoskeletal disorders are also often associated with psychological stress due to work environment. As of knowledge various researches which were done on musculoskeletal problems mainly focus on industry and office work areas. To our knowledge there are only very few studies done among musicians and also studies that specifically describes the playing related musculoskeletal problems among various types of drummers were found lacking.

The musicians have to perform rapid, repetitive movements especially drummers for prolonged period of time. Drummers have musculoskeletal pain while playing or at rest because both the drummers have to adopt different postures during standing as well as sitting while playing the instruments. Hence this study is done to find out the prevalence of musculoskeletal problems among manual drummers and electric pad drummers. Drumming is characterized by involvement of several muscle groups because it has different types of genres which are required to play different types of beats e.g: a heavy rock song needs continuous use of double bass and varieties of rolls so the risk of musculoskeletal problems is high.

Normally, the musicians suffer pain in both the limbs, mainly it takes place in both drummers, mostly the musicians will have pain in shoulder, arm and wrist, and due to these problems they will have some restricted functional activities. The health effects of vibration exposure in drummers can result from extended periods of contact between a drummer and the vibrating surface they are exposed too.

Drummers particularly are at risk since they can be exposed to vibration through multiple body parts such as the hands-stick-drum head, feet-pedals-bass drum head and or hi hat or from the buttocks-seat-floor interfaces. Drummers can develop symptoms including back pain, diminished sensation and dexterity in the hands or feet, decreased grip strength, vascular injury resulting in finger blanching or “white fingers”, tendonitis or a variety of nerve entrapment neuropathies such as carpal

tunnel syndrome. Vibration levels depend on numerous properties including size and weight of the drumstick, types of drums, hand grip and handle location on the stick. While playing instruments, almost every musician have pain and discomfort but usually they have a tendency of ignoring their daily complaints which results in the development of overuse injuries.

This goes in hand with **Steinmetz et. al.** (2010) who stated that insufficiencies of the postural stabilization systems play an important role in the manifestation of musculoskeletal pain and playing-related musculoskeletal disorder in musicians.

Krupagohil et al, (2016) concluded that 80% of musicians were found to have playing related musculoskeletal disorders. Among manual drummers the professional players had musculoskeletal complaints than the practicing students. This study was done among drummers from various academy and music school. 60 professional drummers were taken which includes 30 manual and 30 electric drummers of both male and female and the participants were asked to fill the MUSCULOSKELETAL PAIN INTENSITY AND PAIN INTERFRENCE QESTIONNAIRE FOR MUSICIANS, which consists of four parts that is musicians profile and hours of playing, then four questions about pain and rest five question about the interference.

In manual drum the drummers obtain sitting posture while playing when compared to electric drummers who adopts both sitting and standing posture .While playing the manual drums, as we observe carefully the manual drummers have to rotate their whole body to play the instruments so that the beats come appropriate according to the rhythm and they also use both the lower limbs frequently. While playing, the electric pad drummer does not rotate their body when compared to manual drummers and they can adjust the height of the instrument according to their comfortable levels.

Blanca Del Carmen florers-olivares et al, (2015) stated that the manual drummers adjust the height of some elements of drums such symbols and snare this is done according to the dimension Most of these drummers have upper and lower back pain and also complaints of pain in shoulder, elbow, lower limbs and numbness in metacarpals.

In this study musculoskeletal pain intensity and interference is more in manual drummers as reported by them that they spend more playing sessions in sitting as well as frequent rotation of their body, and they cannot change their posture easily during the manoeuvre but electric pad drummers usually can change their posture according to their comfort. As judged by the above findings of the study both manual drummers and electric pad drummers have reported their pain intensity and interference.

Hence, this study concluded that the musculoskeletal discomfort is more pronounced in manual drummers when compared to electric pad drummers.

Conclusion

This study concludes that the musculoskeletal pain intensity and interference problems among manual drummers were more when compared to electric pad drummers. Most of the musicians were aware about the importance of warm-up and cool down exercises but only very few were found to follow it regularly.

Also, drummers need to be made more aware regarding Physiotherapy and its role in injury prevention as well as post injury rehabilitation. Simply taking a break from an activity that has caused physical problems does not help to find out the underlying cause of the problem. Physiotherapy camps and seminars could be implemented at various music schools and Institutes to help them understand the importance of Physiotherapy in injury prevention. Thus care should be taken and all the musicians should be made aware of these problems and should learn to recognise such injuries at the earliest to prevent further problems.

Effectiveness of Low Level Laser Therapy Versus Ultrasound Therapy with Plantar Fascia Streching in Subjects with Plantar Fasciitis

K. Koteeswaran[1], Ramya K.[2], Rajeshwari[2], Manikumar Muthiah[1], Sankara Kumaran Pandian[3]

[1]Associate Professor, [2]Research Associate Saveetha College of Physiotherapy, Saveetha University, Chennai, [3]Lecturer, School of Physiotherapy, AIMST University, Bedong, Malaysia

Abstract

Aim: To find the effectiveness of low level laser therapy versus ultrasound therapy with plantar fascia stretching in subjects with plantar fasciitis.

Materials and Method: Non equivalent quasi experimental study design was used in this study. Total of 30 subjects with plantar fasciitis were selected using non probability convenience sampling technique. 30 Subjects was divided into two groups by lot system. Group A received low level laser therapy and Group B received ultrasound therapy and for both the group plantar fascia stretching was given. The outcome measures are FAAM (foot ankle ability measure) and NPRS (numerical pain rating scale). Data collected and tabulated was statistically analysed.

Result: Statistical analysis of post-test, foot and ankle ability measure questionnaire (FAAM) and NPRS (numerical pain rating scale) revealed that there is statistically significant difference seen between Group A and Group B.

Conclusion: From the result, it has been concluded that low level laser therapy with plantar fascia stretching (Group A) is more effective than ultrasound therapy with plantar fascia stretching (Group B) in decreasing pain and improving the quality of life in subjects with plantar fasciitis.

Keywords: *Plantar fasciitis, low level laser therapy, ultrasound therapy.*

Introduction

The human foot is a strong and complex mechanical structure and terminal portion of the limb which bears weight and allows locomotion.[1] The plantar fascia is a dense, fibrous, connective tissue structure originating from the medial tuberosity of the calcaneus. It has three-medial, lateral and central portions.[2]

Corresponding Author:
Dr. Mani Kumar Muthiah
Associate Professor, Svaeetha College of Physiotherapy, Saveetha University,Chennai

Phone: 8939164922

Plantar fasciitis is a degenerative condition resulting from compressive forces due to repeated trauma to plantar fascia making the foot's longitudinal arch of flat. Traction forces during the gait on support phase leading to inflammation results in fibrosis and degeneration. Plantar fasciitis is the common reason for heel pain for 80 percentage of cases. It affects most commonly people who are between 40–60 years of age.[3]

The exact etiology of plantar fasciitis still remains unclear but the risk factors which results in plantar fasciitis includes overuse of plantar fascia, exercises like ballet jumping activities, long distance running, long period of standing, obesity, pregnancy, military recruits, athletes. The patient usually complaints of pain over the medial side of plantar heel, usually when taking first few steps after waking up.[4]

The common site of pain in plantar fasciitis is near to the origin of the central band of plantar Apo neurosis at the medial plantar tubercle of the calcaneus.[5]

The windlass mechanism explains these biomechanical stresses and factors. Plantar fasciitis forms the tie-rod that attaches from calcaneus to phalanges. Vertical forces from the weight of the body travel to medial longitudinal arch in downward direction through tibia and flattens the arch. Further, the ground reaction forces that travel in upward direction on the calcaneus and metatarsal heads, even more leads to flatten of arch as these forces fall anterior and posterior to the tibia. Plantar fascia prevent the collapse of arch by its tensile force and orientation.[6]

Plantar fasciitis tends to improve in most cases regardless of the treatment selected. As a result conservative management is effective for nearly 90% of the patient. The conservative treatments used in management of plantar fasciitis vary widely and are dependent on physician specialty.[

Methodology

The subjects were selected from the Saveetha physiotherapy, outpatient department of Saveetha medical college and hospital. 30 subjects with plantar fasciitis were selected based on the inclusion and exclusion criteria. Detailed procedure was explained to the subjects in the colloquial terms about the safety and simplicity of the procedure. Informed concern were given to those who were interested to participate in this study. Selected subjects were randomly assigned in to two groups 15 in each group by using lottery system. The outcome measure used in this study for pain is numerical pain rating scale(NPRS) and for the quality of life is foot and ankle ability measure questionnaire (FAAM) respectively. For all subjects' pre and posttest values were calculated.

Procedure: Group A Were the subjects who received low level laser therapy along with plantar fascia stretch. Group B were the subjects who received ultrasound therapy along with plantar fascia stretch.

For group A Probe method (continuous) of low level laser therapy was used to treat the subjects. Safety precautions was taken to reduce the risk of exposure of laser light to the eyes. Low level laser therapy was given in painful area for 3 days/week for 2 weeks. The wave length used in the treatment is 830nm for 9 minutes. The irradiation area include 3 point over $3cm^2$.

For group B Ultrasound therapy was given to the subjects in the frequency of 3 MHZ in the pulsed mode (1;4) for 8 minutes with the intensity of $0.5W/cm^2$ for 2 weeks (3days/week).

For both the group plantar fascia stretching was given with the hold time for 20-30 seconds with the repetaion of 10 times in the alternative days.

Results

The collected data was tabulated and analyzed using descriptive & inferential statistics. To all parameters mean and standard deviation (SD) was used. Paired t-test was used to analyse significant changes between pre and posttest measurements. Unpaired t test was used to analyse significant difference between the groups. P value <0.05 was considered as statistically significant.

Table 1 represents the FAAM Scale score for group A and B. The group A pre-test mean value is 39.93% (SD 7.93%) and post-test mean value is 66.87% (SD 7.30%).The group B pre-test mean value is 48.20% (SD 13.09%) and post-test mean value is 56.27% (SD 11.81%) .This shows that FAAM Scale score values are gradually increasing in the group A than group B, which is statistically significant.

Table 2 represents the NPRS score for group A and B. The group A pre-test mean value is 7.47cm (SD 1.19cm) and post-test mean value is 3.93cm (SD 0.80cm).The group B pre-test mean value is 6.27cm (SD 0.80cm) and post-test mean value is 5.53cm (SD 0.83) .This shows that NPRS score values are gradually decreasing in the group A than group B, which is statistically significant.

Table 1: Comparison of pre and post test values of FAAM scale for group A and B

FAAM Scale		Mean	SD	t value	p value
Group A	PRE	39.93%	7.93%	38.8492	0.0001
	POST	66.87%	7.30%		
Group B	PRE	48.20%	13.09%	9.9896	0.0001
	POST	56.27%	11.83%		

Group 1: Comparison of pre and post test values of FAAM scale for group A and B

Table 2: Comparison of pre and post test values of NPRS scale for group A and B

NPRS Scale		Mean	SD	t value	p value
Group A	PRE	7.47cm	1.19cm	14.9480	0.0001
	POST	3.93cm	0.80cm		
Group B	PRE	6.27cm	0.80cm	4.7845	0.0003
	POST	5.53cm	0.83cm		

Discussion

Plantar fascia is commonly a repetitive micro trauma overloaded injury of the attachment of plantar fascia at the inferior aspect of calcaneus.

The clinical presentation of plantar fasciitis include gradual insidious onset of heel pain. Pain and stiffness are worse in the morning(during first few steps) or after prolonged walking and increased by climbing stairs or doing raising up activity thus impairing the activity of daily life.

Conservative treatment for plantar fasciitis include ultrasound therapy, cryotherapy, low level laser therapy, medication (steroids), stretching, foot wear modification, manual therapy, splint, tapping and strapping.

This study compares the effectiveness of low level laser therapy and ultrasound therapy with plantar fascia stretching in subjects with plantar fasciitis in terms of pain and quality of life.

The subjects with age group of 30-60 years of both gender with plantar fasciitis were selected. 15 subjects in Group A were treated with low level laser therapy with plantar fascia stretching while 15 subjects in Group B were treated with ultrasound therapy with plantar fascia stretching.

The pre-test and post-test values of this study, revealed that there was a statistical difference ($p<0.0005$) in both the groups in terms of pain and quality of life, but there was more improvement in Group A than Group B.

WOLGIN M, et al stated that low level laser effects causes the stimulation of bodies own processes in healing tissue by light [12]. Phototherapy increases the both local and systemic micro circulation of the body thus it relieves pain and swelling [22]. The 2 major areas for which low level laser therapy is used is tissue healing and pain control. Laser therapy is used for pain relief in many conditions in both acute and long term (England 1998). [23] The laser therapy is found to be very effective in various overuse tendinitis conditions. Laser has its effect on prostaglandin synthesis and thus it relieves inflammation. [24]. DR.ZANG said that 3 to 4 treatment are necessary for acute plantar fasciitis if treatment begins 6 to 8 weeks after the onset of symptoms.

Ultrasound has been utilized for pain through the ability of sound waves to introduce molecules of chemical substances through the skin by a process called phonophoresis [25]. Improvements in plantar fasciitis by the application of ultrasound therapy has been reported by Clarke and stenner (1976) [26]. The application of ultrasound therapy for pain relief, along with plantar fascia stretch is commonly indicated alternative therapy for plantar fasciitis [27]. The pulsed ultrasound is believed to have therapeutic benefits and can be applied to acute injuries [28]. The effects of ultrasound therapy are tissue relaxation, increase in local blood flow, scar tissue breakdown. By increasing the local blood flow level it reduces local swelling and inflammation. WATSON (2006) suggested that application of ultrasound to injured tissues, speed the rate of healing and enhance the quality of repair.

Plantar fascia stretching reduces the tightness in the plantar fascia. Plantar fascia stretching recreates the windlass mechanism by decreasing the micro trauma and inflammation. Plantar fascia stretching helps in reducing pain, improving function and gives overall satisfaction compared to standard Achilles tendon stretching exercises [13].

The post mean value in this study of quality of life [foot and ankle ability measure(FAAM)] and pain [numerical pain rating scale (NPRS)] score of Group A treated with low level laser therapy with plantar fascia stretching was 66.87 and 3.93 and Group B treated with ultrasound therapy with plantar fascia stretching was 56.27 and 5.33 at the end of 2 weeks.

Hence is has been proven that the recovery is earlier and faster in relieving pain and improving quality of life in Group A than Group B. Thus these statistical findings could be attributed to the fact that low level laser therapy with plantar fascia stretching works more statistically over ultrasound therapy with plantar fascia stretching

Conclusion

From the result, it has been concluded that low level laser therapy with plantar fascia stretching (Group A) is more effective than ultrasound therapy with plantar fascia stretching (Group B) in reducing pain and improving quality of life in subjects with plantar fasciitis.

Evaluation of Temporomandibular Disk Position in Symptomatic Temporomandibular Disorder Patients with Gnathological Splint Therapy Using MRI

K. Sridhar[1], M.S. Kannan[2], Faisaltajir[3], Gnanashanmugam[3]

[1]Post Grduate, [2]HOD & Professor, [3]Professor, Department of Orthodontics and Dentofacial Orthopaedics, Sree Balaji Dental College and Hospital, Bharath University, Velachery Main Road, Chennai, Tamil Nadu, India

Abstract

Objective: The aim of this study was to Evaluation of altered temporomandibular disc position in symptomatic TMD patients with pre and post gnathological splint therapy.

Materials and Method: This study included ten patients with a mean age of 21.5 years with maxillary transverse deficiency treated with the skeletal expander. The study consisted of 15 patients with a mean age of 25 years with clinically symptomatic and orthodontically untreated TMD patients with splint therapy. Statistical analysis was performed using paired t-test.

Results: The mean AS, SS, and PS values for right TMJ that was 0.2mm (SD ±0.6mm), 0.5mm(SD± 0.3mm), 0.4mm(SD±0.1mm), respectively and the mean difference between AS, SS, and PS values for left TMJ was 0.2mm (SD±0.1mm), 0.5mm (SD± 0.05mm), and 0.2mm (SD± 0.2mm). The ratio of AS to SS to PS was 0.2to 0.5to 0.4, No significant sex difference was noted in joint space distances. The results showed less variability of condylar position in the fossa than in normal subjects.

Conclusion: Gnathological splints can be used as effectiveness mean for treatment of such patients. This can be easy made good comfort to the patients.

Keywords: *TMJ, Splint, MRI, Joint space.*

Introduction

The temporomandibular joint (TMJ) is a compound articulation of the articular surfaces of the temporal bone and the mandibular condyle[1]. The TMJ functions uniquely in that the condyle both rotates within the fossa and translates anteriorly along the articular eminence. The condyle's ability to translate the mandible can have a much higher maximal Incisal opening than would be possible with rotation alone. The joint is thus referred to as "Ginglymodiarthrodial."[2] a combination of the terms Ginglymoid (rotation) and Arthroidal (translation). TMD is a prevalent disorder most commonly observed in individuals between the ages of 20 years to 40 years. Approximately 33% of the population has at least one TMD symptom and 3.6-7% of the population has TMD with sufficient severity to cause them to seek treatment[3]. The etiology of TMJ disorders remains unclear, but it is likely multifactorial. Capsule inflammation or damage and muscle pain or spasm may be caused by abnormal occlusion, parafunctional habits (e.g., bruxism, teeth clenching, lip biting), stress, anxiety, or abnormalities of the intra-articular disk. Treatment of TMJ disorders are varied. But dental occlusal splinting and permanent occlusal adjustment have been the mainstays of TMJ disorder treatment. Occlusal splint therapy may be defined

as "the art and science of establishing neuromuscular harmony in the masticatory system by creating a mechanical disadvantage for parafunctional forces with removable appliances."Conventional tomographic x rays are commonly used to view the temporomandibular joint area. However because of poor quality of images and variability in interpretation of anatomic areas, it failed to provide necessary information for diagnosing optimal condylar position. Magnetic resonance imaging (MRI) is a non invasive, non ionizing procedure that produces highly sensitive and specific tomographic images in any plane with excellent soft tissue contrast and reduced biologic hazards. Magnetic resonance imaging (MRI) has become the gold standard for examination of soft tissues of the TMJ.The purpose of the study was to evaluation of joint spaces before and after splint therapy by MRI[5,6].

Materials and Method

The sample for the study was recruited from the patients who reported to the Department of Orthodontics at sreebalaji dental Dental College and Hospital. Ethical approval was obtained from the Institutional Review Board and informed written consent was obtained from all the participants. The sample consists of fifteen patients within the age group of 22–30.

Inclusion Criteria: Clicking sound in TMJ area,Tenderness of muscles of mastication, Deviation of the lower jaw on opening, Unilateral or bilateral headaches, shoulder pain and/or neck pain, Generalised attrition/mobility of teeth. **Exclusion Criteria:** Developmental anomalies, Degenerative disc conditions, Orthodontically treated patients**.**

Splint Fabrication: The study was initiated with Maxillary and mandibular impression which were taken using an irreversible hydrocolloid in sterilized metal rim-lock trays and poured with Type 4 Gypsum, facebow transfer, Roth's power centric bite registration, centric occlusion bite registration, articulation, CO-CR discrepancy. After assessing the CO-CR discrepancy splint was fabricated and delivered[12]. Face-bow transfer records were taken using the Axioquick Expansion Kit AX, (SAM Prazisionstechnik GmbH, Fussbergstr 1, Germany). It records the relationship of the maxilla to the cranial base [Figure 1].

a

b

Figure 1: Face bow transfer (a) frontal view (b) profile view

The wax bite recorded in patient's initial CR, which should not be mistaken for terminal CR. It is difficult to capture one's true CR at chair-side during initial visit a true CR can be registered only after the stabilization of condylar position. Centric relation bite (Roth power centric) [Figure 2] was taken with Delar bite registration wax in two sections, one in the anterior region and the other in the posterior region. The patient was seated in the dental chair reclined at an angle of 45° to the floor. To take the anterior section, the wax (2–3 layer thickness) was cut in a shape and appropriate size to register from canine to canine. The wax was then heated until soft in a water bath at 138°F. The wax bite was then placed in the patient's mouth extending from canine to canine. The patient's mandible was then manipulated (to CR) to make an interocclusal registration in the anterior section. The patient was then instructed to close until the posterior teeth were discluded approximately 3 mm in the area of the second molars. While in the closed position, an air syringe was used to begin the cooling process. The anterior record was then removed, and stored in chilled water. The posterior section was trimmed wide enough to include the last molar extended across the arch. The

wax was then softened and placed on the maxillary posterior teeth. With the posterior section in place, the chilled anterior portion was placed back in position again. The patient was then guided in the same manner to close into the hardened anterior segment and asked to bite as firmly as possible and hold it. This allowed the patient's musculature to aid in seating the condyle in CR position. Both the bites were then removed and stored in chilled water.

Figure 2: Roth power centric bite

With the help of face-bow transfer record, the maxillary model is mounted to the articulator with the mounting plate and mounting plaster [Figure 3]. Sufficient time is allowed for the plaster to set. The incisal guide pin is raised by 3 mm. To mount the lower model, the articulator is inverted, the centric wax bites are placed on the maxillary model, and the mandibular model is placed into the wax. A mounting plate is fastened to the lower member of the articulator, and the mandibular model is mounted, using mounting plaster or dental stone.

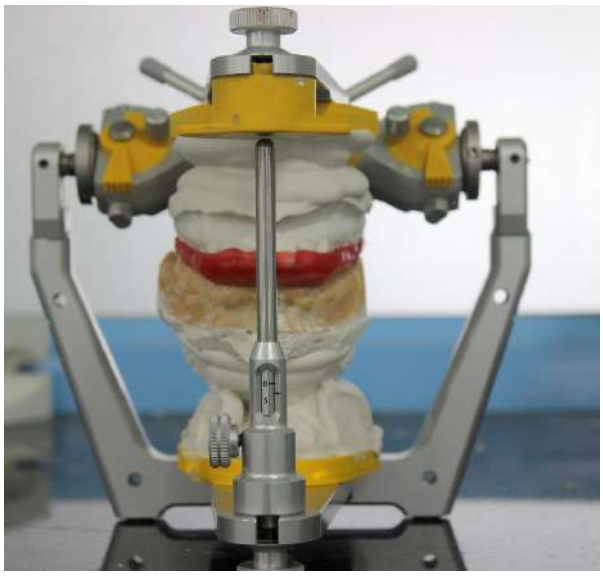

Figure 3: Mounted models

The splint was fabricated on an articulator. Upon closure of the arches, there were simultaneous centric stops with mandibular buccal cusp. Clearance of 0.0005"[8] was provided for the anterior teeth. Splint was fabricated with cold cure acrylic resin at a position with 3 mm clearance from the fulcrum. The splint was then allowed to set for sufficient time. With the splint still not removed from the articulator, initial trimming was done to establish centric stops and mutually protected functional occlusal pattern. The splint later was adjusted in the patient's mouth to do further trimming to establish the same [Figure 4]. The patient was advised to wear the splint full time[9].

Figure 4: Splint with centric stops

Patient was recalled every month, and the splint was checked for centric stops and mutually protected occlusal pattern each time. The mandible was checked and guided to centric, and it was noted that each time, the mandible exhibited lesser resistance indicating the reduction in muscle stiffness due to deprogramming..

Measurements: The condylar joint spaces before and after 6 months of gnathological splint therapy was assessed by MRI

MRI:

Table 3: Right joint space mean values

Pre vs Post Treatment (Right)	**Mean Difference**	**Significant P value**
Pre treatment (AS)	0.2773	0.002
Post treatment (AS)		
Pre treatment (SS)	0.556	0.001
Post treatment (SS)		
Pre treatment (PS)	0.448	0.005
Post treatment (PS)		

Table 4: Left joint space mean values

Pre vs Post Treatment (Left)	**Mean Difference**	**Significant P value**
Pre treatment (A)	0.2987	0.001
Post treatment (AS)		
Pre treatment (SS)	0.5573	0.001
Post treatment (SS)		
Pre treatment (PS)	0.2607	0.004
Post treatment (PS)		

If P-Value is <0.05 then statistically significant

Statistical Analysis: The Normality tests Kolmogorov-Smirnov and Shapiro-Wilks tests results reveal that the variables (Vertical and Horizontal distances) follow Normal distribution. Therefore to analyse the data parametric method are applied. To compare the mean PAIRED SAMPLE t-test were used for each measurement to evaluate the average differences between the right and left side of the each sample. To analyse the data SPSS (IBM SPSS Statistics for Windows, Version 22.0, Armonk, NY: IBM Corp. Released 2013) is used. Significance level is fixed as 5% (p= 0.05).

Result

- Table 1 and 2 shows the pre and post treatment outcomes of mean value of 15 patients in terms of change in the Anterior. Superior, Posterior joint space (AS, SS and PS) (Measured in mm) in the right and left side joint respectively.
- Table 3 and 4 shows the mean difference between AS, SS, and PS values of pre and post-treatment for right TMJ that was 0.2mm (SD ±0.6mm; p-value 0.002), 0.5mm(SD± 0.3mm; p-value 0.001), 0.4mm(SD±0.1mm; p- value 0.005), respectively and the mean difference between AS, SS, and PS values of pre and post-treatment for left TMJ was 0.2mm (SD±0.1mm; p- value 0.001), 0.5mm (SD± 0.05mm; p- value 0.001), and 0.2mm (SD± 0.2mm; p- value 0.004), respectively.
- The result of this study hence showed that there was statistical significant difference in the all anterior,

superior, and posterior space both in the right and left side joint pre and post treatment and the values of post treatment approached the mean values reported by Kazumi et al.

Discussion

Some TMD patients awake with TMD pain that only last m minutes to hours, suggesting that nocturnal factors are the primary contributors to these symptoms. In this third patient group, patients generally report that either their awaking or daytime symptoms are worse, suggesting that the nocturnal or diurnal factors are more significantly contributing to their symptoms[10]. Therefore it's best that the splint is worn 24 hours a day for best effective treatment and so full time wear of gnathological splint was advocated in this study. Roth power centric bite registrations anatomically seat the condyles in anterior superior position within the fossa.[14]

It has been reported that clinical examination for the diagnosis of anterior disc displacement with reduction has an accuracy of 43–75%.This suggests that a clinical examination should be done together with other imaging method in order to determine the relationship between the articular disc and condyle. In recent years, magnetic resonance imaging (MRI) has been used because it is an effective, noninvasive method that does not appear to cause any biological hazard.

The goal of our study was to check the condylar disc position, joint space in pre and post gnathological splint therapy for six months using MRI in patient with TMD problems .Subject were patients who had an anterior disc displacement with reduction before treatment. Our study was designed to identify the condylar disc position, joint space[13].

Kazumi et al (2009) in his study on optimal condylar position in the fossa on sagittal CBCT images in functionally optimal joints without displacement reported that mean AS, SS, & PS values are 1.3mm (SD±0.2mm), 2.5mm (SD±0.5mm) and 2.1mm (SD±0.3mm), respectively. The ratio of AS to SS to PS was 1.0 to 1.9 to 1.6.In our present short term study the patients are symptomatic of TMD and post treatment results were taken after six months. In my study using MRI, the post treatment values approximate the results provided by Kazumi et al.

All the symptomatic patients who were selected in this study exhibited resolution of symptoms such as pain located around the TMJ, pain that was referred to the neck, head and ear and pain that was located immediately in front of the tragus of the ear, projecting to the ear, cheek, and along the mandible. The restricted jaw motion was also resolved in all of the study patients but joint noise such as clicks and crepitus resolved only for a little more than 60% of the patients in the span of just four weeks of total six months.

Conclusion and Summary

TMD should be treated like any other musculoskeletal complaints. If TMD is left untreated, symptoms can be worsen and extend far beyond the jaw and the mouth area. Gnathological splints can be used as effectiveness mean for treatment of such patients. This can be easy made good comfort to the patients.

Amount of change in the right side TMJ

- AS – 0.2773
- SS – 0.556
- PS – 0.448

Amount of change in the left side of TMJ

- AS – 0.2987
- SS – 0.5573
- PS – 0.2607
- Relief of pain and other symptoms
- MRI supported our clinical results with great specificity.

Abstract

Background and Objectives: Dental caries is a common problem encountered in children. Deciduous teeth with deep dental caries can be treated with pulp therapies to allow normal exfoliation process. The process of pulpectomy involves access cavity preparation, cleaning and shaping of the root canal and obturation. Even though all these procedures are essential, irrigation of the root canal during cleaning and shaping is vital in ensuring complete microbial decontamination, which guarantees the success of pulpectomy. Although NaOCl is considered as gold standard among root canal irrigants, the quest for a better irrigant with superior antimicrobial efficacy and biocompatibility was under consideration.

Hence, the present ex vivo study was done to evaluate and compare the antimicrobial efficacy of 0.5% Sodium hypochlorite (Dakin's solution) with 10% Triphala, a herbal root canal irrigant.

Results: The study showed a statistically significant difference in the anti-microbial efficacy of 10% Triphala and 0.5% Sodium hypochlorite (Dakin's solution).

Conclusion: The antimicrobial efficacy of 10% Triphala was better than that of 0.5% Sodium hypochlorite (Dakin's solution) when used as root canal irrigants in infected primary teeth.

Keywords: *Triphala, Sodium hypochlorite, Root canal irrigant, Antimicrobial efficacy.*

Introduction

The dental root canal is not a single microbial environment but is one of the most heavily bacterially contaminated sites in the body. Some of the microbial species reported in the root canal system are *Streptococcus*, *Staphylococcus, Lactobacilli, Enterococcus, Klebsiella, Pseudomonas, Actinomyces* etc. A clinician ensures a patent and clean root canal system by eliminating these microbial floras via endodontic treatment.[1]

Though all the steps of endodontic therapy are vital and should be carried in a systematic manner, irrigation forms the backbone of pulp therapy. Copious irrigation helps in the debridement of the root canal, destruction of microbes, removal of tissue remnants and dentin debris during instrumentation.[2]

Many irrigating solutions such as halogenated compounds (sodium hypochlorite), chlorhexidine, chelating agents (EDTA, citric acid), MTAD, hydrogen peroxide, maleic acid and chlorine dioxide have been used to disinfect the root canal. Among these enumerable

irrigants sodium hypochlorite is considered as the gold standard for endodontic irrigation.[2,3]

Despite being the gold standard, sodium hypochlorite has an unpleasant taste andwhen it comes in contact with the tissue, causes hemolysis and ulceration. It also inhibits neutrophil migration and damages vascular, endothelial and fibroblast cells. Handling this solution also requires utmost care since it can also causes damage to the permanent tooth follicles and periapical tissues if gone beyond the working length and resorbing apex.[2,4]

Due to the constant increase in antibiotic resistant strains and also due to the side effects caused by sodium hypochlorite and other synthetic drugs herbal alternatives are more preferred as root canal irrigant. Various herbal alternatives for endodontic applications are Triphala, *Morindacitrifolia* (Indian mulberry), *Curcuma longa* (Turmeric), Green tea polyphenols, Liquorice, Propolis, *Melaleucaalternifolia* (Tea tree oil) and *Azadirachtaindica* (Neem).[5,6]

Triphala is a herbal formulation consisting of fruits of *Terminaliabelerica* (Bibhitaki), *Terminaliachebula* (Haritaki), and *Emblicaofficinalis* (Amalaki) in 1:1:1 ratio. Triphala showed strong antimicrobial activity against different microorganisms. The beneficial effects of Triphala are that, it can be used as a root canal irrigant, it has anti-caries effect, anti-periodontal disease effect, anti-collagenase effect, anti-microbial effect, anti-fungal effect, analgesics and anti-pyretic effect, anti-oxidant effect and anti-cancer effect.[5,7]

Hence the present study compared the antimicrobial efficacy of 10% Triphala as a root canal irrigant, with 0.5% sodium hypochlorite (Dakin's solution).

Materials and Method

30 patients who reported to the Department of Pedodontics and Preventive Dentistry with deep dental caries involving pulp were selected for the study. After access cavity preparation a barbed broach was inserted into the canal and along with the infected pulp it was transferred to sterile container having 2ml normal saline (Figure 1). The saline container was then taken for microbiological procedures.

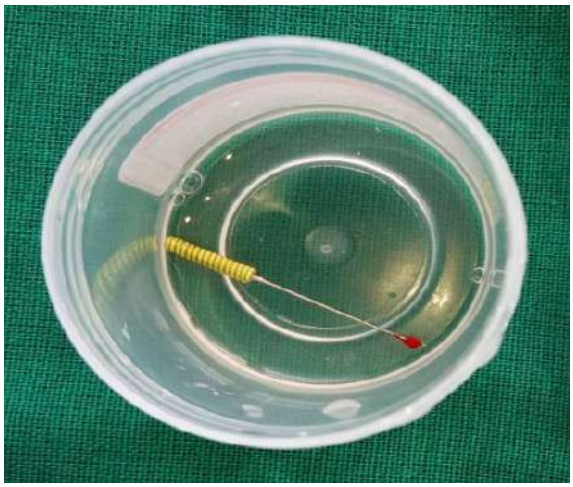

Fig. 1: Collected Sample Stored in a Saline Container

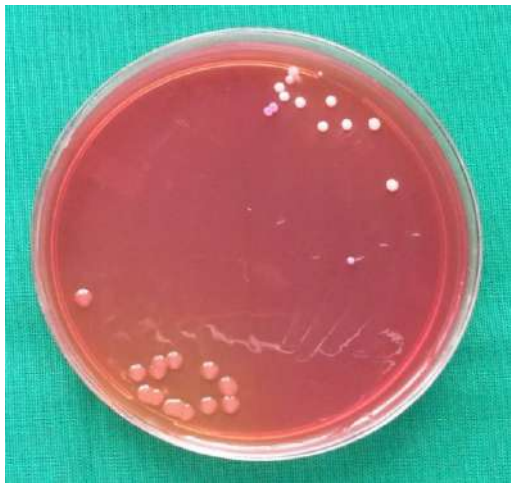

Fig. 2: Microbial growth on MacConkey Agar

The sample was subcultured onto Blood agar and MacConkey agar (Figure 2 and 3). Mac Conkey agar was incubated at 37ºC for 24hours and Blood agar plates was kept in 5-10% CO_2 in a candle jar and incubated at 37ºC for 24hours. After incubation period, the colonies were identified by its colony morphology, gram staining, coagulase and catalase test.

From the incubated plates bacterial colonies were taken and bacterial suspension was made in 1ml of normal saline. A sterile swab was dipped in bacterial suspension and transferred to Muller Hinton agar based Blood agar for *Streptococci* and *Enterococci* species and lawn culture was made using cotton swab. For *Staphylococci* species Muller Hinton agar was used and lawn culture was made.

6mm wells were dug in the plates and in each well 300µl of 10% Triphala, 0.5% Sodium hypochlorite (Dakin's solution) and Normal saline were poured using micropipette. This plate was kept in 5-10% carbon dioxide in a candle jar and incubated at 37ºC for 24 hours. After incubation period, diameter of zone of inhibition was measured for 10% Triphala, 0.5% Sodium hypochlorite (Dakin's solution) and Normal saline, which acted as a negative control and the values were compared with each other to determine the anti-microbial efficacy of root canal irrigants (Figure 4).

All the clinical procedures were carried out following the protocols approved by the Ethics and Review Committee of Sri Siddhartha Dental College and Hospital, Tumkur (IEC 12/2016).

Fig. 3: Microbial growth on Blood Agar

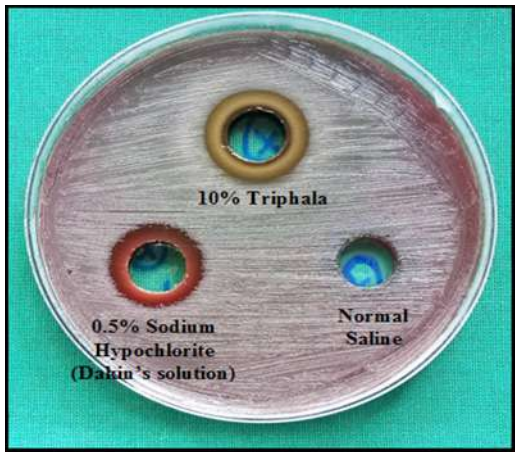

Fig. 4: Agar Plate Showing Zones of Inhibition

Findings: Table 1 shows the mean and standard deviations of zone of inhibition produced by 10% Triphala and 0.5% Sodium hypochlorite (Dakin's solution). It has been calculated from the zone of inhibition values collected from 30 samples. The mean zone of inhibition produced by 10% Triphala was 23.83 mm and that by 0.5% Sodium hypochlorite (Dakin's solution) was 20.97 mm with a p-value of 0.0047. This shows that 10% Triphala has a statistically significant antimicrobial efficacy than 0.5% Sodium hypochlorite (Dakin's solution).

Table 1: Mean Zone of Inhibition produced by 10% Triphala and 0.5% Sodium Hypochlorite (Dakin's Solution)

Irrigant	Minimum (mm)	Maximum (mm)	Mean (mm)	Standard Deviation	P Value	Significant
10% Triphala	16.00	32	23.83	3.141	0.0047**	Significant
0.5% Sodium hypochlorite	14	30	20.97	4.319		

*p value ≤ 0.05, ** p value ≤ 0.01, *** p value ≤ 0.001

The present study was done to assess the anti-microbial effectiveness of 10% Triphala and 0.5% Sodium hypochlorite (Dakin's solution) as intracanal irrigants in infected primary teeth. The anti-microbial properties of the test solutions were evaluated by measuring its mean zones of inhibition.

In the present study the mean zone of inhibition for 10% Triphala was 23.83mm and 20.97mm for 0.5% Sodium hypochlorite (Dakin's solution). The result of this study was in close accordance to the study done byShukla et al.[8] who compared the antimicrobial efficacy of Triphala and 5% Sodium hypochlorite and found mean zone of inhibition for Triphala as 32mm and 22mm for 5% Sodium hypochlorite against *Staphylococcus aureus*. In the same study Triphala showed mean zone of inhibition of 27mm and 5% Sodium hypochlorite showed 24mm against *Enterococcus faecalis*.Shakouie

et al.[9] in a study found the mean zone of inhibition for Triphala as 7.3 +/- 1.3mm and 4.6 +/- 1.6mm for 0.5% Sodium hypochlorite.On comparing the mean zone of inhibition of Triphala and 5.25% Sodium hypochlorite, Karwa et al.[10] found 18mm for Triphala and 24.6mm for 5.25% Sodium hypochlorite against *Enterococcus faecalis*.

The increased zone of inhibition of Triphala can be attributed to its antimicrobial effect. Antimicrobial activity of Triphala is accredited for its formulation which contains three different medicinal plants in equal proportions namely, *Terminalia bellerica, Terminalia chebula* and *Emblica officinalis.* All these components have an additive orpositive synergistic effect. *Emblica officinalis* assists in lipid peroxidation and plasmid DNA assay, while *Terminalia chebula* has noticeable radical scavenging activity. The anti-bacterial property of Triphala includes either inhibition of cell division or damage to the cell walls of the bacterium.[11,12]

The differences in the mean zone of inhibition among the present and other studies can be attributed to the concentration and volume of the solutions used and the microorganisms on which the solutions were tested.

Conclusion

The study concludes that 10% Triphala has a statistically significant antimicrobial action compared to that of 0.5% Sodium hypochlorite (Dakin's solution). However, further in vivo research is needed to conclusively recommend Triphala as a root canal irrigant.

Conflict of Interest: There is no conflict of interest in the research.

Funding: This study has not been funded by any organization.

Ethical Clearance: All the clinical procedures were carried out following the protocols approved by the Ethics and Review Committee of Sri Siddhartha Dental College and Hospital, Tumkur (IEC 12/2016).

Abstract

Introduction: Oral squamous cell carcinoma encompasses at least 90% of all oral malignancies. It is sixth most common malignancy and the major cause of cancer morbidity and mortality worldwide. Early detection of a premalignant oral lesion would improve the survival to a greater extent. Tobacco lays an enormous effect of disease for health, economic, social and environment issues. Cross sectional study was done at tertiary care hospital to find association between urinary cotinine levels and buccal mucosal micronuclei cells of smokeless tobacco chewers.

Method: Study comprised of 300 Smokeless Tobacco chewers (STC) and 300 Non tobacco chewers (NTC). Physical examination and Anthropometric parameters were recorded. Fasting urine samples collected for extraction of cotinine. Buccal smears were prepared for exfoliated cells. Slides were stained by Papanicolaou stain and micronuclei (MN) cells was examined by using 100X, 400X magnification as per the Tolbert et al criteria.

Results: Mean Urinary Cotinine in STC was enhanced as compared to NTC. The MN cells were also increased in STC as compared to NTC & statistically highly significant (Mean SD of STC 21.30±10.55, 95% CI; 20.11 to 22.49, NTC Mean SD 3.74±3.43, 95% CI; 3.35 to 4.12). The MN cells of STC showed strong positive association & statistically highly significant correlation with urinary cotinine levels (r= 0.692, p=<0.0001).

Conclusions: The present study establishes link between rise in exfoliated buccal MN and determination of urinary cotinine levels which is a biomarker of genotoxicity and epithelial carcinogenic progression.

Keywords: *Smokeless tobacco chewers, Non tobacco chewers, Micronuclei, Cotinine.*

Introduction

Oral cancer is one of the commonest causes of disease and death rate nowadays. In developing countries, both smokeless tobacco chewing and smoking have cancerous causing behavior that contributes to increasing global burden of oral cancer. The World Health Organization figured out that proportion of deaths that result due to tobacco-related diseases would rise in India from 1.4% of all in 1990 to 13.3% of all deaths in 2020[1,2].

Tobacco lays an enormous effect of disease for contrary health, economic, social and environment issues. The tobacco epidemic is among the largest public health threat at present situation which almost

Corresponding Author:
Kanchan C. Wingkar
Professor and Head, Krishna Institute of Medical Sciences Deemed University, Dept. of Physiology, Karad, Maharashtra, India

kills six million peoples per year. Among mortality of ten adults in every six seconds, one death is reported due to habitual tobacco. Use of tobacco is an indicatory public health problem on earth and the only cause for preventable hazard for human health[3].

As per latest report intimated by Global Adult Tobacco Survey 2, (GATS-2) 2016-17 in India affirm that 28.6% of adults aged >15 (26.7 crore) use tobacco in various forms. Smokeless tobacco usage is marked in every 5th adult (19.9 crore) and (10.0 crore) in every 10th adult in smokers[4].The frequency of tobacco usage is around 37.97% in men 12.5% in female in Belgaum region and the commonest form of tobacco use is smokeless tobacco (ST)[5].

Biological consequences of Nicotine are widespread and lengthened to all systems of the body including cardiovascular, respiratory, renal and reproductive systems[6]. Smokeless tobacco is thought to be highly addictive due to their high nicotine content. The ST also contain carcinogenic substances like tobacco-specific N-nitrosamines (TSNAs) leading to an increased risk of cancers of oral cavity, pharynx and esophagus. Depending on the type of ST products, nicotine content may vary, and therefore, measurement of nicotine and its metabolites among ST users is important to understand the addictive potential of ST products. The half life of nicotine is very less and its metabolites especially cotinine has a long half life, which is good biomarker of nicotine in urine (urinary cotinine level)[7,8].

Estimation of cotinine concentration levels from urine sample of Smokeless tobacco chewers (STC) and Non tobacco chewers (NTC) by High performance liquid chromatography- Diode array (HPLC-DA) and conformation of cotinine metabolite by Gas Chromatography-Mass spectrometry (GC-MS) serves as useful marker to determine the effects of different forms of tobacco consumption.Studies on nicotine and Cotinine levels in smokers and passive smoking in other ethnic groups are well documented but very few studies are found in STC. This may be fact because of the cultivation of the tobacco crops in specific parts of that region only[9].

Multiple studies have reported that all forms of tobacco use are highly prevalent in both men and women in India. The prevalence of ST use is estimated 33%and 18% for men and women respectively in India[10]. The risk of oral cancer associated with those who use chewing tobacco is approximately 50 times higher than that of non-tobacco users. Nearly 90% of oral neoplasms are caused by smokeless chewing tobacco. Chewing tobacco also results in lesions like leukoplakia caused due to chronic irritation. Many tumorsare likely to be known to arise from these lesions.

Globally, about 5, 00,000 new oral and pharyngeal cancers are diagnosed annually and three-quarters of these are seen in the developing countries, including about 65, 000 cases being reported from India[11]. The micronuclei (MN) assay in exfoliated buccal epithelial cells is potentially an excellent candidate to serve as a biomarker. If not precise, but an arbitrary prediction about the molecular changes that take place in the buccal mucosal cells of tobacco users in individuals without any lesion can hint towards the occurrence of any lesion in those individuals in future[12]. The biomarkers most widely used to quantify exposure to tobacco include nicotine, and their metabolites are cotinine, carbon monoxide, and thiocyanate. Recent investigation has focused on various hemoglobin and DNA (deoxyribonucleic acid) adducts and excretion of nitrosamines in the urine samples[13].

The literature review revealed that there is a paucity of literature regarding the association among smokeless tobacco chewers in Belagavi region. Therefore, the study aimed to study the cytomorphological changes in the buccal mucosa of smokeless tobacco chewers and normal subjects.

Material and Method

This Cross sectional study was conducted in Belagavi region of Karnataka state in India,. The study groups were divided as Smokeless tobacco chewers (STC) and Non tobacco chewers (NTC). Ethical clearance was obtained from the Ethical Committee of the Institution and University. A total of 600 participants were studied in this study. The study population comprised fromBelagavi Institute of Medical Sciences (BIMS), Belagavi, Karnataka, India. Written informed consent was explained and taken from the participants in English and local languages (Kannada and Marathi). Study was done in the month of April 2013 to December 2016.

Inclusion criteria for age were300 smokelesstobacco chewers and 300 Non tobacco chewers between 18 to 65 years.Subjects with pre-existing oral cavity lesions, alcoholics and having recent viral infections and who had received radiotherapy or chemotherapy in last month

were excluded from the study. The study included 183 cases based on the prevalence of 13.9% in Karnataka[14].

Physical examinations of the subjects were done to record Respiratory rate (cycles/minute) Heart rate (Beats/minute).Anthropometric parameters was recorded for (Height (in cms), Weight (in kgs), Body Surface Area (Square meters), Body Mass Index (Kilogram/meter2),

Collection and chromatographic analysis of the urine samples for cotinine has been already reported by the same group[9].

Each individual was asked to rinse his mouth neatly by tap water. The exfoliated cells were taken by scrapping the buccal mucosa by using wooden/steel spatula and the scraped cells were taken on lean grease free glass slide and smears were prepared. All smears were stained by Papanicolaou technique using commercially available staining kit Rapid Pap. From each slide, minimum 100 cells were examined in high power magnification (400X) and location of micronuclei (MN) cells was examined by using 100X, 400X magnification. As per the Tolbert et al criteria identifying of micronucleus cells were done.

The completed questionnaires were entered into a database using MS Excel 2000. Frequency distributions and percentages were examined for each answer. Descriptive statistics,comparison among NTC and STC groups using Mann-Whitney U testand Spearman non parametric correlation analysis was used to indicate a measure of the correlation and the strength of the relationship. The statistical significance level was set at $P < 0.05$. The statistical analysis was conducted using SPSS version 26.

Results

The mean age of participants for NTC was (37.00±16.05) whereas for STC was (37.10±15.99). Distribution of sex for male and female for NTC was 222 (74%) and 78 (26%) respectively, and for STC male and female it was 214 (71.33%) and 86 (28.66%) respectively. The anthropometric data for height (cm) and weight (kg) mean ± SD in case of NTC and STC was 157.85±5.19 and 158.93±6.42 for height (cm) and 59.49±7.24 and 52.00±4.96 for weight (kg). The difference between mean values was statistically highly significant (<0.001).The mean ± SD values of Body Mass Index in Kg/m^2 (BMI), were 24.01±3.13 in NTC and 20.66±2.41 in STC group. Body Surface Area (BSA) m^2 the mean ± SD were 1.59±0.09 in NTC and 1.51±0.08 in STC group. The difference between mean values was statistically highly significant (<0.001). Heart rate in Beats/minute (HR) and Respiratory rate in cycles/minute (RR) on comparison with NTC and STC groups was statistically highly significant. Mean Urinary cotinine value in STC was enhanced as compared to NTC group (NTC, Mean SD, 23.48±11.08 & STC, Mean SD, 1563.68±1198.97) & were statistically highly significant statistically highly significant (<0.001)(Table/Fig 1). The comparison of buccal mucosal micronuclei cells by using Mann-Whitney U test was increased in case of STC (Mean SD of STC 21.30±10.55, 95% CI; 20.11 to 22.49 as compared to NTC Mean SD 3.74±3.43, 95% CI; 3.35 to 4.12) & was statistically highly significant (<0.001) (Table/Fig 2).The buccal mucosal micronuclei cells in case of STC showed strong positive association & statistically highly significant correlation with urinary cotinine levels (r= 0.692, p=<0.0001) by using spearman non parametric correlation analysis (Table/Fig 3).

Table 1: Mean urinary cotinine level in smokeless tobacco chewers and non tobacco chewers group[9].

Urinary cotinine levels (ng/mL)	Mean SD	P value
NTC	23.48±11.08	<0.001**
STC	1563.68±1198.97	

*Significant, ** Highly significant.

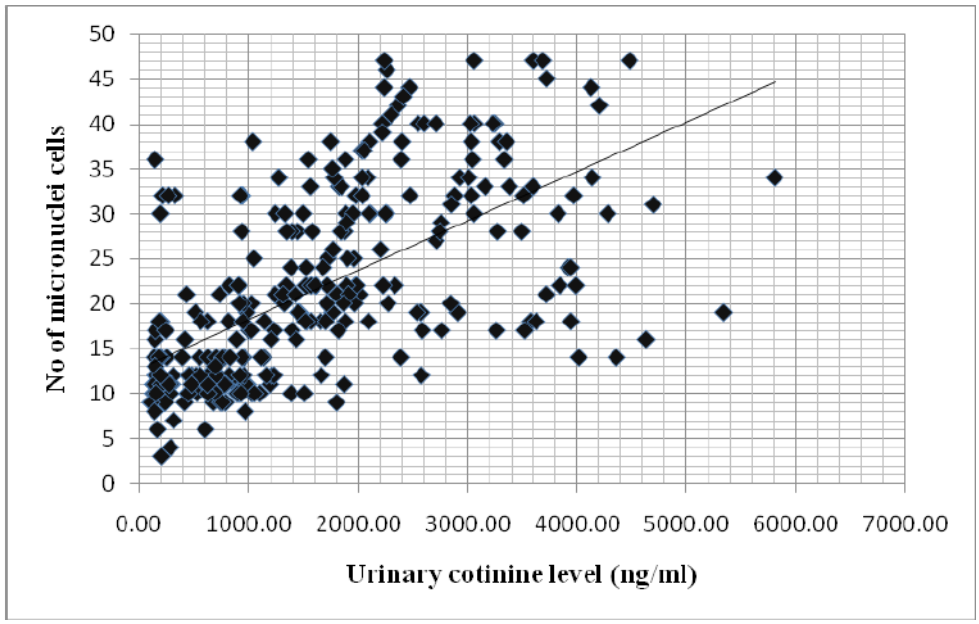

Fig. 3: Buccal mucosal micronuclei cells of STC showing strong positive correlation with urinary cotinine levels.

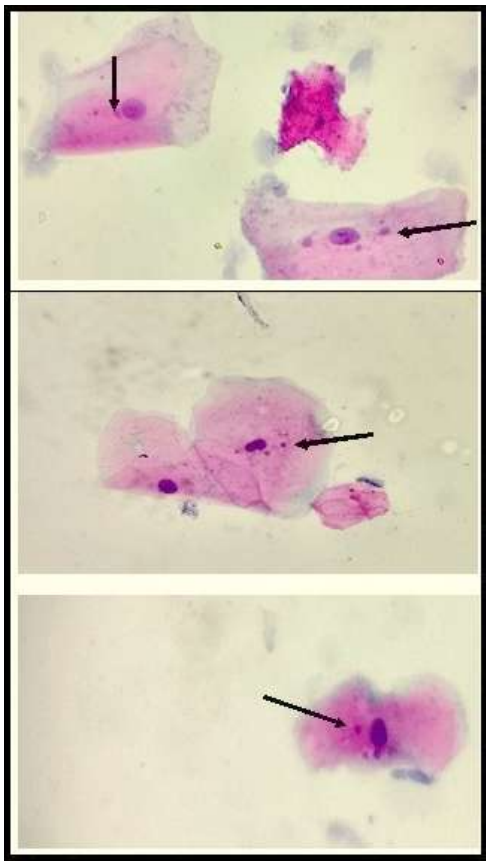

Fig 4: Photomicrograph showing exfoliated cells with micronuclei cells (Arrow) in STC stained by Papanicolaou stain, x 400.(Labomed Bionocular microscope Model LX 400)

Discussion

The present study was aimed to assess and compare micronuclei cells of buccal mucosa in STC and NTC and to establish the correlation between urinary cotinine levels of STC with above findings. Previous researchers[8,13,15,16] found a wide range of urinary cotinine levels which is also seen in the present study in STC and NTC 100.84 -5810 and 10.01- 59.02 ng/mL respectively. Several studies showed that urinary cotinine levels innonsmokers are always less than 100 ng/ml[17, 18]. The variation in range of cotinine depends on the tobacco chewer's dietary intake of nicotine, cotinine excretion, metabolic activity, passive smoking and environmental smoke[8].

From the present study highly statistically significant difference was found between STC and NTC group. Similar findings were also found among previous reports[19, 20, 21].The potential of carcinogenic and genotoxicants effect is very high among tobacco chewers. Habituated chewing tobacco users are the likely odds estimated for oral cancer development[19]. Micronuclei in oral exfoliated cells are the biomarkers of chromosomal damage caused by genotoxic agents from the tobacco and tobacco related substances[20]. Tobacco-specific nitrosamines present in the smokeless tobacco forms also play a significant role in causing the damage[19].

Urinary cotinine levels of STC statistically correlates with micronuclei of buccal mucosa cells (STC MN cells, r = 0.692, p <0.0001) in present study. This was similar to the findings of Poppel GV[22]who studied the serum cotinine levels in tobacco users. Oral carcinogenesis is a multistep process of accumulated genetic damage leading to cell dysregulation with disruption in cell-signaling,DNA repair & cell cycle events, which are fundamental to hemostasis. MN in oral exfoliated cells is a biomarker of chromosomal damage caused by genotoxic agents from tobacco related substances[20].

Conclusion

Early detection of a premalignant or cancerous oral lesion would improve the survival to a greater extent and also will reduce the morbidity associated with the treatment to a considerable extent. There is strong correlation between urinary cotinine levels of smokeless tobacco chewers and exfoliated buccal mucosal micronuclei cells. Thus the present study elucidates the link between rise in exfoliated buccal micronuclei and determination of urinary cotinine levels, which is an importantbiomarker and is valuable measure for diagnosis of health risk.

For definitive and sound results, still larger samples should be studied for longer duration. The buccal exfoliated cells should also be collected after cessation of habit to confirm the prognostic value of MN cells and level of genotoxicity. The cause of micronuclei formation due to tobacco use, different forms tobacco products, difference in the degree and mechanism of action of smokeless variants of tobacco and also the effects of cotinine levels in relation to occurrence of MN should be studied in detailed for strategic tobacco control program.

Balanced Diet: Knowledge and Practice of Adolescents

Krupa Reji[1], Leema Jacob[1], Liby Kuriakose[1], Linsha K.[1], Maria Augustine[1], Maria George[1], Priya Reshma Aranha[2]

[1]IV Year B.Sc. Students, Yenepoya Nursing College, Yenepoya (Deemed to be University), Deralakatte, Mangaluru, [2]Assistant Professor, Department of Child Health Nursing, Yenepoya Nursing College

Abstract

Background: Adolescence is a stage of transition and psychological development. This period needs a well balanced diet for their better growth and development. Adequate knowledge regarding balanced diet may enhance the practice of adolescents regarding balanced diet.

Aim: The aim of the study was to determine the knowledge and practice regarding balanced diet among adolescents, to find the correlation between knowledge and practice and to find the association between knowledge, practice scores and the selected demographic variables.

Material and Method: Quantitative research approach and descriptive survey design was used for the study. The study was conducted in selected urban schools. Using non probability purposive sampling technique, 100 adolescents between the age group of 10- 17 years were selected as study sample. The structured knowledge and practice questionnaire on balanced diet was used to assess the knowledge and practice regarding balanced diet. Data was analysed using descriptive and inferential statistics.

Result: Study findings revealed that 4% of study samples had inadequate knowledge, 64% of study samples had adequate knowledge and other 32% of study samples had good knowledge on balanced diet. 2% of study samples had poor practice and other 98% of study samples had good practice regarding balanced diet. There found a significant positive correlation ($r=0.52$) between knowledge and practice scores. Also it showed a significant association between knowledge scores and selected demographic variables ($p<0.05$).

Conclusion: It was concluded that the adolescents have good knowledge and practice on balanced diet.

Keywords: *Knowledge, practice, adolescents, balanced diet.*

Introduction

According to WHO, adolescence is a period between the age of 10 to 19 years. Adolescents constitute 18 to 25% of the population in member countries of South East Asia Region. Adolescent is a period of accelerated physical growth, social and psychological maturity, sexual maturity, experimentation, development of adult mental process[1] but in this period, a high levels of stress and anxiety develops in each adolescents. Adolescence is also a time of busy schedule. The high stress in some adolescents, may be related to eating disorders as well[2]. It is estimated that during adolescence period, they gain 25% of adult height, 50% of adult weight and 40% of adult bone mass[3].

During adolescence the rate of physical growth actually increases. This sudden growth is associated with hormonal, cognitive and emotional changes that make adolescence an especially vulnerable period of life. There is a greater demand for calories and nutrients. At the same time, adolescence is a time of changing lifestyles and food habits which can affect the intake and nutrition of adolescents. It is also seen that adolescents

strive for individuation, that means more opportunity to assert food choices and expand or narrow healthy options. Studies have revealed that despite possessing considerable food knowledge, many adolescents find it difficult to follow healthy eating recommendations and often consume food that they think is healthy.[4] Adolescence is a nutritionally vulnerable time period. Poor eating habits formed during adolescence period can lead to obesity and diet-related disease in later years. In addition, the high incidence of dieting behaviours can contribute to nutritional inadequacies and to the development of eating disorders.[5] Food choice patterns established during youth may likely influence long-term behaviour[6] Nutrition issues may also arise due to the intake fast food, snack choices, sport nutrition and overweight. Adolescents are not aware of the potential health risks associated with poor habits[7].

It is reported that 49% of adolescent girls (15 years of age) are under height and 67% are underweight.[8] The prevalence of overweight in girls was 24%, obesity 13% and underweight was 14%. The prevalence of anaemia [Hb<12gm/dl] was 29%.[9]In a study it was observed that majority of subjects, i.e., 83.3% were in the habit of skipping at least one meal daily.[10] In another study it was also seen that majority of the study participants had regular meals (72%) and breakfast (80.8%). 46.8% consumed fruits less than 3 times per week, 58% had fried food twice or more per week and 40.5% consumed less than 2 litre of water a day.[11]

Balanced diet helps adolescents to maintain good health and to promote growth and development. Adequate knowledge on balanced diet would improve the practices of adolescents regarding consumption of balanced diet. Hence the researchers were interested to assess the knowledge and practice regarding balanced diet among adolescents.

Materials and Method

Quantitative research approach with descriptive survey design was used for the study. The study was conducted in selected schools at Mangaluru. The sample comprised of 100 adolescents between the age group of 10-17 years. Non probability purposive sampling technique was used to select the sample. Ethical principles followed during data collection as in the guidelines of institutional ethics committee. The tool used for data collection were structured knowledge questionnaire (reliability was 0.8) and practice questionnaire (reliability was 0.7). The baseline characteristics of adolescents including dietary behaviours were collected. There were 25 questions for knowledge on balanced diet, 20 questions on balanced diet practice which was a five point rating scale. The data was analyzed by using descriptive and inferential statistics.

Findings: The study results showed that majority (30%) of the sample belonged to the age group of 10-11 years, majority (56%) were females, majority (44%) were studying in 5- 7 standard,majority, 87% are living in nuclear family, majority (84%) of adolescents were Muslim by religion, majority (20%) had family income greater than Rs. 40,000/ per month, Majority (79%) of adolescents were day scholar, majority(86%) were residing in urban area, majority (63%) were receiving pocket money, majority (82%) received information regarding balanced diet, 40% of adolescents received information from school teachers.

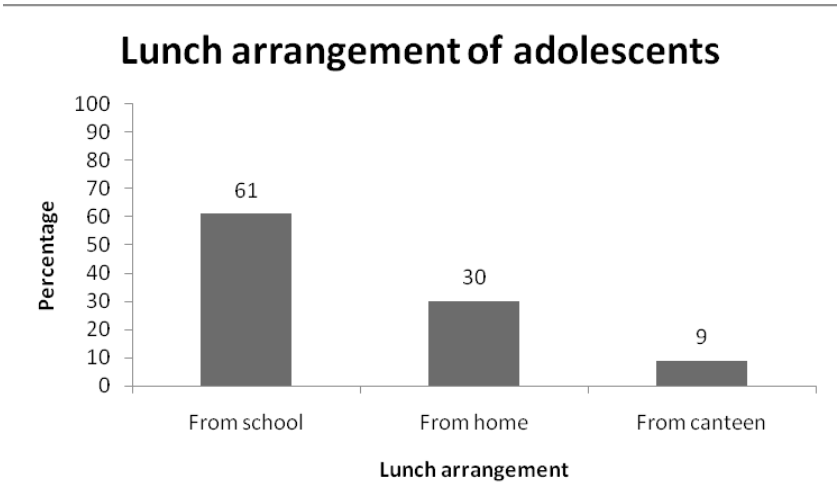

Fig 1: Bar diagram showing the lunch arrangement for adolescents

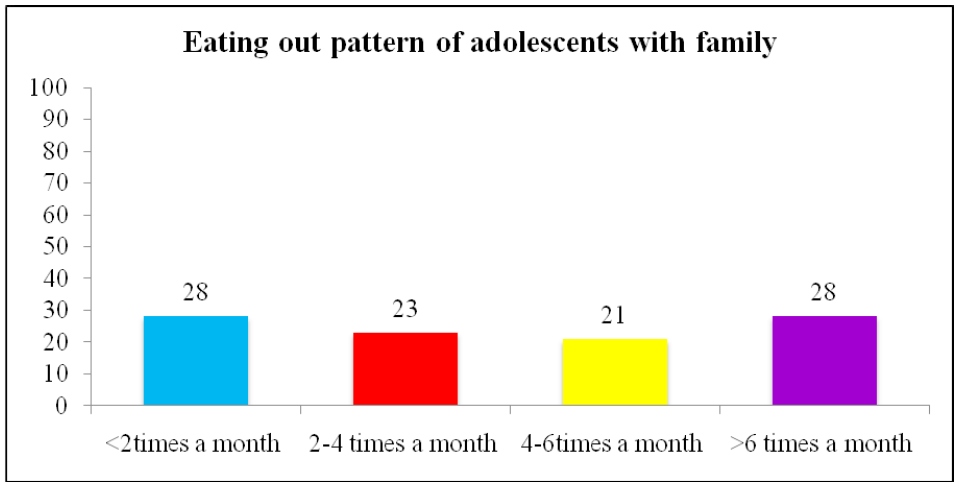

Fig 2: Bar diagram showing the eating out pattern with family

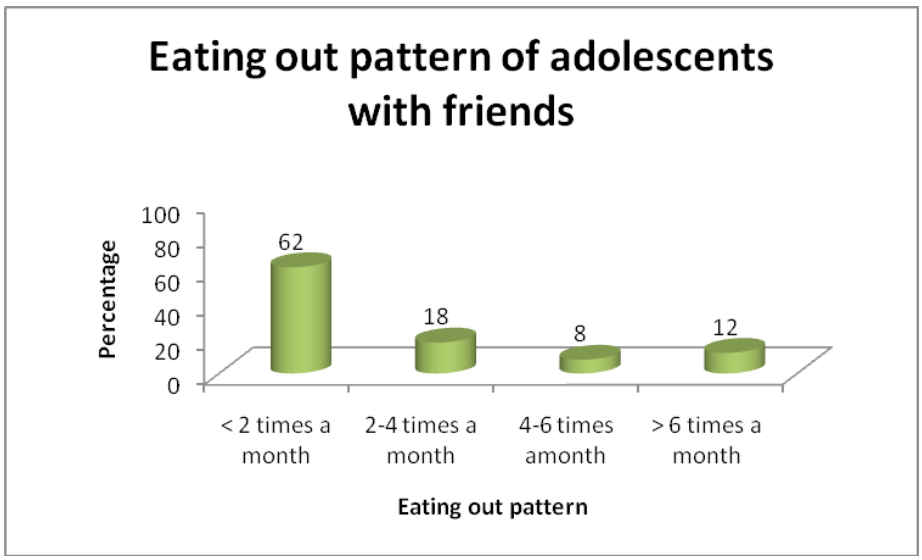

Fig 3: Bar diagram showing the eating out pattern with friends

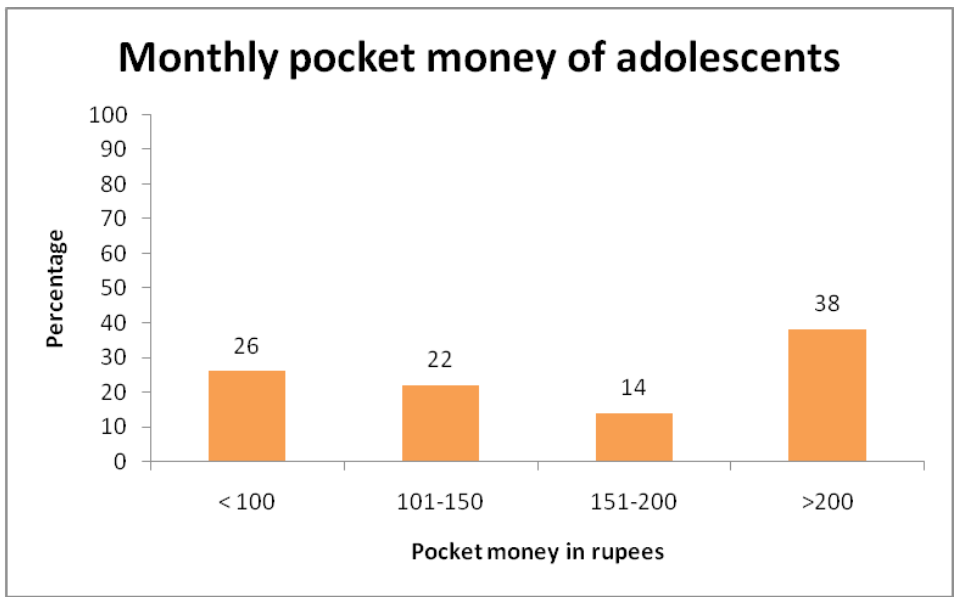

Fig 4: Bar diagram showing the pocket money amount of adolescents per month

Table 1: Frequency and percentage distribution of adolescents according to the arbitrary grading of their knowledge scores n=100

Sl. No.	Knowledge score	Arbitrary Grading	Percentage
1	≤8	Inadequate knowledge	4
2	9-16	Adequate knowledge	64
3	17-25	Good knowledge	32

The data in table 1 shows that 4% of study samples had inadequate knowledge, 64% of study samples had adequate knowledge and other 32% of study samples had good knowledge on balanced diet.

Table 2: Frequency and percentage distribution of adolescents according to the arbitrary grading of their practice scores n=100

Sl. No.	Practice score	Arbitrary Grading	Percentage
1	≤ 40	Poor practice	2
2	>40	Good practice	98

The data in table 2 shows that 2% of study samples had poor practice and other 98% of study samples had good practice regarding balanced diet.

Regarding the practice of balanced diet, it was seen that majority (74%) of the adolescents agreed that they consume breakfast every day. Majority (35%) argued that they never skip meals. Majority (37%) consumed vitamin supplements 4 days a week and 37% consumed mineral supplements every day. Majority (56%) of the adolescents verbalized that they eat three base meals every day. Majority (61%) verbalized that they drink at least 8 glasses of water daily. Majority (52%) argued that they take carbonated beverages 1–2 days a week. 50% said that they do not record what they eat. Adolescents also reported that their daily diet contains breads / cereals / pasta / potatoes / rice daily (74%), fruits such as apples, bananas, oranges etc (82%), vegetable of any kind (64%), dairy products (75%). It was also seen that majority (32%) consume jams, cookies, candies or other sweets daily, majority (34%)snack on foods like potato chips, cakes, etc 3–4 days a week,majority (36%) snack on fruit salads 3–4 days per week, majority (44%) eat fast foods like pizza, sandwich etc. 1–2 days a week, majority (27%) seek out nutrition information every day in the newspaper, TV, school etc. Majority (36%) of adolescents verbalized that they get knowledge on food habits from parents/teachers, majority (29%) have the habit of eating food while seeing TV/mobile phone/ computer every day.

The study showed that there is a significant positive correlation between knowledge and practice scores of adolescents regarding balanced diet,($r = 0.52$). It was also seen that there is a significant association between knowledge score and grade studying in ($\chi^2 = 51.64$, $p<0.05$), knowledge score and area of residence ($\chi^2 = 117.473$, $p<0.05$), knowledge score and lunch arrangement ($\chi^2 = 65.716$, $p<0.05$). It was seen that there is no significant association between practice score and the selected demographic variables ($p>0.05$) .

Discussion

The current study was conducted among the adolescents studying in urban area. It showed that majority (64%) of study samples had adequate knowledge on balanced diet. These findings are in line with a study[11] which showed that 59%of adolescents had quite good knowledge about balanced diet. It was also supported by a study which was conducted on nutrition knowledge, attitude and practice of college students which showed that there was significant difference in nutrition knowledge, attitude and practice score ($p<0.05$).[9] But another study contradicted the present study findings where 41% of the subjects had low knowledge regarding balanced diet.[1]

In the present study 98% of sample had good practice regarding balanced diet. This finding is in line with a study[11] finding where most of adolescent girls had a well-balanced diet practices (53.5%) .Another study also has confirmed this result that the eating behaviour of women is positively correlated with nutrition knowledge[12]. However, in contrary another study[13] showed that nearly 85.6% of students aware of the concept of a balanced nutritious diet (nutritionally balanced food), but only a few (7%) applying this concept when choosing food.

Regarding the practice of balanced diet, majority (74%) of the study participants verbalized that they consume breakfast every day, majority (35%) said that they never skip meals. Other two studies showed a different result where more than a half of respondents rarely eat breakfast, only a third of the subjects have their breakfast every day, and skip breakfast was 15.5%.[11] Yet another study[14] found that 14.9% of students skipping their breakfast.

In the present study majority (56%) of the

adolescents verbalized that they eat three base meals every day. Majority (64%) consume vegetable of any kind every day and majority (82%) adolescents consume fruits every day. These findings are in line with a study[11] where more than half of the subjects were eating three times a day (54.5%), consumption of vegetables 2 times per day (48.8%) and most of the female adolescent eat fruit once a day (47.8%). Another study[15] also found that 56% of female adolescent (14-16 years) in secondary school had their meals 3 times a day and one more study[16] found that 80% of students consumed vegetables 2 times per day.

Conclusion

The present study concluded that the adolescents have good knowledge and practice on balanced diet .The school, parents and peer influence the nutritional knowledge and practice of balanced diet among adolescents. As told by the sample, the current study setting provides nutrition education to the children. Where as in the other studies it was proven that adolescents lack knowledge and practice of balanced diet. Therefore it is essential to create an awareness among the adolescents regarding the sound knowledge and practice to balanced diet and to promote their growth and development.

Acknowledgement: The authors wish to thank the authorities for permitting to conduct the study and the study participants for their whole hearted support.

Conflict of Interest: No conflict of interest.

Source of Funding: Nil

Influence of Self-Efficacy on Student Engagement of Senior Secondary School Students

Kundan Singh[1], Bilkees Abdullah[2]

[1]Assistant Professor, [2]Research Scholar, School of Education, Lovely Professional University, Phagwara Punjab

Abstract

The present study examined to investigate the influence of self-efficacy on student engagement of Senior Secondary School students. The respondents were students from senior secondary school of Jammu and Kashmir. A Sample of 400 senior Secondary School Students (200 boys and 200 girls) were selected from Jammu and Kashmir by employing simple random sampling. T-test, correlations and regression were employed to analyze the data. The study indicated that (a) there exists significant difference between senior Secondary School boys and girls with their self-efficacy (b) there exists Significant Difference Between Private and Government senior Secondary school Students with their self-efficacy (c) there exists Significant Difference Between senior Secondary School Boys And Girls with their student engagement (d) there exists significant difference between private and government senior Secondary school Students with their student engagement. It revealed that significant relationship was found between self-efficacy and student engagement of senior secondary school students. It also found the self-efficacy had significant influence on student engagement of senior Secondary School Students.

Keywords: *Self-efficacy, Student Engagement, Senior Secondary School students.*

Introduction

Self-efficacy refers to a man's conviction that they can proficiently completed at an allocated levels in a specific academic part of information. A man's trust in their ability to make, executes, and guides execution with the ultimate objective to deal with an issue or accomplish an endeavor at an appointed level of capacity and aptitude. Students who are sure about their capacity to execute, to sort out and manage with their basic reasoning or activity execution at an allocated levels of fitness is showing high self-efficacy. Self-efficacy is by and large viewed as a multidimensional develops separated over different spaces of working. Self-efficacy is grounded in principle by[1.] As per Self-Efficacy assumption, Self-Efficacy is a "person's trust in their capacity to compose and execute a given strategy to take care of an issue or achieve an assignment". As indicated by[2] self- efficacy alludes to people's feelings that they can effectively perform given errands at assigned levels. Self-efficacy is the conviction about person's assessed capacity to play out a given task. Self- Efficacy contains convictions individuals have about their capacity to achieve specific results.[3] It is noticed that self-efficacy is the certainty a man has in realizing a particular result. Self-efficacy as persons' confidence about their abilities to make appointed levels of execution that actions affect over events that impact their lives. As shown by him, it chooses how people feel, think, and conscious themselves and carry on.[4] Self- efficacy suggested proposes that Academic Self- efficacy can change in quality as a component of undertaking trouble. Two general classes of academic hope convictions have been assumed. Understanding the distinction between these two types of hope convictions is very important as people can trust that a specific conduct will deliver a specific (result desire), yet may not trust they can play out that conduct (efficacy desire)". Found that there exists a positive correlation between Mental Health of

e-mail: pujubilkees@gmail.com

senior secondary school Boys and girls with their Life Skills and Self-Efficacy.[5] Results demonstrated that self-efficacy mediated the correlation between academic performance and performance accomplishments.[6] found that higher level of academic self-efficacy is positively correlated with scholastic performance.[7]

Student Engagement: The idea of student engagement has progressively increased the consideration throughout the most recent decade.[6] It comprehensively alludes to Students' Engagement in actions that gave up to their knowledge accomplishments and their sense of belongings with their educational network. It additionally included actions other than those straightforwardly identified with course work, for example, non necessary companion learning exercises and administration exercises, for example, positions of authority in student tutoring or study group assistance. Also, engagement is how much students are engage in their learning actions and their commitment is emphatically connected to a large group of preferred results, include student satisfaction and determinations. This definition infers the utilization of three interrelated criteria to evaluate Student engagement levels namely:

Emotional Engagement: Refers to the connections among students and their teachers, schoolmates and school. This has likewise been called 'recognizable proof' with school and learning rehearses. Students are engaged in when they feel incorporated into the school and feel a passionate security with the school, its teachers and their companions.

Cognitive Engagement: It can be understand as a student's psychological importance in their own knowledge. At the point when a student is cognitively engage in, student believe, spotlight on accomplishing objectives, are stretchy in their endeavor and familiarize you to dissatisfaction. This is unique in relation to high achievement a student who is performing great may at present be disengaged whether they are wandering and not inspired to endeavor themselves more than is vital to obtain by.

Behavioral Engagement: Refers to students' involvement in classroom activities and in learning. This includes holding fast to behavior rules, leaving to exercises as necessary and reaching at classes on time. Essentially, Behavioral Engagement refers to the educational performances that are critical for high students' implementation, which may include cooperation and communication with companions. Moreover, it covers students' investment in various elements of school life, e.g., school community activity and extracurricular actions.

The present study is intended to find out how Student Engagement is related to Self-efficacy. Movements like universlization of elementary education as a fundamental right have improved the quality and quantity of school education in India. Kashmir, being a role model, has better education system as compared to other states. Self-efficacy has a significant task in influencing students' academic Success and Student engagement. Many teachers complain that student's are giving less important to their academic activities, because they were not able to cope up effectively with academic success. Improved Self-efficacy may help to increases Student engagement. In this study investigators try to find out whether Self-efficacy had any significant influence on Student engagement.

Objectives:

1. To compare the difference of self-efficacy of senior secondary school students on the based on gender.
2. To compare the difference of student engagement of senior secondary school students on based on gender.
3. To find out the relationship between self-efficacy and student engagement of senior secondary school students.
4. To find out the influence of self-efficacy on student engagement of senior secondary school students.

Hypotheses:

1. There exists no significant difference of self-efficacy of senior secondary school students on the basis of Gender.
2. There exists no significant difference of Student engagement of senior secondary school students on the basis of Gender.
3. There exists no significant relationship between Self-efficacy and Student engagement of senior secondary school students.
4. There exists no significant influence of self-efficacy on Student engagement of senior Secondary School Students.

Methodology

Descriptive Survey Method was used. Data was collected from Senior Secondary School students of Jammu & Kashmir, by employing simple Random Sampling technique. The sample consists of 400 senior secondary school Students.

Instruments:

1. Self-Efficacy Scale: this scale was developed by Bhatnagar and Mathure. Self-Efficacy is the confidence that one can successfully complete in a given circumstance. Self-Efficacy Scale plans to study the dimension of self-efficacy in any age group over 14 years. It comprises of 22 items, managing eight factors. Reliability co-efficient of the scale was estimated by test-retest and found 0.79 to 0.86.
2. Student Engagement Scale: This scale was developed by Dogan (2014) and was adopted in Indian context. The scale is a 5-point Likert Scale consisting of 22 items and 3 sub-dimensions (cognitive, emotional, and behavioral engagement). The final set of statements was check for internal consistency using SPSS-22 version. The Cronbach's alpha for the final set of statements was found out to be .765

Procedure: Initially the investigators randomly identified various secondary schools and contacted the authorities of the secondary school personally. The purpose, objectives and relevance of the study were explained to the head of the institution. Then, the tools were directed to the participant after giving necessary instructions to them. Reassurance was given to each that the information collected from them would be used only for research identity and purpose would not to be disclosed. The scoring was done as per the manual and entered the data in to a spread sheet for further Statistical Analysis by using t-test, correlation and Regression to analyze the data.

Results and Discussions

Table 1: There exists no significant difference of self-efficacy of senior secondary school students on the basis of Gender.

	Gender	N	Mean	S.D	t-value	Levels of significance
Self-efficacy	Boys	200	88.03	4.40	6.33	Significant
	Girls	200	84.91	4.96		

According to the above table reflects that the mean scores of boys and girls of senior secondary school students is 88.03 and 84.91 respectively. The S.D for boys and girls Senior Secondary School Students is 4.40 and 4.96 respectively. Further, the t-value is 6.33 which is significant at 0.05 level. So, that there exist significant difference between Senior Secondary school girls and boys in their self-efficacy.

Further it is evident from the table that mean score (88.03) of boys' Senior Secondary School Students was greater than (84.91) of girls Senior Secondary School Students. So, it can be interpreted that boys' Senior Secondary School Students had higher self-efficacy than girls' senior secondary school students.

According to the above results, it confirmed that the hypothesis no. 1, "there exists no significant difference of Self-efficacy of Senior Secondary School Students on the basis of gender" is thus rejected.

Table 2: There exists no significant difference of Student engagement of senior secondary school students on the basis of Gender.

	Gender	N	Mean	S.D	t-value	Levels of significance
Student engagement	Boys	200	90.98	4.18	7.51	Significant
	Girls	200	88.06	3.49		

According to the above table reflects that the mean scores girls and boys of Senior Secondary School Students are 90.98 and 88.06 respectively. The S.D for girls and boys Senior Secondary School Students is 4.18 and 3.49 respectively. Further, the t-value is 7.51 which are significant at 0.05 levels.. So, that there exist Significant Difference Between Senior Secondary School Girls and Boys in their Student engagement.

Further it is obvious from the table that Mean score (90.98) of Boys Senior Secondary School Students was greater than (88.06) of Girls Senior Secondary School Students. So, it can be interpreted that Boys Senior Secondary School Students had higher Student engagement than Girls Senior Secondary School Students.

According to the above results, it can be confirmed that hypotheses no 2 i.e. "there exists no significant difference of Student engagement of Senior Secondary School Students on the basis of gender" is thus rejected.

Table 3: There exists no significant relationship between self-efficacy and student engagement.

		Student Engagement	Self-efficacy
Student engagement	Pearson's Correlation	1	.316**
	(sig.2 tailed)		.000
	N	400	400
Self-efficacy	Pearson's Correlation	.316**	1
	(sig. 2 tailed)	.000	
	N	400	400

**correlation is significant at 0.01 levels of significance (2-tailed).

According to the above table it can be seen that Self-efficacy significantly correlated with Student engagement. It is observed that there exists a significant relationship between Self-efficacy and Student engagement of Senior Secondary School Students. From the above table it reflects that coefficient of correlation between Self-efficacy and Student engagement of senior secondary school students is .316 that is significant at 0.01level of significance. This indicated that there exists a significant relationship between Self-efficacy and Student engagement of Senior Secondary School Students. It also shows that Self-efficacy had significant Influence on Student engagement of Senior Secondary School Students.

Therefore hypothesis 3, namely "there exists no significant relationship between Self-efficacy and Student engagement" stands rejected.

Thus self-efficacy increased student engagement. Self-efficacy plays an essential position in determining student engagement. Students' who have possessed high self-efficacy are very much more engaged in their studies. It is same as in the case that Student engagement and that those who have high self-efficacy show more Cognitive, Behavioral and Emotional engagement. Manikandan and Neethu (2018) supported our study and found that Student engagement is significantly related to academic Stress and Self-efficacy.

There exists No Significant Influence of Self-Efficacy on Student Engagement.

Table 4: Model Summary for Regression Analysis

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.316*	.100	.098	3.899

According to Above table shows the correlation coefficient of Self-efficacy and Student engagement of adolescents. The coefficient of correlation is .316* and its square is 0.100 Regression suggests that predictive variables i.e. Self-efficacy can explain 1.0% variance of the criterion variable (Student engagement).

In Order to study the influence of self-efficacy on student engagement ANOVA has been applied on the influence of self-efficacy on student engagement.

Table 5: Summary of Anova by Regression

Model	Sum of square	Df	Mean of square	F	Sig
Regression	673.494	1	673.494	44.304	.000*
Residual	6050.203	398	15.202		
Total	6723.698	399			

According to the above table shows that the results of ANOVA of self-efficacy on student engagement. It is clear that acquired F-value is (44.304) which are statistically significant at 0.01 level of significance which shows the statistically significant Relationship Between self-efficacy and Student engagement. The predictive variable (Self-efficacy) can influence the criterion variable (Student engagement). The above findings revealed that Self-efficacy has significant influence on Student engagement. So there exists significant influence of Self-efficacy on Student engagement. Therefore, regression analysis is allowed and feasible.

Therefore hypothesis 4, namely "there exists be no significant influence of Self-efficacy on Student engagement" stands rejected.

Table 6: Summary of coefficient of regression

Model	Unstandardized Coefficient		Standardizes Coefficient	T	Sig.
	B	Std. Error	Beta		
(Constant)	66.734	3.422	.316	19.503**	.000
Self-efficacy	.263	.040		6.656*	.000

According the above table with B=.263 and t=6.656 which is significant at 0.05 level of significance. It implies that Self-efficacy plays an important role in predicting Student engagement. So, it can be revealed that Self-efficacy had significant Influence on Student engagement. The regression equation for predicting student engagement by the predictor variable i.e. Self-efficacy. Therefore, the regression equation formulated from these two variables is given below:

Student engagement = 66.734 + .263× Self-efficacy

Conclusions

The study presented the following conclusions:

- Based on the result analysis it found that there exist significant difference between senior secondary school Boys' and Girls'in their self-efficacy. Boys of senior secondary school students had higher self-efficacy than girls of Senior Secondary School Students.
- There exist significant Difference Between Private and Government senior secondary school students in their Self-efficacy. Government Senior Secondary School Students had higher Self-efficacy than Private senior secondary school Students.
- There exists Significant Difference Between Senior secondary school Girls and Boys in their Student engagement. Boys had higher Student engagement than Girls.
- There exists significant difference between in Student engagement among Seniorsecondary school students on the basis of Type of School. Government Senior Secondary School Students had higher than Private Senior Secondary School Students.
- Self-efficacy had significant Influence on Student engagement. There exists significant influence of Self-efficacy on student engagement.
- There exists a Significant relationship between self-efficacy and Student engagement of Senior secondary school students. It also shows that Self-efficacy had significant Influence on Student engagement of Senior Secondary School Students.

Implications of the study: The findings revealed that self-efficacy is significantly correlated with Student engagement; this also has some suggestion. Since self-

Efficacy alludes to an individuals' opinion of their capability to arrange and achieve the plan of activity essential to bring about prearranged sorts of engagement and worried about the estimation of what one can achieve with the aptitudes one presently achieves. It suggests that students who are Self-efficacious will in general produce and test elective strategies of activities when they don't at first make progress. This implies that students ought to be positive to create, have or develop efficacy disposition. This is essential in light of the fact that it could fill up in as a defense that may support the students up regardless of their experience to be engaged. If students are given tasks that are challenging but not too difficult and they experience success upon completion of these tasks that Self-efficacy to learn may increase. As Self-efficacy to learn increases, so will interest, value, and utility. A strategy such as this one would be very useful for teachers to implement. Teachers can organize and design their instructions to have a constructive result on students' self-efficacy to learn which would lead to improved Student engagement and improved learning.

Declaration of Conflict of Interests: The author(s) declared no potential conflicts of interests with respect to the research, authorship, and/or publication of this paper.

Ethical clearance: All procedures performed in this paper were in accordance with the ethical standards of the institution and the national research committee.

Funding: The author(s) received no financial support of the research, authorship, and /or publication of this paper.

Psychological Effects of Trauma to Anterior Teeth

Lakshmi Nidhi Rao[1], Aditya Shetty[2], Mithra N. Hedge[3]

[1]Lecturer, [2]Additional Professor, [3]Vice Principal and Head of the Department, Department of Conservative Dentistry and Endodontics, A.B. Shetty Memorial Institute of Dental Sciences, Nitte Deemed to be University, Deralakatte, Karnataka State, India

Abstract

Dental trauma has a very distressing experience on physical, emotional and psychological aspects of the patient. The aim of the study was to determine the psychological effects of anterior dental trauma on patients.

A questionnaire study was carried out to know the psychological aspects of trauma to anterior teeth based on the Oral Health Impact Profile (OHIP-14) index. It is regarded as the most comprehensive tool for measuring Oral Health Related Quality of Life. This study concentrated only on psychological discomfort and psychological disability. Each item was scored on a five-point scale ranging from "never" (coded 0) to "very often" (coded 4).

The statistical significance of the scores thus obtained and the mean levels of the severity scores between genders and age groups were calculated using the statistical chi-square test. In our study psychological effects to anterior teeth trauma was most observed in the age group of 18-25. Interestingly when the observation was monitored across genders, we observed large psychological effect in females when compared to male gender.

Keywords: *Anterior dental trauma, psychological effects, OHIP index.*

Introduction

Health is described "a complete state of physical, mental, and social well-being of an individual and not just mere absence of disease" (WHO, 1948). This concept of health embraces the bio-psychosocial model of health into which physical functioning, symptoms, emotional and social well-being are holistically incorporated (Kleinman, 1988). Hence health related researchers have rightly focused on health as a multi-dimensional construct.[1]

Oral Health Related Quality of Life (OHRQoL) forms an integral part of general health and well-being and is recognized by the WHO as an important segment of the Global Oral Health Program (WHO, 2003).[2] It is imperative to evaluate the extent to which the oral diseases impacts on ones normal functioning and psychology.[3]

In the field of dentistry, OHRQo Laddress four dimensions: pain and discomfort; functional aspects concerning the ability to chew and swallow food without difficulty, speaking and pronunciation; appearance and self-esteem; and social aspects reflecting social interaction with others.[4]

So it is fair to qualify that oral health affects various aspects of social life, including social interaction, self-esteem, school and job related performance, specifically when the issues related to anterior dental trauma are involved. Incidents arising from physical fight, traffic accident and sporting injuries contributes the major cause of anterior dental trauma. [5]

Dental trauma is usually a pain filled experience for most people which can impair oro-facial function, negatively affecting growth, aesthetics and occlusion.[6] Unlike a chronic condition, severe dental trauma causes immediate and unexpected pain. The obvious economic cost apart, it can trigger a series of socio-economic consequences affecting the quality of life and possibly lead to the absence from college or work, disturbances during sleep and changes in the normal daily schedule. This could be further compounded by the stress patients may experience as a result of unhelpful behaviour by their peers, society and family members. The impact is quite significant when anterior dental trauma is involved, which is what this study tries to document via Oral Health Impact Profile (OHIP-14) survey.

Since anterior dental trauma is often caused by accidents that cause life-threatening injuries, limb fractures or concussion, emergency care prioritizes on more important issues. As a consequence of this delay, sometimes it becomes impossible to provide timely treatment that would have otherwise allowed the affected front tooth to be saved.[7]

Dental trauma frequently affects the upper central incisors, most likely because of their position in the mouth and also having less of a protection in comparison with the other teeth. Consequently the position and appearance of the anterior teeth have very important psychological and social impacts on the quality of life of the patient. When injuries to incisors produce pain, poor aesthetics/disfigurement or other psychological effects, patient may avoid smiling or laughing and this can affect their social relationships. So overall this has a very distressing experience on physical, emotional, and psychological levels of the patient which is a matter of great concern.[8,9,10]

OHIP-14 index assesses seven dimensions of impacts of oral conditions on one's quality of life including functional limitation, physical pain, psychological discomfort, physical disability, psychological disability, social disability and handicap.[11] This is widely regarded as the most comprehensive assessment for measuring OHRQoL.

The aim of the study was to determine the psychological effects of anterior dental trauma on patients and to assess the impact of these injuries on the quality of life based on OHIP-14 index.

Materials and Method

The study was conducted in the Department of Conservative Dentistry & Endodontics, AB SMIDS, Karnataka, India. Ethical clearance was obtained from Nitte (Deemed to be University), Cert.No: ABSM/EC07/2019.

The total numbers of subjects were 256 based on approximately 20% incidence of anterior tooth fractures. Patients in the age group of 18 and above with anterior tooth trauma were included in the study. Participation was voluntary, anonymous and started off with patients consent.

Study was carried out to know the psychological aspects of trauma to anterior teeth based on the OHIP-14 index, specifically w.r.t psychological discomfort and disability. Each item was scored on a five-point scale ranging from "never" (coded 0) to "very often" (coded 4).[1,2,10,12]

Findings:

1. Gender comparison

Table 1: Psychological discomfort scores

The OHIP-14 data were captured and details were entered into SPSS tool (v.16; IBM Corp, Somers, NY) for further analysis. The dependent variables were based on the responses to the OHIP-14 were made on a five-point ordinal scale ranging from ‘‘never’’ coded as ‘‘0’’, ‘‘hardly ever’’ coded ‘‘1’’, ‘‘occasionally’’ coded ‘‘2’’, ‘‘fairly often’’ coded ‘‘3’’, to ‘‘very often’’ coded ‘‘4’’. The statistical significance of the scores and the mean levels of the severity scores between genders and age groups were calculated using the statistical chi-square test.

Above Tablescaptures the percentage distribution of patients responses across the two dimensions namely psychological discomfort and psychological disabilityfor

the scale ranging from "never" to "very often" (p=0.001).

In Table-1, which is related to psychological discomfort scores related to breakdown w.r.t gender, around 70.9% of the male individuals experienced "occasional" psychological discomfort compared to 76.5% impact of "fairly often" in females (p=0.001).

In Table-2, which is related to psychological disability scores related to breakdown w.r.t gender, around 81% of the male individuals experienced "hardly ever" psychological disability compared to 52% impact of "occasional" in females (p=0.001).

In Table-3, which is related to psychological discomfort scores related to breakdown w.r.t age, around 48.8% of the individuals experienced the impacts of "fairly often". Largest contribution to this came from the age group of 18-25 with 90 individuals out of 138(65.2%) experiencing this impact (p=0.001).

In Table-4,which is related to psychological disability scores related to breakdown w.r.t age, around 46.4% of the individuals experienced the impacts of "fairly often". Largest contribution to this came from the age group of 18-25 with 88 individuals out of 138 (63.8%) experiencing this impact (p=0.001).

Age group 18-25 showed higher scores in the psychological disability and discomfort dimension. The comparison across genders showcased a similar significantly higher uptick for women in the psychological dimensions.

Discussion

Psychological trauma occurs as a consequence of an overwhelming amount of stress experienced that exceeds one's ability to cope or integrate the emotions involved with that experience. Effects of the trauma varies according to one's subjective experiences. So, not all who experience a traumatic event will become traumatized psychologically.

Traumatic injuries constitute painful and distressing event with multilevel consequences for patient and their families. Despite being confined in a small body region as is the oral cavity, dental trauma constitutes a relatively common finding in population-based studies. Andersson noted that although the oral region comprises 1 percent of the total body area, oral injuries account for almost 5 percent of all injuries and for a higher proportion among early adults.

Among these anterior dental trauma forms an important and visible part of human anatomy. These are characterized as major public health problems due to their high prevalence and serious aesthetic and functional consequences. Such trauma can significantly disrupt patients' normal functioning and impact dramatically on the quality of life.

Since anterior dental trauma is often caused by accidents that cause life-threatening injuries, limb fractures or concussion, emergency care prioritizes initially on more critical issues. As a consequence of this delay, sometimes it becomes impossible to provide timely treatment that would have otherwise allowed the affected front tooth to be saved.[8]

The psychological and social impact of dental trauma is widely recognized as having consequences that can affect emotional balance, social contact and also well-being of the patient. There is an evidence of increasing necessity to use indices for measuring the impact of oral health on the quality of life. OHIP-14 index has been the flag bearer in this regard and is thus used for this study.

OHIP-14 index is used to measure patient's perceptions of the social impact of oral disorders on their general well-being. It provides a comprehensive system of measurement for dimensions related to discomfort, self-reported dysfunction and related disability arising from oral conditions.[12]

According to Lockeret al., OHIP-14 is a patient-centred assessment. It gives a greater weight to behavioural and psychological outcomes and is found to be better at detecting psychosocial impacts among individuals. Hence it also satisfies the main criteria for the measurement of OHRQoL.

The study outcome capturedin above set of tables show cases the percentage distribution of responses across age and gender respectively for the two psychological dimensions for category scale ranging from ''never'' to ''very often'' as captured in the OHIP-14 index. The purpose of this paper was to review the impact of anterior dental trauma on psychological discomfort and psychological disability attributes across various age categories and gender respectively.

Psychological effects dimension based on agecriteria: When this psychological effect dimension was reviewed based on age criteria, it was observed that lowest measured age group of 18-25 had the most

psychological impact at 65.2% with the issue tapering down with age.

The younger age group with little maturity has higher psychological impact than the older more mature groups post 25 years of age. Severity of the issue could be higher among lower age groups, since usually nature of accidents occurs from sports or accidents involving rash driving of youngsters.

Psychological impacts of dental trauma for this age group may be severe so aesthetic considerations should not be neglected. It is found to be one of the important considerations of the age group 18-25. Usually dental conditions are the most severe among health issues in early stages of adulthood, however as one age, other health considerations dominate including life threatening ones. It is quite likely as a result of this, older age groups manage the situation in a better way resulting in reduction of psychological discomfort as compared to younger generation.

Equally important is the fact that younger age group usually is just about starting to become independent financially. Hence this is a in-between phase wherein they are largely still reliant on the family for financial support. As a result may neglect the dental treatment at the appropriate time and the effects become severe later on.

Psychological effects dimension based on gender: Interestingly when the observation is monitored across gender, we observe large discomfort in females in comparison with male gender.

Aesthetic dimension forms akey part for female gender, considerations encompass:

1. Beauty affected hence social impact
2. Societal pressureof friends, family, peers and social media like Facebook, Instagram etc.

It is quite likely this impact would be a lot lower among lower income groups as day to day survival is more important compared to other factors.

There are general attributes which adds to the psychological impact and which usually cuts across gender and ages:

1. Affect by presence of blood and visible nature of the dental trauma.
2. Loss of "hours of schooling/work" with economic consequences. Being able to take time from school/work for these procedures might become cumbersome if the dental clinics are not located at comfortable points.
3. Perception of work peers, friends and family members.

Additionally visit to dental emergency can trigger dental anxiety/fear responses among first time visitors. Hence calming effect of dental surgeon, explanation of the procedures in an easy way and anon-hospital like environment goes a long way in helping the patient settle down and reduce the psychological impact.

The data presented in this study provide a insight into patients' feelings and should be considered essential when evaluating further treatment options. In addition to the prognosis and outcomes, clinicians should consider patients' preferences and perceptions as well as the influence each therapy may have on their quality of life both short-term and long-term.

Health psychologists have recognized that behavioural assets such as resilience, social connectedness and optimism have a direct correlation with an individual's quality of life and howwell one is able to cope with health conditions.[1]

Conclusion

In our study psychological discomfort to anterior teeth trauma was most observed in the age group of 18-25. Interestingly when the observation is monitored across genders, we observe large discomfort in females in comparison with male gender.

The study covered suburban areas of Dakshina Kannada district, further studies need to be carried out for a larger population set. Irrespective of age and gender, psychological impact if not handled appropriately could have a life-long impact and affect the general well-being of the patient.

This study will help to create need based and critical psychological adjunct services which can be incorporated into various community-based projects, with the basic idea of integrating dental health with overall well-being and quality of life of the patient.

Communication and positive reinforcement method is most effective way in reducing the psychological impact and should be considered a valuable investment.

This is aptly highlighted by Andersson in his editorial: "empathy for our trauma patients is the common denominator."It helps to build a trusting relationship and plays a key role in relieving the distress experienced by the patient.

Effect of Aerobic Exercises on Selected Physiological Variables among College Long Distance Men Athletes

M. Senthil Kumar[1], P.R. Nagaraj[2], Ampili[3]

[1]Asst. Professor, [2]M.Phil. Scholar, Dept. of Physical Education and Sports Sciences, Srmist, Kattankulathur, [3]Ph.D. Research Scholar, Dept. of Physical Education, Annamalai University

Abstract

The study aims to evaluate the effect of aerobic exercises on selected physiological variables among college long distance men athletes on systolic blood pressure and diastolic resting heart rate. Thirty (N=30) college men, long distance runners who is selected St. Joseph's Prime Sports Academy Chennai Tamilnadu who have been participating in inter collegiate athletics meet was randomly selected as subjects. The age limit is from of old 18 to 25 years respectively Subjects. Subjects who selected were randomly II team groups each 15. Has been under taken as Group I with aerobic exercises acted as experimental group and Group II acted as the Control group.. The duration of the practice period was restricted to twelve weeks of aerobic practice. The pre-test on the chosen criterion variables was taken prior to the administration of the aerobic exercises and the post-test was taken at the end of the twelfth week. The data obtained from the groups prior to and immediately after the training on the chosen criterion variables were analyzed statistically using the t- test to determine whether the groups differ significantly among the pre and post test means. The confidence level was maintained at 0.05 in all the cases to evaluate the hypothesis. The training effects of aerobic practices evidenced significant influence over the physiological variables of college level long distance men athletes.

Keywords: *Aerobic exercises Physiological variables, Systolic blood pressure, Diastolic resting heart rate.*

Introduction

Training with actual effect depends upon various factors such as training loads, means of recovery, assessment of load and performance capacity, sports equipment, nutrition, psychological characteristics and method adopted for imparting theoretical instruction. Physical Education and Sports is a thirsty area which needs many kinds of training means and method to improve the overall performance of the sportsperson.[1] To improve the sports performance the athlete needs to take part in systematic training by the way of scientific method of training. Actual effect of training depends upon several factors such as training loads, means of recovery, assessment of load and performance capacity, sports equipment, nutrition, psychological characteristics and method adopted for imparting theoretical instruction.[2] Physical Education and Sports is a thirsty area which needs many kinds of training means and method to improve the overall performance of the sportsperson. To improve the sports performance the athlete needs to take part in systematic training by the way of scientific method of training.[3]

Importance of training: An individual is said to be physically fit, when he is completely healthy. At long last, it involves time and inspiration to proceed when the tip top competitor needs to dedicate a few hours per day to preparing. Endurance Training, continuance is the capacity to take part in action for quite a while without exhaustion.[4] Perseverance is produced through all medium and physical organs and frameworks. Continuance is ability to keep up a high caliber of work despite weakness. Every athletic ability and occasions expect continuance to some degree; anyway the vitality prerequisites of amazingly concise aptitudes, for example, a solitary punch are typically met effortlessly.[5] Aerobic exercise at a drawn out and moderate power enhances vigorous limits.

Aerobic Exercises: High-impact importance with oxygen is on focus for healthy body. Indeed, even so the elements of the thought are more convoluted than inferred by the definition. High-impact can be seen as a

mind boggling arrangement of real free market activity. That is the body needs vitality for any sort of action and the need is filled by consuming 10 off the sustenance that eat. Oxygen is the start the fuel needs to consume although heart stimulating exercise is the word as a rule use.[6]

Health benefits: The physiological benefits are highly significant where stable autonomic nervous system equilibrium, with a tendency toward parasympathetic nervous system dominance rather than the usual stress– induced sympathetic nervous system dominance, pulse rate, respiratory rate and blood pressure decrease, cardiovascular efficiency increases, respiratory efficiency increases (respiratory amplitude and smoothness increase, tidal volume increases, vital capacity increases, breath–holding time increases), endurance and energy level increases, weight normalizes, sleep improves, immunity and pain decreases.

Statement of the problem: The research aims to evaluate the effect of aerobic exercises on selected physiological variables among college long distance men athletes on systolic blood pressure and diastolic resting heart rate.

Methodology

This procedures and method applied in the selection of subjects, selection of variables, selection of tests, competency of the tester, reliability of the instruments, reliability, orientation to the subjects, validity of the questionnaires, procedure of scoring, pilot study, practice programmed, collection of data, administration of tests, experimental design and statistical technique were presented. The purpose of this study was to find out the effects of aerobic exercises on selected physical and physiological variables of college long distance of runners. Thirty (N=30) college men, long distance runners who is selected St. Joseph's Prime Sports Academy Chennai Tamilnadu who have been participating in inter collegiate athletics meet was randomly selected as subjects. The age limit is from of old 18 to 25 years respectively Subjects.

Subjects who selected were randomly II team groups each 15. Has been under taken as Group I with aerobic exercises acted as experimental group and Group II acted as the Control group.. The duration of the practice period was restricted to twelve weeks of aerobic practice. A written consent has also been obtained from the subjects. However, they can withdraw their consent in case they felt any discomfort during the period of their participation. These are the dropouts in this study. The same Exercise will be followed, and intensity, is increased week by week, for 6 week, weekly three days Monday, Wednesday, and Friday .Before exercise warm–up 10 Min, after exercise warm down 5 min, subjects were followed.

Statistical Analysis: The above study or project pays attention mainly on the testing between means from two treatment groups and also deals with the increase of means between each group from base line to the post treatment for various measures. The statistical was tool used for those which are the individualized effect that are analyzed aerobic exercises ratio. The pre and post practice performance of the groups is analyzed with 't' ratio the level of significance is 0.05 level of confidence.

Results and Interpretations

Table I: Analysis of t ratio on selected physiological variables

Variables	Scores		Control Group	Experimental Group
DBP	Pre test	Mean	78.07	77.73
		SD	2.53	3.09
	Post test	Mean	75.47	73.80
		SD	3.13	2.99
	t value		2.05	7.34*
SBP	Pre test	Mean	122.30	121.07
		SD	3.61	5.77
	Post test	Mean	116.43	111.17
		SD	3.51	3.92
	t value		2.07	7.76*

Table I indicates that experiment and control group's resting diastolic blood pressure (DBP) Mean and Standard deviation of long distance runners. The experimental group Pre and Posttest mean values are 77.73 and 73.80 and standard deviation values are 3.09 and 2.99 and obtained 't value 7.34* greater 2.0 of 14 also with control group mean value are 78.07 and 75.47 and standard devotion are 2.53 and 3.13. The result of 't' value 2.05 which is lesser than table value 2.05. It showed significant improvement on DBP aerobic training on long distance runners.

Table I indicates that experiment and control group's resting systolic blood pressure (SBP) Mean and Standard deviation of long distance runners. The experimental group pre and Posttest mean values are 121.07 and 111.17 and standard deviation values are 5.77 and 3.92 and obtained 't' value 7.76* which are greater than table value of 2.05 with df of 14 also with control group mean value are 78.07 and 75.47 and standard devotion are 2.53 and 3.13. The result of 't' value 2.07 which is lesser than table value 2.05. The findings of the study indicate that experimental group showed significant improvement on SBP aerobic training on long distance runners. The mean difference pre and posttest on physiological variables are presented in figure-I.

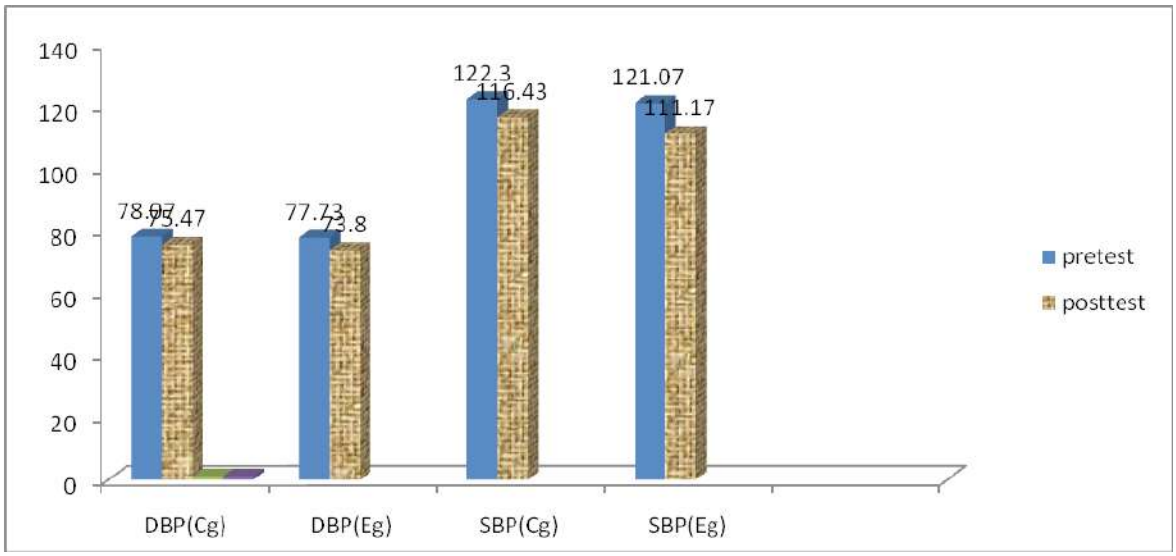

Figure I: Bar diagram shows mean values of pre and post-test of experimental group and control group on physiological variables

Discussion on Findings

The results of SBP shows that the obtained' ratio of experimental group is 7.76 which are greater than required table value of 2.05 with 0.05 level of confidence. It also shows that there was a significant improvement on their SBP of this experimental group. Hence this hypothesis was accepted.

The results of DBP shows that the obtained 't' ratio of experimental group is 7.34 which are greater than required table value of 2.05 with 0.05 level of confidence. It also shows that there was a significant improvement on their DBP of this experimental group. Hence this hypothesis was accepted.

Conclusions

1. There was a significant improvement on systolic blood pressure of the subjects who underwent twelve weeks of aerobic training.
2. There was a significant improvement on diastolic blood pressure of the subjects who underwent twelve weeks of aerobic training.

A Descriptive Study to Assess the Knowledge on Pre-Menopausal Symptoms among Middle Aged Women in a Selected Village at Kanchipuram District, Tamilnadu, India

M. Deepan Babu[1], S.Vasuki[1], K.Sangeetha[1], D. Joaniepriya[2]

1IIIrd Year B.Sc.(N) Student, [2]Asst. Professor-Guide, Chettinad College of Nursing, Rajiv Gandhi Salai, Kelambakkam, Kancheepuram, District Tamil Nadu, India

Abstract

A descriptive study to assess the knowledge on pre-menopausal symptoms among middle aged women in a selected village at Kanchipuram district, Tamil Nadu, India. The objectives are to assess the knowledge of premenopausal symptoms among middle aged women in a selected village at Kanchipuram district, Tamil Nadu, India. To find out the association between level of knowledge with demographic variables. The convenience sampling technique was used to select 109 samples. Validity and reliability data collection tools were established. The data were collected by self-administered questionnaires. The collected data were tabulated and analyzed. Descriptive and inferential statistics were used. The study shows that 0% of the women had adequate knowledge, 15% of the women had moderate knowledge, and 94% of the women had inadequate knowledge regarding pre-menopausal symptoms.

Keywords: *Knowledge, Pre-menopausal symptoms, Middle aged women.*

Introduction

Background of the Study:

"Menopause is just puberty's evil older sister"

Menopause is the permanent end of menstruation and fertility defined as occurring 12 months after the last menstrual period. Menopause is natural biological process, not a medical illness. Even so the physical and emotional symptoms of menopause can disrupt your sleep, say your energy and at least indirectly trigger of sadness and loss. Most women being menopause between the ages of 45 and 60. Early menopause usually refers to onset before age 40[1].

Menopause the time when a women stops having menstrual periods, is not a disease or an illness it is a transmission between two phases of a women life. Menopause is the time in a female life when she gets a formal, official signal from her body that she is getting older. This is the time when her menstruation is on the verge of a complete die down. The hot flashes, irritation, mood swings, insomnia, fatigue etc some symptoms of menopause, and there are many more. These symptoms can be unpleasant and tedious to manage[2].

Many women experience a variety of symptoms as a result of the hormonal changes associated with the transition through menopause .around the time of menopause, women often lose bone density and their blood cholesterol levels may worsen, increasing their risk of heart disease[3].

According to National Institute on Aging (2010) usually menopause happens naturally, but some women develop symptoms of menopause and stop having menstrual cycles much earlier than expected. Before age 40, a menopause-like condition can happen for no known reason, or it can be caused by radiation treatment, some medicines like those used in chemotherapy, an autoimmunity (some of a women's own body

cells attacking herovary or ovaries),or genetic errors. Radiation can make the ovaries stops workings, as can some treatments likechemotherapy for cancer.[4]

Research Methodology

A Quantitative approach with descriptive design was used in the study. The study was conducted among middle aged women at selected village, Kanchipuram District, Tamil Nadu, India. A purposive sampling technique was used to select 149 samples with the following inclusion criteria. Pre-menopausal women who are willing to participate in the study, the women who are under the age group of (45-60)years and who could speak English and Tamil.

Tool for the Study: Self-structured questionnaire used to elicit the demographic variables and to assess the knowledge on pre-menopausal symptoms among middle aged women.

Scoring and Interpretation:

Scoring	Level of Knowledge
Above 75%	Adequate Knowledge
51-75%	Moderated Knowledge
Below 50%	Inadequate Knowledge

Study Findings: The majoriy (36%) of the women were under the age group of 31-40 years, (78.9%) of the women had attained menarche at the age of 11-15 years, (47.7%) of the women have 2 children, (90.8%) of women does not have menstrual irregularity, (51.3%) of women living in nuclear family, (72%) of the women taking mixed diet, (100%) of the women living in the village, (66%) of the women had married at the age of 21-25 years, (43.1%) 0f the women were unemployed, (54%) of the women had monthly income of Rs.5,000-10,000.

The Chi-square association revealed there was no significant association between demographic variables in related with the knowledge aspects of middle aged women with aspects of knowledge on pre-menopausal symptoms. It shows that there is no significant association between knowledge aspects with Age of the women (X^2=2.65), Age at menarche (X^2=7.41), Menstrual irregularity (X^2=1.72), Types of family (X^2=0.33), Dietary pattern (X^2=7.21), Area (X^2=O), Age at marriage (X^2=7.44), Occupation (X^2=10.1), Monthly income (X^2=1.09).There is Significant Association Between No. of . children (X^2=28.67).

Ethical Clearance: Summary, Findings, Discussion, Implication, Limitataion, Recommendation and Conclusion.

The essence of any research project lies in reporting in the findings. This chapter gives a brief account of the present study including conclusion drawn from the findings, recommendations, limitation, suggestion for future studies and nursing implication.

Summary: The study is to assess the knowledge regarding pre-menopausal symptoms among middle aged women in a selected village. This will enhance the middle aged women to improve knowledge regarding pre-menopausal symptoms.

The objectives of the study were: Assess knowledge on Pre-menopausal symptoms among middle aged women.

Associate the knowledge on Pre-menopausal symptoms among middle aged women with selected demographic variables.

The study attempted to examine the following null hypothesis that

H_0: There is no significant association between demographic variables and knowledge on pre-menopausal symptoms among middle aged women in a selected village at Kanchipuram District, Tamil Nadu, India.

The review of literature enabled the investigator to develop methodology of the study literature review was done and organized as studies related to knowledge on pre-menopausal symptoms among middle aged women.

The research approach used was quantitative approach with descriptive design. The main study was done in a selected village at Kanchipuram District, Tamil Nadu India. 109 samples were selected by convenience sampling.

The self-administered questionnaire was used to collect the data regarding demographic variables and the knowledge on pre-menopausal symptoms among middle aged women. The data gathered were analyzed by using descriptive and inferential statistical method. The findings were presented on the basis of objectives of the study.

Findings: Findings of the study were presented under the following headings based on the study objectives

Objective 1: Assess the level of knowledge on pre-menopausal symptoms

The finding of the present study reveals that

0 (0%) had adequate knowledge

15 (13.8%) had moderate knowledge

94(86.2%) had inadequate knowledge

Objective 2: Associate demographic variables with the level of knowledge on pre-menopausal symptoms.

Finding-1: Age and level of knowledge of pre-menopausal symptoms.

There is no significant association between the age and level of knowledge of pre-menopausal symptoms. X^2=2.65, (P<0.05).

Finding-2: Age at menarche and level of knowledge of pre-menopausal symptoms. There is no significant association between the age at menarche and level of knowledge of pre-menopausal symptoms. X^2=7.41, (P<0.05).

Finding-3: Number of children and level of knowledge of pre-menopausal symptoms.

There is significant association between the number of children and level of knowledge of pre-menopausal symptoms. X^2=28.67, (P>0.05).

Finding-4: Menstrual irregularity and level of knowledge of pre-menopausal symptoms.

There is no significant association between the menstrual irregularity and level of knowledge of pre-menopausal symptoms. X^2=1.72, (P<0.05).

Finding-5: Type of family and level of knowledge of pre-menopausal symptoms.

There is no significant association between the type of family and level of knowledge of pre-menopausal symptoms. X^2=0.33, (P<0.05).

Finding-6: Dietary pattern and level of knowledge of pre-menopausal symptoms.

There is no significant association between the dietary pattern and level of knowledge of pre-menopausal symptoms. X^2=7.21, (P<0.05).

Finding-7: Area and level of knowledge of pre-menopausal symptoms.

There is no significant association between the area and level of knowledge of pre-menopausal symptoms. X^2=0, (P<0.05).

Finding-8: Age at marriage and level of knowledge of pre-menopausal symptoms.

There is no significant association between the age at marriage and level of knowledge of pre-menopausal symptoms. X^2=7.44, (P<0.05).

Finding-9: Occupation and level of knowledge of pre-menopausal symptoms.

There is no significant association between the occupation and level of knowledge of pre-menopausal symptoms. X^2=10.1, (P<0.05).

Finding-10: Monthly income and level of knowledge of pre-menopausal symptoms.

There is no significant association between the monthly income and level of knowledge of pre-menopausal symptoms. X^2=1.09, (P<0.05).

Implication: The findings of the study have implication in Nursing services and research.

Nursing Service: Community health nurse conduct educational programs to improve knowledge on pre-menopausal symptoms. In hospital Nurse can provide health education to create knowledge.

Limitation: Middle aged women only included in the study.

Recommendation: This study can be replicated an large sample studies can be conducted in different settings to validate findings

A similar study can be conducted on general public regarding pre-menopausal symptoms.

Conclusion

This study helps the middle aged women to understand about the pre-menopausal symptoms, it becomes necessary to involve the middle aged women as and when during pre-menopausal symptoms and

it can also able to prevent the complications during menopause.

Health Care Services Under Consumer Protection Laws of Union Territories of Jammu and Kashmir: A Socio-Legal Mapping

M.Z.M. Nomani[1], Ajaz Afzal Lone[2], Alaa K.K. Alhalboosi[2], Aijaj A. Raj[2], Zubair Ahmed[2]

[1]Professor, [2]Research Scholar, Faculty of Law, Aligarh Muslim University, Aligarh, U.P., India

Abstract

Ever since the passing of the *Jammu & Kashmir Consumer Protection Act*, 1987, the doctor-patient's relationship came under critical scrutiny, controversy and litigation. The inadequacy of consumer protections laws results in unavoidable contingency, spiralling cost shifting and inordinate health care complexities. It examines health care services as a matter of consumer rights under *Consumer Protection Act,* 1986, *Jammu and Kashmir Consumer Protection Act,* 1987 and *Consumer Protection Act,* 2019. It makes consumers to navigate between hope and despair for access to health care. The paperis driven to analytical study of inadequacy of consumer laws in dealing effectively deficiency of medical service, insufficiency of health care services,lack of medical professionalism and negligence in Sher-i-Kashmir Institute of Medical Sciences (SKIMS), Srinagar by encompassing a legislative survey of consumer laws in inculcating Consumer Right Awareness (CRA) and toning of structural governance of grievance redressal mechanism. The gap between the precept and practice of consumer justice and compensation in health care services is identified for adoption of a robust infrastructural and schematic revamping.

Keywords: *Health Care Services, Consumer Right Awareness, Grievance Redressal Mechanism, Consumer Justice and Compensation.*

Introduction

The health care facilities to the people of the erstwhile state of Jammu and Kashmir (J & K) is marred by constraints of financial resources, difficult topography and terrain, poor road connectivity, low presence of private sector, low accessibility and affordability by under- privileged segments of the population. There has been a gradual decay in the health services of J & K over the last three decades. The state is under shadows of infectious diseases like tuberculosis, RTI, UTI diarrhoea disease.[1] there is growing shadow of chronic diseases like hypertension, coronary artery disease, cancers, and diabetes. Factually speaking there are 3,807 health care institutions in the state which is considered the highest number of hospitals in the country. The annual budget for the health sector in J & K is Rs. 2,423-crore. The per capita spending under plan, non-plan and centrally sponsored schemes is estimated at Rs. 1,931 crore.[2] According to the *State's Economic Survey Report,* 2017,there were 4,433 government health institutions in J & K at the primary, secondary and tertiary levels with 6,674 doctors.[3] The paper examines the efficacy of*J & K Consumer Protection Act,* 1987 to give effect to *Consumer Protection Act,* 1986 to take care of consumer right awareness among patients for robust health care services in two Union Territories of J & K under *Jammu and Kashmir Reorganisation Act,* 2019.

Materials & Method

The material and method applied for the study include analytical method of legal research by undertaking the legislative survey and scrutiny of consumer laws at central and state levels. These laws

are studied under Parsonian Effecttheory in the context of health care services.[4] The comparative consumer law study of *Consumer Protection Act,* 1986,*J & K Consumer Protection Act,* 1987 and *Consumer Protection Act,* 2019 is based on established canons of statutory interpretation. The material and method partakes an empirical frame work of SKIMS, Srinagar a premier medical institution in J & K state. The case study is based on Consumer Right Awareness (CRA) under four major parameters which include consumer right awareness, redressal against medical negligence, and recourse to deficiency of medical service and compensation and consumer justice.

Findings: It is important to note that the both *Consumer Protection Act,* 1986, *J & K Consumer Protection Act*, 1987 and *Consumer Protection Act,* 2019 are public welfare legislation and has been designed to avoid procedural technicalities, delays, and requirement of court fees to protect consumers availing medical facilities and health care services.[5] It contains three-tier consumer disputes redressal system at the District, State and National levels along with Central Consumer Appellate Authority (CCAA) including right to health and environment.[6]

Central Consumer Protection Act, 1986: The *Consumer Protection Act,* 1986 forms the basis of *J & K Consumer Protection Act,* 1987 therefore a perusal of this law in brief is imperative. The Act seeks to promote and protect the interest of consumers against deficiencies and defects in goods or services.[7] It also seeks to secure the rights of a consumer against unfair trade practices, which may be practiced by manufacturers and traders. The Act applies to all goods and services unless specifically exempted by the Union Government and covers all sectors, whether private, public, or cooperative. It ordains simple, speedy and inexpensive machinery for redressal of consumer's grievances, the marketing of goods and services to consumers, as well as the relationships, transactions and agreements between the consumers and the producers, suppliers, distributors, importers, retailers, service providers and intermediaries of those goods and services.[8] The application of *Consumer Protection Act,* 1986 to health services derives life breath and sustenance from Supreme Court ruling in *Indian Medical Association v. V.P. Shantha.*[9] In this casethe question raised was whether the treatment provided by medical practitioners to their patients would constitute "service" under the meaning of the Act and whether patients would be treated as 'consumers' under the same *Consumer Protection Act*, 1986 The court noted that the issues arising in the complaints against medical negligence can be speedily disposed of by the procedure being followed by consumer disputes redressal agencies. Thus the *Consumer Protection Act,* 1986 is pioneering law in protection of consumer from the standpoint of health, environment and consumer justice.[10]

J & K Consumer Protection Act, 1987: The*J & KConsumer Protection Act,* 1987 aims to provide effective safeguards to the consumers against defective goods, deficient services and unfair trade practices.The Act provides speedy redressal to consumer complainants by setting up of a District Consumer Redressal Forum and State Commission having jurisdictionto claim of Rs. 10 lakhs and Rs. 30 lakhs respectively. The State Commission will be vested with appropriate appellate and revisional powers. It shall apply to all goods and services except those which are specially exempted by notification by the state government did not specifically exempted health care services provided by government hospitals. It seems profitable to refer section 2(1) (0) as under:

"Service" means service of any description which is made available to potential users and includes the provision of facilities in connection with banking, financing, insurance, transport, processing, supply of electrical or other energy, board or lodging or both, entertainment, amusement or the purveying news or other information, under a contract of personal service.

The necessary penal and punitive provisions have been incorporated for effective redressal of unfair trade practices, defect in the goods, and deficiency of services. The Consumer Commissions are authorized to impose penalties on trader or person against whom complaint is made if he fails to comply with the order of the redressal agency.

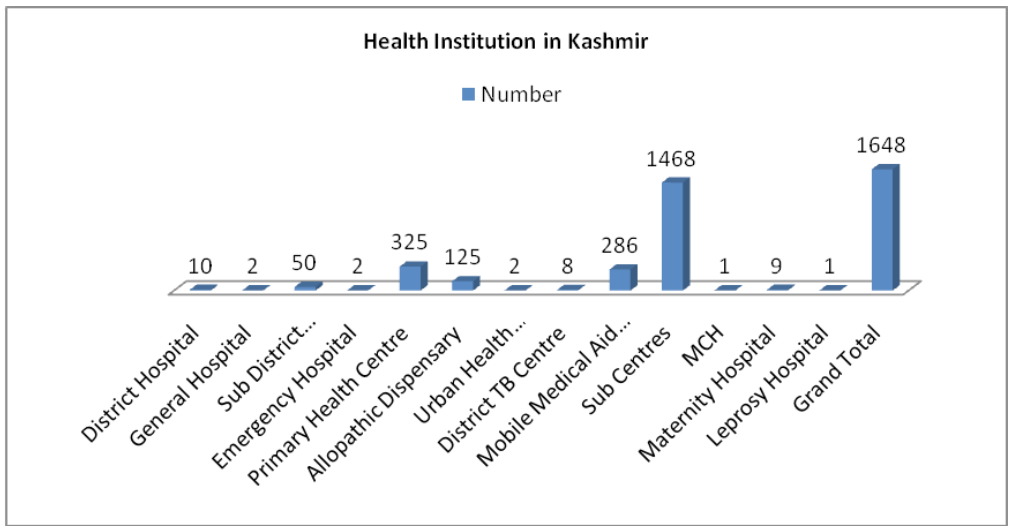
J & K Government Doctors (Relaxation of Restrictions on Private Practice) Rules, 1987: It will be appropriate to see the application of *J & K Consumer Protection Act,* 1987 and *J & K Government Doctors (Relaxation of Restrictions on Private Practice) Rules,* 1987 in holistic perspective in regard to doctor patient relationship and health care services. This is also important to see this law in the context of penalty or punishment may involve imprisonment for a period not more than 3 years or a fine or both. The complaint mechanism by a consumer voluntary organization, registered society, company and state government will

also be scrutinised in pragmatic discourse. Therefore, it is also worthwhile to inquire the synergy of both legislations from the lens of the executive and judicial attitude towards disciplining doctors and foster health care services to patient *vis-a-vis* banning private practice. The J & K High Court in *Dr. Ashutosh Gupta v.State of J & K,* [11]while hearing petition for quashing of Government Order No. 43/HME of 2013 dated 17.01.2013 regarding of banning of private practice by doctors of government medical college, associated hospitals and dental colleges upheld the impugned order of the Government. In *Sukesh Chander Khajuriav. State of J & K,*[12] the J & K High Court dismissed the writ petition regarding validity of *J & K Government Doctors (Relaxation of Restrictions on Private Practice) Rules,* 1987.

Discussions

The study of health care services under consumer protection laws of J & K health institutions is an empirical study of SKIMS with 900 bedded tertiary care hospital and undergraduate medical college with intake capacity of 100 students. According to survey there are total 1648 health institutions in J & KState.[13]

Selection of Area of Study: SKIMS being premier medical institution in India, it provides additional services including prevention, treatment, rehabilitation, obstetrics, substance abuse, health education, and screening for cancers and other diseases.[14]



The case study of SKIMS is based on four major parameters *viz;* consumer right awareness, [15]redressal against medical negligence, recourse to deficiency of medical service and compensation and consumer justice under the *J & KConsumer Protection Act*, 1987 and *J & K Government Doctors (Relaxation of Restrictions on Private Practice) Rules*, 1987. Located in Soura area of Srinagar, this is the largest medical Institute under *Sher-i-Kashmir Institute of Medical Sciences, (Grant of Degrees) Act,* 1983.[16] The *J & K Consumer Protection Act,* 1987 is not applicable to government hospitals because of free medical care services to patients. But the medical services rendered by doctors and hospitals falls within the ambit of a "service" as defined in Section 2(1) (o) of the Act.

Consumer Right Awareness & Health Care Services: By this analogy persons who are rendered free service are "beneficiaries" and as such come within the definition of "consumer" under Section 2(1) (d) of the Act. Similarly the deficiency of service is spelt out under Section 2(1) (g) which covers diagnostic, surgical and therapeutic service.[17] A sample survey of 100 patients admitted to SKIMS was conducted regarding consumer right awareness to healthcare.[18] The following table and chart-1 shows the nature and depth of consumer right awareness among randomised number of patients is in and out patient department. The simple question regarding the legal literacy of consumer law and redressal agencies were put to these patients.

Table 1: CRA & Health Care Services

Patients	Respondents	Yes	%age	No	%age	Indifferent	%age
In Patients	50	10	20	35	70	05	10
Out Patients	50	12	24	34	68	04	08
Total	**100**	**22**	**88**	**79**	**79**	**09**	**09**

Source: Field work

The above table clearly shows that 22% respondents have knowledge about consumer law or redressal agencies while as 79% respondents said that no they were not having any knowledge about consumer laws however 9% respondent didn't said anything about the information of consumer laws. The legal literacy about the complaint mechanism for the deficiency in medical services is also in abysmally low. When we asked patients about the deficiency of medical services gives rise to grievance redressal at appropriate consumer forum almost 2/3 respondents feign ignorance about it.

Table II: CPA & Grievance Redressal Mechanism

Patients	Respondents	Yes	%age	No	%age	Indifferent	%age
In Patients	50	10	20	35	70	05	10
Out Patients	50	11	22	34	68	05	10
Total	**100**	**21**	**21**	**69**	**69**	**10**	**10**

Source: Field Work

The medical negligence on as the part of health care provider is frequent in J & K that is why the patient affected by medical negligence have faint idea about the complaint mechanism as victims. The Table II shows that 21% respondents have knowledge about complaints in consumer forums on the basis of data received from respondents 69% respondents said that they were not aware about the concept of complaints in consumer forums, however 10% respondents didn't say anything about the complaints in consumer forums.

Table III: CPA & Medical Negligence

Patients	Respondents	Yes	%age	No	%age	Indifferent	%age
In Patients	50	10	20	34	68	06	12
Out Patients	50	13	26	32	64	05	10
Total	**100**	**23**	**23**	**66**	**66**	**11**	**11**

Source: Field Work

The Comptroller and Auditor General (CAG) of India has reported that 'even the emergency medicine department has been found to be not fully equipped to deal with cases of road traffic accidents having multiple organ injuries including orthopedic injuries.' This is also pathetic to note that ambulances meant for patients have been found mis-utilized to the extent of 40 to 47 per cent during 2008-12.[19]

Health Care & Medical Negligence: The knowledge regarding negligence in health care services reveals that 23% respondents were aware about the complaints mechanism. The ordinary prudence about medical negligence depicts that 66% respondents don't have knowledge about grievance redressal and 11%remain indifferent to liability of doctors and hospital authorities.

Table IV: Health Care Services & Medical Negligence

Patients	Respondents	Yes	%age	No	%age	Indifferent	%age
In Patients	50	11	22	36	72	03	06
Out Patients	50	10	20	35	70	05	10
Total	100	21	21	71	71	08	08

Source: Field Work

Compensation & Consumer Justice: the compensation incase of medical negligence to the patients and their kith and kin also represent empathtic and ignorance. The patient interviewed regarding their response to compensation in case of medical negligence reveals that 21% respondents show that they have knowledge about penal provisions against doctors.[20] Still majority of patients to the tune of 71% said that they were not having any information related penal provisions where as 8% are either ignorant or indifferent didn't say anything about penal action can be initiated in case of medical negligence on part of hospital and doctor.

Table V: Compensation & Consumer Justice

Patients	Respondents	Yes	%age	No	%age	Indifferent	%age
In Patients	50	08	16	38	76	04	08
Out Patients	50	09	18	36	72	05	10
Total	100	17	17	74	74	09	09

Source: Field Work

The apex court ruling has played seminal role in curbing medical malpractice and making compensation an integral part of consumer justice that 17% respondents have knowledge about compensation given by consumer forums and 74% said that they were not having any information related compensation related consumer forums however 09% respondents didn't say anything about compensation provided by consumer courts. This places the consumer justice in a conundrum especially in the aftermath of Supreme Court decision.

Conclusion

The analysis of health care services under consumer laws of erstwhile J & K state now Union Territories of J & K under *Jammu and Kashmir Reorganisation Act,* 2019 reveals that health status of the people has not been able to keep pace with the national targets. The state has a considerable segment of population living below poverty line, inadequacy of healthcare and burden of disease in an environmentally benign setting.[20] The *J & KConsumer Protection Act,* 1987 has not achieved consumer right awareness and assertiveness in realisation health care services. The health services and disease overburden needs proper regulation. This becomes more important in the wake of unrest of decades has worsened the health status of people especially of population living below poverty line. The only salacious aspect is to note that the purpose and object with which the *J & K Consumer Protection Act,* 1987 has been passed has substantially achieved in the ambit of patient's rights notably compensatory justice. But the SKIMS have been found inadequately equipped to deal with accidents and trauma prevention and gross mis-utilisation of ambulance services despite rich infrastructure. The most significant and equally multifaceted as well complex service in the field of consumer grievances is that of medical malpractice and the doctors of SKIMS and other government hospitals of state need to be more circumspect and careful towards medical services to patients to enlarge the realm of consumer justice, access to health and compensatory jurisprudence.

Comparison of Morphological Features of Second Cervical Vertebra between Genders Using Computed Tomography

Madhavan T.S.[1], Sharath S.[2], Rahul P. Kotian[3]

[1]Assistant Professor, [2]Assistant Professor, [3]Assistant Professor (Selection Grade), Department of Medical Imaging Technology, Manipal College of Health Professions , Manipal Academy of Higher Education

Abstract

Introduction: Gender determination has been the emphasis of many forensic studies and have significance in mass fatality cases where bodies are damaged beyond recognition, as these factors are essential and various method are developed that allows gender determination. Second Cervical vertebra due to its ample degree of sexual dimorphism in its dimension allows sex determination. Forensic investigators can identify the bone by its morphological characteristics, such as the dens, short spinous process and cervical vertebra is known to be the best preserved of all the vertebra in cadavers.

Aim: To compare the morphological features of second cervical vertebra between genders using Computed Tomography.

Materials and Method: This was a retrospective study which included subjects visiting for CT (Computerized Tomography) of cervical spine in Department of Radio-diagnosis and Imaging, Kasturba Medical College, Manipal, Karnataka, India. Sample size was calculated using the formula for estimation of population mean which gave a total sample of 160. A total of 160 patients underwent computed tomography of cervical spine on MDCT Brilliance 64 slice Philips with routine protocol and later post-processed into Multiplanar imaging. In present study nine measurements of the second cervical vertebra were taken. Anthropometric measurements were performed which was calculated using the measurement tools. The data was analyzed using SPSS (V.20.0).

Results: Discriminant function analysis was performed to calculate the mean and standard deviation. Standardized canonical discriminant function was performed to find out the variable dependency and was found that maximum distance measured from the most lateral edges of the superior articular facets (DMFS) contributed much of the separation between genders. Step wise discriminant function test was performed to predict the categorical dependent variable a multivariable model was generated which showed that maximum distance measured from the most lateral edges of the superior articular facets (DMFS) and Maximum sagittal length (AS) reached the accuracy of 77.5% in gender discrimination. The most discriminant variable for the C2 was DMFS followed by AS, with expected accuracies of 73.8% and 71.9%. Among nine variables seven variables (AS, LMA, DMFS, DSD, DTD, WVF and DTMC) showed correct prediction rates approximately 78.8% and two variables (DA, DSMC) yielded no result.

Conclusion: DMFS contributed much separation with high accuracy in comparison to others, affirming that there is considerable sexual dimorphism with respect to the second cervical vertebra which could determine the gender of human based on CT measurements of second cervical vertebra.

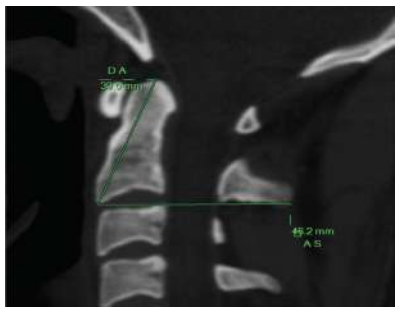
Introduction

Gender determination has been the emphasis of many forensic studies and have significance in mass fatality cases where bodies are damaged beyond recognition, as these factors are essential and various method are developed that allows gender determination[1-3].

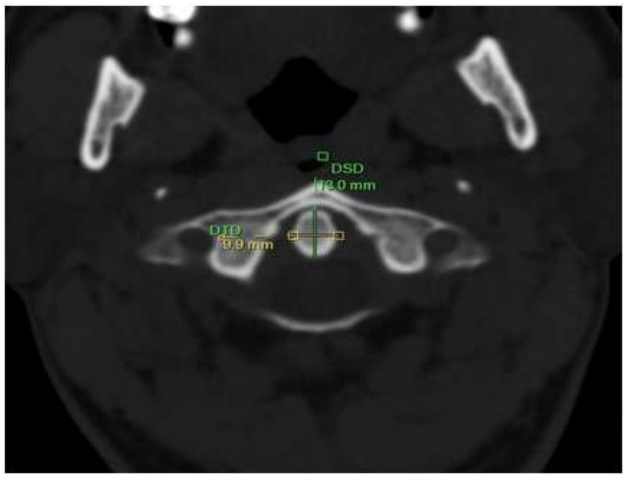
DNA technologies are rational, narrowed down due to the accessibility of forensic legal laboratories and the cost effectiveness. For gender determination the most reliable parts are skull and pelvis which exhibits sexual dimorphism [2,4]. However, some human skeletal parts are found to be damaged due to decomposition and carnivore modification, other parts that are less dimorphic such as tibia, humerus, hyoid bone, foramen magnum should be considered for gender determination, and thus new techniques that deal with such parts should be considered. Second cervical vertebra due to its ample degree of sexual dimorphism in its dimension allows sex determination. Forensic investigators can identify the bone by its morphological characteristics, such as the dens, short spinous process and cervical vertebra is known to be the best preserved of all the vertebra in cadavers [3,5]. Therefore, the aim of the present study was to assess the sexual dimorphism from the 12th thoracic and the first lumbar vertebra measurements and data was obtained from reformatted images of multi-slice computed tomography (MSCT).

Materials and Method

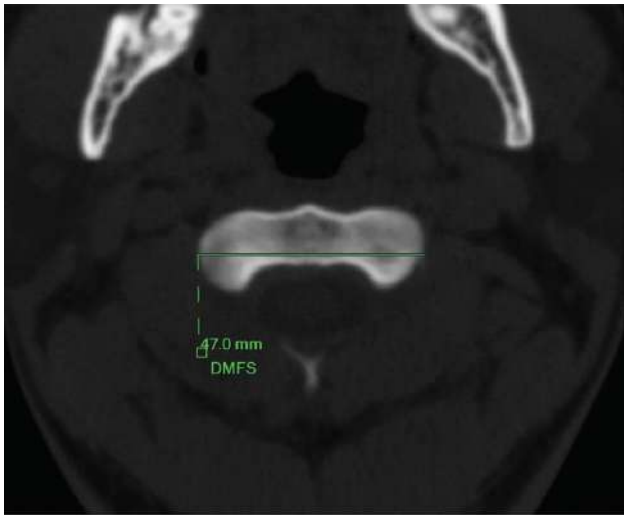
A retrospective observational study was carried out at Department of Radio-Diagnosis and Imaging, Kasturba Hospital, Manipal, Karnataka, India, using Phillips Brilliance 64-SLICE CT. Approval was acquired from institution research committee, School of Allied Health Sciences and ethical committee, Kasturba hospital. Sample size was calculated using the formula for estimation of population mean which gave a total sample of 160. Data from 160 samples (80 males and 80 females) were obtained, who were referred to the Radio-diagnosis department by the treating physician for CT cervical spine over the period of 12 months. Patients with trauma, major injuries and fractures of cervical spine were excluded from the study. CT of cervical spine was performed with patients positioned on the CT couch in supine head first position, with area coverage from tip of mastoidto sternal notch. Scan of the required area of interest was performed on acquired scanogram keeping in mind that the scan is performed with no loss of anatomical structure, axial sections of cervical spine was obtained with 0.9 mm slice thickness and slice increment of 0.45 mm with detail D filter producing standard bone resolution images. Informed consent was obtained from the patient before the start of examination. The original series of cervical spine with slice thickness of 0.9 mm and slice interval of 0.45 mm were selected for the study, Axial images per patient data set which were included in the study were sent to Phillips Extended Brilliance workstation and the acquired axial sections were reformatted into coronal and sagittal sections using MPR (Multi-Planar Reconstruction) technique [6]. Anthropometric measurements were performed on the following section; the maximum length of the parameter was measured on axial and sagittal sections. The Maximum height of the Dens (DA) and Maximum sagittal length (AS) was measured from the sagittal section where tilts can be checked. The axial and coronal planes were used to correct the image to get the orientation of the second cervical vertebra. The other measurements were taken from the axial sections which were checked for tilts and corrected using sagittal and coronal images to acquire the center of the second cervical vertebra. Maximum height of dens (DA) is defined as length from the superior point on the dens to the anterior-inferior point on the vertebral body and Maximum sagittal length (AS) i.e., Length from the anterior-inferior point on the vertebral body to the posterior point on spinous process [Fig-1]. Dens Sagittal Diameter (DSD), (Maximum sagittal diameter measured between the anterior and posterior points on dens). Dens Transverse Diameter (DTD), (Maximum transverse diameter of dens measured between most lateral edges of the dens) [Fig-2]. (Maximum distance measured from the most lateral edges of the superior articular facets) (DMFS) [Fig-3]. Maximum width of the axis (LMA) shown in [Fig-4], Width of Vertebral Foramen (WVF) (Maximum internal width of the vertebral foramen) [Fig-5]. Maximum sagittal diameter of the body (DSMC) (The maximum sagittal diameter of the body measured from the anterior-inferior point on the board to posterior-inferior point). Maximum transverse diameter of the body (DTMC). (The maximum transverse diameter of the body measured between the most lateral edges of the body) [Fig-6], were measured using the measurement tools provided by the Phillips extended brilliance work station.



[Fig-1]: Figure showing maximum height of the dens (DA) and maximum sagittal length (AS).



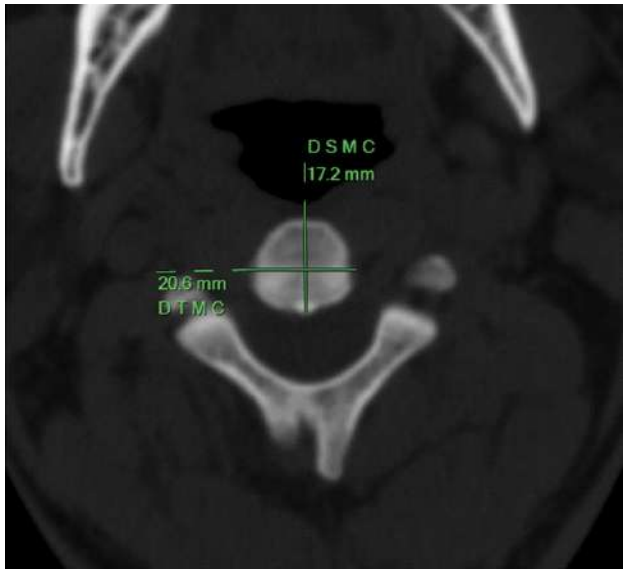
[Fig-2]: Figure showing Dens Sagittal Diameter (DSD) and Dens Transverse Diameter (DTD).



[Fig-3]: Figure showing maximum distance between superior facets (DMFS).

[Fig-4]: Figure showing maximum width of the axis (LMA).

[Fig-5]: Figure showing Width of Vertebral Foramen (WVF).



[Fig-6]: Figure showing maximum sagittal diameter of the body (DSMC) and maximum transverse diameter of the body (DTMC).

Statistical Analysis: The metric data obtained were analyzed by using SPSS Version 20.0 and statistical difference in the cervical vertebra measurements of males and females were assessed using discriminant function analysis to predict the categorical dependent variable and to compare the canonical discriminant function coefficients to recognize which independent variable was more segregating than alternate variables. Discriminant function analysis test was used to evaluate the mean and standard deviation for the anthropometric parameters of both male and female. Standardized and unstandardized canonical discriminant function was determined to assess the variable dependency.

Results

The Mean and standard deviation of both sexes for all the nine variables are reported using descriptive statistics as shown in [Table-1].

[Table 1]: Descriptive statistics for the nine variables are reported which shows mean and standard deviation of both sexes.

Variable	Sex	Mean	Standard Deviation
DA	Male (80)	85.18	421.27
	Female (80)	82.33	421.48
AS	Male (80)	46.35	5.009
	Female (80)	43.18	2.727
LMA	Male (80)	54.54	5.202
	Female (80)	54.83	44.98
DMFS	Male (80)	45.33	2.515
	Female (80)	42.05	2.267
DSD	Male (80)	12.39	10.703
	Female (80)	10.17	1.248
DTD	Male (80)	9.841	1.092
	Female (80)	9.616	3.629
WVF	Male (80)	22.77	1.567
	Female (80)	21.95	1.364
DSMC	Male (80)	17.02	1.399
	Female (80)	32.88	159.2
DTMC	Male (80)	21.24	2.630
	Female (80)	19.81	2.450

[Table-2]: Canonical discriminant function coefficients.

	Function 1
DA	.000
AS	.082
LMA	-.002
DMFS	.321
DSD	.024
DTD	-.044
WVF	.125
DSMC	.000
DTMC	.034
(Constant)	-20.946

Discriminant function analysis was used to predict a categorical dependent variable (called a grouping variable) by one or more continuous or binary independent variables (called predictor variables). On comparing canonical discriminant function coefficients, it was conceivable to recognize that DMFS showed much differentiation followed by WVF, AS, DTMC, DSD, DTD and LMA as shown in [Table/Fig-8].

The most discriminant variable for the C2 is DMFS followed by AS, with expected accuracies of 73.8% and 71.9%. Among nine variables seven variables (AS, LMA, DMFS, DSD, DTD, WVF andDTMC) showed correct prediction rates approximately 78.8% and two variables (DA, DSMC) yielded no result. The equation for sex estimation using the seven variables is as follows:

Z=-020.946+0.082 (AS)+(-0.002) (LMA)+0.321 (DMFS)+0.024 (DSD)+ (-0.044) (DTD)+0.125 (WVF)+0.034 (DTMC). The values ranging from -0.758 to 0 is assigned as Female and 0 to 0.758 is assigned as Male.

Stepwise discriminant function analysis was performed which resulted in multivariable model. Two variable models reached the accuracy of 77.5%. The equation for gender estimation using two variables is as follows.

Z=-19.453+0.082 (AS)+**0.361** (DMFS) The values ranging from -0.723 to 0 is assigned as Female and 0 to 0.723 is assigned as Male as shown in [Table/Fig-9].

[Table-3]: Stepwise discriminant function analysis.

Variable	Unstandardized Coefficient	Group Centroids		Prediction Accuracy	
		Male	Female	Male	Female
AS Constant	0.082 -19.453	0.723	-0.723	76.3	23.8
DMFS Constant	0.361 -19.453	0.723	-0.723	21.3	78.8

Discussion

In present study 160 patients (80 males and 80 females) were included who were referred for the CT scans of the neck and cervical spine where the C2 vertebra is seen, in which the measurements can be taken.

In the present study the overall mean value of the males is larger than the females; this shows the existence of sexual dimorphism. Torimitsu S et al., conducted a study on sexual determination based on multidetector computed tomographic measurements of the second cervical vertebra in a contemporary Japanese population. Multiple DFA with stepwise variable selection resulted in multi variable models a five-variable model reached an accuracy rate of 92.9% [5]. In the present study, descriptive statistics for nine variables were included and all the nine variables demonstrated significant sexual dimorphism. In the present study, descriptive statistics for nine variables were included where only seven variables (AS, LMA, DMFS, DSD, DTD, WVF, and DTMC) demonstrated significant sexual dimorphism and two variables (DA, DSMC) yielded no result. Stepwise variable selection resulted in a multivariable model a two variable model reached an accuracy rate of 77.5%. Torimitsu S et al., reported in his study the most discriminant variable for the C2 was DMFS followed by LMA with an accuracy of 83.5% and 83.1% respectively [5]. In the present study, the most discriminant variable for the C2 is DMFS followed by AS with an accuracy of 73.8% and 71.9% respectively.

Gama I et al., performed a study in documented Portuguese skeletal sample at University of Coimbra. In present study, investigator performed t-test analysis to identify differences among sexes and found that out of 13 dimensions one measurement was not showing significant differences and reported that LMA-followed by DSMC are the most dimorphic dimensions of the second vertebra with the level of dimorphism of 11.18% and 10.6% respectively [7]. In the present study the most discriminant variable for the C2 is DMFS followed by AS with an accuracy of 73.8% and 71.9% respectively. Gama I et al., performed logistic regression analysis with stepwise variable selection to develop a model and reported a multivariate model with four variables reached an accuracy of 89.7% as shown in [Table/Fig-10] [5,7].

[Table-4]: Table showing previous studies percentage accuracy.

Study	No of Patients	Result Accuracy
Sugur Torimitsu, et al	224(112 males & 112 females)	92.9%.
Ines Gama, et al	1st Sample 190(99 males & 91 females) 2nd Sample 47(24 males & 23 females)	89.7%
Current study	160(80 males & 80 females)	78.8%

Stepwise variable selection resulted in a multivariable model a two variable model reached an accuracy rate of 77.5%. In the present study DMFS showed significant variability among males and females which suggests that measurements of DMFS can be obtained and used to differentiate between the genders.

Limitations: The study has certain limitations such as all the parameters measured did not show significant values and were not efficient discriminators among the gender group. Further studies can be carried out using larger sample size which may lead to better accuracy and reveal a stronger conclusion**.**

Conclusion

In the present study nine measurements of the second cervical vertebra were taken out of which seven variables were good discriminators where DMFS contributed much separation with high accuracy in comparison to others. The results allow affirmation that there is considerable sexual dimorphism with respect to the second cervical vertebra which could determine the gender of human based on computed tomographic measurements of second cervical vertebra.

Acceptance of PBL by Students to Learn Pre-Clinical Sciences

Malini Dutta[1], K. Aditya[2], Dilip Mathai[3]

[1]Professor of Physiology, [2]Assistant Professor of Physiology, [3]Professor of General Medicine, Apollo Institute of Medical Sciences & Research, Hyderabad, Telangana

Abstract

Introduction: Medical education needs to be changed both in content and in teaching methodology . The students need to be prepared with high level of knowledge, analytical skills, critical thinking, self-directed learning and group dynamism. Problem Based Learning (PBL) can be used as a tool for teaching undergraduate students. PBL is not problem solving but problem analysing. Here the students need to analyse the problem after they have been taught in the conventional method.

Objectives: Find The attitude of students towards PBL.

Methodology: After a year of PBL practise, a twenty two set feedback questionnaire based on Elizondo–Montemayor with 5 point Likert scale was taken from 98 students with 1 as least acceptable to PBL, 5 as most acceptable and 3 as ambivalent response. The data was analysed by using one sample Wilcoxon's test for two- tailed hypothesis.

Results: Search phase and preparation phase had a median score greater than 3, indicating a positive attitude for these phases. Presentation phase showed ambivalent response towards PBL objectives. Overall response had a mean location above 3 suggesting students acceptance towards the objectives of PBL.

Conclusion: The future PBL sessions can be modified, planned accordingly and executed in a more productive way so as to nurture the development of reflective learning in students to bring maximum improvement in the educational outcome. To have better educational outcome, PBL must be used as an adjunct along with the traditional method.

Keywords: *Problem Based Learning, Self directed learning, medical students, attitude, brain storming.*

Introduction

Medical teaching is undergoing radical changes. In India the curriculum has not been revised since 30 years. The most challenging is to design a curriculum that delivers an optimum level of required knowledge, skills, critical thinking and self- directed learning that would prepare students for professional practice[1]. Currently, the teaching and assessment are not aligned . Students are evaluated on the basis of declarative knowledge. So the curriculum needs to be revised and changed. One of the changes is to introduce PBL to the UG students.

PBL is in alignment of professional practice and learning . This would provide functioning knowledge that can be put to work immediately on graduates or in real life works. This will improve relevance and motivation for learning. PBL is not problem solving but problem analyzing . Here, a medical problem is presented to a small group of students for discussion under the guidance of a facilitator . The students have to analyze the problem after they have been taught in the conventional method. The problems are constructed in a way that the goals of PBL areachieved.

e-mail: duttamalini@gmail.com

- Activates students constraint knowledge that can be put to work.
- Integrate and apply new knowledge to solve the problem.
- Increases self directed learning, self management skills, attitude, knowledge and develops professional wisdom.
- Enhances and optimises the educational outcomes.
- Develops and motivates group skills[2].

Material and Method

We have introduced integrated PBL in Apollo Institute of Medical Sciences & Research (AIMSR), Hyderabad, Telangana to the 1st year students of 2017-18 batch from September 2017 to April 2018. Horizontal integration of the 1st year subjects was done. Twelve problems have been constructed on real life situations on the topics which were covered in the first three semesters.

- Hematology - Erythroblastosisfoetalis
- Gastro Intestinal Tract - Obstructivejaundice
- Cardio vascular system -Hypertension
- Cardio vascular system - Myocardial infarction
- Respiratory system–Chronic Obstructive Pulmonary Disease
- Renal system - Acute Renal Failure
- Endocrine system - Pituitaryadenoma
- Endocrine system -Hyperthyroidism
- Endocrine system - Diabetes mellitus
- Reproductive system - Poly cystic ovarian disease
- Reproductive system - Infertility
- Central Nervous System -Hemiplegia

100 students were divided into five groups of twenty students each guided by a facilitator. The faculty of pre clinical departments constructed the problem with prior discussions . Care was taken in constructing the problems, so that it covered all the objectives pertaining to the subjects of Anatomy, Physiology and Biochemistry which were expected to be learnt by the 1st year MBBS students. The structured problem promoted discussions, activated and incorporated knowledge, required new knowledge that students did not know, stimulated active participation and required self directed learning for meeting the learning outcomes.

Guidelines Followed for Constructing a Problem:

- Title–Given in a way to guide the students in a particular direction.
- Trigger material –A story or a description of phenomena orevents.
- Size - Short as meant only for the 1stYear MBBS students.
- Number of Issues- Direct learning into a limited number of issues.
- Distractions - Less distractors.
- Style - The structured problem was constructed in a way that indicated gaps in what the students already knew.

Each topic of PBL consisted of two sessions with one weeks gap between the two sessions. Each session was for two hours .

The first session is called as the brain storming session where the students attend the session with a note book and a medical dictionary to search for unfamiliar terms. A leader and a scribe was selected by the students in this session . The job of the leader was to see that each student participated actively in the group discussions. The scribe made notes of all the important points that were discussed. After going through the problem, the students analyzed the problem and came to ahypothesis.

Then the students came with the learning objectives pertaining to the problem. As the group comprised of twenty students, so twenty objectives were made and numbered accordingly. The role of the facilitator in this session was passive. The facilitator guided the students if the discussions went out of track and facilitated them till the students came with all the twenty objectives correctly. The names of reference text books, research articles and website links related to the problem were given by the facilitator during this session. At the end of this session, the facilitator gave the feedback to the students based on their participation in the group discussion.

Activity in 1st Session:

- Presentation of the problem
- Analysis of the problem - review the facts of the problem.

- Generation of Hypothesis–explain various aspects of the problem.
- Formulate learning objectives–to identify the content that needs to be learnt in depth.
- Identify the proper learning resources - (e.g. textbooks, internet, etc)–from where to search and gather information regarding the problem.
- Assign tasks to group members - to search for information related to the topic.

In the week to follow, all the group members have to learn all the objectives that were framed in the first session. They could either do group study or study alone according to their convenience by taking the help of the references that was provided by the facilitator. For any doubts, the students could meet the facilitator or any faculty of the concerned department.

Activity in 2nd Session: At the end of the 1st week, the same group of students and the facilitator met at the same time and same place for the second session which is called as the presentation session. In this session, all the students of the group came prepared with all the twenty objectives that they made in the brain storming session. The scribe made twenty lots numbered from 1 to 20 according to the number given for each objective . Each student had to pick one lot so that everyone got one objective. After this, each student presented the objective according to the number mentioned in the lot picked by them. In this session too, the role of the facilitator was passive. The facilitator only gave them any additional knowledge that the students might have missed and clarified if any doubts arose regarding any of the objectives or the problem . The session ended with a summary presented by the leader.

- Share - the gathered knowledge and information among the group members
- Re-analyze - the problem.
- Refine and reformulate - the hypotheses.
- Integrate and apply - the refined hypotheses to explain the issues related to the problem.
- Resolve and summarize - the problem

Institutional research committee permission was taken to undertake a cross sectional study on 1st year MBBS students of 2017 batch in the Department of Physiology, AIMSR. At the end of 3rd semester, a feedback questionnaire was given to the students to find out what factors were enhanced or inhibited in the learning process through the PBL methodology. The questionnaire consisted of a set of twenty two questions with five point Likert scale scoring based on the modified version of standard questionnaire developed by Elizondo–Montemayor[3] . The questionnaire set was prepared for three phases of PBL. Search phase with eight questions, preparation phase with six questions and presentation phase with eight questions.

The students were assembled and after briefing them and taking consent, the questionnaire was distributed. The students were given 20 minutes to complete the questionnaire. They were asked to indicate their degree of agreement for each statement with a tick according to: 1 = strongly disagree, 2 = disagree, 3 = moderate, 4 = agree, 5 = strongly agree. Care was taken to ensure that they do not discuss among themselves. Confidentiality and anonymity was maintained .

Statistical Analysis:

- For every individual, median score was calculated from the Likert scaledata.

- A score of 1 was interpreted as being least acceptable and 5 as most acceptable

- One sample Wilcoxon's test was used to statistically analyze the score for two- tailed hypothesis.
  - Median score of 3 for an individual was assumed to represent ambivalent or uncertain acceptance of PBL.
  - Median score greater than 3 was taken to represent definitive positive acceptance.
  - Median score less than 3 implied that PBL was less acceptable as a learning method.
    - Null hypothesis : median score=3
    - Alternate hypothesis : median score ≠3
- $\alpha = 0.05$ was used as the criterion for statistical significance.

Results

Totally 98 students of MBBS 1st year of 2017 batch participated in the study. The median on the overall score for twenty two questions of the questionnaire was less than 3 for 16 students . For 41 students the median was equal to 3 and for the remaining 41 students the median was greater than 3. One sample Wilcoxon's test for overall score indicated that the true location for median

score was above 3 suggesting students acceptance and adherence of overall PBL objectives (p=0.005919). Figure 1.

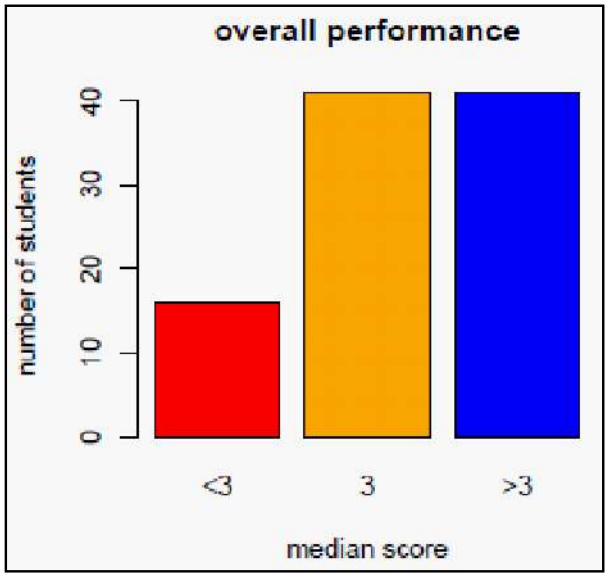

Figure 1

In the search phase, 54 students had a median score greater than 3(p<0.001). 24 students with a median score equal to 3 and 20 students with a score less than 3, indicating a liking for this phase of PBL. Figure 2.

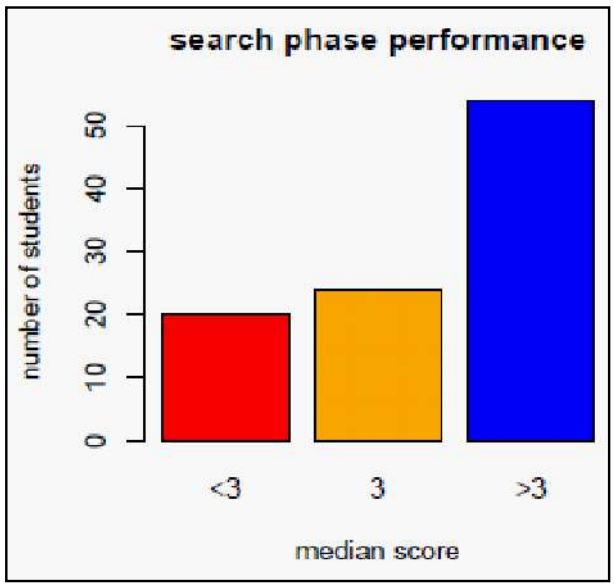

Figure 2

Even the preparation phase indicated a positive attitude of the students towards this phase of PBL with a median score greater than 3(p<0.001) for 62 students. Where else 21 students had a median score equal to 3 and remaining 15 students had a median score less than3. Figure 3.

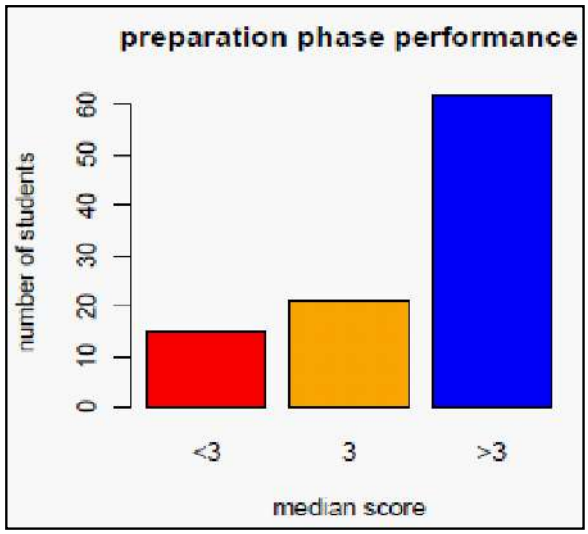

Figure 3

The presentation phase suggested their ambivalent influence on the PBL objectives for this phase with a median score less than 3 for 28 students as well as equal number of students having a median score more than three. 42 students had a median score equal to 3. So the true location of median score was not significantly different from 3(p=0.9633). Figure 4.

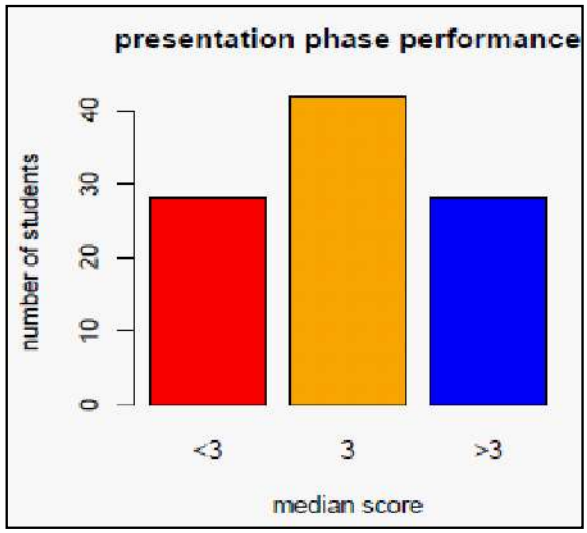

Figure 4

Discussion

Knowledge of medical sciences was previously based on learning plain empirical and observational facts which was memory oriented. With the rapid explosion of information, old method of teaching and learning are no more tenable. The situation demands a paradigm shift in our teaching and learning[4,5]. In order to tune to these situations a series of experiments are going on at global

level with regard to the changing modes of teaching and learning. These transformations are in conformity to the structure of the human brain where the capacity of short term memory is small but there is infinite capacity for long termmemory[6].

In this study, more than fifty percent of the students [54(55.10%)] have agreed to be benefitted by reading the literature from diverse sources which improved their understanding on the topic concerned with an increase in knowledge. A previous study done in Kasturba Medical College, Manipal University, Mangalore, Karnataka also reported a 53.75% increase in reading diverse and recent bibliographic sources for PBL [7].

Van den Hurk et al. noted that the performance in the presentation phase is a direct reflection on the process of preparation for the problem[8]. If the students are well versed on how to search for the literature from the given references, then the learning becomes more easy, under stable and interesting. In the present study also the students have shown a positive attitude in the preparation phase of PBL where the median score was more than three for [62(63.26%)] students. Proper search of literature with analytical understanding of the concepts and making notes and summaries goes a long way in making PBL successful.

The present study has reported uncertain acceptance for PBL [42(42.86%)] in regards to presentation phase. The percentage for acceptance as well as non acceptance for PBL was found to be same [28(28.57%)]. This could be due to the fact that some of the students are not comfortable to open up in front of their faculty and peer to answer or clear any doubts that they had for fear of being ear marked by the teachers or due to lack of confidence level. It may also be due to the presence of strict faculty or due to lack of interest by the student on the subject. The facilitator needs to play a very important role in identifying such students and give them timely counselling to boost up their morale and self confidence. A study done by Bijli Nanda of Sharda University, Greater Noida, Uttar Pradesh has reported that majority of the students coming from abroad believed that there was similarity in the student–teacher relationship in both the traditional method as well as in the PBL methodology. Whereas one third of the Indian students found PBL to be better, another third felt both the method to have equal weight and the remaining third opted for the traditional method in regards to student-teacher relationship. This could be due to the fact that that the students from abroad are already exposed to the PBL approach[9].

Discussions in small groups paved the way for better learning process[10]. Even the present study has shown an overall acceptance to PBL objectives with the true location of median score above3.

Conclusion

Based on the feedback results of the questionnaire, the future PBL sessions can be modified, planned accordingly and executed in a more productive way so as to nurture the development of reflective learning in students to bring maximum improvement in the educational outcome. The shortcomings seen in the presentation phase should be bridged to develop the attitude and professional wisdom of the students. Also, students can have a personal insight of their strengths and limitations with respect to a given area of learning[11]. To have better educational outcome, PBL must be used as an adjunct along with the traditional method.

Limitations: The study was done only to know the students perception towards PBL and not the level of knowledge gained by using it as a teaching methodology.

Conflict of Interest: There was no conflict of interests.

Source of Funding: Self funding .

Ethical Clearance: Ethical committee clearance has been given by institutional research committee vide letter no. AIMSR/IRB/RC/2018/06/35

Abstract

Objective: To find out the effect of dance therapy on stress and anxiety in working women.

Method: A total of 41 women between age group 25 to 40 years were randomly selected to receive aerobic dance therapy. The program was conducted for 4 weeks, scheduled three days in a week, with a session of 10-20 minutes each day. Outcome assessment included perceived stress scale (PSS) and Hamilton anxiety rating scale (HAMA) which was recorded before and after completion of sessions.

Result: There was a reduction in levels of stress and anxiety after 4 weeks of aerobic dance therapy (p value < 0.0001) which was found to be statistically significant; whereas correlation between working hours and scores of PSS (r value -0.16) and HAMA (r value -0.06) Scales were statistically insignificant.

Conclusion: On the basis of results of our study we concluded that aerobic dance therapy was effective in reducing stress and anxiety in working women.

Keywords: *Aerobic dance, Stress, Anxiety.*

Introduction

The lifetime prevalence of stress and anxiety among general population of adolescent age group and young adults ranges between 5-70% in India.[1] The prevalence found worldwide for anxiety in men and women was 10.6% and 16.6% respectively, with a ratio indicating that prevalence is approximately twice among women than men.[2] From the people working for longer duration, it was found out that 8.2% males and (10%) females were suffering from symptoms of anxiety.[3] Prevalence of stress in working population for males was 13% and in females was 3%.With the developing industrialization and urbanization, the status of women has been changing due to which the levels of stress are seen to be elevated;the prevalence of stress was found to be 37% and for anxiety it was 40% among working women in India.[4]

Rapid changes in lifestyle and increasing competitiveness have led to a marked stress among working population.[5] There is an increase in the amount of stress level as women have to deal with both the stress from home as well as stress from work.[6] Symptoms associated with stress such as insomnia, fatigue, irritability, headache, depression, unhealthy behaviors like poor eating habits are commonly seen in working women.[5] Also prolonged stress can adversely affect the cardiovascular, endocrine and central nervous system. Chronic stress is the leading cause of anxiety. Symptoms produced due to anxiety are frequent panic attacks, phobic disorders like agoraphobia, social phobia and unpleasant thoughts.[7] Negative affective conditions are associated with concept of stress. Also, with precipitation of the episodes of anxiety and depression, a stress event of life leads to a characteristic stress response with involvement of chronic arousal and impaired functions. Consider as a mental state, the concept of a stress response has clear affinities with anxiety.[8]

There are certain physiological and biochemical changes that occur in the body with response to stress.

Physiological changes triggered by stress include increased respiration and volumetric consumption (VO_2), dilation of bronchioles and airways. Due to simultaneously increase in cardiac output and blood pressure there will be an increase in blood flow to heart, muscle and skin.[9] Biochemical changes triggered in stressful conditions activate two main pathways, sympatho-adreno-medullary axis (SAM) and Hypothalamus-pituitary-adreno axis (HPA). These two factors are activated by Corticotrophin Releasing Hormone (CRH) which causes release of ACTH by pituitary gland. In SAM, ACTH stimulates the adrenal medulla which releases catecholamines epinephrine and norepinephrine. In HPA axis, Adrenocorticotrophic hormone (ACTH) acts on adrenal cortex which releases Cortisol. Cortisol changes the metabolism of liver by increasing glucose and ATP which repairs the cells in response to stressful conditions.[9]

Along with physiological and biochemical changes there are some psychological symptoms of stress and anxiety such as, mental fatigue, depressed mood, sleep disturbances which aggregate distress and also affect the quality of life;[10] hence, it is necessary to quantify stress and anxiety. Various method used to quantify stress may includes, Singh's Personal Stress Source Inventory (SPSSI)[5], Cortisol for measuring stress level. Pss has good reliability score ICC, 0.86 with good supporting validity.[11] Also,there are various method used to quantify anxiety includeThe State and Trait Anxiety Inventory (STAI) instrument, Structured Interview Guides for Hamilton Anxiety Rating Scales (SIGH-A)[12]but, the test-retest reliability score for Hamilton anxiety rating scale is ICC, 0.86 and validity score is ICC, 0.57 which iseasy way to measure severity of anxiety symptoms.[13]

There are various pharmacological and non-pharmacological therapies used for the treatment of stress and anxiety. Pharmacological treatment consists of antidepressants, antipsychotic and anxiolytic drugs[14] and non-pharmacological treatment includes progressive muscle relaxation technique (PMRT),[5] yoga, behavioral therapy, psychoanalytical therapy, group therapy.[12] Also there are some art therapies such as painting, playing, sculpting, dance therapy and music therapy.[15] Astudy was done on effect of music intervention on stress and anxiety, results of study indicated that music interventions are effective in reducing stress and anxiety.[16] It has been documented that music interventions can decrease the level of stress and anxiety and increasing psychological well being, relieving physical, mental tension and regulates serotonin and dopamine level.[17] There are various types of dance which helps to reduce the stress and anxiety like ballroom dance, street dance, jazz, ballet dance and Zumba but aerobic dance has a highly positive impact in management of stress and anxiety.[18] Aerobic dance is one type of aerobic exercise, word aerobics means "with oxygen".[19]Analysis revealed improvements in fatigue, stress and anxiety were seenafter 10 minutes of exercise, with progressive improvements after 20 minutes and there was no additional improvement over longer period.[20]

Studies have shown a beneficial effect of aerobic dance on stress and anxiety;A study was done the effect of aerobic exercise on depression, anxiety in middle- aged adults, they concluded aerobic training had significant effects and according to the results they concluded that aerobic dance can improve mental health and enhance life quality.[21]

No study is conducted till date hence, this study is necessary to find out effect of aerobic dance on stress and anxiety among working women. The purpose of the study is to determine the effect of dance therapy on stress and anxiety in working women.

Materials and Methodology

Study Design: Pre and post test, Sample size-41, study place-Krishna hospital, Karad, study duration- 3 months, sampling method- simple random sampling, sessions duration-4 Weeks

Participants:

Inclusion Criteria: Working women of age group 25-40, who had mild to moderate stress and anxiety on PSS and HAMA scale scores and women who work for more than 6 hours per day were taken in the study.

Exclusion Criteria: Women with psychological ailments, past history of surgery, pain anywhere in the bodyof varying intensity, any physical injury, and subjects with cardiac and respiratory conditions were excluded from the study.

Outcome Measures: Outcome measures were recorded prior to the 4 week aerobic dance therapy program and again recorded at the end of the program.

1. Perceived Stress Scale 14- PSS 14was given to the subjects which consisted of 14 questions and subjects were asked to fill it by circling the numbers

given in them where, 0=Never, 1= Almost never, 2= sometimes, 3= fairly often, 4=very often and scores were obtained by reversing the scores on the seven positive items 4,5,6,7 and 9 and then summing across all 14 items.[11] A total score range of PSS -14 was 0-56 where <14 indicates mild stress, 15-28 moderate stress and 43-56 indicates severe stress.[24]

2. Hamilton Anxiety Rating-The scale consisted of 14 questions which were filled by the subjects by marking the numbers given in the scale. In which 0= Not present, 1= mild, 2 = moderate, 3= severe, 4=very severe. After addition, a total score range of 0–56, where <17 indicates mild severity, 18–24 mild to moderate severity and 25–30 moderate to severe.[13]

Interventions: The study was designed into three parts as pre-test, the specific training program and post-test. The program was continued for 4 weeks, scheduled three days in a week, having sessions of increasing intensity and duration. In 1st and 2nd week aerobic dance intensity was low and duration was 10-15 minute. In 3rd week and 4th week intensity of aerobic dance was moderate to high and duration was 20- 25 minutes. The training program scheduled as follows.

Table No. 1: Dance therapy session protocol

	1st week	2nd week	3rd week	4th week
Warm-up	2 min	2 min	2 min	5 min
Aerobics	5 min	10 min	15 min	15 min
Cool Down	2 min	2 min	2 min	5 min

Warm up- Stretching of pectorals, stretching of neck muscles, capsular stretching, hamstring stretch, quadriceps stretch, calf stretch, trunk side flexor stretch,lunge stretch, arm rotations, neck rotations, waist twist, wrist rotation, hip rotation,half squats, jumping jacks.

Training program- Heel digs, grapevine, V- box, A-box, front lunges, side lunges, shower dance, skipping, diagonal toe touch, punches, hamstring curls, criss cross with arm movement, toe touch, marching, grapevine with hamstring curls.

Cool down- Stretching of pectorals, stretching of neck muscles, capsular stretching, hamstring stretch, quadriceps stretch, calf stretch, trunk side flexor stretch, lunge stretch, hand kicks, jumping jacks, half squats.

Dance therapy was conducted in well ventilated room and it was carried out in standing position. In warm sessions and cool down sessions, the hold time for stretching was maintained for 10 seconds. From 3rd week onwards, the main workout session was done twice.

Results

1. Age distribution in the study:

Table No. 2: Age distribution

Age	No. of Subjects
20-30	32
30-40	9

2. Comparison of pre and post scores in stress and anxiety:

Table No. 3 comparison of pre and post in stress and anxiety using pss and hama scale

Parameters	Pre Mean ± SD	Post Mean ± SD	Mean DIFF	t value	p value
PSS	28.61±4.73	26.29±4.07	2.31	4.629	< 0.0001
HAMA	16.02±8.79	13.17±8.42	2.85	8.783	< 0.0001

3. Correlation between working hours, PSS and HAMA scale:

Table No. 4: Correlation between working hours, PSS and HAMA scale

Parameters	'r' value	Remark
PSS	-0.16	Not significant
HAMA	-0.06	Not significant

From the above table it is clear that effect of aerobic dance in working women with the use of the parameters PSS and HAMA scales was found to be statistically extremely significant as both the p-value were noted to be (< 0.0001).

Statistics: The outcome measures were used to assess, before the sessions and after completion of sessions. Data analysis was done using paired t test

and analysis was performed using SPSS (version 22). Statistical significance was accepted for values of $p<0.05$ at 95% confidence interval.

Discussion

Stress and anxiety are highly prevalent in the general population.[1] Ability to cope with improving industrialization and competitiveness, the level of stress is increased. Stress and anxiety is more common in women who work for more than 55 hours a week.[22] In the current study, 41 women between the age group of 20-45 years fulfilling the inclusion criteria were included.

Statistically the present study showed that, there were considerable changes in the outcome measures with significant difference seen in stress (mean difference=2.31) (p value <0.0001) and anxiety (mean difference 2.85) (p value<0.0001) levels in working women. In our study we analyzed that the changes in perceived stress scale for stress and Hamilton anxiety rating scale for anxiety, after incorporating aerobic dance therapy for total 12 sessions in duration of 4 weeks were found significant results. It has been studied that aerobic dance therapy offers a way for an individual to defend against stress and anxiety by releasing endorphins and neurotransmitters that increases the feeling of well being which can relieve the stress and anxiety and also it gives positive effects on both musculoskeletal and cardiovascular system and hence maintain good fitness.[23] A study investigated effects of 12 weeks of dance intervention on psychiatric patients with stress and depression they found out that significantly less depression in subjects who participated in dance group than the subjects in music therapy session.[15]

A study was done on effect of aerobic dance for 1 hour session conducted each day for 6 weeks. They found that aerobic dance has highly positive impact in the management of stress related problems and practicing aerobic dance has been shown to improve and sustain physical as well as mental efficiency.[19] A study was done on effect of dance therapy on cardiovascular parameters for 4 weeks they found out that dance therapy was effective on cardiovascular parameters[23] similarly,we set the program for 4 weeks to check whether dance therapy is effective in reducing stress and anxiety, the results were found to be significantly effective in reducing stress and anxiety in working women.

In our study at the end of 4 weeks, it was recorded that the correlation between working hours, stress and anxiety was statistically not significant. But there was statistically significant difference between pre-interventional and post-interventional values of stress and anxiety in a group of working women thus, concluding that there is a positive effect of aerobic dance on stress and anxiety in working women.

Conclusion

On the basis of the results of our study, it was concluded that aerobic dance therapy was significantly effective in reducing stress and anxiety in working women. And it has highly positive impact in management of stress and anxiety related problems.

Ethical Clearance: Ethical Clearance is taken from Institutional Ethics Committee of Krishna Institute of Medical Sciences Deemed to be University, Karad.

Conflict of Interest: The authors declare that there is no conflict of interest concerning the content of the present study.

A Study on Effect of Favorite Film Songs on Heart Rate Variability (HRV) and Heart Rate (HR) with Moderate Exercise

Manibalanvijayaraman

Assistant Professor, Department of Physiology, Vinayaka Mission's Medical College & Hospital, Karaikal–609609, Puducherry

Abstract

Introduction: Heart rate variability (HRV) is the physiological event of variation in the time interval between heart beats. It is measured by the variation in the beat-to-beat interval (R-R interval).The present study aimed at determining the effect of favorite film songs on HRV and HR with moderate exercise.

Materials and Method: This was a cross sectional observational study conducted in the department of physiology, Vinayaka mission's medical college & hospital. Participants were allowed to select favorite slow tempo and fast tempo film songs. Selected songs were played (4-5 minutes) before and during exercise, with 30 minute interval (each day N=10) and their HRV and HR were measured by using time and Frequency domain method. (Standard instrumental protocol was followed).

Results: In this study, participants were able to do exercise at a lower HR with a slow tempo film song when compared to no music or film song during exercise the cardiac activity the HR and HRV was improved and fast recovery too. It was observed that the musical therapy improved the time and frequency domain indices of HRV.

Conclusion: The present study clearly indicates that, a particular favorite tempo of a film song or music has a beneficial effect on HRV and HR changes through the involvement of the PSNS and SNS.

Keywords: *Favorite film songs, Heart rate variability, Heart rate.*

Introduction

Heart rate variability (HRV) is the physiological event of variation in the time interval between heart beats. It is measured by the variation in the beat-to-beat interval (R-R interval).[1] The beat-to-beat alterations in HRV, is an accurate and reliable reflection of the many physiological factors modulating the normal rhythm of the heart. Further, HRV testing is a prognostic (predictive) indicator of cardiac condition, fitness, stress levels, aging, health risk levels and chronic disease condition.[2]

HRV is the immediate variation in heart rhythm due to ANS influences on the Sinoatrial node (SA node).Previous researchers showed that the high HRV indicating good health and a high level of fitness, whilst decreased HRV is linked to stress, fatigue and even burnout. The intervention of music indicating positive effect on HRV. [3]An individual's relaxation response is based on his music generi, which is composed of different basic compositional elements, such as melody, rhythm, harmony, and tonality. Earlier studies had shown the relaxation effects of classical music at both the subjective and objective levels.[4]

It was also indicated that the music therapy has positive effects on HRV in sick patients and also soothing music has a significant effect on decreased HR and improved HRV in healthy youth. HRV alterations relate to the rhythm of the particular type of music.[3] The classical, meditation or relax music are capable of bringing out a number of health benefits including, raising states of consciousness, lowering stress level, changing moods and accessing different states of mind.[5]

Individualizing the type of music used is vital to the success of music therapy and the degree of love towards music is the most important factor in relaxation. In recent years, most of the individuals prefer film songs as a part of relaxation and also individual's preference may vary such as slow tempo or fast tempo songs. These days most of the people while jogging, doing exercise or fitness training frequently, listen to music through the headphone or earphone.

The present study aimed at determining the effect of favorite film songs on HRV and HR with moderate exercise.

Materials and Method: This was a cross sectional observational study conducted in the department of physiology, Vinayaka mission's medical college & hospital. Study was explained to the participants and informed consent was obtained. Study was approved by institutional ethical committee.

Song and Music Selection: Prior to the experimental session, participants were asked to self-report a title of their most favorite film songs (Song by the human voice with composed instrumental music) orally confirmed. Depending on their interest, the fast and slow tempo selected film songs played, then the songs or music were separated based on tempo, the tempo was calculated based on beats/ minute. The Piston soft BPM Detector software was used to find the tempo of a song. 70-80 beats/ minute (BPM) consider as slow tempo, 140-160 beats/minute songs were fast tempo, medium tempo 90-100 beats/ minute.

Film song Intervention:

A. For favorite slow tempo film song intervention, a complete slow song was played (4-5 minutes) before and during exercise, with 30 minute interval (each day N=10) and their HRV and HR were measured.

B. For favorite fast tempo film song intervention, a complete fast tempo song was played (4-5 minute) before and during exercise, with 30 minute interval (each day N=10) and their HRVand HR.

Exercise: In this study, Bicycles Ergometer for exercise was used. All the participants were instructed pre-test one week before the testing to overcome factors that could alter HRV. They will be asked to avoid heavy physical activity, smoking and alcohol and other beverages affect physical activity.

HRV Analysis: Time and Frequency domain method. (Standard instrumental protocol was followed)

Inclusion Criteria: Participants (N= 310) included 160 males and 150 females with an average age of 19 years (ranging from 18 to 23) with normal body weight. All the participants were tested initially -physical fitness, body mass index (BMI), height, waist and hip circumference, The participant's weight was calculated by a digital balance (INCO, India), BMI and with normal body weight and further the participants reported no significant hearing loss and no cardiac conditions were included in the study.

Exclusion Criteria: The participants were screened for self-reported hearing loss and cardiac history using a screening questionnaire. Participants with significant hearing loss or cardiac anomalies, diabetic, pregnant, heart failure, acute and chronic renal failure or any chronic diseases were excluded from the study.

Statistical Analysis: Descriptive data are expressed as mean ± SD, ONE WAY ANOVA was used to analyze the HRV and HR. The level of significance was analyzed. All data were analyzed using SPSS for Windows version 17.0.

Results

A total of 310 participants included in the study. 160 males and 150 females with an average age of 19 years (ranging from 18 to 23). This present study showed that the selected young subjects were able to do exercise at a lower HR with a slow tempo film song or slow tempo instrumental music when compared to no music or film song during exercise the cardiac activity the HR and HRV was improved and fast recovery too.

Table 1: Effect of slow tempo film song on HR. (Frequency Domain Analysis)

Mean HR (beats/mintes)	78.24±32	89.7±11.21	100.2±3.9	120±3.56	P<0.001
RMSSD (ms)	45.17±13.21	40.32±7.88	45.22±12.3	70.99±4.67	
NN50	10.67±13.4	8.56±4.37	6.77±12.89	15.81±8.98	

The RR interval between R to R, heart rate (HR), The Standard deviation of normal-to-normal R-R intervals (SDNN), the percentage of the adjacent RR intervals with a difference of duration greater than 50 ms (pNN50) and root-mean square of differences (RMSSD) between the adjacent normal RR intervals in a given time interval.

Discussion

In this study, participants were able to do exercise at a lower HR with a slow tempo film song when compared to no music or film song during exercise the cardiac activity the HR and HRV was improved and fast recovery too. The relation of music to emotion has been studied for decades and the literature is fruitful.[6]

Our results showed that the favorite slow song has a definite peaceful effect on exercise induced changes in HRV which is in agreement with the work of Pal et al.[7]In their study, the practice of relaxation of song therapy has significant effect in lowering the LF/HF ratio of HRV inparticipants. The present study showed that, listening to slow tempo film songs during exercise increases the HF and listening fast tempo film song or fast tempo music listening during exercise increases the LF. Increased HF indicates PSNS tone increased. [8]But, LF index communicates to both vagal and sympathetic influences on the heart, yet providing predominance of the sympathetic component.[9]

Chuang and co-workers investigated the effects of long-term, 8-month music therapy intervention on autonomic function in anthracycline-treated breast cancer patients. Theauthors observed that the musical therapy improved thetime and frequency domain indices of HRV.[10]Studies on competition stress have been observed to decrease HRV and alter the power spectrum by decreasing the High Frequency (HF) component, increasing the Low Frequency (LF) component.[11] Experimental studies have also shown that athletes report increased positive affect and reduced negative effect in conditions where they listen to arousing music, compared to no music, during moderate to high intensity activity.[12]

As per the study conducted by Lathaet al. The observations obtained revealed that heart rate and mean RR intervals showed significant changes between the music and non-music group in both genders and there was a significant decrease in the RMSSD, SDNN and PNN50 in the male population suggesting a shift towards enhanced vagal activity. From this it could be inferred that music has beneficial effect on the heart rate variability thus favouring cardiovascular health in its long run.[13]

The present study had limitations that affect generalized ability of its results. The study was conducted acute, only in the age group of 18 to 23-years-old with normal BMR. Moreover, only healthy subjects were evaluated in order to homogenize the study sample.

Conclusion

The present study clearly indicates that, a particular favorite tempo of a film song or music have a beneficial effect on HRV and HR changes through the involvement of the PSNS and SNS.

A Proximate Analysis of Phytochemical in Sonalum Trilobatum after the Addition to Leavened Yeast Goods with Sensory Evaluation

Manivel K.[1], John R. William[1], Moyeenudin H.M.[1]

[1]Asst. Professor, School of Hotel and Catering Management, Vels Institute of Science, Technology & Advanced Studies, (VISTAS), Chennai, India

Abstract

Herbs are used as a medicine in curing various diseases, Due to many reasons in recent days the Respiratory-related health issue has become one of the major problems faced by most developing countries. The constant rise in pollution from vehicular traffic, factory smoke emissions and other factors have to lead to a steady rise in global warming. As a result of these factors, certain allopathy medicines fail to have its complete usefulness on ones Therefore to achieve the natural changes and progress a neutralised therapy will help resolve this problem. By incorporating *solanum trilobatum* in bread we can gradually indicate respiratory-related health issues effectively. Since bread is the widely used commodity all over the world. It will help in resolving the deficit. The objective behind this study is to make over the human body in tune with nature. It is our effort to introduce *solanum trilobatum* in 3 different proportions into bread by testing it on the basis of liking, acceptance, taste, etc. It was observed that the procedure resulted in a product that can be effectively accepted and implemented.

Keywords: *Solanum trilobatum, bread products, anti-oxidant.*

Introduction

Solanum Trilobatum is one among the Indian traditional herbs that helps to cure many diseases in the human body. It has been elaborately used in Siddha medicines. The nature of this is, its leaves are covered by thorns, the flower is purple in color,and fruit is red in color. AS the thorn is toxic, it should be removed before using it. *Solanum trilobatum* is known for its nutritional value and numerous health benefits, such as sodium potassium, phosphorous,zinc magnesium and iron. Each part of this plant can be used for various purpose. People in India usually use them in a powder form after dehydrated by sun light; and stored in air tight container. This powder is mixed along with cooking commodities or can be made as decoction and is commonly consumed an empty stomach as per elderly advice[1]. There are numerous home recipes are not revealed out of which to maintain its traditional secrecy. Many of the herbal recipes not recorded. This kind of recipes in every day food or medicines when consumed more than prescribed levels can cause adverse side effects. Proper knowledge of right ratio before intake is most essential before using this for consumption This research was aimed at the incorporation of the *solanum trilobatum* in bread as a medicine substitute to help recover from diseases[2]. In this research, we have used *solanum trilobatum* for making herb bread with different proportion ranging from (10%, 20% and 30%) in a normal bread dough recipe such as soup stick, bun and rusk. The sample were then allowed to be examined by forty untrained customers and were used hedonic scale asked to rank their observation. Then the results were concluded from the sensory evaluation

e-mail: rishimanivelan@gmail.com

of the observation provided by the customers. The tested products were found to have better taste, texture, aroma,and appearance observed by the customers. Most of the multi-grains used in bakery industry

Cereals used in bread: Though the cereals are used to be cultivated in the Nile region and the major source of the good and best quality bread making wheat flour and all-purpose flours. There are many different varieties the durum wheat type is best known for RYE (Secalecereal): Probably of southwest Asian Origin, rye is similar in composition to wheat[3]. In Europe, it is used mainly for making rye bread and crisp bread (particularly in Scandinavia). It is also used in the manufacture of drinks: whiskey in America, Beer in Russia. Millet (Panicum miliaceum): The kernel obtained from the cultivation is widely consumed as a cereal in continents likeAfrica and Asia. It is also used as a source of starch in Russia. CORN (Zea mays): which is Native to Mexico and in some parts of South America, The major grain commonly consumed is corn kernels and it is consumed in various forms during their meal like tortilla made out of corn flour. The corn flour is used in making many Mexican specialties like burritos, Tacos, Nacos, Quesadillas, and Enchiladas. This consumes additional time and liquid than normal grain.

Herbs: The herbs accessible has its bioactive parts which help to turn away and fix any disease. The*solanum trilobatum* is an herb in like manner contains all of the 8 principal amino acids making it one of just a bunch couple of plants that give an all of protein source[4]. It is well off in flavonoids, including Quercetin, Kaempferol, Beta-sitosterol, caffeoylquinic destructive, and zeatin. As well as the herb like *Rosmarinus officinalis,* generally called nursery rosemary, is a nearby to the Mediterranean zone. This herb is a native to mint family, it is an evergreen bramble in like manner related to basil, marjoram, and oregano. It is typically found creating by the ocean, and its Latin name thinks about to "dew of the sea." 4Oregano begins from Origanum, an assortment of the mint family. Oregano at first began from warm environments in western and southwestern Eurasia and the Mediterranean locale. Oregano is a suffering plant that has the properties of herbs, green and leaflike, with round framed leaves [5].

Types of Bread: White bread has a variety of tastes and texture that add delight to meals and snacks. White flour is also an important ingredient in many dark breads which would not raise sufficiently Cottage bread is moist and flaky. It has, however, a somewhat coarser texture than other white loaves. Baked in a casserole, it is easy to preparein the oven in about an hour. When it comes out of the oven an hour later, brush with melted butter, sprinkle with salt and serve[6].A Middle Eastern bread these small loaves puff into hollow balls that can be filled with sandwich spread or butter and honey.[5] Buttermilk bread has a country kitchen lilt, and this loaf has a country –kitchen taste. It is light, of good texture, has a golden-brown crust and creamy white insides[6]. It keeps for a long period deep frozen and makes delicious toast. [6]Fork bread: Bread is rich and tenders a deep, dark brown crust surrounding a lovely yellow interior. [6]Bran, the brown, flaky outer covering of the wheat kernel, has a nut-like flavor and is often mistaken for one of several breakfast portions of cereal with almost the same name. They are bran, too, but of different texture and form. Hardly as exotic in flavor or appearance as its place of origin- Hilo, on the big island of Hawaii-this bread, from a recipe member of the Hilo women's club, is a good straightforward bran loaf .bran and molasses bread. There is an unusual wheat flavor about this bran bread that is underscored by the dark [7]unsulphured molasses. The bran particles are believed to cut the gluten stands which reduce the size of the loaf compared to a loaf off-white made with the same volume of flour. Oats bread Oats have had a plebeian upbringing, mentioned as a weed by the classical writers of Rome, and used infrequently in medicines[7]. In the early Christian era they grained some stature as a foodstuff, yet despite their ability to add flavor and good texture to the bread, oats have come down through the centuries principally as a food for livestock. Blended bread. The bread made with the blended grains are coarser, denser, and darker than most other loaves. They taste of no one grain but the meld of them all. In the seven recipes, there is a total of seven different flours and cereals of French bread in France, bread is seldom baked in the home because the boulangerie is just around the corner producing its bounty of golden loaves, six days of the week potato bread. The potato grew wild in Peru and was taken to Europe by Spanish explorers in 1530.

Materials and Method

The ingredient was sourced as whole grains from a local grocery store as whole grain. It was then combined together and further milled and then stored in airtight containers before its actual use. The recipe was tried in the department of Hotel and Catering Managementat Vels University, Chennai during 2018-2019 in the

month of January

Recipe:

Serial Number	Ingredients	Quantity
1	Multigrain flour	200g
2	Yeast	5g
3	Salt	3g
4	Water	120ml (100ml-120ml)
5	Gingely oil	20ml
6	Sugar	20g

A percentage of 2 grams, 4 grams and 6 grams *solanium trillobatum* was used in three different proportion sample. It was observed that the dough did not crack in spite of having lesser gluten percentage[8]. The dough shaped into soup sticks, sunrise, mini buns etc. The shaped rolls were placed on a clean baking tray and further rested for 15 minutes. It was then baked in an oven at 170*c for 18 minutes to a color of light golden brown.

Results

Sensory Evaluation: The bread prepared with the addition of *solanum trilobatum* in various ratios and shapes was sent for sensory evaluation and their likes and dislikes are identified through hedonic scale.

Table 1: Sensory Evaluation of Soup Stick

Discussion

The bread products made with the addition of *Solanum trilobatum* is used as a sample, taste, texture and colour was good and found to be acceptable in this survey through sensory evaluation in Table 1, Table 2, Table 3. The taste of this product shows higher percentage in Table 3 as colour and aroma also satisfactory. and this food is tested for its phytochemical compounds present after the cooking process the results shows likes and dislikes with the prepration method and In the present examination, the Multigrain Bread fused with thuthuvalai and healthful screening and capacity were researched[10]. The proximate, basic, phytochemical investigation of sustenance test analyzed. The outcomes were talked about as underneath. The real constituents in the consumable bit are water, protein, sugar, lipid (fat or oil) and fiery remains (minerals). Investigation of these essential constituents is frequently alluded to proximate examination[11]. Proximate investigations of nourishment test assume a pivotal job in surveying their dietary hugeness and help to get to the nature of the example (Pandey et al., 2006). Consequences of the proximate sythesis in examined test materials are given in Table 4.

Table 4: Proximate configuration of Extract

Content	Quantity
Moisture content (%)	8.46
Ash (%)	3.41
Crude fibre (%)	4.23
Protein (%)	63.75
Fat (%)	3.42
Carbohydrate (%)	17.12

Minerals are gotten from the soil outside layer. Through the impacts of the climate, shakes that contain minerals are ground into littler particles, which at that point become some portion of the dirt. The mineral substance in the dirt is consumed by developing plants[12]. The plants are devoured by the two creatures and individuals as sustenance. This mineral turns out to be a piece of the natural way of life. The real minerals fill in as basic parts of tissues and capacity in cell and basal digestion and water and corrosive base parity[13]. Consequences of the significant minerals are yielded Table 5.

Table 5: Mineral composition of powder

Contents	Sample Extract (mg/100g)
Calcium	165.43
Potassium	127
Magnesium	88
Zinc	12.42
Iron	65.87
Phosphorous	132.45

Phytochemicals Study: The Phytochemicals hasNutraceuticals significance ofelements which support in advance wellbeing is happen with a convergence in sustenance of pharma businesses[14]. Thesematerials will go to separated supplements, nutritional enhancements with explicit weight control plans to hereditarily built originator sustenance's, natural items, prepared nourishments and refreshments. Isoflavonoids, Phytochemicals present in the herb are comprehensively depicted as phytosterols,limonoids,t erpenoids, carotenoids, phytoestrogens, polyphenols, flavonoids, anthocyanidins and glucosinolates[15]. They have gigantic effect on the social insurance framework and may give therapeutic medical advantages including the counteractive action and additionally treatment of ailments and physiological issue. Lion's share of sustenances, for example, entire grains, beans, natural products, vegetables and herbs contain phytochemicals of nutraceutical significance[16]. These element of phytochemicals more over unaided as well as in blend, have colossal restorative potential in relieving different sicknesses including malignant growth, diabetes, stomach ulcer, Heart related infections, and blood pressure and so on. In the present examination, tannin, flavonoids, steroids, alkaloid and polyphenol were available in the tried example. The nearness of these mixes shows the beneficial outcome on the wellbeing.

Conclusion

The phytochemical study of *solanum trilobatum* herb shows that it is loaded with various minerals with good nutritive value and an proximate analysis of this herb states that this can be stored for a longer period when it is prepared with a combination of all-purpose flour and other yeast made ingredients like sugar, salt,water,*solanum trilobatum* powder to make a bread[6].

The sensory evaluation of this bread on taste, texture and appearance gave maximum satisfactory levels, also we believe the tested products using it can help people with respiratory problem as it has magnesium and iron in it. The popularity of bread products in the market gluten-free bread wholemeal bread rye bread Repopulation is taken place in the bakery industry due to the various lifestyle-related diseases in the search of healthy products with this intention multigrain bread commonly known as one traditional grain leaving more healthy bean used in the bakery for making of a variety of bakery products.

Satisfaction Level of Physiotherapy Students in North India

Manoj Malik[1], Charu Gera[2], Jaspreet Kaur[1], Vandana Yadav[1]

[1]Assistant Professor, Department of Physiotherapy, [2]Student, Bachelor of Physiotherapy, Guru Jambheshwar University of Science and Technology, Hisar, Haryana. India

Abstract

Background: Physiotherapy or physical therapy is one of the allied health services that is used to improve patient's quality of life without use of drugs. This service helps in restoration and improvement of function by applying manual therapy, physical modalities, therapeutic exercises and hydrotherapy etc.

Study Design: A Randomized Survey Design.

Objectives: To find out satisfaction level among physiotherapy students of North India.

Method: Total 161 students from Physiotherapy colleges of North India, voluntary participated in the study among which 55 were male and 106 were female. Inclusion criteria were students of third-year and fourth-year of Bachelor of Physiotherapy degree; both male and female with age limit 19-24 years. First-year and second-year students, Postgraduate students, interns and professionals were excluded from the study.

Results: Average score of DREEM Questionnaire was 127. In the questionnaire, there were five questions (i.e. 1, 2, 10, 18 & 19) that scored highest value and showed high satisfaction rate. Total 142 students (88.19%) were happy to choose this particular field while 19 students (11.18%) were unhappy.

Conclusion: Out of 161 students, 142 students (88.19%) were happy to choose Physiotherapy field. Physiotherapy students of North India have high satisfaction level towards Physiotherapy course.

Keywords: *Physiotherapy, Satisfaction level, DREEM inventory questionnaire.*

Introduction

Physical therapy is defined as "the restoration or treatment of physical deformities, contractures or pain by applying various exercises, electrotherapeutic modalities, mobilizations, manipulations and hydrotherapy etc. without use of any medications oroperative procedure"[1]. The **APTA** (American physical therapy association) defines Physical therapy in which physical therapists examines the patients completely and after that makes an effective treatment plan which primarily focuses on relief of pain, increase range of motion, improvement infunctions and prevention of deformities because of any pathology associated with musculoskeletal, neurology, pediatric, sports, obstetrics and gynecological conditions[1].

Evolution: Electrotherapy (such as water therapy, hot, cold and electric current) mainly used by physiotherapists were developed in Greece by Hippocrates, who is considered as Father of Western Medicine. Various exercises were used in the era of 1500s, 1600s, and 1700s in Europe for the treatment of myopathies, degenerative disorders, bony dysfunctions and many more. At the time of 1800s, sensory or muscle re-education were used to treat various neurological or orthopedic disorders and injuries. Physiotherapy mainly originated during the World War I which required the

Corresponding Author:
Vandana Yadav, MPT
Assistant Professor, Dept. of Physiotherapy, Guru Jambheshwar University of Science and Technology, Hisar-125 001, Haryana, India

treatment of army soldiers mainly injured in war. The outburst of poliomyelitis in the United States during 1920 to 1930 resulted in urgent need of physical therapy. Many individuals in the United States required short term and long term Rehabilitation after the 2nd World War. This raised the physical therapy standard [2].

***Physical Therapy Course Work*:** To raise the profession, university decided to start the basic level course for physical therapy to train the nurses and individuals. To initiate this, University of Southern California in 1992 and Creighton University of Nebraska in 1993, start DPT. This was 2 years diploma in physical therapy. Then bachelor's degree was initiated. Presently, it isof 4 and 1/2 year degree. Then,Initiation of master's degree programs started in physical therapy. It was 2 year specialization degree (American Physical Therapy Association, 2003).At present, a number of universities are offering PhD program in Physiotherapy.

Career in physiotherapy: Physiotherapists are offered clinical jobs ingovernment as well as private hospitalsand academic jobs in institutes, colleges and universities. Physiotherapy services are also required in geriatric and pediatric rehabilitation centers as well as with sports team and individual sports persons. It is also required in corporate sector for prevention and management of work related injuries.

***Current issues in physiotherapy*:** The current issues in Physiotherapy in India are students' perceptions about their profession, career opportunities, level of remuneration, job satisfaction, job retention, patient referrals and public awareness about physiotherapy etc[3]. Student's perception, learning behavior & education is the most important basis for any professional growth and educational satisfaction among students. Thus, World Federation for Medical Education focused on evaluating learning behavior and educational environment[4].

The rationale for DREEM inventory questionnaire was to investigate the role of academic environment in student's learning, perceiving and any effect on their growth, profession, progress, behaviour and social well-being[5].

Methodology

***Eligibility criteria*:** The present study was randomized survey design. Inclusion criteria were3rd & 4thyear undergraduate students,both males & females with age from 19 to24 years pursuing Bachelor's of Physiotherapy degree.An exclusion criterion wasfirst-year and second-year students, Postgraduate students, interns and Physiotherapy professionals.

Tools and Instrumentation: Student's satisfaction level was evaluated by using "**DREEM (Dundee Ready Educational Environment) inventory questionnaire"** and the data collected was kept confidential. DREEM inventory constitutes 50 questions, that are simple, self-allocated and closed-ended questions related to academic environment, teaching and learning[6].Each question consists of 4 to 0 score on a "**5-point Likert response"** as follows: [4= strongly agree; 3 = agree; 2 = unsure; 1= disagree and 0 = strongly disagree]. Averagescores between 3 and 4 mainly indicatetheir satisfaction, questions with anaverage score of 2 represents dilemmaand scoresof 0 and 1 indicate dissatisfaction. There were some negative questions that are question number 4, 8, 9, 17, 25, 35, 39, 48, and 50. Their scoring was reversed.

Procedure: The survey was conducted at different institutes of north India including Haryana, Chandigarh, Punjab, Delhi and Uttar Pradesh. The participation was voluntary. A stratified random probability sampling was used for data collection. The questionnaire was given to undergraduate physiotherapy students. Voluntarily participation was there, and the questionnaires were kept confidential. Total 161 Physiotherapy students participated in the study voluntarily,among them 55 were males and 106 were females.

Results

142 students (88.19%) were happy to choose Physiotherapy field while 19 students (11.18%) were unhappy. Average value of DREEM Questionnaire was 127.In this questionnaire, five questions (i.e.1, 2, 10, 18 & 19) that scored highest value and showed high satisfaction rate. Figure-1 demonstrates satisfaction scale. Figure 2 to 6 demonstrates question's with highest Physiotherapy response value.

Discussion

The primary objective of this survey was to assess the student's perception regarding academic environment of undergraduate physiotherapy students. Academic environmentis the most important factor in student's behaviour, learning, understanding profession and growth[7]. We used DREEM inventory questionnaire

for this purpose. DREEM inventory is a reliable and effective instrument in interpreting the academic environment of various programmes[8]. Present survey was performed in Physiotherapy colleges of North India. In this study, maximum numbers of students perceived the educational environment as positive.

82% students responded that they were actively participating in the class that indicates student's positive perception towards teaching environment. Furthermore, new strategies should be incorporated to enhance the more interest like practical sessions, presentations and live examples. 48% students expressed that the teachers provide good support system for the students under stress while others disagreed with this point. Techniques like Jacobson Relaxation exercises, breathing exercises & regular counseling may be incorporated for effective management of stress. 35% students stated that they are tired to enjoy this course. Therefore,few extra-curricular activities such as sports, annual functions, youth festivals etc should be incorporated for more emphasis. 46% students agreed that the "learning techniques which work for me before continue to work for me now", but 17% students disagreed. Learning strategies should be modified depending upon student's capabilities. Teaching should be simple, understandable and clear. Novel learning strategies should be incorporated such as practical training, case studies, audiovisual aids etc. 12% students expressed that the teaching is not stimulating. Therefore, stimulus should be provided such as open discussion, visual presentations to make teaching more effective. The role of teachers should not be concentrated only on information provider but also a skill facilitator. They should develop attitudes and skills required for professional growth. 22% students believed that the school or institute is not time tabled. A pre-planned timetable and scheduled plan should be established in all departments for better learning. 22.36%students expressed that the teaching is not student-centered while. A revised curriculum should be established for the long term learning of the students and enhance their knowledge and confidence. 44% of participant expressed that the cheating is a main issue in this institute which indicates a serious concern. Therefore, strict rules should be included in the school to avoid cheating such as punishments (physical or mental), fine and suspension etc.

Some students (52%) stated that "there is too much factual learning to memorize" and have reported similar concern. Therefore, teaching should emphasize on long term learning as well as enhancing student's practical knowledge. There should be some holistic knowledge based on values and beliefs.The problem of **"**teacher-centered teaching and factual learning" can be resolved by implementing "Problem Based Learning (PBL) sessions" and "Short-term Student Research Project" which makes students independent. "Personal and Professional Development (PPD) sessions" can also be implemented to reduce tension and stress [9]. The students should be encouraged more towards self-directed learning to raise the confidence of working independently as well as to enhance the student's knowledge, understanding and learning [10].70% of students expressed that "the teaching time is put to good use". This is a good sign that the time is utilized optimally by maximum students. Students should be advised to utilize their time in library, reading room, OPD, and practical room's etc.18% students stated that the teachers not give clear examples. Therefore, simple examples should be given to clear the concept and overcome the doubts.8% students expressed that "they are not clear about the learning objectives of the physiotherapy course". Coordinator should advise to provide clear aims and objectives of the profession i.e.health promotion, health education and improve the quality of life.Almost 60% students agreed that the enjoyment overweighs the stress of study.Excessive stress of the study disturbs their personal life. Therefore, some extracurricular activities and functions should be organized to increase their interest in the profession.88.19% students were satisfied from their education and environment. They perceived their education more positive. Results suggest that educational performance, career and profession can be enhanced by developing or planning effective and efficient strategic techniques and various plans for better understanding, learning and knowledge[11, 12].Although educational environment needs careful ongoing evaluation on regular basis (such as teaching, learning, curriculum etc.) and requires necessary actions and cooperation from both sides (teacher and student). The overall average DREEM score for Indian medical school, Karnataka, was found to be 117/200 (n = 226), indicating that, students' perceptions towards their teaching were more positive[13].The global DREEM scores in other medical institutes such as in Sri Lanka, Nigeria and UK were found to be 108/200 [14], 118/200 [15], and 139/200 [16] respectively. The mean DREEM score for a medical school in India was reported as 107.44/200[17].This survey provides insights to the concerns and standards of Physiotherapy education in

North India. It can be generalized and necessary changes may be incorporated in curriculum as well as teaching and evaluation process to improve the satisfaction levels among the student pursuing Physiotherapy course.

Conclusion

Out of 161 students; 142 students (88.19%) were happy to choose physiotherapy field and 19 students (11.18%) were unhappy. Average score of students was 127. Students pursuing Physiotherapy course in North India are satisfied with the course. However, survey findings can be incorporated by the administration of colleges to further improve the level of satisfaction.

Ethical Approval: Participants were assured about the confidentiality of the study.

Conflict of Interest: The authors report no conflict of interest.

Prevalence of Lumbar Lordosis in Middle-Aged Females

Manpreet Bajaj[1], S. Anandh[2]

[1]Final Year Student, [2]Professor, Department of Community Health Sciences, Faculty of Physiotherapy, Krishna Institute of Medical Sciences 'Deemed to be' University, Karad, Maharashtra, India

Abstract

Objective: The objective of the study was to find out prevalence of lumbar lordosis in females aged between 35 to 45 years as per their gravida status.

Method: Ethical clearance was obtained from institutional ethical committee. A total of 100 healthy females from Karad with age between the age group of 35-45 years were selected for the assessment of their lumbar lordosis curvature. Individuals with any history of congenital spinal deformities or spinal fracture, surgical procedures related to spine, pregnant females were excluded from the study. Outcome measure used to measure lumbar lordosis was flexible ruler. The lordotic angle was calculated using the trigonometric formula θ=4 arc tan 2 h/L. Demographic data was collected, outcome assessment was recorded and later data was analyzed.

Results: We found that there is significant presence of hyperlordosis in 45% females from this study whereas presence of hypolordosis was 2%. Females with normal curvature of lumbar spine were about 53%. Hyperlordotic females with gravida 1, gravida 2 and gravida 3 showed 35%, 52.83% and 37.03% prevalence of lumbar hyperlordosis, respectively.

Conclusion: The study results concluded that hyperlordosis was extremely significant in middle-aged females with gravida 2 whereas hypolordosis was not much significant in this group.

Keywords: *Lumbar lordosis, hyperlordosis, hypolordosis, flexible ruler, gravida.*

Introduction

Lumbar lordosis is the ventral curvature of the spine formed by wedging of the lumbar vertebrae and intervertebral discs.(1) Normal lumbar lordosis angle ranges from 30º to 45º(7) Lumbar lordosis is a key feature for sagittal plane balance maintenance.(8) The balance of the muscles around the pelvis is a factor affecting the lumbar lordosis. Because of relationship between the sacrum and the pelvis through the spine, any change in the position of the pelvis leads to changes in the arch of the spine, especially the lumbar lordosis.(2)

Any increase or decrease in lumbar curvature can affect the body balance and cause various anomalies in the lumbar and pelvic regions.(3)

Figure 1: Lumbar Spine and Sacrum

With normal lumbar lordosis, energy expenditure and stress on the supporting structures is minimised when balance is maintained between the lumbar spine and abdominal musculature.

Normally, the abdominal muscles rotate the pelvis posteriorly and, the erector spinae muscles tilt the pelvis anteriorly. Correct muscle activation patterns result in normal compressive and tensile forces occurring at the lumbar spine. There are minimal stresses placed upon the intervertebral disc and the zygapophyseal joints with lumbar spine in neutral position. Hence chances of low back pain are minimal.(4)

In lumbar region, the line of gravity lies slightly posterior which causes extension of lumbar spine. Passive opposing forces are necessary to counteract this extension which are provided by the anterior longitudinal ligament and iliolumbar ligaments as well as, the anterior fibres of the annulus fibrosus of the intervertebral disc and zygapophyseal joint capsules. Active opposing forces are also necessary to counteract extension at the lumbar spine are provided by the abdominal muscles.(5)

Lumbar curvature is of great significance because it carries the upper body weight and transfers it directly to the pelvis. Any increase or decrease in lumbar curvature can affect the body balance and cause various anomalies in the lumbar and pelvic regions. It is believed that the muscles in this area are one of the factors affecting the lumbar-pelvic balance, as well as the performance of lumbar lordosis and pelvic tilt.(9) Also, weakness of abdominal, dorsal, and lumbar muscles has been recognized as the most common factors increasing the lumbar curvature.(8)

Types of Lumbar Lordosis:

Hypolordosis: When the lordotic angle of lumbar spine is less than 30º it is termed as hypolordosis.(7)

In hypolordosis there is over-compression of the intervertebral discs anteriorly with posterior displacement of the nucleus pulposus.

The zygapophyseal joints are in a close-packed position with lumbar spine extension, therefore with a hypolordotic lumbar spine, the zygapophyseal joints are distracted as a result of its anatomical orientation and also due to the decreased load on the zygapophyseal joints posteriorly.(4)

There will be stretching of the lumbar spine extensors and the posterior lumbar spine ligaments whereas shortening of the abdominal muscles and the anterior longitudinal ligament in hypolordotic lumbar spine.(5)

Hyperlordosis: When the lordotic angle of lumbar spine is more than 45º it is termed as hyperlordosis.(7)

In hyperlordosis there is compression of the posterior vertebral bodies and the posterior zygapophyseal joints since they are in a close-packed position, which increases intervertebral disc pressure and narrowing of intervertebral foramina. There is excessive stretching of the anterior longitudinal ligament and abdominal muscles while shortening of lumbar spine extensors, posterior longitudinal ligament, interspinous ligaments and ligamentumflavum.(4)

With a hyperlordotic lumbar spine posture there is impaction of the zygapophyseal joints. The resultant alteration in the spinal biomechanics results in decreased range of motion of the lumbar spine. The inflammation from the dysfunction phase of the degenerated intervertebral disc along with the decreased range of motion results in the hypersensitivity of proprioceptors and nociceptors in the intervertebral disc, ligaments, joint capsules, zygapophyseal joints and nerves. This hypersensitivity initiates a reflexogenic response thereby inducing muscle spasm.(6)

Materials and Methodology

Type of study: observational study, place of study: Karad., sample size: 100study duration: 3 months

Inclusion Criteria: 1) Age group: 35-45 years 2) Female participants irrespective of low back pain.

Exclusion Criteria: 1) Participants with any congenital spinal deformities. 2) Participants with a history or current status of spinal fracture. 3)Participants who had surgical procedures related to spine. 4) Pregnant females. 5)Participants who are physically disabled.

Outcome measures: The spinal assessment specific to lumbar lordosis was done using flexible ruler.

Ethical clearance was obtained from institutional ethics committee. 100 subjects fulfilling the inclusion and exclusion criteria were included. Prior to testing, each subject read and signed an informed consent form.

To examine the lumbar curvature, a flexible ruler was used. To assess the curvature participants were asked to stand in normal anatomical position.

First lumbar (L_1) and second sacral (S_2) vertebrae were considered as markers for evaluating the lumbar lordosis. Then flexible ruler was placed on L_1 and S_2 while a hand pressed on it to eliminate the gap between the ruler and the skin. The ruler was placed on the graph paper and the curve was drawn. Two ends of the curve were joined and a line L was drawn whose midline vertically reached the middle of the curve through the h line. The lengths of h and L lines were calculated and the a forementioned angle was obtained. θ=4 arc tan 2 h/L

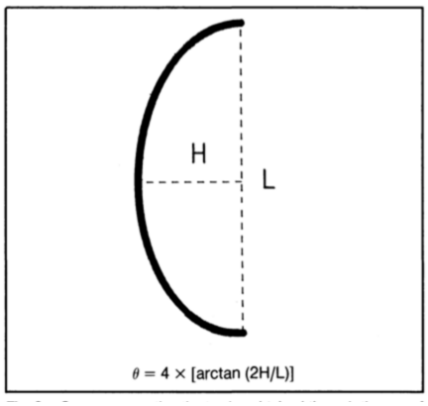

Figure 2: Flexible ruler formula for measuring lumbar lordosis angle

Findings: Distribution according to type of lumbar curvature:

Out of 100 subjects, 2 were having hypolordosis, 53 were having normal lordosis and 45 were having hyperlordosis.

Table 1: Distribution according to type of lumbar curvature

Type	Hypolordosis	Normal	Hyperlordosis
Frequency (Number of subjects)	2	53	45

2% females were having hypolordosis, 53% were having normal lordosis and 45% were having hyperlordosis.

Distribution according to Gravida:

Gravida 1: Out of 100 subjects, 20 subjects with gravida 1, 2 were having hypolordosis, 11 were having normal lordosis and 7 were having hyperlordosis.

Table 2: Distribution for Gravida 1

Type	Hypolordosis	Normal	Hyperlordosis
Frequency (Number of subjects)	2	11	7

With gravida 1, 10% females were having hypolordosis, 55% were having normal lordosis and 35% were having hyperlordosis.

Gravida 2: Out of 100 subjects, 53 subjects with gravida 2, none were having hypolordosis, 25 were having normal lordosis and 28 were having hyperlordosis.

Table 3: Distribution for Gravida 2

Type	Hypolordosis	Normal	Hyperlordosis
Frequency (Number of subjects)	0	25	28

With gravida 2, 0% females were having hypolordosis, 47.16% were having normal lordosis and 52.83% were having hyperlordosis.

Gravida 3: Out of 100 subjects, 27 subjects with gravida 3, none were having hypolordosis, 17 were having normal lordosis and 10 were having hyperlordosis.

Table 4: Distribution for Gravida 3

Type	Hypolordosis	Normal	Hyperlordosis
Frequency (Number of subjects)	0	17	10

With gravida 3, 0% females were having hypolordosis, 62.96% were having normal lordosis and 37.03% were having hyperlordosis.

We found that there is significant presence of hyperlordosis in 45% females from this study. Presence of hypolordosis was not significant from this study.

Females with normal curvature of lumbar spine were about 53%.

Discussion

This study was conducted to find the prevalence of presence of lumbar lordosis in females between the age group of 35- 45 years. Among 100 selected females, hyperlordosis was found significant in 45 females.

Women have more static lumbar sagittal curvature (lordosis) than men and there is no difference in lumbar curvature between those with undifferentiated LBP and those without LBP.

Females with hypolordosis were having lumbar lordosis angle less than 30°. Among 100 females only 2 females were having hypolordosis. This was about 2% of total females.

Females with normal lumbar lordosis were having lumbar lordosis angle ranging between 30°-45°. Among 100 females 53 females were having normal lumbar lordosis. This was about 53% of total females.

Females with hyperlordosis were having lumbar lordosis angle more than 45°. Among 100 females only 45 females were having hyperlordosis. This was about 45% of total females.

Out of 20 females with gravida 1, only 2 were having hypolordosis while 11 were having normal lumbar lordosis and 7 were having hyperlordosis. That is, 10% females were having hypolordosis, 55% were having normal lordosis and 35% were having hyperlordosis.

Out of 53 females with gravida 2, none were having hypolordosis, 25 were having normal lordosis and 28 were having hyperlordosis. That is, 0% females were having hypolordosis, 47.16% were having normal lordosis and 52.83% were having hyperlordosis.

Out of 27 females with gravida 3, none were having hypolordosis, 17 were having normal lordosis and 10 were having hyperlordosis. That is, 0% females were having hypolordosis, 62.96% were having normal lordosis and 37.03% were having hyperlordosis.

There is presence of hyperlordosis in 45% females from this study. Presence of hyperlordosis in middle-aged females with reference to gravida status is as follows-

Gravida 1- 35%, Gravida 2- 52.83% and Gravida 3- 37.03%

Presence of hypolordosis was not significant from this study. In females with gravida 1 only 10% (2 females) presented with hypolordosis.

Females with normal curvature of lumbar spine were about 53%. Presence of normal lumbar lordosis in middle-aged females with reference to gravida status is as follows-

Gravida 1- 55%, Gravida 2- 47.16% and Gravida 3- 62.96%

Conclusion

We found that there is significant presence of hyperlordosis in 45% females from this study whereas presence of hypolordosis was 2% from this study.

Females with normal curvature of lumbar spine were about 53%.

Abstract

Background and Aims: The success of an endodontic treatment depends on various factors and use of an ideal obturating material is one among that.

The aim of this study was to evaluate and compare the radiographic success of different combinations of zinc oxide as an obturating material in pulpectomy of primary mandibular molars at three and six month intervals.

Treatment success or failure was determined by a combination of clinical and radiographic findings at three and six month intervals.

Results: The results at three and six months follow up yielded statistically significant reduction in size of radiolucency, whereas, the resorption rates of the root and the different materials showed no statistical significance.

Conclusions: All the materials used in the study have potential obturating material property, which shows promising results in preserving the tooth in its dental arch.

Keywords: *Pulpectomy, Obturation, Endoflas, Calcium hydroxide, Sodium fluoride, Zinc oxide eugenol.*

Introduction

Dental caries in primary teeth remains a considerable dental health problem. In an irreversibly affected pulp tissue, either due to caries or traumatic injuries, endodontic treatment is considered as the best option. For the success of an endodontic treatment, numerous materials have been tested as an obturating material but none of these possess all the ideal requisite properties required for obturation in primary teeth; especially with regard to the major desirable property of having a rate of resorption matching that of the physiologic root resorption of primary teeth and faster resolution of furcal radiolucency.[1]

Material and Method

The present in vivo study was carried out in a clinical set up; on a sample of one hundred and five primary mandibular molars of children in the age group between 4-9 years of both the sexes using simple random sampling technique. A written informed consent and assent were obtained after being advised about the nature of the study according to the protocol approved by the Ethics and review committee. Inclusion criteria were healthy, co-operative children without any systemic disease, history of spontaneous pain with deep carious lesion which is tender on percussion, radiolucency

involving pulp with loss of continuity of the lamina dura, radiolucency in inter-radicular not involving permanent tooth bud, adequate bone support and root length, with no radiographically discernible pathological internal or external resorption, without sinus formation and those children who can report back for the recall visits. Teeth with abnormal mobility other than the normal exfoliation were excluded from the study.

A single sitting pulpectomy was carried out in these samples after administration of local anesthesia using 2% lignocaine with 1:80,000 adrenaline, isolation was achieved with rubber dam during the entire procedure. All the carious tooth structure was removed to gain good access to the coronal pulp. Access opening was done with No. 2 and 4 round diamond burs and the overhanging dentin was removed from the roof of the pulp chamber with Endo-Z carbide bur. Extirpation of pulpal debris from the root canals were done using K and H files of sizes 8 and 10 and copious irrigation with normal saline. After working length determination, the canals were prepared with K-files and H-files and enlarged upto size 40. The root canals were then thoroughly irrigated with normal saline and the final wash of the canals was done with 0.2% chlorhexidine solution and then dried with sterile absorbent paper points of 0.04 taper. The root canals were then randomly filled with the respective obturating materials based on their groups either with endoflas [Group 1], or a mixture of zinc oxide powder, calcium hydroxide paste, sodium fluoride [Group 2] and zinc oxide eugenol [Group3], as per the manufacturer's instructions and were obturated with lentulospirals mounted in a slow speed hand piece. The teeth were then finally restored with glass ionomer cement. After the removal of the rubber dam, immediate post operative radiographs were taken to assess the endodontic fill. The patient was recalled after a week for the placement of preformed stainless steel crowns.

Patients were scheduled for routine recall visits at every three and six month intervals. During the follow up visits, radiographic evaluation was done by measuring the difference in size of radiolucency and also the resorption rate of the material with that of the root using Boley's gauge. [2] A blinded examiner was asked to evaluate the changes and the data was recorded.

The data obtained from this study were tabulated and statistically analyzed using Statistical Package for Social Sciences software (SPSS version 18). Intragroup data comparison was done by using Wilcoxan Signed Rank Test and intergroup comparison using Kruskal Wallis Test to find out the statistical significance of the obtained results. P value of <0.05 was considered to be statistically significant.

Findings

Out of the treated 105 samples, 34 samples were obturated with Endoflas [Group 1]; 35 samples with a mixture of zinc oxide powder, calcium hydroxide paste and 10% sodium fluoride solution [Group2] and 36 samples with zinc oxide eugenol [Group 3] and were evaluated after three and six months [Figures 1,2 and 3].

In all the three groups, reduction in size of radiolucency was noticed from preoperative, three and six months which was statistically significant except in Group 2 between three and six months [Table 1].

Intragroup evaluation of size of radiolucency and resorption rate among the three groups after 3 and 6 months [Table 2].

The change in size of radiolucency and resorption rates among the different materials after three and six months was statistically not significant [Table 3].

Discussion

A wide variety of materials have been used for obturation of primary teeth with varying success. Among these, the most commonly used is zinc oxide eugenol, sets into a dense mass which irritates periapical tissues,[3] causes necrosis of bone and cementum,[4] resists resorption and has a tendency to be retained even after tooth exfoliation causing deflection of the path of eruption of the succedaneous tooth.[1,2,4,5,6]

Calcium hydroxide is virtually an all purpose medicament in dentistry.[1] Despite its antiseptic and osteoinductive properties, it is not generally preferred in pulp therapy due to fear of internal resorption as its alkaline pH causes metaplasia of undifferentiated mesenchymal cells to odontoclasts leading to resorption.[7] It has a tendency to get depleted from the canals earlier than the physiologic resorption of roots,[1] resulting in a "hollow tube" effect within the canal wherein the unfilled area is permeated with tissue fluid that eventually becomes a site for infection.[8]

A commercially available product- Endoflas, is highly effective against resistant endodontic pathogen, E. Faecalis, so can be used for management of infected primary molars.[9] It is a hydrophilic material, which when used in humid canals, provides a tight seal, biocompatible in nature with antibacterial properties. According to Pandranki J et al,[9] it reduces periapical inflammatory processes and stimulate periapical healing with increased alkaline phosphatase action thus showing excellent healing capabilities and bone regeneration with 95%-100% success rates. When Endoflas was extruded into the dental follicle, it irritates the follicle and causes intense inflammatory reaction resulting in accelerated root resorption. The use of iodoform containing products

raises the safety issue of iodoform being allergic, causing discolouration of teeth and encephalopathy leading to coma.[1]

To overcome the drawbacks of calcium hydroxide and zinc oxide eugenol, a few drops of 10% sodium fluoride solution was added to this mixture in a previous study. It was suggested that this obturating material could leach out fluoride which will be beneficial to the erupting tooth and a reaction product of calcium fluoride was formed that added radiopacity to the material without the addition of another radiopaque material.[1]

The present study was done to evaluate and compare the radiographic success of Endoflas, a mixture of zinc oxide with calcium hydroxide paste & 10% sodium fluoride solution and zinc oxide with eugenol as an obturating material in pulpectomy of primary mandibular molars.

According to Chawla H.S. et al,[1] on obturating with a mixture of zinc oxide powder, calcium hydroxide paste and 10% sodium fluoride solution, a reaction product of calcium fluoride is formed that added radiopacity to the material. In the present study it was noted that, even though the same quantity of ingredients were used for obturation, the radiopacity of the Group 2 mixture in the immediate postoperative radiograph was nearly similar to that of the dentin, making it difficult to appreciate the length of fill of the material in the canals. Hence, it is advisable to add a radiopacifier for optimum evaluation.

In Group 1, all the 34 samples, showed statistically significant reduction in size of radiolucency from preoperative and at 3 and 6 months [Table 1]. Similar to our study, there was 100% reduction in furcation radiolucency with excellent healing capabilities.[10,11] The disparity in the resorption rates noticed in the present study [Table 2], can be attributed to the influence of various factors such as individuals body resistance;[9] preoperative pathologic condition[12] and periapical pathology.[9]

In Group 2, all the 35 samples showed statistically significant reduction in size of radiolucency from preoperative to 3 and 6 months interval but not between 3 and 6 months [Table 1]. This result suggests that maximum resolution of the radiolucency occurs within the first 3 months and the resolution rate lessens by the end of 6 months. Similar to our study, complete obliteration of the radiolucent area and regaining of normal bony trabecular pattern was noticed by about 4 to 6 months.[13] On evaluating the resorption rates [Table2], Chawla et al,[1] reported that the resorption of the material matched the physiologic root resorption at the end of two years which is contrary to our study.

In Group 3, all the 36 samples showed statistically significant difference in size of radiolucency from preoperative, 3 and 6 months and also between 3 and 6 months [Table 1]. Radiolucency was noticed in 9 samples preoperatively which showed decrease in its size at the end of 3 months and only 3 samples among them showed complete resolution at the end of 6 months [Table 2]. Similar to our study Pandranki et al,[9] and Rewal,[14] showed only 45% reduction in size of radiolucency with pre existing pathosis at the end of 9 months. On evaluating the resorption rates [Table 2], similar to our study, Barr et al,[5] Chawla et al,[1,13] Dogra S [7] and Pandranki [9] showed delay in resorption of zinc oxide eugenol to that of the root and contrary to our study, Nadkarni and Damle,[15] and Coll,[16] reported 88.5% and 86.1% success respectively.

There was no statistical significant difference on comparing the size of radiolucency and the resorption rates of the three materials with that of the root at the end of 3 and 6 months [Table 3].

Conclusion

Although the results did not show any statistically significant difference, the success rate of all these materials are quite promising in reduction of the infection rate and can be considered as a valuable material for obturating deep carious tooth. However, a longer follow up period with sufficient sample size is necessary to reach sound conclusions regarding their resorption rates, effect on the succedaneous tooth and the overall radiographic success as an obturating material in primary teeth.

Ethical clearance- All the clinical procedures were carried out following the protocols approved by the Ethics and Review Committee of Sri Siddhartha Dental College and Hospital, Tumkur (IEC 11/2016).

Conflict of Interest: None.

Abstract

The highest percentage of early marriage events for the last 3 years in girls <20 years old is found in Banjar Regency. In 2015 the percentage of early marriages reached 17.36% and in 2016 the percentage of early marriages in Banjar only slightly decreased to 16.47% while in 2017 early marriages in Banjar Regency in girls experienced an increase in cases with a percentage of 17.51% . The general purpose of this study is to explain the "Klinik Dana" Program as an Prevention of early marriage events in adolescents. The design of this study is analytical, with quasy experimental approach. The research subjects were teenagers at Banjar Regency. The number of subjects targeted for the activity was 62 teenagers. In this study, the research instruments were used as follows, questionnaire sheets, knowledge, attitudes and support for adolescent environments before and after the implementation of the program. The independent variable in this study is the development of the young clinic planning, while the dependent variable is the knowledge, attitudes and environment of adolescents. The results showed that before the intervention was obtained less knowledge of 45 respondents (72.6%), negative attitudes of 11 respondents (17.8%), and the environment did not support 3 respondents (4.9%). While the results in the second month obtained good knowledge of 9 respondents (14.5), negative attitudes of 1 respondent (1.6%), environment did not support 3 respondents (4.83%). At the final value, the results of the lack of knowledge are 1 respondent (1.6%), negative attitude 0% and environment that does not support 0%.This activity is proven to be able to increase knowledge, attitudes, and environmental support for the ideal age marriage. So that the Health Office and Puskesmas can apply this concept in an effort to reduce the rate of early marriage.

Keywords: *Early-age marriage, young clinic planning.*

Introduction

According to the National Coordinating and Family Planning Agency, the ideal age for marriage to women is at least 21 years and to men at least 25 years because at that age the female reproductive organs are psychologically well developed and strong and ready to give birth as well as men Men at the age of 25 will be ready to support their family life. Based on data from the United Nations Children's Fund (UNICEF) 2016 every year around 15 million girls in the world marry before the age of 18. One out of every seven girls in Indonesia is married before the age of 18. Indonesia is one of ten countries with the highest absolute number of child brides, namely 1,408,000 women aged 20 to 24 years have been married before the age of 18 (UNICEF, 2016). In Indonesia, in 2015 the Province of South Kalimantan was the second largest province of cases of early marriage with a percentage of 9% after Central Java (52.1%).

One regency in South Kalimantan which is located in the area of the river is Banjar Regency with the main river is the Martapura River. The Martapura River is the largest tributary in Banjarmasin. One of the social problems in Banjar Regency is the highest percentage of early marriages for the last 3 years in girls <20 years old in Banjar Regency. In 2015 the percentage of early

marriages reached 17.36% and in 2016 the percentage of early marriages in Banjar only slightly decreased to 16.47% while in 2017 early marriages in Banjar Regency in girls experienced an increase in cases with a percentage of 17.51% . Based on data from the Ministry of Religion, Kabupaten Banjar, Martapura Kota, was ranked first with girls who were married with age <20 years which reached 241 cases from 1489 marriages (16.19%) in 2015, 167 cases from 1173 marriages (14.24%) in 2016, and in 2017 that is equal to 237 cases from 1410 marriages (17.81%).

One solution that can be used to provide information and as a preventive effort for early marriage is the embodiment of the "Young Planning Clinic (Dana)" which can be used as a forum for adolescents and parents of adolescents to be given Communication, Information and Education (IEC) regarding generation planning in particular early marriage with the formation of "HIMUNG (Hope and Impian Menuntung) Cadres" and PIK-R (Information and Counseling - Youth Centers). This program is conceptualized in such a way that it fits the attractiveness of adolescents (Qiao, 2012).

Materials and Method

The design of this study is analytical, with the Quasy Experimental approach, which aims to determine the effectiveness of the "Clinic Fund" as an Prevention of Early Marriage Events in Adolescents in the Martapura River. In field research, it usually uses quasi-experimental designs (quasi-experiments). The independent variable in this study is the development of the Fund Clinic, while the dependent variable is the knowledge, attitudes and behavior of adolescents in an effort to prevent the occurrence of early marriage[1].

The research subjects were teenagers who were on the riverbank of the Banjar Regency. The number of subjects targeted for the activity was 62 adolescents. The criteria of the counselor in this study were students of the Public Health Study Program at the Faculty of Medicine, Lambung Mangkurat University who had positive knowledge, attitudes and behaviors about the prevention of early marriage. The number of counselors involved was 6 people with a ratio of 1 cadre to 15 young women.

In this study, the research instrument was used as follows, the questionnaire sheet was the knowledge, attitudes and behavior of adolescents before and after the implementation of the program. Program are made in percentage form with the Wilxon Test to see differences after and before program development. In addition, it was also seen an increase in value every week to see the success of the fund clinical program.

Result and Discussion

1. Univariate Analysis

Table 1 shows the distribution of variables according to categories that are likely related to the incidence of osteopenia in respondents.

Table 1. Frequency distribution of respondent and family characteristics

Variabel	Frequency (Person)	Percentage (%)
Knowledge		
a. Less	45	72,6
b. Well	17	27,4
Attitude		
a. Negatif	11	17,8
b. Positif	51	82,2
Environment		
a. Not Supported	3	4,9
b. Supported	59	95,1

Based on table 1 What is known is that students who are respondents in large numbers are still lacking in the amount of 45 respondents (72.6%). Knowledge used relates to age calculations, planning generation goals programs, restrictions on early marriage, factors that influence marriage events, behavior from marriage, family functions, children's rights, and also about maturation of marriage time. Of the 45 respondents, most of them still could not find out about the Genre program, which was as much as 95.5%, unknown about the minimum price of a married woman that is equal to 84.4%, unknown predisposing factors for a person's behavior were 91.1% can not know about the initial action: as much as 88.8%, the abnormalities produced before early as much as 75%.

The results of the study found that the majority of respondents had a positive attitude towards early sensitivity, namely 51 respondents (82.2%). Nevertheless, there are still 11 respondents (17.8%) who have a negative attitude.

The results of the study found that most respondents had a supportive environment for marriage with an ideal value of 59 respondents (95.1%). Nevertheless, there are

still 3 respondents with the assumption that they do not support the ideal day money. The environment used in this environment is ideal. The environment that is not supportive of marriage during ideal periods because of being pregnant in a young place is common in the respondent's place, which is 56.4%. Nationally can be seen by 8% of women 10-59 years of birth 5-6 children, and 3% of children over 7. An ideal woman is pregnant at the age of 20-35 years. The impact that will arise in pregnancy at an early time is maternal death. Based on the 2012 IDHS data, the Maternal Mortality Rate (MMR) is estimated at 359 per 100,000 live births.

2. Bivariate Analysis

Table 2. pre-test and post-test result

Category	P-Value	Information
First Month		
Knowledge	0,0001	Significant
Attitude	0,047	Significant
Environmet	0,002	Significant
Second Month		
Knowledge	0,008	Significant
Attitude	0,0001	Significant
Environmet	0,004	Significant
Third Month		
Knowledge	0,996	not significant
Attitude	0,144	not significant
Environmet	0,851	not significant

*p-value (<0,05)

Table 2 using the Wilcoxon test. Based on the table it is known that the activities in the first month showed significant results between before the implementation of the Fund Clinic with after the implementation of the Dana Clinic with a value of p = 0,0001 (<α) for knowledge so that the results showed a significant change. This increase in knowledge is due to the fact that previously students did not know about the genre program and the impact of early marriage became aware of these things. Through the Clinic program this Fund will be delivered in relation to the genre program and matters relating to early marriage. So the students who became respondents became more aware of this.

The results showed that the attitude of students between before the implementation of the Dana Clinic and after the implementation of the Dana Clinic showed significant results with a value of p = 0.047 (<α). Based on preliminary data there are 17.8% who still have a non-supportive attitude towards the ideal marriage age. After conducting the Dana Clinic program in the first stage, some students, namely 63.6% of 11 female students, changed their attitudes to support the marriage with an ideal age.

The results showed that the environmental variables showed that there was a significant change between before the implementation of the Fund Clinic and after the implementation of the Dana Clinic with a value of p = 0.002 (<α). Counseling is one form of health promotion that is simple and can cover broad goals. One of the initial outcomes of counseling activities was increasing knowledge[2].

Table 2 shows that the activities in the second month showed significant results between before and after the implementation of the Dana Clinic with a value of p = 0.008 (<α) for knowledge so that the results showed significant changes. The change was caused by an increase in the number of female students whose knowledge was good, namely from 17 female students (27.4%) to 53 respondents (85.4%) or 58% increase in knowledge. As for the student's attitude, it shows significant results also with a value of p = 0,0001 (<α). There was an increase in attitude change from 51 respondents (82.2%) to 59 respondents (95.1%) or increased by 12.9%. Whereas in the environmental variable the results show that there is a significant change between before and a myriad of activities with a value of p = 0.004 (<α). The significance of this change is due to an increase in the supporting environment, from the initial 59 respondents (95.1%) who had a positive environment to 61 respondents (98.3%). In the results of this second month, it can be concluded that intervention activities can improve knowledge to be better, change attitudes that are still negative to be positive with significant test results and from environments that do not support being supportive of marriage at the ideal age.

Table 2 shows that activities in the third month showed insignificant results before before the implementation of the Fund Clinic with after the implementation of the Dana Clinic with p = 0.996 (<α) for knowledge so that the results showed no significant changes. This is due to an increase in the number of female students whose good knowledge is not too much, namely from 53 female students (85.4%) to 55 respondents (88.7%) or an increase in knowledge as much as 3.3%. So that the increase in student knowledge does not look significant. The student's attitude showed a non-significant result

with p = 0.144 (<α). Changes in student attitudes after the Fund Clinic activities in the Third Month did not change drastically, ie from 59 respondents (95.1%) to 62 respondents (100%). The environment shows that there is no significant change between before and after the activity with a value of p = 0.851 (<α). Changes that occur are not significant, namely from the initial 61 respondents (98.3%) who have a positive environment to 62 respondents (100%). In the results of this third month all variables did not experience significant changes. This is because the knowledge, attitude, and environment of the respondents who have improved after intervention in the first and second months[4].

3. Final Results After Intervention for 3 Months

Table 3. Knowledge, Attitude and Environment After 3 Months of Intervention

Category	Frequency (Person)	Percentage (%)
Knowledge		
a. Less	7	11,3
b. Well	55	88,7
Attitude		
a. Negatif	0	0
b. Positif	62	100
Environment		
a. Not Support	0	0
b. Support	62	100

Based on table 3, it is known that the knowledge of adolescent students who become respondents is mostly good, that is equal to 55 respondents (88.7%). Good knowledge will shape and influence a person's mindset, then the mindset will form a positive attitude. The impact caused by early marriage is generally more experienced by women5. The results showed that the majority of respondents had a positive attitude towards early marriage in the amount of 62 respondents (100%). Besides knowledge, another factor that is also related to the incidence of early marriage is the attitude towards early marriage. According to Azwar (2009) the factors that influence attitudes are personal experiences where what has been and is being experienced will shape and influence one's appreciation of social stimulus and then form positive or negative attitudes. Other factors that influence the formation of attitudes are emotional. In addition there are mass media factors that can influence the formation of attitudes[6].

Based on table 3, it is known that most respondents have an environment that supports the marriage of the ideal age, which is equal to 52 respondents (83.9%). Environment is one of the factors associated with the incidence of early marriage. According to Puspitasari (2006), adding that the traditional factor of early age marriage is due to parents' fear of gossip from close neighbors, parents feel afraid that their children are said to be spinsters. Early marriage behavior is an operant behavior that is learned by adolescents from the environment where the individual lives. This is related to early marriage behavior which is influenced by the surrounding environment. The environmental influences referred to in this study are the existence of values and norms that develop in the community related to the existence of a young woman and the concept of marriage. The influence of the environment in this study was calculated through the level of adolescent's confidence in the norms and developing values[7].

4. Difference Test Analysis

Table 5. The Differences of Knowledge, Atittude, and Enviroment (before and after intervention)

Variable	P-Value
Knowledge	0,001
Attitude	0,0001
Environment	0,009

Table 4 using the Wilcoxon test. Based on the information, it is known that from the first, the results of the activity that have significant results before the activity and after counseling with a value of p = 0.001 (<α) for knowledge so that the results show there are significant changes . The student's attitude shows significant results also with a value of p = 0,0001 (<α). In the environment variable shows the results that there is a significant change between before and after the activity with a value of p = 0.009 (<α).

Conclusions

The knowledge of teenagers who become respondents is still largely lacking, amounting to 45 respondents (72.6%). Most of the respondents had neutral attitudes towards early marriage, which amounted to 51 respondents (82.2%). The knowledge variable shows that there is a significant change between before and after the activity with a value of p = 0.001. The attitude variable shows significant results between the first month to the third month with a value of p = 0,0001 (<α). In the environment variable shows the results that there is a significant change between before and after the activity with a value of p = 0.009 (<α).

[1]Postgraduate, [2]Assistant professor, [3]Professor & Head, Department of Community Medicine, Deccan College of Medical Sciences, Hyderabad, Telangana, India

Abstract

Introduction: It is estimated that 68% of the World's population shall live in urban areas by 2050; India will have added 416 million to the urban population. With rapid increase in population, the healthcare needs also increase. In 2016, 63% of the deaths were due to non-communicable diseases and 26% due to communicable diseases. India is a country with high level of morbidity. Communicable diseases contribute to the morbidity more than the non-communicable diseases. Despite the increasing public and private expenditure on healthcare, utilization of health services still remain low. The utilization of public health services in India range from 10-30%.

Aim and Objective: To study the Patterns and Determinants of Utilization of Healthcare.

Materials and Method: A cross-sectional study was conducted among 256 attendees of a health camp conducted in urban field practice area, using a predesigned and pretested questionnaire. Data entered into Microsoft excel and analysed using SPSS 20.

Results: The overall population of the area was 7634, 2256 were attended the camp giving a 30% utilisation. Out of 256 patients 40.6% were males and 59.4% were females. 25.7% Respiratory, 12.9% musculoskeletal and 11.7% gastrointestinal problems were common. It was found that the behavioural determinants of subjects utilising healthcare facilities both in public and private sector showed that free services was observed as main factor for approaching public healthcare against reliability. Whereas less waiting time was the principal factor compared to cleanliness for visiting private healthcare.

Conclusion: In the study population, Respiratory problems were found to be highest, private healthcare facility was preferred.

Keywords: *Utilization, determinants, urban Healthcare.*

Introduction

It is estimated that 68% of the World's population shalllive in urban areas by 2050 and India will have added 416 million to the urban population[1]. With rapid increase in population, the healthcare needs also increase. Indian scenario in 2016, 63% of the deaths were due to non-communicable diseases and 26% due to communicable diseases[2]. India is a country with high level of morbidity. Communicable diseases contribute to the morbidity more than the non-communicable diseases. With the concept of universal health coverage at every sector, there seems to be a changein the burden of healthcare cost with utilization[3]. The twelfth five year plan document noted disparities in access to healthcare

e-mail: shaikhson@yahoo.com

services in urban setup[4]. Health being a highly personal responsibility and major public concern takes a backseat when it comes to approaching it, spending from one's own pocket, in a country like India where resources are limited[5]. With increasing population and rapid urbanisation it is of importance that the private sector alongside public sector provides healthcare facilities to the expanding population[6]. At the end, out of pocket expenditure elimination happens to be a corner stone to achieving urban health care. This may seem possible through camp approach to increase coverage and awareness[7].

Despite the increasing public and private expenditure on healthcare, utilization of health services still remain low. The utilization of public health services in India range from 10-30%.Bare provision of primary healthcare facility, its utilization is a major concern added to its access. Doorstep provision of services in the form of Mega Health camps, also suffer some component of underutilization. This needs to be further studied as to understand the factors responsible for the behavioural pattern and scepticism prevalent among the community. There also is variability in the community with regard to demands of basic healthcare services which needs to be addressed at the time of planning stage. Against this backdrop and dearth of knowledge, the study was conducted with the aim of studying the Patterns and Determinants of Utilization of Healthcare in this area.

Materials and Method

A Cross-sectional study was conducted in the urban field practice area of a tertiary care institute in Hyderabad, Telangana during period from August-September 2018. Participants were selected from the attendees of camp by simple random sampling. Study tool consisted of predesigned, pretested questionnaire administered through personal interviews. A clinical examination of the individuals was done and appropriate treatment was provided to the needful. Questionnaire consisted of socio-demographic details, present and past illness, reasons and duration of illness for approaching healthcare, expenditure on healthcare, awareness regarding local healthcare facilities and schemes. A sample size of 256 was calculated using the formula $4pq/d^2$(p=20%, q=80%, absolute error of 5%). Persons more than 18 years of age, co-operative, who gave consent, were included in the study. Data was entered in Microsoft Excel and was analysed using SPSS version 20 and presented as frequency tables and graphs, appropriate tests of significance were applied.

Results

The overall population of the area was 7634, from which 2256 attended the camp, resulting in 30% utilization of healthcare. Data was collected from about 10% of the attendees who were interviewed and adjusted to meet the sample size which was equal to the estimate population given by the formula. It is seen that the most common age group is 18-45 years which constituted 49.6%. Among the study participants 41% were non educated, majority (45.4%) were females. Most of them belonged to class III socio-economic status. Alcohol consumption was seen in 5.5%, any form of tobacco consumption was found in 35.9%.

As seen in **Table 1**, top three common illnesses were Respiratory (25.8%), followed by musculoskeletal (12.9%) and lastly gastrointestinal (11.7%). These were more found among the females as compared to the males. This pattern may be due to the availability of the population during the services provided to them.

As in **Table 2** it was found that the behavioural determinants of subjects utilising healthcare facilities both in public and private sector showed that free services was observed as main factor for approaching public healthcare against reliability. Whereas less waiting time was the principal factor compared to cleanliness for visiting private healthcare. Odds ratio of the above two scenarios was found to be statistically significant.

Table 1: Disease pattern among the subjects

Diseases	Male n=104(40.6%)	Female n=152(59.4%)	Total N=256 (100%)
Diabetes	3(2.9)	19(12.5)	22 (8.6)
Hypertension	6 (5.8)	13 (8.6)	19 (7.4)
Respiratory	33 (31.7)	33 (21.7)	66 (25.8)
Musculoskeletal	8 (7.7)	25 (16.4)	33 (12.9)
Skin	8 (7.7)	10 (6.6)	18 (7)

Diseases	Male n=104(40.6%)	Female n=152(59.4%)	Total N=256 (100%)
Ocular	16 (15.4)	7 (4.6)	23 (9)
ENT	10 (9.6)	15 (9.9)	25 (9.8)
Genitourinary	2 (1.9)	18 (11.8)	20 (7.8)
Gastrointestinal	18 (17.3)	12 (7.9)	30 (11.7)

Table 2: Behavioural determinants of subjects for utilising healthcare facilities

Variable#	Male (n=104) 40.6%	Female (n=152) 59.4%	Total (N=256) 100%	Odds ratio (95% CI)
Public Healthcare	34 (32.7)	36 (23.7)	70 (27.3)	
Free Services*	28 (82.3)	19 (52.8)	47 (67.1)	4.4 (1.06–18.49)
Reliability	3 (8.8)	9 (25)	14 (20)	1
Availability of Doctors	2 (6)	5 (13.9)	5 (7.1)	
Others	1 (2.9)	3 (8.3)	4 (5.7)	
Private Healthcare	58 (55.8)	93 (61.2)	151 (59)	
Cleanliness	16 (27.6)	11 (11.8)	27 (17.9)	1
Less Waiting Time*	21 (36.2)	42 (45.2)	63 (41.7)	2.9 (1.15 -7.37)
Near to Residence	14 (24.1)	28 (30.1)	42 (27.8)	
Others	7 (12.1)	12 (12.9)	19 (12.6)	
Both	12 (11.5)	23 (15.1)	35 (13.7)	

Multiple response to variables * p value < 0.05 were taken as significant

Discussion

The distribution of study population was similar to studies conducted across India[4-7] where 49.6% were in the age group 18-45 years. As compared with literacy status our study showed a high illiterate population which was similarly found by other investigators in their studies[3-7]. In our study 56.2% belonged to class III socioeconomic status, whereas Gaiki et al found it to be 19.07%[3]. In a study by Mihir et al 50.6% of men consumed tobacco in various forms which was found similar to our study 51.6%, however 7.39% men consumed alcohol when compared to our study it was found to be almost double(13.5%). Similarly 23.5% of the females used tobacco (various forms) compared to our study, it was found to be 25%, alcohol consumption was found to be 0.8% in females, and in our study none of the females had the habit of alcohol consumption[8].

Common diseases which were found in our study coincided with other studies such as done by Shaikh et al genitourinary diseases (16%) and digestive diseases (12%) were found in males and genitourinary diseases 18% and digestive diseases (12%) in females[9]. Whereas in our study genitourinary diseases (2%) and digestive diseases (17.3%) was seen in males and genitourinary diseases (11.8%) and digestive diseases (7.9%) was seen in females.

Respiratory illness, diabetes and hypertension were found to be 38%, 22.5% and 23.5% in a study done by Patil et al compared to our study it was found to be 25.8%, 8.6% and 7.4% respectively[10].

In another study done by Datta et al, majority of the illnesses was contributed by respiratory, musculoskeletal and non-communicable diseases, which were 31.1%, 17.8% and 13.7% respectively compared to our study it was found to be 25.8%, 12.9% and 16% respectively[11].

67.15% visited private health facility by Shukla et al, whereas 59% utilised only private health facility and 13.7% utilised both public and private healthcare facility in the present study[5].

In a study done by Kumar et al, 40.25% of men and 46.34% of female utilised public health facility, 59.5% men and 53.66% females utilised private healthcare facility, whereas in our study 32.7% of men and 23.7% of female utilised only public health facility, 55.8% men and 61.2% females utilised only private healthcare facility[12].

Overall 59.15% utilised private healthcare and 33.8% utilised public healthcare in a study done by Kumar et al which was found similar to our study 59% utilised private healthcare and 27.3% utilised public healthcare[13].

In a study done by Shukla et al free services (64.79%) was found to be the major reason for opting public health facility in rural areas which was found similar (67.1%) to urban setup of our study[6].

Reliability (31.5%) and availability of staff (12.75%) influenced utilisation of public healthcare facilities according to a study done by Patil et al whereas our study found reliability (20%) and availability (7.1%) contribution to availing public healthcare facilities[10].

The main factors behind non utilization of public health care in urban setup were waiting time (56.6%),cleanliness (7.14%) and distance (27.2%) according to a study done by Shukla et al which was found to be similar to our study, 41.7%, 17.9% and 27.8% respectively[5].

Conclusion

This study therefore concludes that when facilities are provided for their effective utilization one must keep in mind the cleanliness and waiting time and the management of the crowd in a desirable manner. Not-withstanding the services must also be affordable/free to them for them to be effectively utilized.

Conflict of Interest: The authors would like declare no conflicts of interest.

Source of Funding: The study was self-funded

Ethical Clearance: Prior ethical clearance was taken from the institutional ethics committee

Awareness & Practice of Road Safety Measures among Under Graduate Medical Students of a Medical College in Bengaluru, Karnataka

Shyam A.C.[1], Mubarak Nadeer[2]

[1]Professor, Department of Community Medicine, Rajarajeswari Medical College & Hospital, Bengaluru,
[2]Junior Resident, Department of Community Medicine, Rajarajeswari Medical College & Hospital, Bengaluru

Abstract

Background: Road traffic accidents are considered as one of the important public health problems around the world. Data from India showed that more than 1.3 lakh people died on Indian roads, giving India the dubious honor of topping the global list of fatalities from road crashes. Rapid urbanization, motorization, lack of appropriate road engineering, poor awareness levels, nonexistent injury prevention programmes, and poor enforcement of traffic laws has exacerbated the situation.

Method: This cross sectional study was conducted among the undergraduate medical students from 1st to 9th term. Data was collected using a semi structured questionnaire by interview method. Convenient sampling was done. A sample size of 260 was calculated assuming the awareness levels among medical students as 50%, a relative precision of 6% and confidence level of 95%.

Results: The overall awareness levels among the study participants regarding road safety measures are good. More than 90% students were aware of the basic safety measures like regular use of seat belts, distraction caused by loud music and speed limitations. In the present study only 4 students (1.5%) have admitted being involved in drunken driving.

Keywords: *Road traffic accidents, awareness, medical students, cross sectional studies.*

Introduction

A road traffic accident (RTA) is any injury due to crashes originating from, terminating with or involving a vehicle partially or fully on a public road. It is projected that road traffic injuries will move up to the third position by the year 2020 among leading causes of the global disease burden. They are considerable economic losses to victims, their families, and to countries as a whole.[2]

e-mail: mubzonly@gmail.com

The UN general assembly has declared 2011-2020 as the "Decade of Action for Road Safety".[1]

The declaration holds significance because road traffic accidents (RTAs) have become a major cause of morbidity and mortality, especially among the adults and middle aged individuals who constitute economically most productive age groups of society.[1]

Road traffic accidents (RTAs) are considered as one of the important public health problems around the world.

Data from India showed that more than 1.3 lakh people died on Indian roads, giving India the dubious honor of topping the global list of fatalities from road crashes.[2]

Rather than mechanical, its human factor that

contribute significantly to increasing number of road accidents in India.[2]

According to a report published by Ministry of Road Transport and Highways, 56 accidents occur every hour on Indian roads and at least 14 people are killed in these accidents. Prevention of RTAs thus, becomes very crucial in order to improve the longevity and the quality of life of the individuals' concerned.[1]

Simple measures like being aware of various traffic rules & regulations and practice of road safety measures can effectively reduce the impact of RTAs. There were few studies in relation to road safety measures among young adults across India and abroad.

Objectives:

1. To assess the awareness among undergraduate students regarding road safety measures.
2. To measure the road safety practices of the students.

Methodology

This cross sectional study was conducted among the undergraduate medical students from 1st to 9th term over a period of 2 months (August 2018-September 2018). Data was collected using a semi structured questionnaire by interview method. Convenient sampling was done. A sample size of 260 was calculated assuming the awareness levels among medical students as 50%, a relative precision of 6% and confidence level of 95%. Ethical clearance was obtained from the institutional ethical committee. The students with a valid driving license who gave consent were included in the study.

Results

Mean age group of the study participants was 19.9 years with a standard deviation of 1.52.

Majority of the participants were females–155 (59.6%) and males were 105 (40.4%).

Awareness of Road Safety Measures: Majority of the participants were aware of the fact that drunken driving is dangerous (99.3%) and 4 students have admitted being involved in drunken driving (Fig 1).

Most of the participants were aware of the safe use of newer technological assistance systems like navigation & Bluetooth hands free devices.

An alarming finding is the lack of knowledge on lane discipline taking into consideration the fact that all participants were valid driving license holders. 49 students (18.8%) did not know the correct lane that should be followed while driving/riding in India.

48 students (18.5%) did not know the correct lane for overtaking. We must keep in mind that a majority of accidents happen as a result of improper overtaking maneuvers.

Table 1. Awareness levels among participants (who responded in affirmative) regarding road safety measures

Sl.No.	Road Safety Measures	Total in%
1	Driving after consuming alcohol is dangerous	99.3
2	Cautious driving near schools	99.6
3	Safe time to read maps is when your vehicle is parked	98.5
4	Seat belts should be worn by everyone in the car	91.6
5	Loud music in the car can distract the driver	87.0
6	One should drive in the left lane	81.2
7	One should overtake from the right hand lane only	81.5
8	One should pull over when it is safe to give way to an ambulance	99.2
9	Safest way to use mobile phone while driving is hands free device	97.3
10	One should wait patiently if pedestrians are taking too much time at zebra crossings	89.2
11	Correct knowledge about speed limits is essential	98.5

Practice of Road Safety Measures:

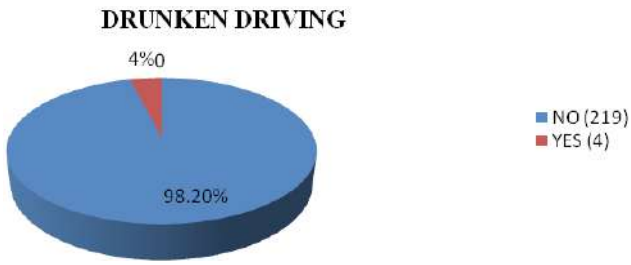

Fig 1. Pie chart showing that majority of students avoid drunken driving

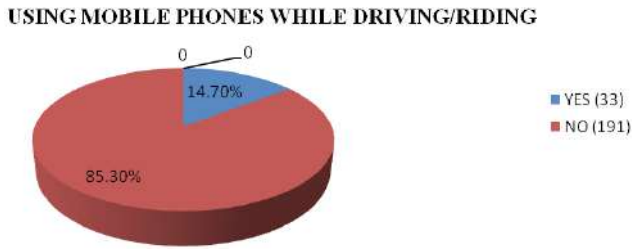

Fig 2. Pie chart showing use of mobile phones while driving/riding

Even though 98.5% of students were aware that knowledge of speed limits is essential, 36.5% of participants have admitted to exceeding the same on roads.

It is also of concern that 14.7% that is, 33 students have admitted using mobile phones while driving/riding including texting, which is a very dangerous behavior (Fig 2). 15% of participants never use helmets regularly & 13.5% use helmets only because of the fear of being fined by the authorities.

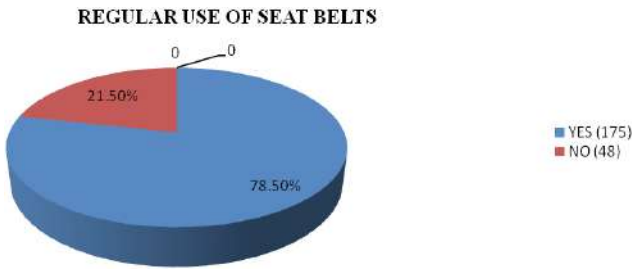

Fig 3. Pie chart showing regular seat belt use among the study participants

Wearing a seat belt may at times be the only difference between life & death during an RTA. 78.5% of participants are regular seat belt users & 91.6% of them are aware that seat belts must be worn by every occupant in a vehicle (Fig.3).

Discussion

The overall awareness levels among the study participants regarding road safety measures is good which is in contrast to a study done by Kulkarni et al in 2012, which revealed very low awareness levels among medical students.[1]

This difference may be due to the fact that there has been an increase in use of social media since the past few years which might have contributed to better awareness of students regarding road safety measures.

More than 90% students were aware of the basic safety measures like regular use of seat belts, distraction caused by loud music and speed limitations.

In the present study only 4 students (1.5%) have admitted been involved in drunken driving which is in contrast to the study done by Kulkarni et al in 2012 in which 54 students (25.4%) have admitted being involved in drunken driving.[1]

This is a positive finding and throws light on the fact that more and more people are aware of risky behaviors on the road & are consciously avoiding the same.

Conclusion

In our efforts to curb the epidemic of road traffic accidents, undertaking proper road safety measures are the best available interventions. The present study revealed good awareness and practice, but there are areas where these should improve and it should be our unending efforts to ensure 100% awareness and practice of road safety measures.

The efforts of increasing road safety measures through sign boards, posters & mass media should be strengthened to reduce the morbidity & mortality in relation to road traffic accidents.

Recommendations:

- Improve the pre-licensure training. Licensing should be made stricter.
- Frequent re-enforcement of traffic rules through mass media and trainings at educational institutions.
- Traffic rule violations should be dealt with more seriously and people should be made aware of all punishable offences.

The Effect of Eye-Hand Coordination Device on Coordination in Subjects with in-Coordination

MuzahidKadir Sheikh[1], Suraj B. Kanase[2]

[1]Post-Graduate Student, [2]Associate Professor, Department of Physiotherapy

Abstract

Coordination or coordinated movement is the ability to execute smooth, accurate, controlled motor responses. The ability to produce these motor responses is a complex process dependent on a fully intact neuromuscular system. Nowadays there are Fewer Devices Which can help in Gaining Eye-Hand Coordination. Objectives: To compare the effect of eye-hand coordination device and conventional Physiotherapy in eye-hand coordination for subjects with in-coordination. Materials and Method: The subjects in Krishna University campus were screened and 44 subjects were divided into 2 groups i.e Group A subjects were given Conventional Physiotherapy for coordination training and Group Eye-Hand Coordination Device along with given Conventional Physiotherapy for coordination training. The interpretation of the study was done on the basis of comparing pre-test and post-test assessment of NCT grading and FMA-UE.

Result: Intra group comparison results showed that NCT grading and FMA-UE scale were statistically significant in both the groups ($p<0.0001$). Whereas the intergroup comparison results showed that Eye-Hand Coordination The device along with Conventional physiotherapy was statistically significant in improving NCT score ($p=0.0021$) and FMA-UE score ($p=0.0001$) than only Conventional Physiotherapy alone for Eye-hand In-coordination.

Conclusion: The Eye-Hand Coordination Device was Significantly effective when Given With Conventional Physiotherapy For treating In-coordination and improvement in coordination. Conventional Physiotherapy is also effective in treating in-coordination, but after certain duration of treatment, the patient starts getting adapted and chances of achieving the plateau phase

Keywords: *Eye-Hand Coordination, coordination device, In-coordination, NCT Grading, FMA-UE.*

Introduction

Coordination or coordinated movement is the ability to execute accurate, smooth and controlled motor responses. It is a complex process dependent on a fully intact neuromuscular system. Coordinated movements are characterized by speed, distance, direction, timing, and muscular tension. Coordination assessments provide physical therapists with information related to motor performance. They help in identifying the source of motor deficits. A variety of observational coordination tests have been presented and researched about the same[1,2].

Eye-hand coordination has been studied as different as the movement of solid objects such as archery, sporting performance, blocks, computer gaming, copy-typing, and even tea-making. It is part of the mechanisms of performing daily tasks; in its absence, most people would not be able to carry out even the simplest of actions such as picking up a book from a table and playing a video game. While it is recognized by the term hand-eye coordination, without exception medical

sources, and most psychological sources refer to the eye-hand coordination etc[3] We use hand-eye coordination whenever we write. As you start making lines, our eyes send information to the brain to tell it where the hand is placed and if your handwriting is legible With this information, the brain form instructions for how the hand has to move in order to create appropriate shapes and lines, resulting in alphabets. Visual feedback also helps correct letters generated by the previous motor instructions. It is a sequence of precise motor actions that require a certain amount of skill and training.[4]

- A similar sequence takes place when we type on a keyboard. The type of movements are different, but we still use visual information to tell the brain how to guide the hand or if a mistake needs to be corrected.
- When you drive, you are constantly using hand-eye coordination because you have to use the visual information to move your hands on the wheel, keeping the car in the middle of the lane and avoiding accidents.
- Almost every sport requires the use of hand-eye coordination to coordinate what you see with your eyes with the movement if your body. Depending on the sport, the hand-eye coordination (tennis, basketball, baseball, etc.) Or foot-eye coordination (soccer, track, etc.) Will be more used. In any the sport, you can count on the fact that the eyes will be coordinating with some part of the body, so a more appropriate term for this type of coordination may simply be called motor coordination.
- Putting a key in a lock also uses hand-eye coordination. Similar examples would be when you insert a debit card in a chip reader, or when a child plays with toys with various shapes that they have to fit into a certain hole.[4]

Conventionally coordination training is mainly object based i.e training is given with the help of Balls of various sizes, various drills, and agility training.

Various types of exercises like:

- Frenkels Exercises
- Ballon tossing
- Juggling
- Small ball tosing
- Target practice
- Dribbling
- Wall ball bounce
- Target practice [5]

Eye-hand coordination device is a device which can be used to increase in patients eye-hand coordination by asking the patients to perform certain activity a number of times which creates a better performance in eye-hand coordination. The device can be used for many other purposes as a diagnosing tool as well as for treatment. Nowadays there is a paucity of instruments or devices to improve eye-hand coordination. Furthermore, the patient is not able to receive biofeedback much in the other treatment so we can motivate him further by using this handheld instrument as we can make new levels in the instrument. Further, this is a new innovative technique which we can add up in our treatment protocol.

Material and Method

Approval for the study was obtained from the Protocol committee and institutional Ethical Committee of Krishna Institute of Medical Sciences Deemed To be University. The subjects in Krishna Institute of Medical Sciences Deemed To be University campus were screened and those fulfilling the inclusion and exclusion criteria were involved. Participants were informed about the study and consent was taken. Pre-test assessment was taken by using Non-Equilibrium Coordination Test, Non-Equilibrium Coordination Test Grading and FMA-UE to assess the patient. 44 subjects were divided into 2 groups, Group A and Group B based on the inclusion and exclusion criteria. The treatment was started the first day when the subject came for consultation. Group A subjects were given Conventional Physiotherapy and Group B subjects were given Eye-Hand Coordination Device Along with conventional Physiotherapy. The post-test assessment was taken by using NCT Grading and FMA-UE to assess the patient. The interpretation of the study was done on the basis of comparing pre-test and post-test assessment of Non-Equilibrium Coordination Test Grading and FMA-UE.

Group A: Conventional Physiotherapy For improving Coordination:

- Frenkels Exercises
- Ballon tossing
- Juggling
- Small ball tosing

- Target practise
- Dribbling
- Wall ball bounce
- Target practise

Group B: Eye-Hand Coordination Device -Patient should be in sitting position, patient will be asked to hold the hand piece which is of diameter 5cm, 4cm, 3cm, 2cm and 1cm accordingly.

- First the therapist will demonstrate the activity.
- The patient will be handed the hand piece and ask to move the hand piece from starting position to ending position and then again reach the starting point without much shaking of hand piece and with steadiness
- If the patient touches the wire then a buzzer will be on and light will blow and that will a biofeedback that means that the patient has to go to the starting point again for
- For starting we have asked the patient to perform the procedure on a wire which will be a straight line which is the basic level.
- The levels will be made difficult by making the wire into many different shapes.
- Once the patient gains confidence that he can perform the procedure easily he can go to the next level.

Findings: Statistical analysis was done manually and by using the statistics software's INSTAT so as to verify the results derived. The statistical analysis of non-parametric data was done by Wilcoxon matched pairs test and Man-Whitney test. Wilcoxon matched pairs test was used for statistical analysis of pre and post intervention within the group. Man-Whitney test will be used for between groups statistical analysis of Group A and Group B (pre-pre and post-post intervention).

Table 1: Data of NCT

	Non-Equilibrium Coordination Test Grading				p valve (Pre-Post)	Inference
	Pre-test		Post-test			
	Mean	SD	Mean	SD		
Group A	1.545	0.8579	2.636	0.7267	<0.0001	Extremely significant
Group B	1.545	0.5096	3.227	0.4289	<0.0001	Extremely significant
p value (Pre-Pre) and (Post-Post)	>0.9999		0.0021			
Inference	Not Significant		Extremely Significant			

Table 2: Data of FMA-UE

	FMA-UE				p value (Pre-Post)	Inference
	Pre-test		Post-test			
	Mean	SD	Mean	SD		
Group A	33.591	5.413	43.455	5.878	<0.0001	Extremely significant
Group B	34.682	6.105	50.727	5.496	<0.0001	Extremely significant
p value (Pre-Pre) and (Post-Post)	0.5340		0.0001			
Inference	Not Significant		Extremely Significant			

Discussion

Eye-hand coordination is central to so many human activities –the tool used eating, sports and work, to name few as to be defining characteristics of typical human life, conversely, its disruption following the stroke, disease, injury, and developmental disorder leads to considerable degeneration in productivity and quality of life. Normal eye-hand coordination involves the synergistic function of several sensory-motor systems including visual, vestibular system proprioception and the eye heads and arm control systems, plus aspects of cognition-

like attention and, memory[6]. Eye-Hand Coordination Plays an important role in daily activities of living Eg-Eating Food, Drinking Water, Writing Activities, Turning a page etc. In Neurological impaired subjects during Rehabilitation usually, eye-hand coordination mostly gets un-noticed. The objectives of this study were to find the effect of eye-hand coordination device on coordination in subjects with in-coordination. To find the effect of eye hand coordination device along with conventional physiotherapy in improving eye-hand coordination. To compare the effect of Eye-hand coordination device and conventional physiotherapy in improving eye-hand coordination.The study was conducted with 44 subjects. Subjects were divided into two groups. Eye-Hand Coordination device along with Conventional physiotherapy (Group A) and Conventional Physiotherapy (Group B). Prior consent was taken. The treatment protocol was carried out for 6 days per week for 5 weeks. The outcome measures for this study were Non-equilibrium coordination test grading and Fugl-Meyer Assessment-Upper Extremity scoring system. The results of this study showed that there was a significant improvement in Coordination, improving quality of life and reducing rehabilitation time after 5 weeks of intervention in both the group A and group B in Subjects with incoordination. Wilcoxon matched pairs test was used to analyze the effect eye-hand coordination device and showed that there was extremely significant improving coordination in NCT Grading score (p=0.0021) and FMT-UE (p=0.0001).

Researches have proved that there is improvement hand pointing accuracy. A Study Done and they showed that the accuracy of pointing motion of the hand, directed at visual acuity 10° to 40° from the centre, was measured in normal subjects. No visual feedback from the moving hand was available to the participants. The head could be either maintained still (head-fixed condition) or free to move (head-free condition) during the pointing movements. It was found that the error in pointing was reduced for all targets in the head-free condition. This reduction was more important for the more eccentric target (40°). Improvement in accuracy was observed without any significant change in either the latency or the duration of eye, head or hand movements[7]. Another Study showed that Examining the Effects of Proprioceptive Training on Coincidence Anticipation Timing, Reaction Time and Hand-Eye Coordination The study stated that the effects of proprioceptive training on coinciding anticipation timing (CAT), reaction time and hand-eye coordination. 42 volunteer students participated in the paper. These students were randomly divided into two groups as control and experimental groups. An exercise program was applied to the experiment and control groups for approximately 3 days in 8 weeks, for about 45 to 60 minutes. Additionally, a 20-minute modified proprioceptive balance program was applied to the experimental group only. Paired sample tests were used. As a result, significant differences were found in the performance, reaction time and hand-eye coordination performances of the experiment group, pretest, and posttest (p<0,05). Significant differences were found in dominant hand visual reaction time and hand-eye coordination performances of the control group, pretest, and posttest (p<0,05). In conclusion, it is seen that proprioceptive training affect CAT performance and reaction time performances in a positive way.[8]

Conclusion

The present study provided evidence to support the use of eye –hand coordination device along with conventional physiotherapy in improving NCT and FMA-UE scores in Subjects with in coordination.

Conflict of Interest: The authors declare that there are no conflicts of interest concerning the content of the present study.

Abstract

This article depicts about depressive symptoms among patients visiting a hospital. Depression is the most common mental illness among people in many parts of the world. A person who suffers from depression experiences many symptoms which affects their day to day life to study the contributing factors associated with various levels of depression, a survey was conducted among patients visiting a private dental college at Chennai, Tamil Nadu. Convenience sampling technique was used for the survey. The patients were categorised according to their age, gender, education and employment status. Socio-economic status of the family head was also assessed in the survey. Marital status of an individual and any medical problems presented was also interviewed in the questionnaire. A list of PHQ-9 questionnaire was used to assess the associating factors among various level of depression.

Keywords: *Depression, patients, socio-economic status, prevalence, mental health.*

Introduction

World health organization quoted that more than 322 million people are suffering from depression[1]. In India, it has been reported that 57% million people i.e. 18% of global estimate, are affected by depression[1]. Depression is the most common and significant mental health disorder[2].

Depending upon the age and sociocultural system, depression manifests in different ways and varied presentation. Due to this varied presentation of subjects with depression, the recognition of depression by members of the family and well-wishers at an early stage, particularly mild to moderate depression, is often challenging[1]. The person with depression will experience loss of interest, less energy, poor concentration, disturbed sleep and appetite. According to the severity of depression, it is categorized as mild, moderate and severe[3]. Depression leads to increased irritability, less activity,less attentiveness and fewer facial expressions. The most serious effect of depression is a suicide attempt or completion [4]. Depressed patient usually requires 4-9 months of regular psychiatric consultation and antidepressant therapy.

Thus, considerable attention must be raised regarding detection of depression, as this can limit the impact of depression on the population. The assessment of severity of depression is additionally necessary for proper guidance and treatment planning.[6] There are many approaches to detect depression, one of them is using a questionnaire like Generalized Anxiety Disorder 7-item (GAD-7), Patient health questionnaire 2-items (PHQ-2) and Patient health questionnaire 15-items (PHQ-15) [8]. Patients health questionnaire (PHQ 9) depression Screener was derived from the Diagnostic and Statistical Manual of Mental Disorders, 4th Edition (DSM IV) [9]. PHQ -9 questionnaires have been widely

used among various populations e. g. in a study by Zakiya Al-Busaidi et al [9] it's been used by Oman university for Prevalence of Depressive Symptoms among university students,and also by Roger Muñoz-Navarro et al [8], in a Spanish primary care Centre to identify major depressive disorder in adult patients.

Within the above-mentioned background, studies are needed to explore the significance and the associated factors contributing to emotional disorder among the population. The aim of this study was to explore whether depression is endorsed among patients visiting a dental college for dental problems. The study also aimed to explore the association between depression,gender and socioeconomic status.

Materials and Method

A cross sectional study was conducted among patients visiting a private dental college at Chennai, Tamil Nadu for two months; from October to November 2018. The questionnaire asked focused on the attitude and behaviour of the participants towards the activities that they normally performed over the past couple of days. Convenience sampling technique was used and consecutive patients were interviewed. Individuals who refused to participate were excluded. The purpose and need of the study were explained and informed consent was obtained from the participants. A total of 500 individuals were interviewed. The collected data was kept confidential.

Statistical Analysis: The collected data was analyzed using SPSS version 21.0. For comparing percentages of demographic variables, Pearson's Chi square test was used.

Results

A total of 500 patients (226 males and 274 females) participated in the study. The average age of the patients was 34 ± 11 years. Nearly a quarter of the participants were single,147 and the rest,347 were married (Table 1). The prevalence of depression by severity according to demographic characteristics of the participants is given in Table 2. Among the study population, 433 individuals scored <10 and the rest, 67 individuals had a depression score of >11.

Among the genders, 10% of males and 16% of females had various levels of depression and it was statistically insignificant. (p-value =0.079).

There was a relation between the severity of depression and the socioeconomic status. Five of the upper-class participants scored above 11 whereas 1 of them scored above 20. In the upper middle class, 3 scored more than 20. Sixteen of the middle-class participants scored more than 11, but none of them scored more than 20. On the other hand, none of the lower middle class participants scored more than 11. In lower class patients only one of them scored more than 20. The average depression score was found to be 5.7(SD=4.3) and the median score was 5.0. thus, the severity of depression was related to the socioeconomic status of the patient.

Table 1: Characteristics of the Patients

Patient Characteristics		**Percentage%**
Mean Age ± SD		**34 ± 11**
Gender	Male	45%
	Female	55%
Marital Status	Single	29%
	Married	69%
	Divorced	1.2%
Education	Illiterate	7%
	Primary school	9%
	Middle school	10%
	High school	11%
	Higher secondary	12%
	Graduate	47%
	Post graduate	4%
Medical Conditions	No diagnosed medical conditions	90%
	Asthma	0.8%
	Diabetics	2.2%
	Hypertension	6%
	Thyroid	0.8%
	Psoriasis	0.2%
Habits of Smoking	Present	12.4%
	Absent	87.6%
Habits of Alcohol	Present	21%
	Absent	79%
Socioeconomic Status		
Class I		4.4%
Class II		38.4%
Class III		34.2%
Class IV		21.6%
CLASS V		1.4%

The frequency and percentage of patients responding to each question regarding depressive symptoms experienced in the last two weeks were measured using

PHQ-9. Final consideration of depression scored that only 5(1.0%) of the patients had experienced extreme difficulty in getting along with other people and take care of things and 15(3.0%) patients had found it very difficult to taking care of things at home. It was somewhat difficult for 47(9.4%) of patients. Four hundred thirty-three (86.6%) of patients did not experience any difficulties from depression.

Table 2: Prevalence of depression by severity according to demographic characteristics of the patients

Demographics		Severe Depresson (Score ≥20) (%)	Moderate Depression (16-19) (%)	Mild Depression (11-15) (%)	Normal Depression (Score≤10) (%)	Total Frequency	p- Value
Gender	Male	3(1%)	7(3%)	13(6%)	203(89%)	226	0.079
	Female	2(1%)	8(3%)	34(12%)	230(84%)	274	
Socio-Economic Status	Class I	1(5%)	2(9%)	3(14%)	16(73%)	22	0.000
	Class II	3(2%)	7(4%)	15(8%)	167(87%)	192	
	Class III	0(0%)	4(2%)	12(7%)	155(91%)	171	
	Class IV	0(0%)	1(1%)	15(14%)	92(85%)	108	
	Class V	1(14%)	1(14%)	2(29%)	3(43%)	7	
Education	Illiterate	1(3%)	1(3%)	6(18%)	25(76%)	33	0.122
	Primary School	0(0%)	1(2%)	4(9%)	38(88%)	43	
	Middle School	0(0%)	0(0%)	2(4%)	49(96%)	51	
	High School	0(0%)	0(0%)	5(9%)	48(91%)	53	
	Higher Secondary School	0(0%)	3(5%)	11(18%)	47(77%)	61	
	Graduate	3(1%)	8(3%)	18(8%)	207(88%)	236	
	Post Graduate	1(4%)	2(9%)	1(4%)	19(82%)	23	
Marital Status	Single	2(1%)	7(5%)	16(1%)	122(83%)	147	0.001
	Married	2(1%)	7(2%)	31(9%)	307(88%)	347	
	Divorced	1(17%)	1(17%)	0(0%)	4(66%)	6	
Total		**5**	**15**	**47**	**433**	**500**	

It was seen that, socio-economic status had statistically significant association with depression as in class V.57% had various levels of depression. The level of education did not have any significant association with levels of depression. Marital status of population had statistically significant association level of depression with 34% among the divorced being depressed in various levels (Table 2).

The frequency and percentage of patients' response to PHQ-9 and their experience of depressive symptoms in the last two weeks was compared. It was observed that 160(32%) of patient reported the symptoms of little interest in doing things. 262(52.4%) felt down and 203(40.6%) reported trouble falling or staying asleep or sleeping too much several days a week. Feeling bad about failure and letting their family down was the most common symptom reported on nearly daily basis by 19(3. 8%). On nearly daily basis, 12(2.4%) of patients experience trouble concentrating on television and newspaper. Eighty-two (16.2%) of patients reported suicidal thought and 13(2.6%) have experienced it on nearly daily. It was seen that only 31.4% never felt down or depressed or hopeless while at rest 75.8% felt these symptoms at various period of time. Also 63% had troubled sleep patterns and felt tired. And 3.8% of the study population, felt bad about themselves or felt they were a failure and had let their family down. About a quarter 23.8% had suicidal thoughts. When the subjects were asked about the effect of depression on their day to day activity, it was seen that it was somewhat difficult for 45.2%: very difficult for 9.8% and extremely difficult for 3.2% of the study population.

Discussion

Depression is common disorder among all ages, gender and different socioeconomic groups.[1] In India,

the lifetime prevalence of depression among individuals is 5.25%[1] for individuals of and above 18 years. In the present study,for adults, a PHQ-9 score of 10 or higher was used to identify patients with depression [3]. According to Laura et al[5] patients who score more than 11 can be considered to be depressed**.**

Four hundred thirty three individuals scored <10 and were graded as without depression and 67 individuals had a depression score of >11 and were graded as having mild to severe depression. In the present study, 16% of females suffered from depression which is similar to the study done by Giora Kaplan et al (2010).

Fifty seven percent of study population who have Class V Socio-economic status i.e. low socio-economic class had with various levels of depression which is similar to the study by Zimmerman FJ, et al (2005). Low financial support and poor nutrition might have been the origin of depression in those people. About one third 34%, who were divorced suffered from various level of depression which is also reported by Jang SN, et al (2009). Dissolution in the marriage life caused loneliness, betrayal of trust and loss of moral support which resulted in depression in one's life. Also 63% of subjects had troubled sleep patterns was also analysed by Lund HG, et al (2010). People who were over thinking and anxious about day - to - day life experienced trouble in sleeping. This over thinking sometimes leads to nightmares which affected the sleeping pattern. Around 3.8% of study population felt that they were a failure nearly every day which is also discussed by Bennet DS, et al (2005). Insecurities in one's life posed a negative feeling about themselves and made them to think they were a failure almost every day of their life.

Among the study population, 23.8% reported that they have suicidal thoughts which is similar to study done by Hawton K, et al (2012). Loneliness, the pain of existence became unbearable to the people who were in depression. Thus people had a thought of harming themselves.

Among the study population, 63% of people felt tiredness or little energy at various period of time which is discussed by Balsis S, et al (2008). Fatigue can affect people emotionally and physically. Depressed people felt tiredness or less energy because their body is battling against them both physically and psychologically.

Conclusion

This is the first study to assess the PHQ-9 to obtain the optimal cut-off values for screening patients with depression visiting private dental hospital. The findings presented in this study indicate that the PHQ-9 is a valuable tool to help to identify suspected cases of depression among patients. Based on our results, in this population we recommend using a cut-off value of 11 instead of the most common cut-off value of 10. We also found that depression is common in patients visiting dental hospital with preponderance among females.

Intelligent System for Physically Challenged Person in Virtual Prototype Environment

N. Prabhakaran[1], N.D. Bobby[2], M. Munireddy[3], G.S. Sivapriya[3]

[1]Asst. Professor, [2]Professor, [3]Asst Professor, Department of ECE, Vel tech High Tech Dr. Rangarajan Dr. Sakunthala Engineering College, Avadi, Chennai, India

Abstract

In this paper, a framework is fabricated to authorize the physically tested individual device for controlling the needed thing like lighting the room, electrical gadgets with small power application used in an indoor environment. The indoor application controls the wheelchair utilizing only a couple of fingers to do the work effectively. The MEMS-based accelerometers sensor is designed without any pressure and makes the device highly favorable to a physically challenged person. The accelerometers are the small gadget equipped for distinguishing the quickening of the article to which they are appended in which the accelerometers are connected to the fingers for a particular application. The individual, to whom the accelerometers are attached, can assign the control gadget using the straight forward development tool of the fingers like tapping them on the surface to do one particular application in indoor environment. So the novel system is designed and implement for physically challenged person to operate both in indoor and outdoor environment.

Introduction

Haptics is a late improvement to practical situations permitting clients to "touch" and "feel" the reproduced objects with which they communicate. Haptics is the investigation of touch. The word from the Greek word haptikos which signify "having the capacity to come into contact with". The investigation of haptics rose up out of advances in virtual reality. Virtual the truth is a type of human-PC connection (rather than console, mouse, and screen) giving a virtual situation that one can investigate through direct cooperation with our faculties. They can cooperate with a domain, and there must be criticism. For instance, the client ought to have the ability to touch a practical question and feel a reaction from it. This kind of criticism is called haptic input. In human-PC collaboration, haptic criticism implies both material and power feedback [1]. Haptics connects to an extensive variety of gadgets. In compelling the accuracy, surgical test system use haptics to give sensible power which imitates the vibe range of proper therapeutic strategy method. In forcing for the size of the input power, the gamers can counter the authentification. Furthermore, the first demonstration of the telephone is vibrating when a call is important and straightforward type of innovation. The clinical aptitudes of restorative experts depend entirely on the feeling of touch, joined with anatomical and analytic learning [2]. Haptic environment produced perceptional properties and human haptic recognition as a valuable tool to restorative examination. The characterization of haptic data, and how it can see, is essential to understand how medicinal experts accomplish the haptics to empower learning and achieve the abnormal amount of execution of man power. Papers which investigate haptic models of the patient, and additionally perceptual or behavioral parts of the haptic methodology are pertinent to therapeutic examinations and strategies, are requested. Haptic frameworks and the role of haptics in preparing and assessing clinical abilities: Haptic test systems address a developing requirement for successfully developing and assessment of clinical attitudes [3]. Such test systems can connect a wide range assortment of restorative callings and ordering the identity, including the surgery part, interventional radiology for monitoring, are the new abilities. Papers that location test system advancement and assessment from these points of view are requested[4].

Background Work: MEMS are comprised of segments between 1 to 100 micrometers in size (i.e.

0.001 to 0.1 mm), and MEMS gadgets covers a broad range in size from 20 micrometers (20 millionths of a meter) to a millimeter (i.e. 0.02 to 1.0 mm). This is often to comprise a focal unit which procedures the information on microchip and a few segments that associate with all surroundings, for example, small-scale sensors. At these size scales, the standard develops of established material science are not generally helpful[5]. Index finger course based robot is a machine that is controlled by a MEMS sensor through Radio recurrence innovation. The sensor which put on our index finger works when the heading of the finger changes. Limited component investigations utilizing human finger model amid element touch demonstrated that spatial data of the textured surface identified the transient recurrence changes at the position of material receptors in the finger print interface [6]. In touch sensor exercises, the people can evaluate one by one by means of relative hand speed between the surface texture and in the investigating finger, of spatial period of the surface can be seen by integrating the transient recurrence of the vibration in sensor mode [7]. So that f=v/p printed on the sensor mode .In counterfeit touch it propagate the signal, while considering innovative methodologies in which mechanical detecting components inserted on skin-like structure elastomeric grid on the surface that copy human skin penetration, such as vibrations analysis sought to be evoked by boost skin interface which releases the effect, by this movement elements are controlled, and by contact mechanics the effect is evoked, and afterwards assembling and detecting the units are situated under the protecting material [8]. Stimuli are the responses, when connected in mean level heads against the surface of the skin tissue -like material of the clusters cells, which may brought about a huge compelling noise of the sensor node component with a unique mark sort surface than that with a smooth surface [9]. A. MEMS Sensor Micro electro mechanical frameworks (MEMS) (additionally composed as miniaturized scale electro-mechanical, Micro Electro Mechanical or microelectronic and smaller scale electromechanical frameworks) is the innovation of little gadgets; it converges at the Nano-scale into Nano electromechanical structures (NEMS) and nanotechnology. MEMS likewise alluded to as micro machines (in Japan), or Microsystems innovation–MST (in Europe) [10].

Material and Method

The figure 1 shows the proposed block diagram for a physically challenged person both indoor and outdoor environment. The proposed block diagram consists of two parts; the first part consists of transmitter section in which the information transmitted through a particular distance with MEMS sensor (micro electronics mechanical system). The mem sensor is controlled by microcontroller through various action of disabled person the output section is controlled. The information is transmitted with antenna through only a small distance the position of antenna alignment is controlled with a particular frequency. The same frequency is controlled by receiver and demodulates the signal according to the input through which it takes the time delay and propagates in the receiving end through which led buzzer and led maintained. The relay is maintained o make the signal low enough and characteristics signal is maintained according to the input. So the wheel chair car controlled in the receiving end also. The proposed block diagram explains about the interferences which is mem sensor both in the transmitting end and receiving end. Further mode the device is completely implement with low cost dynamic system and it takes advantages of reducing the entire size of the hardware with low power dissipation factor. This system can be easy to carry anywhere both indoor and outdoor environment to do particular work and implement in any part of the world for physically handicapped person. The above-shown data are the block diagram implemented in this paper. The entire system divided into two modules; they are the human interface module and the robot interface module. Each one of this module s described below. The MEMS connected to the microcontroller unit which given as a PDA to the physically challenged person. The MEMS placed on the person for the gesture movements which converts the signal level with respect to mean value. Each position of the person holds the MEMS sensor for individual gesture analysis specified. When the person specifies his hand forward or backward or in any direction, that signal received by the microcontroller and sent to the antenna. The robot unit receives the signal obtained from the antenna. This robot unit is nothing but a wheelchair unit. Two relays placed on two wheels which receive the input from the microcontroller. The microcontroller will give the direction to control the motors to move. This direction purely based on the muscle movement of the person which is indeed received by the MEMS placed in them. At the point when the digit on the surface, the movement of the finger identifies the accurate analysis and the same is utilized as a trigger sign to turn an electrical gadget on or off.

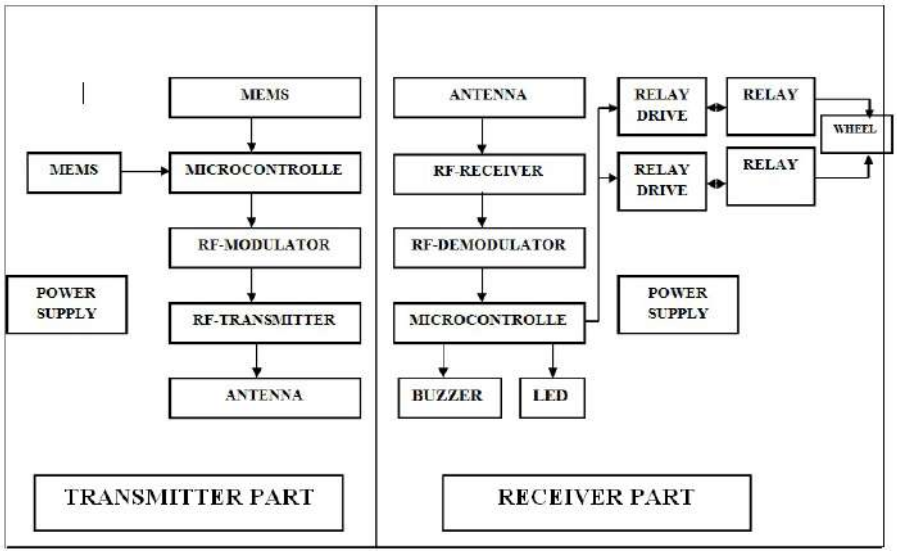

Figure 1 Block Diagram of the Interface Controller for human system

The human machine interface provides a highly visual device with low cost, comprehensive and intuitive design with low power and allow the system to operate efficiently has designed by the designer. For outdoor environment that are very expensive and difficult to observe all the parameters visually. So the proposed system is designed with low cost and low power system device.

Result and Discussions

The figure 2 and figure 3 is implemented with mem based accelerometer is proposed both in the transmitter and receiver end and circuit diagram is also proposed. The hardware device consists of power supply block, microcontroller block, mems sensor and a camera to visualize the entire object both in indoor and outdoor environment. The power supply gives moderate 12.5v to microcontroller mem sensor and camera. The microcontroller revises the voltage and controls the mem sensor and camera to operate the wheel chair car for a physically handicap person. The device can be applicable and implemented all types of physically challenged person

The same trigger sign can use for controlling a wheel seat's development: a microcontroller unit and a drive circuit used for controlling the gadgets. Numerous fingers can use for some such particular reactions from which various devices can control the internal environment. Further, if the individual can control the power of tapping the distinctive intensities of tapping can be utilized to control besides gadgets. Subsequently, the accelerometers are appended to the fingers of a man which can use as a virtual keypad to control any device in indoor environment. Furthermore, the entire framework can be made smaller which gave to remote control gadgets for assembling on a separate sheet. However, this framework can go about as a straightforward and hazel free guide for the physically debilitated.

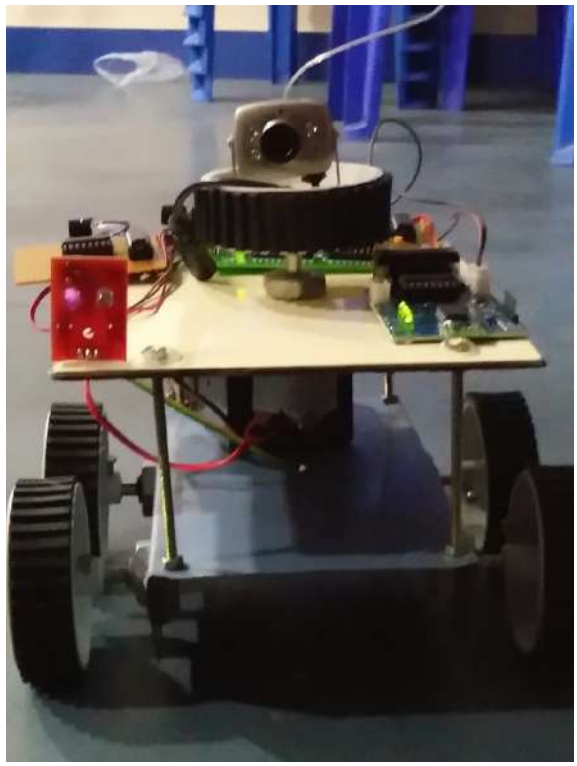

Figure 2. Hardware for Proposed Circuit

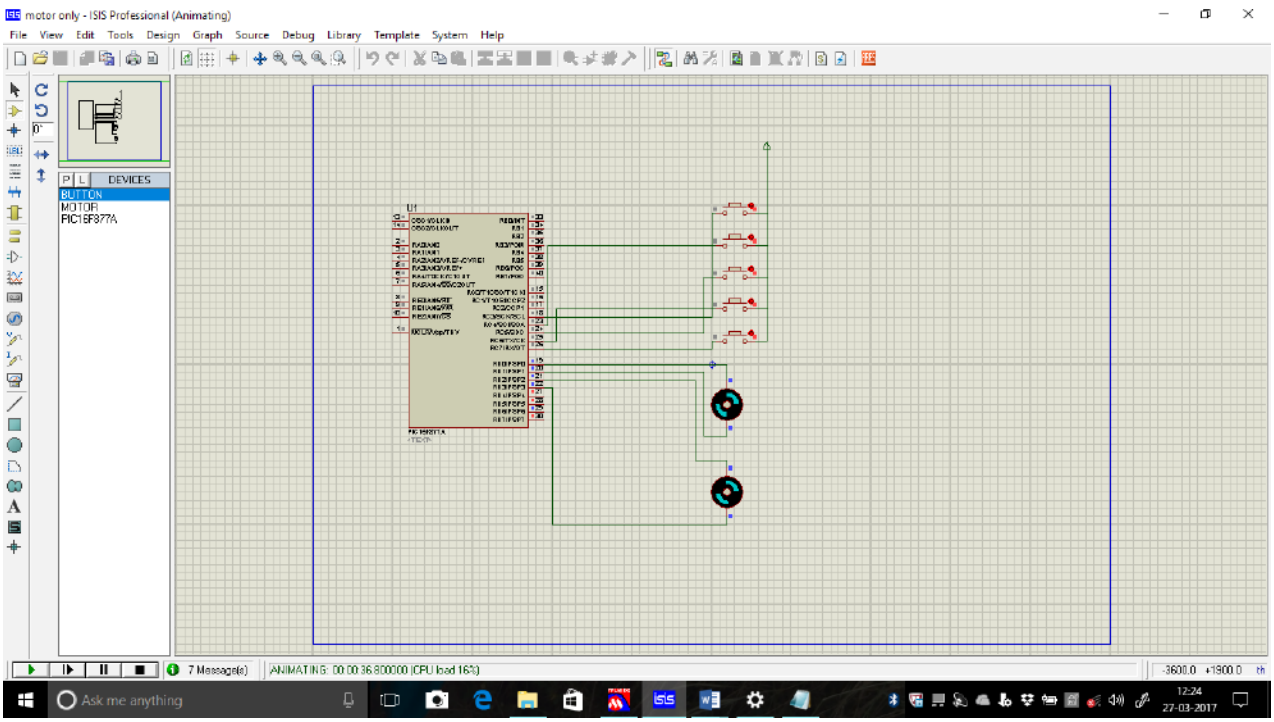

Figure 3: Circuit diagram for the proposed system

Conclusion

The intelligent assisting device designed and implemented to assist the physically challenged people in satisfying their basic needs using MEMS accelerometer sensor. This is accomplished using the physically challenged people who do not depend on others and they are trained by themselves and 60% of their work aligned or motivated using self performance. In future, the same system can e developed in such a way that the height movements of the wheelchair can be adjusted.

Health Insurance Utilisation Pattern in Two Districts of Karnataka

Nagaraj Shet[1], Ghulam Jeelani Qadiri[2], Sunita Saldanha[3], Gayathri Kanalli S.[4], Prajna Sharma[5]

[1]Assistant Medical Superintendent and Assistant Professor, [2]Professor, [3]Professor and HOD, Department of Hospital Administration, Yenepoya Medical College Hospital, Deralakatte, Mangaluru, [4]MBBS, [5]Assistant Professor, Department of Community Medicine, Kanachur Institute of Medical Sciences, Deralakatte, Mangaluru, Karnataka, India

Abstract

Introduction: Health insurance is a widely recognized and preferable mechanism to finance the health care expenditure of the individuals. It is an important mechanism in the modern world to save the individuals from the huge health shock but only a small percentage of people even from educated higher income groups are covered under any health insurance policy. This study was undertaken to know the pattern of health insurance utilization in Uttar Kannada and Udupi districts of Karnataka.

Material and Methodology: A descriptive study was conducted among 550 household of Uttar Kannada and Udupi districts. Household were selected using multistage sampling technique.

Results: Of the 550 study participants, 348 (63.27%) were aware and also subscribed for any type of the health insurance and of these only 89 (25.57%) utilized them. 190 (34.55%) had availed Rashtriya Swasthya Bima Yojana, 42 (7.64%) for Yashasvini, 6 (1.09%) for ESI, 12 (2.18%) for Sampoorna Suraksha and 15 (27.27%) had private insurances. Reasons for not availing health insurances other than being unaware were complicated process 85 (42.08%) and provides only partial coverage 49 (24.26%). The main reasons for not using the health insurance were non availability of empanelled hospital 84 (74.34%), disease not being under the scope of scheme 60(23.17%) and 32 (12.36%) were unaware about the process of availing.

Conclusion: Health insurances being are the best way to help people reduce their financial burden has to be made aware and the drawbacks have to be addressed.

Introduction

Health is multi-dimensional and is 'a state of complete physical mental and social wellbeing and not merely an absence of disease or infirmity and the ability to lead a socially and economically productive life' as defined by World Health Organisation (WHO). An understanding of health is the basis of all health care.[1] In many countries health is a fundamental human right.[2] The glaring contrast in the state of health between the developed and developing countries, between rural and urban areas and between the rich and poor have attracted worldwide criticism as 'social injustice'. The commitment of all countries, under the banner of WHO, is to wipe out the inequalities in distribution of health resources and services, and attain Sustainable Development Goals.[1]

Socio-Economic development and health of community cannot be achieved in isolation as they are

related with each other.[3] Despite large improvements in recent years, life expectancy in India still remains below than other countries following a similar pattern of development.[2]

Health outcomes and service provision vary significantly across different states, with only a few providing access to comprehensive basic healthcare services to all.[2] Various studies reveal that in India more than 80 percent of health care financing is mainly in the form of out-of-pocket (OOP)[3] often posing an enormous burden on underprivileged households. The costs are frequently high enough that households are unable to recuperate them from existing resources.[4]

Human life is unpredictable and in case of emergency health situations, health insurance can make it safe and secure from bearing huge financial loss and decreasing economic burden on the family members.[5] Health insurance is a widely recognized and preferable mechanism to finance the health care expenditure of the individuals.[3]

The International Labour Organization defines health insurance as "the reduction or elimination of the uncertain risk of loss for the individual or household by combining a larger number of similarly exposed individuals or households who are included in a common fund that makes good the loss caused to any one member".[5] Health insurance policy is a contract between an insurance company and an individual and comes in handy in case of severe emergencies.[(6)] These insurance system works on the basic principle of 'pooling of risks of unexpected costs of persons falling ill and needing hospitalization by charging premium from a wider population base of the same community'.[7]

This study was undertaken to know the pattern of health insurance utilization in Uttar Kannada and Udupi districts of Karnataka.

Materials and Methodology

A community based descriptive study was conducted from June 2016 to August 2018 among 310 study participants from Uttar Kannada and 240 study participants from Udupi, a total of 550 households. Households were selected randomly and those houses which were locked at the time of visit and those who did not give consent to participate in the study were excluded Multistage sampling technique used to collect the sample for the study.

The pre-designed and pre-tested proforma was used to collect information on socio-demographic profile and health insurance utilization of the study participants. Data collected were entered in Microsoft Excel and analysis was carried out with the help of Statistical Package for Social Sciences–20.0.1 (SPSS Statistics–20.0.1). Data was presented using proportions and percentages.

Results

The study was conducted in few selected villages in Uttar Kannada and Udupi districts. Of the 550 study participants, 310 were from Uttar Kannada and 240 were from Udupi.

Health insurance (HI) was availed by 185 (59.68%) in Uttar Kannada and by 163 (67.92%) in Udupi. Table II and III shows the district wise distribution of study participants those who subscribed for health insurance and those who used the health insurance respectively.

Table I: Distribution of study participants based on their awareness regarding health insurance.

Awareness		Uttar Kannada, n (%)	Udupi, n (%)	Total, N (%)
Yes and subscribed for HI, 348 (63.27%)	Utilized	42 (2.90)	47 (18.33)	89 (25.57)
	Not utilised	143 (17.42)	116 (13.75)	259 (74.43)
Yes and not subscribed		71 (2.90)	44 (18.33)	115 (20.91)
No		54 (17.42)	33 (13.75)	87 (15.82)
Total		310	240	550

Table II: District wise distribution of study participants based on health insurance subscribed.

Health Insurances Availed	Uttar Kannada, n (%)	Udupi, n (%)	Total, N (%)
RSBY	107 (57.84)	83 (50.92)	190 (54.59)
Yashasvini	23 (12.43)	19 (11.66)	42 (12.07)
ESI	2 (1.08)	4 (2.45)	6 (1.72)
Sampoornasuraksha	7 (3.78)	5 (3.07)	12 (3.45)
RSBY, Yashaswini	22 (11.89)	17 (10.43)	39 (11.21)
RSBY, ESI	1 (0.54)	6 (3.68)	7 (2.01)
Yashaswini, ESI	5 (2.7)	3 (1.84)	8 (2.3)
RSBY, Yashaswini, Sampoornasuraksha	6 (3.24)	4 (2.45)	10 (2.87)
Yashaswini, Sampoornasuraksha	1 (0.54)	2 (1.23)	3 (0.86)
RSBY, Sampoornasuraksha	1 (0.54)	12 (7.36)	13 (3.74)
Private insurances	7 (3.78)	8 (4.91)	15 (4.31)
Yashaswini, Private insurances	3 (1.62)	0	3 (0.86)
Total	185	163	348

Of the 185 study participants from Uttar Kannada who availed health insurance, 162 (87.57%) paid a premium of less than Rs 500, 13 (7.03%) paid Rs 500-1000 and 10 (5.40%) of them paid more than Rs 2000. In Udupi 142 (87.11%) paid <Rs 500, 13 (7.98%) paid Rs 500-1000 and 8 (4.91%) paid > Rs 2000. Frequency of premium payment in all the card holders was annually. Whole family was covered in all those who had health insurance. A coverage of Rs 25001-50000 was provided to 119 (64.32%) from Uttar Kannada and 104 (63.8%) from Udupi and 66 (35.68%) from Uttar Kannada and 59 (36.2%) from Udupi were covered for more than 1 lakh.

Table III: Distribution of study participants based on the health insurance utilized.

Health insurance utilised	Uttar Kannada, n (%)	Udupi, n (%)	Total, N (%)
RSBY	10 (23.81)	8 (17.02)	18 (20.22)
Yashasvini	15 (35.71)	9 (19.15)	24 (26.97)
ESI	5 (11.90)	6 (12.77)	11 (12.36)
Sampoornasuraksha	3 (7.14)	9 (19.15)	12 (13.48)
RSBY, Yashaswini	1 (2.38)	2 (4.26)	3 (3.37)
RSBY, ESI	-	-	-
Yashaswini, ESI	2 (4.76)	2 (4.26)	4 (4.49)
RSBY, Yashaswini, Sampoornasuraksha	-	-	-
Yashaswini, Sampoornasuraksha	1 (2.38)	1 (2.13)	2 (2.25)
RSBY, Sampoornasuraksha	-	4 (8.51)	4 (4.49)
Private insurances	3 (7.14)	6 (12.77)	9 (10.11)
Yashaswini, Private insurances	2 (4.76)	-	2 (2.25)
Total	**42**	**47**	**89**

Table IV: Reasons for not subscribing for HI and not utilizing the HI they availed.

Reasons for not availing (n=202)*	Uttar Kannada, (n=125) (%)	Udupi, (n=77) (%)	Total, (N=202) (%)
Not aware	54 (43.2)	33 (42.86)	87 (43.07)
Process is complicated	51 (40.8)	25 (32.47)	85 (42.08)
Not interested as I can afford The cost of treatment	17 (5.6)	13 (16.88)	30 (14.85)
Most of the Health Insurance provides partial coverage	30 (24)	19 (24.67)	49 (24.26)
It is not cashless	36 (28.8)	15 (19.48)	51 (25.24)

Reasons for not using HI*	Uttar Kannada, (n=143) (%)	Udupi, (n=116) (%)	Total, (N=257) (%)
Unaware about the process of availing	12 (8.39)	20 (17.24)	32 (12.45)
Lack of required documents	6 (4.19)	0	6 (2.33)
Maintained good health	5 (3.49)	32 (27.58)	37 (14.39)
Non availability of empanelled hospital	43 (30.07)	41 (35.34)	84 (32.68)
Health assurance scheme covered the expenses	13 (9.09)	12 (10.34)	25 (9.73)
Disease was not under the scope of scheme	29 (20.28)	31 (26.72)	60 (23.35)
Financial coverage limit of card was drained	0	2 (1.72)	2 (0.780)

*Multiple answers were given.

Two (1.23%) of them who had subscribed for health insurance did not renew even after its validity was expired and the reason was high premium in both the cases. Facilities provided by the health insurance is described in table V. Most 252 (72.41%) of the health insurances provided inpatient services and travel allowance. Only few 21 (6.03%) provided outpatient and emergency services. Among the inpatient services most 190 (54.6%) of the health insurance covered only medical treatment and 114 (32.76%) of them covered both medical and surgical treatment. Only 13 (3.74%) were free to choose the health care institution of their choice.

Table V: Distribution of study participants based on the facilities provided by the health insurance.

Facilities	Uttar Kannada, n=185 (%)	Udupi, n= 163 (%)	Total, N= 348 (%)
In Patient Services	37 (20)	38 (23.31)	75 (21.55)
In Patient Services and travel allowance	140 (75.68)	112 (68.71)	252 (72.41)
Emergency Service, In Patient Services, Travel allowance and daily allowance	8 (4.32)	13 (7.978)	21 (6.03)
IP Facilities			
Medical Treatment	107 (57.84)	83 (50.92)	190 (54.6)
Medical Treatment, Surgery, Implants, Preventive Measures, Ambulance service, Maternity/Delivery services	56 (30.27)	58 (35.58)	114 (32.76)
Surgery, Implants, Preventive Measures, Ambulance service, Maternity/Delivery services	22 (11.89)	22 (13.5)	44 (12.64)
Freedom to select health care institution			
Yes	5 (2.70)	8 (4.91)	13 (3.74)
No	180 (97.3)	155 (95.09)	335 (96.26)

Most 34 (38.2%) them who had utilized health insurance utilized it only once. Five (11.91%) of them from Uttar Kannada and 2 (4.26%) from Udupi utilized it 5 times. Six of them who utilized never had cashless benefit. It was either partial coverage or reimbursement. It can be seen that the health insurance which provided cashless benefits were utilized more.

Table VI: Distribution of study participants based on health insurance utilization and cash benefit.

Number of times heath insurance utilized	Uttar Kannada, n=42 (%)	Udupi, n=47 (%)	Total, N=89(%)
1	17 (40.48)	17 (236.17)	34 (38.20)
2	15 (35.71)	14 (29.78)	29 (32.58)
3	4 (9.52)	12 (25.53)	16 (17.98)
4	1 (2.38)	2 (4.26)	3 (3.37)
5	5 (11.91)	2 (4.26)	7 (7.86)

Number of times cashless method was provided			
0	3 (7.14)	3 (6.38)	6 (6.74)
1	19 (42.24)	18 (38.30)	37 (41.57)
2	10 (23.81)	10 (21.28)	20 (22.47)
3	4 (9.52)	12 (25.53)	16 (17.98)
4	1 (2.38)	2 (4.26)	3 (3.37)
5	5 (11.91)	2 (4.26)	7 (7.87)
Number of times reimbursed			
0	38(90.48)	45(95.74)	83 (93.26)
1	2 (4.76)	0	2 (2.25)
2	2 (4.76)	2 (4.26)	4 (4.94)

Discussion

This cross sectional study was conducted among 550 households in Uttar Kannada and Udupi districts to know their health insurance utilization pattern. This study showed that 20.91% of them did not avail for any health insurance even if they were aware of it and also only 25.57% of them who had health insurance utilized it. This shows the deficiencies in the health insurances available.

In the present study health insurance was availed by 59.68% in Uttar Kannada and by 67.92% in Udupi. In another similar study done in rural areas of Bangalore in 2015 among 399 study participants, 66.9% had health insurance coverage.[8] A study done in St.John's Medical College, Bangalore in 2007 among 200 households to study the awareness, prevalence and utilization of Health Insurance services it was seen that 47.5% of the individuals were aware of health insurance, 42.5% had availed for health insurance, of them 32.9% had utilized health insurance.[9]

In the present study, 34.55% had availed Rashtriya Swasthya Bima Yojana, 7.64% for Yashasvini, 1.09% for ESI, 2.18% for Sampoorna Suraksha and 27.27% had private insurances. In a study in rural Bangalore 92.6% of the study participants were covered by Government health insurance schemes and 7.4% had private health insurance schemes.2 In a another study conducted by Public Health Foundation of India, it was reported that coverage of health insurance by Vajpayee Arogya Shree scheme was 0.95 million families in Karnataka, Rashtriya Swasthya Bhima Yojana covered 22.7 million families across India, 55 million individuals were covered by Yeshaswini scheme in Karnataka and 14.3 million families were covered by ESI scheme.[10]

Conclusion

Even though more than half the study participants subscribed for health insurance, only quarter of those who subscribed utilized it. Major reason for this was not being aware about health insurances or the process for utilization. This shows the gap in communication between the health personals and the general population. There are few more who even if they were aware did not avail for any health insurance. The reasons being non availability of empanelled hospital, limit of financial coverage, the disease not covered and high premium. These drawbacks in the health insurances that are available should be addressed as health insurances are the best way to help people reduce their financial burden.

Hence it is very important to educate the community regarding the best health insurance available so that they can take the maximum benefits from it.

Abstract

Background: India generates about 60 million tonnes of garbage every day, of this around 45 to 50 million tonnes is left untreated. Wastes are thrown on the streets. Open defecation is still a problem in rural India. All these actions cause health hazards among population.

Objective: To assess the knowledge, attitude and practices regarding Swachh Bharat among 8th to 10th standard students.

Methodology: This cross-sectional study was carried out in seven government high schools in the field practice area of a medical college in Mangalore. A total of 441 government high school students from 8th to 10th standard were included in the study. Collection of data was done by interview method using pretested semi structured questionnaire.

Results: Total of 441 students were included in the study. 55.32% were boys and 44.68% were girls. According to scoring done for students, 84.35% had good knowledge, 95.23% had good attitude but only 50.34% had good practice about environmental cleanliness and personal hygiene.

Conclusion: To improve the good practice various health educations and practical demonstrations about the cleanliness and benefits of practicing them can be conducted as school-based initiatives to create awareness among students.

Keywords: *Knowledge, School students, Environment, Sanitation, Awareness, India.*

Introduction

India generates about 60 million tonnes of garbage every day, of this around 45 to 50 million tonnes is left untreated. In 2040, Urban India alone would generate 10 million tonnes waste daily. India's sewage system is among the poorest in the world. Wastes are thrown on the streets. Open defecation is still a problem in rural India. All these actions cause illness, makes the country sicker [1].

Government of India initiated the Central Rural Sanitation Programme (CRSP) in 1986 primarily with the objective of improving the quality of life of the rural people and also to provide privacy and dignity to women. From 1999, a "demand driven" approach under the "Total Sanitation Campaign" (TSC) emphasized more on Information, Education and Communication (IEC), Human Resource Development (HRD), Capacity

Development activities to increase awareness among the rural masses and generation of demand for sanitary facilities. Later "Nirmal Bharat Abhiyan" (NBA) was launched on 1.4.2012 to accelerate the sanitation coverage in the rural areas. Under NBA, the incentives for IHHLs were increased and further focused support was obtained from MNREGA. However, there were implementation difficulties in convergence of NBA with MNREGA as funding from different sources created delays at the implementation mechanism. To accelerate the efforts to achieve universal sanitation coverage and to put focus on sanitation, the Prime Minister of India Shri Narendra Modi launched the Swachh Bharat Mission on 2nd October, 2014. The Mission shall remove the difficulties that were hindering the progress, including partial funding for Individual Household Latrines from MNREGS, and focusing on critical issues affecting outcomes. [2]

Shri Narendra Modi urged people to denote 100 hours every year towards cleanliness. Union Ministry of Rural Development and Drinking Water and Sanitation announced 20 lakhs to be given to every village per year to achieve the goal of Swachh Bharat. [3]

School provides an excellent opportunity for children to learn about healthy hygienic practices and also identified as powerful channel of communicating sanitation messages to homes and communities. Through our study we aim to assess the knowledge, attitude and practices of students about Swachh Bharat and educate them in this regard.

METHODOLOGY: - This cross-sectional study was carried out in seven government high schools in the field practice area of a medical college, in Dakshina Kannada district, Karnataka. The study subjects were selected by Cluster sampling method. A total of 441 government high school students from 8th to 10th standard were included in the study. The purpose of the study and procedure were explained to the students in the local language and oral informed consent was obtained from them. Collection of data was done by interview method using pretested semi structured questionnaire which had questions to assess the Knowledge, attitude and practice amongst the students on Swachh Bharath Mission.

Statistical analysis was done using SPSS software. Data was expressed in tables and graphs. Knowledge was scored, +1 was given for the correct answer and 0 for the incorrect answer. Scoring was done. Score 0-2 was considered as poor knowledge, 2-5 considered as average knowledge and >5 as good knowledge. Attitude was also scored, +1 was awarded for positive attitude and 0 was awarded for negative attitude. Score less than 0-2 was termed as poor attitude, 2-5 as average and more than 5 was taken as good attitude. Practice was also scored the similar way. Inclusion criteria: All the students between 8th to 10th standard who were willing to participate in the study were included. Exclusion criteria: Students who were absent during the time of study, were excluded from the study

Results

Table 1: Socio-demographic distribution of the study subjects (N=441)

Age	No. of Students	Percentage
13	133	30.3%
14	137	31.2%
15	171	38.5%
Place of School		
Sashitulu	48	10.8%
Faringepete	48	10.8%
Hejmady	29	6.5%
Subramanya	65	14.7%
Nitte	121	27.4%
Bailur	100	22.6%
Natekal	30	6.8%
Standard		
8th	128	29.04%
9th	115	26.07%
10th	198	44.89%
Sex		
Boys	244	55.32%
Girls	197	44.68%

Table 1 shows that majority of students were belongs to age 15. Boys (55.32%) were more than the Girls (44.68%). More students were belonging to Government high school (27.4%) of Nitte village.

Table No.2 Knowledge and Attitude about Swachh Bharat Abhayan among study subjects

	Yes	No
Do we require separate toilet for Boys and Girls in school	100%	0
Solid waste disposal should be taught in school	87.98%	12.02%
Proper waste removal and disposal is important	97.95%	2.05%

Any member of household has heard about Swachh Bharat	90.02%	9.98%
Do you feel street should be clean and free of solid waste	94.78%	5.22%
Does improper waste removal and disposal affect environment	90.02%	9.98%
Is water made available for use in toilets	87.98%	12.02%
Soap is available in school toilets for washing hands	57.59%	42.41%
Does your household have a toilet	97.27	2.73%
Did any member of the household defecate in the open in the last three months or after gaining access to toilet	14.06%	85.94
Is there any garbage or litter piled up or dumped within 10 feet perimeter of the house, outside the premises of the household being canvassed	41.04%	58.96%
Does anyone go out and defecate in open in your village	20.1%	79.9%

In table two 57.59% of students told that soap was present in school toilet for washing hand. 41.04% students told that Garbage disposal near the houses still persist in their village. 20.1% students told open air defection was still present in their village.

Table No. 3 Practice of Swachh Bharat Abhayanamong study subjects

	Yes	**No**	
Washing hands with soap after defecation	80.72%	19.28%	
Use of dustbin at school for dumping waste	89.56%	10.44%	
Use of Toilet in the household	97.27	2.73%	
Availability of the water in/for the toilet	92.06	7.94%	
Do the family members segregation of waste as dry waste and wet waste	53.96%	46.04%	
Place of dumping the food waste at school	**Dustbin**	**Compost**	**Other**
	71.42%	28.11%	0.47%
Site of human waste disposal from the toilet	**Drain pit**	**River**	**Open Drain**
	87.52%	1.2%	11.3%

In table three 80.72% of the subjects use soap for washing hands after defecation and 89.56% of subjects use dustbin to dumping waste in school. 97.27% of subjects use toilet for defection. 53.96% of subjects told that the family segregate the waste into dry and wet separately. 71.42% subjects dump the food waste in dust bin and 28.11% into composting. Human waste disposal from toilet mainly to drain pit (87.52%) followed by open drain (11.3%) and to river (1.2%).

Table No 4 Scoring of the Study Subjects Under Knowledge, Attitude And Practice in Swachh Bharat Abhayan

Knowledge	Poor	Average	Good
	0	69(15.64%)	372(84.35%)
Attitude	Poor	Average	Good
	0	21(4.76%)	420(95.23%)
Practice	Poor	Average	Good
	0	219(49.65%)	222(50.34%)

Table four knowledge score was good in 84.35% and average among 15.64% of study subjects. Attitude was good in 95.23% and average among 4.76% of the study subjects. Practice was good in 50.34% and average among 49.65% of study subjects responding to Swachh Bharath Abhiyan.

Discussion

Total of 441 students were included in the study. In that 55.32% were boys and 44.68% were girls with 30.3%, 31.2% and 38.5% belonging to age group of 13, 14 and 15 years respectively.

97.27% said their household had a toilet but only 87.98% had water available in the toilet due to limited supply of water with majority of them stating that human waste was disposed in drain pits rather than river or open drain indicating unsanitary practices and they were educated regarding proper waste disposal. All of them agreed that the schools had separate toilets for boys and girl which were kept clean.

In the present study 80.72% of the subjects use soap for washing hands after defecation and97.27% of subjects use toilet for defection. Study done by Swain P et al showed that only 54% of the individuals were defecating in the toilets and 8% of the respondents didn't wash their hands after defecation.[4]

Hand washing after defecation with soap was practiced by 80.72% of students which was way higher than a study conducted by Shrestha A et al among primary school going children of urban Karnataka.[5]

20.1% students noticed that residents from their area practiced open defecation and most of them had family member who still continues the same even after gaining access to toilet because of their developed as routine

and unawareness about its effect on their health and environment.

Majority of them thought proper waste disposal is important in the house but only 53.96% practiced segregation of waste as they had lack of knowledge and 87.98% asked for education on the subject in schools. For general waste disposal, 89.56% of them used dustbin in school for dumping and only 28.11% used compost for food waste and we educated them the benefits of compost over dustbins.

Almost all of them (99.3%) have good perception of the cleanliness of their school compound but 41.05% noticed garbage near their houses and opinionated that it should be cleaned as improper waste disposal affects the environment. This shows their knowledge towards Swachh Bharat and their willingness to take initiatives for the same. Study conducted by Tiwari S K showed that all students were aware of the mission Swachh Bharat: Swachh Vidyalaya and the level of awareness of the students from public school and private schools was equally good.[6]

Knowledge about the Swachh Bharat Abhayan in the household of these students was about 90.02% which shows the effectiveness of various means promoting this mission. According to scoring done for students, 84.35% had good knowledge, 95.23% had good attitude but only 50.34% had good practice about environmental cleanliness and personal hygiene which was either due to their acclimatization to existing old habits and mindset.

Conclusion

The study conducted showed that study subjects had good knowledge and good attitude towards Swachh Bharat Abhayan but a lack of practice was seen among them. So, various health educations and practical demonstrations about the cleanliness whether environmental or personal and benefits of practicing them can be conducted as school-based initiatives to create awareness among students.

Association of Personality Traits, Life Satisfaction, Subjective Happiness and Oral Health Status in School Teachers of Vikarabad

N. Sindhu Reddy[1], M. Monica[2], T. Abhinav Nithin[3], P. Parthasarathi Reddy[4], Irram Abbas Hameed[5], B. Prathibha[5]

[1]Post Graduate, [2]Professor, [3]Senior Lecturer, [4]Professor and Head, [5]Reader, Department of Public Health Dentistry, Sri Sai College of Dental Surgery, Vikarabad

Abstract

Background: To determine the association between personality traits, life satisfaction, subjective happiness and oral health status in school teachers of Vikarabad.

Material and Method: A cross sectional study was conducted among 400 private and government school teachers of Vikarabad. A validated questionnaire was used (BFI)-10 to measure personality traits, life satisfaction and subjective happiness. Clinical examination was done to measure DMFT and OHI-S. Collected data was subjected to statistical analysis. Spearman's Correlation and multiple regression analysis was done.

Results: Among the teachers 13% were males and 87% were females and their mean age was 30 years. 57% had high and 43% had low levels of extraversion, 55% had high and 45% had low levels of agreeableness in their personality. The mean DMFT score was 1.12 ± 1.41 and mean OHI-S score was 1.71 ± 1.06.

Conclusion: A significant association was observed between personality traits and satisfaction in life of teachers with their oral health. Satisfaction with life will improve the quality of life and wellbeing of individuals.

Keywords: *Personality traits, School teachers, subjective happiness, life satisfaction, dental caries, oral hygiene.*

Introduction

Oral diseases are a significant public health burden in India as well as across the globe. The consequences of widespread poor oral health can be seen at the personal, population, and health systems level.[1] According to previous research,good oral health is independently associated with greater subjective well-being.[2] The term "well-being" is frequently used in literature to mean happiness. However, well being is commonly used in relation to physical factors and happiness used in relation to mental factors.[3] Happiness is a multidimensional construct comprising both emotional and cognitive domains, and has been defined as 'the degree to which an individual judges the overall quality of his or her life favorably as a whole'.Several factors which affect happiness of a person like income, job satisfaction, community values, health, family experience, education, sleep habits, personality based traits and life satisfaction[4]

Life Satisfaction (LS) has been conceptualized as a cognitive constituent of subjective well-being. High satisfaction suggests that the quality of life, in

e-mail: navari.sindhu@gmail.com

the population concerned, is good. Low satisfaction on the other hand marks serious shortcomings of some kind. Research has suggested that stress, depression and ineffective coping may contribute to development of periodontal diseases and dental caries. Dental caries and periodontal diseases are the two major oral diseases, which are universal in distribution and constitute the primary reason for tooth mortality. Particular personality types of people are more prone to ineffective coping with stress, depression and hence may affect their carious experience. Personality Traits (PT) of an individual reflect people's characteristic patterns of thoughts, feelings, and behaviors. People with different PT tend to experience different degrees of subjective well-being.[5,6]

Meshram et al[8] suggest that there exists no co-relation between various personality traits and associated oral health status. Tuchtenhagenet al [4] concluded that oral conditions like dental caries is influenced by happiness of school children. In a study conducted by Dumitrescu et al[10] life satisfaction and subjective happiness indicators seemed to be associated with self-reported oral health status and behavior.

In today's global world, workers like public and private school teachers are put under a lot of stress which influences their psychological well-being. They feel burned-out, unhappy, dull, or unsatisfied because of factors such as high teacher-student ratio, inconvenient or inefficient physical school conditions and low salaries.[11] There exists, no literature about oral health and its association with factors like PT, Subjective Happiness (ST) and LS in this population. Hence, the present study was carried out with an objective to determine the association of the personality traits, life satisfaction and happiness with oral health among school teachers of Vikarabad district.

Methodology

A cross sectional epidemiological study was conducted among school teachers in various government and private schools in Vikarabad District, Telangana. India. A pilot study was carried out to test the feasibility of the study and understanding of the questionnaire. With an estimation of 80% power of study, alpha error of 5%, and assuming the prevalence of dental diseases as 50%, sample size was estimated at 384,which was rounded to 400. Permissionto conduct the study was obtained from DEO of district. School principals who granted permission and teachers willing to participate were included**.** Teachers who have migrated to work place from other population were excluded. Questionnaire recorded socio-demographic factors and questions about sleep quality, smoking status, physical activity and self reporting of their general health status. Standard questionnaires were used for measuring the personality traits (BFI-10)[11], Life Satisfaction Scale (LSS)[12], and Subjective Happiness Scale (SHS)[13]. Both Telugu and English questionnaires were used in the present study. The content validity and the internal consistency was found to be good (Cronbach"s alpha = 0.78).The oral health status of the subjects was recorded using WHO Oral Health Proforma 1997 [14] for recording the dentition status and Oral Hygiene Index Simplified (OHI-S). Collected data was subjected to statistical analysis using SPSS version 20. Outcome variables DMFT and OHI-S were associated with the independent variables like PT, LS and SH. Spearman's correlation and linear regression analysis was done to know the overall association of the outcome variables on all the independent variables.

Results

In this study total male teachers were 13% and females were 87% with a mean age of 35.11±10.21. 48% were government and 52% were private school teachers. 20% of teachers had trouble in night sleeping and 80% of teachers were satisfied with their night sleep. About, 35% had regular daily physical activity. 88% of subjects reported their general health was satisfactory. 57% of teachers were subjectively happy. 70% were satisfied in their life, 7% were neutral and 23% were dissatisfied with their life.

Table 1 shows, mean DMFT score was 1.12 ± 1.41. Mean OHI-S score was 1.71 ± 1.06. Table 2 shows among PT 57% had high and 43% had low levels of extraversion (E), 55% had high and 45% had low levels of agreeableness (A), 59% had high and 41% had low levels of conscientiousness (C), 51% had high and 49% had low levels of neuroticism (N), 63% of teachers had high and 37% had low levels of openness (O). Table 3, shows PT like extraversion, agreeableness, neuroticism, openness and SH was weak and positively correlated DMFT score. C and LS is negatively correlated with the DMFT score.

Table 4, 5 shows sleep quality determining the trouble in falling asleep (p= 0.003*), general health status (p= 0.028*), physical activity (p= 0.022*), PT like neuroticism (p= 0.047*), openness (p= 0.007*),

LS (p= 0.016*) and subjective happiness (p= 0.032*) showed significant association with the DMFT scores. Gender (p=0.001*), marital status (p=0.013*), type of school (p=0.038*) and extraversion (p=0.021*) showed significant association with the OHI-S scores in multiple regression analysis.

Table 1: Distribution of oral health status among the study subjects

Factor	Categories	Respondents	
		n	%
DMFT Score	0	191	48%
	1-3	179	41%
	≥4	42	11%
OHI-S Score	Good	187	47%
	Fair	184	46%
	Poor	29	7%

Table 2: Distribution of personality traits among the study subjects

Personality Traits	High	Low
Extraversion	57%	43%
Agreeableness	55%	45%
Conscientiousness	59%	41%
Neuroticism	51%	49%
Openness	63%	47%

Discussion

Good health and happiness represent critical aspects of individual welfare, and their pursuit as a worthy end of one's living has been a subject of countless treatises. Personality traits imply consistency and stability. Trait psychology rests on the idea that people differ from one another in terms of where they stand on a set of basic trait dimensions that persist over time and across situations. The most widely used system of traits is called the Five-Factor Model. This system includes five broad traits Openness, Conscientiousness, Extraversion, Agreeableness, and Neuroticism.

Extraversion indicates how outgoing and social a person is. In the present study, highly extraversive teachers were relatively happier than introversive, and had increased prevalence of oral diseases. Teachers who were friendly, participate actively in social events and may not spare time to take care of their oral health. Agreeableness is the tendency to be friendly, compassionate and cooperative with others. In the present study, agreeableness was not significant but weak and positively correlated (r= 0.037) to DMFT scores. Teachers with high levels of agreeableness had high caries which could be due to lack of time and self assessment in them. Teachers with high agreeableness had good oral hygiene. It is in contrast to the study conducted by Mesharam et al [8], which suggested that there exists no correlation between various personality traits and oral hygiene.

Conscientiousness implies a desire to do a task well. They tend to be efficient and organized as opposed to easy-goingand disorderly. Conscientiousness and DMFT were not significantly but weak and negatively correlated (r = -.097). Conscientiousness people are more likely to make and keep medical appointments, and they might notice sooner when something is wrong in their oral health. In spite of this lack of time in these personalities may be the reason for poor oral hygiene.

A person who is high in neuroticism has a tendency to easily experience negative emotions. Teachers high in neuroticism were constantly worrying for small things showing negative emotions. In the present study, neuroticism, was significant and positively co related (r =.112, r = 0.036) with DMFT values and OHI-S. As teachers fail to cope with the stress levels it causes poor oral health in them. It is similar to the study conducted by Takeshita et al,[7] where neurotic individuals consistently report worse self perceived health. Personality trait openness, indicates the extent of open-mindedness in a person. A person with a high level

of openness to experience in a personality test enjoys trying new things. Dental caries and high plaque and calculus scores doesn't cause any symptoms initially, leading to negligence towards oral health.

Life satisfaction is the way people show their emotions and feelings (moods) and how they feel about their directions and options for the future. Life satisfaction when correlated with DMFT and OHI-S showed significant and negative correlation (r= -.104, r= -.111) with DMFT. Those teachers who are satisfied in life had less dental caries. This might be attributed to the fact that they maintain a healthy lifestyle and take care of their oral health

Oral health outcomes have the potential to influence happiness. Yoon et al[9] found a significant relationship between oral health related factors and happiness among an elderly Korean sample. In the present study, DMFT was weakly but positively correlated with happiness, though it was not statistically significant. This shows poor awareness and negligent attitude towards oral health among school teachers. In a recent study of Romanian medical students, researchers noticed a strong correlation between gum health and participants' reports of overall life satisfaction. The present study has certain limitations. As there was self reporting of the general health and subjective happiness it might have created improper opinions owing to inhibitions in them. Oral hygiene behaviors like brushing habits of the teachers were not recorded which might have provided the major clue in estimating their oral health status.

14% of the variation in DMFT was explained by all the various predictor variables. With respect to OHI-S 9% of the variation was explained by all the variables. Evidence shows that individual thoughts, perceptions have an influence on general and oral health. Longitudinal research has to be conducted as personality traits are genetic and they may change over time.

Conclusion

There exists a significant association between personality traits and satisfaction in life of teachers with their oral health. Personality traits act as indirect modulators of the state of oral health. Satisfaction with life will improve the quality of life and wellbeing of individuals.

Effect of Structured Exercise Programme on Pulmonary Function and Physical Performance in Geriatric Population

Gaurav S. Chandolkar[1], Javid H. Sagar[2], Govindhan Vardharajulu[3]

[1]MPTh Student, [2]Professor, [3]Dean, Professor, Krishna Institute of Medical Sciences, Faculty of Physiotherapy, Karad, Satara, Maharashtra

Abstract

Objectives: The objective was to evaluate the effect of structured exercise programme on pulmonary function and physical performance in geriatric population.

Methodology: Ethical clearance was obtained from the Institutional Ethical Committee, KIMSDU, Karad. A total of 61 subjects between 60-80 years of age, who were able to ambulate independently and able to understand instructions, who did not suffer from any musculoskeletal, neurological or cardiopulmonary disease were given structured exercise programme which consisted of warmup and cool down period along with resisted training, treadmill walking and static cycling for 4 weeks duration (5times/week). The subjects were assessed using Pulmonary function test (PFT), six minute walk test (6MWT) and Short Form 36 (SF-36) Health- related quality of life questionnaire before and after intervention.

Results: Statistical analysis was performed using Paired t- test. The results showed significant difference in all three measures that is PFT Values (FVC, FEV_1 and FEV_1/FVC ratio), 6MWT with p value of <0.0001 and SF-36 questionnaire with the p value of <0.0005 when compared between pre and post intervention results.

Conclusion: It can be concluded that structure exercise programme on physical performance and pulmonary function along with health-related quality of life in geriatric population has shown significant improvement when assessed with 6 MWT, PFT and SF-36 questionnaire.

Keywords: *Pulmonary function, physical performance, structured exercise programme.*

Introduction

Aging is characterized by the progressive organ system and tissue degeneration. It is mainly determined by genetic and influenced by a variety of environmental factor such as diet, physical exercises, micro-organism exposure, pollutants and harmful ionizing radiation.[1] The Indian geriatric population is currently the second largest in the world[2]. The elderly population is divided in to three subgroups people between 65-74 years are termed as young elderly, people between 75-84 years are classed as Old elderly, and above 85 are Old elderly[3]. Healthy ageing has been defined as the ability to lead a healthy, socially acceptable lifestyle relatively free from illness or disability, and this is more seen in those actively engaging in activities to improve their health and wellbeing[4]. The aging causes reduction in overall physical fitness i.e strength, endurance, agility and flexibility resulting in limitations in ADL and normal functioning in elderly.

Physiological Changes Due to Aging: Sarcopenia is defined as the loss of muscle strength and muscle mass leading to functional impairment that occurs with aging[5]. Sarcopenia results from decreased physical activity with aging appears to be the key factor[6]. Osteoporosis is the skeletal disorder which causes decrease in

bone mass leading to mechanical failure of skelet al. Hormonal factors play important role in development of osteoporosis and it affects women more than male due to menopause[7]. Physical activity contribution to good physical and psychological health at all ages[8]. All this again results in decreased physical performance in elderly population.

The functional residual capacity also increases with age but is opposed by increased stiffness of the chest wall[9]. Around 50 years of age, there in increase in diameter of alveolar ducts due to degeneration of elastic fibers around them. This causes closure of small airways during breathing, hyperinflation hence senile emphysema. With ageing there is change in the surface area which causes decline in diffusion capacity of lung. Due to loss of surface area along with decrease in pulmonary capillary blood volume there is decrease in ventilation to perfusion ratio in elders[10].

World health organization (WHO) has published certain guidelines on what are the benefits of physical activity in geriatric population. Based on this guidelines, exercise is an efficient and cost effective way of improving older people's functional capacity. Strength training, balance training and flexibility exercises are the most effective in preventing falls in elderly populations[11].

Method

The Present study was experimental which was conducted on 61 geriatric subjects with the age group between 60-80 years out of which 41 were male and 20 were female. Before commencement of this study Ethical Clearance was obtained from Institutional Ethical Committee of KIMSDU, Karad. The subjects who fulfilled the inclusion. Both gender, Age group between 60-80 years, Subjects willing to participate, Decreased PFT values considered normal for their age, Reduced air entry and chest wall mobility and exclusion criteria Subjects with neurological disorder, Subjects with hearing and vision impairment, Subjects with any vessel disease, Subjects with previous history surgery within one year, Uncooperative patients were included in this study through consecutive sampling method. This study was carried out in the time period between July 2018- February 2019 Subjects were explained about the procedure of the study in detail and informed consent were obtained from them. The subjects were assessed for physical performance and pulmonary function using six minute walk test, pulmonary function test and SF-36 questionnaire pre and post intervention. The subjects were given a set of structured exercise programme for 4 weeks, 5 times/week for 60 minutes including rest periods.

The Warm-up and cool down exercises included:- Static stretching: Static stretching was given for major muscle group mainly for pectoralis, Biceps, Triceps, hamstrings and quadriceps muscles. The warm-up exercise was done for 5 minutes and cool down exercise for 5 minutes. Dynamic stretching: Front leg swings, hug into chest expansion, arm push back, March and reach. Strength training: strength training was given with theraband exercises, squats, wall pushup. This exercises were given for major muscle groups of upper limb and lower limb at 40-80% of this strength. Aerobic training: Static Bicycle the subject cycled for 7 minutes with no resistance added to cycling. Rest is given if needed by participants. Treadmill walking:- subject walked at their own pace staring at 0.1km/hr till maximum speed till end of 7 minutes. If subject wanted rest in between 1 min rest was given. All vitals were measured before and after exercises.

Outcome Measures: Six minute walk test (6MWT)-intergroup comparison (within group) using paired t-test

Table 1 showed the comparison of mean and standard deviation of pre and post values within group

In this present study pre-interventional six minute walk distance showed the Mean of 313.6±86.26 which was improved post-interventional to mean of 352.65±96.54. The p value by paired t-test was found to be <0.0001 which was extremely significant.

Pulmonary Function Test (PFT) – intergroup comparison (within group) using paired t test

Forced vital capacity: Table 1 FVC showed the Mean 1.98±0.61 pre-intervention which was increased and post-interventional to mean of 2.16±0.62. The intra-group analysis was done using paired 't' test within the group. The post-test interventional analysis considered very significant difference within the group with P value 0.0015.

FEV_1: Pre-interventional Forced Expiratory volume in 1sec showed the mean of 1.43±0.50 and post-interventional FEV_1 showed improvement with mean of 1.59±0.52. The intra-group analysis was done using paired 't' test within the group. The post-test interventional analysis showed extremely significant difference within the group with P value 0.0009

FEV_1/FVC: Pre-interventional Forced expiratory volume in 1sec/Forced vital capacity showed the mean of 70.3±11.4 and post-interventional FEV_1/FVC showed improvement with the mean of 75.3±7.75 The intra-group analysis was done using paired't' test within the group. The post-test interventional analysis showed extremely significant difference within the group with P value < 0.0005.

SF-36 QUESTIONNAIRE (SF-36): Table 3 Pre-interventional SF- 36 questionnaire showed the mean of 0.52±0.11 and post-interventional SF 36 questionnaire showed the mean of 0.66±0.11 The intra-group analysis was done using paired't' test within the group. The post-test interventional analysis showed extremely significant difference within the group with P value < 0.0005

Table 1: Comparison of six minute walk test (Distance Covered)

6MWT (Distance covered)	Pre-intervention	Post-intervention	P value	Inference
Mean ± SD	313.65±86.26	352.6± 96.54	<0.0001	Extremely significant

Table 2: Comparison of PFT values pre and post intervention

Pulmonary function test	Mean ± SD		P value	Inference
	Pre-interventional	Post-interventional		
FVC	1.98±0.61	2.16± 0.622	0.0015	Very significant
FEV_1	1.43±0.50	1.59±0.52	0.0009	Extremely significant
FEV_1/FVC	70.39±11.45	75.32±7.75	0.0005	Extremely significant

Table 3: Comparison of PFT values pre and post intervention

SF-36 questionnaire	Pre-interventional	Post- interventional	P values	Inference
Mean ± SD	0.52±0.11	0.66±0.11	<0.0001	Extremely significant

Discussion

Ageing is a phenomenon and not a disease that causes general decline in function which leads to inactivity and risk of developing disease[12]. As aging progress, there is measurable decline in the physiological function of respiratory system like reduced forced vital capacity and forced expiratory volume in one second, with increase in residual volume and functional residual capacity[13]

A structured exercise programme involves multiple component which includes strength training, exercise to improve cardio-vascular endurance[14]. Structured exercise are recommended by American college of sports medicine for optimal aging, minimizing the adverse effect of aging, reducing risk of disease. In this study strength training was given through theraband for major muscle groups, wall-pushups. Aerobic exercises including treadmill walking and static cycling along with warm-up and cool-down exercises. There was a study done which state that 6 MWT helps to evaluate the exercise capacity in elderly people[15]. In this study Six minute walk test was performed before the administration of exercise programme by the participants. The intra-group analysis was done using Paired 't' test with the p value <0.0001 which was considered extremely significant. The finding of this study correlates with the study of Santakumar Haripriyal et al who stated that multicomponent exercise program causes significant improvement in 6 MWT values[16]. In their study the outcome measures used were 8-foot up and go test for functional mobility, 6 MWT for exercise capacity and SF-36 questionnaire for health related quality of life and in this study instead of 8-foot up and go test PFT were used to assess Pulmonary function. Their study duration was 10 weeks which was long than this study which was only 4 weeks.

Aging negatively correlates with pulmonary function[17]. Pulmonary function has also show to decline with aging, in this study pulmonary function was examined prior to the intervention through forced vital capacity, forced expiratory volume in one sec and forced expiratory volume in one sec/forced vital capacity ratio. There was significant improvement in FEV1 with the p value <0.0009, FCV with the p value

<0.0015 and FEV1/FVC ratio with the P value <0.0005 after the intervention of 4 weeks which correlates with the study of Mahtab Moazamil & Samaneh Farahati who concluded that there was improvement in PFT values after aerobic training in postmenopausal women[13]

Health-related quality of life was assessed using SF-36 questionnaire which showed significant improvement after exercise programme with P value <0.0001 this findings correlates with the study of Dhanesh K who stated that 10 week multi-component exercise program which compromised aerobic, resistance, balance and functional training significantly improved that the health related quality of life[16].

Conclusion

The present study provided evidence to support the use of structure exercise programme for improving physical performance and pulmonary function along with health-related quality of life in geriatric population.

Comparative Evaluation of Depth of Cure of Bulk-fill Composite Resin and Alkasite Restorative Material by Vicker's Hardness Test

Gowrish Bhat[1], Namrata Khanna[2], Mithra Nidarsh Hegde[3], Vandana Sadananda[4]

[1]Reader, [2]Post Graduate Student, [3]Professor and Head of Department, [4]Lecturer, Department of Conservative Dentistry and Endodontics, AB Shetty Memorial Institute of Dental Sciences, Mangaluru, Karnataka, India

Abstract

Background: This study evaluates depth of cure (hardness ratio) of a bulk-fill resin composite and an alkasite material in self cure and dual cure mode and compares and evaluates the Vicker's hardness and depth of cure of a bulk-fill resin composite and an alkasite material in self cure and dual cure mode.

Materials and Method: A dual-cure alkasite material and a bulk-fill composite resin were divided into three parts: Group A- bulk-fill resin composite, Group B- self-cured alkasite material and Group C- light-cured alkasite material. The samples were prepared in a stainless steel split mould of 6mm height and 4mm diameter. Vicker's hardness testing was performed to evaluate depth of cure of 4mm at three levels of 0mm, 2mm and 4mm.

Results: The statistics were analyzed using SPSS Software and One- way ANOVA and Post Hoc tests. The data obtained revealed that Cention N showed the greatest depth of cure in dual cure mode.

Conclusion: Most dual cure restorative materials exhibit better strength post light-curing compared to only the self-cure mode.

Keywords: *Alkasite, bulk-fill resin, composite, depth of cure, Vicker's hardness.*

Introduction

The rationale of this study was to compare and evaluate the claimed depth of cure of 4mm of bulk-fill restorative materials; an alkasite cement cured by itself and dually, with a bulk-fill composite resin.

Resin based composites require isolation, necessary steps for enamel and dentin etching, priming, and bonding, and the gold standard thickness of each increment of 2 mm. However, deeper preparations with 2-mm increments are time consuming and relatively technique sensitive. The validation for this incremental technique is to warrant the penetration of the curing light deeply enough to initiate and complete the curing of the resin, apart from reducing the shrinkage and shrinkage-induced stress associated with polymerization of resin based composites. Recently, the introduction of resin-based bulk-fill composites claim to fill cavities up to 4–6 mm immediately.

Dental bulk-fill resins are increasing in demand, but the clinicians doubt that the in-depth cure may be insufficient. An alternative is possible through newer dual-cured resin based composites that not only save critical clinical time but also provide bioactive properties. Apart from new photo-initiators[1], the given techniques improve the depth in light-cured bulk-fill

resin based composites by reducing the filler–matrix interface by enlarging the filler size[2] and decreasing the amount of pigments. Apart from fast curing and sufficient strength in large increments, modern bulk-fill resin based composites also necessitate the need for an additional feature to make it more acceptable, namely, bioactivity or self-adhesiveness.[3]

The increasing demand for a quick restorative procedure with light-cured, bulk-fill composites raises a doubt whether an adequate depth of cure will be achieved.[4] This factor, along with the trial to offer an aesthetic, basic filling material has proved to be the motivation for the launch of several dual-cure resin based composites in the market, that are also appropriate for a bulk-filling procedure. The bulk fill resin materials also concentrate on bioactive properties that intend to prevent tooth demineralization by releasing acid-neutralizing ions and aid in remineralization. For this sole purpose, one method implemented the addition of alkaline fillers in a methacrylate resin matrix, by introducing a new material category—the alkasites.[5]

Dual-curing resin based composites consists of mixing two components together, each of which, consists of a different initiator system. Currently, dual-cure resin based composites have been mainly used in modern dentistry for core build-up and cementation. However, it needed to be confirmed whether the self-curing polymerization reaction was enough not only in case of impeded light transmittance, but also in the absence of light. On comparing the features of resin based bulk fill composites that were either self-cured or dual-cured, it was found that the impact of light irradiation depended on the final material ranging from no- impact to high-impact.[6] Hence, the concluding factor for a newer dual-cured alkasite cement, apart from its caries preventive ability, is the duration it takes to set, the adequacy of its mechanical properties and early strength, the degree of conversion in depth, and the impact on the properties of the final material with additional light-curing.

The polymerization that is light-initiated facilitates the curing of a material on demand, whereas the polymerization procedure through a redox activation occurs slowly in comparison and may not be conducive enough for a quick restorative procedure that is generally required in modern clinics. The time required to set the material in question should be calculated and adjusted to the required time of a regular clinical treatment, even in the absence of light. Furthermore, the higher refractive index of alkaline fillers when compared to regular silicate glass fillers may alter the filler/resin refractive index match that is crucial for better light transmission for optimum depth. The result would be a more dense material that is able to camouflage the oral cavity or the tooth's structural discolorations effectively rather than the one obtained through several translucent, light-cured, bulk-fill resin based composites.

Materials and Methodology

A dual-cure alkasite material (Cention-N, Ivoclar Vivadent AG, Schaan, Liechtenstein) and a bulk-fill composite resin (Filtek^{TM} Bulk-Fill Posterior Restorative material, 3M^{TM} ESPE, St. Paul, USA) were selected for the study. The materials were divided into three parts: Group A - bulk-fill resin composite, Group B- self-cured alkasite material and Group C - light-cured alkasite material.

A stainless steel split mold of height 6mm and diameter 4mm was used to prepare 10 Samples from each group.

Group A (Cention N-Self Cure) - Powder and liquid was dispensed onto a paper pad in the ratio of about 4.6:1, mixed for about 45-60s and condensed into the mold. They were retrieved after 5 minutes of setting time.

Group B (Filtek Bulk-Fill) - The samples were condensed into the mold and cured for 20 seconds with blue LED Light Source.

Group C (Cention N-Dual Cure) - The powder and liquid was mixed and the cement loaded into the mold to be cured. The samples were cured for 20 seconds with blue LED Light Source (Kerr Demi^{TM} Ultra Ultracapacitor-1200 mW/cm^2) and were retrieved immediately after the curing cycle was complete. The samples were all thermocycled (Thermocycler SD Mechatronik, GmbH Dental Research Equipment, Germany) for 5,000 cycles at 5°C and 55°C (dwelling time: cold bath, 30 seconds; hot bath, 30 seconds).

The Depth of cure was measured by Vicker's Hardness Testing Machine (MMT- X7A, Matsuzawa Co., Ltd., Japan).

Results

The statistics were analyzed using SPSS Software 16.0. One- way ANOVA statistical tests were done to

compare the three groups and on achieving statistically significant results, Post Hoc test was done.

The results obtained (Table I) showed that Group C (Cention N- Dual Cure) had manifested the most coveted results in comparison to the other two groups. Group C showed best results at all three levels of 0mm, 2mm and 4mm.

Group C had the highest VHN value of 65.08 followed by Group B at 54.63 and lastly group C, at 43.87 and the surface layer of 0mm. Even at the claimed depth of 4 mm, Group C did better with the VHN value of 49.86.

Table I: Vicker's Hardness Numbers of Group A, B, C at 0, 2 and 4 mm.

Group	Depth	Sample Size (n)	Mean	Standard Deviation
Group A – Cention N - Self Cure				
	0 mm	10	43.87	0.881
	2 mm	10	39.94	0.910
	4 mm	10	32.45	0.820
Group B – Filtek Bulk- Fill				
	0 mm	10	54.63	0.834
	2 mm	10	48.23	0.824
	4 mm	10	41.35	0.921
Group C – Cention N- Dual Cure				
	0 mm	10	65.08	0.820
	2 mm	10	57.31	0.748
	4 mm	10	49.86	0.625
The mean difference is significant at $p<0.05$.				

Discussion

Currently, bulk-fill resin based composite materials has gained popularity among practitioners owing to the comparative simplicity of the procedure.

Manufacturers, with the help of advanced technology, relate the modifications in the filler content and/or organic matrix as their claim in the main advancement of bulk-fill composite materials i.e, namely increased depth of cure, which probably results from higher translucency, and low polymerization shrinkage stress

Cention N contains an acyl phosphine oxide initiator (Norrish type1 initiator) which requires just one component for radical formation and the photoinitiator, Ivocerin. The presence of this leads to faster polymerization of the resin material and causes better conversion of the monomer to polymer which may have lead to the results developed in this study. Cention N also contains UDMA, DCP, and an aliphatic/aromatic UDMA; which has claimed faster cross-linking of the methacrylate monomers to a high polymer network density and may be responsible for the better depth of cure.[7]

A self-curing material with options for light-curing outlook is the substance of analysis. Although the initiation rate can be very high in the light-curing mode, its significant drawback maybe the fact that the saturation of light energy in depth is quite low. In order to improve this, the alkasite was modified and a redox activation containing a copper salt, a peroxide and a thiocarbamide was added in the powder component.[7]

The use of restorative and viscous composite resins has demonstrated that greater depth of cure up to 4 mm is more effective.[8,9] It has been found that filler size and content in dental composites may reduce light penetration and this, in turn, has an effect on the depth of the cure.[10,11] The pigments present in shaded composite materials have a direct impact on the depth of cure since these are dense particles that hinder the penetration of light and decrease the degree of polymerization at greater depths while a cavity is being treated.[12]

Filtek Bulk-Fill claims to contain AFM (addition-fragmentation monomers) that react with the methacrylate to keep the physical features of the material intact. The kind of monomers being used have an effect on the Methacrylate composites as they have the ability to shrink in varying degrees during polymerization. Filtek Bulk Fill Posterior Restorative consists of two new methacrylate monomers; their properties have served as a catalyst to gain lower polymerization stress that is necessary for better results.

Filtek bulk fill (bulk fill viscous composite) has shown a higher degree of conversion than the conventional viscous composite. Probably the reduced filler volume fraction is convenient compared to the less viscous conventional composite.[13] The composition of 4 high molecular weight monomers, viz. Bis-GMA, Bis-EMA, UDMA and procrylate in Filtek bulk fill facilitates a higher conversion and Depth of cure . Filtek bulk fill flow composites contain a proprietary monomer equivalent to Bis-GMA and patented as Procrylat resin.[14] Procrylat is a high molecular weight monomer with low viscosity similar to Bis-GMA but with a lower viscosity, the lack of pendant hydroxyl groups is the only difference between Bis-GMA and Procrylate.[15]

The decreased hydrogen bonding potential is due to the lack of hydroxyl group which reduces the viscosity of the monomer. Also Bis-EMA and UDMA are high molecular weight monomers with low viscosity so the manufacturers adjust the proportions of the 4 high molecular monomers to decrease viscosity and create hard cross link network.[16]

The monomer aromatic dimethacrylate (AUDMA) with a high molecular weight is responsible for reducing the number of reactive groups in the resin. Polymerization stress is caused mainly due to two factors – the shrinkage in the volume and the stiffness in the developing and final polymer matrix. However, AUDMA is capable of combating both these factors.

Another distinctive methacrylate characterizes a class of compounds called addition-fragmentation monomers (AFM). The AFM reacts like any other methacrylate by forming cross-links between the adjacent polymer chains during the process of polymerization. The third reactive site of the AFM splits into fragments during polymerization. This process provides a technique to relax the developing network that results in greater relief from the stress caused. The fragments, however, still preserve the feature that can not only allow them to react with each other but also with other reactive sites of the developing polymer. Thus the physical features of the polymer are retained along with relief from stress.

Conclusion

Under the limitations of this study, Cention N showed best depth of cure when tested by the Vicker's Hardness Test in dual cure mode. Filtek bulk fill also showed coveted results while maintaining a desirable depth of cure. In self-cure mode, Cention N may not achieve enough curing and we recommend that the alkasite material be used along with light curing protocols.

Population Growth and its Impact on Public Health in India: A Legal Analysis

Hiranmaya Nanda[1], Shyamantak Misra[1]

[1]*Assistant Professor, Faculty of Legal Studies, Siksha 'O' Anusandhan University, Bhubaneswar, Odisha, India*

Abstract

In this article the author after a thorough research on population growth strives to pen down the major factors that envelope the matter of population explosion in India only. The author beautifully states the occurrences of change year wise through the family welfare programs planned and implemented in India along with the consequential changes that took place because of such programs. The National Population Policy, Role of National Commission on Population have been discussed as well followed by the impact of the same on Public health. Most importantly the measures that were taken to control such fast growing population in India have been individually dealt with in order to provide a in depth knowledge to the readers of this article. However the author hopes to have dealt with the matter sensitively and in simple language as well, so as to satisfy the needs of the reader on the mentioned topic.

Keywords: *Population, public health, fertility, family welfare program.*

Introduction

India firstly adopted the population control policy as a matter of national concern before 1951. The goal of the year 1951 was that "the country was working on stabilizing the population at a level consistent with the needs of the national development." The problem of population explosion in the country is considered to be the biggest and most fundamental problem which India is facing till date. Why is it that this matter of population turns out to be the biggest problem an the other major problems like poverty, environmental degradation, unemployment etc are more or less overshadowed by this so called fundamental problem. There is no doubt that the pace and momentum in which population growth is taking place today might very soon lead to disastrous situations due to scarce of food, water and shelter etc. Moreover as we see today water has already become a matter of concern in India.[1]

Development of India's Family Welfare Programs: In the Year 1950: When India achieved independence at that time the country's health care services relating to hospitals were predominately available in the Urban areas only. Rural India at that stage seemed to be very underdeveloped. The general physicians were well versed with the women and child health services. In the year 1951, India became the first nation to develop a state sponsored family planning program in the National Family Planning Program. The main goals of this program are to lower the fertility rates and to slow down the population growth as a means to drive the economic development.[2]

This national program was based on 5 ethical goals such as, "the community must be prepared to feel the need for the services in order that, when provided, these may be accepted, parents alone must decide the number of children they want and their obligations towards them, people should be approached through the media they respect and their recognized and trusted leaders and without off-ending their religious and moral values and susceptibilities, services should be made available to the people as near to their doorsteps as possible, services

have greater relevance and effectiveness if made an integral part of medical and public health services and especially of maternal and child health programs."[3]

In the Year 1960: In the year 1960 many useful medicines which are beneficial for the prevention of six childhood diseaseand for effective contraceptives for birth also became available. The family welfare program and various immunization programs were among the primary programs which were added the national policy. During this ear sterilization remained the aim of the national family planning program. Several awareness programs and efforts were made for the promotion of vasectomy and to provide services exclusively to the rural peoples.

In the Year 1970: However in the year 1970 population explosion was though not considered as the chief threat to the nation but many troubles due to increased population were emerged. The government of India had given main concern to this problem. The parliament of India has enacted a legislation namely The Medical Termination of Pregnancy Act, 1971which can check unwanted pregnancy of women and to get a safe termination of pregnancy after fulfilling the requisite conditions of the law. In this era it is reported a massive sterilization drive done in the year 1976 which is near about 8 million persons.[4]

In the Year 1980:The chief thrust in the year 1980 was to implement the WHO's "Alma Ata Declaration of Health for all by the year 2000 through establishing a network of health care centre's in urban and rural areas." In the year 1986 a Universal Immunization Program started in 30 districts and subsequently it was extended to cover 448 districts by the end of Seventh Plan.[5]

In the Year 1990: In the year 1990 with the starting of Eighth Plan, several efforts were made under "Safe Motherhood and Child Survival and the Social Safety Net Program" to enhance the access to motherhood and childhood health care services.

National Population Policy: A proficient committee headed by M.S. Swaminathan who was appointed by the government to draft a National Population Policy and finally it came into operation from year 2000. The said policy has set out few goals for the year 2010 such as; "to address the unmet needs for basic reproductive and child health services, supplies, and infrastructure; to make school education up to age 14 free and compulsory, and reduce dropouts at the primary and secondary school levels to below 20 per cent for both boys and girls; to reduce the infant mortality rate to below 30 per 1,000 live births; to reduce the maternal mortality ratio to below 100 per 100,000 live births; to achieve universal immunization of children against all vaccine preventable diseases; to promote delayed marriage for girls, not earlier than age 18 and preferably after 20 years of age; to achieve 80 per cent institutional deliveries and 100 per cent deliveries by trained persons; to achieve universal access to information/counseling, and services for fertility regulation and contraception with a wide basket of choices; to achieve 100 per cent registration of births, deaths, marriages, and pregnancy; to contain the spread of the Acquired Immuno-deficiency Syndrome (AIDS) and promote greater integration between the management of reproductive tract infections (RTIs) and sexually transmitted infections (STIs) and the National AIDS Control Organization; and to prevent and control communicable diseases."[6]

National Commission on Population: On May 11, 2000 under the chairmanship of Prime Minister, The National Commission on Population was constituted along with Chief Ministers of all the states, concerned ministers of the related central ministries, secretaries of the concerned departments, distinguished physicians, demographers and the representatives of the civil society are members of the commission. The commission has given the mandate such as, "to review, monitor and give direction for implementation of the National Population Policy with the view to achieve the goals set in the Population Policy; to promote synergy between health, educational environmental and developmental programs so as to hasten population stabilization; to promote inter sectoral coordination in planning and implementation of the programs through different sectors and agencies in center and the states; to develop a vigorous peoples program to support this national effort."

Impact on Public Health: The degree and accentuation of a general wellbeing or public health program are essentially impacted by the changing attributes of the populace it serves. Among the different attributes of ongoing population explosion patterns, aging of the populace is a standout amongst the most major in its bearing on national public health.

Human health is in danger as the denser the populace; the simpler airborne ailments can spread.

The increment in overpopulation has prompted issues like urban swarming and ecological changes that have brought about the development of numerous irresistible diseases. Increment in antimicrobial obstruction turns out to be a sudden issue for illnesses, for example. Tuberculosis, Malaria, Cholera, Dengue fever etc.

The overpopulation also results in the contamination and pollution of water. People also die each year due to contamination of water related diseases. Because the virus spreads faster in water than any other platform.

This population growth also explodes the number of vehicles in the society. Due to vehicular use air in the environments degrades by toxic contents and it affects easily with children and older persons. They suffer from various respiratory diseases like Asthma,Lung cancer, Chest pain, Congestion, Throat inflammation, Cardiovascular disease etc.

Rapid population growth has also led to affect of ozone layer. The UV rays of the sun which causes various skin problems like skin cancer and premature aging of skin. It also results in the eye problems like cataract and sometimes it leads to blindness.

Checking Overpopulation: The government has taken various measures to put a check on overpopulation. Only legislation, rules and regulations cannot only put an end to population however medical assistance through proper sterilization can control this problem in India.

Therapeutic Sterilization: This type of sterilization is performed where a person is of sound mind gives consent to such operations. This is very common in the world. A medical practitioner when performed this type of sterilization with the consent of the patient having very less chance of criminal prosecution. However if it is done without the consent of the spouse then r this may rise to civil liabilities. This is civil liabilities because of the The Hindu marriage Act, 1955 which is a ground for divorce under the purview of cruelty.

Eugenic Sterilization: This is performed where a further procreation capacity of a mother will weaken physically and psychologically. There is no particular legislation available pertaining to eugenic sterilization in India. In most of the states of United States of America this type of legislation prescribes sterilization. However other modes of sterilization which controls the birth process should be made free and voluntary.

The Injectable Contraceptive: This type of process is a threat to life and health of the acceptor which certainly makes the mockery of her fundamental rights. This process affects women's menstruation cycle and may have bleeding and spotting between the periods.[7] It occurs mostly during the first few months of its usage but may also occur after the use of injectable contraceptive for some time. Periods and fertility may take up to a year to return after stopping injections, depending on the type of injectable, and this may vary from woman to woman.

Conclusion

After all the above discussions on population growth the author is of the opinion that if the present ruling government of India strives to strike down the unnecessary policies and programs and go for programs which would make aware the eligible couples about the numerous benefits of birth-control, policies that would provide free education to the single child of a couple, implementing strictly the laws on preventing early marriage, arranging a vigorous training program for the family welfare workers and improving the situation by implementing all the above stated suggestions majorly in the rural sectors of India would yield great results.

Ethical Clearance: Not required, as the research article is based on population explosion and its impact on public health. The research is doctrinally undertaken.

Evaluation of Malondialdehyde, Glutathione Peroxidase and Defensin Levels in Patients with and without Periodontitis

J. Hemashree[1], Sreedevi Dharman[2], Selvaraj[3]

[1]Graduate Student, [2]Reader, Department of Oral Medicine and Radiology, [3]Assistant Professor, Department of Biochemistry,, Saveetha Dental College & Hospital, Saveetha Institute of Medical and Technical Sciences, Chennai, India

Abstract

Aim: Aim of the study is to estimate the levels of Malondialdehyde, glutathione peroxidase and Defensin levels on patients with and without periodontitis.

Materials and Method: The levels of Malondialdehyde and Glutathione peroxidase was estimated using colorimetric estimation and Defensin was estimated using ELISA

Results: Levels of Defensin is increased in patients with periodontitis 9.18+-1.72 when compared to healthy subjects 6.22+-2.73. The mean levels of MDA is increased in patients with periodontitis 2.35+-0.32 when compared to normal patients 3.58+-0.36. The levels of Gpx is lower in patients with periodontitis 2.52+-0.58 when compared to normal patients 3.58+-0.36. The p – value was found to be significant (0.001)

Conclusion: Thus, this study reveals that Malondialdehyde, Defensin and glutathione peroxidase can be considered as biomarkers in the periodontal diseases.

Keywords: *Periodontitis, oxidative stress, inflammation, saliva, tooth.*

Introduction

Periodontitis is an inflammatory disease of supporting tissues of the teeth that are caused by specific microorganisms or groups of microorganisms, which eventually results in progressive destruction of the supporting tissues of the teeth. It is also combined with periodontal pocket formation, gingival recession or both.[1] Periodontitis is a complexive disease resulting from interaction of bacterial infections and host response to such bacterial infections. Environment, acquired risk factors and genetic susceptibility are certain modification factors predisposed to this disease.[2] Periodontitis is one of the most common causes of tooth loss in adults.[3] However this can be prevented by preventing plaque and calculus formation which harbours the periodontal pathogens . The periodontal pathogens in the causal of the disease include a vast list of organisms among which Porphyromonas gingivalis, and Aggregatibacter actinomycetemcomitans, which are commonly seen in the biofilm. The colonization and subsequent invasion of these Gram-positive and Gram-negative microorganisms into the gingival epithelium leads to progression of the disease.

The severity of periodontitis could be diagnosed on the basis of its typical clinical parameters. These include periodontal probing depth, pocket depth, clinical attachment loss and amount of gingival bleeding. Moreover,analysis of saliva as an important laboratory test for the evaluation of many salivary conditions, including periodontitis, has gained attention during the last few decades.[4] Using saliva as a diagnostic marker

Corresponding Author:
Dr. Sreedevi Dharman
Reader, Department of Oral medicine and Radiology, Saveetha Dental College & Hospital, Saveetha Institute of Medical and Technical Sciences, 162, Poonamalle High Road, Chennai -600077 Tamil Nadu, India

for monitoring various biological alternations in human is an emerging trend worldwide. Human saliva is an easily collectable biochemical fluid, which is similar to blood in various biological aspects.It possesses a simple and non-invasive collection with low-cost storage and easily storage nature. Saliva contains both locally and systemically derived biochemical molecules with relatively important diagnostic value, which could be used for detecting periodontal diseases.[5] It can be used to assess both the severity of the disease as well as monitoring the patient's responses towards the treatment. Detection of salivary biomarkers is a non-invasive laboratory examination for early diagnosis of periodontitis.[6]

Glutathione peroxidaseis a marker of oxidative stress and dependent on the micro nutrient selenium (Se).[7] Periodontal diseases are associated with disturbances in the balance between the oxidants and antioxidants. This causes an increase in Reactive oxygen species(ROS) as well as decreased antioxidant activity in saliva.[8] Lipid peroxidation is a outcome of periodontitis. This is caused by free radicals which leads to the production of toxic and reactive aldehyde metabolites such as MDA formed by the peroxidation of poly unsaturated fatty acids.[9] Defensin is an anti microbial peptide of human flora. In case of infection or inflammation, it gets expressed on the surface of neutrophils. They also directly stimulate antigen-presenting dendritic cells and memory T-cell, and thus can link innate and adaptive immune responses.[10,11] So, this study aims at evaluating the salivary bio markers which get expressed in the periodontal diseases. The markers are Glutathione Peroxidase (Gpx), Malondialdehyde (MDA) and Defensin (beta-2) .

Materials and Method

This was a case control study performed in the Department of Biochemistry, Saveetha Dental College and Hospitals, Chennai. It was carried out in 20 subjects among which 10 patients had chronic periodontitis aged 50-70 years (group I) and 10 patients were healthy subjects (group II). Informed consent was obtained from each patient before the study.

Saliva Collection: Unstimulated whole saliva (Resting Saliva) from each participant was expectorated into sterile tubes prior to any kind of treatment.

Inclusion Criteria:

1. Presence of plaque
2. Presence of calculus
3. Generalised clinical attachment loss ≥ 4 mm
4. Probing depth more than 5mm
5. Generalised Gingival recession

Exclusion Criteria:

1. No history of systemic diseases
2. Patients who have undergone periodontal therapy
3. No history of diabetes
4. No history of hypertension

Estimation of levels of MDA and glutathione peroxidase: The levels of MDA and Gpx was determined by the use OF chemical reagents and subjecting it to colorimetric analysis with the help of a colorimeter. Colorimetric analysis is a method of determining the concentration of a chemical element or chemical compound in a solution with the aid of a color reagent

Estimation of Defensin: This was estimated using the Enzyme Linked Immunosorbant Assay(ELISA).

Results

The data was statistically analysed. The table given below shows the statistical data of the bio markers estimated in the study.

It is seen that the levels of Defensin is increased in patients with periodontitis 9.18+-1.72 when compared to healthy subjects 6.22+-2.73(Table 1).The mean levels of MDA is increased in patients with periodontitis 2.35+-0.32 when compared to normal patients 3.58+-0.36 (Table 2). The levels of Gpx is lower in patients with periodontitis 2.52+-0.58 when compared to normal patients 3.58+-0.36 (Table 3). The p – value was found to be significant (0.001). Bar Graph 1,2,3 shows the levels of Defensin, Gpx, MDA respectively among patients with periodontitis and normal patients.

Table 1: Levels of Defensin among patients with periodontitis and normal patients

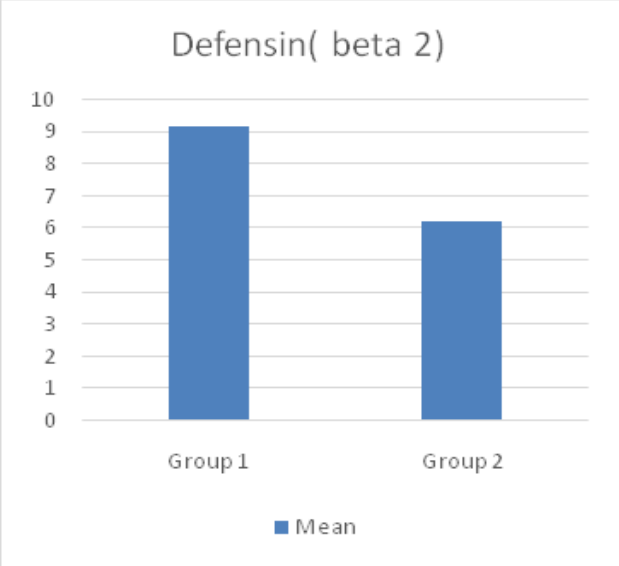
Subject	Mean	Standard Deviation	p value
Group I	9.18	1.72	0.001
Group II	6.22	2.73	

Table 2:Levels of Gpx among patients with periodontitis and normal patients

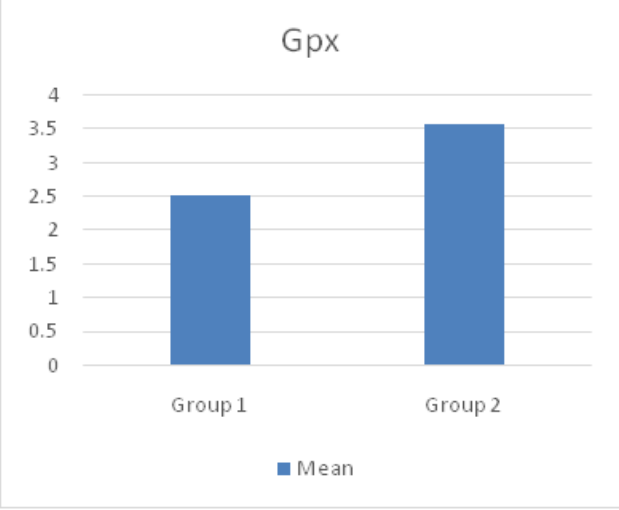
Subject	Mean	Standard Deviation	p value
Group I	2.52	0.58	0.001
Group II	3.58	0.36	

Table 3: Levels of MDA among patients with periodontitis and normal patients

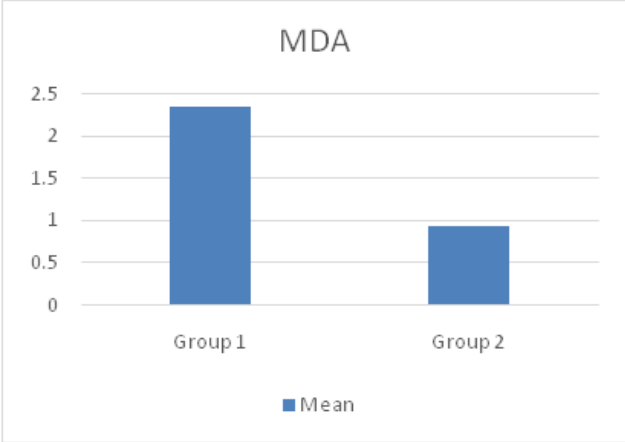
Subject	Mean	Standard Deviation	p value
Group I	2.35	0.32	0.001
Group II	0.94	0.58	



Graph 1: Graph showing comparison of comparison of levels of Defensin (beta 2). among patients with periodontitis and normal patients.



Graph 2: Graph showing Comparison levels of Gpx among patients with periodontitis and normal Patients.



Graph 3: Graph showing comparison of levels of MDA among patients with and without periodontitis.

Discussion

From the above results it is seen that the levels of Defensin beta -2 and Malondialdehyde levels are increased in case of periodontitis patients whereas the level of Glutathione peroxidase is decreased when compared to healthy subjects. The reason for the increased levels of MDA is because, in case of periodontitis, there is an imbalance between the oxidants and antioxidants present in the oral cavity which ultimately leads to the production of ROS. Therefore lipid peroxidation occurs and there is increased MDA. For patients with periodontitis there is increased oxidative stress occurs which causes reduced antioxidant activity causing the decrease of Gpx. Human defensin beta- 2 gets expressed on the surface of neutrophils which involves in innate immunity causing phagocytosis of the bacterial flora. Moreover it protects the undifferentiated stem cells of the periodontium.

Several studies have shown similar results. In a study done by Akalin et al,[12] the levels of MDA was elevated in saliva in patients with periodontitis. Lipid peroxidation causes release of ROS which causes the suitable host environment for resorption of bone, degradation of connective tissue and increase in the matrix metalloproteinase activity.[13] Dhotre et al conducted a study to find of any significant relation between the serum and salivary levels of MDA. It was reported that there was a significant increase in the levels of serum MDA in patients with periodontitis. They even concluded that this increase in the levels of MDA can be referred to the possibility of an association between periodontitis and cardiovascular disease. [14]

In accordance with the studies done to evaluate the levels of glutathione peroxidase there was varying results. In contrary to our study, A study done by Wei et al[15,] showed the levels of Gpx was increased in the gingival crevicular fluid in patients with periodontitis. Not all patients demonstrated the increased level of Gpx in periodontal diseases . For eg. A study by Brock et al[16] reported the levels of GpX was reduced when compared to healthy subjects. This indicates that there is hampered antioxidant capacity in patients with periodontitis. This study is in accordance with the our study. The levels of Gpx might have a positive correlation between the progression of disease.[17]

Human Defensin beta -2 is profoundly indicative of the antimicrobial activity occurring in the oral cavity. They play a major role in the adaptive and innate Immune responses. They provoke efficient epithelial barrier repair to limit entry of invading bacteria.[18] Related to the severity of disease, some study conducted by Ertugrul et al,[19] found that significantly higher level of HBD-2 from chronic periodontitis than gingivitis subjects ($p<0.05$) Another study by Sulijaya et al.[20] reported that HBD-2 protein level was higher in severe chronic periodontitis than other patients.

Conclusion

Thus to conclude the role of biomarkers in periodontal diseases is to prevent the onset as well as the progression of the diseases. Antimicrobial peptides provide multiple benefits as frontline defense molecules and antioxidants can provide better integration of the tissues. Nevertheless, therapeutic considerations for the adjunctive use of glutathione, defensin and the elimination of MDA in management of periodontitis can limit the tissue damage and enhance the wound healing.

Effect of Neurodynamic Sliding Technique on Hemiplegic Stroke Subjects with Hamstring Tightness

J. Anandhraj[1], A. Kumaresan[2]

[1]MPT (Neurology), Saveetha College of Physiotherapy, [2]Assisstant Professor, Saveetha College of Physiotherapy, Saveetha Medical Technical Sciences, Thandalam, Chennai

Abstract

Aim and Objectives: To determine the effect of Neurodynamic Sliding Technique On Hemiplegic Stroke Subjects With Hamstring Tightness.

Methodology: Quasi Experimental study design was used in this study. Total 20 hemiplegic subjects with hamstring tightness were selected. Then pre intervention measurements was taken using goniometer by passive SLR test on affected side. Then all subjects underwent Neurodynamic sliding technique (NDST) for 20 repetitions and 3 sets. NDST was performed for 4 week. At the end of fourth week post test measurement was taken. Then pre and post intervention measurements were taken using goniometer as per pre intervention measurement. The values were tabulated and statistically analyzed.

Results: At the end of study data were analysed the mean score of Passive SLR for hamstring pre-intervention 56.30 and post-intervention 62.55. Finally there is significant change in mean value (p & lt; 0.00).Conclusion: NDST shows minimal observable significance in hemiplegic subjects. Hence this NDST should be practiced for long term effect.

Keywords: *Neurodynamic sliding technique, hamstring flexibility, passive SLR test, Goniometer,hemiplegia.*

Introduction

Stroke occurs when an interrupted blood flow to brain, without oxygen rich blood brain cells die. Stroke is one of the leading causes of death and disability in India. Incidence: 119-145/100000 based on recent population studies. Prevalence: 84-262/100000 in rural and 334-424/100000 in urban[1]. Hamstring muscles have an important role in the performance of daily activities such as controlled trunk movement, walking, and jumping[2]. Muscle tightness is one of the commonest motor system factor which affect the balance. Tightness of calf and hamstring may affect static, dynamic balance of body and mobility[3]. Poor hamstring flexibility appears to be one accepted factor causes of hamstring injuries[4], musculoskeletal disorders and reduction in physical performance[5]. Entire nervous system in the body is a continuous structure which slides as we move and the movement shows physiological processes such as blood flow to neuron. Nerve adhesions in the hamstring may alter neurodynamics causing abnormal mechanosensitivity of the sciatic nerve; which could influence hamstring flexibility[6]. This mechanosensitivity of the neural tissue could limit hamstring length in normal healthy individuals[7]. Before stroke the brain communicated through spinal cord to the muscle when to tighten and relax to control movement. After stroke the affected brain is not able to understand the signals from the affected muscle. The signals has been not transmitted to affected part of brain it undergo safe mode. Spinal cord send its own impulse to muscle in those limb to remain contracted or tight, so that muscle

don't get overstretched and tight hamstring limits the movement of pelvis in relation to the legs. Hamstring pull the pelvis into backward tilt, rounding and putting strain over lower back.

Several stretching method have been used to improve muscle flexibility, including the static stretching, contract-relax stretching, ballistic stretching and neurodynamic sliding technique (NDST)[8-10]. Other conservative techniques robotics to provide physical assistance, virtual reality, extra corporeal shock wave therapy, bilateral training or irradiational therapy, constraints-induced therapy functional electrical stimulation with biofeedback[11]. Neurodynamic is a manual method of stretching in which force is applying to nerve structures through posture and multi-joint movement, aiming to produce a sliding movement of neural structures relative to their adjacent tissues[12]. Neurodynamic is thought to decrease neural mechanosensitivity and can be a beneficial technique in the management of hamstring flexibility[13]. Neurodynamics change in mobility of nervous system achieved through movement and stretching could modify such sensations. NDST interventions to decrease neural mechanosensitivity, this intervention could be beneficial in the hamstring flexibility[14]. Decreased hamstring flexibility as evidenced by limited range in the passive straight leg raise test (SLR) could be due to altered neurodynamics affecting the sciatic, tibial, and common fibular nerves[15]. Altered posterior lower extremity neurodynamics could arguably influence resting muscle length and lead to changes in the perception of stretch or pain[16]. Providing movement or stretching could lead to changes in the neurodynamics and modification of sensation and could help to explain the observed increase in flexibility.

Methodology

Participants: Patients were participate in this study was screened for inclusion subjects of both the gender within the age group of 60 years or more, physically independent, not currently engaged in a structural exercise program, Able to understand and follow simple verbal instructions, and exclusion criteria Physical or functional impairments, Dementia, Alzheimer's disease, Parkinson's disease, Any Musculoskeletal disorder 20 sample was selected using convenient sampling technique. They were explained about safety and simplicity of the procedure and informed consent was obtained. This study is conducted in Saveetha College of physiotherapy OPD Thandalam, Chennai India.

Procedure: As pre-test values was noted for all 20 hemiplegic subject using goniometer measuring passive SLR of hamstring muscle. A pair of examiners needed to measure the passive ROM of hamstring flexibility. The subjects would be in supine lying with wedge is placed under upper back for thorax and cervical flexion also landmark identified and labelled marker: ASIS, greater trochanter, lateral epicondyle of femur. One examiner has to perform passive SLR test by stabilising knee extension and ankle in neutral. Heavy dorsiflexion is avoided to prevent calf muscle stiffness. Another examiner has to place goniometer on axis of hip joint. The stable arm parallel to examine table and movable arm parallel to the measuring limb by performing the passive SLR until the patient get pain over hamstrings and note down the values. All 20 subjects received neurodynamic sliding techniqueand to produce the sliding movement of neural structures to relieve adjacent tissues. Cervical and thoracic spine should be in flexed position. Alternate hip flexion, knee flexion and dorsiflexion then hip extension, knee extension and plantar flexion was performed. NDST were performed for 15 repetitions and 3 sets5 days/week for 4 weeks. Post test measurement is done after intervention.

Result

The statistical analysis revealed significant difference ($P<0.0001$) between pretest and posttest values of hamstring ROM within the group. The pretest mean value is 56.30(SD=8.84) and posttest mean value 62.55(SD=8.87). This shows that hamstring ROM of test in posttest values were comparatively less than pretest value- $p<0.0001$ and t- value is 32.8564 (Table No. 1).

Table 1: Comparison of pre-test and post-test values of Hamstring ROM

Hamstring ROM	Mean	Standard Deviation	t-value	P- value
Pre test	56.30	8.84	32.8564	<0.0001
Post test	62.55	8.87		

Discussion

The results confirmed our initial hypothesis that an isolated neurodynamic sciatic sliding technique would provide a greater immediate improvement in hip flexion, assessed by passive SLR, than hamstring stretching or placebo. Very few studies have examined the effect of neurodynamic interventions on hamstring

flexibility[17,18]. The results of this study can be seen as adding further evidence for the potential role of neural tissue mechanosensitivity in limiting the SLR[19]. There are many approaches to treat the hamstring tightness in stroke like stretching, cryotherapy, Proprioceptive neuromuscular facilitation techniques are commonly provided treatments.

While some theories explaining the therapeutic effects of muscle stretching suggest there is alteration of the viscoelastic properties of muscles, studies have shown the importance of distinguishing between real and apparent increases in muscle flexibility[20]. The pretest measurement of hamstring ROM of stroke subjects were measured with the use of goniometer then NDST is performed to the patient and post measurement of hamstring ROM values are noted with the help of goniometer. In this study NDST shows hamstring flexibility in stroke patients. There is marked significant increase in mean value from pre test to post test mean value. When they added a neurodynamic slider technique they found greater mean increases of 62.55 in the hemiplegic SLR.

Limitations of this study only examined immediate effects of a single episode and the lack of longer term follow-up should be considered. It is not known how long the observed increase in hamstring flexibility might have lasted. Furthermore, it is not known if repetition and an appropriate dosage of the neurodynamic interventions over time might lead to longer lasting effects. Finally, we did not conduct any long-term follow-up to determine if the observed changes in flexibility might have resulted in any change in incidence of hamstring injuries in these subjects with short hamstring tightness in stroke subjects. Further recommendation of the study is long term intervention in neurodynamic sliding technique. And also relatedly with other techniques were included in future study.

Conclusion

These results show that the Neuro dynamic sliding is an acceptable and effective intervention for stroke to promote improvements in important aspects of hamstring flexibility and Range of motion in a sample of stroke subjects. NDST shows minimal observable significance in hemiplegic subjects .Since there is marked clinical outcomes with this immediate technique, Hence this NDST would be practiced for long term effect. Mean value of pre test and post test.

Ethical Consideration: The study was approved by Institutional Ethics committee (017/12/2018/IEC/SU on 27/12/2018) and was done in accordance with Ethical Guidance for the Human Participants. This study protocol was approved by institutional Ethical committee.

To Compare the Flexural Properties of Three Commercially Available Heat Cure Denture Base Resins After Water Immersion Over a Period of Three Months: An in Vitro Study

Neha Chugh[1], Pradeep Sheriger[2], Dhanasekar Balakrishnan[3], Aparna Ichalangod Narayan[4]

[1]Post Graduate Student, [2]Additional Professor, [3]Professor and Head, [4]Professor, Department of Prosthodontics and Crown and Bridge, Manipal College of Dental sciences, Manipal

Abstract

Aim: To evaluate and compare the flexural properties of three commercially available brands of PMMA heat cure denture base resins after water immersion over a period of 3 months.

Method and Material: Commercially available heat cure denture base resins (DPI, Triplex, and Trevalon) were used in the study. An aluminum die was fabricated according to ISO 1567. Each of the tested materials was manipulated according to manufacturer's instructions. Total of 60 samples were made (n=10). With 3 control (dry) groups and three experimental (water immersed) groups. The samples were subjected to INSTRON universal testing machine.

Statistical Analysis Used: Student 't' test, ANOVA and Post hoc tukey's test.

Results: Student 't' test indicated that there is significant difference in the flexural properties of the denture base resins after long term water immersion with $p<0.05$ for all the three groups. ANOVA indicated that there was no significant difference among the three groups/brands.

Conclusions: The flexural properties of heat cure denture base resins was affected by long term water immersion. The ultimate flexural strength decreased, flexural strength at proportional limit remained same and modulus of elasticity decreased. Thus after long term water immersion, the denture base material becomes weaker and stiffer.

Introduction

Acrylic resins were acquainted to dentistry in 1937[1,2] and since that time, none of the materials equaled the appearance of the oral soft tissues with such pronounced reliability as acrylic resin. The acrylic resins are now commonly used in the fabrication of complete & partial dentures, various other intraoral and extraoral prostheses and has an acceptable overall performance.

Skinner and Cooper[3] suggested that a minor lack in dimensional stability must be accepted as one of the short comings of acrylic resin dentures, with shrinkage and expansion being the two unavoidable glitches.

For acrylic prostheses to thrive effectively in a hostile oral environment, it should possess acceptable mechanical and physical properties, i.e. flexural strength, hardness, water sorption, solubility.[4,5] Physical and mechanical properties may vary among different groups of acrylic resins, which is a result of differences in their

e-mail: pradeep.s@manipal.edu

chemical structure and the cycle of polymerization process.[6-9] In addition to distortions which may occur due to thermal softening or release of internal stresses other mechanism such as water sorption may also contribute to dimensional instability as well[10].

A usual weakness of the denture base polymers with respect to fatigue is the flexural strength, which limits its use in demanding clinical situations.[11,12] Studies[13] have been conducted to evaluate the relationship between the flexural strength and the period of water immersion showing a significant decrease in the flexural strength at proportional limit for the denture reline materials when the duration of water immersion was increased from 1 to 30 days. Further studies[14] also exhibited flexural strength at proportional limit remained constant after water immersion.

Other studies also showed that the ultimate flexural strengths and flexural moduli of dry specimens of acrylic resin composites had decreased after 48 weeks of water immersion[15] and fiber reinforced composites after 10 years of water immersion[16].

Some studies have been done investigating the relationship between the mechanical properties of denture polymers and the water immersion period[13, 15-17] however, to best of our knowledge, there is insufficient information to systemically evaluate the effect on the flexural properties of denture immersed in water over a longer period.

In this context, the purpose of this study was to investigate the flexural properties of three brands of commercially available denture base resins subjected to water immersion over a period of three months.

Subjects and Method

The study was directed to evaluate and compare the flexural properties of three commercial brands of Poly methylmethacrylate (PMMA) heat cure denture base resins after water immersion over a period of three months. Efforts were made to select and utilize standard method and materials.

Preparation of the Master Die: Aluminum Master Die of dimension 65×10×3 mm^3 (figure 1) was fabricated using a Milling Machine in accordance with ISO 1567:1999, International Organization for Standardization, Geneva, Switzerland, 1999 for Denture Base Polymers.[18]

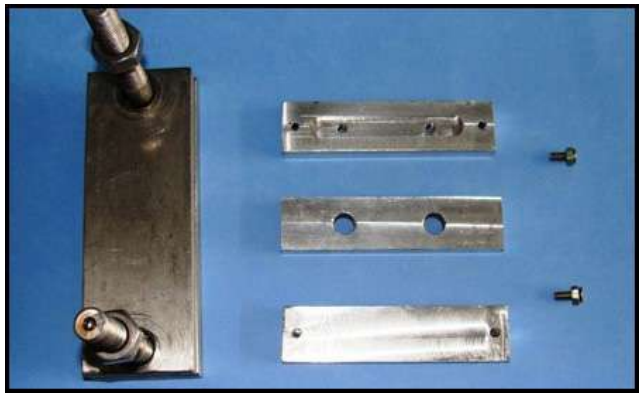

Figure 1

Aliminum die

Selection and Manipulation of denture base materials: Three commonly used Denture Base Materials were used for the study. The materials were divided into three groups of 20 samples each, with a total of 60 samples (figure 2).

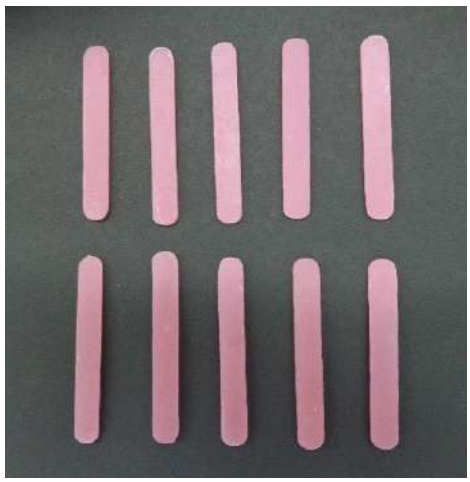

Figure 2

Acrylic Samples:

Group I: PMMA pink heat cure resin (Dental Products of India, Mumbai)

Group II: PMMA pink heat cure resin (SR Triplex Hot, IVOCLAR VIVADENT AG)

Group III: PMMA pink heat cure resin (Trevalon, Dentsply India Private Limited. Gurgaon Haryana)

Preparation of samples:-The heat cure denture base materials were dispensed and mixed following manufacturer's instructions. When the mix reached the dough stage, the die was packed and a cellophane sheet was used as separating medium between the die and the

resin mix. After packing, the die was placed in a Kavo clamp which was subsequently placed in a hydraulic press at 2000 psi for 5 mins. Overnight bench curing was allowed and then the samples were placed in an acrylizer for long curing, bench cooled overnight and samples were removed from the die and finished with 100, 200, 400 and 600grit of sandpaper, followed by polishing with pumice

Storage in water: The samples were divided into six sub groups, three sub groups Ia, IIa, IIIa were used as control. The other three sub groups Ib, IIb, IIIb were weighed and stored in distilled water at 37□C and the specimens were then subjected to flexural testing.

Test for flexural properties: The specimens were tested for ultimate flexural strength (MPa), flexural strength at the proportional limit (MPa) and the elastic modulus (MPa). Height and width of each specimen was recorded before testing. Dry specimens (control group) were tested soon after they were prepared. For water immersed specimens, each specimen was taken out one by one from water storage and placed on a 50 mm-long support for three point flexural testing. A vertical load was then applied at the mid-point of the specimen at a crosshead speed of 5 mm/min on a load testing machine. Load was applied until failure, and fracture load was recorded in Newtons (N) (figure 3).

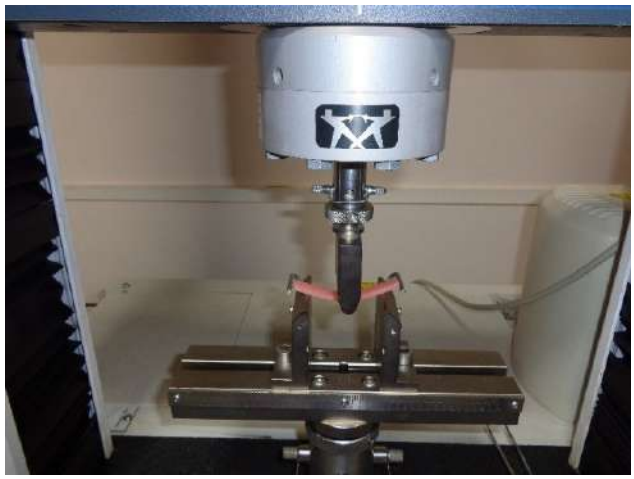

Figure 3

Testing using Instron machine: All the tests were performed under uniform atmospheric conditions of 23.0 ± 1□C and 50 ± 1% relative humidity and calculated using formulas.

Calculation of ultimate flexural strength: UFS = $3FL/2bh^2$

F: Load at fracture, L: Span length that was 50mm, b: Width of the Specimen,h: thickness of the specimen.

Calculation of Flexural Strength at Proportional Limit:-F_{PL} = 3F1L/2bh2

F1: Load at Proportional limit. The load at proportional limit was determined from each load deflection graph that was plotted for every specimen,L: Span length that was 50 mm,b: Width of the specimen, h: Thickness of the specimen.

Calculation of Elastic Modulus: MOE=F2L3/4bh3d

F2: Load at any point on the straight line of the load/ deflection graph,L: Span length 50mm,b: width of the specimen,h: Thickness of the specimen,d: Deflection corresponding to F2.

Statistical Analysis: Data was analyzed using Statistical Package for Social Sciences (SPSS), version 18.0 (SPSS Inc. Chicago IL). Mean (X) and Standard Deviation (SD) was calculated for ultimate flexural strength, flexural strength at proportional limit and modulus of elasticity.

For all the tests a p-value of <0.05 was considered statistically significant. Comparison of mean values was done using ANOVA with post-hoc Tukey's test. Comparison of mean before and after values were done using student t test.

Results

Mean ultimate flexural strength (UFS) for group Ia, Ib; IIa, IIb; IIIa, IIIb were compared using student t test. There were significant differences in the values of ultimate flexural strength among the dry and the wet samples of each group/brands. (Table 1)

Mean flexural strength at proportional limit (F_{PL}) for Ia (dry) (34.89±4.36), Ib (wet) (37.92±5.65), IIa (dry) (32.87±3.58), IIb (wet) (35.16±4.25), IIIa (dry) (37.04±5.48), IIIb (wet) (35.50±6.98) compared with student t test. There was no significant difference in the values of flexural strength at proportional limit among the dry and the wet samples of each group/brands.

Mean modulus of elasticity (MOE) for group Ia, Ib; IIa, IIb; IIIa, IIIb were compared using student t test. There was significant difference in the values of modulus of elasticity among the dry and the wet samples of each group/brands. (Table 2) MOE increased after water immersion.

When compared among the three brands the flexural properties were similar to each other and there was no significant difference.

Table 1: Comparison of ultimate flexural strength (UFS) of dry and wet samples of each group/brands.

UFS	Dry (a)		Wet (b)		p-value
	Mean	SD	Mean	SD	
Group I	93.51	6.55	79.62**	10.17	0.002; Sig
Group II	92.65	5.93	72.92**	8.03	<0.001; Sig
Group III	91.66	8.65	79.88**	8.37	0.008; Sig

* ($P < 0.05$) ** ($P < 0.001$)

Discussion

The ultimate flexural strength of a material reflects its potential to resist catastrophic failure under a flexural load. High flexural strength is crucial to denture wearing success, as alveolar resorption is a gradual, irregular process that leaves tissue-borne prostheses unevenly supported. As a foundation, the acrylic resin materials should exhibit a high proportional limit to resist plastic deformation and also exhibit fatigue resistance to endure repeated masticatory loads.[19] The prime and most frequent site of fracture in the upper denture is in the medial line. During chewing, denture base material is subjected to flexural deformation.[20] An acrylic resin capable of sustaining higher flexure in combination with high resistance to cyclic loading may be less prone to clinical failure.[19] In the present study, INSTRON three point bend test was used to calculate the flexural properties, including the measurement of ultimate flexural strength, modulus of elasticity and flexural strength at proportional limit.

The results of this study revealed that, the ultimate flexural strength of three groups/brands of heat cure denture base resins reduced significantly after long term water immersion. These results were similar to the results as shown by previous studies conducted by Vallittu et al in 1998 for 48 weeks[15] of water immersion and in 2000 for 10 years[16] of water immersion.

The second parameter evaluated in this study was the flexural strength at proportional limit (F_{PL}). Denture base plastics typically exhibit considerable plastic deformation before fracture. The plastic deformation beyond its proportional limit permanently alters the dimensions of a denture and is not clinically acceptable. Hence, in this study, the flexural strength at the proportional limit was also evaluated. The proportional limit of each sample was calculated using the load deflection graph. The values of mean flexural strength at proportional limit (F_{PL}) showed that the flexural strength at proportional limit (F_{PL}) did not show any significant difference after water immersion over a period of three months. These results were in accordance with the previous studies done by Takahashi[17, 21] et al in 1999, and in 2013, and Sasaki[14] et al in 2016.

The third parameter used in the study was modulus of elasticity (MOE). As modulus of elasticity increases, the material becomes more rigid. A denture base material with a high elastic modulus can withstand permanent mastication-induced deformation.[22] The present study showed decrease in the modulus of elasticity after long term water immersion for all the groups. These results are consistent with the previous studies conducted by Vallittu[15, 16] et al in 1998 and 2007 and Sasaki[13] et al in the 2016. The results varied from the study conducted by Takahashi et al in 2103 where the Modulus of elasticity increased after water immersion.[21] This variation in

results may be due to difference in control groups. In the present study the controls were dry samples, while in study done by Takahashi[21] et al the control samples were immersed in water.

Thus, the strength of a denture polymer at a given time after water immersion is affected by the relative number of those molecules present[17]. Similarly, in this study, the outward leakage of the soluble constituents affected the flexural properties and it appeared that the ultimate flexural strengths and the elastic modulus decreased. As a result, the denture base resins became weak and less stiff after long term water immersion. From these results, it appears that denture base resins generally trend toward decreasing the elastic modulus after water immersion over a period of three months.

To summarize, water immersion over a period of three months generally decreased the ultimate flexural strength and did not change the flexural strength at the proportional limit, it also increased the elastic modulus of the denture base resins. The decrease in the ultimate flexural strength of denture resins results in weakness, which is not acceptable in material science. However, no change in the flexural strength at the proportional limit of denture resins means keeping the resistance to plastic deformation and an increase in the elastic modulus of denture resins causes stiffness, which are both clinically acceptable.

Conclusion:

Within the limitations of the study, it was concluded that,

1. The flexural properties of all the three denture base resins were affected by water immersion over a period of three months.
2. The ultimate flexural strength decreased after l water immersion over a period of three months.
3. However the flexural strength at proportional limit remains the same after water immersion over a period of three months.
4. The modulus of elasticity decreased after water immersion over a period of three months.
5. When compared among the three brands the flexural properties were similar to each other and there was no significant difference.

Effect of Weight Bearing and Neurobic Exercises on Bone Health and Physical Function in Elderly Individuals

Neha Dighe[1], S. Anandh[2], G. Varadharajulu[3]

[1]MPTh (Community Health Sciences), [2]Professor, Unit Head (Community Health Sciences), [3]Dean, Professor, HOD, Krishna College of Physiotherapy, Krishna Institute of Medical Sciences Deemed to be University, Karad, Maharashtra, India

Abstract

Aim: To study the effect of weight-bearing and neurobic exercises on bone health and physical function in elderly individuals.

Objectives: The Objectives of the study are as follows: [1] To find out the effect of weight bearing on bone health and physical function in elderly individuals. [2] To find out the effect of weight bearing and neurobic exercises in combination on bone health and physical function in elderly individuals.

Method: Ethical clearance was obtained from Institutional Ethical Committee. 80 elderly individuals were assessed and 62 were included in the study based on inclusion criteria, the individuals were allocated into two groups: Group A (n= 31) received Weight-bearing exercises and Group B (n= 31) received Weight-bearing and Neurobic exercises in combination. Pre and post-test were done for fasting serum calcium, alkaline phosphatase and SF 36 Health related quality of life questionnaire physical function component and the outcome measures were analysed after 6 weeks.

Result: Intergroup statistical analysis for serum calcium ($p<0.0001$), Alkaline phosphatase ($p<0.0001$) and SF 36 physical function component ($p<0.0001$) revealed extremely significant difference post intervention. Analysis of serum calcium, alkaline phosphatase and SF 36 score for group A ($p<0.0001$) and for group B ($p<0.0001$) was extremely significant respectively.

Conclusion: The study results concluded that Weight bearing and Neurobic exercises was significantly effective in improved bone health and physical function both individually and in combination.

Keywords: *Weight bearing, Neurobic, Exercises, Bone health, Physical function, Elderly individuals.*

Introduction

Geriatrics is the branch of medicine dealing with the physiologic characteristics of aging and the diagnosis and treatment of diseases affecting the aged.[1] Elderly people show variations in age related physiological decline and gives rise to disorders. Age related decline in bone metabolism, reabsorption, nutrition, muscle strength, memory, mobility and locomotion. [2] Elderly individuals with nutritional deficiency of calcium, vitamin D and poor mobility experiences decline in normal functioning which gives rise to osteoporosis and imbalance in bone biomarkers such as serum calcium and alkaline phosphatase.[3] Osteoporosis is a systemic, skeletal disease characterised by low bone density and micro-architectural deterioration of tissue with consequent increase in bone fragility. It is more common in postmenopausal women due to cessation of oestrogen secretion. There may be a risk in males also due to calcium and vitamin deficiency of vitamin D, sedentary lifestyle, smoking, alcoholism and excess caffeine. [4] The prevalence of osteoporosis in India (Delhi) as 24.6% in men and 42.5% in women above 50 years of age.[5] There is a positive correlation for prevalence in low calcium levels and hampered reabsorption and bone metabolism. Assessment of specific alkaline phosphatase

has an important role in prevention and treatment bone related disorders Bone biochemical markers can provide practical detection of the exercise response on bone cells. Serum bone alkaline phosphatase (B-ALP) and serum calcium used to indicate bone synthesis. The major regulator of bone metabolism is Parathyroid hormone (PTH) to maintain the calcium-ion concentration, which is a primary determinant of intracellular calcium homeostasis. The stimulation of bone formation and reabsorption can be initiated by weight bearing exercises. The use of biomarkers to determine the mechanism of impact of exercises on bone health. [6,7] On the other hand there is a gradual decline of cognitive function with aging which causes difficulty in conducting activities of daily living and worsens the quality of life, hence SF 36 physical HRQOL questionnaire to assess the quality of life and improve it by exercises for both the domains like physical function and bone health.[8]

Weight bearing exercises are mechanical loading exercises on joints, which are essential for building and maintaining healthy bones, and they include activities recruiting muscle work and stimulate bone metabolism against gravity. During weight bearing, exercise bones adopt to the impact of weight and pull of muscles help building newer bone cells. In addition, it improves strength, joint mobility and reduces risk of fractures as well as osteopenia and osteoporosis. [9]

A unique brain exercise program known as neurobic exercises are based on the latest findings of scientific research, which include the combinations of physical senses such as hearing, vision and memory. Neurobic exercises stimulate neural activity to strengthen and grow brain cells continuously, which activates neural systems to work and increases blood supply to the brain. The cortex and hippocampus are involved during such activities, located at medial temporal lobe. In addition, Neurobic exercise stimulates pattern of neural activity, which in turn improves cognitive function and helps in better physical function. In this study the use of simultaneous performance of multiple tasks is done which will concurrently challenge the motor and cognitive function.[10] These exercises are dual task technique to explore multi-tasking and effect of this training on physical function. [11] Combination of weight-bearing and neurobic exercises may demonstrate positive effects on physical function in aging.

There are literatures which prove both physical and cognitive training have potentials to improve quality of life in elderly individuals. The exercises will amplify the efficacy of both bone health and physical function.

Method

- Study type: Experimental study
- Study design: Pre-test Post-test
- Study duration: 1 year
- Sample size: 31+31 = 62
- Place of study: Krishna Hospital, Karad

Criterion of the Study:

Inclusion Criteria:

- Elderly individuals of age group 60 to 80 years.
- Both men and women are involved.
- Elderly individuals diagnosed with low serum calcium less than 8.5 mg/dL.

Exclusion Criteria:

- Elderly individuals with significant visual or hearing impairment.
- Elderly individuals with neurological disorders.
- Elderly individuals with recent surgeries.

Procedure: An approval for the study was obtained from the Protocol committee and institutional Ethical Committee of KIMSDU. Awareness program was carried out for elderly individuals in karad and surrounding rural areas near Krishna hospital.

Geriatric subjects were screened and those fulfilling the criteria were involved. Participants were informed about the study, thorough information was given, and importance for testing serum calcium and alkaline phosphatase was explained.

Informed Consent was taken from the subjects. Pre-test assessment was taken by using blood investigations of serum calcium and alkaline phosphatase with permission and help of staff from biochemistry department and nursing staff and questionnaire SF 36 health related quality of life, physical function component was taken and data collection sheets were collected.

Subjects involved in the study were divided into two groups. The sampling method was consecutive sampling. Exercise protocol was started.

Group A: Subjects were given used weight-bearing exercises.

Group B: Subjects were given weight bearing and neurobic exercises in combination.

After completing 6 weeks with 3 sessions per week, post-test assessment was taken by using blood investigation of serum calcium, alkaline phosphatase and questionnaire SF 36 health related quality of life, physical component to assess the patient.

The interpretation of the study was done on the basis of comparing pre-test and post-test assessment using outcome measures and were statistically analysed.

Following exercises were given for Group A and B:

Sr. No.	Weight-bearing exercises (Group A)	Weight bearing and neurobic exercises (Group B)
1.	Mini squats 30 x 3 sets	Mini squat and table of 10 aloud as instructed by therapist 30x3
2.	Quadruped transition and leg raises and hand raises 30 x 3 sets	Lunge walking with half kg dumbbells and count backward from 100 30x3 sets
3.	Lunges with alternate legs 30x 3 sets	Transitions in quadruped with reach outs and read the colour of the print shown 30x 3 sets
4.	Standing leg curls with support 30 x 3 sets	Squats and pick up the colour of ball from the basket as instructed by therapist 30x 3 sets
5.	Wide leg squats with sit to stand 30 x 3 sets	Wide leg squats with Swiss ball in the hand 30x3 sets
6.	Seated rowing with half kg dumbbells 30x 3 sets	Standing leg curls with chart on the wall and point out the instructed numbers 30 x 3 sets
7.	Step ups 30 x 3 sets	Alternate step up with random number generation 30x 3 sets

Results

Discussion

In Geriatric age, the ability to carry out multiple tasks or common activities of daily living is diminished and they remain physically inactive, as many activities requires simultaneous performance of dual tasks. There are literatures frequently adopting the dual task techniques and find the effect on ability to perform physical function, but there is limited pool of knowledge in neurobic exercises involving cognitive function that is expected in concomitant performance of different tasks, stability and balance deteriorates with lack of attention and cognitive deficit. The second most important part of the study is prevention of fall. As physical activity is reduced gradual deconditioning occurs which increases the risk of fall. Around 28-35% above age of 65 years fall at least once a year. The present study "effect of weight-bearing and neurobic exercises on bone health and physical function in elderly individuals" was conducted to improve health related quality of life and prevention of declining bone health among elderly.

The objectives of the study were 1. To find the effect of weight-bearing exercises on bone health and physical function in elderly. 2. To find out the effect of weight-bearing exercises in combination with neurobic exercises on bone health and physical function. The study was conducted with 62 subjects. Subjects were divided into two groups. Group A (Weight-bearing exercises) group B (weight-bearing and neurobic exercises). Prior consent was taken. The treatment protocol was carried out for 3 days per week for 6 weeks. The outcome measures for this study were serum calcium levels, alkaline phosphatase and SF 36 health related quality of life questionnaire physical function component. The results of the study showed that there was significant difference in improving physical function component, serum calcium levels and alkaline phosphatase after 6 weeks of intervention in both the groups. Group A (weight-bearing exercises) group B (weight-bearing and neurobic exercises) which was statistically analysed. Paired 't' test was used to analyse the results within the groups (group A pre and post-test and group B pre and post-test) and showed that there was extremely significant improvement in serum calcium (*$p<0.0001$) alkaline phosphatase ($p<0.0001$) SF 36 health related quality of life questionnaire (*$p<0.0001$).

A study done by Cavanagh et. al. in 2005 showed that lack of load-bearing and physical inactivity leads to destructive blood loss, while bone formation increase when immobilised subjects start physical activity. This concludes that physical activity enhances bone formation and stimulates PTH which increases bone metabolism which in turn increases bone biomarkers such as alkaline

phosphatase and serum calcium, thus improves quality of life.[12] A study done by Nirupama Singh et, al. shows that neurobic exercises aim to maintain mental fitness and intact cognitive functions which is responsible for planning initiating and monitoring complex activities, there indispensable for independent ADL and better QoL.[13]

Comparison of serum calcium, alkaline phosphatase and SF 36 health related quality of life physical component score between two groups was done by using unpaired t test to find out the effects in two groups. The statistical analysis revealed that there was extremely significant difference found in serum calcium level in both the groups post-test (*p<0.0001). The statistical analysis revealed that there was extremely significant difference found in alkaline phosphatase (*p<0.0001) in both the groups post-test. The statistical analysis revealed that there was extremely significant difference found in SF 36 health related quality of life questionnaire score in both the groups post-test. Thus this showed that there was improvement in bone health and SF 36 HRQoL questionnaire physical function component in elderly individuals. Primary focus of the study was to improve physical component of health related quality of life and to see the effect of intervention on bone biochemical markers in elderly individuals while performing dual task neurobic exercises improves cognitive function and executes marked improvement in physical function component.

For independent ADLs or better physical functions like vigorous activity. moderate activity, lifting groceries, climbing several flights, climbing one flight of stair, bathing and dressing etc it is necessary to have better bone health. As for example, a person with osteoporosis may not be able to do his physical activities due to lack of bone health causing pain or frequent fractures. Moreover, elderly population have mild cognitive impairment due to aging.

Thus, this study is designed to provide a recreational treatment were involving subjects in interesting neurobic activities to keep the subject's compliance and treating them with weight bearing exercises.

Therefore, the result of the present study showed that intervention was effective in both groups. Group B which consisted weight-bearing and neurobic exercises which showed marked effective results and were helpful in improving bone health and physical component of HRQoL while Group A consisted weight-bearing exercises.

Conclusion

Based on the statistical presentation, analysis and interpretation it can be concluded that the weight-bearing and neurobic exercises has shown significant improvement in serum calcium, alkaline phosphatase and Sf 36 score.

Thus, the present study provided the evidence to support that weight bearing and neurobic exercises has shown improvement in the blood biochemical markers and physical function in elderly individuals.

However, the subjects treated with weight bearing and neurobic exercises in combination showed significant improvement rather than only weight-bearing exercises alone.

Conflict of Interest: The author declares that there are no conflicts of interest concerning the content of the present study.

Funding: The study was funded by Krishna Institute of Medical Sciences Deemed to be University, karad.

Ethical Clearance: The study was approved by Institutional Ethics Committee, KIMSDU.

Knowledge, Attitude and Practice of Biomedical Waste Management in Nursing Staff of a Private and a Government Tertiary Care Teaching Hospital: A Comparative Study

Nishitha K.[1], Alice Matilda Mendez[2], Nisha B.[2], Timsi Jain[3]

[1]3rd Year MBBS, [2]Assistant Professor, [3]Professor and Head, Department of Community Medicine, Saveetha Medical College and Hospital, Thandalam, Tamil Nadu.

Abstract

Introduction: Biomedical waste is "Any waste which is generated in the diagnosis, treatment or immunization of human beings or animals or during research" in a hospital. Improper disposal of hospital waste poses a major threat to the environment. Lack of proper management, awareness, insufficient resources and poor control of disposal of waste are the most pressing problems faced .

Objective: To compare the knowledge, attitude and practice of hospital waste management in nursing staffs and nursing assistants of a private and government tertiary care hospital in Chennai, Tamil Nadu.

Methodology: This is a cross sectional study done in a private and a government tertiary care teaching institute on 300 nursing staff (150 from each) using an orally administered structured questionnaire. The data were entered into excel and analysis was done.

Result: Of the 150 participants from government hospital 71% had training in BMW management, 82% knew where to report in case of a needle stick injury, 61% perceived that they have adequate knowledge regarding BMW management, 98% were willing to attend programmes regarding BMW. 73% had good knowledge regarding BMW management. 90% practice good management of BMW.

Of the 150 participants from private hospital 81%had training in BMW management, 79% knew where to report in case of needle stick injury, 67% perceived that they have adequate knowledge regarding BMW management, 95% were willing to attend programs regarding BMW management. 74% had good knowledge. 85% practice good management of BMW.

Conclusion: The knowledge, attitude and practice of BMW management among nurses and nursing assistants of the private and the government hospital are found to be satisfactory. There is no significant difference (at $p<0.05$) in the knowledge, attitude and practice of BMW management among the nurses and nursing assistants of both the hospitals.

Keywords: *Biomedical waste management, knowledge, attitude, practice, nursing staff.*

Introduction

Biomedical waste(BMW) is the waste that is generated in hospitals and health care centres during diagnosis, treatment or immunisation of human beings, mainly consists of needles, syringes, ampoules, dressing materials, disposable plastics and microbiological wastes[(1)]. With the aim of reducing health problems and treating the sick, health care services inevitably produce wastes that may be hazardous to health. According to the World Health Organisation (WHO), 10-25% of the biomedical waste are estimated to be hazardous[(2)]. Improper handling of biomedical waste increases the airborne pathogenic microbes, adversely affecting the

Dr. Alice Matilda Mendez
Assistant Professor, Department of Community Medicine, Saveetha Medical College and Hospital, Thandalam, Tamil Nadu

hospital environment and community at large. Apart from polluting water, air & soil, it also has considerable impact on human health due to aesthetic effects.

BMW management (BMWM) means the management of waste produced by hospitals using techniques that will check the spread of diseases. The objectives of biomedical waste management are toreduce waste generation, to ensure its efficient collection, handling, as well as safe disposal in such a way that it controls infection as these wastes need a special attention for their proper disposal. Adequate knowledge, attitude and practices regarding biomedical waste management is lacking in developing countries[3]. The volume of the health care wastes have also increased over the last 30 years. The World Health Organisation has hence prepared biomedical waste management guidelines to ensure proper handling of these wastes.

This study was done to assess and compare the knowledge, attitude and practice of biomedical waste management among the nursing staff working in a private tertiary care hospital and a government tertiary care hospital in Chennai.

Materials and Method

This was an observational cross-sectional study done from January 2019 to May 2019. This study was conducted in a private tertiary care hospital and in a government tertiary care hospital situated in Chennai, capital city of Tamil Nadu in South India. The study included the nurses and nursing assistants working in the above mentioned institutions.

The sample size of the study is n=300, 150 from each of the above mentioned institutions. The sample size was measured using the formula {(Za-Z1-b)^2*[P1(100-P1)+P2(100-P2)]}/(P1-P2)^2, where P1 = 35%, P2=20%[4], expected difference of 15%, alpha error of 5% at 95% confidence interval.

After obtaining permission from the human resource department, a list of all the nurses and nursing assistants working in the above mentioned institutions was obtained and the participants were selected randomly using random numbers table. Nurses and nursing assistants not willing to participate in the study were excluded.

The study tool used was an orally administered structured questionnaire containing questions regarding the knowledge, attitude and practice of Biomedical waste management (BMWM) respectively. Questions related to demographic details like the participants name, age, sex,department they are currently working in, total years of experience, years worked in the current hospital,their training in biomedical waste management, years of experience, vaccination against Hepatitis, needle stick injury were also included. It included eleven questions to assess their knowledge, which included questions regarding where they would dispose certain wastes like anatomical wastes, contaminated gauze, disposable intravenous tubes and catheters, broken glass vials, discarded disinfectants, contaminated mattresses and linens . The six attitude questions were regarding whether they thought biomedical waste management as a financial burden on the setup, do they find it as a burden to report a needle stick injury, whether they are interested in attending programs to enhance and upgrade their knowledge on biomedical waste management and if they think it is important to dispose health care wastes in a proper manner. Six questions regarding their practice of biomedical waste management was also included (Table 2). One point was awarded to each correct answer and the wrong answers weren't given any point. Each of the three aspects were assessed separately and a score of more than 60% was considered that the participant had good knowledge, attitude and practice of biomedical waste management. The data was entered in MS- Excel spreadsheet and analysis was done using SPSS software. Qualitative data was expressed as frequencies and proportions, quantitative data were summarised as mean (standard deviation). Bivariate analysis was done using chi square.

Results

A total of 300 nurses and nursing assistants took part in this study, of which 150 were from the private institute and 150 were from the government institute.

The mean age of the participants from the government institute was 32.9 years whereas the that of participants from the private institute was 25.17 years. Of the participants,81% from the government institute and 75% from the private institute were nurses. The mean years of experience was higher in the government, which is 8.29 years compared to 3.06 mean years in the private institute (Table 1).

Significantly more percent of the participants (90%) from the government institute separate biomedical waste during collection and they also collect liquid

waste in leakage proof bags (77%) when compared to the participants from the private institute. Significantly more participants from the private institute collect liquid and other wastes together (43%) whereas more percent (23%) of participants from the government institute store infectious waste together with the other wastes. 83% of the participants from the government institute use personal protection while handling biomedical waste whereas only 77% of the participants from the private institute do so which is significantly less when compared.(Table 2)

Only 71% of the participants from the government institute and 81% of the participants from the private institute have had training in biomedical waste management.(figure 1).

Although the difference is not statistically significant, it was found out that increased percentage of the participants from the government institute had a good knowledge, attitude regarding biomedical waste management and a good practice of biomedical waste management when compared with the participants from the private institute (Table 3).

All the participants from the private institute had been vaccinated against Hepatitis B compared to the 73% from the government institute and 82% of the government institute participants knew to whom they were supposed to report an incident of needle stick injury compared to the 79% from the private institute. 25% of the participants from the private institute have had a needle stick injury in the past and 90% of them had reported the incident to appropriate authority, whereas 33% of the participants from the government institute have had a needle stick injury and all of them had reported the incident to the authority.

61% of the participants from the government institute showed a positive attitude towards biomedical waste management but only 48% of the private institute participants showed positive attitude. 98% of the participants from the government institute and 95% of the participants from the private institute were willing to attend programs regarding biomedical waste management.

70% of the participants from the private institute and 62% of the participants from the government institute think that there is an increased risk of injury if the health care waste is segregated at the source. 45% of the participants from the private institute and 33% of the participants from the government institute think BMWM setup as a financial burden on the institute. 31% of the total study population consider it as a burden to report needle stick injury .

Table 1: General profile of the participants

General Profile	Government	Private
Mean age	32.89 years	25.17 years
Mean years of experience	8.29 years	3.06 years
Nurses	122 (81%)	112(75%)
Nursing assistants	28 (19%)	38 (25%)

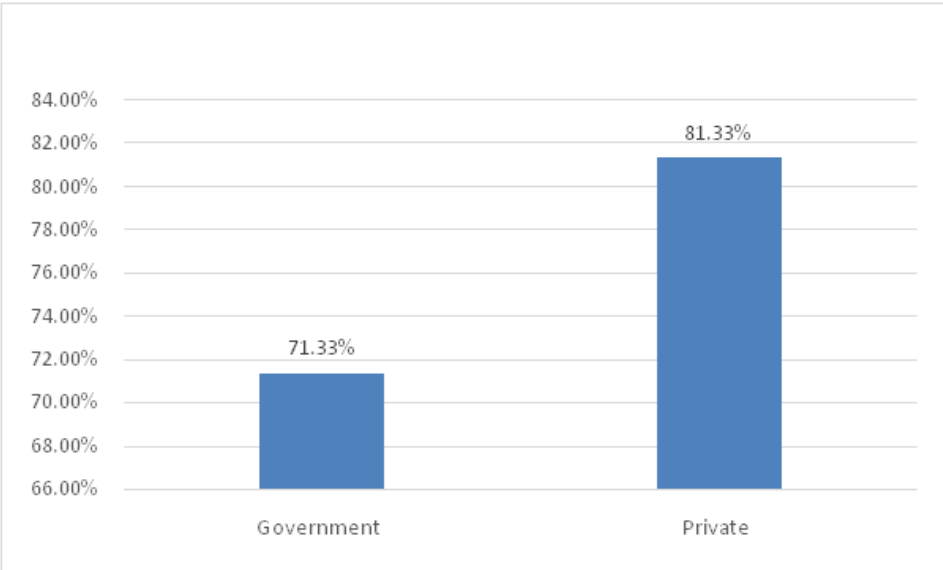

Figure 1: Participants with training in BMWM.

Table 2: Comparison between the various practice habits of the participants from the two institutes

Practice Habits	Government	Private	P- Value
Sort BMW during collection	135 (90%)	120 (80%)	0.015293 *
Separate sharps from blunt waste	140 (93%)	137 (91%)	0.515049
Use personal protection tools while handling BMW	125(83%)	116 (77%)	0.191118
Collect liquid waste in leakage proof bags	115 (77%)	91(61%)	0.002815*
Collect liquid and other wastes together	44 (29%)	64 (43%)	0.016145*
Store infectious wastes together with other wastes	35 (23%)	14 (9%)	0.001039*

* Significant at $P < 0.05$

Table 3 Comparison between the percentage of participants having good knowledge, practicing good management of BMW and having a good attitude regarding the same

	Government	Private	P- Value
Good knowledge	73.33%	74%	0.872707
Good attitude	61.33%	48.33%	0.076136
Good practice	90%	85.33%	0.285049

Discussion

This is a cross sectional study conducted in a private and a government tertiary care hospitals regarding the knowledge, attitude and practice of BMW among their nurses and nursing assistants.

In this study it was found that 71% of the participants from the government institute and 81% of the participants from the private institute had training in biomedical waste management, compared to 68% of the nurses who participated in a study done by Lohani N et al[5].

All the participants from the private institute had been vaccinated against Hepatitis B compared to the seventy three percent (73%) from the government institute. Only 20% of the nurses who participated in the study done by Soyam GC et al[6] had been vaccinated against Hepatitis. Reporting of an incident of needle stick injury was high in both the study groups (100% in the government and 90% in the private institutions) when compared to a study done by Stein et al[7] which showed only 37% reporting .

83% of the participants from the government institute use personal protection while handling biomedical waste whereas only 77% of the participants from the private institute do so. In a study by Madhu Kumar et al[8] all the participants wore personal protective equipments while handling biomedical waste.

98% of the study population knew about the different biomedical waste categories compared to 56% of the participants in a study done by Basu et al[9], 45% of nurses of a study by Anand P et al[10]and 90% of the study population consisting of doctors and nursesin a study conducted by Mathur et al[11].

Sixty one percent (61%) of the participants from the government institute and only forty eight percent (48%) of the private institute participants showed a positive attitude towards biomedical waste management. In a study done by Adekunle Olalfa et al[12], 54% of the staff who participated showed a positive attitude towards biomedical waste management.

70% of the participants from the private institute and 62% of the participants from the government institute think that there is an increased risk of injury if the health care waste is segregated at the source, whereas in a study by Adekunle Olalfa[12]et al 24% of the participants had the same idea. 31% of the participants consider it as a burden to report needle stick injury, while 44% of the nurses who participated in a study by Anand P et al[10] thought the same. But in a study by Malini et al[13], the participants did not consider it as a burden to report an incident of needle stick injury. 45% of the participants from the private institute and 33% of the participants from the government institute think biomedical waste management setup as a financial burden on the institute. In a study done by Khan MJ et al[14],53% of the physicians who took part thought BMWM setup as a financial burden on the institute.

Conclusion

In this study it has been found that the difference in the knowledge, attitude and practice of biomedical waste management was not significant. But certain aspects in the practice of biomedical waste management like segregation of waste during collection and collection

of liquid and other wastes separately were better among the participants from the government institute, whereas more percent of participants from the private institute stored infective and other wastes separately. The attitude regarding biomedical waste management was better in the participants from the government institute than that of the participants from the private institute and more participants from the government institute were willing to attend programs to improve their knowledge and practice of biomedical waste management .

Even though the knowledge, attitude and practice of biomedical waste management are not poor among the participants of this study, it can be further improved by conducting programs stressing not only on the knowledge and practice but also should stress about the attitude of the workers towards biomedical waste management by educating them about the importance of it and by enlightening them about the hazardous effects of improper management of biomedical waste management on the environment, public health and also on health of the health care workers themselves.

WTO and its Impact on Indian Pharmaceutical Production: A Legal Perspective

Nitesh Kumar Srivastava[1], R.L. Koul[2]

[1]Ph.D. Research Scholar, [2]Professor at Amity Law School, Amity University Noida

Abstract

Pharmaceutical Company and Pharmaceutical production plays a significant role in the economic development of a country. It is even more important for developing country like India which needs to generate employment, achieve higher rate of growth, poverty elevation programs, improve the standard of living of its people and stabilize the price level of healthcare. Role of World Trade Organisation (WTO) is very important for regulation. The WTO was established in 1995 and when compared with the GATT is much wider in scope, with a stronger institutional basis and with treaty status. The main aim of this paper is to analyze the Indian pharmaceutical production performance, pre and post implementation of WTO policies. It is clear that the implementation of WTO policies, Compound Annual Growth Rate (CAGR) of India's pharmaceutical production has minute effect on it. The topic is of essence as in based on doctrinal study where by different set of data has been gathered from the primary and secondary sources. The research Article is an outcome of research which the research scholar is under taking in pursuance and for conferment of Ph.d Degree.

Keywords: *GATT, WTO, Pharmaceutical production, Compound Annual Growth Rate, Economic Development.*

Introduction

Pharmaceutical industry has long being regarded as one of the most important areas blocking the way to the strengthening of a liberal trade system. The Indian pharmaceutical industry, now a USD 20 billion (over Rs 90,000 crore) Industry, has shown tremendous progress in terms of infrastructure development, technology base creation and a wide range of products. It has established its presence and determination to flourish in the changing environment. The industry now produces bulk drugs belonging to all major therapeutic groups requiring complicated manufacturing technologies. Formulations in various dosage forms are being produced in Good Manufacturing Practice (GMP) compliant facilities. Strong scientific and technical manpower and pioneering work done in process development have made these possible.[8] The country now ranks 4th worldwide accounting for 8% of world's production by volume and 1.5% by value. It ranks 17th in terms of export value of bulk actives and dosage forms. Indian exports are destined to more than 200 countries around the globe including highly regulated markets of US, Europe, Japan and Australia. Indian Pharmaceutical Industry has made phenomenal progress over the years and made its impact in the global market. Indian Pharmaceutical industry has been recognized as reliable source for drugs and drug intermediates, pharmaceutical formulations. Tremendous opportunities are available for Indian Pharma industry in post 2005 era to manufacture and export many products getting off-patented. Its immense strength in manufacturing quality medicines at affordable prices made the Indian Pharma industry to compete both in regulated and non-regulated markets. Apart from its strengths in manufacturing and exporting allopathic medicines, India is known for its own systems of medicines with about 7000 units manufacturing various Indian system of medicines viz., Ayurveda, Unani, Siddha, Homeopathy etc. Though strong in cultivation/manufacture of Indian system of medicines, India's share in the global herbal market, estimated at US$ 63 billion, is less than 0.2%, which shows that there

is a tremendous scope for export market. Fast growing Biotech industry estimated at about US$ 2 billion market, is a another part of Indian Pharma industry in India, which has great potential in the international market and which needs focused attention to improve its performance in the international market. While its generics market is growing strong, it is also evolving into a cradle for new drug. As one of the strongest emerging market in the global pharma industry, India presents great opportunities for all international pharmaceuticals companies to explore and benefit from.

WTO and TRIPS Agreement: The World Trade Organization's Agreement on Trade-Related Aspects of Intellectual Property Rights (TRIPS) set global minimum standards for the protection of intellectual property. The TRIPs Agreement deals not only with patents but also with other forms of intellectual property rights such as copyright, trademark, industrial designs, geographical indications, and confidential information.[9] The TRIPS Agreement forced not only product patents for pharmaceuticals to be introduced but also twenty-year periods of patent protection at the leastto be ensured. WTO members must comply with the obligations of the TRIPS Agreement. TRIPS compliance was postponed until 2005 for developing countries. Until the deadline for TRIPS compliance, India undertook three amendments in March 1999, June 2002, and March 2005. InMarch 2005, India completed the amendment of the Patent Act of 1970 to comply with the TRIPS Agreement.

The new patent act came into force on 4 April, 2005. It introduced product patents for drugs,foods, and chemical products and the patent term was increased to twenty years. The Indian patent regime has become fully TRIPS compliant. The amendment of the Act changed the institutional factors that had supported the growth of the Indian pharmaceutical industry.

Under the TRIPS agreement, all WTO members have to make patents available for pharmaceutical inventions in their countries. A company that has invented a new pharmaceutical product or process is able to apply for a 20 year patent protection in any WTO member country.

Agreement on Trade Related Investment Measures (TRIMs): The Indian Industry can become more competitive due to inflow of Foreign Direct Investment(FDI) in the fields of Research & Development (R & D) and technology. Governments often impose conditions on foreign investment in order to direct flow of investment in accordance with certain national priorities. Conditions that can affect investment flows are known as Trade Related Investment Measures[10]. There are 24 such TRIMs those countries all over the world use. WTO prohibits use of the following five measures under TRIMS:

- Local Content Requirements (ICRs) imposing use of certain amount of local inputs in production.
- Trade Balancing Requirements: Limiting use of import content in proportion to the export of investing company.
- Trade Balancing Requirements: restricting imports to an amount or value of the producer exported.
- Exchange Restrictions: restrictions on access to foreign exchange to an amount of foreign exchange earnings attributable to the enterprise.
- Domestic sales requirements: requiring a company to sell certain proportion of its production locality.

Once restrictions are removed, MNCs whichare permitted to set up wholly owned subsidiaries as 100% export oriented units, could also start catering to the domestic market and this seriously affect the share of indigenous units.[11]

Indian Position:

The Pharma Industry Prior to Patents Regime: At the time of independence in year 1947 the total drug production in the country was around Rs. 10 crores. At that time the MNCs taking the help of the colonial Patent and Designs Act, 1911 exploited the drug market of our country. They were engaged mainly in the import of drugs from their country of origin. Between 1947-57 99% of the 1704 drugs and pharmaceutical patents in India were held by foreign MNCs. During that time the MNCs who were controlling 80% of the market did not come forward with financial investment and technological help to establish drug production centers in India. Drug prices in India were amongst the highest in the world in 1954[12]. The first public sector drug company Hindustan Antibiotic Ltd.(HAL) was established with the help of WHO and UNICEF. The Indian Drugs and Pharmaceutical Limited (IDPL) were established in 1961 with the help from the Soviet Union. The establishment of these two public sector units and the coming into force of the Drug Policy of 1978 had been mainly responsible for the availability of drugs and medicines at relatively lower prices in India. The

country became almost self-sufficient in the production of drugs.

It is also a fact that after Independence, the Indian government appointed two committees namely Tek Chand Patents Enquiry Committee (1948-50) and Ayyangar Committee (1959) in order to improve accessibility and afford ability of essential drugs in India. These committees recommended amending the Designs and Patents Act of 1911, which recognised product patents for pharmaceuticals. The Designs and Patents Act of 1911 was replaced by the Patent Act of 1970. The Patent Act of 1970 recognised only process patents, and reduced the patent period from sixteen years to seven years. Automatic licenses of right could be issued three years after granting of the patent. The Act allowed Indian pharmaceutical companies to produce alternative processes for drugs that were not patented in India. During the period from the 1970s to the 1980s, Indian companies began to take up R & D work on their own. The weak intellectual property protection regime as envisaged in the Patent Act of 1970 was a turning point in the development of indigenous pharmaceutical R & D. The Act encouraged reverse engineering and the development of alternative processes for products patented in other countries.[13]

The Drug Policy of 1978 was the first comprehensive drug policy enacted in India. The basic framework of the Policy remained largely valid even up until the 1990s. The basic objective of thePolicy was to achieve self-sufficiency in the production of drugs. The Policy emphasised the role of R & D and technology, and enhanced the technological capabilities of the Indian pharmaceutical industry by providing R & D promotion measures. Several measures to guide and control foreign companies with a 75 percent share of the domestic market were implemented so as to be consistent with the basic objective of the Drug Policy of 1978 and promote the production of bulk drugs and intermediates.[14]

The Patent Act of 1970 and the Drug Policy of 1978 paved the way for the progress of indigenous R & D. The ability to develop generic drugs was acquired and improved during the mid-1970s to 1990s. Besides, other industrial policy measures such as the Foreign Exchange Regulation Act of 1974 (FERA) and the Drug Price Control Order of 1970 (DPCO 1970), which were disincentives to foreign companies, also played important roles in the development of the industry.

Case Analysis: Towards the aforesaid deliberation, it is imperative to study some few selected cases concerning pharmaceutical sector involving India as complainant and also as respondent in others before WTO Dispute settlement board. For this purpose, five cases have been indentified where it is found that in three cases India has been the complainant while in two others as respondent. Accordingly the analysis dealt on sere tom basis year wise in manner as under.[15]

(a) Certain Pharmaceutical Products[16] Dispute Settlement (D.S No. 168): In this case India against South Africa. Subject matter of the case is "Anti-Dumping Duties on certain Pharmaceutical Products from India." And the measures at issue include the initiation of the investigation, the conduct of the investigation, and the final determination.

On 1 April 1999, India requested consultations with South Africa in respect of a recommendation for the imposition of definitive anti-dumping duties by the South African Board on Tariffs and Trade (BTT), The BTT allegedly made a preliminary determination on 26 March 1997 that ampicillin and amoxycillin of 250mg and 500mg capsules, exported by M/S Ranbaxy Laboratories Ltd of India, were being dumped into the South African Customs Union (SACU). This was allegedly followed by a recommendation to impose final duties on these products by the BTT, which was reported on 10 September 1997. India contended that:

- the definition and calculation by the BTT of normal value is inconsistent with South Africa's WTO obligations, because erroneous methodology was used for determining the normal value and the resulting margin of dumping;
- the determination of injury was not based on positive evidence and did not include an evaluation of all relevant economic factors and indices having a bearing on the state of the industry, which led to an erroneous determination of material injury suffered by the petitioner.
- the South African authorities' establishment of the facts was not proper and that their evaluation was not unbiased or objectives; and
- the South African authorities have not taken into account India's special situation as a developing country.

India alleged violations of Articles 2, 3, 6(a) to (c)

individually and in conjunction with 12, 12 and 15 of the Anti-Dumping Agreement; and Articles I and VI of GATT 1994.

(b) Import of Pharmaceutical Products: (D.S No.233): In this case India against Argentina. The Subject matter of the case is "Measures affecting the importation of Pharmaceutical products." And the measures at issue include the initiation of the investigation, the conduct of the investigation, and the final determination.

According to India, the above measures require that before entering the Argentinean market, all drugs and other pharmaceuticals must be registered with the National Administration of Drugs, Foodstuffs and Medical Technology, Ministry of Health of Argentina. The above Decree contains two annexes listing countries.

- In respect of Annex I countries, pharmaceutical products are required to be manufactured in facilities approved by the relevant governmental bodies of these countries or by the Argentinean Ministry of Health and meet the National Health Authority's manufacturing and quality control requirements.
- In respect of Annex II countries, manufacturing facilities are required to be inspected and approved by the Ministry of Health of Argentina before export of these pharmaceutical products into Argentina.

India says, it does not figure in either of those two annexes. This alleged discrimination would have led to total lack of market access for Indian drugs and pharmaceutical products in Argentina. India considered that infringement of the following provisions have taken place: Articles 2 (especially 2.2), 5 (especially 5.1 and 5.2) and 12 of the TBT Agreement; Articles I and III of the GATT 1994; and Article XVI: 4 of the Agreement establishing the WTO.

(c) Seizure of Generic Drugs: (D.S No.408): In this case India against European Union and Netherland. The Subject matter of the case is "Seizure of Generic Drugs in Transit." And the measures at issue include the initiation of the investigation, the conduct of the investigation, and the final determination.

On 11 May 2010, India requested consultations with the European Union and the Netherlands regarding the repeated seizures on patent infringement grounds of generic drugs originating in India but transiting through ports and airports in the Netherlands to third country destinations. India alleges that the measures at issue are, in several respects, inconsistent as such and as applied, with the obligations of the European Union and the Netherlands under Articles V and X of GATT 1994 and under various provisions of the TRIPs Agreement, namely, Article 28 read together with Article 2, Articles 41 and 42, and Article 31 read together with the provisions of the August 2003 Decision on TRIPs and Public Health.

India as a Respondent: Dispute Settlement (DS) 50was filed by the US on 9th July 1996, whereas, Dispute DS 79was filed by theEC on 6th May 1997. Both of these disputes pertained to absence of 'either patent protection orformal systems that permit the filing of patent applications for pharmaceutical and agricultural chemical products and that provide exclusive marketing rights in for pharmaceutical and agricultural chemical products'. On the 5th Sept. 1997 the panel submitted its report and on 19thDec. 1997 the Appellate Body report directed India to comply with the TRIPS provisions of the WTO agreement. In response to this Government of India had introduced a Bill in the Indian Parliament to effect certain Amendments to the Patents Act, 1970. These Amendments to the Patents Act, 1970, as passed by both Houses of Parliament, have been approved by the President of India and notified in the Gazette of India on 26th March 1999 as the Patents (Amendment)Act, 1999.

Conclusion & Suggestions

From the aforesaid deliberation this gathered. The Patent Act of 1970 and the DPCO have not only boosted the development of the Indian pharmaceutical industry but have also contributed to improving health and welfare in India. However, since the mid-1990s, the Indian pharmaceutical industry has faced new challenges onaccount of the WTO-TRIPS Agreement. It was considered that introducing pharmaceutical product patents would have a negative influence on the Indian pharmaceutical industry because it would hamper its growth. The industry can no longer manufacture by reverse engineering or export drugs whose product patents are in effect. However, against expectations, the Indian pharmaceutical industry has been growing the post-TRIPS period and its productivity is improving even in post-TRIPS period. It can be said that the introduction of pharmaceutical product patents has given rise to business opportunities for the Indian pharmaceutical industry and is promoting the growth of the industry.

Indian Pharmaceuticals faces both opportunities and challenges with liberalization of domestic and global market. There is need to develop strategy for an Indian pharmaceutical sector. Appropriate measures are require to move away from the traditionally approach and build a productive and internationally competitive products. Rapid pharma growth is important not only to achieve higher economic growth but also to lift healthcare system in India. The most important suggestion is to increase public investment in a pharmaceutical with a view to robust growth of pharmaceutical sector. Public Pvt. Partnership is a key of development in this sector.

Prevalence and Molecular Characterization of Glucose-6-Phosphate Dehydrogenase Deficiency among Brahmins and Muslims of Manipur, India

Nongthombam Achoubi[1], Mohammad Asghar[2], Anand Kumar Gyanendra Singh Wahengbam[3], Soibam Jibonkumar Singh[4], Kallur Nava Saraswathy[5], Benrithung Murry[5]

[1]Research Associate, Department of Anthropology, Manipur University, Manipur, [2]Assistant Professor, Department of Anthropology, Rajiv Gandhi University, Arunachal Pradesh, [3]Research Scholar, Department of Anthropology, University of Delhi, Delhi, [4]Professor, Department of Anthropology, Manipur University, Manipur, [5]Assistant Professor, Department of Anthropology, University of Delhi, Delhi, India

Abstract

G6PD deficiency offers protection against malaria infection and is strongly associated with the distribution of malaria endemicity. Genetic studies, including those of inherited blood disorders at the molecular levels, are very limited in northeastern India including Manipur. The present study aims to determine the prevalence and its molecular characterization of G6PD deficiency among the Brahmins and the Muslims of Manipur. A total of 263 unrelated blood samples (127 Brahmins and 136 Muslims) was screened for G6PD deficiency using Fluorescent Spot Test. DNA was extracted using salting out method and for molecular analysis, PCR was done using 3 most common Indian mutations (G6PD Mediterranean, G6PD Odisha, and G6PD Kerala & Kalyan) and 4 most common Southeast Asian mutations (G6PD Canton, G6PD Kaiping, G6PD Mahidol and G6PD Union). A higher prevalence frequency of 21.32% of G6PD deficient individuals was found among the Muslims as against the Brahmins with 9.45%. Out of the 7 mutations screened for G6PD that are common to Indian populations, only 4 Brahmins are found to have one each of these mutations. The 4 mutations found among the Brahmins were one G6PD Mediterranean, one G6PD Kerala & Kalyan, and two G6PD Mahidol. The Muslim population with a relatively higher frequency of G6PD deficiency as compared to Brahmin population needs special attention by health planners specifically while administering anti-malarial drugs.

Keywords: *G6PD, Meitei Brahmin, Meitei Muslim, Manipur.*

Introduction

Glucose-6-phosphate dehydrogenase (G6PD) deficiency is a common hereditary enzymatic defect worldwide. It is an X-linked inherited disorder most commonly affecting people of Africa, Asia, Mediterranean or Middle-Eastern descent[1]. It is mainly found in Africa, Asia, and Mediterranean Europe, areas where malaria is endemic, or has been endemic[2]. Other evidence supports the idea of a selective advantage of enzyme-deficient cells with regard to *Plasmodium falciparum*. Almost all cases of G6PD deficiency are caused by one amino-acid change due to a point mutation of the genomic DNA, and about 140 molecular abnormalities of the G6PD genotype have been identified[3]. The worldwide prevalence of G6PD deficiency has been estimated to be around 5%[4] but frequency as high as 70% has been reported among the Kurdish Jews[5]. In India, the

e-mail: benrithungmurry@yahoo.co.in
Mobile: +91 9868616678

prevalence varies from 0 to 27.9% across ethnic groups[6]. The average prevalence of Malaria in Manipur is 1,995 per 1,00,000 populations. Rural inhabitants are almost twice as likely to suffer from malaria and the state has seen a substantial increase in malarial cases from 708 to 1,069 (51%) in the year 2009 and an increase in *Plasmodium falciparum* cases has been documented from 356 to 620 during the same period[7]. Only few studies report the prevalence of specific variants and fewer still have reported the prevalence of different G6PD variants at the DNA level in the north-eastern India. Genetic studies, including those of inherited blood disorders at the molecular levels are very limited in this region, including Manipur and such studies may help explain the origin and spread of these disorders and may also shed some light on the history of these ethnic groups. The present study aims to determine the prevalence and its molecular characterization of G6PD deficiency among the Brahmins and the Muslims of Manipur.

Material and Method

Brahmins belong to the larger Manipuri Meitei community of Manipur. Ethno-historically, the Brahmin settlers represent the eastern-most part of the so called Caucasoid types but consequent upon their inter-marriages with Meitei women over a long period of time they show both Caucasoid and Mongoloid features[8]. They inhabit the four valley districts of Manipur namely, Imphal-East, Imphal-West, Thoubal and Bishnupur. But the bulk of the Brahmins is scattered in BamonLeikai of Imphal-East. Muslims are a Caucasoid group, in contrast to the neighboring Mongoloid groups[9]. They spread throughout Manipur and practice consanguineous marriages. However, most of them inhabit the Imphal-East and Thoubal districts of Manipur. The Brahmin samples were collected from Imphal-East district and for Muslims, sampling was done from both Imphal-East and Thoubal districts of Manipur. For screening of G6PD deficiency, a total of 263 (only males) unrelated blood samples (127 Brahmins and 136 Muslims) were collected by finger prick after obtaining prior informed written consent. All the blood samples were tested G6PD deficiency using Fluorescent Spot Test[10]. Intravenous blood (5ml each) was collected from G6PD deficient individuals for further molecular analysis after obtaining prior informed written consent and DNA isolation was done following the standard Salting out method[11]. Molecular analysis was done by using the protocols given in table-1 below.

Results

Out of 127 Brahmin males screened for G6PD deficiency only 12 were found to be deficient with the frequency of 9.45% and of the 136 Muslim males, a higher frequency of 21.32% of G6PD deficient individuals (29) were found among them as shown in Table 2 below. The allele frequencies of G6PD deficiency of Meitei Brahmins (0.0945) and Meitei Muslims (0.2132) are the same as their percentile phenotype frequencies. A Chi square comparison of both the populations with respect to the allele frequencies showed that there is a significant difference between the studied populations ($\chi 2 = 7.0373$; $p= 0.007983$).Of the many mutations reported for G6PD deficiency only 3 most common Indian mutations and 4 most common Southeast Asian variants are selected for the present study. This is because both Brahmins and Muslims are expected to be admixture populations of India and South-East Asian ethnic elements.All the 41 G6PD deficient individuals were screened for the selected 7 mutations. Only 4 individuals out of the 12 Brahmin G6PD deficient could be characterized at the molecular level i.e. G6PD Mediterranean (8.33%) in one individual, G6PD Odisha (8.33%) in one individual and G6PD Mahidol (16.67%) in two individuals, whereas none of the 29 G6PD deficient Muslims could be characterized.

Discussion

The G6PD deficiency prevalence frequency in India varies from 1% to 27% in different communities and regions of India[12]. In eastern India, the frequency is the highest in Angami Nagas (27.1%), followed by Adi (19.4%), Apatani (16.7%), Nishi (16%), Rabha (15.8%), Mikir (15.6%), Santhal (14.1%), etc.[13]. The distribution of G6PD deficiency among the Brahmins (9.45%) and Muslims (21.32%) of the present study is within the reported ranges of India. The reported frequencies of G6PD deficiency in India vary from complete absence among the Ganchha of Rajasthan[14], Lepchas of Assam[15], Dharwa, Halba and Maria of Madhya Pradesh, and Marathi of Maharashtra[16], Brahmin of Manipur and Jamatia of Tripura[17] to 0.279 among Vataliya Prajapati of Surat, Gujarat[18]. Very limited studies have been carried out in Manipur, the prevalence of G6PD deficiency among the Brahmins was reported to be 2.8%[19] and Kabui (7.8%)[20]. In the north-eastern region of India, the highest frequency (27.1%) has been reported among the Angami Nagas of Nagaland[21]. However, zero frequency has been reported among the Lepchas[15]. Among the populations of the eastern region of India, highest frequency (17%) of G6PD deficiency was reported among the Warli of Orissa[22] followed by Munda and Paraja having the same frequency of 15.9%[23]. The lowest frequency (3.6%) was reported among the Hindus of West Bengal[24]. The frequency of G6PD deficiency in Northern India ranges from 1.5% among the Rajputs of Himachal Pradesh[25] to 12% among the Tharu of North India[17]. The frequencies of G6PD deficiency were also reported among the Dhurwa, Halba and Maria of Madhya Pradesh[16]. The frequency of G6PD deficiency range of western India is 2.1% among the Rajputs of Dadra Nagar Haveli[26] to 27.9% among the Vataliya Prajapati of Surat[18].

Conclusion

The spectrum of mutations causing G6PD deficiency in India has not been well elucidated and several studies have revealed that the G6PD Mediterranean mutation is the most common variant followed by G6PD Kerala-Kalyan and G6PD Odisha[27].The prevalence of G6PD deficiency individuals were significantly high among Muslims as compared to that of Brahmins. However, though 4 common mutations were detected in the Brahmin population, all the 7 common mutations screened for in the populations were found to be absent among Muslim G6PD deficient individuals, suggesting a different origin and migrational history in these two groups which is in conformity to their historical records. Further, the Muslim population with a relatively higher frequency of G6PD deficiency are expected to have mutations that are not common to Indian populations. Hence, the Muslim population needs special attention and further in depth molecular research in respect to G6PD deficiency.

Conflict of Interest: No

Ethical Clearance and Consent: The present study is approved by the Ethical Committee of the Department of Anthropology, University of Delhi. Blood samples were collected after obtaining duly signed prior informed written consent from the participants.

Efficacy of Technology Basded Method to Improve Knowledge on Health Promoting Behaviour towards Maternal Hypothyroidism among Primi Mothers with Hypothyroidism

P.M. Arulmozhi Baskaran[1], Prasanna Baby[2]

[1]Professor, (Scholar Student) Head of the Department of Community Health Nursing, Narayana Hrudayalaya College of Nursing, Bangalore, [2]Principal, Sri Ramachandra University, Chennai

Abstract

Background: Maternal hypothyroidism, in simple terms, refers to low thyroid hormone levels during pregnancy. The diagnosis is made by a TSH that is greater than normal, and this situation deserves therapy. Many studies have shown that maternal thyroid hormones are very important in pregnancy[1]. Most importantly, emerging data seems to suggest that thyroid hormones are especially important for fetal brain development, especially during early pregnancy[2]. Pregnancy has a profound impact on the thyroid gland and thyroid function. The gland increases 10% in size during pregnancy in iodine-replete countries and by 20%–40% in areas of iodine deficiency. Production of thyroxine (T4) and triiodothyronine (T3) increases by 50%, along with a 50% increase in the daily iodine requirement. These physiological changes may result in hypothyroidism in the later stages of pregnancy in iodine-deficient women who were euthyroid in the first trimester[3]. The range of thyrotropin (TSH), under the impact of placental human chorionic gonadotropin (hCG), is decreased throughout pregnancy with the lower normal TSH level in the first trimester being poorly defined and an upper limit of 2.5 mIU/L[4,2].

Aim of the study: To determine teaching primigravida mothers with hypothyroidism on health promoting behaviors towards maternal hypothyroidism has efficacy in improving their knowledge.

Method: Evaluative with Quasi experimental study one group pre and post-test design and Simple random sampling technique were adapted for this study. The knowledge questionnaire regarding health promoting behaviour towards maternal hypothyroidism was distributed among 60 primigravida mothers with hypothyroidism followed by the session of technology based education on health promoting behaviour regarding maternal hypothyroidism was given to the primigravida mothers. The data were analysed by using descriptive, inferential statistical method.

Result: In pre-test the mean score of knowledge level is 9.45 and the SD is 3.13. In the post test the mean score of knowledge level is 20.06 and the SD is 11.40, which shows that the technology based education on health promoting behaviour of maternal hypothyroidism is highly significant in improving knowledge.

Keywords: *Primigravida mothers, hypothyroidism, health promoting behaviour, technology based method, knowledge.*

Introduction

Hypothyroidism is a relatively common illness in pregnancy. Between 2.2% and 2.5% of women have been found to have serum thyroid stimulating hormone (TSH) levels of 6 mU/L or greater at 15 to 18 weeks' gestation. Raised maternal serum TSH in the second trimester is also associated with an increased rate of fetal death

after 16 weeks' gestation[5]. Emerging research indicates that thyroid hormones play a key role in fetal brain development, and asymptomatic hypothyroidism during pregnancy may have an adverse effect on fetal growth and neurologic development. Findings published in the past year call our attention to the importance of identifying and adequately treating thyroid-deficient gravidas: Maternal free thyroxine (FT4) concentration below the 10th percentile at 12 weeks is associated with significant impairment of psychomotor development at ages 1 and 2 years[6]. The average serum thyroid-stimulating hormone (TSH) and FT4 levels of neonates born to hypothyroid mothers were significantly higher than those of controls; birth weight and head circumference were significantly lower[7]. Treatment and awareness of maternal hypothyroidism is essential, because adverse outcomes for both mother and baby are greatly reduced, if not eliminated, when patients are treated. Even when treatment is initiated later in pregnancy or is insufficient to restore a euthyroid state, the babies of treated mothers will show more normal neurodevelopment than the babies of non-treated mothersi[8,9].

Objectives: To assess and associate the pre and post intervention of knowledge on health promoting behaviour towards maternal hypothyroidism among primigravida with hypothyroidism with the selected demographic variables.

Hypothesis: Hypothesis were tested at 0.05 level of significance.

H1: There will be significant difference and association in the pre and post-test knowledge and score and their selected demographic variables.

Method and Materials

Research Methodology:

Research Design: Evaluative with Quasi experimental study one group pre and post-test design.

Setting: Narayana Hrudayalaya Hospital, Narayana health city, Bangalore.

Population: The target population for the study includes the primi gravida mothers with hypothyroid with TSH level more than 2.5 mlU/L (I^{ST} trimester) and Free T4 ((thyroxin) decreased with compare to normal. Primigravida mothers attending antenatal OPD in Narayana Hrudayalaya Hospital, Narayana health city, Bangalore.

Sample Size: 60 primigravida mothers with hypothyroidism

Sampling Technique: Simple Random Sampling technique

Independent Variable: Technology based education.

Dependent Variable: Knowledge regarding health promoting behaviour towards maternal hypothyroidism

Sampling criteria

Inclusion criteria:

Antenatal mothers who have:

- Primigravida mothers
- age above 20 years
- Willing to participate in the study.
- Gestational age 1- 12 weeks.
- Registered and attending the antenatal OPD for visits.
- The antenatal mother whose laboratory values falls below criteria:
- TSH level more than 2.5 mlU/L (I^{st} trimester)
- Free T4 ((thyroxin) decreased with compare to normal (Normal reference range- 0.8 -2.8 nanograms per deciliter (ng/dL))

Exclusion Criteria:

- Health professional mothers
- Mothers coming in antenatal OPD in Gestational age of above 13 weeks

Ethical Consideration: The study was conducted after approval from the concerned institution. Assurance was given to the participants regarding the confidentiality.

Description and Development of the Tool:

The tool comprised of 3 sections:

Section A: The demographic variables of the clients.

Section B: Structured Questionnaire on Knowledge regarding Health Promoting Behaviour of Mothers with Hypothyroidism.

Section C: Technology Based method on Maternal Hypothyroidism (Intervention Module)

Sl.No.	Topics	Method of Technology
1	Meaning, causes, risk factors and symptoms of maternal hypothyroidism	Power Point Presentation
2	Adverse Outcomes of Maternal Hypothyroidism (Maternal & Foetal Disorders)	
3.	Screening & Monitoring	Video assisted teaching
4.	Modification of Diet & Activity	
5.	Guidelines for maternal and Newborn care	CD instruction

Scoring Technique:

Section A: Scoring key for demographic data variables.

It consists of antenatal mothers profile such as age in years, type of family, type of food, occupation, monthly income, educational status and source of awareness of maternal hypothyroidism.

Section B: Scoring key for structured interview schedule format.

Knowledge questionnaire consists of 30 questions to assess knowledge. Each correct answer was given a score of one mark and wrong answer or unanswered was given a score of '0'. The maximum score was 30.

Classification of knowledge score based on arbitrary division

Below 50%	Inadequate Knowledge
50-75%	Moderate adequate knowledge
76% and above	Adequate knowledge

Procedure for data collection: The data was collected after the written informed consent obtained from primigravida mothers with hypothyroidism. The pre-test was conducted for primigravida mothers during their first antenatal visit (3rd months) about 15 minutes followed by technology based training to the antenatal mothers with hypothyroidism for 30 minutes. The post test was conducted to the same primigravida mothers during their 3rd antenatal visit at the month of 7th months.

Data Analysis Plan:

The plan of data analysis was as follows:

- Organize data in a master sheet or computer.
- Demographic data would be analyzed in terms of frequency and percentage.
- The knowledge of maternal hypothyroid mothers regarding health promotion behaviour before and after intervention of technology based approach analyzed in terms of frequency and percentage, mean, Standard deviation.
- The significance of the difference between pretest and posttest knowledge score determined by paired 't' test.
- The association between the pre- test levels of knowledge score with demographic variables would be determined by using "Chi-Square".

The analysis of the data was mainly classified as:

Section-A: Frequency and percentage distribution of socio demographic variables of primigravida mothers with hypothyroidism.

Table 1: Frequency and percentage distribution of sample characteristics: n = 60

Sl.No.	Sample Characteristics	Frequency	Percentage
1. Age (in Years):			
a.	20-25	10	16.67
b.	26-30	10	16.67
c.	31-35	18	30.00
d.	36 and above	22	36.66
2. Type of Family:			
a.	Nuclear family	37	61.67
b.	Joint family	23	38.33
3. Occupation:			
a.	House wife	31	51.67
b.	Private employee	15	25.00
c.	Government employee	14	23.33
4. Educational Status:			
a.	Primary school	36	60.00
b.	High school & above	18	30.00
c.	Graduation & above	6	10.00

Sl.No.	Sample Characteristics	Frequency	Percentage
5. Food habits:			
a.	Vegetarian	37	61.67
b.	Non vegetarian	23	38.33
6. Family Income per Month (in Rs):			
a.	Below 3000	21	35.00
b.	3001 – 6000	14	23.33
c.	6001-9000	15	25.00
d.	9001-12000	4	6.67
e.	Above 12000	6	10.00
7. Information sources about the illness:			
a.	Mass media (TV, Radio, News Paper, Magazine)	21	35.00
b.	Professionals (Doctor, Nurses, Health Personnel)	18	30.00
c.	Friends	13	21.67
d.	Relatives	8	13.33

Section B: Structured Questionnaire on Knowledge regarding Health Promoting Behaviour of Mothers with Hypothyroidism.

Table: 2 Pre- test level of knowledge regarding health promoting behaviour of primigravida mothers with Hypothyroidism.

Knowledge level regarding health promoting behaviour on maternal hypothyroidism	Knowledge levels					
Pre-test Overall level of knowledge	Inadequate Below 50%		Moderate 51 – 75%		Adequate Above 75%	
	No	%	No	%	No	%
	50	83.3	10	16.7	00	00

Table No - 2 shows that overall pre-test level of knowledge scores regarding health promoting behaviour of antenatal mothers with Hypothyroidism.

Majority 50 (83.3%) of them had inadequate level of knowledge, 10 (16.7%) of them had moderate level of knowledge and none of them were had adequate knowledge.

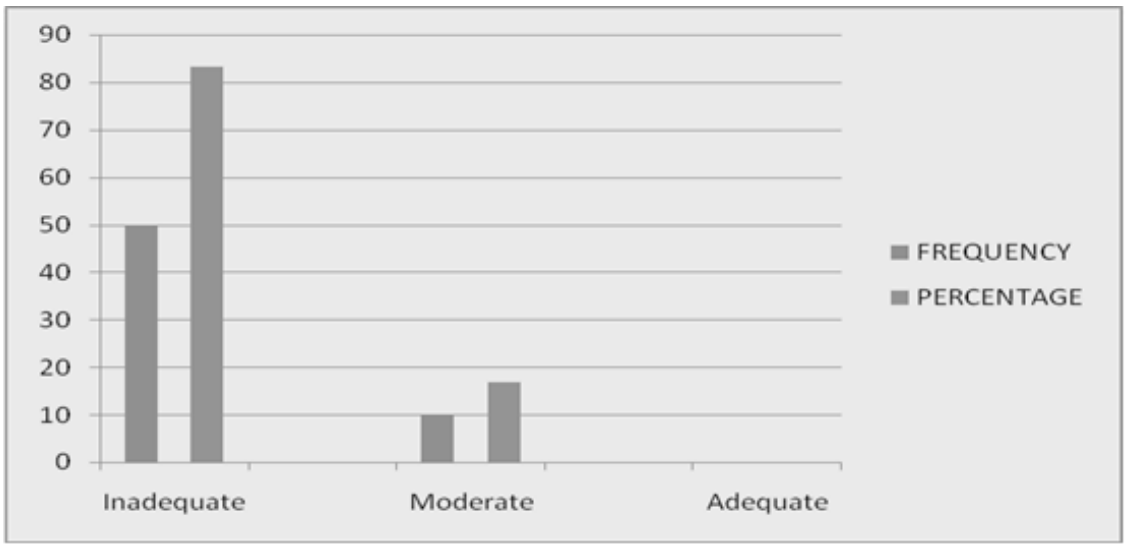

Fig No. 1: Pre- test level of knowledge regarding health promoting behaviour of primigravida mothers with Hypothyroidism

Table No. 3: Post- test level of knowledge regarding health promoting behaviour of primigravida mothers with Hypothyroidism

Knowledge regarding health promoting behaviour on maternal hypothyroidism	Knowledge levels					
Post-test Overall level of knowledge	Inadequate Below 50%		Moderate 51 – 75%		Adequate Above 75%	
	No	%	No	%	No	%
	00	00	15	25	45	75

Table 3 shows that overall post-test level of knowledge scores regarding health promoting behaviour of antenatal mothers with Hypothyroidism

Majority 45(75%) of them had adequate level of knowledge, 15 (25%) of them had moderate level of knowledge and none of them were had inadequate knowledge.

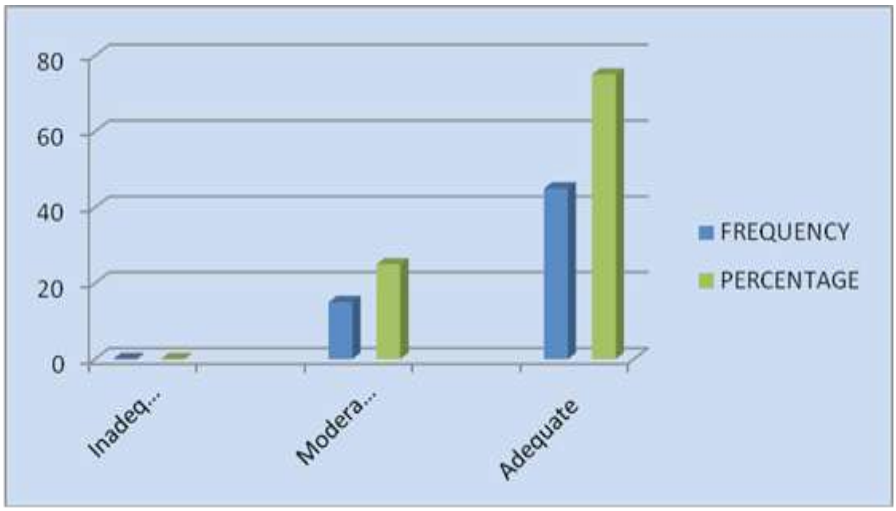

Fig. No. 2: Post- test level of knowledge regarding health promoting behaviour of primigravida mothers with Hypothyroidism

Table No. 4: Mean, standard deviation and paired 't' value of pretest and posttest knowledge scores regarding health promoting behaviour of primigravida mothers with Hypothyroidism

Test	Mean	Standard deviation	Paired 't' value
Pre- test	9.45	3.13	19.68
Post- test	20.06	11.40	D f = 59

T_{tab} = 2.2, P< 0.05 level

Table No. 4 Represents that the mean post-test knowledge score (20.06) is apparently higher than mean pre-test knowledge score (9.45). Standard deviation of post test score is (11.40) and standard deviation of pre-test score is (3.13) and the computed paired 't' test value (t59 = 19.68, P< 0.05) is greater than the table value (t_{tab} = 2.2) which represents significant gain in knowledge through the technology based approach.

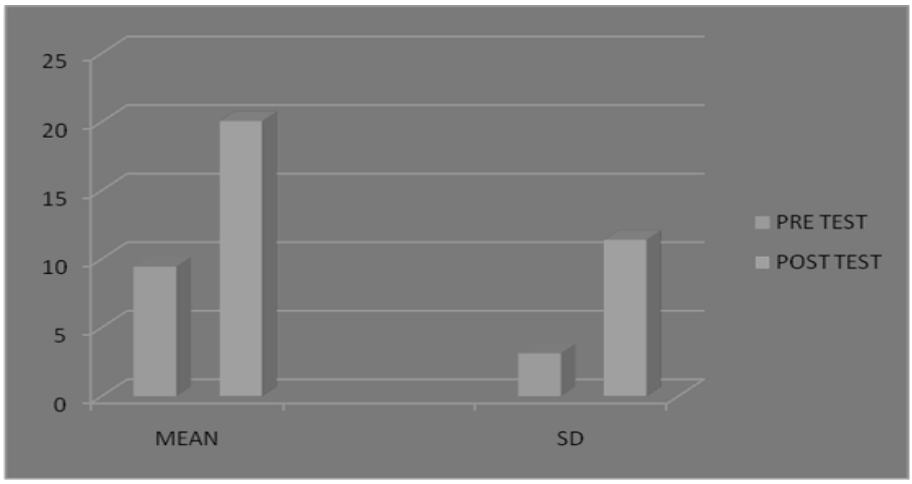

Fig. No. 3: Mean, standard deviation and paired 't' value of pre-test and post-test knowledge scores regarding health promoting behaviour of primigravida mothers with Hypothyroidism

The hypothesis stated as follows:

H1: The mean post-test knowledge score will be significantly higher than the mean pre-test knowledge score of the primigravida mother with hypothyroidism. The findings indicated that the computed Paired 't' test value 19.68 is greater than t table value (2.2). So that the researcher reject the null hypothesis and accepted the research hypothesis

The association between the pre- test levels of knowledge score with demographic variables would be determined by using "Chi-Square" revealed that there was no significant association between level of knowledge score and selected variables such as age, level of education, occupation, type of family and sources of information.

Conclusion

The findings reveal that the majority of primigravida mothers with hypothyroidism had inadequate knowledge regarding hypothyroidism during pregnancy. It indicates that there is a need for creating awareness and regular follow up. The researcher concludes that creating awareness through the technology based had more impact and the subjects were shown more interest and received the teaching content with highly motivated. Hypothyroidism in pregnancy is associated with adverse fetal and maternal outcomes. Women with thyroid disorders should be followed closely and motivate them throughout pregnancy by maintaining daily check, telephonic reminder, text messages to the antenatal mothers hypothyroidism for the prevention of maternal complications, and good perinatal outcome.

Effect of Water Aerobic and Aerobic Exercise on VO2 Max Parameter among College Men Students

P.R. Nagaraj[1], R. Senthil Kumar[2]

[1]M.Phil Scholar, [2]Assistant Professor, Dept. of Physical Education and Sports Sciences, SRMIST, Kattankulathur

Abstract

The motivation behind the present review was to research the impact of water cardio respiratory endurance and oxygen consuming activities on vo2 max parameter among school men understudies. To accomplish the reason for the review thirty school men understudies were chosen from Erode in the year 2018-19. The subject's age ranged from 18 to 25 years. They chose players were isolated into three equivalent gatherings comprises of 10 men understudies each specifically test aggregate I, exploratory gathering II and control gathering. The test bunch I experienced water vigorous exercise and trial assemble II experienced oxygen consuming activities for a month and a half. The control gathering was not partaking in any activity over the span of the review. The reliant variable vo2 max was taken as standard factors and they were tried by utilizing cooper vo2 max test for this review .Pre-test was taken before the activity timeframe and post-test was measured instantly after the a month and a half of preparing period. Factual procedure "f" proportion was utilized to break down the method for the pre-test and post test information of test gatherings and control gathering. The outcomes uncovered that there was a huge distinction found on the paradigm factors.

Keywords: *Water aerobic exercises, Aerobic exercises, Vo2 max, Pre Test and Post Test.*

Introduction

Cardio-Respiratory Endurance: Oxygen consuming activity is any physical movement that requires the heart rate to reach no less than 60% of the maximal heart rate for an augmented timeframe. It is a movement that can be supported for an augmented timeframe without building up an oxygen deficiency. High-impact practice program is to expand the most extreme measure of oxygen that the body can handle inside a given time which is termed as "High-impact limit". It is a required capacity to ¹ quickly inhale a lot of air.[2] It conveys substantial volumes of blood with compulsion.[3] It conveys oxygen to all parts of the body in an adequate amount. To put it plainly, it relies on effective lungs, a capable heart, and a decent vascular framework which shows the states of these crucial organs, the high impact exercise limit is considered to be the best for improving general physical wellness.

Water Aerobics: Water vigorous exercise, sea-going wellness, water wellness, water fit which are the water high impact exercises involve in the execution of oxygen consuming activity in genuinely shallow water, for example, in a swimming pool.[4] Done for the most part vertically and without swimming ordinarily in abdomen profound or more profound water, it is a sort of resistance preparing. Water vigorous exercise is a type of high-impact practice that requires water-submerged members. Most water vigorous exercise is in a gathering wellness class setting with a prepared proficient instructing for 60 minutes. The classes concentrate on high-impact perseverance, resistance preparing, and making a pleasant environment with music. Distinctive types of water vigorous exercise include: water high impact exercise, and water run. While like land high impact exercise, in that it concentrates on cardiovascular preparing, water vigorous exercise varies in that it includes the part of water resistance and lightness.[5]In spite of the fact that heart rate does not increment as much as in land-based high impact exercise, the heart is working similarly as hard and submerged exercise really draws more blood to the heart. Practicing in the water is vigorous, as well as quality preparing focused because of the water resistance. Moving your body through the water makes a resistance that will initiate muscle gatherings. Hydro heart stimulating exercise is a type

of a vigorous exercise that requires water-submerged members.[6]

Statement of the problem: The research aims to assess the impact of water cardio respiratory endurance and oxygen consuming activities on vo2 max parameter among school men understudies.

Methodology

The motivation behind the present review was to explore the impact of water Cardio respiratory endurance and vigorous exercise on the vo2 max parameter of school men competitors. The accomplish this review was haphazardly chosen forty five school men understudies from Erode locale swimming pool relationship amid the year 2016-17 and their age gone from 18 to 25 years. The chosen subjects (N=45) were isolated into three gatherings similarly and arbitrarily. Forty five subjects from school men understudies were haphazardly chosen and they were allocated into three equivalent gatherings. Each gathering comprised of fifteen subjects. Of which Experimental Group I experienced Water oxygen consuming activities (WAEG), Group II experienced Cardio respiratory endurance activities (Aerobic Exercises) (AEG) and Group III gone about as Control Group (CG). The two test gatherings were treated with their individual preparing for one hour for each day for three days seven days for a time of a month and a half.

Water aerobic exercises group performed 10 drills namely toning arms, jumping jacks, side stretch, total body stretch, standing kick backs, leg adduction and abduction, crunch and floating on water. Aerobic exercises group performed 10 drills namely v step, turn step, over the top, L step, basic straddle step, side to side, double step side, knee kick, kick forward, kick sideward. This aqua aerobics exercises group and aerobic exercises group starts with 3 set of 12-10 repetitions in the first two weeks and progressed to 4 set of 10-8 repetitions in the second two weeks and 5 sets of 8-6 repetitions in the last two weeks. 30sec rest was given in between the sets. As the intensity start with 60% for first four weeks, 10% of intensity was increased for every two weeks. The subjects of all the three groups were tested on vo2 max prior to and after the training period. To ascertain vo2 max was used and accordingly cooper vo2 max test was administered mean value count by ml/min/kg.

Statistical Analysis: The significance of the difference among the means of experimental group was found out by pre-test. The data were analyzed analysis of covariance (ANCOVA) technique at .05 levels as confidence. Analysis was performed using SPSS 20.0 (SPSS Inc Software).

Results and Interpretations

Table I: Means Values for water aerobic exercises Group, Cardio Respiratory Endurance and Control Group on Vo2 Max (Cooper vo2 max test Mean value count by ml/min/kg)

Test	Water aerobic exercises	Cardio respiratory endurance	Control Team	Source of varaiance	Sum of Square	Df	Mean Square	F Ratio	Table value
PTM	38.46	30.74	37.03	Between	3.711	2	1.856	0.842	3.45
SD	2.02	1.50	1.29	Within	112.795	42	2.686		
PT	38.92	39.24	33.01	Between	112.035	2	56.017	32.03*	3.35
SD	1.36	1.22	1.37	Within	73.486	42	1.75		
APTM	36.42	36.20	36.34	Between	105.923	2	52.962	40.12*	3.43
				Within	55.32		1.349		

*Significant .05 level of confidence

The table I demonstrated that the pre□test mean esteems on vo2 max for water oxygen consuming activities gathering, cardio respiratory endurance gathering and control gathering are 38.46,30.74 and 37.03 individually. The result of "F" proportion 0.842 for pre□test mean was not as much as the table esteem 3.45 for df 2 and 42 required for importance at 0.05 level of certainty on vo2 max. The post□test mean esteems on vo2 max for water oxygen consuming activities gathering, Cardio respiratory endurance gathering and

control gathering are 38.92, 36.08 and 33.01 individually. The result of "F" proportion 32.03* for post□test mean was more noteworthy than the table esteem 3.35 for df 2 and 42 required for criticalness at 0.05 level of certainty on vo2 max . The adjusted post□test method for water oxygen consuming activities gathering, Cardio respiratory endurance gathering and control gathering are 36.42, 39.24 and 36.34 individually. The got "F" proportion 40.12* for adjusted post□test mean was more noteworthy than the table esteem 3.43 for df 2 and 41 required for centrality at 0.05 level of certainty on vo2 max. Since the got "F" proportion esteem was critical further to discover the matched mean distinction, the Scheffe's post hoc test was utilized and exhibited in table II.

Table II: Cooper vo2 max test Mean value count by ml/min/kg

Means			Mean Difference	Required CI
Aqua aerobic exercises	Aerobic exercises	Control Group		
36.42	36.195	-	.330	1.07
36.42	-	33.053	3.266*	1.07
-	36.195	33.053	3.432*	1.07

*Significant 0.05 level of confidence

The table II demonstrates that the adjusted post-test mean contrast in vo2 max between water aerobic gathering and oxygen consuming activities gathering is .330 it is critical at 0.05 level of certainty and demonstrated there was an inconsequential change. Water oxygen consuming activities gathering and control gathering is 3.266* it is huge at 0.05 level of certainty and demonstrated there was a huge change. Oxygen consuming activities gathering and control gathering is 3.432* it is critical at 0.05 level of certainty and demonstrated there was a huge change. Henceforth, there was critical distinction amongst control and test bunches in vo2 max among school men understudies. The after effects of the review demonstrated that there were a critical contrast between water aerobic gathering and control gathering, oxygen consuming activities gathering and control assemble on vo2 max.

Discussion on Findings

The investigator was convinced with the results that the group training in vo2 max with the aqua aerobic exercises and aerobic exercises improve vo2 max. The training given to the experimental group with aqua aerobic exercises and aerobic exercises had an influence on the experimental group and had shown improvement in vo2 max than the control group in the final test. The training given to the experimental group was planned by the investigator in consultation with his guide and with great care. The investigator felt that anyone could become good athletes if he has good vo2 max.

Conclusions

Significant improvement occurred in vo2 max on college men students.

1. Experimental groups with water aerobic exercises performed better than the aerobic exercises and control group.
2. Experimental groups with aerobic exercises performed better than the control group.

Abstract

Objective: Beauty is often considered as one of the most pleasant aspects of life, and its influence is often almost unavoidable. A person's dental appearance has a significant bearing on his psychological well-being. The various research studies conducted in India have shown prevalence of malocclusion ranging from 20 to 55%.

Method: A cross-sectional Descriptive survey was planned in the school children of Mysuru district. The sample size was 840 subjects. To assess the prevalence of malocclusion and different types of malocclusion present, DHC of the IOTN was used. GIS mapping of prevalence and frequency of different malocclusions was done using Arc GIS software.

Results: The IOTN classification reveals that among 409 Boys, 121 (29.6%) had definite need for orthodontic treatment. Among 436 girls, 124 (28.4%) had definite need for orthodontic treatment. There was no statistically significant difference with regard to orthodontic treatment need between boy and girl study participants in the present study (p = 0.53).

Conclusion: The prevalence of malocclusion is 58.2 & and displacement is the commonest type of malocclusion present.

Introduction

Health is the extent of functional or metabolic regulation of a living body[1]. Oral health connects with other health systems of the body. Malocclusion is a misalignment or incorrect relation between the teeth of the two dental arches when they approach each other as the jaws close[2]. Malocclusion varies from country to country and also among different races. The reported incidence according to previous studies has a broad range varying from 39% to 93% which reveals that majority of the children have malocclusion. The reason for this broad divergence may be because of the differences in ethnic groups, variations in the age group of the sample in different studies and most importantly because of the differences in the method of registration[3].

India is a vast and a developing country. Our country is striving to put an end to the many health related disorders. The results of the epidemiological studies on malocclusion not only helps in planning

orthodontic treatment but also offers a rational approach for determining the etiological factors of malocclusions[4].

Scenario of malocclusion in different states of India (Table 1). Following are some of the states wherein the epidemiological data about malocclusion is available[5,6].

A Geographic Information System (or GIS) is a system which is designed to capture, store, manipulate, analyse, manage and present spatial or geographical data. GIS technology is a powerful aid for public health profession as it provides data which can be used to communicate important facts about community. Also, GIS ties health to where people live.

The objectives of this study are:

1. To assess the severity of malocclusion in 12-year-old school going children of Mysuru district,
2. To assess the different types of malocclusion present in 12-year-old school going children of Mysuru district,
3. To locate the different types of malocclusion present in 12-year-old school going children of Mysuru district using the Geographic Information System (GIS) Data.

Materials and Method

Study Design: A cross-sectional descriptive survey was planned in the school children of Mysuru district.

Study Setting: The epidemiological survey was planned to be conducted in four taluks of Mysuru district. Three grades of school i.e., Government school, Private aided and Private Unaided school in the four taluks of Mysuru district were considered.

Sample and Sampling Technique: Sample size was determined using sample size formula for prevalence study. The prevalence rate was fixed at 40% and relative precision was 0.12. The sample size obtained was 840 subjects.

Two stage sampling was planned for the present study. In the first stage of sampling, four taluks were selected using simple random sampling by lottery method. Out of 840 subjects, 210 subjects were equally distributed to four taluks of Mysuru district. In the second stage of sampling, from each Taluk, schools were selected randomly to include 210 subjects by lottery method. In each school children in the age group of 12 years were chosen using the class Attendance register.

Inclusion Criteria:

1. Children of 12 year old in the sampled schools.
2. Children who provided both informed consent from parents and informed assent to participate in the study.

Exclusion Criteria:

1. History of previous orthodontic treatment.
2. Children undergoing orthodontic therapy.
3. Rampant caries
4. Any other craniofacial anomalies and syndromes.

Ethical considerations- Prior permission to conduct the survey was taken from the Deputy Director Public Instructions (DDPI) and also from the concerned school authorities. The survey protocol was reviewed and approved by the Institutional Review Board. Informed consent and Informed Assent were given a week prior to the parents of the child and the child. Only those children who provided both informed assent and consent were included in the survey.

Data Collection: To assess the normative orthodontic treatment need, DHC of the IOTN was used.

The examination was carried out under bright day light in the school premises. Sufficient sterilized instruments were carried out to the school on the day of examination.

Data Entry: At the end of each day of the survey, the data were entered to the personal computer by the investigator. Data were coded and entered into excel sheet. 10% of the observations were randomly selected and cross-checked to detect any error and to validate the data entry. At the end of the survey, the data were scrutinized again and was handed over to the Statistician.

Statistical Analysis-Data were transformed into SPSS Windows version 16, where cleaning, coding, recoding, cross-checking, and processing and analysis were done by the statistician.

The following statistical tests were applied.

1. Frequency
2. Descriptive
3. Cross-tabulations (Contingency table analysis)
4. Chi-square test.

GIS Mapping:

The Base Map Creation: The Base Map for the study is a district and taluk outer boundary layer that was created for Mysuru district. The individual taluk maps and the district map was merged together to create the overall study area map. The information different types of malocclusion for each taluk and for Mysuru district was incorporated into the baseline map and the maps depicting the frequency of different types of malocclusion for each taluk and the Mysore district was created using Arc GIS software.

Findings: Abundant epidemiological data relating to malocclusion have been published by many others in the developed countries. The number of studies is limited in India due to the orthodoxy of Indian culture.

We have selected 13 schools in 4 taluks of Mysuru district (Government, Private aided and Private un-aided schools) and 845 participants were used for the study. Out of the 845 participants, 409 (48.4%) were boys and 436 (51.6%) were girls.

The malocclusion/IOTN classification reveals that among 409 Boys, 163 (39.9%) had little need for orthodontic treatment while 125 (30.6%) had moderate need and 121 (29.6%) had definite need for orthodontic treatment. Among 436 girls, 190 (43.6%) had little need for orthodontic treatment while 122 (28%) had moderate need and 124 (28.4%) had definite need for orthodontic treatment. There was no statistically significant difference with regard to orthodontic treatment need between boy and girl study participants in the present study ($p = 0.53$),

Prevalence of different types of malocclusion in relation to gender

Among 409 Boys:

- 04 (1%) had Missing teeth,
- 153 (37.4%) had an increased Overjet,
- 35 (8.6%) had Cross bite,
- 191 (46.7%) had Displacement and
- 26 (6.4%) had Overbite.

Among 436 girls:

- 03 (0.7%) had Missing teeth,
- 184 (42.2%) had an increased Overjet,
- 32 (7.3%) had Cross bite,
- 198 (50.9%) had displacement and
- 19 (4.4%) had overbite.

Displacement of teeth was the most common malocclusion trait followed by an increase in Overjet among both Boys and girls in the present study with Missing teeth being the least prevalent. However, the difference in the distribution of these malocclusion traits between Boys and girls was not statistically significant ($p = 0.48$). This was evident even when a separate comparison was made among participants from Mysuru ($p = 0.94$), Nanjangud ($p = 0.38$), Hunsur ($p = 0.07$) T-Narsipurtaluk ($p = 0.07$) (Table 2)

Mapping of different traits of malocclusion- This was done using Arc GIS software.

Discussion

The prevalence of malocclusion had been found to vary with the different population, race and origin[7]. A similar study in Travancore population[8] in Kerala reported 53.3% in need of orthodontic treatment. However, studies done by Singh S et al[9], Narayan RK et al[10] showed 68.4% and 83.8% in need of orthodontic therapy. This difference could because the latter studies were done on the adolscent subjects.

Distribution of malocclusion in population showed that a maximum number of children i.e. 46% presented with Displacement, 39.9% presented with increased overjet, 7.9% presented with crossbite, 5.3% presented with increased overbite and 0.8% presented with missing teeth. The increased frequency of displacement and overjet in the study population can be explained by the fact that there is reduction in the jaw size with evolution and due to the transition of diet from coarse to soft. These results are in accordance with the results of other studies by other researchers[11].Our finding that displacement is the most common feature (46%) contrast with that of Tania Arshad et al[12]. Increased overjet is an obvious sign of malocclusion in one's mouth and patients presenting to clinics will be to some extent aware of their malocclusion status whereas patients presenting displacement may or may not be aware of their clinical malocclusion. The results of our study are also supported by a study done by Borzabadi- Farahani et al[13].

While applying statistical technique we found that there was no statistically significant difference between the type of malocclusion and gender. This is in accordance with the study done by Grand G et al, Kashif Aslam et al, Reddy et al, Onyeaso CO et al, Kaur H et al and Lauc T et al[14-19].

Conclusion

The observations recorded from our study are as follows:

The prevalence of malocclusion was 58.2% as recorded by IOTN.

The malocclusion parameters as recorded by the modified version of IOTN index is as follows,

- Missing teeth- missing teeth is observed in 0.8% of the subjects.
- Overjet- overjet is observed in 39.9% of the subjects.
- Crossbite- crossbite is observed in 7.9% of the subjects.
- Displacement- displacement is observed in 46% of the subjects.
- Overbite- overbite is observed in 5.3% of the subjects

Hair Mercury Exposure and Hypertension among Community Artisanal and Small Scale Gold Mining in Banten, Indonesia

Elvi Sahara Lubis[1], Budi Hartono[1]

[1]*Department of Environmental Health, Faculty of Public Health, Universitas Indonesia, 16424 Depok, Indonesia*

Abstract

Background: Mercury was a heavy metal that persistent in the environment and harmful to human health and still used by Artisanal Small Scale Gold Mining (ASGM), especially in Indonesia. Cimanggu was one of ASGM in Banten province who still active using mercury and had found high levels of mercury that exceed the threshold in wastewater and human hair. Mercury exposure can affect human health, such as hypertension. This research aimed to determine the levels of hair mercury, hypertension, and individual characteristics such as age, sex, and smoking habits. And also determine the association between hair mercury with hypertension among communities in ASGM.

Material and Method: Design studies in this research using cross-sectional design. The data from BBTKLPP Jakarta datasheet "Analysis of Potential Impact of Risk Factors Environment Based for Disease Outbreaks on Interest Mining Society". Retrieved data was hair mercury that analyzed in the laboratory BBTKLPP Jakarta using Mercury Analyzer (MA) 3000 with cold pavor method and blood pressure were measured directly two times using sphygmomanometer merk ABN and individual characteristics taken through a questionnaire. Totaling 100 samples analyzed were taken by quota sampling. Findings: Univariate test showed that most of the respondents had abnormally hair mercury levels (55%), hypertension 29%, woman 78%, smoking 23%, and > 40 years 46%. Chi-square test showed no significant association between hair mercury levels and hypertension (P value=1, OR= 1.01, 95% CI = 0.42-2.40).

Conclusion: Respondents who had normal or abnormally hair mercury levels had the same odds to have hypertension risk. Further research is needed by using a larger sample with high-intensity process mercury use to clarify the association of hair mercury levels with hypertension.

Keywords: *Mercury; hypertension; Artisanal and Small Scale Gold Mining (ASGM).*

Introduction

Mercury emissions in the environment can from human activities such as fossil fuels burning, solid waste burning, and Artisanal Small Scale Gold Mining (ASGM)[(1)]. In the ASGM, mercury used to extract gold from the seeds by forming an amalgam. The widespread of mercury use in ASGM because simple to use, can be done individually, and relatively quick to separate the gold. Globally around 15 million people, including 3 million women and children participate in ASGM in 70 countries[(2)]. Based on the survey results consisting of 800 ASGM in Indonesia with estimated 250,000 miners and 1 million, whereas women and children[(3)]. ASGM had an increase in Indonesia. It's in line with many studies have shown that mercury pollution has occurred the sea, sediments, water wells, fishes, plants, and communities have an impact on public health[(4–6)]. Such as Hartono research which found mercury exposure in fish in Buyat Bay and Teluk Ratotok which has improved health for people who consume air from the Ratotok River Estuary,

Buyat River Hulu, and clean water/drinking water storage PT. Newmont Minahasa Raya[7]. The results of a study conducted in ASGM Gorontalo showed that the concentration of hair mercury respondents had exceeded the established standard of 2 with an average concentration of hair mercury in 5.0480 ppm[8].

ASGM donate 37% of mercury emissions in air and water. Mercury vapor present in the air around ASGM always high and the mercury pollution in water almost exceeds the quality standards by WHO. Continuously exposure can affect the central nervous system, the reproductive system and the cardiovascular system[2].

The last few years, the impact of mercury on the cardiovascular system, especially hypertension has become a concern. Hypertension has been proved as a major risk factor for cardiovascular disease triggers. The incidence of hypertension has increased for the last three decades. Besides food consumption which high salt intake and obesity, exposure to mercury in the environment also one important factor driving the incidence of hypertension. Epidemiological and experimental studies showed association between mercury exposure and increased blood pressure. Chronic mercury exposure levels in humans can be determined by examining the hair biomarker are considered most suitable for chronic exposure, easy to collected, and non-invasive[9]. Several studies in the world showed an association between mercury exposure to increased blood pressure among the gold miners who use mercury were found significant increased sistolee blood pressure ($P < 0.01$) correlated with lipid peroxidation and oxidative stress ($P < 0.01$)[10]. A case-control study showed the incidence of gold miners who have hypertension 46% greater than the control group. Other studies showed that a significant correlation between hair mercury levels with hypertension[11].A study of 251 people in the Brazilian Amazon showed that blood pressure was associated with higher levels of total mercury in the hair where an increased in blood pressure sistolee along with the increased amount of mercury in the hair of <10 lg/g[12]. In Indonesia research about association between hair mercury exposure with hypertension is still not received attention by researchers.

This research aims to determine the levels of hair mercury, blood pressure as well as individual factor characteristics (age, sex, and smoking habits) and determine the association between hair mercury with hypertension in communities around ASGM Cimanggu, Pandeglang, Banten Province. Cimanggu was an area of the ASGM who around a residential area that still used mercury to gold processing and has operated for approximately eight years. Balai Besar Teknik Kesehatan Lingkungandan Pengendalian Penyakit (BBTKLPP) Jakarta in 2017 had found mercury in wastewater in the processing of gold and mercury hair on people living around ASGM above the predetermined quality standards[13]. If it continuously happened could have a negative impact on human health one of hypertension disorders due to exposure to mercury.

Material and Method

This study was conducted using a quantitative method with cross-sectional study design and use secondary data derived from datasheet "Analysist of Potential Impact of Risk Factors Environment Based for Disease Outbreaks on Interest Mining Society" conducted by BBTKLPP Jakarta. This research will describe mercury levels in the hair and it's association with hypertension in community living around ASGM, Cimanggu, Pandeglang, Banten.

The population in this study was communities who live around ASGM in Cimanggu with total of 5442 people, the samples in this study were communities who selected based on inclusion criteria among men or women have equal opportunity to participate, length of stay ≥1 year around ASGM, in good health and willing to become respondents signed an informed consent. Calculation of sample size using the formula Lemeshow sought, in order to obtain a maximum sample is 100 sample. Sampling was conducted using quota sampling.

This study will use Univariate analysist to describe Hair mercury level, blood pressure, and individual characterictics respondents, and bivariate analysist used a chi square test to show association between hair mercury with hypertension. Hair mercury analyzed in the laboratory BBTKLPP Jakarta using Mercury Analyzer (MA) 3000 with cold pavor method and blood pressure were measured directly two times using sphygmomanometer merk ABN and individual characteristics taken through a questionnaire.

Findings: Based on Table 1 showed that of the 100 respondents who checked his blood pressure, only 29% who have hypertension, that was systolic≥140 or diastolic pressure ≥90[14]. Respondents who had hair mercury levels above the quality standards that have been established by UNEP (2 ppm) is 55%. Individual

characteristics show that respondents >40 years old only 46%, which was man 22%, and smokers only 23%.

Table 1. Distribution of Hair Mercury, Hypertension, and Individual Characteristics Around ASGM in Cimanggu 2018

Variables	Total	Presentation (%)
Hypertension		
No (<140/90)	71	71
Yes (≥140/90)	29	29
Hair Mercury Levels		
Normal (≤ 2ppm)	45	45
Abnormally (> 2ppm)	55	55
Age		
≤ 40 years	54	54
> 40 years	46	46
Gender		
Woman	78	78
Man	22	22
Smoking Status		
Do Not Smoke	77	77
Smoking	23	23

The association showed There is no association between hair mercury levels and hypertension (P value = 1, OR= 1.01, CI 95% = 0.42-2.40). OR = 1.01 that means respondents with abnormally hair mercury level have equal odds to have hypertension with normally hair mercury with 95% confidence interval hair mercury respondents between 0.42-2.40 ppm. Mercury exposure in society was measured using hair as a biomarker because can explain mercury levels long term in the body, hair mercury also quite persistent even not lost when washing with shampoo and coloring, and hair mercury levels 250 times in blood[15]. Hair will be examined using Mercury Analyzer (MA) 3000 and cold vapor method with the results of measuring parts per million (ppm) with quality standards set by UNEP (2 ppm)[16].

The analysis showed most of the respondents have hair mercury level abnormally. Abnormally hair mercury level in ASGM communities related to their exposure to mercury from combustion processes and the separation of gold which exposes humans through intermediary of water, air, and land for a long time, in additionally the hair shaft grows to combine mercury from the blood[17]. This result same with previous studies conducted around ASGM in Krueng Sabee, Aceh, 90.28% of respondents contains mercury levels above the quality standard value 10 μg/g set by the WHO. Fillion found 67.9% of the population living around the Amazon River containing hair mercury levels ≥ 10 mg/g[12].

Hypertension was defined as increasing systolic blood pressure or diastolic after at least 2 times measurement. Hypertension in this study defined as blood pressure that had systole pressure of 140 mmHg or diastolic pressure of 90 mmHg[14].This study showed just a few respondents with hypertension. This result was lower than research conducted by Valera et al. that showed 53.9% of people living around the mining have hypertension[18]. And about 46% of miners in Europe have hypertension[10]. Many factors can lead to hypertension such as age, sex, smoking, obesity, lack of exercise, excessive salt consumption, and stress[19]. And from this research, we can show that most of the respondent had a low risk of hypertension, because most of the respondents were woman, ≤ 40 years and do not smoke.

In this study showed no significant association between hair mercury levels and hypertension with OR = 2.072. It's not in line with Bautista et al. where people with high levels of hair mercury was four times more at risk for hypertension (p value= 0.02)[17]. The same results also proved by Fillion et al. and Valera who reported a positive association between mercury levels and hypertension[12,20]. In recent years there had increased attention to mercury effects on cardiovascular system like atherosclerosis, cardiac arithema, and renal dysfunction[21,22]. The mechanism of mercury affecting blood pressure cannot be explained with certainty, but the accumulation of mercury can affect endothelial function by inhibiting NO synthesis[23]and increasing oxidative stress, lipid peroxidation, and TNFα and interculin[17,24,25]. Increased oxidative stress from lipid peroxidation and decrease in antioxidants can trigger endothelial and renal dysfunction, which can increase the risk of hypertension and atherosclerosis, and result increase in blood pressure and pulse[22,23,25].

The same result with this study showed by Rajaee who cannot found association between mercury levels with blood pressure around communities ASGM[26]. The lack of association between hair mercury levels with hypertension because there had many factors causing hypertension behind mercury contaminants such as age, smoking, obesity, alcohol consumption, high natrium consumption, and low physical activities[27]. Besides that small sample size and low hair mercury levels can effect significance result study. Therefore need further

verification by using a larger sample with high intensity process mercury use. Although statistically there's no association between hair mercury and blood pressure, mercury exposure continuously for a long time can had a negative impact on health, one of them is hypertension, so monitoring of mercury use in ASGM areas should be monitored and conducted routine health monitoring in the community around ASGM.

Conclusion

The study concluded that most of (55%) respondent had abnormally hair mercury level, but only 29% had hypertension with the characteristics age >40 years old 46%, man 22%, and smoking 23%. There's no significant association between hair mercury and hypertension (p value = 1) with OR = 1.01 means respondents with abnormally hair mercury level have equal odds to have hypertension with normally hair mercury.

Conflict of Interest: The authors declare they have no conflict of interest.

Source of Funding: This research supported by the grant from PITTA Program in Universitas Indonesia.

Ethical Clearance: The research protocol was approved by the research and community engagement, the ethical committee of public health faculty of the Universitas Indonesia with number of ethics 95/ UN.2.F10/PPM.00.02/2019.

Effect of Lavender Oil Massage on Pain among Patients with Knee Osteoarthritis

Enas Mahmoud El Sayed[1], Hanan Ahmed Al Sebaee[2], Heba Ahmed Mohammed[3], Zeinab Osman Nawito[4]

[1]Clinical instructor, Medical Surgical Nursing, [2]Professor, Medical Surgical Nursing, [3]Assistant Professor, Medical Surgical Nursing, [4]Professor of Rheumatology and Rehabilitation, Faculty of Medicine, Cairo University, Egypt

Abstract

Osteoarthritis (OA) is a progressive chronic joint disease with global relevance with up to 250 million people being affected from knee OA worldwide. The aim of this study was to evaluate the effect of Lavender oil massage on pain among patients with knee osteoarthritis. A convenient sample of 60 adult male and female patients who admitted to Rheumatology and Rehabilitation unit affiliated to Cairo University hospital in Egypt with confirmed diagnosis of knee OA divided into experimental (study) and control group. A quasi-experimental Time Series pre-post test non equivilant interrupted control design was utilized in the current study. Data was collected using Personal and Medical Background Information Form, Pain Numerical Rating Scaleand Lequesne Algo Functional Index of Severity. The study findings revealed that there were significant statistical differences of pain intensity score and OA severity between study and control group after application of lavender oil massage.

Conclusion: Lavender oil massage was proved in this study to be effective on pain and OA severity among patients with knee osteoarthritis.

Keywords: *Lavender oil massage, pain, Patients with osteoarthritis.*

Introduction

Osteoarthritis is one of the most common musculoskeletal diseases, with an estimated prevalence of 12% to 22% worldwide[1]. In Egypt OA is the third leading cause of disability just after heart disease and back disorder; 1.6 million people were affected by OA in Egypt[2]. According to the American College of Rheumatology, OA is defined as a group of conditions which are associated with the defective integrity of articular cartilage result in changes in the underlying bone and articular margins[3].

Knee OA is divided into two types either idiopathic (primary) or secondary (post-traumatic). The primary OA is a gene-dependent disease, while secondary OA occurs after a traumatic event. Clinical characteristic of knee OA include pain, swelling,stiffness, crepitationand loss of movement that results in functional limitation, physical disability and reduced health-related quality of life[3].

Aromatherapy is one of complementary and alternative therapy (CAT) uses essential oils and herbal essences for improving mental health or relieving physical symptoms. Previous studies have examined the effect of aromatherapy on anxiety, pain and wound healing[4]. As result of its simplicity and affordability, aromatherapy has been used as an optional choice in some medical settings, either alone or together with standard pain control protocol[5].

Nursing practices for patient with osteoarthritis should be focused on performing regular follow up,

training, and determining the most effective symptom management method. Aromatherapy and massage are among the non□pharmacological method which nurses may directly and independently use to control pain so they should increase their knowledge and skills regarding aromatherapy massage like recognizing the pharmacological actions of the essential oils and how to apply aromatherapy massage properly[6].

Method

Aim of the Study: The aim of the current study was to evaluate the effect of Lavender oil massage on pain among patients with knee osteoarthritis. To fulfill the aim of this study the following research hypotheses were tested:

H1. Total mean score of pain of OA patients who receive lavender oil massage will be different from total mean score of pain of OA patients who receive routine protocol of care.

H2: The severity of osteoarthritis in OA patients who receivelavender oil massage will be different from the severity of osteoarthritis in OA patients who receive routine protocol of care.

Research Design: Quasi-experimental time series pre-post test nonequivilant interrupted control design was utilized in the current study.

Sample: A convenient sample of adult male and female patients with confirmed diagnosis of OA of the knee, their age ranged between 18 and 50 years. All patients admitted to rheumatology unit and met the inclusion criteria throughout 6 months from July 2018 to January 2019 were allocated to either study or control group starting with control group.

Setting: The current study was conducted in a selected Rheumatology and Rehabilitation unit, at Cairo university hospital, Egypt.

Data Collection Tools:

1. Personal and Medical Background Information Form (PMBIF): It is consisted of two parts: (a) Personal data sheet (b)Medical data sheet related to disease onset, duration, medical treatment, etc.
2. The pain Numerical Rating Scale (NRS): It is an 11-point scale (0-10). Pain intensity can be classified into mild, moderate, and severe levels based on the NRS score.
3. Lequesne Algo Functional Index of Severity: it is a disease questionnaire related to severity of OA. It consists of three scales with eleven items. Its scoring system 0= none, 1-4 mild, 5-7 moderate, 8-10 severe, 11-13 very severe and >= 14 extremely severe

Validity & Reliability: Tools were validated by a panel of five experts in the field of Medical-Surgical Nursing and modifications were carried out. Reliability was tested using Cronbach's alpha with value of 0.98.

Procedure: Patients were randomly divided into study and control group. Participants in the study group were instructed to massage their affected knee joint for 20 min 3 times per week for 3 weeks using 5 ml lavender essential oil diluted in sweet almond oil at a concentration of 3% and continued to receive conventional drugs. While the participants in the control group receive similar conventional drugs described by the rheumatologist.

Results

Section I: Demographic characteristics and medical data of the study and control groups.

The age of 60% of the study group and 56.6% of the control group ranged from41-60 years old and the mean age was 41.83 ± 6.828. Female gender constituted 83.3% of both study and control group.86.7% and 93.4% of study and control group respectively were married. Less than half of study group (40%) and around one third of control group can read and write,66.6% in both groups were housewives and 73.3% were rural areas' inhabitants.

According to medical data, around two thirds and 63% of study and control group respectively had gradual onset of osteoarthritis. 73% and 77% of study and control group respectively had no chronic diseases. 60% and 43% of study and control group respectively had no family history of osteoarthritis.

Section 2: Delineates hypothesis testing for being supported or not among study and control groups.

Table (1): Comparison between pain intensity score at four time points of both study and control group (N=60).

Pain Intensity		Study Group		Control Group		X^2	P value
		No.	%	No.	%

	extremely severe	6	(20)	15	(50)		

*significant at P ≤ 0.05.

Table (2) clarifies that there was significant statistical difference between study and control group along study period.

Figure 1: shows that there was statistical significant difference in pain score among study and control group (ANOVA test: 46.229, p-value: *0.000) respectively along the study period. Alsothere was a statistical significant difference in pain score between study group when compared to control group in the 1st, 2nd, and 3rd weeks of intervention.

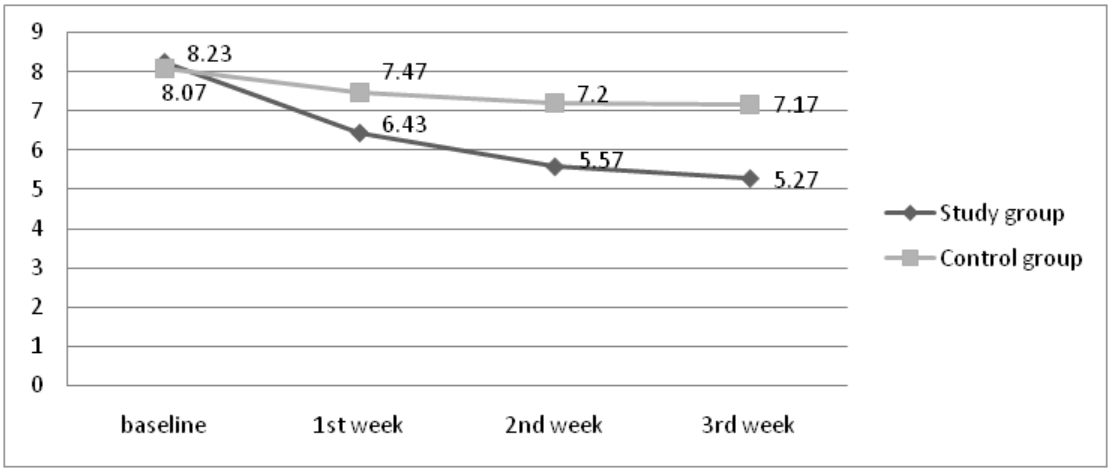

Figure 1: Differences of pain score between study & control group at four time points.

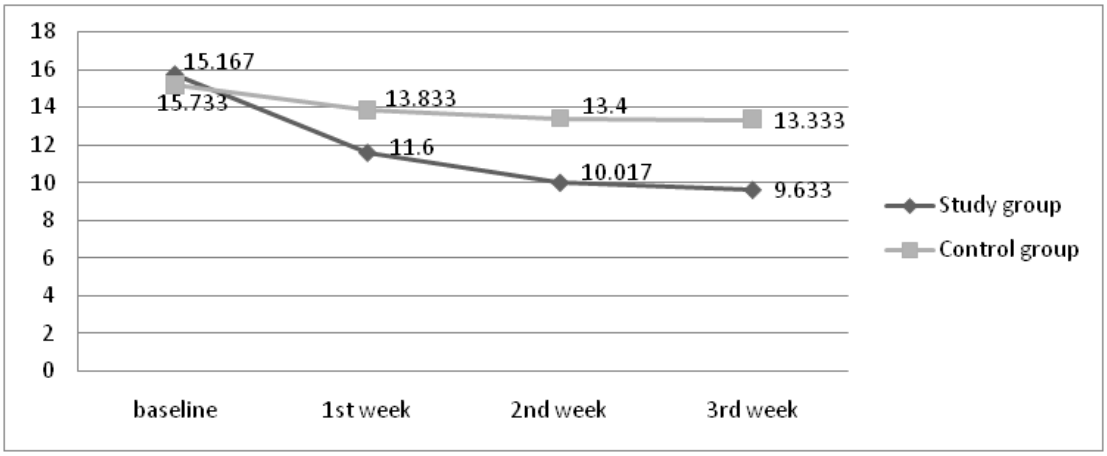

Figure 2: Differences of algofunctional index score between study & control group at four time points.

Figure 2: clarifies that there was statistical significant difference algofunctional index score among study and control group (ANOVA test: 52.260, p-value: *0.000) along the study period.Alsothere was a statistical significant differencein algofunctional index score between study group when compared to control group in the 1st, 2nd, and 3rd weeks of intervention.

Discussion

The current study revealed that, the majority of the study participants aged between 41-60 years old with mean and standard deviation of age 41.83 ± 6.828. This finding is almost consistent with Arslan, Kutlutürkan and Korkmaz, (2019)[7],the majority of their study participants were 35-64 years old. The findings can be explained with the fact that OA development starts much earlier than originally thought, and ranked among the top 20 diseases in the 40–45 years age group.

Regarding gender, more than half of the participants were females. This finding is congruent with the findings of the studies by Nasiri and Mahmodi, (2018); Arslan, Kutlutürkan and Korkmaz (2019) & Pehlivan and Karadakovan, (2019)[8,7,6] all affirmed that the

majority of their study participants were females. In addition, Mahajan and Patni, (2018)[9] confirmed that OA strikes women more often than men and it increases in prevalence, incidence and severity after menopause. The majority of study participants were housewives. These findings were relatively congruent with Nasiriand Mahmodi, (2018); [8]. The finding that the majority of the participants were housewives could be explained that the majority are females and reside from rural areas.

More than two thirds of study participants had gradual onset of disease. This could be explained with that OA develops slowly and that's why it takes time to induce symptoms that appears gradually starting with pain which worsens overtime. The majority of study participants had no comorbidities as diabetes and hypertension. In contrast Swain et al., (2019)[10] reported that 67% of patients with OA had at least one other chronic condition, being 20% higher than those without OA. In addition, Hawker et al., (2017)[11] mentioned that 77% of their study sample had hypertension, added that OA-related difficulty walking was a significant and potentially modifiable risk factor for diabetes complications.The mean age of the current study participants was 41.83 ± 6.828 years old that could be the reason why the majority of study participants had no co morbidities as the prevalence of co morbidities increases with advancing age.

The findings of the present study revealed that a significant reduction in the mean score of pain 5.27 ±2.083 and OA severity 9.633±5.0085 after application of lavender oil massage on knee joint compared to the control group 7.17±1.802 and 13.333±3.4996 respectively. This finding supports the effectiveness of lavender oil massage on pain and OA severity among patients with osteoarthritis. The findings of the present study are consistent with other study conducted by Nasiri & Mahmodi, (2018); Nasiri et al., (2016)[8, 12]. The findings showed that pain severity reduced significantly in the group undergoing massage with lavender oil compared to control group. This finding could be explained in the light of fact that the direct pharmacological effects of lavender oil is possibly because of lynalyl acetate and linalool, which can effectively decrease pain and inflammation, prevent muscle spasms and reduce tensions, leading to improve pain and physical function.

In this respect, other study conducted by Seda Pehlivan (2018)[6], reported that there were significant differences in pain score in the aromatherapy group when compared with the massage and control group. Other study done by Arslan et al.'s (2019)[7]revealed that aromatherapy massage performed in patients with osteoarthritis had positive effect to reduce knee pain scores, morning stiffness, and improve physical functioning status and considered that complementary treatment modalities are useful for nurses who can perform aromatherapy massage for symptom management in OA.

In the current study, there was a statistical significant difference in mean score of pain between study group when compared to control group in the 1st, 2nd, and 3rd weeks of intervention. This findings is consistent with Nasiri and Mahmodi, (2018); Nasiri et al., (2016);[8, 12]who reported that pain severity differed significantly immediately, 1 week, and 4 weeks after the intervention with p value (<0.001) compared with placebo and control groups.

On the same stream, another study finding belongs to Zhang et al., (2018)[13] revealed that patients with bilateral knee OA has been demonstrated that lavender oil aromatherapy massage, significantly reduced the patients' knee pain, tenderness, and morning stiffness. Furthermore, other study conducted by Won andChae, (2011)[14], reported that aromatherapy massage could be recommended as an effective intervention to decrease pain and to increase stride length in the elderly with knee osteoarthritis. Atkins and Eichler (2013)[15]added aromatic massage therapy was more beneficial than massage alone among knee OA patients.

Conclusion:Lavender oil massage was proved in this study to be effective on pain among patients with knee osteoarthritis.Implications:The complementary therapy is useful to healthcare providers who can learn, apply, or recommend aromatherapy massage techniques as a component of care for symptoms management of OA patients.

Recommendations:

- Replication of the study using a larger probability sample selected from different geographical areas in Egypt.
- Longitudinal study should be designed to determine the long term effect of lavender oil massage for this group of patients over a long period of time.

Ethical Clearance: A research approval was obtained from the Research and Ethical committee

at Faculty of Nursing - Cairo University and official permission was obtained from the administrators at study setting. Written informed consent was obtained from each patient.

Conflict of Interest: The authors declare that there is no conflict of interest.

Source of Funding: Self-funding.

How Soon Can You Expect to Get Pregnant after Discontinuing Reversible Contraceptive Method? A Survival Analysis of the 2017 Indonesia Demographic and Health Survey Data

Maria Gayatri[1], Budi Utomo[2], Meiwita Budiharsana[2]

[1]Ph.D. in Public Health, Training and Development Staff, National Population and Family Planning Board, East Jakarta, [2]Professors, Department of Biostatistics and Population, Faculty of Public Health, University of Indonesia, Depok, West Java, Indonesia

Abstract

Objectives: The information about the return of fertility was important for women use contraceptives for delaying and spacing. The objective of this study was to analyze time to pregnancy following contraceptive discontinuation among reproductive women in Indonesia.

Material and Method: Data on the return of fertility after discontinuation of various reversible contraceptive method were collected through a calendar contraceptive history among currently married women taking part in the Indonesia Demographic and Health Survey (IDHS) 2017. There were 3,887 women who discontinued using injectables, 1,641 women who discontinued using oral contraceptives, 228 women who removed their IUDs and 233 women who removed their implants for planning a pregnancy, who were followed up in this study to assess the return of fertility after discontinuation of their respective reversible contraceptives.

Findings: This study found that there is a delay in conception or pregnancy following discontinuation of a reversible contraceptive, but there is no permanent infertility among women after discontinuation of reversible contraceptives. The cumulative pregnancy rate for a-year is 75% for discontinuers of oral contraceptive users, 72% for discontinuers of IUD users, 75% discontinuers of implant users and 64% for discontinuers of injectable users.

Conclusions: The study found that contraceptive method significantly influenced the length time to become pregnant after discontinuation of reversible contraceptive method. However, the duration of contraceptive use has no relationship to time to pregnancy. To conclude, there is no impaired fertility after contraceptive discontinuation. Implication of this study is important for counseling process.

Keywords: *Reversible contraceptives, pregnancy rates, discontinuation.*

Introduction

The success of the family planning program in Indonesia is shown by the rapid decline in the country's fertility. Indonesia's Total Fertility Rate (TFR) dropped by more than half in approximately 50 years from 5.61 children per woman in 1971 to 2.4 children per woman in 2017[1]. In Indonesia, injectables and oral contraceptives are the most commonly used form of modern contraceptive method followed by IUDs and implants. Women who used contraceptive for delaying and spacing pregnancy must consider not only the safety and effectiveness of the chosen contraceptive method for the duration of their use, but also for the reversibility of the method in order to become pregnant after their discontinuation. Method other than sterilization (vasectomy and tubectomy), do not bring about an irreversible change in fertility[2] Therefore, the ideal contraceptive method for spacing is that which can reverse fertility as soon as possible after the method has been discontinued[3].

More than a quarter of all women of reproductive age had discontinued the use of contraceptives[1]. Over

two-thirds of these women had discontinued for reasons other than wanting to have a child, and it can be assumed that none of them had information about precisely when they would become fecund again and have a child. Thus, a considerable proportion of childbearing women would be exposed to the risk of having unplanned or unwanted pregnancies and they would potentially put themselves at the risk of their consequences. Yet, not much is known in Indonesia about when these women would be likely to return to fertile status. It is essential to provide these women with information not only about method of contraceptive and their side effects, but also about information regarding the return of fertility after discontinuation. The objective of this study was to analyze time to pregnancy following contraceptive discontinuation among reproductive women in Indonesia.

Material and Method

This study is a secondary data analysis of the 2017 Indonesia Demographic and Health Survey (IDHS). The contraceptive calendar data of the Women's Questionnaire form the source of data for the present study. The calendar data record the information on history of contraceptive use, history of pregnancy, and other information related to the survey respondents from January 2012 to the date of the interview in 2017. This survey only provides monthly data of reproductive and contraceptive patterns. The data on the date of the last menstrual period are not collected. Therefore, the time of return of fertility (in number of months) is calculated from the month that women stopped using reversible contraceptive method in order to plan a pregnancy, up until the month that women became pregnant and had either a live-born or still-born child.

Survival analysis will form almost all of the multivariate data analyses. With respect to each method, the dependent variable is the time of needed for return of fertility, or the delay in conception. The dependent variable is considered in two ways: In the first case, the dependent variable is *censored* (survival code = 0) if the terminal event has not occurred (i.e., there is no pregnancy from the time of contraceptive discontinuation until the survey date). In the second case, the dependent variable is *uncensored* (survival code = 1) if the terminal event has occurred (i.e., there is a pregnancy from the time of contraceptive discontinuation until the survey date).

The suitable methodology for the analysis of return of fertility which contains *censored* samples is defined as the *life table*. The Kaplan Meier life table method is used to examine the return of fertility and the median time to first ovulation after contraception was stopped. Furthermore, this analysis also utilizes the Cox regression method to estimate the survival experience based on the proportional of hazard model. All analyses are adjusted using the complex survey design. The entire analyses of this study will use a two-tailed p-value. Only the probability values at level of $p \leq 0.05$ are considered significant to the model.

Findings: Based on the IDHS 2017 data set, there are about 5,989 episodes of women having planned a pregnancy following their contraceptive discontinuation. These episodes are divided to 3,887 episodes of women who discontinued using injectables, 1,641 episodes of women who discontinued using oral contraceptives, 228 episodes of women who removed their IUDs and 233 episodes of women who removed their implants for planning a pregnancy.

Of the 5,989 women who had discontinued the reversible contraception in order to become pregnant, almost 60% were aged 25-34 years and 29% of respondents were aged 35-49 years. There were 49% women used contraception for 2 years, 38% women used contraception for 2-4 years and only about 13% used contraception for 4 years or above. More than three-quarters of women in this study were not smoking (neither active smoking nor passive smoking). About a-half of respondents were not working. Most of the women who discontinued reversible contraceptives lived in Java Bali islands and had sexual intercourse for less than twice a week. The data indicates that women who discontinued IUDs and implants for a planned pregnancy are totally parous with at least one child, but women who discontinued injectables and oral contraceptives are both parous and nulliparous.

Considering women of all characteristics the data show that the pregnancy rates after six months of the discontinuation of contraceptives were 59.3% for the use of oral contraceptive, 59.1% for the use of implants, 42.9 for the use of injectables, and 59.6% for the use of IUDs. The cumulative pregnancy rates after a-year of contraceptive discontinuation were 75.4%, 71.5%, 64.2% and 74.9% for women who stopping oral contraceptives, implants, injectables and IUDs respectively (Figure 1).

A cox regression analysis adjusted with complex sample design was performed to estimate some determinants on pregnancy after contraceptive

discontinuation among women in Indonesia. The data shows that the probability to conceive significantly influenced by the types of contraceptive method. In this study, it can be known that IUDs and oral contraceptives have faster time of return to pregnancy, compared to implants and injectables. However, the pregnancy rated after 2-years of discontinuation among four contraceptive method were nearly similar. In this study, the duration of contraceptive use has no influence on the probability to become pregnant following contraceptive discontinuation. Hence, women do not need to be fear to use contraceptive in a long duration because it doesn't impact on the future fertility.

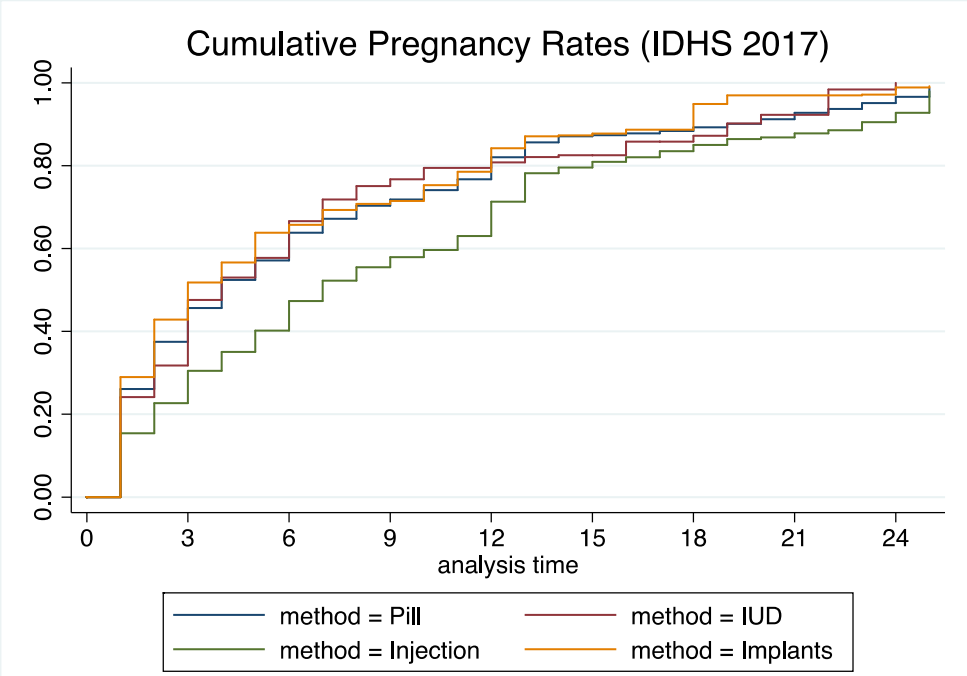

Figure 1. Cumulative Pregnancy Rates

Discussion

This study examined the type and duration of reversible contraceptives used by women in reproductive age. Some factors such as demographic factors and socio-economic factors were used as controlled variables in influencing the time of return to fertility after reversible contraceptive discontinuation. The results showed that oral contraceptive and injectables were the most popular contraceptive method in Indonesia compared to IUDs and implants. About 92% of episodes of contraceptive discontinuation in this study were for injectable and oral contraceptive users. The low uptake of Long-Acting Reversible Contraceptives (LARC) was consistent to the result of Indonesia Demographic and Health Survey[1]. Therefore, improving family planning services to increase the use of long-acting method is still needed to reduce the risk of drop out and unintended pregnancy as consistent to the Government of Indonesia's Medium-Term Development Plan 2015-2019.

The fear of side effect especially related to fertility resumption following contraceptive discontinuation such as infertility have made many women do not use any modern contraception[4–7]. Therefore, comprehensive counselling for every woman is crucial.

Cumulative pregnancy rates for implants did not differ from oral contraceptives and injectables. Another study explains that implants are known to release low doses of progestogen that can clear rapidly from women's circulation followed by the resumption of regular menses and ovulatory[8].

The longest delay to become pregnant is experienced by women who discontinued injectables. Women's

fertility will be returned soon after discontinuation of contraceptive method with the exception of progestogen only injectables – Depot medroxyprogesterone (DMPA) or Norethisterone enantate (NTE-EN)[9]. Furthermore, the length delay to conception following injectables discontinuation is not influenced by the duration of injectable use[10].

However, women's age has an impact on the return of fertility itself. This is because fertility has a strong association with women's age which means that the older women have a reduced ability to conceive naturally[11–13]followed by subsequent stages of overt cycle irregularity. The gradual decline in the size of the antral follicle cohort is best represented by decreasing levels of anti-Mullerian hormone. The variability of ovarian ageing among women is evident from the large variation in age at menopause. The identification of women who have severely decreased ovarian reserve for their age is clinically relevant. Ovarian reserve tests have appeared to be fairly accurate in predicting response to ovarian stimulation in the assisted reproductive technology (ART. It also could be happened in older women who were not succeed to become pregnant after contraceptive discontinuation because they entered the perimenopause or menopause period[8].

The study has concluded that there is no impaired fertility among Indonesian women following discontinuation of reversible contraceptive use (injectables, oral contraceptives, IUDs and implants). Based on this result, there needs to be a policy to inform men and women of reproductive age (and also adolescents) that there is no fear of impairment of fertility from using reversible contraceptives and that fertility returns after discontinuation of these contraceptives, albeit after a delay depending on the type of reversible contraceptive used. This would allay any worry that women (and their partners) may have about the loss of fertility by using reversible contraceptives. This policy needs to supplemented by a policy of increased promotion of reversible contraceptives among reproductive age couples to meet their needs of contraception for spacing pregnancies and also to reduce the probability of unwanted pregnancies. Information about return of fertility is also crucial for ensuring informed choice about contraceptives and for the assessment of the quality of care of reversible modern contraceptive method.

The findings of this study also lead to the need for formulating a policy to strengthen effective counseling to determine appropriate contraception selection and discontinuation. The results of this study should be important as information for the preparation of material for counselling for family planning users. The information about the return of fertility should be conveyed to the couples to clear their misperceptions about the inability to become pregnant after discontinuation of use reversible contraceptive method. Married women who want to choose their contraceptive method should have counselling by the health care providers. This counselling process is important to help women to use the best contraceptive method that suits their family size goals.

Conclusion

In conclusion, there is no impaired fertility after contraceptive discontinuation. The study found that contraceptive method significantly influenced the length time to become pregnant after discontinuation of reversible contraceptive method. The impact of duration of contraceptive use has no significant relationship to the time to pregnancy following contraceptive discontinuation. Implication of this study is important for counseling process.

Reviving the Lost Extremity: A Case Report

Nitika Gupta[1], Jeewan Bachan Dhinsa[2], Urvashi Sukhija[3], Sanjeev Mittal[3]

[1]Assistant Professor, [2]PG Student, [3]Professor, Department of Prosthodontics, MM College of Dental Sciences and Research, Mullana, Haryana, India

Abstract

The hand in the human body plays a major role in daily life, communication, social contact and basic functions such as grasping. Finger and partial finger amputations are the most frequently found forms of hand loss and trauma which lead to an impact on the psychological health, functional abilities and aesthetics of an individual. A prosthesis with good fitting, comfort and aesthetics can make the patient feel capable and whole again. This article describes a technique for fabrication of a custom made glove type finger prosthesis using silicone elastomers along with a ring for providing more retention to the prosthesis. Shade matching has been achieved by using intrinsic acrylic paints. This case report paper describes a technique to prosthetic rehabilitation of an amputated finger by fabrication of custom finger prosthesis by using silicone elastomer, which is aesthetically acceptable, comfortable to use and is cost effective with a simple approach.

Keywords: *Silicone elastomer, finger prosthesis, color matching, retention.*

Introduction

It is rightly said "Grief is in two parts, the first is loss, and the second is the remaking of life." The loss of a limb or a digit has an immense impact on one's mind, it can manifest as anxiety, depression or post-traumatic stress disorder on an individual.[1]Replacement of the missing finger by fabrication of an artificial finger is a very challenging process and technique sensitive procedure in the terms of artistic abilities and skill expertise. Prosthesis made for patients should be comfortable to wear, durable, light weight, aesthetically pleasing and easy to put on and remove.

Case Report: A 60 year old male patient reported to the Department of Prosthodontics Crown and Bridge, Maharishi Markendeshwar College of Dental Sciences and Research, Mullana, Ambala, for the fabrication of Complete Denture. On general examination, it was noticed that the patient had lost part of his left index finger (distal phalange) about 5 years back, due a traumatic injury. On physical examination a solitary healed scar was seen on palmar surface of the amputated finger. The surrounding surface and area of the finger appeared to be normal with no signs of pain, infection or any inflammation. Informed consent was made with a detailed explanation of the procedure. [Figure 1].

Figure 1: Amputated left index finger

Technique:

1. Patient was requested to keep his hand in normal resting position and not stretched. Lubrication with a

uniform thin layer of petroleum jelly is done, which prevents the adhering of the hydrocolloid to the skin on the site of the impression surface. A cardboard box was selected larger in size than the patient's hand. One side of the cardboard box was cut open to place and remove the hand.[2] A thin uniform mix of hydrocolloid (*Zhermack*) was poured inside the box creating the base of the impression on which the patient was instructed to place the palmar aspect of the hand over of the impression material, simultaneously the dorsal surface of the whole hand was covered.[3] In the end, a layer of dental plaster (*Kalabhai Kaldent)* was poured over the impression material for imparting strength to the impression made as well as to prevent its tearing on removal of the patients hand. [Figure 2]

Figure 2: Alginate Impression and Impression surface

2. The impression made was poured with dental stone (*Kalabhai Kalstone)* with vigorous tapping ensuring the complete flow of the dental stone. A positive replica of the site was obtained and finished.[2] [Figure 3].

Figure 3: Dental stone model

3. In this case, the wax pattern was fabricated by Donor Finger which involved making a hydrocolloid impression of the donor index finger. The donor finger should be of the same side of the patient's amputated finger and same sex. The donor was selected by matching the appearance and size of the fingers using the model obtained. The impression made was poured with heated liquid modelling wax (MAARC).[4] The wax pattern is carefully sculpted hollow from the inside followed by finishing and carving to give it a natural appearance. [Figure 4]

4. The custom made glove type wax pattern prosthesis is tried on the patient's amputated index finger. Proper fit and length is established with verification of the correct orientation. [Figure 4].

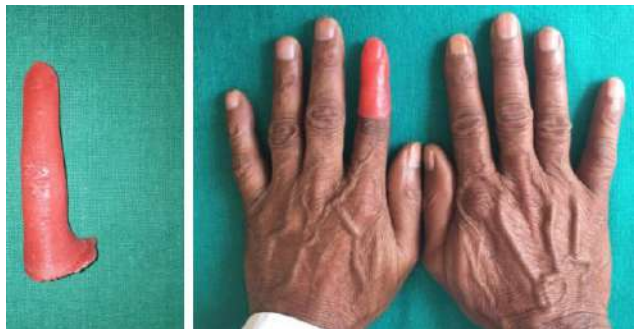

Figure 4: Trial of wax pattern on amputated finger

5. The wax pattern was invested. After complete set, de-waxing is carried out. A mould is obtained.[5]

6. Silicone (RTV Silicone, MP Sai Enterprises, Mumbai) was used along with acrylic paints (KURTZY Acrylic color paintv12 shades) as intrinsic shades. The colors Red, Blue, Yellow, Black, were used to create the natural skin tone of the patients hand, mixing was carried out on a glass slab. Color matching was done in natural light.[6] After desired shade was achieved and the silicone material was packed into the mould, bench pressed and was left overnight for processing. [Figure 5].

Figure 5: Shade Matching

7. A prefabricated artificial nail was used (Electromania Acrylonitrile Butadone Styrene Style Plane Nail Tips Pack of 24).
8. The final prosthesis was retrieved, excess was trimmed and finished. The artificial nail was trimmed and glued according to esthetics, followed by insertion of the final prosthesis on the patient's amputated left index finger.A ring was placed over the silicone finger prosthesis, which provided more retention to it. The prosthesis was delivered to the patient, was completely satisfied and contented with the outcome.[4]
9. To maintain its hygiene, the prosthesis should be washed with antibacterial soap from inside and outside air dried and then worn.[7] Exposure to high temperatures should be avoided. Smoking may discolour and stain the prosthesis. The prosthesis is not to be worn overnight as it will lead to irritation of the underlying skin. [Figure 6]

Figure 6: Silicone Finger Prosthesis

Discussion

It has been reported that the most common found amputations are partial hand amputations, presenting with loss of one more fingers. They are commonly resulted from occupational hazard, automobile accidents.[3] Other causes of amputations can be congenital, diabetes, gangrene and infections resulting from lack of basic public health. Partial finger amputations lead to functional deficiencies, aesthetic problems resulting in poor self-esteem, and psychological instability and economic damage to the individual.Many materials such as Acrylic, Polyurethane, polyvinylchloride have been used to produce finger prosthesis.[7] The restoration of the lost limb, finger depends upon the amount of the tissue involved and bone involvement, the level and the angle of amputation along with the number of fingers involved and the choice and acceptance of the person for the restoration of the finger. There are numerous replacement techniques accessible to restore the finger.[8] A well fitted and color matched prosthesis gets rid of the constant reminder of disability to a person.[9][10]

Conclusion

Rehabilitating the finger or its partial finger segment with an artificial prosthesis can be rewarding and satisfying with a pleasant outcome for a maxillofacial prosthodontist. The artificial prosthesis given can greatly enhance the psychological health, self-esteem of the patient. The process requires great skill, technique sensitivity and artistic skills along with the understanding of the patients need.

Abstract

Introduction: Diabetes as one of Non-communicable diseases has consumed a large share of money, material, time and human resources of health systems. Now, due to advancement in lifestyle and industrial process, prevalence of diabetes and its associated complications have been raised. Among these complications, diabetic foot considered as a common complication of diabetes.

Method: The present study was a quantitative quasi experimental two group pretest posttest design. The study was done at Amrita Hospital, Kochi. The main objective of the study was to evaluate the effectiveness of Burger Allen exercise on level of lower extremity perfusion among patients with type 2 Diabetes Mellitus. Totally 100 samples were taken in which 50 are in experimental and 50 in control group using convenience sampling technique.

Results: In the present study, majority were males with the average age among experimental group were 55.30 +- 4.58, 36(72%) and 55.30+- 4.58, 34 (68%) in the control group. The study result showed that mean and standard deviation of ABPI score among both groups on Day 1(0.07±0.01), day 2 (0.05±0.02) and day 3(0.19±0.01). There was statistical significance with the p value <0.01. There was also significant difference between the groups and within the groups in ABPI scores in 3 days among patients with type 2 DM which is significant at <0.05.

Conclusion: In the light of present study result, it depicted that the Buerger Allen exercise improve lower extremity perfusion among patient with type 2 diabetes mellitus.

Keywords: *Buerger Allen exercise, Lower extremity perfusion, Type 2 diabetes mellitus.*

Introduction

Diabetic mellitus is a group of metabolic disease in which defects in insulin secretion or action result in elevated blood glucose (hyperglycemia). In 2017, The WHO global report on diabetes demonstrates that the number of adults living with diabetes is 422 million adults. 1.6 million deaths are directly attributed to diabetes each year. Type 2 DM accounts for around 90% of all diabetes worldwide.[1] Reports of type 2 diabetes in children have increased globally. Diabetes currently affects more than 62 million Indians, which is more than 7.1% of adult population. The average age of onset is 42 years. Nearly 1 million Indians die due to diabetes every year. Kerala is known as diabetes capital of India as prevalence of diabetes is high 20% which is double the national average of 8%. As compared the prevalence in Thiruvananthapuram was 17%, in Hyderabad and New Delhi 15%, in Nagpur 4% and in Dibrugarh 3%.[2]

Diabetic foot complication is a major cause of disability, reduced quality of life, prolonged hospitalization, financial loss, lower limb amputation and mortality rate. [3,4] People with diabetes develop foot ulcers because of neuropathy, vascular insufficiency and impaired wound healing. [5] Nearly 90% of diabetes relayed lower limb amputations were preceded by foot ulcers.[6] The value of these exercises had frequently been emphasized by Allen, many medical experts considered them as important adjuvant treatment and postoperative

care for circulatory disturbances in the extremities.[7,8] The exercises involve the individual lying flat in bed with the legs elevated at 45 degrees until blanching occurs or for a maximum of 2 minutes. The patient then sits at the edge of the bed with the feet hanging down. Further exercises include dorsiflex, plantar flex, then inward and outward movement of the feet, followed by flexing and extending of the toes for 2 minutes. Finally the individual lies supine with the feet covered with a warm blanket lasting 5 minutes. The whole cycle is repeated 3 to 6 times each session, and the complete sequence is repeated 2- 4 times a day.[9]

The ankle brachial pressure index is a simple non-invasive and inexpensive diagnostic tool of choice for diagnosing peripheral artery disease in diabetic patients. The ABPI is the ratio of the systolic blood pressure in the angle to the systolic blood pressure in the arm. It is an objective indicator of arterial disease that allows the examiner to quantify the degree of stenosis. Doing exercise will help the patient to improve the vascularization and at the same time it will help to improve the wound healing process.

People with long standing Diabetes mellitus develop complication of PAD, which leads to grave complications like gangrene in the lowerlimbs. The most common symptom is muscle pain in the lower limbs on exercise. Indiabetes, pain perception may be blunted by the presence of peripheral neuropathy. Therefore, a patient with diabetes ismore likely to present with an ischemic ulcer or gangrene. The use of ankle-brachial-pressure index in the clinic and bedside provide a measure of blood flow to the ankle. This could help early detection,initiate early therapy and may thus reduce the risk of critical limb ischemia and limbloss.

Buerger Allen Exercise is one of the intervention to stimulate the development of collateral circulation in the legs. Primary care providers should focus on prevention by early recognition and prevention of PAD to those at increased risk. An awareness of diagnostic and treatment strategies will enable primary care provide providers to educate patients. This will help to improve both concordance with treatment and disease outcome. Considering the above factors and review of literature, the investigator felt that all patients with diabetes mellitus should do the

Buerger Allen Exercise to improve lower extremity perfusion.

Methodology

The present study was a quantitative quasi experimental two group pretest posttest design. The study was done at Amrita Hospital, Kochi. The main objective of the study was to evaluate the effectiveness of Burger Allen exercise on level of lower extremity perfusion among patients with type 2 Diabetes Mellitus.

Selection method of the study participants: The study included all patients between 45-60 years with Type 2 Diabetes Mellitus and whose ABPI score was 0.9 -0.4. The sample size was obtained using Master software based on previous article conducted by John J and Rathiga R on effectiveness of Buerger Allen Exercise to improve the lower extremity perfusion among patients with type 2 diabetes mellitus with -80% power, 95% Confidence interval minimum sample size 10 in each group. Totally 100 samples were taken in which 50 are in experimental and 50 in control group using convenience sampling technique. The study excluded patients who are unconscious, disoriented, critically ill, on anti-coagulant therapy, on treatment of deep vein thrombosis and also who are not willing to participate. The ABPI score was obtained by dividing the highest ankle systolic pressure to the highest brachial systolic pressure. After obtaining written informed consent, the ABPI was measured in each subjects and those subjects whose ABPI score was between 0.9 to 0.4 had been given the Buerger Allen Exercise for 12-13 minutes on three days. On the third day again the ankle brachial pressure index was calculated. Ethical clearance had been obtained from the Thesis review committee of AIMS and research Committee of Amrita College of Nursing.

Software Used for Data Entry, Compilation and Statistical Analysis: Microsoft Excel spread sheet was used for data entry and data analysis was done using the SPSS 20.0 version. In this study the quantitative data were expressed in terms of descriptive statistics. Paired t-test had been used for comparing statistical significant to compare the pre- test and post–test scores of ankle brachial pressure index among Type 2 Diabetic Mellitus patients. Chi-Square test was used to find out the association between ABPI score and selected demographic variables.

Ethical consideration: The project has been approved by the ethics committee of the institution. Informed consent was obtained from the participants before initiating the study.

Results

In the study, the average age of experimental group is 55.30 +- 4.58. 36 (72%) were males, almost 45 (90%) had education up to secondary level, 32 (64%) subjects were employed, 23 (46%) were doing sedentary and moderate work each, 46 (92%) were non- vegetarian diet, 29 (58%) had no ill habits and 33 (66%) had type 2 DM for more than 11 years. Whereas in the control group, the average age is 55.30+- 4.58, 34 (68%) were males, 41 (82%) had education upto secondary level, 26 (52%) were unemployed, 31 (62%) were moderate workers, almost 45 (90%) were following non vegetarian diet, 34 (68%) had no ill habits.

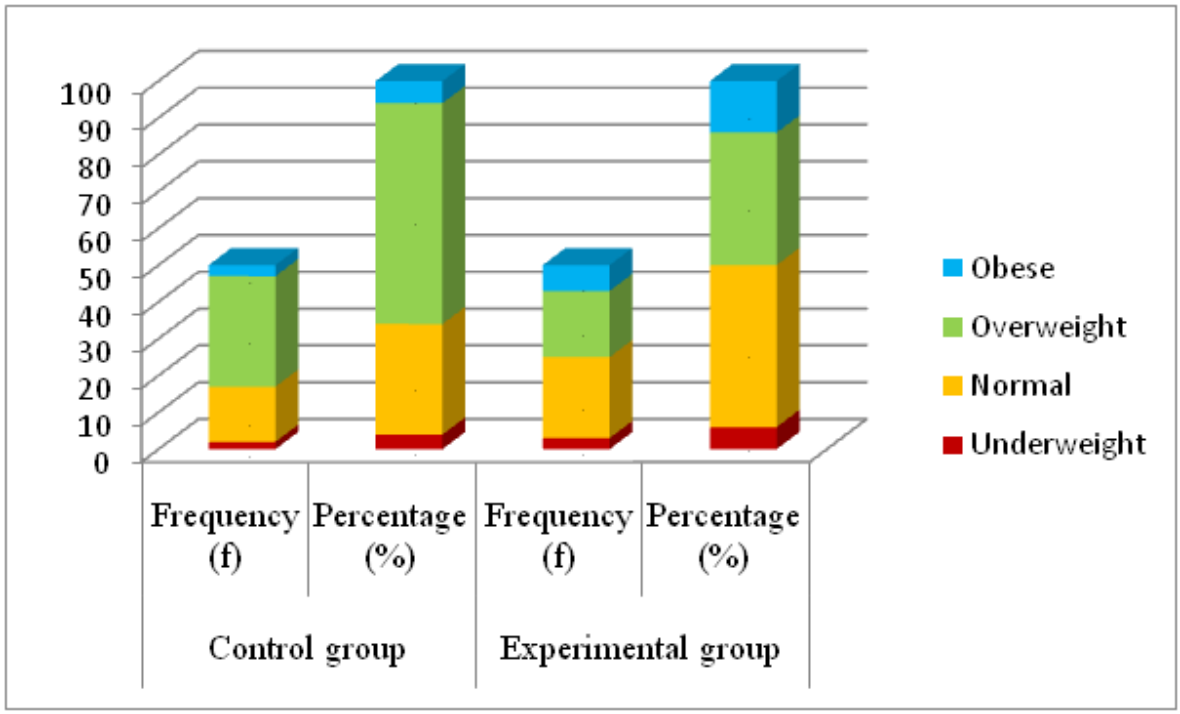

Figure 1: Frequency and percentages distribution of BMI among patients with Diabetes mellitus in control and experimental group. N = 100

In the present study, the result shows that BMI category in control group were 2(4%) underweight, 15(30%) normal, 30(60%) overweight and 3(6%) obese. In experimental group, 18(36%) were overweight and 7(14%) were obese.

Table 1: Comparison of mean, median and standard deviation of clinical variables among patients with diabetes mellitus in control and experimental group. N=100

Group	Clinical Parameters	Mean	Median	Standard Deviation (SD)
Control Group	Height	159.24	158	6.14
	Weight	64.96	65	9.95
	BMI	25.56	25.8	3.10
Experimental Group	Height	159.24	160	5.17
	Weight	64.48	60	11.71
	BMI	25.42	24.69	4.33

The above table shows that among the control group the mean and standard deviation of height, weight and BMI is (159.24± 6.14), (64.96± 9.95) and (25.56± 3.10) respectively. In the experimental group the mean and standard deviation of height, weight and BMI is (159.24±5.17), (64.48±11.71) and (25.42±4.33) respectively.

Table 2: Mean and standard deviation of Ankle brachial pressure index among control and experimental group. N=100

ABPI Score	Mean	Standard Deviation	F	p- value
Day 1	0.07	0.01	4.44	0.00**
Day 2	0.05	0.02	2.88	0.01*
Day 3	0.19	0.01	0.60	0.00**

Data present in the table shows that mean and standard deviation of ABPI score among both groups on Day 1(0.07±0.01), day 2 (0.05±0.02) and day 3(0.19±0.01). There was statistical significance with the p value <0.01.

Table 3: Comparison of ABPI scores among patient with diabetes mellitus in between and within the control and experimental groups. N=100

Variables	Days		Mean	Sum of square	df	F	p-value
ABPI score	Day 1	Between groups	0.135	0.13	1	45.55	0.000*
		Within groups	0.003	0.29	98		
	Day 2	Between groups	0.064	0.06	1	6.68	0.01*
		Within groups	0.009	0.93	98		
	Day 3	Between groups	0.984	0.98	1	349.92	0.000*
		Within groups	0.003	0.27	98		

The table 3 depicts the significant difference between the groups and within the groups in ABPI scores in 3 days among patients with type 2 DM which is significant at <0.05. There was no association between the demographic variables and the ABPI score

Discussion

Diabetes is a complex metabolic disease. A Non pharmacological natural approach is needed to overcome that problem. Burger's Allen exercise is a simple, which is easy to do, have no notable side effects and most acceptable one to reduce Diabetes mellitus.

In the present study, the average age of experimental group is 55.30 +- 4.58. 36 (72%) were males, almost 45 (90%) had education up to secondary level, 32 (64%) subjects were employed, 23 (46%) were doing sedentary and moderate work each, 46 (92%) were non- vegetarian diet, 29 (58%) had no ill habits and 33 (66%) had type2 DM for more than 11 years. Whereas in the control group, the average age is 55.30+- 4.58, 34 (68%) were males, 41 (82%) had education upto secondary level, 26 (52%) were unemployed, 31 (62%) were moderate workers, almost 45 (90%) were following non vegetarian diet, 34 (68%) had no ill habits.

Another study conducted by M. Vijayabarathi (2013) on effectiveness of buergerallen exercise on wound healing process among the diabetic foot ulcer patients admitted in diabetology department which results showed that in considering the age wise distribution, 36.7% of subjects were in 50 to 60 years of age, in the experimental group. In the control group 33.3% of subjects were more than 60 years of age. In the sex wise distribution, females were high in both experimental and control group as 80.0% and 83.3%.In Experimental

group majority was educated up to primary education 50.0% (15) and in Control group 63.3% (19) equally educated up to primary education and High School. When considering the type of family most of them belong to nuclear family in both the groups. In both the groups when considering the education status most of the subjects had only primary education.[10]

The present study shows that 30 (60%) subjects are overweight in control group whereas in the experimental group most of the subjects 22 (44%) have normal BMI.

Leelavathi M. (2015) conducted a study on effectiveness buerger'sallen exercise on improving lower extremity perfusion among patients with diabetes mellitus which inferred that most of the patients with diabetes mellitus had B.M.I. of 25-29 (43.3%, 43.3%). Increased BMI was associated with increased prevalence of diabetes mellitus. An increase in body fat is generally associated with increased risk of metabolic diseases such as type II diabetes mellitus.[11]

Data present in the table shows that mean and standard deviation of ABPI score among both groups on Day 1(0.07±0.01), day 2 (0.05±0.02) and day 3(0.19±0.01). There was statistical significance with the p value <0.01.

Dr. Aruna S, Thenmozhi P (2015) conducted a study on effectiveness of allenbuerger exercise in preventing peripheral arterial disease among people with type 2 diabetes mellitus. Experimental Research Design with 30 samples in experimental group and 30 samples in control group were selected by using random sampling technique at Kuthambakkam village. The findings of the study revealed that there is a significant improvement in Ankle-Brachial index Score in preventing peripheral arterial disease among people with Diabetes Mellitus in experimental group after receiving Allen Buerger exercise at the level of P<0.05. Independent t test revealed that there is significant difference between the experimental group and control group in preventing peripheral arterial disease among people with Diabetes Mellitus at the level of P<0.05.[12]

Anju Kumari, Kanika Rai, Vinay Kumari, Dr Jyoti Sarin conducted a study on effectiveness of buergerallen exercise on foot perfusion among patients with diabetes mellitus showed that (50%) patients were suffering from comorbid illness in which 56.6% were suffering from hypertension, 8/30 (26.6%) were suffering from Chronic Kidney Disease (CKD), 1/30 (3.33%) was suffering from CVA, 04/30 (13.3%) were suffering from CAD, and 30/60 (50%) of patients were not suffering from any comorbid illness.[13]

In the present study, the significant difference between the groups and within the groups in ABPI scores in 3 days among patients with type 2 DM which is significant at <0.05.

Jemcy John and A Rathinga conducted a research study showed a significant improvement in the lower extremity perfusion after the Buerger Allen exercise. Data depicts that the mean post- test ankle brachial index score was higher than the mean pre-test ankle brachial index score. The calculated t value was greater than the table value. The computed t value shows that there was a significant difference between the two mean ankle brachial index score.[14]

Mellisha MS conducted a study on effectiveness of buergerallen exercise on lower extremity perfusion and pain among patients with type 2 diabetes mellitus showed that in the experimental group, the mean score of level of lower extremity pain was reduced from 4.33 to 1.30. The reduction of pain was statistically significant difference at 1% level of significance (p=0.001). The mean score of level of lower extremity perfusion was increased from 44.50 to 52 and it showed a statistically significant difference at 1% level of significance (p=0.001).[15]

The above finding clearly indicates that the Buergerallen exercise was found to be an effective on lower extremity perfusion among patients with type 2 Diabetic Mellitus.

Conclusion

The study concluded that the study participants got benefited by Allen Buerger exercise in preventing Peripheral Arterial Disease among patients with type 2 Diabetic Mellitus. Nurses plays a significant role in preventing Peripheral Arterial Disease there by reducing the risk of amputation and restore normal function of the extremity by encouraging them to do the exercise which will help to improve the quality of life. It also suggests that Buerger's exercises could be an alternative procedure on improving peripheral circulation.

Conflict of Interest: There is no conflict of interest for the study.

Source of Interest: Not a funded study.

A Glimpse of Manual Scavanging in India

Shailla Cannie[1], Aasavri Cannie[2]

[1]Dean, Faculty of Nursing, Shri Mata Vaishno Devi University & Principal, Shri Mata Vaishno Devi College of Nursing, Kakryal, Katra, [2]Second year MBBS Student, The University of Georgia, Tiblisi, Georgia

Abstract

Across India, manual scavenging and its allied forms—the manual cleaning of dry latrines, sewers, manholes and septic tanks, abstraction of debris from sewage canals and any interaction with excreta—are openly prevalent, defined as a "cultural vocation". "In India, every five days, a manual scavenger dies in a sewer, septic tank or a manhole," the report verbally expressed. However, its scope was constrained as its primary source of data was statistics from NCSK, which has disarrayed information organised arbitrarily. The few key features of the Act Prohibits the expression or maintenance of insanitary toilets, Prohibits the engagement or employment of anyone as a manual scavenger, Violations could result in a years' imprisonment or a fine of INR 50,000 or both. The press Information Bureau, Government of India, Ministry of Social Justice and Empowerment has verbally expressed that a Task Force was constituted for carrying out a National Survey of manual scavengers in 2018 in 170 identified districts of 18 states. The right technology is considered as one of the solution to eradicate this scourge. In spite of that, the social and gender issues should be abolished by educating pupil about this ill.

Keywords: *Manual scavengers, manholes, insanitary latrines, health issues.*

Introduction

Across India, manual scavenging and its allied forms—the manual cleaning of dry latrines, sewers, manholes and septic tanks, abstraction of debris from sewage canals and any interaction with excreta—are openly prevalent, defined as a "cultural vocation" annexed to a few make-believe lower castes—Hindu Dalits, a few Dalit Muslims and some converted Dalit Christians. In India, this affair is hazardous, unsafe, unsanitary, degraded and above all, illicitly proscribed by Parliament a few years ago. The level of susceptibility increases as we peregrinate from rural to urban areas. However, reports designate that these days; there is incremented fatality in rural India, as well.[1]

The data from the National Commission for Safai Karmacharis (NCSK) revealed appalling facts on the pattern of the deaths of manual scavengers from January 2017 to September 2018 and were widely shared by media houses and convivial media users. "In India, every five days, a manual scavenger dies in a sewer, septic tank or a manhole," the report verbally expressed. However, its scope was constrained as its primary source of data was statistics from NCSK, which has disarrayed information organised arbitrarily.

Manual Scavenger at work–A bitter truth of reality: The two major Acts have been since 1993 by Parliament to ban and control manual scavenging. One of the Act passed by Narsimha Rao Government in 1993 created a history in the legislation banning manual scavenging altogether and aimed at rehabilitation of scavengers followed by passing of another Act in 2013 by UPA II after it was reported that manual scavenging still persists despite a slow progress.[2]

According to the India census of 2011, there are more than 2.6 million dry latrines in the country. Along with that toilets with human excreta flushed in drains is 13, 14,652 and 7, 94,390 dry latrines are cleaned manually. It has as well been identified that seventy three percent of these are in rural areas and twenty seven in urban areas.

The few key features of the Act are

Prohibits the expression or maintenance of insanitary toilets

Prohibits the engagement or employment of anyone as a manual scavenger

Violations could result in a years' imprisonment or a fine of INR 50,000 or both

Prohibits a person from being engaged or employed for hazardous cleaning of a sewer or a septic tank[3]

Offences under Act are cognizable and non-bailable calls for a survey of manual of scavengers in urban and rural areas within a time limit framework. While the Act is encouraging in that it focuses on the duty of official to ensure its implementation, it does not outline administrative measures beyond conduct rules that can be imposed if officials do not implement the Act.

The mundane accidents include falls/slips fire or explosion, oxygen depletion, heat stress, drowning, asphyxiation arising from gas, gas poisoning, vapour and entrapment by free flowing solids. Amongst these hazardous gases etc are facilely overlooked or neglected leading to earnest causalities.[4]

Definition: Manual scavenging refers to the unsafe and manual removal of raw (fresh and untreated) human excreta from buckets or other containers that are used as toilets or from the pits of simple pit latrines.

According to the Indian Law, 1993, Manual scavengers means a person engaged or employed at the commencement of this Act or any time thereafter, by an individual or a local authority or an agency or a contractor for manually cleaning carrying, disposing of or otherwise handling in any manner, human excreta in an insanitary latrine or in an open drain or pit into which the human excreta from the insanitary latrines is disposed of, or railway track or in such other spaces or premises, as the central government or a state government may notify, before the excreta fully decomposes in such manner as may be prescribed, and the expression 'manual scavenging' shall be construed accordingly.[5]

The prohibition of Employment of Manual Scavengers and their Rehabilitation Act, 2013, defines a manual scavenger as an individual employed by a local authority or agency for manually cleaning, carrying and disposing of human excreta from insanitary latrines.[2]

Categories of Sanitation Workers: A caste predicated and hereditary vocation, which is bequeathed, as a legacy from one generation to the next; "manual scavenging" has been an age-old routine for this community, which is untouched by technological advancement in sanitary practices.

i. **Sewer Cleaners:** These cleaners are involved in unblocking and cleaning of the permissive wastewater drains. The work is need based (pluvial season) and infrequently for preventive maintenance. The sewer gas is a complex amalgamation of toxic and non toxic flatulency engendered and accumulated in sewage system by the decomposition of organic home or industrial waste.

ii. **Latrine Cleaners:** They are involved in cleaning the process of evacuating dry/single-pit latrines preferably in rural areas. The process involves daily amassment and convey/evacuating of faecal matter.

iii. **Faecal Sludge Handling:** The scavengers muddled in faecal sludge by emptying, collecting and transporting human waste from septic tanks. The work is carried out on demand. The frequency of de-sludging ranges from six months to 10 years.

India does not even have categorical licit provisions cognate to the management of faecal sludge, additionally called septage in municipal parlance, albeit a number of laws cover sanitation accommodations and environmental regulations.[6]

iv. **Railway Cleaners:** These employees cleans the human excreta i.e. remains of a train that has ended its journey, leftover food, packets and paper boxes

from the track as well as cleaning of the railway toilets. All these activities are carried out several times a day. These workers are employed by private contractors to whom the India Railways has outsourced. Most of the time when the water doesn't get the job done or the drains get clogged, the cleaners have to scoop up the excreta with ply boards using their bare hands without any precautions.[7]

v. **Treatment Plant Workers:** Treatment plant workers maintain and operate sewage and faecal sludge treatment plants on a quotidian footing. Workers are mostly in urban areas spread across India – working in the 527 STPs/FSTPs.[8]

vi. **Community and Public Toilet Cleaners:** These workers are engaged in maintaining the public toilets on daily basis. The workers belong to the rural and urban areas of slums and public convenience shelters. The task of these cleaners (halalkhors) is still the same as of colonial era.[9]

Statistics on Manual Scavengers in India: According to the findings of the socio-economic and caste census, 2011, the Ministry of Rural Development (Government of India) has revealed that that a paramount number of manual scavengers were analyzed in the state of Maharashtra followed by Madhya Pradesh at second position. The other states in the line of higher number are Jammu and Kashmir, Karnataka, Tripura, Punjab, Uttar Pradesh, Daman and Diu, Bihar. The census has as well acknowledged that Tamil Nadu, Kerela, Goa, Andhra Pradesh, Telengana, Gujrat, Assam and Manipur have no manual scavengers. These statistics are based on the number of households in the states. This survey communicates that India has 18.06 lakh manual scavengers in the country.[10]

The press Information Bureau, Government of India, Ministry of Social Justice and Empowerment has verbally expressed that a Task Force was constituted for carrying out a National Survey of manual scavengers in 2018 in 170 identified districts of 18 states. The national Survey concluded in 163 of the 170 identified districts. A total of 50,644 persons registered themselves in the survey camps. It was claimed that 20,596 persons have been accepted after identification with subsequent verification as manual scavengers. Data of the identified manual scavengers is being digitized in National Safaikaramcharis Finance and Development Corporation. Besides that the data of remaining 11,757 manual scavengers were digitized upto October 2018. Onetime cash assistance has been relinquished to 8438 identified manual scavengers.[11]

Schemes Available for Manual Scavengers: The National Safai Karamcharis Finance and Development Corporation (A Government of India undertaking the Ministry of Social Justice and Empowerment) introduced Self Employment Scheme for Rehabilitation of Manual Scavengers (SRMS) and their dependents in alternative occupations by 2009. According to the updated number announced by States/UTs, 1.18 lakh manual scavengers and their dependents in 18 States/UTs were determined. One from each family of the identified manual scavenger is eligible for receiving cash assistance of Rs. 40000 immediately after their identification. The beneficiary is sanctioned to withdraw an amount of Rs. 7000 maximum in monthly instalments.

The quantum of loan upto a maximum cost of Rs. 10 lacs is permissible under this scheme and a sum of Rs. 15 lacs in case of sanitation related projects such as vaccum loader, suction machine with vehicle, garbage disposal vehicle etc. which are immensely compatible for target group with high success rate and income. The moratorium period is of two years. The repayment mode is of five years including the period of moratorium for the projects upto five years.[12]

Beneficiaries can as well avail the facility of subsequent loan from banks, if needed without capital and interest subsidy.

The training is administered to the beneficiaries for gaining new skills and entrepreneurship capabilities. The training is being provided by govt. agencies/Institutions along with the reputed specialized training agencies. The training is given as per their level of education and aptitude.[12]

Remedies: The solution, it seems, is a public-private partnership. Collaboration would work best because it would ravage the mafia of private cleaners, making them accountable

It was also found that some scavengers have endeavoured to challenge their social and economic status by transmuting their jobs. But determinately, they have to return to their pristine profession because of a social boycott and the lack of foothold from both private and governmental agencies. The law and order machinery has additionally proved inefficient.

Eradication of manual scavenging needs to be worked out on war footing. A mission for total eradication of manual scavenging and rehabilitation of manual scavengers needs to be set up and implemented by the government.

The right technology is considered as one of the solution to eradicate this scourge. In spite of that, the social and gender issues should be abolished by educating pupil about this ill.

The sewage handlers come across with multiple health issues such as respiratory and skin diseases, anaemia, jaundice, carbon monoxide poisoning and sometimes leads to death. The health issues should be taken care by the agency and safety equipments to be provided before handling. Vaccination against hepatitis A, E-Coli, Rotovirus, Norovirus must be administered to these workers to avoid deaths at young age of their life.

The construction of toilets under Swachh Bharat Mission on a large-scale was built under single pit toilets but the cleaning of these excreta is carried out by manual scavengers. Therefore, a technology based structure should be introduced to dispose of waste and reduce the figures of manual scavengers.

Out of Pocket Spending for Natal Care Services: A Comparative Analysis among High and Less developed States in India

A.K. Ravisankar

Assistant Professor, Department of Population Studies, Annamalai University, Tamil Nadu

Abstract

In this paper attempt is made to assess the expenditure incurred on natal health care services in India at two different socio-economic settings. Data for the analyses are drawn from the 71st round of NSSO held in 2014. A logistic regression model used to assess the determinants such as socio-economic and demographic indicators on expenditure incurred for natal care services. It is found that a major proportion of respondents spent money for their natal care however a wide difference was noticed between high and low HDI states in India. The average amount spent from their pockets for natal care services was Rs.6,685/- for high HDI states. It was almost double times higher than the low HDI sates' expenditure incurred for natal care (Rs. 3,400). The results of the logistic regression analysis on expenditure incurred for natal care is positively and significantly associated with all the socio-economic, demographic variables (except age, religion). In India, the natal health care services are offered free, yet many families' average out of pocket natal health care expenditure incurred was relatively high, however, a wide variation is witnessed among high and low HDI states. Hence, it is suggested to increase the share of state's expenditure on healthcare, especially those states which are socially and economically backward states, to reduce the state differences in the country on health outcomes.

Keywords: *Natal care, out-of-packet expenditure, wealth index, Human Development Index.*

Introduction

In many developing countries, household out-of-pocket (OOP) spending on health constitutes a significant share of total health care expenditure. The WHO estimates, that globally, private expenditure on health in most countries is approximately 1.5 to 3.0 percent of their Gross Domestic Product[1]. In much of the Asian region, public funding of healthcare is low, forcing most households to pay essential healthcare bills out of their pockets. These payments hit the poor particularly hard[3]. Globally, the affordability costs of treatment are known to be a major barrier in accessing essential care, potentially imposing considerable burdens on households[2].

The progress in improving maternal health, as envisaged in the UN MDGs, critically depends on the availability, affordability and effective use of reproductive health services[3]. In India, out-of-pocket expenses made up over 70 percent of the total health expenditure[4]. The total health expenditure constituted 4.1 percent of GDP of India (2009), with private and public sectors accounting for 78 percent and 20 percent respectively[5]. These additional expenses not only deter women from accessing health care services but also push households further into poverty[6,7,8,9]. Peters estimated that a quarter of the Indian population fall into poverty as a direct result of the medical expenses incurred through hospitalisation[10].

The expenses incurred during child bearing also varied with the place of antenatal care (ANC), indicating that the contact with private facility at any stage of pregnancy will increase cost per delivery[11]. Studies on OOPE[12], [13] established the fact that out of pocket expenditure on health care services is a significant factor in choice of the institutional facility for ante-natal and delivery care in India. Van DE and others found that Out of pocket payment is the main source of financing health care throughout Asia, more than 72 percent of

expenditure on health care is financed by out of pocket in India[14].

Studies conducted by Mukherjee et al. (2013) and Douangvichit et al. (2012) on OOP expenditure consistently report higher expenditure for deliveries conducted in private health care centres and for complicated deliveries and caesarean deliveries [15, 16]. There are some hidden costs like - transportation cost, medicines, and other expenses, which also affect the utilisation of reproductive health care services. Some studies found that cost of travel, drugs, and hike in fees structure are negatively related with utilisation of health care services[17]. Saraswati Kerketta (2015) found that there were differentials between public and private health facilities in terms of out of pocket expenditure on maternal care services in India[18]. Under this backdrop here an attempt is made to assess the expenditure incurred on natal health care services in India at two different socio-economic settings. The specific **objectives** of the research paper are

- to understand the socio, economic and demographic characteristics of the study population in high and less developed states
- to examine the expenditure pattern of the respondents on natal care services at two different HDI settings
- to explore the relationships between socio-economic and other characteristics of households and natal health care expenditures in different settings of India

Data Method: Data for the analyses are drawn from the 71st round of the National Sample Service Organization held in 2014. Though the survey covered the whole of the Indian Union, this study made an attempt to classify the states into two different socio-economic settings by using the 2011 Human Development Index. The top five HDI states were grouped as High HDI states viz Kerala, Punjab, Himachal Pradesh, Maharashtra and Haryana. The bottom five HDI states were grouped as Low HDI states such as Orissa, Bihar, Chhattisgarh, Madhya Pradesh and Jharkhand. Totally 7,004 women (3285 from High HDI states and 3719 from Low HDI states) who had get pregnancy during the last 365 days were considered for this analysis.

Background characteristics of the sample population: Age distribution of the sample population discloses a slight difference between high and low HDI states. The proportion of ST population among low HDI states was three time higher than the high HDI states (19.5 and 6.4 percent respectively). The illiterate proportion was around four times higher among low HDI states than the low HDI states (30.7 and 8.3 percent respectively). The regular wages/salary earning people was relatively high in high HDI states (42.7 percent) than the low HDI states (29.9 percent). More than one-third of the high HDI states' respondents were fall in the richest wealth (35.8 percent) whereas this proportion for low HDI states was just 5.6 percent.

Payments incurred for Natal care: It is inferred that there is wide difference was noticed between high HDI states and low HDI states with regard to pocket payments on natal care services. Of the 3,094 households who made payment for natal care in the high HDI states, little less than one-fifth of the households spent up to 1,500 rupees for natal care (19.0 percent) and at the same time more than two-fifth of the households in this group spent above 5,000 rupees for natal care services (46.0 percent). The corresponding percentage for the low HDI states was 36.3 percent and 23.8 percent respectively. Overall, the average amount spent from their pockets for natal care services for high HDI states was Rs. 6,685. It was almost double times higher than the low HDI sates' expenditure incurred for natal care (Rs. 3,400).

Table No. 1: Percentage distribution of women by payments incurred for Natal care in High and Low HDI states

Expenditure Incurred (in Rs.)	High HDI		Low HDI	
	%	Total	%	Total
Total expenditure incurred on Natal care* 427.687**				
Up to 1,500	19.0	588	36.3	1148
1,501-3,000	16.5	512	23.2	732
3,001-5,000	18.5	572	16.8	530
Above 5000	46.0	1422	23.8	751
Total	100.0	3094	100.0	3161
Average amount spent (in Rs.)	6685.86		3400.70	

***Refers to significant at 1% level (chi-square results–Expenditure incurred and different HDI states)

Socio-economic and demographic determinants of out of pocket payments for Natal care services: Irrespective of age groups, more than two-fifth of the high HDI states' households was spent above 5,000 rupees for natal care from their pockets. It ranges from 51.5 percent among 30-34 age group to 42.5 percent among 20-24 age group. On contrast, less than one-fourth of the households in the low HDI states incurred above 5,000 rupees for natal car, irrespective of age groups. It is inferred that while age increases, the amount spent for natal care also increase. However, a wide variation was witnessed between high and low HDI states.

Amongst the socio-economic characteristics, place of residence has been found to have the strongest association with the pocket payment for natal health care services. More than half of the urban women who fall in the high HDI states were spent above 5,000 rupees for natal care (52.8 percent). On contrast, just one-third of the respondents in the low HDI states were paid above 5,000 rupees for natal care services (32.7 percent). Religion of the respondents and the pattern of payment incurred for natal care analysis show a strong association among the high and low HDI states. Caste of the respondents can also be an important determinant of the expenditure incurred for natal health care. Both at high and low HDI states, ST population spent for natal care was quite low than the rest of other caste population. However a wide difference was noticed between high and low HDI states' sample population. As educational level of respondents increases, their amount incurred for natal care also increases, irrespective of HDI status. However, a wide difference was noticed between high and low HDI states. A similar observation was noticed with respondents' occupational status at both the HDI settings and at the same time a wide difference also noticed between high and low HDI states.

There is a steady increase in proportion of rural women who spent more money (above Rs.5,000) from 22.7 percent among poorest wealth index women to 34.2 percent among women living at middle wealth index then to 53.2 percent among richest wealth index women in the high HDI states. The corresponding figures for urban high HDI states were 34.7 percent, 48.2 percent and 72.6 percent respectively. A similar increase also noticed among the low HDI states; however the proportions were ranged between 13.1 percent in poorest group to 38.8 percent for richest group among rural women and it ranged from 22.4 to 67.9 percent respectively. The bivariate analysis shows that the women's age, place of residence, caste, educational status, occupation, wealth index and outcome of pregnancy are is significantly associated with the expenditure incurred for natal care both among high HDI states and low HDI states. It is inferred from the analysis on average expenditure incurred for natal care that Kerala state stood at top with Rs. 9,114/- which is the highest spending state among high HDI state. The lowest amount spent for natal care among the high HDI state was Himachal Pradesh with Rs. 3,929/-. On contrast, the maximum amount spent for natal care services among low HDI state was Orissa with Rs. 4,187/- The least amount was recorded by Chhattisgarh with Rs. 2,393/-.

In order to determine the association between each independent variable and the expenditure incurred for natal care, two statistics of the model are used. The results of the logistic regression model (separately for HDI groups as well for rural and urban) comparing households who spent less money (less than 1,500/-) with those of household spent more money (above 1,500/-) (Less money = 0; More money = 1).

The results of the logistic regression analysis on less money spent with those of more money spent for natal care show that households which spent more money is positively and significantly associated with caste, educational status, wealth index and states variables among rural sector both at high and low HDI states. All the variables the odds increase with the categories of a variable when compared to the respective variable's reference category, indicating an increase in expenditure incurred when improving the background conditions of women. This model (rural) also shows that the age, religion, and occupation were insignificantly determining the expenditure incurred for natal care services both at high and low HDI states. A similar observation was noticed for urban high HDI states.

Table 2: Odds ratios from logistic regression examining the effect of selected background variables on expenditure incurred for natal care by place of residence

Conclusion

Though Government of India has been running lot of schemes for availing free of cost maternal health services but still one has to pay from their pocket as medical expenses. This paper also found that the average out of pocket natal health care expenditure incurred during delivery was relatively high particularly for high HDI states. In the multivariate regression analysis, as in the bivariate analysis, women's caste, education, and wealth index variables are continued to be strong predictors of the expenditure incurred for natal health care services. Above all, it is found from the analysis that there is a wide variation between two different socio-economic settings on payments incurred for natal care. Hence, particular attention should be paid to women living in low standard of living condition. In the light of the above discussion it can be suggested that poor people can be protected from maternal health expenditures by reducing a health system's dependence on out-of-pocket payments and to develop social insurance system. In addition, IEC activities must be given more emphasis, so that the under served population may also make the use of currently running health schemes, which may reduce the burden of expenditure. Apart from that the incentives provided to the beneficiaries' mothers must be revised from time to time based on inflation and growth rate. Finally, this research finding suggest to increase the share of state's expenditure on healthcare, especially those states which

are socially and economically backward states, to reduce the state differences in the country on health outcomes.

Abstract

Background: Alzheimer's disease (AD), a category of neurological degeneration generally seen in elderly people which is reflected by memory loss and affecting daily living activities.

Method: The data has been accessed from scopus, pubmed, science-direct and google-scholar which is included in this article.

The literature provide the information about pathological alterations of Alzheimer disease emphasizing on formation of neuritic plaques, beta amyloid protein, neurofibrillary tangle and also updates therapeutics used in Alzheimer's disease including cholinesterase inhibitors, ACE inhibitors, NMDA receptor antagonists, secretase inhibitors and anti-inflammatory drugs, herbal drugs and other naturals.

Results: The research on neuropathology and diagnosis of Alzheimer's disease are determinants of this study. The pathophysiology, diagnosis using biomarkers and therapeutics of disease has been summarized.

Conclusion: The aim of this review paper is to focus on how diagnosis and pharmacotherapy of Alzheimer's disease useful for researchers engaged in the experimental research.

Keywords: *Alzheimer's disease, β-amyloid precursor protein, neurofibrillary tangles, Acetylcholinesterase inhibitors, Secretase inhibitors, biomarkers.*

Introduction

Alzheimer's disease (AD) is approved as a chronic, irreversible neurodegenerative disorder in many countries which produces various cognitive impairments in old people. Alzheimer's disease (AD) is indicated by memory loss and cognitive impairment which affect daily living activities. With an increase in the geriatric population in India, quantities of AD patients are increasing step by step[(1)]. The neuropathologists had distinguished 64 instances of amyloid plaques and NFTs, a cause of disease, at the time of Dr. Alois Alzheimer, in autopsied brains of AD individuals[(2)]. The extracellular deposition of Ab called Amyloid plaques; saw in parenchymatous cells of brain and furthermore in cerebral blood vessels called cerebral amyloid angiopathy (CAA)[(3)].

Currently such medications are approved by USFDA (US Food and Drug Administration), including five medications those are utilized for the treatment

of cognitive manifestations of AD. NMDA receptor antagonist–memantine (Namenda) donepezil (Aricept), AChEIs –rivastigmine (Exelon), tacrine (Cognex) and galantamine (Razadyne, Reminyl) are drug of choice as per indications[4].

Pathophysiology of Alzheimer's Disease: In 1907, AD is known to treat subsequent to recognizing the pathophysiology of AD when neuropathological features of this disease observed and described by amyloidal plaques and hyperphophorylated NFTs and different hypotheses have been proposed[5] (Fig. 1). In last decade, it has been suggested that commonly used Ab hypotheses is responsible for complex pathophysiology of growing disease[6].

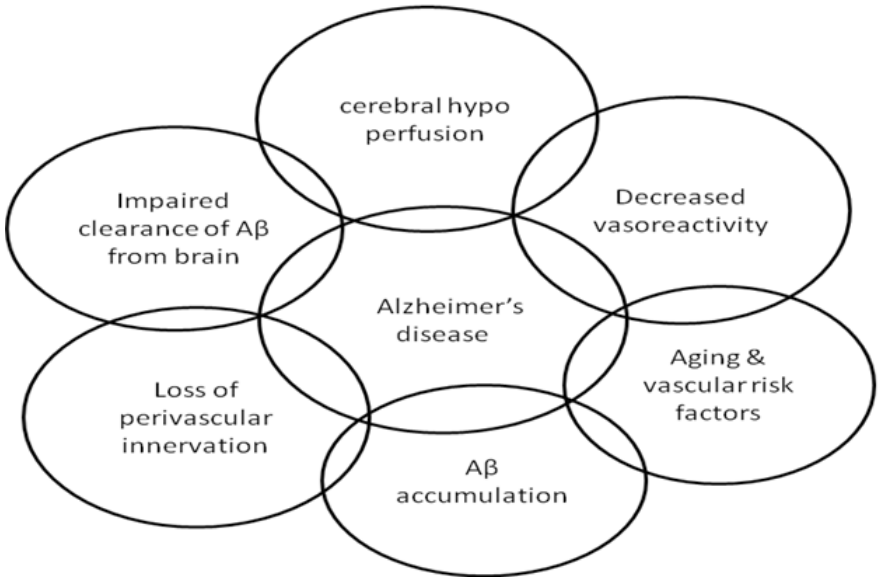

Fig. 1: Various pathophysiological processes causing Alzheimer's disease (AD)

In late stage, development of amyloid plaques is appeared in the older age of patients[7]. The breakdown of APP is occurred by α-secretase which is further by action of β-and γ-secretases in amyloid cascade hypothesis[8]. The activities of neurons and their related astrocytes are responsible for production of Ab42 oligomers. The cytokines like IL-1b, TNF-a, and IFN-g stimulate neighbour astrocyte-neuron which produces Ab42 oligomer[9]. Working of neuron–astrocyte complex is affected by oligodendroglia (OLGs) which are destroyed by Ab oligomers[10]. The aggregation of Ab oligomers also induces degeneration in neurons of AD patients[11]. It was proposed that receptor pharmacology of Ab activates neuroprotectiion mediating Ab42 monomers through signaling pathways of mediating receptors[12].

Use of Biomarkers in alzheimer's Disease: The cholinergic hypothesis of AD mechanism stipulates that most of cognitive manifestations are a result of cholinergic dysfunction[13].

Early Detection Strategies via Biomarkers: The magnetic resonance imaging and fluorodeoxy-glucose positron emission tomography determine hippocampus atrophy and cortical hypo-metabolism in AD progression. Advancements in science, radiology and system biology promotes use of biomarkers in AD research[14].

Biomarkers Using Cerebrospinal Fluid: Scientists have determined levels of Ab-42 peptide by knowing and total phosphorylated Tau protein (t-tau and p-Tau) and by estimating cerebrospinal liquid (CSF) which is responsible for neurodegeneration in AD. All three parameters have been proposed as one of the prevailing biomarkers for this disease which is independent of the apo-lipoprotein E (APOE) genotype [15]. The accuracy in AD symptoms and combining CSF Ab with either t-tau or p-tau level[16].

Biomarkers Using Imaging Techniques: Beta-amyloid load in the brain can be estimated through

positron emission tomography (PET) using amyloid ligands such as Pittsburgh compound B (PiB), florbetapir (AV-45). Amyloid PET is considered a strong biomarker which was incorporated in 2011 and re-evaluated by National Institute on Aging-Alzheimer's Association diagnostic criteria for AD. In spite of being an amazing screening instrument in clinical trials, there is as yet limited evidence as a diagnostic tool for AD in clinical practice [17].

Biomarkers Using Genetic Screening: Early AD was related with special autosomal dominant mutations in amyloid precursor protein (APP), and/or presenilin 1 (PSEN1), or presenilin 2 (PSEN2). At present, genetic testing for both PSEN1 and PSEN2 lay down in one family member with early-beginning of AD[18]. Lanoisele´e et al. observed the occurrence of AD, proposing potential advantage of screening non-familial cases of AD for these mutations[19]. Late-onset AD is most normally connected with APOE4 allele which is situated on chromosome 19q13.2 including regulation of Ab aggregation and clearance [20]. Besides, carriers of this allele have a lower onset of disease and more hippocampal atrophy in dose-dependent manner [21].

Strategies Used for Treatment of AD: Currently available medications N-methyl d-aspartate receptor antagonist (Memantine), acetylcholinesterase inhibitors (Rivastigmine, Galantamine, Donepezil) in the various stages of disease[22]. In AD, deletion of amyloid beta protein deposition is one of the most favorable targets for treatment.

Anticholinesterases: The drugs can change cholinergic neurotransmission, have been approved from regulatory authorities for Alzheimer's therapy [23]. Three ChEIs like Donepezil, Rivastigmine and Galantamine. Donepezil and Galantamine are usually used to get patients with mild to moderate AD. Rivastigmine inhibits both Acetyl cholinesterase and Butyryl cholinesterase associating the degradation of Acetyl choline[24].

NMDA receptor antagonist (Memantine): Memantine is a newer medication used in treatment of moderate to severe dementia. Its mechanism of action is a voltage-dependent, low-moderate affinity, uncompetitive NMDA receptor antagonism[25]. Memantine blocks abnormal glutamate activity which causes neuronal cell death and cognitive dysfunction[26].

Angiotensin-converting Enzyme (ACE) inhibitors: It has been seen that ACE inhibitors decrease aggravation in brains of AD patients [27]. The mechanism includes transformation angiotensin I to angiotensin II. Another possibility is that angiotensin II is converted to angiotensin III after that to angiotensin IV. Angiotensin IV binds at AT_4 receptor sites, which are most predominant in the neocortex, hippocampus, and other areas and improves learning and memory [28].

Nonsteroidal Anti-inflammatory Drugs: Most researches on nonsteroidal anti-inflammatory drugs have concentrated on prevention instead of treatment of AD[29]. Animal models have exhibited that anti-inflammatory cyclooxygenase-2 (COX-2) inhibitors (Rofecoxib) reduced oxidative stress yet nonspecific COX inhibitors (Flurbiprofen and Ibuprofen) [30].

Secretase Inhibitors: Secretases are enzymes forms plaques by breaking APP of cell membranes into βA fragment. Memoquin, an example of β-secretase inhibitors reduce βA production by inhibiting AChE and limits tau hyperphosphorylation in early developmental stage [31].

Herbal Drug Treatment:

Polyphenols e.g. Resveratrol found in red wine, peanuts and other plants, has been used to reduce oxidative stress, inflammation, βA and protect DNA thus, decrease in cell death. A moderate utilization of red wine decreases the danger of growing AD [32].

Curcumin obtained from turmeric is used in AD treatment. Curcumin has neuroprotective, anti-inflammatory, antioxidant activities and cause inhibition of βA formation and clearance of existing βA [33].

Ashwagandha (also known as *Withania somnifera)* proposed to have neuroprotective, anti-inflammatory, antioxidant, AChE inhibitoy, βA inhibitory activities which decrease in cell death[34]. It has been found that its oral use reversed damage to hippocampus and brain cortex by diminishing neurite atrophy, restoring synapses and improving memory in mice ([35].

Nutrients and Hormones:

Alpha-lipoic acid acts as a prevailing micronutrient with various pharmacological and antioxidant properties[36]. LA has been proposed to have anti-dementia in AD by altering antioxidant protective enzymes[37].

Polyunsaturated fatty acids like omega 3-fatty

acids (FAs), docosahexaenoic acid (DHA) found in high levels in the mammalian brain, neuronal membranes and myelin sheath. Their actions were observed by enhanced receptor binding and function of ion channels[38]. The cognitive impairment occurs due to diminished serum DHA levels which obstruct learning and memory[39]. As a result, the scientists have explored possibility of DHA supplement utilization may decrease risk of progression of AD[40].

Vitamin B_{12} and folate in low levels are shown to result into cognitive decline. AD patients have high levels of homocysteine which need to become low. Homocysteine levels seem to relate with aging but not with cognition. A combination of vitamins B_{12} and B_6 and folate brought down homocysteine in people with mild to moderate AD[41].

Retinol commonly known as Vitamin A is essential for learning, memory and cognition. Vitamin A levels in the brain decline in AD people, therefore its need to improve. A metabolite of vitamin A, retinoic acid is known to slow cell death and protect from βA[42].

Lithium Compounds are prescribed for some neurodegenerative disorders. Enhancement of bcl-2 levels (neuroprotective protein) in hippocampus and frontal cortex of the rat has been observed. It also inhibits GSK-3, which is involved in increasing levels of phosphorylated tau and believed to be a factor prompting βA plaques and cell death [43].

Melatonin has antioxidant, anticancer properties and also protects mitochondria against tau tangles and also reduces βA toxic effects [44].

Conclusion

The evidences have been proposed to suggest that Aβ has pivotal role in the pathogenesis of AD, which involves many complex secondary events in the disease. Novel developments like radiology, chemistry and system biology involved use of biomarkers to identify mechanism. Enormous development has proposed to make various strategies for AD treatment including anti-inflammatory, antiamyloid, secretase inhibitor, antihypertensive, cholinesterase inhibitor, and some natural nutrients and hormones.

In this paper, authors have discussed the current research on diagnosis and pharmacotherapy of Alzheimer's disease which may be fruitful for researchers engaged in the experimental research.

Abbreviations: AD, Alzheimer's disease; ACh, acetylcholine; AChRs, acetylcholine receptors; AChEs, acetylcholinesterase; AChEIs, acetylcholinesterase inhibitor; ApoE, apolipoprotein-E; βA, beta amyloid; β-APP, β-amyloid precursor protein; NMDA, N-methyl d-aspartate.

In Vitro Anticancer Study of Bioactive Compound Isolated from Musa Extract (Musa Acuminata)

Arunava Das[1], J. Bindhu[2], P. Deepesh[3], G. Shanmuga Priya[3], S. Soundariya[3]

[1]Associate Professor, [2]Research Associate cum Assistant Professor, [3]III Year Biotech Students, Molecular Diagnostics and Bacterial Pathogenomics Research Laboratory, Department of Biotechnology, Bannari Amman Institute Technology, Sathyamangalam, Erode District, Tamil Nadu, India

Abstract

Banana tree being one of the most economically important tree worldwide is cut once the fruits are harvested. However other parts of the tree are used in medicine worldwide. In this study, the flower extract of *Musa acuminata*is extracted by maceration with methanol and the phenolic and aliphatic compounds present in the flower extract is identified using GC-MS analysis. Phytochemical screening of the banana extract showed the presence of alkaloids, phlobatanning, triterpanoids, flavanoids, lipids, steroids and terpenoids. Potent antibacterial activity is observed from the flower extract against the tested gram positive and negative bacteria. Anticancer activity of the flower extract is assessed on the cervical cancer cell line HeLa. MTT assay is used to evaluate the antiproliferative effects. This study concluded that the economically important *Musa acuminata*is widely used in anticancer studies worldwide.

Keywords: *Musaacuminata, Phenolic compounds, GC-MS analysis, Phytochemical screening, Antibacterial activity, MTT assay.*

Introduction

Recently, *Musa sp*, (Musaceae) also known as Banana has evolved to be one of the largest herbaceous flowering plant recognized by the world. *Musa sp*, being a most popular fruit are widely exported to a number of industrialized countries [1]. Tropical and sub-tropical regions of the world consume more banana in common. Having south western pacific as native, banana is recognized as a tropical fruit.[2] Almost every part of banana plant has got its own significant use that is useful to mankind in many aspects. Being highly polymorphous *Musa acuminata* is spindly plants that are grown in clumps. Musa species is widely used in medicinal and traditional food. The optimum temperature for the growth of *Musa acuminata* is 80˚F (26.67□) and the optimum mean rainfall is 4 in (10 cm) per month.

Being under the kingdom Plantae and coming under the order Zingiberales it belongs to the family Musaceae having genus Musa has a wide range of sub species. It is a perennial monocotyledonous herb. Musa is an bisexual flower having each spathe encloses 2 rows of flowers, upper spathe enclosing male flowers, lower spathe enclosing female flowers, and few middle spathe with bisexual flowers. The flowers are tricarpellary, syncarpous, ovary inferior, placentation axile, style long, stigma capitated. [3] It takes approximately 28 days for *Musa acuminata* for anthesis, 2 to 3 weeks after plantation.

It has high protective action and is widely used to prevent food spoilage. The blossoms of banana to a wide extent is considered as a vegetable and is cooked in various dishes [4]. It is helpful in muscle contraction and response of nerve cells. The banana also enables the stabilization of blood pressure. Being known for its eternal evergreen, Musa species, are widely used for ornamental purposes.

Musa species, highly known for its medicinal purposes is beneficial to mankind. Heart pain, asthma, endocrine problem like diabetes can be treated by the flowers of banana. Stomach cramps and diarrhoea can be treated by consuming banana leaves. Menses pain and bleeding due to menopause can be reduced by the uptake of banana leaves by women. Infantile malnutrition and weak body can be suppressed with the help of banana blossoms. Antioxidants are components that reduce the oxidative stress level by prevention of free radicals from damaging DNA, proteins and lipids. Being a weak primary antioxidant source, *Musa acuminata* has proven to be a powerful secondary antioxidant source[5]. Ascorbic acid, beta carotene, phenolic groups, dopamine are the antioxidant compounds found in *Musa acuminata*. Being a good source of bioactive phytochemicals *Musa acuminata* provide opportunities for functional food industry.

Methodology

Identification and Handling of Sample: Arid flowers of *Musa acuminata* were collected from Sathyamangalam forest. Using plastic bags, the flowers collected were transferred to lab. The powdered and sieved arid flowers are finely powered and is stored in the Non-toxic- polyethylene bag.

Plant Extract Preparation: 10 gm powder mass was extracted using 200 ml Methanol solvent. Dark maceration for 72 hours at 27˚C was considered for the extraction process and muslin cloth was used for filtration. The pasty layer of extract was formed after the filtrate was condensed at 45˚C which were used for further assays.

Phytochemical Screening:

Test for alkaloids: To 3 ml of the extract 1 ml of Mayer's reagent was added and shaken well, presence of Alkaloids was indicated by the white precipitate at the bottom.[12]

Test for phlobatannins: 10 ml of aqueous extract of flower was boiled with 1% HCl. Presence of phlobatannins was indicated by the thick red precipitate deposition in the bottom.[12]

Test for triterpenoids: Salkawasaki Test was used to indicate Triterpenoids in the extract in which 2 ml of extract was taken and 5 drops of concentrated sulphuric acid was added, shaken and allowed to stand. Presence of triterpenoids was indicated by the appearance of greenish blue colour.[12]

Test for flavonoids: Alkaline reagent was used to indicate the presence of flavanoids in the extract. To 1 ml of the extract few drops (3 drops) of 10%NaOH solution was added, flavonoids was indicated by intense yellow colour, which disappeared on addition of a few drops of dilute acid.[12]

Test for lipids: To 10 ml of the extract 0.5 N alcoholic potassium hydroxide was added along with a drop of phenolphthalein. The mixtures were heated on water bath for 1 hour. The presence of lipids was indicated by the formation of foam or soapy layer.[12]

Test for steroids: To 5 ml of aqueous extract 2 ml of chloroform and few drops of concentrated H_2SO_4 was added. The presence of steroids was indicated by the appearance of red colour in the upper layer while yellow with greenish fluorescence appears in the H_2SO_4 layer.[12]

Test for terpenoids: To 1 ml of the aqueous extract 1 ml of chloroform was added and mixed well and left for 5 minutes, 1ml concentrated H_2SO_4 was added after 5 minutes. The presence of terpenoids was indicated by the appearance of greyish layer.[12]

Antioxidant Assay: The antioxidant capacity of *Musa acuminata* was identified through 2,2-Diphenyl-1-picryhydrazyl (DPPH) assay. Equal volumes samples at different concentrations were with 0.1 mM of DPPH. Then the mixture was stored in dark place for 30 minutes. The colour change from violet to yellow indicated the presence of antioxidants. Quantification was calculated by absorbance. The absorbance was performed in triplicates. Ascorbic acid was used as the standard to compare with samples and IC50 (inhibition concentration) was calculated for both sample and standard. The percentage of inhibition was calculated using the following formula.

$$\% \text{ of inhibition} = [A_0\text{-}A_1/A_0] \times 100$$

Where A_0 is absorbance of control (i.e., DPPH solution without sample) and A_1 is absorbance of sample or standard (i.e., DPPH solution with sample/ standard)[12]

GC-MS: The sample was subjected to GC-MS analysis to quantify the number of molecules and its structures. The analysis was carried out using GCMS (Perkin Elmer model: Clarus 680) and also it is equipped with mass spectrometer (Clarus 600(EI) analysed using (TurboMassver5.4.2) software. Fused silica which is packed with Elite-5MS. At a constant flow rate about 1 ml/min, carrier gas such as helium was used to separate the components. The temperature of the injector was adjusted to 260˚C while performing the experiment. The extract sample of 1µL was injected was into the equipment the temperature of the oven were 60˚C(2mins); followed by 300˚C at the rate of $10^{\circ}Cmin^{-1}$; and 300˚C for 6 mins. The conditions of the mass detector were: the temperature of transfer line was 240˚C: and ionization mode electron impact at 70 eV, the duration time of scan interval is 0.2 sec and scan interval is 0.1 sec. The fragments from 40 to 600 Da. The spectrum of components was corresponding to the database of the spectrum of established components gathered in the GC-MS NIST library.

Antibacterial Assay: Antibacterial activity was determined by agar well-diffusion method. Swabbing using sterile cotton swabs was done on Nutrient agar (NA) plates with 8 hour old-broth culture of different bacteria such as *Streptococcus agalactiae, Bacillus cereus, Staphylococcus aureus, Enterobacteraerogenes, Eschericia coli, Bacillus subtilis*. In each of these plates wells (10 mm diameter and about 2 cm a part) were made using sterile gel puncher. From the methanolic flower extract 1 mg/ml concentration of stock solution was prepared.30 µl of varying concentrations of flower solvent extracts were added by sterile micropipette into the wells and allowed to diffuse at room temperature for 2 hrs. Inoculums without plant extract were set up for control experiments. Incubation of the plates is done at 37˚C for 18-24 h for bacterial pathogen. The zone of inhibition was observed and the diameter of the inhibition zone (mm) was measured and the experiment was also calculated. Triplicates were maintained and the experiment was repeated thrice, for each replicates the readings were taken in three different and the average values were recorded.

Cytotoxic assay (MTT method): The sample was performed with an in vitro Cytotoxicity test method. The culture medium from the Hela cells was replaced with fresh medium. The triplicates of the test sample were added on the cells. Incubation at 37°C for 18 hr was done. After incubation MTT (1 mg/ml) were added in the wells and incubation was done for 4 h. DMSO were added in the wells after incubation and read at 570 nm using photometer. Cytotoxicity and cell viability were calculated by

$$\text{Cytotoxicity} = [(\text{Control-Treated})/\text{Control}]\times 100$$

$$\text{Cell Viability} = (\text{Treated}/\text{Control})\times 100$$

Result and Discussion

The chemical composition of the extract was studied using GC-MS analysis. The peak was identified as pentanoic acid, 2-(aminooxy)- an aromatic phenolic group of salicylic acid at a retention time of 26.508. The next compound was identified as 1,3-bis-t-butylperoxy-phthalan belonging to aromatic phenolic group of salicylic acid giving a peak at 27.663 retention time. The next peak was observed at 29.364 retention time which was identified as 1,2-pentanediol, 5-(6-bromodecahydro-2-hydroxy-2,5,5a,8a-tetramethyl-1-naphthalenyl)-3-methylene that belongs to the aromatic phenolic groups of salicylic acid. The final peak was observed at 29.544 retention time and the compound was identified as carpesterol dehydrate an aromatic phenolic group of salicylic acid compound.[6] The GCMS analysis result for major phytocomponents in*Musa acuminata* flower is given in Table 1. Chromatogram of compounds present in *Musa acuminata*is represented in Figure 1.

The crude extract of *Musa acuminata* was obtained from maceration with 80% methanol. Antibacterial assay of the flower extract against gram positive and negative bacteria were determined by the formation of zone of inhibition around the wells. The negative control (methanol) showed zero zone of inhibition. Larger zones of inhibition were observed on the plates with 20 µg/ml of Ampicillin (antibiotic) to the methanolic extract tested. The zone of inhibition of *S.aureus* shows greater diameter of 10mm over the flower extract while the zone of inhibition of other bacterial strains ranges from 5mm to 8mm. The antibacterial activity that is the formation of the zone of inhibition in the agar well diffusion method is due to the presence of active compounds in the flower extract.[7-12]Different Bacteria and its zone of inhibition is tabulated in Table 2.The phytochemical constituents of *Musa acuminata*flower extract is tabulated in Table 3.

The MTT assay resulted in the sample showed Slight to Severe Cytotoxic reactivity to Hela cells. The cell death was increased with increase in concentration on the sample. Another experimental study of anthocyanin extracted from *Musa acuminata* bract showed a strong anticancer activity against of MCF-7 cell lines(Breast cancer)[13-15]. Another experimental result tested against carcinoma of cervix (HeLa) showed increased effect on a dose-dependent manner against the extracts from rhizome of *Musa acuminata*.[16-17] The control gave no cytotoxic reactivity.The activity of sample at different concentrations against the cells are displayed in Figure 2, the cytotoxicity is represented in Figure 3 and the cytotoxic reactivity of *Musa acuminata* flower extract displayed in Table 4.

Conclusion

This study shows us the compounds present in *Musa acuminata*. *Musa acuminata* is rich in phenolic compounds as per this study. Phytochemical study of the extract revealed the presence of certain group of compounds. *Musa acuminata* acts as good antimicrobial agent since it shows a significant inhibition zone against some bacteria. Further Musa extracts acts as good antioxidant sources. Musa extracts are also involved in anticancer studies in medicinal field.

Optimized Feature Selection and Classification in Microarray Gene Expression Cancer Data

B. Lakshmanan[1], T. Jenitha[1]

[1]Department of Computer Science and Engineering, Mepco Schlenk Engineering College, Sivakasi, Tamil Nadu, India

Abstract

Cancer classification can be performed by Microarray Gene Expression data which comprises of thousands of genes and small number of samples. Gene expression data is efficient method for finding which gene causes cancer in human being. In this work, formulate hybrid model containing filter approach, the wrapper approach and partial least square method that used to select the optimized features form the high dimensional dataset. Filter approach uses mutual information, wrapper approach uses genetic algorithm and partial least square method uses t-score estimation for feature selection mechanism. With the reduced dimension of features, classification is performed on the reduced data set to classify the samples into normal or abnormal. To attain the improved classification accuracy both the feature selection and the dimension reduction is performed. By using feature selection technique most possibly cancer related genes from huge microarray gene expression data are selected. The trained classifier model is tested with benchmark cancer dataset which consists of colon cancer dataset comprises 62 samples, 40 of which are tumor and 22 are normal with 2000 genes and the prostate cancer dataset comprises 136 samples, 59 of which is normal and 75 are tumor with 12,600 genes. The proposed model achieves accuracy of 92.7% for wrapper approach with optimal features and also outperforms other two approaches with respect to accuracy and time complexity.

Keywords: *Partial least squares, Feature selection, Mutual Information, Cancer classification, t-score, genetic Algorithm, Support vector machine.*

Introduction

In Human being, Gene expression is the process by which information from a gene is used in the synthesis of a functional gene product. Measuring gene expression is an important part of many life sciences, as the ability to quantify the level at which a particular gene is expressed within a cell, organism or tissue can provide a lot of valuable information. Gene expression profiles based on microarray data are recognized as potential diagnostic indices of cancer.

Feature selection used for microarray gene expression data is called gene selection. Apart from curse of dimensionality there are many other problems faced during gene selection for prediction or classification. The major problems are mislabeled or redundant or noisy data, problem of cross-platform comparisons, bias problem and difficulty in biological information retrieval.

Major feature selection algorithms are the filter model, the wrapper model and partial least square method. The filter model approach depends on general characteristics of the training data to select some features/genes without involving any learning algorithm, therefore it does not inherit any bias of learning algorithm. The wrapper model approach requires one predetermined learning algorithm in feature selection and uses its performance to evaluate and determine which features are selected. As for each new subset of features, the wrapper model needs to learn a hypothesis (or a classifier). It tends to give superior performance as it finds features better suited to the predetermined learning algorithm, but it also tend to be more computationally expensive.

Partial least squares (PLS) technique is another dimension reduction method that is used widely for the gene expression data based cancer classification. PLS is the best method to handle the high-dimension-small-sample-size problem. This kind of problem can be well

handled with partial least squares method and with the t-scores calculated for the feature selection is also used for dimension reduction.

To combine the advantages of above approaches, algorithms in a hybrid model have recently been proposed to deal with high dimensional data. In these algorithms, first, a goodness measure of feature subsets based on data characteristics is used to choose best subsets for a given cardinality and then cross validation was exploited to decide a final best subset across different cardinalities. These algorithms mainly focus on combining filter and wrapper algorithms along with partial least square to achieve best possible performance with a particular learning algorithm at the same time complexity of computational algorithms.

In this work proposes a new filter-based feature selection method uses mutual information (MI) to evaluate the dependence between features and output classes. The most relevant features are retained and used to construct classifiers for respective classes.

In the second method, the selection and classification of gene subsets is performed, the selection is performed by a genetic algorithm, and the classification of the subsets feature is made with a support vector machine and is validated using a cross-validation method.

In the third method, Partial least squares technique uses t-score estimation for dimension reduction in the gene expression data. In this technique, T-scores of the genes are calculated and the individual genes satisfying a particular threshold value will be made into a subset of genes that contributes to the classification. This subset is provided as the input for the dimension reduction that further reduces the dimension of the genes. The reduced subset of data is given to classifier for identifying the cancer and non-cancer samples.

The paper is organized as follows. In section II, we present the related work to our proposed system, In Section III, the materials and method. Results and performance evaluation of the work are provided in Section IV. Finally section V concludes the proposed work.

Related Work: Feature selection is a technique for eliminating irrelevant and redundant features and selecting the most optimal subset of features that produce a better characterization of patterns belonging to different classes.

Forward feature selection algorithm[1] using the mutual information method to measure the relation among features. The optimal feature set given to train the LS-SVM classifier and results good accuracy.

E Alba et al., proposed the hybridization of Particle Swarm Optimization, a Genetic Algorithm and the Support Vector Machine (PSO/GA/SVM) to find few genes with high classification rates[2]. In order to overcome the local optimum problem in GA,it is combined with PSO and SVM to find a better optimal solution.

Correlation-based Feature Subset Selection (CRFS) approach[3] in which two correlation measures are used for feature selection ie., feature-class correlation and feature-feature correlation. Initially, N numbers of features are combined as possible combinations of feature subsets using heuristic-based best-first search, then each subset is evaluated with the two correlation measures. The subset that has lesser feature-feature correlation and higher feature-class correlation compared to other feature subsets is considered as the selected significant feature subset for the classification task.

Mutual Information-based Feature Selection (MIFS) method[4] is used to determine the relevancy between the individual feature and the target-class. The features having similar information are considered as redundant features that are to be removed and this method shows good accuracy results.

Particle swarm optimization (PSO)-based feature selection method[5], in which the feature subsets generated by PSO are evaluated using supervised learning algorithm and results good accuracy.

Mutual information-based max-relevancy min-redundancy (MRMR) feature selection[6],the mutual information is computed between the individual feature and target-class, and to identify the redundant feature, the mutually exclusive condition is applied to get good accuracy.

Conditional mutual info maximization (CMIM)[7] method that recursively chooses the features that have maximum mutual information with the target-class for classification.

Materials and Method

This section provides the description of the proposed system. The system design is shown in Fig. 1. The framework contains three main components. The modules are described here.

Dataset: The genomics dataset[8] are collected from publicly available website which consists of colon and prostrate cancer data.

Some of the gene names included in the 2000 genes that provides the expression levels are H55933, R85482 X63432, L28809, J02763, T63508, U14973

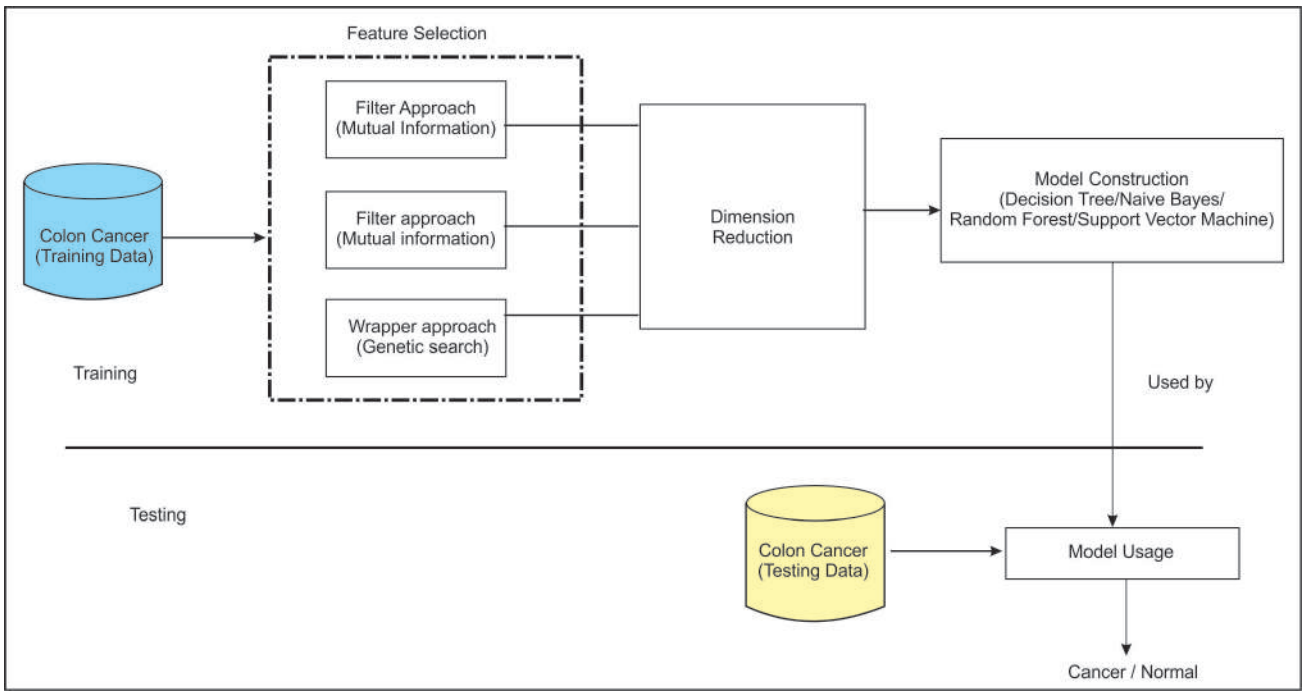

Figure 1: Overall System Design

Mutual Information: In feature selection, a feature is relevant to the class if it contains important information about the class; otherwise it is irrelevant or redundant. Since mutual information is good at quantifying the amount of information shared between two random variables, it is often used as a criterion to evaluate the relevance between a feature and a class label.

Under this context, features with high predictive power are the ones that have larger mutual information I(C; f). On the contrary, in the case of I(C; f) equal to zero, the feature f and the Class C are proven to be independent of each other. This means that feature f contributes redundancy to the classification.

Mutual information is a symmetric measure of the relationship between two random variables.

$$I(f,C) = H(f) + H(C) - H(f,C) \quad (1)$$

where, H(f) and H(C) are the entropies of f and C

Procedure:

Input: Feature set F = $\{f_i, i = 1, \ldots, n\} \in D$

Output: S //Selected feature subset

Step 1: Initialize set S = $\varnothing$

Step 2: Calculate amount of information for each feature f_i with respect to the class

Step 3: Select the feature f_i which has the maximum mutual information.

Step 4: Add the feature f_i to the set S

Genetic search: A genetic algorithm is a type of local search method. It mimics evolution by taking a population of strings, which encode possible solutions, and combines them based on fitness function to produce individuals that more fit.

There are five phases Initial population, Fitness Function, Selection, Cross over, Mutation

Procedure:

Step 1: Encoding of the problem in a binary string

Step 2: Random generation of a population

Step 3: Calculate fitness of each solution

Step 4: Select pairs of parent strings based on fitness

Step 5: Generate new string with crossover and mutation until a new population has been produced.

Repeat step 2 to 5 until satisfying solution is obtained

T-score feature selection: Gene selection is the initial process of preselecting the genes by finding the score. The score is calculated for each gene by using the mean, variance and number of samples. Calculating the t-score provides the information about the informative genes and also about the irrelevant genes.

Steps:

1. Initially split the dataset according to their class labels.
2. Calculate mean $\bar{x}$, variance s_k^2 and also number of samples in each class N_k.
3. Calculate the t-statistics score for each gene and the formula is given as

$$t = \frac{\overline{x_0} - \overline{x_1}}{\sqrt{\frac{s_0^2}{N_0} + \frac{s_1^2}{N_1}}}$$

Where k = 0, 1 that represents the various classes. For each gene t-score value is calculated and the results are provided using the t-score value about eliminating the irrelevant genes and identifying the informative genes. Therefore the feature selection method is for calculating the score and identifying the best scored features. With the best scores subset of features is formed.

Dimension Reduction

Dimension reduction plays an important role in analyzing the suitable subset of data that helps in handling the data in a batter way. Reducing the features alone doesn't provide the better classification results but also in the formation of informative subset of original data. PLS calculates the covariance between the predictor variables and the response variables. Higher the covariance between the predictor variables higher the amount of information provided by the features. The formula for calculating the covariance and reducing the dimension is provided.

$$w1 = \arg\max(\mathrm{Cov}(Xw, y))$$

The objective function is provided above and using the covariance it is calculated.

Classification

Input: S // Selected feature subset,

Output: Class labels

Various classifiers such as SVM, Decision tree C4.5, Naïve Bayes are used for the identification of unknown class labels.

Results and Discussions

This part discusses the results of the each component of the system and provides the performance evaluation of the implemented methodologies.

Feature Selection:

1. Mutual Information:

Table I: Filter approach based on mutual information

Index	Attribute Index	Mutual Information
1	249	0.348689
2	1042	0.344656
3	258	0.329303
4	399	0.293341
5	493	0.283547
6	513	0.283547
7	1771	0.283547
8	377	0.232417
9	1772	0.232417
.....	.....	.....
200	1567	0.86545

Table I shows the results of selected features (Top 200) by using mutual information based feature selection method.

Table II shows the results that comparing them with various classifier such as decision tree, Naïve bayes and Random forest with the accuracy of the feature selected by the filter approach.

Table II: Classification for filter approach

Classifier	Training set	Testing set	Accuracy
Decision tree (C4.5)	75	25	86.3871
	60	40	84
	40	60	75.6757
	80	20	87.09677
Naive Bayes	75	25	87.0968
	60	40	64
	40	60	70.2703
	80	20	91.67
Random forest	75	25	98.3871
	60	40	72
	40	60	70.2703
	80	20	91.667

2. **Genetic Approach:** Genetic Algorithm combined with decision tree, in order to select a small subset of genes ie., 8 features that allows enhancing the classification accuracy of 92.70%

Table III: T-Score Values

Gene Names	T-Score Value
H55933	0.005846
H54676	0.015935
X55715	0.051163
D45887	-0.0123282
T57882	0.042118
R50864	0.033315
X02152	0.024249
U20982	-0.017666
X66363	0.012090
M86842	0.015174

3. **T-Score Feature Selection:** Genes are selected using the T-score value for each gene. Using the T-score value calculated for each gene present in the data particular number of informative genes can be identified and also irrelevant genes can be identified. The calculated T-score value is shown in Table III.

Dimension Reduction

Dimension Reduction is done after the feature selection method is performed. Using the t-statistics value the features are selected from the large number of genes. Informative genes can be identified using the high t-score value and the irrelevant genes can be identified by the low t-score value. PLS method is used for the dimension reduction and the dimension is reduced using the covariance value calculated between the predictor variables.

Performance Analysis and Evaluation: The performance analysis is done by calculating the accuracy.

$$\text{Accuracy } a = \frac{tp + tn}{tp + tn + fp + fn}$$

The table IV shows the performance analysis of various classifiers performed on colon cancer and prostate cancer dataset. Here method adopted for feature selection and dimensionality reduction is partial least square (t-score calculation).

Table IV: Performance analysis

Classifier	Accuracy for colon cancer	Accuracy for prostate cancer
SVM	93.5%	92.8%
Decision Tree	91.25%	90.6%
Naïve Bayes	88.5%	87.2%
Random Forest	92.4%	94.2 %

The Accuracy value for Filter approach, Wrapper approach and T-score estimation is shown in table V.

Table V: Comparison of Filter, Wrapper and PLS approach

Method	Important Features Selected	Number of Features	Accuracy (%) (C4.5)
Mutual information (Filter approach)	N1=249, 1042, 258, 399, 493, 513, 1771,, ...1567	200	87.09677
Genetic algorithm (Wrapper approach)	N2=51, 575, 633, 870, 1244, 1310, 1742, 1952	8	92.70968
T-score Estimation (Partial Least Square)	-	100	91.25

Conclusion and Future Work

The proposed work uses a hybrid technique which uses filter based approach, Wrapper based method, Partial least square method. Classification is performed on reduced gene subsets and is validated using a cross-validation method.

Although the proposed MIFS (Mutual information based feature selection) has shown encouraging performance, it could be further enhanced by optimising the search strategy .In this work, wrapper approach outperforms other two approaches. In future research the combination of other techniques of feature selection will be used, as other local search method (Ant Colony Optimization, Particle Swarm Optimization) or other techniques of data mining, the goal is to maximize the classification accuracy and minimize the number of genes for further analysis.

Evaluation of Autonomic Dysfunction in Underweight, Normal Weight, Overweight and Obese Patients with Chronic Obstructive Pulmonary Disease

Desai Nabil[1], Jyoti Ganai[2], Shobitha M.[3], Nabi N.[4]

[1]Senior Lecturer, Mahatma Gandhi Physiotherapy College, Gujarat University, [2]Assist. Prof. Dept. of Physiotherapy, [3]Professor and HOD Physiology, [4]Demonstrator-MD Pharmacology, Hamdard Institute of Medical Sciences and Research, Jamia Hamdard, New Delhi

Abstract

Background: Though there are several studies available on effects of obesity on cardiac autonomic dysfunction and effects of COPD on cardiac autonomic dysfunction separately but search on combined effect of obesity and COPD on cardiac autonomic dysfunction fails to produce results. Therefore there was a need to evaluate the changes in autonomic dysfunction with increasing BMI in patients with COPD.

Objective: The aims of this study were 1) to compare autonomic dysfunction in patients with COPD with increasing BMI, 2) to correlate autonomic dysfunction in patients with COPD with increasing BMI.

Methodology: In the present study, 42 subjects were categorized into underweight, normal weight, overweight and obese category. Non invasive cardiac autonomic function tests were carried out in these subjects.

Results: The mean ± SD age of underweight, normal weight, overweight, and obese patients with COPD were 57.667 ± 5.1640, 61.007 ±8.8991, 55.800±6.6106 and 56.200±7.1204 respectively. It was found that there was no correlation between BMI and autonomic dysfunction responses in patients with COPD. All four cardiac autonomic function test came out to be non significant statistically [Karl Pearson correlation (r), ns- p >0.05]. Multiple comparisons between underweight, normal weight, overweight, and obese patients with COPD for cardiac autonomic responses, FEV_1, PEF were statistically non significant.

Conclusion: In present study, although the results have shown that there was definite autonomic neuropathy in patients with COPD with increasing BMI, there was no significant difference in autonomic dysfunction with increasing BMI in patients with COPD.

Keywords: *Forced expiratory volume (FEV_1), Peak expiratory flow rate (PEF), Obesity, Chronic Obstructive Pulmonary Disease.*

Introduction

The chronic obstructive pulmonary disease (COPD) is characterized by persistent airflow limitation that is usually progressive and associated with an enhanced chronic inflammation response of the airways. It has been estimated that in 2030, COPD will become the third biggest cause of death.[1,2]

Previous studies show that in COPD patients, cardiovascular autonomic neuropathy (CAN) is a common consequence and has been shown to negatively affect the cardiovascular and autonomic nervous system.[3, 4] Previous studies have demonstrated that COPD patients have depressed heart rate variability (HRV), indicating increased sympathetic activity at rest[5,6] and Bronchoconstriction, hypoxia, hypercapnia, weight loss and systemic inflammation are other associated features.[7, 8] Studies on adults show that the HRV is decreased in overweight young adults especially men indicating sympathovagal imbalance. No changes were

observed in HRV in underweight group. Changes in the autonomic nervous activity begin in the overweight and may become more prominent in the obese thus indicating increased cardiovascular risk. [9] But the number of studies that analysed the autonomic functions in obese adult population is still limited.

Available data suggests that obesity is more prevalent in patients with COPD than in the general population, depending on the severity of chronic airflow limitation. [10, 11] Obesity is an independent risk factor for cardiovascular disease and mortality[12,15.] Autonomic neuropathy is another complication in obese patients.[16,17] But limited literature is available to examine the relation between increasing body mass index (BMI) and cardiac autonomic function tests in patients with COPD. Hence, this study on the evaluation and correlation of autonomic function in the underweight, normal weight, overweight and obese patients with COPD was undertaken

Materials and Method

Subjects: 42 COPD subjects on the basis of BMI were categorized into 6 underweight, 26 normal weight,5 overweight and 5 obese category. Written informed consent was taken from the subjects and approval was obtained from the Institutional ethical committee. Procedures followed were in accordance with the ethical standards of the responsible committee on human experimentation (institutional and national).

Parameters Measured: Autonomic function tests were employed to evaluate the integrity of both parasympathetic and sympathetic innervations of the heart in all the groups.

(A) Parasympathetic Function Tests: Blood pressure was recorded from OMERON digital sphygmomanometer and heart rate beat to beat changes can be measured from a continuous running ECG record (lead II).

1. Valsalva maneuver: The heart rate response to valsalva maneuver i.e forced expiration against resistance to assess baroreceptor integrity was assessed. The valsalva ratio was calculated as the ratio of longest R-R interval after maneuver to shortest R-R interval during maneuver. [16]

2. Heart rate variation (HRV) with respiration was measured in supine position. Resting ECG was recorded and baseline heart rate was measured. The subject was asked to breathe in deeply at a rate of 6 breaths per minute allowing 5 seconds each of inspiration and expiration. The expiratory (E) to inspiratory (I) ratio was calculated as the sum of 6 longest R-R interval, divided by 6 shortest R-R intervals. [16]

B. Sympathetic function tests:

1. **Cold pressor test (CPT):** Subject was asked to immerse his hand in cold water maintained at 4-6 degree Celsius and blood pressure measurement was made from other arm. Failure of systolic BP to rise by 16-20 mm Hg and diastolic BP by 12-15 mmHg was indication of autonomic neuropathy.[16, 17]

2. **Blood pressure response to standing:** After blood pressure measurement in supine position the subject was made to stand. Blood pressure was recorded in 30 second interval. Difference between readings of blood pressure in lying position and then after standing was calculated.[16,17]

Statistical Analysis: SPSS 21.0 software and graph pad prism 3.0 for windows were used. Co-efficient of correlation in bivariate relationship was obtained using the Karl Pearson correlation test. The autonomic responses were compared between underweight, normal weight, overweight and obese COPD using the multiple analysis of variance (MANOVA Tukey). A "p" value of <0.005 was considered as statistically significant.

Result

Table 1: Frequency of different responses to tests of autonomic dysfunction according to severity of COPD

Test	Under Weight N=6	Normal Weight N=26	Over Weight N= 5	Obese N=5
Valsalva ratio <1.20- abnormal, 1.20-1.45, borderline, and >1.45-normal				
Abnormal	2(33%)	8(31%)	3(60%)	1(20%)
Borderline	1(17%)	11(42%)	2(40%)	3(60%)
Normal	3(50%)	7(27%)	0(0)	1(20%)

Test	Under Weight N=6	Normal Weight N=26	Over Weight N= 5	Obese N=5
Heart rate variation (HRV) after deep breathing <10 beats- abnormal, 10-15 beats –borderline, and >15 beats –normal				
Abnormal	6(100%)	10(38%)	3(60%)	3(60%)
Borderline	0	11(42%)	1(20%)	2(20%)
Normal	0	5(19%)	1(20%)	0
BP response to posture change				
Abnormal	1(17%)	1(4%)	0	0
Borderline	2(33%)	8(30%)	2(40%)	0
Normal	3(60%)	17(67%)	3(60)	5 (100%)
BP response to Cold pressor test				
Abnormal	3(50%)	18(70%)	3(60%)	18(70%)
Normal	3(50%)	8(30%)	2(40%)	8(30%)

Table 2: Correlation between BMI and autonomic tests responses

	BMI		
	Pearson Correlation	**P Value**	**Significance**
Valsalva Maneuver	-.17	.28	NS
Heart rate variation after deep breathing	-.05	.75	NS
FEV1	.01	.97	NS
PEF	.19	.23	NS
SBP to posture change	-.25	.12	NS
DBP to posture change	-.08	.61	NS
SBP to cold pressor test	-.02	.90	NS
DBP to cold pressor test	-.08	.60	NS

SBP- Systolic blood pressure, DBP- Diastolic blood pressure, FEV_1- Forced expiratory volume in 1 second, PEF-Peak expiratory flow rate. There were no correlation between BMI and autonomic dysfunction responses in patients with COPD. [Karl Pearson correlation (r), ns- p >0.05] given in Table 2.

Table 3: Between groups MANOVA analysis

Group		Mean	Std. Deviation	F value	P Value
Valsalva Maneuver	1	1.3427	.38015	0.572	0.637
	2	1.2440	.12442		
	3	1.1580	.06058		
	4	1.3533	.20906

	3	5.80	3.271		
	4	6.67	4.676		

Multiple comparisons between underweight, normal weight, overweight, and obese patients with COPD for cardiac autonomic responses. FEV_1, PEF were statistically non-significant (MANOVA Tukey, P>0.05) given in table-3.

Discussion

The role of BMI in the pathogenesis of COPD is not clear. In previous researches it has been found that both, parasympathetic as well as sympathetic divisions have been found to be affected in the adult obese population as compared to the non- obese adult population.[16,17] Whereas Chabra S K et al reported a reduction in both parasympathetic and sympathetic function in subjects with normal BMI with or without hypoxemia.[4] Among patients 21.4% had no evidence of autonomic neuropathy while 28.6% had early neuropathy and 28% had definite neuropathy. The relationship between autonomic neuropathy and BMI was not given by Chabra S K et al. The results of the present study found that there was definite autonomic neuropathy in normal weight COPD population similar to Chhabra S K et al. Amongst all the groups of COPD population in our study 90% have definite or early autonomic neuropathy and 10% have no evidence of autonomic neuropathy (Table-1).

Wu J et al compared autonomic dysfunction in underweight, normal weight, overweight and obese adults. The study compared HRV (hear rate variation during forced breathing) and HF (high frequency spectrum) power and correlated SDNN (the standard deviation of the average NN intervals) autonomic dysfunction in underweight, normal weight, overweight and obese adults. HRV and HF power were statistically significant for obese (p=o.o1) but there were non-significant results for underweight and overweight (P= 0.86, 0.15 respectively). There was no significant independent correlation of SDNN with underweight (p=0.41), overweight (p =0.80) and obesity (p= 0.43) group. It was concluded that underweight was not a correlate of any indices of Cardiac autonomic function (CAF) but over weight and obesity were independently associated factors of altered CAF.[18]

In our present study, we compared autonomic dysfunction in underweight, normal weight, overweight and obese COPD population. Parasympathetic function tests were statistically non- significant between underweight, normal weight, overweight, and obese COPD patients (P-0.64, P-0.24 respectively, table-3). Sympathetic function tests i.e BP response to postural change and BP response to cold pressor tests also were

statistically non-significant between underweight, normal weight, overweight and obese COPD patients. (P-0.8, P-0.84, table-4). We also found non- significant correlation between BMI and autonomic function tests (table-2)

In present study most of the underweight COPD population have definite or borderline autonomic neuropathy (table-1) which was different from the results of study of W u J et al. [18] This may be the reason that COPD patients have enhanced sympathetic tone at rest and are less able to respond to sympathetic and parasympathetic stimuli in comparison to healthy persons. Previous study show that resting muscle sympathetic nerve activity is significantly higher in patients with COPD as compared to age and sex matched healthy control subjects. [11]

Studies show that plasma nor-epinephrine was elevated in patients with emphysema compared with healthy controls. Altered lung inflation reflexes may also mediate sympathetic activation in COPD.[19,20] Sympathetic activation with its chronotropic effects may be responsible for elevated heart rate response seen in COPD patients.[20]

In underweight COPD patients, neuro-humoral activation caused by sympathetic activation may be a cause of skeletal muscle dysfunction. This seems to involve the diaphragm and accessory respiratory muscles, with aggravation of ventilation disturbances characteristic for COPD. Chronic hypoxemia seems to play a role in sympathetic activation, even in healthy subjects.[21]

The results of this study show that there was non-significant (weak positive, r-0.006) correlation for FEV_1 and PEF with increasing BMI [FEV_1(P-0.62, P-0.97), PEF(P-0.39,P-0.23) respectively, table-2]. Lad U et al found in their study that there was positive correlation in underweight male and female with FEV_1 and overweight male, and female had negative correlation with FEV_1.[21]

Conclusion

There were several studies available on effects of obesity on cardiac autonomic dysfunction and effects of COPD on cardiac autonomic dysfunction. But till date no study is available on combined effects of obesity and COPD on cardiac autonomic dysfunction. Therefore present study was done on evaluation of autonomic dysfunction with increasing BMI in patients with COPD. In present study, although the results have shown that there was definite autonomic neuropathy in patients with COPD with increasing BMI, there was no significant difference in autonomic dysfunction with increasing BMI in patients with COPD. Furthermore, in several studies we found that irrespective of the stages of the disease, underweight was an independent risk factor for cardiovascular complication and mortality. In mild and moderate COPD the best prognosis is found in normal weight or over weight subjects. In severe COPD, over weight, and obesity, is associated with better survival (obesity paradox, prognostic). Therefore we suggest that patients with COPD in the normal to overweight range have better prognosis.

Limitations of the Study: Our study was constrained by the small size of the sample available. The morbidly obese were not included in our study.

Conflict of Interest: The authors do not have any conflicts of interest to declare.

Effect of Exercise Program in Reducing Risk of Fall in Elderly People

Elizabeth J. Shende[1], Pranjali M. Gosavi[2], S. Anandh[3], Yogita A. Pawar[1]

[1]Final Year, [2]Assistant Professor, [3]Professor, Faculty of Physiotherapy, Krishna Institute of Medical Sciences Deemed to be University, Karad, Maharashtra, India

Abstract

Objective: To study the Effect of Exercise Program in reducing risk of fall in elderly subject.

Materials and Method: Total 30 elderly subjects(10 males and 20 females) aged above 60 years were having problem with flexibility, balance and high risk of fall were selected for the assessment of their flexibility, gait and balance. Subjects who are bed ridden, having neurological conditions, Psychiatry condition and visual deficit were excluded from the study. Outcome measures used were Morse fall risk assessment tool, Timed up and go test, Functional reach test, Functional gait assessment.

Conclusion: The present study provided evidence to conclude that the exercise programme was significantly effective in improving strength, flexibility and balance along with reducing risk of fall in elderly population.

Keywords: *Fall, Elderly subject, flexibility, balance, gait, strength, exercise.*

Introduction

Fall is defined as unintentionally coming to rest on the ground or other level with or without consciousness. Falls are faced by elderly population. Balance in elderly is affected by both diseases as well as age related issues along with problems like cognitive impairment, various medications and environmental changes all appear to contribute to the increase risk of falls.[1]

Falls among elderly is a major public issue interfering with social essential. It has various physical, medical, psychological, social and economic consequences. This include disability and deformity,fear of repeated falls,direct costs of medical care associated with injuries and loss of potential income. The environment is perceived to play an significant role in falls experienced by the elderly population.[1]

Walking difficulty is very common problem experienced in older adults which leads to loss of independence. Multiple changes in different systems of body contribute to change in walking pattern in elderly. The disability of gait is a gradual process. This group of age related deficits results in inefficient gait. Body mechanics are altered starting with flexed trunk posture, decreased hip extension in mild to late stance, decreased ankle plantar flexion at power push off and movement control is disturbed like reduced rate of forward momentum, stride length and time variability, and timing issues, and difficulty in transitioning from stance to swing. Reduced hip extension causes blocking of the mechanical accumulation of potential energy in the limb tissue during stance phase with release during swing to fuel the limb forward movement, while also eliminating the hip extension. The loss of motor skills, high energy cost of walking is major factor contributing in the age-related decline in physical function and activity for older adults.[2]

The risk factor contributing to falls can be classified into two categories.

Intrinsic and Extrinsic factors. Intrinsic factors typically includes Age, Gender, Poor balance, Weakness, Mobility whereas on the other hand extrinsic factors include Poor lighting, Slippery surface, Obstacles etc.[3]

Gait is one of the basic component to determine independency of function. Many physical therapy interventions are therefore, directed to restore and improve subject ambulation status.[4]

Various studies have been shown the effects of various physical exercise programs on the functional capacity of older subject. Resistance training, endurance training, balance training and combination of this exercise have beneficial effects on certain functional parameters in frail elderly subject.[5]

Studies on resistance training have shown that this type of exercise program can improve neuromuscular activity, muscle mass, strength, power and functional capacity as well as improve cardiovascular function. [5]

Balance training is another type of exercise intervention which can help to prevent fall. [5]

Exercise intervention include gait training, resistance exercise and balance training where resistance training has positive effects on the strength and bone density.[6,7]

Resistance exercises can be used for strengthening weak lower limb musculature as they function as prime movers of the limbs, also act as synergists to stabilize the trunk, and sometimes act as antagonists, which help to decelerate limb. Exercises to improve muscle strength and power helps in enhancing the ability of a weak lower limb musculature, like the plantar flexors of ankle. This helps in aiding the ground reaction forces. [2]

Stretching exercises aiding joint range of motion(ROM) helps in maintaining the postures of the limbs or trunk. Secondly the desired length of muscles can be obtained for optimal activation during dorsiflexion and in heel strike a appropriate lengthening of the calf muscles is needed to facilitate activation and lastly for appropriate movement-related feedback to the nervous system.[2]

A multi-component exercise intervention program that consists of strength, endurance, and balance training appears to be the best strategy for improving gait, balance, and strength, as well as reducing the rate of falls in elderly individuals and consequently maintaining their functional capacity during aging.[5]

Fall in older age population are related to socio economic, environment, behavioral and biological factors. Socioeconomic factors like low income & education levels, inadequate housing and lack of social. Environment al factors like poor building design, slippery floors. Biological factors like age, chronic illness. Behavioral factors like excess alcohol intake, lack of exercise and inappropriate foot.[8]

Materials and Methodology

Study Type: Experimental

Study Design: Pre and post

Sampling Method: Simple random sampling

Sample Size: 30

Study Duration: 6 months

Place of Study: Karad

Participants: Total 30 elderly subjects (10 males and 20 females) aged above 60 years were having problem with flexibility, balance and high risk of fall were selected for the assessment of their flexibility, gait and balance. Subjects who are bed ridden, having neurological conditions, psychiatry condition and visual deficit were excluded from the study. Outcome measures used were Morse fall risk assessment tool, Timed up and go test, Functional reach test, Functional gait assessment. Each and every elderly person was approached and informed consent was taken from the individuals, willing to participate. They were explained about the procedure of the study and then were assessed for flexibility, gait and balance using the outcome measure, after the demographic data from the individuals was collected.

Outcome Measures: Outcome measures used were Morse fall risk assessment tool, Timed up and go test, Functional reach test, Functional gait assessment. After the selection of appropriate candidates fulfilling the criteria they were asked to fill the questionnaire to record the number of falls prior starting the treatment. Subjects were asked to perform the set of exercises according to the set protocol. The set of exercises were practiced for 1 month and follow up was done for 5 months. The results gained after completing the 6 month protocol were noted by Morse fall risk assessment tool, time up go test, functional reach test. The change in individual's number of falls was noted by the pre and post answers noted in the questionnaire.

Statistical Analysis: Within group comparison statistical analysis of all pre and post interventional values was done by paried 't' test. The statistical analysis for MORSE FALL ASSESSMENT TOOL showed significant improvement within the group(p=<0.0001). The statistical analysis for FUCNTIONAL GAIT ASSESSMENT showed significant improvement within the group(p=<0.0001). The statistical analysis for TIMED UP GO TEST showed significant improvement within the group(p=<0.0001). The statistical analysis for FUNCTIONAL REACH TEST showed significant improvement within the group (p=<0.0001).

Table 1: Baseline Parameters

Parameters	Pre	Post	t value	p value	Inference
Timed up go test	3.773 ± 2.087	5.333 ± 2.705	9.252	< 0.0001	Significant
Functional reach test	5.427 ± 0.8542	5.830 ± 0.9692	8.003	< 0.0001	Significant
Functional gait assessment	22.567± 4.006	20.5± 3.138	4.821	< 0.0001	Significant
Morse fall risk assessment tool	48.5±21.502	39.667±19.517	7.737	< 0.0001	Significant

Discussion

This study "effect of exercise program in reducing risk of fall in elderly subject" was conducted among elderly population in Karad. As risk of fall increases among elderly subject due various factors, prevalence of falls is 30% in elderly population. Previously the studies have been conducted on the fall prevention. Until now, there was no study done to find the effect of exercise in reducing risk of fall in elderly subject.

Aim was to study the Effect of Exercise Program in reducing risk of fall in elderly subject. Objectives were to determine the effect of exercise program in reducing risk of fall. Inclusion criteria were age group of 60 years and above, both Male and female with history of fall. Exclusion criteria were bed ridden patient, existing Neurological condition, Patient with Psychiatry condition and Subject with visual deficit.

Total 30 elderly subjects (10 males and 20 females) aged above 60 years were having problem with flexibility, balance and high risk of fall were selected for the assessment of their flexibility, gait and balance. Subjects who are bed ridden, having neurological conditions, Psychiatry condition and visual deficit were excluded from the study. Outcome measures used were Morse fall risk assessment tool, Timed up and go test, Functional reach test, Functional gait assessment.

They were explained about the study and treatment protocol. Written consent was taken from the subjects. They were given the questionnaire to fill and tests were taken to find out the risk of fall. After the selection of appropriate candidates fulfilling the criteria they were asked to fill the questionnaire to record the number of falls prior starting the treatment. Subjects were asked to perform the set of exercises according the set protocol. This set of exercises were practiced for 1 month and follow up was done for 5 months . The results gained after completing the 6 month protocol were noted by Morse fall risk assessment tool, time up go test, functional reach test. The change in individual's number of falls was noted by the pre and post answers noted in the questionnaire.

Conclusion

In this study the exercise programme was significantly effective in improving strength, flexibility and balance along with reducing risk of fall in elderly population.

Hence Alternative hypothesis is proved.

Conflict of Interest: The authors declare that there are no conflicts of interest concerning the content of the present study.

Source of Funding: This study was self funded.

Ethical Clearance: The study was approved by the institutional ethical committee of KIMSDU.

Regenerative Endodontics-The Future? A Questionnaire Based Study

Farhan Ariwala[1], Mahalaxmi Yelapure[2], Mithra N. Hegde[3], Darshana Devadiga[4], Upasana[5]

[1]II-MDS, [2]Reader, [3]Head of the Department, [4]Reader, [5]Lecturer,
Department of Conservative Dentistry and Endodontics, ABSMIDS, Mangaluru

Abstract

Introduction: Regenerative Endodontics is a fast growing field in dentistry showing highly favourable clinical outcomes. It encompasses various procedures that serve as a better alternative to traditional root canal therapy as well as more aggressive treatments such as surgical endodontics. The knowledge and skill of the practitioner plays a pivotal role in the success of any regenerative procedure.

Aim: The purpose of this survey is to evaluate knowledge, attitudes and practice of regenerative endodontics among the dental Interns, dental postgraduates and dental practitioners in mangaluru.

Materials and Method: An online questionnaire comprising of 20 questions was distributed amongst the dental professionals of Manguluru. A total of 448 dental professionals responded over a period of 1 month. Their responses were collected and tabulated to interpret the data and obtain the results.

Results: A total of 448 replies were received, with the majority of the correspondents belonging to the dental post graduates (41.5%). The majority (97%) of the participants of this survey had come across the term 'Regenerative Endodontics', but only 41 out of the 448 had reported performing any regenerative endodontic procedure.

Conclusion: Regenerative endodontic Procedures have shown favourable results in various studies. It can be used as a valuable tool for any dental professional. But, as seen in this study, the knowledge levels as well as attitudes amongst the dental fraternity needs to improve so as to allow the incorporation of regenerative endodontics into clinical practice.

Keywords: *Regenerative, Survey, Knowledge.*

Introduction

Regenerative endodontic procedures(REP's) were proposed to overcome the drawbacks related to the clinical management of necrotic immature permanent teeth and are gaining prominence over traditional apexification procedures amongst researchers and clinicians.[1]

Regenerative endodontic procedures can be defined as biologically based procedures designed to replace damaged structures, including dentin and root structures, as well as cells of the pulp-dentin complex.[2]

In other words, regenerative endodontics is a broad term encompassing various procedures such as pulp revascularisation, apexogenesis, pulp implantation, three-dimensional cell printing etc.[2]

The success of regenerative endodontics, like any other dental procedure, depends upon the knowledge and skill of the practitioner. Although, regenerative

procedures are highly technique sensitive and require a systematic protocol to be followed.

Hence, the knowledge of the practitioner regarding these procedures is of paramount importance. Since very few studies have been conducted in this regard and little information about this is available, the aim of this survey is to evaluate knowledge, attitudes and practice of regenerative endodontics among the dental Interns, dental postgraduates and dental practitioners in mangaluru.

Materials and Method

The study undertaken was a questionnaire-based survey to evaluate the awareness and attitudes towards regenerative endodontics, with a questionnaire comprising of 20 questions. Out of this, 15 questions were framed to evaluate the knowledge and awareness of dental professionals towards REP's, while 5 were framed to reveal their attitudes towards the same.

The questions were arranged systematically to evaluate the awareness, knowledge and attitudes of the dental practitioners in the region of Mangaluru, towards regenerative endodontic procedures.

Using 'Google Docs', an online questionnaire was created to be distributed amongst the dental professionals of mangaluru digitally. This was done by distributing the link to the questionnaire. https://docs.google.com/forms/d/e/1FAIpQLScxYl8XLC4yK2PsDovd4hQHqSQMcYtTULLYucTErJCZ_buKiQ/viewform#start=openform

Printed copies of the questionnaire were also used and were circulated individually amongst the practitioners. Only dental interns, dental post graduates and dental practitioners were provided with the questionnaire. Responses to both the online form as well as the hard copy of the questionnaire were accepted for a period of 1 month.

All the data was then collected and tabulated. This was later analysed to obtain the results of the survey.

Results

A total of 448 replies were received for the survey, both online and offline. Out of this, most of the correspondents were the dental postgraduates (41.5%), followed by the dental practitioners (31.9%) and then the dental interns (26.6%).

The age of the participants ranged from 21 to 52 years, with an average age of 27 years. Amongst the dental practitioners, the average number of years of practice was 7.5 years.

Table 1: Questions drafted so as to determine the knowledge levels of the various participants in the field of regenerative endodontics

Question	Response		
	Yes	No	Not Sure
Do you think Regenerative procedures can serve as a practical and feasible replacement for more aggressive treatment protocols?	292(65.2%)	66(14.7%)	90(20.1%)
Do you think regenerative procedures can serve as an alternative to implants?	128(28.6%)	186(41.5%)	134(29.9%)
Single visit procedure is recommended for regenerative endodontic treatment.	26(5.8%)	338(75.4%)	84(18.8%)
Leaching of Sodium Hypochlorite (NaOCl) into the periapical space has a detrimental effect on revascularisation procedures.	289(64.5%)	42(9.4%)	117(26.1%)
The use of Ethylene-Diamine-Tetra-acetic acid (EDTA) is recommended along with Sodium Hypochlorite (NaOCl) during revitalisation procedures.	161(35.9%)	108(24.1%)	179(40%)
Revascularisation procedures performed on teeth with a large apical foramen diameter are more successful than teeth with a small apical foramen.	172(38.4%)	102(22.8%)	174(38.8%)
Should revascularisation be performed on deciduous teeth?	30(6.7%)	288(64.3%)	130(29%)

Table 2: The technical aspects of regenerative procedures was inquired with these following questions.

QUESTION	RESPONSE			
	Root Resorption	Immature Apex with Necrotic Pulp	Persistent Peri-apical Infection	Peri-radicular Cyst Resolution
Which of the following indications is best suited for treatment by a regenerative endodontic procedure?	62(13.8%)	350(78.1%)	26(5.8%)	10(2.2%)
According to you, which of the following outcomes from regenerative treatments is the most valuable?	Healing of Peri-radicular Bone	Pulp Tissue Revitalisation	Continued Root Development of Immature Teeth	All of The Above
	20(4.5%)	32(7.1%)	83(18.5%)	313(69.9%)
During revascularisation procedures, stem cells are introduced into the canal by?	Placing A Scaffold	Placing A Bioceramic Material	Inducing Bleeding From The Peri-apical Region	Stem Cells Are Not Required
	88(19.6%)	68(15.2%)	265(59.2%)	27(6%)
Which of the following, do you think, best serves as a scaffold during Pulp Revitalisation Therapy?	Collagen	Platelet Rich Plasma	Platelet Rich Fibrin	Bioceramics
	45(10%)	160(35.7%)	179(40%)	64(14.3%)

Table 3: The scope and future aspects of REP's, according to the participants, was Questioned.

QUESTION	RESPONSE			
	Higher Cost Factor	Complicated Procedure	Fear of Performing Such Treatments	Lack of Patient Confidence In Regenerative Procedures
What, according to you, would be the biggest obstacle to regenerative endodontic procedures?	227(50.7%)	115(25.7%)	26(5.8%)	80(17.9%)
When do you think regenerative procedures will be frequently practiced in dental clinics?	Already Being Practiced	1 to 5 Years From Now	6 to 10 Years From Now	More Than 10 Years From Now
	34(7.6%)	50(11.2%)	77(17.2%)	287(64.1%)
How many years, do you think, it will take for dentists to implant teeth grown in a laboratory?	1 to 10 Years From Now	11 to 20 Years From Now	More Than 20 Years From Now	Never
	34(7.6%)	55(12.3%)	332(74.1%)	27(6%)

Discussion

In this survey, 97% (435) of the correspondents had come across the term 'Regenerative Endodontics'. This showed a high awareness amongst the population of dentists in mangaluru. In a similar study conducted amongst dental residents in selected hospitals within Nigeria, 91.2% (114) of the participants had come across the term regenerative endodontics.[3]

Pulp revascularisation and apexogenesis were the 2 procedures(88.2%&78.3%respectively)mostrecognised in this study to fall under the term of Regenerative Endodontics. Few of the correspondents also believed direct pulp capping (20.2%) and apexification (9.6%) to be regenerative procedures, but, even though they fulfil the criteria stipulated for regenerative procedures of growth of tooth structures, they are not considered under the umbrella of regenerative endodontics.

A total of 41(9.1%) respondents reported practicing regenerative procedures, with apexogenesis (18) and pulp revascularisation (14) the most practiced procedures.

A total of 292(65%) of the respondents believed that REP's can replace more aggressive treatment

modalities. This is supported by available literature, displaying a high success rate for procedures such as pulp revascularisation and apexogenesis. A cohort study investigated 20 cases of regenerative endodontic therapy for immature permanent teeth with necrotic pulps and showed that the success or survival rate of treated teeth was 100% in terms of regression of clinical symptoms/ signs and resolution of apical periodontitis or retention of teeth. [4]

But, it is also important to view the failures for REP's. A study conducted by song et.al (2017) showed the presence of Revascularisation Associated Intra-Canal Calcifications in 62% of the cases under the study.[5]

When it came to REP's serving as an alternative to implants, the majority of the correspondents (71%) were sceptical towards it's ability for the same. The current philosophy in tissue engineering is developing/ regenerating a whole new organ. This can be achieved either by seeding tooth germ cells in a tooth shaped scaffold or recreating the tooth germ from detached mesenchymal and epithelial cells.[6] But, this technology is still in its infancy. This may also explain why 332 of the total correspondents believed that it would take atleast 20 years for a tooth developed in a lab to be implanted in the oral cavity.

A multiple visit protocol using a tri-antibiotic paste may be a better treatment option for teeth with complete pulpal necrosis, during revascularisation procedures.[7] 338(75.4%) of the respondents also believed the same, as they did not believe single visit endodontics is recommended for regenerative procedures. Shin et al. had proposed a single visit procedure using an intra canal medicament,but it showed limited success.[7]

Disinfection of the root canal space is paramount towards the success of any Regenerative procedure. Both irrigants as well as intra canal medicaments can be used.[8] The most recognised irrigant in the survey was sodium hypochlorite and the most recognised intra canal medicament was the triple antibiotic paste (TAP). Although TAP has been shown to be more effective in eradicating bacteria,[9] it has the potential for tooth disco-loration, which results from contact between minocycline and the root canal walls during the REP.[10] Exclusion of minocycline (known as double antibiotic paste) or substitution of minocycline by amoxicillin, doxycycline, clindamycin, tetracycline or cefaclor has been reported to solve this problem.[11]

Sodium hypochlorite has a detrimental effect on the stem cells. [12,16] The majority of the correspondents were aware of this fact, with 289(64.5%) believing that leaching of sodium hypochlorite into the periapical space is harmful for the regenerative procedure. Out of those who did not agree to the same, the majority of the correspondents belonged to the group of dental interns.

In a study conducted by martin et al. (2014), the use of 17% EDTA resulted in increased survival and DSPP expression, partially reversing the deleterious effects of NaOCl. [12] This study showed that the highest awareness regarding this information existed amongst the post graduates. As the speciality of the participants were not recorded, the awareness amongst the various specialities could not be determined.

Teeth with pre-operative apical diameters wider than 1 mm have been reported to show a greater increase in root thickness, length, and apical narrowing. This finding suggests that revascularization of necrotic pulps with fully formed (closed) apices might require instrumentation of the tooth apex to approximately 1 to 2mm in apical diameter to allow systemic bleeding into root canal systems. [13]There was reduced knowledge regarding this fact, as only 154(35%) correspondents were aware of it. Again, the post graduates showed the highest awareness regarding the same.

The most recognised scaffold, in this survey, to be used during REP's was Platelet Rich Fibrin. A study comparing platelet rich plasma (PRP), platelet rich fibrin (PRF) and blood clot, showed that PRF had a huge potential to accelerate the growth characteristics in immature necrotic permanent teeth as compared to PRP and blood clot. [14]

227(50.7%) of the correspondents believed that the higher cost factor for regenerative procedures would be its biggest obstacle.In a similar survey conducted by Utneja et al (2012), 74% of the participants believed that the higher cost factor would be the biggest obstacle to regenerative procedures. [15]

For those believing that complicated procedures are the biggest obstacle for regenerative endodontics, the majority belonged to the practicing dentists (40%), which may indicate a lack of trust in such procedures by practitioners.

Conclusion

Traditional root canal therapy of necrotic pulps is mechanically and materially based. But, Regenerative endodontic therapy is biologically based and intended to promote the host's natural wound healing process to restore vitality, immunity, and sensitivity of tissue in the canal space, that was destroyed by infection or trauma.

In order to harness this potential, the dental practitioners need to be aware and well informed regarding the same. This will allow the introduction of a new era in clinical endodontic dentistry, that will help in preserving the vitality of the tooth.

In this study, the dental interns lacked knowledge regarding certain aspects of the regenerative endodontic procedures. Training regarding the same can be done so as to facilitate the incorporation of regenerative endodontics in dental clinics.

A wider study group, incorporating a larger region could be done in the future to analyse the trend of REP's in today's environment.

Limitations: The study did not differentiate between the various specialities of the post graduates as well as the practitioners. Hence, knowledge levels regarding REP's between each speciality could not be determined. The study also did not differentiate between general practitioners and dental specialists.

Breast Cancer Screening: Are 'At Risk Population' Known by Public Health Nurse Practitioners?

G.M. Venkatesh[1], M. Sundar[2]

[1]Assosicate Professor, [2]Professor and Head, Department of Community Medicine, Hassan Institute of Medical Sciences, Hassan

Abstract

Introduction: Health care providers, especially Public Health Nurse who come in regular contact with women, can play an important role in providing the information regarding breast cancer. Hence this study is undertaken to assess the knowledge of risk factors associated with breast cancer and screening for breast cancer among Public Health nurse practitioners.

Method: This is a cross-sectional study designed to assess the Knowledge of risk factors associated with breast cancer and screening for breast cancer among Public Health nurse practitioners working in the Health centres of Dept of Community Medicine of Hassan Institute of Medical Sciences. All (30) Public Health nurse practitioners in the Seven Primary care facilities participated in the study.

Results: Fourteen percent of Public Health Nurse knew that most common cancer among women was breast cancer. However, 43% were aware that the obesity increased the risk of developing breast cancer. Whereas 60% were aware that nulliparity was a risk factor for developing breast cancer and 43% said having 2 or more children decreased the risk of developing breast cancer. However, 33% knew breast feeding was protective against breast cancer. Moreover, early menstruation and late menarche were known to be risk factors by 20% each, and 33% knew physical activity could be a preventive factor for Breast cancer. 96% were aware that a lump in the breast was a sign of breast cancer and 56% said discharge from the nipple was also a sign of cancer in the breast. All 100% knew that Breast Self-Examination was a screening method and only 20% were aware that clinical examination was also a method for identification of breast cancer.

Conclusion: District Health Authorities should periodically train public health nurses to improve their knowledge regarding risk factors, early signs and symptoms of breast cancer and method of cancer screening. This intern would help them to educate, suspect, and detect the breast cancer among the risk population at the earliest.

Keywords: *Breast Cancer, Risk factors, Public Health Nurse.*

Introduction

Breast cancer is the most common female cancer in the world with an estimated 2.08 million (24.2%) new cancer cases diagnosed in 2018. With age standardised incidence rate of 46.3/100000 women and age standardised mortality rate of 13/100000 women. While in India also it has now become the most common female cancer with 162 468 (27.7%) new cases reported in 2018. Whereas the age standardised incidence rate was 24/100000 women, 87090 women died from breast cancer in 2018 giving an age adjusted mortality rate of 13 per 100000 of population. And is estimated to increase to 261850 by 2040.[1]

Breast cancer risk factors include increased age, early menstrual period, late or no pregnancy, starting

Corresponding Author:
Dr. G.M. Venkatesh
Associate Professor, # 66 Doctors Quarters, Hassan Institute of Medical Sciences, Hassan
e-mail: drvenkateshgm@gmail.com

menopause after age 55, not being physically active, being overweight or obese after menopause, having dense breast, using combination hormone therapy, taking oral contraceptives, personal history of breast cancer, family history of breast cancer, previous treatment using radiation therapy and alcohol consumption. [2-8]

Adequate knowledge about the signs and symptoms and early breast cancer detection through breast self-examination (BSE) or clinical breast examination (CBE) or mammogram, is crucial to reducing breast cancer-related morbidity and mortality.[9] Screening asymptomatic women by means of breast self-examination, clinical examination or mammography can play a significant role in decreasing breast-cancer mortality in developing countries.[10] The Breast Health Global Initiative developed appropriate guidelines that can be used in nations with limited health care resources to improve breast cancer outcomes.[11]

Health care providers, especially Public Health Nurse who come in regular contact with women, can play an important role in providing the information regarding breast cancer.[12] Empowering nurses with information about early detection method and their related benefits could help in advancing their skills in performing breast self-examination and expanding their role as client educators.[13] Education and awareness need to be culturally appropriate and targeted towards the relevant risk population, because this may contribute towards an increase in early presentation so that highest benefit can be gained.[14] The information obtained could help to initiate interventions to address the gaps in knowledge of Public Health Nurses towards breast cancer-related risk factors, signs and symptoms and early breast cancer detection through breast self-examination (BSE) or clinical breast examination (CBE). Hence this study is undertaken to assess the knowledge of risk factors associated with breast cancer and screening for breast cancer among Public Health nurse practitioners.

Methodology

This is a cross-sectional study designed to assess the knowledge of, risk factors associated with breast cancer and screening for breast cancer among Public Health nurse practitioner in the Health centres of Dept of Community Medicine of Hassan Institute of Medical Sciences. We have seven Health Centre with following number of Public Health Nurse Practitioners (Salagame PHC (7), Krishna Urban PHC (5), Shantigrama CHC (5), Masalehosahalli CHC (3), Nitturu PHC (4), Dudda CHC (3), Konanuru PHC (3)). All (30) Public Health nurse practitioners in the selected health facilities participate in the study over a period of 2 months. A pretested questionnaire was used to collect the data. The questionnaire included information on sociodemographic profile of the study subjects, knowledge of breast cancer risk factors, knowledge of breast cancer signs and symptoms, knowledge of Breast Self-Examination, Clinical Examination and Mammography. Data collection on Knowledge of breast cancer among the participants was assessed based on knowledge on risk factors of breast cancer, signs and symptoms of breast cancer and knowledge on BSE and CBE. The assessment is done by scoring breast cancer knowledge computed by giving "1" to the correct answer, and "0" for the wrong and 'do not know' answers. The data obtained was entered excel and analysed using epi info software. The data is display using tables and graphs.

Results

Knowledge about the risk factors for breast cancer among the study participants: Thirteen percent of Public health nurse knew that most common cancer among women was breast cancer and 36% said this cancer was inherited. However, 43% were aware that the obesity increased the risk of developing breast cancer and 30% were aware that the large breast increases the risk of developing breast cancer. Whereas 60% were aware that nulliparity was a risk factor for developing breast cancer and 43% said having 2 or more children decreased the risk of developing breast cancer. However, 33% knew breast feeding was protective against breast cancer. Moreover, early menstruation and late menarche were known to be risk factors by 20% each. However, 60% knew that advancing age was a risk factor for Breast cancer and 66% knew consumption of alcohol can be a risk factor for developing breast cancer but only 33% knew that physical activity could be a preventive factor for Breast cancer. (Table -1)

Knowledge about signs and symptoms of Breast Cancer: 96% were aware that a lump in the breast was a sign of breast cancer and 56% said discharge from the nipple was also a sign of cancer in the breast, whereas 80% of the Public health nurse said pain and swelling in the breast was also a sign of Breast Cancer. Dimpling in the breast was understood to be a sign cancer among 50% of Public health nurse and 46% were aware that ulceration in the breast can be a sign of cancer. Only

30% knew that weight loss can also be a symptom of cancer whereas a majority 63% were aware that the change in the shape of the breast tissue can be a sign of cancer. A minimal 16% of Public health nurse had known that inversion of nipple can be a sign of cancer but 46% were aware that a lump in the arm pit could be a sign of breast cancer. But very few 16% knew that the dry skin on the nipple region can be a symptom of breast cancer. (Table 2).

Knowledge about Screening Method: A large majority 100% knew that Breast Self-Examination was a screening method to appreciate sign of cancer and only 20% were aware that clinical examination was also a method for identification of breast cancer and none of them knew about mammography as a screening method for identification of breast cancer. (Table 3).

Table 1: Knowledge about risk factors of breast cancer among the study Participants

		No (30)	%	Sd
1	Breast cancer is the most common cancers among women	4	13	1.4
2	Breast Cancer is an Inherited Disease	11	36	3.5
3	Being Overweight and Obese increase the risk of developing Breast Cancer	13	43	4.4

Discussion

Breast cancer is the most common female cancer in the world as well as in India. Panieri E et al 2012.[15] Opined that screening asymptomatic women by means of breast self-examination, clinical examination or mammography can play a significant role in early detection of breast cancer.[13].

Knowledge about the risk factors for breast cancer among the study participants: Only thirteen percent of Public health nurses knew that most common cancer among women was breast cancer. The study shows that our public health nurses are not oriented to the problem of Cancer in their population and women cancer in particular. However, factors like multiparity, breast feeding and physical activity as protective factors was not known by many. This shows that the respondents are not informed of the protective factors. Shuyuasa et al[16] in their study found that the risk for breast cancer development among single was 49% more as compared to the married women and also nulliparous woman had 38% more risk as compared to women with 5 or more children. A recent meta-analysis by Zhou Y et al[17] in 2015 involving twenty-four articles with 13,907 breast cancer cases showed that breastfeeding was inversely associated with the risk of breast cancer. Wherein the relative risk of breast cancer for the ever breastfeeding compared with never was 0.613 and an inverse association was found for the longest as compared with the shortest duration of breastfeeding with the relative risk of 0.471. Also, Pettapiece-Phillips R et al (2015)[18] in their study reported that physical activity increases the expression of normal *BRCA1* or *BRCA2* gene and their by mitigating inherited *BRCA* mutation. Our study shows that the study population are poorly informed about the association of mensuration on breast cancer. This has been documented by shuyuasa et al[16], that relative risks of breast cancer for women reporting menarche prior to the age of 13 years was twice as high as that for those with menarche occurring after 16 years of age. The author also recorded relative risk of 1.40 for women reporting menopause at 50 years of age or over, as compared to those reporting it prior to 50 years. Also 66% knew consumption of alcohol can be a risk factor for developing breast cancer. This association was recorded by Romieu et al 2015 [19] in their study, wherein it was estimated that, for each 10 g/day increase in alcohol intake the risk increased by 4.2%.

Knowledge about signs and symptoms of Breast Cancer: 96% were aware that a lump in the breast was a sign of breast cancer, which is better than that of a finding reported by Negalign Getahun et al [20] from china where breast lump was the most commonly known symptom of cancer by 61.7% of the respondents. This may be because of the recent experience of the public health nurses with the cases in their field practice areas. Dimpling in the breast was understood to be a sign of cancer among 50% of public health nurse and 46% were aware that ulceration in the breast can be a sign of cancer. Similar observations were reported by Andegiorgish et al [21] in their study, where more than 85% of the respondents stated that a lump in the breast, change in the size of the breast and discoloration/dimpling of the breasts are the major signs of breast cancer.

Knowledge about Screening Method: All 100% knew that Breast Self-Examination was a screening method to appreciate sign of cancer and only few were aware that clinical examination was also a method for identification of breast cancer, Santhana krishnan et al[22] in their study among nursing staff reported that 73.2% mentioned BSE as a screening test and only 20% mentioned CBE as a diagnostic test. This observation is likely because of the training under non communicable disease programme initiative where predominantly teaching is about the signs and symptoms of breast cancer and about breast self-examination.

Conclusion

Our study revealed minimal awareness of risk factors associated with breast cancer among respondents. The study found that majority of the respondents answered the most common symptom of breast cancer and were aware of breast-self-examination. So, we recommend that District Health Authorities to periodically train public health nurses to improve their knowledge regarding risk factors, early signs and symptoms of breast cancer and method of cancer screening. This intern would help them to educate, examine and detect the breast cancer among the risk population at the earliest.

Credibility of Health Care Advertising-An Empirical Understanding of its Multi-Dimensional Structure and Scale Validation with Special Reference to Children's Health Food Drinks

Indu Manish Kumar

Asst. Professor, Department of Commerce and Management, Amrita School of Arts and Sciences, Amrita Vishwa Vidyapeetham, Kochi, Kerala, India

Abstract

Advertising techniques need to be transformed based on the observations of the perceptions of consumers since they can be the directional force to any advertising aimed at those groups. The study fruitfully provides an empirical understanding about the multiple components of advertising credibility of consumer healthcare products. One of the major tasks undertaken in this research was to develop a scale which is statistically reliable and valid to measure advertising credibility in the current marketing environment of Kerala with special reference to children's health drinks.

Keywords: *Advertising credibility, corporate credibility, endorser credibility, message content credibility, consumer health care, health food drinks.*

Introduction

The tough competition in the market and large volume of advertisements make the consumers confused regarding purchase decision making. There is a tendency in the minds of consumers to distrust advertising and to doubt about the genuineness of producers and products. Sometimes they feel exploited by the advertisers. This often results in the failure of advertisements and loss of money. The opportunity for consumers to raise voice and file complaints against non-credible/ misleading advertisements again increases the risk of facing legal actions. According to Rodgers and Moore[1], advertisements that lack credibility, are often ignored or avoided by consumers. Hence knowledge about the perceived credibility of advertisements and consumer psychology may help the advertisers and marketers to avoid mistakes and adopt the right advertisement tactics. In fact, from a careful review of past-related works the researcher could observe that still gaps existed in areas of existing knowledge related to advertising credibility in terms of variables, dimensions, scales,sample, context etc. The previous studies conducted in this area approached advertising credibility with limited dimensions and items. Therefore, this paper attempts to develop a valid scale to measure Advertising Credibility. Children's Health Food Drinks segment is opted to study the dimensions and structure of perceived advertising credibility.

Credibility of Advertising: Credibility has been identified as one of the most important characteristics of a persuasive message which frequently affect the result of persuasive messages[1,2]. Advertising credibility can be defined as "the extent to which the consumer perceives claims made about the brand in the ad, to be truthful and believable"[3,4]. Rodgers and Moore[1] argue that the advertisements those lack credibility are generally ignored or avoided by consumers. According to Lafferty and Goldsmith[5], irrespective of media type, advertising credibility is a crucial inspiration for creation of attitude and subsequent behaviors.

Dimensions of Advertising Credibility: Perceived credibility of an advertisement is influenced by numerous factors, especially by the firm's credibility,

the credibility of the person who brings a message[6] and the credibility of the information content[7]. As per the literature advertising credibility has three components:

Advertiser/Corporate Credibility: Corporate credibility is defined as "the extent to which consumers believe that a firm can design and deliver products and services that satisfy customer needs and wants"[8], and has been found to have direct, positive impacts on attitude toward the ad, attitude toward the brand, and purchase intention[2,6,9].

Endorser Credibility: An endorser is an individual,recognized by the public and uses this recognition on behalf of a consumer good, by appearing with it in an advertisement[10]. Endorser credibility in this research indicates a term used to specify a communicator's positive characteristics and trustworthiness that affect the receiver's acceptance of a message[6,11]. Endorser credibility is further be classified intothree: -'Expertise','Trustworthiness' and 'Attractiveness'[6, 9,11].

Message Content Credibility: Quality of message or argument is another important determinant of ad credibility. In a study Austin and Dong[12] tried to determine if the sender along with the message would have anyimpact on the total credibility of the information. They concluded that the perceived credibility of the information is more influenced by the message than by the sender.

Objectives of the Study:

1. To understand the structure of perceived advertising credibility
2. To develop and validate a multi-dimensional scale for measuring perceived advertising credibility

Research Methodology

Exploratory and descriptive research design and survey approach have been used for the study. A preliminary study was conducted to understand the dimension structure of advertising credibility which comprised a focus group interview and pilot study. The sample for the focus group interview consisted of 50 mothers of children between 5-15 years old, and who are the consumers of CHFD and who watch TV commercials and 6 experts from advertising industry and 4 experts from marketing research. The in-depth interviews with 50 respondents were conducted and the as the second stage a pilot study was conducted by collecting responses from 50 respondents from Kochi, a South Indian City, and ensured the reliability of the instruments used for data collection.

The children's health food drinks (CHFD) industry is selected for studying the credibility of advertising communication. The CHFD brands selected for the study are Horlicks, Bournivita, Complan and Boost. The sample for the study was taken from the six corporations of Kerala state namely Kozhikode, Trichur, Kochi, Kollam, Kannur and Thiruvananthapuram. The mothers of children between 5-15 years were surveyed. For the selection of the wards (divisions) under study and for the selection of the sample respondents from the wards, multistage random sampling is used. The 2011 census document and 2015 voters list of the corporation were taken as sampling frame. The research instruments included structured questionnaires, advertisement story board and recorded TV commercials. The mothers were informed to respond to the questions related to the advertisements of their most preferred children's health drink brand. A total of 1252 responses were used for data analysis.

Measurement Tool Development: The results of focus interview and literature review gave insights in to the dimensions that should be highlighted in the study. After identifying the three relevant dimensions of ad credibility (corporate credibility, endorser credibility and message-content credibility) through focus interview, the items from validated scales used in the previous research were taken to construct the scale for advertising credibility. To measure corporate credibility 7 item scale is used based on the scale developed and validated by Newell and Goldsmith[13]. The endorser credibility measurement (13 items) was based on the scales of Ohanion, R.[11] and Goldsmith, et al.[6]. The message/ content credibility scale is developed based on the measures of Kemp, Deena G.[14], McKenzie and Lutz[4] and Wang[15] and focus group study.

Data Analysis and Discussion: The verification and cleaning of the collected data was done initially. Verification of Missing Values was done using frequency test, Outliers using Z-scores, Normality and Randomness using Kolomogorov-Smirnov test with Lillefors significance correction. Skewness and kurtosis are used to ensure non-normality doesn't exist to a problematic level. Durbin- Watson statistics was found 2.046 thus established independent observations and

"Runs" test was used to confirm randomness. Content validity is ensured through extensive literature review which helped also in the development of the constructs [16]. In this research a pilot study is conducted to ensure that the content validity concept is not violated. Criterion-related validity is ensured by using a common scale (five-point Likert scale) for measurement throughout the questionnaire.

Exploratory Factor Analysis: The next step in the scale validation procedure is to discover the dimension structure of perceived advertising credibility using the EFA. After considering the pilot study results, eliminated 3 items and finally 27 scale items have been used to measure advertising credibility. Exploratory factor analysis (Maximum Likelihood) was done using varimax rotation and the items with loading above 0.5 are taken while items with low loading were dropped. To assess the internal consistency a reliability test was conducted. Following Nunnally's suggestion[17] it is ensured that for all the constructs the Cronbach alpha coefficients were greater than 0.70.

The KMO Measure was 0.940 and the Bartlett test was significant with $p< 0.001$. The Chi-square value of 14267.39 with 351 degrees of freedom affirmed the quality of data for further analysis and served as basis for factorization. The EFA provided four components with an 'Eigen value' greater than 1, which together explained over 54.013 percent of the variance. The items used to measure Advertising credibility is shown in Table 1.

Table 1: Measures of Advertising Credibility

Item Code	Items used in the advertising credibility scale
CC1	The Company has great amount of experience.
CC2	The Company is skilled in what they do.
CC3	The Company has great expertise.
CC4	The Company does not have much experience
CC5	The Company is honest.
CC6	I trust the Company.
CC7	The Company makes truthful claims
MC1	The information about the Product is Truthful
MC2	The health care communication is believable
MC3	The overall presentation of the matter is convincing
MC4	The communicated message is clear and understandable
MC5	The ad is informative
MC6	The content and presentation are ethical
MC7	The communication by the characters seemed unbiased
EC1	The persons appeared in the ad seems Trustworthy
EC2	The persons appeared in the ad seems Dependable
EC3	The persons appeared in the ad seems to be Honest
EC4	The persons appeared in the ad seems Reliable
EC5	The persons appeared in the ad seems Sincere
EC6	The persons appeared in the ad are knowledgeable
EC7	The persons appeared in the ad are Experienced
EC8	The persons appeared in the ad seems Qualified
EC9	The persons in the ad are Skilled
EC10	The persons in the ad seems Classy
EC11	The persons in the ad seems Elegant
EC12	The persons in the ad looks Attractive
EC13	The persons in the ad are Beautiful

After EFA the factor structure evolved with four dimensions. The 27 items used in the scale were classified into 4 dimensions such as Corporate credibility, Message-content credibility, Endorser credibility- Trustworthiness and Endorser credibility- Attractiveness which is given in Table 2. The single dimension endorser credibility is divided into two subgroups here –'trustworthiness of endorser' and 'attractiveness of endorser'. The themes behind the items were the basis for naming the factors. The factors extracted in each case are given in tables below with Cronbach alpha coefficients.

Table 2: Factors extracted after EFA

Sl. No.	Factor name	Items	No. of Items	Cronbach's alpha
1	Corporate Credibility	CC1, CC2, CC3, CC4, CC5, CC6, CC7	7	0.849
2	Message Content Credibility	MC1, MC2, MC3, MC4, MC5, MC6, MC7	7	0.837
3	Endorser Credibility-Trust worthiness	EC1, EC2, EC3, EC4, EC5, EC6, EC7	7	0.85
4	Endorser Credibility- Attractiveness	EC8, EC9, EC10, EC11, EC12, EC13	6	0.841

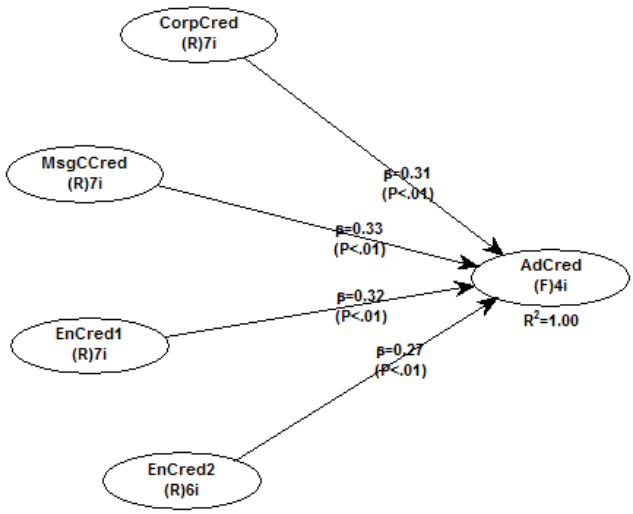

Figure 1: CFA Model - Advertising Credibility

Confirmatory Factor Analysis Using Warp PLS 5.0: The CFA was done to confirm the factor structure model of Advertising credibility construct. The main objective of conducting confirmatory factor analysis is to check the model fit ie., whether the predefined model is fit with the observed data. Confirmatory factor analysis tested the construct validity of Advertising credibility using Warp PLS 5.0 software as it is the most advanced research tool. The results for the measurement model of Advertising credibility showed an acceptable fit.

The various fit criteria are reported below: Average path coefficient/APC=0.308, P < 0.001 and Average R-squared /ARS=1.000, P<0.001 which was found significant. Average adjusted R-squared/AARS = 1.000, P<0.001. AVIF = 1.876 which is acceptable if <=5 and ideally <= 3.3. TenenhausGoF/GoF = 0.744, which should be >= 0.1, >= 0.25, >= 0.36 for small, medium and large effects respectively. Sympson's paradox ratio SPR=1.000 which is acceptable if >= 0.7, ideally = 1. R-squared contribution ratio (RSCR)=1.000 which can be accepted if >= 0.9, ideally = 1. The other fit criteria are given in Tables 4 and Table 5.

Table 3: Various Quality criteria for CFA Model

Advertising Credibility Dimensions	Composite Reliability Coefficients	Cronbach's Alpha Coefficients	Average Variances Extracted
Corporate Credibility (R)7i	0.886	0.849	0.527
Message Content Credibility (R)7i	0.877	0.837	0.506
Endorser Credibility-Trust worthiness (R)7i	0.886	0.85	0.527
Endorser Credibility- Attractiveness (R)6i	0.883	0.841	0.558

Table 4: Correlation among L.Vs. with square roots. of AVEs

Correlations among L.Vs. with sq. rts. of AVEs					
	CorpCre	MsgCCre	EnCred1	EnCred2	AdCred
CorpCre	0.726	0.648	0.539	0.435	0.719
MsgCCre	0.648	0.711	0.671	0.459	0.705
EnCred1	0.539	0.671	0.726	0.434	0.718
EnCred2	0.435	0.459	0.434	0.747	0.696
AdCred	0.719	0.705	0.718	0.696	0.807

Note: Square roots of AVEsare shown on the diagonals.

Results of CFA

The combined loadings and cross loadings ofevery indicator is significant as p-value is less than 0.05. P values less than 0.05 are desirable for reflective indicators. The indicator weights for latent variables are 0.314, 0.336, 0.318, 0.267 for corporate credibility, message-content credibility, endorser credibility-trustworthiness, endorser credibility-attractiveness, respectively.

The reliability of reflective constructs has been established as all composite reliability coefficient and

Cronbach alpha values were above 0.7. For formative constructs, reliability is not a crucial consideration. It is noticed that all average variance extracted values were > 0.5, p- values of the loadings were <0.05. The loadings were equal to or >0.5 and cross loading were <0.5. Thus, the convergent validity of reflective indicators is established. The convergent validity of the formative construct. Advertising credibility is also affirmed by observing that the corresponding AVE was > 0.5 and VIF found <0.5 for all formative indicators and weights were significant at p-value less than 0.05. Since the square root of the average variance extracted was higher than any of the correlations involving that latent variable, the discriminant validity also was confirmed.

Conclusion

Measuring and building credibility in advertising communication lessens consumer's doubt about the intension of marketers and enhances the advertising effects which will positively contribute to an increase in sales. This again will save the companies from the possible legal actions invited by the non-credible advertisements. The empirical investigation into the dimensionality of ad credibility after confirmatory factor analysis, revealed four ad credibility dimensions containing 27 ad credibility attributes.

The factor construction developed after EFA had items with adequate loadings and less conflicting cross loadings. All the 27 items could be classified into 4 dimensions such as Corporate credibility, Message-content credibility, Endorser credibility- Trustworthiness and Endorser credibility- Attractiveness. Almost all the dimensions identified as significant contributors to ad credibility. The CFA model of Advertising Credibility came out as good model with adequate fit and satisfied other quality parameters. This research contributes valid output to equip corporates and their ad agencies to assess the perceived credibility of their advertisement and to study its linkage with other brand related and purchase related variables. Based on such studies they can frame suitable advertising and marketing strategies. Since health is a sensitive issue, consumers are less willing to take risk and involvement in information search for healthcare products is more. This also highlights the need for a credible communication from society's point of view.

Ethical Clearance: The procedures followed were in accordance with the ethical standards of the responsible committee on human experimentation (institutional and national) and with the Helsinki Declaration of 1975, as revised in 2000 (5).

Abstract

Background: Epicardial adipose tissue is known to have adverse effect on local coronary health, cardiac structure and function. Echocardiography has shown to be a reliable method to measure the adipose thickness.

Aim: To study the association between epicardial adipose tissue thickness with resting and post-exercise test cardiac output.

Method: A cross-sectional study of 26 overweight and obese subjects in the age group of 20 to 50 was included. Epicardial adipose tissue thickness was measured using M-mode echocardiogram. Resting and post exercise cardiac output, ejection fraction and heart rate recovery were measured during sub-maximal exercise on treadmill.

Results: There was no significant correlation of epicardial adipose tissue thickness with resting and post-exercise cardiac output, ejection fraction and heart rate recovery.

Conclusion: Cardiac output, Ejection fractionat rest and post - exercise, also Heart rate recovery were not affected by epicardial adipose tissue thickness of less than 4 mm.

Keywords: *Epicardial adipose tissue, cardiac output, sub-maximal exercise test, body mass index, overweight and obesity, echocardiography.*

Introduction

Overweight and obesity are considered as major risk factors for cardiovascular diseases, diabetes, degenerative diseases and cancers.[1] There is an increase in morbidity and mortality resulting from obesity due to lifestyle changes in Indians.[2] Cardiovascular and metabolic diseases are found to be more prevalent in obese individuals with increased visceral adipose tissue.[3] Epicardial adipose tissue (EAT) is the fat located between the myocardium and visceral pericardium[4]. EAT is found to have influenceon local coronary artery health[5,6]. It is the true visceral fat depot of the heart. Increased amount of EAT is associated with abnormal cardiac morphology as it adds to the weight of the ventricles which may further restrict the contraction of

heart and pumping ability[7,8]. EAT has been shown to be very closely related to intra-abdominal adiposity, a marker of entire body visceral adiposity, according to various magnetic resonance imaging studies. It is well known that visceral adiposity rather than subcutaneous adiposity is more responsible for health risks associated with fat deposition in humans.[9,10]

Even though the gold standard method to measure EAT thickness is MRI, echocardiography has shown to be a reliable method to measure the adipose thickness. Epicardial fat thickness is measured on a free wall of the right ventricle from both parasternal long–and short-axis views. The largest amount of epicardial fat is usually seen at this right ventricular free wall site. Epicardial adipose tissue is usually seen as an echo- free or if it is massive, hyper-echoic space.[11,12] Stroke volume can also be measured using echocardiography. Excess VAT has a detrimental effect on sub-maximal aerobic capacity.[13] Fick's principle states that VO_2 peak will occur when the maximal arterio-venous oxygen difference and the cardiac output (CO) reach their maximum during an exercise test.[14] Thus, VO_2 peak is directly related to the maximal arterio-venous oxygen difference and CO. CO has been recognized as the most important measurement in the assessment of cardiac pump function and overall hemodynamic function.[15] The influence of increased amount of epicardial adipose tissue thickness on the cardiac function is unknown. The aim of the study is to determine the association between epicardial adipose tissue thickness and resting and post-exercise cardiac output.

Method and Materials

A cross-sectional study of 26 subjects with convenience was conducted at Cardiology department, Kasturba Hospital, Manipal. The participants of age between 20 to 50 years with BMI $\geq$ 24.9kg/m^2, both male and female sedentary individuals (who exercise less than 3 Times/week) were included. The participants with any known respiratory and musculoskeletal conditions, those on regular medications were excluded from the study

Approval from the University Ethical Committee was obtained, following which a verbal advertisement was given among all staff and students of the constituent colleges of University. Participants went for a complete cardiac evaluation to rule out any undiagnosed cardiac conditions and then subjects were recruited as per the inclusion and exclusion criteria. A written informed consent was obtained from all the eligible subjects. Procedure was explained to the subjects and following data were documented: Age(years), height (cm), weight (kg), BMI (kg/m^2), body fat percentage and the baseline characteristics like EAT thickness(mm), Heart rate (bpm), Stroke volume (ml/beat), Ejection fraction(%) were measured in the left lateral decubitus position.

A single cardiovascular technician measured EAT thickness, SV using 2-D, B-mode echocardiography, with a Trans-thoracic, parasternal view [long – axis measurement of EAT thickness and apical 4- chambered method for stroke volume (which was calculated using the formula: end diastolic volume {EDV} – end systolic volume {ESV})]. And the EF was measured using M-mode parasternal long-axis view. Subjects were then allowed to walk on the treadmill for 2 minutes to familiarize the instrument. Then test was conducted on the treadmill according to stages of Balke protocol (as per mentioned in the appendices). Test was terminated when the subjects complained of fatigue or reached 75–85% of Maximum heart rate (HRmax).The termination criteria for the study include fatigue,onset of angina or angina-like symptoms,significant decrease in SBP of 20mm Hg or more,light-headedness, confusion, ataxia, pallor, cyanosis, nausea, or signs of severe Peripheral circulatory insufficiency,excessive increase in BP systolic >260mm Hg, diastolic >115mm Hg,0 also when subject requested to stop test for whatever reason and the equipment failure. Immediately after cessation of the test, subjects were made to lie on the left lateral position as before to measure SV and EF, within the first minute and simultaneously HRR was measured at 0, 1st, 3rd, 5th minute. The data was analyzed using SPSS version 19. Pearson's correlation was used to correlate EAT with BMI and body fat percentage, EAT with resting and post exercise cardiac output and ejection fraction, EAT with heart rate recovery. Heart rate recovery pattern was analyzed using repeated measures ANOVA

Results

There was a significant difference in the resting and post-exercise cardiac output. There was a moderate correlation between epicardial adipose tissue thickness and body mass index, but no significant correlation was found between EAT and total body fat percentage. There was a significant rise in heart rate during the first minute of recovery, but it did not return to baseline by the 5th minute of recovery. However, there was no significant correlation found between epicardial adipose tissue thickness and heart rate recovery.

Figure B: 2-D, B-mode transthoracic Parasternal view, long axis measurement of EAT thickness.

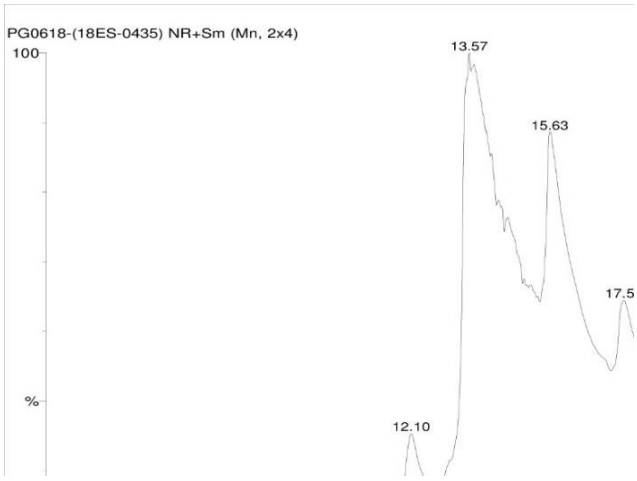

Figure C: B-mode echocardiographic, parasternal view, long axis measurement of EAT showing thickness of 3.9 mm (marked area).

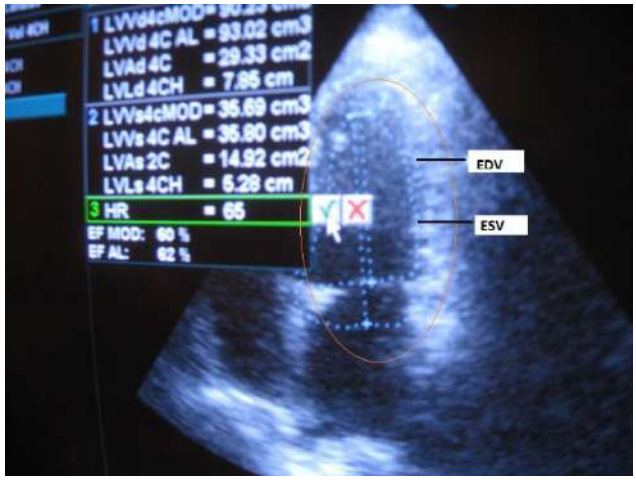

Figure D: Measurement of SV using and apical 4-chambered method (SV=EDV- ESV)

Table 1: Demographic characteristic of subjects from age group 20-50 years

	Mean ± SD (n = 26)
Age (Year)	27.46±8.78
BMI (kg/m^2)	30.16±4.41
Body fat Percentage	38.35±5.6
EAT Thickness (mm)*	2.58±0.447

°BMI – Body Mass Index *EAT- Epicardial Adipose Tissue

Table 2: Comparison of resting and post-exercise cardiac output and ejection fraction

	Resting (L/min) Mean ±SD	Post-exercise (L/min) Mean ±SD	p value
Cardiac output	3.30±0.8	6.8±1.8	<0.05
Ejection fraction	66.5±3.6	74.5±2.9	<0.05

Table 3: Correlation of BMI and body fat percentage with epicardial adipose tissue thickness

	r	p value
BMI & EAT	0.424	0.015
Total body fat % and EAT	0.183	0.186

Discussion

This study was conducted to determine the influence of EAT thickness on cardiac function. Increased amount of EAT is known to have a potential active role in the development of cardiovascular and metabolic disorders.[16] But whether excess amount of EAT thickness influences the cardiac function is not known.

In the present study, we investigated the influence of EAT thickness on CO, EF and HRR. We found that all the participants in the present study were under the categories of overweight and obese (Class 1 & 2) Indian subjects. The EAT values obtained in the present study were relatively low (1.9mm - 3.9mm) [n = 26] in comparison with African American (n = 50) & Non – Hispanic white (n=106) population (6.7- 8.9mm).[17, 18] We found a moderate correlation between overweight as well as class 1 and class 2 obesity with EAT thickness. We could not study the subjects in class 3 obese category.

In our study, a linear increase in the resting and post-exercise cardiac output and ejection fraction was found. It is known that the aerobic capacity is directly proportional to cardiac output and arterio-venous oxygen difference.[19] It has been shown that higher cardiac output in response to exercise testing in overweight people compared with normal –weight people may be explained by higher stroke volume. It is also shown that large differences in VO_2 peak values in general population are due primarily to large differences in maximal stroke volume.[20, 21]

EAT can substantially modulate the cardiac morphology and function.[22] Ejection fraction and stroke volume are good indicators of cardiac function. In this study we found no significant correlation between EAT thickness less than 4mm and resting and post-exercise cardiac output and ejection fraction. We did not find literature on association of EAT thickness with cardiac output and ejection fraction.

Heart rate recovery is a predictor of future cardiovascular events and indicates the autonomic function of the body.[23] We found no significant correlation between EAT thickness and HRR. HRR in the first minute was dropped by more than 20 beats per minutes (mean HRR was 28 bpm), indicating normal autonomic function. However, baseline values were not achieved within the fifth minute. In the study conducted by Kim et al, there was a blunted heart rate response in the 1- and 2- minute of recovery. And the cardiorespiratory fitness which was assessed as VO_2 peak was also reduced in obese men.[24] This study suggests that EAT thickness of less than 4mm does not affect the cardiac function and aerobic capacity was not affected by EAT thickness in overweight, as well as class 1 & 2 obese subjects.

The exact relationship of EAT thickness with cardiac output could not be established because of small sample size and also because of EAT thickness was not more than 4mm. Further studies are required to focus on larger sample size with wider age group distribution. Future research should include all categories of overweight and obesity. There was no significant correlation between epicardial adipose tissue thickness and resting and post-exercise cardiac output. Cardiac output, Ejection fractionat rest and post - exercise, also Heart rate recovery were not affected by epicardial adipose tissue thickness of less than 4mm.

The Effectiveness of Health Belief Model as an Educational Intervention in Improvement of Oral Hygiene: A Systematic Review

Nesa Aurlene[1], Sunayana Manipal[2], Rajmohan[3], Prabu D.[4]

[1]Post Graduate Student (Masters in Dental Surgery), [2]Masters in Dental Surgery, Reader, [3]Masters in Dental Surgery, Senior Lecturer, [4]Masters in Dental Surgery, Head of the Department and Professor, Department of Public Health Dentistry, SRM Dental College and Hospital, Ramapuram, Chennai, India

Abstract

Background: A lot of health education and promotion theories have been put forward for behaviour counselling of patients in a dental operatory. Among these, the Health Belief Model is one of the oldest theories that stats that a person's beliefs and attitudes determine the likelihood of a behaviour change.

Aims and Objectives: A systematic review was conducted to assess the effectiveness of a Health Belief Model based educational intervention in improving the oral hygiene status.

Method: An electronic database search was conducted in the months of September 2018 to November 2018 using the keywords of Health Belief Model (HBM), gingivitis, periodontitis and dental caries. Research papers and original articles using a randomized controlled trial design with assessment of oral health status through any standard indices such as DMFT, Plaque Index (PI), Periodontal pocket depth were included in the review. A total of 41 abstracts appeared, after initial screening, duplicates removal, final screening based on the inclusion criteria for the review and full-text availability of articles, a total of five articles were included in the review.

Results: All the five trials using the Health Belief Model as an educational intervention reported an improvement in the oral hygiene status of study subjects in the intervention group which was significantly different to those in the control group.

Conclusion: The Health Belief Model can be regarded as a useful educational tool to change behaviours and help in the development of behaviours that are conducive for the maintenance of good oral health. Further research is warranted to supplement the evidence that already exists to provide a clearer evidence of the usefulness of Health Belief Model in health education and health promotion.

Keywords: *HBM, dental caries, oral health, gingivitis, periodontitis.*

Introduction

The Health Belief Model developed by Irwin Rosenstock in 1966 is one the oldest health promotion theories that explained the association between health beliefs and behaviour.[1] It was conceptualized based on the reasons people gave for why they accepted or declined an X-ray examination to detect the presence of tuberculosis. This theory holds that a person's behaviour is based on six constructs of the health belief model

which are perceived susceptibility, perceived severity, perceived benefits, perceived barriers, self-efficacy and cues to action.

A person's subjective belief of whether he is susceptible to a condition or health threat, the severity of the threat, the benefits that would be accrued by adopting a recommended behaviour change, the barriers that would likely be encountered in adopting the behaviour change, the degree to which people believe that personal actions will have an effect on a health outcome, and triggers to effect a health behaviour such as mass media campaigns, advice from physicians etc., act in combination to bring about a behaviour change in individuals.[2]In a nutshell, people engage in a cost benefit analysis and then decide to adopt or not adopt a new behaviour.

Thus far, cross-sectional studies have shown a good correlation between oral hygiene behaviours and health belief model.[3] Likewise, various constructs of the health belief model have also been found to be a good predictor of dental health behaviours in studies.[4]

This review was conducted to assess the effectiveness of health belief model as an educational intervention in the improvement of oral hygiene.

Method

Objectives: To assess the effectiveness of health belief model as an educational intervention in oral hygiene improvement

Inclusion Criteria:

Original articles

In-vivo studies

Randomized controlled trials

Articles done on the effectiveness of HBM as an educational intervention in improvement of oral hygiene

Articles with full-text access

Exclusion Criteria:

Review articles

Articles without open access

Studies done on HBM's effectiveness in changing general health behaviours.

Results

The literature search yielded 41 abstracts, out of which 15 were related to the research question. Of these articles, a total of six articles with full text access were included in the final review. Figure 1 represents the flow diagram of the research papers that were searched, identified, screened, assessed for eligibility and included or excluded in the review based on the inclusion and exclusion criteria for the review.

Table 1 shows the characterization of bias in all the five studies included in the review. Most authors had not presented sufficient information in their article for a proper bias assessment. The characterisation of bias was made according to PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analysis) guidelines for randomized controlled trials.

Table 1: BIAS Analysis of the Included Studies

+ High risk, - Low risk, ? unclear risk of bias

Discussion

The cornerstone of the Health Belief Model (HBM) is that health perceptions affect health behaviours. Most studies conducted on the HBM, ascertain only the improvement in patient perceptions and oral health behaviours after an educational intervention, rather than reporting on whether an educational intervention led to any changes in the oral health status.[10-13] Hence, articles for this review were exclusively chosen only if they had reported on the oral health status using intra-oral examination as one of the components of the study.

After electronic database search, screening and retraction a total of five articles with full- text accessibility was included in this review. The first study was conducted by Wickremasinghe et al (2017) on 15-year-old children in Kellage district, Sri Lanka. The study sample was randomized into three groups with 208 members in each group, two groups served as control and one group served as the intervention group. The primary outcomes of plaque scores and bleeding on probing were found to be significantly different when comparisons were made pre and post educational intervention in the intervention group.[5]The strength of this study is that it used a didactic educational intervention in the control groups rather than no intervention. Hence, a comparison could be made between a traditional educational intervention and HBM based intervention. On such comparison, the HBM based educational intervention was found to perform better.

The weaknesses of this study are that sufficient information was not presented by the authors to ascertain the risk of bias in the study. Further, as this was a study with a follow-up period of six months there were some losses to follow up which resulted in a low-risk of bias due to incomplete data in the bias analysis.

The second study included in this review was conducted by Shahnazi et al on 56 mothers of 3-6-year-old children. The primary outcome of interest in this study was the improvement of oral health status of children following HBM based education of the mothers. In this study, the dental plaque scores of children as measured by Navy Plaque Index was found to be significantly different in the intervention and control groups after a one-month interval.[6]

The strength of this study is that, it incorporates the elements of other behavioural theories such as the Precede-Proceed model and Theory of reasoned action, which state that behaviour modification is not only based on internal factors but also external factors with "important others" playing a major role in influencing behaviours.[14-16] Primary care-givers' knowledge and attitudes have been determined to be a predictor of oral health of children in many studies.[17,18]. The weakness of this study was that sufficient information was not presented by the authors to ascertain the risk of bias in the study. Also, no attempt was made to evaluate whether a HBM based intervention affected the oral health status of the mothers participating in the study. The response rate was found to be 100% at the end of the study period with no losses to follow up. This resulted in an ascertainment of low risk of bias due to incomplete data in this study.

The third study included in this review was a study conducted by Solhi M et al (2010) on 291 twelve-year-old school children. The main outcome of this study was a reduction in mean DMFT and OHI in the HBM based intervention group at the end of six months in comparison to the control group which showed no improvement in DMFT or OHI.[7] There were considerable limitations in this study, one of which was substantial losses to follow up which led to the classification of high risk of bias due to incomplete data. Also, the methodology presented by the authors was not sufficient to ascertain the risk of other biases in this study.

The fourth study included in this review was a study conducted by Shahnazi et al (2016) on eighty-eight women in their first trimester of pregnancy. It was postulated that pregnant women were a vulnerable group prone to developing oral diseases due to a number of reasons including but not limited to hormonal changes and nutritional deficiencies.[19,20]The primary outcome of this study was that the DMFT status of pregnant mothers in the HBM intervention group remained unchanged at the four months follow up period whereas there was an increase in DMFT status of pregnant mothers in the control group.[8]The weakness of this study was that the mean DMFT was assessed at the four months follow up period for mothers in intervention and control group but no other covariates that could have confounded the study results were assessed. This study had a 100% response rate at the end of the study period and hence it could be ascertained that bias due to attrition could not have occurred in the present study. There was not sufficient information provided by the authors to ascertain other kinds of biases in the study.

The last study included in this review was a study done by Rivandi SH et al (2017) on 196 30-60-year-old outpatients attending a dental clinic in Tehran, Iran. The patients were randomized equally into a HBM based educational intervention group and control group. The primary outcome observed in the study was a reduction in microbial plaque scores and periodontal pocket depth at the one-month and three-month follow up in the HBM intervention group which was statistically significant in comparison to the control group.[9] There was a considerable loss to follow up at the third month interval in this study which led to the ascertainment of a high risk of bias due to incomplete data. The authors did not present sufficient information to ascertain risk of other biases in the study.

In this review, it was found that all the five studies unanimously reported an improvement in oral health status following a HBM based educational intervention in comparison to control groups which received alternate or no intervention. The limitation of this review is that all the five articles assessed did not provide enough information to judge the risk of most biases. Even so, this review can act as sufficient evidence as all the randomized trials included in this review showed an improvement in oral health, as shown by an improvement in standard indices measuring dentition status or periodontal status in the study subjects included in these trials. Further research with HBM based educational intervention is warranted to understand whether health education based on a theoretical model is more effective than traditional or routine method of health education.

Conclusion

A systematic review was conducted to assess the effectiveness of a theory-based approach of health education using the Health Belief Model in improvement of oral health status. However, bias ascertainment could not be done properly with the information presented by the authors and hence this review can be taken as moderate evidence for the effectiveness of HBM based health education.

Ethical Clearance: The ethical clearance for this study was obtained from the Institutional Review Board of SRM Dental College and Hospital.

Abstract

Objective: To explore effect of mental illness on marriage and marital life among the tribal Patient with Mental Illness (PMI).

Method: To achieve the objective of the study, qualitative method with multiple case study has been adopted.

Population and Sampling Technique: Population is a tribal Person with Mental Illness (PMI) and Purposive Sampling Technique is used.

Findings: The analysis has been categories into two broad areas, that is, effects of mental illness among married patient and unmarried patient with mental illness. Results indicate that, there is an adverse effect of mental illness on marriage and marital life among the patient with mental illness.

Conclusion: Marriage and mental health problems are closely related and multi-faced one. The evidence shows that, there is an adverse effect of mental illness on marriage and marital life among the tribal patient with mental illness.

Keywords: *Marriage, Mental Illness, Marriage Trajectories, Marital Life, Tribal*

Introduction

Everybody will have aspirations in their life. Marriage is one among them. In general, Marriage is a union between a man and a woman for the rest of the life. They are united not only physically, but psychologically, and socially too. The united souls now form a family. Marriage is considered as a sacred religious obligation between heterosexuals that admits individual into a family life[1]. It gives more balanced to individual's lives through establishing an enduring and continuing bond between husband and wife. It helps in solving and reducing emotional, psychological, economical and other problems[2]. So marriage is not only gratifying the sexual needs of the individuals but also helps the individuals in achieving the personality maturation through psycho-social status.

If any one of the spouse becomes mentally ill, there comes the problem in the union. If the problem is more, then the gap between them will be more. Sometimes it may result in break of the union also. There is an adverse effect of mental illness on the marriage and marital life among the patient with mental health problems[3-5]. Even there is positive association between mental illness and subsequent divorce also[4]. Different legislatures on marriage also have certain constraints on the marriage of person having mental health problems. In Hindu Marriage and Special Marriage Acts, marriage became voidable in the presence of severe mental illness[6]. Because the impact of illness will decrease the social abilities from successful marital life. Marital discord is one of the consequences among people having chronic mental health problems[7]. Behere, Rao and Verma (2011) have mentioned that, mental illness and problems in marriage are closely associated. Even patient with

mental illness is considered as a burden to the spouse[8].

When compared to men, if the woman in a family is educated, then the family will blossom. The same is in the case of illness. When compared to men, if the women in a family fell in ill, then the family will be affected more. Among the spouses, if the women are affected, then the trouble is more. The condition for married women having mental illness is very worst as they are sent back to their natal homes, divorced, or in the form of abandoned[9-10]. In Indian society, the expectation of a married woman is different from natal house to in-laws house[10]. In Indian marriage system, the severity notion of suffering is more when women married a mentally ill man than men married a mentally ill women[10]. Studies show that, constant neurotic behaviour of the patient creates a marital tension to the spouse and increase the alienation among them[11-12].

Mental illness also reduces the probability of getting married. Pre-existing mental illness reduce the chance of marriage along with in delaying the marriage process also[4, 9]. Low marital rates have been reported among the patient with mental health problems from the several studies[9]. In case of schizophrenia, patients are more likely to be staying alone or unmarried[7].This piece of research tries and find how mental is related to prosperity of marriage and the married life.

Objective of the Study: The present research explores the impact of mental illness on marriage and marital life among the tribal patient with mental illness.

Materials and Method

Study Design: The study is based on qualitative design with multiple case study method. Qualitative methods are more suitable for understanding the phenomenon of mental illness, as it focuses on the experience of the subjects.

Study Area: The purposed study has been carried out in the institutional setup. The researcher has selected the Department of Psychiatry, Ispat General Hospital (IGH), Rourkela, Odisha. IGH is a multi-speciality hospital located in the sector 19 of Rourkela city. The hospital was setup and administered Rourkela steel plant.

Study Population and Sampling: The present study has fifty cases of tribal people with mental illness. The sampling procedure had followed the 'purposive sampling' with inclusion and exclusion criteria. **Inclusion Criteria:** Following are included: Gender of the sample is both male and female; the age group is from 18 and above who is diagnosed with any form of mental disorder as per International Classification of Disease (ICD) 10; Currently admission in the hospital (In-door patients). **Exclusion Criteria:** Following are excluded: Outdoor patients (OPD); Refused to give the information; Mental retarded persons.

The key subject of the study is tribal person with mental illness. Since the subject is affected with mental illness, their cognitive ability may be reduced and the information provided by the patient may be incomplete. In order to get the in-depth information, it is required to collect the information from the family members or care givers also.

Data Collection procedure: Data sources for the study include the interviews with the tribal patient with mental illness. Data collection for this study consisted of face to face structured interviews with fifty patients and their family members / care givers. The researcher conducted interviews between June 2015 and May 2016. The mean duration of personal interview is 56.74 minutes with range of 22 minutes to 150 minutes. A specially designed interview schedule was used to collect the information. The interview process has conducted with one case in several times as per the availability of the respondent, the family members / care givers, time and their mood.

Ethical Consideration and confidentiality: The proposed study has been approved by the Ethical Committee Review Board (ECRB) of Ispat General Hospital (IGH), Rourkela, India. All the information including personal identifications shared by the respondents have been kept confidential; only the average information has been used for the research purpose.

Data Analysis and Interpretation

Socio-demographic details of the responded: The representation of male and female proportion is 28 (56%) and 22 (44%) respectively. The age of the patients with mental illness ranged from 18-72 with the mean age of the sampling 36.34. Majority of the sample (56%) belongs to the age group of 21-40. 64% respondents with mental illness are married while 36% respondents are unmarried. The unmarried age ranges from 18 to 40.

Impact of Illness on marriage and marital life of the patient with mental illness

The impact of mental illness on marriage and marital life among the patient with mental illness has been categories into two broad areas i.e. effects of mental illness after marriage and before marriage. As a result, the respondents are divided into two broad categories: married (64%) and unmarried (36%). The married category again divided into three types, namely: normal, disturbances, and divorce or separated. Likewise unmarried category has divided into four types: not attend the marriage age, not to marry, wait till the recovery of the illness, and worry about the marriage.

Impact of illness on Marital Life: Data representing on impact of illness on marital life shows that, out of 64% married PMI, 42% represents a normal marital life without any marital discord, 12% respondents have family discord and rest 8 % are divorced or staying separate.

Normal: In most of the married patient those have reached their adult hood or/and late adult hood stage, they don't have marital discord. They are trying to cope up with the situation and manage the illness along with their family members also. And in the rest of the case, where the partner is cooperative they are also maintain the balanced marital life and try to control the illness. In case of married female, where the husband and other in-laws members are cooperative, in that case family life going smooth and normal. Family support is the main reason to maintain normal life for the patient with mental illness.

Disturbances: The researchers found below mentioned reasons for the marital discord among PMI. In case where the partner is not supporting or not understanding the situation about the patient, the disturbances have started. The interference of the in-laws members or not getting support from them is also creating marital discord among the female patient and husband. If the male person is consumes alcohol during the medication is the main reason for the family disturbances. The researchers also found some other reasons like lack of proper sexual relationship, dubious attitude towards the partner, create the disturbances. These are the causes are the symptoms or side effects of the illness or psychiatric medicines.

Divorce/separated: The main reason for the divorce or separated is, where the patient (male) is not leaving alcohol and it has its subsequent negative effects to the family and the children. In that case wife is staying separately for the better future of the children with a peaceful and dignified life.

Impact of Illness on Marriage among Unmarried Patient: Data representing on impact of illness on marriage among unmarried patient shows that, 8% not attended marriage age, another 8% responded not to marry, yet another 8% reported that they wait till recovery of the illness, and worry about the marriage represents for 16% sampled population.

Not to marry: Three important reasons found by the researchers for 'not to marry'. The family members of the PMI don't want to spoil another (partner) life. Sometimes, it is believed by the patient and the family members that, the patient may suffer after marriage, if the partner may not able to cope with the patient. In some cases, though family members are interested for marriage but the patient don't want to go for marriage because s/he doesn't want loose the freedom of another human being.

Worry about the marriage: For most of the male cases where age is not reaching the marriage age or nearly about to marriage age, the family members are ready to wait till recovery of the illness. But in the case of female attending the marriage age, it is creating headache to the family members.

Discussion

Evidence from the data shows, there is high impact of mental illness on marriage and marital life among the PMI. This finding is supported by the findings of the existing study[13].The present research also shows that, in adulthood and in late adult hood, the marital life is normal. Research conducted by Miller et al.[14] shows that, mental disorders are positively associated with the marital disputes but for later age populations it is negatively associated. Another research which supports the same is by Oltmanns and Balsis (2011) which states that Well-being in long-term marriages seems to be influenced by factors that are somewhat different from those factors that have been identified in younger couples[15]. Mental illness is a risk factor for both marriage and marital life. Nambi (2005)[9] has mentioned that, alcohol addict is one of the prominent cause of family disturbance among the substance user's patients. So, high rate of divorces and family disturbances are virtually inevitable among families with alcohol addicts due to high incidence of

domestic violence[16].

16% of the samples are worried about their change of getting married. This report is supported by the two findings. a. Pre-existing mental illness having worsen condition for marriage and reduce the chance of marriage (Behere et al., 2011; Nambi, 2005).b. Premarital mental health problems are associated with lower likelihood of ever marrying (Breslau et al., 2011).

Limitations: The study has focused only limited sample size due to time constraint.

Conclusion

The authors conclude that, marriage and mental health problems are closely related and multi-faced one. The evidence shows that, there is an adverse effect of mental illness on marriage and marital life among the tribal patient with mental illness. Mental health problems are working as conflagration in marriage and marital life in the Indian marriage system. So, further extensive and large sample empirical studies are to be undertaken to understand the severity of the problem.

Abstract

Background: Iodine Deficiency Disorders is a significant public health problem all over the world.Iodine is essential element for thyroid function, necessary for normal growth, development and functioning of brain and body. **Objectives:**To estimate the prevalence of goiter among school children and to assess the prevalence of useof iodized salt. **Material and Methods:** A Cross sectional study conducted among Children between 6-12 years of ageinMappedu area.A pre-tested questionnaire, Rapid test kit to find iodine content of salt and clinical examination to assess goitre was done for the study subjects.The sample size calculated was120.Dataanalysis:Proportions and chi-square was used for analysis. **Results:** 65% were using iodized salt and remaining 35% were using non-iodised salt.The prevalence of goiter was found to be 17(14.2%).**Conclusion**:One-third of children and their family were not consuming adequately iodized salt. The consumption of iodized salt is still less in the community and Iodine Deficiency Disorders continue to be a public health problem.

***Key words**: IDD, Goiter, Iodized Salt, Rapid test kit.*

Introduction

Iodine Deficiency Disorders is known to be a significant public health problem all over the world. Iodine is essential element for thyroid function, necessary for normal growth, development and functioning of brain and body.Iodine deficiency is known to cause endemic goitre.[1]

Salt iodization programs is being implemented in many countries of the world for more than five decades ,currently only two-thirds of the global population (71%) is estimated to be covered by iodized salt, while the rest (31%) of the world population have insufficient iodine intakes, with the most affected WHO regions being South-East Asia and Europe.[2]

Corresponding Author:
Dr. D. Jayashri,
Post Graduate, Department Of Community Medicine, Saveetha Medical College. Email id: jayashri49@gmail.com, Ph no:9943080711

Iodine deficiency disorders are estimated to result in loss of 2.5 million disability adjusted life years (DALYs) (0.2% of total globally).[3]In India it is estimated that more than 71 million individuals suffer from Iodine Deficiency Disorder, while another 200 million people stay in iodine deficient areas.[4]The Iodine Deficiency Disorder control goal in India was to reduce the prevalence of IDD below 10% in the entire country by 2012.[5]

In Tamil Nadu, the IDD control cell was established with Central Government assistance and is functioning since 1st July 1994.Goiter surveys and resurveys of all the districts are being carried out periodically since 1991. According to National Family Health Survey (NFHS)-4 in Tamil Nadu proportions of households using iodized salt is 82.8%.TotalGoitre rate is reported as 13.5% in Tamil Nadu.[6]

Although the importance of iodized salt and its usage has increased in the community,Iodine deficiency poses a threat to health, wellbeing and economic productivity of the community.Progress toward the elimination of Iodine Deficiency Disorder can only be demonstrated if

it is measured.

Monitoring iodine levels of salt and iodine status of population are the two important components of Iodine Deficiency Disorder program monitoring, hence the study has been conducted.

Objectives

1.To estimate the prevalence of goiter among school children in rural area.

2.To assess the prevalence of use of iodized salt among them .

Methodology

A cross sectional study was conducted in Primary School,Mappedu between May 2018 – July 2018. Children between 6-12 years of age were selected by using Simple Random Sampling method. The sample size of 120 was calculated by using 76.2% of households residing in rural area were using iodized salt.[7]Using a pre-tested questionnaire,details regarding edible salt used within the family was obtained. Children were asked to bring 1-2 teaspoon of salt which is used for cooking purpose at their home in a sealed plastic bag and Iodine content in salt wasestimated using Rapid Test Kit.

Children were clinically examined for the presence of enlargement of thyroid gland.Children who were not present in the school at the time of data collection and those who are not willing to participate were excluded from the study. Data was entered in MS Excel. Proportions and chi-square were used for data analysis.

Salt Sample Collection & Testing:

One teaspoon of salt was obtained from each household for testing purposes.Rapid test kit was used to estimate the iodine content of salt. [8,9,10]

- One to two drops of the test solution was put on the salt sample,if the colourchanged from white to blue/ purple, indicated the presence of iodine to threshold of 15ppm.
- For alkaline salt samples or salt with high moisture content, one drop of recheck solution followed by starch solution was used to test the presence of iodine in salt.

Clinical Examination:

Enlargement of thyroid gland was assessed and presence of goiter was graded as per WHO guidelines. [6,11]

- Grade 0: Thyroid gland was neither palpable nor visible/ no goiter.
- Grade 1: A mass in the neck that is consistent with an enlarged thyroid that is palpable but not visible when the neck is in normal position. The mass moves upwards with deglutition/goitre palpable not visible.
- Grade2: A swelling in the neck that is visible when the neck is in normal position and consistent with enlarged thyroid when the neck is palpated/goiter visible and palpable.

Operational Definition For Iodised Salt:

Iodised salt is defined as one which contains iodine content of ≥ 15ppm at the household level as determined by Rapid Test Kit.[12,13,14]

Results

120 children participated in the study, they belonged to 6-12 years age group mean age was found to be 9.14 years. Majority of them (50.8%) were using powdered form of salt. 80% of the study population were storing salt away from the fire.More than 90% of respondents have kept the salt in closed container.Majority of the households have bought packed type of salt 88.3% while 11.7% were found to purchase unpacked type of salt. (Table-1)

Table 1: Background Characteristics of Study Subjects (N=120)

Background Characteristics of the study subjects (N = 120)			
S.no	**Characteristics**	**(N)**	**(%)**
1	AGE		
	6 years	18	15.0
	7 years	15	12.5
	8 years	14	11.7

Discussion

This study was carried out to assess the utilization of iodized salt in the rural community and prevalence of Clinical goiter.In the present study only 65% of the participants were consuming iodized salt which was less than reported by NFHS 4 in rural Tamil Nadu 76.2%.[7]

In our study 49.2% of the participants were using crystalline form of salt and 11.7% were getting unpacked salt.

The prevalence of goiter was found to be 14.2% in our study which was found to be similar to the results of national level survey data conducted by ICMR where the goiter prevalence was 14.1% (5-14 years age group).[15]Chandrakant et al reported 13.5% of school children showed enlargement of thyroid gland.[6] Zargar et al reported a higher prevalence of goiter30.2 % in children less than 6 years old and 50.6 % in children greater than 12 years old in Kashmir.[15]

In the present study all except 1 child who were diagnosed to have clinical Goiter were not consuming iodised salt. Odd's Ratio was found to be 47, this shows all those who were not consuming iodised salt were at 47 times greater risk of getting Goiter. Goiter is just one of the clinical manifestation of Iodine Deficiency Disorders,IDDs can also manifest as mental retardation, still birth, abortion, deafness, mutism, squint and neuromotor defects.[16]

More number of packed and powdered salt samples were found to be iodized in comparison to unpacked and crystalline salt. Indian government has issued the notification on banning the sale of non-iodised salt for direct human consumption in the country in May 2006 under the Prevention of Food Adulteration Act 1954.[17] In the present study one third of the families are found to consuming non-iodised salt. Therefore Government should take necessary actions to check the sale of unpacked salt and non-iodised crystalline salt in the market.

Conclusion

One-third of children and their family were not consuming adequately iodized salt. National Iodine Deficiency DisordersControl Programmewas startedfifty years back, but the consumption of iodized salt is still less and Iodine Deficiency Disorders continue to be a public health problem. Hence health education regarding Iodine deficiency disorders and adequate utilization of iodized salt is the need of the hour. Strict actionsshould be taken on the sale of non-iodised salt to have significant impact on the health and well-being of the country.

Limitation: The Urinary iodine excretion level was not estimated in this study.

Conflict of Interest:nil

Source of Funding:nil

Ethical Clearance: Ethical approval was obtained from the Institutional Review Board (IRB) and Institutional Ethics committee. Written informed consent was obtained from the parents of the study participants and information sheet regarding the study was given to all the participants.

E-waste: The Serious Health Hazard

Trailokya Deka

Assistant Professor, Deptt. of Economics, B. P. Chaliha College, Nagarbera, Kamrup (Assam)

Abstract

Science and technology have led to production of many electronics and electric tools and equipments starting from 18th century. Especially twenty first century is characterized by change in traditional habits and customs and adoption of modern technologies in all around the works and activities of the world. Electronic gadgets are meant to make our life happy and smooth functioning. These electronic gadgets have penetrated every aspects of our life. Frequent change of television sets; computers and mobile phones become the general habit of majority individuals in the world. We like to keep ourselves updated with the current scientific advancements. In all such a situation we never think about appropriate recycling of old electronic equipments. We frequently throw out the old electric items and usually become interested to purchase updated new items. Electronic wastes (e-waste) are increasing all around the life and works of human being. Each unit of e-waste may create every types of hazardous situation especially the health related. Electrical equipments contain toxic substances and their disposal and recycling becomes a question of health nightmare. Paper discussed definition, types and all about the health hazards of e-waste. Paper also explained little about the recycling of e-wastes in India.

Keywords*: E-waste, Hazards, Human Health, Recycling, Technology, etc.*

Introduction

Advances in science and technology have led to production of many electronics and electric tools and equipments starting from 18th century. More specifically 21st century is characterized by change of traditional habits and customs and adoption of modern technology along with luxurious tools or equipments. All electronic gadgets are meant to make our lives happy and smooth functioning. These electric gadgets have penetrated every aspect of our lives. Frequent change of television sets; computers and mobile phones become the general habit of every individual. Some times to make ourselves updated with the current scientific advancements we also become bound to change our electronic items. In all such situation we never think about reuse or appropriate recycling of old electronic items. We frequently throw out the old electric items and purchase regularly the updated new items. In that way electronic wastes (e-wastes) are increasing day by day in every walk of works and human life. Each unit of e-waste may create every types of hazardous situation especially the health related. Electronics and electrical equipments contain toxic substances and their disposal and recycling become a question of health nightmare. Though the problem varies region to region but urban areas suffers more than the rural areas.

Defining E-waste

Electronic waste or e-waste refers to all forms of electronics and electrical equipments and it's different small and big parts that have been redundant by it's owner as waste without the intent of re-use[1]. E-waste encompasses various forms of electrical and electronic equipments that may be old, might have reached the end of life and most importantly cease to be of any value to the present owner. E-waste is also synonymously called WEEE, the short form of Waste Electrical and Electronic Equipment and has been identified as one of the fastest growing waste streams in the world. E-waste may or may not create visible mountains like municipal waste but definitely a very complex, non biodegradable and toxic form of modern waste. With scientific and technological advancements total quantity of e-waste and at the same time problems generated by e-waste has been increasing day by day.

Types of E-waste:

Electronics and electrical goods are broadly

classified into major heads- 'White goods' comprise of household appliances like refrigerator, washing machine, dishwashers, air conditioner etc., 'Brown goods' that include television, cameras etc. and 'Grey goods' include computers, scanners, printer, mobile phones etc[2]. Including all the above mentioned categories, total E-waste emphatically covers the following important tools and equipments-

- **Temperature Exchange Equipments:** It include different types of cooling and freezing items like refrigerators, freezers, air conditions, heat pumps etc.

- **Screens and Monitors:** It include different types of televisions, monitors, laptops, notebooks and tablets.

- **Large Equipments:** It includes washing machines, dryers, dish washing machines, electric stoves, large printing machines, copying equipments etc.

- **Small Equipments:** It includes vacuum cleaners, microwaves, ventilations, toasters, electric kettles, radio, calculators, video camera, electric toys, small medical devices, etc.

- **IT and Telecommunication Equipments:** It includes all types of mobile phones, GPS, routers, telephones and personal computers.

- **Different Lamps:** It include high intensity discharge lamps, LED lamps, fluorescent lamps etc.

All the above mentioned electric and electronic items or equipments have different life period and respective economic values. After the end of lifetime owners generally throw out the equipments and respectively add to total quantity of E-waste.

E-waste Statistics:

Global quantity of E-waste generation in 2016 was around 44.7 Mt. or 6.1 KG per inhabitant. The global quantity of e-waste in 2016 is mainly comprised of small equipment (16.8 Mt.), large equipment (9.1 Mt.), temperature exchange equipment (7.6 Mt.), and screens (6.6 Mt.) respectively. Lamps and small IT represent a smaller share of the global quantity of e-waste generated in 2016, 0.7 Mt. and 3.9 Mt. respectively. According to one estimate, about 20 to 50 million tonnes of E-waste are being generated annually worldwide. Significantly, most of the E-waste in 2016 was generated in Asian continent which is around 18.2 Mt. or 4.2 KG per inhabitant. In Asia, China generates the highest e-waste quantity both in Asia and the world (7.2 Mt.). Japan generated 2.1 Mt, and India 2 Mt. The top four Asian economies that have the highest e-waste generation in relative quantities are- Cyprus (19.1 KG per inhabitant), Hong Kong, China (19 KG per inhabitant), Brunei and Singapore (around 18 KG per inhabitant) (Balde, CP et al, 2017). Amount of E-waste is expected to grow to 52.2 Mt. in 2021 with an annual growth rate of 3% to 4%.

Quantity of current (2016) E-waste generation for a few countries of the world is given in the following table. As it is shown in the table, quantity of E-waste generation ranges between 0.8 to 28.5 KG per inhabitant.

Table: Country wise domestic E-waste generated in 2016

Sl. No.	Country	E-waste generated (in KG per inhabitant)
1	Australia	23.6
2	Bangladesh	0.9
3	Bhutan	2.5
4	China	5.2
5	France	21.3
6	Germany	22.8
7	India	1.5
8	Italy	18.9
9	Japan	16.9
10	Malaysia	8.8
11	Myanmar	1.0
12	Nepal	0.8
13	Norway	28.5
14	Pakistan	1.6
15	Singapore	17.9
16	Sri Lanka	4.5
17	Thailand	7.4
18	USA	19.4
19	Vietnam	1.5

Source: The Global E-waste Monitor, 2017, Balde, C.P. et.al.

If we see the level of E-waste generated in developed and developing countries of the world then the difference is quite large. The richest country in the world in 2016 generated an average of 19.6 KG per inhabitant whereas the poorest generated only 0.6 KG per inhabitant.

In India, total 65 cities generated more than 60 percent of the total E-waste in the country. Among the top ten cities that generate E-waste in India, Mumbai ranks first, followed by Delhi, Bangalore, Chennai, Kolkata, Ahmadabad, Hyderabad, Pune, Surat and Nagpur respectively. Department of IT wants to provide internet connectivity in all villages in India and wants to increase the internet penetration to 90 subscribers per 1000 people by 2019. Further, the replacement rate of PCs in new age service sectors like BPOs, IT advertising etc. are on the rise. India by 2020, targeted to achieve a PC penetration of 80 per 1000 from the existing 14 per 1000 people. At present India have approximately 15 million computers, target being 85 million computers by 2020. Unfortunately, if all these goals are attained that will directly lead to manifold increase in E-waste in India (*https://rajyasabha.nic.in...E-Waste in India; 2011).*

E-waste Health Hazards

E-waste now makes up around 05 percent of all municipals' solid wastes worldwide, more or less the same amount as general plastic waste, but much more hazardous. With the fast and rapid technological change and lesser lifespan of all electric and electronic products, the problem of E-waste seems to be further compounded in future days to come. E-waste has different potential environment and health impacts if not recycled or cycled inappropriately.

Electronic products are the multifaceted mixture of several hundreds of tiny components. Most of the components in electronic devices contain Lead, Mercury, PVCs, Brominated Flame Retardants (BFRs), Chromium, Beryllium and, Phthalates. Many of these tiny components and substances contain deadly chemicals. These chemicals are the sprain on human health and the environment. Long term exposure to these substances can damage the nervous system, kidney and bones, and the reproductive and endocrine systems of human health. Some of the problems are even Carcinogenic. Heavy amounts of BFRs are used to manufacture several millions of mobile phones in the world. BFRs have been linked to neurotoxicity[3].

Besides, wastes from medical operations are directly dumped on nearby soil and water bodies. These activities are carried out without wearing any protective measures like masks, gloves etc. In many urban regions people are using cable wastes as fuel to cook food. In fact, people are being exposed to toxins 24 hours a day as they live, cook and sleep in the same place where waste is being recycled. Thus, in absence of suitable process and protective measures, recycling E-waste results toxic emissions to the air, water, soil and poses a serious environmental and health hazard.

Some of the available academic literature also explained the same serious types of issues developed from e-waste. As it is explained by Yu, Welford and Hills (2006), overall human health risks from e-waste include breathing difficulties, respiratory irritation, coughing, choking, pneumonitis, tremors, neuropsychiatric problems, convulsions, coma and even death. According to Raghupathy, K., Chaturvedi, Arora, Henzler (2010), e-waste workers are also exposed to other hazards leading to physical injuries and chronic ailments such as asthma, skin diseases, eye irritations and stomach disease. Similarly Yang, Jin, Xu & Lu (2011) explained that particulate matter collected from e-waste recycling areas can lead to inflammatory response, oxidative stress and DNA damage. Thus the health related hazardous issues of e-waste are serious to discuss in every works of human life. It is urgently needed to tackle the problem generated from the waste electronics and electric tools and equipments.

E-waste Recycle:

Currently, out of total e-waste recycled in the country mere 05 percent is recycled by the handful of formal recyclers and the rest is recycled by the informal recyclers. The E-waste recycled by the formal recyclers is done following environmentally sound practices which ensure that the damage to environment is minimized. Formal recyclers also adopt processes so that the work force is not exposed to toxic and hazardous substances released while recycling the waste. Most of the processes used by the informal recyclers are manual, using simple tools like hammer, screw driver, scissor etc. and by the use of rudimentary techniques like burning of wires in

open and using acid baths for the extraction of precious metals.

The situation in India is alarming because of adoption of unethical practices. India has also become the dumping ground of all kinds of waste from the developed countries. E-waste finds it's way into India in the name of second hand use or scrap metals. E-waste is being recycled in all most all the metros in India. Problem of E-waste recycling gets further complicated due to the adoption of unethical practices by corporate and IT companies. According to one estimate, only a few quantity of available e-waste in India is being recycled through the authorized recycling facility. This shows that some corporate are selling the waste to informal recyclers to make some quick money without realizing that they are putting people and the environment at great risk.

Conclusion

Handling of E-waste is dangerous due to chemicals present in the products and the way to tackle the problem is to design clean products that free from chemicals with longer life span. They should be easy and safe to recycle and not expose workers and the environment to hazardous chemicals. Manufacturers of electronic products must stop using hazardous chemicals and substitute them with safer alternatives.

Unfortunately, the trend of going green and clean manufacturing products free from chemicals is slowly catching up in the world as well as the country India. In April 2008, Ministry of Environment and Forest, Government of India has issued 'Guide lines for environmentally sound management of E-waste'. It focuses on the need to facilitate the recovery or reuse of useful electric materials. It incorporates reduction of e-waste quantity in every walk of life. If appropriately implemented, government initiative will reduce the wastes destined for final disposal and subsequently ensure environmentally sound management of all materials in India.

A Survey of Oral Medicine Curriculum and Practice in India

Priyanka.S.R[1], M.Arvind[2]

[1]Post Graduate Student, [2]Professor & Head, Department of Oral Medicine and Radiology, Saveetha Dental College and Hospital, Saveetha Institute of Medical and Technical Sciences, Chennai, India

Abstract

Background: Oral Medicine specialists provide clinical care to patients with a wide variety of chronic diseases affecting the oral and maxillofacial region, oral manifestations of systemic diseases and behavioral disorders and provide general dental care to patients with medically compromised states. It is important to conduct studies that address the strengths and shortcomings of our specialty and the current system of its education and practice in order to yield highly skilled professionals and truly serve the oral health care needs of the public.

Aim & Method: This study aims to describe the current status of Oral Medicine curriculum and practice in India. A survey was designed to assess the current status of oral medicine education and clinical practice. The survey was sent to Oral Medicine Specialists across India to assess their opinion and analyze the benefits and shortcomings of the present system.

Results: 52 respondents completed the survey from various states across India. More than 87% of respondents considered management of oral mucosal diseases, salivary dysfunction, oral manifestations of dermatological diseases, HIV, oral manifestations of systemic disease and facial pain as part of Oral Medicine. Only 27% of respondents reported participating in multidisciplinary clinics for treatment of patients, and 85% of respondents agreed to the need for presence of multidisciplinary clinics. 85% of respondents agreed to the suggestion of developing a curriculum for training in Special Care Dentistry for Oral Medicine postgraduates in India.

Conclusion: Limitations to this survey study include a small sample size. Future efforts at defining the scope of oral medicine practice in India and improvements in training and education can help model future graduates and inspire undergraduates to choose Oral Medicine as a career.

Keywords: *Oral Medicine, Survey, Clinical Practice, Oral Medicine curriculum*

Introduction

Oral Medicine is a specialty largely credited to Dr.Lester Burket, considered as the Father of Oral Medicine [1]. It has been a recognized specialty in many but not all countries and has been a way to integrate Medicine and Dentistry, via oral health and its effects on systemic health and vice versa. The American Academy of Oral Medicine defines it as the discipline of dentistry concerned with the oral health care of medically compromised patients and the diagnosis and nonsurgical treatment/management of medically related disorders or conditions affecting the oral and maxillofacial region [2].

Oral Medicine experts typically provide non-surgical treatment to various oral mucosal diseases, soft and hard tissue lesions, salivary gland disorders, viral, bacterial and fungal infections of the oral cavity, temporomandibular joint disorders, orofacial pain syndromes, chemosensory disorders, oral complications of cancer chemo/radiotherapy and also care for patients with oral manifestations of systemic illnesses[1]. Oral Medicine as a specialty is driven by the type of training

Corresponding Author:

Saveetha Dental College, 162, Poonamallee High Road,
Velappanchavadi, Chennai – 600077

offered, and the scope of clinical practice. Very few articles have been published that have investigated the standard of training in postgraduates and the scope of clinical practice globally [3, 4]. In two global survey studies, results have been quite parallel, most of the respondents recognizing postgraduate Oral Medicine training as a distinct field, and that the scope of practice and training competence in diagnosing and managing oral conditions that have been previously listed [3, 4]. Stoopler et al have reported that India had the largest number of oral medicine specialists compared to other countries, maybe because the Oral Medicine specialist initially screens patients in dental hospitals [4]. The objectives of this survey is to describe the status of Oral Medicine training and clinical practice among experts in India, to discuss the benefits of the current system, to address any possible shortcomings and to make recommendations to remodel future training and practice.

Materials and Method

The survey was designed using existing information from previous studies, with a closed response pattern. Standardized emails linked to online survey questionnaires (using Google Forms) were used. The email invitation to participate in the survey was sent to Oral Medicine specialists across India. A total of 52 respondents fully completed the survey. Data obtained were analyzed using simple descriptive statistics.

Results

The average age of Oral Medicine practitioners in India among the respondents was 33.8 years, with an average experience of 7.8 years. The distribution of respondents based on location has been illustrated in Figure 1. The average number of colleagues practicing with the respondents in a hospital setting was 7.6. Respondents reported a mean of working 27 h per week including clinical practice, teaching and administrative duties with a maximum of 40 hours per week

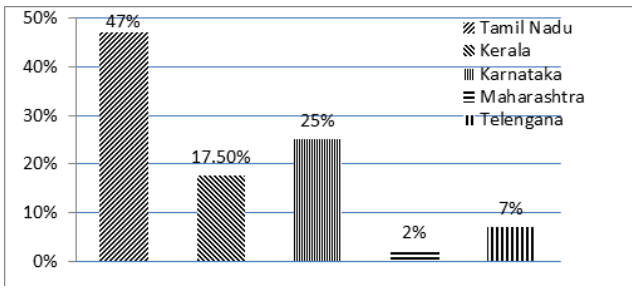

Figure 1 Percentage of respondents by state.

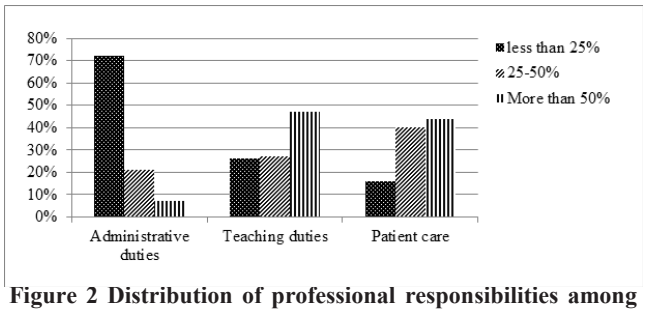

Figure 2 Distribution of professional responsibilities among practitioners

Less than 25% of the time was spent on research among practitioners.

94.3% of participants had a formal training for three years followed by an examination for certification. 24% of participants hold a PhD. 5.7% of participants had a fellowship or equivalent by a board examination and certification. Majority of respondents reported that no funding was obtained and training was predominantly self-funded.

Most commonly, practitioners reported to be a part of Oral Medicine department in Hospital/ Dental College settings with maximum time spent on teaching duties. The most common settings for Oral Medicine practice were dental hospitals and dental schools, followed by private practice. Practice in medical schools was the least common.

When asked about the definition of Oral Medicine, more than 87% respondents considered management of oral mucosal diseases, salivary dysfunction, oral manifestations of dermatological diseases, HIV, oral manifestations of systemic disease and facial pain as part of their duties. Fewer respondents considered management of patients with physical and mental disabilities and general dentistry for medically complex patients in the definition of Oral Medicine. Oral medicine plays an important role in detection, treatment and monitoring of oral potentially malignant disorders, oral manifestations of systemic diseases and oral treatment of medically compromised states. The latter two are important as they are the link between medicine and dentistry that can be a useful service for both the patient and the medical practitioner. Oral manifestations can sometimes be the starting point of diagnosis of a systemic illness or may be a sign of progression of the disease state which highlights the importance of collaboration between doctors and oral medicine practitioners [5].

A prospective survey conducted by the Diplomates of the American Board of Oral Medicine showed an

increase in patients with medically compromising states, with more than 80% of cases requiring a comprehensive evaluation of the medical condition and dental treatment for patients with severe systemic disease. Majority of referrals were from general dentists and medical practitioners [6]. This highlights the changing scenario in oral medicine treatment needs among the public. A survey conducted among medical practitioners in Chennai about the awareness of Oral Medicine as a specialty in dentistry. Only 71% of respondents were aware of the specialty of Oral Medicine and the scope of the specialty. 29% were not aware of it and many oral manifestations and orofacial disorders were not always referred to the right dental practitioner [7]. The aging population will lead to an increase in oral complications in medically compromised patients and practitioners will spend most of the times caring for the elderly and severely ill patients. So, the integration of medicine and dentistry becomes even more important and training oral medicine graduates in managing oral health needs of medically compromised, physically challenged and behaviorally compromised patients is imperative [8]. Figure 3 shows the types of oral and maxillofacial diseases that constitute the definition of oral medicine according to the survey respondents.

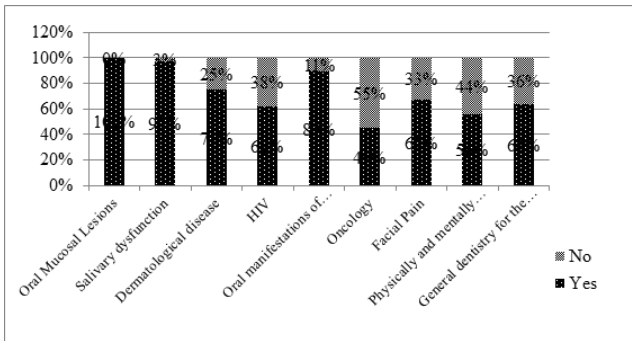

Figure 3 Definition of Oral Medicine

95% of survey respondents agreed that there is a need for better communication and integration between dental and medical practitioners. Collaboration between the dental and medical profession can highly benefit the patient, especially, patients undergoing cancer therapy, patients in intensive care units and patients in long term care facilities where dental care can be provided by a trained professional rather than non-dental personnel as poor oral health can contribute to increased morbidity and decreases quality of life [9]. This reinforces the need for educating the oral medicine graduates to serve as a partner to physicians thereby enhancing the level of care provided to patients [9].

Only 27% of respondents reported participating in multidisciplinary clinics for treatment of patients, and 85% of respondents agreed to the need for presence of multidisciplinary clinics. The use of multidisciplinary clinics is especially important when treating oncology patients, patients with severe systemic illnesses.

24% of respondents reported less than 25% of patients are seen on follow up, 45% of respondents had more than 50% of patients with follow up visits.

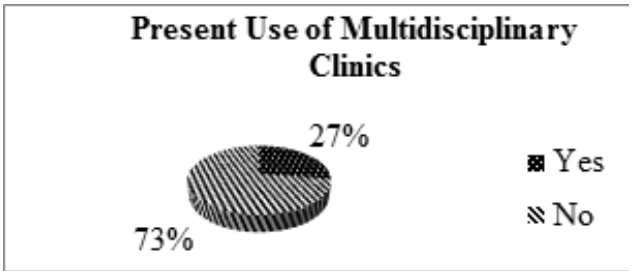

Figure 4 Use of Multidisciplinary clinics

Figure 5 represents the types of oral and maxillofacial diseases and conditions seen in oral medicine practices in India as reported by the respondents. Previous studies from other countries have reported the scope of practice, sources of referral, lesion occurrence and types of patients reporting to Oral Medicine Practices [10, 11]. Reports such as these are required to be done periodically and methodically to better understand the scope of oral medicine practice in India and to improve the curricula of postgraduate students for them to be better equipped with knowledge and skills needed to handle patients [10].

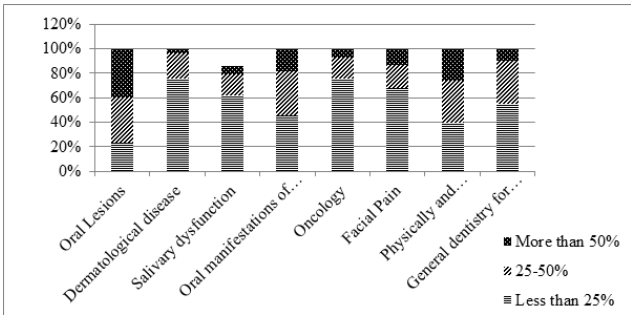

Figure 5 Percentage of patients with different orofacial diseases.

85% of respondents agreed to the suggestion of developing a curriculum for training in Special Care Dentistry for Oral Medicine postgraduates in India. Various studies have reported the medical problems in these patients and the rate of occurrence demonstrates the importance of general medicine knowledge and training in handling such patients [12-14]. Inclusion of Special Care Dentistry in the Oral Medicine curriculum does pose challenges in obtaining national consensus. Studies to identify types of patients, services available

and core skills required to qualify dentists are required for the introduction of Special Care Dentistry in the curriculum [15].

90% of respondents were open to the introduction of the internet and Smartphone applications in communication among clinicians and between patients and clinicians. Although studies have confirmed safety and benefits of Smartphone use in healthcare, adequate training and awareness of possibilities and limitations is imperative. This can be an adjunct in doctor-doctor and doctor-patient communication and help in referral and documentation [16, 17].

Discussion

This preliminary study was an attempt to investigate the current status Oral Medicine education and clinical practice across India. Our objective was to assess the practitioner and practice characteristics, investigate the types of patients treated, and the opinion of oral medicine specialists in on recommending changes and improvement in training and curriculum. Our findings suggest that oral medicine specialists in India treat a wide variety of patients including oral mucosal lesions, mucocutaneous diseases, salivary gland disorders, temporomandibular joint disorders, and oral manifestations of systemic diseases. Fewer respondents reported participation in multidisciplinary clinics, the presence of a Special Care Dentistry curriculum in the Oral Medicine postgraduate training. But almost all respondents considered provision of dental care for medically compromised patients, physically and mentally disabled patients to be a part of Oral Medicine Practice [4]. The diversity in practice characteristics can be attributed to regional variations in opinions among specialists, different systems of training and clinical practice.

There is increasing evidence that oral health has a significant effect on overall systemic health and that there are inadequacies in the interrelationships between dental and non-dental health care providers. It is time for dental education to establish integration of dental and medical training and practice in order to increase oral health knowledge among medical professionals and to increase the knowledge of oral-systemic health interface and a working knowledge of General Medicine among dental professionals. Oral Medicine Specialists may be considered the best choice for this integration because of its close connection with general health and systemic disease [18, 19]. Oral Medicine graduates should be competent enough to understand the interactions between, oral health, nutrition, general health, drug interactions, oral effects of systemic diseases, and also be familiar with provision of dental care to severely ill and physically/mentally challenged patients in a hospital setup. Training in Special Care Dentistry can provide the specialists the ability to handle challenges associated with treating physically/medically/mentally compromised patients including the management of medical emergencies, management of anxiety, management of frail/elderly patients, patients with severe systemic disease, patients in long term care facilities, treatment under general anaesthesia and sedation, and provision of dental treatment in different setups like hospitals, intensive care units, nursing homes, special schools and general practice [15, 20].

Older trends of procedure driven/mechanical dentistry are gradually being replaced by a more preventive/regenerative approach. Oral medicine is the best choice to handle the noninvasive and preventive aspects of future oral healthcare and for the integration into the medical field [21, 22]. Future studies are recommended to obtain a more detailed report of the status of oral medicine in India. Efforts at defining the scope of oral medicine practice in India and improvements in training and education can help modeling future graduates and inspire more students to choose oral medicine as a career.

A Retrospective Study on Side of Nerve Involvement and Distribution of Pain in Patients with Trigeminal Neuralgia

Priyanka.S.R, M.Arvind[1], Priyanka.S.R[2]

[1]Post Graduate Student, [2]Professor & Head, Department of Oral Medicine and Radiology, Saveetha Dental College and Hospital, Chennai, India

Abstract

BACKGROUND: Trigeminal neuralgia is chronic, debilitating and painful condition involving the trigeminal nerve and has a major impact on patients' quality of life. It is characterized by brief attacks of excruciating pain in the area of distribution of one or more branches of the trigeminal nerve. It has an annual incidence of about 4.5 to 12.6 per 100,000 population and has a female predilection. According to studies, it commonly occurs in the older age group and a hallmark of idiopathic trigeminal neuralgia is that it occurs twice as often on the right side of the face. There are various hypotheses proposed to explain this side predilection.

AIM: To evaluate and analyze the side of occurrence, distribution of pain in patients diagnosed with trigeminal neuralgia among patients visiting Saveetha Dental College.

MATERIALS AND METHOD: The retrospective clinical data of 42 patients who reported with a complaint of orofacial pain and diagnosed with trigeminal neuralgia in the department of Oral Medicine and Radiology, Saveetha Dental College from Jan 2016 to Dec 2017 were obtained. The data regarding age of onset, gender, side of nerve involvement, and distribution of pain was retrieved and analyzed.

RESULTS: Trigeminal neuralgia was mostly diagnosed in the 5th and 6thdecades of life with a mean age of 55.3 years. Male patients were affected more than female patients but the difference was not comparable. It affected the right side more frequently and the maxillary branch was the most commonly involved.

CONCLUSION: This study investigated the clinical characteristics of 42 patients diagnosed with trigeminal neuralgia. Further multicentre studies need to be done to investigate the clinical characteristics and imaging studies need to be done along with anatomical studies to investigate causes for nerve entrapment as an etiological agent for trigeminal neuralgia.

Introduction

The trigeminal nerve is the principal nerve that provides general sensory supply to the face, scalp and mouth. First described by Galen in 200 A.D as 2 pairs of separate nerves due to its large peripheral branches, Fallopius (1500's) later said that the three branches merged as one within the cranial cavity. The name "trigeminal nerve" meaning "three twins" was derived from the name "nerf trijumeau" given by a Danish anatomist Jacques-Benigne Winslow [1]. The mesencephalic nucleus, main sensory nucleus, spinal nucleus and the motor nucleus give rise to sensory and motor fibres. The nerve from the pons has a relay in the Meckel's cave wherein the Gasserian ganglion lies. Three divisions of the trigeminal nerve arise from the gasserian ganglion and exit the cranial cavity through the superior orbital fissure, foramen Rotundum and Ovale. The 3 divisions are the ophthalmic (V1) and Maxillary (V2) and the Mandibular division (V3). The nerve may be involved in a number of pathologies. A thorough understanding of its anatomy is of vital importance in

diagnosis and treatment of disease [2].

Trigeminal neuralgia (TN) is a rare condition causing excruciating, intermittent, short lasting, usually unilateral facial pain, also called as tic doloreux meaning "painful spasm". The prevalence tends to be higher in females than in males and most commonly reported above the age of 40 with a peak at 50-60 years. The right side has been reported to occur more frequently than the left [3, 4]. Sharp, stabbing or shooting, electric shock-like pain occurs in the area of distribution of one or more branches of the nerve. Pain is provoked by light touch to areas of the face termed as trigger zones. Trigger factors include washing the face, brushing teeth, shaving, and others [5].TN can be classified as Classical TN (idiopathic or primary TN) and Symptomatic TN (secondary TN). Patients with multiple sclerosis are also susceptible and frequently have bilateral facial pain [6]. While classical TN occurs without an apparent cause, symptomatic TN can usually be attributed to a recognizable disorder or pathology in intrinsic or extrinsic locations such as trauma, infections such as herpes zoster, multiple sclerosis, space occupying lesions including cysts and tumours[7, 8].

Several mechanisms attempt to explain the pathogenesis of classical TN. The leading theory is the demyelination of sensory nerve fibres due to compression by blood vessels at the nerve root. The offending vessel is the superior cerebellar artery or the anterior inferior cerebellar artery. Histological studies have revealed focal demyelination in the vicinity of the vascular compression. The demyelinated axons allow spontaneous generation of ectopic nerve impulses and ephaptic transmission to adjacent fibres[9]. The "Ignition hypothesis" (Devor et al) is the most accepted hypothesis stating that TN arises from abnormalities of the afferent neurons in the root or ganglion. Injury from neurovascular conflict causes axons hyperexcitability, resulting in paroxysmal painful sensory discharge. Neighbouring neurons are recruited, leading to a rapid buildup of electrical activity (ephaptic cross talk) and pain amplification as the demyelinated neurons lie in close contact. Devor described the stop mechanism as due to post-discharge hyperpolarisation which makes the nerve refractory to further excitation. This is seen as asymptomatic periods between attacks of pain [10]. The disease is characterized by recurrences and remissions with 50% of patients reporting periods of spontaneous remission lasting weeks, months or years [11]. Patients with new onset TN typically undergo an MRI to rule out recognizable causes and to visualize possible compressing vessels on the nerve root [9].

One clinical hallmark of classical TN is that the right side is more commonly affected than the left but there are no reasons for the blood vessels causing vascular compression to be more tortuous in the right side. One hypothesis which said that higher incidence on the right side is caused by improper brushing on this side by right handed people leading to a higher incidence of caries was discarded because the frequency of left sided TN in left handed people is not different from right handed individuals [12]. Anatomical and radiological studies have reported that foramina rotundum and ovale are asymmetrical and that the left side is wider and larger than the right [13] [14]. Vascular compression produces demyelination, an inflammatory reaction and an increase in perivascular lymphocytes, lipid laden macrophages and collagen content of the neuronal extracellular matrix distal to the site of compression [15] [16]. Neto et al [17] say that these changes can cause entrapment of the nerve on the right side more commonly than the left because of the difference in size of the foramina which could explain the higher incidence of TN on the right side. For example, cases of TN related to multiple sclerosis is also more common in the right side, and in bilateral neuralgia, the right side had more severe symptoms than the left [18]. No differences in size of foramina have been established in women and men [17]. Although earlier reports show a strong female predilection, recent reports suggest that only 60 % of the TN patients are female. No known racial or ethnic risk been reported [19]. The objective of this study is to investigate the clinical characteristics of patients diagnosed with TN.

Materials and Method

This descriptive study was carried out in the department of Oral Medicine and Radiology. Clinical data was retrieved retrospectively from the electronic clinical record database of patients diagnosed with TN from January 2016 to December 2017. 42 patients who were diagnosed with TN based on clinical features and response to treatment with carbamazapine were included. All patients were examined using orthopantomography to rule out any pathology or other odontogenic causes. Clinical data regarding age, gender, side and distribution of pain over areas supplied by the trigeminal nerve were collected and analyzed for applying descriptive statistics.

Results

The age of patients varied from 31 to 85 years with

a mean age of 55.3 years at presentation. Table 1 shows the distribution of patients based on age of onset.

Table 1 Age distribution among patients

Age in years	Male (n=23)	Female (n=19)	Total (n=42)	Percentage (%)
31-40	1	3	4	9.5%
41-50	4	3	7	16.6%
51-60	5	8	13	30.9%
61-70	12	4	16	38%
71-80	0	1	1	2.3%
>80	1	0	1	2.3%

Out of 42, 23 (54.7%) patients were male and 19 (45.2%) were female. Most of male patients were in their 6th decade of life and most of the female patients were in their 5th decade of life. Most common age group for occurrence of TN was 51-60 years (30.9%). Table 2 shows the side involved in male and female patients. 61.9% of patients had right sided TN and 33.3% had left sided neuralgia. The difference in side involved is more apparent in female patients – 14 (73.6%) patients had right sided neuralgia and only 3 (15.7%) patients had left sided neuralgia. No cases of bilateral TN were found.

Table 2 Side of involvement among male and female patients

Side of Involvement	Male (n=23)	Female (n=19)	Total (n=42)	Percentage (%)
Right	12	14	26	61.9%
Left	11	3	14	33.3%

Table 3 shows the involvement of various divisions of the trigeminal nerve in the sample. The right maxillary division was the most commonly involved nerve seen in 26.1% of patients. This was followed by equal involvement of left maxillary and right mandibular division of the trigeminal nerve seen in 19% of cases each. A combination of right maxillary and right mandibular division of the trigeminal nerve was involved in 11.9% of patients. The involvement of the ophthalmic division was the least common. Only 1 patient was diagnosed with TN of the left ophthalmic division. 1 patient had involvement of right ophthalmic and maxillary nerves. In female patients, the most common area involved is the area distributed by the right mandibular division and in male patients, the most commonly involved nerve was the right maxillary nerve.

Table 3 Pain distribution among divisions of trigeminal nerve

Division of Trigeminal nerve involved	Male (n=23)	Female (n=19)	Total (n=42)	Percentage (%)
Right ophthalmic (V1)	0	0	0	0
Left ophthalmic (V1)	1	0	1	2.3%
Right maxillary (V2)	7	4	11	26.1%
Left maxillary (V2)	5	3	8	19%
Right mandibular (V3)	3	5	8	19%
Left mandibular (V3)	3	1	4	9.5%
Combinations				
Right maxillary and mandibular (V2,V3)	1	4	5	11.9%
Left maxillary and mandibular (V2,V3)	2	2	4	9.5%
Right ophthalmic and maxillary (V1,V2)	1	0	1	2.3%
Total	23	19	42	100%

Discussion

Neuralgic pain imposes substantial amount of burden to affected patients. Patients experience excruciating pain that lasts seconds to minutes followed by a painless refractory period in between attacks. Even during the refractory period, patients are overwhelmed with fear that the pain could occur at any instant. This causes significant impairment in function and daily life [20]. Clinical criteria for diagnosis based on pain characteristics are given by the International Headache Society. Neurological examinations, MRI scanning, Sensory testing, electrophysiological studies may be used as specific investigations to rule out organic causes for symptomatic TN [8]. Early epidemiological studies have reported the right trigeminal nerve to be more involved than the left. There is very little research to explain this phenomenon. Neto et al have stated the following reasons to support their hypothesis that nerve entrapment following vascular compression of nerve root is responsible for more incidence of right sided TN [17]. The difference in size of foramen ovale and rotundum is one reason. But, while the difference in size of foramen ovale is found in 75% of cases, difference in size of foramen rotundum is seen only in 8% of cases [13, 14]. Another finding that supports this hypothesis is related to Bell's palsy. In Bell's palsy, the facial nerve also shows oedema and both right and left sides are involved with equal frequency. This could because there is very little asymmetry in the stylomastoid foramen and internal acoustic meatus for the right and left side [13, 21]. In other syndromes involving the cranial nerves such as glossopharyngeal neuralgia, hemifacial spasm, the right and left sides are equally affected and the foramina of these nerves are only slightly asymmetrical [13, 22]. Even TN occurring due to cysts and tumours in the posterior cranial fossa occur predominantly on the right side even though the cysts and tumours showed no side predilection [17].

As substantial recurrence rates are reported after decompression surgery, involvement of other factors is more likely. Nerve entrapment in the foramina may be one such factor. So, more studies are required to test this hypothesis as it may improve treatment and patient selection for surgery. In this investigation, as reported in previous studies [23-26], right side was more commonly involved than the left side. But, in contrast, male patients were affected more than female patients. This may be attributed to the small sample size. Anatomical studies could also reveal an asymmetry in foramina in the right and left side in different populations. Imaging and anatomical studies should be done to detect and quantify any such discrepancies which could explain the side and gender predilection in the Indian population.

Conclusion

This study investigated the clinical characteristics of 42 patients diagnosed with TN. It was more common in the right side and more common in male patients. The major limitation to the present study is the small sample size which could have caused discrepancies in the results compared to previous studies and the results cannot be generalized to a larger population. Further multicentre studies need to be done to investigate the clinical characteristics and imaging studies need to be done along with anatomical studies to investigate causes for nerve entrapment as an etiological agent for TN.

A Comparative Analysis of Self-Efficacy in Low Fidelity Vs High Fidelity Simulation Post Advanced Cardiac Life Support (ACLS) Sessions on Cardiac Arrest Algorithm amongst EMS Students of Pune, India

Parag Rishipathak[1], Anand Hinduja[2], Navnita Sengupta[3]

[1]Director, [2]Adjunct Faculty, [3]Medical Officer, Academics, Symbiosis Centre for Health Skills, Symbiosis International (Deemed University), Pune, India

Abstract

Background: Self-efficacy is a personal characteristic believed to increase an individual's abilities to be successful in a task. Self-efficacy, as defined by Albert Bandura is a "belief" that one possesses the requisite skills to do what is needed to reach a successful outcome."

Cardiac arrest is one of the most common emergencies encountered by EMTs in real clinical world, hence self-efficacy in such a situation is of paramount importance. Self-efficacy is composed of two key components i.e. satisfaction and confidence in one's own abilities.

Objective: The objective of the study is to compare self-efficacy reported by EMS students after

ACLS protocol on cardiac arrest algorithm using High fidelity vs low Fidelity simulation.

Methodology: Hundred PGDEMS students were chosen for the study by convenience sampling. The students were divided into two groups of fifty each after matching for age, sex and previous course grades.

Both groups were taught ACLS protocol on Cardiac Arrest Algorithm by classroom teaching over a four hour session conducted on two days.

The students were provided with a standardized and pretested "Student Satisfaction and Self- Confidence Learning Questionnaire consisting of 13 items (5 items on Satisfaction and 8 items on Self Confidence in learning). Each item was rated on a 5 point Likert Scale.

Discussion: The students in HFS group found the High Fidelity methodology to be more helpful and effective. Also the students reported greater enjoyment during the simulation activity on the High Fidelity manikin.

In terms of confidence, the HFS group reported statistically significant higher scores in 6 out of the 8 items on the questionnaire.

Conclusion: The findings of the study favor the use of High Fidelity Simulation (HFS) as the preferred methodology to teach cardiac arrest algorithm to EMS students.

Keywords: *High Fidelity Simulation (HFS), Low Fidelity Simulation (LFS), Emergency Medical Services (EMS)*

Background

Self-efficacy is a personal characteristic believed to increase an individual's abilities to be successful in a task. Self-efficacy, as defined by Albert Bandura is a "belief" that one possesses the requisite skills to do what is needed to reach a successful outcome."[1]

Self-efficacy is a very important trait required in Emergency medicine as Emergency Medical Technician

(EMT) has to respond to complex unpredictable situations in an extremely short period of time.[2]

The Post Graduate Diploma in Emergency Medical Services (PGDEMS) trains medical professionals in the basics of Emergency Medical Services (EMS).These students are taught life saving skills which help them provide medical aid even before the patient reaches the hospital. Currently EMS students are taught with the help of part-task trainers, a form of Low Fidelity Simulation (LFS) wherein students engage in problem based learning with the help of case studies. In recent years High Fidelity Simulation (HFS) using hi-tech manikins and dynamic clinical scenarios are being utilized to teach EMS students.[3]

A study by Massoth et.al[4] (2019) concluded that simulation based training has evolved into an indispensable tool in medical education. Simulation can nurture self-efficacy with the necessary motivation to create behavioral shifts that might positively influence the individual, team and patients. A study conducted by Hoadley Theresa et.al[5] (2009) showed a positive correlation between enhanced practice and learning using HFS but no significant correlation was found between the posttest and skills test scores obtained in the students of the two groups.

Another study conducted by Stellflug SM et.al6 (2017) concluded that HFS in critical emergencies increases Health Care Providers (HCPs') ability to recall valuable knowledge that can positively impact patient's outcomes.

A study by Cynthia A Blum et.al7 (2010) indicated an overall improvement in self-confidence and competence among nursing students trained on simulation. Another study by Morfoot et.al8 (2018) concluded that self-efficacy, or the belief in one's ability to succeed, is a commonly cited outcome of simulation training and can influence confidence, achievement and performance.

Cardiac arrest is one of the most common emergencies encountered by EMTs in real clinical world, hence self-efficacy in such a situation is of paramount importance. Self-efficacy is composed of two key components i.e satisfaction and confidence in one's own abilities.9

Objective

The objective of the study is to compare self-efficacy reported by EMS students after ACLS protocol on cardiac arrest algorithm using High fidelity vs low Fidelity simulation.

Methodology

Hundred PGDEMS students were chosen for the study by convenience sampling. The students were divided into two groups of fifty each (Low Fidelity simulation group and High Fidelity Simulation group) after matching for age, sex and previous course grades.

Both groups were taught ACLS protocol on Cardiac Arrest Algorithm by classroom teaching over a four hour session conducted on two days.

On the day of simulation session, students of both groups were further divided into batches of ten each. The Low Fidelity Simulation group was given a case scenario of Cardiac arrest on a part task trainer (LFS) while the High Fidelity Simulation group was given a simulated case scenario of cardiac arrest designed on High Fidelity Manikin. Each simulation session lasted for fifteen minutes.

The students then underwent a focused debriefing of five minutes after each simulation session. On completion of debriefing, the students were provided with a standardized and pretested "Student Satisfaction and Self- Confidence Learning Questionnaire consisting of 13 items (5 items on Satisfaction and 8 items on Self Confidence in learning). Each item was rated on a 5 point Likert Scale. The questionnaire's Cronbach's alpha for Satisfaction is 0.94 and for self- confidence is 0.87

The data collected was tabulated and analyzed for significance in difference of means using two-tailed t - test on Statistical Package for Social Sciences (SPSS) v23.

Results

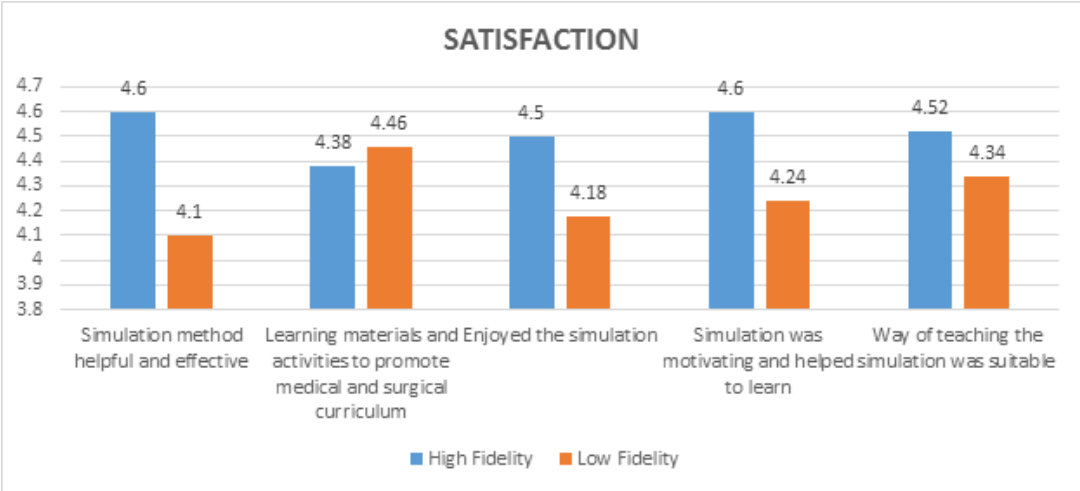

Figure 1.

The above Figure 1. depicts the comparative total mean scores obtained on the 5 items of satisfaction questionnaire by the two groups of students with High Fidelity vs low Fidelity simulation. The High Fidelity group gave higher satisfaction scores on all items except the one pertaining to the variety of learning materials and activities used during simulation.

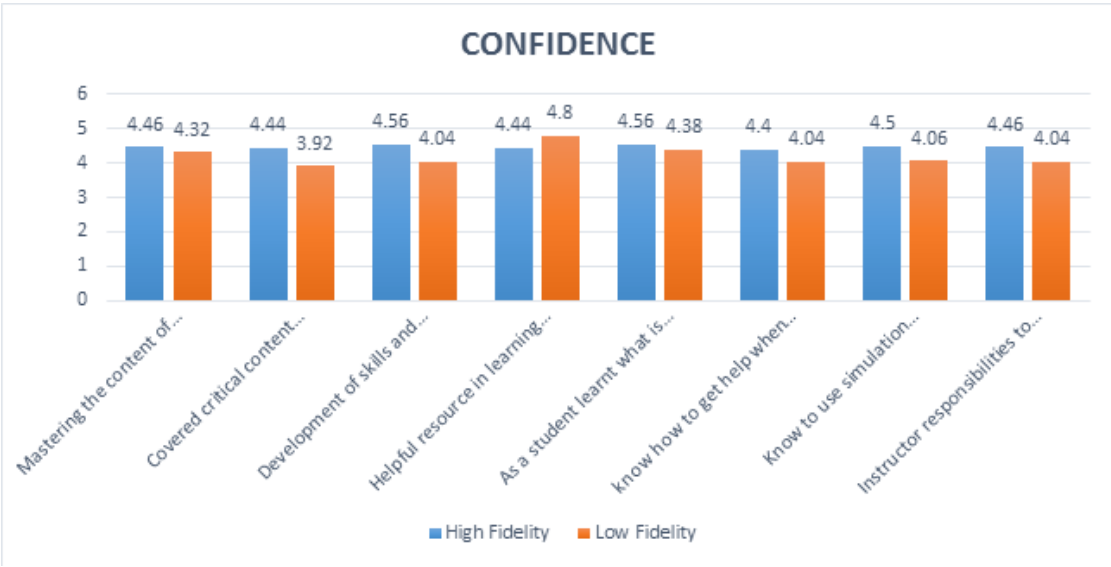

Figure 2.

The above Figure 2. depicts the comparative mean score obtained in the 8 items of self -confidence questionnaire by the two groups of students. The High Fidelity Simulation (HFS) group exuded greater confidence in all parameters except the one pertaining to the resourcefulness of the techniques in learning simulation.

Table No 1: p value for 13 items of Student Satisfaction and Self Confidence in Learning Questionnaire:

Satisfaction	**p Value**
Teaching methods used in simulation helpful and effective	0.00004*
Promote learning the medical and surgical curriculum	0.59
Enjoyed the simulation	0.006*
Teaching materials used in simulation was helpful and effective	0.14
Way the simulation taught was suitable	0.24
Confidence	
Mastering the content of simulation activity	0.00002*
Simulation covered critical content necessary for the mastery of medical and surgical curriculum	0.00002*
Developed skills and obtained required knowledge from simulation to perform necessary task in clinical settings	0.00002*
helpful resource to teach the simulation	0.0001*
Responsibility as a student to learn what is needed to know from simulation activity	0.09
To get help when didn't understand the concepts covered in simulation	0.002*
To use simulation activities to learn critical aspects of these skills	0.0001*
Instructor responsibilities to tell what is needed to learn out of simulation content	0.0008*

*indicates significance

Discussion:

The study aimed to compare the self-efficacy after a cardiac arrest reported by EMS students after a cardia arrest algorithm on Low Fidelity Simulation (LFS) vs High Fidelity Simulation (HFS). In terms of satisfaction, 2 items on the questionnaire showed statistical difference between the two groups.

The students in HFS group found the High Fidelity methodology to be more helpful and effective. Also the students reported greater enjoyment during the simulation activity on the High Fidelity manikin. It is essential that students enjoy a learning activity in order to increase the retention of knowledge and to motivate the students to participate in further learning activities.

In terms of confidence, the HFS group reported statistically significant higher scores in 6 out of the 8 items on the questionnaire. The students agreed that coverage of critical content necessary for mastering the topic of cardiac arrest algorithm was achieved better with high Fidelity technique. The HFS group considered High Fidelity as a better alternative for developing skills and obtaining knowledge on the subject. The students also felt more confident regarding the utility of simulation activities in learning, role of facilitation and instructor's responsibilities in HFS.

Interestingly the LFS group reported greater confidence in attributing simulation as a helpful resource in learning.

This finding indicates greater comfort zone shown by students to LFS as they are routinely exposed to the technique during the course. HFS being a new technique shall need more frequent exposure to be considered as a truly precise and helpful resource.

Conclusion

The findings of the study favor the use of High Fidelity Simulation (HFS) as the preferred methodology to teach cardiac arrest algorithm to EMS students. A single session positively impacted confidence and satisfaction thereby boosting the self-efficacy of EMS students. Repeated sessions of HFS for various emergencies can further augment self-efficacy among students. This can be explored in future research.

Concept Map Prebriefing Versus Traditional Prebriefing in Ischemic Stroke Management amongst EMS Students of Pune, India

Parag Rishipathak[1], Shrimathy Vijayraghavan[2], Anand Hinduja[3]

[1]Director, [2]Medical Officer, Academics, Pune, India, [3]Adjunct Faculty, Symbiosis Centre for Health Skills, Symbiosis International (Deemed University), Pune, India

Abstract

Introduction: Worldwide, stroke is the commonest cause of mortality after coronary artery disease. Majority of the stroke cases present in Emergency Department (ED). Therefore, the clinical acumen of medical staff in pre-hospital and ED in assessment of stroke is can significantly reduce the morbidity and mortality. Prebriefing helps to build confidence before exposure to the clinical scenario. This can prove to be very helpful in ischemic stroke assessment.

Objective: To study difference in competency performance amongst EMS students who participate in concept Map Prebriefing versus Traditional Prebriefing in clinical simulation scenario on Ischemic Stroke Management.

Methodology: Seventy-two PGDEMS students were chosen for the study by convenience sampling. The students were divided into two groups, A and B of 36 each after matching for age, sex and previous course grades. On the day of Simulation session, Group A was administered traditional prebriefing while Group B underwent Concept Map Prebriefing on the topic of Ischemic Stroke. The prebriefing concluded with narration of a case of Ischemic stroke. Each group was further subdivided into 6 smaller groups for ease of conducting assessment. A structured debriefing for each subgroup lasting for 20 minutes followed the Simulation session. The competency performance was scored using The LAPSS survey. The score obtained by a group could range from 0 to 8.

Discussion: The students prebriefed by the concept map methodology scored better than their peers on a number of parameters including key points in history taking. The above findings emphasize the role of comprehensive concept map prebriefing in impacting the student performance as measured by the LAPSS survey.

Conclusion: Traditional prebriefing orients the student to simulation environment but is found to be inferior to concept map prebriefing in terms of improving competency performance assessment in ischemic stroke.

Keywords: *rebriefing, Concept Map, Ischemic Stroke, high fidelity Simulation.*

Introduction

The World Health Organization (WHO) defines stroke as "rapidly developing clinical

Signs of focal (at times global) disturbance of cerebral function, lasting more than 24 hours or leading to death with no apparent cause other than of vascular origin"[1]. It is classified into two major types: Ischemic and Hemorrhagic. Ischemic stroke is by far the commonest, accounting for 85% of all strokes while hemorrhagic stroke accounts for the rest.

Worldwide, stroke is the commonest cause of mortality after coronary artery disease. In addition, it is the commonest cause of chronic adult disability. More than four-fifth of all strokes occur in developing countries In contrast to industrialized Western countries where there has been a steady decline in stroke over the

past 30 years. India is currently facing the challenge of a high stroke incidence.[3] 8–12% of patients die within 30 days of their first stroke and those that survive the first attack are at increased risk of a recurrence[4]. Hence, early assessment and management of patient is of paramount importance.

Majority of the stroke cases present in Emergency Department (ED). Therefore, the clinical acumen of medical staff in pre-hospital and ED in assessment of stroke is can significantly reduce the morbidity and mortality. Identifying signs and symptoms of a suspected stroke patient is a challenging task. Usage of standardized tools for assessment can definitively improve the diagnostic accuracy[5].

Los Angeles Prehospital Stroke Screen (LAPSS) is an 8-item survey tool consisting of four items pertaining to history taking, one item pertaining to blood glucose measurement and three items pertaining to examination for detecting unilateral motor weakness. The LAPSS allows prehospital personnel to identify patients with acute cerebral ischemia with a high degree of sensitivity and specificity. The assessment of a suspected stroke patient involves quick and accurate clinical judgement . Prompt assessment can help prehospital personnel to initiate neuroprotective drug administration in the field thereby providing treatment in the narrow therapeutic window[6].

Varying degrees of simulation have been used to teach cases of ischemic cases of ischemic stroke of EMS students. The purpose of simulation is to act as an adjunct to clinical hours, for specialty experiences ,for competency assessment, for crisis resource management or team training, and for inter-professional education[7].

Simulation experiences involve three main dimensions: pre-briefing, unfolding the scenario and debriefing. Prebriefing is the first step in a simulation based education experience.

In simulation, traditional prebriefing activities assist learners by introducing scenario objectives, and typically include communication of the patient presentation, participant roles, tasks, time allotment, and an orientation to equipment and to the general environment.[8] rebriefing helps to build confidence before exposure to the clinical scenario. There are numerous studies, which have evaluated the impact of debriefing in competency assessment, but very few studies have focused on the contribution of prebriefing in building competencies. An emerging alternative view to traditional prebriefing is utilization of concept mapping. Concept Mapping serves to connect the cognitive and reflective processes in a framework that is understandable to the learner. It enables them to use pre-existing knowledge and their assessment of a situation to develop clinical decision-making skills.[9]

This can prove to be very helpful in ischemic stroke assessment.

Objective

To study difference in competency performance amongst EMS students who participate in concept Map Prebriefing versus Traditional Prebriefing in clinical simulation scenario on Ischemic Stroke Management.

Methodology

Seventy-two PGDEMS students were chosen for the study by convenience sampling. The students were divided into two groups, A and B of 36 each after matching for age, sex and previous course grades.

On the day of Simulation session, Group A was administered traditional prebriefing while Group B underwent Concept Map Prebriefing on the topic of Ischemic Stroke.

Group A was shown a powerpoint presentation on assessment and management of Ischaemic Stroke and Group B was taught the algorithm of assessment and management of Ischemic Stroke by a concept map devised by Danielle Devine[10]

Both groups were given an orientation of the simulation lab, manikin and supplies . The prebriefing concluded with narration of a case of Ischemic stroke.

The prebriefing session lasted for 25-30 minutes for both groups followed by actual simulation session for 10 minutes. Prebriefing by both methods was conducted by the same trainer to avoid trainer bias.

Each group was further subdivided into 6 smaller groups for ease of conducting assessment. The Simulation session was followed by a structured debriefing for each subgroup lasting for 20 minutes.

The entire simulation session was video recorded with consent of the students and were later reviewed by two educators to avoid bias. The competency performance was scored using The LAPSS survey. The

score obtained by a group could range from 0 to 8.

The data was tabulated and compared for difference in means.

Result

Table 1. Traditional Prebriefing Group: The below tables show the scores obtained by each group on the items of LAPSS survey.

CRITERIA	Subgroup 1	Subgroup 2	Subgroup 3	Subgroup 4	Subgroup 5	Subgroup 6
Age over 45 years	Y	Y	Y	Y	Y	N
No prior History of Seizure Disorder	N	N	Y	Y	N	N
New onset of Neurologic Symptoms in last 24 hours	N	N	Y	N	N	Y
Patient was ambulatory at baseline	Y	Y	N	N	N	N
Blood Glucose between 60 and 100	Y	Y	Y	Y	Y	Y
Facial Grimace	Y	Y	Y	N	Y	N
Grip	Y	Y	Y	N	Y	N
Arm Weakness	Y	Y	Y	Y	Y	N
Y Score out of 8	6	6	7	4	5	2

KEY: Y indicates '**assessment done'** as per LAPSS survey

N indicates '**assessment not done'** as per LAPSS survey

Table 2. Concept Map Prebriefing Group

CRITERIA	**Subgroup 1**	**Subgroup 2**	**Subgroup 3**	**Subgroup 4**	**Subgroup 5**	**Subgroup 6**
Age over 45 years	Y	N	Y	Y	Y	Y
No prior History of Seizure Disorder	Y	N	Y	Y	N	Y
New onset of Neurologic Symptoms in last 24 hours	Y	Y	Y	Y	Y	Y
Patient was ambulatory at baseline	Y	Y	Y	Y	Y	Y
Blood Glucose between 60 and 100	Y	Y	N	Y	Y	Y
Facial Grimace	Y	Y	Y	Y	Y	Y
Grip	Y	Y	Y	Y	Y	Y
Arm Weakness	Y	Y	Y	Y	Y	Y
Y Score out of 8	8	6	7	8	7	8

Discussion

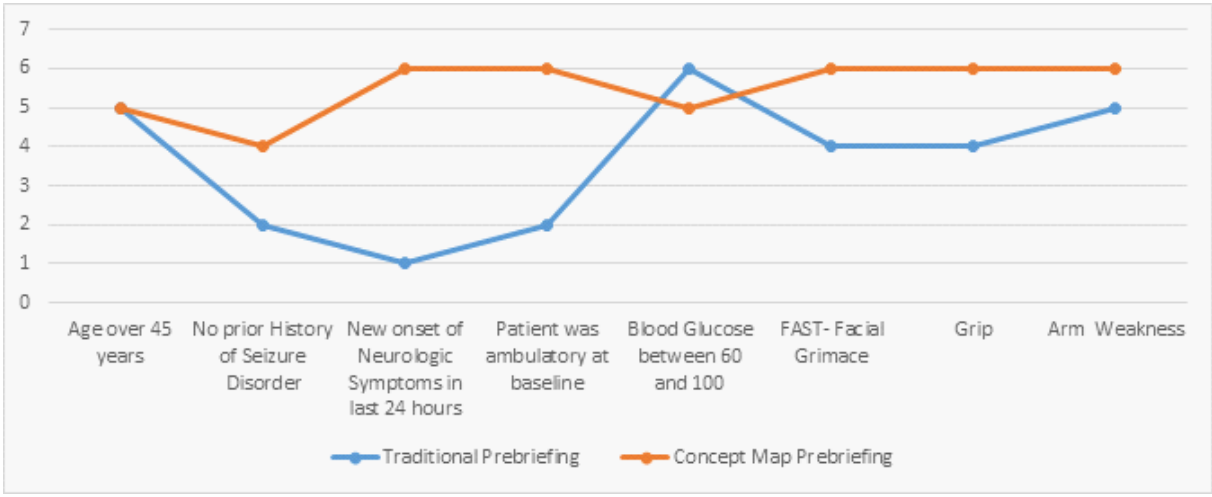

Figure 1. : Average score obtained on each parameters in Concept Map based Prebriefing versus Traditional Prebriefing Groups

As seen in figure 1. the students prebriefed by the concept map methodology scored better than their peers on a number of parameters including key points in history taking.

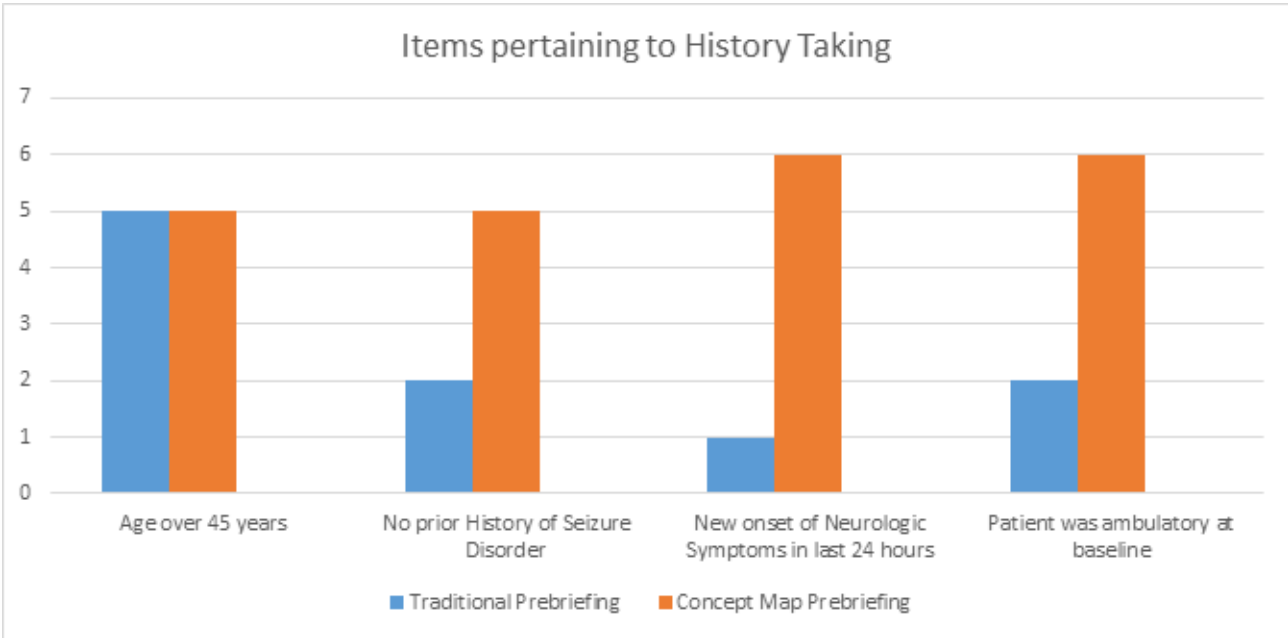

Figure 2: Items pertaining to History Taking

Five out of 6 subgroups of students who had concept map prebriefing were successful in ascertaining the age of patient as being over 45 years and history of past seizure whereas all 6 groups were successful in seeking history of existence of neurologic symptoms in last 24 hours and the information regarding ambulation of patient before the event. Contrastingly the students who underwent traditional prebriefing performed poorly on the history taking with four of the six groups failing to inquire about history of prior seizure and ambulatory status while only one group found it significant to inquire about the history of neurologic symptoms in last 24 hours.

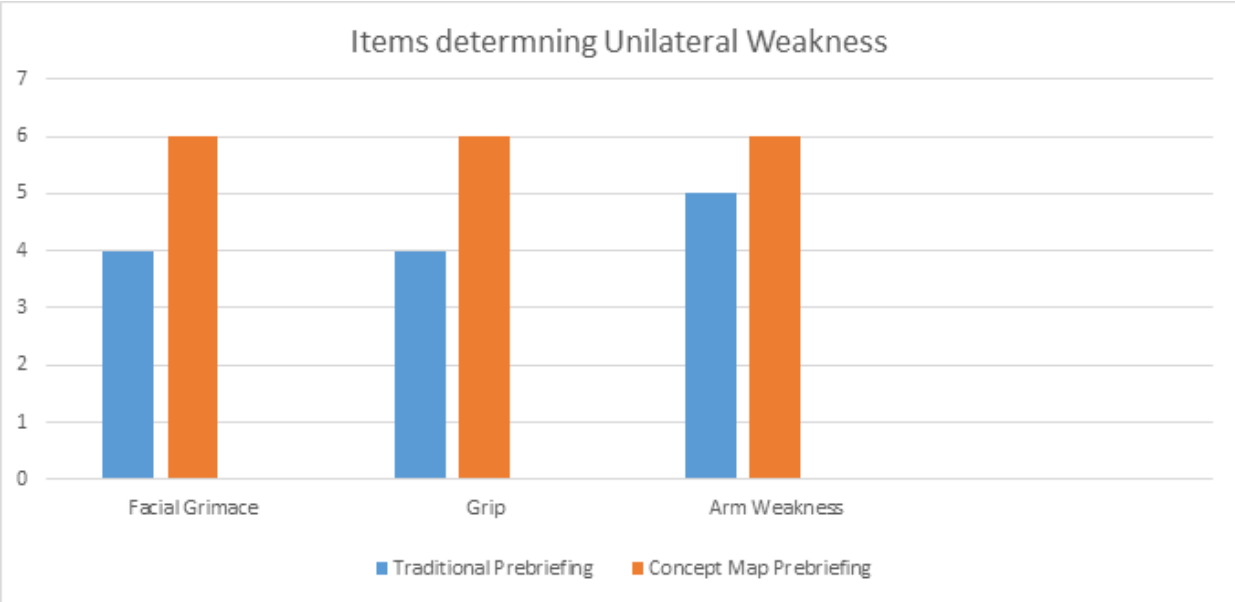

Figure 3. Items determining unilateral weakness

As seen in figure 3, in terms of clinical examination all the concept map prebriefing subgroups performed excellently and assessed all the three key parameters for unilateral weakness.

The traditional prebriefing subgroups weren't far behind in accurate assessment. Although two subgroups missed assessing the facial grimace and grip.

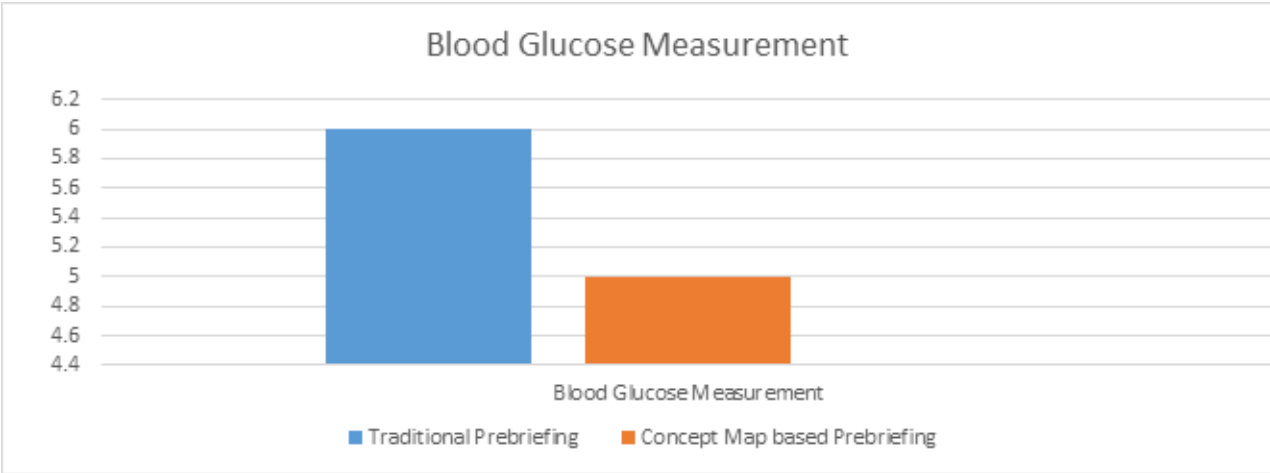

Figure 4. Blood Glucose Measurement

The concept map prebriefing subgroup did not cover the aspect of blood glucose measurement in a suspected stroke patient. This was reflected during the simulation activity when one subgroup failed to perform this action. All subgroups in the traditional prebriefing successfully carried out blood glucose measurement.

LAPSS is a reliable tool to assess competency performance in an ischemic stroke patient. The above findings emphasize the role of comprehensive concept map prebriefing in impacting the student performance as measured by the LAPSS survey.

Concept maps help users develop critical thinking and clinical judgment to support informed decision-making. It enables them to use pre-existing knowledge and their assessment of a situation to develop clinical decision-making skills. The cyclical, rather than linear nature of learning, in terms of reflecting on prior experience during prebriefing for example facilitates the continual development of decision-making skills and competent judgment in practice, and contributes to a more meaningful experience.

Conclusion

Traditional prebriefing orients the student to simulation environment but is found to be inferior to concept map prebriefing in terms of improving competency performance assessment in ischemic stroke. Further studies involving more students and multiple simulation sessions would be required to reaffirm the findings.

Incidence, Prevalence and Mortality Rates of Malaria in India, 1990-2015: An Analysis for the Global Burden of Disease Study

Ravi Prakash Jha[1], Krittika Bhattacharyya[2], Nisha Tiwari[1], Durgesh Shukla[1], Pawan Kumar Dubey[1]

[1]Research Scholar, Department of Community Medicine, Institute of Medical Sciences, Banaras Hindu University, Varanasi, Uttar Pradesh, [2]Research Scholar, Department of Statistical Genomics, National Institute of Biomedical Genomics, Kalyani, West Bengal

Abstract

Introduction: Malaria is the most important parasitic diseases of humans and one of the leading causes of morbidity and mortality in tropical countries as far parasitic disease is concerned. India is the most populous country in which malaria is common. About 95% population in the country resides in malaria endemic areas and 80% of malaria reported in the country is confined to areas consisting 20% of population residing in tribal, hilly, difficult and inaccessible areas.

Data &Methods: In this study, the 2015 global burden of diseases, injuries and risk factors (GBD) data were used to measure the incidence, prevalence, mortality, and disability-adjusted life years lost (DALY) rates of malaria during 1990–2015.Age and gender-specific causes of death for malaria were estimated using cause of death ensemble modeling.

Result: The number of new cases of malaria declined from 82.16million (95% UI 41.22–151.76 million) in 1990 to 74.83 million (95%UI 34.72–144.45) in 2015.Age-standardized mortality rate of malaria has declined by 41.07% between 1990 and 2015.The number of DALY due to malaria decreased from6.41 million (95% UI 5.52–7.42 million) in 1990 to 3.76million (95% UI 2.95–4.79 million) in 2015 with a total reduction of 41.31%.

Conclusion: India has achieved the MDG target related to malaria. In order to achieve SDG target of eliminating malaria by 2030, the Strategic Plan should aims at improving the availability and access to health care primarily to people residing in high-risk geographic areas, women and children.

Key words: *Malaria, Mortality, Incidence, Prevalence, DALY*

Introduction

Malaria is the important parasitic diseases of humans and one of the leading causes of morbidity and mortality in tropical countries as far parasitic disease is concerned. Once believed and preached that most serious and life-threatening complications of malaria patients are caused only by *Plasmodium falciparum* infection, while *Plasmodium vivax* infections are relatively mild, run a benign course and usually do not require hospitalization is changing. The malaria-endemic countries with limited health facility are still more prone to death due to malaria.[1-2]

India is the most populous country in which malaria is common.[1]More than 90% of country population settles in malaria endemic area. Also, 80% of malaria reported in the country is constrain to area with around 20% of population nest in tribal, hilly and difficult to reach areas.[3]The cases and deaths reported by the Indian Government are concentrated mainly in a few states in east and northeast India.[4] Because the Indian national malaria Programme cures nearly all the cases it treats, it detects only about 1000 malaria deaths each year, and misses most deaths caused by malaria.[5] WHO estimates

Corresponding Author:
Pawan Kumar Dubey
E-mail: pawan.dubey1@bhu.ac.in

that malaria causes only about 15000 deaths each year in India (5000 children, 10000 adults), but this too depends indirectly on the low death rates in diagnosed patients.[1]Small studies in specific regions of India or in special sub populations cannot directly estimate national numbers of malaria deaths.[5–13]

India has experienced malaria burden from the time long past. In 1950s India faces the worst period of malaria incidences with 75 million estimated cases and about 0.8 million deaths per year.[3]The launch of the National Malaria Control Program (NMCP) resulted in a drastic drop of malaria cases to less than 50,000 with no reported malaria mortality in 1961. However, malaria staged a dramatic comeback, with 6.45 million estimated malaria cases in 1976.[14]Since then, a downward trend of reported cases has begun, though slowly, as confirmed cases came down from 3 million in 1996 to 1.8 million cases with about 1,000 deaths in 2005[15] and 1.5 million reported cases and 1173 deaths in 2007.

According to the World Malaria Report 2014, 22% (275.5m) of India's population live in high transmission (> 1 case per 1000 population) areas, 67% (838.9m) live in low transmission (0–1 cases per 1000 population) areas and 11% (137.7m) live in malaria-free (0 cases) areas.[16] In 2013, 0.88 million cases have been recorded, with 128 million tests being conducted on the suspected cases, with P. falciparum causing 53% and P. vivax causing 47% of the infections. The incidence of malaria in India accounted for 58% of cases in the South-East Asia Region of WHO.[16]

The World Health Organization (WHO) recently launched the global technical strategy (GTS) for malaria, which aims to reduce the incidence and mortality rates of malaria at least by 90% by 2030.To achieve the GTS and SDG malaria targets, malaria endemic countries should have robust surveillance and health management information systems to monitor mortality and incidence rates of malaria.[17]

In the present article, global burden of diseases, injuries and risk factors-2015 (GBD) data[18–21]were utilized to estimate the incidence, prevalence, mortality, and disability-adjusted life years lost (DALY) rates of malaria for the period 1990–2015.

Method

India, with a population of nearly 1.25 billion, is the second most populous country in the world with diverse population. The unique geographic position of India in the world makes it one of the most topographically and climatically diverse country. In India, malaria cases are reported almost throughout the year, since a perfect combination of average temperature (15-30°C), rainfall and precipitation-inducing conditions persist across the different parts of the country over all the seasons.[22]The eastern and central regions of India are the most exposed to malaria.[23]

Data sources

The comprehensive source of data and rigorous analysis has been used by GBD 2015 to measure cause-specific mortality rates and risk factors for 188 counties. [20]The key sources of data to model the burden of malaria in India included verbal autopsy (VA), Medical certification of cause of deaths, National Family Health Surveys (NFHS), other surveys on cause of death and published scientific articles.[20]

Causes of death modelling

Causes of death by age groups, gender and year for malaria were measured using ensemble modeling (CODEm) by the GBD collaborators. A detailed description of CODEm is reported elsewhere.[18,20,24-25]. CODEm tests a various models, for example mixed effects linear models and spatial–temporal Gaussian process regression (ST-GPR)models and formulate an ensemble model rest on the performance of the different models.[20] In this model, uncertainty intervals (UI) are generated by sampling the posterior distribution of each component model in proportional to the weight of each model in the ensemble. Vital registration and VA data were reformed for debris codes based on the GBD algorithm.[20]

DALY, due to malaria, was measured by summing years of life lost (YLL) due to premature mortality and years lived with disability (YLD), a measure of non-fatal health loss, in a single metric. One DALY can be considered as equivalent to one lost year of healthy life. YLL were approximated by using classic GBD methods by which each death is multiplied by the normative standard life expectancy at each age. YLD were determined utilizing sequelae disability weights and prevalence, which is obtained from the general public (a population-based study) of to earmark disability weights to each sequela and combination of sequelae.[26-27]

Results

The number of new cases of malaria declined from 82.16million (95% UI 41.22–151.76 million) in 1990 to 74.83 million (95%UI 34.72–144.45) in 2015. Age-standardized incidence rate among all ages and gender declined by 30.43% over the 25 years. Malaria caused an estimated 87846.6 deaths (95% UI 77223.40–101061.07) in 1990 and 70703.34 deaths (95% UI 54588.13–94705.82) in 2015, a 19.52% reduction over the 25 years. Age-standardized mortality rate of malaria has declined by 41.07% between 1990 and 2015(Table 1).Malaria mortality rate was highest among neonates (7–27 days), post-neonatal infants (28–364 days) and older individuals (≥65 years) and lowest among individuals 10–14 years in both gender (Fig. 1).

The reduction of age-standardized incidence and mortality rates of malaria were more marked between 2005 and 2010. Like mortality and incidence rates, a reduction of (57.59%) was observed for the age-standardized prevalence rate over the last 25 years (Fig. 2).The number of DALY due to malaria decreased from 6.41 million (95% UI 5.52–7.42 million) in 1990 to 3.76million (95% UI 2.95–4.79 million) in 2015 with a total reduction of 41.31%. Similarly, age standardized DALY rate declined by 52.59% during the same period (Table 1).The reduction of age-standardized DALY rate was marked during 2005 and 2010 (Fig. 3). The age-standardized DALY rate was higher among neonatal and post-neonatal period compared to the other age groups (Fig. 1).

Table 1: Mortality, incidence, DALY and prevalence rates of malaria and percentage changes between 1990 and 2015

Measure	**1990 # or rate (95% UI)**			**2015 # or rate (95% UI)**			**% change between 1990 and 2015**
# deaths	87846.61	77223.40	101061.07	70703.34	54588.13	94705.82	-19.52

Discussion

There is a target (6C) in MDG which says of halting mortality rate from malaria by 2015 and begun to reverse the incidence of malaria. This target have been encouraging worldwide although there were variations among regions and countries.[28]India has shown some progress in reversing the burden of malaria in the last two decades. Mortality and incidence rates of malaria declined by around 41% and 30%, respectively, between 1990 and 2015 [Table 1].

As per the report of WHO, in Southeast Asia out of total malaria cases India contributes 77%. Most of the population has little or no immunity towards malaria due to the low and unstable transmission dynamic. However, some surveys have shown that in some foci, mainly in forested areas, the transmission intensity is very intense with the disease burden to a large extent concentrated in children. Malaria is particularly entrenched in low-income rural areas of eastern and north-eastern states, but important foci are also present in the central and more arid western parts of the country. About 95% population in the country resides in malaria endemic areas and 80% of malaria reported in the country is confined to areas where 20% of population resides in tribal, hilly, hard-to-reach or inaccessible areas.[29]

In India malaria cases have consistently declined from 2.08 million in 2001 to about 8.4 lakhs in 2017.[30]Malaria control measures in India include improved access to early diagnosis, the involvement of the accredited social health activists (ASHAs) at the community level, the introduction of artemisinin-based combination therapy, and intensified vector control, including long-lasting insecticidal nets (LLINs). In most of the states, the recent declines in malaria cases and mortality have been achieved chiefly through the successful control of P. falciparum, though malaria control programs have had footprint on both Plasmodium falciparum and P.vivax malaria, [31]

For prevention and control of vector borne diseases (like malaria) the National Vector Borne Disease Control Programme (NVBDCP) is an umbrella programme. The attention of the NVBDCP is on resource challenged settings and vulnerable groups.[29]NVBDCP has developed the national strategic Plan (NSP) with the support of WHO to provide a road map for making India malaria free by 2027.[30]

However, the malaria control strategy also faces several challenges to achieve WHO's targets to reduce malaria mortality and incidence rates. Lack of service providers, especially health workers and laboratory technicians, compounded by shortage of health assistant/ supervisors (Male), malaria inspectors and assistant malaria officers is a main factor affecting surveillance and service delivery, particularly in remote areas. Also, in many districts virtual absence of Rapid Response

Teams for epidemic/outbreak response is pronouncing. There is still a large gap in allocation for scaling up specific interventions like provision of RDTs, ACT and LLINs, and for positioning health care delivery and management staff both at district level and state levels to successfully attain universal coverage and impact.[29]

Moreover, inadequate malaria knowledge at community and household level, inadequate community mobilization, and inadequate appreciation of malaria as a serious disease with related consequences hinders the target.

Conclusion

India has achieved the MDG target related to malaria. In order to achieve SDG target of eliminating malaria by 2030, the Strategic Plan should aims at improving the availability and access of health care primarily to women and children. As a further matter, improving surveillance and taking care of difficult to reach areas play a crucial role in controlling spread of the disease with a view towards achieving sustainable development goal.

Effectivness of Structured Exercise Protocol for Post Menopausal Stress Urinary Inncontinence

Pooja Rajendra Mane[1], S. Anandh[2], G. Varadharajulu[3]

[1]MPTh(Community Health Sciences), [2]Professor/Unit Head (Community Health Sciences), [3]Dean/Professor/ HOD, Krishna College of Physiotherapy, Krishna Institute of Medical Sciences Deemed to be University, Karad, Maharashtra, India

Astract

Aim: To study the effect of structured exercise protocol for post menopausal stress urinary incontinence .

Objectives: To evaluate the effectiveness of structured exercise protocol for post menopausal stress urinary incontinence.

Methods: Ethical clearance was obtained from the Institutional Ethical Committee, KIMSDU, Karad. Initially the awareness program was conducted in karad and nearby areas. The selected sample was then studies at Krishna hospital, karad. 58 patients were equally divided into two group using convenient sampling with random allocation.Group A (n=29) , Group B (n= 29). Baseline treatment was IFT and bladder training program. Group A was given structured exercises, Group B was given conventional exercises.Outcome measures were analyzed after 6 weeks.

Result: Intergroup comparison in group A result showed improvement in pad test (p= <0.0001).Group B was statistically extremely significant in improvement in pad test (p = 0.0002).Group A result showed that improvement in pelvic floor muscle strength (p= <0.0001). whereas Group B showed improvement in pelvic floor muscle strength (p=<0.0001). Group A result showed improvement in all parts of kings health questionnaire (p=0.0001) and group B also showed improvement in kings health questionnaire (p= 0.0001)

Intra group analysis reviled one hour pad test, KHQ, PFM strength considered significant in both groups.

Conclusion : The study concluded that structured exercises protocol along with IFT and bladder training was equally effective in reducing dribbling of urine, improvement in QOL, PFM strength.

Key Words : *Urinary incontinence, Post menopausal women , Bladder training, Structured exercises protocol , IFT*

Introduction

Post menopause is the final stage of climetric during which stress urinary incontinence is more common. Among the symptoms stress urinary incontinence interferes in the ADL. Recurrent symptoms of vaginal dryness, hot flushes, etc. lead to urinary tract infection. Prevalence of stress urinary incontinence is 16. 13 % [1]. Estimated age for menopause world widely accepted is 45-55 years[2,3,4]. Causes of stress urinary incontinence are Pelvic floor muscle weakness or damage, Hyper mobility of the urethra, Persistent heavy straining, Chronic coughing, Neurologic damage, Decreases estrogen during the menopause [5,6] **Structured exercises:**

Specific goal oriented treatment used for treat urinary incontinence such as breathing reeducation, functional exercises with use pelvic floor muscles, modified pilates exercises and progressive vaginal cone exercises.

Effect of structured exercises :

- Improve strength of pelvic floor muscles
- Reduced stress urinary incontinence
- Improve quality of life

Interferential current therapy (IFT)

Interferential therapy helps to improve control of urination, interferential current stimulates the pudential nerve which causes the detrusar muscle inhibition and there is action of slow twitch muscle fiber which causes the control of urination [7].

Bladder training

Behavioral therapy has been used for urinary incontinence since 1940. The aim of behavioral therapy is to improve bladder control by changing the patient's behavior, especially patients voiding habits and by teaching skills for preventing urine loss. There are number of approaches for behavioral therapy which include bladder drill and bladder training, and promote voiding [8]

Method

- Study type: Experimental study
- Study design: Consecutive sampling with random allocation
- Study duration: 1 year
- Sample size: 29+29 = 58
- Place of study: Krishna Hospital, Karad

Criterion of the study

Inclusion criteria:

- Age group of 45- 65 years.
- Subject having history of urinary stress incontinence present at least 4 months.

Exclusion criteria:

- Disable subjects
- Psychiatric illness
- Subjects waiting for surgical treatment
- Subjects with spinal surgery
- Subjects with grade 3 and grade 4 osteoarthritis

Rocedure

An approval for the study was obtained from the Protocol committee and institutional Ethical Committee of KIMSDU. Awareness program was carried out for women in karad and surrounding rural areas near Krishna hospital.

It was a comparative study conducted in the Physiotherapy Department of Krishna Institute of Medical Sciences. 58 patients were equally divided into two groups using convenient sampling with random allocation . Baseline treatment was given both groups which consist IFT and bladder training . Group A was given structured exercise protocol , Group B was given conventional exercises .The patient were selected according to inclusion and exclusion criteria. Written informed consent was taken and the whole study was explained to them . detailed evaluation was done to screen the patients.

Group A – structured exercises , IFT , bladder training (with progression)

Group B – conventional exercises , IFT , bladder training (with progression)

Exercises were gave for 6 weeks / 3 alternative days

After completing 6 weeks with 3 sessions per week, post-test assessment was taken by using one hour pad test , kings health questionnaire , pelvic floor muscle strength .

The interpretation of the study was done on the basis of comparing pre-test and post-test assessment using outcome measures and were statistically analysed.

Following exercises were given for Group A and B:

Group A (Structured exercises)	Group B(conventional exercises)
Breathing Reeducation	Manual Facilitation
Functional Exrcises with Using Pelivic Floor Muscle	Gravity Elimination Exercises
Modified Pilates	Activation of Core Stabilization Exercises
Progressive Vaginal Cone Exercises	Squatting Exercises

Results

Table No 1 : Comparison of one hour pad test within group

	Pre	Post	P Value	T Value	Intererence

Discussion

SUI is serious medical condition that causes perineal rashes, pressure ulcers and urinary tract infection. . SUI causes psychological stress, disability, social seclusion and economic burden , problems in sexual relationship, decreased quality of life

40% women suffering from menopause have problem of UI with vasomotor symptoms and termed as menopause syndrome.[9,10]

Reviewing various studies , it was analyzed that the use of electrical nerve stimulation kegal exercises and surgical intervention were the line of treatment routine used for urinary stress incontinence .

The study was undertaken considering all the mentioned points, and the aim of the study was evaluate effectiveness of structured exercise protocol for post menopausal stress urinary incontinence .

In this study , 58 subjects with post menopausal stress urinary incontinence fulfilling the inclusion and exclusion criteria , between age group 46-65 years were taken. Out of 58 subjects Group A had 29 females and Group B had 29 females The mean age of the participants in group A was 52.41±4.99 and in group B 52.62±5.63, which shows there is no significant difference between the mean ages of participants in both groups,

Structured exercises with progression like diaphragmatic breathing exercises which are useful to improve pelvic floor muscle strength is found significant in preventing urinary incontinence. In this the diaphragm moves caudally, enlarge thoracic cavity, anterior wall bulges outward, this decreases urethral pressure and prevent urinary incontinence which in turn helps to relax abdominal muscles.[11]

Functional exercises such as hip abduction and adduction combined with pelvic floor muscular contractions help in increasing levator ani muscles to

produce force which may help to improve endurance and strength of pelvic floor muscles. [12] Stability exercises like dead bug exercise might have help to improve stability and coordination of the movements and maintain spinal stability [13] Modified pilates exercises is an approach which involves slow controlled movements focusing on posture and breathing, these form of exercises help to increase flexibility of whole body rather than specific muscles [14]A weighted vaginal cone helps to improve strength of pelvic floor muscles

In the study, within group analysis of one hour pad test score reveled statically reduction in dribbling volume of urine after the intervention in both group. This test was done by using paired T test. Inter group analysis of one hour pad test score was done by using unpaired t test. Pre intervention analysis showed no significant difference between group A and Group B (p=0.1672). Post intervention analysis showed significant difference between group A and group B (P= 0.0191). Thus in this study the dribbling of urine was reduced after session of both groups. So dribbling volume of urine was reduced after the 6 week session treatment of both groups, the treatment method were similarly effective in both groups. The reduction of dribbling of urine can be explained possibly due do stimulation of pudental nerve which trigger long latency spinal cord reflex response. In addition to direct motor response, this reflex stimulus causes a contraction of pelvic floor muscle. These contraction strengthen pelvic floor muscle, elevating neck of bladder and resist the outflow of urine.

For assessing quality of life, kings health questionnaire was used. Kings health questionnaire is a subject's self administered self report and has 3 parts consisting of 21 items. .

In this present study, both groups showed significant improvement in kings health questionnaire score. However there is no significant difference in part 1 and part 2 and there is significant difference in part 3 .After the 6 weeks subjects can self analyze the all component of kings health questionnaire and felt difference after the treatment

Part 1,2,3 showed reduction in kings health questionnaire score , this could be possibly due to improvement In strength of pelvic floor muscle and relaxation technique

elvic floor muscle strength was evaluated by using oxford pelvic floor muscle grading .

In the present study, pelvic floor muscle strength showed significant improvement in both groups, however the post session analysis between the groups showed structured exercise protocol was better than conventional exercises program. In structured exercises program subjects involvement was better because of help of swiss ball, verbal stimulus and biofeedback , so participants were able to initiate contract PFM.

The result from the statistical analysis of present study supports alternative hypothesis which stated that there is equal beneficial effect to subjects treated with structured exercise protocol and conventional exercises in post menopausal stress urinary incontinence. Hence above study showed that subjects treated with structured exercises and conventional exercises showed better strength, quality of life and reduces stress urinary incontinence . This study is simple , safe, and physical procedure like structured exercises adjunct with interferential current therapy are helpful in trating urinary incontinence in post menopausal women.

Conclusion

Hence , on the basis of the results of our study , it was concluded that structured exercise program along with IFT , bladder training and conventional physiotherapy along with IFT , bladder training shows improvement in quality of life, pelvic floor muscle strength ,volume of dribbling of urine in post menopausal women who suffering from stress urinary incontinence.

Conflict of Interest: The author declares that there are no conflicts of interest concerning the content of the present study.

Treatment Success Rate among Multi-Drug Resistant Tuberculosis Patients Registered Under Programmatic Management of Drug Resistant Tuberculosis Services in District Amritsar, Punjab, India

Pooja Sadana[1], Vishal Verma[2], Priyanka Devgun[3]

[1]Associate Professor, Department of Community Medicine, Sri Guru Ram Das Institute of Medical Sciences and Research, Sri Amritsar, [2]District TB Officer, Office of Civil Surgeon, Tarn Taran, Punjab, [3]Professor & Head, Department of Community Medicine, Sri Guru Ram Das Institute of Medical Sciences and Research, Sri Amritsar

Abstract

Background: MDR-TB has become an urgent public health problem worldwide, threatening the global TB control. The success rate of treating multi drug resistant remains very low.

Method: This cross-sectional study was conducted on all MDR-TB patients who were registered and being treated under PMDT services in Amritsar district from 1st January 2015 to 31st December 2016. The treatment outcome with their clinico-demographic determinants was ascertained. Data management and analysis was done by using Microsoft excel and SPSS.

Results: Out of 110 registered MDR-TB patients, 88 (80.0%) were males and 22 (20.0%) were females. The various treatment outcomes observed were- 36 (32.7%) cured, 20 (18.2%) treatment completed, 16 (14.5%) defaulted, 22 (20.0%) died, 11 (10.0%) regimen changed or shifted to XDR TB regime, 5(4.5%) transferred out. The success rate (cured+ treatment completed) was 50.9%.

Conclusions: On statistical analysis, it was observed that age (p=0.012), weight band of patients under RNTCP (p=0.040) were significantly associated with the treatment outcome. Other factors like sex, residence, type of tuberculosis and the HIV status of the patient did not affect the treatment outcome.

Keywords: *Multi-drug resistant TB, Treatment outcomes, success rate.*

Introduction

The emergence of Multidrug-resistant TB (MDR TB) has created increasing constraints on effective tuberculosis control and has caused tremendous morbidity and mortality worldwide. Globally in 2017, there were an estimated 558 000 new cases of Rifampicin resistant TB (RR-TB), of which almost half were in three countries: India, China and the Russian Federation. Among RR-TB cases, an estimated 82% had multidrug-resistant TB (MDR-TB). Globally, 3.5% of new TB cases and 18% of previously treated cases had MDR/RR-TB, with the maximum proportions (>50% in previously treated cases) in countries of the former Soviet Union.[1] The treatment of MDR-TB, is long, expensive and requires the use of toxic drugs and has substantially lower success rates than for drug-sensitive TB.[2]

Despite progress in tuberculosis (TB) control, the response to the multidrug- resistant TB continues to be limited. Treatment success remains low, at 55% globally.[1] This is considered to be one of the major challenges to progress towards the country's targets to end TB by 2025. While prevention of development of drug resistance is of paramount importance for ending TB, early detection and treatment completion are keys to interrupt on-going transmission.[3] Therefore, it is imperative to analyze the treatment outcomes of MDR-TB patients treated by standardized 2nd line chemotherapy. Hence the present study was planned to investigate the treatment outcomes and to assess the impact of different demographic and clinical conditions

on the outcome among MDR-TB patients.

Method

The study was a cross-sectional study conducted on all MDR-TB patients registered and being treated with second line anti-tuberculosis drugs under Programmatic management of drug resistant tuberculosis services in Amritsar City.

Study sample

All MDR-TB patients registered from 1st January 2015 to 31st December 2016.

Inclusion criteria

All drug sensitivity tested (DST) confirmed MDR-TB cases who signed written informed consent.

Exclusion criteria

Critically ill patients and pregnant females were excluded from the study.

Data collection and analysis

A total of 110 patients registered with District Tuberculosis Centre (DTC), Amritsar and being treated with second line anti TB drugs were included in the study. A pre-designed and pre –

tested proforma was administered to the subjects after taking his/her consent. The consent of the caretaker or guardian/parent was sought on behalf of all child participants. Questionnaire included questions regarding the socio-demographic and clinical profile, of the patients. The possible outcomes of the MDR TB patients under DOTS can be: cured, treatment completed, died, failure, defaulted, regimen changed/shifted to XDR and transferred out.[3]

Cured: Treatment completed as recommended by the national policy without evidence of failure and three or more consecutive cultures taken at least 30 days apart during CP are negative including culture at the end of treatment.

Treatment completed: Treatment completed as recommended by the national policy without evidence of failure but no record that three or more consecutive cultures taken at least 30 days apart are negative after the intensive phase.

Failure: Treatment terminated or need for permanent regimen change of at least two or more anti-TB drugs in CP because of lack of microbiological conversion by the end of the extended intensive phase or microbiological reversion in the continuation phase after conversion to negative or evidence of additional acquired resistance to FQ or SLI drugs or adverse drug reactions .

Died: A patient who dies for any reason during the course of treatment.

Transfer out: A patient who has been transferred to another reporting unit (DR-TB Centre in this case) and for whom the treatment outcome is not known.

Regimen changed/shifted to XDR: A TB patients need for permanent regimen change of at least one or more anti-TB drugs prior to being declared as failed/A MDR-TB patient who is found to have XDR-TB by an RNTCP certified CDST laboratory and who has subsequently switched to a regimen for XDR-TB treatment initiation.

Outcomes were classified as Favourable outcome which includes cured and treatment completed patients and Unfavourable outcome that includes cases with outcome as defaulted, died, transferred out and those who were shifted to XDR TB or changed regime. Cured and treatment completed, these together define treatment success.

All the information so collected was compiled, analyzed statistically with help of SPSS version 20.Chi-square test was used to evaluate differences in categorical variables and $p<0.05$ was considered to be significant.

Ethics: The research proposal was approved by the college ethical committee at the time of commencement of the study.

Results

A total of 110 patients with a diagnosis of MDR-TB were registered under PMDT services in Amritsar city during 2015–2016. The total sample comprised of, 88 (80.0%) males and 22 (20.0%) females. The mean age of the patient is 33.13 years (SD ±12.4 years), ranging 11 to 68 years. 84 (76.4%) cases were in the age group of 11-40 years. Most of the patients 88(80.0%) were males and 67(60.9%) patients resided in urban areas. Almost all patients, 107(97.3%) had pulmonary tuberculosis and only 3(2.7%) had extra-pulmonary tuberculosis. Maximum patients 58(52.7%) belonged to weight band of 46-70 kg .Only 4 (3.6%) patients were HIV positive. 7(6.3%) patients were resistant to both drugs Rifampicin and Isoniazid.

Table 1 shows the distribution of cases according to their treatment outcomes. Out of the total 110 patients, 36 (32.7%) were cured, 20 (18.2%) were categorized as treatment completed, 16 (14.5%) patients defaulted, 22 (20.0%) died, in 11(10.0%) patients regimen was changed or shifted to XDR TB regime and 5 (4.5%) patients were transferred out. Treatment success rate (cured and treatment completed) was 50.9% in the present study.

Table 2 depicts the clinical and demographic factors affecting treatment outcome in MDR TB cases. It is evident from the above table that favourable outcome was seen in younger age group i.e. 11-25 yrs. Out of 110 patients,30 (69.8%) patients had favourable outcome. Unfavourable outcome was seen in 80.0% of patients of more than 55 yrs age. The results were found to be statistically significant(p=0.012). 43(48.9%) males and 13(59.1%) females had favourable outcome. The results were not found significant. Favourable outcome was significantly higher among patients with weight band 46-70 kg i.e 36(62.1%) as compared to patients belonging to other weight bands (p=0.040). Sex, residence, type of TB and HIV status of the patient were not significantly associated with treatment outcome.

Discussion

In the present study it was observed that out of the total 110 patients, 76.4 % of patients were in age group of 11-40 yrs Similar study by Nair et al in Chennai showed that 70% were in the age group of 15-44 yrs.[4] The demographic profile of MDR-TB patients in our study was similar to other studies, with a majority of patients, 62(56.4 %), in the economically productive age group (26-55 years) with male patient predominance.[5,6] Our study participants included 88 (80.0%) males and 22 (20.0%) females. The mean age of the patient was 33.13 years. A study conducted in Uttar Pradesh also revealed that more than 2/3rd of patients were male and the mean age was 32 years.[7] Similar male preponderance was observed in the study by a study on MDR-TB patients in Cairo, Egypt and in Indonesia showing that out of the total, 72.9% and 68.6% were males respectively. [8,9]

Table 1 revealed the outcome of the total 110 patients, 36 (32.7%) were cured, 20 (18.2%) completed treatment, 16 (14.5%) patients defaulted, 22 (20.0%) died, in 11 patients (10.0%) regimen was changed or shifted to XDR TB regime and 5 (4.5%) patients were transferred out. In the present study, treatment success rate, which consist of cured and treatment completed was 50.9%. The result is consistent with reported global (52%) and national (56%) MDR-TB treatment success rates.[10,11]

MDR-TB treatment success rate recorded in a study conducted in patients from Chinese referral hospitals also showed similar success rate.[12] Another study done in china showed success rate of 57 %.[13] A study undertaken to analyze the clinical profile and treatment outcome in pulmonary drug tuberculosis (TB) patients under programmatic management of multidrug resistant tuberculosis (PMDT) at a tertiary care center in Mumbai showed 48.4% of MDR-TB patients were successfully treated (cured +treatment completed), 43.47% were cured, 10.1% completed treatment, 13.04% died, 1.4% failed, 15.4% defaulted, 4.3% stopped treatment due to adverse drug reactions and 11.5% transferred.[14] Another study in Karnataka showed that at the end of treatment, 44.2% were cured, 12 defaulted, 9 died, 1 failure and 2 were under XDR TB evaluation.[15] Studies in Portugal and China showed the treatment success of 62% and 68.3% respectively.[16,17]

Table 2 shows the clinic-demographic determinants of treatment outcome. Our study observed that favourable outcome was significantly higher among the age group of 11-25 yrs. 30 (69.8%) patients had favourable outcome. Unfavourable outcome was seen in 80.0% of patients of more than 55 yrs age. Studies by Dengkui et al in Shanghai, Nair et al in Chennai and Gafar et al in South Africa on predictors of treatment

outcome showed that unfavourable outcomes in MDR TB cases were significantly higher among cases >45 years.[18,4,19]

Favourable outcome was significantly higher among patients with weight band 46-70 kg i.e 36(62.1%) as compared to patients belonging to other weight bands (p=0.040). A study by Agarwalla, *et al* on outcome of MDR patients that majority of the patients in this study are of low BMI (<18.5 kg/m^2) and their success rate is significantly less compared to patients having BMI more than 18.5 kg/m^2.[20]

Other factors like sex, residence, type of family and HIV status did not affect the treatment outcome.

Conclusion

Treatment of MDR-TB is major challenge due to the prolonged regimens, multiple drugs used and high incidence of drug toxicities. This is, in turn, contributes to poor treatment adherence and further exponential magnification of drug resistance which can have devastating consequences. The treatment success rate (cured and treatment completed) in the present study was 50.9% which is similar to global treatment success rates of a 55%. Favourable treatment outcome was present in 50.9% cases. The predictors of unfavourable outcome were age ≥26 years and weight band of 26-45 under RNTCP

Microbial Contamination of Tooth Paste Tube Orifice

Pooja.M.R[1], Jithesh.Jain[2], Ananda.S.R[2], Bhakti Jaduram Sadhu[3], Rohit A Nair[4], **Aparna H gopalakrishna[5]**

[1]Post Graduate Student, [2]Professor, [3]Assistant Professor, Department of Public Health Dentistry, Coorg Institute of Dental Sciences, Virajpet, Karnataka, India, [4]PhD Scholar, A.B.Shetty memorial institute of dental sciences, Mangalore, Karnataka, India, [5]Researcher and Consultant Oral Pathologist, No 21, 11th block, SBM colony, Srirampura, Mysore

Abstract

Introduction: Tooth brushes are a vital component of routine oral hygiene aids used in promotion of oral health and prevention of oral diseases. Unfortunately, they are often stored in unsanitary conditions such as bathrooms. These unsanitary conditions are the settings that harbour millions of different pathogenic microbes.

Objective: To determine the microbial contamination of used toothpaste tube orifice.

Method: Sealed tooth brush and tooth paste tube were given to individual participants and to the families. Toothpaste tubes were collected from each family and from individuals after 30 days of usage. Microbiological samples were collected from the toothpaste orifice using sterile cotton swab. Organisms from swabs were cultured on selective media (nutrient agar) for the identification of certain groups of microorganisms. Colony Forming Units (CFU) was calculated using CFU counting unit. Gram staining was done to find out the nature and character of the organisms.

Results: A Clinical In-vitro study, the mean number of colony forming units was 246.6± 305.73 among single user and 709.5± 492.61 among multiple users as shown in Table 1. The distribution of microorganism CFU (Colony Forming Units) among single user and multiple users was found to be statistically significant (p=0.021).

Conclusion: In the present study, it was found that toothpaste tube can also be the possible source for potential pathogens that can compromise not only the health of the individual but also the individuals using the same toothpaste tube.

Keywords: *Micro organisms, Toothpaste, Toothbrush, Cross contamination*

Introduction

With the dawn of 21st century, dentistry has witnessed advances in the arena of diagnosis, treatment and prevention. Primary level of oral disease prevention has attracted many investigators to conduct clinical and field trials to provide effective prevention at this level. The increased awareness of the need for good dental health and the emphasis on preventive procedures by dentists and dental educators has made the role of a tooth brush and tooth increasingly important[1]. The neglect in the appropriate maintenance of tooth brushes is attributed to lack of public awareness on the possibilities of tooth brush contamination while they are stored after brushing.[2] The colonization of pathogenic micro-organisms on toothbrush while being stored in unsanitary conditions represents a potential cause of re-contamination of the oral cavity.[3] Tooth brushes can get contaminated with microorganisms which are present

in oral cavity and from the environment. Retention and survival of microorganisms on tooth brush after brushing represents a possible cause of recontamination of mouth and other toothbrushes[4]

Numerous studies have shown that prolonged use of the tooth brush facilitates contamination by various microorganisms such as *Streptococcus*, *Staphylococcus, lactobacilli*, *Pseudomonas, Klebsiella*, *Escherichia coli* and *Candida*. These microorganisms are implicated to cause dental caries, gingivitis and stomatitis in an individual[2]. These bacteria are also found to be implicated in the causation of many life threatening diseases such as infective endocarditis besides influencing the occurrence of oral diseases such as dental caries and gingivitis[5].

Microbiological contamination of the oral cavity has long been a widely discussed topic and the subject of scientific publications; however, the same attention has not been given to the contamination of toothbrushes[6]. M. Svanberg[7] conducted a study to assess the contamination of toothpaste and toothbrush by *Streptococcus mutans* and found that fifteen minutes after brushing > lO^6 *S. mutans* were isolated from the toothbrushes and after ordinary storage for 24 h 10^4 were recovered. From two out of 10 toothpaste tubes *S. mutans* was isolated from the orifice of the tube.

Even though the use of the single toothbrush is mostly confined to one individual, the same toothpaste tube is generally used by several family members and hence there is a chance of spread of microorganism through the toothpaste tube. There is complete lack of evidence on contamination of toothpaste by microorganisms from toothbrush or by environment. There is increased need to determine the contamination of toothpaste tube orifice by multiple users and by individual users. Hence the Hypothesis of the study is that toothpaste tube orifice is free of microorganism.

Materials and Method

In the present Clinical In-vitro study, Subjects residing individually in hostel rooms who used personal toothpaste tubes and families consisting of minimum 3 people who shared a common tooth paste tube.Subjects who brush at least once daily using toothpaste and between the age group of 25-35 years. Toothpastes of participants that are kept inside the bathrooms with attached toilets were included.Subjects with history of antibiotics usage 3 months prior to the study, undergoing orthodontic treatment or with extensive intraoral prosthesis, any systemic diseases and undergone recent periodontal therapy were excluded. Ethical clearance was obtained from the Institutional Review Board. Sample Size was calculated to be 40 individuals who filled the inclusion and exclusion criteria were chosen and divided into Group I: Consisting of 20 individuals and Group II: Consisting of 20 families with minimum 3 members.

Method of collection of data:

Top brand of toothpaste which is commonly used by people was chosen as samples for the study. The average pack size of 200gms, packed in squeeze tubes manufactured within past 6 months was used in the study.

After obtaining the informed consent, a set of sealed tooth brush and tooth paste tube were given to individual participants and to the families, sealed single toothpaste tube and tooth brushes were given depending on number of members in the family. All the participants were instructed to use it for 30 days once daily. Toothpaste tubes were collected from each family and from individuals after 30 days of usage.

Study Procedure:

Microbiological samples were collected from the toothpaste orifice wearing gloves by using sterile cotton swab moistened with saline which were then kept in test tubes containing Robertson's Cooked Meat Broth. Organisms from swabs were cultured on selective media (nutrient agar) for the identification of certain groups of microorganisms. All the agar plates are incubated at 37^0c for 24 hours. Agar plates of single users were coded as SU (1-20) and multiple users were coded as MU (1-20).

After incubation, different patterns of colonies of microorganisms were identified by observing their colony morphology on all the agar plates. Colony Forming Units (CFU) was calculated using CFU counting unit. Gram staining was done to find out the nature and character of the organisms. Sub culturing of the required samples were done to isolate the microorganisms. Bio chemical tests such as Catalase test which will demonstrate the presence of catalase, an enzyme those catalyses the release of oxygen from hydrogen peroxide (H_2O_2). It is used to differentiate those bacteria that produce an enzyme catalase, such as *staphylococci*, from non-catalase producing bacteria such as *streptococci*. 3% H_2O_2 has been used for the routine culture. Citrate tests

are used to differentiate among the Gram-Negative bacilli in the family Enterobacteriaceae. Urease test is used as part of the identification of several genera and species of Enterobacteriaceae including *Proteus and Klebsiella.* Indole test is a commonly used biochemical test (e.g. in IMVIC test) which was done for 4 samples from each group. Indole test helps to differentiate **Enterobacteriaceae** and other genera.

Statistical Analysis

The data obtained was coded and fed into the SPSS (Statistical Package for Social Sciences) version 17 for analysis. All statistical tests were performed at 95% confidence interval. A p value less than 0.05 was considered as statistically significant.

Table 1: Distribution of microorganism CFU among single user and multiple users

Groups	Mean	Std. Deviation	t value	Significance
SU	246.60	305.73	2.525	0.021 S
MU	709.50	492.61		

<0.05, S – Significant

Neisseria species	0 .0%	4 20.0%	4 10.0%	
Escherichia coli species	2 10.0%	2 10.0%	4 10.0%	

The mean number of colony forming units was 246.6± 305.73 among single user and 709.5± 492.61 among multiple users as shown in Table 1. Table 2 shows the distribution of microorganism based on gram staining among single user and multiple users. Table 3 shows the distribution of microorganism strains among single and multiple users.

Discussion

Contaminated tooth brush and tooth paste tubes have been characterized as a means of microbial transport, retention and growth. It can be the cause of reinfection of a person with pathogenic bacteria or can be the reservoir for environmental microorganisms.[6,7] Toothbrushes can become contaminated through contact with the environment and bacterial survival is affected by toothbrush storage containers. ***Dayoub et al***.[8] found that toothbrushes placed in closed containers and exposure to contaminated surfaces yielded higher bacterial counts than those left open to air.

The mean numbers of colony forming units were 246.6± 305.73 among single user and 709.5± 492.61 among multiple user samples. These results are in accordance with the study conducted by ***M. Svanber7***[3] conducted among 10 individuals, which showed that on the toothbrushes *S. mutans* represented 1.5 and 6.0 X 10^ CFU 15 min after the cleaning of the teeth. The results are also in accordance with the study conducted by **Lais Kuhn Rodrigues et.al**[9], wherein 91% of the toothbrushes had some type of microbial growth on them.

In the present study, distribution of microorganism based on gram staining showed that 26 (65%) were gram positive and 14 (35%) were gram negative organisms. In the study conducted by ***Snezana Pesevska et.al***[10], there was a high contamination of the used toothbrushes at 100% of the analyzed samples, with a domination of coliform bacilli. The results of the present study showed that both single user and multiple user toothpaste tube orifices were contaminated by different microorganism species such as *Staphylococcus, Klebsiella, Streptococcus, Neisseria and Escherichia coli.* These results are in accordance with the study conducted by ***Jagadeeshwar Rao Sukhabogii***[2]**,** in which *Pseudomonas, Candida, Streptococcus pyogens, Klebsiella, Staphylococcus aureus, Lactobacillus, Proteus and E.coli* was demonstrable in the tooth brush samples preserved in bathrooms with attached toilets. ***Bello et al***[11] reported *Staphylococcus, Escherichia,* and *Pseudomonas* in used toothbrushes; while ***Contreras et al***[12] reported that the most frequent microorganisms found in toothbrushes used by parents and children for one month were *Enterobacteriaceae* and *Pseudomonadaceae*. ***Kozai et al***[13] also reported that *Streptococcus mutans* and pathogenic microorganisms can be transferred readily when a toothbrush is used, increasing the risk of dental caries and infectious diseases.

In the present study, distribution of microorganism strains among single and multiple users are presented in the table, the organisms identified are in accordance with the study results of **Onuorah Samuel et.al**[14] in which *Staphylococcus aureus* was isolated from 60% of the samples while *Pseudomonas aeruginosa, Staphylococcus epidermidis, Streptococcus mutans, Escherichia coli* and *Enterobacter aerogenes* was isolated from 50%, 45%, 25%, 20% and 10% of the samples.

In the present study two freshly sealed packs were checked before the start of the study which did not show any colony formation. This is in contrast with the study conducted by **Efstratiou M et.al**[15]**,** in which multiplication of flora on usage at regular intervals and at different phase of time during the life of tooth paste pack was analysed and the results showed that aerobic spores were identified on day 1, where in it was company sealed pack and was opened under sterile conditions in a laboratory to dispense the sample for testing before any use.

Staphylococcus species was detected in 65% of the used toothpaste tubes examined, while *Staphylococci* are usually common skin inhabitants. *Enterobacter species* were also found in 10% of the samples. *Escherichia coli* are coliforms and members of the family Enterobacteriaceae. They are also pathogenic to humans in significant numbers. The presence of *Escherichia coli* on the toothbrushes examined was indicative of fecal contamination. *Streptococci species* were found to be 5% in the present study and these are aetiological agents of tooth decay and are important bacteria found on the teeth, buccal cavity and throat.

In the present study biochemical tests are used for identification of organisms. According to ***Holt et al***[16], the morphological and biochemical method of identification of bacteria is the classical method of characterization of bacteria. Classical identification of individual bacterial

species in environmental samples typically involves isolation, laboratory culture and then taxonomic characterization. But, biochemical tests have certain drawbacks such as less accurate, less discriminatory, phenotype may be unstable, induceable (i.e. influenced by gene expression) and subjective interpretation (less reproducible)[16]. Considering the available techniques for identifying LAB isolates, the advanced technique such as 16S rDNA sequencing and species specific PCR reactions might give more specific results.

Different brands of toothpastes are marketed to the public every year. There is a little research and information on their contamination by bacteria with use. In the field of Public Health Dentistry, it is important to understand that even though use of tooth brush is confined to each individual, toothpaste tubes are shared between multiple people especially among family members. The use of uncontaminated toothpaste will assist in the maintenance of sound oral hygiene and reduce the health risk posed by the contaminating bacteria to humans. It is recommended to use individualized toothpaste tubes like the individualized toothbrushes.

Conclusion

In the present study, it was found that toothpaste tube can also be the possible source for potential pathogens that can compromise not only the health of the individual but also the individuals using the same toothpaste tube. As toothbrushes, Toothpaste tubes may also have an important role in transferring microorganisms and increasing the risk of infection, because they can be a reservoir of microorganisms in healthy individuals, in those with oral diseases, as well as in those with impaired general health.

Since Public Health Dentistry underlines the prevention and control of infection, it is very important that they create an awareness about the issue of choosing, keeping and maintaining the hygiene of the toothbrushes and toothpaste tubes, as well as their replacement in an optimal time intervals in healthy population and especially in individuals affected with oral or systemic diseases.

Effectiveness Bearing Down Techniques During Second Stage of Labour on Maternal and Neonatal Outcome among Primigravida Mothers

PoonamYadav[1], Shital VWaghmare[2], Seeta Devi A[3], Manuacharoy[4]

[1]Msc, II year M.Sc (N), [2]Assistant Professor, [3]Assistant Professor, [4]Tutor, Symbiosis College of Nursing, Symbiosis International (Deemed University)Pune, Senapati Bapat Road, Pune

Abstract

Background: Maternal bearing down efforts plays a vital role in expulsive phase of labor. Various types of bearing down efforts has got its own advantages and disadvantages on mother and fetus. Various studies are done to evaluate the best bearing down techniques and have different results .The investigator personally felt there is a need to investigate the best bearing down technique with less complications to the mother and newborn **Objective:** 1.To assess the effect of vulsalva bearing down technique during second stage of labour on maternal and neonatal outcome among primigravida mothers admitted in selected hospitals of pune city. 2.To assess the effect of spontaneous bearing down technique during second stage of labour on maternal and neonatal outcome among primigravida mothers admitted in selected hospitals of pune city.3.To compare the effectiveness of vulsalva bearing down techniques and spontaneous techniques and duration of second stage of labour on maternal and neonatal outcome among primigravida mothers admitted in selected hospitals of pune city **Methodology:** In the present study, Quantitative research approach is applied and approach is applied and pre experimental ,Post test only control group design is used. The setting of the study was selected hospital of Pune. The sample size for study was 60, selected by using Non Probability Purposive Sampling Technique. The structured questionnaire and observation checklist was administered. In order to establish the reliability of the tool inter rater method was used. The scores were calculated and the reliability was established by Kappa method, which was 0.90. **Results:** On Comparison of the Spontaneous and vulsulva bearing down techniques on various maternal and neonatal outcome. Since the P values corresponding to the Maternal outcome, oxytocin given, Perineal laceration ,Type of episiotomy, size of episiotomy ,mode of delivery and fatigue and Neonatal outcome Crown heel length of newborn ,Head circumference of newborn, Neonate Resuscitation, Admission to NICU,APGAR score are small (less than 0.005) suggests that vulsulva bearing down technique is significantly different that spontaneous bearing down technique in the above maternal and neonatal outcomes and good result for the health of mother and newborn **Conclusion:** The Spontaneous pushing method has a negative effect on various factors related to maternal and neonatal outcome factors according to the results in this study. Vulsalva pushing has various benefits towards the better health of Mother and Newborn so it should be accepted as best clinical practice.

Keywords: *Effectiveness, Vulsalva Bearing Down , Spontaneous Bearing Down Techniques ,Second Stage of Labour Neonatal outcome , Maternal outcome*

Introduction or back ground

Labor is a physiological process which is normal, which takes place with the expulsion of the fetus out from maternal uterus into the outside world. Labor is divided into three stages. The most challenging stage is the second stage .This stage refers to the passage of the baby through the birth canal until delivery(6). The second stage begins when the cervix has fully dilated and voluntary pushing is initiated. Several times this stage is also referred to as the "pushing" stage . During the second stage, maternal bearing down efforts aid in fetal descent as the fetus completes the cardinal movements of labor, rotating and descending through the maternal pelvis Maternal bearing-down efforts and their effect on the mother and the fetus have been studied and debated for decades. Maternal bearing down efforts plays a

vital role in expulsive phase of labor. Various types of bearing down efforts has got its own advantages and disadvantages on mother and fetus. Mothers who are in 2nd stage of labor must have a knowledge regarding maternal bearing down efforts when and how to push because if she bear down in 1st stage it may slow down the FHR during pushing and it should come to normal once the contraction is over and Even comfortable position during pushing also plays an important role in 2nd stage of labor .

The investigator has observed primigravida mothers suffer from complications during 2nd stage of labour because of the following reasons like lack of knowledge and practice about when to bear down, how to bear in 2nd stage and associated complication on both mother and fetus. The researcher referred various research data conducted data and find that In the present situation mothers are encountering many problems during the time of intra natal period Specially during second stage of labour. One of the major problems is management of maternal bearing down efforts. The investigator personally felt there is a need to investigate the best bearing down technique with less complications to the mother and newborn and increase the knowledge of the mothers regarding maternal bearing down efforts.

Material and Method

A Pre-experimental study design with quantitative approach was used, as this study was aimed, the approach was found to be most appropriate. A post test only control group research design was adopted for the present study. This study was conducted in selected hospital of Pune city. The selection was based on easy geographical accessibility, cooperation and availability of samples. Total 60 Primigravida mothers from Yashwantrao RaoChavan Memorial Hospital Pimpri Chinchawad ,Pune city who met the inclusion criteria were selected. Tool used for the collection of data was a observational checklist and structured questionnaire. **Findings: The** analysis and interpretation of the data collected to determine the Effectiveness of bearing down techniques is carried out based on objectives set by the researcher taking the level of significance as 0.05

Discussion

In this study analysis, there was comparison on various components of maternal and neonatal outcome first The APGAR Score recorded of the newborns in Vulsulva Bearing Down Techniques have good score as compare to Spontaneous Bearing Down Technique A study suggesting that prolonged second stage of labour is associated with low apgar was refred to compare the result , Second stage of labor was Prolonged and it was reported which were associated with an increased risk of low 5 min APGAR score for neonates of nulliparous women in a Swedish study from research group(1). Trauma is an important factor to consider when assessing overall efficacy of vulsulva bearing down technique .Tears are a measurable outcome, since they can be categorized in terms of intact perineum, first, second or third degree tears and episiotomy (2) . Retrospectively requested information about perineal damage in 39 primiparous women who had had spontaneous vaginal births. Similarly in this study the record of perinieal laceration in less when compared with the spontaneous bearing down techniques

Conclusion

Vulsulva pushing during in second-stage labour is a safe and less exhausting pushing technique, it was not associated with demonstrable adverse outcome .it is significantly, decrease incidence of perineal laceration. Also it has good outcome in regard to maternal fatigue and neonatal Apgar score and reduces the chances of neonatal resuscitation and fetal injury when compared to Spontaneous pushing during the second stage of labour.

Denture Identification Methods: A Review

Prabhjot Kaur[1], Anchal Arora[2], Navjot Kaur[3]

[1]Former BDS Student, Genesis Institute of Dental Sciences & Research, Ferozepur, Punjab, [2]Tutor, Genesis Institute of Dental Sciences & Research, Ferozepur, Punjab, [3]BDS Intern, Genesis Institute of Dental Sciences & Research, Ferozepur, Punjab

Abstract

Denture marking is accepted as a means of identifying dentures and persons in geriatric institutions, during war, crimes, and civil unrest, natural and mass disasters, post mortem and medico-legal investigations. This review highlighted the various methods of denture marking and significance of placing identification marks on dentures.

Key words:- *Denture marking, Geriatric, Identification*

Introduction

Denture marking is accepted as a means of identifying dentures and persons in geriatric institutions, or post-mortem during war, crimes, civil unrest, natural and mass disasters. Due to the lack of a comprehensive fingerprint database, dental identification is growing as an essential part of forensic investigation. Prosthodontists are playing very important role in forensic dentistry as they are concerned with fabrication of various prostheses which can serve as an important tool for identification. The denture marking is important for the following reasons:[1]

a. It serves to identify an unknown denture wearer in cases involving amnesia or senility, loss of memory, psychiatric cases, homicide, suicide, victims of fire, explosion, floods, earthquake, plane crash, or war.

b. In cases of lost and found, the denture can be returned to the owner.

c. A rapid and accurate method other than finger printing is essential for identification of the individuals.

d. In the laboratory, the dental technicians will find it easy to identify a denture, especially at the deflasking stage, if it is marked / labeled.

Corresponding author:
Prabhjot Kaur,
Former BDS Student, Genesis Institute of Dental Sciences & Research, Ferozepur, Punjab

e. To ensure the correct denture delivery to the respective patient.

Medicolegal Importance of Denture Marking Systems[2]

1. Identification of the dead or deceased when all other means have failed.

2. Identification of individuals for forensic, social and legal reasons.

3. Victim identification in case of mass disasters like terrorism, bombings, earthquakes, hurricanes, typhoons, air crashes and other transportation mishaps.

4. Identification of mutilated and decomposed bodies when all other parameters like scars, tattoos, and facial features have failed.

Methods of denture identification

Various methods of denture marking have been reported in the literature. However, there are two main methods in marking dentures, namely the surface method and the inclusion method. As compared to surface methods, inclusions methods are permanent but require more skills and are time consuming.[3]

Surface Methods

Scribing or engraving method

In this method letters or numbers are engraved on the denture surface with the help of a small round dental bur.[4]

Disadvantage: Food entrapment occurs in the engraved grooves.

Embossing method

In this technique name and other particulars of the patient are scratched on the master cast. After processing it produces stamped or embossed letters on the impression surface of dentures.[5]

Disadvantage: This technique has been associated with malignancy, possibly due to continued tissue irritation.

Invisible Ink Method

Harvey described a method wherein the patient's details are written with an invisible ink that is rendered visible by ultraviolet light. This is useful on acrylic resin dentures of those patients who object to normally visible identification marks.

Disadvantage: The mark is not readily visible and examination under special conditions is required to determine its presence.[6]

Fibre Tip Pen Method

atient's details are written on the tissue-fitting surface or the polished surface of the denture with a fibre-tip pen. The patient's identification details are then covered by at least two thin coats of varnish in order to prolong the life of the marking.[7]

Disadvantage: This method resulted in an unesthetic denture.

Denture Bar Coding Method

A bar code consists of a machine-readable code of a series of bars and spaces printed in defined ratios. The technique described for denture bar coding involves printing a number code on paper, photographing the paper, making and transferring the negative to a piece of silk. An image of the bar code appeared on a prepared faience, by a machine that forced the paint through the silk, when heated to 860 degree C for 30 min in an industrial porcelain oven. The bar code is directly placed onto the denture surface and cyanoacrylate resin is painted to conceal the marking.[8]

Disadvantage: Incorporating the bar code into the curved denture flange is relatively cumbersome due to rigidity of the laminated strip.

Lenticular card method

In this technique a lenticular lens is used to produce images with an illusion of depth, morph, or the ability to change or move as the image is viewed from different angles. Lenticular printing is a multi-step process consisting of creating a lenticular image from at least two or more existing images, and combining it with a lenticular lens. Each image is sliced into strips, which are then interlaced with one or more of the other images. These are printed on the back of a synthetic paper and laminated on the lens The most common materials used for making lenticular images are polyvinyl chloride (PVC), amorphous polyethylene terephthalate (APET), acrylic, spectra, and polyethylene terephthalate glycol (PETG). The lens is incorporated in the channel cut on the denture and auto-polymerizing clear acrylic resin is added around and not on the identifier.[9]

Paper Strip method

It utilizes onion skin paper. The acrylic resin fitting surface situated adjacent palatally between the ridge and the center of the palate is moistened with monomer on a small brush. The strip of typed paper is laid on this surface and the paper is moistened with the monomer. Clear resin is then placed over the paper before final closure of the denture flask.[10]

RFID Tags

RFID stands for radio-frequency identification, which is a wireless electronic communication technology. The radio-frequency identification (RFID) system consisted of a data carrier, or tag, and an electronic handheld reader that energizes the transponder by means of an electromagnetic field emitted via the reader's antenna. It then receives the coded signal returned by the transponder and converts it into readable data.[11]

Advantages

This method is a cosmetic, effective labeling method permitting rapid and reliable identification of the wearer.

b.) They are preferred because of their small size (8.5×2.2 mm).

c.) A large amount data can be stored in them.

d.) No special training is required to set the tag in the denture.

e.) The chip is resistant to disinfectants and solutions of 1% hypochlorite, 4% chlorhexidine, and 4% sodium perborate.

Photographic method

In this technique patient's photograph is embedded in the denture with the help of clear acrylic resin.

The name, age and geographic location of the patient are written on the obverse of the photograph using a micro-tip graphite pencil. The marker is particularly useful in the countries with low literacy rate where a photograph is the easiest method of identification.[12]

Advantage:

The identity is easily ascertained by lay persons with the unassisted eye.

Incorporation of Min. I. Dent

atient's details are typed on Min. I. Dent denture identification strip and the strip is heated in an oven at 325 degree C for 30 s to 1 min. This allows shrinkage of lettering or numbers and the strip becomes a chip. The chip is trimmed to required size using carbide bur. A groove is cut into the denture and the chip is incorporated into the groove and sealed with orthodontic resin.[13]

Lead Foil

A piece of lead foil from a used IOPA radiographic film is cut and patient's details are engraved with a sharp pointed pen or instrument and is embedded in the denture with the help of clear acrylic resin.[14]

Advantage

This technique is easy to operate. b.) It is economical. c.) It is radiographically visible.

Ceramic Crown Engraving Method

After baking the opaque layer of porcelain, dentin porcelain is applied and initials of name of the patient or letters are carved with the brush. Stains are applied on carved initials followed by enamel porcelain application shaped with soft brush so that the initials are maintained. Few initials can be carved in crown and bridges due to lack of available space.[15]

Conclusion

Denture marking should be compulsorily carried out for hospitalized patients, unconscious patients and patients in geriatric institutions. There is a strong need to adopt an international policy for denture marking and international collaboration should be encouraged, with different opinions from the world-wide community of forensic odontologists discussed and with the aim of reaching some kind of consensus for the future.

Conflicts of Interest: The authors declare that there is no conflict of interest regarding the publication of this paper.

Maternal Tobacco Use and Risk for Congenital Anomalies

Prabhuswami Hiremath[1], R P Patange[2], J A Salunkhe[3], Vaishali R. Mohite[4], Prakash Naregal[1], Ajit Pawar[5], Tejas Bhosale[5]

[1]Lecturer, [2]Professor and Head, Department of OBG, [3]Professor,[4]Dean and Principal, [5]Clinical Instructors, Krishna Institute of Nursing Sciences, Karad

Abstract

Over a period of decades non genetic causes are controlled and mortality and morbidity is considerable reduced due to malformation[5,6]. Although 50% of causes for malformation are unknown Origen, but, with primary prevention 50% of birth defects could be prevented. Research for finding the risk factors are continuous and such results would help to implement preventive strategies to improve maternal and child health.

Methodology: This is cross sectional; hospital based study, conducted in Krishna Hospital Karad, included all the Pregnant Mother diagnosed to have congenital birth defected fetus through antenatal examinations, delivered baby with diagnoses of congenital malformation, who were admitted at Tertiary care hospital Karad.

Results: Total 283 cases were diagnosed with birth defects. Parent's history for tobacco use states that16 (5.7%) mothers and 149 (53%) of fathers of malformed babies used tobacco. Among these 16 (5%) tobacco user mothers, maximum babies 5 (1.7 %) babies had born with neural tube defect and among fathers 149 (53%) maximum babies 41 (14%) Circulatory System defect.

Conclusion: There is a need to make the rural women aware about hazardous effects of use of mishri[20] through health education sessions to wean them out of this addiction, which is passed from one generation to the next as a tradition at an early age.

Key words*: Maternal, risk factors, Tobacco Use, Congenital Anomalies*

Introduction

According to WHO, Nearly six million people die due to tobacco use per year in that five million deaths are the result of direct tobacco use and more than 600,000 are the result of non-smokers being exposed to second-hand smoke[1]. In India, as per Global Adult Tobacco Survey India (GATS) estimated number of tobacco users being 274.9 million where 163.7 million users of only smokeless tobacco, 68.9 million only smokers and 42.3 million users of both smoking and smokeless tobacco). It means around 35% of adults (47.9% males and 20.3% females) in India use tobacco in some form or the other. Use of smokeless tobacco is more prevalent in India (21%).[2] adverse effect of tobacco on human physiology is well documented. The effect of tobacco on growing fetus when pregnant mother is exposed to tobacco is matter of concern as it effect fetus in various ways and also leading cause for congenital malformations. This is true for the passive or second hand exposure to tobacco also.

Many etiological factors contribute for the malformation and these are either genetic or non-genetic (environmental) and some time combined. Non genetic causes are exposure to any teratogenic substance or toxic including harmful drugs, organic chemicals, nutritional deficiencies and radiations. The exact relation between birth defect and tobacco use is not clearly understood, although hypotheses states that nicotine has direct effect on blood vessel. Nicotine causes Vasoconstriction which

Krishna Institute of Nursing Sciences, Karad.
Phone: 9665620425, Email: prabhuispn@gmail.com

leads to decreased blood supply to placenta is major reason for birth defect[3]. Other reason may be, carbon monoxide combines with hemoglobin and reduces the placental oxygen availability. Another reason of tobacco use is, it increases the repture of capillaries from neovasculirisation of placenta leading to hypoxia to the fetus which results in abnormal fetal morphogenesis[4].

Over a period of decades non genetic causes are controlled and mortality and morbidity is considerable reduced due to malformation[5,6]. Although 50% of causes for malformation are unknown Origen, but, with primary prevention 50% of birth defects could be prevented. Research for finding the risk factors are continuous and such results would help to implement preventive strategies to improve maternal and child health.

Methodology

resent descriptive, cross sectional; hospital based study was conducted in Krishna Hospital Karad, which provides specialist's tertiary care services to patients largely belonging to lower/middle socio-economic strata of the society with both rural and urban background. The study included all the Pregnant Mother diagnosed to have congenital birth defected fetus through antenatal examinations, delivered baby with diagnoses of congenital malformation, who were admitted at Tertiary care hospital Karad or came for reference services between September 2016 to august 2017. The study was initiated after approval of the Institutional Ethics Committee of Krishna Institute of Medical Sciences Deemed University's. Maternal and paternal data was collected to evaluate the relation between parental tobacco use and congenital malformations.

Results

Prevalence of congenital malformation

Data was collected from Pediatric and Maternity unit. Total Babies 75136 visited to pediatric outpatient department, 4092 kids admitted at pediatric ward and 774 neonates identified in Neonatal Intensive Care Unit as congenital malformations. Prevalence is being maximum in the Neonatal Intensive Care Unit 41 (5.3%), followed by Pediatric Ward 14 (0.3%) and pediatric Outpatient Department 45 (1%). 50856 patients were visited to Maternity Outpatient Department in that 131 patients had the diagnosis of having congenital malformation fetus contributing to 0.3% of prevalence. Whereas maternity ward had 3847 admission among those 52 (1.4%) had delivered congenital malformed babies. Total 283 cases were diagnosed with birth defects.

Table no: 01: Prevalence of tobacco use among Mothers of malformed babies

Used Of Tobacco	Maternal	
	Frequency F	Percentage %
No	267	94.3 %
Yes	16	5.7 %
Total	283	100%

Total 283 malformation cases were identified. Parent's history for tobacco use states that16 (5.7%) mothers and 149 (53%) of fathers of malformed babies used tobacco.

2. System wise distribution of congenital malformation

Distribution of congenital malformation according to International Classification of Disease (ICD – 10) carries out after collecting data which shows, maximum Congenital malformations of nervous system 63(22%), followed by circulatory system 57 (20%) and deformations of the musculoskeletal system 47 (17%). Other deformities includes Cleft lip and cleft palate 29 (10%), malformations of the digestive system 23 (8%), malformations of genital organs 19 (7%), malformations of the urinary system 21 (7%), other congenital malformations 2 (1%), Chromosomal abnormalities, not elsewhere classified 15 (5%) malformations of the respiratory system 5 (2%) and Congenital malformations of eye, ear, face and neck 2 (1%).

Number of Congenital Malformation with Use of tobacco

Table no: 02: System wise classification of Congenital Malformation according to tobacco use

ICD CODE	System Of Congenital Malformation	Maternal tobacco use				Total malformations
		No	%	Yes	%	
Q00-Q07	Nervous System	58	20.5	5	1.8	63
Q10-Q18	Eye, Ear, Face And Neck	2	0.7	0	0.0	2
Q20-Q28	Circulatory System	54	19.1	3	1.1	57
Q30-Q34	Respiratory System	5	1.8	0	0.0	5
Q35-Q37	Cleft Lip And Cleft Palate	29	10.2	0	0.0	29
Q38-Q45	Digestive System	22	7.8	1	0.4	23
Q50-Q56	Genital Organs	19	6.7	0	0.0	19
Q60-Q64	Urinary System	21	7.4	0	0.0	21
Q65-Q79	Musculoskeletal System	44	15.5	3	1.1	47
Q80-Q89	Other Congenital Malformations	2	0.7	0	0.0	2
Q90-Q99	Chromosomal Abnormalities	11	3.9	4	1.4	15
Total		267	94.3	16	5.7	283

The above table explains congenital malformation and history of Use of tobacco. 267(94%) mothers stated no history of using tobacco and only 16 (6%) mother's found using tobacco during and before their pregnancy. Among these 16 (5%) tobacco user mothers, 5 (1.7 %) babies had born with neural tube defect, 3 (1%) babies with Circulatory System and Musculoskeletal System defects and 1(0.3%) with digestive deformities.

As per fathers' tobacco use concern, 149 (53%) fathers of malformed babies gave history of tobacco use. Among tobacco user, maximum babies 41 (14%) Circulatory System defect, 25 (10%) Musculoskeletal System, 24 (9%) nervous system malformations, 14 (5%) Urinary System, 12 (4%) Cleft Lip and Cleft Palate and Chromosomal Abnormalities, 11 (3.9%) Genital Organs, 9 (3%) Digestive System and only 1 baby diagnosed with respiratory defect.

Discussion

In our study 283 congenital malformation were identifies. Among these, 267(94%) mothers stated no history of using tobacco and only 16 (6%) mother's found using tobacco during and before their pregnancy. This pattern indicates that very few (6%) mother were at risk due to tobacco use. Malformations other than tobacco use are major risk in our study, but, the babies born to tobacco used mother must not be neglected in concluding the effect of tobacco on birth defect.

In India, per capita smokeless tobacco consumption has increased among the poor population between 1961 and 2000 in both rural and urban areas and both in males and females[7]. In India, the use of smokeless tobacco is common in various forms like chewed, sucked or applied to teeth and gums [8]. Maximum samples responded that they use chewable or applied form of tobacco. These kinds of smokeless tobacco products contain large amount of sodium (sodium bicarbonate) which is necessary to facilitate nicotine absorption[9]. The effect of sodium bicarbonate is not well understood but the effect of nicotine on malformation is well documented. Parents also reported that they use the powdered form of tobacco called a 'MISHRI', prepared by roasting tobacco leaves, and principal constituent being alkaloid nicotine in 1 to 7%[10]. The prevalence of tobacco use in this region is 17 – 45%[10].

Despite these methodological differences, the association of tobacco use during pregnancy and malformation is well cited by many authors such as Bird TM[11], Bracken MB[12], Cedergren MI[13], Christensen K[14], De Roo LA[15], Dickinson KC[16], Feldkamp ML[17], Ramirez D[18], and Williams LJ[19]. The results of these research were similar in regards to the association

between maternal smoking during pregnancy and defects of the cardiovascular, respiratory, digestive, nervous, Urogenital and musculoskeletal systems.

Conflict of Interest – NO Conflict of interest

Source of Funding- NO Self or other source

Conclusion

There is a need to make the rural women aware about hazardous effects of use of mishri[20] through health education sessions to wean them out of this addiction, which is passed from one generation to the next as a tradition at an early age.

Ethical Clearance: The study was initiated after approval of the Institutional Ethics Committee of Krishna Institute of Medical Sciences Deemed University's.

Repair of Cast Partial Denture Made Easy– An Alternative Approach

Pradeep S

Additional Professor, Dept. of Prosthodontics, Manipal College of Dental Sciences

Abstract

Patients wearing cast partial denture might face breakage of denture due to any reasons. The ideal approach for repair of broken cast partial is electrosoldering. This paper presents an alternative approach for repair of cast partial denture using heat cure acrylic resin.

Key words: *Repair of denture, Electrosoldering, Cast Partial Denture.*

Introduction

Despite careful planning and competent construction with materials of good quality occasional breakage and distortion of Cast Partial Denture is seen.

Breakage can be either of the acrylic, major or minor connectors, clasps or the tooth. Need for repair may arise due to careless handling by the patient, inadequate mouth preparation, poor construction, metal fatigue, loss of fit, careless handling in the laboratorary[1]. Ideally electro-soldering is used to repair cast partial denture which is a process of building up of a localized area with a filler metal or joining two or more metal components by heating them below their solidus temperature and filling the gap between them using a molten metal. [2,3]

This clinical report describes an alternative approach for repair of cast partial denture using heat cure acrylic resin.

Clinical Report

A 51-year-old male reported to the department of Prosthodontics with the chief complaint of broken maxillary cast partial denture. On examination, a fracture was observed on both ends of the longitudinal component (strap) of the major connector that was joining the anterior and posterior palatal strap (Fig.1). To repair this cast partial denture the ideal procedure was electro soldering, but an alternate approach was planned. This clinical report describes an alternate approach to repair the broken cast partial denture using heat cured acrylic resin.

Procedure

An impression of maxillary arch was made using alginate with the broken cast partial denture in place. After retrieving the impression, the cast partial denture was removed from the impression and impression poured in die stone. After the cast had set the fractured fragments of cast partial denture were approximated on the cast (Fig.2). Once approximated, mechanical grooves were made on both ends of the broken cast partial denture using a disc and a mandrel to enhance mechanical bonding between metal and acrylic resin (Fig.3). Wax up of the cast partial denture was completed and it was acrylized in usual manner (Fig.4). The final product was finished and polished to prevent affinity towards food debris (Fig.5). When seen through light the thickness of acrylic resin and the joint can be appreciated (Fig.6). The repaired cast partial denture was then placed intraorally and checked for the fit (Fig.7). Any difficulty in placement or any occlusal discrepancy was eliminated.

Advantages

1. Comparatively easy to repair
2. Less technique sensitive
3. Economical
4. No complicated equipment required

Disadvantages

1. Only major & minor connectors can be repaired

2. Can be bulky
3. Less thermal perception
4. Shrinkage can cause distortion
5. Less strength compared to metal
6. If not polished, then can cause irritation

Fig. 1 – Broken cast partial denture

Fig. 2 – Broken Partial denture on cast

Fig. 3 – Mechanical grooves for retention

Fig. 4 – Wax up

Fig. 5 – After acrylization

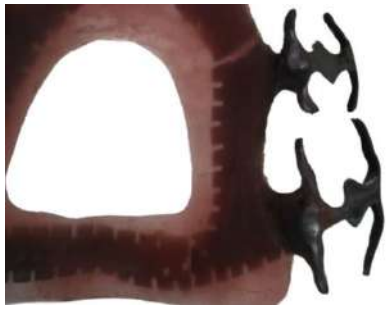

Fig. 6 – Through light

Fig. 7 – Intraoral Placement of Cast Partial

Discussion

Breakage of cast partial denture is very uncommon which can be a result of careless handling by the patient, inadequate mouth preparation, poor construction, metal fatigue, loss of fit, careless handling in the laboratory. Electro soldering is the process by which broken cast partial dentures are repaired which involves the process of building up of a localized area with a filler metal joining two or more metal components by heating them below their solidus temperature and filling the gap between them using a molten metal. Advantages of this technique includes adequate strength in thin sections, less bulky, non-irritating and light weight, whereas disadvantages include technique sensitivity and is expensive.

The technique described in this paper uses heat cured acrylic resin for the repair of broken cast partial denture. The advantages include less technique sensitivity hence easy to repair, economical and less complicated equipments are required. The disadvantages include bulkiness to the cast partial denture, shrinkage of heat cure resin can cause distortion, less strength than metal and if not polished well can cause irritation.

Role of Demographic, Cognitive, Social Factors and Personality Trait on Treatment Modality Related Decision Making: A Conceptual Framework

Praheli Dhar Chowdhuri[1], Kaushik Kundu[2]

[1]PhD Scholar, [2]Associate Professor, Both from Department of Management and Business Administration, Aliah University, Kolkata

Abstract

Purpose: Understanding individual's treatment modality related preference and choice-behavior is prerequisite for equitable distribution of community medicine and Health Human Resource planning. Standard models emphasize on demographic determinants and need-based perception, loosely incorporating social affecters, cognitive components and personality trait. This study addresses these factors separately and integrates into a statistically valid model.

Methodology: Cross sectional study with sample size n=300 and 30 point questionnaire. Items are treated with exploratory factor analysis and regressed with preference and choice. Maximum likelihood estimates led to a path model.

Results: 40.3% prefer CAM and 51.3% used it in last 12 months. Male, people with higher education, low disease burden and making decision in-group, choose CAM and believe Conventional Medicine has side effect, CAM cures all disease, cheaper and usage along-with Conventional Medicine, is better. Extraversion has positive ($B=0.693, p<0.001$), Conscientiousness ($B=-.306, p<0.001$) has negative effect on CAM usage. The integrated model shows 12 months usage score has strong negative prediction to stated CAM preference, whereas cognitive component is strongest predictor of CAM preference and conscientiousness acts negatively on choice and preference. Disease burden acts as need factor and social effect as external influence over CAM preference.

Conclusion: Separately, demographic, cognitive, social factors, disease burden and personality traits influence treatment decision but the integrated path model shows factors act differently on preference and choice behaviour and also at different levels. This understanding will contribute to modify the existing conceptual models of healthcare utilization, facilitating the healthcare strategic planning and distribution system, related to health human resource management.

Keywords: *CAM, Human Resource for Health, Treatment Decision, Big 5 personality trait, Path analysis, Behavioral Choice Model*

Introduction

With the objective of 'leaving no one behind', the developmental policies of the United Nations aim at "universal access to good quality health care services, without anyone having to face financial hardship as a consequence" [1]. Towards materializing such equitable distribution of healthcare service, it has to be meaningful and more importantly acceptable, which largely depends upon understanding of people's healthcare preferences, including their treatment modality related preference, decision making process and choice behavior. The National Comprehensive Cancer Network Guideline states that even for end-of-life care, optimal management should incorporate psycho-social and spiritual aspects of not only the patients alone, but also of their family members and care givers as per their need, value, belief and culture (NCCN Palliative care guideline)[2]. Hence, a systematic research is of paramount importance to identify the significant aspects, influencers and factors

partaking treatment related decision making process at both macro and micro level.

Treatment modalities are broadly diverged into two categories; Conventional Medicine, based on principles of physics, chemistry and biology and Complementary and Alternative Medicine (CAM) in form of Ayurveda, Homeopathy, Chiropractic, Reiki, Acupuncture, Kampo, etc. Choosing whether to use Conventional Medicine or Complementary Medicine is a "Nonlinear Complex Dynamic procedure"[3].

Decision-making is defined as a cognitive process (Princeton University definition, 2006). During the treatment related decision making process patients seek information on treatment alternatives and want to be involved in treatment decisions [4], which is in turn highly intervened by the community, family members and their social values[5,6]. While choosing a treatment modality, studies show that an individual's choice may be affected by external factors like demographic, financial condition, peer pressure, treatment availability, culture, belief, habit[7] etc. or internal factors like personality trait, cognitive ability, philosophical congruence[8] etc. However, for conceptualization and prediction of individual's choice of treatment modality, these data need to be presented in a structured, systematic flow. Though, behavioural healthcare utilization models loosely describe the choice making process of treatment modality, doesn't validate it with quantization. Among the existing conceptual models of healthcare related decision making, the Andersen Healthcare Utilization Model has been widely accepted, (Anderson, 1995)[9] demonstrating three determinants- predisposing factors, enabling factors, and need. (Figure 1)

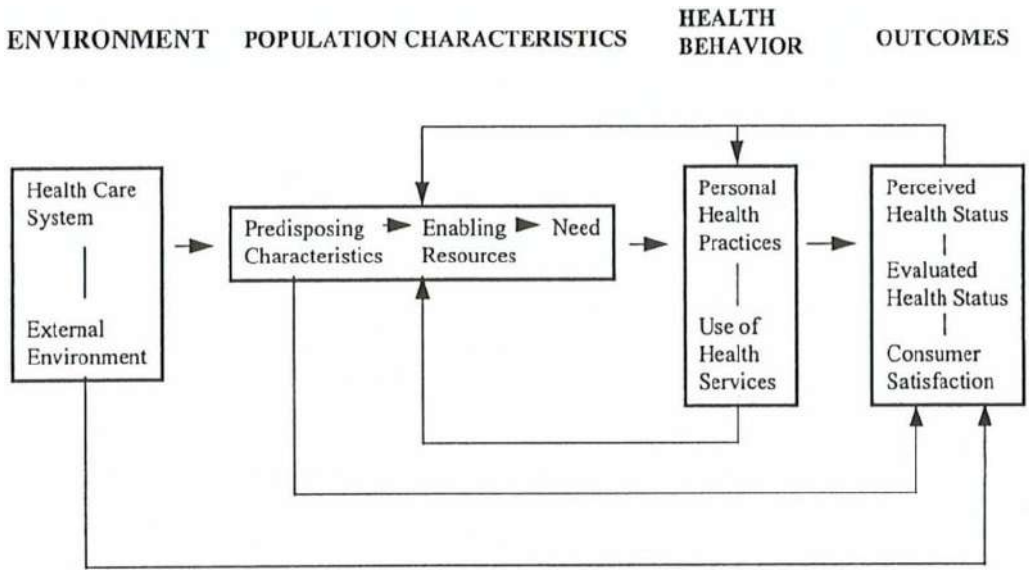

Figure 1. Andersen Healthcare Utilization Model (1995)

Another prominent model, i.e. Charles' Healthcare Decision model[10] shows Information exchange, Deliberation and Decision Control are the main determinants. Most healthcare utilization models emphasize on need based perception and demographic determinants, vaguely incorporating social affecters and cognitive components, with no reference of individual's personality trait. On the other hand, modern workers have emphasised on personality trait in all treatment related decision making (Flynn and Smith, 2007; Sorensen, 2008)[11,12]. Besides, as previously discussed, apart from need (perceived disease burden), philosophy and effect of previous choice behaviour in current preference would change the healthcare utilization pattern greatly.

Thus, a gap is observed in terms of integration of all treatment modality related decision making factors into a statistically validated model and measuring relative importance of each factor. From existing literatures, we have Social and community based decision modifiers along with cognitive, personality and need based factors acting as major contributors in decision function. In view of this, the study aims to identify the factors determining individual's preference and choice towards a particular treatment modality and separately addresses

each factor to understand their relative importance by factorising the external influencers and regressing the internal cognitive elements with the decision outcome. Further, this study also tries to integrate the identified factors into a statistically valid structure, by assimilating them through a path model, where some influencers have been observed not to play significant role while acting simultaneously with other variables.

Methodology

This cross sectional study includes responses from a pretested and pre-structured 30 point questionnaire from a sample of 300 responders distributed in the rural and urban setting of Kolkata and 25 km surroundings area, as collected from December'2016 to May'2017. Responders belong to age group of above 18; having basic idea of both Conventional Medicine and Complementary and Alternative Medicine. The questionnaire having 7 point Likert scale and dichotomous scale (yes/no) is sub-structured into demographic variables, disease burden, social, cognitive and personality trait items, which are later factorised. Results are analyzed using IBM SPSS ver.23. The questionnaire has been tested with a pilot study of 50 samples for reliability with Crohnbach alpha (>.7 for all subparts with Likert scale items) and validity with inter-correlation coefficients. The 7 point Likert scale value of CAM usage has been tested and shown to be similar to normal data (Shapiro Wilk test Normalcy= 0.908, p<0.001) and hence is taken into parametric analysis. Chi square test has been done on demographic variables determining their dependence on choice behaviour and preference. The responses of the disease burden items are transformed linearly to disease burden score. Factor analysis is done on items related to social, cognitive and personality trait effectors. For social and personality trait items, with factor scorings as independent variables, parametric regression analyses have been done taking CAM usage as dependent variable. Cognition being an all or none process is itemised with dichotomous scale. Items for different cognitive components are used as independent variable for binary logistic regression. From the significant variables, cognitive factor score has been calculated. From statistically significant regressive factors, likelihood estimates were done on prevalence and preference alongwith covariances and is plotted for path analysis through AMOS ver.20.The final model has been tested for fitness with validation methods.

Results

Demographic outcomes

121 responders (40.3%) prefer CAM at the point of study where 51.3% people have actually used in last twelve months, which, in this study has been considered as CAM prevalence. There is thus, a significant difference between preference and prevalence of choice behaviour over CAM related decision making (p=.007). With different demographic variables such preference and prevalence have been tested for dependence (chi square test for 2 X n contingency tables). Unlike the usage, preference pattern is independent of age. Male responders prefer (p=.001) and use (p=.026) CAM. People with higher education and higher socioeconomic status are using CAM (p=<0.001). Responders with higher disease burden of self and family tend to prefer conventional medicine (p=<0.001) and people taking decision in group prefer and choose CAM. Table 1 depicts the summary of the demographic outcomes.

Table 1: Significance of demographic variables in CAM spreference and prevalence

Proportinal comparison of CAM preference vs CAM prevalence		**Z= 2.70** ***P*= 0.0069**
Demographic Character	**CAM vs CONV preference (*P* value)**	**CAM vs CONV prevalence (*P* value)**
Age	0.546	0.005
Gender	0.001	0.026
Education level	0.055	<0.001
Socio-economic status	0.925	0.017
Desease Burden	<0.001	0.043
Decision in group	0.001	<0.001

The Personality Factor

Exploratory factor analysis extricated three underlying factors as per big five personality trait model; neuroticism, extraversion and conscientiousness. After rotation, cumulative sum of squared loading on three factors came to be 64.23%, i.e. well explanatory. The component weights are summarized in table 2.

Table 2

Factor Explanation of personality traits *(From rotated component matrix)*

Factor	Item wise subcomponents	Component Weightage	Personality trait
Factor 1	Apprehension	0.758	Neuroticism
	Anxiety	0.766	
	Cost-driven decision	0.565	
Factor 2	Goal Oriented	0.696	Conscientiousness
	Rationalism	0.708	
Factor 3	Suggesting/ discussing with others	0.924	Extraversion

To estimate the effects of the factors on decision making towards CAM usage, a linear regression analysis has been done. The model shows CAM usage is driven by Conscientiousness negatively (beta= -0.306, P<0.001) and Extraversion positively (beta=0.693, p<0.001). Neuroticism has not been proved contributing (vide table 3). The equation of this regression is-

Y (CAM usage) = 2.930 – 0.306 X_1 (Conscientiousness) + 0.693 X_2 (Extraversion)

Table 3: The regression table of CAM usage and personality traits

	Unstandardized Coefficients		Standardized Coefficients			95.0% Confidence Interval for B	
Model	B	Std. Error	Beta	t	Sig.	Lower Bound	Upper Bound
(Constant)	2.930	.057		51.441	.000	2.818	3.042
Neuroticism	-.068	.057	-.045	-1.189	.235	-.180	.044
Conscientiousness	-.462	.057	-.306	-8.098	.000	-.574	-.350
Extroversion	1.045	.057	.693	18.308	.000	.932	1.157

Social Effect

The social effect questions are factorized. Component matrix reveals only one underlying factor, i.e. pro-CAM Social Influence Factor. The regression analysis shows decision making of CAM usage is positively influenced by pro-CAM social influence factors (beta= 0.538 ±0.074, p=<0.001), with linear equation as, Y [CAM usage] = 2.930 + 0.538 X [Social Factor]

Effect of Cognitive components

Cognitive factors are tested with logistic regression. It is identified that individual's perception that conventional medicine has side effect [OR=8.178, 95% CI= 2.91-22.97], CAM can treat all diseases [OR=4.158, 95% CI= 1.85-9.31], it's cheaper [OR=2.612, 95% CI= 1.18-5.76] and usage along with Conventional Medicine is better [OR=6.199, 95% CI= 2.66-14.41], are the significant mobilisers of CAM use. The logistic regression table showing influence of cognitive

components on CAM usage is depicted in Table 4. From the significant factors a cognitive factor score has been computed which is later used in integrated model.

Table 4: The logistic regression table of cognitive effect on CAM usage

	B	S.E.	Wald	df	Sig.	Exp (B)	95% C.I.for EXP(B)	
							Lower	Upper

The integrated decision path

The maximum likelihood estimates of the path are calculated and demarked in the figure of the decision model. Path variables, only with significant regression weights are taken. Covariance among the factors is estimated and found to be significant and included in the path diagram. While testing fitness of the model, it is observed that chi square value is 0.19, goodness of fit index (GFI)= 0.989 and other model fit indices are at par. The integrated path diagram lucidly emulates the factors and their effects on CAM preference and usage. As per the maximum likelihood estimates, the relative importance can be quantised in form of regression weights.

Conscientiousness has negative effect on both CAM preference and choice. Similarly, higher disease burden opposes preference towards CAM and is not significant component of 12 months usage of CAM. Past CAM usage has strong negative influence on current CAM usage (standardised weight= -0.21, p=<.001). Strongest predictor of choice behaviour is extraversion and that for preference is cognitive factor. The Integrated Path Model is shown in Figure 2.

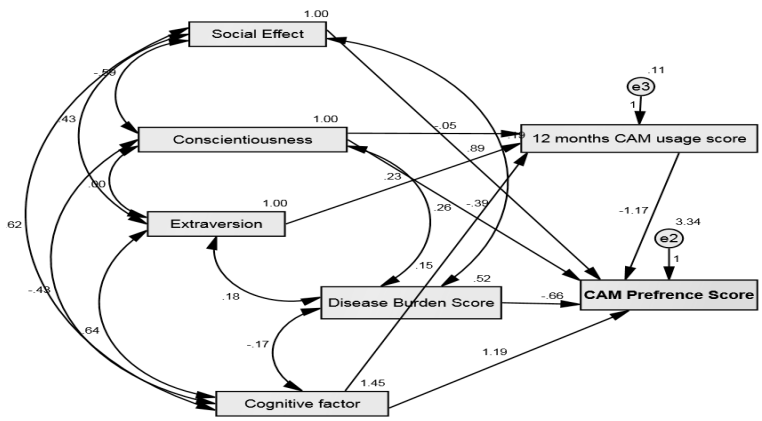

Figure 2. The integrated path model

Discussion

Choosing a treatment modality, in contrast to utilitarian consumer choice, involves people's overall wellbeing and quality of life. This study has taken into consideration the important components of healthcare decision making process, illustrated in studies of shared decision making. The classical linear model of healthcare utilization, based on need – preference-choice behaviour triad has been scrutinised through an integral analysis of multiple factors. This cross sectional study takes two dependent variables in form of 12 month CAM usage, which is considered as individual's choice behaviour and current 'Stated Preference'.

CAM is found to have significant taking among people (40.3% preference and 51.3% usage). This is significantly higher than western countries, which is 26% (Coelho et al., 2010)[13] – 38% (Barnes, 2008)[14]. However, according to WHO (2002)[15], the incidence of CAM prevalence can be as high as 70%. The 11% difference in choice behaviour and preference score (p=0.069) may be explained by post choice dissonance which has been proved to be strong predictor of current preference. Epidemiologic trends are highly intertwined with social effect, in form of decision making practises by discussion within the community. Strikingly, this does not differ among the socio-economic strata. Although Flynn, Smith and Vanness (2006)[16] argue that socio-demographic factors and current health status are poor predictors of patient's preference, current study differs from this view. Rather, demographic factors can be assumed as predecessor of social effect. Social effect has highly significant dependence on Community based decision making practice (R^2=0.103, F=34.37, p=<.001). Again, in contrast to studies of Sirois[6], Coelho[12] where female responders are prone to CAM, this study shows that male responders preferred CAM. As decision in group is found to be a major contributor of CAM preference, acting through pro-CAM social factors, such gender inequality may be caused by less female participation in community meetings.

Personality trait, as a factor of individual's treatment related decision making process, has rarely been described till date. The role of personality factor has been discussed by Flynn and Smith (2007)[11] showing increased conscientiousness most active decision-making style. Whereas, Sörensen et al. (2008) [12] found higher levels of neuroticism, openness, and agreeableness were associated with greater awareness of care needs. This study obviates the statistical significance of neuroticism but emphasises positive effects of extraversion and negative effect of conscientiousness, along with quantising their effects, which has not been done in other studies. Background knowledge, philosophical attitude and perception about cost are the major components of cognitive factor, determining treatment related preference and proving most important predictor of stated preference. This supports the findings of Astin (1998)[17] and MacFadden (2010)[18]

In comparison to Anderson's Healthcare Utilization model, in this study the disease burden plays as need factor; cognitive factor, social effect and personality trait as enabling factors for preference, leading to usage. However, the Anderson's model is unidimensional and essentially hypothesises preference to be congruent with usage. But in the neo-classical studies in economics, preference and choice are often described as independent identities. The integrated path model described in this study aptly delineates this multidimensionality and treats choice and stated preference as different entity. This finding is at par with the calculated predictions by Sirois and Purc -Stephenson, (2008)[6] who modelled social factor, symptom burden and post decision dissatisfaction to be the major players of CAM choice and Wapf and Busato (2007)[8] who emphasised on post-choice behaviour. Hence, this study conceptualizes a new multi-strata decision making model integrating preference-choice model and post-choice holistic preference model.

Conclusion

Apart from identifying a novel trend of integrating different factors into the preference and choice based healthcare utilization, this study also attempt to bridge the gap between behavioural models and economic theories of preference-choice discordance. Besides, the findings can be useful for the social researchers to understand the physician-patient dynamics. Architecture of the integrated model will contribute to betterment of existing conceptual models of healthcare utilization, facilitating the healthcare strategic planning and distribution system related to health human resource management.

Factors Associated with Use of Dental Sealants among Dental Professionals in Mangalore—A Cross Sectional Study

Hussain Lokhandwala[1], Prashanthi S Madhyastha[2], G Rajesh[3], Srikant N[4], Ravindra Kotian[5]

[1]Post Graduate Student, Department of Orthodontics & Dentofacial Orthopaedics, Dr R Ahmed Dental College & Hospital, West Bengal Health University, Kolkata, [2]Selection Grade Lecturer, [3]Professor, Department of Public Health Dentistry, [4]Professor and Head, Department of Oral Pathology, [5]Professor and Head, Department of Dental Materials, Manipal College of Dental Sciences, Mangalore, Affiliated to Manipal Academy of Higher Education, Manipal, Karnataka, India

Abstract

Introduction: Dental caries is one of the most infectious diseases in the world. Dental sealants have been proved as effective way to prevent caries, hence can play a vital role in preventing caries.

Objective: The primary objective of the study is to obtain insight into dental sealant status and factors associated with sealant use among dental professionals in Mangalore, by a questionnaire method.

Method: A cross sectional, questionnaire based study was done on both private practitioners and professionals working in various colleges in Mangalore, to assess knowledge, attitude, behaviour, perceived effectiveness, willingness to apply sealants, familiarity with recent guidelines and barriers to the use dental sealants in Mangalore city.

Results: A total of 134 respondents took part in study. Half of the respondents (50%) said that they had never applied sealants. A majority (96.3%) of them said that they were willing to apply sealants as a preventive measure. On correlation analysis there was a statistically significant association between knowledge and attitude ($p=0.001$, $r=0.296$), behaviour ($p=0.001$, $r=0.280$) and perceived effectiveness ($p=0.001$, $r=272$). There was also statistically significant association between attitude and behaviour ($p<0.001$, $r=0.433$), perceived effectiveness ($p<0.001$, $r=0.521$) and barriers ($p=0.014$,$r=0.228$). Overall 86.6% of the respondents reported that dental sealants are underused with poor attitude of patients towards sealants being the major barrier for their use followed by unawareness of treatment choice in patients.

Conclusion: The present study highlights the need to change the dental curriculum regarding dental sealants and has definite policy implications for preventive re orientation of dental education and dental practice for long term oral health benefits to the populace. The results also throw light on a number of barriers to the use dental sealants in a developing nation like India, thus indicates the need for patient education and awareness programs for the population in terms of oral health.

Introduction

Among the childhood infections, the prevalence of dental caries is ubiquitous in most developing countries. Over the years, even though the prevalence and severity of dental caries has declined, yet significant population remains at high caries risk [1, 2]. The first global map with data on DMFT for 12 year olds was presented in 1969

by WHO. A data base was established over the number of years showing increase in prevalence of caries in the developing countries[3]. Voluminous literature exists on the status of the dental caries in India. A very extensive and comprehensive National Oral Health Survey conducted in 2004 throughout India has shown dental caries prevalence of 51.9% in 5-year-old children, 53.8% in 12-year-old children and 63.1% in 15-year-old teenagers[4]. In 2005, prevalence record of dental caries in Mangalore, was: 5-7 year ~ 94.3%; 8-10 year ~ 82.5%; 11-13 year ~ 82.5%.[5]

Deep pits and fissures are vulnerable to caries as they are virtually impossible to clean, owing to the tooth anatomy, leading to accumulation of plaque and eventually caries[6]. About 44% of caries in primary teeth are on pits and fissures and about 90% of carious lesions are found in the pits and fissures of the permanent teeth. Pit and fissure sealants can be used effectively as a part of a comprehensive approach to caries prevention on an individual basis or as a public health measure for at risk populations**.** Over more than 11 guidelines and systematic reviews have recommended pit and fissure sealant use for at-risk populations[7,8,9]. In spite of the scientific evidence supporting their effectiveness,[10] they have been underutilized by dental profession[11]. In latest data available indicates just 15 % of children ages 6-17 years have dental sealants[11].

Although there are many reasons for the sparse use of sealants in caries prevention, lack of knowledge about sealants has frequently been cited as a possible determent to its adoption[12,13,14]. It has also been found that the theoretical frame for behavior change is an assessment of knowledge and attitudes affecting practice. However, the adoption of pit and fissure sealants for preventive purposes by the dentists' in Mangalore has not been evaluated. The present study aimed to provide information about sealants to the dentists working in dental colleges and in private dental practices in Mangalore City and to determine whether dentist's knowledge, attitude and practice of sealants could truly be an added link to reduce the prevalence of dental caries. The objectives were to obtain insights into dental sealants status and factors associated with sealant use among dental professionals in Mangalore by accessing the knowledge, attitude, practice and perceived effectiveness by a questionnaire method.

Materials and Method

Study area: Mangalore city**,** Karnataka, India.

Study population: The survey's target population is dental professionals of Mangalore.

Study design: A cross sectional descriptive study was employed in the present study

Sampling Methodology: Purposive sampling technique

Ethical approval: The ethical approval was obtained from the Institutional Ethical Committee of Manipal College of Dental Sciences, Mangalore.

Pilot study: The questionnaire with 46 questions was reviewed for clarity, validity and pretesting of questionnaire was done on 10 dentists - 5 M.D.S & 5 B.D.S. from 1 dental college and 2 individual practice clinics. Questionnaire with minor corrections after the pilot study was slightly modified and final questionnaire was prepared.

Sample size: The sample size was assessed based on convenient sampling technique.

Inclusion Criteria:

- Dentists practicing part time or full time in dental colleges and private clinics in the selected areas
- Dentists who were willing to participate in the study were included.

Exclusion Criteria:

- Post graduates & Interns working in these clinics and colleges.

Samples:

- Teaching faculty (with and without private practice) from different dental colleges in Mangalore
- Dental clinics with individual setup and multi-specialty setups were visited for the survey. 1 dentist per clinic to more than 5 dentists per multi-specialty setups practiced in these clinics was taken in the survey.
- 4 dental colleges in Mangalore were selected.

Data collection: The knowledge, attitude and behavior of the study subjects regarding pit and fissure sealants was assessed by means of a self-administered

questionnaire. Overall, a total of 46 items were included in the questionnaire, with 11 items assessing knowledge, 12 assessing attitude and 11 behaviors respectively. Information pertaining to perceived effectiveness of respondents in applying pit and fissure sealants was also collected by employing 3 questions. Information related to willingness to apply pit and fissure sealants, prior training and familiarity with recent guidelines on pit and fissure sealants was collected by employing 3 questions. Information related to inhibitory factors (barriers) regarding the use of pit and fissure sealants was collected by 5 questions. Information regarding demographic details of the study subjects was also collected.

Scheduling the Survey:

- For dentist in dental colleges: Preferably during working hours of the college (in morning).

- For private practitioners: Preferably evening time was chosen to visit the clinics as evening time is considered to be the peak time of clinics which would ensure inclusion of most of the part time/ full time practicing doctors in the survey.

Data management: Complete questionnaire was coded and spread sheet was created for data entry. The range of possible scores for knowledge, attitude, behaviour, perceived effectiveness and barriers were 0-11, 12-60, 11-55, 3-15 and 5-25 respectively. The range of scores for willingness to apply sealants, familiarity with recent guidelines and previous training were 0-1. Correct answers for knowledge were scored as 1 whereas wrong answers were scored as 0. Five point Likert scale was employed for attitude, behaviour, perceived effectiveness and barriers. However before answering the questions on barriers respondents were asked if pit and fissure sealants are underused, those who answered yes were then asked to answer the barrier section. Score of 1 was given to those who answered yes for willingness, familiarity with guidelines and previous training. Score 0 was given to those who answered no.

Data analysis: Data analysis was conducted by employing Statistical Package for Social Sciences (SPSS), version 20.0 (SPSS Inc, Chicago IL). Demographic variables like age, gender, qualification and work experience were assessed with knowledge, perceived effectiveness, attitude, behaviour and barrier using T test. Association between work place and the domains was calculated using One way anova test. Chi square test was done between demographic variables and willingness, previous training, application of sealants and familiarity with recent guide lines. Pearsons correlation was done to correlate the variation among the domains.

Observations and Results

A total of 134 respondents in the present study were distributed 64 were ≤ 30 years, 60 were male, 85 were MDS, 110 respondents were having ≤ 10 years of experience and Majority of the participants were both dental institution and private practice (n=51). The mean(sd) knowledge, attitude and behaviour scores of the respondents were 5.88(1.85), 49.27(7.07) and 32.31(9.95) respectively. The mean perceived effectiveness and barriers score were 12.90(1.88) and 17.97(1.88) respectively.

The results showed that respondents who had completed their masters training (MDS) had higher mean knowledge, attitude, and behavior & perceived effectiveness scores. Respondents with ≤10 years of experience had higher mean knowledge scores. Respondents working in dental institutions or combined practice/institution had significantly higher mean perceived effectiveness scores than the ones working in private practice (p=0.001 and P =0.007 respectively). Similarly behaviour scores was also significantly higher in individuals attached to an institution compared to those working in private practice($p<0.05$). Half of the respondents (50%) had applied pit and fissure sealants, however 96.3% were willing to apply pit and fissure sealants as a preventive measure. Majority, 52.2% had not undergone any previous training in pit and fissure sealants and 64.9% were not aware of any recent guidelines for pit and fissure sealants. **(Figure 1)**

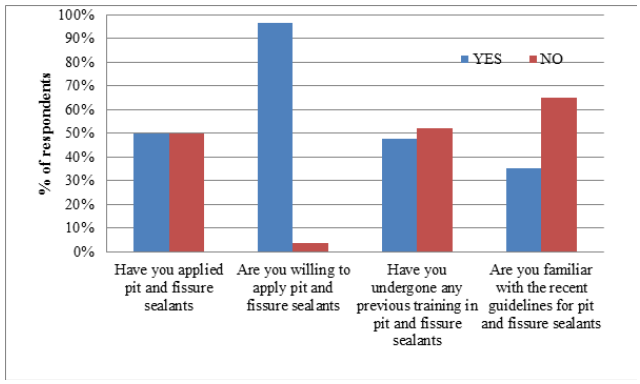

Figure 1: Application, willingness, previous traning and familiarity of pit and fissure sealants

Willingness was significantly associated with educational qualification of the respondents, while

previous training was significantly associated with the type of work place. Familiarity with recent guidelines was significantly associated with educational qualification and the type of work place in the present study. It can also be observed that application of pit and fissure sealants was significantly associated with educational qualification and the type of work place. The results of the correlation analysis indicated that there was a statistically significant association between knowledge and attitude (p=0.001, r=0.296), behavior (p=0.001, r=0.280) and perceived effectiveness (p=0.001, r=272). There was also statistically significant association between attitude and behaviour (p<0.001, r=0.433), perceived effectiveness (p<0.001, r=0.521) and barriers (p=0.014, r=0.228). Statistically significant association was also seen between behaviour and perceived effectiveness (p=0.001, r=0.479) of the study subjects. A majority of the respondents (86.6%) in the present study reported that dental sealants were under used. Various potential barriers to the use of sealants were also probed among the study subjects. Cost factor as a barrier was considered by 64.7% of respondents. On being asked if unawareness of treatment choice in patients was a barrier, a majority (81.0%) said yes, 12.0% were neutral and 7.0% said no. They were asked if poor attitude of the patients towards pit and fissure sealants was a barrier, to which a majority (83.6%) said yes, 8.6% were neutral and 7.8% said no.

Respondents considered lack of good retention of pit and fissure sealants was a barrier to their use (43.9%). Poor attitude of patients towards pit and fissure sealants emerged as a major barrier for sealant use among the study subjects. **Figure 2**

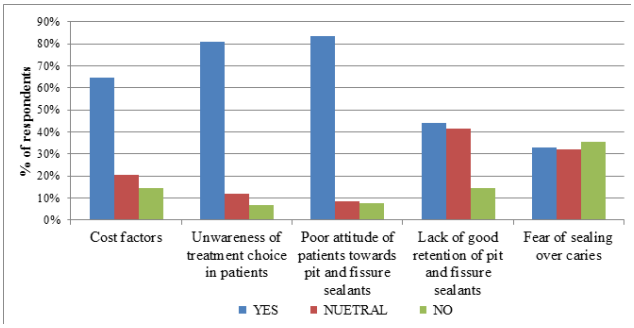

Figure 2: Barriers to pit and fissure sealant use

Discussion

The present study was conducted to explore various issues related to the use of pit and fissure sealants among dental professionals in Mangalore. Numerous systematic reviews have established its clinical efficacy of sealants in the prevention of dental caries[7,8,9]. The present study can pave the way for optimizing the use of sealants among dental professionals in India.

The mean knowledge score percentage of the dentists was observed as 53.46% in the present study. This is in agreement with the findings of Govindaiah et al[15], who reported low knowledge about sealant use among dentists in Florida. In a similar study conducted by San Martin et al[16], the respondents had neutral to favourable knowledge, which is contrasting to that observed in the present study. The findings were also in contrast to a similar study carried out by Asawa et al[17], who reported sufficient knowledge amongst the dentists in Bhatinda, India. It was observed that the mean knowledge scores were higher in professionals with a post-graduate degree as compared to those without a post-graduation degree. This may be due to knowledge and training regarding pit and fissure sealants being imparted to the post graduates during their course. It was also observed that knowledge was higher among respondents with an experience of ≤10 years. This could be due to the respondents having cleared their qualifying examination in the recent years and being familiar with various aspects of sealants. With increasing experience among the respondents, they may tend incline themselves to more practically issues rather than those related to knowledge.

The mean attitude score percentage was 82.11% which is an indication of positive attitude among the respondents. This is in contrast to that reported by San Martin et al[16], who reported neutral to favourable attitude scores among Spanish dentists. It was noticed that the attitude was more positive in dentists holding a post graduate degree. This could imply that the further training received in the form of post-graduation would have had a positive influence on the attitude of the respondents.

The mean behaviour and perceived effectiveness percentage score among the study subjects were 58.75% and 85.97% respectively. San Martin et al[16] have reported neutral to positive behaviour scores among Spanish dentists. It was seen that respondents with a post graduate degree had higher mean behaviour and perceived effectiveness scores than those without a post graduate degree. There was statistically significant difference in mean behaviour and perceived effectiveness scores amongst the different categories of workplace. Respondents working in dental college had higher mean perceived effectiveness than the ones

working in private practice. Respondents working in both private clinics and dental institutions had higher perceived effectiveness scores than those working only in private practice. Involvement in teaching and imparting knowledge to students might have influenced mean perceived effectiveness scores in the present study. Besides, playing the role of a teacher might impart greater perceived effectiveness among the respondents.

Respondents working in both private clinics and dental institutions had higher mean behaviour scores than those working only in private practice. Academic environment provided in dental institutions does have a role to play in the observed results. However, further studies are required to shed more light into the potential role of workplace on sealant use.

On being enquired if they applied pit and fissure sealants, only half, 50% of the respondents reported that they apply sealants. This is in contrast to that reported by Main et al[18], who reported that 90% of respondents in Ontario apply sealants in their practices. The results are also in contrast to that reported by Govindaiah et al[15], who reported that 98% of respondents in Florida apply sealants as a routine preventive measure. The results of the present study indicate that pit and fissure sealants are underused in Mangalore. The potential role of barriers to the use of sealants should be further explored to address the reasons for the same. The study subjects were also enquired if they were willing to apply pit and fissure sealants, to which a majority of 96.3% of them responded in the affirmative. This reflects the positive attitude of respondents towards the use of sealants. The results of the present study are thus encouraging, and act as a facilitating factor for further training and implementation of sealant use among the respondents.

When enquired if they had undergone any previous training for the application of dental sealants a majority of 52.2% replied in the negative. This might be due lack of emphasis on pit and fissure sealants during their undergraduate and/or postgraduate training. This might also be due to lack of continuing professional development programs and/or workshops on pit and fissure sealants.

On being asked if they were familiar with the recent guidelines for pit and fissure sealants a majority of 64.9% replied that they were not familiar with the same. This is in agreement with the findings reported by O'Donnell et al[19] among American dentists. The lack of accreditation systems after graduation might be one of the factors influencing the aforementioned results. Willingness to use sealants was significantly associated with educational qualification and previous training was significantly associated with the type of work place of the respondents. Similarly, familiarity with guidelines was significantly associated with educational qualification of the study subjects.

Knowledge showed significant correlations with attitude, behaviour and perceived effectiveness, while attitude showed significant correlations with behaviour, perceived effectiveness and barrier scores. Results also revealed significant correlations between behaviour and perceived effectiveness scores among the respondents. Application of pit and fissure sealants was also associated with workplace and educational qualification. Greater academic exposure might favourably influence various aspects of use of sealants among the study subjects. Being involved in training students might entail dental professionals themselves undergoing some form of training in sealant use. Preventive measures might not be cost effective in the short term, but they are cost effective in the long term. Employing dental auxiliaries to provide sealants might further offset the cost of sealant application.

When asked if unawareness of treatment choice in patients was a barrier, a majority of 81% of the respondents reported in the affirmative. This in indicative of the lack of awareness about preventive dentistry amongst the patients. It becomes imperative on the part of dental professionals to explain to their patients about the benefits of pit and fissure sealants.

Poor attitude of patients towards pit and fissure sealants has been the most significant barrier with 83.6% of the dentists agreeing to the same. Dental professionals help is sought only if there is pain to the patient. They may fail to appreciate the value of using pit and fissure sealants when there is no pain in the teeth. Sealant use is also compounded by the fact that milk teeth are lost anyhow. Spending money and time on the care of painless milk teeth might be perceived to be of no apparent importance. The present study highlights the potential role that dentists can play in informing the patients about the potential benefits of sealant use.

A majority, 43.9% of the respondents reported that lack of good retention of pit and fissure sealants was a barrier to their use. This could be because application of

pit and fissure sealants is technique sensitive and requires previous training. In a study conducted by Olmsted et al[20], simple clinical practices using 4-handed dentistry and strict isolated techniques led to 95% or higher cumulative sealant retention rate. The respondents were also asked if fear of sealing over carious lesions was a barrier, to which a majority of the respondents, 35.3% did not concur. This is in contrast with the finding reported by Govindaiah et al[19] in which 44% of the respondents agreed that the possibility of sealing in decay was a major concern in using dental sealants as a preventive measure. Results of the present study are also in contrast with those reported by Asawa et al[18] who reported that 80% of the respondents were avoiding sealants out of fear of sealing over caries.

The results of the present study represent to one geographical area. Further, research related to sealant use among dental professionals in various parts of the nation is thus warranted to have a representation of all dental professionals in India.

The present study has definite implications for curriculum changes in dental education in India. Appropriate modifications in dental curriculum might be one of the ways in which issues related to low knowledge scores on sealant use among the respondents can be addressed. The present study highlights the need for greater emphasis on preventive care of the patients during undergraduate and postgraduate training. Regular continuing professional developmental programs which highlight the long term benefits of sealant use are also the need of the hour. High attitude and willingness scores of the respondents towards sealant use are encouraging and might indicate that the respondents have favourable disposition towards further training regarding the same.

Policy changes regarding the need for greater emphasis on the longterm benefits of preventive care is of critical importance. This is of special relevance in the context of developing and underdeveloped nations, which face greater disease burden as well as a definite shortage of resources.

Conclusion

The present study highlights the need for changes in the dental curriculum regarding the use of pit and fissure sealant. Policy makers and decision makers should consider placing greater emphasis on preventive dentistry in the dental curriculum in India. Continuing dental educational programs on preventive dentistry in general and sealants in particular will have to be conducted on a regular basis for dental professionals. The present study has definite policy implications for preventive re-orientation of dental education and dental practice for lo long term oral health benefits of the populace. The results of the present study are especially relevant in the context of a developing nation like India with an increasing burden of oral diseases and a definite paucity of resources. Dental professionals might be more receptive towards further training in sealant use and other aspects of preventive dentistry. The study also throws light on various barriers to the use of pit and fissure sealant, out of which poor attitude towards the application of sealants was the most significant. Thus, the role of awareness programs for populations regarding preventive dentistry should be assessed in details.

In Vitro Comparative Study of Dimensional Stability of Three Different Polyvinyl Siloxane Interocclusal Recording Matereials after Storage for Different Time Intervals of 12Hours, 24Hours, and 48Hours

Priscilla Shalini.S[1], Narayana Reddy[2], Sanjna Nayar[3]

[1]PG Student, [2]Professor, [3]Professor and Head of the Department, Department of Prosthodontics, Sree Balaji Dental College and Hospital, Chennai

Abstract

Background: Interocclusal recording materials are generally used in prosthetic dentistry to register the jaw relationship. These materials have a wide range of viscosity, elasticity, and volumetric changes within various material groups. Newer elastomeric interocclusal materials are chemical modifications of elastomers whose comparative properties relevant to clinicians are yet to be studied.

Aims: To compare the dimensional change between the polyvinylsiloxane bite registration materials manufactured by different brands within the duration of 12hours,24hours, and 48 hours storage.

Methodology: The dimensional changes of the different polyvinylsiloxe bite registration pastes were compared three - dimensionally in different time intervals with the standardised die measurement was 25mm between the vertical lines .

Conclusion: Within the limitations of the study, it was found that all 3 interocclusal recording materials NEOSILK, CADBITE, AND O-BITE showed no significant distortion when stored in-vitro for 12 hours. All Materials showed significant distortion when stored in-vitro for 24 hours and 48 hours. All three materials showed more distortion when stored in 48hours compare to 24 hours. Among polyvinyl siloxane interocclusal recording materials NEOSILK showed better dimensional stability when compared with CADBITE and O-BITE when stored in-vitro 24hours and 48hours. Hence we recommend Neosilk bite material for better dimensional stability when compare with other materials.

Keywords: *Dimensional stability, comparison, bite registration pastes*

Introduction

The stomatognathic system in humans is a complex that combines the organs, structures and nerves involved in a multitude of functions like speech, mastication and deglutation. Functions of occlusion can influence the overall pattern and the foundation of the stomatognathic system. Long term success of any restoration is dependent on maintenance of harmony between various components of stomatognathic system. The goal of any restorative treatment is to establish posterior occlusal contacts that stabilize the occlusion and to provide anterior guidance which will provide predictable amount of disocclusion during protrusive and lateral excursions. To achieve proper occlusion in a dentate or edentulous patient, the precise articulation of patient's diagnostic or working casts is a required. Recording and transferring of accurate existing occlusal records is of prime importance for a successful restoration.

Interocclusal recording material should ideally become rigid enough to resist distortion that might result from the weight of the dental casts and exhibit minimal dimensional change after setting before mounting of the casts in the articulator.

The basic principle approach should be that the interocclusal record must be at the correct vertical and

horizontal relation with an accurate, dimensionally stable recording material and recording of eccentric maxillomandibular relations an appropriate method of mandibular guidance.[1] Among the errors in interoclusal recording, only iatrogenic and material based ones are preventable by the operator. Hence, it is essential to know properties of interocclusal recording material.[1]

Earlier interocclusal recording materials were impression plaster, bite waxes and zinc oxide eugenol pastes. The newer materials polyvinyl siloxane and polyether are being used commonly due to their elastic properties and dimensional stability. The polyvinylsiloxane bite registration materials have the advantages of less rigidity with easy removal from undercuts compare to polyether materials.

Hence, this study was done to study the dimensional change between the different polyvinylsiloxane interocclusal recording materials commonly used in clinical practice namely CADBITE, NEOSILK AND OBITE at different time intervals.

Materials and Method

The following polyvinylsiloxane interocclusal recording materials were selected for the study: Viz. Virtual CADBITE, NEOSILK, and O-BITE interocclusal recording materials.

Armamentarium used for the study were Stainless steel die (ADA specification – 19), OPUS Nikon profile projector, Auto mixing gun with mixing tips and permanent marker.

1. Preparation of stainless steel die:

For the present study 2 stainless steel dies were prepared according to ADA specification No.19 for preparation of test specimens with different polyvinyl siloxane bite registration materials. According to ADA specification 19 each die consisted of a cylindrical stainless block of 38mm diameter, with 30mm diameter step on its superior surface. The die was scored with 3 horizontal lines and 2 vertical lines on the top of impression surface . The horizontal lines were marked as X, Y, Z and vertical lines were marked as CD and C'D' for ease in making measurements. The distance between two horizontal lines was 25mm and between two vertical lines was 25mm. The die was subjected to Nd-YAG Laser treatment and 3 horizontal and 2 vertical line were scribed, with the width of 0.016mm on top of 30mm diameter surface. According to above-mentioned specifications a total 2 dies were prepared.

Each die had a highly polished surface and also contained a ring that surrounds the periphery of it, which serves as a tray or as a container for the interocclusal recording material.

2. Manipulation of Materials:

olyvinyl siloxane materials were supplied in the form of cartridge containing base and accelarator paste. Manufacturer's instructions were meticulously followed for manipulation and the material which extruded from gun was uniformly spread over the surface of the die. Glass plate covered with polyethelene sheet was placed on the die over with a weight of 500g was kept and allowed to set for 4-5mins.

3. Specimen fabrication:

Each material was manipulated as mentioned above and total force of 5.55N was applied. The whole assembly was then submerged into a water bath for the setting time suggested by manufacturer plus 3mins to ensure polymerization. After removal from water bath the material was separated from the die by using brass disk or Riser to remove the excess flash trimmed using scalpel. Thus prepared specimens were measuring 30mm in diameter 3mm in thickness and had lines X,Y,Z,CD,C'D' lines on it . Similarly all the 40 bite registration record samples were obtained.

In between the days of observation, the samples were stored in moisture free polyethylene bags at room temperature of 28±2 ^{o}C.

4. Testing of specimens:

The distance between the lines, CD and C'D' reproduced on the sample, was measured at three different points PP', QQ' and RR' (i.e. intersections of these lines with the lines XYZ) by using Nikon Profile Projector V-12 with 10X magnification. Readings were obtained for each sample, and the mean of these three values were noted. Likewise, readings were made at different time intervals, viz. immediately after removal of the material from die, 12hours, 24hours and 48hours, respectively for each of the samples. All the readings thus obtained were tabulated and subjected to statistical analysis for the comparison and correlation of dimensional stability.

Statistical Analysis

The descriptive statistics was given by mean and standard deviation. The dimensional change over time was analysed by Friedman's repeated measures (ANOVA). For significant values, post hoc test was done using Wilcoxon Signed Rank test (Paired). At every time interval, the groups were analysed by Kruskal Wallis test with post hoc Dunn test, where values were significant. $P < 0.05$ was considered significant. Analyses were performed with IBM-S

Result

Table 1 – Dimensional Stability of the Bite Registration Pastes

Brand	12HRS	24HRS	48HRS	P Value
CAD-BITE	24.72 ± 0.0424	24.70 ± 0.0759	24.66 ± 0.0884	0.1224*
NEO SILK	24.73 ± 0.0297	24.72 ± 0.0272	24.71 ± 0.0352	0.2019*

Discussion

The properties of the dental materials vary with the temperature and humidity. Most of the materials used in prosthodontic procedures should be stored in the ambient temperatures to maintain their shelf life. The operator skill in the manipulation of the material is very important apart from the storage conditions of the material.

The dimensional changes in the recording materials will not transfer the true maxilla-mandibular relation from the mouth to the articulator and the prosthesis fabricated will have occlusal contacts in the mouth different from the one fabricated in the articulator. The time elapsed between the interocclusal record, and the mounting in the articulator extends up to three days as the work is sent to distant laboratory. The casts and the interocclusal record are sent to laboratory in different conditions as separately with the casts, casts tied with the rubber bands or mounted immediately. The dimensional changes in the interocclusal recording materials can be expected when the material is removed from the mouth due to the variation in the temperature between the oral cavity and the dental office and the plastic deformation when the material is removed from the mouth. This distortion is possible even when the casts are mounted immediately.

The distortion of the material is expected when the upper and the lower casts are tied using the rubber bands with the interocclusal material interposed and transferred to the laboratory. This distortion is due to the constant pressure till the casts are mounted in the articulator by the laboratory technician.

The time elapsed between the interocclusal recording and the casts mounted in the articulator will cause distortion due to the prolonged setting or polymerisation and the variation of the temperature between the dental office and the laboratory. The average time for mounting of the casts using the interocclusal record varies from few hours when the laboratory is situated locally to two days when sent to distant place.

The current study was done to assess the distortion of the interocclusal record at the intervals of 12 hours, 24 hours and 48 hours similar to the normal clinical situations. The study was done with the interocclusal record without any pressure application to check distortion at different time intervals.

Poly vinyl silicone and poly ether materials, when used as interocclusal materials solved most of the problems associated with the earlier materials. These materials are elastic with moderate stiffness (elastic modulus) so that they can be removed from the mouth and mounted in the articulator without breakage.

These materials are supposed to high dimensional stability, as they do not release any by-product during polymerisation. Polyvinyl siloxane materials have lower stiffness with the comfortable removal from the mouth and mounting with articulator than the polyether so that poly vinyl siloxane interocclusal materials are commonly used as interocclusal record.

Direct interocclusal record is the most commonly used technique to record maxilla-mandibular relationship. The recording material is soft initially, and it fills the space between the teeth, hardens, and records the specific relationship of the arch. The set material is transferred to cast and mounted on the articulator.[3]

Nisan et al. observed that addition type polyvinylsiloxane was the most accurate and stable interocclusal recording material. Previous studies have also demonstrated that handling PVS bite materials remain dimensionally stable up to 7 days.[4] Many authors have evaluated the dimensional change of bite registration materials by means of stone casts and different devices such as three dimensional Zeiss meter, digital caliper, microscope, and stereomicroscopes and Profile Projectors.[4, 5, 6] In the current study Nikon Profile Projector was used for the evaluation of dimensional stability due to its higher precision combined with ease of use.

The stainless steel die used in the present study was similar to the standard die given by ADA specification No 19.[7] The surface of this die is smooth and shiny; therefore, it is easier to evaluate dimensional changes compared to tooth surface with cusps and fossa. In the standard ADA dies, the diameter and angles of the flutes are important for evaluation of the accuracy of impression materials.[8] This study evaluated the distance between the vertical lines at different time intervals with different interocclusal recording materials. The test die has 25mm distance between the vertical lines.

The distance between vertical lines for Cadbite poly vinyl siloxane interocclusal material in the present study was 24.71 mm for 12 hours, 24.72 mm for 24 hours and 24.62 mm for 48 hours. In Neosilk poly vinyl siloxane interocclusal material the measured values between the vertical lines was 24.74 mm for 12 hours, 24.71 mm for 24 hours and 24.68 mm for 48 hours. In O-Bite material it was 24.72 mm for 12 hours, 24.30 mm for 24 hours and 24.31 mm for 48 hours.

Balthazar-Hart et al, (1981) had done a study with polyether and zinc oxide eugenol paste and concluded that Polyether shows the least distortion, and zinc oxide eugenol paste presents higher distortion.[9] Lassila et al, in 1986 had done a study with acrylic resin, zinc oxide eugenol pastes and elastomeric materials and concluded that elastomeric materials have good dimensional stability when compared with acrylic resin and zinc oxide eugenol paste.[10] Karthikeyan et al, in 2007 has done a study with polyvinylsiloxane bite material, zinc oxide eugenol pastes, and bite registration wax (aluwax) and concluded that Polyvinylsiloxane (Virtual, Group A) was dimensionally more stable followed by zinc oxide eugenol paste (Superbite, Group C) and then Bite registration wax(Alumax, Group B).[11]

According to the results obtained in a study done by Sampath Kumar Tejo et al in 2012, Polyether was found to be more dimensionally stable than polyvinylsiloxane followed by zinc oxide eugenol.[12] They recommended the use of polyvinylsiloxane recording material should be articulated within 24 hrs. They also recommended that polyether should be articulated within 48 hrs and Zinc oxide eugenol within 1 hr to prevent distortion. Polyvinylsiloxane bite registration material is popular contemporary bite registration material along with polyether material.

The newer polyvinyl siloxane bite registration materials used in this study Cadbite, Neosilk and O-bite have a major composition of vinyl polysilaxone, methyl hydrogen siloxane, silicone dioxide. They polymerize by addition polymerization and do not form any by-product in the reaction. They have longer polymerization period resulting in sustained contraction period. These are the reasons for these materials being more dimensionally stable than earlier materials.

Conclusion

Within the limitations of the study following conclusions were drawn. Polyvinyl siloxane interocclusal recording materials NEOSILK, CADBITE, and O-BITE showed no significant distortion when stored in-vitro for 12 or 24 hours, but showed significant distortion when stored in-vitro for 24 hours and 48 hours. Among polyvinyl siloxane interocclusal recording materials NEOSILK showed marginally better dimensional stability when compared with CADBITE and O-BITE when stored upto 48 hours.

Factors of Happiness among Indian Adolescents

Priyamvada Shrivastava[1], Gayatri Jay Mishra[2], Mahendra Kumar[2]

[1]Professor and Head, [2]Research Scholar, Department of Psychology, Pt. R.S.U. Raipur, C.G. India

Abstract

The main objective of the study was to explore the factor of happiness among the adolescent's students the other objective was to formulate the theoretical structure of the happiness for the adolescent's population of Chhattisgarh India. For these purpose 250 adolescents studying in different schools of Chhattisgarh constituted the sample for the study. The students were asked to give an open-ended answer to a question "what makes them happy" analysis was performed for their responses 28 common responses after analyzing the responses were identified. A hypothetical exploratory factor analysis (EFA) and confirmatory factor analysis (CFA) was computed to find out the factors of happiness among adolescents. The results of the EFA revealed 5 factors of happiness for adolescents. The results of CFA reveal a low correlation between the 5 factors.

Keywords: *Happiness, EFA, CFA,*

Introduction

In psychology, happiness is a mental or emotional state of well-being which can be defined by positive or pleasant emotions ranging from contentment to intense joy. Happiness has been considered a major life goal in common philosophy[(1)]. In the present generation, happiness is an amazing thing. We all want to experience, for the reason that happiness is one of the most important values in life for all human[(2)]. Happy mental states may reflect judgments by a person about their overall well-being. *Happiness is when what you think, what you say, and what you do are in harmony.* Happiness is defined as a multi-dimensional component of unconscious, cognitive, and motivational processes that are unique to how life is interpreted and received by individuals[(3)]. A commonly used definition of happiness is the degree to which an individual judges the overall quality of his/her life as a whole favourably[(4-6)]. *Happiness is when what you think, what you say, and what you do are in harmony.* The concepts of happiness affected by the cultural and historical variations, many studies have identified individual-level factors of happiness, such as biological, personality, lifestyle, socio-demographic and socio-economic factors[(7-11)]. Definitions of happiness vary with respect to region culture. It is reported that various definitions are available worldwide[(12)]. In contemporary psychology, there is much emphasis on well being, contentment and Happiness. People are healthy normal but feel discontentment. Happiness issue is major public health situation it differs according to different stages of life. The adolescent stage is a transition stage adolescents suffer from emotional turmoil and stress[(13-14)]. It is important to explore the factors of happiness among Indian adolescents. Development of a screening tool of happiness among adolescents in the Indian context is essential. There is a dearth of studies on happiness factors of Indian adolescents'. Hence, there is a need to find out the factors of happiness in Indian cultural contexts and to develop culturally appropriate assessment measures for happiness. For this purpose, the main objective of the study was to find out the factors of happiness and to examine the theoretical structure of the happiness of the Indian adolescent population. Therefore a study exploring happiness among adolescents has been undertaken which highlights the factors contributing to happiness reactions of adolescents and can provide a baseline for the development of the tool.

Method

Sample

The total 250 (125 male & 125 female) adolescent's participants of the study were selected from Raipur, Bhilai and Durg, cities of Chhattisgarh. Mean age of the was =19. Incidental random sampling technique was used for the selection of the participants.

The adolescents who fulfilled the following criteria were included in the study:

Inclusion criteria

- Students of class 10, 11 and 12.
- Able to communicate, read, write and comprehend in English.
- Willing to participate.

Exclusion criteria

- Students below 10^{th} class and above 12^{th} class were not included in the study.
- Not present at the time of the study.
- Not willing to participate in the study.
- Those with any chronic disease were excluded.

Design

The survey research design was used.

Procedure

Participants, who met inclusion criteria, were contacted individually, it was essential to making rapport with the participants, to win their trust. They were ensured that their information will be kept strictly confidential. The information given by them would be used for research purpose only. After getting consent in writing from the participants, they were interviewed. Qualitative information related to the happiness of the adolescents was gathered by putting one Question "What are the events that make you feel happy. 28 dimensions were observed in the responses of the adolescents further the 28 dimensions were put to exploratory factor analysis and confirmatory factor analysis the results of which are given in the figure.

Statistical Analysis

The data were analyzed by excel, SPSS 16.0 version and ADANCO (advanced analysis of composites) version 2.0.1[15]. Responses from participants were coded and entered into SPSS. Missing data were excluded from the relevant analysis. To have an idea of the basic factors of the happiness in Chhattisgarh state, India, maximum likelihood method was performed to explore the links between the observed and latent variables, and to identify the factor structure. The nature of the principal component analysis is exploratory rather than confirmatory[16]. The factors with eigenvalues greater than 1.00 were retained. Factor coefficients of 0.40 or greater can be used for the interpretation of the factor structure[17]. The factors showing more than .40 coefficient were interpreted as a factor structure[18]. Confirmatory factor analysis (CFA) was used with ADANCO.

Results

Mainly two types of factor analysis were used in the study: exploratory factor analysis (EFA) and confirmatory factor analysis (CFA). The EFA approach describes how and to what extent the observed variables are related to their latent constructs.

Exploratory Factor

To conduct the exploratory stage of factor analysis, extraction methods in Principal Analysis Factoring technique (PAF) was used. The method was chosen from the available methods because it is a good method for assessing the underlying dimension of a domain. Varimax rotation was used for factoring methods. Five factors were identified from the initial domain run that exhibited eigen values greater than one.

Varimax rotation was done to clarify the loading on these factors. There were 28 domains which had significant loadings on any of the five factors. Obtained loading of items on the five factors is presented in the figure-1. Kaiser – Mayer - Olkin (KMO) value for eighteen domains were found to be .652 which indicates the sample is adequate. Education 10.36%, Sociability 10.13%, Health 9.66%, Entertainment 8.82% and Sensation Seeking 8.14% overall responses explained 47.12% of the variance. In the field of social sciences factor loading is considered minimum 0.30 or 0.35 when sample size less than 100, but above 200 minimum cut – off above 0.40 was considered[19]. Also in the field of

social science research Communalities (h^2) is generally considered between a range of 0.40 to 0.70,[20].

Confirmatory Factor Analysis

A measurement model was tested for all samples using confirmatory factor analysis (CFA) after the EFA. Model fit was excellent in all samples:

Model fitting – Model fit analysis was performed for a decision on the goodness of fit. The fitness of the model was excellent with the data it was evaluated with guideline [{the Unweighted least squares discrepancy (d_{ULS}) P < .01, The geodesic discrepancy (d_G) P < .01[15] and the standardized root mean squared residual (SRMR) P < .01}].

Table 1. Confirmatory factor analysis (Decision on model goodness of fit)

The goodness of model fit (saturated model)	Value	HI95	HI99
SRMR	0.0863	0.0632	0.0661
dULS	1.4144	0.7592	0.8299
dG	0.4193	0.2603	0.2805

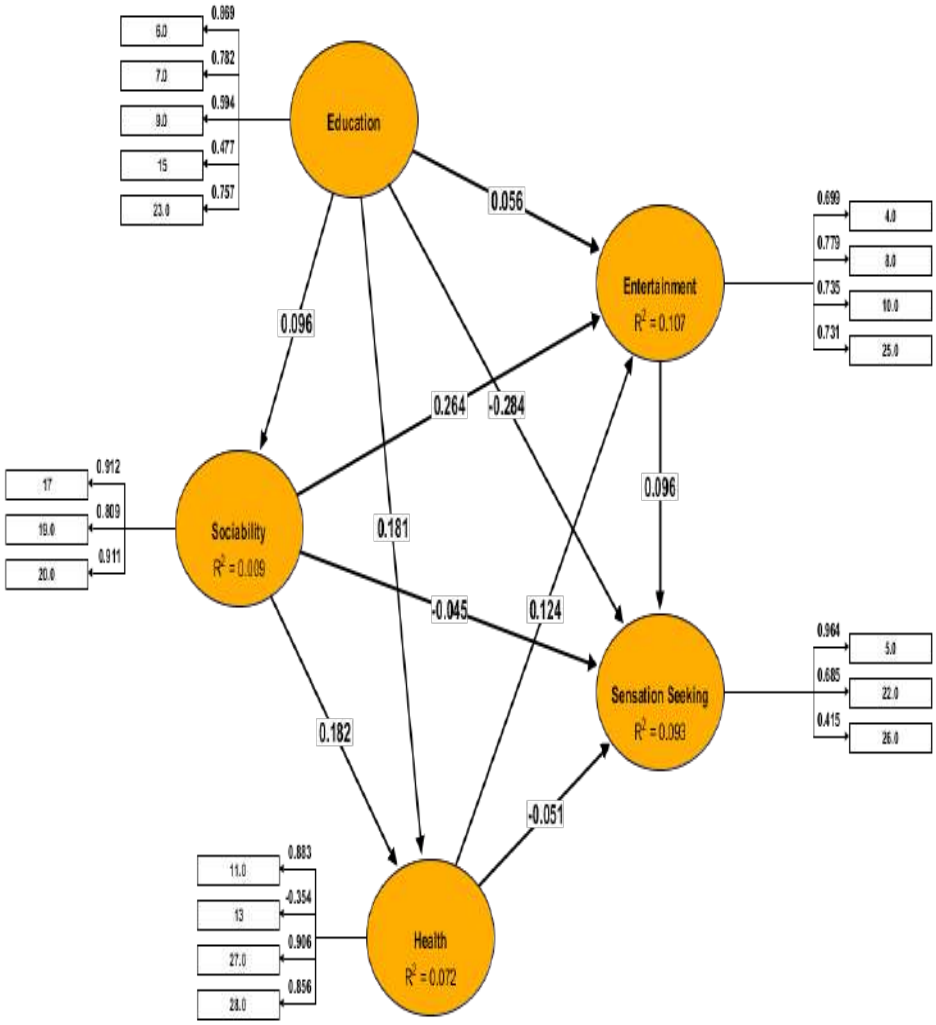

Figure 1 SEM explaining factorial validity and regression weight of factors for happiness

(6.0=Academic Achievement, 7.0=work completion, 9.0=study, 15=obey the teacher, 23.0=learning, 17=purchasing, 19.0=surprises, 20.0=shopping, 11.0=food, 13=independence, 27.0=hygiene, 28.0=health, 5.0=trawling, 22.0=nature, 26.0=adventure, 4.0=t.v. movie, 8.0=music or dance, 10.0=outdoor work, 25.0=festival).

A measurement model was tested for all samples using confirmatory factor analysis. In this model, factor educations explain the five subcomponents: Academic Achievement, work completion, study, obey the teacher and learning. Factor sociability explains the three subcomponents: purchasing, surprises and shopping. Factor Health explains the four subcomponents: food, independence, hygiene and health. Factor Sensation Seeking explains the three subcomponents: trawling, nature and adventure. Entertainments explain the four subcomponents: television. movie, music or dance, outdoor work and festival. (Figure 1) shows the regression weights. All values depicted in Fig.1 for all adolescents students- Academic Achievement, work completion, learning, purchasing, surprises, shopping, food, hygiene, health, trawling, nature, t.v. movie, music or dance, outdoor work, and festival show the largest values (>.68). The study, obey the teacher, independence and adventure show the lowest weight for the sample (.59 to .35). The results of CFA also indicate low correlation between the 5 factors.

The result of factor analysis revealed five important factors namely- Education, Sociability, Health, Entertainment and Sensation Seeking, which are predicts 5 domains in Education, 6 domains in Sociability, 4 domains in Health, 5 domains in Entertainment and 06 domains in Sensation Seeking. The statistical properties reveal that the all happiness factor is reliable in the Indian population.

Discussion

The result of the present study revealed 5 factors of adolescents' happiness is. Education, Sociability, Health, Entertainment and Sensation Seeking, by sociability it is meant that adolescents feel happy when they are free to purchase, give surprises to others and they love shopping. For adolescents education also matters, particularly good performance in academics, studying obeying the teachers make them feel happy when they are acknowledged. The young adolescents enjoy food and are also more pleased in hygienic conditions. They also like adventurous activities, traveling, and nature, they like thrilling experiences. Many adolescents love entertainment, enjoy music, movies & festivals.

The finding of the various researches provides support for an association between social and physical environmental factors and happiness. For example, social environmental factors such as neighborhood social capital have consistently been positively associated with happiness and related constructs such as subjective well-being[21-23]. Some aspects of the physical environment have also been studied extensively; found that settings that were aesthetically more attractive and had more green space have consistently been related to higher levels of happiness[24-27]. Perceived access to public transport, culture and leisure facilities have been positively related to happiness[24]. while another study found that happiness to be more closely associated with cultural, sporting, shopping and transport amenities (place variables) among young people and with quality of government services (performance variables) among older people[28].

Thus the results of the present study are important in understanding adolescent's happiness and accordingly help them to overcome the stress. Various studies have revealed that students who have high-stress levels are less likely to report high perceived happiness[29]. The study suggested that students were least happy about their financial situation, at work, and at school, low perceived happiness reported higher stress levels and lower emotional closeness to others[30]. The finding of the present study are in line with the findings of the study reported that adolescents who reported sufficient time spent with family members and the highest level of love and connectedness were happiest[31]. Those living in a two-parent family were happiest, followed by those living with a married father or a married mother (in a single parent family). Those living in an unmarried mother family were unhappiest, controlling for household economic status. These findings highlight the important role of a father in a country with a matriarchal family system. Regarding non-family factors, adolescents with the highest school attendance, highest self-esteem, and highest economic status who also regularly participated in extracurricular activities were happiest. Adolescents who were older and who had to do chores regularly tended to be less happy than their peers. The reason for the findings of the study can be included as every adolescent belongs from different family environment, the family attention, parents' time to share care, parental cooperation and conversation with their children, drug addiction, and financial condition, etc., of the family, is important factors for adolescent happiness. The factors identified for happiness among adolescents provide a base for the development of happiness scale.

Conclusion

The happiness among adolescents is an area which is a major concern among society members and requires exploration of happiness factor for adolescents in the present study. 280 adolescent students responded to their happiness reasons. The results of CFA reveal 5 domains which lead to happiness among adolescents. The present work has application in understanding the factors of happiness among adolescents and accordingly their behaviours can be dealt. The work is also helpful in the development of tools for the measurement of happiness among Indian adolescents' population. The measurement of happiness would be helpful in the health sector because happiness can increase physical activity and significantly decrease depression[32]. Physical activity makes us look better, feel better, and sleep better by releasing dopamine into the brain.

Clinical Decision Making for Biopsy of Oral Mucosal Lesions

Priyanka.S.R[1], M.Arvind[2]

[1]Post Graduate Student, [2]Professor & Head, Department of Oral Medicine and Radiology, Saveetha Dental College and Hospital, Saveetha Institute of Medical and Technical Sciences, Chennai, India

Abstract

Accurate diagnosis and treatment of oral diseases is an essential component of a comprehensive oral care practice. Accurate diagnosis also helps formulate the appropriate treatment plan and helps to avoid further complications from inadequate treatment and to avoid adverse effects from treatment that is not necessary for the particular patient. Obtaining an oral biopsy allows the clinician to diagnose many precancerous conditions and ensure early treatment. Biopsy may be the gold standard for final tissue diagnosis but any invasive procedure comes with its own risks and side effects. When a clinician is faced with a patient with signs and symptoms that are suggestive, but not diagnostic of a disease, he/she has the responsibility to decide between the option to treat empirically or not to treat or to perform further diagnostic tests. This paper aims to review the basic indications and contraindications of performing an oral tissue biopsy and to identify different oral mucosal lesions that may benefit from empirical therapy better than a biopsy in the early stages. Knowledge of these lesions will help the clinician avoid the undesirable outcomes that may be associated with an oral biopsy.

Keywords: *Biopsy, Oral lesions, Decision analysis, Oral Mucosa, Oral Medicine*

Introduction

"Biopsy" is the process of obtaining a sample of tissue from a living body with the objective of providing a confirmatory histopathological diagnosis following microscopic examination of the tissue sample. Biopsies are important diagnostic tools for the diagnosis of lesions ranging from periapical lesions to benign mucosal lesions to malignancies. In general, when the clinician is well-versed with anatomy, biopsy will be a safe and reliable diagnostic tool. But, biopsies should only be performed by the clinician if a thorough clinical examination has been done and all prior investigations have been performed. This will help avoid untoward consequences or iatrogenic induction of complications.[1]

The patient's main concern is for a quick and painless procedure which serves the diagnostic purpose. The pathologist always appreciates receipt of an undamaged specimen that is properly labeled and handled by the clinician. So, the clinician performing the biopsy has the responsibility to ensure that all parties involved are satisfied.[2] This can be done only with the appropriate knowledge of the indications, contraindications, pros & cons of performing a biopsy and also knowledge of the situations where biopsy may not be initially necessary in order to satisfactorily treat a patient.

Types of Biopsy

The different situations which might warrant a biopsy in a dental setup include oral mucosal lesions, apical lesions associated with teeth, lesions associated with jaw bone, mucocutaneous lesions, suspected malignancies and precancerous conditions.

Direct biopsy is when the lesion lies superficially with ease of access. Indirect biopsies will have to be done in lesions which are located in deeper tissues and are covered by normal appearing mucosa or tissue.[3] The incisional technique involves removal of a representative part of the lesion along with a part of the healthy tissue. It

is indicated when the lesion is large, difficult to remove in entirety, in a complicated location or if it is part of a systemic disease process. The excisional technique is used when the lesion can be removed in toto with a peripheral safety margin.[4] Intraoperative biopsies are speedily processed and diagnosis is received in the operating room in a short period of time, which allows the clinician to continue as required. The various procedures involved in processing the biopsy specimen includes, fresh examination, frozen sectioning and paraffin/methacrylate embedded examination. [5]

Approach to Lesions:

A systematic approach should be sought for every oral lesion with the chief complaint as the starting point of the investigation. There are certain points which would help the clinician decide whether biopsy is the right investigation. Biopsy should be done to confirm clinical and radiographic findings and for the purpose of determining the type of treatment to be instituted in certain diseases or it should be for the purpose of teaching, for eliminating cancerophobia or for the purpose of medico-legal records if needed.[6]

Indications And Contraindications Of Oral Biopsy:

Indications

Biopsies should be taken for lip and oral lesions that do not originate from apparent local irritating factors (trauma or inflammation). Lesions which persist for more than 3 weeks and lesions suspected of malignancy should also be biopsied. Rapidly expanding lesions and those that cause pain, paresthesia and other ominous symptoms and lesions that were considered benign but have subsequently undergone significant changes in the appearance should also be biopsied. Biopsies are also useful in confirming cases of certain lesions resulting from infections such as syphilis, tuberculosis, deep fungal infections, and some lesions of mucocutaneous vesiculobullous type.[7] Rapid bone loss, irregular widening of the periodontal ligament, spiking root resorption and tooth mobility in the absence of identifiable traumatic or inflammatory causes are the ominous signs that warrant a biopsy.[8]

Contraindications:

Oral biopsies may be contraindicated in patients when the general health condition is very poor, which keeps the patient unable to cope with the invasive procedure and may cause delay in healing. Biopsies are also avoided when there is an acute, virulent, pyogenic infection in order to avoid spread of infection. Lesions of vascular origin and those in patients who have a history of blood dyscrasias may complicate the situation. [9] Biopsies may require medical clearance in the case of medically compromised patients. In addition, they may cause iatrogenic worsening of the condition in certain patients. These include patients on radiotherapy, patients in bisphosphonates. Biopsies should also be avoided in patients whose lesions may resolve when allowed a benefit of doubt after removal of any local causative factors. Biopsy at the first visit should be avoided unless the clinician has substantial evidence for suspicion of malignancy or other serious lesion which require mandatory biopsy.[5]

Pros and cons of empirical therapeutic trial versus an immediate biopsy of oral mucosal lesions:

In certain cases of oral mucosal lesions, like vesiculobullous lesions, certain precancerous lesions, infective, traumatic and other inflammatory lesions, a therapeutic trial offers many advantages over immediate biopsy on the first visit. The basic formula for treatment of any disease is accurate diagnosis which would indicate the appropriate treatment plan. But, there are situations where empirical treatment of non-specific lesions on the basis of history, clinical features or a provisional diagnosis may be acceptable or preferable. If the empirical therapy given for a 2-3 week period sufficiently clears the lesion, the biopsy can be avoided. In addition, in precancerous conditions, dysplasia may be present in only localized areas. If these areas are overlooked and other areas biopsied at the initial visit, the diagnosis will be missed. When empirical therapy is given, if the lesion does not respond or if a particular localized area is refractory to treatment, biopsy of the refractory area is more likely to give the correct diagnosis.[10] Certain benign lesions may sometimes bear resemblance to premalignant lesions or even resemble malignancy. The clinician must be aware of the history, clinical features and other features which will help differentiate these conditions. Some clinicians may feel more comfortable having the results of an immediate biopsy before treatment. But, clinically practical patient management favours a therapeutic trial of drugs first and biopsies to be performed for refractory lesions.[11]

On the other hand, a more confident diagnosis and treatment plan can be done when the results of a biopsy

are also used. A biopsy of representative tissue must be obtained when lesions don't adequately respond to a therapeutic trial. Histopathological diagnosis also helps to reassure the patient and helps instill a greater degree of confidence in the treatment modalities. Sometimes, a lesion may heal with a therapeutic trial, and a therapeutic diagnosis may be made. But if the disease recurs, then the clinician is again in a dilemma about the diagnosis. Malignant transformation is also a risk in certain oral mucosal lesions. Due to this possibility, confirmation with a biopsy is a good approach.[12]

Patient preferences and behavior regarding/ following oral biopsies:

Patients' participation in the decision making process is an important part of healthcare. People who are given information about the planned investigations and treatment are usually less anxious. When patients are told that they require a biopsy they are usually concerned about both the procedure and the results. Any invasive/surgical procedure is linked to stressors such as pain, cost of treatment, fear of needles, failure of the surgeon and fear of infectious diseases[13] . So, the decision to perform a biopsy should be based on sound evidence from examination and other investigations in order to avoid putting the patient through unnecessary stress associated with the invasive procedure [14].

Pitfalls and complications associated with a biopsy:

In spite of being the gold standard, histopathology is subjective and results may not accurately represent severity of lesions. Since sample is taken only from a localized area, the results may overdiagnose or underdiagnose the lesion. Histological assessment alone cannot predict the transformation of an oral lesion into a malignancy.[15] Rapid proliferation in a malignant lesion can outgrow the nutrient supply and result in ulceration or necrosis. Similar ulceration, necrosis and epithelial sloughing may be present in vesiculobullous disorders. These lesions can be a challenge when selecting a biopsy site. Palatal and gingival biopsies heal by secondary intention and may cause delayed healing, exposure of denuded bone for several weeks or may result in unesthetic gingival recession and root exposure. Local haemostasis and tissue stabilization can be a challenge in lip biopsies. Improper technique can compromise esthetics. Tongue lesions cause difficulties in stabilization, suturing with increased risk of the wound reopening.[5] Further, lack of correlation between the clinical signs and symptoms and the histological picture may be observed, especially when unrepresentative tissue samples are submitted. Incorrect handling and fixation can induce artefacts and render the tissue non-diagnostic.[16] Meticulous surgical techniques should be used during biopsy procedure to avoid clot disruption, wound dehiscence, and bleeding problems. Some patients may also report paresthesia following biopsy which may last several days to months. [7]

Some lesions where empirical treatment can help avoid immediate invasive biopsy:

Presence of Candida in oral potentially malignant disorders has been researched frequently. The epithelial changes seen in mucosa with a leukoplakic lesion allows Candida to infiltrate and invade the mucosal surface. [17] In addition to its effect on carcinogenesis, Candida in a leukoplakic lesion may also interfere with the histopathological examination and may not provide an exact picture of the degree of dysplasia. An initial exfoliative cytology done to detect the presence of Candida can help to prescribe a topical antifungal agent for an initial period of 2 weeks following which a biopsy can be done. This would provide a more accurate picture.

Oral Lichenoid reactions may be induced by either a systemic medication or topical antigen exposure. Withdrawal of the drug or removal of the triggering agent usually resolves the condition. Lichenoid reactions associated with dental amalgam restorations are very common. Common anatomical sites include the lateral border of tongue and the buccal mucosa which may be in direct contact with the surface of the restorations. The lesion is usually well demarcated and fits the outline of the restoration. They may also be caused by use of systemic medication and substances like cinnamon. [18] Sometimes, the lesion may not exhibit a close topographical relationship and may have similarities to a leukoplakia or erythroplakia. It is therefore essential for the clinician to be familiarized with the individual variations in the clinical presentation of a lichenoid reaction in order to avoid an unnecessary invasive biopsy.

Mucosal ulcerations are common lesions encountered in daily practice. The most common cause of a solitary ulcer is chronic trauma resulting from sharp cusp margins, broken teeth or ill-fitting dentures. Other less common causes include a traumatic ulcerative

granuloma, infections like tuberculosis, late stage of syphilis, fungal infections like histoplasmosis. Some cases may eventually be diagnosed as a squamous cell carcinoma. Usually ulcers of traumatic origin are soft on palpation and may have rolled margins and keratinization in the surrounding mucosa. The lesion may sometimes be firm with indurated margins, thereby mimicking a malignancy. This may be due to continuous trauma or chronicity.[19] But lesions may show a dramatic response when extraction of broken teeth is done or when the probable local causative factor is removed. A period of 2-3 weeks can be given for the chance to heal after elimination of the local factor.

Necrotizing sialometaplasia is a benign self-limiting, inflammatory lesion of the salivary gland tissue where there is squamous metaplasia of the ducts and acini after ischaemic necrosis of the salivary gland lobules, most frequently occurring on the hard palate. Diagnosis is usually based on a thorough and complete clinical history.[20]. It may clinically mimic a malignant ulcer but a history of local trauma like administration of local anaesthetic, ill-fitting dentures, intubation or surgical procedures will be present.[21] Usually the lesion heals by secondary intention in 3-4 weeks. The hassle of an invasive biopsy may be avoided in such cases.

Socket Granuloma / Overhanging Clot occur as post-operative complications 1-3 days following a tooth extraction, usually as a consequence of not following post-operative instructions. They may give the appearance of a proliferative lesion arising from the socket, prompting the clinician to perform a biopsy. An overhanging clot may need to be removed followed by placement of sutures along with local haemostatic measures or it may resolve on its own. The dentist should therefore be familiar with the incidence of post-operative complications and their management.[22]Medication induced oral ulceration like Nicorandil-induced ulceration may appear as a large, deep, persistent ulcer. They are poorly responsive to steroids and only respond to discontinuation or reduction in the dose of the drug. Therefore, careful probing about the history is important to diagnose these cases.[23] Vesiculobullous diseases may cause generalized ulcerations in the oral mucosa. When the history and clinical presentation is “classic”, biopsy can be deferred until a therapeutic trial is given in the initial visits. This could help avoid adverse effects or inducing more ulceration.[10]

Conclusion

This paper highlights some clinical points that could help a clinician to give a good clinical diagnosis based on history and examination before performing an invasive biopsy. If these situations are encountered clinically, the dentist can render invaluable service to the patients with diagnosis and prompt treatment.

Role of Oral Physicians in Special Care Dentistry

Priyanka.S.R[1], M.Arvind[2]

[1]Post Graduate Student, [2]Professor & Head, Department of Oral Medicine and Radiology, Saveetha Dental College and Hospital, Saveetha Institute of Medical and Technical Sciences, Chennai, India

Abstract

Over 15% of the world's population has some form of disability with 110-190 million people experiencing functional difficulties, which includes people with physical, sensory, intellectual, medical, mental or social impairments. WHO has emphasized the need for oral health care in these patients as they generally have greater levels of oral disease. Poor oral health can complicate the underlying systemic condition and cause deterioration of general health. Dental treatment of people who are medically compromised, disabled or older poses challenges as they might require multiple interventions and are less likely to receive adequate care compared to their apparently normal counterparts. The solution is to have a speciality designed specifically to treat these patients by training professionals in treatment of patients with special needs. Oral Medicine is the speciality concerned with dental and "medical" related disorders of the oro-facial region, including oral manifestations of systemic disease and management of medically complex patients. One of the competencies of an Oral Medicine graduate is the ability to effectively manage patients with medically complex conditions and special needs. Oral Medicine specialists may be considered the best choice for integration with the field of Special Care Dentistry as they have knowledge on medical diseases and their effect on oral health. This paper highlights the need for Special Care Dentistry in the Oral Medicine Curriculum and why Oral physicians are best suited for provision of dental care in this population.

Keywords: *Special Care Dentistry, Oral Medicine, Oral Physician, Special Needs, Medically Compromised.*

Introduction

WHO international classification of Functioning describes "Disability" as an "Umbrella term", which includes impairments, activity limitations and participation restrictions. Disability is diverse and includes any condition that restricts everyday activities, an impairment that may be cognitive, intellectual, physical, mental, and sensory or a combination of the above. Disability rates continue to rise around the world due to the increase in life expectancy, the ageing population and increased likelihood of acquiring chronic diseases.[1] As more people grow older and more retain their teeth, this presents challenges to the dental professionals in providing care to the medically compromised and the multiply disabled. Global oral health goals to be achieved by 2020 by FDI/WHO/IADR have emphasized the importance of promoting oral health in the populations with the greatest disease burden.[2] Although improvements in oral health care have occurred across all sections of the community, disadvantaged and disabled people continue to have the poorest levels of oral health. Oral health in these people as they are often unemployed, earn less, have difficulties in communication, transport and usually depend on caretakers for help and support. So, they may require additional and specific care when compared to the general population. As professionals, we have the responsibility to ensure that the oral health care needs of these people are met and treatment is best when provided by a professional with adequate training in handling patients with special health care needs.[3]

Special Care Dentistry Around the World

"Special care dentistry" (SCD) is concerned with the improvement of oral health of individuals who have physical, sensory, intellectual, mental, medical and emotional or social impairment and a combination of the above. It also includes people with complex health conditions, people under long term hospitalization and critical care and people in residential care units.[4]

As this need for SCD is recognized, we have seen the development of various undergraduate curricula

and postgraduate courses in countries like U.S, Canada, Europe, Oceania and the UK. Dental schools in the UK (Dublin, King's College, Cardiff, Birmingham) conduct workshops and lecture series before students spend time in the departments and it is also required as a part of the curriculum for dental nurses and hygienists, which enables them to participate in provision of dental care for disabled people.[5]

There are a variety of postgraduate programs currently being offered in the UK and Ireland. Bristol University, King's College, London, Eastman Dental institute and Trinity College, Dublin are among the institutions which offer full time and part time courses. The General Dental Council of the UK has formally recognized SCD as a dental speciality in 2008. The United States has founded the American Board of Special Care Dentistry and training programmes have been offered in numerous universities. They also have founded the Special Care Dentistry Association, which is an international organization of oral health professionals who are dedicated to providing and promoting oral health for patients with special oral health care needs. [6, 7] The Australian society for Special Care in Dentistry (ASSCID) has been added as an affiliate professional organization of the Australian Dental Association. Universities in Australia and New Zealand provide postgraduate courses in Special Needs Dentistry and Hospital Dentistry.

According to the 2001 census, 21 million people in India have some form of disability constituting 2% of the world population and 75% of these people are concentrated in the rural areas. A formal organization for treating oral problems of these patients has still not been organized. Collaborative efforts of AIIMS (All India Institute of Medical Sciences) and WHO have recommended actions to be taken by governmental and non-governmental sectors in this issue. SCD as a part of a postgraduate curriculum is a necessity in today's scenario.[8]

Barriers and issues in treating special care dentistry patients

The special needs patients are one of the neediest and most underserved populations in the current scenario in India and other countries. The physical, mental and medical disabilities make it difficult for the patients to visit a dental office and they are also limited in their ability to afford therapeutic and preventive treatment. This is also augmented by the scarcity of dentists that provide appropriate care. A more important factor is dental students not being exposed to caring for the disabled during undergraduate or postgraduate training. Most of the work with disabled persons is estimated to be treatable by general practitioners but the issue here is their little experience in handling these patients.[9]

There are a number of barriers to oral health care for people with special needs that have to be overcome in order to address their needs. Scully et al have classified these barriers as – barriers with reference to the individual which include a lack of perception of need difficulty following instructions and access problems, barriers with reference to the dental profession which include lack of training and a lack of time and resources, societal barriers which include a general lack of awareness and a lack of positive attitudes towards oral health and governmental barriers include a lack of resources for oral health services. [10, 11] Barriers to physical access continue to exist in the form of lack of facilities like ramps for wheelchairs, suitable parking, accessible toilets, hoists or stairlifts.[12] Barriers in communication may be encountered in patients with hearing and/or visual impairment, neurological deficits, psychiatric or cognitive difficulties.[13] Patients with a reduced mental capacity or inability to communicate their decision can also present a challenge while obtaining consent for dental procedures.[14] Dentists are required to work in new ways using extended teams and taking responsibility for educating the team into incorporating a holistic approach to oral health care for each individual with a disability.[5] Certain conditions that might predispose patients to complications or emergency situations (epilepsy, allergies, bleeding disorders, etc) in the dental chair. Ensuring that the dental team knows how to manage such situations can be life-saving.[15]

Value of education in special care dentistry

The lack of dental service available for disabled people is partly because of the reluctance among professional to treat them and most practitioners receive minimal education to prepare them to work with such patients. Having positive attitudes, positive experiences and positive social contact has been shown to improve interest in serving these populations.[16] Dental professional who are trained and willing to care for disabled people are needed. Clinical contact with older and disabled people, positive clinical experiences are essential for students to overcome anxieties and develop

sound management skills.[17] A survey showed that dental practitioners with no contact or experience with treating special needs patients were less likely to care for such patients whereas practitioners who had hands-on educational experiences were less likely to consider disability as obstacles to oral care and were more likely to desire further education in caring for these patients.[18-20] Reports also say that practitioners feel the pressures of time and lack of reimbursements creates disincentives to treat these patients. Practitioners may abstain from treating these patients if they felt that these issues have not been resolved.[21]

Providing necessary education and training for practitioners and students implies the creation of an academic and clinical discipline to provide teaching, training and a career pathway. Development of a discipline may aid in the development of specialist services for patients with complex dental needs. In addition to the UK, US, Canada, Australia and New Zealand, other countries like Japan, the Netherlands, Spain, Argentina and Mexico are in the process of recognizing SCD as a stand-alone speciality.[22]and a large proportion of these persons will require Special Care Dentistry at some point in their lifetime. It is estimated that 90% of people requiring Special Care Dentistry should be able to access treatment in a local, primary care setting. Provision of such primary care is only possible through the education and training of dentists. The literature suggests that it is vital for the dental team to develop the necessary skills and gain experience treating people with special needs in order to ensure access to the provision of oral health care. Education in Special Care Dentistry worldwide might be improved by the development of a recognised academic and clinical discipline and by providing international curricula guidelines based on the International Classification of Functioning, Disability and Health (ICF, WHO In India, there is neither a recognized speciality nor a clear career pathway for dentists to be trained in SCD.

Oral medicine and the potential role of oral physicians in special care dentistry

Dr. Lester Burket, a pioneer in the field of Oral Medicine, considered by many to be the father of this discipline, was one of the first educators to promote the concept of integration of medicine into dental education and clinical practice. Burket's textbook previously defined Oral Medicine as a "speciality within dentistry that focuses on the diagnosis and management of complex diagnostic and medical disorders affecting the mouth and jaws. Clinicians manage oral mucosal disease, salivary gland disorders, facial pain syndromes and also provide dental care for patients with complicating medical disease." The newest edition of Burket's Oral Medicine (2015), as "a specialized discipline within dentistry that focuses on provision of dental care for medically complex patients, diagnosis and management of medical disorders involving the mouth, jaws and salivary glands.[23] The American academy of Oral Medicine has defined Oral Medicine as the discipline of dentistry concerned with the oral health care of medically compromised patients and the diagnosis and non-surgical management of medically related disorders and conditions affecting the maxillofacial region".[24]

Hundreds of medical diseases impact the oral cavity and oral pathological conditions also have an impact on systemic health. Unfortunately in our country lack of access to primary medical / dental care prevents patients from seeking treatment until a negative event or complication has occurred. So the best way is to create awareness among patient and for dental professionals to have a clear understanding of the chronic conditions that affect the oral and systemic health of the patient. Since Oral Medicine is the intersection of medicine and dentistry and a window to the general health of the patient, we may be the best suited among all specialities to provide dental care for medically compromised patients.

The American Academy of Oral Medicine has described clearly defined minimum competencies that are required of all individuals to successfully complete an Oral Medicine Training program. The scope of Oral Medicine was divided into three domains that represent required clinical expertise.

1. Diagnosis and Non surgical management of oral mucosal and salivary gland disorders.

2. Diagnosis and Non surgical Management of temporomandibular disorders, orofacial pain and orofacial neurosensory disorders.

3. Management of medically compromised patients.

So, an Oral Medicine graduate must have a thorough knowledge of how systemic diseases affect oral health and vice versa, and how management may

require modifications of treatment when compared to healthy patients. They must assess wound healing, risk of infection, bleeding risk, medication/drug interactions and behavioural issues. This comprehensive evaluation should be accompanied by diagnostic tests and expert medical consultations when indicated. The clinician will then apply this knowledge to implement modifications that are necessary in delivery of dental treatment.[25-26]

A survey conducted on the Oral Medicine curriculum and training was presented in the World Workshop of Oral Medicine in 2010 which explored the Oral Medicine post graduate training and curricula in 22 countries. Oral Medicine was not a recognized speciality in 8 of these countries and in 9 countries oral medicine is combined with another distinct field of study like Oral Pathology, Oral Radiology or SCD. There was a significant variability of responses regarding the integration of oral medicine with special care dentistry with most agreement from participants from India, Israel, Italy, Spain, Brazil, Canada, USA, UK and Thailand.[27]Oral Medicine and Radiology as a specialty was introduced in India in the year 1971 at the Government Dental College, Bangalore with huge improvements in the practice in the past 46 years. Several recent reviews have discussed the nature and extent of training Oral Medicine graduates and the need to further enhance their curricula. [28] As there is a scarcity of specialists who deal with the active management of dental issues in medically compromised patients and patients with special needs, this could be the right step to include Special Care Dentistry as part of the Oral Medicine curriculum.

Conclusion

Why should Oral Medicine accept a new speciality as its own? As the only speciality at the crossroads of Medicine and Dentistry, we are already positioned to diagnose and treat oral/systemic conditions. Having a unified speciality could be a referral point for the medical fraternity and improve communication. In addition, training in Special Care Dentistry could help bring out robust professionals who are competent in handling patients with disability and provide graduates with better career opportunities.

Lifestyle Diseases among Girl Child in Urban India

Puja Gupta[1], Papia Raj[2]

[1]Research Scholar, [2]Assistant Professor, Indian Institute of Technology Patna

Abstract

The paper will focus on the problems due to lifestyle in the health status of girl child in urban India. To access lifestyle changes among the girl child, different lifestyle diseases and their impact on health will be emphasized. Lifestyle is an individually constructed behaviour that determines the health and well-being of an individual. Health of the girl child is determined by a wide range of factors like family background, their socialization process, social class, peer group influence and their like. Girl child in urban India is more vulnerable to lifestyle diseases owing to lack of physical activities and improper food habits resulting due to transformation in consumption pattern. As a result, they are susceptible to obesity which leads to health problems in the long run. Besides obesity, lifestyle also develops the risk of other diseases like type-2 diabetics, cardiovascular disease, cancer, etc. In recent years, these diseases have developed a severe public health concern not only among adults but also for children. This study is based on an extensive literature review to identify the evolving problems and significant health risks associated with such diseases. It is observed that the role of media such as television, mobile phone, and access to a computer also play a prominent role in the lifestyle of the girl child. Therefore, this paper also delineates the effect of digital accessories that has changed the preferences and choices of the girl child in multiple ways.

Keywords: *Lifestyle diseases, Girlchild, Urban India, Consumption pattern, Public Health*

Introduction

In the contemporary society, fast production and consumption are some of the critical areas of life that has given rise to into unplanned urbanization and globalization particularly in developing countries[9]. Not surprisingly, this principle of ever advancing social acceleration in developing countries has led to the emergence of non-communicable diseases (NCDs) like cardiovascular disease, cancer, chronic respiratory disease, and diabetics. It is estimated that globally 41 million deaths each year are the result of NCDs where 85% of these premature deaths occur in low and middle-income countries[2]. In a country like India, the incidence of the NCDs has developed stern public health concern not only in the health of adults but also among children[25].

Girls are particularly more vulnerable to NCDs as in many developing countries they are discriminated in terms of their marriageability which in some societies represents the route for economic and social status. The vulnerability of girl child is also observed in physical mobility which is often associated with diabetics, obesity, cardiovascular disease and certain types of cancer[1].

Various Social Determinants of Health (SDOH) like gender, lifestyle, standard of living, social norms and attitude, geographical location, and culture impact health and well-being of the girl child[4, 32, 13]. SDOH is the condition in which people are born, grow, live, work, and age and the circumstances that are shaped by the distribution of money and resources at global, national and local level. SDOH are responsible for health disparities where unfair differences in health status are seen within and between countries[33]. Interestingly, in the health of girl child, the SDOH like lifestyle, gender, and culture play a prominent role in bringing health disparity[34]. Lifestyle is a crucial SDOH that shape the choices and preferences of the girl child[16]. The

formative years of the girl child stand fundamental in their lifespan as, during this period of the life cycle, lifestyles are formed and hence becomes established where girls become more independent and make their own choices[3,2]. Thus, the objective of this paper is to understand the growing prevalence of lifestyle diseases among girl child resulting due to less physical activity, sedentary lifestyle, and dietary practices.

Methodology

This study is based on secondary data which includes published academic of literature. Therefore, an extensive literature review was conducted for the same. The age group of girl child was chosen between 8-18 years based on literature, the problem concerning lifestyle disease among girl was found within the specified age-group[4,3,22]. The literature search was done on an available public domain such as Google Scholar, Jstor. The keywords used for the search included but not limited to lifestyle and urban children, gender and Social Determinant of Health, technological use and impact on children health. Journals were chosen concerning the health of girl *Journal of Child Health Care*, *Indian Pediatrics, Asia-Pacific Journal of Public Health, Health Promotion International,* etc.

Children Lifestyle and Health

WHO (2019) defines a child to be any person within the age of 19 years or younger. However, a child is also defined to be any human being below 18 years of age unless s/he attends a majority under the prescribed law[35]. Apart from this, childhood is a social construction and not merely a biological fact. It is not only determined by culture but also conceived according to social class, ethnicity, and gender[7]. The sociological understanding of childhood perceives a child as a social actor who reflexively constructs their environment[18]. The social character of childhood is recognized as an essential factor in shaping experiences of the children[15].

Lifestyle, on the other hand, is defined as a set of mediating structure that seeks to reflect upon activities, attitudes, social values, and an array of behavioural patterns depending upon age, education, economic and social factor, among other[36]. It also represents the steady form of personal behaviour where independent choice provides a way to solve social system antagonisms[21]. Lifestyle in the contemporary society is considered to be integrated into the bodily regimens where people have become more responsible for both health and design of their bodies[8]. Moreover, lifestyle pattern of children particularly girl child cannot be characterised by a single entity as it is determined by the range of factors like family background, social class, cultural milieu, and religious affiliation[7]. It is in fact shaped during their childhood that makes a lasting effect in their adult lifestyle and later life [6].

Health, as perceived from the social model, is influenced by various factors like political, economic, social, psychological, cultural, and environmental [5]. WHO (1998, p.1) defines health as a "state of complete physical, mental, spiritual and social well-being and not merely the absence of disease or infirmity." As for the health of girl child is concerned adherence to basic lifestyle behaviour as a result of imposition by the adult member of the society becomes a part of imitation in their early life[21]. Under such conditions identifying the risk of ill health problems can serve as a useful measure to stop the preventable lifestyle-related health problems among girls and for future generations[1]. In most of the situation self-reflection in behaviour patterns among the girl child in adopting healthy lifestyle becomes inherently blurred in the absence of adult control. As a result of which they violate basic principles of a healthy lifestyle in later life[21]. Moreover, failure to act on the problems of NCD will undermine developmental gains that also include progress by recognising the importance of girl child in the contribution to society[1].

Delineating causes of lifestyle diseases among the girl child

NCDs are generated with increased indulgence in a social and physical environment designed to influence the way we work, produce, process, and consume[9]. This advanced level of development and change in structures can be perceived in the consumption patterns and physical inactivities that have ultimately led to epidemiological transition[30]. According to WHO (1996), the epidemiological transition is the condition where a general shift from acute infectious and deficiency disease to chronic NCD become widely visible. India is in the midst of the epidemiological transition due to the emerging conditions of NCDs[23]. Given this background, identifying the factors responsible for rising risk of NCDs becomes essential. Hence, it is of particular significance to investigate causes of NCDs on many counts.

First, in addition to lifestyle as a SDOH, technology has an important role to play in health of a girl child[4].

At one hand technology has been praised for reinforcing educational advancement that has enhanced learning while on the other, it has induced anomie and anti-social behaviour among girls[14]. Prolonged television viewing along with snacking behaviour is allied with the risk for development of overweight among the girl child[10]. Here the risk is presumed in a way where society actively tries to break away from the past to that of a modern system of lifestyle[12]. Lifestyle choices are also shaped by the conditions where girls are not provided with a safe environment due to lack of opportunity[17]. This brings us to analyze the role of gender which is an essential SDOH and their impact on health of the girl child. Cultural differences in terms of gender forbid girls to engage in outdoor play activity as compared to boys. Due to this, they invest their time in watching television or computer which also develops the risk of NCDs among the girl child[4].

Second, advertisements commercialize living standards of the girl child in such a way that the images that are sold through advertisements become the symbols of their childhood[14]. Their childhood is in fact trapped in 'steel-hard' cage where advertisement media are also responsible for reinforcing hegemonic control over the mind of a girl child[9]. However, in India, the pervasive influence of advertisements mainly through audio and visual aids has influenced the dietary pattern of girls[20]. This is for the fact that in India advertisement promotes an unhealthy diet including food that is rich in fat, sodium or added sugar[16,29]. Such kind of shift in food pattern develops the problem of obesity which is not just a physical problem but also a social problem like eating disorder and obsession with body shape[26].

Third, urban settings are mostly associated with lower levels of physical activity as compared to rural settings[1]. Limited space in the cities does not provide an adequate and safe environment due to which the girls are sequestered in their home thereby focusing on the use of television or computer[28]. SDOH like gender also plays a significant role in bringing health differences among the girl child where interests on sports are emphasized among the boys as compared to the girls[28]. Moreover, despite the involvement of girl child in activities like walking and cycling, the overprotective nature of the parents often restrict them from such physical activities[19]. Therefore, the above factors show the susceptibility of girl child in urban areas. Under such circumstances, an interactive approach through intensive and repetitive intervention can serve as an effective pillar in preventing NCDs among the girl child[24].

Discussion and Conclusion

The UNCRC (1989) recognises the right of every child to self-determination, dignity, respect, non-interference, and the right to make an informed decision. UNICEF (2003) claimed that 'World Fit for Children' will only be accomplished with full participation of children and young people. Children's participation in research should advocate in understanding their needs to determine health literacy capacities across diverse communities by adopting a child-centred approach in research. Ironically, the active involvement of children in the study is not acknowledged in academic discourse [27].

In addition to this, the development of the curriculum should be such that it resonates with the experiences of children in terms of both media and health[37]. SDOH like gender and lifestyle should also be addressed by focusing on the gender-responsive health system to provide adequate attention to gender needs and priorities[1]. In the Indian context, awareness among the parents in making right choices in food and physical activity should be internalized as they play an active role in the socialization process. Their role in addressing purchasing power and choices relating to food should also be discussed to minimise the health consequences[26].

Moreover, in India understanding the problems of lifestyle diseases among the girl child is a national concern. It is because problems associated with the NCD are emerging at a time when undernutrition is still a significant public health concern[13].

Besides, not many studies have specifically provided insight into the health of a girl child. Furthermore, studies related to the problem of NCDs in India correlates with affluence while it is also prevalent among children belonging to the middle-income group. Therefore, to elude the risk of NCDs, empowerment and equal access to knowledge and resources should be emphasized through interventional programme. Such programme can assist policymakers in reducing the growing problems of risks associated with lifestyle among girl child.

Effect of Core Training with and without Yogic Practices on Elasticity among College Female Athletes

R. Meera[1], R.Mohanakrishnan [2], T. Arun Prasanna[3]

[1]Research Scholar, Dept. of Physical Education And Sports Sciences, Srmist, Kattankulathur, [2]Hod, Dept.of Physical Education And Sports Sciences, Srmist, Kattankulathur, [3]Research Scholar, Dept. Of Physical Education And Sports Sciences, Srmist, Kattankulathur

Abstract

The present study evaluates the impact of core strength training with and without yogic practices on elasticity among the college female athletes. To attain the aim of the study forty five (N=45) female students were selected randomly as subjects from Chennai, Tamilnadu, India aged between 17 to 25 years at random. The athletes were separated into groups of three with 15 students each named as experimental group I with core strength training , experimental group II with core strength training with yogic practices and group - III with controlled training. Prior to and after the twelve weeks of experimentation, the subjects were tested. The core strength training and the yogic practices were selected as training protocol. The core strength training given based on stress given in each exercise and sets and the load administered between 5 and 10 repetitions in a set with the time lapse of 15 to 10 seconds for a set. The training protocol followed by proper warming up and cooling down regime. The yogic practice was given on morning time with proper prayer and warming up practice. The load of the yogic practice increased by the number of yogic practices by 2 to 8 repetitions with 2 to 5 sets. The obtained data from the experimental and control group initial and final readings underwent statistical analysis along with analysis of covariance (ANCOVA) with the application of Scheffe's post hoc test to examine the groups' difference and testing condition. The level of confidence had a fixation of 0.05 confidence level. The group that acted as the experimental group had improved significantly on flexibility in comparison with control group.

Keywords*: Core strength training, Yogic practice, Female Athletes, Flexibility.*

Introduction

The spine, hips, pelvis, lower limb at the proximal level and structures in the abdomen which forms the musculoskeletal core of the body are responsible for stabilizing spine and pelvis. During the sports activities of a person, they help in the energy transformation between the large and small parts of the body.[1] Thoracic lumbar fascia, abdominals, hip girdle musculature, para spinals, hip joints, diaphragm, pelvic floor and spine have a central location as core muscles. They perform the required stabilising functions of the body for the distal segments to do their functions specifically. Also they provide proximal stability of the limbs for their distal mobilization and function. Along with these functions, the core activity is involved with the activities that are limited, for example agility, kicking, throwing etc.[2]

A wide practice of core strength training is undergone by professionals. It aims to develop core stability and improve core muscular strength leading to the improvement of the performance of the athletes. Core strength training is considered as an element of strength and conditioning by the professionals of health and fitness as it enhances the performance of the athletes and prevents injuries. [3] But few studies failed to show the significance of changes in the lower extremity stability or performance. However, further studies are needed to transform core strength training to performance. Scientific studies that are limited were done to evaluate the effect of core strength training on the stability of lower extremity and the performance of the athletes. [4]

The practice of Yogasana includes stretching, moving and holding the body of an individual into various positions comfortably. This improves the muscle

flexibility, where the positions are believed by many practitioners. It helps in the maintenance of the balance of varied internal glands and organs of the body. Hence, the study examines the effect of yogasana exercise that may influence the significant changes in the flexibility on experimental group.

Yoga is considered as the discipline of psycho-somatic-spiritual being that helps in the unity and peace of our mind, body and soul. It also helps in the unity of consciousness of an individual eventually with the universe.[5] It allows a person to synchronize with breathing through meditation and relaxation with a body technique. Yoga is one of the most effective methods, by which the perfection of the latent potentialities, partially expressed in man is attained. Perfection is not an addition – addition of capacities or it is the manifestation of those potentialities which are inherent in man and which lie idol until and efforts is made to bring them to the surface. Jnana, Bhakti, Karma and Raja are the several means to attain the perfection of personality.[6] Flexibility can also be called the capacity for joint movements fluidly through its complete motion. It is the capability of a person to move a part or body parts with a variety of purposeful movements at the speed required. It helps in joint movements with a normal variety of motion devoid of undue stress to the muscular tendinous unit. [7] Flexibility has important interrelationship with other performance factors. The traction of anteflexion, skin among the two fixed points in the midline of the back was tested for the ante flexibility of the lumbar spine. The mark in the beginning was positioned on the process of spine LV, set up by the` intersection of the midline in the dorsal region with the connecting line of both lateral lumbar fossae.

Active flexibility is also of two types – static and dynamic. Static flexibility is required for movement done while individual is in the static state i.e. standing, sitting or lying. Dynamic flexibility is required for executing movement with greater range when individual is moving. Active flexibility is always less than the passive flexibility. [8] The dynamic flexibility is always less than static flexibility and is heavily dependent on the motor coordination. The terms general & specific flexibility are also commonly used to denote the levels of flexibility of all the important joints of the body specifically shoulder, hip & trunk whereas special flexibility is the ability to do movements of a sport with greater range. As stated earlier flexibility is largely depend upon anatomical structure of the joint. The manner in which the bone ends are joined each other basically decides the type of movements possible in the joint. Greater mobility is in ball and socket joint. The elasticity of ligaments can be increased up to some extent by training, but length of the ligaments can't be change by training.

There are very few studies, which are measuring effect of core stability training with and without yogic practices on flexibility in female athletes. Hence there is need to analyse the influence of core stability training with and without yogic practices on flexibility among female athletes.

Statement of the problem

The research aims to assess the impact of core strength training with and without yogic practices on elasticity among college female athletes.

Methodology

To attain the aim of the study forty five (N=45) female athletes were selected randomly as subjects from Chennai city, Tamilnadu, India aged between 17 and 25 years at random. The athletes were divided into groups of three with 15 each named as selected experimental group I with core strength training, experimental group II with core strength training with yogic practices and group - III controlled . The athletes were tested before and after the twelve weeks of experimentation. The core strength training and the yogic practices were selected as training protocol. The core strength training given based on stress given in each exercise and sets and the load administered between 5 and 10 repetitions in a set with the time lapse of 15 to 10 seconds for a set. The training protocol followed by proper warming up and cooling down regime. The yogic practice was given on morning time with proper prayer and warming up practice. The load of the yogic practice increased by the number of yogic practices by 2 to 8 repetitions with 2 to 5 sets. The core training protocol are Crunches, Decline Crunch, Cable Crunch, Oblique Crunches, Jack knife Sit-Up, Barbell Side Bend, Leg lift, Leg lift - Hang Position , Oblique Leg lift and yogic practices protocol are Suryanamaskar. Tadasana, Trikonasana, Paschimottanasana, Chakrasana, Bhujangasana, Nadi Sodhana, Bhastrika and Kapalapathi. The criterion variables measured by using sit and reach based test. The obtained data from the experimental and control group initial and final readings underwent statistical analysis with ANCOVA and Scheffe's post hoc test to examine the groups difference and testing condition. The

confidence level is fixed at 0.05. The statistical analysis computed with IBM-SPSS – v21 software.

Results and Discussions

Table – I: The descriptive analysis of experimental and control group on flexibility

Test		Core Strength Training group	Core Strength Training with Yogic practice group	Control Group
Pre Test	Mean	21.20	22.30	22.35
	SD	0.86	0.58	1.45
Post Test	Mean	25.45	28.56	22.56
	SD	0.86	1.25	1.02
Adjusted Post Test	Mean	25.78	28.89	23.45
Magnitude of Improvement		17.76%	21.66%	4.69%

Table – II: ANCOVA on flexibility among groups

Test	Sum of Squares	Df	Mean Square	F	'P' Value
Pre Test	8.01	2	4.00	3.07	0.065
	54.62	42	1.30		
Post Test	135.25	2	67.62	44.48*	0.000
	64.20	42	1.52		
Adjusted Post Test	136.89	2	68.44	44.15*	0.000
	63.58	41	1.55		

*Significant at 0.05 level of confidence

TABLE-III: Scheffe's post hoc test of paired mean difference on flexibility

Core Strength Training group	Core Strength Training with Yogic practice group	Control Group	Mean Difference	'P' Value
25.78	28.89	-	3.11*	0.000
25.78	-	23.45	2.33*	0.000
-	28.89	23.45	3.44*	0.000

*Significant at 0.05 level of confidence

The results in table I-III on flexibility were similar before the training programme. The post test found significant among the groups on the chosen criterion variables. Further, the Scheffe's post test showed that the adjusted post test paired mean differences on flexibility between core strength training and training of core strength with yoga, core strength training and control groups and core strength training with yoga

training groups and control group found significant with the P value 0.000. Hence, the results show that the flexibility in the training with core strength along with yoga training groups and core strength training groups improved significantly. The control group have shown insignificant on flexibility. The data is represented graphically in Figure I and II.

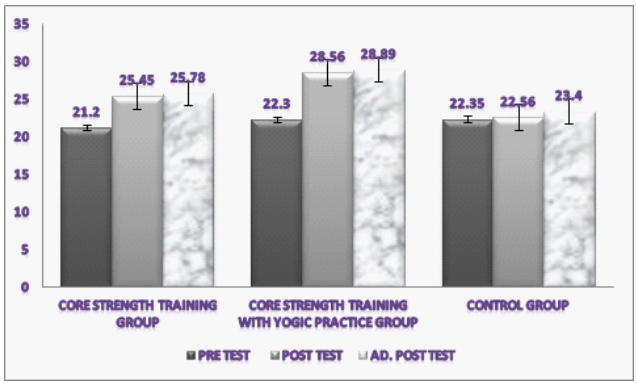

Figure I: The graphical presentation of data of descriptive statistics on flexibility

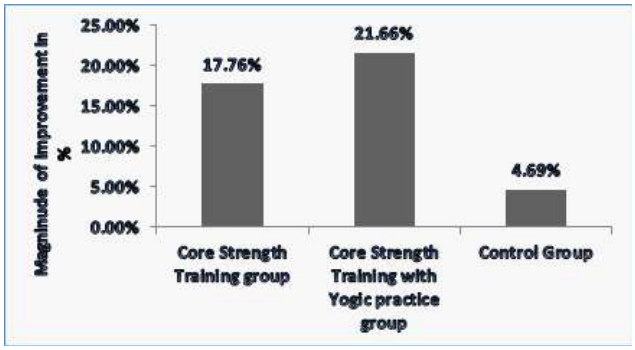

Figure II: The graphical presentation of magnitude of improvement from the initial to final means on flexibility

Discussion on Findings

Most of the previous research confirmed the finding of the present study. It is apparent that core strength training and yogic practices is very specific to the flexibility. No well established was observed on the independent effects of aerobic training on flexibility. Two previous studies showed no improvement on flexibility through the aerobic training**.** [9] Without the inclusion of the stretching based exercises in the training schedule there was no development in the flexibility with land- or water-related aerobic training. The present study which involves the yogasana exercises improved the flexion and extension of the hip.[10] The reason is the increase of the strength of muscle and collagen in the region of lower limbs. [11] However, this research also supports the present study to derive the better training programme. In our study, we found that 12 weeks of yogasana training at medium intensity significantly improves lumbar flexibility in obese females. Study done by Stanton, R et al[1] observed the impact of Swiss ball based training for 6-week on running economy and core stability. in an athletic population. After giving core stability training program in improving function mobility as above study. Core stability extensively benefits the sport performance with a foundation for extensive force production in the upper and lower level of extremity.

Conclusions

The conclusion based on the result and discussions that the flexibility has improved both the experimental groups such as core strength with yogic practice group and core strength training group, in comparison with the control group. Further, the core strength with yogic practice group shows better improvement on flexibility when compare with isolated core strength training group on flexibility.

A Study on Impact of Environmental Pollution on Health in Referance to Tuticorin Industrial Town, Tamil Nadu

R.V.Suganya[1], R.lakshmi[2]

[1]Assistant Professor, [2]Associate Professor, Department of Commerce, School of Management Studies & Commerce, VELS University, Chennai

Abstract

The paper highlights impact of environmental pollution on Health. The present study has been taken up in Tuticorin industrial town area. Major industries numbering 12 established in the district. They are engaged in the production of cotton, staple yarn, caustic soda, PVC Resin, fertilizers, soda ash, carbon-di-oxide gas in liquid etc., The important major industries are sterlite, SPIC, Tuticorin Alkali Chemicals, Dharangadhra chemicals work, Madura coats, Kilburn chemicals industries. The public sector undertakings are the Thermal power unit (620mm), Heavy water plant, and port trust. The district contributes 70% of the total salt production of Tamil Nadu and meets 30% of salt requirement of our country. Aside from deficiencies in the life support system, men is subjected to a variety of environmental Hazards. Some of these are natural, but increasingly environmental hazards result from man's activities and numbers. Sometimes manmade hazards are direct in their impact on other man. But they may be indirect in their influence, acting through other biological systems or overburdening the capacity of natural systems for renewal, dispersion, or assimilation. The following factors can be used in categorizing environmental hazards. (1) Biological (2) Chemical (3) Physical (4) Psychological and (5) Sociological. Hence more than 12 major industries have established in and around Tuticorin. This becomes one of the source of air pollution, water pollution, Noice pollution, in this area. Air pollution may be broadly defined as the presence of one or more contaminants like dust, smoke, must and odour. The atmosphere which are injurious to human beings, plants and animals which unreasonably interfere with the comfortable enjoyment of life or property. Air pollution seriously damages human beings.

Keywords: *Environmental pollution, Health Problems in India, Impact on Pollution.*

Introduction

Environmental sociology in the study of the reciprocal interaction between the physical environment, social organization, and social behaviour. Within this approach, environment encompasses all physical and material bases of life in a scale ranging from the most micro level to the biosphere. An important development of this sub discipline was the shift from a sociology of Environment to an Environmental sociology while the farmer refers to the study of environmental issue through the lands of traditional sociology, the later encompasses the societal environmental relations[1].

A major challenge for the 21st Century is not the creation of wealth, but the management of health. Concern over the rapid depletion and degradation of the World's biological resources and the implications of this loss on the global biosphere and human welfare have been mounting in recent years. Loss and modification of ecosystems and habitats are occurring at an alarming rate, although it is much difficult to quantity or estimate on a global scale. The continuing loss of the biological wealth may leave us with a smaller and less 'varied' stock of global biological resources. The result may leave the human livelihood and the future of the biosphere at risk. Development efforts along with modern warfare have created an uneasy and irreparable environmental consequences, the world over[2]. Human life and health are at great jeopardy and the burden of diseases and ill health raise questions on the development efforts in the pursuit of global prosperity and wealth.

The environmental pollution and degradation may rise in step with such a rise in output, the result leading to an appalling environmental pollution and damage. Tens

of millions more people may become sick or die each year from environmental causes. Water shortages may become intolerable and tropical forests and other natural habitats may decline to a fraction of their current size. The earth's 'sources' are limited and so is the absorptive capacity of its 'sinks'. Whether these limitations will hinder the growth of human activity will depend on the scope for substitution, technical progress and structural change[3].

Environmental Health in India

Environmental health can be defined as "the aspect of public health that is with all external conditions such as all forms life, substances, forces, problems and challenges and any other condition in the surroundings of man that that may extent an influence on man's health and well-being". Disease in this sense represents maladjustment of the human being to his environment. This rapid industrial growth has made water pollution, air pollution, and hazardous wastes pressing environmental problems in many areas of the developing world. Industrial emission's combine with vehicle exhausts to cause air pollution, while concentrations of heavy metals and ammonia loads are often high enough to cause major fish kills down- River from industrial areas. The lack of hazardous waste facilities compounds the problem with industrial wastes[4].

The physical environment has a major influence on human health not only through temperature, precipitation and composition of air and water but also through its interaction with the type and distribution of the flora and fauna (the biological environment). The biological environment is a major influence on the food supply and on the reservoirs and transmission mechanisms of, many diseases. The following gives the simplified illustration of these relationships.

The scale and nature of human activities including agricultural, industrial, and energy production, the use and management of water and wastes, urbanization, the distribution of income and assets within and between countries, the quality of health and other public services and the extent of protection of the living, working, and natural environment.

Environmental hazards to health fall into two broad categories. On the one side is the lack of accessibility to basic environmental resources like sanitation, water, fresh air, shelter and the like. On the other side is the exposure to hazardous environment. These hazards include biological agents viz., micro-organisms such as bacteria and viruses and parasites which contribute to the global burden of infectious disease, chemical pollutants, ultra violet radiation and the like which cause birth defects and damage the body immunity system and which render people susceptible' to a variety of health risks[5].

Table: 1: Statement Showing That General Environmental Problems

S.N	Environmental Problem	Effect on Health
1	Water pollution and water scarcity	More than 2 million deaths and billions of illnesses a year attributable to pollution, poor household hygiene and added health risks caused by water scarcity.
2	Air pollution	Many acute and chronic health impacts excessive matter levels arc responsible for 300, 00 - 70, 0,000 premature deaths annually and for half of childhood chronic diseases; women and children in poor rural areas affected by smoky indoor air.
3	Atmospheric disasters	Possible shifts in vector-borne diseases; risks climatic natural: diseases attributable to ozone changes depletion (perhaps 300,000 additional cases of skin cancer a year worldwide; 1.7 (million cases of cataracts).

Source: Report of Indian public health organization

Among the environmentally-based diseases water, food and oil borne diseases affect a majority of the world population. Diarrohea, Cholera and Hepahtis A and E have the clearest link to the environment and spread by both bacteria and virus.

According to a study, Diarrohea deaths were around 2.5 million in 1996. Around 4 billion cases of diarrohea

cause widespread debilitations each year. The nuclear development and use, the world over is a major threat to human health today. The radiation hazard arising from Extra Low Frequency (ELF) magnetic fields of between one and one hundred hertz (HZ) as well as the very High frequency fields of 147 MHZ, which can alter the outflow of calcium ions from the brain tissue of children, in particular with steadily weakening resistance causes tumour formation in the human body. Health is a fundamental resource to individual and community and is a pre-requisite for their social, spiritual and physical well-being, the protection and preservation of which is dependent on the ecological status of the environment and sustainable development.

Objectives

The following objectives are framed for the purpose of the present study:

- To study the socio-economic life of the respondents in Tuticorin town.
- To analyse the problems of environment in the study area.
- To find out the defects and problems in the existing environment hygiene and discomfort at their life.

Methodology

This study attempts to examine the respondents' behaviour on environmental hygiene and sanitation practices by making an experiment in Tuticorin town, Tamil Nadu. This study deals with environmental hygiene issues relating to environmental pollution and its impact on land, water, health etc., this study analyses the extent to which urban people have knowledge of environment and awareness. It analyses their behaviour on environmental conservation and preservation. It outlines the respondents' awareness of various environmental hygiene and sanitation issues and measures.

It is generally an exploratory framework of identifying the awareness of among urban people about environmental issues along with their action oriented activities to preserve and conserve rural environment in particular. Thus, this study is partlyexploratory in nature. Thus it constitutes the analytical aspect of the study. Hence, this study is partly exploratory in nature and partly analytical in nature.

Limitations

The findings of this study are applicable on to selected areas only mid it is not applicable to the entire areas of Tuticorin. This study covers only environment related aspects and studying of all aspects of hygiene and sanitation is not possible at the level of an individual researcher due to constraints imposed by money, time, energy and efforts.

Results and Discussion

The actual process of research findings, data analysis, data interpretation and logical arguments are discussed. This chapter starts with the socioeconomic background of the households followed by information seeking behaviour, information use pattern, information sharing behaviour, and data search behaviour and so on for statistical analysis. All tabular data and statistical analysis are presented in this chapter.

Table: 2: Sex wise distribution of the respondents

S. No.	Sex	No. of Respondents	Per cent
1	MALE	301	75.25
2	FEMALE	99	24.75
Total		100	100

Source: primary data

The above table shows that the majority 301 (75.25 %) of the respondents were male, the remaining 99 (24.75%) of them were female. It inference that the majority of the male were ready to replay for the problem of environmental pollution.

Table: 3: Impact of Environmental Pollution

S. N	Name of the Disease	No. of Respondents	Per cent
1	Skin diseases	371	93.00
2	Eye irritation	380	95.00
3	Asthuma	153	38.00
4	Deftness	298	75.00
5	Allergy	312	78.00
6	Unhygienic conditions	390	98.00
7	Respiratory problems	393	98.00
8	Cancer	09	2.00
9	Hypertension	91	23.00

Source: primary data

The above table prove the impact of environmental pollution an account of establishment of hazard industry such as Kilburn chemical industries, Sterlite Copper Plant, Thermal power plant, Spic Industries, Heavy Water Plant and Madura Coats, in this regard they replayed that an account of the establishment of the above hazardous industries, the majority 371 of the respondents faced the problems of skin diseases, 380 of them were facing the problem of eye irritation, 153, of the faced the problem of Asthuma 298 of them were facing the problem of deftness 312 of them facing the problem of allergy, 390 of the facing the problems of unhygienic conditions, 393 of the facing problem of respiratory problem, 9 of the were facing the problem of cancer and 91 of them were facing the problem of hypertension.

The inference drawn from above discussion is that the majority of the respondents facing the problem likes in diseases, eye irritation, deftness, allergy, unhygienic condition respiratory problems and diarriah.

Conclusion

Industrial disposals and other chemical contaminates that enter waterways through agricultural runoff, storm water drains, and industrial discharges may persist in the environment for long periods and be transported by water or air over long distances. They disturbed the function of the endocrine system, resulting in reproductive, developmental, and behavioral problems. The endocrine disrupters reduced the fertility and increased the occurrence of still births, birth defects, and hormonally dependent Cancers such as breast, testicular, and prostate cancers. The effects on the developing nervous system can include impaired mental and psychomotor development, as well as cognitive impairment and behavior abnormalities and pharmaceuticals such as antibiotics and synthetic sex hormones from contraceptives. The GOs and NGOs should take effective steps to clean and green the streets, schools, public safety, etc. Even though it's obvious that society stands to benefit from such things, people have always struggled to find some sensible, acceptable way to pay for them. This perennial wrangle. Far on the right, they tell us that self-interested private ownership is the fairest and most efficient way to assign resources[6].

The developing countries like India should be instrumental in raising societal concerns about environmental problems. The scientists should contribute in ways to increasing scientific input in public policy. The governmental agencies, as members of organized scientific bodies such as the National

Academy of Sciences, and as researchers in universities and environmental nongovernmental organizations or, conversely, in industries. There are some debates about whether too much or too little science is reflected in actual policy making, few will deny that significant human and institutional resources are expended in an effort to make scientific analyses responsive to policy needs. Therefore, an appropriate forum like scientists, academicians, policy makers and panchayat raj institutions should take effective step to protect environment in all aspects[7].

Seasonal Variation and Malaria in Endemic Mangalore City in South India

Rakshita Maskeri[1], Animesh Jain[2], Sheetal Ullal[3], Suchitra Shenoy[4], Damodar Shenoy[5], Sharada Rai[6]

[1]Tutor, Department of Pharmacology, [2]Professor and Head, Department of Community Medicine, [3]Associate Professor, Department of Pharmacology, [4]Associate Professor, Department of Microbiology, [5]Professor and Head, Department of Emergency Medicine,[6]Professor and Head , Department of Pathology, Kasturba Medical College, Mangalore, Manipal Academy of Higher Education, Manipal, Karnataka, India

Abstract

Background: In the year 2017 India has contributed to 4% of global malaria cases and Mangalore is endemic to malaria. Malaria transmission also depends on the season of the year, i.e. the wet or dry season. Regardless of huge endemicity and massive health burden, at present limited data has been documented on malaria prevalence and factors contributing to prevalence of malaria and its association with seasonal factors in Mangalore region.

Objective: To study the seasonal variations in malaria burden and species prevalence in Mangalore.

Settings and Design: This is a cross-sectional study conducted at District hospital

Methods and Material: Patients with microscopically confirmed malaria attending the District hospital were included in the study. Demographic details were collected from participants.

Statistical analysis used: Descriptive statistics

Results: In this region malaria is present all around the year and *Plasmodium vivax* is more predominant than *Plasmodium falciparum*. The number of cases peaks during the rainy season suggesting that high rains provide an ideal environment for malaria transmission.

Conclusions: A complex relationship exists between rainfall, temperature, occupation and malaria. Implementing malaria elimination interventions such as preventing water clogging, cleaning the water bodies and increasing awareness for use of prevention practices might help in reducing malaria burden in Mangalore.

Keywords: *Malaria, Infectious disease, Public Health, Mangalore, India*

Introduction

According to the WHO there were 219 million cases and 4,35,000 deaths due to malaria worldwide in 2017. Though most of the malaria burden is in the African countries, a considerable number of cases are reported from South-East Asia, where, India accounts for the highest malaria burden of around 70%.[1]

The National Malaria Control Program launched in 1953 resulted in a decrease of malaria cases to lower than 50,000 in mid-sixties. However, after its near eradication malaria staged a dramatic comeback with nearly 2 million recorded cases every year since 1995 and a clear change in malaria epidemiology: an increase in insecticide resistance, rise in proportions of *Plasmodium falciparum* malaria and rise in urban

malaria[2]. Between 2010 to 2014, annually there have been 7–16 lakh confirmed cases of malaria and 400-1,000 deaths.[3] In the year 2017 India has contributed to 4% of the global malaria cases.[1]

Malaria was unknown in the coastal city of Mangalore till 1990 but as a consequence of industrialization and urban development it has become endemic in the recent times.[4]

Despite the endemicity and health burden, limited data has been documented on malaria prevalence, contributing factors and its association with seasonal variations in Mangalore region.

Objective: The purpose of this study was to evaluate the seasonal variations in malaria burden and species prevalence in Mangalore.

Materials and Method

Study area: Mangalore is located 12.91°N, 74.85°E on the shores of Arabian Sea in Dakshina Kannada district, Karnataka, South India. Mangalore city has hot and humid tropical climate with two seasons, rainy and summer. The climate of the city makes it a perfect place for breeding of *Anopheles* species and malaria transmission, thus making the city highly endemic to malaria.

Study Setting: Wenlock District hospital, a tertiary care centre

Study design: A cross-sectional study was carried out among patients attending the malaria clinic. Giemsa-stained thick and thin blood smear examination was done and confirmed cases of malaria were recruited in the study. Demographic details were collected from the participants.

Study duration: The study was carried out for a period of one year from January 2017 to December 2017.

Ethical considerations: The study was started after getting permission from the Institutional Ethics Committee, Kasturba Medical College, Mangalore, India. Written informed consent was taken from all the participants.

Results

Data was collected from 1095 consecutive patients with confirmed malaria. Table 1 depicts the demographic details of the participants. The mean age was 32 years. Males outnumbered females presenting to the hospital.

Table 1: Demographic details of Participants

Mean age (± SD)	**32 (±12) years**
Males	1038
Females	57
Occupation	
Construction workers	411
Labourers	154
Hotel workers	145
Others*	385

*Others included security guards, police personnel, bus drivers and conductors, businessmen, fishermen, students, homemakers, retired people

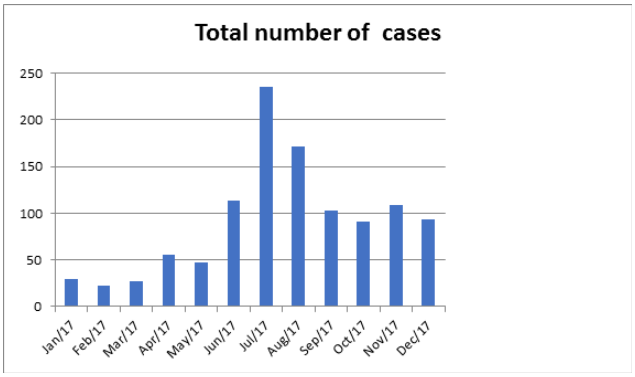

Figure 1 - Summary of total number of smear positive malaria cases and the average temperature every month (2017)

Figure 1 shows the total number of microscopically positive cases of malaria every month and average temperature in the year 2017.[5] This shows that highest number of cases were recorded during the peak rainy season during July and August. The highest recorded temperature during the year is in April and May at around 33 °C while later the temperature gradually reduces to 26 °C in December. During the dry season, though the cases reduced, it was still substantial in number.

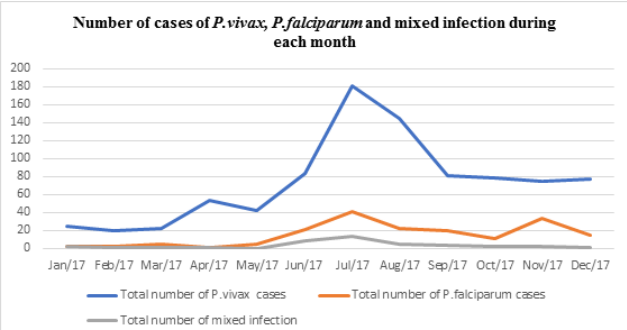

Figure 2-Month-wise distribution of *P.vivax, P.falciparum* and mixed infection cases

Figure 2 depicts the number of cases of *P.vivax, P.falciparum* and mixed infection during every month. *P.vivax* was found in highest number followed by *P.falciparum* and mixed infection.

Discussion

Malaria is a grave health problem in certain parts of India and Mangalore city is known to be endemic to malaria. In the present study the ratio of *P.vivax, P.falciparum* and mixed infections was 81%, 16 % and 3% respectively. The results found in our study are similar to results published in the study conducted by Dayanand KK et al[6].The data recorded by District Vector Borne Disease Control Programme (DVBDCP) office of Dakshina Kannada has shown 80% of malaria cases were by caused by *P.vivax* and 20% cases were by caused by *P.falciparum* which is compatible with results found in our study.[4,7]

The total of malaria cases in the year 2013 in Mangalore was 4714 which drastically increased to 11021 in 2015 and 11037 in 2016 which has now reduced to 8075 in the year 2017 and to 6110 in the year 2018.[4]Thus the decrease in number of cases suggests the success NVBDCP's strategies to reduce the cases. The framework for malaria elimination in India (2016–2030) launched by the government of India in 2016 also aims to control and eradicate malaria.[8]In the year 2018 the number of cases has reduced, and the deaths has drastically reduced to only 85.[3]

In various other endemic regions in the world including Africa, malaria usually affects younger age groups mainly children.[9]In Mangalore the majority of the cases with malaria are adults. It is similar with other cities in India and South East Asia. A high number of study participants were construction workers and labourers leading to skewing of the gender ratio towards males. Majority of the construction workers stay in and around the construction sites. These sites have stagnant water used for curing concrete and construction related activities making it an ideal breeding site for the *Anopheles* species. Lack of prevention methods like bed net use and mosquito sprays is putting these workers at a higher risk of malaria. Additionally, limited prevention practices against malaria is one the major factor for the high number of malaria cases as found by these studies[10,11].

Climatic conditions such as rainfall, temperature and humidity affect mosquito survival and malaria transmission rates. In various places the transmission is seasonal and usually peaks during and after the rainy season. The present study shows that there is a strong relationship between rainfall and malaria. Mangalore during the monsoon season from May to October receives an annual average of 3479 mm rainfall[12]. The number of cases peaked between June to August suggesting that high rains provide an ideal environment for malaria transmission. There was a decline in cases during the dry seasons. In the month of July even though the temperature was 32 °C the highest number of cases, 10 times more than number of cases during February was recorded, as in drier months when the weather is hot the breeding sites of the mosquitoes are dried, and the number of cases reaches low.

Both, *Plasmodium* parasite and *Anopheles* mosquitoes are known to be temperature sensitive. The optimal temperature for most of the *Anopheles* species is in the range of 20°C to 30°C.[13]

Mangalore has the optimum temperature throughout the year. Hence malaria is present in the city throughout the year. *P.vivax* predominates as the causative agent in urban malaria. In Mangalore too, the highest burden of malaria is caused by *P.vivax*. Both *P.vivax* and *P.falciparum* are present all around the year. *P.vivax* is in higher ratio of about 80% throughout the year compared to *P.falciparum*. In comparison, in other parts of the country like in Orissa *P.falciparum* is more predominant than *P.vivax;* in Tamil Nadu it is again *P.vivax* and in the west it is mixed species infections which are more prevalent.

P.vivax has the potential to act as a hypnozoite reservoir and cause multiple relapses leading to an increased burden. *P.vivax* which was earlier considered to be a benign form of malaria is now being found to be not so benign thus making it an issue of concern.

Conclusion: In summary high transmission is found in Mangalore area. The results depicted here show a complex relationship between rainfall, temperature, occupation and malaria cases. The results of this study will be useful for malaria elimination control program of India. Implementing malaria elimination interventions such as preventing water clogging, cleaning the water bodies etc and increasing awareness for use of prevention practices might help in reducing malaria burden in Mangalore.

Recommendation Malaria is a huge health burden in Mangalore. It has been found that the number of cases generally peaks with the rainy season. Thus, awareness and malaria preventive measures have to be concentrated mainly before and during the rainy season during which the number of cases are higher. We also found that the construction workers are mainly affected by malaria. Hence the results may help in targeting a seasonally focused malaria interventions to specific target population like construction workers. Further strategies have to be developed to create public awareness mainly among the construction workers and implement protective measures to reduce the risk of transmission.

Limitation of the study There are a few limitations in our study. Firstly, since it is a hospital based study it doesn't depict the exact picture of overall cases of malaria in Mangalore. Secondly, the study period is one year which is a little short to study the prevalence trends. Thirdly, doing a community based study would give clearer insight of seasonal variation.

Relevance of the study In Mangalore, malaria is highly endemic and a huge health burden to the society. Despite this, very limited data has been documented regarding the malaria cases, contributing factors and its association with seasonal variations in Mangalore region. This study depicts that in Mangalore a complex relationship exists between rainfall, temperature, occupation and malaria and further adds to the scientific evidence.

Conflict of Interest: NIL

Source of Funding: This study is a part of project funded by Women Scientist Scheme- A, Department of Science and Technology (Government of India) file number SR/WOS-A/LS-523/2016

Ethical Considerations: The study was started after getting permission from the Institutional Ethics Committee, Kasturba Medcial College, Mangalore, India (IEC KMC MLR 06-15/126). Written informed consent was taken from all the participants.

A Study to Assess the Level of Burden and Coping Strategies among Caregivers of Patient with Affective Disorders at Selected Hospitals of Sangli, Miraj, Kupwad Corporation Area

Ramesh Giramalla Honamore[1], Narayan K Ghorpade[2]

[1]M.SC Nursing at BharatiVidyapeeth (Deemed to be University), College of Nursing, Sangli,
[2]Assistant Professor, B.V.D.U.College of Nursing,Sangli

Abstract

Introduction Interactions with caregivers of patients with severe mental illness like schizophrenia and bipolar affective disorder have revealed negative feelings about the disability status of their relative and burden related to caring for their relative with mental illness. Many caregivers have expressed that the patient‘s disability status affects the family pattern, roles of family members, prosperity of the family and relationship among the family members. Patient outcome and compliance with treatment are also dependent on optimal care giving and addressing family‘s needs. Unfortunately these needs are not routinely considered, addressed or met. Addressing the burden perceived by caregiver and improving their coping can assist with good clinical care of patients with severe mental illness and hence these study to assess the burden perceived by caregiver and their coping.[1] **Objectives**: To assess the levels of Burden among care givers of patients with affective disorders and To assess the coping strategies among the caregivers of patients with affective disorders. **Materials and Method:** The researcher used quantitative research approach to assess burden and coping strategies. The research design was descriptive research design. The tool reliability coefficient ‘r’ of the scale was 0.7, hence it was found reliable. Total 120 samples were selected by non Probability convenient sampling technique. Total two scale namely Zarit burden interview and Rating scale for assessing coping strategies to collect data. The conceptual framework adopted is Sr.Calista Roy’s adaptation model (1984) the main concept of this conceptual framework is human being, stimuli, adaptation models and nursing. **Results and Conclusion:** In this study found the level burden among the care givers of affective disorders patients have experienced 60(50%)were had moderate to severe level of burden,29(24.17%) were had severe burden, 13(10.83) were had no or little burden and 18(15%) were had mild to moderate burden and levels of coping strategies among care givers, 19(15.83%) were had moderately adequate coping strategies, 93(77.50%) were had adequate coping strategies and 08(6.67%) were had inadequate coping strategies.

Key words: *Care giver, Burden, Coping strategies,*

Background of Study

In 1896, Kraeplin according ‘manic-depressive psychoses’ as a circumscribed illness entity. Ever since, frenzied depressive mental disease, or the present term used nosologically as ‘bipolar’ mood disorder, has been studied within the Indian perspective. The mood disorders are commonly known as affective disorders. Broadly speaking, the emotions can be described as two main types Affect which is a short-lived emotional response to an idea or an event, and Mood, which is a sustained and pervasive emotional response which colors the whole psychic life[1].Caregivers of patients of schizophrenic disorder and bipolar major affective disorder (BAD) expertise appreciable burden whereas caring their patients. They develop totally different cope methods to cope with this burden. Care giving is a chronic stressor and different coping methods are used to handle such a situation. The present study

Corresponding Author:
Mr. Narayan K Ghorpade,
Assistant Professor, B.V.D.U.College of Nursing,Sangli.Email.ID:nkghorpade@gmail.com

attempts to assess coping in caregivers of Chronic Schizophrenia and Bipolar Affective Disorder and make a comparison between them. The study also tries to assess the relationship between the burdens experienced by the caregivers of both these groups of patients with the coping strategies adopted by them. It was a hospital based cross sectional and comparative study, conducted in the Department of Psychiatry, Assam Medical College and Hospital with a sample size of 30 primary caregivers of equal number of patients of Chronic Schizophrenia and 30 Primary caregivers of equal number of Bipolar Affective Disorder patients. Appropriate statistical tests were used for analysis of obtained data setting significance threshold at p coping (90%) followed by external attribution and magical thinking. Among the caregivers of patients of BPAD the most commonly used coping strategies included help seeking (93.33%) followed by religious coping strategies and external attribution. [2] **Materials and Method:** The researcher used quantitative research approach to assess burden and coping strategies. The research design was descriptive research design. The tool reliability coefficient 'r' of the scale was 0.7, hence it was found reliable. Total 120 samples were selected by non Probability convenient sampling technique. Total two scale used namely Zarit burden interview and Rating scale for assessing coping strategies to collect data. The conceptual framework adopted is Sr.Calista Roy's adaptation model(1984) the main concept of this conceptual framework is human being, stimuli, adaptation models and nursing.

ASSUMPTION 1. The caregivers of affective disorders patients may experience some level of burden and The caregivers of affective disorders patients may use some coping strategies.

Results

SECTION I: Deals with analysis of data related to assessment of the level of burden among care givers in terms of frequency, percentage.

Table.No.1: Classification of respondents based on levels of burden among care givers of affective disorders.

N=120

Sr. No	Level of Burden	Score	Frequency	Percentage%
1	No or little burden	0-20	13	10.83%
2	Mild to moderate burden	21-40	18	15%
3	Moderate to severe burden	41-60	60	50%
4	Severe Burden	61-88	29	24.17%

The above table describes the levels of burden among care givers of affective disorders, 60(50%) were had moderate to severe burden, 29(24.17%) were had severe burden, 13(10.83%) were had no or little burden and 18(15%) were had mild to moderate burden.

SECTION II: Deals with analysis of data related to assessment thecoping strategies among care givers of affective disorders patients in terms of frequency and percentage.

Table No.2: Classification of respondents based on coping strategies among care givers of affective disorders.

N=120

Sr. No	Strategies	Score	Frequency	Percentage %
1	Inadequate coping strategies	01-24	08	6.67%
2	Moderately adequate coping strategies	25-50	19	15.83%
3	Adequate coping strategies	51-75	93	77.50%

The above table describes the coping strategies among care givers, 19(15.83%) were had moderately adequate

coping strategies, 93(77.50%) were had adequate coping strategies and 08(6.67%) were had inadequate coping strategies.

Discussion

The study was descriptive in nature and the population taken for the study was of a low socioeconomic status. An Exploratory study to assess the level of burden and coping strategies among caregivers of patients with affective disorder at selected hospitals of sangli miraj kupwad corporation area. The findings of the study have been discussed with reference to objective and assumption.

Discussion regarding demographic variables:

• Majority of the caregivers, 30(25%) were between 31-35 years. The majority of care givers were 70(58.30%) were females. With regard to religion, 80(66.7%) were Hindus. Majority 69(57.5%) were graduates. With regard to monthly income, 50(41.66%) were had Rs. 10000 -15000 income per month. In relation to the type of family, 80(66.70%) were from joint family. With regard to duration of care giving, majority 40(33.33%) were giving for 1 to 3 years, In relation to the care givers relationship, 30(25%) were fathers, 30(25%) were son.

Objective 1.To assesses the levels of Burden among care givers of patients with affective disorders.

The study reveals that the majority caregivers of affective disorders patient 60(50%) were had moderate to severe burden, 29(24.17%) were had severe burden, 13(10.83%) were had no or little burden and 18(15%) were had mild to moderate burden.

Objective 2.To assesses the coping strategies among the caregivers of patients with affective disorders.

The coping strategies among care givers, 19(15.83%) were had moderately adequate coping strategies, 93(77.50%) were had adequate coping strategies and 08(6.67%) had inadequate coping strategies.

Conclusion

This chapter deals with the conclusion, implication, recommendation and data collected from 120 individual samples regarding the level of of burden and coping strategies among care givers of affective disorders. The data was collected by using the Zarit burden Interview and Rating scale for assessing coping strategies. The study was conducted at selected hospitals, Sangli and Miraj,kupwad corporation area. The data analysis was done by descriptive and inferential statistics. The findings of the study are as follows; The study reveals that the care givers of affective disorders patients was 60(50%) were had moderate to severe levels of burden, 29(24.17%) were had severe burden, 13(10.83%) were had no or little burden and 18(15%) were had mild to moderate burden. The mean percentage score was 54.71 with mean and standard deviation of 48.15±2.75. The coping strategies among care givers of affective disorder using 19(15.83%) were had moderately adequate coping strategies, 93(77.50%) were using adequate coping strategies and 08(6.67%) were using inadequate coping strategies.

Cognitive Impairments and its Associated Risk Factors among Patients with Diabetes Mellitus

Rasika Panse[1], Ujwal Yeole[2], Nikita Aher[3]

[1]Assistant Professor, [2]Associate Professor and Principal, [3]Student, Department of Physiotherapy Tilak Maharashtra Vidyapeeth Pune

Abstract

Background: Diabetic patients are considered to be more prone to develop cognitive dysfunction and further leading to dementia, hence systematic assessment and identification of risk factors plays a key role. Aim and objectives: To study cognitive impairments and its associated risk factors among patients with diabetes mellitus . Settings and Design: A hospital-based Multicentre cross-sectional study was conducted. Methods and Material: In this study 245 individual medically diagnosed to have diabetes mellitus were recruited according to inclusion and exclusion criteria. Demographic data included age gender and duration of diabetes smoking, BMI, Family history of diabetes and Hypertension *HbA1c* was noted. Cognitive assessment was done using Modified Mini Mental Scale (3MS). Data was collected and subjected to statistical analysis. Results: The result shows about 22% had moderate cognitive impairment and associated risk factors can be medications, age, glycaemic control, Hypertension, family history. There is no correlation of Cognition and duration since diagnosed to be diabetic and BSL whereas weak linear relationships exist between cognition and Age and *HbA1c* and strong linear relationship between cognition and BMI in Patients with diabetes. Conclusions: Diabetic patients do exhibit Mild cognitive dysfunction with various associated risk factors.

Key-words: *Diabetes, smoking, Duration of diabetes, Obesity, Hypertension, Cognitive impairment, HbA1c, Modified mini Mental Scale.*

Introduction

Diabetes mellitus is autoimmune metabolic disorder, caused by insulin deficiency, is complex in nature and has various factors related to it, long-term complications and co-morbidities can affect the cerebral cortex [1]. Islets of langerhans in Pancreas especially the beta (β) cells secrete insulin. Defect in response of insulin causes diabetes mellitus. Type 1 Diabetes Mellitus also called as Insulin-Dependent Diabetes Mellitus (IDDM) or juvenile onset diabetes is caused by destruction of β cells which leads to deficiency of insulin. Type 2 Diabetes Mellitus also called as Non-Insulin Dependent Diabetes Mellitus (NIDDM) or maturity onset diabetes caused due to impaired insulin secretion or insulin resistance [(1,2,3)] Long term diabetes affects central nervous system, peripheral nervous system mainly manifest in the clinical impact of diabetes.[4]

Type 2 diabetes is often associated with increased risk of accelerated cognitive decline and almost two times more susceptible to experience cognitive decline compared to those with normal glucose tolerance. Various researches have suggested that Type 2 diabetes affects cognitive domains like verbal memory, attention and processing speed and executive functions when performing task with change in environment and challenges. Diabetes has also been consistently related with cognitive decrements such as reduced abstract reasoning, complex motor functioning and working memory. [1]

Cognitive dysfunction affects memory, learning and attention. In mild cognitive impairment there is cognitive

dysfunction without affecting the daily activity of life. Person with mild cognitive impairment can self manage their daily routine. Conditions for cognitive dysfunction are hyperglycemia, hypoglycaemia, insulin resistance and insufficiency of insulin in patients with diabetes. In young population due to immediate hypoglycemia, acute cognitive dysfunction can be observed. (5)

Subjects and Method

Study setup and design: A Multicentered hospital based Cross-sectional study was conducted.

Method: 398 participants had a diagnosis of type 2 diabetes according to the World Health Organization 1999 criteria, and 245 individuals were included in the study. Study was conducted from July 2018 to January 2019. [6] Both males and females were included. Subjects who willing five Informed Consent were included in study. An exclusion criterion was patient with Dementia, Alzheimer's disease and any psychological disorder pregnancy. Demographic data included age gender and duration of diabetes, smoking, Family history of diabetes, obesity and Hypertension, BMI, BSL, HBA_1C was noted. Cognitive assessment was done using Modified Mini Mental Scale (3MS). Data was collected and subjected to statistical analysis.

Results

Demographic data for diabetic patients with mean age 73.22+7.9 , Mean duration since diagnosed to be diabetic was 18+10.82, mean Cognition in diabetics was 75.59+1.6.Also mean BMI was 25.67 +5.351 with Mean BSL and HbA1c as 190+54.13 and 7.118+0.958 respectively. Table 1 shows that Family history was exhibited in 72.72%, Hypertension in 50%, Diabetic Male were 48% and Females were 52% and diabetic had addiction of Smoking in 68%.

Table 2 shows that there is no correlation of Cognition and duration since diagnosed to be diabetic , and BSL whereas weak linear relationships exist between cognition and Age and HbA1c and strong linear relationship between cognition and BMI in Patients with diabetes.

Table 1: Percentage of Family History Of Diabetes Cognitive dysfunction Gender Distribution, Hypertension among Diabetics with Cognitive dysfunction.

Risk Factors	**Percentage**
Family History of Diabetes	72.72%
Hypertension	50%
Gender Male	48%
Female	52%
Smoking	68%

Table 2: Correlation of Age Duration of Diabetes, BMI, BSL, HbA1c and Cognitive Dysfunction in Patients with Diabetes.

Parameters	**Mean+SD**	**Person correlation (r)**
Age	73.22+7.9	0.0175
Duration since diagnosed to be diabetic	18+10.82	-0.03622
BMI	25.67 +5.351	0.1337
BSL	190+54.13	-0.1996
HbA1c	7.118+0.958	0.0846

Discussion

Study showed that 22% had moderate cognitive impairment (MCI). There is no correlation of Cognition and duration since diagnosed to be diabetic whereas weak linear relationships exist between cognition and Age and HbA1c and strong linear relationship between cognition and BMI in Patients with diabetes. Risk factors of smoking family history of diabetes, Hypertension are coexisting with patients with diabetes.

The prevalence in urban Kerala of Mild cognitive impairment in patients with diabetes was 26.06%. This prevalence is reported from different areas of the world varies widely between 3% and 42%. Previous researches from India estimated prevalence between 15% and 33%[7]

A research showed that Deficits in memory is correlated with decrease in gray matter density and reduced glucose metabolism in the regions of orbital and prefrontal cortex, temporal cortex (middle gyrus, parahippocampus, and uncus), and cerebellum. Both Type 1 and type 2 diabetes are associated with impaired cognition; the current statistically analyzed data suggests a stronger association of cognitive decline with T2DM. Early Cognitive impairment is observed in individuals who have impaired blood fasting glucose. [8]

The various studies have shown that prevalence of diabetes is higher in men than women, but there are more women Suffering with diabetes than men in recent years. Similar results have been observed related to the proportion of females was much higher than the males suffering with diabetes in our study. Studies have truly delineated that cognition impairment correlates with the glycaemic control as well as the duration of diabetes.

Mohammed Abdul Hannan Hazari and others concluded in the study that due to long duration specifically exceeding 5 years of onset of diabetes showed prominent decline in cognition in as Diabetes is considered a potential atherogenic factor. Also hypertension along with Diabetes further increases the risk of cognitive decline.[10] In type 2 diabetes mellitus, chronic hyperglycemia can be cause of cognitive decline. [10]

Medha N. Munshi concluded in the study that poor glycaemic control i.e. Hypoglycemia and chronic hyperglycemia can factor that can lead to cognitive dysfunction better management of Diabetes is required to prevent cognitive decline in older adults.[5]

E. van den Berg and others concluded in their study that obesity, hypertension, and dyslipidaemia are features that have risk of cognitive dysfunction in younger old. At the age up to 75, increased cholesterol levels and increased BMI are related with accelerated cognitive decline up. [11]

In the general population, studies on other risk factors for accelerated cognitive decline were hypertension and obesity. Hypertension has been suggested to be an important factor of impaired cognition in diabetes. A similar result is seen in this study that A higher HbA1c level was largely unrelated to cognitive dysfunction. [11]

Omorogieva Ojo and others in their study concluded that neurotransmitter acetylcholine functions for cognition and memory formation. Dysfunction in insulin production and insulin resistance could lead to a decrease in acetylcholine levels which may have impact on cognition and memory. Diabetes is a risk factor for decline in cognitive. Hyperglycaemia and hypoglycaemia may result from poor self management of diabetes which can lead to cognitive decline. [12]

Insulin crosses the blood brain barrier and binds with insulin receptor. Insulin plays an important role in cognitive function and also in food intake. Insulin is present in abundance in cerebral cortex and hippocampus which play important role in memory. Due to insulin resistance there is decrease in insulin receptors and decrease insulin in brain. It result impairment in cognition. For some time, cognitive decline has been reported in patients receiving insulin therapy. A recent study showed that up to half of all cases of Alzheimer's disease are attributable to potentially modifiable risk factors – diabetes, midlife hypertension, midlife obesity, smoking, depression, low education level and physical inactivity. Most of these risk factors also contribute to the incidence or progression of diabetes mellitus.[13]

Conclusion

Study concludes that 22% Diabetic patients had moderate cognitive impairment (MCI) wherein they exhibited no correlation between Cognition and duration since diagnosed to be diabetic. Furthermore there exist a weak linear relationships exist between cognition, Age and HbA1c and strong linear relationship between cognition and BMI in Patients with diabetes. The other modifiable and non modifiable risk factors were smoking,

family history of diabetes, Hypertension which coexist in patients with diabetes contributing towards potential cognitive decline irrespective of the age of the patients.

A Study on Antibiotic Utilization in Pediatric Hospitalized Patients and Antibiotic Stewardship

Ratikanta Tripathy[1], Shantadeepa Chopdar[2], Nirmal Kumar Mohakud[3], Suresh Chandra Pradhan[4], Prasanna Kumar Panda[5]

[1]Associate Professor , Dept. of Pharmacology, KIMS Hospital, Bhubaneswar, [2] M. Pharma (Pharmacology), Bhubaneswar, University Dept. of Pharmaceutical Sciences, Utkal University, Bhubaneswar, [3]Associate Professor, [4]Professor, Dept. of Pharmacology, KIMS Hospital, Bhubaneswar, [5]Professor, Pharmacology, University Dept. of Pharmaceutical Sciences, Utkal University, Bhubaneswar

Abstract

Background: There is an increasing trend of use of antibiotics in pediatric ward/intensive care unit has resulted in increasing health care costs and the emergence of resistant bacteria. **Objective:** We evaluated the utilization of antibiotics in a pediatric teaching hospital aiming to identify targets for improvement of prescription. **Methods:** Clinical, laboratory and treatment data of patients hospitalized in patient department (IPD) and a pediatric intensive care unit (PICU) were prospectively collected during a 6-months period. A subsequent review of the collected data by a pediatric infectious disease specialist, taking into consideration existing in-house treatment guidelines, was carried out **.Results:** Most common age group receiving antibiotics are between 1-5 years of age. Ceftriaxone alone and in combination with other antibiotics was most commonly prescribed (71.4%). Average number of antibiotics per patient was 1.2 and 70% of patients were on single antibiotic. **Conclusion:** The most cause of hospitalization in our set up is due to gastrointestinal diseases and the antibiotics used frequently is ceftriaxone. It is high time for continuous education of doctors on judicious antibiotic use and strict implementation of existing guidelines for it. Improvement in the availability of rapid diagnostic methods to discern viral from bacterial infections may help reduce the numbers of empiric therapies in favor of pathogen-targeted therapeutic treatments.

Key Words: *Antimicrobials,Infections, Pediatrics, Stewardship,antibiotic utilization*

Introduction

The goals of antimicrobials chemotherapy may involve the time course events of infection. This may be prophylactic, pre emptive, empiric, definitive or suppressive.[1] The empirical therapy involves in giving antimicrobial agents without confirming infection with evidence of the microorganism from the culture and sensitivity. Standard medical treatment depends upon the accurate diagnosis and optimal use of antibiotics. Antimicrobials agents are potentially toxic and may promote resistance in microorganism, very often, there agents are prescribed irrationally in conditions like common cold, upper respiratory tract infection and surgical prophylaxis.[1] Antibiotics are the most commonly prescribed medicines in children with highest incidences found in preschoolers. It has been documented that the prescribing doctors lack the knowledge about antibiotics which leads to irrational prescribing and adds to the medical expenses.[2,3] However, hospitals are considered to be the centre of antimicrobial resistance owing to the higher use of broad-spectrum agents in both adults and children [2].

According to the results of various antibiotic drug utilization studies, 50% to 85% of children receive antibiotics in developed and developing countries.[4] In European countries and the United States, 23-38% of in-patients are given some kind of systemic antibiotic treatment. Antibiotics take the lead among most commonly used drugs in Turkey and account for

Nirmal Kumar Mohakud
Associate Professor, Dept. of Paediatrics,
KIMS Hospital, Bhubaneswar. 0674-2725228

20% of the drug market.[5] Unfortunately, 20-50% of antibiotic treatment is used irrationally. In India the sale of antibiotics is on the rise with 40-60% increase observed over last five years.[6] The fact that one of the most important causes of acquiring antibiotic resistance is the lack of rational antibiotic use has been reported in many studies and has taken its place in the literature as evidence. Inappropriate use of antibiotics leads to some undesired effects such as an increase in mortality and morbidity, drug toxicity and interactions, extended periods of hospitalization, and an increase in expenditures.[7] This problem has been largely observed in developing countries through inappropriate prescribing habits, over interested desires to treat every infection children are mostly suffering from. The present study was designed to determine the antimicrobial utilization pattern in a tertiary care hospital and to ascertain the resulting treatment consequences in a selected pediatric in patients and also intensive care unit.

Materials and Method

This work was a prospective, observational and cross sectional study conducted in the department of paediatrics in collaboration with department of pharmacology, Kalinga Institute of Medical Sciences (KIMS), Bhubaneswar, a tertiary care hospital of Eastern Odisha, in the duration of March to August 2018. This hospital is a 1750 bedded teaching and super speciality hospital. In this study paediatric patients aged 1month-14 years admitted to IPD & PICU prescribed with antibiotics were included.

All the consecutive cases those were eligible for the study during the study period within 6 months was taken into consideration. Institutional ethical committee approval was obtained from hospital and parents given consent were included in the study.

Properly designed form sheet was used for data collection. It includes socio-demographic and clinical characteristics of pediatric patients as well as patterns of antimicrobial utilization during the study period. The format includes degree of polypharmacy of all drugs and antimicrobials in particular, dosage regimen, route of administration, prevalence of single and combination antimicrobials, and prevalence of disease states to which antimicrobials were prescribed, among others.

The collected data were compiled, tabulated and entered in Microsoft Excel 2014. The statistical analysis of data is done by STATA 15.1(College Station, TX: StataCorp LLC). Descriptive statistics followed by cross tabulation was employed to pro- vide the frequency and percentage distributions of the vari ables included in the study. The result was presented using tables, figures, and pie charts.

Results

Figure 1 shows the use of antimicrobials in pediatric ward and PICU patients. A total of 133 patients were selected in the study period rceived antibiotics during their hospital stay. It shows that ceftriaxone alone and in combination with other antibiotics were most commonly prescribed (71.4%) antibiotics. Piperacillin Tazobactum & Cefpodoxime were prescribed in 9.8% of cases each. Ciprofloxacin (1.5% cases), Co-amoxyclav (3% cases) were used in minimally.

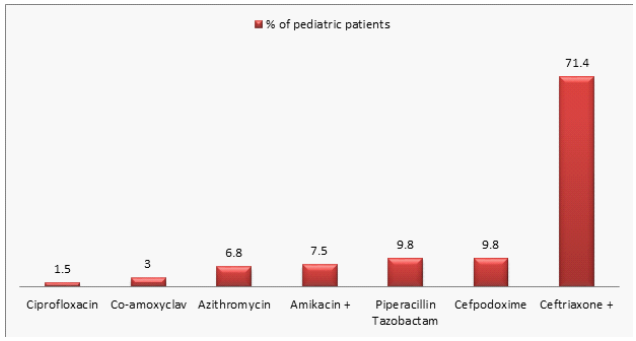

Figure no. 1 : Use of anti-microbials in pediatrics ward and pediatric intensive care unit (n= 133)

(+) denotes in combination with other anti-microbials.

Figure 2 shows the organ system involvement of the pediatric patients. Gastrointestinal system is involved in 27.8% of cases followed by 21% cases where systemic infection prevailed. Less commonly involved systems were respiratory (12.8%) and Cetral Nervous System (11.8%). Skin was least commonly involved in 1.5 % cases.

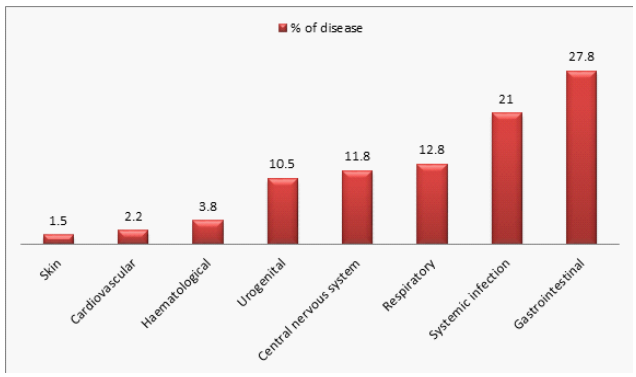

Figure. 2: Morbidity pattern of pediatric inpatients and pediatric intensive care unit (n=133)

As Shown in Figigure 3 maximum number of children belong to 1-5 years age groups (45%) followed by 6-10 years age groups in 23% of cases. Children less than 1 year age group and 11-14 years constitute the lowest (16%) among all cases.

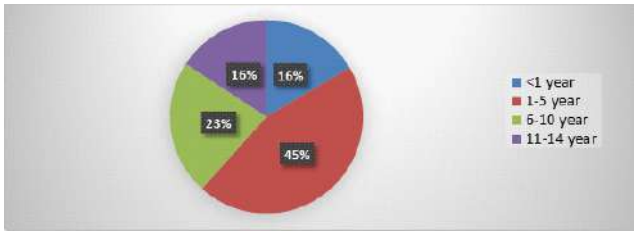

Figure no.3 : Age distribution of patients

Table 1 shows distribution of patient in relation to route of antibiotic administration. Maximum patients (82.7%) were administered intravenous antibiotics whereas only 4.5 % cases administered with oral antibiotics.

Table 1 :Patient distribution regarding route of administration of antibiotic

Route of Antibiotic administration	No. of patient
IV	110 (82.7%)
Oral	06 (4.5%)
Both	17 (12.8%)

Table 2 shows maximum patients (70%) received antbiotic monotherapy, 27% cases received 2 antibiotics and only 3% cases were on 3 or more number of antibiotics.

Table 2: Patient distribution regarding number of antibiotics received

No. of Antibiotic	No. of patient
1	93 (70%)
2	36 (27%)
≥3	04 (3%)

Table 3 shows maximum no of patients i. e. 70.67% were admitted in the hospital for 1-7 days. The duration of hospital stay was 8-15 days in 18.8 % cases. Only 4.5 % of children stayed in the hospital for more than one month.

Table3: Distribution of duration of stay in hospital

Number of days	No. of patient	Percent (%)
1-7	94	70.67
8-15	25	18.79
16-30	8	6.01
≥31	6	4.51

Discussion

Antibiotics are most commonly prescribed and effective drugs which are used to treat microbial infections. The present study was conducted in the department of paediatric IPD (In-Patient Department) & PICU (Paediatric Intensive Care Unit), KIMS, Bhubaneswar between March to August 2018. A total number of 133 patients of 1mo -14 years were included comprising of 120 IPD and 13 PICU patients.. We compared the demographic profile of our patients with that of other studies done in pediatric population in regard to the antibiotic utilization.

The present study shows the percentage of female patients (61.6%) was more than the male patients (38.4%), whereas other previous studies had shown the males majority.[8-11] This may be due to perceived male child bias has grasually changing in the society due to increase female lireracy and education. Also a study by Laya et al had stated that the equal ratio of males and females indicate the current trend equality of both sexes.[12]

As evident from this study , the maximum number of paediatric patients belonged to the age group of 1-5 years followed by the group of <1 year which were 45.11% and 16.54% respectively.This may be due to immature immunity system in the age group of 1-5 years, which made them more prone to infections. Our finding was similar compared to some other studies.[8]

In this study, most frequent clinical indication for which antimicrobials were prescribed was gastro intestinal tract infection i.e. 27.82% followed by systemic infection with fever 21.05% which was similar to the study done by Shivaleela et. Al.[8] Another study had shown that most frequent infection was respiratory tract infections.[12] As our study was conducted during the

months of winter and summer season, GI tract infections were more prevalent.

The study shows the use of antibiotics were accounting 22.32% of prescriptions in IPD and PICU. A study conducted in Nagpur in 2008 which included paediatric outpatient prescription of 500 in a Bombay tertiary care hospital showed antibiotics constituted 79% per prescription.[13] However a study done by Sunil Krande et. al showed the use of antibiotic per prescription to be 39.6%.[14] Its an indication that antibiotic stewardship program in this institute has an impact on antibiotics prescription.

Table 4: Comparision of our study with other studies in regards to number of drugs and antibiotics used

Study	No. of drugs used	No. of antibiotics used
Our study,2018	5.55±2.24	1.24±0.49
Shivaleela et. al, 2014	4.26	2.13
Gizework et. al, 2015	1.70±0.93	1.45±0.59

Table 4 shows the average number of drugs prescribed per patients was 5.5 and average number of antibiotics prescribed per patients was 1.2. But the studies showing result on average number of drugs and antibiotics as per patient was less from our studies.[8,9] The WHO recommends that the average number of drugs per prescription should be less than two.[15] In present study this number is more than two, so it indicates polypharmacy. The average number of drugs per prescription value should be low as possible to prevent the unfavorable outcomes of polypharmacy such as increased risk of drug interactions, increased cost of therapy, non-compliance and emergence of resistance in case of use of antimicrobials. Since these patients were treated in tertiary care hospital & some of them were critically ill, therefore number of drugs used was more. On the other hand our study showed average no of antimicrobial was 1.2. Therfore rational antimicrobial therapy has been followed in the studied institute.

As per the study of Achalu et.al, 22.8 % cases prescribed with single antibiotic, and two antibiotics were prescribed in 51.5% cases.[10] In our study the single antibiotic was prescribed in 70% cases. Multiple antibiotics were prescribed in 28.6% patients according to study of Shivaleela et. al and this was comparable to the study of Choudhury et. al (29%). [8,16]. Out of 30% of cases having more than 2 antibiotics only 3 % cases had three or more antibiotics were used. In present study, most common route of antibiotic administration was found to be I.V route (82.7%) followed by oral route (4.5%). The same study done by Shivaleela et. al and Tadesse et. al.[8,10] This study was conducted on admitted cases, so most common route of administration was I.V route.

According to our study, the mean duration of stay in hospital was 9.5 which was nearby similar to the study of Srivastava et.al (7.3) and Roy et. al (6.3) and also it was compared to Gupta et. al (5.28) and Rasheed et. Al (4.5).[17-20] It may be due to 14 patients who stayed for more than 20 days because of chronic illness like tuberculosis, post encephalitis sequelae and cerebral palsy leading to increase in hospital stay as compared to other studies. But in majority (89%) of children had average duration of hospital stay was around 7 days.

Our study will be of help to develop evidence based medicine with high quality information in the health care facilities. Further, standard treatment guidelines may be developed like in CMC Vellor for antimicrobial uses in adults.[21] Similar guidelines may be developed to treat paediatric patients. This will minimize the off level use of medicines for pediatric use which is very wide spread in India.[22] Research questions relevant to India getting especially on antimicrobial resistant is lacking.Our study will be of help in evidence based guidelines for making for treatment of pediatric patients.

Limitations of the study:

This study was conducted for period of 6 month extending from March to August 2018. As the study was not conducted by full year as a result the seasonal variations in paediatric illness was not documented.

Conclusion

The most cause of hospitalization in our set up is due to gastrointestinal diseases and the antibiotics used frequently is ceftriaxone. Efforts need to be undertaken towards continuous education of doctors on judicious antibiotic use, as well as ensuring compliance with existing guidelines. Improvement in the availability of rapid diagnostic methods to discern viral from bacterial infections may help reduce the numbers of empiric therapies in favor of pathogen-targeted therapeutic treatments.

Understanding the Basics of Research as a Beginner: A Highlighter

Ravishankar M.V,[1] Vidya C.S. [2]

[1]Assistant Professor, [2]Associate Professor Dept. of Anatomy JSS Medical College JSS Academy of Higher Education & Research, Mysuru

Abstract

Research has grown beyond leaps and bounds; scientific progress solely depends on inquisitiveness and tireless coordination of teamwork. The word research is so attractive for a beginner, the student fraternity is overwhelmed about this process. Irrespective of any field, now the research is becoming an indispensable part of the educational system. This article is intended to create basic awareness about research and its components, especially for the research-oriented students in the field of medical, paramedical, allied health sciences, etc.

Key words: *Research, bioethics, clinical trials, good clinical practice*

Introduction

Biomedical research is based on fundamental biological scientific principles, which will focus on personal healthcare and public health. Basic research is also called as bench side research; it deals with in-vitro and in vivo experimental models involving the organisms or animals to obtain a valid outcome to further try on the humans. When the basic research results are tried on clinical patients it is called translational research, which is solely intended to trial the results of basic research from bench side to bedside, clinically by using patients virtually[1].

Research is practiced by humans since the time of evolution on earth. In history, the ancient practice of folklore medicine stands as the best example for the oldest model for clinical research; with the time it has gradually evolved through trial and error method. India is at the forefront of contributing to the field of clinical research; medical science like Ayurveda, Siddha, Unani; their medical literature has mentioned the use of medications for several human ailments for thousands of years. Based on its principles, Ayurveda has mentioned therapeutic interventions, and a number of herbs and mineral formulations applied directly to the human subjects with the sole purpose of alleviating human sufferings[2,3].

Classification of type of study:

Basic research: the basic medical research deals with understanding the functional, cellular or molecular mechanisms in primates through in vivo or invitro studies.

Preclinical research: preclinical research deals with the study on humans, which further supports the clinical trials on patients.

Clinical research: it is conducted on patients in the hospital or on the selected population; it is supervised by physicians.

What is the research question...?

It is the main inquiry of the issue which needs to be addressed through research. The research question should be clear, targeted and simple.

What is a pilot study...?

It is the study performed on a small scale by using a minimum number of participants/subjects.

This study gives every opportunity to the researcher/ investigator to understand all aspects of the main study including its feasibility, sample size, time duration, troubleshooters, etc.

What are the study parameters...?

Parameters are study exponents in the research; which are later subjected to analysis.

Bioethics

Bioethics deals with the study of ethical dimensions of medicine and biological sciences.

Important principles of bioethics are including Autonomy (respect to self-governing), Beneficence (best interest of the subject), Non-maleficence (causing no harm) and Justice (fair treatment)4

Basic research in non-human primates:

Research on non-human primates is a prerequisite for conducting trials on subsequent levels. Animal experiments mean, the use of animals preferably mammals in the experiments for education and research. The basic experiments use nonhuman primates like rats, mice, rabbits, hamsters, guinea pig, monkey, chimpanzee, dog. It can also be done by using fruit flies, cell lines, fish, etc. There are millions of animals that will be sacrificed worldwide for the sake of research every year. Experiments performed by using both vertebrates and non-vertebrates, but using the vertebrates will be taken into account as they are under more strict ethical vigilance. For research, all these animals should be procured from the authorized breeders who are registered under CPCSEA (committee for control and supervision of experiments on the animal) guidelines or from the recognized higher research centres.

Importance of animal testing in biomedical research

In the field of biomedical research, the use of the animal model experiments stands as "**Hall Mark**" of an interventional research study. The great scientists like Aristotle, Erasistratus Galen, etc. have tried their initial experiments on the animals for scientific purposes[5]. Age back, the use of animals got much attention, particularly to test the surgical procedures or use of drugs or devises before applying them clinically to humans. In spite of heavy criticism by the public and the animal protection activists there is a rise in several basic research experiments on animals; because in history, we have learned about the adverse effects of drugs that were used directly on patients. Causing harm to the animals can't justify the human benefit. But still, animal-based research outcome retains its importance in several aspects including, toxicological studies, where the animal experiment model stands as an inevitable tool in supporting the increasing hierarchy of evidence.

In the present situation to justify the rationality and inevitability of the use of animals in the experiments we need to follow principles of 4R.

Replacement: Use of alternate to animal model Ex: in silico i.e. use of computer modeling, in vitro cell line studies, etc.

Reduction: Method which minimizes the number of animals in experiments

Refinement: It deals with the reduced invasiveness, by adopting improved, non-invasive, non-painful procedures by using the most appropriate methods[6].

Rehabilitation: As a 4th component, the rehabilitation of animals will be done after its justified usage[6].

Toxicity study: it is a branch of science deals with the toxins and poisons and their effect and treatment. As per US food and drug administration (FDA), for the development of a new drug entity, it is essential to conduct toxicity tests in the biological subjects[7].

Trials before regulations

In the olden days, before formulating guidelines for clinical research activities, any individual or group of people would be a part of the research event; it was tried on the helpless community like war prisoners or people who convicted under crime, children, patients, aged people, etc. The direct use of drugs like thalidomide and Elixir Sulfanilamide on humans has resulted in the death of the study participants. Based on such consequences of unethical trials on humans, the present era has formulated a code that is mainly focused on obtaining voluntary consent. **By considering the above discrimination in the clinical research, a judgment formulated with a code known as "Nuremberg code" which has** streamlined the research at all levels with the sole intention to protect the safety and dignity of the participants to achieve more precise and valid outcome[8].

History of Clinical trials

The credit of clinical research goes to a Scottish physician Dr. James Lind, M.D. (1716–1794) has treated the disorder called scurvy in sailors, where patients were presented with the sign of bleeding through their gums. He has noticed that the administration of the orange and lemon has shown drastic improvement in their condition[9].

Regulations of clinical trials:

Good Clinical Practice (GCP): It is an international ethical and scientific standard protocol for conducting biomedical and behavioral research involving human participants; which protects participants' safety, rights and confidentiality at all levels[10].

International Conference on Harmonization (ICH): It is an international council that bringing together the regulatory authorities and pharmaceutical industry to discuss the technical aspects of drug registration. ICH's regulations are intended to achieve greater harmony worldwide to ensure safety, effectiveness, and quality of medicines; which are developed and registered in a hassle-free manner[11].

Institutional Ethics Committee (IEC): It plays a role in appointing members; it will review the protocol and informed consent forms (ICF), and periodic progress of the study[12]

World medical declaration of Helsinki: It is developed by the World Medical Association (WMA) in the year 1964; it is including ethical guidance for physicians and all other participants in the research team involving in clinical trials on human subjects. This rule binds all the research participants to the applicable law under its declaration[13]

Role of the investigator: all trial investigations are conducted by qualified and trained persons who are personally supervising the work.

Sponsor for trials:

The sponsor for a clinical trial may include an individual, an industry, an institution, etc. which takes the responsibility of initiation, management, financing, and auditing. They are also taking the responsibility of subjecting the study participants under sufficient insurance coverage, and compensating the subjects in any untoward incidence or reactions[14].

Role of statistics in research

Since the time of conception of the research protocol, the statistics play an important role to format different components of research like study design, conduct, sample size, data analysis, reporting, etc. they are essential to derive a valid and precise conclusion.

What is the placebo effect...?

Placebo is an inert substance without any therapeutic value; it is used to compare with standard control groups. The psychosomatic profile is an important factor to be considered in assessing the placebo drug response. The placebo effect can be better appreciated in the alleviation of symptoms of the pain rather than any other condition[15].

Clinical trials

Clinical trials are research study on human subjects, which is intended to evaluate the effect of biomedical interventions like vaccines, drugs, treatments, devices, new ways of using known drugs or to study drug interactions, etc. The study may also include the evaluation of behavioral interventions[16].

The ultimate goal of CT is to ascertain the drug safety of the subject, risk and benefit ratio before its final approval for marketing. There are many factors involved in research, out of which some are can be controlled, and some others are beyond one's control. Randomization means being nonselective to any application or intervention. Randomization in clinical trials is considered as the basis for the "Evidence-based Medicine"[17].

Blind experiments

Bias is the main concern of the clinical trials where blinding becomes essential to reduce the bias and increase the validity of the outcome. **Blinding is a process where one or the other participants in the study were deliberately kept unaware of intervention. Blinding is an important factor to ensure objectivity in the clinical trial by avoiding or preventing the conscious and unconscious bias in the study[18].**

Types of blind trials:

Open clinical trials: it is the trial where all the level of study participants in the research group will be knowing the intervention.

Single-blind study: where the subject alone in the research study is unaware of intervention.

Double-blind study: where the subject, as well as the researcher both, are unaware of the intervention

Triple-blind study: where the subject, researcher, and analyser are unaware of intervention.

At the end of the study result analysis, all masked or blinded interventions will be disclosed.

Protection of subjects

The protection of the clinical trial participants at all levels is an important issue. Concerned authorities should take care of all necessary precautions to address personal, social and legal issues during and after completion of trials. Any relevant issues should be addressed, and it should be properly compensated for the loss. It is essential to ensure proper compensation for all the study participants who are involved in the clinical trials.

Importance of Informed Consent (IC)

Clinical trial participants are strictly volunteer in its true sense without coercing them for any benefit.

Informed consent is an important prerequisite before allocating any human subject to the clinical trials. Privacy and confidentially of IC should be maintained in all the circumstances. It is very much essential to know whether the subject is a literate or illiterate, or whether he is fit to give valid consent. The investigator should explain and clarify all the doubts of participants regarding the research protocol before taking consent[19].

Types of clinical trials

Screening trial: screening for the possibility of occurrence of diseases in a healthy population

Prevention trail: it deals with the prevention of disease by using supplements, vaccines, devices, lifestyle modifications, etc.

Diagnostic trail: it deals with the accuracy of the disease

Treatment trail: it deals with the effectiveness of treatment in diseased

Conventionally the CT is having the following phases:

Phase 0: It is an Exploratory Investigational New Drug (IND) Study. It will be conducted first on humans; it is also known as human micro-dosing studies by using the sub-therapeutic dose. It is conducted by using 10-15 numbers of limited volunteer healthy human subjects to understand the pharmacokinetics, pharmacodynamic activity, and safety of a new drug or a molecule.

Phase I or Clinical pharmacology trial: It is also called "First in Man", done in small groups with 20-100 in number in healthy volunteers. It is to assess safety through pharmacovigilance and the details of the pharmacokinetic and pharmacodynamic effects of a drug. Dose escalation trial can give an idea about the appropriate maximum tolerable dose which can be used under subsequent trials.

Phase II or Exploratory Trial; the third phase of the clinical trial can be done in 200-300 number of larger healthy human volunteers. It is done in Phase I A is to assess the clinical efficacy or biological activity, and Phase II B is to assess and match the optimum dose, benefit with minimum side effects

Phase III trial or Confirmatory trial: It is a randomized control multicentric trials in a large number of volunteer patients in a group of 300-3000 or more. Such trials are more expensive, time-consuming and difficult to handle, especially while dealing with chronic disease conditions or disease with a long latency/ incubation period.

Phase IV or Post-marketing surveillance: Called post-marketing surveillance trial. It involves a pharmacovigilance study after receiving permission to market an approved drug. If the drug/treatment is found satisfactory in three phases, then it will be approved under the country's national regulatory authority for its use in the general population. Phase IV trials are invariably always under the research radar. [20,21]

Multicentric clinical trials

It includes a large number of participants from different parts of the world, including a wide range of populations; which will compare the results of different centers.

Accessibility of clinical trial reports

Accessing clinical trial data or information is an important prerequisite to tackle the challenges before considering them under policymaking. Archiving the

clinical trial documents is a must, which helps to analyze the data retrospectively in a systematic manner. Now online updates are available on the registered websites which are developed at the national institute of health under the national library of medicine. CT information is always accessible to any common man, through website clinicaltrials.gov and also through Cochrane Library, it is a collection of databases in medicine and other healthcare specialities22,23. The ultimate goal of accessing the clinical trial results is to introduce newer government policies and regulations to provide improvised health care facilities for the benefit of the population at large.

Conclusion

For a beginner, the present review will highlight the components of basic research, preclinical and clinical research. It has created basic awareness about the ethical factors involved in the research at different levels.

Ethical Clearance: Obtained from Institution ethical committee

Conflict-of-Interest: Nil

Source of Funding: Self funding

Food Insecurity, Standard of Living and Nutritional Status of People Living with HIV/AIDS (PLHAs) on ART: Rural–Urban Differences

Ravishekar N Hiremath[1], Shailaja S Patil[2], DB Kadam[3]

[1]PhD Student, Department of Community, Medicine, Shri B M Patil Medical College, Hospital & amp; Research Centre, BLDE (Deemed to be University), Vijayapura, Karnataka, [2]Professor and Head, Department of Community Medicine, Shri B M Patil, Medical College Hospital & amp; Research Centre, BLDE (Deemed to be University), Vijayapura, Karnataka, [3]Professor and Head (Retd), Department of Medicine, BJ Medical College, Pune, Maharashtra, India

Abstract

Background: Synergistic effect of malnutrition, food insecurity and poor standard of living pour significant changes and poor outcome in already compromised PLHAs due to increased financial burden as well as emotional breakdown.

Objective: To assess the nutritional status , food insecurity and standard of living (SLI) with rural urban differences and their association if any among the PLHAs who have been stablished with one year of treatment

Methodology: A facility based cross-sectional study on PLHAs was carried out in tertiary care centre of western Maharashtra with a sample size of 246. Data was collected by means of pretested semi structured questionnaire after taking Institutional clearance. Strict confidentiality was maintained throughout the study.

Results: The mean age of the study participants was 43.37 years with majority (50.9% rural, 39% Urban) were secondary class educated. Only 20% of urban and 8.5% of rural had income above 10,000 per month. Maximum (48.2 %) of rural were doing heavy works (construction/agricultural) while majority of urban were unemployed (30.5%) followed by business (21%) work. 36.9% (Rural) and 28.6 % (Urban) had spouse positive for HIV status. Even after one year of treatment, only 36.9% rural and 41% urban PLHAs were having CD4 count above 500. 49.6% (Rural) and 46.7% (Urban) were food insecure while 27.7% (Rural) and 14.3% (Urban) had low standard of living. 36.2% (Rural) and 30.5% (Urban) were undernutrition with 51.8% (Rural) and 54.3% (Urban) having abnormal waist circumference. BMI Category had statistically significant association with SLI and food insecurity in urban participants while it was not statistically associated with rural participants

Conclusions: Inspite of freely delivered ART for one year and majority having good adherence rate, there were actionable changes in nutritional changes among PLHAs of both rural and urban areas. Neglected factors like food insecurity and standard of living needs to given special focus to affectively crub the high incidence of undernutrition among them. Immediate long term measures need to be taken to provide them adequate food and basic amenities of life with secure Job status.

Key Words: *HIV, Nutritional status, food insecurity, standard of living*

Introduction

HIV/AIDS is modern day epidemic with estimated total of 36.7 million people living with HIV/AIDS (PLHAs) globally[1] and 21.17 lakhs Nationally[2]. With sustained international focus and recent scientific

advancement, measures are been taken to curtail the epidemic. In this view, Global strategy has been adopted to end the AIDS epidemic by 2030 with zero new HIV infections, HIV related deaths and discrimination and making people live longer healthier life[3].

With the latest WHO and NACO policy of starting the Anti-Retroviral treatment (ART) at the diagnosis level, will go a long run in making PLHAs lead a happy comfortable life similar to any lifestyle disorders like diabetes and hypertension. However there are various other factors which would determine how well PLHAs lead their life and maintain their clinical stability. Important among them are socio-economic conditions and nutritional status which form the pillars for ART accessibility, adherence, action and disease stability per se.

Nutritional status depends on various factors such as food insecurity, standard of living, income status, awareness level, diet-drug interaction, loss of weight due to opportunistic infections and disease per se[4].

Synergistic effect of malnutrition, food insecurity and poor standard of living pour significant changes and poor outcome in already compromised household conditions due to increased financial burden as well as emotional breakdown. With this even a minor amount of weight loss would result in significant morbidity and decreased survival rate among PLHAs[5]. It is also hypothesized that rural people maybe incurring higher impact due to these as compared to urban PLHAs due to lack of resources, income generation and facilities hinting the need for a study these differences. Undernutrition is thus one the significant factor for increased morbidity and mortatality among PLHAs inspite of ART and highlight the importance of measures to be taken to improve nutrition including food security and standard of living in addition of free ART availability[6].

In view of above, this study was carried out among the PLHAs who have been stablished with one year of treatment with the objective to assess the nutritional status , food insecurity and standard of living (SLI) with rural urban differences and their association if any

Methodology

A facility based cross-sectional study on people living with HIV/AIDS was carried out in tertiary care centre of western Maharashtra. Considering the prevalence of food insecurity, undernutrition and Standard of living (SLI) as per previous studies[7,8,9], the sample size was calculated as 246. Adult PLHAs who came for collecting the medicines, after completion of one year of treatment and consented to be part of the study were included in the study based on systematic random selection. PLHAs with permanent residence were taken for the study while migratory PLHAs with opportunistic infections, HIV wasting syndrome and those who didn't consent for the study were excluded. Institutional clearance was obtained, Informed consent was taken from all study participants as per format and strict confidentiality was maintained throughout the study

Data Collection

Data was collected by means of pretested semi structured questionnaire which included basic demographic profile along with anthropometric measurements, clinical parameters, food insecurity scale[10] and parameters assessing household status using standard of living scale[11]. Urban/rural status, Standard of living, food insecurity and nutritional status were the main variables in the study. Data was entered in excel sheet and was analyzed using stata version 10 and rural urban differences among various variables was studied.

Standard of living (SLI) index was defined in terms of ownership of household goods (as per the NFHS-2 survey principals[11]) by adding the nine components (Table 1). Out of total score of 9, household with 1-3 marks were labelled as low SLI, 4 to 6 scores as medium SLI and 7 to 9 scores were labelled as high SLI. All households were categorized into food secure and Food insecure by means of WHO Household food insecurity access scale (HFIAS) Measurement Tool[10]. Nutritional status was categorized into underweight, Normal and overweight based on WHO BMI (Body mass Index) classification for Asians

Results

The mean age of the study participants was 43.37 years with majority (50.9% rural, 39% Urban) were secondary class educated. 22.9% of urban and 8.5% of rural were college and above educated. 20% of urban and only 8.5% of rural had income above 10,000 per month. Maximum (48.2 %) of rural were doing heavy works (construction/agricultural) while majority of urban were unemployed (30.5%) followed by business (21%) work. 36.9% (Rural) and 28.6 % (Urban) had spouse positive for HIV status. 51.1% (rural) and 41% (urban) were female

ART adherence was above 90% (as per pill count) among 89.9% rural and 96.2% urban. Majority (92.4% urban, 89.4% rural) had started their ART at the time of detection. Even after one year of treatment, only 36.9% rural and 41% urban PLHAs were having CD4 count above 500. 49.6% (Rural) and 46.7% (Urban) were food insecure (Fig 2) while 27.7% (Rural) and 14.3% (Urban) had low standard of living (Fig 3). 36.2% (Rural) and 30.5% (Urban) were undernutrition with 51.8% (Rural) and 54.3% (Urban) having abnormal waist circumference. BMI Category had statistically significant association with SLI and food insecurity in urban participants while it was not statistically associated with rural participants

Discussion

Nutritional status has multidimensional effect on HIV disease progression. It hampers immune system, thereby increase the frequency, severity, duration and complications of infections, the symptoms of which lead to increase weight loss and thereby starts the viscous cycle. In our study, in rural areas, majority (36.2%) were undernutrition while in urban areas majority (37.1 %) had normal BMI followed by 32.4% obese/overweight and 30.5% being undernutrition. The higher number of undernutrition in rural areas may be due to most PLHAs in rural areas had income less than 5000 (77.3%) than urban areas (42.8%) and majority were doing Heavy (construction/agriculture) job getting less pay and more energy expenditure. To co-relate undernutrtion, majority (63.1%) of rural had CD4 count less than 500, even after ART of one year.

In a study carried out in Iran by Hamzeh B et al[12], mean BMI of PLHAs men and women was 22.12 and 25.54 KG/m2. Although the malnutrition was seen in 42.2 % but undernutrtion was seen only in 11.08% and rest were obese/overweight. Majority of undernurtion was seen in men and married PLHAs and main reason was low consumption of diet as compared to standard recommendations. In the contrary, in our study, the undernutrtion was quite high (36.2% Rural and 30.5% Urban) with low CD4 counts (less than 500) inspite majority of them had 90% ART adherence for one year,

While another study carried out by Anand D et al[7] in India showed mean BMI of PLHAs was 19.73 KG/m2 with 40 % undernutrtion among PLHAs which was much higher as compared to our study among both rural and urban PLHAs and major reason was poor consumption of diet (both quantity and quality).

Food insecurity being an important marker for malnutrition even in PLHAs. In our study only 50.4% of rural and 53.3% of urban were food secure. The higher percentage of undernutrition in rural (36.2%) and urban (30.5%) areas inspite of one year of free ART probably hints at higher level of food insecurity (Urban – 49.6%, Urban-46.7%) among them. In our study, BMI had statistically significant association with food insecurity among Urban PLHAs only but not the rural ones

Dasgupta P et al[13] in a study in Darjeeling, India showed that 50.9% of the PLHAs were food insecure. Higher education, higher standard of living and males has statistically significantly associated with high food security while poor morbidity status, more people with HIV positive status in family were associated with high food insecurity. PLHAs used to take loans , burrow money from family, friends and banks to cope up with financial hardship.

Gebremichael DY et al[5] conducted a study in Central Ethiopia showed that 23.6% of PLHAs were malnutrition, 35.2% were food insecure. Important factors which led to malnutrition were no job, clinical morbidity, low CD4 counts and opportunistic infections and importantly the food insecurity similar to our study. Similar findings were also seen in a study carried out by Thapa R et al[14] in Nepal where in one out of five PLHAs were undernourished and important contributing factors being low literacy, low CD4 counts, home care, clinical morbidity and opportunistic infections. The study also assessed the Quality of life domains among the PLHAs and found to be statistically significant association with Body mass Index.

Water sources, water processing technique, sanitary facilities, overcrowding and house type which determine the standard of living have an important influence on the health of household members, especially PLHAs. In our study, only 12.1% rural and 15.2% urban were having high standard of living while majority (Rural – 60.3%, Urban -70.5%) were having middle SLI. As per NHFS 2 survey[11], Standard of living index was low in 24.1 % of Urban and 61.7% rural households with Bihar (57%) being highest in low SLI where as in our study on PLHAs households - 27.7% rural and 14.3% urban had low SLI which had influence on nutritional status. We couldn't find any other studies comparing the standard of living among rural and urban PLHAs

Conclusions

Inspite of freely delivered ART for one year and majority having good adherence rate, there were actionable changes in nutritional changes among PLHAs of both rural and urban areas. With freely available ART, the neglected factors like food insecurity and standard of living needs to given special focus among both Urban and rural areas to affectively crub the high incidence of undernutrition among them. Immediate long term measures need to be taken to provide them adequate food and basic amenities of life with secure Job status.

Evaluation of Lung Function in Automobile Diesel Mechanics in a Semi Urban Town of South India-Kumbakonam Urban Rural Epidemiological Study–KURES 6

M.R.Suchitra[1], S. Parthasarathy[2], Mohamed Hanifah[3]

[1]Assistant Professor, Department of Biochemistry and Biosciences, Sastra University, Thanjavur, India, [2]Professor, Department of Anesthesiology, Mahatma Gandhi Medical College and Research Institute., Sri Balaji Vidyapeeth University, Puducherry –India, [3]Associate Professor, Department of General Medicine, Mahatma Gandhi Medical college and research institute., Sri Balaji Vidyapeeth university, Puducherry –India

Abstract

Automobile mechanics are constantly exposed to dust from the exhausts of petrol and diesel. We recruited 50 petrol two wheeler mechanics and subjected them to lung function tests. All were non-smokers without any respiratory symptoms. All mechanics were regular workers with a minimum of three years and at least an exposure of 5 hours of more per day. They were explained about the methodology and asked to attempt three times and the best of three were selected. The incidence of obstructive lung disease (FEV1/FVC< 70%) was only 2%. But the incidence of reduction of effort independent MEF 25- 75 in a significant manner is around 38% which coincided with reduction in PEFR values. [FEV1 = Forced expiratory volume in 1 second. PEFR = peak expiratory flow rate. MEF (25-75) = mean forced expiratory flow between the 25% and 75% of the FVC.] We did not find any correlation with body mass index. We did not resort to analyses of deterioration of lung function with differing exposure years with a low sample size. We suggest that a regular PEFR with practice of established preventive measures may prevent the progress from asymptomatic illness to a symptomatic stage in such health workers.

Keywords: *Spirometry, lung function, automobile, mechanics.*

Introduction

Automobile repair workers of the informal sector are frequently exposed to dusts, chemicals and toxic substances which are harmful to their health. The small auto-body repair workshop is actually an industry in which workers are exposed to hazardous amounts of airborne contaminants. Auto mechanics have risks of inhalational lung injury from both fine and particulate matters, gasoline, petroleum products and many other hydrocarbons[1]. Chattopadyaya [2]has reported an incidence of 25 % obstructive lesions and 21 % restrictive lesions on automobile mechanics. Hence with such a high incidence of abnormalities in lung function tests in the background, we wished to find out the incidence of such defects in our semi urban town of India.

Methods

This observational epidemiological study of lung function among automobile petrol/diesel mechanics was done in a semi urban town of South India in March-2019**.** After approval from the ethics committee (IRBSTH-103/2019), automobile especially two wheeler mechanics working in the small town were enumerated. Among these mechanics, regular workers with a minimum of three years and at least an exposure of 5 hours of more per day were selected. This number was based from an experience from the auto mobile engineer rather any scientific background as there were no earlier clear-cut demarcations regarding this exposure limits in earlier studies. Around sixty seven such persons were spotted out of which seventeen did not give consent for the study. Hence we did pulmonary function tests for all the fifty mechanics who fit into the category of three years and five hours. The study did not include road side mechanics. All the mechanics were studied with --Spirolab-III, a calibrated spirometer with built in computer program; they were explained about the equipment and then the procedure of doing

the test. All the mechanics were given three chances to use and the best test was taken for the study. The study variables were Forced Expiratory Volume in 1 second (FEV1), Forced Vital Capacity (FVC), Peak Expiratory Flow Rate (PEFR), FEF 25-75, age, smoking habit, duration of work, years of experience, and any respiratory symptoms. Considering the literacy of mechanics, the reference values being for non-Indians, we considered a FEV1/FVC % of less than 70 % was significant for obstructive lung disease. Any FVC less than 70% was considered restrictive. We took 70 % as the value to detect any milder form of obstruction in such asymptomatic cases. The incidence of combined diseases was also noted. With such less sample size, we did not resort to sub classifying the same with duration of exposure and lung function. All data were fed into computer and SPSS version 20 was used. Any untoward event was recorded.

Results

Out of the seventy people who fulfilled the inclusion criteria, only, fifty mechanics were willing to undergo the study. The demographic data is tabled in Table 1.

	Mean ± Std.Deviation
Age (years)	37.44 ± 11.4
Weight (kilograms)	65.54 ± 13.69
Height (cm)	155.06 ±11.07
BMI	27.27 ±5.18

All the fifty mechanics were non-smokers without any history of wheezing or allergic bronchitis. The mean years of exposure to dust were 10.46±5.22. The mean hours of exposure per day were 6.38±0.67 hours. The details of lung function among the mechanics are tabled below.

Table 2 showing the pulmonary function test values: (mean±SD)

FVC (litres)	3.48± 0.88
FVC % of predicted	109.3±32.2
FEV1 %	89.22±13.95
FEV1/FVC %	74.83±11.95
PEFR	233.22±89.89
MEF(25-75) litres	2.37±1.03
MEF %	77.06±35.05

FVC = forced vital capacity

FEV1 = Forced expiratory volume in 1 second

PEFR = peak expiratory flow rate.

MEF (25-75) = mean forced expiratory flow between the 25% and 75% of the FVC

From the gross data, it can be easily assumed that there is no gross dysfunction in volumes of mechanics. The values were near normal in majority of mechanics. There was only patient who showed a FEV1/FVC percentage of 66% and hence deemed as obstructive. There was neither a single case of restrictive lesion or combined lesion. The mean PEFR was 233 litres which was less than the expected. Nineteen out of fifty patients had an MEF 25-75 value of less than 70 %. Out of the 19 patients 11 had a value of less than 50%. As such there was no awareness about exposure and lung function in any of the mechanics.

Discussion

Automobile repair mechanics are engaged in a variety of activities which include mechanical work, body repair and reconstruction, re-treading of tyres, spray painting and repair of battery. This work routine exposes them to various occupational health hazards and dangers. In a study of 151 automobile male workers earlier, obstructive impairment was noticed in 25.83% of the workers while restrictive impairment was in 21.19% of the workers. Mixed disease was seen in 10.6% of the workers. The study included smokers and nonsmokers.[2] The incidence in our study was very less compared to them; they have also differentiated the mechanics with age and found out the differences. As such we have not done such comparison. We have found only one case which corresponds to a 2% incidence of obstructive lesion. In a study by Krishnakumar[3] et al, 56.7% of workers had some form of defective pulmonary function. Smoking, increased duration of working hours and years of work showed significant pulmonary impairment. But our incidence is very low. In a few Nigerian studies[4,5], the authors have claimed a reduction of FVC and FEV1 even with five years of exposure. The PEFR was not significantly changed in their study. Dahlquist et al [6]have found out a significant reduction of lung function in mechanics especially exposed to asbestos. As they have found a reduction in major components of pulmonary function tests, they have not looked into the details of MEF 25 even though those values were also decreased. In our case there was a significant reduction of MEF-25-75 up to 38% of cases. The basic difference is that all our

cases were non-smokers and there were no confounding variables as such like any other irritant exposure. Alex et al[7] have also demonstrated a decreased lung function among petroleum product workers. They had a 50 % incidence of lung symptoms. In our study there was no symptom in any of the cases. There were nineteen cases of a significant decrease in the MEF 25-75 values. In these patients we had a significant reduction of PEFR of less than 250 litres. Hence in our study, the PEFR and MEF 25-75 values coincided and a reduction was found in both values. Our study was restricted to asymptomatic two wheeler mechanics and hence the sample size was low. Parker[8] et al had described an incidence of 25 % of obstructive lung diseases in automobile workers. In the same study, they had only FEV1/FVC ratio as a marker of obstruction as a fiftieth percentile. There was no mention about MEF 25-75. Marseglia GL[8] et al have described that MEF 25-75 is early marker of pulmonary dysfunction especially allergic bronchitis. Hence in our case study, we have found out the values of MEF 25-75 were significantly decreased. The limitations of our study were the sample size and absence of age, weight matched controls in the same population. The major new finding which we have found in our study is the reduction of MEF 25- 75 which is an effort independent lung function being affected in our cases. Hence by virtue of age, physical exercise and motivation, the performance of FEV1/FVC may be altered while MEF 25- 75 can't be changed by effort[9]. We had also found that PEFR correlated with MEF 25-75 values. In only one study by Anupama et al[10], they have noted FEF25-75 and found a decrease in 8.57 % which is far less than our results. In our study the average BMI was around 27. There were only three cases of BMI more than 35 all of which showed decrease in PEFR and MEF 25-75 but the FEV1 were normal in these cases. Hence we deduced that the BMI is not affecting the results of our study even though we can't comment with authority as the sample size was low. We planned to take up both petrol and diesel vehicles, but we could muster mechanics with exposure to petrol exhausts only. The exposure to such exhausts alone and decreased lung function has not been studied earlier.

Conclusion

The awareness about allergen exposure and lung function is absent among mechanics. The incidence of obstructive lung disease (FEV1/FVC reduction below 70%) in automobile mechanics is only 2 %. But there was a significant decrease in an effort independent function (i.e MEF25-75) in 38% of cases, which is an early sign of allergen exposure. The PEFR values coincided with reduction of MEF 25-75 values. We suggest that a routine PEFR testing can be done in such workers and protective measures can be taken to prevent the progress to a significant symptomatic deterioration of lung function in automobile mechanics.

Estimation of Thyroid Stimulating Hormone Level in Normal Female School Children in A Semi Urban Indian Town-Kumbakonam Urban Rural Epidemiological Study-KURES-2

M.R.Suchitra[1], T.S.Shanthi[2], S. Parthasarathy[3]

[1]Assistant Professor, Department of Biochemistry and Nutrition,, SASTRA University, India, [2]Consultant Obstetrician, ST Hospital, Kumbakonam, [3]Professor, Department of anesthesiology, Mahatma Gandhi Medical College and Research Institute, Sri Balaji Vidyapeeth university, Puducherry –India

Abstract

Symptoms of thyroid dysfunction are non-specific, yet common and hence screening for abnormalities becomes a necessity. To identify subclinical thyroid dysfunction and offer them the correct medical treatment especially in adolescent female children is an excellent option as a public health prophylactic measure. Hence in this study, we sampled 264 asymptomatic school female children for TSH and found an incidence of 3.4% of high TSH (>5). On the other side, the lower values were found in six (if TSH <0.5) or only two children (if TSH < 0.4). The mean with standard error of TSH values were 2.99 ±0.567. The fasting status was not complied with, and all were random blood samples. All children with abnormal results were counselled with parents and necessary medical advice given. This prevalence is the lowest among similar studies done in any Asian country which is a new finding in our study. Only one child showed a value of 150 who was given drugs and followed up. We theorize that this lesser incidence may be partly due to the study being done in a delta area of a semiurban town.

Key words*: children, female, TSH, hypothyroidism, subclinical,*

Introduction

Subclinical hypothyroidism (SCH) is more a biochemical than a clinical condition which is characterized by serum levels of Thyroid Stimulating Hormone (TSH) above the defined upper limit of reference range, but with normal concentration of thyroid hormones. There are no frank clinical features of hypothyroidism. It's still not clear that these clinically normal children will go in future to develop increased incidence of complications. As such there are very few studies which randomly sample normal children in Indian semi urban population. In a study of young females in south India[1], the incidence of thyroid dysfunction is around 11.7%. There are a few studies which state that the incidence of subclinical hypothyroidism is around 4.15 to 13 % in Asian pregnant population[2,3]. In view of such variations, we proposed to conduct estimation of TSH levels in normal asymptomatic female school children in kumbakonam, a semiurban town of South India.

Aims

The primary aim was to find out the incidence of subclinical hypothyroidism in female school children in kumbakonam , a semiurban town of India.

The other aims were to counsel the students and parents and the need for drug therapy in affected children

Material and Methods:

This prospective epidemiological observational study was conducted in a semiurban town of India

with a population of 150000 in October 2018. It was done in school going female children between 15 – 17 years of age. The institutional review board (IRBSTH 02/2018) has approved the proposal to conduct the study. The administration of the school has accepted to conduct the study. The procedure of collecting blood from children was explained to parents in vernacular language and consent was obtained from each of them. TSH assay was done in all the collected blood samples as a screening test for thyroid disease. TSH assay was done using electro chemiluminescence immunoassay to the accuracy guidelines given by WHO as standard.

Abnormal TSH values were grouped into two categories:

• TSH elevation: TSH of more than 5 mIU/ml

• Suppressed TSH: TSH <0.4 mIU/ml.

All the subjects with abnormal TSH were instructed to come for follow-up with parents for further testing and advice.

Statistics

With a town population of 150000 and a target population of 3500 of the age group described above, the application of Qualtrix software in sample size estimation for epidemiological studies was done. For a study to have 90 % confidence level and a margin of error 5 %, a sample size of 252 was necessary. Hence a sample size of 264 was made in our study. All data were entered in an excel spread sheet and fed into the statistics software SPSS 20.0 for descriptive statistics and confidence intervals.

Results

All the 264 subjects completed the study. There were no untoward events. All the children were females in the age group of 15-17. The mean with standard error of TSH values were 2.99 ±0.567. The descriptive statistics is tabled below (see Table 1). Only 9 children out of 264 had a TSH value of more than 5. The incidence of abnormally high TSH is 3.4 %. One child had a value of 150, yet she did not have symptoms. Only two out of 264, had a value less than 0.4. but children with values between 0.4 and 0.5 were four in number. Hence If 0.5 had been the cut off for a low TSH , 6 out of 264 had a low TSH values which is around 2.27%.Hence the abnormal TSH values overall is only 5.67%. The parents were called and a counselling session was held along with students giving them proper advice regarding drug intake and further tests.

Table 1 showing descriptive statistics

			Statistic	Std. Error

	Kurtosis		248.642	.299

Discussion

The prevalence of thyroid disorders especially subtle subclinical dysfunctions depends on a number of factors such as age, sex, geographical factors and iodine intake. The focus should be young females, as a lot of menstrual problems with infertility is on the rise with a possible link with thyroid disorders. Nair et al [4]demonstrated that TSH levels showed a statistically significant decrease postprandial when compared to fasting values. Our samples were taken randomly. Early and effective treatment of any thyroid disorder will ensure a safe pregnancy with minimal maternal and neonatal complications[5]. Hence any screening at the age of 15 – 17 and their correction may be highly useful in reducing infertility and pregnancy associated complications. Hence in this study, we focussed on adolescent female children. Kumaravel et al[1] have shown a prevalence of TSH abnormalities in young females as 12.5 % with a higher TSH in 9.7 %. In a study in Lebanese children[6], the prevalence was found to be 5.4%- 5.7 %. The mean serum TSH 2·57–3·6 mIU/l for boys and 1·83–3·58 mIU/l for girls in an Indian study by Marvaho et al[7], But our study proved the subclinical hypothyroid values to be less than that of the earlier studies to be only 3.4%. But the prevalence of lower TSH values coincides with earlier studies by kumaravel et al. In yet another study in Indian population, the prevalence of high TSH is around 7.7 %. The authors have also correlated the TSH values with abnormal lipid profiles which we have not done[8]. Many of the studies were not clearly mentioning the timing of taking the blood sample whether it's fasting or postprandial. We conducted the study in children where they have taken a very mild breakfast 4 hours ago. We consciously omitted children from the study who have symptoms and are on thyroid drugs. One patient of our study where the TSH was 150 also did not know she was a hypothyroid. She was prescribed drugs with a follow up advice of a complete thyroid profile check-up along with antibody titres. None of the children with subclinical thyroid dysfunction had goitre in our study. We did not enquire whether they are on iodine rich diet or not, as the area of the study is a delta. Nonrandomized continuous sampling may be a limitation in our study. Only two out of 264 children had a TSH value below 0.4 which is also less than the earlier studies. These patients were also advised to have follow up for full thyroid profile testing.

Conclusion

In a sample epidemiological survey of subclinical hypothyroidism in asymptomatic semi urban school female children of India, we found a mean TSH value of 2.99 mIU/l. Lower TSH values (<0.4) were noted only in two children. The prevalence of subclinical hypothyroidism (TSH >5) was 3.4% only which is far less than the previous studies. We probably hypothesize that the decreased incidence may be due to the fact that study being conducted in a delta area of a semiurban town.

Financial Support – Partly funded by Rotary club of kumbakonam grand and KRG nursing home kumbakonam.

Conflict of Interest – Nil

Dr. MRS designed and conducted the study. DR.TSS helped in data collection. Dr. SPS did the supervision with write up.

A Review on Medical Tourism in India

S.Gunaseelan[1], N.Kesavan[2]

[1]Assistant Professor, Department of Commerce, Vels Institute of Science, Technology and Advanced Studies, Pallavaram, Chennai; [2]Assistant Professor, Department of Commerce, Annamalai University, Deputed to Sethupathy Govt. Arts College, Ramanathapuram

Abstract

Developing country India is the place for medication at an affordable cost than other developed countries in the world. The tourists have been visiting India along with aim of medication needs in various sources of Indian medication services. The Yoga, Ayurveda, Unani, Homeopathy, Siddha, spiritual medication, Mooligai hills station hospitality services and government of India has been providing multi-specialty and higher medical services to the general public at a cheaper cost. The state governments of India and union territory governments are also doing the medication services to the residents of India and also NRIs. Along with the stream of medication service, the private sectors have emerged in a higher end level of medication services as corporate as well as general public utility services with an affordable cost spent by the beneficiaries along with the government health insurance schemes assistances. These infrastructures of India is looking ahead the other countries are mostly utilized the medication services. These are increased now a day, through medical tourism. There is an evident in Indian economy the tourism is one of the indicators to enhance the GDP, among the general tourism, medical tourism is a major apportion of economic resources scattered throughout the country. Particularly in Tamilnadu, Chennai, Coimbatore, Madurai, and Vellore are the major cities attracted other countries people have frequently visited hospitals of government and private corporate hospitals with good results. The present article revealed the previous studies in health tourism in India.

Keywords: *Medication, Tourism, Reviews of Medical Tourism*

Introduction

Tourism is a relaxation of human being visiting various parts/places of the world after attaining certain needs as per their financial strengths. But, in the case of medical tourism is a need of patients and their capacities in the ground of financial supports to take the medical treatment. The tourism is in the behind of various modes of transports. The selection of medical tourism is also impacted on the time, demand, money, availability, political, natural calamities, national securities and other uncontrollable economic conditions. In this juncture, authors have revealed previous studies in the field of medical tourism in India for the past two decades from 1999 to 2018. The authors have collected the previous studies from the available information from the various sources of books, journals, magazines, newspapers, and websites.

Medical Tourism

The concept of medical tourism has interlinked with marketing, finance, insurance, transport, corporate, human resources and other electronics communication and technology. The wellness tourism is the emerging marketing environments booming in an exuberant level due to corporate investors are concentrating medication industries. It results, franchise of corporate hospitals promulgated new ventures on different facilities (transport, residence, physicians, guides and assistances, medical technicians, labs and diagnosis centre and the like) linked with medication industries in certain packages as per the needs of the customers/patients.

Support of Medical Tourism

There are several supporting systems have been done for the betterment of medical tourism such as medical educational institutes conducting seminar, workshop and symposia; government initiations on publicity and promotional activities for the medical tourism. Many of the international brands are promoting the medical tourism (Incredible India, and Wellness or Medical Tourism Service Providers).

Present Scenario of Indian Health Care Sector[1]

With increasing urbanisation and problems related to modern-day living in urban settings, currently, about 50 per cent of spending on in-patient beds is for lifestyle diseases; this has increased the demand for specialised care. In India, lifestyle diseases have replaced traditional health problems. Most lifestyle diseases are caused by high cholesterol, high blood pressure, obesity, poor diet and alcohol Vaatsalya Healthcare is one of the first hospital chains to start focus on Tier 2 and Tier 3 for expansion. To encourage the private sector to establish hospitals in these cities, the government has relaxed the taxes on these hospitals for the first five years. Many healthcare players such as Fortis and Manipal Group are entering management contracts to provide an additional revenue stream to hospitals. Telemedicine is a fast-emerging sector in India; major hospitals (Apollo, AIIMS, Narayana Hrudayalaya) have adopted telemedicine services and entered into a number of PPPs. As of FY16, telemedicine market in India was valued at US$ 15 million and is expected to rise at a CAGR of 20 per cent during FY16-20, reaching to US$ 32 million by 2020.

Telemedicine can bridge the rural-urban divide in terms of medical facilities, extending low-cost consultation and diagnosis facilities to the remotest of areas via high-speed internet and telecommunication. Developments in information technology (IT) and integration with medical electronics, has made it possible to provide high quality medical care at home at affordable prices. It enables the customers to save upto 20-50 per cent of the cost. The home healthcare market stood at US$ 3.2 billion in 2016 and is estimated to reach US$ 4.46 billion by the end of 2018 and US$ 6.21 billion by 2020.

In FY18 (till September 2017), gross direct premium income from health insurance stood at 23.90per cent of overall gross direct premium income for non life insurance segment. Health insurance is gaining momentum in India; witnessing growth at a CAGR of 23.6 per cent during FY15-17. Gross healthcare insurance premium in the month of September 2017 stood at US$ 2.7 billion. Strong mobile technology infrastructure and launch of 4G is expected to drive mobile health initiatives in the country.

Cycle tel Humsafar is a SMS based mobile service designed for women, it enables women to plan their family in a better way. Mobile health industry in India is expected to reach US$ 0.6 billion by 2017. Digital Health Knowledge Resources, Electronic Medical Record, Mobile Healthcare, Electronic Health Record, Hospital Information System, PRACTO, Technology-enabled care, telemedicine and Hospital Management Information Systems are some of the technologies gaining wide acceptance in the sector. AIIMS has converts all its payment transaction as cashless, for which it has associated with mobile wallet company. (MobiKwik, in January 2017) A new trend is emerging as luxury offerings in healthcare sector. More than essential requirements, healthcare providers are making offerings of luxurious services. For example: pick and drop services for patient by private helicopters and luxurious arrangements for visitors to patient in hospital. The Indian medical tourism industry is expected to reach US$ 6 billion by 2018 from US$ 3.0 billion in April 2017, growing at a CAGR of 27 per cent over 2013-16. The number of foreign tourists coming to India for medical purposes rose by almost 50 per cent to 201,333 in 2016 from 134,344 in 2015. Cost of surgery in India is nearly one-tenth of the cost in developed countries. There are 21 Joint Commission International (JCI) - accredited hospitals in India and growing.[2]

Reviews of Literature

Literature evident is the base of conceptual and civilized development. The followings table consisted relevant literatures in the aspects of medical or wellness tourism. The table also segregates as name of the author(s), year of publication, subject area of medical tourism, problems, findings, suggestions, and conclusion.

Table.no.1

Name of the Author	Year	Title	Findings/Problems/Suggestions	Factor
Lydie Ehouman et al	2002	Tamil Nadu: The Path to Becoming India's Leading State	Tamil Nadu has immense natural and cultural resources, giving it great potential to launch into one of India's - and even the regions-top tourist destinations. Furthermore, ICT/ biotech development and direct foreign investment can be tapped into both for ICT solutions to tourism management and marketing challenges, and as a source of financing high-level travelers.	ICT/biotech development and direct foreign investment
The Hindu News	2009	Top Indian hospitals woo medical tourism from Canada	India has launched a big initiative to woo medical tourism from Canada, showcasing the country's high-end and much cheaper healthcare industry to Canadians. Lots of Canadians are already coming to India for medical treatment because of long waiting period here...even for an MRI you have to wait for three to four months. After the IT sector, the Indian medical tourism sector is the next big thing.	High-end and much cheaper healthcare
Tamilnadu Govt. Policy Note	2011	Tourism and Culture Department, Tourism Policy Note 2010-2011	A large number of corporate hospitals and specialized Government hospitals make the State world renowned for cost effective treatment and postoperative facilities. There are three important components that make Tamil Nadu a favoured medical tourism spot. There is no waiting time for the patients. The cost of treatment is less compared to the West. The patients can convalesce at their convenience in the hospitals. Specialised doctors and well equipped Para-medical staff have made this possible by their dedicated efforts.	Time, Cost, convalesce and Physicians Conveniences
Richard Smith et al	2011	Medical tourism: A review of the literature and analysis of a role for bi-lateral trade	Priority needs to be given to data capture, both in individual countries and in the international system. Without data, it will be impossible to assess the impact of opening trade in health services on the importing and exporting countries. Further, countries need to consider aspects of trade from the perspective of greater bi-lateral initiatives, weighing up possible benefits and risks from engaging in trade relationships with different countries individually.	Need of Data
Rose Mary	2014	Medical Tourism in India-Its Strength, Weakness, Opportunities and Threats	The growth of medical tourism in India contributes for the development of infrastructure in medical facilities, medical sciences, national income, employment opportunities and urbanization. Study has argued to minimize or reduce the adverse effects of medical tourism through proper policy framework.	infrastructure in medical facilities and policy framework
Lakhvinder Singh	2014	An evaluation of medical tourism in India	Medical tourism providers should try to maintain service quality and vigorously strive to make India the world leader in medical tourism, a path it is certainly on.	Service Quality

Conclusion

From the above Meta analysis of review of literature authors have found that the Indian medical tourism is expected to meet the challenges, such as Branding, Cost of medication, Fake insurance claims, FDI, Foreign exchange, Hospital standardization and policy framework, Infrastructural development of the Medication Service Provider (MSP), Need of data of Indian MSP, Need of expertise, New structure of medical tourism, Packages, Policy framework of government, Service quality and Supporting health care. Hence, the new research on medical tourism should focus the above area will give a fruitful idea to develop the medical

tourism in India.

Ophthalmomyiasis Due to Oestrus Ovis Complicated with Methicillin Ressistant Staphylococcus Aureus First Report Near Coastal Area

Shaik Khaja Moinuddin[1], Anandi.V, Amirtha C[2]

[1]Research Scholar, [2]Professor, Department of Microbiology, Vinayaka missions medical college &Hospital, Karaikal, Puducherry, India, [3]MS (OG) Post graduate, Balaji medical college and hospital, Chennai, India

Abstract

Ophthalmomyiasis, is the infestation of any anatomic structure of the eye. Larvae of sheep nasal botfly, Oestrus ovis is the most common cause of human ophthalmomyiasis. A 19-year-old male, presented to the ophthalmology outpatient department with a 1 day history of moving foreign body sensation, redness, and excessive watering from his right eye. Multiple larvae were found on bulbar conjunctiva. Larvae were removed and identified as *Oestrus ovis*. Bacterial infection was proved by isolating a heavy growth of methicillin resistant Staphylococcus aureus(MRSA) from conjuctival swabs. Dsual infection of parasitic and bacterial infection of young male adult is proved and also found to be a rare dual manifestation of eye. Hence this case is being reported here.

Key words: *Dual infection, Oestrus ovis, Staphylococcus aureus.*

Introduction

Myiasis is the term applicable to the infestation of human beings and other vertebrates with the larvae (maggots) of Diptera flies. Different parts of the human body may get affect due to myiasis infestation. Most commonly skin and body cavities (mouth, nostrils, ear and eye.). Involvement of any anatomical site of eye is called as Ophthalmomyiasis. [1] Larvae, most commonly, attack the external surface of the eyes or ocular adnexia, e.g. the lids, conjunctiva or lacrimal ducts (external ophthalmomyiasis). In uncommon instances they may penetrate into the eyeball itself (internal ophthalmomyiasis) or may involve the orbit (orbital myiasis).[2] From different parts of the world ophthalmomyiasis have been reported. [3]. Mostly reported were from rural areas and had history of contact with cattle. [4] Oestrus ovis is the most common cause of human ophthalmomyiasis.[5] Dual infection due to Oestrus ovis and Staphylococcal infections have not been reported in Indian literature and is being reported here as a rare case report.

Case Report

A 19 year-old male, fisherman by occupation, presented to the ophthalmology outpatient department with a 1-day history of moving foreign body sensation, redness, and excessive watering from his right eye, following insect hit into his eye while riding motor bike through sheep raising areas. He gave no past history of ocular or medical problems.

On examination, his visual acuity was 20/20 in both eyes. Eyelids of the affected eye were absolutely normal. The conjunctiva was mildly congested with profuse lacrimation. On slit-lamp examination, multiple, tiny and translucent worms, 1–2 mm in size, crawling over the bulbar conjunctiva were seen. Anterior chamber was found to be normal. Using 4% xylocaine drops as topical anesthesia, 8 worms were removed manually with the help of sterile forceps. While removing worms mechanically with the help of forceps, they were tightly adhering to the bulbar conjunctiva. After removal of all larvae, three swabs were collected for bacteriological

and mycological culture. Two swabs were inoculated on bacteriological media such as blood agar, chocolate agar and Mac Conkey agar. One swab was inoculated on Sabouraud s dextrose agar and processed according to standard microbiological procedures.[6]

Laboratory findings:

On microscopic examination, spindle-shaped skeleton with multiple segments and intersegmental spine bands were seen. The larvae also showed a pair of sharp dark brown oral hooks and tufts of numerous brown hooks on the anterior margin of each body segment and they were identified as *Oestrus ovis.[Figure]*

Staphylococcus aureus was isolated from bacteriological media was found to be methicillin resistant Staphylococci and it was sensitive to, chloramphenicol, Moxifloxacin and cefazolin. No fungus was isolated from Sabouraud dextrose agar even after 14 days.

The patient improved dramatically after a mechanical removal of the larvae and a topical application of antibiotic (Moxifloxacin) –steroid combination therapy. When the patient came for a follow-up after five days, he was completely relieved of his symptoms of foreign body sensation and excessive watering.

Oestrus ovis larvae

Discussion

Hope was the first person to describe myiasis. [7] Worldwide, human myiasis is distributed with various species and larger abundance in poor socioeconomic areas of tropical and semitropical countries. [2] Ocular involvement happens in less than 5 percent of all cases of human myiasis. [8] The most common cause of external ophthalmomyiasis is the larvae of sheep botfly, *Oestrus ovis* Other agents involved in causing myiasis are *Rhinoestrus purpureus* , *Dermatobia. hominis* , *Chrysomya. bezziana* , *Lucilia* spp. , and *Cuterebra*[2]

Morphologically adult bot fly resembles honeybee, which is yellow to gray brown, 10– 12 millimeters long. The gravid fly deposits larvae (Oestrus ovis) in or around the nostrils of cattle (host). These early stage larvae (first instar) deposited, adheres to the mucous membranes within the nasal cavities, then transform to second instars and crawl till the sinuses, where they develop further and mature into third instars, which are shed out for pupation under the soil [9]. The life cycle of this parasite is variable, from couple of weeks to many months, depending on changes in the atmosphere. [10]

Man is accidental host, with the eye being point of adherence for larvae. In man, the larvae cannot be alive beyond the early larval stage and are believed to die within ten days if not taken out [11] Although the threat of orbital penetration and future serious consequences seems to be low, it is prudent to get rid of the larvae from the mucosa of conjunctiva promptly.

External ophthalmomyiasis usually presents with ocular itching, foreign body sensation and a watery-mucopurulent discharge confined to the conjunctiva. [11] Draining of conjunctival sac with saline is ineffective in cleasing out the larvae. Larvae hold the conjunctiva firmly with the help of tiny spines on its outer surface and anterior hooks. Possibilities of misdiagnosis as viral or allergic conjunctivitis is not uncommon. External ophthalmomyiasis typically happens in the summer and autumn which differs from other microbial conjunctivitis, which may occur throughout the year.

A heavy growth of Staphylococcus aureus was isolated from conjunctival swab after 24 hours of incubation at 37 ^{0} C. Based on this preliminary report of Staphylococcus aureus, the patient was started on moxifloxacin and the patient recovered completely. Antibiotic susceptibility testing by Kirby Bauer disk diffusion method also revealed susceptible to moxifloxacin. The patient had bacterial infection following the traumatic episode by the bot fly which could be during the hit by the bot fly or due to the rubbing of the eye by the patient.

Conclusion

A rare case of co infection of external ophthalmomyiasis due to Oestrus ovis and methicillin

resistant Staphylococcus aureus(MRSA). Early diagnosis and prompt initiation of appropriate interventional procedure to remove the Oestrus ovis and anti bacterial treatment saved an eye.

A Descriptive Study to Assess the Effect of Habitual Usage of Mobile Phone on the Sleep Quality among Adolescents in Selected Colleges, Chennai

Sandhya R[1], Sujitha Jebarose T[1]

[1]Assistant Professor, Faculty of Nursing, Dr.M.G.R. Educational and Research Institute, Chennai

Abstract

Background: Smartphone has become an indispensable part of our day to day living due to its countless advantages. This habituated the people to become more dependent on mobile phones especially the adolescent age group. They become addicted to mobile technology which in turn declines their cognitive function , academic performance and a poor sleep pattern.

Objective: The purpose/ intention of the study is to assess the sleep disturbances due to the use of mobile phones especially in the night among adolescents.

Materials & Method: A descriptive study conducted on students from selected arts and science colleges in Chennai. The sample size was 100 adolescents selected through simple random sampling technique. Mobile phone use questionnaire, Modified Pittsburgh sleep quality index (PSQI) were used to Assess the Effect of Habitual Usage of Mobile Phone on the Sleep Quality

Results : The results revealed that most of them (38%) received text messages every night, majority of them (43%) sent text messages every night . Majority of them (55%) have experienced sleep latency and sleep disturbances (atleast once a week), most of them (53%) had varied sleep duration. This study analyzed that use of mobile phone every night is significantly associated with quality of sleep at $P < 0.001$ (highly significant)

Conclusion: This study findings shows that habitual usage of mobile phones during night especially after lights are out invariably affects the sleep quality among adolescents

KeyWords: *mobile Phones ,sleep quality,adolescents.*

Introduction

Background: Mobile devices have become widely prevalent over the past decade, the declining cost and increasing computational power of mobile devices, such as smart phones and tablet computers, has created a revolution in personal communications[(1)(10)]. Mobile devices have a remarkable ease of access due to instant-on technology. Adolescents are at an age where good quality sleep, mental and physical wellbeing is of utmost importance. Sadly, to keep up with today's fast paced, technologically oriented society, they engage in habitual mobile phone use which affects their cognitive function and general wellbeing. "It is believed that sleep is a restorative process and a basic biologic need," said Dr. Neil Kline, "When humans are deprived of sleep, there are many body systems that fail. Not only do our performance, memory and attention span suffer, our immune system and endocrine system is also impaired." Deep sleep is essential as it is the time when the body rejuvenates cells and repairs damage suffered during the day. Melatonin, a hormone which regulates the sleep is suppressed due to the exposure of blue light from the

mobile screen. This causes intruption in the initiation and regulation of sleep cycle.

Habitual use of cell phones late at night after lights are out is particularly popular among younger generations for talking or mailing messages. Moreover, it is a mere entertainment object and serves to keep them in constant contact with their peers. Due to uncontrolled use of mobile devices they become dependent to it termed as Nomo phobia. Difficulty in "shutting off" leads to various sleep disturbances leading to insomnia , tiredness , headache, dizziness, irritability. This lack of sleep can result in attention disorders and poor academic performance in adolescents.

A cross sectional study was done by Munezawa et al., 2011[2] in order to find out the association between the use of mobile phones after lights out and sleep disturbances among Japanese adolescents. The study findings revealed that mobile phone use after lights out has significant association with all forms of sleep disturbance.

The recent studies reported that the habitual mobile phone usage causes marked decline in academic performance[3]. Li et al. (2015) reported that under graduate students (n = 516) participated in the study by competing the validated surveys assessing their cell phone use, locus of control, sleep quality, academic performance, and reduced subjective well-being. This study concluded that use of the cell phone in the class, and at bedtime has a negative effect on sleep quality and academic performance.

Fossum et al., 2014; Li et al., 2015; Exelmans & Van den Bulk, (2016)[4] examined the association between the use of a television, computer, gaming console, tablet, mobile phone, or audio player in bed before going to sleep with insomnia, daytime sleepiness among 532 students aged 18 - 39. The results showed that mobile phone usage for playing/surfing/texting was positively associated with insomnia

Hence, it is important to have an accurate understanding of the impact of mobile phone on health to develop strategies to overcome the adverse effects and enhance the quality of life.

Objective

To assess the Impact of Mobile Phone Usage on the Sleep Quality among adolescents.

Materials and Method

The present study was a descriptive study conducted on students from selected arts and science colleges in Chennai. The sample size was 100 adolescents selected through simple random sampling technique. Data was collected using a demographic questionnaire, mobile phone use questionnaire , Modified Pittsburgh sleep quality index . Ethical commitee clearence was obtained from Institutional Review Board (IRB). The aim and the purpose of this study was explained to the study participants and the confidentiality was assured to them. Data was collected by the above said questionnaire.

Results

Overall, 100 students participated in this study, of which, 62% were females and 38% were males, 48% were aged 18 – 20 years, 52% were aged between 20 – 22 years,95% were single, 5% got married. Out of 100 students, 50% are studying literature, 50% are studying computer science. Majority of the students 83% did not have any other occupation, while 17% are working besides studying.

Table 1: Frequency and Percentage Distribution of Mobile Phone Usage among Adolescents

Type of Use	Every Night	More Than Once in a Week	Once in a week	1 - 3 Times in a Month	Never
Receiving text messages	38 (38 %)	30(30%)	20 (20%)	7 (7%)	5(5%)
Sending text messages	43 (43%)	37 (37%)	8 (8%)	8(8%)	4(4%)
Receiving phone calls	26 (26%)	30 (30%)	25 (25%)	10 (10%)	9(9%)
Calling	18 (18%)	15 (15%)	30 (30%)	20 (20%)	15 (15%)

The above table depicts that, Most of them (38%) receive text messages every night, majority of them (43%) send text messages every night , while 4% of the study participants never send text messages in the night.26% of the study participants receive phone calls every night while 30% receive phone calls in the night more than once a week and 9 % of the study participants never receive phone calls in the night. Approximately 30% of them make phone calls once in a week during night time, while 18% make phone calls every night and 15% never make calls in the night.

Table 2: Frequency and Percentage Distribution of the Sleep Quality among Adolescents

Components of Pittsburgh Sleep Quality Index	Frequency and percentage	Mean and standard deviation
Sleep latency	55 (55%)	M- 2.12,SD - 0.81
Sleep duration	53 (53%)	M-2.17 , SD – 0.80
Sleep disturbance (at least once a week)	55 (55%)	M- 2.29 , SD – 0.73
Habitual sleep efficiency	30 (30%)	M- 2.56 , SD – 0.50
Subjective sleep quality	17 (17%)	M- 2.7, SD – 0.56
Use of sleep medications (at least once a week)	0	0
Daytime dysfunction (at least once a week)	30 (30%)	M- 2.7 ,SD -0.47
		M- 14.14 SD- 3.92

The above table depicts that majority of them (55%) have experienced sleep latency and sleep disturbances (atleast once a week) ,most of them (53%) had varied sleep duration , 30 % of them had day time dysfunction and habitual sleep efficiency is reduced but none were using sleep medications

Table 3: Association Between Mobile phone usage and the sleep quality

Mobile phone usage	Sleep quality	
	Chi square	P value
Every Night	11.45*	0.001* (Significant)
More Than Once a Week	7.65	0.01
Once a Week	6.75	0.01
1 - 3 Times a Month	2.04	0.10

It is inferred from the above table that use of mobile phone every night is significantly associated with disturbances in the quality of sleep at $P < 0.001$ (highly significant).

Discussion

Overall, 100 students participated in this study, of which, 62% were females and 38% were males, 48% were aged 18 – 20 years, 52% were aged between 20 – 22 years,85% were single, 15% got married. Out of 100 students, 50% are studying literature, 50% are studying computer science. Majority of the students 83% did not have any other occupation, while 17% are working besides studying.

Frequency and Percentage Distribution of Mobile Phone Usage among Adolescents

Most of them (38%) receive text messages every night, majority of them (43%) send text messages every night, while 4% of the study participants never send text messages in the night.26% of the study participants receive phone calls every night while 30% receive phone calls in the night more than once a week and 9 % of the study participants never receive phone calls in the night. Approximately 30% of them make phone calls once in a week during night time, while 18% make phone calls every night and 15% never make calls in the night.

Davey S, Davey A. (2014)[5].conducted a mixed method study to assess the smart phone addiction among adolescents and its consequent impact on their health. Systematic review was done using websites of

EMBASE, MEDLINE, PubMed, Global Health, Psyc-INFO, Biomed-Central, and Web of Science, Cochrane Library, and world library - World-Cat, Indian libraries such as National Medical Library of India from 1 January, 1995 to March 31, 2014. Finally, meta-analysis on only Indian studies was done using Med-Calc online software. A total of 45 articles were considered in systematic-review globally; later on 6 studies out of these 45 related to Smartphone's addiction in India were extracted to perform meta-analysis, in which total 1304 participants (range: 165-335) were enrolled. The smart phone addiction magnitude in India ranged from 39% to 44% as per fixed effects calculated ($P < 0.0001$). Smartphone addiction damages the interpersonal skills and can lead to significant negative health risks and harmful psychological effects among Indian adolescents.

The Present study conducted is also among adolescents who are at an urge of smart phone addiction.

Frequency and Percentage Distribution of the Sleep Quality among Adolescents

Majority of them (55%) have experienced sleep latency and sleep disturbances (at least once a week) ,most of them (53%) had varied sleep duration , 30 % of them had day time dysfunction and habitual sleep efficiency is reduced but none were using sleep medications.

The results are consistent with a study conducted by Orzech K, Grandner M, et.al (2016)[6]. Aimed at investigating the association between the self-reported sleep patterns and digital media use in a first-year University student (N = 254, 48% male) population. Students tracked their sleep through daily online diaries and provided digital media use data in 15-min blocks for 2 h prior to bedtime on nine occasions. A longer duration of digital media use was associated with reduced total sleep time and later bedtime, while greater diversity of digital media use was associated with increased total sleep time and earlier bedtime. Analysis of activities in the last hour before bedtime indicated that activity type plays a role in digital media's effect on sleep, with computer work, surfing the Internet, and listening to music showing the strongest relationship to multiple sleep variables. These findings have implications for physical and mental health of University students and can inform design of devices to minimize negative effects of digital media on sleep.

Amra B, AliShahsavari, (2017)[7] associated sleep and late-night cell phone use among 2400 adolescents aged 12-18 yrs in Iran. Age, body mass index, sleep duration, cell phone use after 9 p.m., and physical activity were documented. The Pittsburgh Sleep Quality Index questionnaire was used to assess the quality of sleep. 1270 participants reported to use cell phone after 9 p.m. Overall, 56.1% of girls and 38.9% of boys reported poor quality sleep, respectively. Wake-up time was 8:17 a.m. (2.33), among late-night cell phone users and 8:03 a.m. (2.11) among non-users. Most (52%) late-night cell phone users had poor sleep quality. Sedentary participants had higher sleep latency than their peers. Adjusted binary and multinomial logistic regression models showed that late-night cell users were 1.39 times more likely to have a poor sleep quality than non-users (p-value < 0.001).

Association Between Mobile phone usage and the sleep quality

This study analysed that use of mobile phone every night is significantly associated with disturbances in the quality of sleep at $P < 0.001$ (highly significant).

The above findings are consistent with a cross sectional study conducted by Sahin S, Ozdemir K, (2013)[8] conducted to assess the mobile phone addiction level in university students between 01 November 2012 and 01 February 2013, to examine several associated factors and to evaluate the relation between the addiction level and sleep quality.. The study group included 576 students. The Problematic Mobile Phone Use Scale was used for evaluating the mobile phone addiction level and the Pittsburgh Sleep Quality Index for assessing the sleep quality. The study group consisted of 296 (51.4%) females and 208 (48.6%) males. The mean age was 20.83 ± 1.90 years (min:17, max:28). The addiction level was determined to be higher in the second-year students, those with poor family income, those with type A personality, those whose age for first mobile phone is 13 and below and those whose duration of daily mobile phone use is above 5 hours ($p < 0.05$ for each). The sleep quality worsens with increasing mobile phone addiction level ($p < 0.05$).

Exelmans L, Van **den Bulck** J (2015)[9] assessed the bedtime mobile use and the sleep quality among 844 Flemish adults (18–94 years old). Self-reported sleep quality, daytime fatigue and insomnia were measured using the Pittsburgh Sleep Quality Index

(PSQI), the Fatigue Assessment Scale (FAS) and the Bergen Insomnia Scale (BIS), respectively. Data were analyzed using hierarchical and multinomial regression analyses. Half of the respondents owned a smart phone, and six out of ten took their mobile phone with them to the bedroom. Sending/receiving text messages and/or phone calls after lights out significantly predicted respondents' scores on the PSQI; particularly longer sleep latency, worse sleep efficiency, more sleep disturbance and more daytime dysfunction. Bedtime mobile phone use predicted respondents' later self-reported rise time, higher insomnia score and increased fatigue. Age significantly moderated the relationship between bedtime mobile phone use and fatigue, rise time, and sleep duration. An increase in bedtime mobile phone use was associated with more fatigue and later rise times among younger respondents (≤ 41.5 years old and ≤ 40.8 years old respectively); but it was related to an earlier rise time and shorter sleep duration among older respondents (≥ 60.15 years old and ≥ 66.4 years old respectively).

Conclusion

The habitual usage of mobile phones at late-night has a significant effect with poorer sleep quality among adolescents.Findings reveals that mobile phone use at bedtime is negatively related to sleep outcomes. Longer average screen-time was associated with shorter sleep duration and worse sleep-efficiency. The sleep quality worsens with increasing smart phone addiction level. Young people suffer more than the older adults. Adolescents have to be motivated to have an adequate sleep for a better physical and mental wellbeing.

Neck Circumference as an Indicator of Obesity and its Comparison with Body Mass Index and Waist Circumference in Coastal Karnataka

Sanjay Kini[1], Avinash kumar[2], Unnikrishnan B[3], Siddharudha Shivalli[4], Vaman Kulkarni[2], Prasanna Mithra[2], Nithin Kumar[2]

[1]Associate Professor, Department of Community Medicine, Srinivas Institute of Medical Sciences and Research Centre, Mangalore, [2]Associate Professor, [3]Professor, Department of Community Medicine, Kasturba Medical College, Mangalore, [4]Assistant Professor, London School of Hygiene and Tropical Medicine, London

Abstract

Background: Neck circumference can be a simple screening tool for measurement of overweight and obesity. The present study aims to depict neck circumference as a valid measurement of obesity and tries to find out its correlation with BMI and waist circumference among young adults in the age group of 20-30 years.

Methodology: A community based cross-sectional study was conducted in 6 coastal villages of Udupi taluk, Udupi district, Karnataka, among 750 subjects. A pre-tested, semi structured questionnaire was administered to the study subjects after obtaining their consent. The questionnaire comprised of details on socio-demographic variables and anthropometric measurements.

Results: The study showed a strong positive correlation (r) between weight (0.7), waist circumference (0.7) and hip circumference (0.7) with neck circumference among the males, it showed a correlation of (0.6) for all the parameters like weight, waist circumference and hip circumference among the females. ROC analysis showed that the cut off for males at 36.25 cm has a sensitivity of 80% and specificity 77% and the area under the curve is 0.84. Whereas the cutoff for females was found to be 31.75 cm having the sensitivity of 69% and specificity 77% and the area under curve was 0.73.

Conclusion: Neck circumference (NC) measurement is simple and timesaving screening measure that can be used to identify overweight and obesity. Patients with NC >36.25 cm cm for men and >31.75 cm for women require additional evaluation of overweight/obesity.

Key words: *Neck circumference, Waist Circumference, obesity*

Introduction

As we define the term "globesity" synonymous with an escalating global epidemic of overweight and obesity, it is taking over many parts of the world and is seen to be paradoxically coexisting with undernutrition[1]. Serious diet related non-communicable diseases, including diabetes mellitus, cardiovascular disease (CVD), hypertension, and certain forms of cancer have a direct association with obesity[2-5].

An increased risk of morbidity and mortality is seen with both generalized and abdominal obesity[6-7]. Obesity is a predisposing factor for cardio-vascular disease (CVD), which is the main cause of obesity related deaths. Body mass index (BMI), waist circumference, waist–hip ratio or even hip circumference are various important risk of CVD in adults[8,9]. In India, measurement of hip and waist circumference is cumbersome in females due

Email- avinash.kumar@manipal.edu

to cultural barrier, which is the main problem with most of these anthropometric measurements.

The building blocks of the country's economy as well as country's health are the young adults. The rates for obesity among the 18-30 years old population with some college education have increased significantly in the last decade. In order to have a productive population it is very important to ensure their healthy health status. The present study focuses on a new anthropometric measurement which is neck circumference, as a valid measurement of obesity and aims to find its relation with BMI and waist circumference among young adults.

Methodology

Study settings

The present study was conducted in Udupi taluk in coastal district of Udupi, Karnataka.

Ethical Clearance

Ethical clearance was obtained from the Institutional Ethics Committee of Kasturba Medical College, Manipal University vide letter no: (IEC 216/2012 dated 12/09/2012) and it followed the tenets of the Declaration of Helsinki. An informed written consent was obtained from all the study participants after explaining them the purpose of the study in the local language, Kannada.

Study design

A community based cross-sectional study was conducted in Udupi taluk, Udupi district, Karnataka. We selected 6 coastal villages for the study by simple random sampling. The total population of the young adults (20–30 years) in selected 6 villages was 9546 (males: 4566 and females: 4980).

Sample size

Sample size was estimated using Epi Info™ 7.1.5 software. According to a similar study done by Ben-Noun L et al[10], considering sensitivity of 99% at cut off levels of neck circumference of 37 cm in males and 34 cm in females a sample size of 720 was calculated for the study. Considering a non-response rate of 5% the sample size was estimated to be 750.

Inclusion and exclusion criteria

All young adults aged between 20-30 years and willing to participate in the study were included in the study. People with conditions affecting the neck circumference like goiter, cervical lymphadenopathy and any other neck masses, pregnant women, seriously ill patients and those not consenting for the study were excluded.

Sampling

Stratified sampling with proportional allocation was used to select the required number of study subjects. Locality and gender were considered as the basis for stratification. The centre of a particular locality was visited by the corresponding author, along with a trained female assistant (Auxiliary Nurse Midwife) and the nearest house was taken as the first house for the study in that locality. They then moved in one particular direction and covered all the houses till they achieved the required sample for the locality. At the house, all the members satisfying the inclusion criteria were considered eligible for the study.

Study tool

A pre-tested, semi structured questionnaire was administered to the study subjects after obtaining their consent. The questionnaire comprised of details on socio-demographic variables and anthropometric measurements.

Family structure was categorized as nuclear, joint or three generation (grandparents, parents and children)[11]. Socio-economic status was assessed based on the modified version of Uday Parikh scale for rural areas in India[12]. Occupation was stratified as professional, white collared job, skilled worker, semiskilled worker, unskilled worker, housewife, student and unemployed. Literacy status was classified as literate (if she can read and write with understanding in any language) or illiterate (can neither read nor write or can read but cannot write in any language) and literacy level was the highest level of education completed (Census India 2011)[13].

Weight was measured to the nearest 100 g, in light clothing, using a standard weighing machine after correcting the zero error. Height was measured to the nearest 0.5 cm with the person standing upright against the wall with heels together and touching the wall, and the head held in upright position. BMI was classified according to WHO expert consultation recommendations for Asian population[14].

Waist circumference was measured at the mid-point between the lower margin of the lowest rib and the top of the iliac crest, in mid expiration, in standing position, using a stretch resistant tape. Hip circumference was measured at the inter-trochanteric level in standing position, with the tape parallel to the floor.

Neck Circumference was measured at the mid-point of the neck, between mid-cervical spine and mid anterior neck, to within 1 mm, using non-stretchable plastic tape with the subjects standing upright. In men with a laryngeal prominence (Adam's apple), it was measured just below the prominence. While taking this reading, the subject was asked to look straight ahead, with shoulders down, but not hunched.

Statistical analysis:

Data was analyzed using Statistical Package for the Social Sciences (SPSS) for Windows, Version 16.0. Chicago, SPSS Inc.

Results

We approached 812 subjects to get the required sample of 750 (response rate 92.36%). Out of 812 subjects, 58 subjects denied to consent for the study and 4 subjects were excluded as they were in the category of our exclusion criteria.

The present study had a total of 750 study participants with equal number of males (375) and females (375). Out of 375 males 26.7% males were involved in semi-skilled work followed by 22.7% in skilled work whereas 44.3% females were homemakers. A small percentage (0.8%) were illiterate. Most of the study participants were unmarried (68.7%). Of the total 750 subjects, 462 (61.61%) belonged to nuclear family, 259 (34.53%) belonged to joint family and the rest 29 (3.86%) belonged to three generation family.

Table 1: Anthropometric measurements of young adults (20-30 years) in selected coastal villages of Udupi taluk, Karnataka, India

Measurements	Males (n1 375) Mean ± SD	Correlation (r) of NC with	Females (n2 375) Mean ± SD	Correlation (r) of NC with
Age	25.03 ± 3.37 years	-	25.18 ± 3.36 years	-
Height	169.90 ± 6.34 cm	0.15	156.17 ± 7.05 cm	0.27
Weight	63.42 ± 105.98 kg	0.77	51.10 ± 9.86 kg	0.69
Waist circumference	78.34 ± 8.20 cm	0.79	70.58 ± 9.47 cm	0.68
Hip circumference	92.83 ± 6.88 cm	0.79	86.43 ± 8.11 cm	0.68
Neck circumference	35.79 ± 2.40 cm	-	31.13 ± 2.63 cm	-
BMI ≥ 25kg/m2	21.92 ± 3.20 cm	-	20.96 ± 4.01 cm	-

It was found that 45 (12%) males and 62 (16.5%) females were overweight and 63 (16.8%) males and 45(12%) females were in pre obese and obese category. It also showed that 58 (15.5%) males and 103(27.5%) females were underweight, whereas 209 (55.7%) males and 165 (44%) females had normal BMI.

The table no 2 depicts the mean BMI, Waist circumference and Neck circumference among the various categories of BMI

Table 2: Comparison between mean Body mass index (BMI), Waist Circumference (WC), Neck Circumference (NC) among the various BMI categories (n=750)

	Underweight Mean ± std dev		**Normal Mean ± std dev**		**Overweight Mean ± std dev**		**Obese Mean ± std dev**	
	Males	Females	Males	Females	Males	Females	Males	Females
BMI	17.34 ± 0.53	16.73±1.15	21.12 ± 1.25	20.47±1.26	23.77 ± 0.77	23.82±0.48	27.20 ± 1.67	28.46±3.95
Waist circumference (cm)	69.62 ± 3.66	61.94±5.13	76.20 ± 5.20	70.43±6.70	81.93 ± 3.77	75.10±6.27	90.37 ± 7.06	84.50±8.82
Neck circumference (cm)	33.40 ± 1.20	29.36±1.45	35.18 ± 1.57	31.02±2.52	36.53 ± 1.64	32.23±2.15	39.28 ± 1.94	34.10±2.47

Neck circumference (NC) showed a positive linear correlation with waist circumference (WC) and weight of the study participants as shown in the figure no 1 and 2 respectively.

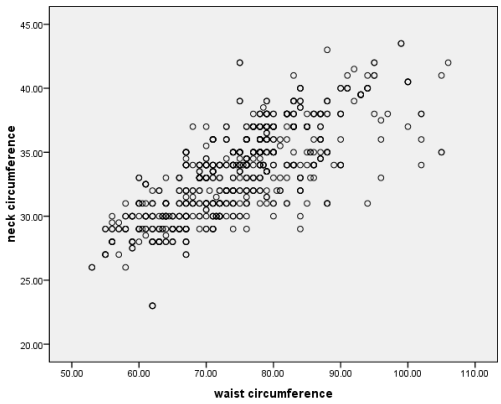

Fig 1: Correlation of WC with NC

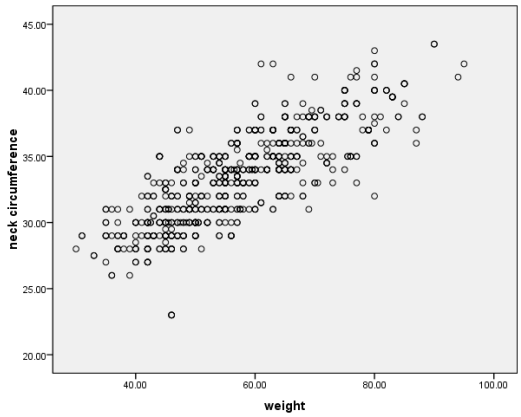

Fig 2: Correlation of weight with NC

Figure no 3 and 4 shows the ROC curve for males and females respectively. The cut off for males at 36.25 cm has a sensitivity of 80% and specificity 77% and the area under the curve is 0.84. Whereas the cutoff for females was found to be 31.75 cm having the sensitivity of 69% and specificity 77% and the area under curve was 0.73.

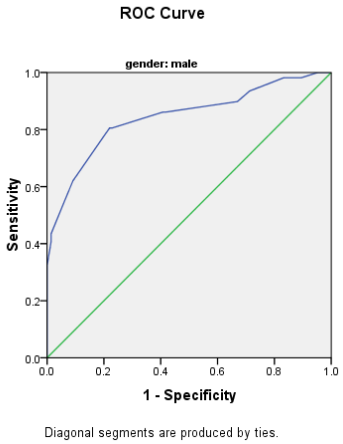

Fig 3: ROC curve comparing overweight/obesity with NC for males

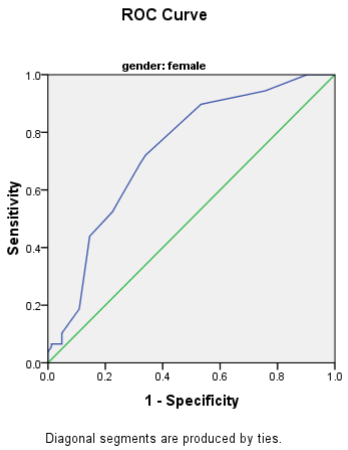

Fig 4: ROC curve comparing overweight/obesity with NC for females

Discussion:

Obesity is the mother of most of the non-communicable diseases and is one of the modifiable risk factors which contribute significantly to diabetes and other non-communicable diseases. India harbors the highest number of diabetic patient in the world next to China and the number is increasing each day[15]. Contrary to the common believe that non-communicable disease are more prevalent among people with central obesity, Patel P et al[16] showed that other risk factors like upper body fat also contributed to the disease number. Considering the above the risk factors, the current study focusses on upper body obesity by measuring neck circumference. The study tries to emphasize that neck circumference can be used as a marker for obesity with a cutoff for Indian population.

Studies have showed that the risk of CVD and other non-communicable disease remains high among the Asian population even at normal range of BMI[14].

The study showed a strong positive correlation (r) between weight (0.7), waist circumference (0.7) and hip circumference (0.7) with neck circumference among the males, it showed a correlation of (0.6) for all the parameters like weight, waist circumference and hip circumference among the females. The above finding is in sync with the study done by Hingorjo MR[17] which claimed similar strong correlation between Neck circumference and Waist circumference. The fact was also advocated by a study done by Onata et al[18] which reported a strong correlation between BMI and Neck circumference. A strong positive correlation between BMI, waist circumference, and NC was also stated by Yang GR et al[19] which was done among 3000 participants in China with a mean age of 64.0±10.1 years. Another study by Ben -Noun et al[10] among 979 subjects (460 and 519 Israeli men and women) showed a strong positive relation between Neck Circumference & BMI for both men and women in his test samples.

There is a strong positive correlation of NC with weight and WC in the study subjects. Several studies have examined the association of conventional anthropometric measures of obesity with NC[20,21]. Neck circumference is a valid marker for identifying obese individuals and correlated well with other anthropometric measurements. Neck circumference has also been shown to correlate positively with insulin resistance and biochemical components of the metabolic syndrome which is a known risk factor of diabetes and other non-communicable disease[10,18,22].

In studies carried out in other countries among healthy population, the standard neck circumference was determined using a BMI index. Also, previous studies in Iran have used cutoff points from studies from other countries or simply used correlation between neck circumference and variables of interest[23-25]. However, in the present study we first calculated proper neck circumference with receiver output curve and in relation with BMI $\geq$ 25 as a valid index of overweight. Using the above mentioned procedure the appropriate cut off for males was 36.25 cm whereas the cutoff for females was found to be 31.75 cm.

Conclusion

One of the simple and time saving measure that

can be used to identify overweight and obese adults is the neck circumference. Using BMI and waist circumference as standards for obesity grading, men with neck circumference of 36.25 cm and above & women with neck circumference of 31.75cm and above are considered to be overweight. So evaluation for NCD risk factors can be done specifically focused on subjects falling under the above mentioned category.

Potential Role of Electromyography in Kinesiology: A Review

Saranya S[1], Poonguzhali S[1]

Centre for Medical Electronics, Department of ECE, Anna University, Chennai, India

Abstract

Human beings follow a unique bipedal walking pattern referred to as gait and kinesiology is the scientific study pertaining to movement. Gait analysis has been an evolving area of study and in recent years its application in the development of orthosis, exoskeletons and rehabilitative devices is inevitable. Electromyogram (EMG) being a natural occurring physiological signal providing valuable information on neuro-muscular and musculoskeletal morphologies, its role is indispensable in analysing the underlying cause of movement pathologies. This paper reviews the contributions of EMG in movement analysis so far and its significance to the development of patient specific control of orthotic and rehabilitative applications.

Keywords: *Gait, Kinesiology, Movement Analysis, Electromyography, orthosis, Exoskeleton.*

Introduction

Locomotion is the primary means of survival of animal species and myriads of methods have been devised to enable and refine movement. The specialised bipedal movement referred as Gait is a complex interaction of the musculoskeletal, sensori-motor and neural systems that has optimized and stabilized the gait pattern of human beings [1].

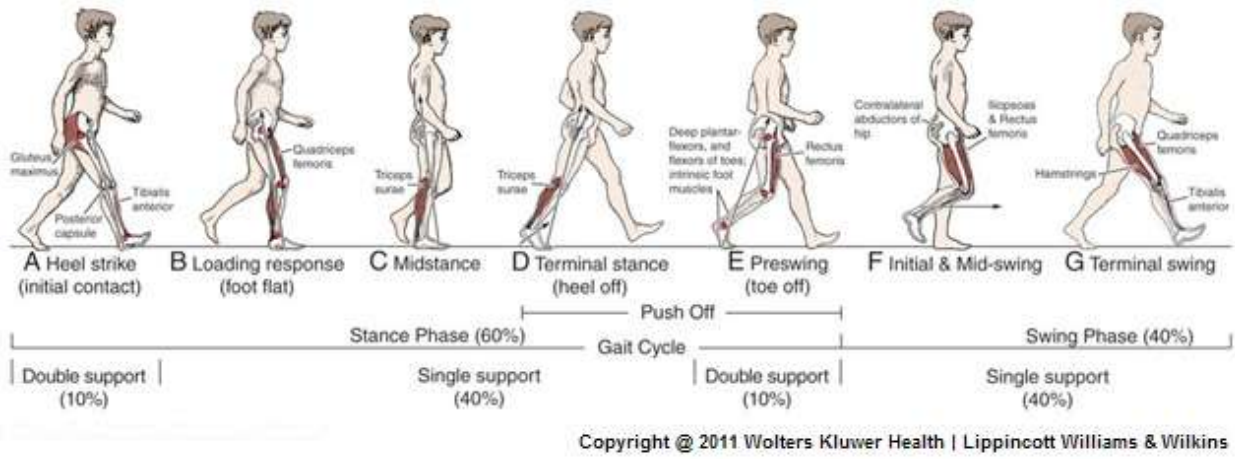

Fig.1. Various Phases of Gait Cycle

Gait is expressed as percentage of gait cycle considering the position of one limb as reference. The various phases of gait are shown in fig.1. It comprises of an initial stance phase during which the reference limb is always in contact with the ground followed by swing phase that corresponds to the period when foot is in the air. Stance phase occupies majority 60% of the

Phone: 9941163265

gait cycle with further subphases namely, initial contact, loading response, midstance, terminal stance, pre swing and swing phase represents the remaining 40% of gait cycle comprising of initial swing, mid swing, terminal swing respectively[2,3]. Analysis of Gait involves two major research components that includes quantification of biomechanical aspects of gait namely, measurement of kinematics (spatio-temporal parameters) and kinetics (forces and torques) of human joints that govern movement followed by analysing the musculoskeletal morphologies that support gait predominantly involving Electromyography(EMG) techniques [5,6,7]

Among the aforementioned technologies, the use of electromyography for comprehensive analysis of gait is at present gaining momentum and has been the current focus of researchers in this area. Being a naturally occurring physiological signal that gives deep insight into muscle activity, EMG explores the biophysical area for understanding human movement. Kinesiological Electromyography applies the potential of EMG in movement analysis and therefore, is an established subfield of modern locomotion biomechanics [8]. As a measure of electrical activity of muscle, its activation patterns & timings can be better quantified to analyse the role of muscles during specific movements thus helping in developing specific solutions to orthopaedic and neuromuscular insufficiency [9,10]. Furthermore, EMG has become an indispensable tool in detecting and analysing various forms of gait pathologies and its underlying neuromuscular etiology[11].

Current paper will focus on the potential role of EMG in gait analysis. The research methods used to analyse the contribution of different muscle and muscle groups during normal/abnormal gait which serves as a valuable tool in gait rehabilitation is reviewed.

Electromyography in Kinesiology

State-of-Art

Electromyography has evolved as a unique method to monitor and evaluate human movement. As a basic actuator that produces necessary mechanical force to cause movement, skeletal muscle and its associated EMG bridges the underlying physiology and biomechanics significantly contributing to the understanding of Human movement[12,13]

Remarkable contributions in analysing EMG patterns during gait were made by specific group of researchers who explored the area of Kinesiological electromyography for two decades [14,15,16,17,18,19,20,21,22,23,24]. The studies were critical in understanding the phasic activity of all major muscles individually, providing useful insights into the neuromuscular system. An initial technology review revealed that the studies on dynamic EMG will parallel and lead to a better understanding of kinematics and kinetics for clinical assessment of injuries specifically in the field of sports biomechanics [25].

The analysis of muscle forces during human movement were the next benchmark contribution in the field of movement science. The famous Hill's muscle model was used to demonstrate a relationship between EMG and muscle forces [26] followed by correlating muscle force information to dynamic joint moments during walking[27,28]. Since last decade more research has been focussed in analysing EMG information along with inertial measurements for movement analysis to precisely analyse the spatio-temporal parameters of gait [29,30,31]. The spatial coordinates of anatomical points of the lower limb define a number of spatial parameters and temporal parameters refer to time marked events with reference to various phases of gait [32,33].

Pathophysiological Gait

Deviations from the normal phasic sequence of bipedal walking is considered as abnormal gait. Many factors contribute to gait abnormalities either as compensation (antalgic) or consequence of a specific impairment (non-antalgic). Antalgic disorders owe to compensatory mechanisms which are characterized by shortening of stance phase, adapted to prevent pain in the affected leg [34,35,36].

Gait disorders are classified into three levels, viz., lowest, where disturbance is usually self-limited or compensated[37], middle, that are mostly multifactorial involving gait modifications due to spasticity, movement disorders etc.[38,39] and highest-level disorders that are mostly due to age related factors like dementia, disequilibrium, cognitive and psychogenic disorders [40,41].

As a bottom-up approach, EMG proves to be the sole opportunity for direct analysis of pathophysiological mechanisms responsible for gait modifications due to non-neuronal factors like alterations in passive muscle-tendon properties [42]. Any compensations during walking as a result of cognitive impairment has opened arenas

to diagnosis and treatment options[43]. Variations in gait between normal control and subjects with poliomyelitis were analysed based on EMG and accelerometers[44,45]

Gait Rehabilitation

Atypical gait patterns that result from joint replacement surgeries and neuromuscular dysfunctions such as stroke often end up in rehabilitation to restore/ assist normal gait [46]. EMG based evaluation and compensation system for pathological gait due to neuromotor disorders are popular research interests at present, since it proves to be the sole opportunity to identify the desired movement, or to assess the subject's motor capability[47]. EMG appear in lower limb muscles approximately 10ms before the muscle actually contracts as an effect of electromechanical delay and when evaluated within this delay a robust coupling between the human and the machine can be achieved thus allowing for the development of EMG driven human-machine interfaces[48]. Electromyography based evaluation on the level of residual activation and neural control strategies were used as the primary control for post-stroke patients undergoing Electromechanical gait training with simultaneous FES[49]. It was seen that motor learning is promoted by the use of residual EMG activity and used to trigger external devices assisting movement[50].

Exoskeletons

An advancement in the field of orthotic development is the Exoskeleton, an active mechanical device essentially anthropomorphic in nature that work in co-ordination with the operator's movements either by augmenting the performance of an able-bodied wearer or assisting the movements of a physically challenged person[51]. To be more precise, exoskeletons are divided into three broad categories namely, Performance-augmenting Exoskeletons (BLEEX, NTU-LEE,HAL-5), Rehabilitation Robots (Locomat, NaTUre-gaits, WalkTrainer, ALEX, LOPES) and Mobile Medical Exoskeletons (eLEGS, MIT Medical Exoskeleton, ReWalker, REX Honda Leg,Hybrid Assist Leg(HAL)) [52]. Among the successful exoskeletons that are developed, HAL uses surface EMG as a sensing modality for control. HAL-based training for improving walking ability or balance and its benefits for patients with chronic stroke, paraplegia and other neuromotor disorders has been successfully reported[53,54].

Conclusion

Kinesiological Electromyography has evolved in the past decade to be one of the major biomechanical measurement methods without a serious competitive method within its class. EMG provides a true understanding and objective evaluation of the neuromuscular activation during movement, paving way for considerable analysis. After a serious review performed based on the available literature it is concluded that

- Electromyography can explore the link between physiological and biomechanical aspects of movement leading to better diagnosis of movement impairment.
- The relationship between muscle co-activations and the distribution of forces among recruited muscles need considerable understanding to discover the synergistic control processes involved in regulating muscular activity during gait. This can greatly help in developing EMG based control for assistive devices.
- Rehabilitation and strength training of muscles also need good understanding of motor control and its underlying rules of neuromuscular system that coordinates/creates movement.
- EMG is one of the major Kinetic variable that are of interest to uncover clues to neuromuscular strategies in learning movements and can be used to document the temporal location and size of muscular demands.
- EMG to muscle force relationships have long been an area of research focus. It has great potential for studying altered muscle function due to varying gait patterns that cannot be readily examined by optimization techniques.

With so many thrust areas of research, Kinesiological Electromyography need more focus in the field of movement science upon overcoming certain limitations. Practical drawbacks related to unpredictable nature of EMG signals and the occurrence of crosstalk remain to be a challenge in analysis. A reliable sensing technology that overcomes the effect of crosstalk can surpass the challenges related to acquisition. Research findings need to be extended in building commercial EMG based systems that can be used for diagnosis, treatment and incorporation into assistive technologies as a mode of sensing and control.

Hence research that focusses more in the analysis of musculoskeletal models scaled and customized to individuals whose EMG and gait data can be used to simulate the actual action of muscles in normal/ abnormal movements and the associated joint forces is needed. Once optimal models are validated, the concept can be extended to real time estimation of muscle forces. Overall, Electromyography for kinesiological studies really seem promising in answering many questions related to movement disorders. As an effective tool for sensing and control, EMG has great potentials to be utilised in the field of rehabilitation and assistive technology.

Oral Health Literacy and its Relationship with Level of Education and Self-Efficacy among Patients Attending a Dental Rural Outreach Clinic in India

Shatakshi Srivastava[1], Shashidhar Acharya[2], Deepak Kumar Singhal[3], Abhishek Dutta[4], Kush Kalra[5], Nishu Singla[6]

[1]Lecturer, Dept. of Public Health Dentistry, MGM Dental College and Hospital, Navi Mumbai, Maharashtra, India, [2]Professor, [3]Associate Professor, Dept. of Public Health Dentistry, Manipal College of Dental Sciences, Manipal , Manipal Academy of Higher Education (MAHE), Karnataka,India, [4]Lecturer, Dept. of Oral and Maxillofacial Surgery, MGM Dental College and Hospital, Navi Mumbai, Maharashtra, India, [5]Senior Lecturer, Dept. of Public Health Dentistry, Santosh Dental College, Santosh University, Ghaziabad, U.P., [6]Associate Professor, Dept. of Public Health Dentistry, Manipal College of Dental Sciences, Manipal, Manipal Academy of Higher Education (MAHE), Karnataka, India

Abstract

Objective:To evaluate the relationship between Oral health literacy (OHL) with the level of education and self-efficacy among adults (age 18-77 years) patients attending a dental outreach clinic in Udupi Taluk. ***Basic research design:*** A cross-sectional study of adult patients attending a dental outreach clinic by convenience sampling. ***Method:*** Information was obtained about patient's sociodemographic factors along with the self-efficacy by using Dental Copings Belief's scale (DCBS) questionnaire and OHL was assessed by using a word recognition instrument Rapid Estimate of Adult Literacy in Dentistry (REALD-30).One way ANOVA and Pearson's χ^2 test were used for analysis. ***Participants:*** 200adult patients age range of 18- 77 years who wanted to seek dental care in a dental outreach clinic. ***Main outcome measures:*** Oral health literacy (OHL) and Self efficacy (DCBS) ***Results:*** In this study the OHL was significantly associated with the level of education of patients.Among the 200 subjects who claimed to be able to read and write English language andhad completed education till class 10^{th}; more than 50% of the subjects had Low (≤21)OHL scores.Only 12.5% of the total study population had High OHL (≥26) and were clearly able to understand simple dental terminology. Moderate levels of literacy was recorded in 75.6% in graduate and postgraduates indicating that even these people partially understood dental terms. There was no significant association between oral health literacy and self-efficacy.***Conclusion:***Our study suggests level of education to be a strong indicator of the OHL in the Indian Population. Further research to develop new instruments to measure the OHL, in a culturally diverse country like India, which has people of different mother tongues should be encouraged.

Keywords: *Oral health; health literacy; self- efficacy; community outreach.*

Introduction

The concept of Oral health literacy (OHL) has developed over several years and the existing literature is ever increasing in this field. Health literacy refers to the ability of individuals to obtain, understand and act upon health information and to make appropriate health decisions.[1-3] Oral health literacy (OHL) refers to the degree to which individuals have the capacity to obtain, process and understand basic oral health information and services needed to make appropriate health decisions.[4] This concept has not yet gained sufficient weightage in regular dental practice.

Oral Health literacy is like a bridge between the dental care provider's instructions and the comprehension, thereby abiding of the patient to the same. This role of OHL makes it important for the dentist to ascertain the level of OHL of the patient before any procedure and then treat the patient according to the level of understanding of the patient. After identification of the level of OHL attention should be paid by the dentist to communicate with the public and remove literacy-related barriers to information, decision making, and healthful action. [5] A significant number of patients may have a low level of oral health literacy, which possibly interferes with their ability to process and understand oral health information. Providers should identify patients who are having difficulty understanding and using dental health information and address their needs. [6]

According to Paasche-Orlow and Wolf conceptual model of causal pathways between health literacy and health outcomes the effect of literacy on health outcomes is mediated by patient-level and extrinsic factors grouped as [1] access to and utilization of health care, [2] provider–patient interaction, and self-care.[7] Many factors are related to OHL but amongst the recent ones focus has been given to those that affect behavior because behavior is amenable to change. A successful dental practice is not only related to dental treatment provided, but also to the patient's attitude and behavior towards the treatment. [8] Individual health practices such as oral self-care are based on personal choices.[9] According to the model proposed by Lee et al., Personal characteristics such as self-efficacy mediate and/or modify the impact of literacy on oral health behaviors.[10]

Self-efficacy-Perceived self-efficacy is concerned with people's beliefs in their capabilities to produce given attainments.[11] Perceived self-efficacy is a judgment of capability to execute given types of performances and outcome expectations are judgments about the outcomes that are likely to flow from such performances. Perceived efficacy has a pivotal role because it affects behavior and its impact on other determinants such as goals and aspirations; outcome and expectations. Self-efficacy appraisals reflect the level of difficulty individuals believe they can surmount. [11]

The aim of the present study was to evaluate the relationship between Oral health literacy (OHL) by using Rapid Estimate of Adult Literacy in Dentistry (READ-30)with the level of education and self-efficacy by using a questionnaire on Dental Coping Beliefs Scale (DCBS) among adult (age 18-77 years) patients attending a dental outreach clinic in Udupi Taluk.

Objectives-

1) To evaluate the Oral health literacy in adults visiting a dental outreach clinic in India by using word recognition instrument- Rapid Estimate of Adult Literacy in Dentistry (REALD-30).

2) To evaluate the Self-efficacy using Dental Coping Beliefs Scale (DCBS) questionnaire in the same subjects.

3) To evaluate the relationship between OHL with level of education.

4) To evaluate the relationship between OHL and self-efficacy.

Method-

Sample and data collection- A convenience sample of participants (N=200) was recruited from patients presenting for an initial consultation to a dental rural clinic in Udupi. Written informed consent was obtained for all study participants. Study Design-A Cross-sectional questionnaire study. Inclusion Criteria were-subjects who claimed to be able to read English words, subjects more than 18 years of age but younger than 80 years, subjects who had completed education till a minimum of 10th class, subjects without cognitive impairment, subjects without vision or hearing problems and subjects without obvious signs of drug/alcohol intoxication. Exclusion Criteria: were subjects who are not able to read English words, subjects less than 18 years of age and more than 80 years, subjects who have completed education less than 10th class, subjects not willing to participate in the study, subjects with psychiatric disorders and subjects with other severe systemic illness. Ethical clearance was obtained from the Kasturba Hospital Ethics Committee, Manipal before commencement of the study(IEC 277/2014). Informed consent was obtained from all patients prior to the start of the study. The Oral Health Literacy Assessment was done using REALD-30 which is a word recognition instrument which has 30 dental related words arranged in order of increasing difficulty. [12] The words were read aloud by the subject to the interviewer. The participants were asked not to phonetically deduce the words, but rather to skip a word if they did not know it. One point is given to each word pronounced correctly (zero point if incorrectly). The READ-30 score was categorized as

Low (≤21), Moderate (22 to 25) or High (≥26).[13]

In addition to the above, each patient completed a questionnaire regarding Self-efficacy. This questionnaire was a part of Dental Coping Beliefs scale (DCBS). [14] The participants were asked to mark only one response to each question. Total Self- efficacy was calculated by adding each of the responses. It had 9 questions and the responses were recorded on a Likert scale.The responses were-(1) Strongly agree, (2) Agree, (3) Neither, (4) Disagree and (5) Strongly disagree. Additionally, socio-demographic data was included in the questionnaire -Age, gender, education, occupation, monthly income.

Data Analysis-Statistical analysis was performed using SPSS (version 16.0).One way ANOVA was used to assess the relation between REALD-30(categorized-low, moderate, high)and self-efficacy (continuous variable). Pearson's $\chi 2$ test was used to assess association between education and REALD-30. The level of significance was set at 0.05.

Results

The study population consisted of 200 English speaking adults who visited the dental outpatient clinic. Questionnaire was administered to 200 adults and the response rate was 100.0%.The mean age of the respondents 38.33 years who were in the age range of 18 to 77 years. Among the respondents 41% were males and 59% were females. An individual's completion of the entire questionnaire was ensured by checking for it during the oral health examination. The respondents were asked to complete the incomplete forms. The demographic characteristics of the participants are presented in Table 1. The distribution of REALD-30 is presented in Table 2 of which 12.5% people have high OHL, 30.5% have moderate OHL and 57.0% have low OHL. Self-efficacy in results have been presented in Table 3. The self-efficacy range is 9-29 with a median of 18.0.The co-relation between REALD and Self efficacy was analyzed by One way ANOVA and presented in Table 4.There was no significant association between OHL and self-efficacy.Pearson's χ^2 test was used to test for association between Education and REALD has been presented in Table 5. The OHL was significantly associated with the level of education of patients. 6.0% of the participants completed high school education, 33.0%Intermediate/PUC, 58.5% Graduate/Post graduate and 2.5% Profession/ Honors.

Discussion

The aim of this study was to evaluate the oral health literacy (OHL) and its relationship with self-efficacy among adult patients attending a dental outreach clinic. To the best of our knowledge this is the second study done in India to assess the OHL using READL-30 as the assessment tool and the first study done to look closely into the association between OHL and self-efficacy in an adult Indian population in an outreach dental clinic. In this study the OHL was significantly associated with the level of education of patients which is similar to the findings of another study on Health Literacy. [15]

The dental copings beliefs scale was used to assess self-efficacy. DCBS helps the oral health professional in understanding a patients' belief either in internal or external controls and also the ability to which patient perceives himself/herself to be able to perform given tasks. [14] In the present study, there was no significant association between oral health literacy and self-efficacy. The self-efficacy has been assessed using a self-reported questionnaire, thus this finding could be attributed to the social desirability bias.

Among the 200 study English speaking subjects who had completed education at least till 10th class, who participated in the study OHL scores were very low in more than 50% of the subjects (57%-low OHL). These subjects scored less than 21 which mean these patients are likely to struggle to understand simple dental terminology which is used by the dentists while communicating to the

patients. Only 12.5% of the total study population had High OHL (≥26).This means only a little more than 10% of the whole of the study population is actually clearly able to understand the dental terms used by the dentists. Only moderate levels of literacy was recorded in 75.6% in graduate and postgraduates indicating that even these people understand only some of the dental terms and not all. The findings in the present study indicate that even in an Indian population with a basic level of education who are able to read and write in English have low levels of Oral health literacy. Similar findings are reported by M D'Cruz et al.,2014. [16]

Demands for reading, writing, and numeracy skills are intensified due to health-care systems' complexities, advancements in scientific discoveries, and new technologies. In this study there was no significant association between Oral health literacy and caries status and periodontal status. This could be attributed to the fact that the oral health literacy was taken by a word recognition instrument the REALD-30 which has several limitations.

This instrument is only a word recognition instrument and does not take into account whether the individual comprehends the dental words. Also, pronunciation of words vary in the Indian population due to a difference in dialect. It is possible that incorrect pronunciation may not necessarily mean that meaning of the word is also not known, more so among individuals with lower levels of education.[17] Therefore, the evaluation of oral health literacy via a word recognition instrument like REALD may be misleading. Due to these reasons, an association of oral health literacy with DMFT or CPI is difficult to assess.

Newer tools for assessing oral health literacy should be developed which test comprehension along with simple word recognition. Then the level of health literacy can be measured accurately and associated with oral health outcomes like caries status and periodontal status.

Conclusion

Demands for reading, writing, and numeracy skills are intensified due to health-care systems' complexities, advancements in scientific discoveries, and new technologies. [18] Poor health literacy has been described as a "silent epidemic" which needs to be taken care of by professionals and policy makers in order to improve quality of health care delivery, reduce costs and disparities. [18] The ''roots of health literacy problems have grown as health practitioners and health care system providers expect patients to assume more responsibility for self-care at a time when the health system is increasingly fragmented, complex, specialized, and technologically sophisticated". [19] Thus dentists should identify patients who are having difficulty understanding and using dental health information and address their needs.

Considering the importance of measuring oral health literacy and the numerous instruments available for the same, it becomes imperative to determine the applicability of the particular instrument to be used in the population under consideration.[15] Thus, for further research in the field of oral health literacy in a culturally diverse country like India with people of different mother tongues, other instruments which measure oral health literacy rapidly and also test comprehension of the participants should be developed.

There is no known conflict of interest for this study. There was no funding obtained for this study.

A Study of Relationship between Maternal Height and Fertility: Indian Concern

A. K. Tiwari[1], Shivam Mishra[2], Ravi Kant Maurya[2]

[1]Associate Professor, Department of Statistics, Institute of Science, Banaras Hindu University, Varanasi-221005

[2]Research Scholar, Department of Statistics, Institute of Science, Banaras Hindu University, Varanasi-221005

Abstract

Demographers, as well as public health professionals, have been quite interested to study the relationship between maternal body size and fertility. In this paper, the relationship between mother height, number of surviving children and parity is investigated for India and its major states. The mean number of children ever born is high in shorter mother and mean duration of first birth interval among the taller mothers is less than the shorter mothers. Taller women tend to have fewer children but more surviving children. The National Family Health Survey (NFHS) collect the information on fertility, infant and child mortality and the practice of family planning. For this study authors have used NFHS-4 data.

Key Words: *Fertility, maternal height, first birth interval, children ever born, surviving children, parity etc.*

Introduction

Human biologists are concentrated on describing the associations between fertility differentials with maternal shape and assessing the evolutionary implications of these associations.

Fertility is considered one of the most important factor in the study of population dynamics. It is determined by a complex set of biological, socio-economic, and psychological factors. So, social scientists and thinkers from different disciplines have made attempts to develop calibrate theories of fertility suited to their disciplinary approaches. For the convenience of researchers, these theories are grouped under three broad categories: biological theories, social or cultural theories and economic theories. Biological theories of fertility stimulated the concept that human growth is similar to other living beings. While, social theories tend to describe fertility in terms of a person's psychological attitude, which is determined by the prevalent culture. The socio-economic theories stress the significance of economic factors in the overall process of social change, which directs the fertility behaviour of a population. Among many biological, psychological, cultural and socio-economic factors, Davis and Blake[1](1956) had identified a set of eleven factors called intermediate variables which affect the process of reproduction either directly or indirectly. Bongaarts[2](1978) refined Davis and Blake's fertility framework and identified a smaller set of seven variables and named them proximate determinants of fertility; among them, four determinants were considered most important in terms of explaining variations in fertility levels of populations by Bongaarts[3](1982).

From the above theories, it has resulted that reproductive success is determined by numerous biological, behavioural, ecological, cultural and socioeconomic factors. Besides these factors, some studies suggest that the physical structure of a person may also affect fertility behaviour. The anthropometric measure which is used basically to measure growth, development and health status of an individual is the quantitative body measurement. Anthropometrics may be considered as a determining factor of fertility. Outside India, there have been quite a few studies which dealt with the correlation between fertility and physical structure, while in India there is a little literature in this context.

To find the impact of physical structure on fertility, early investigations were done by Davenport[4](1923) and Frassetto[5](1934); and observed that stockier couples had larger families than lean couples. Mitton[6](1975) observed significant differential fertility for height among males.

He indicated that men who were closer to mean height and weight (in some cases) had higher fertility than average. Vetta[7](1975) found significant relationships of fertility with height, weight and ponderal index.

In developed societies, some evidence about the association of large maternal size with higher fetal survival has been found by Bernard[8](1952) and Bressler[9](1962). In these studies, it is found that factors linked with tall statures such as enriched nutritional status and enhanced health care facilities, resulting in more successful pregnancies. Furusho[10] (1964) found that short couples had more live births than the tall in Japan, but there was no significant difference in the number of surviving children between tall and short. Among Peruvian urban poor, Frisancho et al.[11](1973) found that short mothers had a higher proportion of survivors per couple than tall mothers of similar age. Martorell et al.[12](1981) investigated the association between maternal stature, parity, offspring mortality and the number of surviving children. Sear et al.[13](2004) examined the relationship between height and reproductive success.

In this study, authors have made an attempt to examine the relationship between maternal stature and fertility in India.

Material and Method

The National Family Health Survey (NFHS) is a large-scale, multi-round survey conducted in a representative sample of households throughout India. Starting from the first round of this survey (NFHS-1) in 1992-93, four rounds of NFHS have been conducted in India till now. The recent round of National Family Health Survey (NFHS-4)[14] has been conducted in 2015-16. In this study, data related to fertility measures and anthropometric measures are taken from NFHS-4.

In this study, females of major states of India aged between 15 to 49 years have been considered as the target population. NFHS-4 collected anthropometric data on the height and weight of women which were used to calculate nutritional status measures. Females are categorized into two groups based on their height i.e. women having height ≤145.0cm, and having height >145.0cm. Literature review suggests about a number of important fertility parameters. Among them, four fertility parameters children ever born, first birth interval, most recent close birth interval and open birth interval have been considered for the study. Descriptive statistics have been used to get the estimated mean values of selected fertility parameters. The t-independent test is also used to compare the selected fertility parameters of shorter and taller mothers. The surviving ratio has been estimated to study the relationship between surviving children and maternal stature. Parity-wise proportion of females are also given for both groups to answer the question of whether parity, the number of previous deliveries, differs by mother's height.

Findings:

Table represents estimated means of selected fertility parameters i.e. children ever born, first birth interval, most recent close birth interval and open birth interval; for Indian females who are classified into two groups on the basis of their height which are height ≤145.0cm and height >145.0cm (shown in table). As it can be seen in the table, the mean number of children ever born is high in shorter mother in compare to taller. By considering females of all the major states of India, it is observed that the mean duration of the first birth interval among the tall females is less than the short females and statistically significant (p=0.000). Short females have a higher number of children ever born in comparison of tall females and it is statistically significant i.e. p=0.041 (shown in table).

The study shows that the mean number of surviving children of shorter females is lower than taller females in maximum states. It also indicates that taller mothers had a higher proportion of survivors (Mean number of surviving children/Mean number of children) when compared to shorter mothers. The analysis answers the question of whether one of the most meaningful measures of fertility, the number of surviving children varies with mother height. The table explains the proportion of females on each order of births and the analysis shows that the proportion of females at the first and second order is greater in taller and it starts decreasing after second order births. On another side, the proportion of females is more at high parity and it is less in the beginning orders.

Conclusion & Discussion

Over the decades, many public health professionals and demographers have tested the relationship between height and fertility. Many researchers found that mortality was significantly more for children of shorter women and they also observed a tendency for shorter women to have higher parities. Some researchers found no relationship between maternal stature and fertility

and few researchers found shorter females to have higher fertility.

In our study firstly, we studied the fertility parameters of shorter and taller mothers and found short females have more children ever born than tall females as well as longer duration of first birth interval. Secondly, we studied the mean number of surviving children and calculated survival ratio of children for major states of India and it has been observed that survival of children is low among short females in comparison of tall females. Earlier works by researchers on different populations show that mortality is greater in children of short mothers (Furusho[10],1964; Lechtig et al.[15,16]1975,1976). Last, it is observed that there is a tendency to have higher parities among short females. Survival of children may be caused due to deliberate efforts by short females to have more children to recompense for their child losses. Besides this, it is also known that after the death of a baby, the cessation of breastfeeding accelerates the return of the menstrual cycle which shortens the intervals between births (Martorell et al.[12],1981). This leads short females to achieve higher parities.

On the basis of the above analyses, we must conclude that there is a relationship of mother's height with fertility parameters, the number of surviving children is a function of height and mother height is related to the proportion of females at different parities. The taller mother tends to have fewer children but more surviving children, the survival of children is lower in shorter mothers. The study can be looked in light of the concern of public health professionals.

Table: Estimates of Fertility Parameters for Indian Females

Fertility Indicators	**Females having a height**	
	≤145.0cm	**>145.0cm**
Children ever born	2.00	1.87
	(t=1.841, p=0.041*)	
First birth interval (in months)	30.95	28.01
	(t=7.626, p=0.000**)	
Most recent close birth interval (in months)	37.77	37.73
	(t=-1.225, p=0.117)	
Open birth interval (in months)	99.84	104.00
	(t=1.155, p=0.131)	
Children survived	1.87	1.75
Proportion of children survived	0.91	0.94
Proportion of females on each birth order		
1	0.182	0.198
2	0.285	0.336
3	0.227	0.224
4	0.140	0.122
5	0.079	0.061
6	0.044	0.031
7	0.023	0.015
8	0.021	0.012
Note: t-test is applied by considering all the major states of India.		
* p-value is significant at α = 0.05 level of significance.		
** p-value is significant at α = 0.01 level of significance.

Risk Factor Associated with Anthrax Transmission among the Tribal Communities of Odisha

Sipra Makhija[1], Kumar Sumit[2], Shah Hossain[3]

[1]Post-Graduation in Public Health, [2]Assistant Professor, [3]Associate Professor, Prasanna School of Public health, Near KMC greens, Manipal, Udupi

Abstract

Context: Anthrax is a neglected tropical disease caused by Bacillus anthracis. The condition primarily affects herbivores. Human contacts the natural disease directly or indirectly from animals or their products.

Aims: The purpose of the study was to assess the risk factors associated with the transmission of anthrax.

Settings and Design: A mixed methods study was conducted among the tribal population of Lamtaput block, Koraput from January to May 2018

Methods and Material: A set of pre-tested and validated structured and unstructured questionnaires were used in order to conduct the study.

Statistical analysis used: Statistical package for the social sciences(SPSS) version 15.0.

Results: Overall, the respondents heard about anthrax were found to be 62.91 %. 52.98% of respondents were aware anthrax can affect both humans and animals. The risk factors and risky behaviour were found to be statistically significant with a p-value of < 0.05. Nevertheless, the qualitative findings suggested the level of awareness varied among the respondents, and the cause behind transmission was due to consumption of dead carcasses. The quantitative data showed only 30.464 % of people vaccinated their animals, the qualitative interviews also proposed that fewer respondents vaccinated their animals, 45.69% of respondents threw the carcasses in the open air, 52.98 % respondents ate the meat while sharing it with the community members when an animal died. Food insecurity, poverty, geographical barriers were the reasons cited for consuming dead carcasses.

Conclusions: The cause of transmission of anthrax in Koraput was dead carcasses consumption, high-risk behaviour and practices such as eating, selling, or sharing were found to be common among the respondents. These risk factors are influenced by the low socio-economic status, education level, lack of proper health education messages and poor veterinary services

Key-words: Anthrax, Awareness, Exposure practises, Risk factors, Tribal communities.

Introduction

Globally, anthrax accounts for 20,000 to 1,00,000 of human cases where livestock are not vaccinated, whereas due to underreporting and geographical distributions the actual incidence is not known in India[1]. 18 out of 30 districts in the state have witnessed outbreaks of anthrax as many as 61 times during the last ten years affecting 750 people out of that 418 had died[2]. According to Department of Animal Husbandry, Odisha, every year number of anthrax outbreak are reported from Koraput district[3]. Anthrax outbreaks are an annual phenomenon in Odisha, especially in the region of Koraput[4]. A sizeable portion of Koraput district's land area is covered with forests; the soil has good moisture which creates

Corresponding author:
Dr. Kumar Sumit
Assistant Professor, Prasanna School of Public health, Near KMC greens, Manipal, Udupi

favourable condition for anthrax spores to be dormant and be activated to give rise to transmission.

In addition to these eco-environmental factors social factors plays a vital role in anthrax disease transmission[5]. The purpose of this study was to assess the social risk factors associated with the transmission of anthrax in the tribal population of Koraput district of Odisha

Material and Method

Subjects and Methods:

A mixed method study was conducted in which case, survey was conducted with in-depths and key informants' interviews from January 2018 to March 2018 Lamtaput block of Koraput district, Odisha. The study included males/females aged 18-59 years, medical workers and veterinary officers, who were willing to participate in the study. This was done in order to conduct a deeper understanding of the underlying factors which influences the anthrax transmission in the community. The study had 2 components

Quantitative questionnaires

Data analysis

Koraput districts has 14 blocks, out of which Lamtaput is one of the most endemic for anthrax, and frequent outbreaks are reported every year. The block is bordered with Boipariguda on the north west and Nandapur on the south east, both of them the other two most endemic anthrax blocks of Koraput. Lamtaput block had a total population of 59873 in 2011 of which 46% were tribal[7]. The block had a livestock population of 27088 by the last animal census. We took a sample spread across 12 tribal villages across the length and width of the block recruiting a total of 150 households to conduct this cross sectional survey to assess social risk factors for anthrax in the area.

We used a questionnaire to assess prevalence of known risk factors that favour anthrax transmission in animals and humans and supported the same with key depth interviews to look into the perceptions and beliefs determining the presence or absence of these risk factors.

The administrative permission to conduct the study was obtained from the Chief district medical officer and District collectorate. Ethical permission was obtained from ethical committee of the Kasturba Medical College, Manipal Academy of Higher Education, Manipal. We took informed consent of the interviewee and each interview was conducted in the presence and with the help of grass roots health personnel.

Demographic tables were prepared where the categorical variables were expressed in frequency and percentage and the continuous variables. Fisher exact test and Chi-square test was performed to assess strength of association of variables the descriptive data was coded and entered and analysed in SPSS version 15.0. Thematic analysis was used to analyse the qualitative data, firstly, the data was translated into the English language, then coding of the data was done, then the code was translated to the category, and finally the category was translated into themes

Findings

Sixty percent of our respondents were in the age group of 28 to 48, 80% were male and 4% completing school education. Ninety percent of them were currently married and 80% of them farmers by occupation, an additional 10% agricultural labourers. Most of them are aware that the anthrax disease is there and it affects both animals and humans and also that the animals bleed from natural orifices at death. Most of the respondents said they are not visited by veterinary health personnel and mostly depend on traditional (desi) treatment or that of quacks for treating their dead animal. Only 30% allowed their livestock to be vaccinated against anthrax in the last round. Though some people discarded a dead carcass by throwing it outside the human habitations, most of them believed there is no harm in consuming them. They justified it with their hunting festivals when they are allowed to hunt and eat bush meat. On their own health seeking behaviour, they preferred the village healers or quacks rather than reach the local health facility, as they do not have trust in the health facilities or personnel The perception of the villagers substantively varied from that of the local health care workers, who see the villagers stubborn on keeping to their own beliefs and practices and not listening to health advice, even when they reach them. During the survey a few households were witnessed drying salvaged carcass meat for preservation for future use.

Table 1: Awareness Related to Anthrax

Variables	Category	n (%)
Ever heard of anthrax	Yes	95 (62.91)
	No	56 (37.09)
Awareness about who can be affected	Human/Animals/Both	80(52.98)
	Don't know	71(47.02)
Awareness about vaccination as prevention	Yes	52(34.43)
	No	99(65.56)
Major sources of information	Mass media	96(63.57)
	Personal	55(36.42)

Conclusion

The study findings showed that general awareness among the communities' members varied, also the vaccination rates were low due to numerous challenges, cultural beliefs, myths and perception which influences how community treats the dead carcasses. the high-risk behaviour and practices such as eating, selling, or sharing were found to be common among the respondents. These risk factors are influenced by the low socio-economic status, education level, lack of proper health education messages and poor veterinary services.

A backward community that is deprived of awareness and modern interventions to combat an easy to prevent and difficult to cure disease and its transmission suffer in isolation because of repeated outbreaks of anthrax that has become endemic in the region. This calls for a wider intervention involving non health line departments to stop the transmission cycle of anthrax in Odisha.

Abstract

Introduction: Diabetes is an "iceberg" disease and is one of the major causes of premature illness and death worldwide. From 108 million in 1980, the number of people living with diabetes has increased to 422 million in 2014. In india it was the 7th biggest cause for early death in 2016. There are many screening tools available to identify the risk for diabetes, of which IDRS tool is one of them.

Objective: To assess risk of diabetes mellitus among selected bank employees using Indian diabetes risk score.

Methodology: A cross sectional study was conducted over a period of 2 months (February to march 2019) among 205 employees of 4 branches of a selected bank. Data was collected by purposive sampling using a pre-tested, semi-structured questionnaire and IDRS scale. Clinical examination and GRBS was carried out. Chi-square test was used as test for association.

Results: Among 205 respondents, IDRS score showed that 61% belonged to high risk category, 25% to moderate risk & 14% belonged to low risk.

Conclusion: Present study showed 61% to be in high risk category for DM; it also revealed significant association between overweight and high IDRS. Age, abdominal obesity in males, family history of diabetes and physical activity were significantly associated with high IDRS. Early screening aids in early diagnosis and treatment which can reduce the burden of DM.

Keywords: *IDRS, Diabetes Mellitus, Bank employee, BMI, GRBS.*

Introduction

Diabetes Mellitus' a disease known since ancient times finds its description in vedic literature being described as 'Madhumeha' meaning 'honey-urine'.[1]

World Health Organization (WHO) defines the term diabetes mellitus as- 'a metabolic disorder of multiple etiology characterized by chronic hyperglycemia with disturbances of carbohydrate, fat and protein metabolism resulting from defects in insulin secretion, insulin action, or both.[1] Increasing at a rapid rate this disease is posing a major public health challenge. A disease finding its description in vedic literature, WHO estimates around 422 million to be affected with diabetes around the world.[2] The Eastern Mediterranean Region and the Region of the Americas have highest prevalence (11% for both sexes) and Western Pacific Regions & WHO European regions (9% for both sexes) have lowest.

The prevalence that was 2.3% in urban areas in 1970's according to ICMR study has currently risen to 12-19% in recent years.[4,5] The most recent estimates by ICMR show that there are 66.58 million cases and 2.26 million DALYs loss due to diabetes.[6] According to the Diabetes Atlas 2013 published by the International Diabetes Federation, the number of people with diabetes in India currently is 65.1 Million, which is expected to rise to 142.7 million by 2035 unless urgent preventive steps are taken[7.] The elimination of risk factor, early diagnosis and adequate treatment can reduce the risk of disease. Sedentary lifestyle, work pressure increasing stress amongst individuals are well known factors in the causation of disease. Since bank employees come under this group, the present study has been conducted to assess their risk for diabetes.

Objective

To assess risk of Diabetes mellitus among selected Bank Employees using Indian Diabetes risk score.

Methodology

A cross sectional study was carried out over a period of 2 month (February to March 2019) among employees of 4 branches of Karnataka Bank in Mangalore city, Karnataka.

After obtaining the written permission from managers of respective branches subjects were studied individually in their leisure time with informed consent. Employees who were present on the day of visit and who were willing to participate were enrolled for the study. Those with pre existing diabetes (Self-reported) were excluded. A total of 205 employees were available for the study. Sampling technique used was purposive sampling.

A pre-tested, semi-structured questionnaire was used to elicit socio-demographic parameters like age, sex, marital status, education, occupation, per capita income; IDRS scale [8] having parameters including Age in years, family history, physical activity and abdominal circumference was used.[8] Examination in the form of BP, PR, Height and Weight, GRBS was tested using glucometer. BMI was also calculated.

Ethical Clearance was obtained from institutional ethical committee.

Certain definition used in the study[10]

1. **Age:** Age was recorded in completed years as revealed by subjects and categorized into 3 groups; age <35 years was given a score of 0, 35- 49 years as 20 and >=50 years as 30.

2. **Waist circumference:** Males: Individuals with waist circumference <90cm were given a score as 0, 90 – 99 cm as 10, and those with >=100 cm as 20. Females: Individuals with waist circumference <80cm were given a score as 0, 80 -89 cm as 10, and those with > 90 cm as 20.

3. **Family history of diabetes:** Individuals with no family history of diabetes were given score as 0, those with one diabetic parent as 10 and those with both diabetic parents as 20.

4. **Physical activity:** Individuals were given a score as 0 if they did leisure time exercise and in addition had physically demanding work in their occupation; individuals who either did exercise or performed physically demanding work were given score as 20 and the individuals who neither did any exercise or who are leading a sedentary lifestyle were given score as 30.

The total scores were added up and the subjects were classified as high risk, moderate

risk and low risk, based on the IDRS as follows – < 30 as low risk, score 30-50 as

moderate risk and score 60 and above as high risk.

5. **GRBS:** Cut of 110mg/dl was used as cut of to devide the study subjects into low risk & high risk.[11]

Statistics:

Data was entered in excel. Results presented as percentages and proportions. Chi-square test was used as test for Association

Results

Mean age of the study subjects was 45.45±11.98. Males 159 (74.6%) out numbered females 52 (25.4%). In our study about 59 (28.8%) were in the age group of <35, 74 (36.1%) were in the age group of 35-49 yrs and about 72 (35.1%) were aged >=50yrs. Most of the employees 152 (74.2%) were Professional. By IDRS, most of the subjects, 125 (61%) were having high risk for type 2 DM. About 51 (25%) were at moderate risk and 29 (14%) were at low risk of developing type 2 DM. (Table 2).

Discussion

There is a clear association between increasing age and greater diabetes prevalence. Among 205 respondents, IDRS score was found to reveal high risk in the age group >35 years (96.34%) and in patients with high BMI (56%). Overall, 61% of the patients had high risk of Diabetes. Higher the age group more was the risk score. The National Institute for Health and Care Excellence (NICE) states that being older than 40 years, or older than 25 years for some black and minority ethnic groups, is an important risk factor for developing type 2 diabetes.[12]

An increase in waist circumference is seen as an important risk factor for developing diabetes with a gender based difference where in men are seen to have a higher risk with a waist circumference of 94 – 102 cm and Women are at higher risk if the waist circumference is 80 – 88cm.[13] In our study, majority of male 52 (24 %) and females 14 (6 %) were seen in group 2 i.e., males (90-99cm) and females (>90) and these showed to have a higher risk for diabetes though it was significant only in males($p = 0.00$). This could be because of the risk jobs that most have at Banks which invariably lessens physical activity. Over the past 4 decades, a huge number of the working population has shifted from manual labor associated with agriculture sector to physically less demanding office jobs.[14] It has been observed in other studies that prevalence of diabetes is 3 times higher in individuals with light physical activity compared to those doing heavy physical activity.[14] In our study 57% of individuals involved in exercise or strenuous work belonged to moderate risk and 54% in high risk group which was also significant ($p = 0.00$). Strenuous work may have added to stress factor contributing to higher risk . Similarly, 25% and 44% of individuals following a sedentary pattern showed to have moderate and high risk scores respectively. Genetic susceptibility and common environmental factors including cultural background are factors that determine the family history for a disease specially so in diabetes.[15] The disease risk increases to 40% when a 1st degree relative has history of diabetes.[15] In our study, 85 (41.5% %) subjects had positive family history of type 2 DM in one parent, 33 (16 %) had positive history in both parents of whom 125 (61 %) were in high risk group, 51 (25 %) of them were in moderate risk group and 29 (14 %) were in low risk group and these factors were significantly ($p = 0.00$) associated with higher risks according to IDRS. In a similar study by Raja Subramanian et al[16] it was seen those with family history showed a higher risk for diabetes. In our study, 120 individuals had a GRBS reading of > 110 mg/dl. Acoording to Reshma S Patil etal[18] study showed that those individuals having GRBS of more than equal to 110mg/dl have recommended oral glucose tolerance test to detect status of diabetes in future. In our stud showed of the 120 individuals who had a GRBS reading of more than 110 mg/ dl 59% of them were belonged to moderate risk and 62% were in high risk group based on IDRS. Though not significantly associated it can be taken as ameasure for risk scoring for diabetes.

Conclusion

IDRS is a simple and cost-effective tool to screen and assess people at high risk for DM. The present study brought out 61% of Bank employees to be at high risk & also revealed significant association between BMI and a high risk score of DM. Due to sedentary nature of work for most bank employees, they are at risk of developings a disease like diabetes. Our study found 61% of the study population at high risk for DM using IDRS. IDRS can be used as a baseline screening tool to assess the risk of individuals and take measures accordingly.

Early screening aids in early diagnosis and treatment which can reduce the burden of DM.

Limitations of Study: Sample size was small for want of time. Blood Glucose levels of subjects at high risk were not assessed because of cost factor.
